Label-based scheduling provides job placement control on a multi-tenant Hadoop cluster. Administrators can control exactly which nodes are chosen to run jobs submitted by different users and groups. An administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When users run jobs, they can place them on specified nodes on a per-job basis (using a job label) or on a per-queue level (using a queue label).

The ResourceManager caches the mapping file, and checks every two minutes (the default monitoring period) for updates. If the file has been modified, the ResourceManager updates the labels for all active ApplicationMasters immediately.

Each application runs an ApplicationMaster to negotiate resources from the ResourceManager. The ApplicationMaster works with the NodeManagers to execute and monitor tasks. The duties of the ApplicationMaster are divided as follows:

- NodeManager: One instance runs on each node, to manage that node's resources.
- Container: An abstraction representing a unit of resources on a node.

The NodeManager provides containers to an application. The ResourceManager and the NodeManager provide the system for distributed management of applications and resources.

ResourceManager
Describes the role of the ResourceManager.

The ResourceManager is mainly concerned with arbitrating available resources in the cluster among competing applications, with the goal of maximum cluster utilization. The ResourceManager includes a pluggable scheduler called the YarnScheduler, which allows different policies for managing constraints such as capacity, fairness, and service level agreements.

The ResourceManager manages resources as follows:

- Each NodeManager takes instructions from the ResourceManager, reporting and handling containers on a single node
- Each ApplicationMaster requests resources from the ResourceManager, then works with containers provided by NodeManagers

The ResourceManager communicates with application clients via an interface called the ClientService. A client can submit or terminate an application and gain information about the scheduling queue or cluster statistics through the ClientService.

Administrative requests are served by a separate interface called the AdminService, through which operators can get updated information about cluster operation.

Behind the scenes, the ResourceTrackerService receives node heartbeats from the NodeManager to track new or decommissioned nodes. The NMLivelinessMonitor and NodesListManager keep an updated status of which nodes are healthy so that the scheduler and the ResourceTrackerService can allocate work appropriately.

A component called the ApplicationMasterService manages ApplicationMasters on all nodes, keeping the scheduler informed. A component called the AMLivelinessMonitor keeps a list of ApplicationMasters and their last heartbeat times, in order to let the ResourceManager know what applications are healthy on the cluster. Any ApplicationMaster that does not heartbeat within a certain interval is marked as dead and re-scheduled to run on a new container.

At the core of the ResourceManager is an interface called the ApplicationsManager, which maintains a list of applications that have been submitted, are running, or are completed. The ApplicationsManager accepts job submissions, negotiates the first container for an application (in which the ApplicationMaster will run) and restarts the ApplicationMaster if it fails.

The ResourceManager and NodeManagers communicate via heartbeats.

Configure the ResourceManager for high availability so that the failure of the ResourceManager service is a not single point of failure for the cluster. High availability of the ResourceManager is configured by default when you run `configure.sh` without specifying the `-RM` parameter.

ApplicationMaster
Describes the role of the ApplicationMaster.

The ApplicationMaster is an instance of a framework-specific library that negotiates resources from the ResourceManager and works with the NodeManager to execute and monitor the granted resources (bundled as containers) for a given application. An application can be a process or set of processes, a service, or a description of work.

The ApplicationMaster is run in a container like any other application. The ApplicationsManager, part of the ResourceManager, negotiates for the container in which an application's ApplicationMaster runs when the application is scheduled by the YarnScheduler.

While an application is running, the ApplicationMaster manages the following:

- Application life cycle

last-updated: Apr 11, 2022

- Dynamic adjustments to resource consumption
- Execution flow
- Faults
- Providing status and metrics

The ApplicationMaster is designed to support a specific framework, and can be written in any language since its communication with the NodeManagers and the ResourceManager is accomplished using extensible communication protocols. The ApplicationMaster can be customized to extend the framework or run any other code. For this reason, the ApplicationMaster is not considered trustworthy, and is not run as a trusted service.

An ApplicationMaster typically requests resources on multiple nodes to complete a job by sending the ResourceManager requests that include locality preferences and attributes of the containers. When the ResourceManager is able to allocate a resource to the ApplicationMaster, it generates a lease that the ApplicationMaster pulls on a subsequent heartbeat. A security token associated with the lease guarantees its authenticity when the ApplicationManager presents the lease to the NodeManager to gain access to the container.

The Application Master heartbeats to the ResourceManager to communicate its changing resource needs, and to let the ResourceManager know it is still alive. In response, the ResourceManager can return a lease on additional containers on other nodes, or cancel the lease on some containers. The ApplicationMaster can then adjust its execution strategy to fit the increase or decrease in available resources. When cluster resources become scarce, the ResourceManager can also request that the ApplicationMaster relinquish some resources. The ApplicationMaster can move work to other running containers in order to give up resources gracefully.

Containers

A YARN container is a result of a successful resource allocation, meaning that the ResourceManager has granted an application a lease to use a specific set of resources in certain amounts on a specific node. The ApplicationMaster presents the lease to the NodeManager on the node where the container has been allocated, thereby gaining access to the resources.

To launch the container, the ApplicationMaster must provide a container launch context (CLC) that includes the following information:

- Environment variables
- Dependencies (local resources such as data files or shared objects needed prior to launch)
- Security tokens
- The command necessary to create the process the application plans to launch

The CLC makes it possible for the ApplicationMaster to use containers to run a variety of different kinds of work, from simple shell scripts to applications to virtual machines.

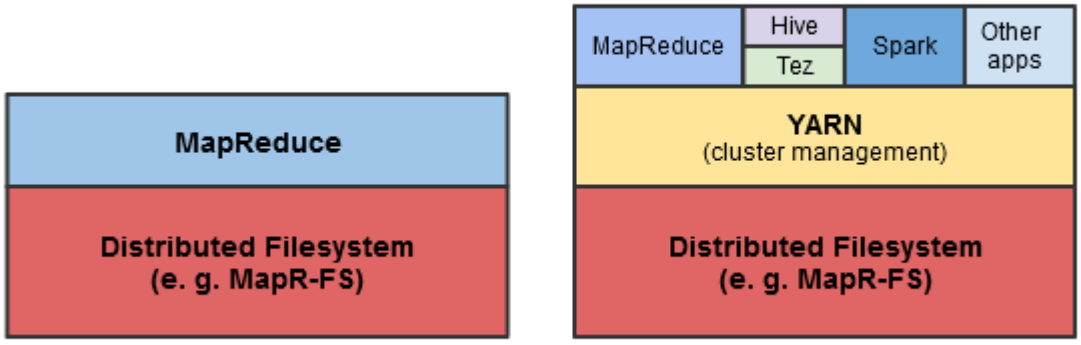
MapReduce Version 2

Provides an overview of how MapReduce works.

YARN dynamically allocates resources for applications as they execute. The MapReduce version 1 (MRv1) has been rewritten to run as an application on top of YARN; this new version is called MapReduce version 2.0 (MRv2).

Figure 2. A comparison between MapReduce 1.0 and MapReduce 2.0

last-updated: Apr 11, 2022



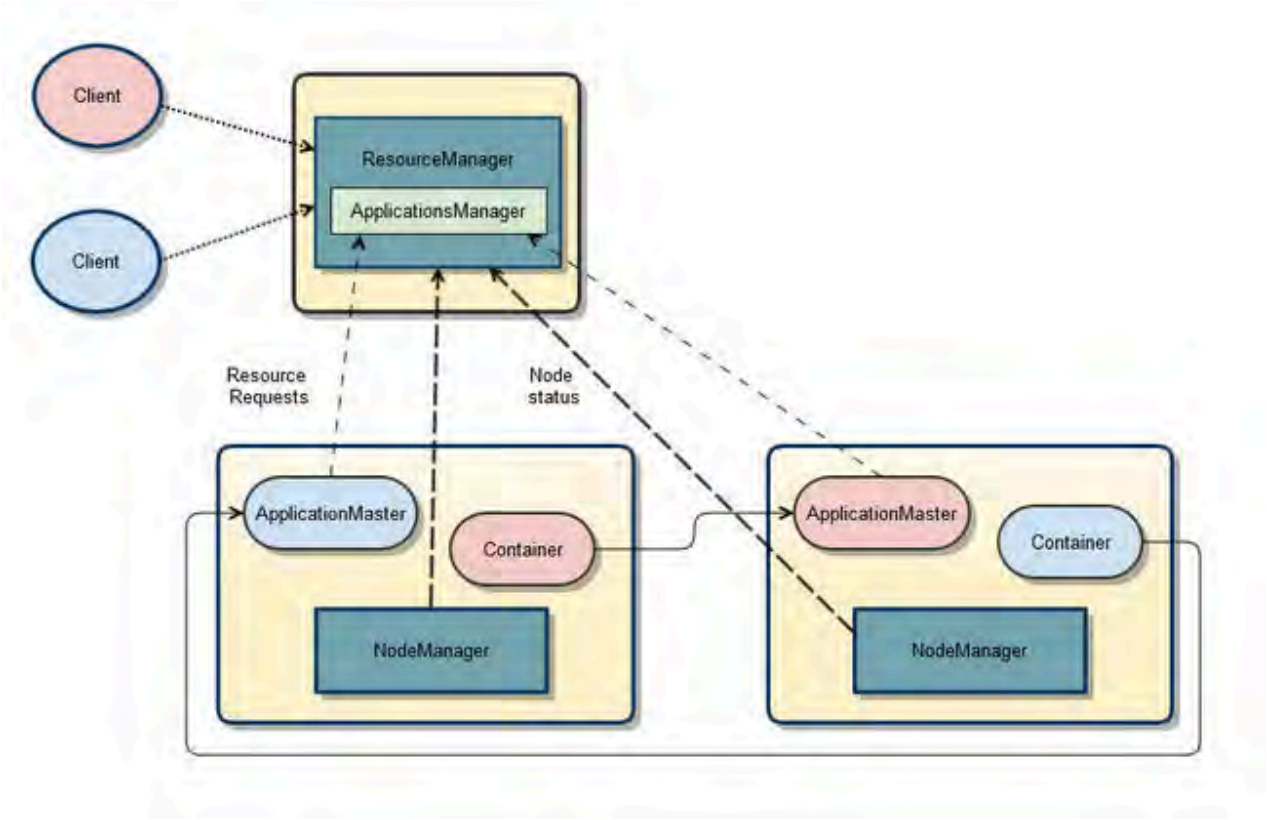
The main advancement in YARN architecture is the separation of resource management and job management, which were both handled by the same process (the JobTracker) in Hadoop 1.x. Cluster resources and job scheduling are managed by the ResourceManager, while resource negotiation and job monitoring are managed by an ApplicationMaster for each application running on the cluster. In MapReduce, each node advertises a relatively fixed number of map slots and reduce slots. This can lead to resource under-utilization, for example, when there is a heavy reduce load and map slots are available, because the map slots cannot accept reduce tasks (and vice versa).

YARN generalizes resource management for use by new engines and frameworks, allowing resources to be allocated and reallocated for different concurrent applications sharing a cluster. Existing MapReduce applications can run on YARN without any changes. At the same time, because MapReduce is now merely another application on YARN, MapReduce is free to evolve independently of the resource management infrastructure.

How Applications Work in YARN
Describes the data flow during application execution in YARN.

The following diagram and steps describe how data flows during application execution in YARN.

last-updated: Apr 11, 2022



The following steps summarize execution of the application:

1. A client submits an application to the YARN ResourceManager, including the information required for the Container Life Cycle (CLC).
2. The ApplicationsManager (in the ResourceManager) negotiates a container and bootstraps the ApplicationMaster instance for the application.
3. The ApplicationMaster registers with the ResourceManager and requests containers.
4. The ApplicationMaster communicates with NodeManagers to launch the containers it has been granted, specifying the CLC for each container.
5. The ApplicationMaster manages application execution. During execution, the application provides progress and status information to the ApplicationMaster. The client can monitor the application's status by querying the ResourceManager or by communicating directly with the ApplicationMaster.
6. The ApplicationMaster reports completion of the application to the ResourceManager.
7. The ApplicationMaster deregisters with the ResourceManager, which then cleans up the ApplicationMaster container.

Direct Shuffle on YARN
Explains the shuffle phase of a MapReduce application.

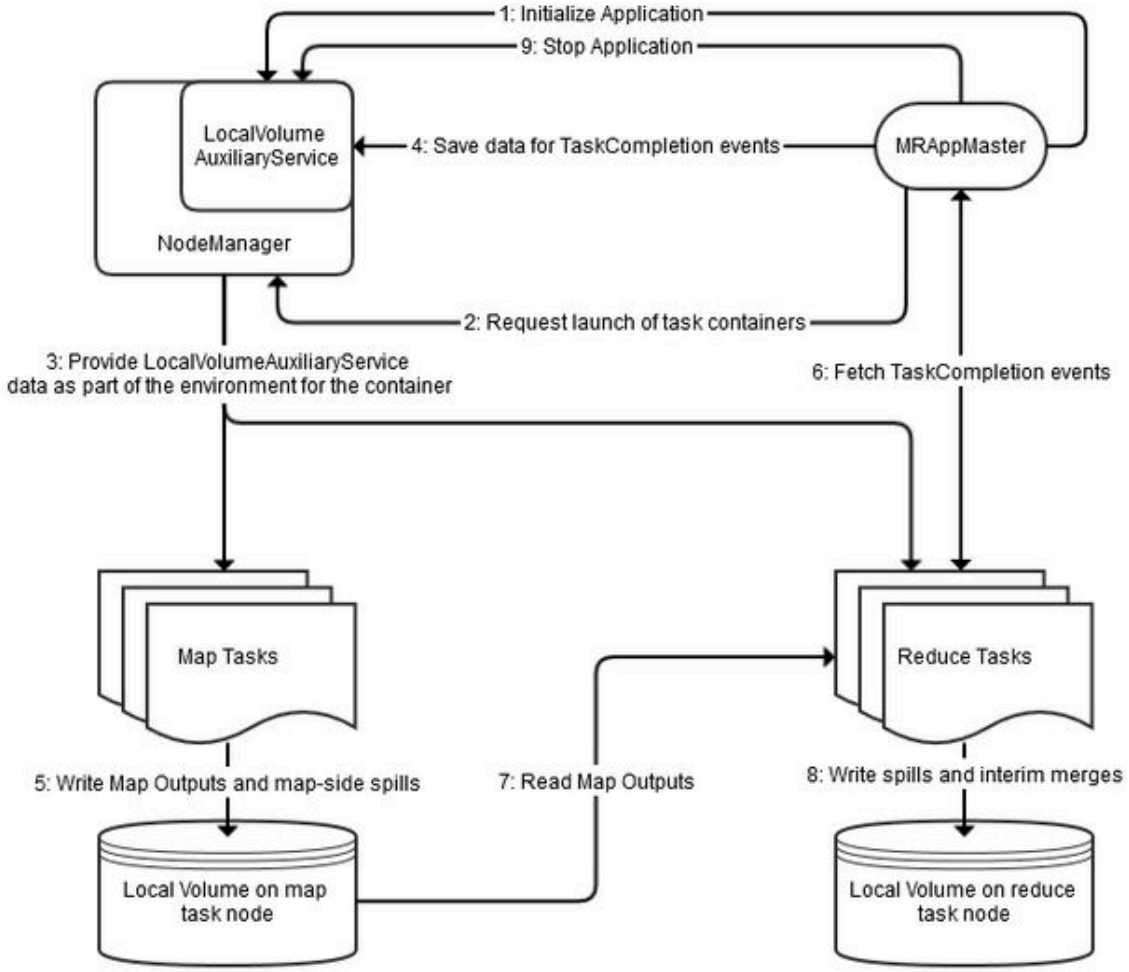
Overview of Direct Shuffle

During the shuffle phase of a MapReduce application, MapR writes to a MapR File System volume limited by its topology to the local node instead of writing intermediate data to local disks controlled by the operating system. This improves performance and reduces demand on local disk space while making the output available cluster-wide.

last-updated: Apr 11, 2022

Direct Shuffle is the default shuffle mechanism for MapR Data Platform. However, you can modify the `yarn-site.xml` and `mapred-site.xml` configuration files to enable Apache Shuffle for MapReduce applications. See Apache Shuffle on YARN.

The LocalVolumeAuxiliaryService runs in the NodeManager process. The LocalVolumeAuxiliaryService manages the local volume on each node and cleans up shuffle data after a MapReduce application has finished executing.



1. The MRAppMaster service initializes the application by calling `initializeApplication()` on the LocalVolumeAuxiliaryService.
2. The MRAppMaster service requests task containers from the ResourceManager. The ResourceManager sends the MRAppMaster information that MRAppMaster uses to request containers from the NodeManager.
3. The NodeManager on each node launches containers using information about the node's local volume from the LocalVolumeAuxiliaryService.
4. Data from map tasks is saved in MRAppMaster for later use in TaskCompletion events, which are requested by reduce tasks.
5. As map tasks complete, map outputs and map-side spills are written to the local volumes on the map task nodes, generating Task Completion events.

last-updated: Apr 11, 2022

6. ReduceTasks fetch Task Completion events from the Application Manager. The task Completion events include information on the location of map output data, enabling reduce tasks to copy data from MapOutput locations.
7. Reduce tasks read the map output information.
8. Spills and interim merges are written to local volumes on the reduce task nodes.
9. MRAppMaster calls `stopApplication()` on the LocalVolumeAuxiliaryService to clean up data on the local volume.

Configuration for Direct Shuffle

The deafult YARN parameters for Direct Shuffle are as follows:

```
<property>
    <name>yarn.nodemanager.aux-services</name>
    <value>mapreduce_shuffle,mapr_direct_shuffle</value>
    <description>shuffle service that needs to be set for Map Reduce to
run</description>
</property>
<property>
    <name>yarn.nodemanager.aux-services.mapr_direct_shuffle.class</name>
    <value>org.apache.hadoop.mapred.LocalVolumeAuxService</value>
</property>
```

The default mapred parameters for Direct Shuffle are as follows:

```
<property>
    <name>mapreduce.job.shuffle.provider.services</name>
    <value>mapr_direct_shuffle</value>
</property>
<property>
    <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
    <value>org.apache.hadoop.mapreduce.task.reduce.DirectShuffle</value>
</property>
<property>
    <name>mapreduce.job.map.output.collector.class</name>
    <value>org.apache.hadoop.mapred.MapRFsOutputBuffer</value>
</property>
<property>
    <name>mapred.ifile.outputstream</name>
    <value>org.apache.hadoop.mapred.MapRIFileOutputStream</value>
</property>
<property>
    <name>mapred.ifile.inputstream</name>
    <value>org.apache.hadoop.mapred.MapRIFileInputStream</value>
</property>
<property>
    <name>mapred.local.mapoutput</name>
    <value>false</value>
</property>
<property>
    <name>mapreduce.task.local.output.class</name>
    <value>org.apache.hadoop.mapred.MapRFsOutputFile</value>
</property>
```

Apache Shuffle on YARN

You can disable Direct Shuffle and enable Apache Shuffle by modifying the configuration options in the `yarn-site.xml` and `mapred-site.xml` files. This page describes how to configure Apache Shuffle for MapReduce applications.

last-updated: Apr 11, 2022

The shuffling phase in Hadoop is the process of transferring mappers intermediate output to the reducers. Direct shuffle increases the load on MapR File System disks. You can enable the Apache Shuffle to reduce the load on MapR File System disks.

Configuration for Apache Shuffle

Add the following property to `yarn-site.xml` file:

```
<property>
    <name>yarn.nodemanager.aux-services</name>
    <value>mapreduce_shuffle</value>
</property>
```

Add the following properties to `mapred-site.xml` file:

```
 <property>
    <name>mapreduce.job.shuffle.provider.services</name>
    <value>mapreduce_shuffle</value>
</property>
<property>
    <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
    <value>org.apache.hadoop.mapreduce.task.reduce.Shuffle</value>
</property>
<property>
    <name>mapreduce.job.map.output.collector.class</name>
    <value>org.apache.hadoop.mapred.MapTask$MapOutputBuffer</value>
</property>
<property>
    <name>mapred.ifile.outputstream</name>
    <value>org.apache.hadoop.mapred.IFileOutputStream</value>
</property>
<property>
    <name>mapred.ifile.inputstream</name>
    <value>org.apache.hadoop.mapred.IFileInputStream</value>
</property>
<property>
    <name>mapred.local.mapoutput</name>
    <value>true</value>
</property>
<property>
    <name>mapreduce.task.local.output.class</name>
    <value>org.apache.hadoop.mapred.YarnOutputFiles</value>
</property>
```

Logging Options on YARN

Describes the logging options that are available on YARN.

For YARN applications, there are various logging options to choose from based on the MapR version and the types of applications that you run. In 4.0.2 and later versions, you have the following logging options:

- For MapReduce version 2 (MRv2) applications, the default logging option is to log files on the local filesystem. However, central logging and YARN log aggregation are also available.
- For non-MapReduce applications, the default logging option is to log files on the local filesystem. However,YARN log aggregation is also available.

Centralized Logging for MRv2	Centralized logging provides an application-centric view of all the log files generated by NodeManager nodes throughout the cluster. It enables users to gain a complete picture of application execution by having

	all the logs available in a single directory, without having to navigate from node to node. The MapReduce program generates three types of log output: • Standard output stream: captured in the `stdout` file • Standard error stream: captured in the `stderr` file • Log4j logs: captured in the `syslog` file Centralized logs are available cluster-wide as they are written to the following local volume on the MapR filesystem: / `var/mapr/local/<NodeManager node>/logs/yarn/userlogs` Since the log files are stored in a local volume directory that is associated with each NodeManager node, you run the `maprcli job linklogs` command to create symbolic links for all the logs in a single directory. You can then use tools such as `grep` and `awk` to analyze them from an NFS mount point. You can also view the entire set of logs for a particular application using the HistoryServer UI.
YARN Log Aggregation	The YARN log aggregation option aggregates logs from the local filesystem and moves log files for completed applications from the local filesystem to the MapR filesystem. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

Support for ADLS
Starting with MapR 6.1, you can use Azure Data Lake Store (ADLS) as a data source or destination for all applications.

Prerequisites for Using ADLS
Setting up Azure Data Lake Store (ADLS) on the Azure portal enables you to access ADLS from any application.

- Create an account on the Azure portal.
- Create an Azure Data Lake Store (get started with Azure Data Lake Storage).

Authenticating ADLS Account
To access data stored in Azure Data Lake Store (ADLS), you must first authenticate your ADLS account using your ADLS credentials.

1. Obtain the following properties from your Azure application:
   - `dfs.adls.oauth2.access.token.provider.type`

     `ClientCredential`, `Refresh Tokens`, or `Client Keys` to obtain the authentication type.
   - `dfs.adls.oauth2.client.id`

     Create an Azure Active Directory application and get your application ID and authentication key.

- `dfs.adls.oauth2.refresh.url`

  Navigate to Azure Active Directory and click on `Endpoints`. Use the `OAUTH 2.0 TOKEN ENDPOINT` value.

- `dfs.adls.oauth2.credential`

  Obtain the access token key value from `App Registrations` in your Azure account.

2. Add the properties obtained in step 1 to the `core-site.xml` file:

```
<!--ADL-->
<property>
   <name>dfs.adls.oauth2.access.token.provider.type</name>
   <value>ClientCredential</value>
</property>

<property>
   <name>dfs.adls.oauth2.client.id</name>
   <value>f377fab9-c0a3-4531-a1c9-77345105</value>
</property>

<property>
   <name>dfs.adls.oauth2.refresh.url</name>
   <value>https://login.microsoftonline.com/25735fb/oauth2/token</
value>
</property>

<property>
   <name>dfs.adls.oauth2.credential</name>
   <value>WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/d2z2CGiw=</value>
</property>
```

   Note: The `core-site.xml` file can be overwritten using the command line. You can also specify these properties at runtime. The syntax for overwriting ADLS properties at runtime using the command line is as follows:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
-Ddfs.adls.oauth2.access.token.provider.type=ClientCredential
-Ddfs.adls.oauth2.client.id=f377fab9-c0a3-4531-a1c9-77345105
-Ddfs.adls.oauth2.refresh.url=https://login.microsoftonline.com/
25735fb/oauth2/token
-Ddfs.adls.oauth2.credential=WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/
d2z2CGiw= adl://testhue.azuredatalakestore.net/some_folder/testfile
adl://testhue.azuredatalakestore.net/some_folder/wordcountout
```

   To provide your ADLS credentials securely, see Securely Providing ADLS Credentials on page 42.

3. Provide your application with file access.

4. For secure clusters, MapR-SASL (Simple Authentication and Security Layer), and Kerberos, import the required CA certificate.

- Open source documentation
- Azure documentation
- Azure documentation on authorization and access control

last-updated: Apr 11, 2022

-

Securely Providing ADLS Credentials
You can provide your ADLS credentials securely by hiding the open, readable configuration on the command line using the Hadoop credential provider.

1. Generate a `jceks` file for ADLS authorization:

```
hadoop credential create dfs.adls.oauth2.client.id -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client ID
hadoop credential create dfs.adls.oauth2.credential -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client secret
hadoop credential create dfs.adls.oauth2.refresh.url -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value refresh URL
```

2. Run the `DistCp` example using the `jceks` file:

```
hadoop distcp
[-D hadoop.security.credential.provider.path=localjceks://hdfs/user/
USER_NAME/adlskeyfile.jceks]
hdfs://<NameNode Hostname>:9001/user/foo/007020615
adl://<Account Name>.azuredatalakestore.net/testDir/
```

3. Configure the `core-site.xml` file to use the `jceks` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://hdfs/user/USER_NAME/adlskeyfile.jceks</value>
  <description>Path to interrogate for protected credentials.</
description>
</property>
```

Using ADLS for Data Input or Output
You can use Azure Data Lake Store (ADLS) as a source or destination for your application data.

For general information about the features of ADLS, refer to the Azure Data Lake Store documentation.

For information about configuring ADLS as storage for a Hadoop cluster, refer to the official Apache documentation.

The Azure Data Lake Storage access path syntax is:

```
adl://<Account Name>.azuredatalakestore.net/
```

You can use ADLS the same way as you use MapR File System, substituting an `adl` scheme instead of `maprfs`, `hdfs`, `webhdfs`, and so on.

1. Create a directory and read data:

```
[mapr@node4 ~]$ hadoop fs -mkdir adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/

Found 1 items
drwxr-xr-x - 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:09
adl://<username>.azuredatalakestore.net/testdir
```

2. Put data into ADLS from your local MapR File System:

```
[mapr@node4 ~]$ hadoop fs -put testfile adl://
<username>.azuredatalakestore.net/testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
testdir

Found 1 itemsrw-rr- 1 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:10
adl://<username>.azuredatalakestore.net/testdir/testfile
```

3. Delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

4. Run YARN jobs with your input and output stored in ADLS:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
adl://<username>.azuredatalakestore.net/testdir/testfile adl://
<username>.azuredatalakestore.net/wordcountout
```

Deleting Data from ADLS

You can delete your data from Azure Data Lake Store (ADLS).

- To delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

List of YARN Enhancements for MapR 6.0.1

MapR 6.0.1 runs the 2.7.0 version of Hadoop. A number of new features were incorporated into the version of Hadoop that MapR Converged Data Platform 6.0.1 uses.

You can enable or disable additional debug logs. See yarn debugcontrol on page 5352

The aws-java-sdk version for hadoop was updated to 1.11.199

Maven and MapR

This section discusses topics associated with Maven and MapR.

Maven Artifacts for MapR

Maven artifacts can be used for dependency management when developing applications based on the MapR platform.

You can access the MapR Maven repository by browsing Nexus or as follows:

```
<repositories>
  <repository> <id>mapr-releases</id>
```

```
    <url>https://repository.mapr.com/maven/</url>
    <snapshots><enabled>false</enabled></snapshots>
    <releases><enabled>true</enabled></releases>
  </repository>
</repositories>
```

Maven Artifacts for EEP 7.1.1

Maven artifacts for EEP 7.1.1 are unchanged from the Maven artifacts for EEP 7.1.0.

See Maven Artifacts for EEP 7.1.0 on page 4233.

Maven Artifacts for EEP 7.1.0

Listed are all Maven artifacts for EEP 7.1.0 components.

Table

Group Id	Artifact Id	Version	Maven Coordinate

com.mapr.db	maprdb-spark_2.12	2.4.7.100-mapr-710
		Browse
			`<dependency>`

Integrating the MapR GitHub and Maven Repositories

This topic provides instructions for cloning the GitHub and Maven repositories for a MapR open source project into your Eclipse IDE.

Integrating Git

1. Open the Git Repository perspective by selecting **Window**>**Open Perspective**>**Other...** then choosing **Git Repository Exploring**.

last-updated: Apr 11, 2022

2. From the Git Repository perspective, click the  button to display the **Clone Git Repository** dialog.

3. From a web browser, navigate to the MapR repository, then select the project you want to clone.

4. Copy the git URI from the project page to your clipboard by clicking the  button.

5. In the **Clone Git Repository** dialog, paste the git URI into the **URI:** field, then click **Next**. Eclipse will connect to github and download the repository metadata, then display a list of branches.

6. Select the branches you wish to clone, then click **Next**.

7. Configure the destination directory, then click **Finish**. Eclipse downloads the project from github and adds it to your view.

Integrating Maven

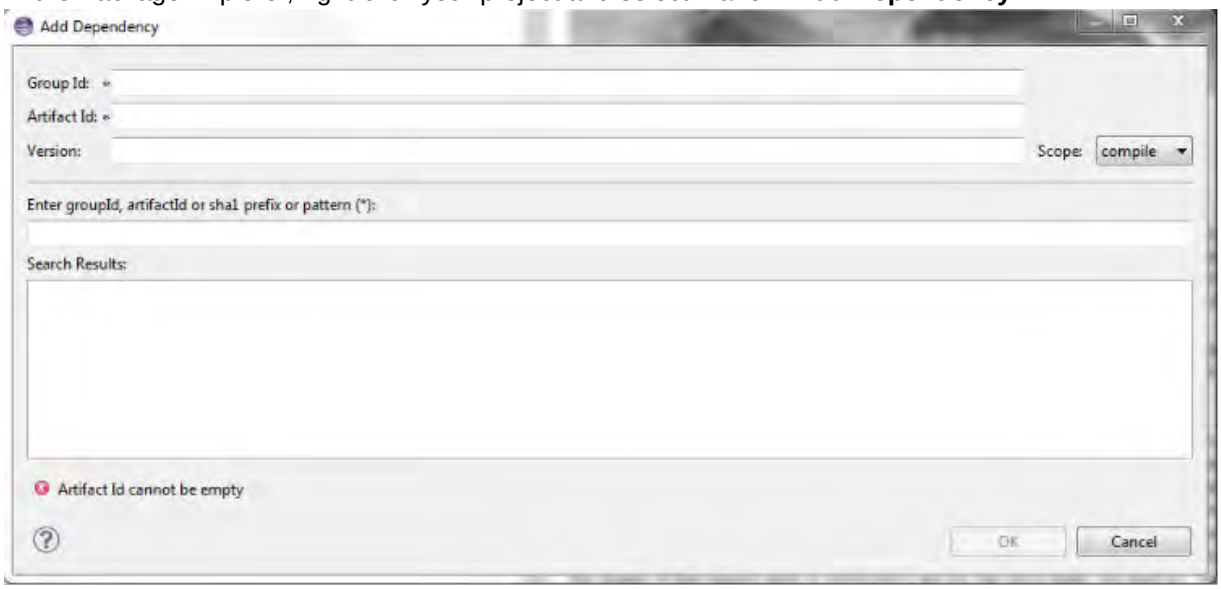
1. Start a new Maven project, or convert your current project into a Maven project if necessary.

last-updated: Apr 11, 2022

2. Select **Window**>**Show View**>**Package Explorer** to show your current Maven project.
3. Add the following lines to your project's `pom.xml` file:

```
<repositories>
              <repository>
              <id>mapr-releases</id>
              <url>https://repository.mapr.com/maven/</url>
              <snapshots><enabled>false</enabled></snapshots>
              <releases><enabled>true</enabled></releases>
              </repository>
              </repositories>
```

4. In a browser, navigate to the MapR Maven Repository and search for the Maven artifact your project depends on. You can also browse the repository.
5. In the Package Explorer, right-click your project and select **Maven**>**Add Dependency**.



6. Enter the `groupId`, `artifactId`, and `version` values for the dependency, then click **OK**.
7. Refresh the workspace by pressing F5. Your Maven dependencies download automatically.

Developer's Reference

This section contains in-depth information for the developer.

MapR Database Shell (JSON Tables)

The mapr dbshell is a tool that enables you to create and perform basic manipulation of JSON tables and documents. You run dbshell by typing `mapr dbshell` on the command line after logging into a node in a MapR Data Platform cluster.

Note: MapR Database Shell does not support MapR Event Store For Apache Kafka streams operations.

last-updated: Apr 11, 2022

Permissions

Before running dbshell, your user ID must have both the `readAce` and `writeAce` permissions on the volume. For information about these permissions, see Managing Whole Volume ACEs on page 1458.

SUSE Linux Error Messages

When you run dbshell on SUSE Linux, you might see the following messages:

```
[INFO] Unable to bind key for unsupported operation: backward-delete-word
[INFO] Unable to bind key for unsupported operation: up-history
[INFO] Unable to bind key for unsupported operation: down-history
```

To suppress these messages, edit the `/etc/inputrc` file and rename the keywords as follows:

Original name	New name
`backward-delete-word`	`backward-kill-word`
`down-history`	`next-history`
`up-history`	`previous-history`

Command Descriptions

To get a list of supported dbshell commands, run `help` at the shell prompt:

```
* ! - Allows execution of operating system (OS) commands
* // - Inline comment markers (start of line only)
* ; - Inline comment markers (start of line only)
* cat - Print the content of the specified file on the standard output
* cd - Change the current directory to the specified path.
* clear - Clears the console
* cls - Clears the console
* create - Create a json table at the given path.
* date - Displays the local date and time
* debug - Sets/shows the debug mode.
* delete - Delete a document from the table.
* desc - Describes the properties of a table.
* drop - Deletes a MapR-DB json table.
* exists - Returns true if the table exists.
* exit - Exits the shell
* find - Retrieves one or more documents from the table.
* findbyid - Retrieves a single document from the table.
* help - List all commands usage
* indexlist - Retrieves the list of indexes for the specified table.
* indexscan - Scan the index and return the document in their natural order.
* insert - Inserts or replaces a document into the table.
* jsonoptions - Sets/shows the Json output options.
* list - Lists all tables in a folder or matching the specified pattern.
* ls - Lists files and folders.
* mkdir - Create a directory at the specified path.
* pwd - Print the absolute path of the current working directory.
* quit - Exits the shell
* replace - Replace a document based on condition.
* script - Parses the specified resource file and executes its commands
* system properties - Shows the shell's properties
* tableoptions - Sets/shows the MapR-DB Table access options.
* update - Update field in a single document.
* version - Displays shell version
* whoami - Prints the current MapR-DB Shell user.
```

last-updated: Apr 11, 2022

Parameters

Various components of these commands will be either be in JSON (in case a list of key-value is required) or a single value following a switch identifying the component.

To get a list of parameters for a specific command, run `help <command>` at the prompt. For example: `help find` returns the following:

```
maprdb root:> help find
Command:                    find
Description:                Retrieves one or more documents from the table.
Options:
  *, --t, --table           Table path. [required]
  --id                      Document Id.
  --fromid                  Document Id to start from (inclusive)
  --toid                    Document Id to stop at (exclusive)
  --limit                   Maximum number of documents to return.
  --withtags, --withTags    Enables/disables printing with extended Type
Tags.
  --pretty                  Enables/disables pretty printing of the document.
  --offset                  Skip first n number of rows in the result.
  --orderby                 Sort result by the given fields.
  --c, --where              Condition in JSON format
  --f, --fields             Projections in JSON documents
  --q, --query              Query in JSON documents
Examples:
  find /tables/users
  find /tables/users --fromid user001 --toid user00a --limit 32
```

Value Types

Extended type values are shown using type tags. The scalar types are represented as follows:

- {"$binary":"AAAASw=="} for binary values
- {"$numberLong":21491} for whole numbers like long, short, byte, short
- {"$numeric":47.92} for numeric types like float and double
- {"$time":"14:35:28.981"} for time type values
- {"$date":"2017-04-24T22:35:28.981Z"} for timestamp values
- {"$dateDay":"2017-04-23"} for date type values

Bulk Operations

Currently, bulk conditional operations are not supported.

dbshell create

Describes how to use MapR Database shell to create a JSON table.

Description

To create JSON tables, run the `create <table path>` command.

When you create a JSON table using `mapr dbshell`, the default column family is created automatically. There are no commands for creating additional column families. To create column families, exit the shell and use the `maprcli table cf create` command.

last-updated: Apr 11, 2022

Note: If you are using a 5.2.x dbshell client to connect to a 6.0 (or later) server, you must set the `insertionorder` table option to false before creating your table. The `insertionorder` option is not support as of 6.0. See the following example:

```
tableoptions --insertionorder false
```

Run `tableoptions` in dbshell to see the current setting of `insertionorder`.

Parameters

create Options	Description
`--t`, `--table` `<table path>`	Table path Although the `--t` and `--table` qualifiers are optional, you must specify a `<table path>`.

Syntax

```
create <table path>
```

Example

In the following example, **data** is the volume name and **movies** is the new table name.

```
create /data/movies
```

dbshell delete

Description

The dbshell `delete` command deletes a single JSON document. To delete a document, specify the path of the table where the document is located, the ID of the document, and an optional condition. If the condition for the specified document evaluates to true, the document is deleted.

Parameters

delete Options	Description
`*`, `--t`, `--table` (Required)	Table path
`--id` (Required)	ID of the document to delete **Note:** You can specify this parameter only once.
`--c`, `--where`	OJAI condition, in JSON format The condition must qualify to perform the delete. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.

Syntax

```
delete <table path> --id <row-key> --c <condition>
```

last-updated: Apr 11, 2022

Example: Delete a Document if a Condition is Met

The following example deletes the document with the `_id id1`, if the condition `(a.b[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1))` is met:

```
delete /tbl --id id1
    --c {
        "$and":[
            {"$eq":{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":{"a.b[1].decimal":1}}
            ]}
        ]}
```

Example: Delete a Document

The following example deletes a document with `_id movie0000002` from the `movies` table:

```
delete /data/movies --id movie0000002
```

dbshell drop

Description

To run the `drop` command, specify the path to the MapR Database JSON table.

Parameters

Table

drop Options	Description
*, `--t`, `--table` (Required)	Table path

Syntax

```
drop <table path>
```

Example

```
drop /data/movies
```

dbshell find or findbyid

To query JSON documents in MapR Database shell, use either the `find` or `findbyid` command. The `find` command enables you to scan complete tables and retrieve rows that satisfy projection and/or condition clauses. The `findbyid` command enables you to retrieve a single document with a given ID.

When you review the `find` examples, note that they are sometimes shown split across multiple lines for readability. You must enter the commands on a single line when you run them in dbshell.

Note: If your `find` query requires the OJAI Distributed Query Service on page 505, you must install the `mapr-drill-internal` package on the nodes where you run dbshell. The package is available in the MapR repository from which you download MapR Ecosystem Packs. See MapR Repositories and Packages on page 128 for details.

last-updated: Apr 11, 2022

Syntax

```
find <table path> <options>
```

```
findbyid <table path> --id <key-row ID>
```

Parameters

find Options	findbyid Options	Description
`*`, `--t`, `--table` (Required)	`*`, `--t`, `--table` (Required)	Table path
`--id`	`--id` (Required)	Document ID For conditions on a single document ID, you can provide the ID either by using the `--id` switch or by specifying the ID in a condition payload. For example, `--id id1` is equivalent to `--c {"$eq": {"_id":"id1"}}`. **Note:** You cannot specify multiple IDs using either syntax.
`--fromid`	n/a	Document ID to start from (inclusive)
`--toid`	n/a	Document ID to stop at (exclusive)
`--limit`	n/a	Maximum number of documents to return
`--withtags`, `--withTags`	`--withtags`, `--withTags`	Enables or disables printing with extended type tags Value: `True`|`False` Default: `True`
`--pretty`	`--pretty`	Enables or disables pretty printing of documents Value: `True`|`False` Default: `True`
`--offset`	n/a	Omits the first n number of documents in the result
`--orderby`	n/a	Sorts the result by the given fields Specify sort order as either ascending or descending using the keywords, `ASC` or `DESC`, respectively. Default: `ASC` **Note:** The keywords `ASC` and `DESC` are case insensitive. Syntax: `find <table path> --orderby <field path>:<sortorder>` See Query with --orderby on page 5296 for examples.

last-updated: Apr 11, 2022

find Options	findbyid Options	Description
`--c`, `--where`	`--c`, `--where`	Condition, in JSON format See OJAI Query Condition Syntax on page 2606 for a description of the syntax. See Return Documents Using Projection and Conditions on page 5298 for a dbshell example that uses a condition specified in JSON format.
`--f`, `--fields`	`--f`, `--fields`	Projections in JSON documents See JSON Document Field Paths on page 515 for details about how to specify field paths. See Return Documents Using Projection and Conditions on page 5298 for an example.

`--q`, `--query`	n/a	Query JSON documents
		This option accepts a query string in JSON format with predefined keywords that define the behavior of the query.
		The following examples shows a query that uses three keywords:
		`find table/test --q { "$select":"a", "$limit":2, "$offset":1 }`
		Note: The `find` command does not allow `--query` to work with other options, such as `--fields`, `--where`, and `--orderby`. For example, the following command ignores the `--f` option:
		`find table/test --f "a" --q {"$limit":2}`
		In addition, you should not enter the same keyword twice:
		`// Incorrect {"$select":"a","$select":"b"}`
		`// Correct {"$select":["a","b"]}`
		See Query with --query on page 5292 for more examples.

Query with --query

When querying JSON documents with the `find` command, you can use OJAI query syntax with the `--query` option. With this option, you can specify keywords that determine the documents and the fields from those documents that the command returns.

Syntax

```
find <table path> --query <keywords>
```

Note: The `find` command does not allow `--query` to work in tandem with other options such as `--fields`, `--where`, and `--orderby`.

For example, the following command does not return your desired results:

```
find /tbl --f a --q {"$limit":2}
```

In addition, repetition of keywords in the `--query` option is not supported. You should not enter the same keyword twice:

```
// Incorrect
{"$select":"a","$select":"b"}

// Correct
{"$select":["a","b"]}
```

Keywords for the `--query` Option

The `--query` option supports the following keywords:

--query Keywords	Equivalent `find` Option
$select	Equivalent to the `--f`, `--fields` option
$where	Equivalent to the `--c`, `--where` option
$limit	Equivalent to the `--limit` option
$offset	Equivalent to the `--offset` option
$orderby	Equivalent to the `--orderby` option
$options	No equivalent option

The following sections provide examples of each keyword. For more details, see OJAI Query Syntax on page 2603.

Sample JSON Document

The examples in this topic use the following sample JSON document:

```
{
    "_id": "id1",
    "a": {
            "b": [{"boolean":false}, {"decimal": 123.456}],
            "c":{
                  "d":10,
                  "e":"Hello"
                }
          },
    "m":"MapR wins"
}
```

$select Syntax and Example

The `$select` keyword defines the field path projections to be displayed in the result set.

The following syntax shows single and multiple field path projections:

```
// Single field path projection syntax
find <table path> --q {"$select":"<fieldpath>"}
```

last-updated: Apr 11, 2022

```
// Multiple field path projection syntax
find <table path> --q {"$select":
["<fieldpath1>","<fieldpath2>","<fieldpath3>"]}
```

The following examples show single and multiple field path projections:

```
// Single field path projection example
find /tbl --q {"$select":"a.c.d"}

// Multiple field path projection example
find /tbl --q {"$select":["a.c.d","a.c.e","m"]}
```

See OJAI Query Projection on page 2604 for more information about `$select`.

$where Syntax and Example

When using the `$where` keyword, define the condition using OJAI Query Condition Syntax on page 2606.

```
find <table path> --q {"$where":<condition>}
```

The following example performs a `find` operation with a projection and a condition:

```
find /tbl --q {"$select":"a.c.e",
            "$where":{
                    "$and":[
                            {"$eq":{"a.b[0].boolean":false}},
                            {"$or":[
                                    {"$ne":{"a.c.d":5}},
                                    {"$gt":{"a.b[1].decimal":1}},
                                    {"$lt":{"a.b[1].decimal":10}}
                                    ]
                             }
                            ]
                    }
              }
```

The projection is on field `a.c.e`. The condition is the following expression:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

$limit Syntax and Example

The `$limit` keyword sets the maximum number of documents to return. It only accepts positive integers. It throws an exception for negative or decimal values.

```
find <table path> --q {"$limit":<positive integer>}
```

The following example performs a `find` with a projection on the `a.c.e` and `m` fields and limits the result set to a max of 10 documents:

```
find /tbl --q {"$select":["a.c.e","m"],
              "$limit":10
             }
```

See OJAI Query Limit on page 2605 for more information about `$limit`.

$offset Syntax and Example

The `$offset` keyword skips the first n number of rows in the result. If n is greater than the total number of documents, no documents are returned. It only accepts positive integers.

```
find <table path> --q {"$offset":<positive integer>}
```

The following example performs a `find` operation with projection on the `a.c.e` and `m` fields and offsets the result set to skip first five documents:

```
find /tbl --q {"$select":["a.c.e","m"],
               "$offset":5
              }
```

See OJAI Query Offset on page 2605 for more information about `$offset`.

$orderby Syntax and Examples

The `$orderby` keyword sorts the result on the specified fields.

The following shows the syntax and example of sorting a single field in the default ascending order:

```
// Syntax for sorting a single field in the default ascending order
find <table path> --q {"$orderby":"<field path>"}

// Example sort on field path a.c.e in the default ascending order
find /tbl --q {"$orderby":"a.c.e"}
```

The following show the syntax and examples of sorting a single field in ascending or descending order where `<order>` is `ASC` for ascending and `DESC` for descending:

```
// Syntax for sorting a single field in ASC/DESC order
find <table path> --q {"$orderby":{"<field path>":"<order>"}}

// Example sort on field path a.c.e in ascending order
find /tbl --q {"$orderby":{"a.c.e":"asc"}}

// Example sort on field path a.c.e in descending order
find /tbl --q {"$orderby":{"a.c.e":"desc"}}
```

Note: The keywords `ASC` and `DESC` are case insensitive.

The following shows the syntax and an example of sorting multiple fields in ascending and descending order:

```
// Syntax for sorting multiple field paths in ascending/descending order
find <table path> --q {"$orderby":[{"<field path1>":"<order>"},
                                   {"<field path2>":"<order>"},
                                   {"<field path3>":"<order>"}
                                  ]
                      }

// Example sort on field path a.c.d (in the default ascending order)
// and field path a.c.e in descending order
find /tbl --q {"$orderby":["a.c.d",{"a.c.e":"desc"}]}
```

See OJAI Query Order By on page 2605 for more information about `$orderby`.

last-updated: Apr 11, 2022

$options Syntax and Example

The `$options` keyword enables you to influence a query's execution path. The general syntax is as follows:

```
find <table path> --q {"$options":{<option name>:<option value>}}
```

When specifying the `<option name>`, you must separate the components of the option name, replacing the dots with curly braces and colons and enclosing each component in quotes. The following example shows you how to do this for the `ojai.mapr.query.hint-using-index` option. The example forces the query to use a secondary index named `colIndex`:

```
find /apps/test --q {
    "$where":{"$eq":{"col":10}},
    "$options":{"ojai":{"mapr":{"query":{"hint-using-index":"colIndex"}}}}
    }
```

See OJAI Query Options on page 2588 for a complete list of available query options.

Query with --orderby

When querying JSON documents with the `find` command, you can use the `--orderby` option to order the data. You can specify either an ascending or descending sort using the keywords, `ASC` and `DESC`.

General Syntax

```
find <table path> --orderby <field path>:<sortorder>
```

The keywords `ASC` and `DESC` are case insensitive. Ascending is the default sort order.

Sample JSON Document

The following sample JSON document is used in examples in this section:

```
{
    "_id": "id1",
    "a": {
            "b": [{"boolean":false}, {"decimal": 123.456}],
            "c":{
                  "d":10,
                  "e":"Hello"
                 }
          },
    "m":"MapR wins"
}
```

Simple Sort

The following syntax and example are a simple sort on a single field path in the default ascending sort order:

```
// Syntax
find <table path> --orderby <field path>

// Example
find /tbl --orderby a.c.d
```

Specific Sort on Single Field

The following syntax and example are a sort with a specified ordering on a single field path:

```
// Syntax
find <table path> --orderby <field path>:<sort order>

// Example
find /tbl --orderby a.c.d:desc
```

Specific Sort on Multiple Fields

The following syntax and example specify a sort ordering on each field path:

```
// Syntax
find <table path> --orderby <field path>:<sort order>,<field path>:<sort
order>

// Example
find /tbl --orderby a.c.d:asc,a.c.e:desc
```

Mixed Mode Sort on Multiple Fields

The following syntax and example specify a sort ordering on one field path and use the default sort order (ascending) on another field path.

```
// Syntax
find <table path> --orderby <field path>:<sort order>,<field path>

// Example
find /tbl --orderby a.c.d:DESC,a.c.e
```

Query Examples with Other Options

This section contains examples of `findbyid` and `find` commands using options not used in examples in other sections.

Return all Documents

When you do not specify other options to `find` except the table path, the command returns all documents. The following example returns all documents that are in the `/data/movies` table:

```
find /data/movies
```

Return Limited Number of Documents with Specified Range of IDs

The following example returns at most 32 documents within a range of IDs that includes the specified starting ID and excludes the specified ending ID:

```
find /data/movies --fromid movie0000001 --toid movie0000100 --limit
32
```

Return all Documents with Specified ID

The following example returns the document that has the specified ID:

```
findbyid /data/movies --id movie0000002
```

last-updated: Apr 11, 2022

Return Documents Using Projection and Conditions

The following example performs a `find` operation with a projection and condition and limits the result to 10 documents:

```
find /tbl --c {
              "$and":[
                 {"$eq":{"a.b[0].boolean":false}},
                 {"$or":[
                    {"$ne":{"a.c.d":5}},
                    {"$gt":{"a.b[1].decimal":1}},
                    {"$lt":{"a.b[1].decimal":10}}
                 ]}
              ]}
           --fields m,a.c.e --limit 10
```

The projection is on fields on `m` and `a.c.e`. The condition is the following expression:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Returns Documents in Specified Order

The following example is identical to the previous one, except it also includes an ordering on the result:

```
find /tbl --c {
              "$and":[
                 {"$eq":{"a.b[0].boolean":false}},
                 {"$or":[
                    {"$ne":{"a.c.d":5}},
                    {"$gt":{"a.b[1].decimal":1}},
                    {"$lt":{"a.b[1].decimal":10}}
                 ]}
               ]}
           --fields m,a.c.e
           --orderby m,a.c.e:desc
           --limit 10
```

dbshell indexscan

Description

The `indexscan` command scans secondary indexes and returns the document ID and the values of the indexed and included fields. This includes displaying information about errors encountered inserting into the index.

Syntax

```
maprdb root:> indexscan
        <table path>
        --indexname <index name>
        --limit
        --withtags
        --pretty
        --mode
        --where
        --fields
        --decodeindexedfields
```

Parameters

Parameters	Description
`*`, `--t`, `--table` (Required)	Path of the JSON table
`--indexname`, `--indexName` (Required)	Name of the secondary index
`--limit`	Maximum number of documents to return
`--withtags`, `--withTags`	Enables or disables printing with extended JSON type tags Values: `true`|`false`
`--pretty`	Enables or disables pretty printing of documents Values: `true`|`false`
`--mode`	Enables display of the error information for the index Value: `err` If you specify `--mode err`, the command scans only rows with errors and prints the `_id` and `$ERROR` fields. If you do not specify `--mode`, the command prints the `_id`, indexed, and included fields of rows that do not have errors. The following lists the types of errors: • `KEY_TOO_LONG` • `INVALID_CAST`
`--c`, `--where`	Condition, in JSON format, that filters the rows returned See OJAI Query Condition Syntax on page 2606 for a description of the syntax.
`--f`, `--fields`	Fields from the index to return See JSON Document Field Paths on page 515 for details about how to specify field paths.
`--decodeindexedfields`	Enables display of values for indexed fields that are nested documents or arrays Value: `true` **Note:** This parameter ignores all other values, including specifying no value.

Example: Simple Index

The following example uses a simple index where `index1` is on `table1`, field `a`.

```
// Insert one document
maprdb root:> insert /table1 --id 1 --value '{"a":7}'
Document with id: "1" inserted.

// Create index1 on table1 and index field a
```

last-updated: Apr 11, 2022

```
# maprcli table index add -path /table1 -index index1 -indexedfields a

// Perform a normal indexscan; the _id field and the indexed field for the
document is displayed
maprdb root:> indexscan /table1 --indexname index1
{"_id":"1","a":7}
1 document(s) found.

// Insert another document with _id value as 2 with field a as a map
maprdb root:> insert /table1 --id 2 --value '{"a":[1,2,3]}'

// Perform a normal indexscan; the document that does not have the error is
displayed
maprdb root:> indexscan /table1 --indexname index1
{"_id":"2","a":[1,2,3]}
{"_id":"1","a":7}
2 document(s) found.

// Perform an indexscan with error mode; no errors are displayed because
MapR-DB 6.1 allows
// you to create indexes on array fields
maprdb root:> indexscan /table1 --indexname index1 --mode err
0 document(s) found.
```

Example: Composite Index

The following example uses a composite index with included fields, in which `index2` is on table `table1`, with indexed fields a and b and included field c.

```
// Insert a document with fields 'a', 'b' and 'c'.
maprdb root:> insert /table1 --id 2 --value '{"a":7,"b":"mapr","c":"db"}'
Document with id: "2" inserted.

// Create index2 on table1 withindexed fields a and b, and included field c
# maprcli table index add -path /table1 -index index2 -indexedfields
a,b -includedfields c

// Perform an indexscan
maprdb root:> indexscan /table1 --indexname index2
{"_id":"2","c":"db","a":7,"b":"mapr"}
1 document(s) found.

// Insert a document that has field a as a map
maprdb root:> insert /table1 --id 1 --value '{"a":
{"m":4},"b":"mapr","c":"db"}'
Document with id: "1" inserted.

// Perform a normal indexscan
maprdb root:> indexscan /table1 --indexname index2
{"_id":"1","c":"db","a":{"m":4},"b":"mapr"}
{"_id":"2","c":"db","a":7,"b":"mapr"}
2 document(s) found.

// Perform an indexscan with error mode; no errors are displayed because
MapR-DB 6.1 allows
// you to create indexes on array fields
maprdb root:> indexscan /table1 --indexname index2 --mode err
0 document(s) found.
```

last-updated: Apr 11, 2022

Example: Index on Container Field Paths

Assume you have a table in the path `/apps/indexExample` with the following document:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
      {"Type": "Home", "Number": "555-555-1234"},
      {"Type": "Mobile", "Number": "555-555-5678"},
      {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

The following example creates a composite index on the `Type` and `Number` subfields in the nested documents in the `Phones` array:

```
// Create idx3 on the table with indexed fields Phones[].Type and
Phones[].Number
# maprcli table index add -path /apps/indexExample -index idx3 \
    -indexedfields Phones[].Type,Phones[].Number

// Perform an indexscan WITHOUT the decodeindexedfields parameter.
// Three rows are returned, one for each element in the Phones[] array.
// The output contains no values for the indexed fields.
maprdb root:> indexscan /apps/indexExample --indexname idx3
{"_id":"10000"}
{"_id":"10000"}
{"_id":"10000"}
3 document(s) found

// Perform an indexscan WITH the decodeindexedfields parameter set to true.
// The output includes the values in the indexed fields.
maprdb mapr:> indexscan /apps/indexExample --indexname
idx3 --decodeindexedfields true
{"_id":"10000","$idx":["Home","555-555-1234"]}
{"_id":"10000","$idx":["Mobile","555-555-5678"]}
{"_id":"10000","$idx":["Work","555-555-9012"]}
3 document(s) found.
```

Troubleshooting Use Cases

Situations where you can use this command are as follows:

- List the contents of an index.
- Resolve encoding errors encountered inserting into an index.

last-updated: Apr 11, 2022

See Troubleshooting Secondary Indexes on page 1092 for more information on these use cases.

dbshell insert

Description

The dbshell `insert` command adds documents to JSON tables. Specify the ID of the document in one of two ways:

- As the value of the `_id` field in the document
- As the value of the `--id` parameter in the `insert` command

If a document with the specified ID already exists, the command replaces the document with the new one.

Parameters

insert Options	Description
`*`, `--t`, `--table` (Required)	Table path
`--id`	ID of the document to insert or replace
`--v`, `--value` (Required)	JSON document to insert or replace
`--c`, `--where`	OJAI condition, in JSON format The condition must qualify to perform the insert. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.

Syntax

```
insert --table <table path> --value '{"_id": "<row-key", < table field >}'
```

```
insert --table <table path> --id <row-key> --value '{"_id": "<row-key", <
table field >}'
```

Example: Insert with `_id` Field

The following examples insert a document into a table using an `_id` field value:

```
insert /data/movies --value '{"_id":"movie0000002",
                              "title":"Developers on the Edge",
                              "studio":"Command Line Studios"}'
```

```
insert /tables/users --value '{"_id":"user001",
                               "first_name":"John",
                               "last_name":"Doe"}'
```

last-updated: Apr 11, 2022

Example: Insert with `--id` Parameter

The following examples insert a document into a table using the `--id` parameter in the insert command:

```
insert /data/movies --id movie0000003 --value '{"title":"The Golden
Master",
                                                "studio":"All-Nighter"}'
```

```
insert /tables/users --id user002 --value '{"first_name":"Jane",
                                             "last_name":"Dane"}'
```

dbshell jsonoptions

Description

The `jsonoptions` command sets the JSON output and displays the output appropriately.

Parameters

Table

jsonoptions Options	Description
`--pretty`	Enables or disables pretty printing mode Value: `true`|`false` Default: `true` Pretty print mode displays the content of the documents as an indented hierarchy of field/value pairs. For example, if the value is `true`, the DATE data type appears as a Map: `"dob" : {"$dateDay":"2012-10-20"}`
`--withtags`, `--withTags`	Enables or disables printing with extended JSON data type tags Value: `true`|`false` Default: `true` For example, if the value is `false`, the DATE data type appears as a simple value: `"dob" : "2012-10-20"`

Syntax

```
jsonoptions --pretty <true|false>
jsonoptions --withTags <true|false>
```

Example

```
jsonoptions --pretty true
jsonoptions --withTags false
```

dbshell list

last-updated: Apr 11, 2022

Description

Lists all JSON tables in a folder or that matches a specific file pattern where the table resides.

Parameters

Table

list Options	Description
*, --p, --patternOrPath	A path and/or a file pattern

Syntax

```
list <path>
```

Example and Output

```
maprdb root:>list /demo
/demo/user
/demo/checkin
/demo/review
/demo/business
/demo/tip
5 table(s) found.
```

dbshell replace

Description

The dbshell `replace` command replaces a document in a JSON table. You can specify a condition with the command.

Parameters

replace Options	Description
*, --t, --table (Required)	Table path
--id (Required)	ID of the document to replace If the specified ID does not exist, the command inserts a new document with the values provided in the command. **Note:** You can specify this parameter only once.
--v, --value (Required)	JSON document to insert or replace
--c, --where	OJAI condition, in JSON format The condition must qualify to perform the replace. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.

Syntax

```
replace /tbl --id <id> --v {<document to replace>} [--c <condition>]
```

last-updated: Apr 11, 2022

Example

```
replace /tables/users --id user002 --value '{"first_name":"Jane",
"last_name":"Doe"}'
```

dbshell update

Description

The dbshell `update` command updates JSON documents using OJAI mutations. An OJAI mutation allows you to append, decrement, delete, increment, combine, replace, and update fields in a JSON document.

The following table lists the mutations OJAI supports. See Using OJAI Mutation Syntax on page 2561 for a detailed description of all operations. Each operation in the table links to examples in this topic.

Mutation Operation	Description
Append	Appends values to binary, string, and array fields
Decrement	Decrements field values
Delete	Deletes fields
Increment	Increments field values
Merge	Combines nested documents with existing documents
Put	Replaces field values or adds new fields
Set	Updates field values or adds new fields

Parameters

update Options	Description
`*`, `--t`, `--table` (Required)	Table path
`--id` (Required)	ID of the document to update **Note:** You can specify this parameter only once.
`--m`, `--mutation` (Required)	OJAI document mutation in JSON format See Using OJAI Mutation Syntax on page 2561 for a description of the syntax.
`--c`, `--where`	OJAI condition, in JSON format The condition must qualify to perform the update. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.

Syntax

```
update <table path> --id <id> --m <mutation> [ --c <condition> ]
```

Note: If the mutation provided as a part of the `--m` parameter has spaces, then you must enclose it within single quotes.

last-updated: Apr 11, 2022

Sample JSON Document

The dbshell update examples in this topic use the following sample JSON document:

```
{
  "_id": "id1",
  "a": {
       "b": [{"boolean":false}, {"decimal": 123.456}],
       "c":{
             "d":10,
             "e":"Hello"
           }
       },
  "m":"MapR wins"
}
```

Append Operation

This example performs append operations on fields `a.b` and `a.c.e`:

```
update /tbl --id id1 --m {
      "$append":[{"a.b":{"appd":1}},{"a.c.e":" MapR"}]
      }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 }, { "appd" : 1 }
],
    "c" : {
      "d" : 10,
      "e" : "Hello MapR"
    }
  },
  "m" : "MapR wins"
}
```

For more details about the `$append` operation, see OJAI Append Mutations on page 2562.

Decrement Operation

This example performs a decrement operation:

```
update /tbl --id id1 --m {
      "$decrement":{"a.c.d":5}
      }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 5,
      "e" : "Hello"
    }
```

last-updated: Apr 11, 2022

```
  },
  "m" : "MapR wins"
}
```

Note: To decrement multiple fields, use an an array to specify the fields.

For more details about the `$decrement` operation, see OJAI Decrement Mutations on page 2563.

Delete Operation

With the following example, the operation deletes multiple field paths in the document in a single command:

```
update /tbl --id id1 --m {
      "$delete": ["a.b[1]","a.c.e"]
      }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false } ],
    "c" : {
      "d" : 10
    }
  },
  "m" : "MapR wins"
}
```

The following example shows that if you need to delete only a single field, do not use the array notation:

```
update /tbl --id id1 --m {
      "$delete":"a.b[1]"
      }
```

For more details about the `$delete` operation, see OJAI Delete Mutations on page 2563.

Increment Operation

This example performs an increment operation:

```
update /tbl --id id1 --m {
      "$increment":{"a.c.d":5}
      }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 15,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

last-updated: Apr 11, 2022

Note: To increment multiple fields, use an an array to specify the fields.

For more details about the `$insert` operation, see OJAI Increment Mutations on page 2564.

Merge Operation

This example performs a merge operation:

```
update /tbl --id id1 --m {
      "$merge":{"a.c":{"d":11,"y":"yo"}}
      }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello",
      "y" : "yo"
    }
  },
  "m" : "MapR wins"
}
```

Note: `$merge` does not support the array format for merging two maps at two different field paths in the document.

For example, the following syntax is incorrect:

```
// WRONG Syntax
update /tbl --id id1 --m {"$merge":["a":{"b":1},{"a":{"d":"MapR"}}]}
```

The following syntax is correct:

```
// CORRECT Syntax
update /tbl --id id1 --m {"$merge":{"a":{"b":1,"d":"MapR"}}}
```

It results in the following document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : 1,
    "c" : {
      "d" : 10,
      "e" : "Hello"
    },
    "d" : "MapR"
  },
  "m" : "MapR wins"
}
```

To merge multiple field paths that are non-overlapping, use the syntax described at either Multiple Mutation Operations on page 5310 or Updates Without Explicit Mutation Operation Names on page 5311.

For more details about the `$merge` operation, see OJAI Merge Mutations on page 2565.

last-updated: Apr 11, 2022

Put Operation

This example performs a put operation. Unlike the set operation, the put *replaces* field values. Like the set operation, you do not need an array representation for a single field.

```
update /tbl --id id1 --m {
      "$put":[{"a.b":{"boolean":true},{"a.c.d":"eureka"},{"a.x":1}]
      }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : { "boolean" : true },
    "c" : {
      "d" : "eureka",
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

For more details about the `$set` operation, see OJAI Put Mutations on page 2566.

Set Operation

With this example, the command updates the document fields `a.b[0].boolean`, `a.c.d`, and `a.x`. If the field does not exist, the update command creates and sets it. The update fails if the existing field type does not match the new value. If the field exists and is the same type, the value is updated.

```
update /tbl --id id1 --m {
       "$set":[{"a.b[0].boolean":true},{"a.c.d":11},{"a.x":1}]
       }
```

When you apply this update command to the sample JSON document, the following is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : true }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

Note: If you need to set only a single field, the command looks like the following:

```
update /tbl --id id1 --m {
         "$set": {"a.b[0].boolean":true}
         }
```

For more details about the `$set` operation, see OJAI Set Mutations on page 2567.

last-updated: Apr 11, 2022

Multiple Mutation Operations

You can combine more than one mutation operation in a single OJAI mutation by specifying each operation separated by a comma.

The following is an example that combines multiple operations:

```
update /tbl --id id1 --m
        '{
        "$set":{"x":[1,2,3]},
        "$put":{"a.c.e":{"$binary":"AAAADg=="}},
        "$increment":"a.b[1].decimal",
        "$delete":"a.b[0]",
        "$merge":{"newDoc":{"k":"MapR DBShell rocks!!"}},
        "$append":{"m":"!!!"}
        }'
```

The following is the resulting output:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "decimal" : 124.456 } ],
    "c" : {
      "d" : 10,
      "e" : { "$binary" : "AAAADg==" }
    }
  },
  "m" : "MapR wins!!!",
  "newDoc" : { "k" : "MapR DBShell rocks!!" },
  "x" : [ 1, 2, 3 ]
}
```

The operations behave in the following manner:

- The `$set` operation adds a new array `[1,2,3]` with field path `x` into the document.
- The `$put` operation replaces the existing string `"Hello"` with a nested document `{"$binary":"AAAADg=="}`.
- The `$delete` operation deletes the field path `a.b[0]` from the document.
- The `$merge` operation merges a new nested document `{"newDoc":{"k":"MapR DBShell rocks!!"}}`.
- The `$append` operates appends the string `"!!!"` to the end of the string `"MapR wins"`.
- The `$increment` and `$delete` operate on different elements of the array `a.b`:
  - The `$increment` operation increments the value `123.456` in the second element of the array `a.b`.
  - The `$delete` operation deletes the field path `a.b[0]`, resulting in a single element array `a.b`.

Conflicting Operations

When you specify a mutation with field paths that are overlapping, MapR Database detects the conflict, discards the previous conflicting operation, and proceeds with the next operation.

For example, suppose you have the following document:

```
{"_id":"id1", "a":{"b":{"c":5}}}
```

last-updated: Apr 11, 2022

The following mutation has two operations with overlapping fields `a.b`:

```
{"$delete":"a.b","$set":{"a.b.d":10}}
```

You may have intended for the mtuation to first delete `a.b` and then to replace it with `a.b.d` as follows:

```
{"_id":"id1", "a":{"b":{"d":"10"}}}
```

But the *actual* result is the following:

```
{"_id":"id1", "a":{"b":{"c":5,"d":"10"}}}
```

In this case, the set operation on **`a.b.d`** causes the delete operation on **`a.b`** to be discarded.

Note: In the earlier example in this section, the `$increment` and `$delete` operations are not conflicting because one operates on `a.b[1]`, while the other operates on `a.b[0]`. On the other hand, the following are conflicting operations:

```
{"$increment":"a.b[1].decimal","$delete":"a.b"}
```

Updates Without Explicit Mutation Operation Names

As part of the update command, you can merge a nested document with a document without specifying a mutation operation name. When applying this type of update, the behavior is the same as the merge operation.

For example, suppose you run the following command:

```
update /tbl --id id1 --m {
      "k":"eureka",
      "a":{"c":{"d":1234}}
      }
```

If the document with key `"id1"` exists, the update command merges the nested document with the original document. If the document does not exist, the update creates a new document with the input provided.

Application of the command to the sample document results in the following:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 1234,
      "e" : "Hello"
    }
  },
  "k" : "eureka",
  "m" : "MapR wins"
}
```

For the following update command:

```
update /tbl --id id1 --m {
      "k":"eureka",
      "a":{"c":{"d":null}}
      }
```

last-updated: Apr 11, 2022

This is the resulting document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : null,
      "e" : "Hello"
    }
  },
  "k" : "eureka",
  "m" : "MapR wins"
}
```

Note: In this example, field `a.c.d` remains in the document and is set to null.

Utilities for MapR Database JSON Tables

MapR Database JSON provides utilities to copy, export, and import data, compare table content, and verify the consistency of secondary indexes.

You can use the following utilities with MapR Database JSON tables:

MapR Database JSON CopyTable
Copies data from one MapR Database JSON table to another MapR Database JSON table.

If the destination table does not exist, `mapr copytable` creates the destination table with the same metadata (column families and access control expressions) as the source table, and then copies data.

If the destination table exists, `mapr copytable` copies data only.

Required Permissions

The user that runs `mapr copytable` must have the following permissions, which you can grant with access-control expressions:

- The permission `readAce` on the volume where the source table is located, and the permission `writeAce` on the volume where the destination table is or will be located.
- The permission `adminperm` on the source table.
- The permission for column-family and column reads (`readperm`) on the data in the source table that you want to copy.
- When bulkload = `false`, the permission for column writes (`writeperm`) on the destination table.
- When bulkload = `true` (default), the permission to load the destination table with bulk loads (`bulkloadperm`).
- If the destination table does not yet exist: `createrenamefamily` on the source table.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on tables, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr copytable
-src <source table path>
-dst <destination table path>
[-fromID <start key>]
[-toID <end key>]
[-bulkload <true|false> (default: false)]
[-mapreduce <true|false> (default: true)]
[-cmpmeta <true|false> (default: true)]
[-numthreads <number of threads> (default: 16)]
[-maxsplits <integer> (default: 2000)]
```

Parameters

Parameter	Description
src	The path of the table that you want to copy from.
dst	The path of the table that you want to copy to.
fromID	The value of the `_id` field in the first document of the range of documents to copy. `startRow` is an alias for this parameter.
toID	The value of the `_id` field in the last document of the range of documents to copy. `stopRow` is an alias for this parameter.
bulkload	A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is not to use bulk loading (`false`). To use bulk load, you must set the `-bulkload` parameter of the table to `true` by running the command `maprcli table edit -path <path to table> -bulkload true`.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads to read rows of the source table and write rows to the destination table.
cmpmeta	A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true). Such comparisons are done when the destination table exists before `mapr copytable` is run and checks that the user ID that runs `mapr copytable` has the proper permissions on the destination table. Set the value of this parameter to `false` before copying a table that contains a single column family to a table that contains two or more column families.
numthreads	When -mapreduce is false, this parameter specifies the number of threads allocated to perform the copying of data. The default is 16. If additional CPU resources are available, you might want to increase the number of threads to achieve better performance.

last-updated: Apr 11, 2022

Parameter	Description
maxsplits	Sets the maximum number of destination table presplit tablets. Default is 2000. If `copytable` fails with an Error NO ENTry message during table creation, the operation could not complete within the timeout (10 minutes). Reduce the value of `-maxsplits`. This functionality requires a patch. See Applying a Patch.

Example

The following example copies documents starting from ID `user000001` to ID `user009999`:

```
[user@hostname ~]$ mapr copytable -src /user1/tableA -dst
/mapr/clusterB/vol1/tableB -fromID user000001 -toID user009999
```

Monitoring `mapr copytable` Operations

Use one of the following methods to monitor the progress of the copying of table data:

- If the copy table operation runs as a MapReduce v2 application, monitor the application using the ResourceManager UI.
- If the copy table operation runs as a client process, go to the Tables view of the destination table in the MapR Control System. Then, on the Region tab, monitor the pace at which the number of rows increases.

MapR Database JSON DiffTables

Compares the row keys, column families, and field values in two JSON tables. Then, generates two directories that contain sequence files that you can use to merge the rows from the two JSON tables.

Sequence files are binary flat files. For more detail, see Sequence File. To convert a sequence file into a format that you can read, use the `mapr formatresult` utility.

This utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that it contains a superset of the rows defined in both tables at the time at which the utility was run.

This utility generates both of the following output directories in the output directory that you specify:

opsForDst	A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.
opsForSrc	A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

A user with write permissions on a table can run the `mapr importtable` utility to implement the changes that are specified in the sequence files.

Required Permissions

The user that runs the `mapr difftables` utility must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

last-updated: Apr 11, 2022

For information about how to set permissions on tables, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr difftables
-src <source table path>
-dst <destination table path>
-outdir <output directory>
[-first_exit Exit when first difference is found. ]
[-columns comma-separated list of field paths ]
[-mapreduce] <true|false> (default: true)]
[-numthreads <numThreads> (default:16, valid only when -mapreduce is false)]
[-cmpmeta <true|false> (default: true)]
```

Parameters

Parameter	Description
src	The path of the first table to include in the comparison.
dst	The path of the second table to include in the comparison.
first_exit	By default, the utility compares all the table cells in the specified tables. Use this parameter if you want to exit after the first difference is identified between the tables. The parameter takes no value.
outdir	The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.
columns	By default, the utility compares all fields in JSON tables. If you do not want to compare all fields, you can specify specific fields to include in the comparison. For example, suppose that want to compare a source table in table replication with a replica of that table. When you set up replication, you chose to replicate the default column family and two additional column families: `cf1` and `cf2`. For the -columns parameter, you would specify the value `",cf1,cf2"`, where the default column family is represented by the empty string.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the comparison. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads to perform the comparison.
numthreads	When -mapreduce is false, this parameter specifies the number of threads allocated to perform the comparison. The default is 16. If additional CPU resources are available, you might want to increase the number of thread to achieve better performance.

last-updated: Apr 11, 2022

Parameter	Description
cmpmeta	A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true).

Example

The following example shows a comparison of two JSON tables

```
[user@hostname ~]$ mapr difftables -src /source_JSON_table -dst /
destination_JSON_table -outdir output/comparison1 -columns
"dateRange.endYear","contributors.date"
Header: hostName: maprdemo, Time Zone: Pacific Standard Time, processName:

Mismatch row count in '/source_JSON_table' : 1
Mismatch row count in '/destination_JSON_table' : 1
Rows with mismatch are stored in output/comparison1
```

MapR Database JSON DiffTablesWithCrc

This utility uses a cyclic redundancy check to detect differences between sets of rows in the specified MapR Database JSON tables. Then, for each set of non-identical rows, it performs a detailed comparison. Finally, it generates one or more directories of sequence files. You can use these files either to merge the rows from two MapR Database JSON tables.

Sequence files are binary flat files. You can learn more about them here. To convert a sequence file into a format that you can read, use the MapR Database JSON FormatResult on page 5318 utility.

This utility requires less network bandwidth than the `mapr diffTables` utility because it performs a detailed table comparison only on the sets of rows where the CRC algorithm detected a difference. Therefore, consider using this utility when the tables you compare are very similar and you are concerned about the data transfer rate.

This utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that each table can contain a superset of the rows in both tables at the time at which the utility was run.

This utility generates the following output directories:

- **opsForDst.** A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.

last-updated: Apr 11, 2022

- **opsForSrc.** A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

Run the `mapr importtable` command to implement the puts and deletes specified in the sequence files.

A user with write permissions on a table can run the `mapr importtable` utility to implement the changes that are specified in the sequence files.

Requirements

- When the cluster runs YARN, it must use zero configuration failover for the ResourceManager.
- The user that runs the `mapr difftableswithcrc` utility must have the following permissions:
  - The permission `readAce` on the volumes where the tables are located.
  - The permission for column reads (`readperm`) on each table.

  For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

  For information about how to set permissions on tables, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr difftableswithcrc
-src <source table path>
-dst <destination table path>
-outdir <output directory>
[-first_exit] Exit when first difference is found.
[-columns <comma separated list of field paths> ]
[-exclude_embedded_families <true|false>] (default: false)
  Don't include the  other column families with path embedded in specified
columns
[-cmpmeta <true|false> (default: true)]
```

Parameters

Parameter	Description
src	The path of the first table to include in the comparison.
dst	The path of the second table to include in the comparison.
outdir	The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.
first_exit	By default, the utility compares all the table cells in the specified tables. Use this parameter if you want to exit after the first difference is identified between the tables. The parameter takes no value.

last-updated: Apr 11, 2022

Parameter	Description
columns	By default, the utility compares all fields in JSON tables. If you do not want to compare all fields, you can specify specific fields to include in the comparison. For example, suppose that want to compare a source table in table replication with a replica of that table. When you set up replication, you chose to replicate the default column family and two additional column families: `cf1` and `cf2`. For the -columns parameter, you would specify the value `",cf1,cf2"`, where the default column family is represented by the empty string.
cmpmeta	A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true).

MapR Database JSON FormatResult

Parses a sequence file generated by the difftables utility for JSON tables and converts the results into a format that makes the results easier to understand.

Required Permissions

The user that runs the `FormatResult` utility must have the `readAce` and `writeAce` permissions on the volumes where the input and output paths are located.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr formatresult
-indir <input file path>
-outdir <output file path>
[-mapreduce <true|false> (default: false)]
```

Parameters

Parameter	Description
indir	The path to a file or directory of files that contains the output of the `mapr difftables` utility.
outdir	The path to a file or a directory for the output. If the file or directory already exists, the utility fails. When a single sequence file is provided as input, the utility generates a single output file. When a directory of sequence files is provided as input, the utility generates a directory with output files.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true).

Example

This example shows the results of the following actions that followed a comparison by difftables of two JSON tables:

last-updated: Apr 11, 2022

1. Formatting the sequence file for the source JSON table.
2. Formatting the sequence file for the destination JSON table.
3. Viewing the content of the first sequence file.
4. Viewing the content of the second sequence file.

This is the command that was used for `maprdb difftables`:

```
mapr difftables -src /src_table -dst /dest_table -outdir
output/diffs -columns dateRange.endYear
```

Here is the command that was used for `mapr formatresult` and the resulting output:

```
[user@hostname ~]$ mapr formatresult -indir output/diffs/
OpsForSrcTable -outdir output/outputForSrcTable5
Header: hostName: maprdemo, Time Zone: Pacific Standard Time, processName:
null, processId: null

MapR Database JSON ExportTable and ImportTable
Use these utilities together to export data from JSON tables into binary sequence files, and then import the data from the binary sequence files into other JSON tables. You can also use the `mapr importtable` utility to import changes that are specified in sequence files output by the `mapr difftables` utility.

- Syntax of `mapr exporttable`
- Parameters of `mapr exporttable`
- Syntax of `mapr importtable`
- Parameters of `mapr importtable`
- Example of using `mapr exporttable` and `mapr importtable` together

Required Permissions

- The `readAce` permission on the volume where the source table for `mapr exporttable` is located.
- The `writeAce` permission on the volume in which to save the output from `mapr exporttable`.
- The `readAce` permission on the volume where the files output by `mapr exporttable` is located.
- The `writeAce` permission on the volume in which the destination table is located.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run these utilities unless that user is given the relevant permission or permissions with access-control expressions.

Syntax of `mapr exporttable`

```
mapr exporttable
(option)
-src Name of table
-dst Directory path
[-columns Fields to include]
[-mapreduce : <true|false>, default is true]
```

Parameters of `mapr exporttable`

Parameter	Description
src	The path of the JSON table to export from.
dst	The directory within the MapR filesystem to export the files to.
columns	A comma-delimited list of fields to include in the exported files. **Example** `a,b,c` Do not use quotation marks and do not include spaces after commas.

last-updated: Apr 11, 2022

Parameter	Description
mapreduce	The cluster must have YARN installed and configured for this option to work. A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads.

Syntax of `mapr importtable`

```
mapr importtable
(option)
-src Input binary file or directory path
-dst Destination table
[-bulkload <true|false>, default is false ]
[-mapreduce : <true|false>, default is true]
```

Parameters of `mapr importtable`

Parameter	Description

src	The path of the binary file or files to import.
	Examples
	`-src /temp/part0`
	`-src /temp/*`

dst	The JSON table to import the data into.
bulkload	A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is not to use bulk loading (`false`). To use bulk load, you must set the `-bulkload` parameter of the table to `true` by running the command `maprcli table edit -path <path to table> -bulkload true`.
mapreduce	The cluster must have YARN installed and configured for this option to work. A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads.

Example of using `mapr exporttable` and `mapr importtable` together

```
[user@hostname ~]$ mapr exporttable -columns contributors,creditLine -src /
collection/artworks -dst /tempExport
Header: hostName: hostname, Time Zone: Pacific Standard Time, processName:
null, processId: null
2015-10-01 23:02:38,044 INFO org.apache.hadoop.io.compress.zlib.ZlibFactory

```

MapR Database JSON ImportJSON
Imports one or more JSON documents into a MapR Database JSON table. The JSON documents must be flat text files.

Required Permissions

- The `readAce` permission on the volume where the JSON documents to import are located.
- The `writeAce` permission on the volume in which the destination table is located.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr importJSON
[-idfield <Name of ID field in JSON Data>]
[-bulkload <true|false>, default is false]
[-mapreduce : <true|false>, default is true]
-src <text file or directory>
-dst <JSON table>
```

Parameters

-

Parameter	Description
idfield	The name of the field that contains the value to use for each document's `_id` field. An `_id` field is inserted into each document that is imported into a table, if the document does not already contain one. Documents that do not already contain an `_id` field must contain a field with a value that can be used for the inserted `_id` field. For example, each document might have a `product_ID` field with a value that would be suitable for the `_id` field. Use quotation marks around the name.
bulkload	A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is not to use bulk loading (`false`). To use bulk load, you must set the `-bulkload` parameter of the table to `true` by running the command `maprcli table edit -path <path to table> -bulkload true`. This parameter cannot be set to `true` when the `-mapreduce` parameter is set to `false`.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true).
src	The path of a JSON document in text format or a directory of such documents. If you specify a directory and that directory contains only the JSON files to import, use an asterisk at the end of the path, as in this example: `/user/data/*` If you specify a directory and that directory contains both the JSON files to import and other files, use a more specific wildcard, such as `*.json` . The path must be in the MapR filesystem. To move files there from the Linux filesystem, use the command `hadoop fs -copyFromLocal`.
dst	The path of the destination MapR Database JSON table.

Example

Suppose you have the following three JSON documents in the `/tmp/users` directory in your MapR filesystem:

```
$ hadoop fs -cat /tmp/users/bcummings.json
{"_id":"bcummings","first_name":"Bettie","last_name":"Cummings"}

$ hadoop fs -cat /tmp/users/gjones.json
{"_id":"gjones","first_name":"Gilberto","last_name":"Jones"}

$ hadoop fs -cat /tmp/users/jdoe.json
{"_id":"jdoe","first_name":"John","last_name":"Doe"}
```

last-updated: Apr 11, 2022

The following command imports the three documents into the JSON table in the path `/apps/users`:

```
$ mapr importJSON -idField _id -src /tmp/users/* -dst /apps/users
```

You can run `mapr dbshell` to see the imported documents:

```
maprdb mapr:> find /apps/users
{"_id":"bcummings","first_name":"Bettie","last_name":"Cummings"}
{"_id":"gjones","first_name":"Gilberto","last_name":"Jones"}
{"_id":"jdoe","first_name":"John","last_name":"Doe"}
3 document(s) found.
```

MapR Database JSON verifyindex

Describes how to use the MapR Database JSON `verifyindex` command to verify that the data in a secondary index is consistent with its JSON table.

Syntax

```
mapr verifyindex
        -path < table path >
        -index < index name >
        -first_exit < true | false >
        -numthreads < thread number >
```

Parameters

Parameter	Description
path	(Required) Path to where the table exists.
index	(Required) Name of the secondary index on the table.
first_exit	(Optional) Exit when the first difference is found. Options: true or false. Default: false.
numthreads	(Optional) Number of parallel threads to use for the verification. Default: 16

Example

The following example creates a table, creates a secondary index on the table, inserts some documents, and then runs the `verifyindex` command to verify that there is data consistency between the JSON table and the secondary index. See Troubleshooting Secondary Indexes on page 1092 for an example where `verifyindex` detects data inconsistency.

```
// Create a table using dbshell add
# mapr dbshell

maprdb root:> create /t1
Table /t1 created.

// Create an index using maprcli table index add
# maprcli table index add -path /t1 -index i1 -indexedfields a -json
{
"timestamp":1499788406380,
"timeofday":"2017-07-11 08:53:26.380 GMT-0700",
"status":"OK",
"total":0,
"data":[ ]
```

```
}

// Insert documents into the table using dbshell insert
# mapr dbshell

maprdb root:> insert /t1 --v {"a":1,"b":2} --id 1
Document with id: "1" inserted.

maprdb root:> insert /t1 --v {"a":"mapr","b":3} --id 2
Document with id: "2" inserted.

maprdb root:> insert /t1 --v {"a":{"$numberLong":3},"b":4} --id 4
Document with id: "4" inserted.

// Run verifyindex to verify indexed data
# mapr verifyindex -path /t1 -index i1

Number of rows in table but not in index: 0
Number of rows in index but not in table: 0
Mismatch row count: 0
```

Troubleshooting Use Cases

Situations where you can use this command are as follows:

- Examine details on updates that have not yet propagated from a JSON table to one of its indexes.
- Detect if there are documents that are missing from an index.
- Detect other data consistency issues between an index and its parent JSON table.

See Troubleshooting Secondary Indexes on page 1092 for more information on these use cases.

MapR Database HBase Shell (Binary Tables)

You can manage MapR Database tables using HBase shell commands and additional HBase shell commands included in the MapR Data Platform distribution of Hadoop.

The HBase shell command is used on binary tables only. To run this command, execute the following:

```
hbase shell
```

Note: Before running the shell, ensure that your user ID has both the `readAce` and `writeAce` permissions on the volume. For information about these permissions, see Managing Whole Volume ACEs.

When you specify a table in HBase shell, use the following syntax:

- For a table on the local cluster, start the path at the volume mount point. For example, for a table named test under a volume with a mount point at /volume1, specify the following path as the table name: “/volume1/test”
- For a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customer under volume1 in the sanfrancisco cluster, specify the following path as the table name: “/mapr/sanfrancisco/volume1/customer”

Note: You can access a table on a remote cluster when the remote cluster has an entry in the mapr-clusters.conf file on the node where the HBase shell is running.

The following table lists the supported HBase shell commands that you can use to manage MapR Database tables:

Command	Description
alter	Performs the following actions on MapR Database tables: • Adds a new table or column family • Modifies the following table-level attributes: • • BULKLOAD - A Boolean value that specifies whether to perform a full bulk load of the table. The default is false. For more information, see Bulk Loading and MapR Database Tables. • MAX_FILESIZE • AUTOSPLIT - A Boolean value that specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the `regionsizemb` parameter. The default value is true. If you set the value to false, you can manually split tables into regions by using the maprcli table region split command. • Modifies the following attributes of a column family: • • TTL • VERSIONS (max or min) • COMPRESSION • IN_MEMORY Aside from the attributes listed above, no other attributes apply to MapR Database tables. Unlike HBase, you do not need to disable a table before altering a table.
alter_async	On MapR Database tables, this has the same behavior as the alter command.
count	Counts the number of rows in a specified table.
create	Creates a table in the specified path.
delete	Deletes a value in a specified table, row, and column. Optionally, you can also specify the timestamp associated with the value that you want to delete.
deleteall	Delete all values in a row based on the table name and row. Optionally, you can also specify the timestamp associated with the values that you want to delete.
describe	Describes a specified table.
disable	Marks a specified table as disabled. This state is recorded only in the client process (HBase shell) memory and does not actually disable any operations on a MapR Database table.
disable_all	Marks tables as disabled if they have names matching the specified regular expression. This state is recorded only in the client process (HBase shell) memory and does not actually disable any operations on the MapR Database tables.

last-updated: Apr 11, 2022

Command	Description
drop	Drops a specified table that is marked as disabled.
drop_all	Drops all tables that are marked as disabled.
enable	Marks a specified table as enabled. This state is recorded only in the client process (HBase shell) memory.
enable_all	Marks tables as enabled if they have a table name that matches the specified regular expression. This state is recorded only in the client process (HBase shell) memory.
exists	Returns boolean value true if the specified table exists.
exit	Exits the HBase shell.
get	Gets the contents of a row or cell.
get_counter	Returns the value of a counter at a specified table, row, and column.
incr	Increments a value at a specified table, row, and column.
is_disabled	Returns a value that indicates if a specified table is disabled. You can perform operations on MapR Database tables that are disabled.
is_enabled	Returns a value that indicates if a specified table is enabled. You can perform operations on MapR Database tables even if they are not enabled.
list	For HBase 1.1 or above, if the mapr.hbase.default.db property is set to maprdb, this command returns the MapR Database tables under the user's home directory.
list_perm	Lists all permissions set by Access Control Expressions for a specified table. This HBase shell command only operates on MapR Database tables. For more information, see list_perm.
put	Puts a value at a specified table, row, and column. Optionally, you can also specify the timestamp for that value.
scan	Scans a specified table. Optionally, you can also specify a dictionary of scanner specifications.
set_perm	Sets permissions with Access Control Expressions on a specified table, column family, or column qualifier. This Hbase shell command only operates on MapR Database tables. For more information, see set_perm.
show_filters	Shows all the filters supported by the Hbase or MapR Database tables. Provide the link to 4.1 supported filters doc
truncate	Disables, drops, and recreates a specified table.
version	Returns the HBase client version.
whoami	Returns the current user.

MapR Database does not support the following HBase shell commands:

- add_peer
- alter_status

last-updated: Apr 11, 2022

- assign
- balance_switch
- balancer
- close_region
- compact
- disable_peer
- enable_peer
- flush
- grant
- hlog_roll
- list_peer
- major_compact
- move
- remove_peer
- start_replication
- stop_replication
- status
- split
- revoke
- unassign
- user_permission
- zk_dump

For more information about the HBase shell commands, see the Apache HBase documentation.

list_perm

Lists all permissions set by Access Control Expressions for a specified MapR Database table

Syntax

```
list_perm "<table path>"
```

Example

```
hbase(main):006:0> list_perm "/table/"
        Scope Permission Access Control Expression
        defaultappendperm u:jon
        createrenamefamilyperm u:jon
        deletefamilyperm u:jon
```

```
        bulkloadperm u:jon
        defaultreadperm u:jon
        defaultwriteperm u:jon
        packperm u:jon
        replperm u:jon
        defaultmemoryperm u:jon
        adminaccessperm u:jon
        splitmergeperm u:jon
        defaultversionperm u:jon
        defaultcompressionperm u:jonr
        13 row(s) in 0.0070 seconds
```

set_perm
Set permissions with access control expressions on a MapR Database table, column family, or column qualifier.

Set permissions with *ACE* on a MapR Database table, column family, or column qualifier.

Syntax

To set the permission on a table:

```
set_perm "<table path>", "<permission>", "<ACE expression>"
```

To set the permission on a column family or column qualifier:

```
set_perm "<table path>", {COLUMN => "column family[:qualifier]", PERM =>
          "<permission>", EXPR => "<ACE expression>"}
```

Examples

Assigns user `jon` and user `mapr04` the `defaultreadperm` permission on table `/table`:

```
hbase(main):004:0> set_perm "/table/","defaultreadperm","u:jon|u:mapr04"
```

Assigns user `jon` and user `mapr05` the `compressionperm` permission on the `cf1` column family in table `/table`:

```
hbase(main):005:0> set_perm "/table/",{COLUMN => "cf1",PERM =>
"compressionperm", EXPR =>"u:jon|u:mapr05"}
```

Assigns user `jon` and user `mapr05` the `writeperm` permission on the `col1` column qualifier in `cf1` column family in table `/table`:

```
hbase(main):009:0> set_perm "/table/",{COLUMN => "cf1:col1",PERM =>
"writeperm", EXPR =>"u:jon|u:mapr05"}
```

Utilities for MapR Database Binary Tables

MapR Database provides utilities to copy and compare data in MapR Database binary tables.

You can use the following utilities with MapR Database binary tables:

MapR Database Binary CopyTable

Copies data from one MapR Database binary table to another MapR Database binary table.

The MapR Database `CopyTable` utility is different from Apache HBase's `CopyTable` utility. This utility has the following capability:

last-updated: Apr 11, 2022

- If the destination table does not exist, `CopyTable` creates the target table with the same metadata (column families and access control expressions) as the source table, and then copies data.
- If the destination table exists, `CopyTable` copies data only.
- If you manually set up replication to a MapR Database table, `CopyTable` can be used to perform an initial load of source data to the replica before table replication begins.

Note: When copying data to MapR Database tables, it is recommended that you use the MapR Database version of `CopyTable`.

Required Permissions

The user that runs the `CopyTable` utility must have the following permissions:

- The permission `readAce` on the volume where the source table is located, and the permission `writeAce` on the volume where the destination table is or will be located.
- The permission `adminperm` on the source table.
- The permission for column-family and column reads (`readperm`) on the data in the source table that you want to copy.
- When bulkload = `false`, the permission for column writes (`writeperm`) on the destination table.
- When bulkload = `true` (default), the permission to load the destination table with bulk loads (`bulkloadperm`).
- If the destination table does not yet exist: `createrenamefamily` on the source table.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

If `CopyTable` is run between tables on different clusters, the user that runs the command must have the required permissions on each cluster.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on tables, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable
    -src <source table path> -dst <destination table path>
    [-columns cf1[:col1],...] [-maxversions <max number of versions to
copy>]
    [-starttime <time>]
    [-endtime <time>]
    [-mapreduce <true|false> (default: true)]
    [-bulkload <true|false> (default: true)]
    [-numthreads <numThreads> (default:16, valid only when -mapreduce is
false)]
```

last-updated: Apr 11, 2022

Parameters

Parameters	Description
src	The path to the source table that you want to replicate. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customersrc`
dst	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at /volume1, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customerdst`
columns	By default, all columns in the source table are copied. If you do not want to copy all columns in the table, you can specify columns to copy. Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to copy only the purchases column family and the stars column in the reviews column family: `-columns purchases,reviews:stars`
maxversions	By default, all versions from the source table are copied. If you do not want to copy all versions, use this parameter to specify the number of versions to copy.
starttime	By default, all table values regardless of their associated timestamp are copied. You can specify a timestamp to indicate the table cell version at which to start the copy. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps lower than the specified timestamp will not be copied to the destination.
endtime	By default, all table values regardless of their associated timestamp are copied. You can specify a timestamp to indicate the table cell version at which to end the copy. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps greater than or equal to the specified timestamp will not be copied to the destination.

last-updated: Apr 11, 2022

Parameters	Description
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads to read rows of the source table and write rows to the destination table.
bulkload	A Boolean value that specifies whether or not to perform a full bulk load of the table. The default is to use bulk loading (`true`). When you use bulk loading, the utility automatically unsets the bulk load mode on the table to restore normal client operations at the end of the table copy operation. For more information, see Bulk Loading and MapR Database Tables.
numthreads	When -mapreduce is false, this parameter specifies the number of threads allocated to perform the copying of data. The default is 16. If additional CPU resources are available, you might want to increase the number of threads to achieve better performance.

Monitoring the CopyTable Operation

Use one of the following methods to monitor the progress of the copying of table data:

- If the copy table operation runs as a MapReduce v2 application, monitor the application using the ResourceManager UI.
- If the copy table operation runs as a client process, go to the Tables view of the destination table in the MapR Control System. Then, on the Region tab, monitor the pace at which the number of rows increases.

Example
Copies table data with timestamp greater than 1423226300000 (Fri, 06 Feb 2015 12:38:20 GMT) from one MapR Database table to another MapR Database table:

```
[user@hostname ~]$
hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable -src /t1 -dst /
t1_copy7  -starttime 1423226300000
```

MapR Database Binary DiffTables

Compares the row key, column family, timestamp, and value of each table cell in each specified MapR Database table. Then, it generates one or two directories with sequence files that you can use to either make a MapR Database table identical to its master or merge the rows from two MapR Database tables.

Sequence files are binary flat files. To convert the sequence file into a format that is easier to understand, use the FormatResults utility.

By default, the DiffTables utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that it contains a superset of the rows defined in both tables at the time at which the utility was run.

When you specify a master table, the DiffTables utility generates one of the following output directories:

- **opsForDst.** A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.

- **opsForSrc.** A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

A user with write permissions on a table can run the `hbase org.apache.hadoop.hbase.mapreduce.Import` command to implement the puts and deletes specified in the sequence files.

Required Permissions

The user that runs the DiffTables utility must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on tables, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.DiffTables
  -src <source table path>
    -dst <destination table path>
      -outdir <output directory>
    [-master <src|dst> ] The master table to use for the diff.
    [-first_exit] Exit when first difference is found.
    [-columns <comma separated list of family[:column]> ]
    [-starttime <start diff at timestamp>]
    [-endtime <end diff at timestamp>]
    [-maxversions] <max number of versions to diff>
    [-mapreduce] <true|false> (default: true)]
    [-numthreads <numThreads> (default:16, valid only when -mapreduce is
      false)]
      [-cmpmeta <true|false> (default: true)]
```

Parameters

Parameter	Description
src	The path to the source table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customersrc under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`

last-updated: Apr 11, 2022

Parameter	Description
dst	The path to the destination table. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at /volume1, specify the following path: /volume1/testdst • For a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customerdst`
master	The table that is considered to be the master table. The values are `src` and `dst`. By default, both the source table and the destination tables are considered to be a master.
first_exit	By default, the utility compares all the table cells in the specified tables. Use this parameter if you want to exit after the first difference is identified between the tables. The parameter takes no value.
outdir	The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.
columns	By default, the utility compares all columns. If you do not want to compare all columns in the table, you can specify specific columns to include in the comparison. Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to include the column family purchases and the column stars in the reviews column family: `-columns purchases,reviews:stars`
starttime	By default, the utility compares all table values regardless of their associated timestamp. You can specify a timestamp to indicate the table cell version at which to start the comparison. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps lower than the specified timestamp will not be included in the comparison.
endtime	By default, the utility compares all table values regardless of their associated timestamp. Values with timestamps greater than or equal to the specified timestamp will not be included in the comparison.
maxversions	By default, all versions from the master table are included in the comparison. If you do not want to compare all versions, use this parameter to specify the number of recent versions to include in the comparison.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the comparison. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads.

last-updated: Apr 11, 2022

Parameter	Description
numthreads	When -mapreduce is false, this parameter specifies the number of threads allocated to perform the comparison. The default is 16. If additional CPU resources are available, you might want to increase the number of thread to achieve better performance.
cmpmeta	A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (true).

Examples
The following example compares two MapR Database tables:

```
[user@hostname ~]$ hbase com.mapr.fs.hbase.tools.mapreduce.DiffTables -src /
customerTableA -dst /customerTableB -outdir /customerTableABCompare
2015-03-04 18:04:52,059 INFO  [main] Configuration.deprecation:
hadoop.native.lib is deprecated. Instead, use io.native.lib.available
DiffTablesMeta completed. Metadata of the two tables is same.
...
Mapreduce job completed. The tables mismatch.
NUM_ROWS_MISMATCH_IN_SRC:32; NUM_ROWS_MISMATCH_IN_DST:30. Please check diff
in /customerTableABCompare
```

MapR Database Binary DiffTablesWithCrc

This utility uses a cyclic redundancy check to detect differences between sets of rows in the specified MapR Database binary tables. Then, for each set of non-identical rows, it performs a detailed comparison. Finally, it generates one or more directories of sequence files. You can use these files either to make a MapR Database binary table identical to its master or merge the rows from two MapR Database binary tables.

Sequence files are binary flat files. You can learn more about them here. To convert a sequence file into a format that you can read, use the MapR Database Binary FormatResult on page 5338 utility.

This utility requires less network bandwidth than the `DiffTables` utility because it performs a detailed table comparison only on the sets of rows where the CRC algorithm detected a difference. Therefore, consider using this utility when the tables you compare are very similar and you are concerned about the data transfer rate.

Requirements

- When the cluster runs YARN, it must also use zero configuration failover for the ResourceManager.

By default, the utility considers both the source table and the destination table to be a master table. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each table so that it can contain a superset of the rows defined in both tables at the time at which the utility was run.

When you specify a master table, the `mapr difftableswithcrc` utility generates one of the following output directories:

- **opsForDst.** A directory containing sequence files that correspond to each put and delete required to make the destination table identical to the source table.
- **opsForSrc.** A directory containing sequence files that correspond to each put and delete required to make the source table identical to the destination table.

last-updated: Apr 11, 2022

A user with write permissions on a table can run the `hbase org.apache.hadoop.hbase.mapreduce.Import` command to implement the puts and deletes specified in the sequence files.

Required Permissions

The user that runs the `mapr difftableswithcrc` utility must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- The permission for column reads (`readperm`) on each table.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on tables, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.DiffTablesWithCrc
-src <source table path>
-dst <destination table path>
-outdir <output directory>
[-master src|dst ] The master table to use for the diff.
[-first_exit] Exit when first difference is found.
[-cf <comma separated list of column families>]
[-starttime <start diff at timestamp>]
[-endtime <end diff at timestamp>]
[-maxVersions <max number of versions to copy>]
[-cmpmeta <true|false> (default: true)]
```

Parameters

Parameter	Description
src	The path to the source table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path:`/volume1/testsrc` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`

last-updated: Apr 11, 2022

Parameter	Description
dst	The path to the destination table. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at /volume1, specify the following path: `/volume1/testdst` • For a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customerdst`
master	The table that is considered to be the master table. The values are `src` (the source table) and `dst` (the destination table). By default, both the source table and the destination table are considered to be the master.
first_exit	By default, the utility compares all the table cells in the specified tables. Set this parameter if you want to exit after the first difference is identified between the tables.
outdir	The path to a directory for the sequence files. The utility will create the specified directory. If the specified directory already exists, the command will fail.
cf	By default, the utility compares all columns from the master table. If you do not want to compare all columns in the table, you can specify specific columns to include in the comparison. Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to include the column family purchases and the column stars in the reviews column family: `-columns purchases,reviews:stars`
starttime	By default, the utility compares all table values regardless of their associated timestamp. You can specify a timestamp to indicate the table cell version at which to start the comparison. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps lower than the specified timestamp will not be included in the comparison.
endtime	By default, the utility compares all table values regardless of their associated timestamp. You can specify a timestamp to indicate the table cell version at which to end the comparison. The timestamp is a long integer value that is either user-defined or system-defined (epoch in milliseconds). Values with timestamps greater than or equal to the specified timestamp will not be included in the comparison.
maxVersions	By default, the utility compares all versions from the master table. If you do not want to diff all versions, use this parameter to specify the number of recent versions to include in the comparison.
cmpmeta	A Boolean value that specifies whether or not to compare table metadata such as column families and ACEs. The default is to compare metadata (`true`).

last-updated: Apr 11, 2022

Example
Compares two MapR Database tables:

```
[user@hostname ~]$
hbase com.mapr.fs.hbase.tools.mapreduce.DiffTablesWithCrc -src /
customerTableA -dst /customerTableB -outdir /customerTableCompare
2015-03-04 17:52:40,912 INFO  [main] Configuration.deprecation:
hadoop.native.lib is deprecated. Instead, use io.native.lib.available
DiffTablesMeta completed. Metadata of the two tables is same.
....
Mapreduce job completed. The tables mismatch.
NUM_ROWS_MISMATCH_IN_SRC:32; NUM_ROWS_MISMATCH_IN_DST:30. Please check diff
in /customerTableCompare
```

MapR Database Binary FormatResult

Parses a sequence file generated by the `DiffTables` utility or the `DiffTablesWithCrc` utility and converts the results into a format that makes the results easier to understand.

Required Permissions
The user that runs the `FormatResult` utility must have the `readAce` and `writeAce` permissions on the volumes where the input and output paths are located.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
hbase com.mapr.fs.hbase.tools.mapreduce.FormatResult
-input <input file path>
-output <output file path>
[-mapreduce <true|false> (default: false)]
```

Parameters

Parameters	Description
input	The path to a file or directory of files that contains the output of either the DiffTables utility or the DiffTablesWithCrc utility.
output	The path to a file or a directory for the output. If the file or directory already exists, the utility fails. When a single sequence file is provided as input, the utility generates a single output file. When a directory of sequence files is provided as input, the utility generates a directory with output files.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the FormatResult operation. The default is not to use a MapReduce program (false).

Example
Formats a sequence file:

```
[user@hostname ~]$ hbase
com.mapr.fs.hbase.tools.mapreduce.FormatResult -input /dif1/tf4/opsForDst/
opsForDst-m-00001 -output /dif1/tf4/opsForDst_single/nomr -mapreduce false
2015-03-06 18:58:56,210 INFO  [main] Configuration.deprecation:
fs.default.name is deprecated. Instead, use fs.defaultFS
2015-03-06 18:58:57,492 INFO  [main] mapreduce.FormatResult: Translated
sequence file maprfs:///dif1/tf4/opsForDst/opsForDst-m-00001 to text file /
dif1/tf4/opsForDst_single/nomr
2015-03-06 18:58:57,527 INFO  [main] mapreduce.FormatResult: Total 1
text files created.
```

MapR Event Store For Apache Kafka Utilities

You can use the following utilities to with MapR Event Store For Apache Kafka streams:

`mapr copystream`
This utility copies data from one MapR Stream to another MapR Stream. You can use it, for example, if you want to set up replication manually from one stream to another.

If the destination stream does not exist, `mapr copystream` creates the destination stream with the same metadata as the source stream, and then copies data.

If the destination stream exists, `mapr copystream` copies data only.

Requried Permissions

To use this utility, you must have the following permissions:

- The permission `readAce` on the volume where the source stream is located, and the permission `writeAce` on the volume where the destination stream is located.
- On the source stream: either `consumeperm` or `copyperm`.
- On the destination stream: either `copyperm` or all three of the following permissions: `produceperm`, `consumeperm`, `topicperm`

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on streams, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr copystream
-src <srcStream>
-dst <dstStream>
[-mapreduce true/false default:false]
[-numthreads <nthreads> default:16]
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
src	The path and name of the stream to copy messages from.
dst	The path and name of the stream to copy messages to.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the copying operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads to read from the source stream and write to the destination stream. The MapReduce program runs as a MapReduce version 2 application based on the MapReduce mode that is configured on this node.
numthreads	When -mapreduce is false, this parameter specifies the number of threads allocated to perform the copying of data. The default is 16. If additional CPU resources are available, you might want to increase the number of threads to achieve better performance.

`mapr diffstreams`

This utility compares the message IDs, metadata, and data in two MapR Streams. Then, generates two directories that contain sequence files that you can use to merge the rows from the two MapR Streams.

Sequence files are binary flat files. You can learn more about them here. To convert a sequence file into a format that you can read, use the MapR Database JSON FormatResult on page 5318 utility.

This utility considers both the source stream and the destination stream to be a master stream. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each stream so that it contains a superset of the rows defined in both tables at the time at which the utility was run.

This utility generates both of the following output directories in the output directory that you specify:

opsForDst	A directory containing sequence files that correspond to each put and delete required to make the destination stream identical to the source stream.
opsForSrc	A directory containing sequence files that correspond to each put and delete required to make the source stream identical to the destination stream.

Required Permissions

To use this utility, you must have the following permissions:

- The permission `readAce` on the volumes where the tables are located.
- On the source stream: either `consumeperm` or `copyperm`.
- On the destination stream: either `consumeperm` or `copyperm`.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on streams, see Enabling Table and Stream Authorizations with ACEs on page 1461.

last-updated: Apr 11, 2022

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr diffstreams
-src <srcStream>
-dst <dstStream>
-outdir <output directory>
[-first_exit] Exit when first difference is found
[-mapreduce true/false default:false]
[-numthreads <nthreads> default:16]
```

Parameters

Parameter	Description
src	The path of the first stream to include in the comparison.
dst	The path of the second stream to include in the comparison.
outdir	The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.
first_exit	By default, the utility compares all the data in the specified streams. Use this parameter if you want to exit after the first difference is identified between the streams. The parameter takes no value.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the comparison. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads. The MapReduce program runs as a MapReduce version 2 application based on the MapReduce mode that is configured on this node.
numthreads	When -mapreduce is false, this parameter specifies the number of threads allocated to perform the comparison. The default is 16. If additional CPU resources are available, you might want to increase the number of thread to achieve better performance.

`mapr diffstreamswithcrc`

This utility uses a cyclic redundancy check to detect differences between sets of messages in the specified MapR Streams. Then, for each set of non-identical messages, it performs a detailed comparison. Finally, it generates one or more directories of sequence files.

You can use these files either to make a MapR Stream identical to its master or merge the messages from two MapR Streams.

Sequence files are binary flat files. You can learn more about them here. To convert a sequence file into a format that you can read, use the MapR Database JSON FormatResult on page 5318 utility.

last-updated: Apr 11, 2022

This utility requires less network bandwidth than the `mapr diffstreams` utility because it performs a detailed table comparison only on the sets of messages where the CRC algorithm detected a difference. Therefore, consider using this utility when the streams you compare are very similar and you are concerned about the data transfer rate.

This utility considers both the source stream and the destination stream to be a master stream. Therefore, it generates two directories with sequence files. These sequence files contain the puts required to update each stream so that each stream can contain a superset of the messages in both streams at the time at which the utility was run.

These are the directories that the utility generates:

opsForDst	A directory containing sequence files that correspond to each put and delete required to make the destination stream identical to the source stream.
opsForSrc	A directory containing sequence files that correspond to each put and delete required to make the source stream identical to the destination stream.

Requirements

- When the cluster runs YARN, it must also use zero configuration failover for the ResourceManager.
- To use this utility, you must have the following permissions:
  - The permission `readAce` on the volumes where the tables are located.
  - On the source stream: either `consumeperm` or `copyperm`.
  - On the destination stream: either `consumeperm` or `copyperm`.

  For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

  For information about how to set permissions on streams, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Run the `mapr importstream` command to implement the puts and deletes specified in the sequence files.

Syntax

```
mapr diffstreamswithcrc
-src <srcStream>
-dst <dstStream>
-outdir <output directory>
[-first_exit] Exit when first difference is found
```

Parameters

Parameter	Description
src	The path of the first stream to include in the comparison.
dst	The path of the second stream to include in the comparison.

last-updated: Apr 11, 2022

Parameter	Description
outdir	The path to a directory in which to place the generated sequence files. The utility creates the specified directory. If the specified directory already exists, the command fails.
first_exit	By default, the utility compares all the data in the specified streams. Use this parameter if you want to exit after the first difference is identified between the streams. The parameter takes no value.

`mapr exportstream` and `mapr importstream`

Use these utilities together to export data from MapR Streams into binary sequence files, and then import the data from the binary sequence files into other MapR Streams. You can also use the `mapr importstream` utility to import changes that are specified in sequence files output by the `mapr diffstreams` utility.

- Syntax of `mapr exportstream`
- Parameters of `mapr exportstream`
- Syntax of `mapr importstream`
- Parameters of `mapr importstream`

Required Permissions

To use the `mapr exportstream` utility, you must have the following permissions:

- The `readAce` permission on the volume where the source stream for `mapr exportstream` is located.
- The `writeAce` permission on the volume in which to save the output from `mapr exportstream`.
- On the source stream: either `consumeperm` or `copyperm`
- On the destination directory: write permission

To use the `mapr importstream` utility, you must have the following permissions:

- The `readAce` permission on the volume where the files output by `mapr exportstream` is located.
- The `writeAce` permission on the volume in which the destination stream is located.
- On the source directory: read permission on the directory and all of the files within it
- On the destination stream: either `copyperm` or all three of the following permissions: `produceperm`, `consumeperm`, `topicperm`

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on streams, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run these utilities unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Syntax of `mapr exportstream`

```
mapr exportstream
-src <srcStream>
-dst <dstDir>
[-mapreduce true/false default:false]
```

Parameters of `mapr exportstream`

Description	Parameter
src	The stream to export data from.
dst	The directory within the MapR filesystem to export the files to. This directory must already exist before you run the utility.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads.

Syntax of `mapr importstream`

```
mapr importstream
-src Input binary file or directory path
-dst Destination stream
[-mapreduce true/false default:false]
```

Parameters of `mapr importstream`

Description	Parameter

src	The path of the binary file or files to import.
	Examples
	`-src /temp/part0`
	`-src /temp/*`

dst	The stream to import data into.
mapreduce	A Boolean value that specifies whether or not to use a MapReduce program to perform the operation. The default, preferred method is to use a MapReduce program (true). When this parameter is set to false, a client process uses multiple threads.

`mapr perfconsumer`

This utility runs a consumer reading messages from topics in a MapR Stream. Use this utility to run consumers when you want to estimate the performance of consumers for your MapR Streams applications, given your network configuration.

This utility works in conjuction with the `mapr perfproducer` utility. When starting this utility, you can specify how many topics to read from, how many partitions to read from in each topic, and how many messages to read.

last-updated: Apr 11, 2022

The `mapr perfconsumer` utility uses the default values for all of the configuration parameters that apply to consumers. For a list of these parameters, see MapR Event Store For Apache Kafka Configuration Parameters.

The utility uses the default values for all of the configuration parameters that apply to consumers.

Each consumer runs as a single thread. You can run multiple instances of the utility at the same time. However, because consumers can be CPU-intensive, it is recommended to run at most 4 or 5 on a single cluster node.

When you run multiple instances of this utility, you can use the `-group` parameter to create consumer groups.

Monitor the performance of the running instances of the `mapr perfconsumer` utility by following the instructions that are given in Monitoring Consumers.

Prerequisites for running this utility

- Ensure that there is a MapR Stream that one or more instances of `mapr perfproducer` have already published messages to or are actively publishing messages to.
- Ensure that the user ID that runs the `mapr perfconsumer` utility has the `consumeperm` permission on the stream.
- Ensure that the user ID that runs the `mapr perfconsumer` utility has the `readAce` and `writeAce` permissions on the volume where the stream is located.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on streams, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr perfconsumer
-path <stream-full-name>
[ -ntopics <num topics> (default: 2) ]
[ -npart <numpartitions per topic> (default: 4)
[ -nmsgs <num messages per topicfeed> (default: 100000) ]
[ -group <consumer group id> (default: null)
[ -topicsubscription <true/false> (default: false) ]
```

Parameters

Parameter	Description
path	The path to the stream.
ntopics	The number of topics for the consumer to subscribe to. The default is 2. If the number that you specify is greater than the number of topics that are in the stream, the utility hangs.

last-updated: Apr 11, 2022

Parameter	Description
npart	The number of partitions to read from in each topic that is subscribed. The default is 4. If the number that you specify is greater than the number of partitions that are in each topic, the utility hangs. If you specify a group ID with the `-group` parameter, the consumer's committed cursors are saved. If you do not specify a group ID, then the consumer's committed cursors are not saved. If you use the `-group` parameter to specify a group ID and you set the `-topicsubscription` parameter to `true`: • If the consumer fails, it's partitions can be redistributed among other consumer in the same group. If the consumer is the only consumer within a group, restarting the consumer with the same group ID causes the consumer to begin reading from the offsets of the saved committed cursors. • If the consumer fails and is then restarted, it starts at the oldest message in each partition.
nmsgs	The number of messages to read from each partition. The default is 100,000.
group	The identifier of a consumer group. When two or more consumers belong to a consumer group, they must read from the same number of topics. MapR Event Store For Apache Kafka distributes the partitions for those topics among the consumers in the group. The default is null.
topicsubscription	A vaue of `true` subscribes the consumer to topics. A value of `false` subscribes the consumer to topic partitions. The default is `false`.

`mapr perfproducer`

This utility runs a producer, generating messages and publishing them to a MapR Stream. Use this utility to run producers when you want to estimate the performance of producers for your MapR Streams applications, given your network configuration.

This utility starts a producer and generates data for the producer to publish in messages to a MapR Stream. When starting the utility, you can specify how many topics the producer publishes to, how many partitions to create for each topic, and how many messages to publish to each partition. You can also specify the method for distributing messages among the partitions in each topic.

For example, suppose you run the utility by issuing this command:

```
mapr perfproducer -path /myVolume/myDirectory/stream_a -ntopics
40 -npart -5
-nmsgs 100000 -rr true
```

The producer automatically creates 40 topics in the stream, creating each topic as it writes the first message to that topic. Each topic is created with 5 partitions. The producer writes 100,000 messages

last-updated: Apr 11, 2022

to each partition for a total of 20,000,000 messages. After publishing all of the messages, the utility terminates.

The `mapr perfproducer` utility uses the default values for all of the configuration parameters that apply to producers. For a list of these parameters, see MapR Event Store For Apache Kafka Configuration Parameters.

Each producer runs as a single thread. You can run multiple instances of the utility at the same time. However, because producers can be CPU-intensive, it is recommended to run at most 4 or 5 on a single cluster node.

When multiple instances of the `mapr perfproducer` utility publish to a single stream, the separate instances share topics. For example, if -ntopics is set to 40 for each instance that publishes to a single stream, together those instances create no more than 40 topics in the stream and they share those topics.

It is recommended that all producers that publish to a single cluster publish to the same number of topics and partitions within those topics. Therefore, use the same values for -ntopics and -npart for each instance of the `mapr perfproducer` utility that shares a stream with other instances.

Monitor the performance of the running instances of the `mapr perfproducer` utility by issuing the `maprcli` command `stream topic info` at intervals, as described in Monitoring Producers. The command `stream topic info` shows statistics for single topics. Because all of the topics that `mapr perfproducer` creates have the same number of partitions, and because `mapr perfproducer` writes the same number of messages to each partition, you can assume that the statistics that the command `stream topic info` displays for any one topic are close to the statistics for any other topic. The naming convention that `mapr perfproducer` uses when creating topics is simply `topic`*n*, which produces the names `topic0`, `topic1`, and so on. You can run the command `stream topic info` with any one of these names as the value of the `-topic` parameter.

To simulate consumers to estimate the performance of MapR Event Store For Apache Kafka in your network configuration, run one or more instances of the `mapr perfconsumer` utility against the stream.

Prerequisites for running this utility

- Create a MapR Stream in a MapR cluster for the `mapr perfproducer` utility to publish messages to. See stream create on page 1758.

  If you plan to replicate the stream for the purposes of the performance estimate, create the replica stream. Then, start replication from the first stream to the replica stream. For instructions on setting up replication between streams, see Managing Stream Replication on page 1130.

- Ensure that the user ID that runs the `mapr perfproducer` utility has the `readAce` and `writeAce` permissions on the volume where the stream is located.

- Ensure that the user ID that runs the `mapr perfproducer` utility has the `produceperm` and `topicperm` permissions on the stream.

For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

For information about how to set permissions on streams, see Enabling Table and Stream Authorizations with ACEs on page 1461.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr perfproducer
-path <stream-full-name>
```

last-updated: Apr 11, 2022

```
[ -ntopics <num topics> (default: 2) ]
[ -npart <numpartitions per topic> (default: 4) ]
[ -nmsgs <num messages per topicfeed> (default: 100000) ]
[ -msgsz <msg value size> (default: 200) ]
[ -rr <round robin true/false> (default: false) ]
[ -hashkey <true/false> (default: false) ]
```

Parameters

Parameter	Description
path	The path to the stream.
ntopics	The number of topics for the producer to publish to in the stream. The default is 2.
npart	The number of partitions to create for each topic. The default is 4.
nmsgs	The number of messages to publish to each partition. The default is 100,000.
msgz	The size of each message in bytes. The default is 200 bytes.
rr	Specifies to publish messages to partitions within a topic in round-robin fashion. See How Partitions are Chosen for Messages for detail about this method of distributing messages among topic partitions. **Note:** This parameter is incompatible with the `-hashkey` parameter. You must set one or the other to true, but not both. The default is `false`.
hashkey	Specifies to distribute messages among topic partitions according to the hash of each message key. See How Partitions are Chosen for Messages for detail about this method of distributing messages among topic partitions. **Note:** This parameter is incompatible with the `-rr` parameter. You must set one or the other to true, but not both. The default is `true`.

`mapr streamanalyzer`

This light-weight utility, which is a sample application for the `Streams` Java class for analytics on MapR Streams, lets you count the messages in a stream or a subset of the topics in a stream. The utility also lets you print either whole retrieved messages or a subset of the fields in each message.

You can download the source code for this utility here: `StreamAnalyzer.java`

For information about the `Streams` Java class and building applications that use it, see MapR Event Store For Apache Kafka Java API Library on page 2756. See Logical Schema of Messages on page 635 for information about how messages are structured.

last-updated: Apr 11, 2022

Ensure that the user ID that runs the utility has the `readAce` permission on the volume where the stream is located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this utility unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

```
mapr streamanalyzer -path <stream-full-name>
[ -topics <comma separated topic names> ]
[ -regex  <regular expression representing topic names> ]
[ -countMessages <true/false> (default: true) ]
[ -printMessages <true/false> (default: false) ]
[ -projectFields <comma separated field names> (default: all fields) ]
```

Parameters

Parameter	Description
`path`	The path and name of the stream.
`topics`	A comma-separated list of the names of topics to retrieve. If you do not specify this parameter or the `-regex` parameter, all of the topics in the stream are retrieved. Do not use this parameter if you use the `-regex` parameter.
`regex`	A regular expression that represents the names of the topics to retrieve. If you do not specify this parameter or the `-topics` parameter, all of the topics in the stream are retrieved. Do not use this parameter if you use the `-topics` parameter.
`countMessages`	Prints the number of retrieved messages to the standard output.
`printMessages`	Prints the contents of retrieved messages to the standard output.
`projectFields`	If the `-printMessages` parameter is set to `true`, this parameter causes only the specified fields to be printed to the standard output for each message. In the list of field names, separate the names with commas. Default: all fields. Valid field names: key, value, topic, offset, partition, and producer. If the `-printMessages` parameter is set to `false`, this parameter has no effect.

YARN Commands

This section describes the YARN commands.

last-updated: Apr 11, 2022

Commands

All YARN commands are invoked by the `/usr/bin/yarn` script.

```
Usage: yarn [--config confdir] [COMMAND] [COMMAND_OPTIONS]
```

COMMAND_OPTION	Description
`--config confdir`	Overrides the default Configuration directory. Default is `${HADOOP_HOME}/conf`.
`COMMAND`	Commands
`COMMAND_OPTIONS`	Command options

The following `yarn` commands may be run on the MapR Data Platform distribution of Apache Hadoop:

Command	Description
`application`	Lists applications, or prints the status or kills the specified application.
`classpath`	Prints the class path needed to get the Hadoop jar and the required libraries
`debugcontrol`	Saves additional DEBUG logs for scheduling to a separate file without restarting the RM
`daemonlog`	Gets and sets the log level for each daemon
`jar`	Runs jar file
`logs`	Dumps container logs
`node`	Prints node report(s)
`queue`	Prints queue information
`rmadmin`	Performs administrative tasks for Resource Manager
`version`	Print the version

The following yarn commands are not supported on the MapR Data Platform distribution of Apache Hadoop:

- `yarn applicationattempt`
- `yarn cluster`
- `yarn container`
- `yarn nodemanager`
- `yarn proxyserver`
- `yarn resourcemanager`
- `yarn sharedcachemanager`
- `yarn scmadmin`
- `yarn timelineserver`

last-updated: Apr 11, 2022

You can use the maprcli node services command or the Control System to start the services. For more information, see Managing Services on page 827.

yarn application
The `yarn application` lists applications, or prints the status or kills the specified application.

Syntax

```
yarn application
   [-list [<-appStates States>] [<-appTypes Types>] ]
   [-status ApplicationId]
   [-kill ApplicationId]
```

Parameters

The following commands parameters are supported for `yarn application`:

Parameter	Description
-list [<-appStates States>] [<-appTypes Types>]	Lists applications. Optionally, you can filter the applications based on type or state. • Use `-appTypes` to filer applications based on a comma-separated list of application types. • Use`-appStates` to filter applications based on a comma-separated list of the following valid application states:ALL, NEW, NEW_SAVING, SUBMITTED, ACCEPTED, RUNNING, FINISHED, FAILED, KILLED
-status ApplicationId	Prints the status of the application.
-kill ApplicationId	Kills the application.

yarn classpath

The `yarn classpath` command prints the class path needed to access the Hadoop jar and the required libraries.

Syntax

```
yarn classpath
```

Output

```
$ yarn classpath
/opt/mapr/hadoop/hadoop-<version>/etc/hadoop:/opt/mapr/hadoop/
hadoop-<version>/etc/hadoop:/opt/mapr/hadoop/hadoop-<version>/etc/
hadoop:/opt/mapr/hadoop/hadoop-<version>/share/hadoop/common/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/common/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/hdfs:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/hdfs/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/hdfs/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/lib/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/*:
/contrib/capacity-scheduler/*.jar:
```

last-updated: Apr 11, 2022

```
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/*:
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/lib/*
```

yarn daemonlog

Gets or sets the log level for each daemon.

Syntax

```
yarn daemonlog
[-getlevel <host:port> <name>] | [-setlevel <host:port> <name> <level>]
```

Parameters

Parameter	Description
-getlevel <host:port> <name>	Prints the log level of the daemon running at <host:port>. This command internally connects to `http://<host:port>/logLevel?log=<name>`.
-setlevel <host:port> <name> <level>	Sets the log level of the daemon running at <host:port>. This command internally connects to `http://<host:port>/logLevel?log=<name>`.

yarn debugcontrol
used to save additional DEBUG logs for scheduling in YARN to a separate file without restarting the RM.

The logs are saved in /opt/mapr/Hadoop/Hadoop<version>/logs/yarn-mapr-scheduling-debug.log

Syntax

```
yarn debugcontrol
[-addapp <application_name>] | [-addqueue <queue_name> ]| [-removeapp
<application_name> ] | [-removequeue <queue_name> ] | [-getapps ] |
[-getqueues ]
```

Parameters

Parameter	Description
-addapp <application_name>	enables additional scheduling DEBUG on the application
-addqueue <queue_name>	enables additional scheduling DEBUG on the queue
-removeapp <application_name>	disable addition scheduling DEBUG on the application
-removequeue <queue_name>	disable addition scheduling DEBUG on the queue
-getapps	lists the applications with additional scheduling DEBUG
-getqueues	lists the queues with additional scheduling DEBUG

yarn jar

Runs a jar file that contains YARN code.

Syntax

```
yarn jar <jar> [<mainClass>] [<arguments>]
```

Parameters

The following commands parameters are supported for `yarn jar`:

Parameter	Description
`<jar>`	The JAR file.
<mainClass>	Sets the applications entry point.
`<arguments>`	Arguments to the program specified in the JAR file.

yarn logs
Dumps the YARN container logs.

Syntax

```
yarn logs -applicationId <application ID> [OPTIONS]

general options are:
 -appOwner <Application Owner>   AppOwner (assumed to be current user if
                                 not specified)
 -containerId <Container ID>     ContainerId (must be specified if node
                                 address is specified)
 -help                           Displays help for all commands.
 -nodeAddress <Node Address>     NodeAddress in the format nodename:port
                                 (must be specified if container id is
                                 specified)
```

Parameters

Parameter	Description
-applicationId	Specifies an application ID.
-appOwner <Application Owner>	Specifies the application owner. Defaults to the current user if this option is not specified.
-containerId <Container ID>	Specifies the container ID. Required when `-nodeAddress` is specified.
-nodeAddress <Node Address>	Specifies the node address in the following format: `nodename:port`. Required when `-containerId` is specified.

yarn node

Prints node report(s)

Syntax

```
yarn node
     [-list [-states <States>] | [-all]]
     [-status NodeId]
```

Parameters

Parameter	Description
-list [-states <states>] | [-all]]	Lists all running nodes. Optionally, filter nodes based on state or choose to list all the nodes. • Use `-states <states>` to filter nodes based on a comma-separate list of node states. • Use `-all` to list all nodes.
-status NodeId	Prints the status report of the node.

yarn queue

Prints queue information

Syntax

```
yarn queue -status <queue name>
```

Parameters

The following command parameter is supported for `yarn queue`:

Parameter	Description
`status`	The queue name.

yarn rmadmin

Runs the ResourceManager admin client.

Syntax

```
yarn rmadmin
    [-refreshQueues]
    [-refreshNodes]
    [-refreshUserToGroupsMapping]
    [-refreshSuperUserGroupsConfiguration]
    [-refreshAdminAcls]
    [-refreshServiceAcl]
    [-getGroups <username>]
    [-help <cmd>]
    [-transitionToActive <serviceId>]
    [-transitionToStandby <serviceId>]
    [-getServiceState <serviceId>]
    [-checkHealth <serviceId>]
```

Parameters

Parameter	Description
-refreshQueues	Reloads the queues' acls, states, and scheduler specific properties. The ResourceManager reloads the mapred-queues configuration file.
-refreshNodes	Refreshes the host information at the ResourceManager.
-refreshUserToGroupsMappings	Refreshes user-to-groups mappings.

last-updated: Apr 11, 2022

Parameter	Description
-refreshSuperUserGroupsConfiguration	Refreshes superuser proxy groups mappings.
-refreshAdminAcls	Refreshes acls for administration of ResourceManager.
-refreshServiceAcl	Reloads the service-level authorization policy file. The ResourceManager reloads the authorization policy file.
-getGroups <username>	Gets the groups that the user belongs to.
-help <cmd>	Displays help for the given parameter or all parameters if no parameter is specified.
-transitionToActive <serviceId>	Transitions the service into the Active state. You can use this parameter when the ResourceManager is configured to failover manually.
-transitionToStandby <serviceId>	Transitions the service into Standby state. You can use this parameter when the ResourceManager is configured to failover manually.
-getServiceState <serviceId>	Returns the service state. You can use this parameter when the ResourceManager is configured to failover manually or automatically but not with the zero configuration failover option.
-checkHealth <serviceId>	Requests a health check for the service. If the health check fails, the RMAdmin tool exits with a non-zero exit code. You can use this parameter when the ResourceManager is configured to failover manually or automatically but not with the zero configuration failover option.

yarn version

Prints the YARN version.

Syntax

```
yarn version
```

Output

```
$ yarn version
Hadoop 2.7.6.100-eep-800
Subversion git@github.com:mapr/private-hadoop-common -r
80dc89ae5df3a2cd01089f192c5d8a886e4788c9
Compiled by root on 2021-10-08T11:26Z

Source Code for MapR Software

MapR releases source code to the open-source community for enhancements that HPE has made to the Apache Hadoop project and other ecosystem components.

HPE regularly releases updates to Apache Hadoop ecosystem projects as the projects are released by Apache, after HPE can verify that the changes do not impact product stability. Releases of ecosystem components are independent of the release cycle for the core MapR software, so that new updates can be released quickly and efficiently.

last-updated: Apr 11, 2022

Source code developed by HPE can be found on GitHub at http://github.com/mapr as of March 2013, coincident with version 2.1.2 of the MapR distribution. HPE may also release source code for other MapR projects at github.com/mapr. For each release that HPE includes in its distribution, HPE branches and tags the release on GitHub using the underlying project release number appended by `-mapr`.

Component Repositories on GitHub

The following repositories are available on GitHub for components that HPE has enhanced, patched, or created.

- oozie
- hcatalog
- pig
- hive
- mahout
- hbase
- flume
- whirr
- opentsdb

  Note: Select the highest MEP version supported by the MapR version that you are using.
- sqoop
- scribe

Finding Source Changes Prior to February 2013

GitHub is the single, central location for tracking changes that HPE applies to components in releases of the MapR distribution. Prior to February 2013, HPE included a list of patches in each component directory, as shown below. This information is no longer stored in the installation directory for recent releases, and instead is available at GitHub.

Example: Location of Information about Patches to HBase Prior to February 2012

```
$ ls /opt/mapr/hbase/hbase-0.92.1/
bin          hbase-0.92.1.jar        LICENSE.txt         pom.xml
CHANGES.txt  hbase-0.92.1-tests.jar  logs                README.txt
conf         hbase-webapps           mapr-hbase-patches  security
conf.new     lib                     NOTICE.txt          src

$ ls /opt/mapr/hbase/hbase-0.92.1/mapr-hbase-patches/
0000-hbase-with-mapr.patch                  0006-hbase-6285-fix.patch
0001-hbase-wait-for-fs+set-chunksize.patch  0007-hbase-6375-fix.patch
0002-hbase-source-env-vars.patch            0008-hbase-6455-fix.patch
0003-hbase-6158-fix.patch                   0009-bug-7745-fix.patch
0004-hbase-6018-fix.patch                   Readme.txt
0005-hbase-6236-fix.patch
```

Hadoop Commands

This section describes the Hadoop commands.

last-updated: Apr 11, 2022

All Hadoop commands are invoked by the `bin/hadoop` script.

Overview

This section contains the following:

Syntax Summary

The following syntax summary applies to all commands.

```
hadoop [--config confdir] [COMMAND] [GENERIC_OPTIONS] [COMMAND_OPTIONS]

hadoop2 [--config confdir] [COMMAND] [GENERIC_OPTIONS] [COMMAND_OPTIONS]
```

Hadoop has an option parsing framework that employs parsing generic options as well as running classes.

COMMAND_OPTION	Description
`-mode`	For both the hadoop and hadoop2 commands, setting this option is no longer valid. Both commands default to `yarn`, the only valid mode for the current MapR version.
`--config confdir`	Overwrites the default Configuration directory. Default is `${HADOOP_HOME}/conf`.
`COMMAND`	Various commands with their options are described in the following sections.
`GENERIC_OPTIONS`	The common set of options supported by multiple commands.
`COMMAND_OPTIONS`	Various command options are described in the following sections.

Note: Running the `hadoop` script without any arguments prints the help description for all commands.

Supported Commands for Hadoop 2.x

MapR supports the following `hadoop` commands for Hadoop 2.x:

Command	Description
`archive -archiveName NAME <src>* <dest>`	Creates a Hadoop archive, a file that contains other files. A Hadoop archive always has a `.har` extension.
CLASSNAME	The hadoop script can be used to invoke any class. `hadoop CLASSNAME` runs the class named CLASSNAME.
`classpath`	Prints the class path needed to access the Hadoop JAR and the required libraries.
`conf`	The `hadoop conf` command prints the configuration information for the current node.
`daemonlog`	The `hadoop daemonlog` command may be used to get or set the log level of Hadoop daemons.

last-updated: Apr 11, 2022

Command	Description
`distcp <source> <destination>`	The `hadoop distcp` command is a tool for large inter- and intra-cluster copying. It uses MapReduce to effect its distribution, error handling and recovery, and reporting. It expands a list of files and directories into input to map tasks, each of which will copy a partition of the files specified in the source list.
`fs`	The `hadoop fs` command runs a generic filesystem user client that interacts with the MapR filesystem.
`jar <jar>`	The `hadoop jar` command runs a JAR file. Users can bundle their MapReduce code in a JAR file and execute it using this command.
`mfs`	The `hadoop mfs` command performs operations on directories in the cluster. The main purposes of `hadoop mfs` are to display directory information and contents, to create symbolic links, and to set compression and chunk size on a directory.
`version`	The `hadoop version` command prints the Hadoop software version.

Warning: For Hadoop2, some `hadoop` commands are deprecated and replaced by the `mapred` command.

For example, if you run the `hadoop job` command, you see this message:

```
# hadoop job
DEPRECATED: Use of this script to execute mapred command is deprecated.
Instead, use the mapred command for it.
```

The syntax for the `mapred` command is:

```
mapred [--config confdir] [--loglevel loglevel] COMMAND
```

Commands used with `mapred` include:

Command	Description
`historyserver`	Runs job history servers as a standalone daemon
`hsadmin`	The job history server admin interface
`job`	Manipulates MapReduce applications
`pipes`	Runs a `pipes` job
`queue`	Gets information regarding `JobQueues`

Generic Options

Implement the Tool interface to make the following command-line options available for many of the Hadoop commands.

Generic Option	Description
`-conf <filename1 filename2 ...>`	Add the specified configuration files to the list of resources available in the configuration.

last-updated: Apr 11, 2022

Generic Option	Description
`-D <property=value>`	Set a value for the specified Hadoop configuration property.
`-fs <local|filesystem URI>`	Set the URI of the default filesystem.
`-jt <local|jobtracker:port>`	Specify a ResourceManager for a given host and port. This command option is a shortcut for `-D mapred.job.tracker=host:port`
`-files <file1,file2,...>`	Specify files to be copied to the map reduce cluster.
`-libjars <jar1,jar2,...>`	Specify JAR files to be included in the classpath of the mapper and reducer tasks.
`-archives <archive1,archive2,...>`	Specify archive files (JAR, tar, tar.gz, ZIP) to be copied and unarchived on the task node.

hadoop archive

The `hadoop archive` command creates a Hadoop archive, a file that contains other files. A Hadoop archive always has a `*.har` extension.

Syntax

```
hadoop [ Generic Options ] archive
    -archiveName <name>
    [-p <parent>]
    <source>
    <destination>
```

Parameters

Parameter	Description
`-archiveName <name>`	Name of the archive to be created.
`-p <parent_path>`	The parent argument is to specify the relative path to which the files should be archived to.
`<source>`	Filesystem pathnames, which work as usual with regular expressions.
`<destination>`	Destination directory, which would contain the archive.

Examples

Archive within a single directory

```
hadoop archive -archiveName myArchive.har -p /foo/bar /outputdir
```

The above command creates an archive of the directory `/foo/bar` in the directory `/outputdir`.

Archive to another directory

```
hadoop archive -archiveName myArchive.har -p /foo/bar a/b/c e/f/g
```

last-updated: Apr 11, 2022

The above command creates an archive of the directory `/foo/bar/a/b/c` in the directory `/foo/bar/e/f/g`.

hadoop classpath
The `hadoop classpath` command prints the class path needed to access the Hadoop jar and the required libraries.

Syntax

```
hadoop classpath
```

Output Example

```
$hadoop classpath
/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/
share/hadoop/common/lib/
*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/*:/opt/mapr/hadoop/
hadoop-2.7.0/share/hadoo
p/hdfs:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/hdfs/lib/*:/opt/mapr/
hadoop/hadoop-2.7.0/shar
e/hadoop/hdfs/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/lib/*:/opt/
mapr/hadoop/hadoop-2
.7.0/share/hadoop/yarn/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/
mapreduce/lib/*:/opt/mapr/h
adoop/hadoop-2.7.0/share/hadoop/mapreduce/*:/contrib/capacity-scheduler/
*.jar:/opt/mapr/lib/kvs
tore*.jar:/opt/mapr/lib/libprotodefs*.jar:/opt/mapr/lib/baseutils*.jar:/opt/
mapr/lib/maprutil*.
jar:/opt/mapr/lib/json-20080701.jar:/opt/mapr/lib/flexjson-2.1.jar
```

hadoop daemonlog
The `hadoop daemonlog` command gets and sets the log level for each daemon.

Hadoop daemons all produce logfiles that you can use to learn about what is happening on the system. You can use the `hadoop daemonlog` command to temporarily change the log level of a component when debugging the system.

Syntax

```
hadoop daemonlog
    -getlevel | -setlevel
    <host>:<port>
    <name>
    [ <level> ]
```

Parameters

The following command options are supported for `hadoop daemonlog` command:

last-updated: Apr 11, 2022

Parameter	Description
`-getlevel <host:port><name>`	Prints the log level of the daemon running at the specified host and port, by querying `http://<host>:<port>/logLevel?log=<name>` • `<host>`: The host on which to get the log level. • `<port>`: The port by which to get the log level. • `<name>`: The daemon on which to get the log level. Usually the fully qualified classname of the daemon doing the logging. For example, `org.apache.hadoop.yarn.server.resourcemanager.resourcemanager` for the ResourceManager daemon.
`-setlevel <host:port> <name> <level>`	Sets the log level of the daemon running at the specified host and port, by querying `http://<host>:<port>/logLevel?log=<name>` * `<host>`: The host on which to set the log level. • `<port>`: The port by which to set the log level. • `<name>`: The daemon on which to set the log level. • `<level`: The log level to set the daemon.

Examples

Getting the log levels of a daemon

To get the log level for each daemon enter a command such as the following:

```
hadoop daemonlog -getlevel 10.250.1.15:50030
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Connecting to http://10.250.1.15:50030/logLevel?
log=org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Submitted Log Name:
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Log Class: org.apache.commons.logging.impl.Log4JLogger
Effective level: ALL
```

Setting the log level of a daemon

To temporarily set the log level for a daemon enter a command such as the following:

```
hadoop daemonlog -setlevel 10.250.1.15:50030
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager DEBUG
Connecting to http://10.250.1.15:50030/logLevel?
log=org.apache.hadoop.yarn.server.resourcemanager.resourcemanager&level=DEBU
G
Submitted Log Name:
org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
Log Class: org.apache.commons.logging.impl.Log4JLogger
Submitted Level: DEBUG
Setting Level to DEBUG ...
Effective level: DEBUG
```

last-updated: Apr 11, 2022

Using this method, the log level is automatically reset when the daemon is restarted.

To make the change to log level of a daemon persistent, enter a command such as the following:

```
hadoop daemonlog -setlevel 10.250.1.15:50030
log4j.logger.org.apache.hadoop.yarn.server.resourcemanager.resourcemanager
DEBUG
```

hadoop distcp
The `hadoop distcp` command is a tool used for large inter- and intra-cluster copying.

It uses MapReduce to effect its distribution, error handling and recovery, and reporting. It expands a list of files and directories into input to map tasks, each of which will copy a partition of the files specified in the source list.

Syntax

```
hadoop [ Generic Options ] distcp
    [-p[erbugp] ]
    [-i ]
    [-log ]
    [-m ]
    [-overwrite ]
    [-update  ]
    [-f <URI list> ]
    [-filelimit <n> ]
    [-sizelimit <n> ]
    [-delete ]
    <source>
    <destination>
```

Parameters

Command Options

The following command options are supported for the `hadoop distcp` command:

Parameter	Description
`<source>`	Specify the source URL.
`<destination>`	Specify the destination URL.
`-p[erbugp]`	Preserve e: ACE `r`: replication number b: block size u: user g: group p: permission `-p` alone is equivalent to `-perbugp`. Modification times are not preserved. When you specify `-update`, status updates are not synchronized unless the file sizes also differ.
`-i`	Ignore failures. As explained in the below, this option will keep more accurate statistics about the copy than the default case. It also preserves logs from failed copies, which can be valuable for debugging. Finally, a failing map will not cause the job to fail before all splits are attempted.
`-log <logdir>`	Write logs to `<logdir>`. The `hadoop distcp` command keeps logs of each file it attempts to copy as map output. If a map fails, the log output will not be retained if it is re-executed.
`-m <num_maps>`	Maximum number of simultaneous copies. Specify the number of maps to copy data. Note that more maps may not necessarily improve throughput. See *Map Sizing*.

Parameter	Description
`-overwrite`	Overwrite destination. If a map fails and `-i` is not specified, all the files in the split, not only those that failed, will be recopied. As discussed in the *Overwriting Files Between Clusters*, it also changes the semantics for generating destination paths, so users should use this carefully.
`-update`	Overwrite if `<source>` size is different from `<destination>` size. As noted in the preceding, this is not a "sync" operation. The only criterion examined is the source and destination file sizes; if they differ, the source file replaces the destination file. See *Updating Files Between Clusters*.
`-f <URI list>`	Use list at <URI list> as source list. This is equivalent to listing each source on the command line. The value of <URI list> must be a fully qualified URI.
`-filelimit <n>`	Limit the total number of files to be <= n. See *Symbolic Representations*.
`-sizelimit <n>`	Limit the total size to be <= n bytes. See *Symbolic Representations*.
`-delete`	Delete the files existing in the `<destination>` but not in `<source>`. The deletion is done by FS Shell.

Generic Options

The `hadoop distcp` command supports the following generic options: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|file system URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see Generic Options.

Symbolic Representations

The parameter <n> in `-filelimit` and `-sizelimit` can be specified with symbolic representation. For example,

- 1230k = 1230 * 1024 = 1259520
- 891g = 891 * 1024^3 = 956703965184

Map Sizing

The `hadoop distcp` command attempts to size each map comparably so that each copies roughly the same number of bytes. Note that files are the finest level of granularity, so increasing the number of simultaneous copiers (i.e. maps) may not always increase the number of simultaneous copies nor the overall throughput.

If `-m` is not specified, `distcp` will attempt to schedule work for `min (total_bytes / bytes.per.map, 20 * num_task_trackers)` where `bytes.per.map` defaults to 256MB.

Tuning the number of maps to the size of the source and destination clusters, the size of the copy, and the available bandwidth is recommended for long-running and regularly run jobs.

Examples

For all of the below examples, the cluster name must be specified in the mapr-clusters.conf on page 2200 configuration file.

Basic inter-cluster copying

last-updated: Apr 11, 2022

The `hadoop distcp` command is most often used to copy files between clusters:

```
hadoop distcp maprfs://cluster1/foo \
maprfs://cluster2/bar
```

The command in the example expands the namespace under `/foo/bar` on cluster1 into a temporary file, partitions its contents among a set of map tasks, and starts a copy on each NodeManager node from cluster1 to cluster2. Note that the `hadoop distcp` command expects absolute paths.

Only those files that do not already exist in the destination are copied over from the source directory.

Updating files between clusters

Use the `hadoop distcp -update` command to synchronize changes between clusters.

```
$ hadoop distcp -update maprfs://cluster1/foo maprfs://cluster2/bar/foo
```

Files in the `/foo` subtree are copied from cluster1 to cluster2 only if the size of the source file is different from that of the size of the destination file. Otherwise, the files are skipped over.

Note that using the `-update` option changes distributed copy interprets the source and destination paths making it necessary to add the trailing `/foo` subdirectory in the second cluster.

Overwriting files between clusters

By default, distributed copy skips files that already exist in the destination directory, but you can overwrite those files using the `-overwrite` option. In this example, multiple source directories are specified:

```
$ hadoop distcp -overwrite maprfs://cluster1/foo/a \
maprfs://cluster1/foo/b \
maprfs://cluster2/bar
```

As with using the `-update` option, using the `-overwrite` changes the way that the source and destination paths are interpreted by distributed copy: the contents of the source directories are compared to the contents of the destination directory. The distributed copy aborts in case of a conflict.

Migrating Data from HDFS to MapR File System

The `hadoop distcp` command can be used to migrate data from an HDFS cluster to a MapR File System where the HDFS cluster uses the same version of the RPC protocol as that used by MapR. For a discussion, see Copying Data from Apache Hadoop.

```
$ hadoop distcp namenode1:50070/foo maprfs:///bar
```

You must specify the IP address and HTTP port (usually 50070) for the namenode on the HDFS cluster.

hadoop fs

The `hadoop fs` command runs a generic file system user client that interacts with the MapR File System.

Warning: On the Windows client, make sure that the `PATH` contains the following directories:

- `C:\Windows\system32`
- `C:\Windows`

If they are not present, the `hadoop fs` command might fail silently.

Syntax

```
hadoop [ Generic Options ] fs
        [-cat <src>]
        [-chgrp [-R] GROUP PATH...]
        [-chmod [-R] <MODE[,MODE]... | OCTALMODE> PATH...]
        [-chown [-R] [OWNER][:[GROUP]] PATH...]
        [-copyFromLocal <localsrc> ... <dst>]
        [-copyToLocal [-ignoreCrc] [-crc] <src> <localdst>]
        [-count[-q] <path>]
        [-cp <src> <dst> -p[e]]
        [-df <path>]
        [-du <path>]
        [-dus <path>]
        [-expunge]
        [-get [-ignoreCrc] [-crc] <src> <localdst>]
        [-getfattr [-R] {-n name | -d} [-e <encoding>] <path>]
        [-getmerge <src> <localdst> [addnl]]
        [-help [cmd]]
        [-ls <path>]
        [-lsr <path>]
        [-mkdir <path>]
        [-moveFromLocal <localsrc> ... <dst>]
        [-moveToLocal <src> <localdst>]
        [-mv <src> <dst>]
        [-put <localsrc> ... <dst>]
        [-rm [-skipTrash] <src>]
        [-rmr [-skipTrash] <src>]
        [-setfattr -n name [-v value] | -x name <path>]
        [-stat [format] <path>]
        [-tail [-f] <path>]
        [-test -[ezd] <path>]
        [-text <path>]
        [-touchz <path>]
```

Parameters

Command Options

The following command parameters are supported for `hadoop fs`:

Parameter	Description
`-cat <src>`	Fetch all files that match the file pattern defined by the `<src>` parameter and display their contents on *stdout*.
`-chmod [-R] <MODE[,MODE]... | OCTALMODE> PATH...`	Changes permissions of a file. This works similar to shell's `chmod` with a few exceptions. `-R` modifies the files recursively. This is the only option currently supported. `MODE` Mode is same as mode used for `chmod` shell command. Only letters recognized are `rwxXt`. That is, `+t,a+r,g-w,+rwx,o=r` `OCTALMODE` Mode specifed in 3 or 4 digits. If 4 digits, the first may be 1 or 0 to turn the sticky bit on or off, respectively. Unlike shell command, it is not possible to specify only part of the mode E.g. 754 is same as u=rwx,g=rx,o=r If none of 'augo' is specified, 'a' is assumed and unlike shell command, no umask is applied.

last-updated: Apr 11, 2022

Parameter	Description
`-chown [-R] [OWNER] [:[GROUP]] PATH...`	Changes owner and group of a file. This is similar to shell's `chown` with a few exceptions. `-R` modifies the files recursively. This is the only option currently supported. If only owner or group is specified then only owner or group is modified.The owner and group names may only consists of digits, alphabet, and any of `-.@/` *i.e.* `[-.@/a-zA-Z0-9]`. The names are case sensitive. **Warning:** Avoid using '.' to separate user name and group though Linux allows it. If user names have dots in them and you are using local file system, you might see surprising results since shell command `chown` is used for local files.
`-chgrp [-R] GROUP PATH...`	This is equivalent to `-chown ... :GROUP ...`
`-copyFromLocal <localsrc> ... <dst>`	Identical to the `-put` command.
`-copyToLocal [-ignoreCrc] [-crc] <src> <localdst>`	Identical to the `-get` command.
`-count[-q] <path>`	Count the number of directories, files and bytes under the paths that match the specified file pattern. The output columns are: `DIR_COUNT FILE_COUNT CONTENT_SIZE FILE_NAME` or `QUOTA REMAINING_QUATA SPACE_QUOTA REMAINING_SPACE_QUOTA DIR_COUNT FILE_COUNT CONTENT_SIZE FILE_NAME`
`-cp <src> <dst> [-p[e]]`	Copy files that match the file pattern `<src>` to a destination. When copying multiple files, the destination must be a directory. Specifying `-p` with the e option preserves an ACE applied to the file. Specifying `-p` without an argument preserves the ACE by default.
`-df [<path>]`	Shows the capacity, free and used space of the file system. If the file system has multiple partitions, and no path to a particular partition is specified, then the status of the root partitions will be shown.
`-du <path>`	Show the amount of space, in bytes, used by the files that match the specified file pattern. Equivalent to the Unix command `du -sb <path>/*` in case of a directory, and to `du -b <path>` in case of a file. The output is in the form name(full path) size (in bytes).
`-dus <path>`	Show the amount of space, in bytes, used by the files that match the specified file pattern. Equivalent to the Unix command `du -sb`. The output is in the form `name(full path)` size (in bytes).
`-fs [local | <filesystem URI>]`	Specify the file system to use. If not specified, the current configuration is used, taken from the following, in increasing precedence: `core-default.xml` inside the hadoop jar file `core-site.xml` in `$HADOOP_CONF_DIR`. The `local` option means use the local file system as your DFS. `<filesystem URI>` specifies a particular file system to contact. This argument is optional but if used must appear appear first on the command line. Exactly one additional argument must be specified.
`-get [-ignoreCrc] [-crc] <src> <localdst>`	Copy files that match the file pattern <src> to the local name. <src> is kept. When copying multiple files, the destination must be a directory.

last-updated: Apr 11, 2022

Parameter	Description
`getfattr [-R] -n <name> | -d [-e <encoding>] <path>`	Retrieve all the extended attribute values (if any) for a file or directory. Here: **`-R`** Recursively list the attributes for all files and directories. **`-n <name>`** The name of the extended attribute to retrieve. **`-d`** Retrieve all extended attributes associated with the pathname. Extended attributes to which the calling process does not have access may be omitted from the list. **`-e <encoding>`** Encode values after retrieving them. Valid encodings are text (enclosed in double quotes), hex (prefixed with 0x), and base64 (prefixed with 0s). **`<path>`** The file or directory.
`-getmerge <src> <localdst>`	Get all the files in the directories that match the source file pattern and merge and sort them to only one file on local fs. `<src>` is kept.
`-help [cmd]`	Displays help for given command or all commands if none is specified.
`-ls <path>`	List the contents that match the specified file pattern. If path is not specified, the contents of `/user/<currentUser>` will be listed. Directory entries are of the form `dirName (full path) <dir>` and file entries are of the form `fileName(full path) <r n>`. size where n is the number of replicas specified for the file and size is the size of the file, in bytes.
`-lsr <path>`	Recursively list the contents that match the specified file pattern. Behaves very similarly to `hadoop fs -ls`, except that the data is shown for all the entries in the subtree.
`-mkdir <path>`	Create a directory in specified location.
`-moveFromLocal <localsrc> ... <dst>`	Same as `-put`, except that the source is deleted after it's copied.
`-moveToLocal <src> <localdst>`	Not implemented yet
`-mv <src> <dst>`	Move files that match the specified file pattern `<src>` to a destination `<dst>`. When moving multiple files, the destination must be a directory.
`-put <localsrc> ... <dst>`	Copy files from the local file system into fs. To copy files, user must have write permission on the directory or the `addchild`, `deletechild`, and `writefile` access set using ACEs.
`-rm [-skipTrash] <src>`	Delete all files that match the specified file pattern. Equivalent to the Unix command `rm <src>`. The `-skipTrash` option bypasses trash, if enabled, and immediately deletes `<src>`
`-rmr [-skipTrash] <src>`	Remove all directories which match the specified file pattern. Equivalent to the Unix command `rm -rf <src>` The `-skipTrash` option bypasses trash, if enabled, and immediately deletes `<src>`

last-updated: Apr 11, 2022

Parameter	Description
`-setfattr -n <name> [-v <value>] | -x <name> <path>`	Set or remove an extended attribute name and value. Here: **`-n <name>`** The name of the extended attribute to set. **`-v <value>`** The value of the extended attribute to set. **`-x <name>`** The name of the extended attribute to remove. **`<path>`** The file or directory.
`-stat [format] <path>`	Print statistics about the file/directory at `<path>` in the specified format. Format accepts filesize in blocks (%b), filename (%n), block size (%o), replication (%r), modification date (%y, %Y)
`-tail [-f] <file>`	Show the last 1KB of the file. The `-f` option shows appended data as the file grows.
`-touchz <path>`	Write a timestamp in `yyyy-MM-dd HH:mm:ss` format in a file at `<path>`. An error is returned if the file exists with non-zero length.
`-test -[ezd] <path>`	If file { exists, has zero length, is a directory then return 0, else return 1.
`-text <src>`	Takes a source file and outputs the file in text format. The allowed formats are zip and TextRecordInputStream.

Generic Options

The following generic options are supported for the `hadoop fs` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|file system URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see Generic Options.

Examples

Set an extended attribute on a file, file1.txt:

```
hadoop fs -setfattr -n user.key1 -v val1 /xattrs/m7user1/file1.txt
```

Remove an extended attribute specified by name:

```
hadoop fs -setfattr -x user.key1 /xattrs/m7user1/dir1
```

Retrieve an extended attribute for a file encoded in text:

```
[root@qa-node110 ~]# hadoop fs -getfattr -n user.key1 -e text /xattr/file1
# file: /xattr/file1
user.key1="value1"
```

Retrieve an extended attribute for a file encoded in hex:

```
[root@qa-node110 ~]# hadoop fs -getfattr -n user.key1 -e hex /xattr/file1
# file: /xattr/file1
user.key1=0x76616c756531
```

last-updated: Apr 11, 2022

Retrieve an extended attribute for a file encoded in base64:

```
[root@qa-node110 ~]# hadoop fs -getfattr -n user.key1 -e base64 /xattr/file1
# file: /xattr/file1
user.key1=0sdmFsdWUx
```

Retrieve an extended attribute specified by name:

```
[root@qa-node110 ~]# hadoop fs -getfattr -n user.key1 /xattr/file2
# file: /xattr/file2
user.key1="value1"
```

Retrieve all the extended attributes associated with the given file:

```
[root@qa-node110 ~]# hadoop fs -getfattr -d /xattr/file2
# file: /xattr/file2
user.key2="value2"
user.key1="value1"
```

Retrieve extended attributes recursively:

```
[root@qa-node110 ~]# hadoop fs -getfattr -R -d /xattr/
# file: /xattr
# file: /xattr/file1
user.key2="value2"
# file: /xattr/file2
user.key2="value2"
user.key1="value1"
```

Retrieve a specific extended attribute recursively on a directory:

```
[root@qa-node110 ~]# hadoop fs -getfattr -R -n user.key1 /xattr/
# file: /xattr
user.key1="value1"
# file: /xattr/file1
getfattr: No such attribute
# file: /xattr/file2
user.key1="value1"
```

Suppressing Warning Messages for the hadoop fs Command

After an upgrade to 4.0.x, the `hadoop fs` command returns the following warning message:

```
WARNING: org.apache.hadoop.metrics.jvm.EventCounter is deprecated. Please
use
org.apache.hadoop.log.metrics.EventCounter in all the log4j.properties
files.
```

This message does not cause any problems, but you can suppress it by modifying the following file:

```
/opt/mapr/hadoop/hadoop-0.20.2/conf/log4j.properties
```

In this file, replace the following line:

```
log4j.appender.EventCounter=org.apache.hadoop.log.EventCounter
```

with this line:

```
log4j.appender.EventCounter=org.apache.hadoop.log.metrics.EventCounter
```

last-updated: Apr 11, 2022

hadoop jar

The `hadoop jar` command runs a program contained in a JAR file. Users can bundle their MapReduce code in a JAR file and execute it using this command.

Syntax

```
hadoop jar <jar>
     [<arguments>]
```

Parameters

The following commands parameters are supported for `hadoop jar`:

Parameter	Description
`<jar>`	The JAR file.
`<arguments>`	Arguments to the program specified in the JAR file.

Examples

Streaming Application

Hadoop streaming applications are run using the `hadoop jar` command. The Hadoop streaming utility enables you to create and run MapReduce applications with any executable or script as the mapper and/or the reducer.

```
$ hadoop jar $HADOOP_HOME/hadoop-streaming.jar \
    -input myInputDirs \
    -output myOutputDir \
    -mapper org.apache.hadoop.mapred.lib.IdentityMapper \
    -reducer /bin/wc
```

The `-input`, `-output`, `-mapper`, and `-reducer` streaming command options are all required for streaming jobs. Either an executable or a Java class may be used for the mapper and the reducer. For more information about and examples of streaming applications, see *Hadoop Streaming* at the Apache project's page.

Running from a JAR file

The simple Word Count program is another example of a program that is run using the `hadoop jar` command. The `wordcount` functionality is built into the `hadoop-0.20.2-dev-examples.jar` program. You pass the file, along with the location, to Hadoop with the `hadoop jar` command and Hadoop reads the JAR file and executes the relevant instructions.

The Word Count program reads files from an input directory, counts the words, and writes the results of the application to files in an output directory.

```
$ hadoop jar /opt/mapr/hadoop/hadoop-0.20.2/hadoop-0.20.2-dev-examples.jar
wordcount /myvolume/in /myvolume/out
```

hadoop job

The `hadoop job` command enables you to manage MapReduce jobs.

Warning: This command is deprecated.

last-updated: Apr 11, 2022

Syntax

```
hadoop job [Generic Options]
        [-submit <job-file>]
        [-status <job-id>]
        [-counter <job-id> <group-name> <counter-name>]
        [-kill <job-id>]
        [-unblacklist <job-id> <hostname>]
        [-unblacklist-tracker <hostname>]
        [-set-priority <job-id> <priority>]
        [-events <job-id> <from-event-#> <#-of-events>]
        [-history <jobOutputDir>]
        [-list [all]]
        [-list-active-trackers]
        [-list-blacklisted-trackers]
        [-list-attempt-ids <job-id> <task-type> <task-state>]
        [-kill-task <task-id>]
        [-fail-task <task-id>]
        [-blacklist-tasktracker <hostname>]
        [-showlabels]
```

Parameters

Command Options

The following command options are supported for `hadoop job`:

Parameter	Description
`-submit <job-file>`	Submits the job.
`-status <job-id>`	Prints the map and reduce completion percentage and all job counters.
`-counter <job-id> <group-name> <counter-name>`	Prints the counter value.
`-kill <job-id>`	Kills the job.
`-unblacklist <job-id> <hostname>`	Removes a tasktracker job from the jobtracker's blacklist.
`-unblacklist-tracker <hostname>`	Admin only. Removes the TaskTracker at `<hostname>` from the JobTracker's global blacklist.
`-set-priority <job-id> <priority>`	Changes the priority of the job. Valid priority values are `VERY_HIGH`, `HIGH`, `NORMAL`, `LOW`, and `VERY_LOW`. The job scheduler uses this property to determine the order in which jobs are run.
`-events <job-id> <from-event-#> <#-of-events>`	Prints the events' details received by jobtracker for the given range.
`-history <jobOutputDir>`	Prints job details, failed and killed tip details.
`-list [all]`	The `-list all` option displays all jobs. The `-list` command without the `all` option displays only jobs which are yet to complete.
`-list-active-trackers`	Prints all active tasktrackers.

last-updated: Apr 11, 2022

Parameter	Description
`-list-blackisted-trackers`	Prints the TaskTracker nodes that JobTracker blacklisted with the reason for blacklisting.
`-list-attempt-ids <job-id><task-type>`	Lists the IDs of task attempts.
`-kill-task <task-id>`	Kills the task. Killed tasks are *not* counted against failed attempts.
`-fail-task <task-id>`	Fails the task. Failed tasks are counted against failed attempts.
`-blacklist-tasktracker <hostname>`	Pauses all current tasktracker jobs and prevent additional jobs from being scheduled on the tasktracker.
`-showlabels`	Dumps label information of all active nodes.

Generic Options

The following generic options are supported for the `hadoop job` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|file system URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see Generic Options.

Examples

Submitting Jobs

The `hadoop job -submit` command enables you to submit a job to the specified jobtracker.

```
$ hadoop job -jt darwin:50020 -submit job.xml
```

Stopping Jobs Gracefully

Use the `hadoop kill` command to stop a running or queued job.

```
$ hadoop job -kill <job-id>
```

Viewing Job History Logs

Run the `hadoop job -history` command to view the history logs summary in specified directory.

```
$ hadoop job -history output-dir
```

This command will print job details, failed and killed tip details.

Additional details about the job such as successful tasks and task attempts made for each task can be viewed by adding the `-all` option:

```
$ hadoop job -history all output-dir
```

Blacklisting Tasktrackers

The `hadoop job` command when run as root or using `sudo` can be used to manually blacklist tasktrackers:

```
hadoop job -blacklist-tasktracker <hostname>
```

last-updated: Apr 11, 2022

Manually blacklisting a tasktracker pauses any running jobs and prevents additional jobs from being scheduled.

hadoop mfs
The `hadoop mfs` command displays directory information and contents, creates symbolic links and hard links, sets, gets, and removes Access Control Expressions (ACE) on files and directories, and sets compression and chunk size on a directory.

Syntax

```
hadoop mfs
  [ -count <path> ]
  [ -delace [-R] <path> ]
  [ -getace [-R] <path> ]
  [ -help <command> ]
  [ -ln <target> <symlink> ]
  [ -lnh <target> <hardlink> ]
  [ -ls <path> ]
  [ -lsd <path> ]

  [ -lso <path> ]
  [ -lsor <path> ]
  [ -lsr <path> ]
  [ -Lsr <path> ]
  [ -lsrv <path> ]
  [ -lss <path> ]
  [ -offload <file_path> [-v] ]
  [ -recall <file_path> [-v] ]
  [ -rmr <path> ]
  [ -setace [-R]
     [-readfile <ace>] [-writefile <ace>] [-executefile <ace>]
     [-addchild <ace>] [-deletechild <ace>] [-lookupdir <ace>] [-readdir
<ace>]
     [-aces "[rf:<ace>],[wf:<ace>],[ef:<ace>],[ac:<ace>],[dc:<ace>],
[rd:<ace>],[ld:<ace>]"]
     [-preservemodebits <true|false>] [-setinherit <true|false>] <path> ]
  [ -setaudit  on|off <dir|file|table> ]
  [ -setcompression  on|off|lzf|lz4|zlib <dir|table> ]
  [ -setchunksize <size> <dir> ]

  [ -setnetworkencryption on|off <target> ]
  [ -stat <path> ]
  [ -tierstatus <file_path> [-v] ]
```

Parameters

The normal command syntax is to specify a single option from the following table, along with its corresponding arguments. If you do not set compression and chunk size for a given directory, the values are inherited from the parent directory.

Parameter	Description
`-count <path>`	Counts and returns the number of directories and (regular, symbolic link, volume link, kvstores, and device) files in the specified path (recursively).

last-updated: Apr 11, 2022

Parameter	Description
`-delace [-R] <path>`	Deletes all ACEs associated with the specified file or directory and sets *ACE*s for the specified file or directory to the default value, which is the empty string. Here: • `[-R]` — Enables recursion allowing you to perform the operation in subdirectories as well. • `<path>` — Specifies the path to the file or directory. You cannot delete specific access types with this parameter. Instead, if necessary, reset the value for the specific access type to an empty string using the `-setace` parameter. If you use an empty string to deny a specific type of access, then that type of access is denied to all users. To deny specific types of access to specific users only, use the negation operator (`!`). The mode bits corresponding to the *ACE*s being deleted, do not change.
`-getace [-R] <path>`	Returns the permissions -- POSIX mode bits and ACEs -- for the given file or (recursively) for the directory. Recursion is enabled only if -R is specified; if -R is not specified, this parameter returns the permissions only for the given directory. Here: • `[-R]` — (Optional) Enables recursion allowing you to perform the operation in subdirectories as well. • `<path>` — (Required) Specifies the path to the file or directory. If one or more *ACE*s are available for the file or directory, a plus sign (+), which indicates that both *ACE*s and POSIX mode bits are set for the given file or directory, is returned. If the *ACE* on the file or directory is an empty string, the plus sign is not returned.
`-help <command>`	Displays help for the `hadoop mfs` command.
`-ln <target> <symlink>`	Creates a symbolic link `<symlink>` that points to the target path `<target>`, similar to the standard Linux `ln -s` command.
`-lnh <target> <hardlink>`	Creates a hardlink that associates a new name or a file path with an existing file. You must specify the following: **`<target>`** — File name, including the full path, of the file to link to. **`<hardlink>`** — New name, including the full path, of the file to link with.

last-updated: Apr 11, 2022

Parameter	Description
`-ls <path>`	Lists files in the directory specified by `<path>`. The `hadoop mfs -ls` command corresponds to the standard `hadoop fs -ls` command, but provides the following additional information: • Chunks used for each file • Server where each chunk resides • Whether compression is enabled for each file • Whether encryption is enabled for each file • Whether audit is enabled (A) or disabled (U) for each file
`-lsd <path>`	Lists files in the directory specified by `<path>`, and also provides information about the specified directory itself: • Whether compression is enabled for the directory (indicated by z) • The configured chunk size (in bytes) for the directory.
`-lso <path>`	Lists files in the directory specified by `<path>`. The `hadoop mfs -lso` command corresponds to the standard `hadoop fs -ls` command, but provides the following additional information: • Whether compression is enabled for each file • Whether encryption is enabled for each file • Whether audit is enabled (A) or disabled (U) for each file This command is faster than `hadoop fs -ls` as it uses an optimized printing method to dump data on screen.
`-lsor <path>`	Recursively lists files in the directory specified by `<path>`. This command is the recursive variant of the `hadoop mfs -lso` command.
`-lsr <path>`	Recursively lists files in the directory and subdirectories specified by `<path>`. The `hadoop mfs -lsr` command corresponds to the standard `hadoop fs -lsr` command, but provides the following additional information: • Chunks used for each file • Server where each chunk resides
`-Lsr <path>`	Equivalent to `lsr`, but additionally dereferences symbolic links
`-lsrv <path>`	Lists all paths recursively without crossing volume links.
`-lss <path>`	Lists files in the directory specified by `<path>`, with an additional column that displays the number of disk blocks per file. Disk blocks are 8192 bytes.

last-updated: Apr 11, 2022

Parameter	Description
`-offload <file_path> [-v]`	The file to offload to the storage tier. This is a blocking operation; the control is not returned until the operation is complete and the file has been offloaded. Use `-v` (for verbose) to view the status of the ongoing offload operation.
`-recall <file_path> [-v]`	The file to recall from the storage tier. This is a blocking operation; the control is not returned until the operation is complete and the file has been recalled. Use `-v` (for verbose) to view the status of the ongoing recall operation.
`-rmr <path>`	Recursively deletes files and directories in the specified path. This is a highly optimized version of the normal generic `hadoop fs rmr` command and is 10X faster for large directories. This option is useful when one or more directories in the specified path contains many (millions of) files.

last-updated: Apr 11, 2022

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td><pre>-setace [-R] [-readfile <ace>]
[-writefile <ace>] [-executefile
<ace>] [-addchild <ace>] [-deletechild
<ace>] [-lookupdir <ace>]
[-readdir <ace>] [-aces "[rf:<ace>],
[wf:<ace>],[ef:<ace>],[ac:<ace>],
[dc:<ace>],[rd:<ace>],[ld:<ace>]"]
[-preservemodebits <true|false>]
[-setinherit <true|false>] <path></pre></td><td>
Sets or modifies the read, write, and execute permissions for files or directories. This argument will:

Overwrite existing values with new values, if specified, for access types that were previously set.
Set new values for access types that have not yet been set.
Not set or modify access types that were not passed in with the command, whether they were previously set or unset.

Specify the ACEs immediately after the <code>-setace</code> parameter. Specify all the other parameters, after the ACE.

Here:
<table>
<tr><td><code>-R</code></td><td>Enables recursion allowing you to perform the operation in subdirectories as well. Recursion is enabled only if <code>-R</code> is specified; if <code>-R</code> is not specified, sets or modifies the permissions for the given directory only.</td></tr>
<tr><td><ace></td><td>ACE Syntax on page 1448 defined using boolean expressions and sub-expressions.</td></tr>
<tr><td><code>-readfile</code>
<code>-writefile</code>
<code>-executefile</code></td><td>Specifies permissions (defined using ACEs) for reading, writing, or executing the file.</td></tr>
<tr><td><code>-readdir</code>
<code>-lookupdir</code></td><td>Specifies permissions (defined using ACEs) for accessing the directory. To permit users to read files in the directory, grant the <code>lookupdir</code> access permission. To permit users to write to or execute files in the directory, grant the <code>readdir</code> and <code>lookupdir</code> access permissions.</td></tr>
<tr><td><code>-addchild</code>
<code>-deletechild</code></td><td>Specifies permissions (defined using ACEs) for adding or deleting subdirectories.</td></tr>
<tr><td><code>-aces</code></td><td>Specifies ACEs as a single string. Specify a comma-separated list of ACEs within quotes, up to 60 KB in length. You can set the following permissions.
<table>
<tr><td><code>rf</code></td><td>Refers to read file access.</td></tr>
<tr><td><code>wf</code></td><td>Refers to write file access</td></tr>
<tr><td><code>ef</code></td><td>Refers to execute file access</td></tr>
</table>
</td></tr>
</table>
</td></tr>
</table>

Parameter	Description
`-setaudit on|off <dir|file|table>`	Enables auditing of the specified directory, file, or MapR Database table. Enabling auditing of a directory does not enable auditing of files and subdirectories that exist in the directory. You must enable auditing on those existing files and subdirectories. However, any new files and subdirectories that you create will automatically be enabled for auditing. See How Does Auditing Work? on page 760. For operations on the object to be logged, auditing also needs to be enabled on the cluster and the volume in which the object is located. See Managing Auditing on page 757 for details. If auditing is enabled for a directory, new files and directories created within that directory are also enabled for auditing.
`-setchunksize <size> <dir>`	Sets the chunk size in bytes for the directory specified in `<dir>`. The `<size>` parameter must be a multiple of 65536.
`-setcompression on|off|lzf|lz4|zlib <dirtable>`	Turns compression on or off on the directory specified in `<dir>` or on the specified table, and sets the compression type to one of the following if compression is not turned off: • `on` — turns on compression using the default algorithm (LZ4) • `lzf` — turns on compression and sets the algorithm to LZF • `lz4` — turns on compression and sets the algorithm to LZ4 • `zlib` — turns on compression and sets the algorithm to ZLIB
`-setnetworkencryption on|off <target>`	Sets network encryption on or off for the filesystem object defined in `<target>`. The cluster encrypts network target to or from a file, directory, stream, or MapR table with network security enabled.
`-stat <path>`	Displays the statistics for the given file. Only the root user and the MAPR_USER user (user name under which MapR services run) have permissions to run this command. The path is required and specifies the path (to the file) on which to run the command. The output fields for this command are as follows.

last-updated: Apr 11, 2022

Parameter	Description

`tierstatus <file_path> [-v]`	The status of the offload or recall of the given file. If `-v` (for verbose) is also specified, for the given file, the command specifies whether data is local or offloaded as the final output. If the file:
	• Contains local data, returns the following final output:
	`File has local data`
	• Is completely offloaded, returns the following final output:
	`File does not have local data`
	See Output on page 5379 for more information.

Output

When used with the `-ls`, `-lsd`, `-lso`, `-lsor`, `-lsr`, or `-lss` options, `hadoop mfs` displays information about files and directories. For each file or directory `hadoop mfs` displays a line of basic information followed by lines listing the chunks that make up the file, in the following format:

```
{mode} {compression} {encryption} {audit} {diskFlush} {replication} {owner}
{group} {size} {date} {chunk size} {name} {chunk} {fid} {host} [{host}...]
{chunk} {fid} {host} [{host}...] ...
```

Volume links are displayed as follows:

```
{mode} {compression} {encryption} {audit} {diskFlush} {replication} {owner}
{group} {size} {date} {chunk size} {name} {chunk} {target volume name}
{writability} {fid} -> {fid} [{host}...]
```

The following table describes the values:

mode	A text string indicating the read, write, and execute permissions for the owner, group, and other permissions. See also Managing Permissions on page 755.
compression	• U: uncompressed • L: LZf • Z (Uppercase): LZ4 • z (Lowercase): ZLIB
encryption	U: unencrypted; E: encrypted
audit	U: disabled; A: enabled
disk flush	U:disabled; F:enabled
replication	The replication factor of the file (directories display a dash instead)
owner	The owner of the file or directory
group	The group of the file of directory

last-updated: Apr 11, 2022

size	The size of the file or directory
date	The date the file or directory was last modified
chunk size	The chunk size of the file or directory
name	The name of the file or directory
chunk	The chunk number. The first chunk is a primary chunk labeled "p", a 64K chunk containing the root of the file. Subsequent chunks are numbered in order.
fid	The chunk's file ID, which consists of three parts: • The ID of the container where the file is stored • The inode of the file within the container • An internal version number For volume links, the first `fid` is the chunk that stores the volume link itself; the `fid` after the arrow (`->`) is the first chunk in the target volume.
host	The host on which the chunk resides. When several hosts are listed, the first host is the first copy of the chunk, while subsequent hosts are replicas.
target volume name	The name of the volume pointed to by a volume link.
writability	Displays whether the volume is writable.

, `hadoop mfs` displays only the file ID (fid) and the file name of each file in the path.

When used with the `-stat <path>`option, `hadoop mfs` displays statistics for the given file. For each file, it displays the following:

Output field	Description
`uid`	The user ID of the owner.
`mtime`	The last modified time.
`nlink`	The number of hard links.
`type`	The type of the file. Value can be one of: • regular • directory • symlink • vollink • kvstore • device
`size`	The size of the file or directory. Depending on the type of file, it can be the actual size or the number of entries.
`mode`	The UNIX style permission mode bits for the file/directory.

last-updated: Apr 11, 2022

Output field	Description
`networkencryption`	The network encryption setting. Determines whether network encryption is enabled for this file.
`subtype`	The subtype for the specified type. The following subtypes are supported for some of the types: **regular** • FSTRegBucket • FSTRegCF • FSTRegKeyMap **kvstore** • FSTKvTable • FSTKvTabletMap • FSTKvSchema • FSTKvTablet • FSTKvSegMap • FSTKvSpillMap • FSTKvKeyMap • FSTKvXattr **device** • FSTDevPipe • FSTDevSocket • FSTDevBlock • FSTDevChar For all other types, subtypes are not valid.
`gid`	The group ID.
`compression`	The compression setting.

When used with `tierstatus`, the output varies based on whether or not data is local, was offloaded, or was recalled. The output looks similar to the following if:

- Data was completely offloaded:

```
File does not have local data
```

- Data could not be completely offloaded or data was recalled:

```
File has local data
```

Examples

View File Information

last-updated: Apr 11, 2022

The `hadoop mfs` command is used to view file contents. You can use this command to check if compression is turned off in a directory or mounted volume. For example,

```
# hadoop mfs -ls /
Found 121 items
vrwxr-xr-x  Z E U U   3 mapr mapr        121 2018-08-10 01:07

In the preceding example, the letter `Z` indicates LZ4 compression on the directory; the letter `U` indicates that the directory is uncompressed. In the following example, the listed item is both uncompressed (first `U`) and unencrypted (second `U`).

```
[root@node1-302 ~]# hadoop mfs -ls /hbase
Found 10 items
drwxr-xr-x  Z E U U   - root root          1 2018-08-09 19:26  268435456 /

...
```

Set ACEs

Example 1: The following command shows how to set separate read, write, and execute permissions (using *ACE*) on a file:

```
hadoop mfs -setace -readfile p -writefile 'g:group1&!u:user1' -executefile
p /file
```

When the command shown above runs, the POSIX mode bits for:

- Read access is set for owner, owning group, and others.
- Write access is set for none.
- Execute access is set for owner, owning group, others.

All other POSIX mode bits are set to 0.

Example 2: The following command shows how to set read, write, and execute permissions (using *ACE*) as a single string on the specified directory and force all files and subdirectories under the specified directory to inherit the parent *ACE*. *ACE*s that are not specified will be set to the empty string.

```
hadoop mfs -setace -aces "rf:u:root,wf:group1&!
user1,ef:p,rd:u:m7user1" -setinherit true /dir
```

When the command shown above runs, the POSIX mode bits for listing the contents (r) of the directory is set for owner/user and all other POSIX mode bits on the directory are set to 0; all new directories under this directory will inherit the parent POSIX mode bits. Also, new files in the directory will inherit the following POSIX mode bits:

- Read access is set to owner/user.
- Write access is set to none.
- Execute access set for others.

All other POSIX mode bits are set to 0.

Example 3: The following command shows how to set permissions (using *ACE*) as a single string on the specified directory and all the files and subdirectories recursively.

```
hadoop mfs -setace -R -aces "rf:p,wf:g:group1&!
u:user1,ef:p" -preservemodebits true /dir
```

When the command shown above runs, the POSIX mode bits are not modified to match the *ACE* setting.

Example 4: The following command shows how to deny a specific type of access, `writefile`, which was set in the first example above, without removing all other access types associated with the file. The empty string used in the following example will deny write access to all users, *role*s, and groups.

```
hadoop mfs -setace -writefile "" -preservemodebits false /file
```

When the command shown above runs, the POSIX mode bit for writing to the file is set to 0.

Get ACEs

The following command shows the *ACE*s and POSIX mode bits for the specified file only.

```
hadoop mfs -getace /m7user1/file1.txt
```

Output

```
Path: /m7user1/file1.txt
  readfile: !u:m7user1
  writefile: !u:m7user1
  executefile: !u:m7user1
  mode: ---------
```

Delete ACEs

The following command deletes all *ACE*s associated with the specified file and sets the ACE for the file to the empty string.

```
hadoop mfs -delace /file
```

The following command deletes all *ACE*s associated with the specified directory.

```
hadoop mfs -delace /dir
```

The following command deletes all *ACE*s associated with the specified directory and *ACE*s associated with the files and directories (recursively) below the specified directory.

```
hadoop mfs -delace -R /dir
```

Create a Hard Link to File

The following command shows how to create a hard link to the file, file1, using a new name, file2.

```
# hadoop mfs -lnh /madvol1/file1 /madvol1/file2
Creating Hardlink: /madvol1/file2 -> /madvol1/file1
```

Retrieve the Number of Hard Links

The following command shows how to retrieve the number of hard links (and other statistics) associated with a given file.

```
# hadoop mfs -stat /vol1/file1
Path: /vol1/file1
  fid: 23185.32.131232
  uid: root
  gid: root

  mtime: 2016-07-01 18:01:54
  nlink: 2
  type: FTRegular
  subtype: FSTInval
  size: 1024000000
  blocksize: 268435456
  mode: 644
  networkencryption: false
  compression: off
```

View the status of the offload or recall operation for the file named file2 in volume named vol1:

```
# hadoop mfs -tierstatus  /vol1/file2
File has local data.
```

View the status of file named test1 in volume named vol1:

```
# hadoop mfs -tierstatus /vol1/test1 -v
        FID          Has Local Data
2154.109.1049824        Yes
2172.143.524906         Yes
2172.153.524926         Yes
2172.166.524952         Yes
2172.167.524954         Yes
File has local data.
```

hadoop mradmin

The `hadoop mradmin` command runs Map-Reduce administrative commands.

Warning: This command is deprecated.

Syntax

```
hadoop [ Generic Options ] mradmin
      [-refreshServiceAcl]
      [-refreshQueues]
      [-refreshNodes]
      [-refreshUserToGroupsMappings]
      [-refreshSuperUserGroupsConfiguration]
      [-help [cmd]]
```

Parameters

The following command parameters are supported for `hadoop mradmin`:

last-updated: Apr 11, 2022

Parameter	Description
`-refreshServiceAcl`	Reload the service-level authorization policy file Job tracker will reload the authorization policy file.
`-refreshQueues`	Reload the queue acls and state JobTracker will reload the mapred-queues.xml file.
`-refreshUserToGroupsMappings`	Refresh user-to-groups mappings.
`-refreshSuperUserGroupsConfiguration`	Refresh superuser proxy groups mappings.
`-refreshNodes`	Refresh the hosts information at the job tracker.
`-help [cmd]`	Displays help for the given command or all commands if none is specified.

The following generic options are supported for `hadoop mradmin`:

Generic Option	Description
`-conf <configuration file>`	Specify an application configuration file.
`-D <property=value>`	Use value for given property.
`-fs <local|filesystem URI>`	Specify a filesystem.
`-jt <local|jobtracker:port>`	Specify a job tracker.
`-files <comma separated list of files>`	Specify comma separated files to be copied to the map reduce cluster.
`-libjars <comma seperated list of jars>`	Specify comma separated jar files to include in the classpath.
`-archives <comma separated list of archives>`	Specify comma separated archives to be unarchived on the computer machines.

hadoop pipes

The `hadoop pipes` command runs a pipes job.

Warning: This command is deprecated.

Hadoop Pipes is the C++ interface to Hadoop Reduce. Hadoop Pipes uses sockets to enable tasktrackers to communicate processes running the C++ map or reduce functions.

Syntax

```
hadoop [GENERIC OPTIONS ] pipes
    [-output <path>]
    [-jar <jar file>]
    [-inputformat <class>]
    [-map <class>]
    [-partitioner <class>]
    [-reduce <class>]
    [-writer <class>]
    [-program <executable>]
    [-reduces <num>]
```

last-updated: Apr 11, 2022

Parameters

Command Options

The following command parameters are supported for `hadoop pipes`:

Parameter	Description
`-output <path>`	Specify the output directory.
`-jar <jar file>`	Specify the jar filename.
`-inputformat <class>`	InputFormat class.
`-map <class>`	Specify the Java Map class.
`-partitioner <class>`	Specify the Java Partitioner.
`-reduce <class>`	Specify the Java Reduce class.
`-writer <class>`	Specify the Java RecordWriter.
`-program <executable>`	Specify the URI of the executable.
`-reduces <num>`	Specify the number of reduces.

Generic Options

The following generic options are supported for the `hadoop pipes` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|filesystem URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see Generic Options.

hadoop queue

The `hadoop queue` command displays job queue information.

Warning: This command is deprecated.

Syntax

```
hadoop [ Generic Options ] queue
    [-list] | [-info <job-queue-name> [-showJobs]] | [-showacls]
```

Parameters

Command Options

The `hadoop queue` command supports the following command options:

Parameter	Description
`-list`	Gets list of job queues configured in the system. Along with scheduling information associated with the job queues.

last-updated: Apr 11, 2022

Parameter	Description
`-info <job-queue-name> [-showJobs]`	Displays the job queue information and associated scheduling information of particular job queue. If `-showJobs` option is present, a list of jobs submitted to the particular job queue is displayed.
`-showacls`	Displays the queue name and associated queue operations allowed for the current user. The list consists of only those queues to which the user has access.

Generic Options

The following generic options are supported for the `hadoop queue` command: `-conf <configuration file>`, `-D <property=value>`, `-fs <local|filesystem URI>`, `-jt <local|jobtracker:port>`, `-files <file1,file2,file3,...>`, `-libjars <libjar1,libjar2,libjar3,...>`, and `-archives <archive1,archive2,archive3,...>`. For more information on generic options, see Generic Options.

hadoop version

The `hadoop version` command prints the hadoop software version.

Syntax

```
hadoop  version
```

Output

```
$ hadoop version
Hadoop 2.7.6.100-eep-800
Subversion git@github.com:mapr/private-hadoop-common -r
80dc89ae5df3a2cd01089f192c5d8a886e4788c9
Compiled by root on 2021-10-08T11:26Z
Compiled with protoc 3.11.1
From source with checksum 124ac1b54c81145154c71d2be2a66fc
This command was run using /opt/mapr/hadoop/hadoop-2.7.6/share/hadoop/
common/hadoop-common-2.7.6.100-eep-800.jar
```

hadoop conf

The `hadoop conf` command outputs the configuration information for this node to standard output.

Syntax

```
hadoop [ generic options ] conf
```

Examples

Displaying the configured value of a specific parameter

```
[user@hostname ~]$ hadoop conf | grep mapreduce.map.memory.mb
<property><name>mapreduce.map.memory.mb</name><value>1024</
value><source>mapred-site.xml</source></property>
```

The above command returns 1024 as the configured value of the `mapreduce.map.memory.mb` parameter.

last-updated: Apr 11, 2022

Dumping a node's configuration to a text file

```
[user@hostname ~]$ hadoop conf | grep ... >nodeconfiguration.txt
```

The above command creates a text file named `nodeconfiguration.txt` that contains the node's configuration information.

The following information displays when you use the `tail` utility to examine the last few lines of the file:

```
[user@hostname ~]# tail nodeconfiguration.txt
            <property><name>yarn.app.mapreduce.am.resource.mb</
name><value>1536</value><source>mapred-default.xml</source></property>
            <property><name>mapreduce.framework.name</name><value>yarn</
value><source>mapred-default.xml</source></property>
            <property><name>mapreduce.job.reduce.slowstart.completedmaps</
name><value>1.00</value><source>mapred-default.xml</source></property>
            <property><name>yarn.resourcemanager.client.thread-count</
name><value>50</value><source>yarn-default.xml</source></property>

<property><name>mapreduce.cluster.temp.dir</name><value>${hadoop.tmp.dir}/
mapred/temp</value><source>mapred-default.xml</source></property>
            <property><name>yarn.resourcemanager.staging</name><value>/var/
mapr/cluster/yarn/rm/staging</value></property>
            <property><name>fs.mapr.working.dir</name><value>/user/
$USERNAME/</value></property>
            <property><name>mapreduce.jobhistory.intermediate-done-dir</
name><value>${yarn.app.mapreduce.am.staging-dir}/history/done_intermediate</
value><source>mapred-default.xml</source></property>
            <property><name>fs.s3a.attempts.maximum</name><value>10</
value><source>core-default.xml</source></property>
            </configuration>
```

API Documentation

MapR Data Platform supports public APIs for MapR File System, MapR Database, and MapR Event Store For Apache Kafka. These APIs are available for application-development purposes.

Important: Development using MapR Data Platform non-public (private or internal) APIs is not supported.

Table

Feature	Language	Link to Location	Description
MapR Event Store For Apache Kafka Administration	Java	For source Java APIs, see: • MapR Event Store For Apache Kafka Java API Library • Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka See MapR Event Store For Apache Kafka Java Applications on page 2754 for streams and topics information for application development.	MapR Data Platform Streams Java API for performing administrative tasks on streams and topics, setting values for the attributes of streams, and accessing streams for analytics purposes. MapR Data Platform modified Kafka interfaces, classes, and packages used for MapR Data Platform streams API. This library is a MapR Data Platform modified version of the open source Kafka library.

last-updated: Apr 11, 2022

Table (Continued)

Feature	Language	Link to Location	Description
MapR Database JSON Client	Java	MapR Database JSON Client API Database Client API **Note:** Beginning with core version 6.0, the MapR Database `Table` interface in the MapR Database JSON Client API is deprecated and replaced by the `DocumentStore` interface in the OJAI API library. For details, see the next row.	Java API for administration and management of MapR Database JSON tables.
Java OJAI Client	Java	Java OJAI Client API	OJAI is a general-purpose JSON access layer that sits on databases, file systems, and message streams and enables access to structured, semi-structured and unstructured data using a common API. Used for working with MapR Database JSON.
Java OJAI Thin Client	Java	Java OJAI Client API	Allows you to write OJAI applications in Java to access MapR Database JSON. This is the thin client version of the Java OJAI Client.
OJAI REST API	REST	Using the MapR Database JSON REST API on page 2696	Provides an alternative to writing a Java OJAI application. Using HTTP calls, you can perform basic operations on MapR Database JSON tables.
Node.js OJAI Client	Node.js	Node.js OJAI Client API provides the Node.js API documentation.	Allows you to write OJAI applications in Node.js to access MapR Database JSON.
Python OJAI Client	Python	Python OJAI Client API provides the Python API documentation.	Allows you to write OJAI applications in Python to access MapR Database JSON.
C# OJAI Client	C#	C# OJAI Client API provides the C# documentation.	Allows you to write OJAI applications in C# to access MapR Database JSON.
Go OJAI Client	Go	Go OJAI Client API provides the Go documentation.	Allows you to write OJAI applications in Go to access MapR Database JSON.
MapR Database Binary tables	C	Creating C Apps - Binary Tables on page 2453	C API library (`libMapRClient`) for creating and accessing MapR Database binary tables. This library is a MapR Database-specific version of `libhbase`.
MapR Database JSON MapReduce	Java	MapR Database JSON MapReduce API Database JSON MapReduce API	Java API library that extends the Apache Hadoop MapReduce framework. Used to create MapReduce applications that write data from one JSON table to another.
File Access Control Expressions	Java	File ACE APIs	APIs to grant different permissions to multiple users, groups, and roles for files, directories, and whole volume data using boolean expressions and subexpressions.
	C	FileACE C APIs on page 1457	
MapR File System	C	Accessing the File System with C Applications on page 2378	MapR Database `libMapRClient` library supports access to the MapR Database filesystem. This library is a MapR Database modified version of `libhdfs`. Used to manage MapR File System files.

last-updated: Apr 11, 2022

Table (Continued)

Feature	Language	Link to Location	Description
MapR File System	Java	Accessing MapR XD Distributed File and Object Store in Java Applications on page 2434	MapR Database's native maprfs library for accessing the MapR Database filesystem.
Extended Attributes	Java	Extended Attributes API	APIs to associate additional metadata with a regular file or directory.

Other Docs

This section contains release-independent information, including: MapR Installer documentation, Ecosystem release notes, interoperability matrices, security vulnerabilities, and links to other MapR version documentation.

Products Covered in the MapR Data Platform Documentation

This section lists the products covered in the MapR Data Platform documentation portal and provides links to the related product documentation.

The MapR Data Platform documentation portal provides information and instructions for the following MapR Data Platform components and features:

MapR Data Platform File Store

File Store Documentation

Most of the file store conceptual and overview documentation is located in the MapR XD Distributed File and Object Store on page 451 section of the documentation portal. Additional file store documentation, including installation and upgrade, configuration, and administration is located in the 6.1 Installation on page 107, 6.1 Administration on page 752, and 6.1 Development on page 2358 sections of the documentation portal.

The following list provides some direct links to file store topics:

- Distributed datastore for files and persistent storage for containers
- POSIX Client
- Platinum POSIX Client
- Container Client including PACC, Flex Volume Plugin and CSI
- NFSv4 and NFSv3
- Multiple file server instances per node
- HDFS API and HttpFS
- Quotas
- Snapshots
- Data Topologies

last-updated: Apr 11, 2022

- Data Protection Replication
- Multi-site volume mirroring
- Data tiering (Cold) to 3rd party external stores
- Data tiering (Warm) to erasure coding
- Global Namespace
- Compression
- Unified Security including authentication, authorization, encryption (wire and data-at-rest) and auditing
-
- HPE Ezmeral Data Fabric Management using CLI, REST, and GUI
- Rolling Upgrades
- HPE Ezmeral Data Fabric Monitoring
- HPE Ezmeral Data Fabric Installer
- Resiliency and self-healing
- Auto-balancing
- Disaster recovery - See also Mirror Volumes on page 463.
- Multitenancy on File System on page 488

MapR Data Platform Document Database

Document Database Documentation

Most of the document database conceptual and overview documentation is located in the MapR Database on page 496 section of the documentation portal. Additional document database documentation, including installation and upgrade, configuration, and administration is located in the 6.1 Installation on page 107, 6.1 Administration on page 752, and 6.1 Development on page 2358 sections of the documentation portal.

The following list provides some direct links to document database topics:

- Column-Oriented Database using HBase API
- JSON document database using OJAI API
- Multi-master table replication
- Secondary indexes
- Multiple file server instances per node
- Change Data Capture (CDC)
- HPE Ezmeral Data Fabric DB Data Access Gateway
- Strong consistency - See also Mirroring and Replication and High Availability on page 502.
- Resiliency and self-healing - See also High Availability on page 502.

last-updated: Apr 11, 2022

- Disaster recovery - See also Mirroring and Replication and High Availability on page 502.
- Automatic compactions
- Multitenancy
- Unified Security including authentication, authorization, encryption (wire and data-at-rest) and auditing
- HPE Ezmeral Data Fabric Administration
- HPE Ezmeral Data Fabric Monitoring
- HPE Ezmeral Data Fabric Installer
- Rolling upgrades
- Apache HBase

MapR Data Platform Event Data Streams

Event Data Streams Documentation

Most of the event data streams conceptual and overview documentation is located in the MapR Event Store For Apache Kafka on page 627 section of the documentation portal. Additional event data streams documentation, including installation and upgrade, configuration, and administration is located in the 6.1 Installation on page 107, 6.1 Administration on page 752, and 6.1 Development on page 2358 sections of the documentation portal..

The following list provides some direct links to event data streams topics:

- Distributed publish-subscribe messaging infrastructure
- Support for Kafka API
- Kafka Connect
- Kafka REST Proxy
- KSQL
- Kafka Streams
- Kafka Schema Registry
- Multi-site Stream replication
- Automatic partition balancing
- Multi Tenancy
- Unified Security including authentication, authorization, encryption (wire and data-at-rest) and auditing
- HPE Ezmeral Data Fabric Administration
- HPE Ezmeral Data Fabric Monitoring
- HPE Ezmeral Data Fabric Installer
- Rolling upgrades

MapR Data Platform Analytics with Hadoop

Analytics with Hadoop Documentation

Most of the documentation related to analytics with Hadoop is located in the Ecosystem Components on page 3174 section of the documentation portal.

The following list provides some direct links to analytics with Hadoop topics:

- Apache YARN
- Apache MapReduce v2
- Apache Hive
- Apache Pig
- Apache Sqoop
- Apache Flume
- Apache Oozie
- Apache Hue
- HPE Ezmeral Data Fabric DB OJAI Connector for Apache Hive
- S3 Gateway on page 3959

MapR Data Platform Advanced Analytics with Spark

Advanced Analytics with Spark Documentation

Most of the documentation related to analytics with Spark is located in the Apache Spark on page 4022 section of the documentation portal.

The following list provides some direct links to analytics with Spark topics:

- Apache YARN
- Apache Spark
- Apache Spark SQL
- Apache Spark Streaming
- Apache Spark MLlib
- GraphX
- SparkR
- Support for Spark Standalone and Spark on YARN
- HPE Ezmeral Data Fabric DB OJAI Connector for Apache Spark
- HPE Ezmeral Data Fabric DB Binary Connector for Apache Spark
- HPE Ezmeral Data Fabric Streams Integration
- S3 Gateway on page 3959

last-updated: Apr 11, 2022

MapR Data Platform Interactive SQL Engine with Drill

Drill Interactive SQL Engine Documentation

Most of the documentation related to the Drill interactive SQL engine is located in the Apache Drill on page 3185 section of the documentation portal. You may also want to refer to the Apache Drill documentation at https://drill.apache.org/docs/.

The following list provides some direct links to Drill topics in the documentation portal and on the Apache Drill site:

- Schema-less ANSI-compliant distributed SQL query engine
- Queries on File
- Queries on HPE Ezmeral Data Fabric Document Database tables and secondary indexes
- Queries on Hive tables and views - See also CREATE VIEW.
- File formats (Text,JSON,Parquet)
- Multiple data type support
- Impersonation
- Support for Drill standalone and Drill-on-YARN
- Drill query and administration UI - See also Starting the Web UI.
- JDBC/ODBC drivers
- Drill Explorer
- SQLLine - See also Configuring the Drill Shell.
- REST API - See also REST API Introduction.
- Drill Monitoring
- S3 Gateway on page 3959- See also S3 Storage Plugin.

MapR Data Platform Platform Bundle

Platform Bundle Documentation

The following list provides some direct links to platform documentation topics:

- HPE Ezmeral Data Fabric File Store
- HPE Ezmeral Data Fabric Analytics with Hadoop
- HPE Ezmeral Data Fabric Advanced Analytics with Spark
- HPE Ezmeral Data Fabric Interactive SQL Engine with Drill
- HPE Ezmeral Data Fabric Document Database
- HPE Ezmeral Data Fabric Event Data Streams

MapR Installer

You must download and run the MapR Installer setup script before you can start the MapR Installer web interface or issue MapR Installer Stanza commands.

The MapR Installer web interface simplifies the installation of a MapR cluster. After taking you through the process of selecting services and configuring the cluster, the installer installs MapR software. You can use the MapR Installer to install:

- New-feature releases, such as 6.1.0 and 6.2.0
- Maintenance releases, such as 6.0.1 and 6.1.1
- Ecosystem components, such as Spark, Hive, and HBase – or other components contained in a MapR Ecosystem Pack (EEP)

Before you begin, review the MapR Installer Prerequisites and Guidelines on page 5396, which describe user, node, and security requirements for using the Installer. For cluster-planning information, see Planning the Cluster on page 107.

Watch a Video About Setting Up and Running the Installer

To view a demonstration of setting up and running the Installer, click here.

Steps for Setting Up and Running the MapR Installer

To set up and run the installer, complete the following steps:

1. **Select a node from which to run the MapR Installer.** The node from which you run the MapR Installer does not need to be one of the nodes on which you plan to install the cluster.
2. **Download the mapr-setup.sh script.** Choose *one* of the following options:
   - Download the setup script directly from package.mapr.hpe.com to the node that will run the MapR Installer:

     MapR 6.0.0 and later

     ```
     wget https://package.mapr.hpe.com/releases/installer/
     mapr-setup.sh -P /tmp
     ```

     MapR 5.2.2 and earlier (for more information, see Selecting an Installer Version to Use on page 5402)

     ```
     wget https://package.mapr.hpe.com/releases/installer-v1.11.0/
     mapr-setup.sh -P /tmp
     ```

   - Download to your local workstation, and copy to the node that will run the MapR Installer:
     a. On the Download Page, click **Download**, and save the setup script to a location on your workstation.
     b. Use a tool such as SCP to copy the file to the node that will run the MapR Installer:

        ```
        scp mapr-setup.sh user@server:/tmp
        ```

last-updated: Apr 11, 2022

3. **Change the file permissions so that you can run the file.**

```
chmod +x /tmp/mapr-setup.sh
```

4. **Run the `mapr-setup.sh` script to configure the node to run the MapR Installer**. Run the following command as the `root` user from the directory that contains the script. The script prompts you for some information. If you have not used this script before, consider reviewing Using mapr-setup.sh on page 5404 to be prepared.

```
/tmp/mapr-setup.sh
```

5. **Start the MapR Installer.** Open the MapR Installer URL:

```
https://<Installer Node hostname/IPaddress>:9443
```

   You are prompted to log in as the cluster administrator user that you configured while running the `mapr-setup.sh` script.

Other Tasks You Can Perform with the MapR Installer

Once the initial installation completes, you can use the same MapR Installer URL to upgrade the cluster, apply a patch, or add nodes and additional services:

Use this option	To
Extend Cluster	Add a host to an existing cluster.
Incremental Install	Add or upgrade services that are already installed on the cluster.
Maintenance Update	Update your cluster to a new patch version of MapR core or apply a patch.
Version Upgrade	Upgrade the cluster to a newer MapR release, apply a patch, and upgrade services that are already installed on the cluster.
Shutdown	Stop MapR services on the cluster.
Uninstall	Remove existing MapR software before proceeding with a new installation.

Note: The MapR Installer definitions are updated frequently. See Updating the MapR Installer on page 5409 to get the latest ecosystem components and MapR software.

HPE Privacy Statement

To learn how HPE uses, shares, transfers, and manages personal information, see the HPE Privacy Statement.

Getting Started with the Installer

This section describes things you need to do to start using the MapR Installer.

MapR Installer Prerequisites and Guidelines

The node on which you run the MapR installer and the nodes you plan to include in your MapR cluster must meet certain user, connectivity, and security requirements.

Installer Requirements

The node that runs the MapR Installer must meet the following requirements:

Installer Node

Beginning with MapR Installer 1.6, the node that runs the MapR Installer does not need to be one of the nodes you plan to install the cluster on. Ensure that the default umask for the root user is set to `0022` on all MapR nodes in the cluster. You can change the umask setting in the `/etc/profile` file, or in the `.cshrc` or `.login` file. The `root` user must have a `0022` umask because the cluster admin user requires access to all files and directories under the `/opt/mapr` directory, even those initially created by `root` services.

Package Dependencies

Depending on the operating system, the MapR Installer requires the following packages. If these packages are not found, the MapR Installer attempts to download them from Internet repositories:

Ubuntu Nodes	Red Hat / CentOS Nodes	SLES Nodes
• ca-certificates • curl* • debianutils • dnsutils • iputils-arping • libnss3 • libssl1.0.0 • libsysfs2 • netcat • nfs-common • ntp • ntpdate • openssl • python-dev • python-pycurl • sdparm • sudo • syslinux • sysstat • uuid-runtime • wget	• curl* • device-mapper • iputils • libsysfs • lvm2 • nc • nfs-utils • ntp • nss • openssl • python-devel • sdparm • sudo • syslinux • sysstat • wget • which • yum-utils • compat-openssl10 (required only when running MapR 6.1.x on RHEL version 8 and above)	• ca-certificates • curl* • device-mapper • iputils • libopenssl1_0_0 • sysfsutils • lvm2 • mozilla-nss • nfs-client • ntp • sdparm • sudo • syslinux • sysstat • util-linux • wget • libfreebl3

last-updated: Apr 11, 2022

*The curl version must be greater than 7.51.0.

Repository Connectivity

The MapR Installer requires connectivity to valid repositories for the:

- Operating system
- MapR Core
- MapR Ecosystem Pack (EEP)

The Installer can connect to an Internet repository or to a preinstalled local repository, as described in Using a Local, Shared Repository With the MapR Installer on page 5418. If the Installer dependencies and MapR packages are present, but there is no connectivity to an OS repository, the Installer fails with the following message:

```
ERROR: Unable to install dependencies
(installer). Ensure that a core
OS repo is enabled and retry
mapr-setup.sh
```

Java

The MapR Installer requires JDK 1.7 or higher. Even though MapR 6.0 requires JDK 1.8 or higher, the MapR Installer can function with JDK 1.7 because the installer can run outside the MapR cluster.

If JDK 1.7 or higher is unavailable, `mapr-setup.sh` will install OpenJDK.

- On RedHat/CentOS, `mapr-setup.sh` installs Open JDK Java 1.8.
- On Ubuntu, `mapr-setup.sh` installs Open JDK Java 1.7.

For more information about the supported Java JDK versions, see the JDK Support Matrix on page 5596 and Java on page 135.

SSH Access

The Installer must have SSH access to all nodes that you want to include in the cluster.

Port Availability

Port 9443 or the non-default port that you configure using `mapr-setup.sh` must be accessible on the MapR Installer node to all nodes that you want to include in the cluster.

Files Extracted into /tmp Require Execute Privileges

Do not mount `/tmp` with the `noexec` option. The HPE Ezmeral Data Fabric extracts certain files into `/tmp` and must run them from `/tmp`. Some processes can fail if `noexec` is set for `/tmp` because some files extracted into `/tmp` require execute privileges. In addition, if you use the `java.io.tmpdir` variable to change the location of the temporary directory used by Java processes, then the newly specified temporary directory must not be mounted with the `noexec` option.

Perform the following steps to change the location of the temporary directory used by Java processes using java.io.tmpdir variable:

last-updated: Apr 11, 2022

1. Create a custom tmp directory for mapr and set its permission similar to /tmp.

```
# mkdir /opt/mapr/tmp
# chmod 1777 /opt/mapr/tmp
```

2. Set the custom `tmp` directory as `java.io.tmpdir`.
   a. For Java version 8 and previous, append the following command to `/opt/mapr/conf/env_override.sh` location.

```
export
_JAVA_OPTIONS="-Djava.io.tmpdir
=/opt/mapr/tmp"
```

   b. For Java version 9 and later, run the following command:

```
export
JDK_JAVA_OPTIONS="-Djava.io.tmp
dir=/opt/mapr/tmp"
```

3. Restart `mapr-warden` service on the node.

Note: You cannot hide the `Picked up _JAVA_OPTIONS: <…>` message due to Java sources implementation.

Supported Web Browsers

Once the MapR Installer is installed and configured, you can use the following web browsers to access the MapR Installer web interface:

- Safari
- Firefox
- Chrome

User Requirements

The installation process requires a valid cluster admin user to be present on all nodes in the cluster. The MapR Installer can create a user (the `mapr` user) for you or use a user that you have created. If you choose to create a cluster admin user, make sure the following conditions are met:

- The user must have a home directory and a password.
- The user must be present on all nodes in the cluster.
- The numeric user and group IDs (MAPR_UID and MAPR_GUID) must be configured for the user, and these values must match on all nodes.
- The `mapr` user and `root` user must be configured to use bash. Other shells are not supported.

If the user is not a valid user, installation errors can result. For information about creating the user, see Managing Users and Groups on page 752.

last-updated: Apr 11, 2022

If you choose to have the Installer create the user, the Installer runs the following command to add a local user to serve as the cluster admin user:

```
useradd -m -u $MAPR_UID -g $MAPR_GID -G $(stat -c '%G' /etc/shadow)
$MAPR_USER
```

In this command:

- MAPR_USER defaults to `mapr`.
- MAPR_UID defaults to 5000.
- MAPR_GID defaults to 5000.
- The home directory is typically `/home/mapr`.

The installer also adds the following to the MAPR_USER `.bashrc` file:

```
[[ -f /opt/mapr/conf/env.sh ]] && . /opt/mapr/conf/env.sh
```

Node Requirements

Nodes that you want to include in the cluster must meet the following criteria:

Enabling Package Repositories for SLES 15

Before using the Installer for a new data-fabric installation on SLES 15 SP2, run the following command on all nodes to enable the Python 2 package repository. You must also run the command on the Installer node if the Installer node is not part of the cluster and is running SLES 15 SP2 (or a later supported service pack):

```
SUSEConnect -p
sle-module-python2/15.<version>/x86_64
```

If you are developing applications on the cluster, run the following command on all nodes:

```
SUSEConnect -p
sle-module-development-tools/
15.<version>/x86_64
```

To view the available SLES modules and learn how to enable or disable them, use the `SUSEConnect -l` command.

Fully Qualified Domain Names (FQDNs)

The nodes are expressed as fully-qualified domain names (FQDNs), as described in Connectivity on page 133. DO NOT specify hostnames as aliases or IP addresses.

OS and Security Updates

Nodes are configured to accept operating system and security updates. They must also be patched with the latest security fixes. See your operating-system vendor documentation for details.

Disk Space Requirements

Nodes meet the requirements listed in Preparing Each Node. The MapR Installer verifies the requirements prior to installation.

OS-partition, disk, and swap-space requirements are the same whether you install the cluster manually or by

using the Installer. See Minimum Disk Space on page 132.

For data disks, MapR Installer versions 1.12.0.0 and later require a minimum disk size that is equal to the physical memory on the node. If a data disk does not meet the minimum disk size requirement, a verification error is generated.

Access to the Installer Node

Nodes have HTTPS access to the MapR Installer node over port 9443.

Proxy Server Requirements

If nodes in the cluster use an HTTP proxy server, the nodes must also meet the following requirements:

- The no_proxy environment variable must be set.

  Nodes in the MapR cluster need to be able to communicate without the use of a proxy. If the `https_proxy` and `http_proxy` environment variable is set for nodes in the cluster, you must also set the `no_proxy` environment variable for the cluster admin user and the `root` user on each node. Configure the `no_proxy` environment variable to the IP range of the MapR nodes or to the sub-domain that contains the MapR nodes.

  In addition, you must follow this guideline from the Python documentation: "The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`."

  For cloud-based clusters (Amazon EC2, Google Compute Engine (GCE), and Microsoft Azure), you must include this entry in the no-proxy configuration:

  ```
  169.254.169.254
  ```

- The global proxy for package repositories must be set.

  The Installer creates repository files. However, the proxy setting is not configured for each repository. Therefore, configure global proxy settings on each node in the cluster.

  - On CentOS/RedHat, set global proxy settings in `/etc/yum.conf`.
  - On Ubuntu, set global proxy settings in `/etc/apt/apt.conf`.

Security Requirements

Before installing or upgrading MapR software using the MapR Installer, make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6569. If a vulnerability applies to your release, contact your MapR support representative for a fix, and apply the fix immediately, if applicable.

last-updated: Apr 11, 2022

Cloud Requirements

When you run the MapR Installer on nodes in the cloud, you must:

- **Verify that port 9443 is open**.

  The MapR Installer requires that this port is available.

- **Ensure that the MapR Installer and service UI URLs should refer to an external URL and not an internal URL.**

  For example, when you open the MapR Installer URL, replace any internal hostname or IP address with its associated external address. For Amazon EC2 and Google Compute Engine (GCE) clusters, the MapR Installer automatically translates internal addresses to external addresses.

- **On the Configure Nodes page of the MapR Installer web interface, make sure that you do the following:**

  - Define each node using a fully-qualified domain name (FQDN) and internal, resolvable hostnames, as described in Connectivity on page 133.

  - For the remote authentication, use the same user ID and private key that you use to ssh into your cloud instances. This user must be `root` or a user with `sudo` permissions.

Some MapR Installer features require you to use the latest version of the Installer. You can check the MapR Installer version easily from within the user interface.

Related reference

MapR Installer Support Matrix on page 5599
This matrix shows the operating systems that are supported by the MapR Installer.

Selecting an Installer Version to Use

Beginning with the EEP 6.2.0 release, several MapR Installer versions are available for use. The version that you use depends on your current MapR core version and whether or not you need to upgrade using the MapR Installer or Stanzas.

Choosing an Installer Version

In general, you should always use the latest available MapR Installer version. The latest MapR Installer version provides access to the latest MapR Ecosystem Packs (EEPs). To download the latest version, see Installer Downloads on page 5403 later on this page. For a list of recent Installer versions, see MapR Installer Updates on page 5481.

However, the newer MapR Installer versions do not support Release 5.x. You must use Installer 1.11.0.0 or 1.12.0.0 if your cluster is on a 5.x release. Installer 1.11.0.0 is the last version of the Installer to support installation for Release 5.x. Installer 1.12.0.0 is the last version of the installer to support upgrades from Release 5.2.x to Release 6.x.

If your cluster runs Release 5.2.x or a lower version of MapR core, you must use MapR Installer 1.11.0.0 to perform the following operations:

- New installs
- Incremental installs
- Patch installs

- Maintenance updates
- Extend-cluster operations

This table describes how to select the MapR Installer version based on your current MapR software and your upgrade plans:

MapR Core Version	Use This MapR Installer Version
5.1	Use Installer 1.11.0.0 for all operations, including upgrades to Release 5.2.x. Note that you must upgrade to MapR 5.2.x with EEP 3.0.1 or later if you eventually want to upgrade to Release 6.x. After upgrading to 5.2.x, if you need to upgrade to Release 6.x, update the MapR Installer to 1.12.0.0 before upgrading.
5.2.x	Use Installer 1.11.0.0 until you need to upgrade to Release 6.x. To upgrade to Release 6.x using the MapR Installer, your cluster must have Release 5.2.x with EEP 3.0.1 or later. Before upgrading, update the MapR Installer to 1.12.0.0.
6.x and later	Except for Ubuntu 16.04 clusters, you may use the latest MapR Installer version for all operations. See the Special Considerations for Ubuntu 16.04 Clusters on page 5403.

Special Considerations for Ubuntu 16.04 Clusters

As indicated in the MapR Installer Support Matrix on page 5599, Installer 1.17 and later are supported only on Ubuntu 18.04 and 20.04. If your cluster is installed on Ubuntu 16.04:

- The Installer version that you can use depends on whether or not the Installer node is part of the cluster where you plan to install data-fabric software:
  - If the Installer node is part of the cluster, and the cluster is running Ubuntu 16.04, you must use Installer 1.16.0.x to install the software. You cannot use Installer 1.17 or later unless you upgrade the cluster to Ubuntu 18.04 or 20.04.
  - If the Installer node is not part of the cluster, and the cluster is running Ubuntu 16.04, you can use the latest Installer version on a node that is running any supported version of Ubuntu, RHEL, or SLES to install core 6.1.0 or core 6.2.
- If you need to upgrade from core 6.1.x to core 6.2, you must first upgrade your operating system to Ubuntu 18.04 or 20.04 and then install Installer 1.17 or later to perform the core software upgrade.

Installer Downloads

This table summarizes download information for the MapR Installer:

Installer Version	Download Location	The `mapr-setup.sh` script provided in this location installs . . . .
Latest MapR Installer	`package.mapr.hpe.com/releases/installer/`	The most current version of the MapR Installer
Installer 1.16.0.x	`package.mapr.hpe.com/releases/installer-v1.16`	Installer 1.16.0.2
MapR Installer 1.12.0.0	`package.mapr.hpe.com/releases/installer-v1.12.0`	MapR Installer 1.12.0.0
MapR Installer 1.11.0.0	`package.mapr.hpe.com/releases/installer-v1.11.0`	MapR Installer 1.11.0.0

last-updated: Apr 11, 2022

Downloading Older Versions of the Installer

By default, the `mapr-setup.sh` file provided in the `installer-v<version>/` directories in `http://package.mapr.com/releases/` installs the most current version of the Installer – and *not* the version for which the directory is named.

However, you can download older Installer versions by using the latest `mapr-setup.sh`:

1. Download the 1.17 or later version of `mapr-setup.sh`. See MapR Installer on page 5395.
2. Add the following environmental variable to your current shell:

   ```
   export MAPR_INSTALLER_REPO_DIR=installer-v<version>
   ```

   The `export` command tells `mapr-setup.sh` to install the Installer package from the directory you specify. For example, the following command causes `mapr-setup.sh` to install the v1.11.0 Installer:

   ```
   export MAPR_INSTALLER_REPO_DIR=installer-v1.11.0
   ```

3. Run `mapr-setup.sh` as described in MapR Installer on page 5395 to install the Installer version you specified using the `export` command.

Using mapr-setup.sh

This topic describes how you can use and run the MapR Installer setup script.

Before you can run the MapR Installer, you must run the `mapr-setup.sh` script to set up the installation environment on a node that may or may not be part of the cluster. Then, you can run the MapR Installer to perform the installation.

To download and run the `mapr-setup.sh` script, see MapR Installer on page 5395.

mapr-setup.sh

The `mapr-setup.sh` script performs the following steps to prepare the node to run the MapR Installer:

1. Verifies and installs the operating system dependencies and Java requirements on the current node.

2. Checks for Internet connectivity to the remote repository.
   - If access to https://package.mapr.hpe.com/ is not available, the script prompts for the archive tarballs. Provide the full paths of these tarballs in a space-delimited list.
3. Asks for the hostname and port that cluster nodes can use to connect to the MapR Installer node.
4. Asks for the cluster admin user account and creates the account if it does not exist. This account must exist or be created on each node in the cluster.
5. Sets up a custom `yum` or `apt` repository.
   - If no archive file is provided, the script configures access to the https://package.mapr.hpe.com/ repository. For example, on RedHat / CentOS, the script creates the following remote repository: `/etc/yum.repos.d/mapr.installer.repo`
   - If archive files are provided, the script sets up a local repository.
6. Starts the MapR Installer.

Syntax

```
/opt/mapr/installer/bin/mapr-setup.sh
[docker client]
[docker installer]
[-a <full_path_to_archive_file(s)>]
[install]
[reload]
[remove]
[update]
[-h]
[-i <full_path_to_installer_package>]
[-n]
[-p <hostname:port>]
[-r <repository_URL>]
[-y]
```

Options

In general, you should run the `mapr-setup.sh` script without using any additional options. Consider using the following options only if you have a known Internet connectivity issue, your MapR Installer packages are not located in the default repository, or you need help with the installation process.

Option	Description
`docker client`	Use this option to create a MapR PACC image. For more information, see Creating a MapR PACC Image Using mapr-setup.sh on page 409.
`docker installer`	Use this option to create a MapR Installer container.
`install`	Use this option to install the MapR Installer and definition files. If you don't specify an option for `mapr-setup.sh`, the `install` option is invoked by default. **Example:** `./mapr-setup.sh install`

last-updated: Apr 11, 2022

Option	Description
`reload`	Use this option to reinstall the MapR Installer and definition files. This option is helpful in debugging. No prompt is returned when you use this option. **Example:** `./mapr-setup.sh reload`
`remove`	Use this option to remove the MapR Installer and definition files. This option does not remove the `mapr-setup.sh` script. **Example:** `./mapr-setup.sh remove`
`update`	Use this option to update the installer packages. The setup script checks https://package.mapr.hpe.com/ for new packages and installs the packages if they are available. **Example:** `./mapr-setup.sh update`

`-a|--archives`	Use this option to bypass the Internet connectivity check and directly create a local repository. Specify a space-delimited list of the full paths to the following archive files (the order of the files is important) as an argument to the option:
	• MapR Installer archive
	• MapR Ecosystem Pack (EEP) archive
	• MapR archive for the current release
	For more information, see Using a Local, Shared Repository With the MapR Installer on page 5418.
	Note: Use this option when the MapR Installer node does not have access to the Internet or is behind a restricted VPN or firewall.
	Example for Releases 5.2 and later:
	`./mapr-setup.sh -a mapr-installer-v1.5.201705041557.deb.tgz mapr-mep-v3.0.0.201704051422.deb.tgz mapr-v5.2.1GA.deb.tgz`
	Example for Releases 5.0 and 5.1:
	`./mapr-setup.sh -a mapr-5.0-5.1.201705082100.deb.tar.gz`
	For Releases 5.0 and 5.1, you only need to provide the core archive file.

`-h|--help`	Use this option to display the command-line help for the MapR Installer. **Note:** If you use this option with other options, the MapR Installer will ignore all options except for `-h`. **Example:** `./mapr-setup.sh -h`

Option	Description
`-i|--install`	Use this option to override the MapR Installer packages stored in the remote or local repository. This option take a space-delimited list of the two local packages needed to install the Installer (the order of the files is not important): • MapR Installer package • MapR Installer definitions package **Example:** `./mapr-setup.sh -i mapr-installer-definitions_1.5.201705021610_all.deb mapr-installer_1.5.201705021610_all.deb`
`-n|--noinet`	Use this option when you don't want `mapr-setup.sh` to fetch packages from the Internet. Instead of taking the files as an argument like `-a`, this option prompts you for a complete set of archive files (the order of the files is important): • MapR Installer archive • MapR Ecosystem Pack (EEP) archive • Core archive for the current release **Note:** Configure this option when the MapR Installer node does not have access to the Internet or is behind a restricted VPN or firewall. If you use this option together with `-a`, `mapr-setup.sh` will ignore `-n`. **Example:** `./mapr-setup.sh -n`
`-p|--port`	This option specifies the `hostname:port` to use for installation-related communication between the MapR Installer node and other nodes in the cluster. The MapR Installer also adds the hostname provided as a default entry for the list of cluster nodes on the *Configure Nodes* page. Both the `hostname` and the `port` are not required when configuring this option; you can choose to configure one or both values. **Note:** Configure this option when the MapR Installer node has multiple interfaces or hostnames and the result of `hostname` is not a value that other nodes in the cluster are able to communicate with. **Example:** `./mapr-setup.sh -p perfnode131.perf.lab:9441`
`-r|--repo`	When the MapR Installer packages are not located in the default repository, specify the top-level URL of the repository in which the MapR Installer packages are located. The default URL is https://package.mapr.hpe.com/. **Example:** `./mapr-setup.sh -r http://myrepo.download.pkgs/mapr/releases/`
`-R|--new_repo_url`	Specify a new repository URL for both ecosystem and MapR core components. Use this option only with the `reload` command: **Example:** `./mapr-setup.sh -R <new_url> reload`

last-updated: Apr 11, 2022

Option	Description
`-v|--verbose`	Use this option when you want additional information about the setup process. **Example:** `./mapr-setup.sh -v`
`-y|--yes`	Use this option to bypass the MapR Installer's usual prompts and immediately proceed with the default options. This option produces the same installation result as going through the `mapr-setup.sh` script prompts and choosing all of the default options, but with increased speed. **Example:** `./mapr-setup.sh -y`

Stopping mapr-setup.sh

If you need to stop `mapr-setup.sh` while it is running, press **Ctrl + C**. Depending on when you issue the **Ctrl + C** command, the script either stops or continues to execute until it is able to stop gracefully. You can run the script again or use the `remove` option, described earlier on this page, to remove the MapR Installer and definition files and then rerun the script.

Another way to exit the script is to answer NO when the script prompts for a YES or NO reply. For example, when the script asks if you want to upgrade dependent packages, if you reply NO, the script exits.

After Running mapr-setup.sh

To validate that the MapR Installer started correctly, do one of the following:

- Log in to the MapR Installer web interface using the cluster admin user name and password.
- Run the MapR Installer Stanza `export`command using the cluster admin user name and password.

If the MapR Installer does not start up correctly, check the logs. See Logs for the MapR Installer on page 5453.

If you want to change any parameter that you provided to `mapr-setup.sh` on a previous run (for example, the repository URL, the cluster admin user name, or another parameter), you can safely rerun `mapr-setup.sh` with the new parameters. Doing so updates the MapR Installer configuration to use the new parameters. However, do not rerun `mapr-setup.sh` while an installation or a `probe` command is in progress.

MapR Installer Web Interface

When you run the MapR Installer web interface, it performs the following tasks:

1. Displays the MapR services and ecosystem components that you can install based on the software version that you select.
2. Provides the option to install MapR Monitoring.
3. Guides you through node and cluster configuration.
4. Verifies that each node meets the node requirements.
5. Sets a default, configurable service layout across the nodes in the cluster based on the requirements of each service.

last-updated: Apr 11, 2022

6. Installs or upgrades the MapR software and associated operating-system dependencies.
7. If you chose to install a trial or community license, it will attempt to apply the license to your cluster.

MapR Installer Stanzas

Running `mapr-setup.sh` also installs MapR Installer Stanzas. Stanzas give you a script-based tool to perform all the installation tasks you can perform using the MapR Installer web interface. See MapR Installer Stanzas on page 5503. In addition, Stanza commands make it possible to probe a cluster that was installed without using the MapR Installer and use the `import` command to set up the installer database. See Using probe and import to Generate the Installer Database on page 5514.

MapR Installer Components

The MapR Installer uses the following components to set up the installation environment:

Name	Filename	Description
Configuration Script	`mapr-setup.sh`	Script that configures a node to run the MapR Installer. This includes setting up an Internet or local repository. The `mapr-setup.sh` script can also be used to create a MapR Persistent Application Client Container (PACC) or a MapR Installer Container. For more information, see • Creating a MapR PACC Image Using mapr-setup.sh on page 409
Installer Package	`mapr-installer-<version>`	Package that contains the MapR Installer.
Installer Definitions Package	`mapr-installer-definitions-<version>`	Package that contains the list of software versions, services, and ecosystem components that you can install with the MapR Installer.
Service Packages	various	If you use a remote repository, the MapR Installer accesses the installation packages from https://package.mapr.hpe.com/. If you use a local repository, the MapR Installer accesses the installation packages from the local repository. The `mapr-setup.sh` script creates the local repository with the packages available in the archive files that you provide to the `mapr-setup.sh` script. For more information, see Using a Local, Shared Repository With the MapR Installer on page 5418.

Updating the MapR Installer

Update the MapR Installer to include the latest MapR ecosystem packages and installer fixes. Once you update the MapR Installer, you can install ecosystem components and software versions that were made available after you first configured the MapR Installer.

To check the version of the MapR Installer, see Checking the MapR Installer Version on page 5412.

Update the MapR Installer Using an Internet Repository

If the node that runs the MapR Installer uses an Internet repository that points to https://package.mapr.hpe.com/, use **one** of the following options to gain access to the latest packages:

- **Option 1:**

last-updated: Apr 11, 2022

1. Rename the `mapr-setup.sh` script for the current version of the Installer.
2. Download the `mapr-setup.sh` script for the version of the Installer to which you want to update. For example, if your current version of the script is 1.11 and you want to update to 1.14, download version 1.14 of the script using the steps in MapR Installer on page 5395.
3. Run the following command:

```
bash /opt/mapr/installer/bin/mapr-setup.sh update
```

- **Option 2:** Use a package manager to update the packages:

On RHEL/CentOS	`yum update mapr-installer mapr-installer-definitions`
On Ubuntu	`apt-get install mapr-installer mapr-installer-definitions`
On SLES	`zypper update mapr-installer mapr-installer-definitions`

Once the update is complete, open the MapR Installer URL (`https://<hostname/IPaddress>:9443`) to update the cluster.

Update the MapR Installer Using a Local Repository

If the node that runs the MapR Installer uses a local repository, perform the following manual steps to get the latest packages for the MapR cluster version that you are updating or upgrading to:

1. Download the latest versions of the following archive files.

last-updated: Apr 11, 2022

For Releases 5.2 and later	• **The MapR Core archive file.** Download the core archive file `mapr-<version>GA.<dep|rpm>.tgz` from one of the following locations, based on the operating system of the node:
	  • https://package.mapr.hpe.com/releases/v.<version>/redhat/
	  • https://package.mapr.hpe.com/releases/v.<version>/ubuntu/
	  **Note:** The package `mapr-v<version>GA-upgrade.<rpm/deb>.tgz` is not for use with the MapR Installer.
	• **The MapR Installer archive file**. Based on the operating system of the node, download `mapr-installer-<version>.<yyyymmdd>.<dep|rpm>.tgz` from one of the following locations:
	  • https://package.mapr.hpe.com/releases/installer/redhat/
	  • https://package.mapr.hpe.com/releases/installer/ubuntu/
	• **The MapR Ecosystem Pack (EEP) archive file**. Based on the operating system of the node, download `mapr-mep-<version>.<yyyymmdd>.<dep|rpm>.tgz` from one of the following locations:
	  • https://package.mapr.hpe.com/releases/MEP/MEP-<version>/redhat
	  • https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu

For Releases 5.0 and 5.1	**The Core archive file.** Download the `mapr-5.0-5.1.<yyyymmdd><dep|rpm>.tgz` archive file from one of the following locations, based on the operating system of the node: • https://package.mapr.hpe.com/releases/installer/ubuntu/ • https://package.mapr.hpe.com/releases/installer/redhat/

2. Run the following command:

```
bash /opt/mapr/installer/bin/mapr-setup.sh -a <full path to each archive file> update
```

   For more information about `mapr-setup.sh` options, see Using mapr-setup.sh on page 5404.

3. Once the update is complete, open the MapR Installer URL (`https://<hostname/IPaddress>:9443`) to update the cluster.

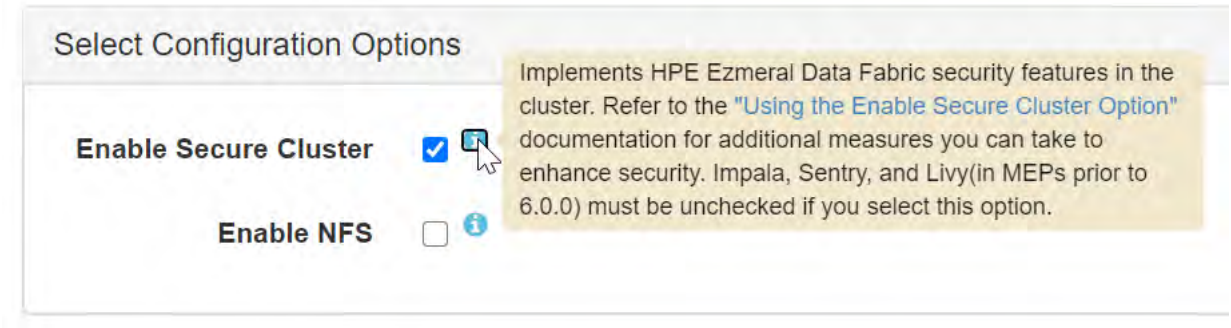
last-updated: Apr 11, 2022

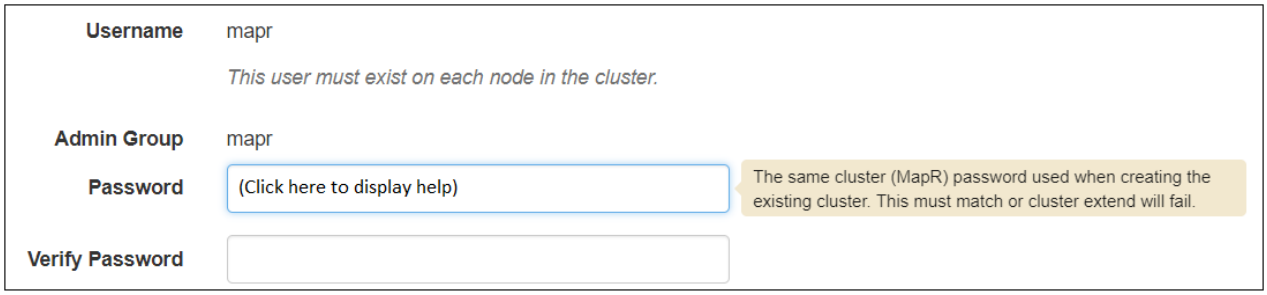
Online Help for MapR Installer Fields

This page describes how to use field-level help for the MapR Installer.

To get more out of using the MapR Installer, hold your cursor over the information icon ( ) next to each field or option. The help text can make it easier for you to use Installer options and fill in required information. For example:



If no information icon ( ) is visible near a field, place your cursor in the field to display the online help:

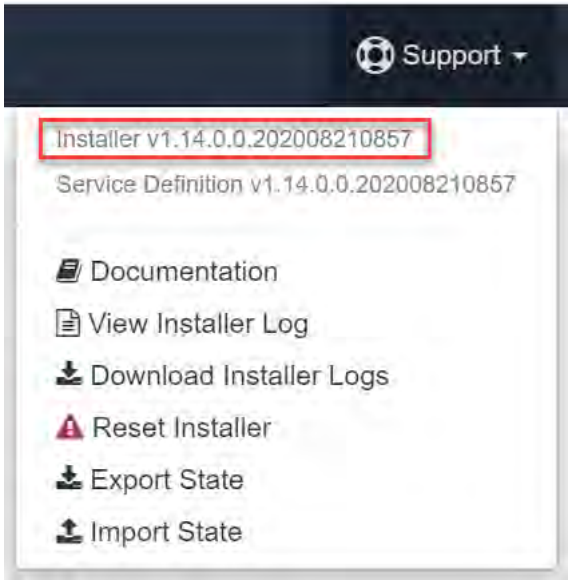


Checking the MapR Installer Version

Some MapR Installer features require you to use the latest version of the Installer. You can check the MapR Installer version easily from within the user interface.

To check the version of the currently installed MapR Installer:

1. From the MapR Installer web-based interface, click **Support**. The drop-down menu shows the MapR Installer version:



last-updated: Apr 11, 2022

2. **Optional:** Check your version against the recently released versions to see if a newer version is available. To update the MapR Installer, see Updating the MapR Installer.

Related concepts

Selecting an Installer Version to Use on page 5402
Beginning with the EEP 6.2.0 release, several MapR Installer versions are available for use. The version that you use depends on your current MapR core version and whether or not you need to upgrade using the MapR Installer or Stanzas.

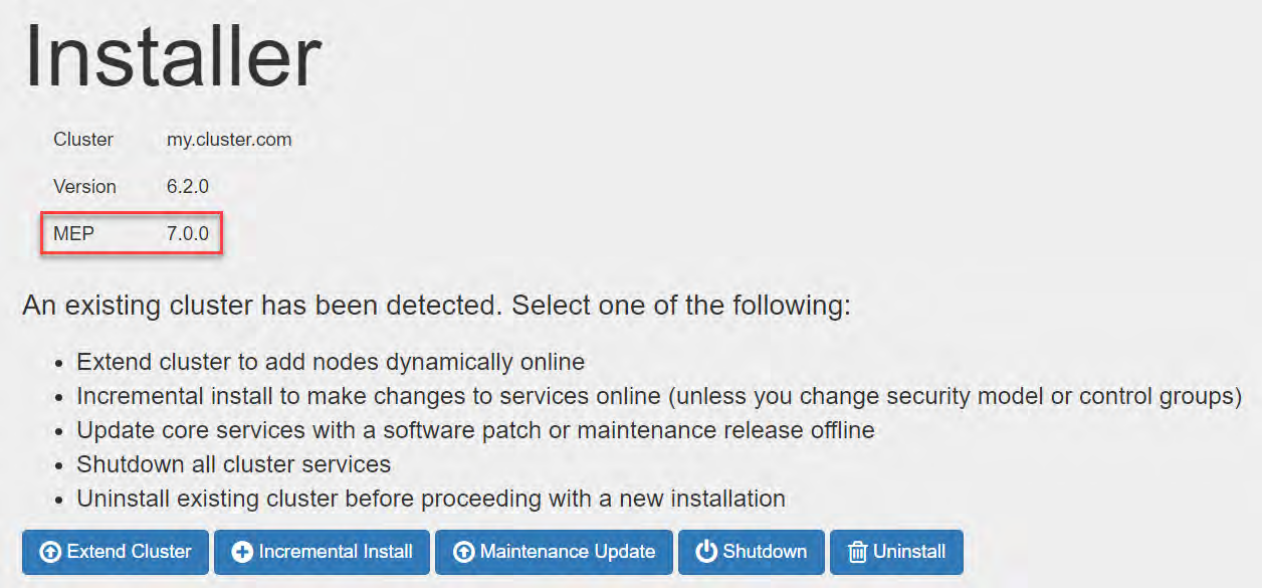
Checking the EEP Version on page 5413
Some MapR Installer operations require you to know the version of the currently installed MapR Ecosystem Pack (EEP). You can check the EEP version easily from within the MapR Installer user interface or derive the EEP version from your repository information.

Checking the EEP Version

Some MapR Installer operations require you to know the version of the currently installed MapR Ecosystem Pack (EEP). You can check the EEP version easily from within the MapR Installer user interface or derive the EEP version from your repository information.

Checking the EEP Version Using theMapR Installer

The Control System does not indicate the version of the currently installed EEP. However, if you used the MapR Installer to install the cluster, you can view the EEP version on the home page:



Checking the EEP Version in the Repository

If you installed the cluster manually, you can learn the EEP version by checking the `/etc/yum.repos.d/mapr_ecosystem.repo` file:

```
cd /etc/yum.repos.d/
ls -l
    total 52
    -rw-r--r-- 1 root root 1664 Apr 28  2018 CentOS-Base.repo
    -rw-r--r-- 1 root root 1309 Apr 28  2018 CentOS-CR.repo
    -rw-r--r-- 1 root root  649 Apr 28  2018 CentOS-Debuginfo.repo
    -rw-r--r-- 1 root root  314 Apr 28  2018 CentOS-fasttrack.repo
    -rw-r--r-- 1 root root  630 Apr 28  2018 CentOS-Media.repo
    -rw-r--r-- 1 root root 1331 Apr 28  2018 CentOS-Sources.repo
    -rw-r--r-- 1 root root 4768 Apr 28  2018 CentOS-Vault.repo
    -rw-r--r-- 1 root root  957 Dec 27  2016 epel.repo
```

last-updated: Apr 11, 2022

```
    -rw-r--r-- 1 root root 1056 Dec 27  2016 epel-testing.repo
    -rw-r--r-- 1 root root  169 May 14 10:04 mapr_core.repo
    -rw-r--r-- 1 root root  186 May 14 10:04 mapr_ecosystem.repo
   -rw-r--r-- 1 root root  171 May 13 11:25 mapr_installer.repo
more mapr_ecosystem.repo

    [MapR_Ecosystem]
    name = MapR Ecosystem Components
    baseurl = https://package.mapr.hpe.com/releases/MEP/MEP-6.2.0/redhat
    gpgcheck = 1
    enabled = 1
    protected = 1
```

Checking the EEP Version Using the Installed Packages

If the `/etc/yum.repos.d/mapr_ecosystem.repo` file is not available for any reason, another way to learn the currently installed EEP version is to check the versions of the installed packages. Use one of the following commands to display the MapR package versions:

OS	Command
On CentOS / RHEL	`yum list installed`
On SLES	`zypper packages --installed-only`
On Ubuntu	`apt list --installed`

For example:

```
yum list installed
    Loaded plugins: fastestmirror
    Loading mirror speeds from cached hostfile
     * base: mirror.sjc02.svwh.net
     * epel: mirror.sjc02.svwh.net
     * extras: mirror.sesp.northwestern.edu
     * updates: mirrors.syringanetworks.net
    Installed Packages

@MapR_Core
    ...
```

Then compare the package versions against the component versions in the MapR repository. Some MapR package versions can be the same for multiple EEPs, so it is best to compare multiple packages to confirm the installed EEP.

Related concepts

MapR Ecosystem Packs on page 3174

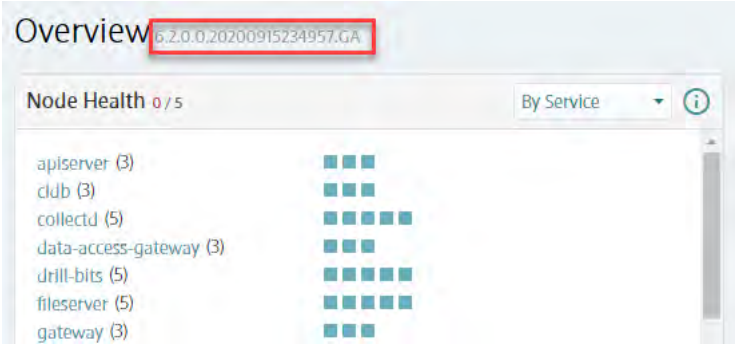
EEP Support and Lifecycle Status on page 5531
This page shows the EEPs that are supported for different core releases and the current lifecycle status for each EEP.

Checking the MapR Core Version

Some maintenance operations require you to know the version of the currently installed MapR release (sometimes referred to as the "MapR core version"). You can check the MapR core version easily from within the Control System or MapR Installer user interface or identify the version from your installed packages.

Checking the MapR Core Version Using the Control System

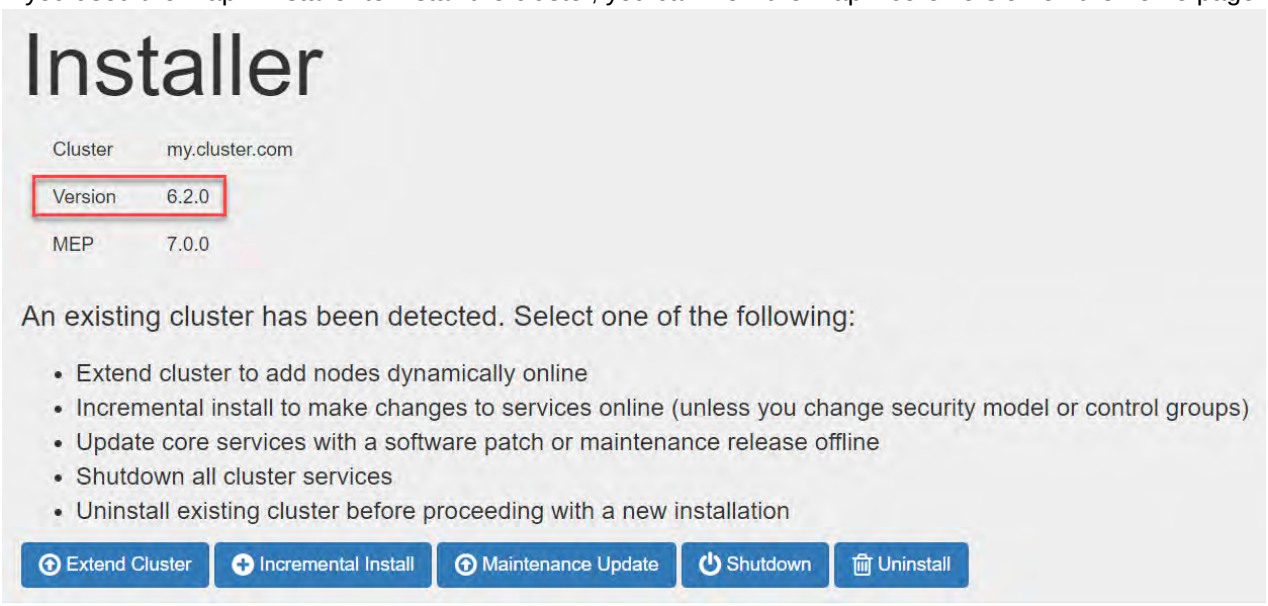
The Control System displays the MapR core version on the **Overview** page:



To connect to the Control System, see Setting Up the Control System on page 423.

Checking the MapR Core Version Using the MapR Installer

If you used the MapR Installer to install the cluster, you can view the MapR core version on the home page:



To set up the MapR Installer, see MapR Installer on page 5395.

Checking the MapR Core Version Using maprcli

Another way to view the currently installed MapR core version is to use the `maprcli dashboard info` command:

```
cd /opt/mapr/bin
maprcli dashboard info -json
    {
        "timestamp":1586880602331,
        "timeofday":"2020-04-14 09:10:02.331 GMT-0700 AM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "version":"6.1.0.20180926230239.GA",
                        "cluster":{
                                "name":"bridget.cluster.com",
                                "secure":true,
                                "dare":false,
                                "ip":"10.10.82.24",
                                "id":"6083111376716482211",
```

                                "totalNodesAllowed":-1
                        },
                        "volumes":{
                                "mounted":{
                                        "total":16,
                                        "size":1543
                                },
                                "unmounted":{
                                        "total":3,
                                        "size":1
                                }
                        },
                        "utilization":{
                                "cpu":{
                                        "util":38,
                                        "total":8,
                                        "active":3
                                },
    ...
```

Checking the MapR Core Version Using the Installed Packages

Another way to view the currently installed MapR core version is to check the versions of the installed `mapr-core.x86_64` or `mapr-core-internal.x86_64` packages. Use one of the following commands to display the MapR package versions:

On CentOS / Red Hat	`yum list installed`
On SLES	`zypper packages --installed-only`
On Ubuntu	`apt list --installed`

For example:

```
yum list installed
    Loaded plugins: fastestmirror
    Repodata is over 2 weeks old. Install yum-cron? Or run: yum makecache
fast
    Determining fastest mirrors

Related concepts

Checking the EEP Version on page 5413
Some MapR Installer operations require you to know the version of the currently installed MapR Ecosystem Pack (EEP). You can check the EEP version easily from within the MapR Installer user interface or derive the EEP version from your repository information.

Using a Local, Shared Repository With the MapR Installer

The MapR Installer can use a local repository instead of an Internet repository.

When you run the `mapr-setup.sh` script, it attempts to connect to https://package.mapr.hpe.com/ and configures an Internet repository. If there is no Internet connectivity, the script asks for archive files so that it can create a local repository.

Note: Passing `-a <full path each archive file>` to the `mapr-setup.sh` script bypasses the Internet connectivity check and automatically creates a local repository with the provided archive files.

To install with a local, shared repository, the node that runs `mapr-setup.sh` needs the following:

- **Any OS dependencies or Java Development Kit (JDK) packages that are required.**
- **A webserver.** The script will attempt to install a webserver on the node if a webserver is not available. The webserver is needed to provide the MapR package files to each node in the cluster. Note that this webserver is not configured to start automatically after a server restart. However, you can start the webserver manually by using the `systemctl start httpd` command.
- **Archive file(s).** To install release 5.2 and later, you need to download mutiple archive files. To install release 5.1 or 5.0, you need to download a single archive file.

last-updated: Apr 11, 2022

For release 5.2 and later	• **The MapR Core archive file.** Download the archive file `mapr-<version>GA.<dep|rpm>.tgz` from one of the following locations, based on the operating system of the node:
	  • https://package.mapr.hpe.com/releases/v.<version>/redhat/
	  • https://package.mapr.hpe.com/releases/v.<version>/ubuntu/
	  • https://package.mapr.hpe.com/releases/v.<version>/suse/
	  **Note:** The package `mapr-v<version>GA-upgrade.<rpm/deb>.tgz` is not for use with theMapR Installer.
	• **The MapR Installer archive file**. Based on the operating system of the node, download `mapr-installer-<version>.<yyyymmdd>.<dep|rpm>.tgz` from one of the following locations:
	  • https://package.mapr.hpe.com/releases/installer/redhat/
	  • https://package.mapr.hpe.com/releases/installer/ubuntu/
	• **The MapR Ecosystem Pack (EEP) archive file**. Based on the operating system of the node, download `mapr-mep-<version>.<yyyymmdd>.<dep|rpm>.tgz` from one of the following locations:
	  • https://package.mapr.hpe.com/releases/MEP/MEP-<version>/redhat
	  • https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu
	  • https://package.mapr.hpe.com/releases/MEP/MEP-<version>/suse
	The MEP-<version> directory can be represented by a 2-digit number or a 3-digit number. The 3-digit directory contains a fixed MEP version, including patches, and is not continuously updated. The 2-digit EEP directory points to the latest MEP and patches and is continuously updated. See Understanding Two-Digit and Three-Digit EEPs on page 5450.

last-updated: Apr 11, 2022

For releases 5.0 and 5.1	• **The MapR archive file.** Download the `mapr-5.0-5.1.<yyyymmdd><dep|rpm>.tgz` archive file from one of the following locations, based on the operating system of the node:
	  • https://package.mapr.hpe.com/releases/installer/ubuntu/
	  • https://package.mapr.hpe.com/releases/installer/redhat/
	• **The MapR Core archive file.** Download the archive file `mapr-<version>GA.<dep|rpm>.tgz` from one of the following locations, based on the operating system of the node:
	  • https://package.mapr.hpe.com/releases/v.<version>/redhat/
	  • https://package.mapr.hpe.com/releases/v.<version>/ubuntu/
	  • https://package.mapr.hpe.com/releases/v.<version>/suse/
	  **Note:** The package `mapr-v<version>GA-upgrade.<rpm/deb>.tgz` is not for use with the MapR Installer.

- **The `mapr-setup.sh` script.**

 **Note:** Red Hat clusters must have access to a local EPEL repository, as described in Set Up the Internet Repository: RHEL/CentOS on page 310. The EPEL repository enables installation of these packages:

- clustershell
- pdsh
- pdsh-rcmd-ssh
- sshpass*

*Before installing a cluster on a SLES image, you must install `sshpass`, as described in Adding the MapR Repository on SUSE on page 144.

After downloading the `mapr-setup.sh` script and the archive files to the node that will run the MapR Installer, run the following command from the directory that contains the `mapr-setup.sh` script:

```
bash ./mapr-setup.sh -a <full path to the archive files>
```

MapR Installer FAQ

Review frequently asked questions about the MapR Installer.

General

What is the difference between the MapR Installer and the Quick Installer?	The MapR Installer is a robust, user-friendly replacement for the Quick Installer. You can use the MapR Installer to install a cluster with MapR

last-updated: Apr 11, 2022

	services and ecosystem components. You can also use the MapR Installer to update an existing cluster with additional nodes, MapR services, and ecosystem components. However, the MapR Installer does not install the MapR client.
Which versions of MapR software can I install?	You can use the MapR Installer to install releases 4.1, 5.0, 5.1, 5.2.x, and 6.x.
Can I use the MapR Installer to upgrade my cluster?	Yes. The MapR Installer can be used to upgrade a cluster that was installed using the MapR Installer or an Installer Stanza. See Upgrading MapR Core With the MapR Installer on page 308 for information about how to upgrade with the MapR Installer. If the cluster was manually installed, you can install the Installer and enable it to be used with subsequent installations or upgrades by following the steps in Using probe and import to Generate the Installer Database on page 5514.
Can I use the MapR Installer to install a patch?	Yes. See Applying a Patch on page 437.
Does the MapR Installer support adding a "compute-only" node?	A compute-only node is a node that is capable of performing computational tasks but is not expected to perform long-term data storage. The MapR Installer does not explicitly support adding a compute-only node to a MapR cluster. However, you can effectively work around the issue by adding a node that has the MapR File System and sufficient associated disk space. The disk space must be equal to or greater than the amount of physical memory on the node.

Preparing to Install

What are the MapR Installer requirements?	See the Prerequisites.
What information should I have before I start?	The `mapr-setup.sh` script requests the following information: • The fully-qualified domain name for each host and the port number that other nodes in the cluster can use to connect to the MapR Installer node. • A user for the cluster admin user account. If the user account doesn't exist, the `mapr-setup.sh` script prompts for the UID, GID, group name, and password so that it can create the account. The MapR Installer requests the following information: • The EEP that you want to install on a 5.2.x or later cluster • The MapR services that you want to install on the cluster • Hostnames of the nodes that you want to include in the cluster (specify fully-qualified domain names as described in Connectivity on page 133) • Credentials for the `root` user or a user with sudo privileges on each node in the cluster
What are the node requirements?	See the Prerequisites.

What are my options if I don't want to use an Internet repository?

See Using a Local, Shared Repository With the Installer.

Using the MapR Installer

Which license edition applies to my installation?

As of release 5.1, MapR licenses are categorized by new editions and modules that further define the features supported by an edition.

See the following table for descriptions of the license options. For more information about licensing, see HPE Ezmeral Data Fabric Software Licensing.

License Edition	Description
Community Edition	An unlimited, free, community-supported MapR edition with one free NFS Gateway. This edition includes Hadoop, MapR Database, and MapR Event Store For Apache Kafka. However, real-time global replication of MapR Database tables orMapR Event Store For Apache Kafka is not included.
Enterprise Edition	MapR Edition that enables enterprise-class features such as high availability, multi-tenancy, and disaster recovery. Each of the following modules for the Enterprise Edition unlocks a portion of the total platform capabilities: **Analytics** Enables enterprise-class features for analytic use cases, such as highly-available NFS and support for services like YARN and MapReduce. **Database** Enables enterprise-class features for operational NoSQL database, with MapR Database

last-updated: Apr 11, 2022

License Edition	Description
	JSON and binary tables, and real-time global database replication. **Streams** Enables enterprise-class features for publish/subscribe event streaming, with MapR Event Store For Apache Kafka and real-time global stream replication. For more information about MapR editions, see What's Included.

What happened to the M3, M5, M7, or Enterprise Edition licenses?

With the release of 5.1 and MapR Streams, the licensing model has been simplified, allowing more choice in which specific features are licensed on a cluster.

See the following table to understand how the new MapR licenses correspond to the legacy license editions that you are familiar with. For more information about licensing, see HPE Ezmeral Data Fabric Software Licensing. For more information about MapR editions, see What's Included.

Legacy Edition	New Edition & Module(s)
M3 or Community Edition	Community Edition. Starting in 5.1, the Converged Community Edition includes MapR Streams.
M5 or Enterprise Edition	Enterprise Edition with Hadoop Module
M7 or Enterprise Database Edition	Enterprise Edition with Hadoop and Database modules

What expressions can I use to specify multiple nodes?

You can enter the following types of expressions to specify nodes:

- `[0-99]` => Expands hostnames to 0, 1, 2, ...99. The second delimiter allows one or more digits.

last-updated: Apr 11, 2022

- `[00-99]` => Expands hostnames to 00,01,02,...99. Allows two or more digits of the same length
- `[a-z] or [A-Z]` => Expands hostnames to a,b,c,...z or A,B,C,...Z

To group hosts based on racks for performance or reliability, append ":" followed by the rack name to each expression.

Examples:

- `host1, host2, host3`
- `host[A-Z][0-99]` => hostA0, hostA1, hostA2 ,...hostZ99
- `host[000-333]` => host000, host001, host002, ... host333
- `host[0-3],otherhost[00-05]` => host0, host1, host2,...host3 and otherhost00,...otherhost05
- `host[0-5]:rack1,host[6-10]:rack2` => host1, host2, host3,...host5 on rack1. host6, host7, host8,...host10 on rack2

How do I change the service layout?

The MapR Installer uses groups to organize nodes and services. A group is a set of services that you can run on one or more nodes. A service can only be assigned to one group.

On the **Configure Service Layout** page, you can use the **Advanced Configuration** option to drag and drop services between existing groups to specify where the services are to be installed. You can also create new groups or change the list of nodes assigned to a group.

Note: Some services can only be assigned to one node.

Can I install a single-master service, such as Hive, on multiple nodes?

When you use the MapR Installer, single-master services are added to the default MASTER group. By design, only one node can be assigned to the MASTER group.

To install a single-master service on more than one node:

1. On the Configure Service Layout page, create a new group.
2. Assign multiple nodes to the new group.
3. Drag the single-master service to the new group.

Can I install a secure MapR cluster with the MapR Installer?

Yes. MapR Installer versions 1.10 and later support security by default.

Are there limitations to what you can do when you update an existing cluster?

See the restrictions documented in Using the Incremental Install Function on page 5443.

How do I uninstall the MapR Installer?

See Uninstalling Software Using the MapR Installer Uninstall Button on page 5452. If the installer node

last-updated: Apr 11, 2022

is part of the cluster, the MapR Installer packages can remain on the installer node after the cluster is uninstalled.

If you have uninstalled the cluster, you can also run one of the following commands to uninstall the MapR Installer packages from the installer node:

- On CentOS / Red Hat:

```
yum remove 'mapr-installer*'
```

- On Ubuntu:

```
apt-get remove 'mapr-installer*'
```

- On SLES

```
zypper remove 'mapr-installer*'
```

Troubleshooting

What can I do if I need to rerun mapr-setup.sh with a new repository URL and the script still points to the old URL?

The `/opt/mapr/installer/data/properties.json` file stores information such as the user ID of the cluster administrator, the user ID of the MapR Installer, the OS type, Internet access information, and the repository URLs for MapR Core and the ecosystem components. Once a repository URL has been stored in `properties.json`, the MapR Installer assumes that the URL will not change. Rerunning the setup script does not update the URL. Even upgrading the installer packages does not update the repository URL in `properties.json`. To pass a new repository value into `properties.json`, you have two options:

Option 1

You can remove the installer files and rerun the setup script:

```
mapr-setup.sh remove
```

Using the `remove` command removes `properties.json`, the installer database, and the installer packages, but not the setup script. After the files are removed, you can rerun the setup script to specify the new repository URL. For more information about options you can use with `mapr-setup.sh`, see Using mapr-setup.sh.

Option 2

If you need to retain the installer database and the cluster state information (for example, because you need to do an upgrade), you can:

1. Edit the `properties.json` file manually to change the `repo_core_url` and the `repo_eco_url` entries to the correct values.

last-updated: Apr 11, 2022

2. Restart the MapR Installer:

```
systemctl restart mapr-installer
```

What can I do if drop-down menus aren't working?	Try any or all of the following to correct the problem: • Refresh the browser page. • Clear the browser cache. • Close and restart the browser or browser tab.
Why does the Installer URL not work?	Check that the URL you are trying to access is external. For example, if you install on a cluster that is in the cloud, the URL that the MapR Installer lists may not work if it is an internal URL. Try accessing the external URL that is associated with the internal URL.
Why doesn't the MapR Installer list the ecosystem component that I want to install?	The MapR Installer Definitions package contains the MapR versions and services that you can install. Once you update the MapR Installer Definitions, you can install ecosystem components that were made available after you first configured the MapR Installer. See Updating the MapR Installer on page 5409.
On the Verify Nodes page, how can I get more information about a warning or error?	Hold your cursor over the warning or error in the right pane to see more information about the specific warning or error condition.
Why are the nodes listed on the Verify Nodes page different from those that I chose to install on?	If you abort an installation and then install on a different set of nodes, you must use the *Verify Nodes* page to manually remove nodes that were part of the aborted installation but are no longer part of the current installation.
I can't log in to Hue. What credentials should I use to log into Hue for the first time?	Log in with the cluster administrator username that you configured while running `mapr-setup.sh` and the password `mapr`.
What should I do if rerunning mapr-setup.sh generates errors because the properties.json file has incorrect information?	See Troubleshooting Repository URL Errors on page 5459.

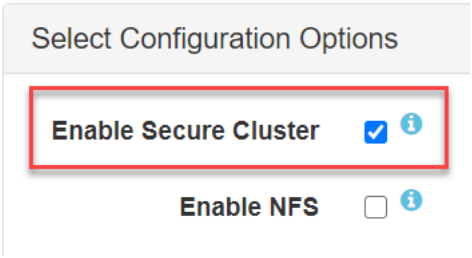
Installer Operations

This section describes operations you can perform using the MapR Installer.

Using the Enable MapR Secure Cluster Option

You use the Enable MapR Secure Cluster option to control whether or not the cluster is configured as a secure cluster.

This option appears on the **Version & Services** page of the web-based MapR Installer.



About the Enable MapR Secure Cluster Option

Using this option controls platform and ecosystem security in a MapR cluster. When you select the option, the MapR Installer runs the `configure.sh` script on the primary container location database (CLDB) to generate security keys and then distributes the keys to all the other CLDBs. The installer also distributes certificates to all the other nodes and activates security for the ecosystem components that support security.

Certain ecosystem components either do not support security or cannot be secured by the MapR Installer. If you enable security, you will not be allowed to select services such as Impala or Sentry.

Beginning with Release 6.1, data-on-wire encryption is enabled by default for newly created volumes when the **Enable** MapR **Secure Cluster** option is selected. Data-on-wire encryption encrypts data in a volume during transmission over the wire. In a secure cluster, you can enable or disable data-on-wire encryption for individual volumes using the Control System, the maprcli, or the REST API commands.

Using the Option With New and Already Installed Clusters

You can select or deselect the **Enable** MapR **Secure Cluster** option during a new installation or during an Incremental Install.

- For new installations:
  - The option is selected by default, meaning that new installations are configured with security unless you deselect the option.
  - Deselecting the option causes the cluster to be installed as a nonsecure cluster.
- For clusters that are already installed with EEP 4.0.0 or later:
  - You can select or deselect the option during an Incremental Install:
    - If security is not currently configured and you select the option, the cluster will be configured with security.
    - If security is already configured, you can remove security by deselecting the option.

      Note: If Drill is installed, be sure to review the limitations described in Securing Drill on page 3275 before removing security. Additional steps must be taken so that Drill in a nonsecured cluster can access all Drill znodes.

Using the Option During an Incremental Install

Normally, **Incremental Install** operations are conducted online. However, selecting or deselecting the **Enable** MapR **Secure Cluster** option during an **Incremental Install** requires the MapR Installer to stop the Warden and Zookeeper services, bringing the cluster offline temporarily.

In some instances, the **Enable** MapR**Secure Cluster** option is unavailable. For example, you cannot select this option during an upgrade of a nonsecured Release 5.x cluster to Release 6.0 or later. You must complete the upgrade to Release 6.0 or later first and then use the **Incremental Install** function to enable security.

Using the Enable MapR DARE Option

You use the Enable MapR DARE option to enable data-at-rest encryption for MapR volumes.

This option appears on the **Version & Services** page of the web-based MapR Installer when the **Enable** MapR **Secure Cluster** option is selected. The **Enable** MapR **DARE** option is *deselected* by default.

For more information about data-at-rest encryption, see Encryption in MapR on page 688.

last-updated: Apr 11, 2022

Considerations for Enabling MapR DARE Using the MapR Installer

Before using the **Enable** MapR **DARE** option, review these considerations:

Important: Once enabled, the **Enable** MapR **DARE** option cannot be disabled, since disk encryption cannot be turned off without reformatting the disks.

- The **Enable** MapR **DARE** option can only be used during the initial installation of a MapR cluster or during an incremental install.
- You cannot select the **Enable** MapR **DARE** option when:
  - The **Enable** MapR **Secure Cluster** option is deselected.
  - You perform an upgrade operation using the MapR Installer. Security changes are not allowed during an upgrade using the MapR Installer.
- If you select the **Enable** MapR **DARE** option, you can no longer deselect the **Enable** MapR **Secure Cluster** option during an **Incremental Install** operation.

Installing the S3 Gateway Using the Installer

Using the web-based Installer, you can install the S3 Gateway on the cluster.

You can install the S3 gateway during a new or incremental installation of Release 6.2 or later. The following option appears on the **Version & Services** page of the MapR Installer:

Object Store Gateway with S3-Compatible API (2.0.0)

Note these considerations for installing the S3 gateway using the Installer:

- Installer 1.15 installs S3 gateway 2.0.0 with EEP 7.0.0 and 7.0.1.
- If **Enable NFS** is specified, the Installer configures the S3 gateway to use NFS servers.
- If **Enable NFS** is not specified, by default the Installer installs Loopback NFS (`mapr-loopbacknfs-<version>`) on all nodes in the cluster. If you later perform an incremental install to **Enable NFS**, the Installer uninstalls Loopback NFS and uses NFS servers to interface with the S3 gateway.
- The S3 gateway:
  - Accesses the MapR file system through `/mapr`
  - Uses port 9000
  - Uses either the http or https protocol
- You cannot upgrade S3 gateway 1.0.x to S3 gateway 2.0.0 manually or by using the Installer. Upgrades are not supported.

To install the S3 gateway manually, see Installing S3 Gateway on page 204. To learn more about managing and using the S3 gateway, see S3 Gateway on page 3959.

Installing NFS Using the MapR Installer

Using the web-based MapR Installer, you can install version 3 or version 4 of the Network File System (NFS) on the cluster.

You can install NFS during a new or incremental installation of Release 6.1 or later. The **Enable** MapR **NFS** option appears on the **Version & Services** page of the MapR Installer.

Note these considerations for installing NFS using the MapR Installer:

last-updated: Apr 11, 2022

- Previous versions of the MapR Installer installed NFS (version 3) by default. MapR Installer 1.10 and later do NOT install NSF by default. You must select the **Enable** MapR **NFS** option to instruct the installer to install NFS. When you select the **Enable** MapR **NFS** option, the **NFS Version** option appears. NFSv3 is always selected by default. NFSv4 is available as an option for MapR 6.1.0 or later releases.

  CAUTION: The MapR Installer installs but does not secure NFS. Neither NSFv3 nor NSFv4 provides security by default. You can configure NFSv4 server to work with Active Directory and Kerberos servers, but you must first install Active Directory and Kerberos servers. For more information, see Configuring NFSv4 Server for Kerberos on page 1209. NFSv3 does not support security.

- With the MapR 1.10 installer, if you specify a pre-6.1.0 release, you must select the **Enable** MapR **NFS** option to install NFS. Selecting the option causes the installer to install NSFv3 by default. The **NFS Version** option is not available for pre-6.1.0 releases.

- When upgrading to Release 6.1 or later, the MapR Installer keeps the NFS version at version 3. After a new installation of Release 6.1 in which you specified NFSv3, or an upgrade to Release 6.1 using the MapR Installer, you can switch to NFSv4 by using the Incremental Install function of the installer.

- The software supports mixed-mode NFS configurations in which some nodes of a cluster use NFSv3 and other nodes use NFSv4, but mixed-mode configurations cannot be installed using theMapR Installer. The MapR Installer installs all nodes as NFSv3 or all nodes as NFSv4.

- NFSv3 and NFSv4 cannot be used on the same node concurrently.

- A new installation using a MapR Installer Stanza installs NFS only if you set `enable_NFS: true` in the config section of the stanza.

To install NFS manually, see Installing MapR NFS on page 386. To learn more about managing and using NFS, see Managing the MapR NFS Service on page 1176.

Using Custom Playbooks

Installer 1.12.0.0 and later enable you to use custom playbooks that can run a set of predefined tasks during or after operations using the MapR Installer or MapR Installer Stanzas.

Using custom playbooks, you can inject specific commands into the Installer 1.12.0.0 and later workflows to make configuration changes and ensure that those changes persist even after incremental installations or upgrades. For example, suppose you want to install a specific software package on all nodes before starting an installation. Custom playbooks enable you to check for and install the software as needed.

Or suppose you want to change a configuration setting before starting MapR Core. Custom playbooks enable you to change the setting as part of an installation or upgrade.

Restrictions to Using Custom Playbooks

Note these restrictions:

- You can use custom playbooks with any MapR cluster as long as the MapR Installer version is 1.12.0.0 or later. However, MapR Installer 1.12.0.0 and later have limited functionality when used with older MapR releases. See Selecting an Installer Version to Use on page 5402.

- Custom playbooks are not supported for manual installations. Custom playbooks are supported only for use with the MapR Installer and MapR Installer Stanzas on page 5503.

Prerequisite for Using Custom Playbooks

To create a custom playbook file, you must be familiar with Ansible. Ansible is a simple automation language that uses plain-text YAML files to describe the desired state of the cluster. You do not have to

install Ansible. Ansible 2.7 is installed whenever you load the MapR Installer using `mapr-setup.sh`. To begin learning Ansible, see these resources:

- Quick Start Video
- Getting Started with Ansible
- Introduction to Playbooks

Creating and Running a Custom Playbook

Follow these steps to use a custom playbook with the MapR Installer or MapR Installer Stanzas:

No.	Step	See for more information
1.	Prepare the roles structure and YAML files for the custom playbook.	• Predefined Roles for Custom Playbooks on page 5431 • Example Playbook Files on page 5432
2.	Test the roles using standalone Ansible.	• Testing the Roles on page 5433 • Playbook Debugger
3.	Convert the YAML files to a zipped archive file that has a `tgz` or `tar.gz` file extension.	• Creating the Zipped Archive on page 5433
4.	In the MapR Installer or a MapR Installer Stanza, specify the option to upload the zipped archive file.	• Installer Options for Custom Playbooks on page 5433 • MapR Installer Stanza Parameters for Custom Playbooks on page 5435
5.	Run the MapR Installer or MapR Installer Stanza to invoke the playbook.	• MapR Installer on page 5395 • MapR Installer Stanzas on page 5503
6.	If the operation returns a syntax error, fix the error and retry the operation.	• Troubleshooting Custom Playbook Errors on page 5435

Predefined Roles for Custom Playbooks

The role structure is an important part of your custom playbook. Your custom playbook must contain one or more of the following roles, and each role must be a directory in the zipped archive. The roles do not need to follow a specific order.

Role	Tasks in this role are run *after* . . .
preinstall	The MapR Installer has verified the nodes but before the installation workflow has begun
postecoreconfigure	`configure.sh` has run for MapR Core but before MapR Core has been started
postecoconfigure	Ecosystem components are configured and started
postinstall	The cluster is completely installed and running (at the end of the Installer Stage2 playbook)

last-updated: Apr 11, 2022

Here is an example role structure:

```
preinstall
   tasks
      main.yml
postcoreconfigure
   tasks
      main.yml
   vars
      main.yml
```

The uploaded tarball must contain relative path names with just the top-level role directories, and the tarball structure must adhere to the Ansible role-structure rules. If you need to configure your own roles in the tarball, you must include them as sub-roles to be run from within the pre-defined roles. For more information, see Ansible Roles.

Note: Because MapR Installer maintenance updates only update MapR Core and do not change any configuration settings on the cluster, the MapR Installer handles them differently from other operations. This means that whenever you perform a maintenance update, the Installer does *not* run the postecoconfigure and postinstall playbooks during the maintenance update.

Example Playbook Files

This example shows a preinstall task that installs the Midnight Commander application on all nodes in the cluster before the MapR Installer workflow is initiated. The example is contained in the `preinstall/tasks/main.yml` file:

```
---
- name: Install misc stuff - Midnight commander
  vars:
    packages_Suse: ['mc']
    packages_RedHat: ['mc', 'lsof']
    # syslinux-utils is for gethostip, libpython is required for collectd
    packages_Debian: ['mc']

  package: name={{ item }} state=present
  with_items: "{{ vars['packages_' + ansible_os_family] }}"
```

The following example shows the `postcoreconfigure/tasks/main.yml` file for the previous role structure. This example sets the number of RPC threads in `mfs.conf` from the current setting to 4 threads. The variable used to point to the file is defined in `postcoreconfigure/vars/main.yml`:

```
---
- debug: var=mapr_home

- name: Bump MFS RPC threads
  lineinfile:
    path: "{{ mapr_conf_dir }}/mfs.conf"
    regexp: '^(?P<threads>mfs.numrpcthreads=).*$'
    line: '\g<threads>4'
    backrefs: yes
```

This example shows the contents of the variables file (`postcoreconfigure/vars/main.yml`):

```
---
mapr_conf_dir: "{{ mapr_home }}/conf"
```

last-updated: Apr 11, 2022

Testing the Roles

Before uploading your zipped archive, develop and test your role files outside the installer using the standalone Ansible 2.7 debugger. You cannot use the Ansible debugger from within the MapR Installer. For more information, see Playbook Debugger.

Testing the roles by running them using the MapR Installer can be time-consuming. If a role contains logic errors, these errors won't be visible until the playbook is initiated. For example, a postinstall playbook that you run during a new installation does not generate an error until the installation is completed. A new installation can take 20 minutes or more, depending on the cluster size. Therefore, you can avoid having to re-run the Installer and playbook by testing the roles for logic errors before using them.

You can run the playbook debugger from the Installer node by using the `virt_runner` program in the`/opt/mapr/installer/bin/` directory. Use this command:

```
virt_runner ansible-playbook -i, -k <Playbook-file-name>
```

When you run the playbook in this fashion, you do not have access to the variables (for example, `mapr_home`) that the Installer defines. So you must set those up manually.

Creating the Zipped Archive

To create the zipped archive, you can use a tool such as 7-Zip or Linux commands. The following example uses the Linux `tar` command to create an archive of the directory structure and the `gzip` command to zip the archive.

Before using the `tar` command, change the directory to the directory in which you created the role structure. For example, if you created the role structure in the `/tmp` directory, you must issue the `tar` command from the `/tmp` directory:

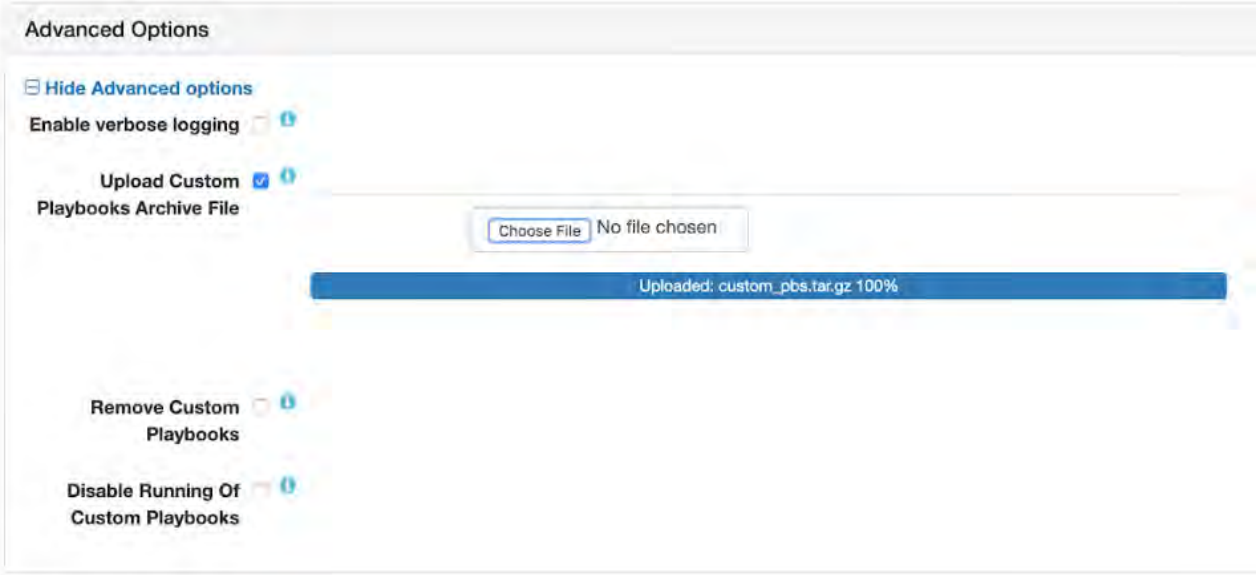
```
tar -cvf /tmp/custom_pbs.tar .
./
./preinstall/
./preinstall/tasks/
./preinstall/tasks/main.yml
./postcoreconfigure/
./postcoreconfigure/tasks/
./postcoreconfigure/tasks/main.yml
./postcoreconfigure/vars/
./postcoreconfigure/vars/main.yml
gzip /tmp/custom_pbs.tar
```

The `gzip` command creates a `custom_pbs.tar.gz` file in the `/tmp` directory. If you are using the MapR Installer, move the zipped file to the node hosting your browser so that you can upload it using the MapR Installer upload option.

Installer Options for Custom Playbooks

In the MapR Installer, the custom playbook options appear on the **Version & Services** page under **Advanced Options**. The following screen shows the options that are visible when a playbooks archive file has been uploaded:

last-updated: Apr 11, 2022



To use the options, you select an option and then advance through the Installer menus to complete the Installer task. You can access these options from the following MapR Installer tasks:

- Install
- Incremental Install
- Upgrade Version
- Maintenance Update

Whichever option you select, the Installer obeys the option *every time* you use the Installer for any operation. Therefore, if you select the option to upload a custom playbook, the Installer will run the playbook every time you use the Installer. If you select the option to disable playbooks, playbooks will be disabled until you select a different option. If a value has been set by a custom playbook and you run the same playbook again, the value is left unchanged.

Option	Description
Upload Custom Playbooks Archive File	Uploads a zipped TAR file for your custom playbook to `/opt/mapr/installer/data/tmp/custom_playbooks/`. The Installer displays the file name of the uploaded archive. An error is displayed if you upload a file that does not have a `tgz` or `tar.gz` file extension. The Installer allows you to upload one playbook at a time. If you upload a new playbook when another playbook is already loaded, the previously loaded playbook and its archive are removed, and the new playbook is loaded.
Remove Custom Playbooks	Removes the installed custom playbook and its archive from `/opt/mapr/installer/data/tmp/custom_playbooks/`. Both the playbook and the directory structure are removed.
Disable Running of Custom Playbooks	Enables you to run the MapR Installer or MapR Installer Stanzas on page 5503 *without* executing the uploaded custom playbook.

last-updated: Apr 11, 2022

MapR Installer Stanza Parameters for Custom Playbooks

To upload a custom playbook using a Stanza, specify the `cpbs_location` parameter followed by the path to the playbook in quotations. For example:

```
environment:
  mapr_core_version:6.1.0
  #DOC path to tar.gz archive of custom playbooks to be installed
  #DOC to remove the custom playbooks, provide an empty string
  #DOC for the filename, or remove cpbs_location all together
  cpbs_location: "/tmp/custom_plays.tar.gz"
```

To remove a custom playbook using a Stanza, specify an empty string for the file name:

```
environment:
  cpbs_location: ""
  ...
```

Or remove `cpbs_location` from the `environment` section.

To disable a custom playbook without removing it, set the `custom_pbs_disable` parameter to `true`

```
config:
  #DOC flag to indicate if you want to skip running of installed custom
playbooks
  custom_pbs_disable: true
```

Troubleshooting Custom Playbook Errors

The MapR Installer loads the custom roles and reports any syntax errors at execution time. The failure of a custom role causes a failure in the Installer operation. If a role has a syntax error, the MapR Installer can show an error like this:

> **Tip:** To view node details in the right pane of the **Installing MapR** screen, you need to select a red node icon on the left.

If the node detail indicates a custom playbook hook error, refer to the Installer Log for more information. Click **Support > View Installer Log**. For example:

last-updated: Apr 11, 2022

(Clicking the node log provides limited information for syntax errors.) For more information about the MapR Installer logs, see Logs for the MapR Installer on page 5453.

Using the Retry Button

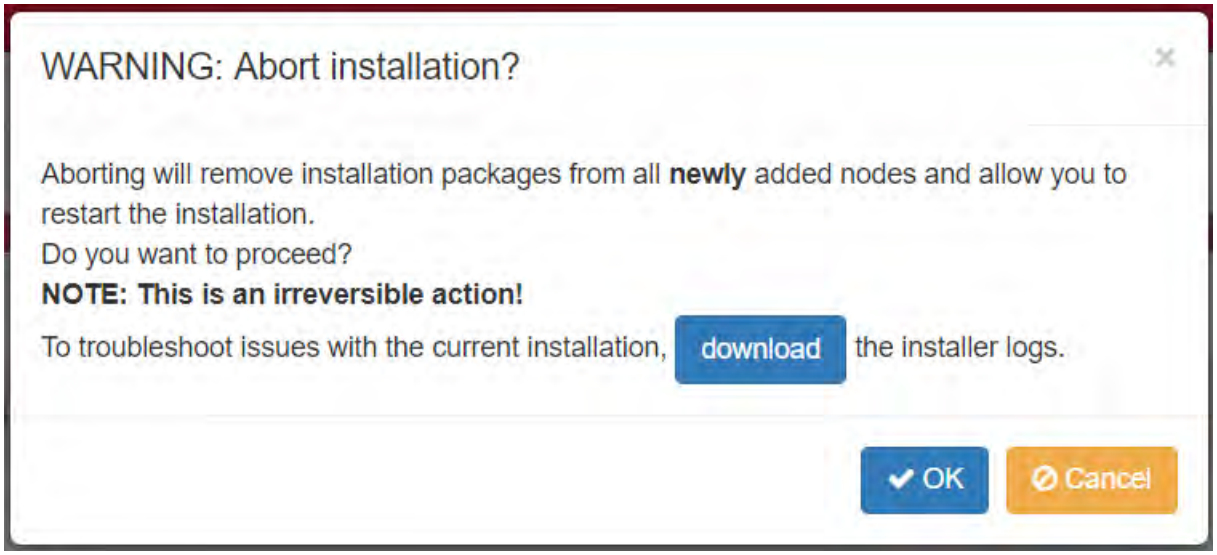
You have several options for fixing the issue. You can fix any problems by logging on to the Installer node and making changes directly in the playbook files located at `/opt/mapr/installer/data/custom_playbooks`. Then click the **Retry** button in the MapR Installer GUI interface. If you use this method, note that you must eventually propagate any fixes to your original tarball if you want to reuse the tarball.

Using the Abort Installation Button

Another option is to abort the installation and repeat the operation after fixing the error and uploading a corrected playbook. Before using this option, it is important to know that using **Abort Installation** does not remove changes made to the Installer database during the operation that you aborted. After an abort, the Installer can display the desired state rather than the actual state of the nodes.

For example, if you attempted to upgrade a EEP from EEP 6.1.0 to EEP 6.2.0 and then aborted the operation, the MapR Installer can display the currently installed EEP as EEP 6.2.0 even though EEP 6.2.0 has not been installed on the cluster nodes. This condition persists until you rerun the upgrade operation successfully or revert to the last known cluster state by using **Support > Import State**. See Importing or Exporting the Cluster State.

To abort the operation and start over, click **Abort Installation**. A confirmation dialog appears:



Click **OK** to return to the Installer home page. Fix the playbook error and retry the operation.

Extending a Cluster by Adding Nodes
This section describes how to add capacity to a MapR cluster by adding nodes.

You add nodes to a cluster by using the web-based MapR Installer (version 1.6 or later) or MapR Installer Stanzas. The nodes are added to a pre-existing group *online* without disturbing the running cluster. You can add nodes to on-premise clusters or to cloud-based clusters.

Important: After completing these steps, if you added a node to a group containing a CLDB or ZooKeeper, you must also perform the Post-Expansion Steps for Extending a Cluster on page 5442.

You can add multiple nodes to a group in the same operation, and you can add nodes to custom groups. You can also add the same node to multiple groups. The MapR Installer installs the new nodes with the same patch level as the existing nodes.

Note: Before adding nodes, use the MapR Installer to ensure that your cluster uses three-digit EEPs. If your cluster uses two-digit EEPs, adding a node can result in a version mismatch between the cluster and the newly added node. To change from two-digit to three-digit EEPs you can perform an **Incremental Install** using the MapR Installer. For more information, see Understanding Two-Digit and Three-Digit EEPs on page 5450.

Restrictions

Note these restrictions for using the **Extend Cluster** operation. When adding nodes:

- The cluster must already be installed before nodes can be added.
- You cannot add a node to a MASTER group, since these services can run only on one node.
- If you add a node to a CONTROL group that has a CLDB, you must do a manual, rolling restart of the entire cluster.
- If you add a node to a group that has OpenTSDB, you must add the same node to the group that contains AsyncHBase (currently, the MapR Installer does not check to ensure that this dependency is met).
- You cannot add services.
- You cannot change the EEP version or MapR Core version.
- You cannot add new service groups.

last-updated: Apr 11, 2022

- New nodes are added automatically to the DEFAULT group.
- A node added to a MapR secure cluster will be configured for security automatically. If the cluster is custom secure, you cannot use the MapRInstaller. See Customizing Security in MapR on page 1474.

Before Adding Nodes

1. Determine the group(s) to which new nodes will be added.
   You can add nodes to the following types of groups:
   - CLIENT
   - DATA
   - CONTROL
   - MULTI_MASTER
   - MONITORING_MASTER

   Note: If you add a node to a group containing a CLDB, you must restart all the nodes except for the new node. If you add a node to a group containing Zookeeper (but not CLDB), you must restart Zookeeper on all the Zookeeper nodes except for the new node. And you must restart the lead Zookeeper last.

   To gather information about groups, see Getting Information About Services and Groups on page 5512.
2. Ensure that the node(s) to be added meet the installation prerequisites described in the MapR Installer Prerequisites and Guidelines on page 5396.

Adding Nodes Using the MapR Installer Web Interface

1. Use a browser to connect to the cluster using the MapR Installer URL:

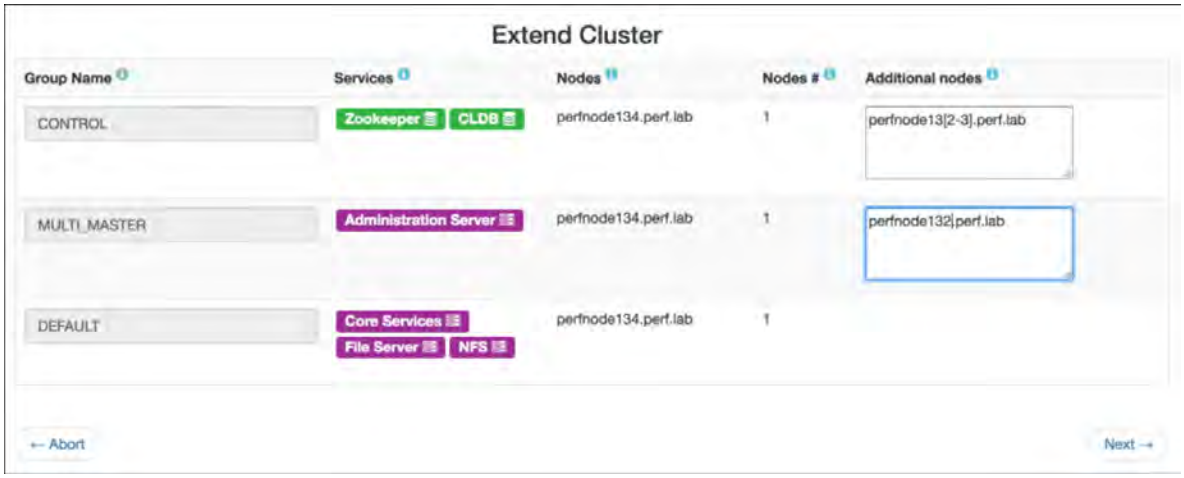
   ```
   https://<Installer Node hostname/IPaddress>:9443
   ```

2. On the status screen, click the **Extend Cluster** button. The MapR Installer displays the **Extend Cluster** screen showing the currently configured groups and services.

   Note: If the **Extend Cluster** button is not visible, you might need to clear your browser cache and refresh the browser page.
3. Specify the nodes to be added:
   - **On-Premise Cluster**

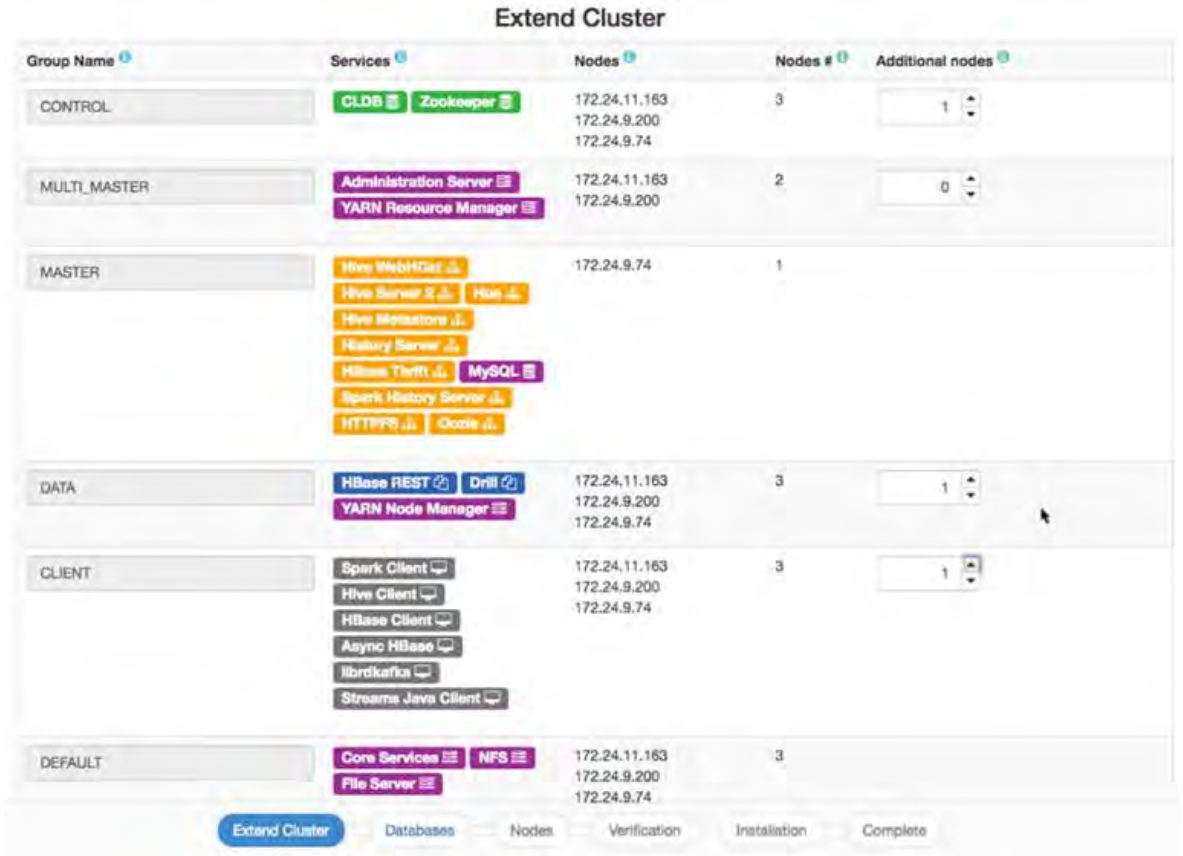
     In the **Additional Nodes** column, specify the host name(s) or IP address(es) of the nodes to be added. If you are adding multiple nodes, you can specify an array. The following example adds *perfnode132.perf.lab* and *perfnode133.perf.lab* to the CONTROL group and *perfnode132.perf.lab* to the MULTI_MASTER group:

last-updated: Apr 11, 2022



- **Cloud-Based Cluster**

  In the **Additional Nodes** column, specify the number of nodes to be added. You do not need to specify the host name or IP address. The following example adds a node to each of the CONTROL, DATA, and CLIENT groups:



4. Click **Next**. The MapR Installer checks the nodes to ensure that they are ready for installation and displays the **Authentication** screen.

last-updated: Apr 11, 2022

5. Enter your SSH password and other authentication information as needed, and click **Next**. The installer displays the **Verify Nodes** screen.

   Note: For a cloud-based cluster, the **Authentication** screen requests information that is specific to the type of cluster (AWS or Azure). Use the tooltips to learn more about the authentication information needed for your cluster.

6. Click a node icon to check the node status and see warnings or error information in the right pane. The node-icon color reflects the installation readiness for each node:
   - Green (ready to install)
   - Yellow (warning)
   - Red (cannot install)

   Note: If there are warnings or errors, hold your cursor over the warning or error in the right pane to see more information.

   Important: If node verification fails, try removing the node and retrying the operation. If node verification fails and you abort the installation, you must use the **Import State** command to reset the cluster to the last known state. Otherwise, you will not be able to perform subsequent MapR Installer operations. See Importing or Exporting the Cluster State on page 5447.

7. When you are satisfied that the nodes are ready to be installed, click **Next**. The MapR Installer adds the nodes. After the nodes are added, you can use the MapR Control System to view the nodes in the cluster.

8. Perform any post-expansion steps. Post-expansion steps are necessary only if you added a node to a group containing a CLDB or Zookeeper.

If you added a node to a group containing . . .	Do this
Zookeeper only	One node at a time, stop and restart the Zookeeper service on all Zookeeper nodes, restarting the master Zookeeper node last. You do not need to restart the Zookeeper node that was added. See Post-Expansion Steps for Extending a Cluster on page 5442.
Zookeeper and CLDB or CLDB only	One node at a time, restart all services on all nodes following the order prescribed in Manual Rolling Upgrade Description on page 319. You do not need to restart the node that was added. See Post-Expansion Steps for Extending a Cluster on page 5442.

Adding Nodes Using a MapR Installer Stanza

To add nodes using a MapR Installer Stanza, you add the `scaled_hosts2:` parameter (on-premise clusters) or the `scaled_count:` parameter (cloud-based clusters) to the Stanza file for the group that you want to scale. Then you run the Stanza using the `install` command. The services contained in the group are configured for the added node.

Note: If the group you are trying to scale does not contain the `mapr-core-5.2.x` service, the first group containing `mapr-core-5.2.x` will automatically get scaled.

1. In the Stanza file, add the `scaled_hosts2:` or `scaled_count:` parameter:

- **On-Premise Cluster**

  Add the `scaled_hosts2:` parameter to the group that you want to scale, specifying the host name(s) or IP address(s) of the nodes to be added. In the following example, the perfnode132.perf.lab node is added to the CLIENT group:

Stanza Before Scaling	Modified Stanza with scaled_hosts2 Parameter (On-Premise Cluster)

`groups:`
`- hosts:`
`  - perfnode131.perf.lab`
`  label: CLIENT`
`- services:`
`  - mapr-spark-client-2.0.1`
`  - mapr-hive-client-1.2`
`  - mapr-hbase-1.1`
`  - mapr-asynchbase-1.7.0`
`  - mapr-kafka-0.9.0`
	`groups:`
	`- hosts:`
	`  - perfnode131.perf.lab`
	`  label: CLIENT`
	`  scaled_hosts2:`
	`  - perfnode132.perf.lab`
	`- services:`
	`  - mapr-spark-client-2.0.1`
	`  - mapr-hive-client-1.2`
	`  - mapr-hbase-1.1`
	`  - mapr-asynchbase-1.7.0`
	`  - mapr-kafka-0.9.0`

- **Cloud-Based Cluster**

  Add the `scaled_count:` parameter to the group that you want to scale. Include a number after the parameter to indicate the number of additional nodes to be added to the group. You do not need to specify the host names or IP addresses of the nodes to be added. In the following example, one additional node is added to the CLIENT group:

Stanza Before Scaling	Modified Stanza with scaled_count Parameter (Cloud-Based Cluster)

`groups:`
`- hosts:`
`  - perfnode131.perf.lab`
`  label: CLIENT`
`- services:`
`  - mapr-spark-client-2.0.1`
`  - mapr-hive-client-1.2`
`  - mapr-hbase-1.1`
`  - mapr-asynchbase-1.7.0`
`  - mapr-kafka-0.9.0`
	`groups:`
	`- hosts:`
	`  - perfnode131.perf.lab`
	`  label: CLIENT`
	`  scaled_count: 1`
	`- services:`
	`  - mapr-spark-client-2.0.1`
	`  - mapr-hive-client-1.2`
	`  - mapr-hbase-1.1`
	`  - mapr-asynchbase-1.7.0`
	`  - mapr-kafka-0.9.0`

2. Run the Stanza file using the `install` command. See Installing or Upgrading MapR Core Using an Installer Stanza on page 5509. The MapR Installer SDK detects the new scaled_host(s) and gives you the option to proceed with the installation or cancel.

last-updated: Apr 11, 2022

3. Perform any post-expansion steps. Post-expansion steps are necessary only if you added a node to group containing a CLDB or Zookeeper.

If you added a node to a group containing . . .	Do this
Zookeeper only	One node at a time, stop and restart the Zookeeper service on all Zookeeper nodes, restarting the master Zookeeper node last. You do not need to restart the Zookeeper node that was added. See Post-Expansion Steps for Extending a Cluster on page 5442.
Zookeeper and CLDB or CLDB only	One node at a time, restart all services on all nodes following the order prescribed in Manual Rolling Upgrade Description on page 319. You do not need to restart the node that was added. See Post-Expansion Steps for Extending a Cluster on page 5442.

Post-Expansion Steps for Extending a Cluster
You must perform post-expansion steps if you added a node to a group containing the CLDB or Zookeeper.

For more information about extending a cluster, see Extending a Cluster by Adding Nodes on page 5437.
Restarting Zookeeper Nodes

If you used the MapR Installer **Extend Cluster** function to add a node to a group containing Zookeeper only, you must restart Zookeeper on all Zookeeper nodes except for the added node.

One node at a time, stop and restart the Zookeeper service on all Zookeeper nodes, restarting the primary Zookeeper node last. Use the following restart steps.

Restarting All Services for Zookeeper and CLDB

If you used the MapR Installer **Extend Cluster** function to add a node to a group containing Zookeeper and CLDB, or CLDB only, you must restart all services on all nodes.

One node at a time, restart all services on all nodes following the group upgrade order prescribed in Manual Rolling Upgrade Description on page 319. You do not need to restart the node that was added. Use the restart steps below.

Restart Steps

1. Change to the `root` user (or use `sudo` for the following commands).
2. Stop Warden.

```
sudo service mapr-warden stop
```

3. Stop Zookeeper.

```
service mapr-zookeeper stop
```

4. Start the ZooKeeper on nodes where it is installed.

```
service mapr-zookeeper start
```

5. On all nodes, start Warden. Example:

```
service mapr-warden start
```

6. Over a period of time (depending on the cluster size and other factors) the cluster comes up automatically. After the CLDB restarts, there is a 15-minute delay before replication resumes, in order to allow all nodes to register and heartbeat. This delay can be configured using the `config save` command to set the `cldb.replication.manager.start.mins` parameter.

Using the Incremental Install Function

Use the Incremental Install function of the web-based MapR Installer to control MapR security, add or upgrade services, upgrade MapR Ecosystem Packs (EEPs), and perform other maintenance functions.

Things You Can Do Using the Incremental Install

Using the Incremental Install function, you can:

- Enable or disable security by using the **Enable MapR Secure Cluster** option
- Add services that are supported for your current EEP
- Apply a patch
- Delete a service from a cluster by deselecting the service
- Upgrade the MapR Ecosystem Pack (EEP) to upgrade your services
- Change a 2-digit EEP to the equivalent 3-digit EEP (see Understanding Two-Digit and Three-Digit EEPs on page 5450)

Note: Before enabling security using the Incremental Install function, be sure to review the known issue (IN-1084) related to custom certificates. See MapR Installer Known Issues.

You cannot perform the following functions using an Incremental Install:

- Add a node to a cluster
- Delete a node from a cluster
- Upgrade the MapR Core version

Online Versus Offline Operations

Most **Incremental Install** operations are performed online. However, applying a patch or selecting or deselecting the **Enable MapR Secure Cluster** option are offline operations. See Using the Enable MapR Secure Cluster Option on page 5427. Making a change to security requires the MapR Installer to stop the Warden and Zookeeper services, bringing the cluster offline temporarily.

Using Incremental Install

1. Using a browser, log in to the MapR Installer:

   ```
   https://<Installer Node hostname/Ipaddress>:9443
   ```

2. Click the **Incremental Install** button. The **Version & Services** page appears.
3. Make the desired changes to add or remove security, add or delete services, apply a patch, or upgrade the EEP. Then click **Next**.
4. Advance through the MapR Installer screens, providing the admin password or other information as needed.
5. After the **Incremental Install** finishes, if you added services, use the Control System **Services** tab or the `maprcli service list -node` command to ensure that the services are running. If the services are not running, you might need to restart the nodes. For more information, see IN-1332 in MapR Installer Known Issues on page 5460.

last-updated: Apr 11, 2022

Enabling or Disabling Metrics Collection or Logging

You can use the MapR Installer to enable or disable metrics collection and logging during a new or incremental installation.

During installation using the MapR Installer, you can configure metrics and logging using settings on the **Monitoring** page of the MapR Installer user interface. Installing the metrics collection infrastructure is selected by default because the MapR Control System relies on these metrics to provide graphs and charts. Logging is deselected by default.

If you did not install metrics collection or logging during your initial installation, you can add it later by selecting the feature during an Incremental Install.

If you installed metrics collection or logging during your initial installation but you want to disable it, you can do so by deselecting the feature during an Incremental Install.

Note: If you do not install (or choose to uninstall) the metrics collection infrastructure, the MapR Control System cannot display graphs and charts.

Using the MapR Subnet and MapR External Advanced Options

Using the Installer advanced options available under Node Configuration, you can restrict the cluster to a subset of network interface cards (NICs) or specify public IP addresses that can be used with the cluster nodes.

Using these options in the Installer has the same effect as manually inserting the MAPR_SUBNETS and MAPR_EXTERNAL environment variables into the `env_override.sh` file on all nodes.

Attention: The MapR Installer does not validate the functionality of the subnets or IP addresses that you provide. If you provide incorrect values, it is possible for the installation to succeed initially and later develop connectivity issues. For this reason, it is critical that you supply accurate values for the Installer **MapR Subnet** and **MapR External** advanced options.

MapR Subnet

Allows you to set a subnet mask to restrict cluster services to certain interfaces. The values specified in this field are used to populate the MAPR_SUBNETS environment variable.

Specify one or more comma-separated subnet masks. For example:

```
10.10.15.0/24,10.10.16.0/24
```

The information on this page is specific to the web-based Installer. To configure the MAPR_SUBNETS environment variable for a manual installation, see Designating NICs for MapR on page 844.

MapR External

Allows you to specify external IP addresses for the CLDB, MapR File System, and MAST Gateway nodes.

Do NOT use DNS names. Specify a comma-separated list of tuples of host names and external IP addresses. For example:

```
node1:1.1.1.1,node2:1.1.1.2,node3:1.1.
1.3
```

The specified node names need to match the host name you specified for the host earlier in Node Configuration. The information on this page is specific to the web-based Installer. To configure the MAPR_SUBNETS environment variable for a manual

last-updated: Apr 11, 2022

installation, see Designating NICs for MapR on page 844.

Related reference

Environment Variables on page 2289
Describes the environment variables specific to the MapR Data Platform.

Related information

Designating NICs for MapR on page 844
Explains how to assign IP address blocks for MapR.

Online vs. Offline Operations

Most MapR Installer operations are offline operations, meaning that the cluster must be brought down in order to perform the operation. But there are some exceptions.

The following table shows which MapR Installer operations are offline and online:

Offline Operations	Online Operations
Upgrading MapR Core With the MapR Installer on page 308	Using the Incremental Install Function on page 5443*
Performing a Maintenance Update on page 5447	Extending a Cluster by Adding Nodes on page 5437**
Applying a Patch Using the MapR Installer on page 438	
Using the Enable MapR Secure Cluster Option on page 5427	

*Using the **Incremental Install** function to apply a patch or change security settings is an offline operation.

**Adding a node to a CONTROL group requires a manual, rolling restart of the entire cluster.

Starting Up a Cluster Using the MapR Installer Startup Button

You can use a single button to start MapR software on a cluster.

The **Startup** button is a feature of MapR Installer 1.8 or later. The **Startup** button appears on the status page of the MapR Installer web interface when the cluster is in the shutdown state. The **Startup** button starts Warden and Zookeeper, which in turn start other running services that are part of a MapR cluster.

Note: If the **Startup** button is not visible and the **Shutdown** button is present, the cluster is still running and is not in the shutdown state

The **Startup** button works differently depending on your cluster deployment:

Deployment	Startup Button Behavior
On premise	Starts the Zookeeper and Warden services on all nodes.
In the cloud	Starts the virtual machine nodes and then starts Zookeeper and Warden services on all nodes.

To use the **Startup** button:

1. For a cluster deployed in the cloud, use the AWS console or the Azure portal to ensure that the nodes are shut down before you try to start them.
2. Use a browser to connect to the cluster using the MapR Installer URL:

```
https://<Installer Node hostname/IPaddress>:9443
```

3. On the status screen, click the **Startup** button. The MapR Installer displays the **Authentication** screen.
4. Enter your authentication information if requested, and click **Startup**. The installer begins the startup process.
5. To shut down MapR software on the cluster, see Shutting Down a Cluster Using the MapR Installer Shutdown Button on page 5446.

Shutting Down a Cluster Using the MapR Installer Shutdown Button
You can use a single button to shut down MapR software on a cluster.

The **Shutdown** button appears on the status page of the MapR Installer web interface when you connect to an installed cluster using MapR Installer 1.6 or later. The **Shutdown** button shuts down Warden and Zookeeper, which in turn shut down other running services that are part of a MapR cluster. When you use the **Shutdown** button, the MapR Installer implements the same orderly shutdown used to perform software upgrades.

The **Shutdown** button works differently depending on where the cluster is deployed:

Deployment	Shutdown Button Behavior
On premise	Does not stop non-HPE software and does not power off the nodes.
In the cloud	Shuts down (but does not remove) all the nodes in the cluster: • If the installer node is part of the cluster, the installer node is not shut down, but Warden shuts down the services on the installer node. • To shut down the installer node, use AWS-console or Azure-portal commands to stop the instance. **CAUTION:** If a shutdown is initiated on an AWS cluster using an instance store, all data will be lost.

To use the **Shutdown** button:

1. Review Shutting Down a Cluster on page 795 for some pre-shutdown steps you may want to perform before shutting down Warden and Zookeeper.
2. Use a browser to connect to the cluster using the MapR Installer URL:

   ```
   https://<Installer Node hostname/IPaddress>:9443
   ```

3. On the status screen, click the **Shutdown** button. The MapR Installer asks you if you want to continue.
4. Click **OK**. The MapR Installer displays the **Authentication** screen.
5. Enter your authentication information if requested, and click **Shutdown**. The installer begins the shutdown process.
6. To restart MapR software on the cluster, see Starting Up a Cluster Using the MapR Installer Startup Button on page 5445.

   Note: Do not attempt to restart the cluster until you have confirmed that it is shut down. For an on-premise cluster, the presence of the **Startup** button on the MapR Installer status page indicates that the cluster is shut down and ready to be started. For a cluster deployed in the cloud, the **Startup** button must be present, *and* you must use the AWS or Azure console to verify that the servers are down before restarting.

Importing or Exporting the Cluster State

You can use the Import State and Export State commands to upload or download a YAML configuration file (a "Stanza") that describes the state of the cluster.

In the web-based MapR Installer, the **Import State** and **Export State** commands can be useful if you encounter a failure while using the installer and you want to revert to a previous cluster state. You can access these commands from the **Support** menu at the top of the MapR Installer user interface.

Import State	Opens the **Cluster State** dialog box, which enables you to reset the cluster to the last known state or to a desired state recorded in a YAML configuration file that you specify. You can use the **Import State** command at any time.
Export State	Downloads a YAML file capturing the current state of the cluster. You can use the **Export State** command at any time.

For more information about using MapR Installer Stanza files, see Installer Stanzas.

To import the cluster state, follow these steps:

1. Using a browser, log in to the MapR Installer:

   ```
   https://<Installer Node hostname/Ipaddress>:9443
   ```

   For more information about the MapR Installer, see MapR Installer on page 5395.

2. Click **Support > Import State**. The **Cluster State** dialog box appears.
3. Chose *one* of the following options:
   - Click **Reset** to revert the cluster to the last known state. (After a successful installation or Incremental Install using the MapR Installer or Stanzas, the last known state of the cluster is saved to `/opt/mapr/installer/data/last_known_state.yaml`.)
   - Click **Choose File**, select a YAML file, and then click **Reset** to load the YAML file.

To export the cluster state, follow these steps:

1. Using a browser, log in to the MapR Installer:

   ```
   https://<Installer Node hostname/Ipaddress>:9443
   ```

   For more information about the MapR Installer, see MapR Installer on page 5395.

2. Click **Support > Export State**.

   The cluster state is downloaded as `stanza.yaml`.

Performing a Maintenance Update

Perform a maintenance update when you want to upgrade to a new patch version of MapR core or apply a patch.

A maintenance update is an update to your installed MapR software that does not require configuration-file changes. Performing a maintenance update has no effect on the ecosystem packages (EEP components). You perform a maintenance update when you want to do either or both of the following:

- **Update to a new patch version of MapR core.** For example, you can perform a maintenance update to change your MapR core version from MapR 6.1.0 to MapR 6.1.1. You cannot use a maintenance update to change your MapR core version from a minor version, such as 6.1, to another minor version, such as 6.2. Use the **Version Upgrade** button for minor-version upgrades. The **Version Upgrade** button also permits an upgrade to a patch version of MapR core.

last-updated: Apr 11, 2022

- **Apply a patch.** The **Maintenance Update** page is one of several installer screens that offer the **Patch file** option. See Applying a Patch Using the MapR Installer on page 438.

You cannot perform a maintenance update if your current EEP version is incompatible with the selected MapR core version. For example, you cannot do a maintenance update from MapR 6.1.0 and EEP 6.3.0 to MapR 6.1.1 because EEP 6.3.0 is not compatible with MapR 6.1.1. For EEP and core compatibility information, see EEP Support and Lifecycle Status on page 5531.

Note: The maintenance update is an offline update (not a rolling update).

You perform a maintenance update using the MapR Installer. To perform a maintenance update:

1. Verify that your installed EEP is supported by the core version you plan to select for the maintenance update. To check your EEP version, see Checking the EEP Version on page 5413. For EEP and core compatibility information, see EEP Support and Lifecycle Status on page 5531.
2. Update the MapR Installer to the latest supported version. See Updating the MapR Installer on page 5409.
3. Prepare the cluster for a maintenance update by referring to one or both of these topics:
   - Preparing to Upgrade MapR Core on page 303
   - Verify Cluster Readiness for a Patch
4. Start the MapR Installer. For more information, see MapR Installer on page 5395.
5. Click the **Maintenance Update** button.
6. Change the MapR core version, or install a MapR core patch, or both.

   Important: During patch-file installation, do not refresh the browser page while the patch file is being uploaded. Doing so can interrupt the upload process.
7. Click **Next** to complete the update.

Related concepts

Checking the EEP Version on page 5413
Some MapR Installer operations require you to know the version of the currently installed MapR Ecosystem Pack (EEP). You can check the EEP version easily from within the MapR Installer user interface or derive the EEP version from your repository information.

MapR Installer Updates on page 5481
MapR Installer updates provide new features or bug fixes.

Auto-Provisioning Templates

Describes the MapR Installer auto-provisioning templates.

Auto-provisioning templates let you select from different provisioning options to address a range of computing requirements. Each template provides a different mix of services and capabilities. You can select the template you need when installing using the MapR Installer web-based interface, MapR Installer Stanzas, or a cloud marketplace offering.

MapR Installer 1.14 provided the following auto-provisioning templates:

last-updated: Apr 11, 2022

Template Names in MapR Installer and Azure Templates	Template Names in AWS Templates	Template Name for Stanzas	Description
MapR Data Platform: Batch, interactive and real-time analytics	MapR-Data-Platform	`template-05-converged`	Deploys YARN, MapR Database, MapR-Streams, Drill, and Spark.
Data Lake: Common Hadoop Services	Data-Lake	`template-10-hadoop`	Provides the most common services deployed in an Apache Hadoop cluster for getting started with a Hadoop data lake. Includes YARN, MapReduce, Spark, and Hive on top of the MapR Data Platform.
Data Exploration: Interactive SQL with Apache Drill	Data-Exploration	`template-20-drill`	Provides services needed for users to perform schema-free interactive exploration of their data, including the Apache Drill SQL engine and the Hive Metastore.
MapR Database (MapR-DB) for Analytics	MapR Database-Analytics	`template-30-maprdb`	Deploys the MapR distributed NoSQL database, providing both JSON and binary data models to enable analytic applications to perform in-situ data processing.
MapR Database for Operational Applications	MapR Database-Operational-Analytics	`template-30-maprdb2`	Deploys the MapR distributed NoSQL database, providing both JSON and binary data models to enable operational applications to read and write data at high rates.
MapR Database and Distributed Query Service for Operational Applications	MapR Database-DQS-Operational-Analytics	`template-30-maprdb3`	Deploys the MapR distributed NoSQL database, providing both JSON and binary data models to enable operational applications to read and write data at high rates. It also deploys Drill as distributed query service performant distributed query execution.
Real-time Analytics: Apache Spark Streaming including SparkML and GraphX	Real-Time-Analytics-with-Streams	`template-40-maprstreams`	Deploys Spark Streaming and MapR Streams for real-time streaming applications.
MapR XD Distributed File and Object Store (MapR XD)	(Not Available)	`template-60-maprxd`	Provides common services for MapR-XD (MapR Core, MapR-FS, NFS).
Real-time and batch analytics with Apache Spark on MapR including SparkML and GraphX	Real-Time-Analytics-with-Spark	`template-60-spark`	Deploys real-time and batch analytics with Apache Spark on MapR, including SparkML and GraphX.
Custom Services	Custom-Configuration	N/A	Selecting this template allows you to customize the services that are installed. No services are selected by default. For cloud installations, see Customizing Your Deployment by Using the MapR Installer Web Interface.

MapR Installer 1.10 Updates to the Auto-Provisioning Templates

The following templates were renamed in MapR Installer 1.10:

last-updated: Apr 11, 2022

Old Name (MapR Installer 1.9)	New Name (MapR Installer 1.10)
MapR Converged Cluster: Batch, interactive and real-time analytics	MapR Data Platform: Batch, interactive and real-time analytics
Analytics with MapR Database	MapR Database (MapR-DB) for Analytics
Operational Applications with MapR Database	MapR Database for Operational Applications
Operational Applications with MapR Database and Distributed Query Service	MapR Database and Distributed Query Service for Operational Applications
MapR XD: Cloud Scale Data Platform	MapR File System and Object Store (MapR XD)

For MapR Installer 1.10, these features were added to the MapR File System and Object Store (MapR XD) template:

- MAST Gateway
- NSFv4

MapR Installer 1.9 Updates to the Auto-Provisioning Templates

For MapR Installer 1.9, the following changes to the auto-provisioning templates were implemented:

- A new auto-provisioning template was added. The **Operational Applications with MapR Database and Distributed Query Service** template includes the MapR DataBase and the OJAI Distributed Query services.
- Other templates were changed to enable the use of Drill as an optional selection with the OJAI Distributed Query Service. The following table compares the contents of the various MapR Database templates:

Template	MapR-DataBase	OJAI Distributed Query Service*	Drill
MapR Converged Cluster: Batch, interactive and real-time analytics	Y	Y	Y
Analytics with MapR Database	Y	Y	Y
Operational Applications with MapR Database	Y	N	N
Operational Applications with MapR Database and Distributed Query Service	Y	Y	N

*Prior to MapR Installer 1.9, this service was called the OJAI Query Service.

Understanding Two-Digit and Three-Digit EEPs

Understanding the differences between the EEP directories on https://package.mapr.hpe.com/releases/MEP/ can help you prevent versioning issues.

To install or update a MapR Ecosystem Pack (EEP), either manually or by using the MapR Installer, you must first choose a EEP version. The EEP version that you choose has a corresponding subdirectory on https://package.mapr.hpe.com/releases/MEP/ from which the ecosystem packages are retrieved.

For each released EEP, the https://package.mapr.hpe.com/releases/MEP/ directory includes both two-digit and three-digit subdirectories:

last-updated: Apr 11, 2022

Index of /releases/MEP

Name	Last modified	Size	Description
Parent Directory		-	
MEP-1.0.0/	02-Sep-2016 20:26	-	
MEP-1.0/	02-Sep-2016 20:26	-	
MEP-1.1.0/	29-Sep-2016 03:18	-	
MEP-1.1.1/	13-Dec-2016 19:24	-	
MEP-1.1.2/	05-Apr-2017 21:25	-	
MEP-6.0.2/	28-May-2019 16:26	-	
MEP-6.0/	28-May-2019 16:26	-	
MEP-6.1.0/	22-Feb-2019 06:38	-	
MEP-6.1.1/	28-May-2019 15:55	-	
MEP-6.1/	28-May-2019 15:55	-	
MEP-6.2.0/	14-Aug-2019 19:30	-	
MEP-6.2/	14-Aug-2019 19:30	-	
MEP-6.3.0/	13-Dec-2019 00:12	-	
MEP-6.3.1/	17-Sep-2020 08:44	-	
MEP-6.3.2/	02-Feb-2021 05:35	-	
MEP-6.3.3/	23-Mar-2021 20:49	-	
MEP-6.3.4/	01-Jun-2021 16:04	-	
MEP-6.3/	01-Jun-2021 16:04	-	
MEP-7.0.0/	17-Sep-2020 07:51	-	
MEP-7.0.1/	02-Feb-2021 05:37	-	
MEP-7.0/	02-Feb-2021 05:37	-	
MEP-7.1.0/	01-Jun-2021 16:08	-	
MEP-7.1/	01-Jun-2021 16:08	-	

The following table compares the two-digit and three-digit subdirectories and describes how they are used:

last-updated: Apr 11, 2022

EEP Subdirectory	Example	Continuously Updated?	Description
Two-digit	`MEP-3.0/`	Yes	Subdirectories using two digits (for example, MEP-3.0) contain the latest EEP and patches and are continuously updated. For example, if you select EEP 3.0 when using the MapR Installer, the installer installs or upgrades your cluster with the packages from the most current version of EEP 3.0.x. If the most current version is EEP 3.0.1, EEP 3.0.1 is installed. If the most current version is EEP 3.0.2, EEP 3.0.2 is installed, and so on. If you later decide to make changes to the cluster, the MapR Installer applies the packages from the most current version, which can be different from the version you installed originally. Two-digit EEP version numbers make new patches available automatically without the need for system reconfiguration.
Three-digit	`MEP-3.0.0/`	No	Subdirectories using three digits contain a fixed EEP version, including patches, and are not continuously updated. For example, if you select EEP 3.0.0 when using the MapR Installer, the installer uses the packages from the MEP-3.0.0 subdirectory and continues to use the MEP-3.0.0 subdirectory until you change the specified EEP version. Three-digit EEP version numbers ensure that your cluster uses only the specified EEP version. They are best for users who install MapR software manually and do not require automatic updates.

MapR Installer Use of Two-Digit and Three-Digit EEPs

MapR Installer version 1.5 automatically uses two-digit EEPs. MapR Installer versions 1.6 and later use three-digit EEP versions and do not allow you to select two-digit EEPs.

Upgrades from MapR Installer 1.5 to 1.6 or later

If you upgrade the MapR Installer from version 1.5 to a later version, you see both two-digit and three-digit EEPs in the EEP drop-down list for an Incremental Install. The two-digit EEPs continue to operate as they did previously, installing the latest three-digit EEP with the same first two digits. The three-digit EEPs operate as described earlier on this page. MapR Installer version 1.7 displays and supports only three-digit EEPs.

Note: If your cluster uses two-digit EEPs, MapR recommends that you upgrade to three-digit EEPs as soon as it is convenient to do so. Doing so enables you to use new features such as the "Extend Cluster" feature without introducing EEP version inconsistencies. You can upgrade by performing an Incremental Install and selecting a three-digit EEP.

Related concepts

MapR Installer Updates on page 5481
MapR Installer updates provide new features or bug fixes.

Related tasks

Checking the MapR Installer Version on page 5412
Some MapR Installer features require you to use the latest version of the Installer. You can check the MapR Installer version easily from within the user interface.

Uninstalling Software Using the MapR Installer Uninstall Button

You can use a single button to uninstall MapR software on all nodes in the cluster.

last-updated: Apr 11, 2022

The **Uninstall** button appears on the status page of the MapR Installer web interface when you connect to an installed cluster. The **Uninstall** button removes MapR software (but does not remove the MapR Installer) from all nodes in the cluster.

Note: You can also use MapR Installer Stanzas to uninstall software. See Uninstalling MapR Core Using an Installer Stanza on page 5511.

To use the **Uninstall** button:

1. Use a browser to connect to the cluster using the MapR Installer URL:

   ```
   https://<Installer Node hostname/IPaddress>:9443
   ```

2. On the status screen, click the **Uninstall** button. The MapR Installer displays the **Uninstall** screen.
3. Enter your SSH password and other authentication information as needed, and click **Next**. The installer begins the uninstall process.

Installer Troubleshooting

This section describes how to identify and solve problems when you use the MapR Installer.

Logs for the MapR Installer

This topic describes the logs generated by the MapR Installer and MapR Installer Stanzas.

MapR Installer logs are written to the following folder: `/opt/mapr/installer/logs`.

The following list describes each log:

`<nodename>.log[.x]`	Shows installation activities associated with a particular node. Every time you run the MapR Installer or a MapR Installer Stanza, a new copy of this log is created for each node in the cluster. When you encounter errors, you should check this log first, and then check the `mapr-installer.log`. The node log is created only if the software was able to run Ansible successfully on the node. If incorrect credentials were provided for the root user, or if there was an issue and Ansible quit before issuing the first logging callback, no log file is created for the node. If this happens, you must consult `mapr-installer.log`.
`installer.log[.x]`	Logs the REST calls sent to the installer and the database events that the installer runs. Every time you run the MapR Installer or a MapR Installer Stanza, a new copy of this log is created. If the log is not present, you might need to restart the installer (`service mapr-installer restart`).
`installer-cli.log[.x]`	Shows the progress of installation for a MapR Installer Stanza. Every time you run a MapR Installer Stanza, a new copy of this log is created.
`installer-process.log`	Serves as the top-level log file for the Ansible part of the installer. This log is created by the main Python script that runs the installer backend. This log typically shows the same information as `mapr-installer.log`.
`mapr-installer.log[.x]`	Shows the progress of Ansible scripts performed by the installer server. This log is useful if back-end issues prevent the creation of `<nodename>.log`.

last-updated: Apr 11, 2022

Every time you run the MapR Installer or a MapR Installer Stanza, a new copy of this log is created.

Creating an Archive of MapR Installer Logs
This topic describes how you can create a .zip archive of the logs generated by the MapR Installer and MapR Installer Stanzas. The .zip archive is a handy way to share log information with HPE support personnel.

To create a .zip archive of all the installer logs, use one of these commands:

- From the MapR Installer web-based interface, click **Support > Download Installer Logs**.
- From a browser, specify the following URL. When prompted, supply the user name and password for the MapR Installer:

```
https://<host_name>:9443/api/process/installer.zip
```

- From a terminal, specify the following syntax:

```
wget --no-check-certificate
https://mapr:mapr@<host_name>:9443/api/process/installer.zip
```

For information about MapR Installer logs, see Logs for the MapR Installer.

Using Service Verification
The service verification feature provides an easy way to verify that services on all nodes in the cluster are running and functional.

Important: Service verification is not currently implemented for all services. Support for additional services will be added in subsequent releases.

For secure or non-secure clusters, you can run the service verification feature from the Installer user interface. Service verification is useful after a new installation. For example, service verification can detect whether all services have successfully joined a cluster. You can run a service verification any time after the cluster is installed to check the general health of services on all nodes.

Before Using Service Verification

Before you can use the service verification feature:

- The cluster must be installed, and you must have installed it by using the Installer or Installer Stanzas.
- Ensure that the Installer is up to date. Service verification is supported only on Installer versions 1.15.0.0 and later.
- Service verification can only be performed from the Installer node. The Installer node is the node where you run the Installer.
- Running service verification requires `root`-user access (or sudoer access to `root`) for remote authentication. (When you perform service verification, the Installer node must ssh into each of the cluster nodes.)

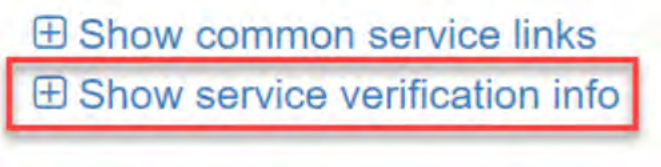
Performing Service Verification Using the Installer User Interface

To perform service verification from the Installer user interface:

1. On the Installer node, use a browser to navigate to the Installer home page, and log on as the cluster admin:

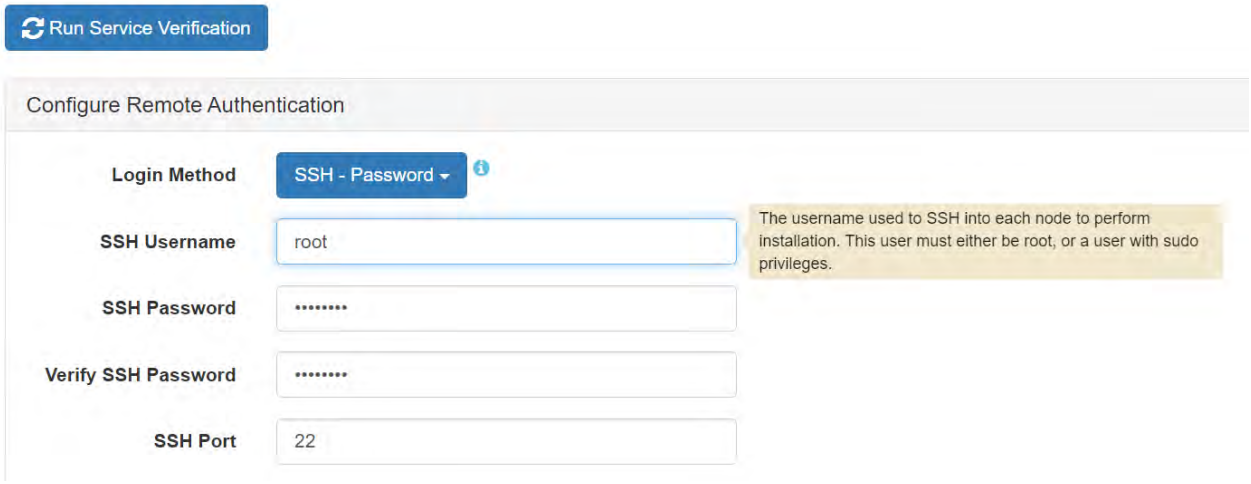
```
https://<Installer Node hostname/IPaddress>:9443
```

2. Scroll down until you see the following links:



3. Click the **Show service verification info** link to display the list of services and nodes.

4. Click **Run Service Verification** to start the verification. The Installer prompts for the `root` user password:



5. Enter the `root` user credentials, and click **Run Service Verification**. Verification can take anywhere from a few seconds to several minutes, depending on the size of the cluster, the network, and other attributes that affect performance. When the verification activity is complete, the Installer shows a list of

last-updated: Apr 11, 2022

services with the verification output for each service. For example:

Service Name			
Apiserver	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_INSTALLED
CLDB	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_IMPLEMENTED
Collectd	VERIFIED	VERIFIED	VERIFIED
Data Access Gateway	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_INSTALLED
File Server	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_IMPLEMENTED
Gateway	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_INSTALLED
Grafana	RUNNING_NOT_RESPONDING	RUNNING_NOT_RESPONDING	NOT_INSTALLED
HBase Client	RUNNING_NOT_RESPONDING	RUNNING_NOT_RESPONDING	RUNNING_NOT_RESPONDING
HBase Thrift	NOT_INSTALLED	NOT_INSTALLED	NOT_IMPLEMENTED
History Server	NOT_INSTALLED	NOT_INSTALLED	NOT_IMPLEMENTED
Apache Kafka Java Client	RUNNING_NOT_RESPONDING	RUNNING_NOT_RESPONDING	RUNNING_NOT_RESPONDING
Apache Kafka REST API	NOT_RUNNING	NOT_RUNNING	NOT_RUNNING
Mastgateway	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_IMPLEMENTED
YARN Node Manager	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_IMPLEMENTED
Oozie	NOT_INSTALLED	NOT_INSTALLED	NOT_RUNNING
OpenTSDB	VERIFIED	VERIFIED	VERIFIED
YARN Resource Manager	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_INSTALLED
Spark History Server	NOT_INSTALLED	NOT_INSTALLED	NOT_IMPLEMENTED
Spark Thrift Server	NOT_INSTALLED	NOT_INSTALLED	NOT_IMPLEMENTED
Zookeeper	NOT_IMPLEMENTED	NOT_IMPLEMENTED	NOT_IMPLEMENTED

Possible values are:

- FAILED_TO_EXECUTE
- NOT_IMPLEMENTED
- NOT_INSTALLED
- NOT_RUNNING
- NOT_STARTED
- RUNNING_NOT_RESPONDING
- VERIFIED

6. To rerun service verification – for example, after running it once and discovering some services are not responding – click **Run Service Verification** again.

Service Verification Logs

On each node where a service is installed, logged output from the service verification feature is saved to:

```
$MAPR_HOME/<service>/<service>-<version>/var/log/<service>/
verify_service.<date>
```

For example, service verification output for OpenTSDB might be found here:

```
# pwd
/opt/mapr/opentsdb/opentsdb-2.4.0/var/log/opentsdb
```

```
# ls
metrics_tmp                     ot_purgeData.log-20210414.gz
opentsdb_daemon.log             ot_purgeData.log-20210415.gz
opentsdb.err                    ot_purgeData.log-20210416.gz

```

Possible return codes for the log output are:

- 0 – running and responding to a simple interaction test
- 1 – not running

- 2 – running but not responding to a simple interaction test
- 3 – not started*

*From Warden's point of view, the service is enabled, but Warden has not started it yet.

Related concepts

Updating the MapR Installer on page 5409
Update the MapR Installer to include the latest MapR ecosystem packages and installer fixes. Once you update the MapR Installer, you can install ecosystem components and software versions that were made available after you first configured the MapR Installer.

MapR Installer Prerequisites and Guidelines on page 5396
The node on which you run the MapR installer and the nodes you plan to include in your MapR cluster must meet certain user, connectivity, and security requirements.

Starting and Stopping the Installer

Describes how and when you need to shut down and restart the Installer.

It is seldom necessary to shut down and restart the Installer, but you might need to do so in the following scenarios:

- You are troubleshooting an Installer issue, and stopping and restarting the Installer might resolve the issue.
- You need to upgrade the OS for a node.
- You want to run the Installer node in FIPS-compliant mode, and you cannot leave the Installer running because the Installer is not FIPS compliant.

Checking the Installer Status

When you are not sure if the Installer is running, use the following command to check the status:

```
systemctl status mapr-installer
```

Starting and Restarting the Installer

To start or restart the Installer (requires `root` authentication):

```
systemctl start mapr-installer
```

Stopping the Installer

Note that if you stop the Installer while an installation is in progress, any passwords that you provided to the Installer user interface are lost. The Installer retains password information in memory and not in the Installer database. If you then restart the Installer to continue the installation, the installation fails. In this scenario, you must restart the Installer and the Installer user interface and re-enter the password information to resume the installation.

To stop the Installer (requires `root` authentication):

```
systemctl stop mapr-installer
```

Related concepts

Resetting the Installer Database on page 5459
The `reset` command uninstalls the metadata from the Installer database. `reset` is for advanced users.

Related tasks

Starting Up a Cluster Using the MapR Installer Startup Button on page 5445
You can use a single button to start MapR software on a cluster.

Shutting Down a Cluster Using the MapR Installer Shutdown Button on page 5446
You can use a single button to shut down MapR software on a cluster.

Resetting the Installer Database

The `reset` command uninstalls the metadata from the Installer database. `reset` is for advanced users.

You can reset the Installer database by using the CLI `reset` command or by using the MapR Installer web interface (**Support > Reset Installer**).

The reset function can be useful for testing purposes, but use reset with caution. If you reset the installer database while packages are installed on the nodes, you will need to remove the packages manually.

Note: If you experience a failure while installing or uninstalling, the installer prompts you to retry the operation or uninstall and then reinstall from scratch. You should always retry or uninstall before considering using `reset`.

This example resets the Installer database. The `-nv` option specifies that certfificates will not be checked and the output mode is verbose:

```
./bin/mapr-installer-cli reset -nv
```

Troubleshooting Repository URL Errors

This page describes how to troubleshoot an issue in which an incorrect repository URL is stored in the MapR Installer `properties.json` file.

How Repository URL Errors Can Occur

The `properties.json` file stores information such as the user ID of the cluster administrator, the user ID of the MapR Installer, the OS type, Internet access information, and the repository URL. Once the repository URL has been stored in `properties.json`, the MapR Installer assumes that the URL will not change.

If you run `mapr-setup.sh -r <url>` and you make a mistake when typing the URL, the incorrect URL is added into the MapR Installer `properties.json` file. If you later run `mapr-setup.sh -r <url>` again but with the correct URL, the `properties.json` is not updated. Even upgrading the installer packages does not update the repository URL in `properties.json`.

Some versions of the MapR Installer generate a warning if you try to correct the URL by running `mapr-setup.sh -r <url>` again, but older versions of the MapR Installer do not generate a warning. Whether or not a warning is generated, you can correct the issue, but how you do so depends on the version of the MapR Installer that is installed.

Fix Using MapR Installer 1.10 or Later

MapR Installer 1.10 and later versions generate a warning if you run `mapr-setup.sh -r <url>` and provide a new URL. The warning describes two ways to change the URL currently stored in the `properties.json` file:

- You can use the `reload` or `remove` command, and then specify a new URL:

last-updated: Apr 11, 2022

1. Use *one* of the following commands:

   ```
   bash /tmp/mapr-setup.sh -R <new_url> reload
   ```

   or

   ```
   bash /tmp/mapr-setup.sh remove
   ```

   Using the `remove` command removes `properties.json`, the installer database, and the installer packages, but not the setup script.

2. Specify the new URL:

   ```
   bash /tmp/mapr-setup.sh -r <new_url>
   ```

- You can manually edit the `properties.json` file:

  1. Edit the `properties.json` file to specify the new URL:

     ```
     edit /opt/mapr/installer/data/properties.json
     ```

  2. Reload the MapR Installer:

     ```
     systemctl restart mapr-installer
     ```

Fix Using MapR Installer 1.9 or Earlier

MapR Installer 1.9 and earlier do NOT generate a warning if you run `mapr-setup.sh -r <url>` and provide a new URL. To pass a new repository value into `properties.json` for MapR Installer versions 1.9 or earlier, you must first remove the installer files:

```
mapr-setup.sh remove
```

Using the `remove` command removes `properties.json`, the installer database, and the installer packages, but not the setup script. After the files are removed, you can rerun `mapr-setup.sh` to specify the new repository URL:

```
bash /tmp/mapr-setup.sh -r <new_url>
```

To run `mapr-setup.sh`, see MapR Installer. For information about options you can use with `mapr-setup.sh`, see Using mapr-setup.sh.

MapR Installer Known Issues

This topic describes some MapR Installer known issues that you should be aware of while troubleshooting.

If you are viewing this page from within the Installer application, click here to display the information in a browser.

IN-3016	On Installer 1.16 and earlier, clicking **Abort** during the **Extend Cluster** operation returns you to the verification page and does not reset the Installer database back to its initial state. (Note that on Installer 1.17 and later, clicking **Abort** resets the Installer database automatically so that you can retry the operation.)

last-updated: Apr 11, 2022

Workaround: On Installer 1.16 and earlier, use these steps to reset the Installer database manually and retry the **Extend Cluster** operation:

1. Click **Support > Reset Installer**. This command uninstalls the metadata from the Installer database. For more information, see Resetting the Installer Database on page 5459.
2. Click **Support > Import State**. The **Cluster State** dialog box appears, enabling you to reset the cluster to the last known state. For more information, see Importing or Exporting the Cluster State on page 5447.
3. Click **Reset** to recover the Installer to the last known state and return to the Installer home page.
4. If necessary, retry the **Extend Cluster** operation.

IN-3007

During a multinode installation of core 6.2 on SLES 15 SP2, the Installer returns the following error:

```
 "msg": "user {{ ssh_id }} does
not have the ability to elevate
privileges - check for correct
sudoers config for example"
```

This issue can occur when Python is not installed on all cluster nodes.

Workaround: Check to ensure that Python is installed on all cluster nodes. Install Python, if it is not already installed.

IN-2924

Upon restart, cluster nodes running Loopback NFS do not remount `/mapr`. This issue can occur when using Installer 1.16.0.0 to perform a new or incremental installation. The issue is caused by a missing symlink.

Workaround: Manually create a symlink from `/usr/local/mapr-loopbacknfs/conf/mapr_fstab` to `/opt/mapr/conf/mapr_fstab`, and use the following commands to restart NFS and mount `/mapr`:

1. Restart the Loopback NFS service:

   ```
   maprcli node services -nodes <node
   names> -nfs restart
   ```

2. Run the `mount_local_fs.pl` script to mount `/mapr`:

   ```
   /opt/mapr/bin/mount_local_fs.pl
   ```

IN-2397

The Verify phase of the Installer can fail if the `authorized_keys` file contains a command such as the following:

```
no-port-forwarding,no-agent-forwarding
,no-X11-forwarding,command="echo
```

last-updated: Apr 11, 2022

```
'Please login as the user \"admin\"
rather than the user
\"root\".';echo;sleep 10" ssh-rsa ...
```

Any command in the `authorized_keys` file prevents the Installer from authenticating with remote nodes.

Workaround: Verify that the `authorized_keys` file does not contain commands that prevent the Installer from authenticating with remote nodes. In addition, if you are using keys for remote authentication, you must ensure that you can ssh into all nodes in the cluster using the user and password that you specified when you configured remote authentication.

IN-2500

After a new installation, the Installer home page displays two YARN ResourceManager links, but one of the links does not work.

Workaround: This is normal. Click the YARN ResourceManager links until you find the link that works. Even if the ResourceManager is installed on multiple nodes, the YARN ResourceManager only has one server running at a time, . If the running ResourceManager fails, a new ResourceManager is started on one of the other nodes.

IN-2705

If you used the Installer to install Sentry on an insecure cluster, you must manually add Sentry to the list of services that Warden monitors. To add Sentry to the list of services that Warden monitors, copy `/opt/mapr/sentry/sentry-<version>/conf.d/warden.sentry.conf` to `/opt/mapr/conf/conf.d`.

Neither Hive nor Impala is configured to use Sentry by default; however, you can configure Hive and Impala to use Sentry, as described in Configure Hive to use Sentry Authorization on page 3830 and Configure Impala to Use Sentry Authorization on page 3825

SPYG-1136

During a manual installation or upgrade, Collectd provided in core 6.1.0 won't start on RHEL / CentOS 8.2 because it expects the Python 2 libraries to be installed, and RHEL / CentOS 8.2 provides the Python 3 libraries instead. This issue does not affect installations or upgrades performed using the Installer.

Workaround: Before installing the monitoring components, check to see if Python 2 is installed. If the following error is generated, try installing Python 2 on RHEL / CentOS 8.2:

```
failed: libpython2.7.so.1.0: cannot
open shared object file
```

IN-2637

After a manual installation, Oozie and Hive services can fail to connect to a MySQL or MariaDB database because the server time-zone value is unrecognized or represents more than one time zone. The issue affects your installation if you applied the `mapr-patch` released on or after February 21, 2021 (including the latest `mapr-patch`). This issue affects manual installations but is fixed in Installer 1.14.0.0.

Workaround: For manual installations, you must configure either the server or JDBC driver (using the `serverTimezone` configuration property) to use a more specific time-zone value if you want to utilize time-zone support. After running `configure.sh` but before starting the Oozie or Hive services, update the `serverTimezone` parameter in the `hive-site.xml` or `oozie-site.xml`. For more information, see MySQL Bug #95036.

IN-2935

On RHEL or CentOS 8.3, new installations using the Installer can fail with the following error message:

```
mount.nfs: access denied by server
while mounting localhost:/mapr
```

This happens when the Installer cannot start the `mapr-loopbacknfs` service because the RHEL or CentOS NFS/NFS4 service is running.

Workaround: Edit the `/etc/systemd/system/mapr-loopbacknfs.service` file to add the following Conflicts directive to the `nfs-mountd.service`:

```
[Unit]
Description=MapR Technologies, Inc.
loopbacknfs service
After=rc-local.service
After=network.target syslog.target
Conflicts=nfs-mountd.service
```

The `Conflicts` command stops `nfs-mountd` before installation so it cannot interfere with starting `mapr-loopbacknfs`. After editing the `loopbacknfs.service` file, perform a daemon reload using the following command, and then retry the installation:

```
systemctl daemon-reload
```

IN-2947

For Installer 1.16.0 on Ubuntu 18.04, the **Extend Cluster** operation fails for clusters larger than three nodes. The operation fails on nodes where ZooKeeper is not installed. The failure occurs because the Installer attempts to update the ZooKeeper service file on a node that has no roles file for ZooKeeper.

Workaround: Make sure ZooKeeper is running on every node in the cluster, and retry the **Extend Cluster** operation.

ES-77, FLUD-55

During an upgrade from EEP 6.x to EEP 7.0.0 or EEP 7.0.1, some monitoring components do not get updated because of an error in the fourth digit of the package version. This issue can occur during manual upgrades or upgrades performed using the Installer. The affected components can include any or all of the following:

- Elasticsearch

last-updated: Apr 11, 2022

- Fluentd
- Grafana
- Kibana

Workaround: See Reinstalling Monitoring Components After an Upgrade in the data-fabric documentation.

IN-1976

During a version upgrade from core 6.0.1 and EEP 5.0.x to a later version of core, the upgrade succeeds, but the following error message is generated:

```
This version of Kibana requires
Elasticsearch v6.2.3 on all
nodes. I found the following
incompatible nodes in your
cluster: v5.4.1 @ 10.10.103.231:9200
(10.10.103.231), v5.4.1 @
10.10.102.21:9200 (10.10.102.21), v5.4.1
@ 10.10.103.230:9200 (10.10.103.230)
```

This happens because the Elasticsearch package script does not remove Elasticsearch completely and does not shut it down. Even though a new version of Elasticsearch is installed, the old version is still running and using the port needed by the new version.

Workaround:

1. Use the `jps` command to find the process for the old Elasticsearch.
2. Use `kill -9` to shut down the old Elasticsearch process. Warden will restart the newly installed Elasticsearch.

IN-2742

A `configure.sh` operation can hang because of a system control hang if you try to install on top of a "minimal" operating system installation and the RDMA RPM or service is not present. This issue can occur during manual installations or during installations using the Installer.

Workaround: Before running `configure.sh`, use one of the following workarounds:

Workaround #1 - Install the missing RDMA Dependencies

- **RHEL / CentOS**
  1. Install `libibverbs`:

     ```
     yum
     install
     libibverbs
     ```

2. Enable and start the RDMA service:

```
systemctl enable rdma && systemctl start rdma
```

3. Retry the MapR Data Platform installation.

- **Ubuntu 18**
  1. Install the `rdma-core` package:

```
apt-get install rdma-core
```

  2. Install `libibverbs1`:

```
apt-get install libibverbs1
```

  3. Enable and start the RDMA service:

```
systemctl enable iwpmd && systemctl start iwpmd
```

  4. Retry the installation.

- **Ubuntu 16**

  Release 6.2 does not provide RDMA support for Ubuntu 16 because Ubuntu 16 does not have the `rdma-core` package.

last-updated: Apr 11, 2022

Workaround #2 - Disable RDMA Support	**1.** Rename `/opt/mapr/lib/libibverbs.so`. For example: `mv /opt/mapr/lib/libibverbs.so /opt/mapr/libibverbs.so.sv` **2.** Restart the ZooKeeper and Warden nodes.
Workaround #3 - Install the Latest Core Patch	The latest patch contains the `export MAPR_RDMA_SUPPORT=false` environment variable, which removes RDMA support. For patch information, see "Downloading a Patch" in the data-fabric documentation.
IN-2784 & MFS-11853	Stopping a cluster by stopping ZooKeeper and Warden can cause clients that are accessing the file system through POSIX (for example, the S3 gateway) to hang if Loopback NFS is installed on a cluster node and is not stopped first. Note that beginning with Installer 1.15, the Installer installs Loopback NFS on all cluster nodes unless NFS is enabled. **Workaround:** If Loopback NFS is running and you need to stop the cluster, you must first unmount `/mapr` and stop Loopback NFS on all nodes. Then, you can stop ZooKeeper and Warden. For more information, see "Managing the mapr-loopbacknfs Service" in the data-fabric documentation.
IN-1343	In a new installation of six nodes or more using the MapR Installer, if only data nodes fail to install, retrying the installation can fail. **Workaround:** Use the MapR Installer uninstall feature, and retry the installation from scratch. See "Uninstalling Software Using the Installer Uninstall Button" in the data-fabric documentation.
IN-2132	On a SLES cluster, using MapR Installer version 1.10 or earlier of the `mapr-setup.sh` script can complete successfully even if sshpass is not installed. **Workaround:** Upgrade to the latest MapR Installer. You must use version 1.11 or later of the `mapr-setup.sh` script. If you cannot use MapR Installer version 1.11 or later of the `mapr-setup.sh` script, install sshpass before running the `mapr-setup.sh` script on a SLES cluster.

IN-2008

When you upgrade from a secure MapR 6.0.0 cluster to MapR 6.0.1 using MapR Installer 1.9, a security certificate for log monitoring is overwritten. As a result, Elasticsearch can fail to start after the upgrade. This issue is not present during a new installation of MapR 6.0.0 or MapR 6.0.1 or during an upgrade to MapR 6.1.0. This issue is fixed in MapR Installer 1.10 and later.

Workaround: To resolve the issue, you must remove the `.keystore_password` file, re-run the command to generate new Elasticsearch certificates, and then re-distribute the certificates. Use these steps:

1. Remove or rename the `.keystore_password` file. For example:

   ```
   rm /opt/mapr/elasticsearch/
   elasticsearch-x.x.x/etc/
   elasticsearch/.keystore_password
   ```

2. Perform steps 3 through 7 of "Step 9: Install Log Monitoring" in the data-fabric documentation. Completing steps 3 through 7 regenerates the Elasticsearch certificates and copies them to the other nodes.

IN-2443

An internal server error that includes a NullPointerException can be generated if you install a cluster on Ubuntu 16 using a MapR Installer Stanza. The error appears if Hive is installed but no password for Hive is included in the `.yaml` installation file.

Workaround: Add the Hive password to the `.yaml` installation file and re-run the Stanza.

IN-18

When using the `-v` or `--verbose` options with MapR Installer Stanzas, detailed error information is not provided on the command line. For example, if a `mapr` user or group is not present on a host during a new installation, the `mapr-installer-cli` reports "Verification Error" on the command line.

Workaround: To view more detailed error information when using the `-v` or `--verbose` options, check the `installer-cli.log[.x]` file after running the Stanza. For information about the MapR Installer logs, see "Logs for the Installer" in the data-fabric documentation.

IN-2200

Deploying a release 6.0.1 cluster on AWS fails when the following parameters are specified:

- `diskType: io1`
- `installerOnitsOwn: false`

Workaround: Try using a `diskType` of `gp2` (general-purpose SSD) instead of `io1` (provisioned IOPs SSD), or set `InstallerOnitsOwn` to `false` instead of `true`. Then retry the deployment.

IN-2152

During a MapR Installer upgrade from any release to MapR 6.0.1, core files can be generated for ecosystem components, which can cause alarms in

last-updated: Apr 11, 2022

	the MapR Control System following the upgrade. This happens because the upgrade sequence shuts down the cluster, then upgrades MapR Core packages, and then restarts MapR Core. Restarting MapR Core is necessary to upgrade some ecosystem components. When the old ecosystem components are started, version incompatibilities with the new version of MapR Core can cause core dumps. This is a temporary issue. Upgrading the ecosystem component, which happens later in the upgrade process, resolves the issue. The issue does not exist in MapR 6.1 and later releases, which have the ability to prevent services from restarting during an upgrade. **Workaround:** Ignore the Control System alarms, or upgrade to MapR 6.1 or later, which should not generate core alarms.
IN-1940	In MapR Installer versions 1.9 and earlier, the `probe` command can fail because of a runtime error if you have installed the Operational Applications with MapR Database template. The error is caused by the presence of the `mapr-drill-internal` package. Any node running the MapR Data Access Gateway requires the `mapr-drill-internal` package to be installed even though Drill is not installed as a service. The `mapr-drill-internal` package provides a set of client libraries used by the MapR Data Access Gateway. **Workaround:** Before using the `probe` command, update the Installer. The `probe` command is fixed in versions 1.10 and later.
IN-1635	In MapR Installer Stanza versions 1.9 and earlier, the `probe` command was hard coded with a cluster admin user of `mapr`. If you configured a cluster admin user other than `mapr`, the `probe`-generated YAML file could not be imported using the `import` command. **Workaround:** Before using the `probe` command, update the Installer to version 1.10 or later. Or, if you must use version 1.9 or earlier, edit the `probe`-generated YAML file to specify the correct cluster admin user.
IN-2123	In a secure cluster, the **Extend Cluster** operation fails if you try to extend the control group. The new control node cannot join the cluster because it inadvertently receives a new set of keys. This issue affects versions 1.7 through 1.10 of the MapR Installer and is fixed in MapR Installer 1.10.0.201812181130 and later versions. **Workaround:** You can resolve the issue by manually copying mapruserticket into the `/opt/mapr/conf` directory of the node to be added to the cluster.
IN-2141	The following issue applies to MapR Installer versions 1.7 through 1.10, but not all 1.10 versions. The issue is fixed in MapR Installer 1.10.0.201812181130 and later versions. An extend cluster (add node) operation can fail when you:

1. Install a MapR 6.x cluster manually with security enabled.
2. Run the MapR Installer Stanza `probe` command on the cluster or on a node to be added to the cluster.
3. Use the `import` command to import the `probe` .yaml file into the Installer.
4. Perform an extend cluster operation immediately after the `import` operation.

The extend cluster operation fails because keystore, truststore, and MapR server ticket (`maprserverticket`) files are not present on the installer node.

Workaround:

Before attempting the extend cluster operation, copy the keystore, truststore, and MapR server ticket (`maprserverticket`) files from any CLDB node to `/opt/mapr/installer/data/tmp` on the installer node. The files that need to be copied are:

- `cldb.key`
- `dare.master.key*`
- `maprserverticket`
- `ssl_keystore`
- `ssl_keystore.p12`
- `ssl_keystore.pem`
- `ssl_truststore`
- `ssl_truststore.p12`
- `ssl_truststore.pem`

*The DARE primary key is required only if DARE is enabled.

If metrics monitoring is configured on the cluster, you must also copy the tickets related to Fluentd, Kibana, and Elasticsearch to the same location.

IN-2217

During an upgrade to EEP 6.1.0 using the MapR Installer, the MapR Installer does not back up the Drill `conf`, `log`, and `jar` directories into `${MAPR_HOME}/drill/OLD_DRILL_VERSIONS`. This can happen when you upgrade Drill from an old version (for example, Drill 1.10 in EEP 3.0) to Drill 1.15.0.0 in EEP 6.1.0.

Recent packaging changes in Drill contribute to this issue. Drill 1.10 consists only of `mapr-drill-1.10` (role and binaries), whereas Drill 1.15.0.0 consists of `mapr-drill-1.15` (roles) and `mapr-drill-internal-1.15` (binaries). During the upgrade, the `mapr-drill-1.10` binaries are successfully uninstalled, but the

last-updated: Apr 11, 2022

OLD_DRILL_VERSIONS directory that is needed to back up Drill 1.10 is not created.

Workaround:

Before upgrading, perform the following steps:

1. Shut down the `mapr-drill-1.10` Drillbits.

```
maprcli node services -name
drill-bits -action stop -nodes
<node hostnames separated by a
space>
```

2. Create `${MAPR_HOME}/drill/OLD_DRILL_VERSIONS/drill-1.10`.
3. Copy the following directories of `mapr-drill-1.10` into the `OLD_DRILL_VERSIONS` directory:
   a. Copy the `conf` directory to `${MAPR_HOME}/drill/OLD_DRILL_VERSIONS/drill-1.10.0/conf`.
   b. Copy the `logs` directory to `${MAPR_HOME}/drill/OLD_DRILL_VERSIONS/drill-1.10.0/logs`.
   c. Copy the `jars/3rdparty` directory to `${MAPR_HOME}/drill/OLD_DRILL_VERSIONS/drill-1.10.0/jars`.
4. Proceed with the upgrade.
5. After successfully upgrading and starting `mapr-drill-1.15.0.0`, you may remove the `${MAPR_HOME}/drill/drill-1.10.0` directory.

IN-1915

During an upgrade using the MapR Installer, refreshing the browser page can cause the Installer to forget upgrade parameters that were specified before the refresh.

Workaround: Avoid refreshing the browser page during an upgrade operation. If you must refresh the page, go back to the first page of the upgrade operation and start over again to ensure that the Installer has the correct parameters before it begins the Verify phase of the upgrade.

IN-2035

During a version upgrade using the MapR Installer, if you select the **Advanced Configuration** button and then click **Previous** (one or more times) followed by **Abort**, the Installer can indicate that the upgrade completed even though the upgrade was aborted.

Workaround:

If this happens, you must reset the installer and reload the last known state. Follow these steps to reset the cluster state:

last-updated: Apr 11, 2022

1. Click **Support > Reset Installer**. A warning screen appears.
2. Click **OK**.
3. Click **Support > Import State**.
4. Click **Reset** to recover the cluster to the last known state. It is safe to retry the upgrade at this point.

For more information about the **Reset Installer** and **Import State** commands, see "Resetting the Installer Database" and "Importing or Exporting the Cluster State" in the data-fabric documentation.

IN-2065

`/mapr` sometimes does not get mounted after you enable NFS (v3 or v4) using the MapR Installer Incremental Install function. The Incremental Install function is an online operation. Enabling NFS using an Incremental Install can create a race condition between when the `mapr_fstab` file gets created and NFS is started by Warden. If NFS is started by Warden before the `mapr_fstab` file is created, `/mapr` does not get mounted.

Workaround:

If `/mapr` is not mounted, check the time stamp of the `/opt/mapr/conf/mapr_fstab` file to see if it is older than the time stamp in the `warden.log` file for starting NFS. For example:

```
[root@atsqa4-61 logs]# ls -ld /opt/
mapr/conf/fstab
rw-rr- 1 mapr mapr 39 Sep 26
11:31 /opt/mapr/conf/mapr_fstab

[root@atsqa4-61 logs]# fgrep starting
warden.log | fgrep nfs
2018-09-26 11:29:33,407 INFO
com.mapr.warden.service.baseservice.Se
rvice
[Thread-34]: -------------Service is
starting for: nfs4
```

If the time stamp of the `mapr_fstab` file is older than the Warden time stamp:

1. Restart the NFS service:

   ```
   maprcli node services -nodes <node
   names> -nfs4 start
   ```

2. Run the `mount_local_fs.pl` script to mount `/mapr`:

   ```
   /opt/mapr/bin/mount_local_fs.pl
   ```

INFO-420

The procedure for configuring storage using `disksetup` does not work for new installations of DARE-enabled MapR 6.1 clusters. With DARE

enabled, `disksetup` fails on any node that is not a CLDB node because there is no local copy of the `dare.master.key` file. When you use disksetup, non-CLDB nodes try to contact the CLDB, which must be running when the nodes attempt contact.

Workaround:

After running `configure.sh`, you must:

1. Format the disks on the CLDB nodes.
2. Start ZooKeeper on the ZooKeeper nodes.
3. Start Warden on the CLDB nodes.
4. Format the remaining node disks using `disksetup`.
5. Start Warden on the remaining nodes.

IN-2057

A fresh install of MapR 6.0.0 using the `sample_advanced.yaml` file for MapR Installer Stanzas (Installer version 1.9) can fail with the following error message:

```
ERROR: install command failed
Service mapr-data-access-gateway must
be a member of a template group.
Configured services require it:
['mapr-data-access-gateway']
```

The error is generated because the `.yaml` file is missing an entry for the `mapr-data-access-gateway` in the MASTER services section. The `mapr-data-access-gateway` service is needed for MapR Database installations.

Workaround:

In the MASTER services section of the `sample_advanced.yaml` file, add `mapr-data-access-gateway` to at least one of the host groups, and retry the installation.

IN-1272

During an upgrade to MapR 6.0 or later (Drill 1.11), `configure.sh` sometimes fails to disable the storage plugin for HBase. The HBase server is not supported in MapR Core 6.0 or later, so the HBase storage plugin should be disabled before a cluster is upgraded to MapR 6.0 or later. Otherwise, Drill queries against HBase will hang.

Workaround:

Before upgrading to Drill 1.11 or later, manually disable the HBase storage plug-in. To manually disable the plug-in, you can use the Drill Web Console or Drill REST API commands. You can disable the HBase storage plugin on the **Storage** page of the Drill Web

last-updated: Apr 11, 2022

Console at `http(s)://<drill-hostname>:8047`. For more information, see this page:

```
https://drill.apache.org/docs/
rest-api-introduction/#delete-/
storage/{name}.json
```

IN-1747

If you use the MapR Installer 1.10 **Uninstall** button to uninstall MapR software and a node is unreachable, you will not be able to uninstall the node later when the node is reachable.

Workaround:

Uninstall the MapR software on the node manually. See "Decommissioning a Node and Uninstalling Data Fabric Software from the Command-line" in the data-fabric documentation.

IN-2015

A fresh install of MapR 6.0.0 with EEP 4.1.1 using MapR Installer 1.9 can fail with the following error message:

```
file not found: /opt/mapr/
elasticsearch/elasticsearch-5.4.1/etc/
elasticsearch/sg/
admin-usr-clientCombo.pem
```

Workaround: Update the Installer to version 1.10 or later, and retry the operation.

IN-2018

Logging on to Kibana results in an authentication failure. This can happen on a CentOS cluster if you use MapR Installer 1.10 to install MapR 6.0.1 EEP 5.0.0, and then upgrade to MapR 6.1.0 and EEP 6.0.0.

Workaround: Try using MapR Installer 1.9 to install the MapR 6.0.1 cluster and MapR Installer 1.10 to upgrade the cluster. See "Updating the Installer" in the data-fabric documentation.

CORE-150

After using the **Incremental Install** function of the MapR Installer to apply security to an Azure-based MapR 6.1.0 cluster, the Hue and Spark-thrift server links are not accessible in the Installer interface. This issue can occur on an Azure-provisioned cluster whose internal DNS suffix starts with a number rather than a letter.

Workaround: Re-create the cluster in Azure so that the internal DNS suffix starts with a letter and not a number.

IN-2025

The **Extend Cluster** operation can fail during the **Verify Nodes** phase with an error indicating `Unscalable host groups found`. This error can occur when the MASTER group is missing or a single-instance service (for example, Grafana) has been moved out of the MASTER group. The `mapr-installer.log` reveals which cluster services are supposed to be in the MASTER group.

Workaround: Move any original MASTER services that caused the error back to the MASTER group. The `mapr-installer.log` indicates the services

last-updated: Apr 11, 2022

	that need to be moved along with the `Unscalable host groups found` error.
IN-2006	On a cluster with `mapr-drill` installed, the `probe` command can return the wrong database type value. **Workaround:** After using the `probe` command, check to see if the resulting YAML file has the correct `mapr_db` setting. Possible settings are: • `QS` • `DRILL` • `DRILLQS` If necessary, change the setting in the YAML file to match the value from the probed cluster.
IN-1955	If you install cluster software using the MapR Installer in a browser and then upgrade the MapR installer in the same browser tab and attempt an upgrade without starting a new browser, the stale browser cache can cause upgrade errors. **Workaround:** Clear your browser cache or open a new browser tab whenever you need to update the MapR Installer and perform a new installer operation.
IN-1983	After an upgrade from release 5.x to release 6.1 and EEP 6.0.0 using the MapR Installer, the `kafka-connect` service fails to start. This issue has been noticed on platforms that use `systemd`. **Workaround:** Stop the `kafka-connect` service manually, and restart the service.
IN-1972	During an upgrade from release 5.x to release 6.1, the MapR Installer prompts you for the MySQL user ID and password. If you enter a password that is different from the password you provided when you originally configured MySQL through the MapR Installer, the upgrade fails with this error: "Unable to connect to database.…" **Workaround:** When the MapR Installer prompts you for the MySQL user ID and password, enter the password that you specified when you first installed the cluster. If you did not specify a password for MySQL when you installed release 5.x, leave the password field blank.
IN-1904	If you initiate a system startup by clicking the **Startup** button on the Installer web interface, the **Authentication** screen is displayed. If you subsequently click the **Previous** button, the following buttons are shown as active even though they are not usable during system startup: • Extend Cluster • Incremental Install • Maintenance Update

last-updated: Apr 11, 2022

- Shutdown
- Uninstall

Workaround: Do not use the **Previous** button during startup.

IN-1657

After updating the Installer 1.7 or later, the Installer can lose awareness that a cluster was previously installed. For example, the MapR Installer might indicate the need for a fresh install.

Workaround: If this happens, do NOT proceed with installation or upgrade operations. Follow these steps to reset the cluster state:

1. Click **Support > Reset Installer**. A warning screen appears.
2. Click **OK**.
3. Click **Support > Import State**.
4. Click **Reset** to recover the cluster to the last known state. It is safe to use the Installer at this point.

IN-1804

For release 6.0 or later clusters, enabling security by using the Incremental Install function can overwrite custom certificates in the `ssl_truststore` and `ssl_keystore` files. When you turn on security, the MapR Installer runs the `configure.sh` script on the CLDB primary node to generate security keys and then distributes the keys to all the other CLDB nodes. The installer also distributes certificates to all the other nodes. This process can cause custom certificates to be overwritten. However, before enabling security, the MapR Installer makes a backup of the existing `ssl_keystore` and `ssl_truststore` files.

Workaround:

After enabling security, locate the backup of the `ssl_keystore` and `ssl_truststore` files. The backup uses this format:

```
/opt/mapr/conf/
ssl_keystore.sv.<timestamp>
```

Extract any custom certificates from the backup files, and manually merge or add them into the new `ssl_keystore` and `ssl_truststore` files.

To merge the files, you can use the `/opt/mapr/server/manageSSLKeys.sh` utility, as shown in "Configuring Secure Clusters for Running Commands Remotely" in the data-fabric documentation.

IN-997

When using MapR Installer 1.9 with Ubuntu distributions, an upgrade of the MapR Installer definitions requires a restart of the installer service. The restart is needed because the MapR Installer services version is not updated properly when you use either of the following commands:

last-updated: Apr 11, 2022

- `mapr-setup.sh reload`
- `apt-get install mapr-installer-definitions`

Workaround: After installing or reloading the MapR Installer definitions, issue one of these commands to fix the services version:

- `service mapr-installer restart`
- `systemctl restart mapr-installer`

IN-1671

For MapR Installer 1.8 and earlier, installation on Ubuntu 16.04 can fail if Python 2 is not available or if the default is set to Python 3. The installer requires `python` and `python-yaml` to be installed on all nodes.

Workaround: To install the Python packages manually:

```
sudo apt-get install python
python-yaml -y
```

IN-1336

The MapR Installer **Retry** function can be affected if the installer operation fails. Suppose you deselect a service during an **Incremental Install** operation. If the **Incremental Install** fails and you need to **Retry**, it's possible that the service will not be deselected (uninstalled).

Workaround: Manually remove (uninstall) the service by using one of these commands:

- **Red Hat / CentOS:** `yum remove`
- **Ubuntu:** `apt-get remove`
- **SLES:** `zypper remove`

IN-1392

During an **Extend Cluster** (add node) operation using the MapR Installer, if installation of the added node fails and you abort the operation, the installer can display the added node even though it did not get installed.

Workaround: When the MapR Installer indicates that a node did not get added correctly (typically during the Installation phase), select the node and click **Remove Node**. Then retry adding the node.

IN-1396

An installation using the MapR Installer fails with the following Ansible module error:

```
nValueError: need more than 1 value
to unpack
```

Workaround: Check for syntax errors in the `/etc/sysctl.conf` file, which can cause an Ansible error when the MapR Installer is attempting to set various kernel parameters.

last-updated: Apr 11, 2022

IN-1398

In the MapR Installer **Verify Nodes** page, if you click a host, the **Disks Selected for MapR** box in the right pane displays the disks that were specified for the host either manually or automatically. If you deselect a disk in the right pane and click **Retry**, the deselection is not always implemented.

Workaround: Click **Previous** to go back to the **Node Configuration** page, and re-specify the disks that you want. Then continue with the operation.

IN-1386

On a secure MapR cluster, YARN jobs can fail if you specify IP addresses rather than host names when you configure nodes using the MapR Installer.

Workaround:

Do not use an IP address for node configuration with the MapR Installer. If you already used an IP address, change the IP address in the yarn-site.xml file on all nodes. In the following example, the 10.10.10.7 IP address must be changed to a host name, such as `bld73.qa.lab`:

```
<property>
<name>yarn.timeline-service.hostname</
name>
<value>10.10.10.73</value>
</property>
```

IN-1333

On Ubuntu clusters, the `mapr-setup.sh` script fails to reload the MapR Installer definitions during an update of the MapR installer and definitions.

Workaround: After updating, restart the installer to load the definitions:

```
service mapr-installer restart
```

IN-907

The MapR Installer service fails if the `mapr` user or `root` user already exist and they are configured to use a shell other than bash. For more information about user requirements, see "Installer Prerequisites and Guidelines" in the data-fabric documentation.

Workaround: Configure the users to use bash. For more information about user requirements, see "Installer Prerequisites and Guidelines" in the data-fabric documentation.

IN-1079

Verification fails when the installed language pack is for a language other than English.

Workaround: Remove the non-English language pack and install the English language pack. In the following example, the non-English language pack is shown as German. Also, make sure your system locale is set to `en_us`, as described in "Infrastructure" in the data-fabric documentation.

```
sudo apt-get install language-pack-en
language-pack-en-base manpages
sudo apt-get remove language-pack-de
language-pack-de-base manpages-de
```

last-updated: Apr 11, 2022

IN-804	Using the Incremental Install operation to add a third node to a CONTROL group generates an error: `ERROR: configure_refresh.sh failed`. This issue applies to MapR Installer versions 1.6 and earlier. **Workaround:** Update the MapR Installer to version 1.7 or later, and retry the operation. See "Updating the Installer" in the data-fabric documentation.
IN-1314	When you use the MapR Installer to install ecosystem components that require a MySQL component such as Hive, Oozie, or Hue, the passwords you provide to install the MySQL database are displayed in the `mapr-installer.log` and `<nodename>.log` files. Beginning with MapR Installer 1.7, the permissions for the `mapr-installer.log` and `<nodename>.log` files are changed so that these passwords are not world readable. However, the passwords are still present in log files created with earlier versions of the MapR Installer. **Workaround:** For increased security, remove the earlier logs or change the user permissions for them.
IN-1042	Installation of the 5.2.x `mapr-metrics` package on SLES 12 SP2 fails because the `libmysqulclient16` package is not present. This can happen when `mapr-metrics` is installed manually or using the MapR Installer. This issue was detected during installations of release 5.2.x with EEP 3.0.0. **Workaround:** None.
IN-870	If your cluster uses 2-digit EEPs, and you use the MapR Installer **Extend Cluster** button to add a node, the node can be added with a patch version that is different from the patch version of other nodes in the cluster. See "Understanding Two-Digit and Three-Digit MEPs" in the data-fabric documentation. **Workaround:** A one-time change can prevent this issue. After updating the MapR Installer from version 1.5 to version 1.6 or later, but before performing any MapR Installer operations, use an Incremental Install function to change your 2-digit EEP version to the equivalent 3-digit EEP version. See "Updating the Installer" in the data-fabric documentation.
ES-27, IN-1387	On a new installation of a secure cluster using the MapR Installer, Elasticsearch fails to start, and logs indicate that Elasticsearch key generation failed. When this happens, Kibana and Fluentd also do not start. The MapR Installer allows the installation to complete. **Workaround:** Check the installer log for a message indicating that Elasticsearch could not be secured. Use the **Incremental Install** feature of the MapR Installer to retry installation of the MapR Monitoring logging components. Alternatively, you can configure security for the logging components manually. See "Step 9: Install Log Monitoring" in the data-fabric documentation.
IN-1332	On clusters with less than the recommended memory configuration (16 GB per node), services added during an Incremental Install operation might fail to

start because Warden allocated available memory to the MapR filesystem. The MapR Installer might not indicate a problem with the newly added services. If this issue occurs, the MapR filesystem cannot relinquish memory without restarting Warden.

Note: This issue can also occur on clusters with more than 16 GB of memory per node if the installed services require more memory than is currently installed.

Workaround:

Use the Control System or the `maprcli service list -node` command to determine if the added services are running. If not, perform a rolling restart of the nodes to which the new services were added. The rolling restart will rebalance memory across the filesystem and services. One node at a time, restart Warden on each node following the group upgrade order prescribed in "Manual Rolling Upgrade Description" in the data-fabric documentation. Use the following steps:

1. Change to the `root` user (or use `sudo` for the following commands).
2. Stop Warden.

   ```
   sudo service mapr-warden stop
   ```

3. Restart Warden.

   ```
   service mapr-warden start
   ```

IN-1339

Installation fails with the Installer reporting an **Unexpected failure during module execution**, and the following entry is present in the "Logs for the Installer" described in the data-fabric documentation:

```
os.write(self.sshpass_pipe[1],
to_bytes(self._play_context.password)
+ b'\n')
OSError: [Errno 9] Bad file descriptor
```

Workaround: Change the ssh settings as described in known issue IN-405 later on this page, and retry the installation.

IN-553

New installations on Ubuntu 14.04 using MapR Installer 1.6 or 1.7 can fail because of a JDK 1.8 issue.

Workaround:

If you are installing on Ubuntu 14.04, you must install Java JDK 1.8 before running the MapR Installer. For more information, see this website. If you are installing on RHEL/CentOS or SLES, the MapR Installer installs Java JDK 1.8 for you.

IN-405

MapR installation or cluster import using the probe command fails with the error message:

last-updated: Apr 11, 2022

	"Failed to resolve remote temporary directory from ansible-tmp- ...." **Workaround:** To proceed using the MapR Installer, disable SSH connection reuse by including this entry underneath the `[ssh_connection]` property of `/opt/mapr/installer/etc/ansible.cfg`: `ssh_args=-o ControlMaster=no -o ControlPath=none -o ControlPersist=no` This workaround can lead to longer install times. We recommend that you resolve any network connectivity issues in your environment.
IN-250	An upgrade to a new MapR core version and a new EEP using the MapR Installer can fail if the cluster being upgraded was initially installed with Hive Metastore but not with Hive. The Hive Metastore package has an installation dependency on Hive, but the Hive Metastore definitions do not enforce the dependency, resulting in inconsistencies in the installer database. This issue has been observed on Ubuntu platforms. **Workaround:** Before upgrading, if you have Hive Metastore installed by itself, use the **Incremental Install** feature of the MapR Installer to install Hive. Then proceed with the upgrade. Performing an upgrade without doing the **Incremental Install** of Hive will cause the upgrade to fail. In this scenario, you will have to reinstall or rebuild the database by using Stanza commands. You can use the `reset` command, followed by `probe`, and then edit the versions in the resulting YAML file. The last step is to import the edited YAML using the `import` command. See "Using probe and import to Generate the Installer Database" in the data-fabric documentation.
N/A	The MapR Installer Web Interface can inadvertently deselect services that you have selected, preventing them from being installed. For example, if you select an auto-provisioning template on the **Select Services** page, and you also select additional services (for example, Streams Tools), and go to the next page, when you return to the **Select Services** page, Streams Tools will be deselected, and you will need to reselect it to ensure that it is installed. **Workaround:** Reselect any services that are deselected.
MAPR-20606	The Configure Service Layout page may assign services to a group with the name "Unprovisioned Services." **Workaround:** In the MapR Installer Web Interface, click **Restore Default**.
N/A	You cannot use the MapR Installer after you upgrade the cluster using the command line.

After you use the command line to upgrade a cluster that you installed with the MapR Installer, the MapR Installer is not aware that the cluster runs the upgraded version. Therefore, MapR Installer does not install nodes and ecosystem components that apply to the upgraded version.

Workaround: Use the MapR Installer Stanzas `probe` and `import` commands to update the installer database. See "Using probe and import to Generate the Installer Database" in the data-fabric documentation.

Changing Timeout Values to Resolve MapR Installer Errors
Change timeout values to reduce errors when using the MapR Installer.

Sometimes the MapR Installer can return errors because the maprcli or filesystem commands that it uses time out because of network latency. For example, if logs indicate that the installer could not obtain the nodelist, or a filesystem operation timed out, changing a timeout value can enable the same MapR Installer operation to succeed.

You can change the following timeout parameters to improve the success of MapR Installer operations:

Timeout	Description	Default Value (minutes)
`standard`	The timeout used for maprcli commands and Hadoop filesystem operations.	2
`configure`	The timeout used for `configure.sh` operations.	10

You must specify timeout values as an integer greater than or equal to 0.

To change the `standard` or `configure` timeout values:

1. On the MapR Installer node, navigate to the following directory:

   ```
   /opt/mapr/installer/ansible/playbooks/group_vars/
   ```

2. Edit the `all` file to change one or both timeout values to a number greater than or equal to 0. In this example, the timeouts are set to 7 minutes and 15 minutes respectively:

   ```
   timeout:
     standard: 7
     configure: 15
   ```

3. If a MapR Installer error prompted you to change the timeout, retry the operation that failed.

Installer Release Notes

This release of the MapR Installer works with RedHat/CentOS, Ubuntu, and SLES.

The MapR Installer consists of the following packages along with the `mapr-setup.sh` script:

- **MapR Installer** - Package that contains the MapR Installer.
- **MapR Installer Definitions** - Package that contains the list of MapR versions, services, and ecosystem components that you can install with the MapR Installer.

The release notes include the following sections:

MapR Installer Updates
MapR Installer updates provide new features or bug fixes.

The following table shows the MapR Installer new-feature updates by version:

Version	Updates
1.17.0.1.202201201546-1	This version: • Provides Log4j fixes. For more information, see advisory 4916. • Fixes CVE-2021-42392 in the Installer.

1.17.0.0.202110261002-1	This version:
	• Adds support for EEP 8.0.0, EEP 7.1.1, EEP 6.3.5, and version updates to many ecosystem components. For a list, see What's New in EEP 8.0.0 on page 6509.
	• Is built on Ubuntu 18.04 and is not supported on Ubuntu 16.04. Note that core 6.2.0 is supported on Ubuntu 16.04. You can use Installer 1.17.0.0 to install core 6.2.0 on Ubuntu 16.04 as long as the Installer node is running an OS that Installer 1.17.0.0 supports. For details, see Selecting an Installer Version to Use on page 5402. For supported OS versions, see the MapR Installer Support Matrix on page 5599.
	• Includes some terminology updates. References to the *ecosystem pack (MEP)* have been changed to *Ezmeral Ecosystem Pack (EEP)*. For more information, see What's New in EEP 8.0.0 on page 6509.
	• Includes numerous fixes, the most significant of which are:
	  • IN-2264: Probe does not detect hive database settings like it does for hue and oozie
	  • IN-2490: Change ansible source module to mapr_ansible
	  • IN-2560: Releases installer-v1.11.0 and installer-v1.12.0 - mapr-setup.sh by default installs the most current version of the Installer
	  • IN-2848: correctly detect and report ansible syntax errors
	  • IN-2856: Installer Failing when doing incremental upgrade
	  • IN-2924: need to create symlink for mapr_fstab when using mapr-loopbacknfs
	  • IN-2934: Ubuntu16 - mapr-setup.sh gpgkeys: protocol `https` not supported
	  • IN-2935: Centos83 - fresh install failing with "mount.nfs: access denied by server while mounting localhost:/mapr"
	  • IN-2947: extend cluster on ubuntu fails on nodes that do not have zookeeper installed

last-updated: Apr 11, 2022

Version	Updates
1.16.0.3.202201072207-1	This version: • Provides Log4j fixes. For more information, see advisory 4916. • Fixes CVE-2021-42392 in the Installer.
1.16.0.2.202110191345-1	This version provides defect repair and enables installation for clusters running Ubuntu 16.04. See the special considerations for Ubuntu 16.04 clusters in Selecting an Installer Version to Use on page 5402. This version was released at the same time as Installer 1.17 and includes fixes for the following issues: • IN-2895: permission errors reading pid files due to systemd changes • IN-2984: SLES15 fails in verify - python3 incompatibility • IN-2989: Error during cluster installation - 'ascii' codec can't encode character • IN-2995: add check to the os prereq to check for mep-7.1.0 or above with SLES15 • IN-2996: java 11 jre is not being upgraded to jdk • IN-2997: installer does not install java11 on SLES15
1.16.0.1.202108210519-1	This version includes fixes for the following issues: • IN-2924: need to create symlink for mapr_fstab when using mapr-loopbacknfs • IN-2925: installer no longer correctly detects if zk are running • IN-2934: Ubuntu16 - mapr-setup.sh gpgkeys: protocol `https` not supported • IN-2935: Centos83 - fresh install failing with "mount.nfs: access denied by server while mounting localhost:/mapr" • IN-2947: extend cluster on ubuntu fails on nodes that do not have zookeeper installed • IN-2950: Bug in regex for mapr-setup.sh causes update command to fail

last-updated: Apr 11, 2022

Version	Updates

1.16.0.0.202105261033-1	This version:
	• Adds support for EEP 7.1.0, SLES 15 SP2, and the following ecosystem component version updates:
	  • Hadoop 2.7.5
	  • Object Store 2.1.0
	  • HTTP-FS 1.1
	  • Kafka 2.6.1
	• Includes fixes for the following issues:
	  • IN-2821: DB services fail with error - Could not connect to the database: java.sql.SQLException: The server time zone value 'PDT' is unrecognized or represents
	  • IN-2849: prereq check for services does not figure out that it needs to look for chronyd instead of ntpd for SLES 15
	  • IN-2862: Couldn't install cluster by mapr user with sudo
	  • IN-2879: FreshInstall - error while configuring mysql
	  • IN-2883: mapr-installer-cli probe fails on Ubuntu-based MapR 6.2 cluster
	  • IN-2892: mysql prereq check fails if no password is given - should only do so if not password was given on fresh install
	  • IN-2893: make sure cron is installed - both OT and ES depend on it
	  • IN-2895: permission errors reading pid files due to systemd changes

last-updated: Apr 11, 2022

Version	Updates

1.15.0.1.202103220200-1	This version:
	• Adds support for MapR Data Platform maintenance release 6.1.1, EEP 6.3.3, and SLES 12 SP5.
	• Includes fixes for the following issues:
	  • IN-2669: WebUI Node Configuration - usage of 'hostname -A' value
	  • IN-2727: Support for SLES 12 SP4 and SP5 for Installer versions that support MapR 6.1
	  • IN-2782: Tez UI not configured on security correctly via UI installer
	  • IN-2784: Can't install cluster on CentOS 8.1 EEP-7.0.1
	  • IN-2787: Check that sudoers file allow all commands for certain user if non-root user selected for installing
	  • IN-2793: add check to network prereq check to make sure nodes have a domain portion in FQDN hostname
	  • IN-2805: installer fails to parse mapr-patch file pattern for ubuntu files and 6.2.0 files

last-updated: Apr 11, 2022

Version	Updates

1.15.0.0.202101220818-1	This version:
	• Adds support for installing the S3 Gateway. For installation considerations, see Installing the S3 Gateway Using the Installer on page 5429.
	• Installs Loopback NFS (`mapr-loopbacknfs-<version>`) on all nodes in the cluster unless **Enable NFS** is specified.
	• Adds support for Oracle Enterprise Linux 8.2 on release 6.2.0.
	• Includes fixes for the following issues:
	  • IN-1289: Allow removal of installer node during verify
	  • IN-2004: Install loopbacknfs by default if customer does not install NFS
	  • IN-2232: We complain about firewall services being enabled on ubuntu
	  • IN-2608: mapr-setup.sh installing with local repository - error on mapr-installer.service start
	  • IN-2726: Installer should use HTTPS while connecting to https://package.mapr.hpe.com/
	  • IN-2728: Mapr-installer failed installation with "Module did not set no_log for update_password"
	  • IN-2735: Installer-master/ui1.14 - add mep506 632 701 support
	  • IN-2742: Ansible execute shell script with no TTY
	  • IN-2743: Certify Installer support for 6.2 on OEL (Oracle Enterprise Linux) 8.2
	  • IN-2744: Implement simple UI for service verification feature in the Installer UI
	  • IN-2754: Add loopbacknfs installation and configuration via MapR Installer
	  • IN-2770: Installer needs to reflect minimum cluster requirement for 4 node clusters, rather than 5 node
	  • IN-2778: need to change localhost login for root on shared mysql on ubuntu
	  • IN-2785: Installer logs plenty of 'loglevel_int' exception messages
	  • IN-2789: Centos 8 Installer with Use existing DB - database_existing.yml "No package MySQL-python available."

last-updated: Apr 11, 2022

Version	Updates
1.14.0.1.202010161154-1	This version adds support for Red Hat / CentOS 8.2 and Oracle Enterprise Linux 7.8, as indicated in MapR Installer Support Matrix on page 5599. This version also includes fixes for the following issues: • IN-2680: mapr-setup.sh should provide option to setup Proxy preload • IN-2714: Support MapR core (no EEP) for Oracle Enterprise Linux 7.8 for MapR 6.1 • IN-2715: Installer won't start on centos 8.2 when java 8 is installed • IN-2716: mapr-setup.sh - errors via Shell Script plugin validation • IN-2717: Installer Specification for versions supported and paths navigated on OS, java, and python environments • IN-2718: mapr-setaup.sh - ERROR: environment variable is set but do not contain http[s]: prefix - fix • IN-2719: proxy setting for mapr_core, mapr_installer.repo mep rep is incorrectly set to _none_always when installer on HPE network • IN-2720: install core 6.1.0 on centos 8 • IN-2721: centos8 610_631 fresh install error on Stanza - Running task: Calling do_configure.sh from 'configure.yml' MODULE FAILURE • IN-2723: Please try an upgrade from core 6.1.0 to core 6.2.0 via installer on centos 8.x • IN-2724: Probe is broken in 1.14 - python3 and 4 digit issues
1.14.0.0.202009160311-1	This version includes the following new functionality or characteristics: • MapR Installer 1.14.0.0 supports EEP 7.0.0. • MapR Installer 1.14.0.0 supports Red Hat / CentOS 8.1, Ubuntu 18.04, and Ubuntu 16.04, but does not support SLES, as indicated in Operating System Support Matrix on page 5522. • Unlike MapR Installer 1.13.0, MapR Installer 1.14.0.0 runs on JDK 11. • The Installer can install Kafka Schema Registry 5.1.2.0.

last-updated: Apr 11, 2022

Version	Updates
1.13.0.0.201912130933-1	This version includes the following new functionality or characteristics: • MapR Installer 1.13.0.0 supports EEP 6.3.0. • MapR Installer 1.13.0.0 supports Red Hat / CentOS 7.6 and 7.7 but does not support Ubuntu 18.04, as indicated in Operating System Support Matrix on page 5522. • MapR Installer 1.13.0.0 supports HBase 1.13.0. • Unlike MapR Installer 1.12.0, MapR Installer 1.13.0.0 requires Java 8 and cannot run on Java 7.
1.12.0.0.201905241518-1	This version includes the following new functionality or characteristics: • MapR Installer 1.12.0.0 and later support the upload of a zipped tarball containing custom Ansible roles. These instructions can be executed in the installer workflow to customize the installation. For more information, see Using Custom Playbooks on page 5430. • You cannot use MapR Installer 1.12.0.0 or later to perform basic installer operations with MapR 5.2.x releases. You must use MapR Installer 1.11.0.0 instead. See Selecting an Installer Version to Use on page 5402. • For data disks, MapR Installer versions 1.12.0.0 and later require a minimum disk size that is equal to the physical memory on the node. If a data disk does not meet the minimum disk size requirement, a verification error is generated. • If you click a link in a MapR Installer tooltip, the link is displayed in a new browser tab. Previously, clicking a tooltip link caused the browser to display the link in the same browser tab, and any changes made in the user interface were lost. This behavior has been corrected. • IN-2389 & INFO-1120: Sqoop2 cannot be installed using MapR Installer 1.12. • IN-2417: Extending a secure cluster no longer fails with a `maprusertickets` error when you add a CONTROL node and DATA node at the same time.

Version	Updates
1.11.0.0.201902141709-1	No new features. This version includes the following fixes: • IN-2254: Ran out of memory on 1.10 installer - bump memory limits. • IN-2171: Unable to install Installer from packages on SLES. • IN-2155: Restrict expanding cluster groups based on service type not on group name. • IN-2154: Installer verification phase fails with error "ValueError: zero length field name in format." • IN-2123: Unable to extend secure cluster, maprusertickt not copied into new node. • IN-2108: Adding node with Extend Cluster fails at "get list of the ECO warden config files." • IN-2094: Installer verification fails for LUKS encrypted disks. • IN-2078: AttributeError in prereq check about OS. • IN-2025: Installer Error "Unscalable Host Groups" during 'extend cluster' or 'incremental install'.
1.11.0.0.201901301400-1	This version includes the following new functionality or characteristics: • Support for EEP 6.1.0. For more information about EEP 6.1.0, see What's New in EEP 6.1.0 on page 6529. • The Installer provides a new advanced option that allows you to restrict the software to a subset of network interface cards (NICs) or to specify public IP addresses that can be used with the cluster nodes. See Using the MapR Subnet and MapR External Advanced Options on page 5444. • The Installer warns you if you specify a host name using an IP address rather than a fully qualified domain name (FQDN). See Connectivity on page 133. • The Installer warns you if you run `mapr-setup.sh -r <url>` and specify a URL that is different from the URL currently stored in the `properties.json` file. See Troubleshooting Repository URL Errors on page 5459. • The installer version (1.11.0.0) now uses four digits rather than three or two digits. For more information about 4-digit versions, see What's New in EEP 6.1.0 on page 6529.

last-updated: Apr 11, 2022

Version	Updates
1.10.0.201812181130-1	No new features. This version includes the following fixes: • IN-2171: Unable to install Installer from packages on SLES. • IN-2155: Restrict expanding cluster groups based on service type not on group name. • IN-2154: Installer verification phase fails with error "ValueError: zero length field name in format." • IN-2123: Unable to extend secure cluster, maprusertickt not copied into new node. • IN-2108: Adding node with Extend Cluster fails at "get list of the ECO warden config files." • IN-2094: Installer verification fails for LUKS encrypted disks. • IN-2078: AttributeError in prereq check about OS. • IN-2025: Installer Error "Unscalable Host Groups" during 'extend cluster' or 'incremental install.'
1.10.0.201809200839-1	This version includes the following new functionality: • The installer provides a new option for setting Data-at-Rest Encryption (DARE). See Using the Enable MapR DARE Option on page 5428. • The installer provides a new option for setting the NSF version. See Installing NFS Using the MapR Installer on page 5429. • Changes have been made to the auto-provisioning templates. See Auto-Provisioning Templates on page 5448. • With MapR Installer 1.10, metrics collection is enabled by default on MapR 6.1 or later and cannot be disabled. Metrics collection is required for metering. To support metrics collection, collectd is installed on all nodes in the cluster. Users can specify the full collection configuration for collectd or a minimum configuration to support only metering for billing purposes. If the minimum configuration is selected, MapR Database table metrics are disabled. • With MapR Installer 1.10, the installer no longer includes an option to support off-cluster Elasticsearch and OpenTDSDB when security is turned on. • When installing Oozie 4.3.0, MapR Installer 1.10 leverages the Hadoop credential provider API to encrypt the Oozie database user password.

<table>
<tr><th>Version</th><th>Updates</th></tr>
<tr><td>1.9.0.201803291415-1</td><td>This version includes the following new functionality:
In the MapR Installer, password verification is implemented for every password entered.
Passwords for the <code>admin</code> user are now requested during the configuration of Grafana and ElasticSearch if the security mode requires them. For more information, see theMapR Installer operational changes in Operational Changes (MapR 6.1.0).
Changes have been made to the auto-provisioning templates. See Auto-Provisioning Templates on page 5448.
The following services are renamed in MapR Installer 1.9:<table><tr><th>Old Name</th><th>New Name</th></tr><tr><td>OJAI Query Service</td><td>OJAI Distributed Query Service</td></tr><tr><td>HBase/MapR Database Common</td><td>MapR DataBase</td></tr></table></td></tr>
<tr><td>1.8.0.201801312110-1</td><td>This version includes support for MapR 6.0, EEP 4.1.0, and the following new features:
Support for Starting Up a Cluster Using the MapR Installer Startup Button on page 5445.</td></tr>
<tr><td>1.7.201801021321-1</td><td>No new features. This version includes the following fixes:
IN-1417: Cannot decode unicode character running Stanza
IN-1451: CFT_converged.yml when used with customized AMI errors out while creating stack.
IN-1445: URLs not accessible in AWS Marketplace offering.
IN-1422: Hue broken on fresh Install Azure and AWS Marketplace offers.
IN-1391: Use private hostname for Azure provisioning.</td></tr>
</table>

last-updated: Apr 11, 2022

Version	Updates
1.7.201711082221-1	This version includes the following new features: • Support for Version 6.1.0 Release Notes on page 34 and MapR Ecosystem Pack (EEP) Reference on page 6504 4.0.0, 3.0.2, 2.0.3, and 1.1.4. • A new option for enabling or disabling security for the cluster. See Using the Enable MapR Secure Cluster Option on page 5427. • **Import State** and **Export State** commands that allow you to recover more easily from MapR Installer failures. See Importing or Exporting the Cluster State on page 5447. • The ability to change timeout parameters to improve the success of MapR Installer operations. • The ability to uninstall a service by deselecting it during an Incremental Install operation. • Support for the `scaled_hosts2:` parameter for MapR Installer Stanzas. MapR Installer 1.7 (which includes MapR Installer Stanzas) no longer supports the `scaled_hosts:` parameter for adding nodes to an on-premise cluster. Instead, you need to use the `scaled_hosts2:` parameter. See Extending a Cluster by Adding Nodes.
1.6.201708241301-1	This version includes the following new features: • Support for Installing MapR in the cloud.
1.6.201708012220-1	This version includes the following new features: • Support for adding nodes. See Extending a Cluster by Adding Nodes on page 5437. • A new one-click **Shutdown** command. See Shutting Down a Cluster Using the MapR Installer Shutdown Button on page 5446. • Support for 3-digit EEPs. See Understanding Two-Digit and Three-Digit EEPs on page 5450. • Support for creating a MapR Installer PACC using the MapR Installer setup script. See Creating an Installer Container Using mapr-setup.sh on page 5498.

Version	Updates
1.5.201704051050-1	This version includes the following new features: • Support for EEPs 3.0, 2.0.1, and 1.1.2. See MapR Ecosystem Pack (EEP) Reference on page 6504. • Support for maintenance updates. See Performing a Maintenance Update on page 5447. • Enhancements to MapR Installer Stanzas. See Using probe and import to Generate the Installer Database on page 5514. • Enhancements to `mapr-setup.sh` in support of user-created MapR PACC containers. See Creating a MapR PACC Image Using mapr-setup.sh on page 409. • Support for applying patches. See Applying a Patch Using the MapR Installer on page 438. • Support for SLES 12 SP1.
1.4.201612081140-1	This version includes the following new features: • Support for EEP 2.0. • Support for MapR Installer Stanzas. • MapR Streams Tools. Note these restrictions: • MapR Installer 1.4 prevents you from downgrading a EEP. • MapR Installer 1.4 shows only EEP versions equal to or greater than the version currently installed on your cluster. This version includes the following updates: • 24891: Installer should not allow you to downgrade the EEP version. • 25213: Error in the process of upgrading Sentry by UI Installer 1.4. • 25277: v..swappiness should be set to "1" rather than "0" in RHEL/CentOS kernels > 2.6.32-303. • 23285: Installer leaves children behind after a stop. • 25421: mapr-setup fails to upgrade java.
1.3.201609291954-1	This version includes the following updates: • 23258: The installer now creates a new log for each node for each iteration of the installer. Previously, the installer overwrote the original log file. • 23868: The installer now updates the livy_server_host property on Hue nodes and restarts the live server correctly.

last-updated: Apr 11, 2022

Version	Updates
1.3.201608121412-1	This version includes the following new features: • When you install or upgrade to MapR 5.2, you select a EEP version before you select ecosystem components. • When you install or upgrade to MapR 5.2, you have the option to install MapR Monitoring. • For local MapR 5.2 installations, the `-a` parameter of `mapr-setup.sh` expects three archive files: MapR Installer archive, MapR Ecosystem Pack (EEP) archive, and the MapR 5.2 archive. This version includes the following updates: • 23853/22267: The installer validates advanced disk layouts such as /dev/mapper/luks-sdd or /dev/mapper/<lvm_logical_volume_name>. • 22904: The installer now allows you to update the cluster license during an incremental installation. • For local MapR 5.0 and 5.1 installations, the archive filename has changed to mapr-5.0-5.1.<yyyymmdd>.*.tgz. • 24295: The installer detects disks correctly on Red Hat 7 operating system versions. • 24340: The installer no longer points to an old package manager (RPM) for the EPEL repository.
1.2.201606140935-1	Version number change only.
1.2.201605032042-1	This version includes the following updates: • 23137: On each node in the cluster, MapR Installer automatically applies the latest patch available for the installed JDK version. • 22892: MapR Installer no longer fails on Red Hat operating system versions that do not support systemd.
1.2.201602260909-1	This version includes the following updates: • 21115: The installer performs a prerequisite check on the operating system version of Ubuntu and CentOS/Redhat nodes. • 21877: The `mapr-setup.sh` script provides the ability to specify a non-default hostname and port that nodes in the cluster can use to communucate with the MapR Installer node. You can set a non-default hostname or port using the new prompt that appears while mapr-setup.sh configures the MapR Installer node or pass the script the `-p <hostname:port>` option when you run the command to execute the mapr-setup.sh script.

last-updated: Apr 11, 2022

Version	Updates
1.1.201601080826-1	This version includes the following updates: • 21861: The installer sets the no_proxy environment variable for http connections to the MapR Installer node. • 21440: On Safari and Internet Explorer web browsers, the Advanced Configuration settings for the service layout are now accessible.
1.1.201510241120-1	This version includes the following updates: • 19850: The installer now configures the MySQL database to work with local connections. • 20115: The installer disables SELinux without requiring a reboot. • 19156: When you abort an installation, the installer provides a link to download the installation logs.
1.0.201508041436-1	This version includes the following update: • If Java is not installed on RedHat/CentOS, mapr-setup.sh installs Open JDK Java 1.8.
1.0.201507171311-1	This version includes the following updates: • 19541: The installer no longer supports SSL DHE cipher. It will also disable SSLv3. • 19465: When you use a custom service template, the installer now accurately displays service compatibility.
1.0.201507091731-1	This version includes the following updates: • 18888: You no longer need to restart the mapr-installer process after you use the package manager to upgrade the installer package.
1.0.201506081725-1	This version includes the following updates: • 18926: Installations no longer terminate due the restart of the sshd process. • Minor changes to text and layout on the Services page.
1.0.201506011415-1	Version number change only.
1.0.201505261302-1	This version includes the following fixes: • 18682: When you use package manager to update the installer definition file, you no longer need to re-run mapr-setup.sh. • 18748: The MapR Installer no longer fails to install Hive 0.13 on Ubuntu when the repository includes Hive 1.0.

Installer Help Links

Here are some topics that can help you use the MapR Installer Web Interface.

last-updated: Apr 11, 2022

Using the MapR Installer

To get started using the MapR Installer, see MapR Installer on page 5395.

Version-Specific Topics

Release 7.0 Links	• Upgrading MapR Core or EEP Components on page 284
	• For upgrades to core:
	  • Upgrade Workflows on page 285
	  • Preparing to Upgrade MapR Core on page 303
	  • Finishing the MapR Core Upgrade on page 322
	• For upgrades to ecosystem components:
	  • Preparing to Upgrade the MapR Ecosystem Pack on page 335
	  • Finishing the MapR Ecosystem Pack Upgrade on page 372
	• For cluster expansion using the Installer **Extend Cluster** function:
	  • Post-Expansion Steps for Extending a Cluster on page 5442

Release 6.1 Links	• Upgrading MapR or MapR Ecosystem Components
	• For upgrades to MapR Core:
	  • Upgrade Workflows on page 285
	  • Preparing to Upgrade MapR Core
	  • Finishing the MapR Core Upgrade
	• For upgrades to MapR Ecosystem components:
	  • Preparing to Upgrade the MapR Ecosystem Pack
	  • Finishing the MapR Ecosystem Pack Upgrade
	• For cluster expansion using the MapR Installer **Extend Cluster** function:
	  • Post-Expansion Steps for Extending a Cluster on page 5442

last-updated: Apr 11, 2022

Release 6.0 Links	• Upgrading MapR or EEP Components
	• For upgrades to MapR Core:
	  • Preparing to Upgrade MapR Core
	  • Finishing the MapR Core Upgrade
	• For upgrades to MapR Ecosystem components:
	  • Preparing to Upgrade the MapR Ecosystem Pack
	  • Finishing the MapR Ecosystem Pack Upgrade
	• For cluster expansion using the MapR Installer **Extend Cluster** function:
	  • Post-Expansion Steps for Extending a Cluster

Release 5.2 Links	• Upgrading MapR or MapR Ecosystem Components
	• For upgrades to MapR Core:
	  • Preparing to Upgrade MapR Core
	  • Finishing the MapR Core Upgrade
	• For upgrades to MapR Ecosystem components:
	  • Preparing to Upgrade the MapR Ecosystem Pack
	  • Finishing the MapR Ecosystem Pack Upgrade
	• For cluster expansion using the MapR Installer **Extend Cluster** function:
	  • Post-Expansion Steps for Extending a Cluster on page 5442

Release 5.1 Links	• MapR 5.1 Upgrade Guide • MapR 5.1 Pre-Upgrade Steps • MapR 5.1 Post-Upgrade Steps • Post-Expansion Steps for Extending a Cluster on page 5442

MapR Installer Containers

This section describes how you can obtain the MapR Installer as a Docker container.

A MapR Installer container is a Docker container that contains the MapR Installer. You can use a MapR Installer container to perform basic installer operations from a node that is not necessarily a part of a MapR cluster. For example, from a MapR Installer container, you can perform the following actions:

- Start and run the web-based MapR Installer to install a new cluster, apply a patch, or perform an update.
- Run Installer Stanza commands to probe an installed cluster.

You can create your own MapR Installer container by using the `mapr-setup.sh` script. Or you can download a pre-built container image for theMapR Installer.

last-updated: Apr 11, 2022

Creating an Installer Container Using mapr-setup.sh

This section describes how to create an Installer Container image by using the `mapr-setup.sh` script.

Creating the Image

To create an Installer image using `mapr-setup.sh`:

1. Download the `mapr-setup.sh` script to a Linux or Mac OS X platform where Docker 1.12.5 or later is installed and the Docker daemon is up and running. Choose *one* of the following download options:

   Note: Running `mapr-setup.sh` on Windows is not supported.

   - Download the setup script directly from package.mapr.hpe.com to the node that will run the MapR Installer:

     ```
     wget https://package.mapr.hpe.com/releases/installer/
     mapr-setup.sh -P /tmp
     ```

   - Download to your local workstation, and copy to the node that will run the MapR Installer:

     a. On the Download Page, click **Download**, and save the setup script to a location on your workstation.

     b. Use a tool such as SCP to copy the file to the node that will run the MapR Installer:

     ```
     scp mapr-setup.sh user@server /tmp
     ```

2. Run the `mapr-setup.sh` script with the `docker installer` command to create the Docker image:

   ```
   ./mapr-setup.sh docker installer
   ```

3. Respond to the command-line prompts to provide the information to configure the image. The following table describes each prompt. If you press **Enter** without specifying a value, `mapr-setup.sh` uses the default value shown in the square brackets ([]):

Prompt	Notes
`Build MapR UI Installer image? (y/n) [y]`	Type y to continue or n to exit the script.
`Image OS class (centos7, ubuntu16) [<local OS>]:`	Specify the base operating system on which to build the image. **Note:** SLES is not currently supported.
`Docker FROM base image name:tag [centos:centos7]:`	Specify the starting image used to create the new image. If necessary, you can enter your own tag and image name to choose a base image already created for your installation. If you do not enter a name, the script provides one for you.
`MapR installer image tag name [<name>]`	Accept the software-provided name for the container image, or provide your own name. This is the name you will use to run the image to create the MapR Installer container.

`Container memory: specify host XX[kmg] or 0 for no limit [0]:`	Specify the maximum amount of memory (in kilobytes, megabytes, or gigabytes) that Docker allows the container to access. For example: • 2g • 4096m • 0 Accepting the default (0), means there is no restriction on memory, and the container can use as much memory as the platform makes available.

4. After the last prompt, press **Enter**. The script:
   - Prepares the installer
   - Installs or verifies installer package dependencies
   - Installs installer packages
   - Cleans up unneeded files
   - Creates the `mapr-docker-installer.sh` sample-run file and displays the location of the file:

     ```
     Edit '/root/docker_images/installer/mapr-docker-installer.sh' to
     configure settings and then execute it to start the container
     ```

     `mapr-docker-installer.sh` contains environment variables for the image and makes it easy for you to start the container.
5. *(Optional)* Edit the `mapr-docker-installer.sh` script file if you want to change any environmental variables. For more information about the environmental variables, see Environmental Variables for the MapR Installer Container on page 5501.
6. Run the `mapr-docker-installer.sh` file to start mapr-installer services:

   ```
   ./docker_images/installer/mapr-docker-installer.sh
   ```

   After the installer service is started, you can issue Stanza commands or open the web-based MapR Installer in a browser:

   ```
   installer (380) started with log /opt/mapr/installer/logs/installer.log
   Started service mapr-installer

   ...Success

       To continue installing MapR software, open the following URL in a
   web browser

                If the address '172.17.0.2' is internal and not accessible
              from your browser, use the external address mapped to it
   instead

                                https://172.17.0.2:9443
   ```

last-updated: Apr 11, 2022

Note: The MapR Installer maintains the state of the cluster. When the installer is run from a container, the installer database is only as persistent as the container itself. If you need the installer data to be persistent, here are some options:

- If you shut down a MapR Installer container, use the `docker start` command (not the `docker run` command) to restart the same instance of the container. If you create a new instance of the container, the database will have no information.
- Mount the `/opt/mapr/` data directory outside the container to persistent storage to maintain the cluster state.
- Use the Stanza `export` command to export the state of the cluster before you shut down the container. See Exporting a Cluster Configuration.

Running the MapR Installer Container Using Stanza Commands

You can also use the sample-run file to execute a MapR Installer Stanza command. In this scenario, the command creates the installer container, runs a Stanza command, and then shuts down the container. For example, the following command runs the Stanza `probe` command on node 10.10.88.53:

```
./docker_images/installer/mapr-docker-installer.sh probe -o
config.ssh_id=root config.ssh_password=mapr
config.hosts='["10.10.88.53"]' -nv
```

For a list of the Stanza commands, see MapR Installer Stanza Commands on page 5515.

Using the Pre-Built MapR Installer Container Images

This section describes how to obtain and run the pre-built MapR Installer container images.

Pre-built MapR Installer container images are available on Docker hub. Images are available for:

- Ubuntu 16.04
- Ubuntu 14.04
- CentOS 7
- CentOS 6

The pre-built images are about 200 MB. A sample-run script that you can use to start the container is available on GitHub.

To use a pre-built image:

1. Download the pre-built MapR Installer container image and the sample-run script to a Linux or Mac OS X platform where Docker 1.12.5 or later is installed and the Docker daemon is up and running.
   - You can download the pre-built image from the data-fabric public repository.
   - You can download the sample-run script (`mapr-docker-installer.sh`) from this GitHub location.
2. *(Optional)* Edit the `mapr-docker-installer.sh` script file if you want to change any environmental variables. For more information about the environmental variables, see Environmental Variables for the MapR Installer Container on page 5501.
3. Run the `mapr-docker-installer.sh` file to start mapr-installer services:

   ```
   $ ./docker_images/installer/mapr-docker-installer.sh
   ```

After the installer service is started, you can issue Stanza commands or open the web-based MapR Installer in a browser:

```
installer (380) started with log /opt/mapr/installer/logs/installer.log
Started service mapr-installer

...Success

    To continue installing MapR software, open the following URL in a
web browser

              If the address '172.17.0.2' is internal and not accessible
          from your browser, use the external address mapped to it
instead

                              https://172.17.0.2:9443
```

The MapR Installer maintains the state of the cluster. When the installer is run from a container, the installer database is only as persistent as the container itself. If you need the installer data to be persistent, here are some options:

- If you shut down a MapR Installer container, use the `docker start` command (not the `docker run` command) to restart the same instance of the container. If you create a new instance of the container, the database will have no information.
- Mount the `/opt/mapr/` data directory outside the container to persistent storage to maintain the cluster state.
- Use the Stanza `export` command to export the state of the cluster before you shut down the container. See Exporting a Cluster Configuration.

Environmental Variables for the MapR Installer Container
This section describes environmental variables that you can modify to customize the sample-run script for the MapR Installer container.

About mapr-docker-installer.sh

`mapr-docker-installer.sh` is the sample-run script for the MapR Installer container. The script contains the `docker run` command that runs the container and environmental variables that can be passed into the container at run time. Modifying the variables is optional; the script can run without any changes to the environmental variables.

The following environmental variables can be changed in `mapr-docker-installer.sh`:

Environmental Variables in mapr-docker-installer.sh

Key	Variable	Description
`MAPR_CONTAINER_USER`	`<user-name>`	The user that the user application inside the Docker container will run as. This configuration is functionally equivalent to the Docker native `-u` or `--user`. Do not use Docker `-u` or `--user`, as the container needs to start as the `root` user to bring up FUSE before switching to the MAPR_CONTAINER_USER.

Key	Variable	Description
		The user specified here is the user that all storage operations on the MapR cluster will be performed as. Therefore, HPE recommends not using `root` or `mapr`. This user also owns the `/opt/mapr` directory tree.
`MAPR_CONTAINER_UID`	`<uid>`	The UID that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a UID is not provided, the default is UID 1000. Providing a UID is strongly recommended.
`MAPR_CONTAINER_GROUP`	`<group-name>`	The group that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a group name is not provided, the default is `users`. Providing a group name is strongly recommended.
`MAPR_CONTAINER_GID`	`<gid>`	The GID that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a GID is not provided, the default is GID 1000. Providing a GID is strongly recommended.
`MAPR_PKG_URL`	`<mapr-pkg-url>`	The URL of the repository that hosts the MapR packages (typically https://package.mapr.hpe.com/). If you change MAPR_PKG_URL, use the full URL to your MapR repository (for example, `<hostname>/releases`).
`MAPR_CONTAINER_PASSWORD`	`<mapr-password>`	The password for the `mapr` user. This password must be set if the container will remaining running. The password defaults to `mapr`.
`MAPR_STANZA_FILE`	`<stanza-file>`	The path to a MapR Installer Stanza file that needs to be mounted from the host. You must specify this field if you issue the Stanza `install` command as an argument to the script. For example: `mapr-docker-installer.sh install -nv`
`MAPR_MEMORY`	`<mapr-memory>`	Specify the maximum amount of memory (in kilobytes, megabytes, or gigabytes) that Docker allows the container to access. For example: • 2g

last-updated: Apr 11, 2022

Key	Variable	Description
		• 4096m • 0 Accepting the default (0), means there is no restriction on memory, and the container can use as much memory as the platform makes available.
MAPR_TZ	<time-zone>	The time zone inside the container. For a list of time-zone settings, see this website. The default is UTC.

MapR Installer Stanzas

This section describes how to prepare for and use MapR Installer Stanzas to install, upgrade, or uninstall MapR software.

MapR Installer Stanzas enable API-driven installation of MapR clusters. An extension of the Spyglass Initiative, MapR Installer Stanzas enable the creation of a YAML configuration file (a "Stanza") that describes a cluster. A command-line addition to the web-based MapR Installer allows you to execute the configuration file programmatically to automate new deployments.

You can use MapR Installer Stanzas when you need a script-based tool to install MapR software and you do not want to click through the menus and options provided by the MapR Installer. MapR Installer Stanzas provide less visual feedback than the MapR Installer, but they can be faster and more efficient at installing software on clusters with many nodes.

To use MapR Installer Stanzas:

1. **Review the** Installer Stanza Prerequisites.
2. **Use the steps in** Installer **to download and run the mapr-setup.sh script.** Performing these steps installs both the web-based MapR Installer and the MapR Installer Stanzas feature.
3. **Review or edit the Stanza file.** The Stanza file specifies the installation parameters for your cluster. See Working with MapR Installer Stanza Files on page 5504.
4. **Run the MapR Installer Stanza file.** See Running Installer Stanza Files.

MapR Installer Stanza Prerequisites

This topic describes some limitations and guidelines that you must understand before using MapR Installer Stanzas.

Most prerequisites that apply to the MapR Installer also apply to MapR Installer Stanzas. To review the MapR Installer prerequisites, see MapR Installer Prerequisites and Guidelines on page 5396.

Some additional prerequisites are unique to MapR Installer Stanzas:

- To install MapR Installer Stanza features, you must download version 1.4 or later of the MapR Installer. For more information, see MapR Installer Updates on page 5481 and Updating the MapR Installer on page 5409.
- You can use MapR Installer Stanzas to install, upgrade, or uninstall only Release 5.1 and later releases.
- You can use MapR Installer Stanzas to upgrade or uninstall only clusters that were previously installed using the MapR Installer or a MapR Installer Stanza. If your MapR software was installed manually, you cannot use MapR Installer Stanzas on the cluster because the cluster does not have the installer database.

last-updated: Apr 11, 2022

Working with MapR Installer Stanza Files

This topic describes how to use the sample Stanza files that are provided with the MapR Installer.

The MapR Installer Stanza file specifies how the cluster should be configured, including the configuration of nodes, disks, software versions, and services. You must configure a Stanza file before using MapR Installer Stanzas to install or upgrade a cluster. Sample Stanza files (basic and advanced) are located in this directory:

`/opt/mapr/installer/examples`

To create your Stanza file:

1. Make a copy of one of the sample files. For example, make a copy of the `sample_basic` or `sample_advanced` Stanza file, and rename the copy to a name of your choosing.
2. Using any text editor, edit the Stanza file to address the needs of your installation. Comment out any instructions that you don't need.

This table describes how to complete the fields in the Stanza file:

Section	Parameter	Required/Optional	Directions
environment	mapr_core_version	Required	Specify 5.1.0 or later. Be sure to include the third digit (for example, 5.1.0 or 5.2.0).
	patch_location	Optional	Specify the location of a MapR core patch file. The file name must use the format `mapr-patch-${mapr_core_version}`. For example: `mapr-patch-5.2.0.39122.GA-4198.x86_64.rpm` Use an absolute path to specify the patch file location.

config	hosts	Required	Specify the list of hosts on which you want to install packages. You can list the hosts on a single line as follows:
			`- examplenode[1-3].example.com`
			Or you can use multiple lines:
			`- examplenode1.example.com`
			`- examplenode2.example.com`
			`- examplenode3.example.com`
			Note:
			• The installer host must be one of the hosts in this list.
			• A comma-separated list of hosts is not supported.
			• You can override hosts and disks from the command line. The following example specifies installing only on hosts 01 through 04. To pass an array into an override, use single quotes, double quotes, and brackets as follows:
			`cli install -nv -t sample_adv.yaml -o config.hosts='["lab[01-04].yourlab.com"]'`
			Note: In a command with an override, the `key=value` pair or pairs that follow `-o` must not contain a blank space. For more information about `key=value` pairs, see MapR Installer Stanza Commands on page 5515.

last-updated: Apr 11, 2022

	ssh_id	Required	Specify the user ID that the installer will run under when it installs the packages. This user must have root access and must be present on every host defined in the hosts section.
	ssh_password	Optional	Specify the password (for use with the password-based login). This is the password that the installer uses to log into the node using ssh. Comment this line if you want to use a private-key-based login.
	ssh_key_file	Optional	Specify the path to a file that contains the private key (for use only with the private key-based login). Uncomment this line if you want to use a private-key-based login. If both the ssh_password and ssh_key_file lines are uncommented, the installer will default to the ssh_key_file.
	ssh_port	Optional	Uncomment this line if you need to specify a port other than the default, which is 22.
	license_type	Required	Specify M3 for the community edition or M5 for the enterprise edition.
	mep_version	Required for MapR 5.2.0 and later	Specify a currently supported EEP, such as 2.0. For EEP information, see EEP Components and OS Support on page 5536.
	disks	Required	List the disks on which the packages will be installed. The disk names should be the same on every node. This field is required, and you must use the following notation: `- /<diskname>` `- /<diskname>` `- /<diskname>` A comma-separated list of disks is not supported. Not all of the disks need to be present, but at least one disk on each node must be present.

	disk_stripe	Optional	Uncomment this line if you need to specify a disk stripe value other than the default, which is 3.
	elasticsearch_path	Optional	Uncomment this line if you need to specify a path where Elasticsearch data will be stored.

	services	Optional	Specify a predefined template of services. Services are the MapR core or ecosystem components (or tools) that run on each group. The installer configures default services automatically unless you specify a "groups" section in the Stanza file. To view the predefined templates, use the `list` command with the `--type TEMPLATE` argument. **Note:** • Metrics are provided by default. The metrics services apply only to MapR 5.2 and later. • Logging services, if specified, apply only to MapR 5.2 and later. • If you do not specify any services, the Installer will install only MapR core services. • For an incremental install or upgrade, the Installer discovers any services already installed. Additional services are installed only if you request specific services, a EEP upgrade, or a MapR core upgrade. • You can override services using a command such as the following: `-o config.services='{"mapr-oozie": {} , "mapr-hivemetastore": {"database": {"name": "hive", "user": "hive", "password":`

last-updated: Apr 11, 2022

groups (advanced layout only)		Optional	To provision the cluster manually, add services in groups. A group is a collection of hosts (nodes) that runs a specific set of services. The installer creates groups automatically unless you specify the groups manually (manual provisioning). To specify the groups manually, you must include a groups section and define the hosts, labels, and services that your cluster needs. For an example, see the sample_advanced Stanza file. The services you specify must not be of type GROUP. To view the type for a given service, use the `list services` command with the `--name <name-of-service>` argument. Also, when provisioning manually, you must ensure that the mapr-core service is present on every node.
	hosts	Required (if a groups section is specified)	Hosts are nodes that run a specific set of services.
	label	Optional	The label is a descriptor for each group. Use the label to describe the group function or some other aspect of the group that is meaningful to your installation. If a label is not specified, the installer will auto-generate a label based on the service names.
	services	Required (if a groups section is specified)	See the "Services" section earlier in this table.

Running MapR Installer Stanza Files
This section describes how to install, upgrade, and uninstall MapR software and check the progress of these operations by using MapR Installer Stanza commands.

Note: To run MapR Installer Stanza commands, you must navigate to the installer directory. This applies to all the examples in this section:

```
cd /opt/mapr/installer
```

Installing or Upgrading MapR Core Using an Installer Stanza
Use the Stanza `install` command to install Release 5.1 or later, install additional features, upgrade a cluster, perform a maintenance update, or apply a patch.

You can use the `install` command of the MapR Installer Stanza command suite to:

last-updated: Apr 11, 2022

- Perform a fresh install of Release 5.1 or later.
- Perform an incremental install (add or upgrade services that are already installed on the cluster).
- Upgrade a cluster to a newer data-fabric software version or a newer EEP version.
- Perform a maintenance update.
- Apply a patch (see Applying a Patch Using an Installer Stanza on page 444).
- Extend the cluster by adding nodes (see Extending a Cluster by Adding Nodes on page 5437).

For the `install` command syntax and options, see MapR Installer Stanza Commands on page 5515 later in this section.

This example installs data-fabric software using the parameters specified in the `sample_basic.yaml` Stanza file. To run this command, you should be logged in as the `mapr` user. The `-nv` option specifies that certificates will not be checked and the output mode is verbose. The `-t`option, which is required, specifies the use of a template file:

```
./bin/mapr-installer-cli install -nv -t ./examples/sample_basic.yaml
```

If you are using a MapR Installer Stanza to install data-fabric software on a cluster that has never had data-fabric software installed (a fresh installation), it is recommended to create the `mapr` user on all nodes. You can create the `mapr` user by using the `config.cluster_admin_password` override. For example:

```
./bin/mapr-installer-cli install -nv -t ./examples/sample_basic.yaml -o
config.cluster_admin_password=mapr
```

If you use the `install` command and an existing cluster is detected, the installer attempts an incremental install or upgrade using the parameters in the specified Stanza file:

- For incremental installs, the installer does not check or verify the configuration.
- You cannot add nodes or services during a version upgrade.

Note: If the password in the Stanza file or in the command contains a special character, such as an exclamation point (!), you might need to escape the character with a backslash (\). For example:

```
./bin/mapr-installer-cli install -u mapr:mapr\!@localhost -nv -t ../
examples/sample_basic.yaml
```

If you do not want to include a password in the Stanza file, you can specify a value contained in a secured file. This example uses a Stanza file (`sample_nopwd.yaml`) in which the `ssh_password` line has been removed. The secured file (`installer.cfg`) stores the value of `ssh_password` as `config.ssh_password=mapr`. The contents of `installer.cfg` are piped to the `install` command via an override (`-o -`). You must include the `-` after the `-o`; otherwise, the file contents are not read.

```
cat examples/installer.cfg | ./bin/mapr-installer-cli install -nv -t
examples/sample_nopwd.yaml -o -
```

To check the progress of the installation or upgrade, see Checking the Progress of Operations. For another example of using the `install` command, see How to Build Stanzas (blog).

New Installation of Release 6.0 Secure Cluster Using Stanzas

To install a Release 6.0 secure cluster using Stanzas, you must add two parameters to the Stanza:

- `config.security: "true"`

- `config.cluster_admin_password: "<mapr_user_password>"`

For example:

```
config:
  security: "true"
  cluster_admin_password: "mapr"
```

After the installation completes, `secure=true` should be set in the `/opt/mapr/conf/mapr-clusters.conf` file. This command should print the ticket details:

```
maprlogin print -ticketfile /opt/mapr/conf/maprusertickет
```

Note these considerations for installing a Release 6.0 secure cluster:

- If you use a Stanza to perform a secure install, you must log out and then log in one time for the bashrc to take effect.
- For non-bash environments, you must manually add the above epxort to your login profile.
- You can use the `probe` command to detect whether a cluster is secure or not.

Uninstalling MapR Core Using an Installer Stanza
Specifies how to uninstall MapR Core from the command line.

You can use the `uninstall` command to uninstall the current data-fabric software version. The `uninstall` command requires that you specify two overrides:

- `config.ssh_id`
- `config.ssh_password` or `config.ssh_key_file`

Note: Using the the `uninstall` command requires `root` privileges. You can provide the `root` ID and password or the `root` ID and `ssh_key_file`.

This example uninstalls the currently installed data-fabric software. The command uses an override to provide the `ssh_id` and `ssh_password` and includes `-nv` so that certificates will not be checked, and the output mode is verbose.

```
./bin/mapr-installer-cli uninstall -nv -o config.ssh_id=root -o
config.ssh_password=mapr
```

This example uninstalls the currently installed data-fabric software. The command uses an override to provide the `ssh_id` and `ssh_key_file` and includes `-nv` so that certificates will not be checked, and the output mode is verbose. The `ssh_key_file` for root normally resides in `/root/.ssh`. In this example, the file has been copied to `/home/mapr/root` so that the `mapr` user can access the key file.

```
./bin/mapr-installer-cli uninstall -nv -o config.ssh_id=root -o
config.ssh_key_file=/home/mapr/root_user_id_rsa
```

Exporting a Cluster Configuration

If a cluster was installed using the MapR Installer or a MapR Installer Stanza, you can use the `export` command to generate a Stanza that captures the state of the cluster. You can then modify the Stanza to perform incremental installs or upgrades.

last-updated: Apr 11, 2022

This example uses the `export` command to generate the `tt.yaml` Stanza file. The command includes `-n` so that certificates will not be checked:

```
./bin/mapr-installer-cli export -n --file /tmp/tt.yaml
```

Note: The `export` command does not export the `config.ssh_password` field. When using the exported YAML file, you need to provide the password manually, pass it as an override, or specify a value contained in a secured file, as described in Installing or Upgrading MapR Core Using an Installer Stanza on page 5509.

For another example of using the `export` command, see MapR Stanzas (blog).

Getting Information About Services and Groups

Use the Stanza `list` command to get additional information about your cluster.

You can use the `list` command and its arguments to get information about the configuration, services, groups, hosts, and services in the cluster. While the `list` command provides the state of the cluster, `list` output is not suitable for incremental installs and upgrades. You must use the `export` command if you want to generate a Stanza file that can be used for upgrading.

This example displays a listing of all the services, groups, and hosts that were installed:

```
./bin/mapr-installer-cli list installed -n
```

This example lists all the groups:

```
./bin/mapr-installer-cli list groups -n
```

This example lists all the hosts:

```
./bin/mapr-installer-cli list hosts -n
```

This example lists the installation status for all the hosts:

```
./bin/mapr-installer-cli list hosts_install_status -n -u https://
mapr:<password>@<installer_ip_addr>:9443
```

This example lists the services by template:

```
./bin/mapr-installer-cli list services -n --type TEMPLATE|more
```

You can use the `list services` command to learn about different kinds of services. For example:

Group Type	Example Command
CONTROL	`./bin/mapr-installer-cli list services -n --type CONTROL`
MULTI_MASTER	`./bin/mapr-installer-cli list services -n --type MULTI_MASTER` `./bin/mapr-installer-cli list services -n --type MONITORING_MASTER`

Group Type	Example Command

DATA	`./bin/mapr-installer-cli list services -n --type DATA`
	`./bin/mapr-installer-cli list services -n --type DEFAULT`
	`./bin/mapr-installer-cli list services -n --type CLIENT`

SINGLE MASTER	`./bin/mapr-installer-cli list services -n --type MASTER`

Verifying the Nodes

You can use the `check` command to verify that the nodes specified in the Stanza file are ready to be installed. The `check` command does not check the Stanza file and does not do any provisioning or installation. The `check` command runs the same checks that the MapR Installer runs during its Verification phase. For example, it checks that the nodes have the right OS version, that they have enough disk space, and that they have enough memory to support installation or other Installer operations.

This example verifies the nodes specified in the `sample_advanced_demo.yaml` file. The `-nv` option specifies that certificates will not be checked and the output mode is verbose. The `-t` option, which is required, specifies the use of a template file:

```
./bin/mapr-installer-cli check -nv -t sample_advanced_demo.yaml
```

Resetting the Installer Database

The `reset` command uninstalls the metadata from the Installer database. `reset` is for advanced users.

You can reset the Installer database by using the CLI `reset` command or by using the MapR Installer web interface (**Support > Reset Installer**).

The reset function can be useful for testing purposes, but use reset with caution. If you reset the installer database while packages are installed on the nodes, you will need to remove the packages manually.

Note: If you experience a failure while installing or uninstalling, the installer prompts you to retry the operation or uninstall and then reinstall from scratch. You should always retry or uninstall before considering using `reset`.

This example resets the Installer database. The `-nv` option specifies that certfificates will not be checked and the output mode is verbose:

```
./bin/mapr-installer-cli reset -nv
```

Adding a License Using Stanzas

Explains how to add a license using Installer Stanzas.

In addition to using `maprcli`, REST commands, or the Control System to add a license, you can add a license using MapR Installer Stanzas. After obtaining a valid license file from your MapR sales representative, copy the license file to a cluster node (for example, to `/tmp/license.txt`). You can then use the `license` command to apply the license to the cluster. For example:

```
mapr-installer-cli license -n -l <path-to-license-file>
```

Checking the Progress of Operations

This topic describes how to use the MapR Installer web interface and installer logs to check the status of MapR Installer Stanza operations.

last-updated: Apr 11, 2022

Using the MapR Installer to Check Status

The installer provides messages and progress bars to indicate the status of MapR Installer Stanza operations. However, you can also use the Installer interface to check the current status of your cluster. The MapR Installer provides a quick visual summary of the currently installed software versions and services.

To view the MapR Installer web interface:

```
https://<Installer Node hostname/IPaddress>:9443
```

Viewing the Installer Logs

To view or understand the logs generated by the MapR Installer or MapR Installer Stanza operations, see Installer Log Descriptions.

Shutting Down a Cluster Using an Installer Stanza Command

Use the Stanza `shutdown` command to shut down an on-premise or cloud-based cluster.

The Stanza `shutdown` command is available with MapR Installer 1.6 or later. The command shuts down Warden and Zookeeper, which in turn shut down other running services that are part of a data-fabric cluster. When you use the `shutdown` command, the MapR Installer implements the same orderly shutdown that it uses to perform software upgrades.

You must supply the ssh ID and password or the ssh ID and `ssh_key_file`.

The `shutdown` command works differently for cloud-based clusters. Note these considerations for the behavior of the `shutdown` command:

Cluster Location	Shutdown Command Behavior
On premise	Does not stop non-data-fabric software and does not power off the nodes.
In the cloud	Shuts down (but does not remove) all the nodes in the cluster. If the installer node is part of the cluster, the installer node is not shut down. To shut down the installer node, use AWS-console or Azure-portal commands to stop the instance.

This example shuts down a MapR cluster. The command uses an override to provide the `ssh_id` and `ssh_password` and includes `-nv` so that certificates will not be checked, and the output mode is verbose.

```
./bin/mapr-installer-cli shutdown -nv -o config.ssh-id=root -o
config.ssh_password=mapr
```

This example shuts down a MapR cluster. The command uses an override to provide the `ssh_id` and `ssh_key_file` and includes `-nv` so that certificates will not be checked, and the output mode is verbose. The `ssh_key_file` for root normally resides in `/root/.ssh`. In this example, the file has been copied to `/home/mapr/root` so that the `mapr` user can access the key file.

```
./bin/mapr-installer-cli shutdown -nv -o config.ssh_id=root -o
config.ssh_key_file=/home/mapr/root_user_id_rsa
```

Using probe and import to Generate the Installer Database

If a cluster has data-fabric software installed but has no installer database, you cannot install or upgrade the cluster using MapR Installer Stanza commands. And you cannot use the web-based MapR Installer on the cluster. However, you can generate an installer database on a cluster by using the `probe` and `import` commands. Once the installer database is generated, you can use the web-based installer and all MapR Installer Stanza commands on the cluster.

last-updated: Apr 11, 2022

Note: Using `probe` and `import` to generate the installer database is supported only on release 5.2 and later. If you need to use this feature on an earlier data-fabric software version, please contact your support representative.

Note: If you are not sure if your cluster has an installer database, you can use the `export` command to generate a YAML file that describes the cluster configuration. See Exporting a Cluster Configuration on page 5511.

Using probe

Before using the `probe` command, you must know the host names or IP addresses of the cluster nodes and the `root` user, which must be the same on all nodes. The probe command generates a template that will be used by the `import` command.

Note: Do not make changes to the `probe`-generated template file. After the installer database is created, you can use the `export` command to export a YAML for making changes.

In this example, the probing user, `mapr1`, probes an array of hosts (`config.hosts`) and generates a template file `/tmp/location.yaml`. The `-u` option provides login credentials for the MapR Installer. Note that the probing user must be able to do rpm and pkg queries and have permission to read certain files and directories within `/opt/mapr`.

```
mapr-installer-cli probe -n -o config.ssh_id=mapr1
config.ssh_password=xyz config.hosts='["hostname[1-3]","hostname7"]' -u
mapr1:xyz@<installer_hostname>:9443 > /tmp/location.yaml
```

Note: The `probe` command can use various methods to determine the EEP version of a node. One method checks the EEP repo URL defined on the node. If multiple EEP repos are defined on the same node, the `probe` command ignores all of them and tries to determine the EEP version based on theMapR packages that are present.

Using import

The `import` command prepares the installer database based on the probed template file. This example imports the probed YAML template file from the previous example. `-t` specifies the location of the template file:

```
mapr-installer-cli import -n -t /tmp/location.yaml
```

After you use the `import` command, the installer database should be operational. You can then use the web-based MapR Installer or Stanzas to perform additional operations on the cluster. See MapR Installer on page 5395.

MapR Installer Stanza Commands

This topic provides the syntax and options for MapR Installer Stanza commands.

Command Usage

To use MapR Installer Stanza commands, you must log in as the cluster administrator user that you configured while running the `mapr-setup.sh` script. For more information, see Managing Users and Groups.

`check`

last-updated: Apr 11, 2022

Use the `check` command to verify that the nodes specified in the Stanza file are ready to be installed. For more information, see Verifying the Stanza File.

```
check [-h]
     [--overrides [OVERRIDES [OVERRIDES …]]]
     [--no_check_certificate][--url URL]
     [--force][--verbose] --template TEMPLATE
```

`export`

You can use the `export` command to discover a currently installed cluster and generate a Stanza file that captures the configuration, the groups, and the hosts for the cluster. You can then modify the Stanza file to install other clusters. For more information, see Exporting a Cluster Configuration.

Note: The Stanza file generated by the `export` command does not contain the `ssh_password` or `ssh_key_file` values. You need to add those values manually or provide them on the command line by using an override.

```
export [-h]
     [--overrides [OVERRIDES [OVERRIDES ...]]]
     [--no_check_certificate] [--url URL]
     [--file FILE]
```

`import`

The `import` command prepares the installer database using the template generated by the `probe` command. You must specify a template (YAML file) to use the import command. For more information, see Using probe and import to Generate the Installer Database on page 5514.

```
import [-h][--no_check_certificate][--url URL][--verbose]
       --template TEMPLATE
```

`install`

You can use the `install` command to perform a fresh install, an incremental install, or an upgrade. For more information, see Installing or Upgrading MapR Core Using an Installer Stanza on page 5509.

```
install [-h]
     [--overrides [OVERRIDES [OVERRIDES …]]]
     [--no_check_certificate][--url URL]
     [--force][--verbose] --template TEMPLATE
```

`license`

Use the `license` command to add a license from a license file. For more information, see Adding a License Using Stanzas on page 5513.

```
license [-h]
      [--no_check_certificate][--url URL]
      --license LICENSE <license-file>
```

`list`

You can use the `list` command to display information about the configuration, services, groups, and hosts that are present in the MapR Installer database. For more information, see Getting Information About Services and Groups.

```
list [-h]
    {config,groups,hosts,hosts_install_status,installed,services} ...
```

`probe`

The `probe` command generates a template file that can be used to create an installer database on a cluster that doesn't have one. A cluster must have an installer database in order for you to use MapR Installer Stanzas on the cluster. If the installer database is not present, you can use the `probe` command followed by the `import` command to generate one. For more information, see Using probe and import to Generate the Installer Database on page 5514.

```
probe [-h]
      [--no_check_certificate][--url URL]
      [--force][--verbose] --template TEMPLATE
      [--overrides [OVERRIDES [OVERRIDES …]][--verbose]]
```

`reset`

The `reset` command uninstalls the metadata from the installer database. For more information, see Resetting the Installer Database.

```
reset [-h] [--overrides [OVERRIDES [OVERRIDES ...]]]
      [--no_check_certificate] [--url URL]
      [--force] [--verbose]
```

`shutdown`

The `shutdown` command shuts down the cluster. For more information, see Shutting Down a Cluster Using an Installer Stanza Command on page 5514.

```
shutdown [-h] [--overrides [OVERRIDES [OVERRIDES ...]]]
      [--no_check_certificate] [--url URL]
      [--force] [--verbose]
```

`uninstall`

The `uninstall` command removes MapR software. For more information, see Uninstalling Core Using an Installer Stanza.

```
uninstall [-h]
      [--overrides [OVERRIDES [OVERRIDES ...]]]
      [--no_check_certificate] [--url URL]
      [--force] [--verbose]
```

Command Options

All of the following command options are optional except for the `TEMPLATE` option:

Option	Description
`-h` or `--help`	Show this help message and exit.
`-o [OVERRIDES[OVERRIDES …]]` or `--overrides[OVERRIDES[OVERRIDES …]]x = y list of overrides or - for stdin`	Use the specification provided on the command line instead of the Stanza file instructions. Overrides are typically used when you want to specify a host name, user ID, password, or key file on the command line.

last-updated: Apr 11, 2022

	Note:
	The `key=value` pair or pairs specified in a Stanza override must not include blank spaces. For example, do not use this command:
	`./mapr-installer-cli probe -o config.hosts='["host1", "host2", "host3"]' .....`
	Use this command instead:
	`./mapr-installer-cli probe -o config.hosts='["host1","host2","host3"]' .....`
	In the second command, `config.hosts` is the `key`, and `'["host1","host2","host3"]'` is the `value`. An override can specify multiple `key=value` pairs with each pair separated by a space:
	`-o <key1=value1> <key2=value2> <key3=value3>`

`-n` or `--no_check_certificate`	Do not verify SSL certifications.
`-u URL` or `--url URL`	Installer URL (user:password@host:port)
`--file FILE`	The `export` file path.
`-f` or `--force`	Force action. This option eliminates user input and answers yes to all questions returned by the software.
`-v` or `--verbose`	Verbose output.
`-t TEMPLATE` or `--template TEMPLATE`	The specified Stanza template file (required for the `install` and `import` commands). The template file can be a local file on the installer node, or it can be a remotely accessible URL.

Command Line Help

You can access online help at the command line using any of these commands:

Command	This command displays...
`./bin/mapr-installer-cli -h`	Top-level help for the installer
`./bin/mapr-installer-cli <cmd> -h` where <cmd> is one of the following: • `check` • `export` • `import` • `install` • `license`	Help for the specified command

last-updated: Apr 11, 2022

• list • probe • reset • uninstall	

Interoperability Matrices

This section provides tables that show the operating system (OS), JDK, ecosystem, and MapR client support for the MapR Data Platform. Check these tables for information about software compatibility.

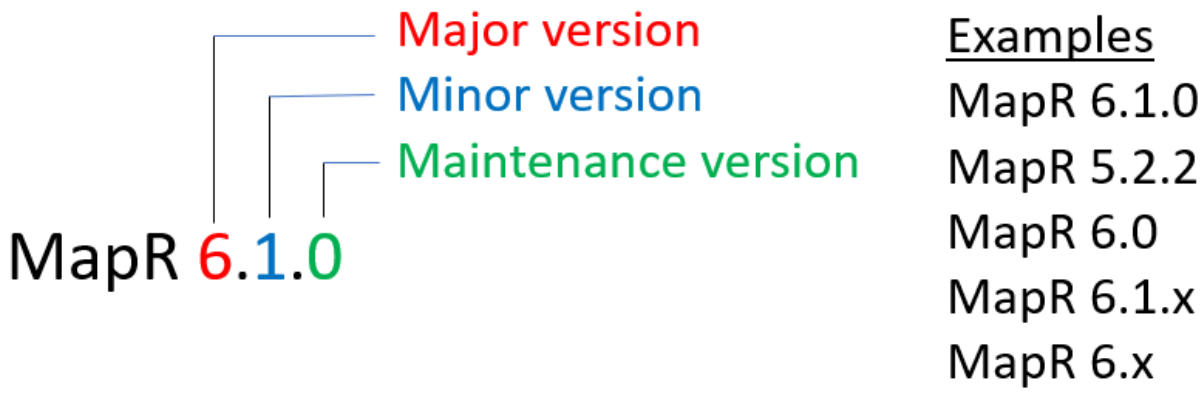
Understand MapR Versions

Understanding the version numbers used by MapR core, MapR Ecosystem Packs (EEPs), EEP components, and MapR patches can help you keep your software up to date and plan for upgrades.

MapR release versions generally follow the industry-standard **<major>.<minor>.<maintenance>** format, with a number representing each version. However, some MapR software products use different versioning formats. The following sections describe the characteristics of the various MapR versioning formats.

MapR Core Versions

In MapR interfaces and documentation, MapR core versions are expressed as a dot-separated string of numbers having two or three places. For example:



A Change to This Version	Typically Includes	For Example
MapR core major version	Significant new features and API changes that can introduce incompatibilities with the previous version.	MapR 6.x followed MapR 5.2.x and added built-in security features, database features (secondary indexes), new APIs (Apache OJAI and Change Data Capture), a new EEP series (EEP 4.x), filesystem enhancements, a new installer version, and a redesigned MapR Control System for monitoring the cluster.
MapR core minor version	New features, bug fixes, and API changes that are sometimes incompatible with the previous version.	MapR 6.1 followed MapR 6.0.1 and added security by default, a new ZooKeeper version, several new database features (Node.js and Python OJAI clients, complex type support, table metrics, support for the OJAI 3.0

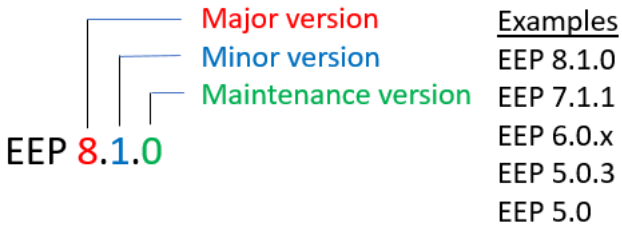
last-updated: Apr 11, 2022

A Change to This Version	Typically Includes	For Example
		API), a new installer version, a new EEP series (EEP 6.x), and storage tiers for the file system.
MapR core maintenance version	Bug fixes only. This version typically does *not* introduce incompatibilities with the previous version.[1]	MapR 5.2.2 followed maintenance releaseMapR 5.2.1 and introduced new EEPs, improvements to the disk space balancer tool, and a new MapR Installer version, but did not include new features or API changes.

[1]MapR 6.0.1 was an exception to this rule, adding REST API access to MapR Database JSON tables, event timestamp support for stream processing, streaming audit logs for the MapR XD Distributed File and Object Store, and a new EEP series (EEP 5.x).

EEP Versions

In MapR interfaces and documentation, MapR Ecosystem Pack (EEP) versions are expressed as a dot-separated string of numbers having two or three places. For example:



A Change to This EEP Version	Typically Includes	For Example
Major version	A new EEP series that supports a new major, minor, or maintenance version of MapR core.	EEP Support and Lifecycle Status on page 5531 shows how EEP major versions change when new versions of MapR core are introduced.
Minor version	A significant change in features or APIs but no change in support for the current MapR core version.	EEPs 6.0.1 and 6.1.0 both support MapR 6.1.0, but EEP 6.1.0 introduced new MapR Database features, such as the C# and Go OJAI clients, as well as new features for ecosystem components (Flume, Oozie, Tez, and Apache Kafka). EEP 6.2.0, which also supports MapR 6.1.0, introduced new ecosystem component versions (Hue, Impala, Spark) and updated some components (Oozie and Hive).
Maintenance version	Bug fixes only. EEP maintenance versions do not add new features or API changes and are backward compatible in the same EEP series.	EEPs 5.0.3, 5.0.2, and 5.0.1 added bug fixes to the EEP 5.0.x line while preserving compatibility with MapR 6.0.1.

About the MapR Patch Version

Beginning with EEP 6.1.0, version numbers for some ecosystem components and MapR tools use a dot-separated string having four places instead of two or three places. For example:

- Oozie 5.1.0.0
- MapR Installer 1.11.0.0

last-updated: Apr 11, 2022

The fourth numeral represents the MapR patch version. The MapR patch version adds a unique descriptor for patches that can occur between releases. In future releases, as new versions of components are released, more components and tools will transition to a version string that includes the MapR patch version.

How the MapR Patch Version Increments

Beginning with EEP 6.2.0, the MapR patch version can be a number in the range 0 through 999. For a newly released component, the patch version starts at 0 and increments by 1 when there is an EBF update. For example, if the EEP 6.1.0 general availability (GA) package version for Oozie is 5.1.0.0, the first bug-fix (EBF) package version will be Oozie 5.1.0.1. The next bug fix package version will be Oozie 5.1.0.2, and so on.

If the same version of a component is present in multiple EEPs, the patch version increments by 100 to provide a range of usable version numbers for future patches. This numbering scheme ensures that all patches have a unique version. The following table shows how the Oozie patch version increments for EEPs 6.1.0, 6.1.1, and 6.2.0:

EEP	Oozie GA Version	1st Oozie Patch Version	2nd Oozie Patch Version
6.1.0	5.1.0.0	5.1.0.1	5.1.0.2
6.1.1	5.1.0.100	5.1.0.101	5.1.0.102
6.2.0	5.1.0.200	5.1.0.201	5.1.0.202

To obtain EBF patches, you must contact HPE Support. HPE Support makes EBF patch versions available for specific known issues. See Patches for Known Issues.

Maven Version Format

Beginning with EEP 6.2, the MapR patch version also is present in Maven artifacts for components that use the four-place versioning. In addition, the Maven version format changes to include the associated EEP instead of the YYMM timestamp:

Old Maven format with YYMM timestamp: `maprdb-spark-2.2.1-mapr-1803.jar`

New Maven format with EEP number: `maprdb-spark-2.3.3.0-mapr-602.jar`

The Maven version increments in the same way that the MapR patch version increments. This table shows how the Spark package version and Maven versions increment when new EBF patch versions become available:

EEP	EEP 6.0.2	EEP 6.1.1	EEP 6.0.3*	EEP 6.1.2*
Spark Package Version	`mapr-spark-2.3.3.0.<timestamp>`	`mapr-spark-2.3.3.100.<timestamp>`	`mapr-spark-2.3.3.200.<timestamp>`	`mapr-spark-2.3.3.300.<timestamp>`
Spark 1st EBF Package Version	`mapr-spark-2.3.3.1.<timestamp>`	`mapr-spark-2.3.3.101.<timestamp>`	`mapr-spark-2.3.3.201.<timestamp>`	`mapr-spark-2.3.3.301.<timestamp>`
Spark Maven Version	`2.3.3.0-mapr-602`	`2.3.3.100-mapr-611`	`2.3.3.200-mapr-603`	`2.3.3.300-mapr-612`
Spark 1st EBF Maven Version	`2.3.3.1-mapr-602`	`2.3.3.101-mapr-611`	`2.3.3.201-mapr-603`	`2.3.3.301-mapr-612`

*This release is not currently available and is included only for illustration purposes.

A patch release can trigger periodic updates to the Maven repository. You may notice patches in the sftp.mapr.com repository that are not updated in the Maven repository. This is normal. The

last-updated: Apr 11, 2022

Maven repository will be updated eventually. The latest patch versions are always propagated first to sftp.mapr.com. If you have questions about patches, contact your HPE support representative.

Oracle Enterprise Linux[3]	8.4	Yes	No	No	No	No	No
	8.3	Yes	No	No	No	No	No
	8.2	Yes	Yes	No	No	No	No
	7.8	No	No	No	Yes[1]	No	No
	7.4	No	No	No	Yes	Yes	Yes
	7.3	No	No	No	Yes	Yes	Yes

[1]Requires a patch. See this support advisory. To install patches, see Applying a Patch on page 437.

[2]Use Installer 1.10 or later with this release. Before upgrading your operating system to Red Hat Enterprise Linux 7.5, CentOS 7.5, or SLES12 SP3, be sure to update the Installer to version 1.10 or later. See Updating the MapR Installer on page 5409.

[3]Releases 7.0.0 and 6.2.0, including core and ecosystem components (EEP 7.x.x and later), can be used on the supported versions of Oracle Enterprise Linux. Releases 6.1 and 6.0 support Oracle Enterprise Linux for core installations only (ecosystem components are not supported).

[4]Supported only for EEPs 6.3.0 and later.

[5]NFSv4 is not supported for core 6.1.0 on Red Hat Enterprise Linux / CentOS 8.x.

[6]Requires a patch. Certified only for EEP 5.0.4. Other EEPs supported by release 6.0.x might work but have not been certified.

[7]Hue 4.3.0 in EEP 6.3.0 and 6.3.1 is not supported for Red Hat Enterprise Linux (RHEL) or CentOS 8.x. However, Hue 4.3.0.300 in EEP 6.3.2 can be used with RHEL or CentOS 8.x.

[8]RDMA is not supported with release 6.2 on Ubuntu 16.04.

[9]Installing release 6.1.0 on RHEL or CentOS 8.x requires you to enable the EPEL repository. Starting in RHEL 8.x, a `mapr-core-internal` package dependency (`sdparm`) is deprecated and moved to EPEL, and installation cannot complete without enabling it. For information about adding repositories, see Adding the MapR Repository on RHEL, CentOS, or Oracle Linux on page 143.

[10]CentOS Linux 8 has reached End of Life (EOL) status. For more information, see this page. See also the HPE Ezmeral Data Fabric Advisory in response to CentOS 8 Discontinuance.

[11]NFS v4 is not supported for releases 7.0.0 and 6.2.0 on SLES 15.

[12]Requires a patch (core 6.2.0.7 or later). The https://package.mapr.hpe.com/ repository automatically provides the right patch version.

Operating System Support Matrix (MapR 5.x)

This matrix shows the operating systems and versions supported by each MapR 5.x release.

OS Version / MapR Version	MapR 5.2.2	MapR 5.2.0, 5.2.1	MapR 5.1.0	MapR 5.0.0	MapR 4.0.2	MapR 4.0.1

	6.4	No	No	Yes	No	No	No

last-updated: Apr 11, 2022

[1]MapReduce (MRv1) metrics are supported only on Red Hat/CentOS 6. MapReduce (MRv1) metrics are not installable on SLES or RedHat / CentOS 7.

[2]MapR Installer 1.9 and earlier are not supported on Red Hat 7.5 or CentOS 7.5 with MapR 5.2.2. Before upgrading your operating system to Red Hat 7.5 or CentOS 7.5, be sure to update the MapR Installer to version 1.10 or later. See Updating the MapR Installer on page 5409.

[3]If you are installing MapR on CentOS Version 6.3 or earlier, see the Known Issues section in the Release Notes.

[4]Secure MapR clusters are not supported on SLES 11 platforms.

[5]MapR 5.2 and 5.1 support Oracle Enterprise Linux for Core installations only. Ecosystem components are *not* supported.

[6] MapR 5.0 supports RHEL/CentOS 7.0, but service management with `systemd` is not supported. Starting in RHEL/CentOS 7.0, `systemd` was included alongside the legacy process manager, `initd`, but was not enabled by default. In RHEL/CentOS 7.1, `systemd` became the default. Some RHEL/CentOS 7.0 ISOs may have a different default for `systemd` (on), but these will not work with MapR 5.0. Service management integration with `systemd` is only supported if you install MapR 5.1 or 5.2 on RHEL/CentOS 7.1. Customers who encounter issues with `systemd` support may choose to disable `systemd` on RHEL/CentOS 7.0 nodes, downgrade to RHEL/CentOS 6.x, or upgrade to MapR 5.1 or 5.2.

[7]MapR does not support RedHat when its kernel patch level is below kernel-2.6.32-504.16.2.el6. Patch levels below kernel-2.6.32-504.16.2.el6 include Linux kernel 3.14-3.17, which has a bug that may cause the following issues:

- Lost wake-ups between process threads.
- MapR processes hang.

For more information, see https://rhn.redhat.com/errata/RHSA-2015-0864.html.

> **Tip:** You can run the following command to determine the kernel patch level of your operating system:
> `uname -r`

[8]The MapR Installer and MapR Installer Stanzas are currently not supported for use with this OS version.

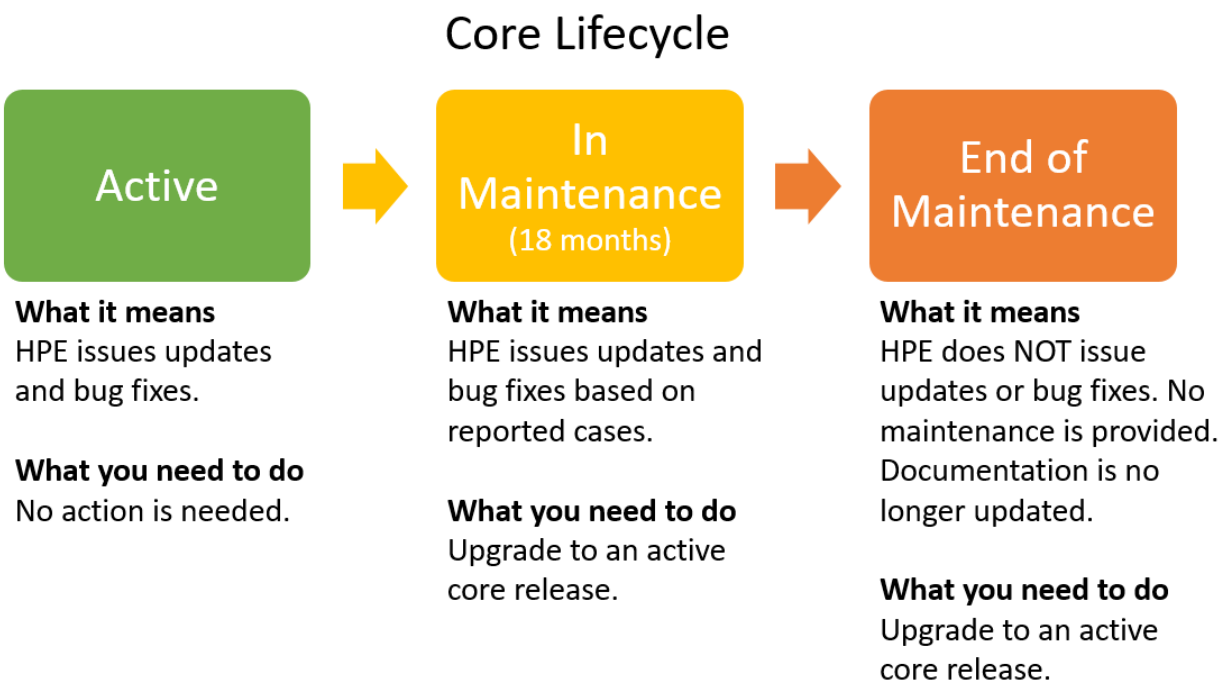
Understand the Core Lifecycle

Describes the MapR Data Platform core lifecycle and defines the lifecycle stages, which are Active, In Maintenance, and End of Maintenance.

Core Lifecycle Stages

Hewlett Packard Enterprise periodically releases new core software. Each core release is supported for an amount of time that can vary depending on the new releases that follow it. When new core versions are released, older core versions are deprecated or discontinued. Each core version therefore has its own lifecycle. As shown in the diagram, a core release can transition through three lifecycle stages:

- Active
- In Maintenance (18 months)
- End of Maintenance



Typically, within six months after a new release, Hewlett Packard Enterprise issues an advisory to indicate the end of maintenance for older versions of core. Eighteen months after the advisory is issued, the In-Maintenance core version reaches the End-of-Maintenance stage and is discontinued.

To view the current lifecycle status for every core release, see Core Support and Lifecycle Status on page 5530. The following table describes the lifecycle stages:

Support and the Lifecycle Stages

Support Activity	Notes	Lifecycle Stage		
		Active	In Maintenance	End of Maintenance
Proactive Maintenance (Minor, Maintenance, Patch)	Includes proactive fixes for security vulnerabilities, critical bugs, and other issues.	Yes	No	No
Reactive Maintenance (Escalation Support + Patch)	Requires the user to open cases resulting in tactical fixes for critical bugs, where backporting is feasible.	Yes	Yes[1]	No
Assisted Support (Usage / Debug Support)	Does not include patch fixes.	Yes	Yes	No

[1]Includes fixes for critical bugs and CVEs reported to Support. Does not include documentation updates.

Core Versions

In MapR Data Platform interfaces and documentation, core versions are expressed as a dot-separated string of numbers having two, three, or four places. Updates and bug

last-updated: Apr 11, 2022

fixes result in changes to the major, minor, maintenance, and patch versions of a core

release:

Notification of Changes in Support for Released Core Versions

To notify users about changes in EEP support, Hewlett Packard Enterprise issues periodic support advisories. When core releases are deprecated or discontinued, users of those releases are encouraged to upgrade to newer versions.

For service advisories, see:

- All Advisories
- Security Vulnerability Advisories
- Critical Issue or Bug Advisories
- Product Discontinuance (EOL) Advisories

Understand the EEP Lifecycle

This page describes the EEP lifecycle and defines the lifecycle stages, which are Active, Deprecated, and Discontinued.

EEP Lifecycle Stages

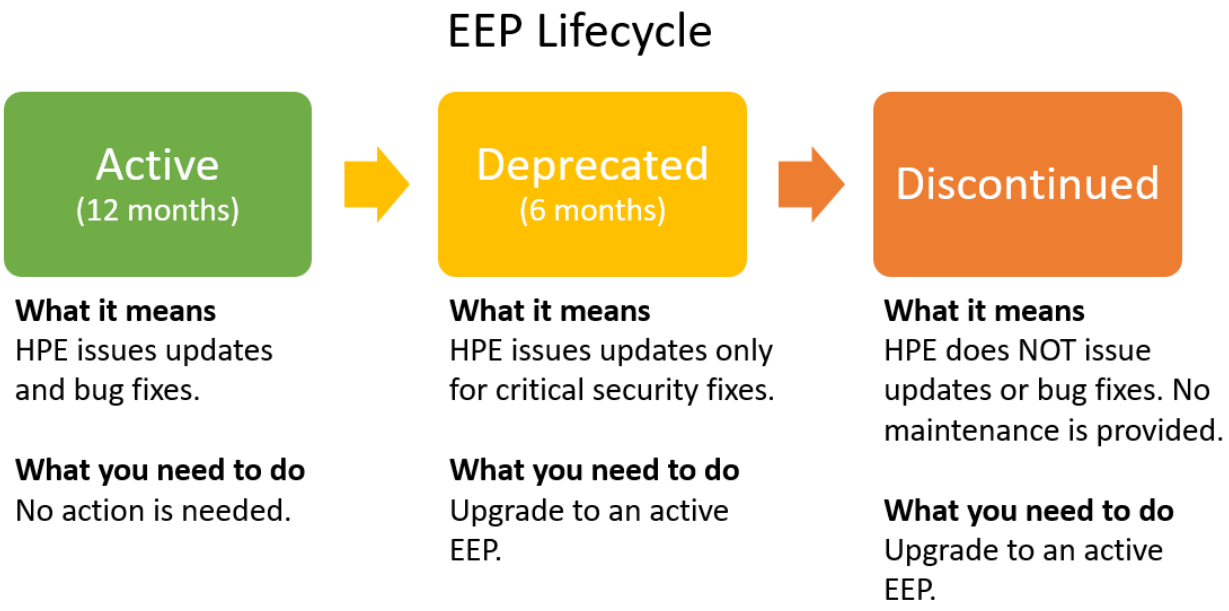
HPE periodically releases new ecosystem components as ecosystem packs (EEPs). Each EEP is supported for 18 months. When new EEPs are released, older EEPs are deprecated or discontinued. Each EEP therefore has its own lifecycle.

As shown in the diagram, an EEP can transition through three lifecycle stages:

- Active (12 months)
- Deprecated (6 months)
- Discontinued

The lifecycle stage determines if HPE issues updates and bug fixes for the EEP, which are reflected in changes to the major, minor, and maintenance versions of the EEP:

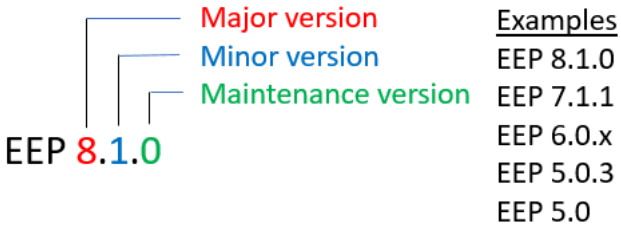
last-updated: Apr 11, 2022



To view the current lifecycle status for every EEP, see EEP Support and Lifecycle Status on page 5531.

EEP Versions

In MapR interfaces and documentation, MapR Ecosystem Pack (EEP) versions are expressed as a dot-separated string of numbers having two or three places. For example:



A Change to This EEP Version	Typically Includes	For Example
Major version	A new EEP series that supports a new major, minor, or maintenance version of MapR core.	EEP Support and Lifecycle Status on page 5531 shows how EEP major versions change when new versions of MapR core are introduced.
Minor version	A significant change in features or APIs but no change in support for the current MapR core version.	EEPs 6.0.1 and 6.1.0 both support MapR 6.1.0, but EEP 6.1.0 introduced new MapR Database features, such as the C# and Go OJAI clients, as well as new features for ecosystem components (Flume, Oozie, Tez, and Apache Kafka). EEP 6.2.0, which also supports MapR 6.1.0, introduced new ecosystem component versions (Hue, Impala, Spark) and updated some components (Oozie and Hive).
Maintenance version	Bug fixes only. EEP maintenance versions do not add new features or API changes and are backward compatible in the same EEP series.	EEPs 5.0.3, 5.0.2, and 5.0.1 added bug fixes to the EEP 5.0.x line while preserving compatibility with MapR 6.0.1.

last-updated: Apr 11, 2022

Notification of Changes in Support for Released EEPs

To notify users about changes in EEP support, HPE issues periodic support advisories. When EEPs are deprecated or discontinued, users of those EEPs are encouraged to upgrade to newer EEPs.

For service advisories, see:

- All Advisories
- Security Vulnerability Advisories
- Critical Issue or Bug Advisories
- Product Discontinuance (EOL) Advisories

Core Support and Lifecycle Status

This page shows the support and lifecycle status for all versions of MapR Data Platform core software.

Whenever possible, upgrade to the latest version of data-fabric core so that you can take advantage of new features, usability enhancements, and defect repair. If your installed version of core is "in maintenance," you have a limited amount of time to plan and execute a core upgrade.

For information about the core lifecycle, see Understand the Core Lifecycle on page 5526. For core compatibility with the leading Linux operating systems, see Operating System Support Matrix on page 5522.

Core Lifecycle and Maintenance Dates

Core Release	Release Date	Lifecycle Status	In Maintenance	End of Maintenance
7.0.0	March 7, 2022	Active	N/A	N/A
6.2.0	September 18, 2020	Active	January 2023	June 2024
6.1.1	March 29, 2021	Active	January 2023	June 2024
6.1.0	September 28, 2018	Active	January 2023	June 2024
6.0.1	April 6, 2018	In Maintenance	March 2022	September 2023
6.0.0	November 21, 2017	In Maintenance	March 2022	September 2023
5.2.2	August 2, 2017	End of Maintenance	December 13, 2017	April 30, 2019
5.2.1	April 6, 2017	End of Maintenance	N/A	April 30, 2019
5.2.0	August 19, 2016	End of Maintenance	N/A	April 30, 2019

3.0.1	September 6, 2013	End of Maintenance	N/A	February 29, 2016
3.0.0	May 1, 2013	End of Maintenance	N/A	February 29, 2016

Related concepts

Understand MapR Versions on page 5519
Understanding the version numbers used by MapR core, MapR Ecosystem Packs (EEPs), EEP components, and MapR patches can help you keep your software up to date and plan for upgrades.

Checking the MapR Core Version on page 5415
Some maintenance operations require you to know the version of the currently installed MapR release (sometimes referred to as the "MapR core version"). You can check the MapR core version easily from within the Control System or MapR Installer user interface or identify the version from your installed packages.

Upgrading MapR Ecosystem Packs on page 335
Describes how to upgrade MapR Ecosystem Packs (EEPs), either as part of a MapR core upgrade or to take advantage of a new EEP for the current version of MapR core.

Related reference

Understand the Core Lifecycle on page 5526
Describes the MapR Data Platform core lifecycle and defines the lifecycle stages, which are Active, In Maintenance, and End of Maintenance.

Understand the EEP Lifecycle on page 5528
This page describes the EEP lifecycle and defines the lifecycle stages, which are Active, Deprecated, and Discontinued.

EEP Support and Lifecycle Status

This page shows the EEPs that are supported for different core releases and the current lifecycle status for each EEP.

Whenever possible, upgrade to the latest EEP supported by your core version so that you can take advantage of bug fixes and usability enhancements. If your installed EEP is deprecated or discontinued, see the corresponding upgrade recommendation and support advisory to understand your options.

To learn more about the EEP lifecycle, see Understand the EEP Lifecycle on page 5528. For core lifecycle information, see Core Support and Lifecycle Status on page 5530.

Core Release 7.0.0

EEP	EEP Lifecycle Status	EEP Is Deprecated	EEP Is Discontinued	EEP Upgrade Recommendation	Support Advisory
8.1.0	Active	March 6, 2023	September 30, 2023	N/A	N/A

Core Release 6.2.0

EEP	EEP Lifecycle Status	EEP Is Deprecated	EEP Is Discontinued	EEP Upgrade Recommendation	Support Advisory
8.1.0	Active	March 6, 2023	September 30, 2023	N/A	N/A
8.0.0	Replaced by EEP 8.1.0				
7.1.1	Active	October 31, 2022	April 30, 2023	N/A	
7.1.0	Active	June 30, 2022	December 31, 2022	N/A	
7.0.1	Deprecated	January 31, 2022	July 31, 2022	Upgrade to latest EEP 7.1.x	
7.0.0	Deprecated	September 18, 2021	March 31, 2022	Upgrade to latest EEP 7.1.x	

Core Release 6.1.1

last-updated: Apr 11, 2022

Core Release 5.2.x

EEP	EEP Lifecycle Status	EEP Is Deprecated	EEP Is Discontinued	EEP Upgrade Recommendation	Support Advisory
3.0.5	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	Prepare for MapR 5.x End of Maintenance by April 2019
3.0.4	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
3.0.3	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
3.0.2	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
3.0.1	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
3.0	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
2.0.3	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
2.0.2	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
2.0.1	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
2.0	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
1.1.4	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
1.1.3	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
1.1.2	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
1.1.1	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	
1.1.0	Discontinued	October 31, 2018	April 30, 2019	Upgrade to EEP 6.3.x or later (requires a core upgrade)	

*Before using this EEP with the specified core version, you must apply the latest core patch. See Downloading a Patch on page 437.

last-updated: Apr 11, 2022

**EEP 5.0.7 is supported on core 6.0.1 until core 6.0.1 is discontinued or a newer EEP 5.0.x (with x > 7) becomes available.

EEP Components and OS Support

MapR Ecosystem Packs consist of ecosystem components and MapR-monitoring components that can run on a variety of operating systems.

MapR 6.0 and later support multiple MapR Ecosystem Packs (EEPs). For information about the EEPs supported by various core versions, see EEP Support and Lifecycle Status on page 5531. For more information about the components in each EEP, see the EEP Release Notes on page 5658.

EEP 8.1.0 Components and OS Support

This topic lists the ecosystem and MapR-monitoring components that are included in EEP 8.1.0 and shows the operating system support for each component.

To understand which MapR core versions can use this EEP, see EEP Support and Lifecycle Status on page 5531.

For the Linux operating-system versions supported by MapR software, see Operating System Support Matrix on page 5522.

[5]Supported for monitoring use cases only.

EEP 4.1.3 Components and OS Support

This topic lists the ecosystem and MapR-monitoring components that are included in EEP 4.1.3 and shows the operating system support for each component.

To understand which MapR Core versions can use this EEP, see EEP Support and Lifecycle Status on page 5531.

For the Linux operating-system versions supported by MapR software, see Operating System Support Matrix on page 5522.

Ecosystem Components	SUSE	RHEL / CentOS	Ubuntu
AsyncHBase 1.7[1]	Y	Y	Y
Drill 1.12	Y[2]	Y	Y
Flume 1.7	Y	Y	Y
HBase-compatible API[1]	Y	Y	Y
Hive 2.1.1	Y	Y	Y
HttpFS 1.0	Y	Y	Y
Hue 3.12[3]	Y	Y	Y
Impala 2.7.0	Y (12 SP1)	Y	N
Myriad 0.2	Y	Y	Y
Oozie 4.3.0	Y	Y	Y
Pig 0.16	Y	Y	Y
Sentry 1.7.0[4]	Y	Y	Y
Spark 2.1	Y	Y	Y
Sqoop 1.4.6	Y	Y	Y
Sqoop2 1.99.7	Y	Y	Y
MapR Monitoring Components[5]			

last-updated: Apr 11, 2022

Collectd 5.7.2	Y	Y	Y
Elasticsearch 5.4.1	Y	Y	Y
Fluentd 0.14.20	Y	Y	Y
Grafana 4.4.2	Y	Y	Y
Kibana 5.4.1	Y	Y	Y
OpenTSDB 2.4.0	Y	Y	Y

[1]Supported for use only with MapR Database binary tables.

[2]Supported with Open JDK 1.8 and Oracle JDK 1.8.

[3]The Spark Notebook UI in Hue is a beta feature.

[4]MapR support for Sentry is limited to Impala users.

[5]Supported for monitoring use cases only.

EEP 4.1.2 Components and OS Support

This topic lists the ecosystem and MapR-monitoring components that are included in EEP 4.1.2 and shows the operating system support for each component.

To understand which MapR Core versions can use this EEP, see EEP Support and Lifecycle Status on page 5531.

For the Linux operating-system versions supported by MapR software, see Operating System Support Matrix on page 5522.

Ecosystem Components	SUSE	RHEL / CentOS	Ubuntu
AsyncHBase 1.7[1]	Y	Y	Y
Drill 1.12	Y[2]	Y	Y
