The MapR filesystem permissions are similar to the POSIX permissions model. Each file and directory is associated with a user (the *owner*) and a group. You can set read, write, and execute permissions separately for:

- the owner of the file or directory.
- members of the group associated with the file or directory.
- all other users.

The permissions for a file or directory are called its *mode*. The mode of a file or directory can be expressed in two ways:

- Text - a string that indicates the presence of the read (`r`), write (`w`), and execute (`x`) permission or their absence (`-`) for the owner, group, and other users respectively. Example: `rwxr-xr-x`
- Octal - three octal digits (for the owner, group, and other users), that use individual bits to represent the three permissions. Example: `755`

Both `rwxr-xr-x` and `755` represent the same mode; the owner has all permissions, and the group and other users have read and execute permissions only.

When you access the MapR filesystem layer over NFS, the file-level permissions are controlled through the Linux interface by using the `chmod` (change mode) command or the `chown` (change owner) command, as well as the `hadoop fs -chmod` and `hadoop fs -chown` equivalents. For example:

```
chown jsmith /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chown jsmith /mapr/my.cluster.com/jsmith/fileA
chmod 744 /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chmod 744 /mapr/my.cluster.com/jsmith/fileA
```

These commands grant a user whose username is `jsmith` the read, write, and execute privileges on `fileA`.

Once you set file permissions, authorization checks are performed when a file is opened, *and* on every file access.

Note: To further protect your data, the MapR filesystem data cache is never included in a file server core dump.

Text Modes

String modes are constructed from the characters in the following table:

Text	Description
u	The file's owner.
g	The group associated with the file or directory.
o	Other users (users that are not the owner, and not in the group).
a	All (owner, group and others).
=	Assigns the permissions Example: "a=rw" sets read and write permissions and disables execution for all.

last-updated: Apr 11, 2022

Text	Description
-	Removes a specific permission. Example: "a-x" revokes execution permission from all users without changing read and write permissions.
+	Adds a specific permission. Example: "a+x" grants execution permission to all users without changing read and write permissions.
r	Read permission
w	Write permission
x	Execute permission

Octal Modes

To construct each octal digit, add the value of each permission that you want to grant:

- Read: 4
- Write: 2
- Execute: 1

For example, 7 which provides read, write, and execute permissions because 4+2+1=7.

Syntax

You can change the modes of directories and files in the MapR storage using either the `hadoop fs` command with the `-chmod` option, or using the `chmod` command via NFS. The syntax for both commands is similar:

- ```
  hadoop fs -chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]
  ```
- ```
  chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]
  ```

Parameters and Options

The following table provides the command parameters and options with their descriptions:

Parameter/Option	Description
-R	If specified, this option applies the new mode recursively throughout the directory structure.
MODE	A string that specifies a mode.
OCTALMODE	A three-digit octal number that specifies the new mode for the file or directory.
URI	A relative or absolute path to the file or directory for which to change the mode.

Examples

The following examples are all equivalent:

last-updated: Apr 11, 2022

- `chmod 755 script.sh`
- `chmod u=rwx,g=rx,o=rx script.sh`
- `chmod u=rwx,go=rx script.sh`

Managing File and Directory ACEs

Describes the implications of setting access control expressions on files and directories.

File *ACE* allows you to define access (whitelist and blacklist) to files and directories for a combination of users, groups, and roles. If *ACE*s are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set *ACE*s, MapR sets or resets the corresponding POSIX mode bits to match the permissions granted through *ACE*s. For more information, see Setting/Modifying File and Directory ACEs.

- If both *ACE*s and POSIX mode bits are set, access is granted if access is allowed through *ACE*s or POSIX mode bits.
- If *ACE*s are not set, POSIX mode bits are used to grant access.
- If neither *ACE*s nor POSIX mode bits are set, access is denied.

The owner of the file or directory (and mapr and root users) can set, modify, and remove *ACE*s for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files using the `hadoop mfs` command or the FileACE Java APIs on page 1457 and FileACE C APIs on page 1457. Specifically, the following access types are supported.

Access Type		Description
Command-Line	**Java API (Enum)**	
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.

For more information, see `hadoop mfs`, FileACE Java APIs on page 1457, and FileACE C APIs on page 1457.

Directory ACEs

You can set the same *ACE*s on directories as for files. In addition, directory *ACE*s support permissions to list, add child, delete child, and lookup directories using `hadoop mfs` command. Specifically, the following access types are supported.

Access Type		Description
Command-Line	**Java API (Enum)**	
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.

last-updated: Apr 11, 2022

Access Type		Description
Command-Line	**Java API (Enum)**	
`-executefile`	`EXECUTEFILE`	Execute a file.
`-readdir`	`READDIR`	List the contents of a directory. This access is required to write and/or execute files in the directory.
`-lookupdir`	`LOOKUPDIR`	Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory.
`-addchild`	`ADDCHILD`	Add a file or subdirectory.
`-deletechild`	`DELETECHILD`	Delete a file or subdirectory.

Although you can set both file and directory *ACE*s on directories, only the directory *ACE*s are used for determining access to the directory. The file *ACE* on the directory is used as the default *ACE* setting for new files under that directory.

By default, when you set *ACE*s on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.
- New files under that parent inherit the file *ACE*s and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default *ACE*, the empty string (""), which indicates that no one has permissions to read, write, or execute the file; POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file *ACE*s and corresponding POSIX mode bits from the parent directory.

Note: When accessing files and directories, the *ACE*s on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACES are set on an executable file

When *ACE*s are set on any file, mode bits are cleared. However, for a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with *ACE*s set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRAces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set access control expressions (ACEs) for files and directories.

For files and directories, run the `hadoop mfs` command to set *ACE*s. When *ACE*s are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding *ACE*s. POSIX mode bits for others is set only if `"p"` is given as the value for an *ACE*.

The following table lists the POSIX mode bits that correspond to the access types.

last-updated: Apr 11, 2022

	ACE	POSIX Mode Bits
File	`readfile`	r
	`writefile`	w
	`executefile`	x
Directory	`readdir`	r
	`addchild`	w
	`deletechild`	w
	`lookupdir`	x

The POSIX mode bit granting write (`w`) access to directory is set only if user, role, or group is granted permission for both (`addchild` and `deletechild`) access types.

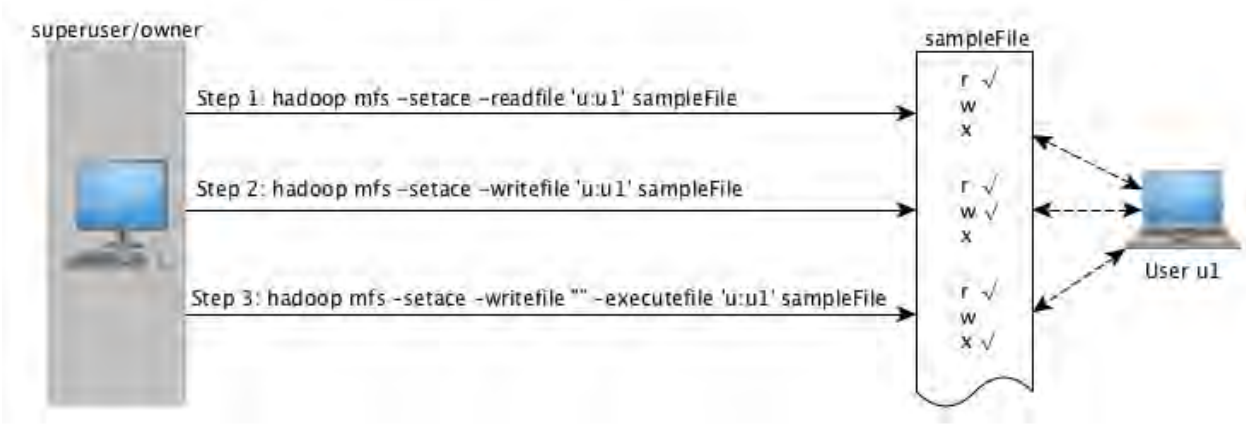
The `hadoop` command, by default, sets the POSIX mode bits corresponding to the given *ACE*s, and:

- Overwrites existing *ACE* values with new values, if specified, for access types that were previously set.
- Sets *ACE* values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, whether or not they were previously set.

Warning: Changing the POSIX mode bits using `chmod` does not change the corresponding *ACE* setting and may result in different, conflicting permissions to files and directories.

File ACE Example
Illustrates setting access control expressions for files.

Suppose the following sequence of file *ACE* settings (and corresponding POSIX mode bits) are set for user u1.



As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, `sampleFile`.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (write and execute) access types.

last-updated: Apr 11, 2022

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

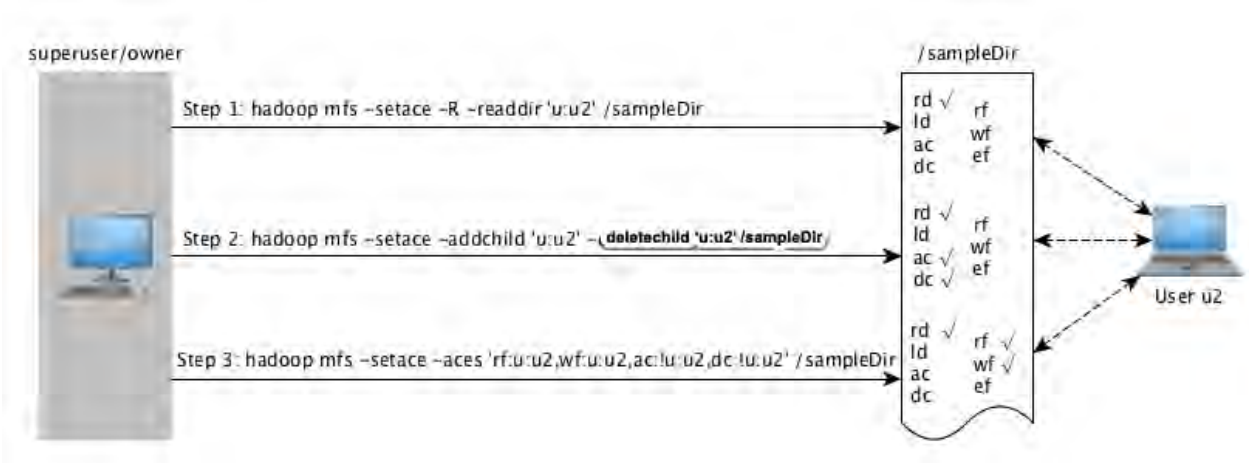
Note: When the empty string (`""`) is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`).

There is no change in *ACE*s or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory *ACE* settings for user u2:



As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory, and sampleDir, while all other directory/file *ACE*s are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (`r`) is set to u2 for owner/users.

last-updated: Apr 11, 2022

	There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.
Step 2:	User u2 is granted permission only to add and delete child directories, while all other directory/file *ACE*s are not specified. After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (`w`) to the directory for owner/user is set to u2 because user u2 is granted access for both (`addchild` and `deletechild`) access types. If user u2 creates child directories, the child directories, by default, inherit the *ACE* settings of the parent directory. There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.
Step 3:	User u2's permissions are modified to grant access to read and write to files in the directory, user u2's permissions for adding and deleting child directories are removed (using the negation operator), and all other directory/file *ACE*s are not specified. After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add and delete child directories. The POSIX mode bits for directory write access (`w`) is set to 0 for owner/user. Although, at the directory level, user u2 has permissions to read and write to files in the directory, for existing files, the file level *ACE*s or the POSIX mode bits for the file are used to determine access. However, by default, user u2 gets read and write permissions to all new files created under the directory. If user u2 creates new files under the directory, the files inherit the file *ACE*s from the parent directory by default and the POSIX mode bits for read (`r`) and write (`w`) access are set to u2 for owner/user. There is no change in *ACE*s or POSIX mode bits for all other (`lookupdir` and `executefile`) access types.

Deleting File and Directory ACEs

Describes how to delete file and directory ACEs using the CLI.

You can remove all *ACE* associated with a file or directory using the `hadoop mfs -delace` command. When you delete all the *ACE*s, the system sets the *ACE* for the file or directory to the default value, which is the empty string (""). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

You cannot remove specific access types that have been set; instead, use the empty string to deny specific types of access. When the empty string ("") is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`). If you use the empty string ("") or the negation operation (`!`) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the *ACE* setting.

Managing Chunk Size

Describes the considerations for managing the chunk size for map tasks.

Files in the MapR filesystem are split into *chunks* (similar to Hadoop *blocks*) that are normally 256 MB by default. Any multiple of 65,536 bytes is a valid chunk size, but tuning the size correctly is important:

last-updated: Apr 11, 2022

- Smaller chunk sizes result in larger numbers of map tasks, which can result in lower performance due to task scheduling overhead.
- Larger chunk sizes require more memory to sort the map task output, which can crash the JVM or add significant garbage collection overhead. MapR can deliver a single stream at upwards of 300 MB per second, making it possible to use larger chunks than in the stock Hadoop implementation. Generally, it is wise to set the chunk size between 64 MB and 256 MB.

Chunk size is set at the directory level. Files inherit the chunk size settings of the directory that contains them, as do subdirectories on which chunk size has not been explicitly set. Any files written by a Hadoop application, whether using the file APIs or over NFS, use chunk size specified by the settings for the directory where the file is written. If you change a directory's chunk size settings after writing a file, the file will keep the old chunk size settings. Further writes to the file will use the file's current chunk size.

Note: If chunk size is zero (`0`), when an application makes a request for block size, MapR will return 1073741824 (1GB); however, `hadoop mfs` on page 5373 commands will continue to display `0` for chunk size.

Configuring Chunk Size

Chunk size also affects parallel processing and random disk I/O during MapReduce applications. A higher chunk size means less parallel processing because there are fewer map inputs, and therefore fewer mappers. A lower chunk size improves parallelism, but results in higher random disk I/O during shuffle because there are more map outputs. Set the `io.sort.mb` parameter to a value between 120% and 150% of the chunk size.

Here are the general guidelines for chunk size:

- For most purposes, set the chunk size to the default 256 MB and set the value of the `io.sort.mb` parameter to the default 380 MB.
- On very small clusters or nodes with not much RAM, set the chunk size to 128 MB and set the value of the `io.sort.mb` parameter to 190 MB.
- If application-level compression is in use, the `io.sort.mb` parameter should be at least 380 MB.

Note: If you have Drill running in the cluster, change the `store.parquet.block-size` parameter in Drill so that the Parquet block size is the same as the chunk size in the MapR filesystem. See Configuring the Parquet Block Size for more information.

Setting Chunk Size

You can set the chunk size for a given directory in two ways:

- Change the `ChunkSize` attribute in the .dfs_attributes file at the top level of the directory
- Use the command `hadoop mfs -setchunksize <size> <directory>`

For example, if the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test` you can set the chunk size to 268,435,456 bytes by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `ChunkSize=268435456`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setchunksize 268435456 /mapr/my.cluster.com/projects/test
```

Managing Compression

Lists the advantages of using compression.

last-updated: Apr 11, 2022

MapR provides compression for files stored in the cluster. Compression is applied automatically to uncompressed files unless you turn compression off. The advantages of compression are:

- Compressed data uses less bandwidth on the network than uncompressed data.
- Compressed data uses less disk space.

Choosing a Compression Setting

Lists the compression algorithms supported by MapR.

MapR supports three different compression algorithms:

- lz4 (default)
- lzf
- zlib

Compression algorithms can be evaluated for compression ratio (higher compression means less disk space used), compression speed and decompression speed. The following table gives a comparison for the three supported algorithms. The data is based on a single-thread, Core 2 Duo at 3 GHz.

Compression Type	Compression Ratio	Compression Speed	Decompression Speed
lz4	2.084	330 MB/s	915 MB/s
lzf	2.076	197 MB/s	465 MB/s
zlib	3.095	14 MB/s	210 MB/s

Note that compression speed depends on various factors including:

- block size (the smaller the block size, the faster the compression speed)
- single-thread vs. multi-thread system
- single-core vs. multi-core system
- the type of codec used

- LZO vs Snappy vs LZF vs ZLIB

Setting Compression on Files

Compression is set at the directory level. Any files written by a Hadoop application, whether via the file APIs or over NFS, are compressed according to the settings for the directory where the file is written. Sub-directories on which compression has not been explicitly set inherit the compression settings of the directory that contains them.

If you change a directory's compression settings after writing a file, the file will keep the old compression settings—that is, if you write a file in an uncompressed directory and then turn compression on, the file does not automatically end up compressed, and vice versa. Further writes to the file will use the file's existing compression setting.

Warning: Only the owner of a directory can change its compression settings or other attributes. Write permission is not sufficient.

File Extensions of Compressed Files

Lists extensions of compressed files.

last-updated: Apr 11, 2022

By default, MapR does not compress files whose filename extensions indicate they are already compressed. The default list of filename extensions is as follows:

- bz2
- gz
- lzo
- snappy
- tgz
- tbz2
- zip
- z
- Z
- mp3
- jpg
- jpeg
- mpg
- mpeg
- avi
- gif
- png

The list of filename extensions not to compress is stored as comma-separated values in the `mapr.fs.nocompression` configuration parameter and can be modified with the `config save` command. For example, you can add `parquet` to the default list:

```
maprcli config save -values
'{"mapr.fs.nocompression":"bz2,gz,lzo,snappy,tgz,tbz2,zip,z,Z,mp3, \
jpg,jpeg,mpg,mpeg,avi,gif,png,parquet"}'
```

The list can be viewed with the `config load` command. Example:

```
maprcli config load -keys mapr.fs.nocompression
```

Turning Compression On or Off on Directories Using the CLI
Explains how to turn off or turn on compression and optionally specify an algorithm, using the command line.

You can turn compression on or off for a given directory in two ways:

- Set the value of the `Compression` attribute in the .dfs_attributes file at the top level of the directory.
  - Set `Compression=lzf|lz4|zlib` to turn compression *on* for a directory.
  - Set `Compression=false` to turn compression *off* for a directory.

- Use the command hadoop mfs -setcompression on|off/lzf/lz4/zlib <dir|table>.

If you choose `-setcompression on` without specifying an algorithm, lz4 is used by default. This algorithm has improved compression speeds for MapR's block size of 64 KB.

The symbols for the various compression settings are explained here:

Symbol	Compression Setting
Z	lz4
z	zlib
L	lzf
U	Uncompressed, or previously compressed by another algorithm

Example

Suppose the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test`. You can turn off compression by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `Compression=false`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setcompression off /projects/test
```

You can view the compression settings for directories using the hadoop mfs -ls command. For example,

```

```

last-updated: Apr 11, 2022

Suppose three directories `abc`, `klm`, and `xyz`. You can turn on compression and set different compression algorithm for the directories by running the following commands:

```
hadoop mfs -setcompression on /ksTestVol1/abc
hadoop mfs -setcompression lzf /ksTestVol1/klm
hadoop mfs -setcompression zlib /ksTestVol1/xyz
```

You can then view the compression settings for the directories using the hadoop mfs -ls command. For example:

```
hadoop mfs -ls /ksTestVol1/
  Found 3 items
  drwxr-xr-x  Z U U   - root root    0 2017-12-11 08:41  268435456 /
ksTestVol1/abc
           p 2432.32.131194  doc24.lab:5660
  drwxr-xr-x  L U U   - root root    0 2017-12-11 08:42  268435456 /
ksTestVol1/klm
           p 2432.34.131198  doc24.lab:5660
  drwxr-xr-x  z U U   - root root    0 2017-12-11 08:42  268435456 /
ksTestVol1/xyz
           p 2432.33.131196  doc24.lab:5660
```

Setting Compression During Shuffle

By default, MapReduce uses compression during the Shuffle phase. You can use the `-Dmapreduce.maprfs.use.compression` switch to turn compression *off* during the Shuffle phase of a MapReduce job. For example:

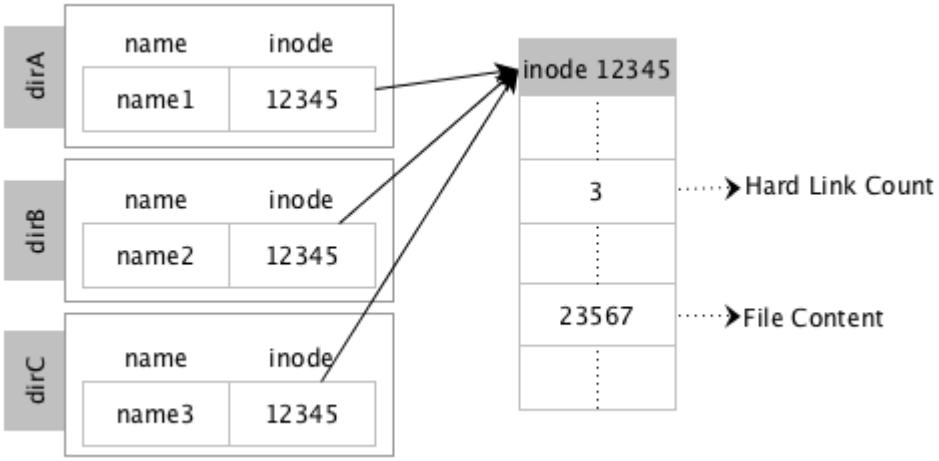
```
hadoop jar xxx.jar -Dmapreduce.maprfs.use.compression=false
```

Managing Hard Links

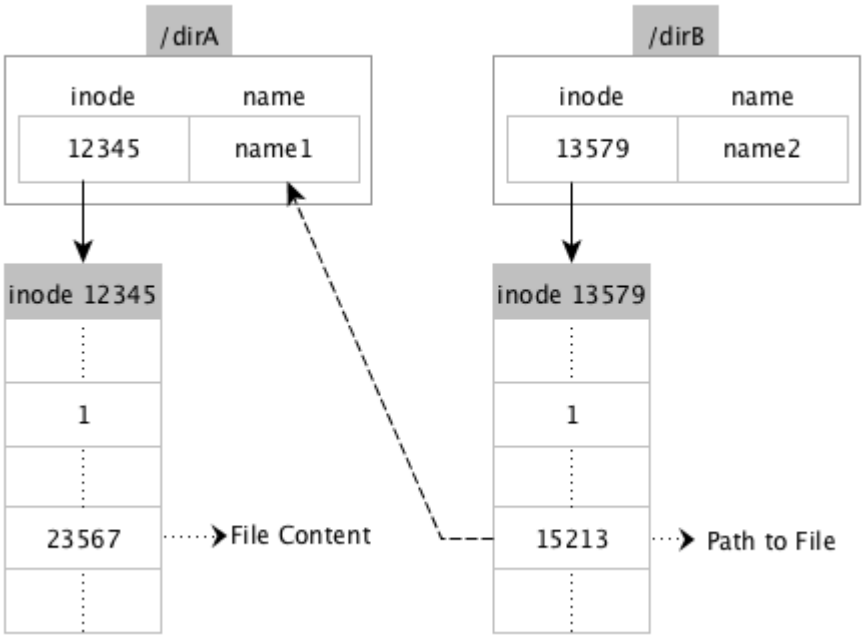
Explains what hard links are, and their limitations.

A hard link is a directory entry that associates a name with a file (or physical data) on the filesystem. Hard links allow multiple names to be associated with the same data (and associated inode) from within or outside of a directory. Every time a hard link is created, a directory entry is created and the inode (associated with the directory entry) remains the same across all hard links associated with that data. That is, all names associated with the data point to the same inode.

The following diagram illustrates the hard link semantics. Here, directory entries in dirA, dirB, and dirC for file names name1, name2, and name3 respectively all point to the inode 12345, which contains metadata including the text in the file and a count of the number of hard links to the file (or physical data).



In contrast, when a symbolic link is created, a new inode is created and the text part of the inode (associated with the symlink file) contains the path to the actual file. The following diagram illustrates the symbolic link semantics. Here, the directory entry in dirA for file name, name1, is associated with inode 12345, which contains the text in the file. The directory entry in dirB for symbolic link file, name2, is associated with inode 13579, which contains the path to file in dirA (*/dirA/name1*). Deleting the file, name1, in dirA will result in the symlink file in dirB, name2, pointing to stale content, which in turn will return errors when accessed.



Hard links can be created on regular files, symlink files, device files, and tables.

Limitations

- Hard links cannot be created on directories.
- Hard links cannot be created across volumes or clusters. Instead, use symbolic link to link to a file on a different volume.

last-updated: Apr 11, 2022

- Hard links within a volume are carried over to mirror volumes and volume snapshots. During cross-mirroring, there will be an error if support for hardlinks is not enabled on both the clusters.
- The `hadoop distcp` command cannot be used for creating and preserving copies of hard links.
- The maximum number of hard links is constrained by the integer width (32 bits), which means the maximum number possible for a file is 2^{32}.

Usage

Any user with access to the directory can create a hard link to any file under that directory. To create hard links, the user must have write permissions on the directory and execute permissions (to do the lookup for the path) on the target file. To read or modify the file, the user must have read or write permissions respectively on the file.

Errors

For information on the type of failures and errors, refer to the man page. In addition, please note that the EXDEV error is returned if command is run to create cross-volume or cross-cluster hard links.

Enabling Hard Links

By default, this feature is enabled on all new installation. If you upgrade, you must enable this feature. To enable this feature, run the following command:

```
maprcli cluster feature enable -name mfs.feature.hardlinks.support
```

Setting a Hard Link

Explains how to create a hardlink to a file.

To set a hard link using:

- POSIX loopbacknfs client or NFS client, run the following command:

  ```
  ln <sourcefile> <newfile>
  ```

  where <sourcefile> is the name of the file to link to and <newfile> is the name of the hard link, which must *not* already be present.

- Hadoop, run the following command:

  ```
  hadoop mfs -lnh <sourcefile> <newfile>
  ```

  where <sourcefile> is the name of the file (including full path) to link to and <newfile> is the name of the hard link (including the full path). When running this command, specify the full path to both files.

Retrieving the Number of Hard Links

Explains how to retrieve the number of hard links to a file.

To retrieve the number of hard links associated with a file, run the following command:

```
ls -l
```

The command, `ls -l`, will print the number of hardlinks in the second column. For example, your output will look similar to the following:

```
ls -l sample-link
  rw-r--r- 2 root root 0 Apr 21 11:09 sample-link
```

To retrieve the list of the hard links associated with a file, run the following command:

```
find <dirpath> -samefile <sourcefile>
```

where `<dirpath>` is the path to the source file and `<sourcefile>` is the source file for the hard link. For example, your output will look similar to the following:

```
find . -samefile file8
  ./file8-link2
  ./file8-link100
  ./file8-link101
  ./file8
  ./file8-link
```

For POSIX (loopback NFS) clients, the number of hardlinks to a file can be retrieved using the `stat64` system call. For example, your output will look similar to the following:

```
stat samplefile
  File: 'samplefile'
  Size: 0               Blocks: 0          IO Block: 131072 regular empty
file
  Device: 14h/20d Inode: 853785146   Links: 4
  Access: (0644/-rw-r--r--)  Uid: (    0/    root)   Gid: (    0/    root)
  Access: 2016-05-12 13:06:21.000000000 -0700
  Modify: 2016-05-12 13:06:30.002560000 -0700
  Change: 2016-05-12 13:06:30.002560000 -0700
```

If you are not using NFS or the POSIX clients, to retrieve the number of hard links, you can run the `hadoop` command to retrieve the fid and then run the `maprcli` command to retrieve the number of hard links as follows. The `nlink` variable will print the number of links.

```
hadoop mfs -ls /p1
  Found 1 items
  -rw-r--r--  Z U U   3 root root       3054 2016-05-05 13:49  268435456 /p1
  p 2049.40.262550  node-31.lab:5660

maprcli fid stat -fid 2049.40.262550
  xattrInum  uid  atime       nblocks  deleteFlags     mtime
parent     nlink  type       version  size  mode  networkencryption
subtype   gid  compression
  0          0    1462481255  1        DeleteTypeNone  1462481376
2049.16.2  2      FTRegular  2097165  3054  644   false
FSTInval  0    lz4
```

Removing Hard Links

To remove a hard link using:

- Linux, run the following command:

  ```
  rm -f <hard link>
  ```

- Hadoop, run the following command:

  ```
  hadoop fs -rm <path to hard link>
  ```

Example

For example, suppose there are **4** hard links to file cite75_99.txt.

```
$ ls -l
total 1289433
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite75_99.txt
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link1
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link2
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link3
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link4

$ maprcli fid stat -fid 2142.34.131274
parent     deleteFlags     atime       gid  nlink  type       mtime
version  mode  uid  xattrInum  size       subtype   networkencryption
nblocks  compression
2142.16.2  DeleteTypeNone  1469738740  0    5      FTRegular  1469738771
1048600  755   0    0          264075431  FSTInval  false
8        lz4
```

To remove a hard link using:

- Linux, run the following command:

  ```
  rm -f cite-link1
  ```

  To verify that the command ran successfully, run the following command:

  ```
  $ ls -l
  total 1031546
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite75_99.txt
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link2
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link3
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link4
  ```

- Hadoop, run the following command:

  ```
  $ hadoop fs -rm /test-hl/cite-link2
  16/07/28 13:52:00 INFO Configuration.deprecation: io.bytes.per.checksum
  is deprecated. Instead, use dfs.bytes-per-checksum
  16/07/28 13:52:00 INFO fs.TrashPolicyDefault: Namenode trash
  configuration: Deletion interval = 0 minutes, Emptier interval = 0
  minutes.
  Deleted /test-hl/cite-link2
  ```

  To verify that the command ran successfully, run the following command:

  ```
  $ maprcli fid stat -fid 2142.34.131274
  parent  deleteFlags     atime       gid  nlink  type       mtime
  version  mode  uid  xattrInum  size       subtype   networkencryption
  nblocks  compression
  0.0.0   DeleteTypeNone  1469738740  0    3      FTRegular  1469738771
  1048603  755   0    0          264075431  FSTInval  false
  8        lz4
  ```

Managing Extended Attributes

Describes what extended attributes are, and the POSIX permissions that you need to manage them.

Extended attributes (referred to as `xattrs`) allow user applications to associate additional metadata with a regular file or directory. Unlike system-level inode metadata, such as file permissions or modification time, extended attributes are not interpreted by the system but are instead used by applications to store additional information about an inode. Multiple extended attributes can be associated with a single inode. The maximum size allowed for an extended attribute is 64 KB.

An extended attribute is a name-value pair, with a string name and binary value. The extended attribute names are prefixed with a namespace. For example, an `xattr` named `myXattr` in the user namespace would be specified as `user.myXattr`.

Limitations

- For the five valid namespaces supported by HDFS, MapR supports the following:

Namespace	MapR Functionality
user	Commonly used by client applications. Access to these extended attributes in the user namespace is controlled by corresponding file/directory permissions. For more information, see Permissions for Extended Attributes.
trusted	Available to superusers only. Access is denied for all other users. The extended attribute is not available through userspace methods.

Note: MapR does not support the raw namespace.

- Extended attributes cannot be associated with symbolic links. If extended attributes are used on symbolic links, they are instead applied to the symbolic link target file.
- The preserve options of commands like `cp -px` and `distcp -px` will work on extended attributes only in the following cases:
  - With Hadoop commands such as `hadoop fs`.
  - On FUSE mounted file paths.

Note: Extended attributes are not supported on NFS file paths.

Permissions for Extended Attributes

The following table lists the permissions (POSIX mode bits or *ACE*s) you will need to set, retrieve, or modify extended attributes.

To...	For directories, you need...	For files, you need...
Set extended attributes	Mode bits: write (OR) *ACE*: addchild	Mode bits: write (OR) *ACE*: writefile
Remove extended attributes	Mode bits: write (OR) *ACE*: deletechild	Mode bits: write (OR) *ACE*: writefile
Retrieve extended attributes	Mode bits: read (OR) *ACE*: readdir	Mode bits: read (OR) *ACE*: readfile

last-updated: Apr 11, 2022

Enabling Extended Attributes

Extended attributes are enabled by default on all new installation. If you are upgrading, this feature must be explicitly enabled. To enable, run the following command:

```
maprcli cluster feature enable -name mfs.feature.fileace.support
```

Setting, Retrieving, and Removing Extended Attributes

You can set and retrieve extended attributes on files, directories, and FUSE mounted file path using Hadoop commands, Linux commands, and Java APIs.

Hadoop Commands

Lists the Hadoop commands to set, retrieve, and remove extended attributes on files, directories and FUSE mounted paths.

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using the `hadoop fs` command. When setting an extended attribute:

- The name must be prefixed with a namespace.
- The extended attribute value must be encoded as one of the following:

text	The given string must be enclosed in double quotes to be treated as text.
hex	The given string must begin with 0x or 0X to be treated as hexadecimal number.
base64	The given string must begin with 0s or 0S to be treated as base64 encoding.

Note: You must have the right permissions to set, retrieve, and/or remove extended attributes.

Set Extended Attributes

To set an extended attribute name and value for a file or directory, run the following command:

```
hadoop fs -setfattr -n name [-v value] <path>
```

For example:

```
hadoop fs -setfattr -n system.name -v system-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n user.name -v user-hadoopfs /volforsnap/smallfile.txt
hadoop fs -setfattr -n security.name -v security-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n trusted.name -v trusted-hadoopfs /volforsnap/
smallfile.txt
```

Retrieve Extended Attributes

To retrieve the extended attributes associated with a file or directory, run the following command:

```
hadoop fs -getfattr [-R] -n name | -d [-e en] <path>
```

For example:

```
hadoop fs -getfattr  -d /volforsnap/smallfile.txt
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding
in [jar:file:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/
slf4j-log4j12-1.7.10.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/opt/mapr/lib/
```

```
slf4j-log4j12-1.7.12.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an
explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
# file: /volforsnap/smallfile.txt
system.name="system-hadoopfs"
trusted.name="trusted-hadoopfs"
security.name="security-hadoopfs"
user.name="user-hadoopfs"
```

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
hadoop fs -setfattr -x name <path>
```

For example:

```
hadoop fs -setfattr -x user.key1 /xattrs/m7user1/dir1
```

Linux Commands

You can set, retrieve, restore, and remove extended attributes on files, directories, and FUSE mounted file paths using Linux commands. For more information, refer to the respective Linux man page.

To use extended attributes on files on a MapR cluster with a FUSE client mounted path, see Configuring the MapR FUSE-Based POSIX Client on page 1240 to enable extended attributes through FUSE client.

Set Extended Attributes

To set an extended attribute name and value on a file/directory and/or a FUSE mounted file path, run the following command:

```
setfattr [-h] -n name [-v value] pathname...
```

For example:

```
setfattr -n system.name -v system /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n security.name -v test /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n trusted.name -v trusted /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n user.name -v user /mapr_fuse/testcluster/volforsnap/
smallfile.txt
```

For more information, refer to the Linux man page.

Retrieve Extended Attributes

To retrieve extended attributes, run one of the following commands:

```
getfattr [-hRLP] -n name [-e en] pathname...
getfattr [-hRLP] -d [-e en] [-m pattern] pathname...
```

For example:

```
getfattr  -d -m - /mapr_fuse/testcluster/volforsnap/smallfile.txt
getfattr: Removing leading '/' from absolute path names
  file: mapr_fuse/testcluster/volforsnap/smallfile.txt
```

last-updated: Apr 11, 2022

```
  security.name="test"
  system.name="system"
  trusted.name="trusted"
  user.name="user"
```

For more information, refer to the Linux man page.

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
setfattr [-h] -x name pathname...
```

For example:

```
setfattr -x user.test test2
```

For more information, refer to the Linux man page.

Restore Extended Attributes

To restore extended attributes from a file, which must be in the format generated by the `getfattr` command with the `--dump` option, run the following command:

```
setfattr [-h] --restore=file...
```

For example:

```
setfattr --restore=testout
getfattr -d test2
 file: test2
 user.test="test"
```

For more information, refer to the Linux man page.

Java APIs

Java APIs to manage extended attributes

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using Extended Attribute Java APIs.

Set Extended Attributes

To set extended attributes, use the following APIs:

`public void setXAttr(Path path, String name, byte[] value) throws IOException`	Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`. By default, if a given extended attribute exists, then it will be replaced with the specified attribute.
`public void setXAttr(Path path, String name, byte[] value, Enum<SetXAttrSetFlag> flag) throws IOException`	Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`. The `XAttrSetFlag` value can be: • `CREATE` to create a new extended attribute. An error is returned if an extended attribute with the given name already exists.

last-updated: Apr 11, 2022

- REPLACE to replace an existing extended attribute. An error is returned if the specified extended attribute does not already exist.

Retrieve Extended Attributes

To retrieve extended attributes, use the following APIs:

`public byte[] getXAttr(Path path, String name) throws IOException`	Get an extended attribute name and value for a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`.
`public Map<String,byte[]> getXAttrs(Path path) throws IOException`	Get all the extended attribute name/value pairs for a file or directory. Only those extended attributes that the logged-in user has permissions to view, are returned.
`public Map<String,byte[]> getXAttrs(Path path, List<String> names) throws IOException`	Get the extended attributes specified by the given list of names. Only those extended attributes that the logged-in user has permissions to view, are returned.
`public List<String> listXAttrs(Path path) throws IOException`	Get all the extended attribute names for a file or directory. Only those extended attribute names that the logged-in user has permissions to view, are returned.

Remove Extended Attributes

To remove an extended attribute associated with a file or directory, use the following API:

`public void removeXAttr(Path path, String name) throws IOException`	Remove an extended attribute of a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`.

Managing Core Files

Describes how to set the location for core files.

The Linux `core_pattern` file (in `/proc/sys/kernel/core_pattern`) can be used to specify the location for storing core files. If any process launched by MapR crashes, the core files are created in the directory specified by the `core_pattern` file. A valid location in the `core_pattern` file is a full path to the directory you want to use. For example:

```
/tmp/dir1/cores/%e.core.%p.%h
```

> **Tip:** For details about the standard Linux `%` specifiers that you can use to name core files, see the core man page.

If the `core_pattern` file is empty, if the file does not contain a full path, or if it uses the `"|"` redirection feature, by default, MapR sets the location for core files (in the event of a core dump on a node) to `/opt/cores` directory when:

- The `configure.sh` utility is run.
- The Warden init script is run.
- The MapR File System init script is run by Warden.

The default directory (`/opt/cores`) is also used if the `core_pattern` file contains the default MapR value for core files.

For MapR software, the directory being used to store core files should not be used for other purposes and should be empty. The cores directory cannot be the home directory, as it can cause problems during SSH

access. The hoststats service monitors the directory specified in the `core_pattern` file and raises the node-level alarm if the directory contains any entry other than "`.`" and "`..`". When Warden is started, sticky bit is set on the cores directory.

Migrating Files From MapR Edge Cluster to AWS S3

The File Migration service for MapR Edge on page 6579 clusters monitors a set of configured directory trees (referred to as *policies* in the service UI) on the MapR cluster for new and changed files. When the service detects new or changed files, it automatically uploads them to AWS S3 (Amazon's storage environment) using the AWS SDK TransferManager object. The File Migration service is a long-running process that is controlled by Warden.

Note: For information on installing File Migration Service on your Edge cluster, see Installing the File Migration Service on the Edge Cluster on page 222.

How the File Upload Process Works

The File Migration service maintains in memory information regarding directories, subdirectories, and files within each directory tree to monitor. When started, the service first looks for changed and new files in the configured directories. To detect changes to existing files, the service looks at the extended attribute `user.s3uploadtime`, which is set on each file and contains the modification time (in milliseconds) when the file was last uploaded to the AWS S3 bucket. It then places the new and changed files in a queue for upload, sorted by the oldest modification timestamp. The service then uploads multiple files in parallel and provides logs as files upload, fail to upload, or complete uploading.

Note: For each directory tree, you can set up any file or directory that matches a specified regex pattern to be ignored. For example, all files ending in `.tmp` or all files in `/tmp` directory can be set up to be ignored. Additionally, only files are considered for upload; empty directories, symbolic links, and tables or streams are ignored.

Scanning for New and Changed Files

The service scans for new and changed files in the monitored directories using a full scan or a lite scan.

Full Scan	The service performs a full scan when it is first started and periodically or randomly for a subset of the directories in the directory tree after. This allows you to spread the cost of the full scan over time rather than performing a full scan of all directories at once. During a full scan, the service examines each file in a directory to determine if it has changed since the last time the directory was examined. If the file contains changes, then the file is examined more carefully. If the file was uploaded, the service retrieves the modification time of the file, which was set on the file at the time the file was uploaded. If the file was not uploaded or if the file was uploaded but the modification time changed since the last upload, the service places the file in the queue for upload. A full scan also discovers new directories and adds them to the list of directories to be monitored.
Lite Scan	The service performs an incremental scan to detect the last modified timestamp on each directory recursively using the in-memory directory tree from the last scan. If there is no change in the timestamp since the last scan, the service does not examine the directory contents and proceeds to the next directory; this makes the incremental scan very fast. If there is

last-updated: Apr 11, 2022

a change in the timestamp since the last scan, the service performs a full scan on the directory.

Note: Before starting an incremental scan, the service checks to see if a directory tree is due for a full scan. Only a full scan allows the service to detect if a file was modified after upload. With a lite scan, the service checks only the modification time of the directory, which is not changed by the modification (such as due to late writes) of a file.

Queueing Files for Upload

Files are placed in the queue with a configurable delay from the last known modification time of the file to avoid uploading a file that is still changing.

For example, with the default of 15 seconds, a file that was modified 5 seconds ago would remain on the queue for another 10 seconds, whereas a file modified 5 minutes ago would be immediately considered for upload. This allows files to be uploaded roughly in order by last modification time.

The service places (by default, 10) files in the queue for parallel upload. The scanning service is paused if the pending queue exceeds 10 times the number of files allowed for parallel update to avoid too many pending files.

Uploading Files to S3

Uploads are in one of three states: waiting to be uploaded, uploading, finished with uploading. By default, the service performs a check on the status of the files being uploaded every 3 seconds and detects uploads that are approaching completion. The service then sets the extended attribute (`user.s3uploadtime`) to the file on MapR File System to indicate that the file was uploaded.

If an error occurs during upload, the file is requeued for another try after a brief wait, which is 5 minutes by default. If the file could not be uploaded after a specified number of attempts, the file is dequeued to allow other files to upload. Note that the file is rediscovered, if it is still there, during the next full scan and queued for upload.

Note: When files are uploaded, although the file name remains the same, but the leading slash is removed and the full path is converted to a key on the AWS S3 bucket. For example, `/tmp/foo` after upload becomes the key `tmp/foo` on AWS S3 bucket.

Setting Extended Attributes

When the upload completes, the service uses an extended attribute, `user.s3uploadtime`, to set the timestamp on the file to when the file was uploaded. This extended attribute, which contains the last upload timestamp, is used by the service to determine if a file has changed since the file was last uploaded.

Purging the Files and Directories

The service also optionally deletes files after uploading and deletes empty directories. You can configure file deletion after upload in hours or fractions of an hour and configure empty directory deletion in minutes. Both can be set to zero, which disables the deletion function. Both functions are disabled by default.

Deletion of files and directories happen only during a full scan:

For files	For files, the modification timestamp on the file is examined to see how far back in time it was last modified.

last-updated: Apr 11, 2022

	If the file has been uploaded in its present form and if it matches or exceeds the interval configured for file deletion, the file is immediately deleted. If it does not match the configured interval for file deletion, a message is printed (to the log file, `filemigrate.log`) as to when the file will be deleted if it will be deleted fairly soon. Files that were never uploaded (such as the files that were ignored) will not be deleted by the service.
For directories	For directories, the contents of the directory and the modification timestamp on the directory are examined. If the directory is empty and the modification timestamp matches or exceeds the configured interval of time for directory deletion, the directory is deleted. The act of deleting a file or directory from a parent directory causes the modification timestamp of the parent directory to change. Therefore, an idle or empty (parent) directory is deleted only after the configured interval of time since the deletion of its children (file or subdirectory). The recursive deletion of directories has a slow bottom up behavior: first empty leaf directories are deleted and then the parents are deleted during a future full scan after the interval of time has elapsed. If a directory contains files that were never uploaded (ignored), the directory will not be deleted.

Configuring MapR for HTTPS Upload to S3

Describes how to validate and trust security certificates to permit files to be uploaded to Amazon S3.

By default, MapR only trusts its own self-signed certificates. To configure MapR to trust the certificates used by AWS S3 for HTTPS upload, you must configure additional trusted certificates. Add one of the following to the `/opt/mapr/conf/ssl_truststore` file on every node in the cluster:

- The actual certificate used by the S3 endpoints you are using
- A signer of the actual certificate used by the S3 endpoints you are using
- A certificate higher in the trust chain that ultimately does sign the certificate for the S3 endpoint

Note: Currently, the root certificate used by AWS S3 is the Baltimore CyberTrust root certificate provided by Digicert.

The following instructions are based on the assumption that you are adding the root certificate (known as the Baltimore CyberTrust root) provided by Digicert with a fingerprint of D4DE20D05E66FC53FE1A50882C78DB2852CAE474 and an expiration date of May 12, 2025. You can also add other certificates to the truststore.

Warning: Most Baltimore CyberTrust root certificates will expire in 2025 and expired certificates cannot be used for connecting to S3. When Amazon replaces its certificates with those issued by new certificate authorities, you must update the truststore to hold both the old and new root certificates for a smooth transition.

1. Download the Baltimore CyberTrust root certificate from the URL specified by Digicert, as in the following example:

```
cd /tmp
wget https://www.digicert.com/CACerts/BaltimoreCyberTrustRoot.crt
```

2. Add the certificate to the MapR truststore.
   a) Go to the directory where the `ssl_truststore` file is located.
      For example:

```
cd /opt/mapr/conf
```

   b) Run the command to add the certificate.
      For example:

```
keytool -importcert -file /tmp/BaltimoreCybrTrustRoot.crt -keystore
ssl_truststore
```

   c) Enter the keystore password when prompted.
      The default password is `mapr123`.

   d) Specify whether to trust this certificate by entering y when prompted.

      Note: The default value is **[no]**.

      For example:

```
cd /opt/mapr/conf
keytool  -importcert -file /tmp/BaltimoreCyberTrustRoot.crt -keystore
ssl_truststore
 Enter keystore password:
 Owner: CN=Baltimore CyberTrust Root, OU=CyberTrust, O=Baltimore, C=IE
 Issuer: CN=Baltimore CyberTrust Root, OU=CyberTrust, O=Baltimore,
C=IE

 Trust this certificate? [no]:  y
 Certificate was added to keystore
```

      Wait for the message "Certificate was added to keystore" before proceeding.

last-updated: Apr 11, 2022

e) Copy the `ssl_truststore` file to all other MapR nodes in the same location (for example, `/opt/mapr/conf/`).

Ensure that the correct truststore is available on all nodes because the service can be run on any node.

Accessing the Service UI
Describes how to access the MapR Service interface.

You can access the service UI directly and using the Control System.
Accessing the Service UI Using the Control System (from MapR v6.0.1)

- Log in to the Control System and click **Services**.
  The list of services installed on the cluster displays.
- Locate File Migrate service in the list and click **File Migrate**.
  The login page for the service UI displays.
- Enter the credentials (username and password) to log in to the page and click **login**.

Accessing the Service UI Directly

- Enter the following URL in your browser (for both secure and unsecure clusters):

```
https://<hostname>:9444/
```

To change the port:

a) Modify the environment variable property that specifies the `JETTY_PORT` (whose default value is 9444) in the `/opt/mapr/conf/conf.d/warden.filemigrate.conf` file, as shown in the following example:

```
service.env=JAVA_HEAP=200m,JETTY_PORT=9444
```

b) Wait for a few minutes and then restart the service by running the following command:

```
maprcli node services -name filemigrate -nodes <node to
restart> -action restart
```

Setting up Authentication for Users

The File Migration service uses PAM Shiro to authenticate the user in a dialog presented when opening the UI. The service authentication consults the PAM configurations in `/etc/pam.d` in the following order (first file in list that exists in that directory is the one used):

1. mapr-admin
2. sudo
3. sshd
4. passwd

The UI authorizes the following users to login and use the filemigrate service:

- The owner of the filemigrate process (on the cluster, this will be the MAPR_USER).
- Any users belonging to comma-separated list of authorized users in the properties file.
- Any users belonging to any group in comma-separated list of authorized groups in the properties file.

Setting up Authentication for Users in the Properties File

Specify a comma-separated list of users and/or groups who are authorized to log in to the UI in the `FileMigrate.properties` file in `maprfs:///var/mapr/filemigrate` directory. If the properties file is not in the directory, follow the steps in Configuring the File Migration Service Using the Properties File on page 1009.

To set up the list of users and/or groups manually, set the following properties in the `FileMigrate.properties` file:

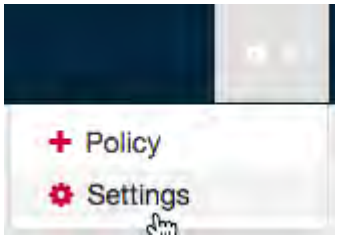
- authorized.users
- authorized.groups

To edit the file, see Managing Policies on page 1010. For more information on the properties, see FileMigrate.properties on page 2191.

Setting up Authentication for Users Using the UI

Only authorized users can log in to the UI. To set up authentication for other users:

1. Log in to the UI and select Settings from the drop-down menu.



2. Specify a comma-separated list of:
   - Users in the **Authorized Users** field under **Upload Settings**.
   - Groups in the **Authorized Groups** filed under **Upload Settings**.
3. Click **Save Changes** for the changes to take effect.

Configuring File Migration Service Using the UI

After installing and starting the service, you can access the service UI by directly entering the URL in the browser. You can then proceed to configure the properties for scanning, uploading, and monitoring the files.

Configuring Settings

Describes the interface settings for scanning and uploading files.

You can configure the settings in the interface for scanning and uploading the files.

1. Log in to the interface and select Settings from the drop-down menu.

   The **File Migration Settings** page displays.
2. Optionally, set the following for file upload:

- Full Scan Frequency
- Upload Scan Frequency
- Completion Scan Frequency
- Minimum Wait Before Upload
- Maximum Active Uploads
- Minimum Wait After Failure
- Maximum Retries Per File
- Maximum System Retries
- Minimum Idle Time Before Error

See FileMigrate.properties on page 2191 for more information.

3. Set the following to enable the service to connect and upload to AWS S3:
   - Proxy Host
   - Proxy Port
   - Proxy Username
   - Proxy Password

   See FileMigrate.properties on page 2191 for more information.
4. Click **Save Changes** for the changes to take effect.

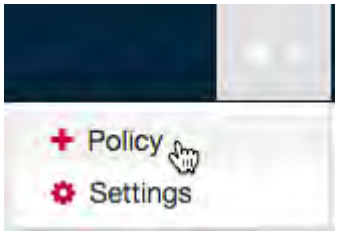
Setting up Policy

To add a new policy for file upload:

1. Log in to the UI and click **Add New File Migration Policy**.

   Alternatively, select Policy from the drop-down menu.

2. Create policies in the **Add Data Migration Policy** page.
   To create a new policy, set the following:
   - Directory Path
   - Target Bucket
   - Purge Interval

- Delete Empty Directories
- Ignore Files Regex
- X-Attributes

See FileMigrate.properties on page 2191 for more information.

3. Click **Create New Policy**.
4. Click **Restart File Migration Service**.

Configuring the File Migration Service Using the Properties File
Lists the procedure to configure the File Migration Serivce using a properties file.

To configure the File Migration Service:

1. Stop the service (if it is currently running).
   See Starting, Stopping, and Restarting the Service Using the CLI on page 1010 for more information.
2. Make a copy of the `/opt/mapr/filemigrate/filemigrate-1.0.0/conf/FileMigrate.properties.default` file and rename it to `FileMigrate.properties` if you have not yet set any properties and wish to start from the defaults, as in the following example.

   ```
   cp /opt/mapr/filemigrate/filemigrate-1.0.0/conf/
   FileMigrate.properties.default FileMigrate.properties
   ```

   Alternatively, you can use the `maprfs:///var/mapr/filemigrate/FileMigrate.properties` file if you have already used the interface to set some properties and want to perform further edits manually. See Managing Policies on page 1010 for more information.
3. Edit the `FileMigrate.properties` file to change the settings for the service, if/where necessary, and save the file.
   For more information, see FileMigrate.properties on page 2191.
4. Copy the `FileMigrate.properties` file to the `/var/mapr/filemigrate/` directory, as in the following example.

   ```
   hadoop fs -copyFromLocal /tmp/FileMigrate.properties /var/mapr/
   filemigrate
   ```

   Note: If the directory does not already exist, create it by running the `hadoop fs -mkdir` command. The `FileMigrate.properties` file contains sensitive information and the recommendation is to limit read access to the directory. If the service creates the directory, by default, only the MAPR_USER and MAPR_GROUP have read access to the directory.
5. Restart the service using the `maprcli` command, as in the following example.

   ```
   maprcli node services -name filemigrate -nodes <node to restart> -action
   restart
   ```

Managing the Service
Describes how to start, stop, and restart services using either the Control System or the CLI.

You can start, stop, and restart the service and view the service dashboard.

Starting, Stopping, and Restarting the Service Using the Control System

1. Log in to the Control System and click **Services** to display the list of services installed on the cluster.
2. See Managing Services on page 827 for information on starting, stopping, and restarting the services using the Control System.

Starting, Stopping, and Restarting the Service Using the CLI

- To:
  - Start the service, run the following command:

    ```
    maprcli node services -name filemigrate -nodes <node to start> -action start
    ```

  - Stop the service, run the following command:

    ```
    maprcli node services -name filemigrate -nodes <node to start> -action stop
    ```

  - Restart the service, run the following command:

    ```
    maprcli node services -name filemigrate -nodes <node to start> -action restart
    ```

Restarting the Service Using the Service UI

- Log in to the UI and click **Restart File Migration Service**.

Viewing the Service Dashboard

- Log in to the service UI to view the following:
  - **Uploaded Files** - Displays the number of files uploaded in the last hour.
  - **Waiting Uploads** - Displays the number of files waiting to be uploaded.
  - **Uploaded Data** - Displays the number of bytes uploaded in the last hour.

Managing Policies
Explains how to edit the Purge Interval policy and enable or disable Server Side encryption.

You can modify the Purge Interval policy and Server Side Encryption settings using the UI. You can also modify the properties directly in the properties file.

Note: Editing the properties both through the service UI and directly in the properties file may lead to inconsistencies.

Modifying Purge Interval

1. Log in to the UI and click associated with the purge interval value to edit.
2. Enter the value you want in the field.
3. Click to save the changes.

   If you want, you can click to cancel the edit operation.
4. Restart the service for the changes to take effect.

   See Restarting the Service Using the Service UI on page 1010.

Enabling or Disabling Server Side Encryption

1. Log in to the UI and select (to enable) or clear (to disable) the checkbox ( ) associated with the policy.
2. Restart the service for the changes to take effect.
   See Restarting the Service Using the Service UI on page 1010.

Editing Properties in the Properties File

You can directly edit the `maprfs:///var/mapr/filemigrate/FileMigrate.properties` file. See `FileMigrate.properties on page 2191` for complete list of properties that can be set or modified in the file.

1. Stop the File Migration service.
2. Make the necessary changes.
3. Restart the service using the `maprcli` command.
   See Starting, Stopping, and Restarting the Service Using the CLI on page 1010.

   Note: If you modified the file directly, you must restart the service using the `maprcli` command.

Removing a Policy

- Log in to the UI and click associated with the policy to remove.

Configuring Logging

Provides an overview of standard Log4J configuration.

The service uses standard Log4J configuration to control its logging. The `log4j.properties` file can be found in `<MAPR_HOME>/filemigrate/filemigrate-1.0.0/conf/` directory. By default, INFO logging is enabled. You can edit the file and restart the service to change the logging behavior.

The service logs the key actions related to scanning, uploading files, and deleting files at the INFO level in the `filemigrate.log` file. The log file also includes WARN and ERROR messages if there were problems preventing the upload of files (for example, AWS S3 was unreachable). If additional detail is needed, edit the `log4j.properties` file to increase logging to the DEBUG or TRACE levels in the properties file.

Troubleshooting

Determining if a File was Uploaded

The service externalizes the status of file uploads as an extended attribute on the files uploaded. Therefore, the service recovers easily from arbitrary crashes and restarts. Files not uploaded will be rediscovered and then uploaded.

To determine if a particular file has been uploaded by the service to AWS S3, you can examine the extended attribute on the file as shown in the following example using the unsupported script `printupload.sh`, which is included in `<MAPR_HOME>/filemigrate/filemigrate-1.0.0/bin/` directory:

```
/opt/mapr/filemigrate/filemigrate-1.0.0/bin/printupload.sh /tmp/afile
    Thu Jan  5 00:32:26 EST 2017
```

Ensuring that Login is Successful

If the username and password do not work correctly, make sure that the following properties are configured correctly in the properties file:

- `authorized.users`

last-updated: Apr 11, 2022

- `authorized.groups`

See `FileMigrate.properties` on page 2191 for information on these properties.

Managing Tiered Files from the Command-line

After creating a tiered volume and associating a tier with the volume, you can manually trigger offload and recall of individual files in the volume using the CLI. This section describes how to offload file to and recall file from the tier, retrieve status of a file-level tiering operation, and how to perform certain tiering operations when hadoop and maprcli are not available on the host you wish to use for triggering the tiering operation.

Offloading a File to a Tier Using the CLI and REST API

Describes how to offload files to a tier using the CLI and the REST API.

Files, in tiering-enabled volumes, can be offloaded individually using the CLI and REST API. See Data Offload and Purge on page 475 for more information. For information on offloading files using (loopbacknfs or FUSE-based) POSIX or NFS clients when `maprcli` or `hadoop` commands are not available, see Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1014.

Note: Offloading a single file to a warm-tier might result in wasted space. See Data Offload and Purge on page 475 for more information

The user offloading the file data must have write permission (mode bit or *ACE*) on the file to offload data.

You can also offload all data in a tiering-enabled volume to the associated tier. see Offloading a Volume to a Tier on page 933 for more information.

CLI	Run one of the following commands to offload file data to a tier: • `hadoop mfs -offload <file-path>` For more information, see `hadoop mfs` on page 5373. • `/opt/mapr/bin/maprcli file offload -name <file>` For more information, see `file offload` on page 1659.
REST API	Send a request of type POST. For example: `curl -k -X POST 'https://abc.sj.us:8443/rest/file/offload?name=fileName' --user mapr:mapr`

If the manual offload succeeds, the command returns nothing. If the offload fails, the command returns an error code. For more information on the codes, see Retrying Failed Operation on page 939.

Recalling a File to MapR File System Using the CLI and REST API

You can recall individual files from a storage tier. When you recall a file, the MAST Gateway fetches a copy of the data to the cluster. Based on the expiration time setting on the volume, recalled data is automatically:

- Offloaded again based on the storage policy (rules) if there are changes to the recalled data.
- Purged when the compactor runs if there are no changes to the recalled data.

See Data Reads, Writes, and Recalls on page 481 for more information.

Note: You can recall all data from the tier to the volume. See Recalling a Volume to MapR File System on page 936 for more information.

Recalling a File Manually Using the CLI

- Run one of the following commands to recall a file:
  - ```
    hadoop mfs -recall <pathToFile>
    ```

    For more information, see `hadoop mfs` on page 5373.
  - ```
    maprcli file recall -name <pathToFile>
    ```

    For more information, see `file recall` on page 1660.

Note: For information on recalling files using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprcli or hadoop commands are not available, see Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1014.

Recalling a File Using the REST API

- Send a request of type POST to the URL. For example, send a request similar to the following:

```
curl -k -X POST 'https://abc.sj.us/rest/file/recall?name=fileName' --user
mapr:mapr
```

Terminating a Running File-Level Tiering Job

Explains how to terminate file tiering jobs using the Control System and the CLI.

You can terminate an ongoing offload or recall of a file using the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the `file offload` on page 1659 or `hadoop mfs` on page 5373 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See Recalling a Volume to MapR File System on page 936 for more information.

For information on terminating a running offload or recall operation using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprcli or hadoop commands are not available, see Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1014. For information on terminating a running volume-level job, see Terminating a Running Volume-Level Tiering Job on page 938.

Terminating a Running File-Level Offload or Recall Operation Using the CLI and REST API

CLI	Run the following command to terminate a currently running file-level offload or recall operation: ``` maprcli file tierjobabort -name <filePath> ``` For more information, see `file tierjobabort` on page 1662 .

last-updated: Apr 11, 2022

REST API	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/file/tierjobabort?name=<filePath>' --user mapr:mapr`

Running Tiering Commands when maprcli and hadoop Commands are not Available

You can offload and/or recall a file with NFS, loopbacknfs, and FUSE-based POSIX clients even if `maprcli` or `hadoop` commands are not available. To perform file-level data tiering operations like offload and/or recall using NFS, loopbacknfs, and FUSE-based POSIX clients when `maprcli` or `hadoop` commands are not available, after mounting, provide the tiering command such as `offload`, `recall`, `tierjobstatus`, and/or `tierjobabort` as described below. When you run the command, the command creates a hidden `.tier_attributes` file (similar to `.dfs_attributes` file) that is purged immediately after the operation is submitted to the server.

Note: When you run the command, the tiering command is triggered immediately and storage policy (or rule), if any, at the volume-level is ignored.

Usage

```
/bin/echo "<command> <file-name>" > .tier_attributes
```

Note: Do not use `echo` in the terminal; instead, use `/bin/echo`.

Options

Option	Description
command	The tiering related command to run. The following commands are supported: • `offload` • `recall` • `tierjobstatus` • `tierjobabort`
file-name	The name of the file.

Return Values

On success, the command returns nothing. Otherwise, the command returns one of the following `/bin/echo` return codes, which are displayed as write errors:

Code	Message	Description
EEXIST	File exists	Indicates tier job is queued or is already in progress.
ENOTEMPTY	Directory not empty	Indicates that tier job queue is full.
ENOENT	No such file or directory	Indicates that the specified file or job ID does not exist.

Code	Message	Description
EIO	I/O error	Indicates that the job could not be submitted. Run the `tierjobstatus` command to determine the reason for this error.
EINVAL	Invalid argument	Indicates that the given command is invalid or not available. See Options on page 1014 for the list of supported commands.

Examples

Offload file named test

```
# /bin/echo "offload test"
> .tier_attributes
/bin/echo: write error: File exists
```

Recall a file named test

```
# /bin/echo "recall test"
> .tier_attributes
/bin/echo: write error: File exists
```

Check the status of a running job for a file

```
# /bin/echo "tierjobstatus test"
> .tier_attributes
```

Abort a running job

```
# /bin/echo "tierjobabort test"
> .tier_attributes
/bin/echo: write error: No such file
or directory
```

Retrieving Status of File-level Tiering Operation and File Data

You can retrieve the status of a file-level tiering operation using the CLI and REST API. For information on volume-level tiering operation, see Retrieving the Status of a Volume-level Tiering Operation on page 942.

Retrieving the Status of a Running Tiering Operation

- Run the maprcli command or send a request of type GET to check the status of an active or completed offload, abort, and/or recall operation.

  See `file tierjobstatus` on page 1663 for more information. For example:

  CLI

  ```
  maprcli file tierjobstatus -name
  <file_name> -json
  ```

  REST

  ```
  curl -k -X
  GET 'https://<host>:8443/rest/file/
  tierstatus?name<file_name>' --user
  mapr:mapr
  ```

  See Output on page 1663 for more information.

Retrieving Status of File Data

- Run the maprcli command or send a request of type GET to determine the status of file data.

  See `file tierstatus` on page 1676 for more information. For example:

CLI	`maprcli file tierstatus -name <file_name>`
REST	`curl -k -X GET 'https://<host>:8443/rest/file/tierstatus?name=<file_name>' --user mapr:mapr`

See Output on page 1677 for more information.

Administering Tables

Administration of the MapR Database is done primarily via the command line (maprcli) or with the Managed Control System (MCS). Regardless of whether the MapR Database table is used for binary files or JSON documents, the same types of commands are used with slightly different parameter options. MapR Database administration is associated with tables, columns and column families, and table regions.

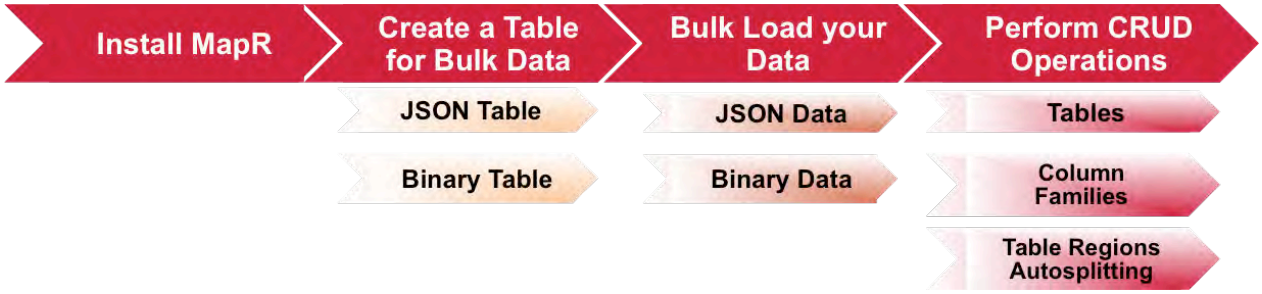
Why use MapR Database?

From an administrator's point-of-view, MapR Database provides the following capabilities:

- **Minimal administration**: Single namespace for files, tables and streams, flexible schema that allows built-in data management and protection, automatic splits and merges as data grows and shrinks, and easy bulk data loading.
- **Self-healing from HW and SW failures**: Replicated state and data for instant recovery and automated re-replication of data.
- **Global low-latency replication**: Multi-master (that is, active to active) replication which is important for disaster recovery. Includes reduced risk of data loss, application failover, and faster data access.
- **High performance and low latency**: Integrated system with fewer software layers, single hop to data, and no compactions with low I/O amplification.
- **Fine-grained security**: Access permissions can be granted to tables (as well as files and streams) at a granular level using MapR Access Control Expressions (ACEs), which are designed for flexibility and ease-of-use.

How Do I Get Started?

The following graphic shows the basics steps (with hotspot links) for getting started.



1. Install MapR
2. Creating a table for bulkloading data involves specifying the table type (JSON or binary) and setting the bulkload flag.

3. Bulkloading can be done either as a full or incremental bulkload. Different utilities are used for the bulk load depending on what you are trying to accomplish.
4. Both full and incremental bulkloads can be performed for MapR Database JSON tables. This topic describes the three command-line utilties available for loading documents into JSON tables.
5. Administration of tables describes how to create, read, update, and delete tables as well as other tasks such as managing permissions and auditing.
6. This section cover the administration of column families including how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.
7. This topic describes administrative tasks associated with table regions including how to set autosplitting.

Useful Administrator Resources

Links to Resources	Descriptions
maprcli and REST API Syntax on page 1522	Command line reference for MapR operations. For MapR Database, the commands particularly applicable are assocociate with the `maprcli` table on page 1788 command. These commands include not only table CRUD operations but also table column family, table region, and table replication operations.
Utilities for MapR Database JSON Tables on page 5312	Utilities for MapR Database JSON tables. These utilities are used form managing JSON tables icluding importing and exporting data to and from JSON tables. Particularly useful are: • MapR Database JSON ImportJSON on page 5322 utility with imports JSON documents into a MapR Database JSON table. • MapR Database Shell (JSON Tables) on page 5286utility which performs CRUD operations on JSON documents and tables.
Utilities for MapR Database Binary Tables on page 5329	Utilities for MapR Database binary tables. These utitlies are used for managing binary tables. Particulary useful is MapR Database Binary CopyTable on page 5329 which is used to copy data from one MapR Database binary table to another. **Note:** To import HFile or Result files in a MapR Database binary table, the hbase command can be used. See Loading Data into Binary Tables on page 1040.
Configuring Security on page 1402	Information on security tasks for configuring MapR security, managing secure clusters, and administering auditing.
Hadoop and Big Data Security	MapR information on Security and Big Data Governance that identified key unique advantages including authentication, authorization, auditing, and encryption.
Provisioning Secure Access Controls in MapR Database	MapR blog discussing MapR's boolean Access Control Expressions (ACEs) which provide granular-level permissions including topics and examples of best practices.

Managing Tables

MapR Database supports two types of table: binary tables and JSON tables. This section covers how to create, edit, and delete tables, as well as how to set parameter values, display parameter values, grant permissions and access, replicate tables, and more using the Control System and the CLI.

When you log in to the Control System and click **Data** > **Table**, the **Tables** page displays the following in the various panes:

- Active Alarms — The active table (replication) alarms
- **Recently Viewed Tables** — The tables that were most recently accessed from the Control System
- List of volumes that you have access to and a search field to retrieve a table by table path

Click **Create Table** button to create a new binary or JSON table. For a conceptual overview of:

- Binary tables, see MapR Database Binary Tables on page 540.
- JSON tables, which contain JSON documents, see MapR Database JSON Tables on page 524.

Creating a Table

Explains how to create binary and JSON tables using either the Control System, or the CLI.

There are several methods that you can use to create MapR Database tables including the maprcli, and hbase shell, mapr dbshell commands, and through the Control System. There are two methods that you can use to create both binary tables and JSON tables:

- Control System
- CLI

Creating a Table Using the Control System

To create a table from the Control System, under **Data** > **Tables**:

Note: This option is not available on the Kubernetes version of the Control System.

1. Click **Create Table**.
   The **Create New Table** page displays.
2. Choose the table type:
   - JSON — see MapR Database as a Document Database on page 507
   - Binary — see MapR Database as a Column-Oriented Database on page 539
3. Specify the following properties under **PROPERTIES**.
   a) Enter path to the table in the **Table Path** field.
   Tables are stored in the MapR filesystem. When providing the path to a table, use these conventions.
   - For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
   - For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customer in volume1 in the sanfrancisco cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

b) Select the interval of time to apply when logging table metrics.

You can choose to log metrics every 10 seconds, 1 minute (default), or 10 minutes. For visualizing the metrics, see Visualizing Table Metrics in the Control System on page 1303.

c) Enable (**Yes**) or disable (**No**) auto-splitting of table.

If enabled, the table will be split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, auto-splitting is enabled.

d) Enable (**Yes**) or disable (**No**) full bulk load of the table.

For more information, see Loading Documents into JSON Tables on page 1036. By default, full bulk load is disabled.

e) Enable (**Yes**) or disable (**No**) auditing of table operations.

If auditing is enabled at the cluster and volume levels, enabling auditing will cause auditing to start for the table operations. For more information, see Auditing of Operations on MapR Database Binary Tables and JSON Tables on page 700.

4. Specify users, groups, and/or roles that have and/or do not have the following types of access to the table under **USER ACCESS CONTROLS**.

JSON Table

Administration	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Index	Can create index for this table.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

Binary Table

Administration	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.

last-updated: Apr 11, 2022

Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

By default, all permissions are given to the user creating the table.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (`&`) and negation (`!`) operations that are supported by advanced settings are not supported in the basic settings.

You can proceed to:

- Step 5 to set default column family permissions.
- Step 6 to create the table.

5. Click **Default Column Family Authorization**.
   You can set up default permissions for column families on this page.

JSON Table

Specify public, (OR) users, groups, and/or roles that have and/or do not have the following types of access to the column families under **USER ACCESS CONTROLS**.

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

last-updated: Apr 11, 2022

Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.

Binary Table

Specify public, (OR) users, groups, and/or roles that have and/or do not have the following types of access to the column families under **USER ACCESS CONTROLS**.

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.

Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

By default, all permissions are given to the user creating the table.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

6. Click **Create Table** to create the table.
   You can proceed to:
   - Add column families to the table.
   - View the table information for the newly created table.

Creating a Table Using the CLI or the REST API

The basic command to create a binary table is:

```
maprcli table create -path <path>
```

last-updated: Apr 11, 2022

To create a JSON table, include the `-tabletype` parameter and set it to `json`:

```
maprcli table create -path <path> -tabletype json
```

The `-tabletype` parameter is set to `binary` by default.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  Note: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

When you create a table with this command, you can set a number of properties. See `table create` on `page 1788`.

Creating Tables Using shell Command

JSON Tables	The MapR Database shell command is used only on JSON tables. To run this command, execute the following: `mapr dbshell` After starting the shell, run the `create` command. See `MapR Database Shell (JSON Tables)` on `page 5286`.

Binary Tables	The HBase shell command is used on binary tables only. To run this command, execute the following: `hbase shell` After starting the HBase shell, run the `create` command. Type `help` to see a list of commands and their syntax. See MapR Database HBase Shell (Binary Tables) on page 5325.

Configuring Maximum Row Sizes Using the CLI

The default maximum row size at installation is 32MB. You can configure this maximum by changing the value of the `mfs.db.max.rowsize.kb` parameter with the `maprcli config save` command.

Tables support rows up to 2 GB in size. Rows in excess of 100MB might show decreased performance.

Here is an example of changing the maximum row size:

```
maprcli config save -values {"mfs.db.max.rowsize.kb":<value in KB>}
```

The value of this parameter affects both JSON tables and binary tables.

To view the current setting of this parameter, use the `maprcli config load` command, as in this example:

```
maprcli config load -json | grep mfs.db.max.rowsize.kb
```

Editing Tables

Use either the `maprcli` command `table edit` or the Control System to edit the attributes of a MapR Database binary or JSON table. You can also use the HBase shell to edit a binary table.

Editing Tables Using the Control System

To edit a (JSON or Binary) table using the Control System:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Edit Table** to display the **Edit Table** page.
3. Make changes (optional) to the following properties:

Metrics Interval	The interval of time for logging metrics.
Auto Split	Enable (**Yes**) or disable (**No**) auto-splitting of table. If enabled, the table will be split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this is enabled.
Bulkload	Enable (**Yes**) or disable (**No**) full bulk load of the table.
Enable Auditing	Enable (**Yes**) or disable (**No**) auditing of table operations. If auditing is enabled at the cluster and volume levels, enabling auditing will cause auditing to start for the table.

4. Make changes (optional) to table administration control settings.
   a) Make changes to **USER ACCESS CONTROLS** under **Table Setup and Authorization**.
      Modify the list of users, groups, and/or roles that have and/or do not have the following types of access to the table:

Admin	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.

last-updated: Apr 11, 2022

Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

b) Make changes to **Default Column Family Authorization**.

JSON Table	Modify the list of users, groups, and/or roles that have and/or do not have the following types of access to the default column family:

last-updated: Apr 11, 2022

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

Binary Table

Modify the list of users, groups, and/or roles that have and/or do not have the following types of access to the default column family:

last-updated: Apr 11, 2022

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (`&`) and negation (`!`) operations that are supported by advanced settings are not supported in the basic settings.

5. Click **Save Changes** for the changes to take effect.

Editing Tables Using the CLI or the REST API

Run the command `maprcli table edit -path <path>`.

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  Note: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

When you edit a table with this command, you can change a number of properties.

- Enable or disable auditing, autosplitting, and bulkloading
- Set permissions on table
- Set permissions for default column families

For full reference for this command, see `table edit` on page 1822.

Editing Binary Tables Using HBase Shell

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Removing a Table
Use either the Control System or the `maprcli table delete` command to drop a MapR Database table.

Removing a Table Using the Control System

To remove a table:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Remove Table**.
   The **Remove Table** confirmation window displays.
3. Click **Remove Table** to remove the table.
   After the table is removed, data in the table cannot be recovered.

Removing a Table Using the CLI or REST API

Run the command `maprcli table delete -path <path>`.

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  Note: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

For more information, see `table delete` on page 1820.

Defining ACEs
Indicates how to build access control expressions (ACEs) using the Expression Builder.

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.
   Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and/or role to access the volume.
Any	OR (|) operation	Indicates that any one of the conditions must be met for public or user, group, and/or role to access the volume.

2. Click:

+	To add an expression.
( )	To add a subexpression.
x	To remove an expression or subexpression.

3. Select Public or User, Group, or Role from the drop-down menu and:
   a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
   b) Enter name of the user, group, or role.
4. Click **Save Changes** to create an Access Control Expression.

Setting Whole Volume ACEs Using the CLI

See Setting Whole Volume ACEs on page 1459.

Setting Table ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Setting Stream ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Viewing the List of Tables

Describes how to view the list of tables using either the Control System or the CLI.

Viewing the Tables in a Volume Using the Control System

1. Log in to the Control System and click **Data** > **Tables** to view all the volumes to which you have access.

   Note: This option is not applicable on the Kubernetes version of the Control System.

   For each volume, the pane displays the following:

Column Name	Column Description
Name	The name of the volume.
Type	The type. Value can be: • — Volume • — Directory • — Table

last-updated: Apr 11, 2022

Column Name	Column Description
Owner	The name of the owner.
Last Modified	The last modification date and timestamp.

2. Click on the name of the volume (to browse to the path to the table) or enter the name of the volume in the text field.
   The tables in the selected volume display. If necessary, click the name of the directory to browse further or  to return to **All** volumes view.

Viewing a Table by Table Path Using the Control System

1. Log in to the Control System and click **Data** > **Tables**.

   Note: This option is not applicable on the Kubernetes version of the Control System.

2. Enter the path to the table and click **GO**.
   The tables information page for the specified table displays.

Listing the Tables in a Directory From the Command-line
Method for Binary Tables Only (HBase Shell)

After starting the HBase shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory. Type `help` to see a list of commands and their syntax.

Method for JSON Tables Only (`mapr dbshell`)

After starting the shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory. See MapR Database Shell (JSON Tables) on page 5286.

Retrieving a Table by Table Path Using the CLI or the REST API

To retrieve table details for a table by specifying the table path from the CLI, run the following command:

```
maprcli table info -path <table-path>
```

For information on this command, see `table info` on page 1838.

Viewing Table Information
Explains how to view table information including table properties, column families, regions, replicas, upstream source, and indexes using either the Control System or the CLI.

Use either the `maprcli` command or the Control System to display all of the information that MapR Database stores about a particular table including:

- The path to the table
- Whether a table is a binary or JSON table
- The number of rows in the table
- The logical size (in bytes) of the table
- The physical size (in bytes) of the table
- The maximum size (in bytes) of regions of the table
- Whether auditing is enabled or not

- Whether autosplitting is on or off
- Whether the bulkload flag is set or not
- The interval for logging metrics
- The permissions on the table

Note: The logical and physical sizes of the table are estimated values.

Displaying Table Information Using the Control System

To view table information using the Control System:

1. Search and retrieve the table either by volume or by table path.
   For information on retrieving, see:
   - Viewing the Tables in a Volume Using the Control System on page 1031
   - Viewing a Table by Table Path Using the Control System on page 1032
2. Click the name of the table to see the table details.
   The page displays the following tabs:
   - Summary
   - Column Families
   - Regions
   - Replication
   - Change Data Capture
   - Indexes
   - Metrics

   You can:
   - Edit table
   - Remove table

   The **Summary** tab displays:
   - The active and recent alarms in the **Active Alarms** pane.
   - The table settings and permissions in the **Detail** pane.

Displaying Table Information Using CLI

Run the command `maprcli table info -path <path> -json` .

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/♦=#;{}&()/"  (or)
maprcli table create -path '/♦=#;{}&()/'
```

To use either the **'** or the **"** character in the table name, enclose:

- the **'** character within double quotes (")
- the **"** character within single quote (')

For example:

```
maprcli table create -path "/'♦=#;{}&()/"  (or)
maprcli table create -path '/"♦=#;{}&()/'
```

The `json` parameter displays the output as a JSON document.

Viewing Table Regions
Use either the Control System or the CLI to list the regions in which a table's data is located.

MapR Database tables are split into regions on an ongoing basis. Administrators and developers do not need to manage these regions or restructure data on disk when data is added and deleted. These operations happen automatically. You can view region information for tables to get a sense of the size and location of table data on the MapR cluster.

Displaying the Regions Using the Control System

To display the regions of a table:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Do one of the following:
   - Click **Regions** to view the list of regions for the table.
   - Click the name of the index in the **Indexes** tab to view the regions for the index.

   For each region, the **Regions** pane displays the following:

Column Name	Column Description
Start Key	Value of the start key for this region. For the first region in a table, this value is exclusive. For all other regions, it is inclusive.
End Key	Value of the end key for this region. This value is always exclusive.
Physical Size	The physical size of the region with data compression (excluding replication).

Column Name	Column Description
Logical Size	The logical size of the region without data compression (excluding replication).
No of Rows	Number of rows in the region.
Primary Node	The host name and port of the primary node for this region.
Secondary Node	The host names and ports of the secondary nodes where this region is replicated.
Last HB	The time since last heartbeat from the region's primary node.
Region Identifier	The region's FID.

Displaying Region Information Using the CLI or the REST API

The basic command to retrieve the list of regions that make up the table is:

```
maprcli table region list -path <path>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  Note: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

The `json` parameter displays the output as a JSON document.

To run this command, your user ID must have the following permissions:

- `readAce` on the volume

last-updated: Apr 11, 2022

- `lookupdir` on directories in the path

See `table region list` on page 1844.

Loading Documents into JSON Tables
There are three command-line utilities for loading documents into JSON tables: `mapr copytable`, `mapr importtable` (which works in conjunction with the `mapr exporttable` utility), and `mapr importJSON`

You can choose whether to have these utilities perform bulk loads or incremental loads.

For bulk loads, the `-bulkload` parameter of the JSON table must be set to `true`. During a bulk load, client applications are unable to access the table. After the utility is finished, you must set the table's `-bulkload` parameter to `false`, so that client applications can access the table again.

When you set the `-bulkload` parameter to true, you cannot enable replication on the table. Since this effectively disables logging on the table, MapR Database also does not capture log data that Elasticsearch can use to index the table.

Note: Incremental loads allow client applications to access the table as the documents are loaded. However, incremental loads are slower than bulk loads.

`mapr copytable`

The `mapr copytable` utility copies documents -- all documents or a subset determined by a range of row keys, and all fields or a subset of fields -- directly from oneJSON table to another.

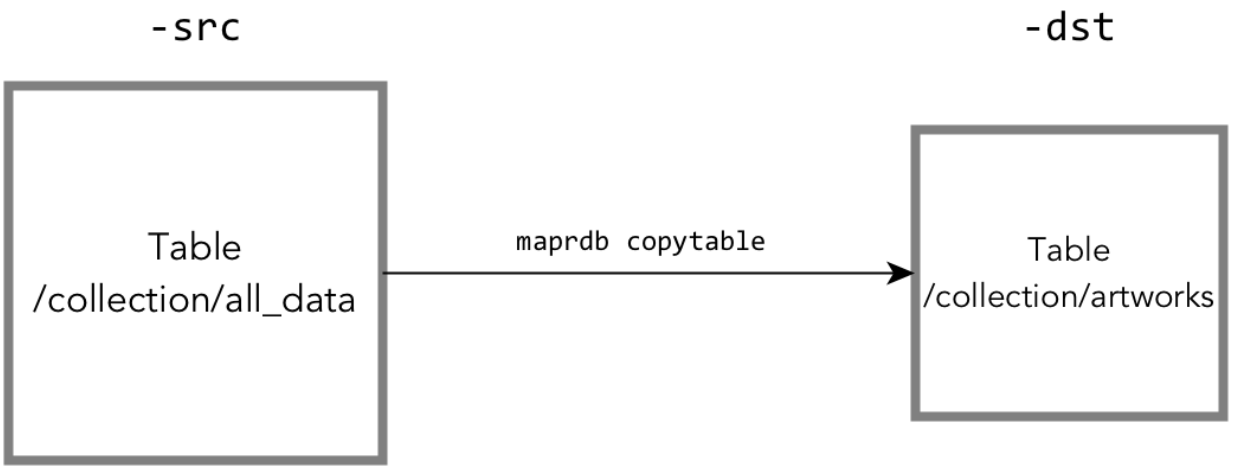


Figure 14: Copying a subset of data from one table to another

For reference information about this utility, see `mapr copytable`.

`mapr exporttable` and `mapr importtable`

The `mapr exporttable` utility exports data from a JSON table to binary sequence files that you can import into another JSON table by using the `mapr importtable` utility.

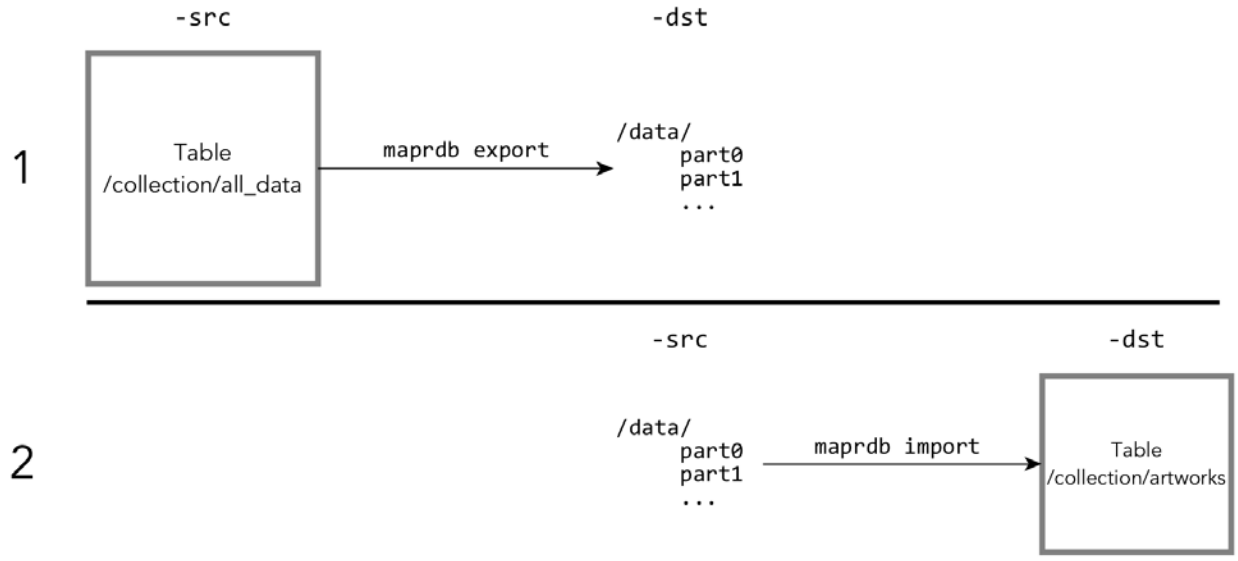

Figure 15: JSON documents exported from a JSON table as binary sequence files and then imported into another JSON table

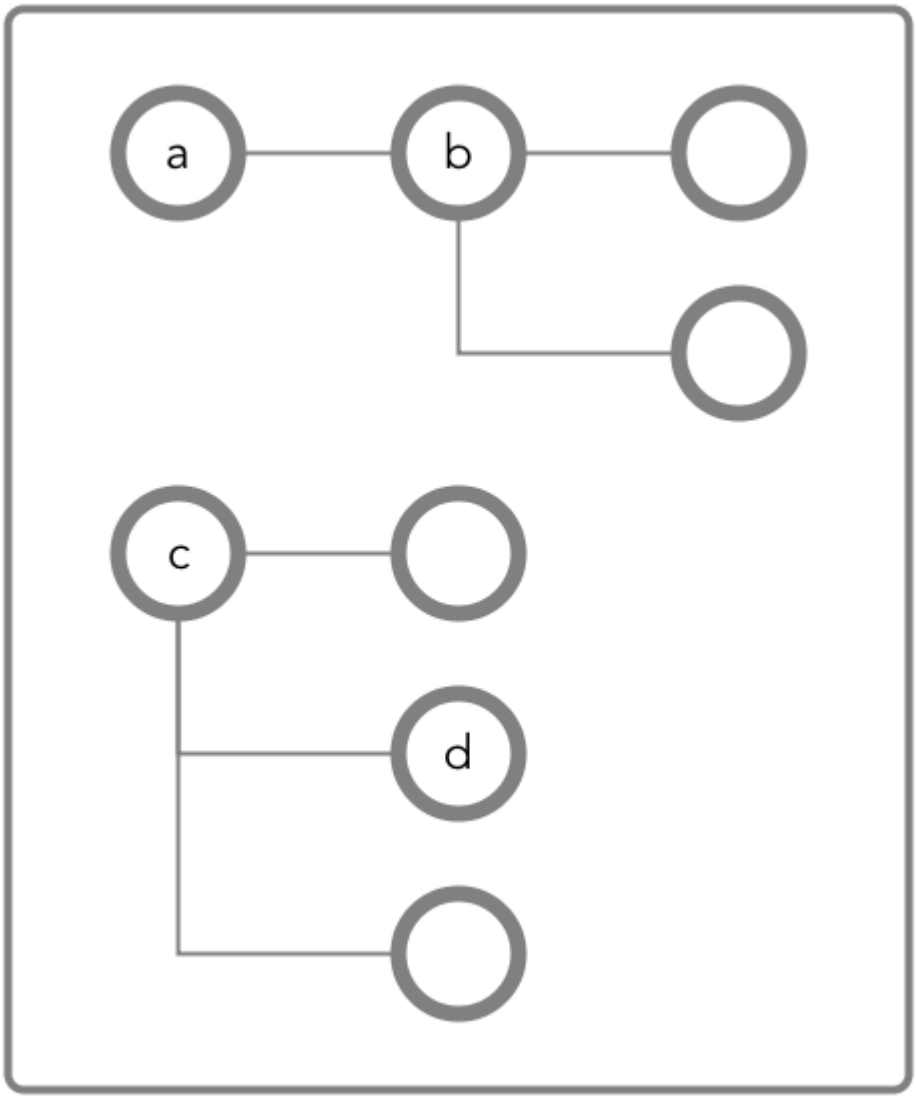
The destination directory is created by the `mapr exporttable` utility. To prevent accidental overwriting of data, the `mapr exporttable` utility fails if the destination directory already exists.

The command for running the `mapr importtable` utility in step 2 of the diagram above would look like this:

```
mapr importtable -src /data/* -dst /collection/artworks
```

The `-columns` parameter of the `mapr exporttable` utility lets you export subsets of the fields in the documents that are in a table. For example, to export field b, the fields under it, and field d from documents with the following structure, the command to run the `mapr exporttable` utility would look like this:

```
mapr exporttable -columns a.b,c.d -src /collection/all_data -dst /data
```



For reference information about these commands, see MapR Database JSON ExportTable and ImportTable on page 5320.

`mapr importJSON`

This utility imports one or more JSON documents that are text files into a JSON table.

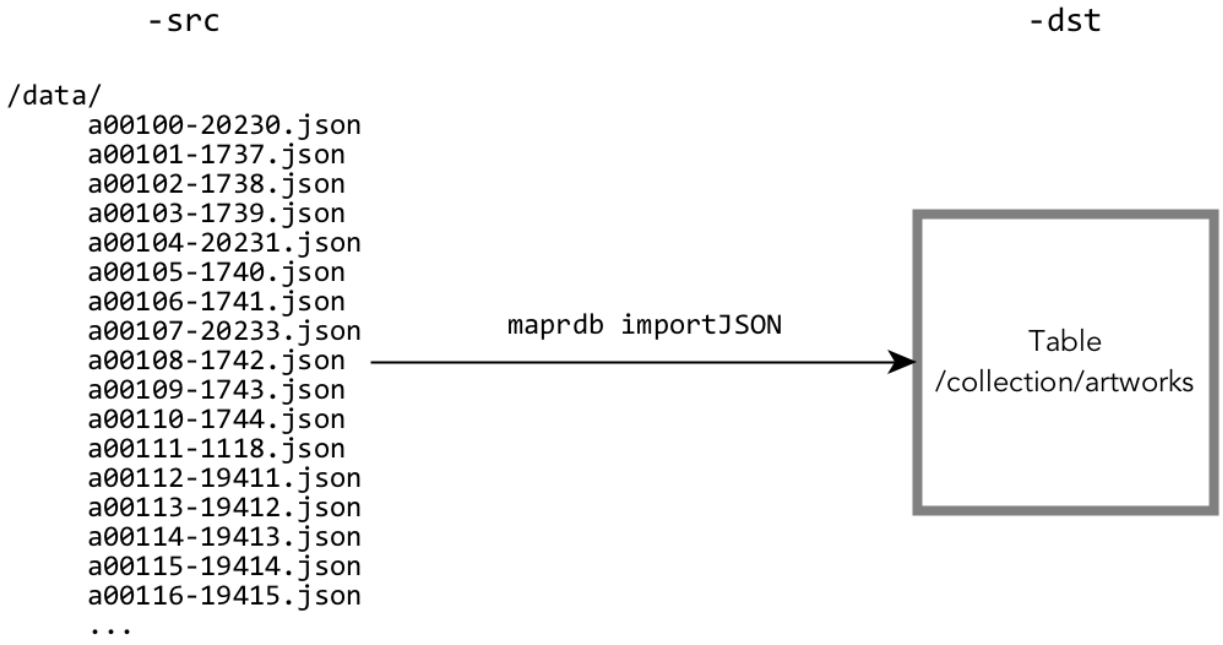


Figure 16: JSON documents in a folder named /data being imported into a JSON table

If the each document does not already contain an `_id` field to use as a document ID, the `mapr importJSON` utility adds an `_id` field during the import. Use the `-idfield` parameter to specify the name of the field that contains the value to copy into the value of the `_id` field.

For example, each document might have a `product_ID` field that contains a universally unique identifier. You could run the utility with this command:

```
mapr importJSON -idfield "product_ID" -src /data/* -dst /collection/artworks
```

For reference information about this command, see `mapr importJSON`.

Accessing MapR Database Binary Tables Using HBase APIs
This section describes how to access MapR Database binary tables via HBase APIs, HBase Shell, and MapReduce applications.

MapR Core extends the HBase component to handle access to MapR Database binary tables. MapR Database binary tables do not support low-level HBase API calls that are used to manipulate the state of an Apache HBase cluster.

For a full list of supported HBase Java APIs, see Creating Java Apps - Binary Tables on page 2478.

For a full list of supported commands in the HBase shell, see HBase Shell for MapR Database.

To enable the HBase API and `hbase shell` access, install the `mapr-hbase` package on every node in the cluster. The HBase component of the MapR distribution for Hadoop is typically installed under `/opt/mapr/hbase`. Install the `mapr-hbase` package that provides the version that corresponds with the current EEP and MapR version you are running.

For MapR installation procedures, see Installing MapR and MapR Ecosystem Components on page 128.

Note: The version of HBase provided by MapR has been modified to work with MapR Database binary tables. Do not download and install stock Apache HBase on a MapR cluster that uses MapR tables.

Note: If you use fat JARs to deploy your application as a single JAR including all dependencies, be aware that the fat JAR may contain versions of HBase that override the installed MapR versions, leading to problems. Check your fat JARs for the presence of stock HBase to prevent this problem.

Loading Data into Binary Tables
Bulkload operations can be performed as a full bulkload or as an incremental bulkload.

The most common way of loading data into a MapR Database Binary Tables is with a put operation. However, at large scales, bulk loads offer a performance advantage over put operations.

Bulk loading is supported by the following tools, which can be used for both full and incremental bulkload operations:

- Hbase MapR Database Binary CopyTable on page 5329 utility which copies MapR Database binary table data, table metadata, access control expressions, and more to another MapR Database binary table.

  ```
  hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable
  ```

- Hbase `ImportFiles` utility which imports HFile or Result files into MapR Database binary tables. For example:

  ```
  hbase com.mapr.fs.hbase.tools.mapreduce.ImportFiles
     -Dmapred.reduce.tasks=2
     -inputDir < input directory, for example: /test/tabler.kv >
     -table < table name, for example: /table2 >
     [ -format < Result|HFile > ]
     [ -sample < true|false > ]
     [ -mapOnly < true|false > ]
  ```

Full Bulk Loads

Full bulkload operations offer the best performance advantage because it skips the write-ahead log (WAL) typical of MapR Database binary table operations. Full bulkload operations can only be performed on empty tables that have the `bulkload` attribute set to **true**. This value is set only when creating a table.

When you set the `bulkload` attribute, you cannot enable replication on the table. Since this effectively disables logging on the table, MapR Database also does not capture log data that Elasticsearch can use to index the table.

Important: Tables are unavailable for normal client operations, including put, get, and scan operations, while a full bulkload operation is in progress.

To create a MapR Database binary table for bulkloading, use one of the following:

- maprcli table create command with tthe `-bulkload` parameter set to true.
- Apache HBase shell `create` command with the `BULKLOAD` parameter set to `true`. For example:

  ```
  hbase> create '/a0','f1', BULKLOAD => 'true'
  ```

  If you want to pre-split a table, separate the `BULKLOAD` parameter from the `SPLITS` parameter. For example:

  ```
  hbase> create '/t1', 'f1', {SPLITS => ['10', '20', '30']}, {BULKLOAD =>
  'true'}
  ```

- Control System with **Will table be bulkload?** option set to **Yes** under table **PROPERTIES**.

Note: Attempting a full bulkload on a table that does not have the bulkload attribute set to true results in an incremental bulkload being performed instead.

After you perform a full bulkload on a table, you cannot perform a full bulkload on it again. For example:

- You cannot use the `maprcli table edit` command to set the `bulkload` parameter to TRUE again.
- You cannot use the Apache HBase shell `alter` command to set the `BULKLOAD` parameter to TRUE again.
- In the Control System, the **Will table be bulkload?** option cannot be modified after table creation.

Incremental Bulk Loads

Incremental bulk loads can add data to existing tables concurrently with other table operations, with better performance than put operations. This type of bulk load makes use of write-ahead log files.

Note: Tables are available for client operations, such as put, get, and scan operations, during incremental bulk loads.

You can use incremental bulk loads to ingest large amounts of data to an existing table. Tables remain available for standard client operations such as put, get, and scan while the bulk load is in process. A table can perform multiple incremental bulk load operations simultaneously.

Note: Whether you create a table with the `maprcli table create` command, with the hbase shell's `create` command, or in the Control System, incremental loads are supported by default.

Performing File System Operations on MapR Database Tables

The data-fabric file system stores tables in the same namespace as files. You can move and delete tables in much the same way as you can with files. All file system operations remain accessible with the `hadoop fs` command.

Volume properties, such as replication factor or rack topology, that apply to the specified location also apply to tables stored at that location. You can move a table with the Linux `mv` command or the `hadoop fs -mv` command.

When you use Direct Access NFS or the `hadoop fs -ls` command to access a MapR cluster, tables and files are listed together. Because the client's Linux commands are not table-aware, other Linux file manipulation commands, notably file read and write commands, are not available for MapR Database tables.

This section describes the operations that you can perform on MapR Database tables through a Linux command line when you access the cluster through NFS or with the `hadoop fs` commands.

Setting Permissions

MapR Database tables do not support setting user permissions through the UNIX `chmod` command or the `hadoop fs -chmod` analogue. Instead, MapR Database table access is controlled with Access Control Expressions (ACEs). See Enabling Table and Stream Authorizations with ACEs on page 1461.

Read and Write

You cannot perform read or write operations on a MapR Database table from a Linux file system context. For example, you cannot use the `cat` command to view the content of a table or search through a table with the `grep` command. MapR File System returns an error when an application attempts to read or write to a MapR Database table.

last-updated: Apr 11, 2022

Move

You can move a MapR Database table within a volume with the `mv` command over NFS or with the `hadoop fs -mv` command. These moves are subject to the standard permissions restrictions. Moves across volumes are not currently supported.

Remove

You can remove a table with the `rm` command over NFS or with the `hadoop fs -rm` command. These commands remove the table from the namespace and asynchronously reclaims the disk space. You can remove a directory that includes both files and tables with the `rm -r` or `hadoop fs -rmr` commands.

Note: To prevent users from deleting a particular table, you must ensure that users do not have WRITE permission on the folder in which the table is located. Permissions on the table itself are not used in evaluating whether a user can delete the table. This convention follows standard UNIX rules for file and directory permissions.

Copy and Recursive/Directory Copy

Table copying at the file-system level is not supported. See Migrating Between Apache HBase Tables and MapR Database Tables for information on copying tables using the HBase shell.

Managing Column Families and Columns

This section covers overviews of column families in binary tables and JSON tables, how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.

For a conceptual overview of column families in binary tables, see Column Families in Binary Tables.

For a conceptual overview of column families in JSON tables, see Managing Column Families.

Creating Column Families

Explains how to create column families using either the Control System, the CLI, or the HBase shell.

There are several methods that you can use to create column families in MapR Database tables. To create column families, you must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path to the table
- `createrenamefamilyperm` on the table

Creating Column Families Using the Control System

To create a column family from the Control System, under **Data** > **Tables**:

Note: This option is not available on the Kubernetes version of the Control System.

1. Click:
   - **Take me to Add Column Family** after creating a new table.
   - **Add Column Family** in the **Column Families** tab in the table information page.

     See Viewing Table Information on page 1032.
2. Specify the following properties to set up column families.

JSON Table

Column Family Name	The name of the column family.

JSON Path	The path to the column family in dotted notation. For example, suppose the table contained JSON documents that were of this general structure: `{ "_id" : "ID", "a" : { "b" : { "c" : "value", }, "e" : "value" } }` If you want to create a column family at the field `d` nested within `b`, your new path would be `a.b.d`. **Note:** Ensure that the field at which you want to create the column family does not yet exist. If the field exists, it could become inaccessible after the column family is created.
Compression	The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 990.

last-updated: Apr 11, 2022

Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.  **Note:** If the value for an existing column family in a JSON table is not 0, you cannot add another column family.

In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.  **Note:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Apr 11, 2022

Binary Table

Column Family Name	The name of the column family.
Version	• Minimum — The minimum number of versions of column values to keep. The default is zero. • Maximum — Maximum number of versions of column values to keep. The default is one.
Compression	The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 990.
Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.

In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.  **Note:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Apr 11, 2022

3. Set up access to column families for users, groups, and/or roles.
   You can use either the default permissions or proceed to define new permissions for this column family.

JSON Table

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on `a.b`, but not on `a`. For sjohnson to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

Binary Table

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

By default, all permissions are given to the user creating the table.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (`r`) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - `!` — Negation operator.
  - `&` — AND operation.
  - `|` — OR operation.

  Use `( )`, parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

last-updated: Apr 11, 2022

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (`&`) and negation (`!`) operations that are supported by advanced settings are not supported in the basic settings.

4. Specify:

Field Permissions (for JSON Tables)

Specify a name for the field and the permissions to access the field. By default, a field inherits permissions from the column in which the field is located. Permissions set at this level override permissions inherited from the column. You can set the following permissions by selecting the associated checkbox:

Read Data	Can read from the field. This permission extends to fields that are nested below as well unless explicitly denied on any of the nested fields.
Write Data	Can delete the field, insert a value into the field, or overwrite the field's value. **Note:** Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.
JSON Traverse	Can descend a hierarchy of fields to access the fields to read or write.

By default, all permissions are given to the user creating the table. See Permission Types for Fields and Column Families in JSON Tables on page 1462 for more information.

Column Permission (for Binary Tables)

Create (by clicking **Add Column** and specifying a name in the **Column Name** field) and set permissions for columns in the column family. You can set the following permissions by selecting the associated checkbox:

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

last-updated: Apr 11, 2022

Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.

Note: When a user, group, or role requests to read data from, write data to, or append data to a column, MapR Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. MapR Database checks whether this user has write permission on `cf1` AND `col1` AND `col2`. If the user does not have all three permissions, MapR Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, MapR Database would simply not return the data. If the user tried to read from those two columns and additional columns on which the user had read permissions, the results would contain the data for those additional columns, but exclude the data for `col1` and `col2`.

You can add columns to a table at any time. Null columns for a given row don't take up any storage space.

Note: Extremely wide tables with very large numbers of columns can sometimes reach the recommended size for a table split at a comparatively small number of rows because MapR Database tables split at the row level, not the column level.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

last-updated: Apr 11, 2022

Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

5. Click **Add Column Family** to add the column family to the table.

Creating Column Families Using CLI or the REST API

JSON Table

To create a column family in a JSON table, include the parameters `-jsonpath` and `-force` :

```
maprcli table cf
create -path <path> -cfname
<name_of_column_family> -jsonpath

<path> -force true
```

For the full list of options for this command, see `table cf create` on page 1799.

The `-jsonpath` parameter specifies the path to the column family. The path is in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" :
"value",
                    },
               "e" : "value"
```

```
            }
}
```

You want to create a column family at the field `d` in the new path `a.b.d` because you plan to store image files in fields in that column family.

Important: Ensure that the field at which you want to create the column family does not yet exist. Also ensure that there are no secondary indexes defined on the field. If the field does exist or is a field in an index, the data in the field could become inaccessible after you create the column family.

By default, every time you try to create a non-default column family in a JSON table, this command fails and returns a warning message that you should ensure there is no existing data at the specified path. Set the `-force` parameter to `true` if you want to override this warning mechanism and create a column family.

Binary Table

The command to create a column family for a binary table is:

```
maprcli table cf create -path
<path> -cfname <name_of_column_family>
```

For the full list of options for this command, see `table cf create` on page 1799.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster.

Creating a Column Family for a Binary Table Using HBase Shell

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Listing Column Families

Explains how to view the column families for a table using either the Control System or the CLI.

Viewing Table Column Families Using the Control System

To view the column families for a table:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Column Families**.
   The page displays the default permissions for the column families in the **Default Column Family Authorization** pane and for each column family, the **All** pane displays:

Column Name	Column Description
Column Family Name	The name of the column family.
JSON Path	The JSON path for the column in the JSON file in dotted notation.
Compression	The compression scheme used for the column family.
Time-to-Live	The amount of time to keep the data in the column family.
In Memory	Whether or not this column value resides in memory.

last-updated: Apr 11, 2022

Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

- Add a column family to the table
- Remove a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/♠=#;{}&()/"  (or)
maprcli table create -path '/♠=#;{}&()/'
```

To use either the **'** or the **"** character in the table name, enclose:

- the **'** character within double quotes (")
- the **"** character within single quote (')

For example:

```
maprcli table create -path "/'♠=#;{}&()/"  (or)
maprcli table create -path '/"♠=#;{}&()/'
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the paths
- `adminaccessperm` on the table

For complete reference, see `table cf list` on page 1810.

Removing Column Families

Explains how to delete column families using either the Control System or the CLI.

Important: Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Removing Column Families Using the Control System

To remove one or more column families:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Column Families** tab.
   The page displays:
   - Default column family permissions
   - All the column families for the table
3. Select the checkbox associated with the column families to delete in the **All** pane.
4. Click **Remove Column Family**.
   The **Remove Column Families** confirmation dialog displays.
5. Verify the list of column families and click **Remove Column Family**.
   If necessary, click ✕ to remove a column family from the list of column families to delete.

Removing a Column Family Using the CLI or the REST API

To remove a column family by name using the CLI or the REST API, run the following command:

```
maprcli table cf delete -path <path> -cfname <name>
```

See `table cf delete` on page 1805 for more information.

Altering Column Families

Explains how to modify the permissions and properties of column families using either the Control System, the CLI, or the HBase shell.

There are several methods that you can use to edit column families in MapR Database tables. These methods also let you change permissions on column families.

Modifying a Column Family Using the Control System

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Column Families** tab.
   The page displays:
   - Default column family permissions
   - All the column families for the table
3. Click the name of the column family to modify.
   The **Edit Column Family** page displays.
4. Make changes to the following properties (under **PROPERTIES**) as desired.

JSON Table

Column Family Name	The name of the column family.

last-updated: Apr 11, 2022

Compression	The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 990.

In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.  **Note:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Apr 11, 2022

Binary Table

Column Family Name	The name of the column family.
Version	• Minimum — The minimum number of versions of column values to keep. The default is zero. • Maximum — Maximum number of versions of column values to keep. The default is one.
Compression	The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 990.
Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.

In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.  **Note:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Apr 11, 2022

5. Make changes to permissions as desired.
   a) Modify USER ACCESS CONTROLs for the column family as desired.

JSON Table

Modify or set the following permissions for the column family:

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.

Binary Table

Modify or set the following permissions for the column family:

last-updated: Apr 11, 2022

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

b) Modify or set:

Field Permission (for JSON Tables)

Modify permissions for the following on existing fields and/or create new fields and set permissions for the following on the new fields:

Read Data	Can read from the field. This permission extends to fields that are nested below as well unless explicitly denied on any of the nested fields.
Write Data	Can delete the field, insert a value into the field, or overwrite the field's value.  **Note:** Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

last-updated: Apr 11, 2022

JSON Traverse	Can descend a hierarchy of fields to access the fields to read or write.

Column Permission (for Binary Tables)

Modify following permissions for existing columns and/or create new columns and set permissions for the following:

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

6. Click **Save Changes** for the changes to take effect.

Modifying a Column Family Using the CLI or REST API

The basic command to edit a column family is:

```
maprcli table cf edit -path <path> -cfname <name_of_column_family> options
```

For the full list of options for this command, see `table cf edit` on page 1806.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  Note: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

Modifying a Column Family in a Binary Table Using HBase shell

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Displaying Default Column Family Permissions

Use either the Control System or the `maprcli` command to find out the users, groups, or roles that have permissions on the default column family.

last-updated: Apr 11, 2022

Viewing Default Column Family Permissions in the Control System

- Log in to the Control System and go to the **Column Families** tab in the table information page.

  The **Default Column Family Authorization** pane displays the following permissions for users, groups, and roles.

Binary Table

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

JSON Table

Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

last-updated: Apr 11, 2022

Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on `a.b`, but not on `a`. For sjohnson to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

Retrieving the Default Column Family Permissions Using the CLI

To display the permissions on a column family, run this command:

```
maprcli table cf colperm get -path <path> -cfname <name of column
family> -json
```

To display the permissions on a column, add the `-name` parameter:

```
maprcli table cf colperm get -path <path> -cfname <name of column
family> -name
            <name of column> -json
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster.

The `json` parameter displays the output as a JSON document.

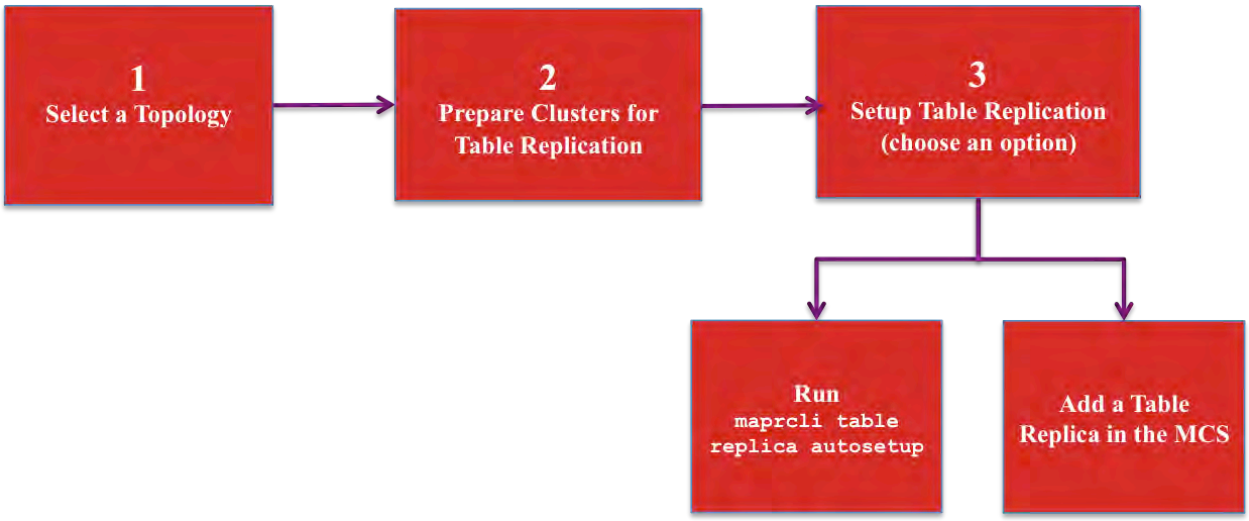
Managing Table Replication

This section contains topics about setting up table replication and administering existing replicas.

last-updated: Apr 11, 2022

The process to set up table replication consists of the following steps:

1. Select a Topology
2. Prepare Clusters for Table Replication.
3. Set up Table Replication using one of the following options:
   - Run maprcli table replica autosetup.
   - Add a Table Replica in the Control System.



1. Select a Table Topology
2. Prepare Clusters for Table Replication
3. Run maprcli table replica autosetup
4. Add a Table Replica in the MCS

Note: After setting up replication, replicas can be administered using either the Control System or the CLI.

Preparing Clusters for Table Replication
Preparing clusters for table replication includes configuring gateways on destination clusters, configuring the `mapr-clusters.conf` file on the source cluster, and, if the clusters are secure, setting up secure communications between the clusters. After you prepare the clusters for table replication, you can setup replication between tables.

Before You Begin

The following topics identify concepts and tasks that you need to do before setting up your environment for table replication.

- Plan which replication topology you want to use. For information about the various topologies, see Supported replication topologies on page 611.

- In general, if you are replicating tables, you should store them in their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a table in a promoted mirror lags behind the table's replica.

  For example, suppose `/vol` mirrors to `/vol.mirror` and contains a table `srcTab` that replicates to `/replVol/replTab`. If `/vol` fails, `/vol.mirror/srcTab` may lag `/replVol/replTab` when `/vol.mirror` is promoted.

  To avoid this problem, starting with the 6.1 release, after MapR Database promotes a mirror volume, replication terminates with `REPLICA_STATE_UNEXPECTED` for any tables in that volume.

  The following sample output shows this behavior:

```
[mapr]# /opt/mapr/bin/maprcli table replica list -path /vol.mirror/
srcTab -refreshnow true -json
{
  "timestamp":1534805233244,
  "timeofday":"2018-08-20 03:47:13.244 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"mirrorSrc",
      "table":"/replVol/replTab",
      "type":"MapRDB",
      "replicaPath":"/replVol/replTab",
      "replicaState":"REPLICA_STATE_UNEXPECTED",
      "paused":false,
      "throttle":false,
      "idx":1,
      "networkencryption":false,
      "synchronous":false,
      "networkcompression":"lz4",
      "propagateExistingData":false,
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "uuid":"8b4563e1-884d-7852-f257-078c397b5b00",
      "copyTableCompletionPercentage":0,
      "errors":{
        "Code":"ErrReplicaTableUpstreamMismatch",
        "Host":"10.10.104.35",
        "Msg":"OpenStream: Upstream table does not match original
Upstream cluster mirrorSrc table /replVol/replTab"
      }
    }
    ]
}
```

  This change in behavior applies to only tables that have replication enabled starting in 6.1. See Table Replication States on page 625 for more details.

- Ensure that your user ID has the `readAce` permission on the volume where the source tables are located and the `writeAce` permission on the volumes where the replicas are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

- Ensure that you have administrative authority on the clusters that you plan to use.

- If you upgraded your source cluster from a previous version of MapR, enable table replication by running this `maprcli` command: `maprcli cluster feature enable -name mfs.feature.db.repl.support`
- Depending on your use case, replication requires the installation of gateways and may also require the HBase client. For more information about installation requirements, see Service Layout Guidelines for Replication on page 116

Setting Up Table Replication

The following steps show how to set up your environment for table replication including setup for secure clusters.

1. In the `mapr-clusters.conf` file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster. This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See mapr-clusters.conf for the format to use for the entries.
2. On the destination cluster, configure gateways through which the source cluster sends updates to the destination cluster. See Configuring Gateways for Table and Stream Replication on page 1152.
3. If your clusters are secure, configure each cluster so that you can access them all from one cluster. This way, you need not log into each secure cluster separately and run `maprcli` commands locally on them. See Configuring Secure Clusters for Running Commands Remotely on page 1484 for more information.
4. If your clusters are secure, add a cross-cluster ticket to the source cluster, so that it can replicate data to the destination cluster. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.
5. **Optional:** If your clusters are secure, configure your source cluster so that you can use the Control System to set up and administer table replication from the source to the destination cluster.

   These steps make it convenient to use the Control System for setting up and managing replication involving two secure clusters. However, before following them, perform these prerequisite tasks.

   Note:

   - Ensure that both clusters are managed by the same team or group. The UIDs and GIDs of the users that are able to log in to the Control System on the source cluster must exactly match their UIDs and GIDs on the destination cluster. This restriction applies only to access to both clusters through the Control System, and does not apply to access to both clusters through the maprcli. If the clusters are managed by different teams or groups, use the maprcli instead of the Control System to set up and manage table replication involving two secure clusters.
   - Ensure that the proper file-system and table permissions are in place on both clusters. Otherwise, any user who can log into the Control System and has the same UID or GID on the destination cluster will be able to set up replication either from the source cluster to the destination cluster or vice versa. A user could create one or more tables on the destination cluster, enable replication to them from the source cluster, load the new tables with data from the source cluster, and start replication. A user could also create tables on the source cluster, enable replication to them from tables in the destination cluster, load the new tables with data from the destination cluster, and start replication.

a. On the source cluster, generate a service ticket by using the `maprlogin` command:

```
maprlogin generateticket -type service -cluster <destination cluster>
-user mapr -duration <duration> -out <output folder>
```

Where `-duration` is the length of time before the ticket expires. You can specify the value in either of these formats:

- `[Days:]Hours:Minutes`
- `Seconds`

b. To every node of the source cluster, add the service ticket to the file `/opt/mapr/conf/maprusertickets` file that was created when you secured the source cluster:

```
at <path and filename of the service ticket> >> /opt/mapr/conf/
maprusertickets
```

c. Restart the web server by running the `maprcli node services` command. For the syntax of this command, see node services on page 1730.

d. Add the following two properties to the `core-site.xml` file. For Hadoop 2.7.0, edit the file `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml`.

```
<property>
      <name>hadoop.proxyuser.mapr.hosts</name>
      <value>*</value>
 </property>
 <property>
      <name>hadoop.proxyuser.mapr.groups</name>
      <value>*</value>
 </property>
```

Setting Up Table Replication Using the CLI

You can run the `maprcli table replica autosetup` command to set up primary-secondary or multi-master replication from an existing source table.

Note: This procedure describes how to use the `maprcli` to automatically set up table replication. As an alternative, you can use the Control System to automatically setup table replication or use the `maprcli` command to manually setup primary-secondary replication or manually setup multi-master replication.

Before you begin, complete the following steps:

- Verify that you have completed the steps to configure the clusters for table replication. For more information, see Preparing Clusters for Table Replication on page 1066.
- On the source table, run the `maprcli table info` command to verify that you have the following permissions:
  - `readperm`, which is required for reading from the table.
  - `replperm`, which is required for replicating from the table.

  On the destination table (if it already exists), run the `maprcli table info` command to verify that you have the following permissions:
  - `bulkload`, which is required for the initial copy of source data into the destination table.

- `replperm`, which is required for receiving replicated updates from the source table.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permissions for updates to column families and columns are irrelevant; gateways have implicit authority to update replicas.

Note: If you are setting up a primary-secondary replication loop for *n* clusters, repeat these steps for *n-1* primary-secondary relationships to set up basic primary-secondary topologies.

1. Log into both the source and destination clusters.
2. Run the `maprcli table replica autosetup` command.
   - For primary-secondary replication:

     ```
     maprcli table replica autosetup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table>
     ```

   - For multi-master replication:

     ```
     maprcli table replica autosetup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table> -multimaster true
     ```

     Note:

     The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

   For example, to set up multi-master replication between the `customers` table in the `sanfrancisco` cluster and a new `customers` table in the `newyork` cluster, you could use this command:

   ```
   maprcli table replica autosetup -path /mapr/sanfrancisco/
   customers -replica /mapr/newyork/customers -multimaster true
   ```

   To set up primary-secondary replication between the `customersA` table in the `sanfrancisco` cluster and a new `customersB` table in the same cluster, you could use this command:

   ```
   maprcli table replica autosetup -path /mapr/sanfrancisco/
   customersA -replica /mapr/sanfrancisco/customersB
   ```

   Note: For information about additional parameters that you can configure, see table replica autosetup on page 1854.
3. To check the replication status, run table replica list on page 1863.

Additional Information:

- With multi-master replication, if one of the tables goes offline, you can direct client applications to the other table. For more information, see Multi-Master Replication on page 616.
- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see Adding a Column Family to a Replica on page 1086
- Check the Control System for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication. See Table-Replication Alarms.

last-updated: Apr 11, 2022

Setting Up Primary-Secondary Replication Manually
You can run `maprcli` commands to set up primary-secondary replication manually.

1. Ensure that you have followed these prerequisite steps:
   - Verify that you have complete the steps to configure the clusters for table replication. For more information, see Preparing Clusters for Table Replication on page 1066.
   - Run the `maprcli table info` command on the source table to verify that you have the following permissions:
     - `readperm`, which is required for reading from the table.
     - `replperm`, which is required for replicating from the table.
   - Run the `maprcli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
     - `bulkload`, which is required for the initial copy of source data into the destination table.
     - `replperm`, which is required for receiving replicated updates from the source table.
2. Create the replica manually with the `maprcli` command `table create`. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

   ```
   maprcli table create -path <path to the replica> -copymetafrom <path to the source table>
   ```

   For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli table create -path /mapr/newyork/customers -copymetafrom /mapr/sanfrancisco/customers
   ```

3. Register the replica as a replica of the source table by running the `maprcli table replica add` command.

   ```
   maprcli table replica add -path <path to the source table> -replica <path to the replica> -paused true
   ```

   For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli table replica add -path /mapr/sanfrancisco/customers -replica /mapr/newyork/customers -paused true
   ```

   The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step 4.

   Note: For more information about additional parameters that you can configure, see table replica add on page 1851.

last-updated: Apr 11, 2022

4. Verify that you specified the correct replica by running the `maprcli table replica list` command.

   ```
   maprcli table replica list -path <path to the source table>
   ```

   To verify that the customers table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

   ```
   maprcli table replica list -path /mapr/sanfrancisco/customers
   ```

5. Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

   ```
   maprcli table upstream add -path <path to the replica> -upstream <path
   to the source table>
   ```

   To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

   ```
   maprcli table upstream add -path /mapr/newyork/customers -upstream /mapr/
   sanfrancisco/customers
   ```

6. Verify that you specified the correct source table by running the `maprcli table upstream list` command.

   ```
   maprcli table upstream list -path <path to the replica>
   ```

   To verify this in our example scenario, you could use this command:

   ```
   maprcli table upstream list -path /mapr/newyork/customers
   ```

7. If you set `-paused` to `true` when adding the replica, follow these steps:
   a) Load the replica with data from the source table by using the MapR Database CopyTable utility for binary tables or the MapR Database JSON CopyTable on page 5312 utility for JSON tables.

   b) Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

      ```
      maprcli table replica resume -path <path to the source
      table> -replica <path to the replica>
      ```

      For our example scenario, you could use this command:

      ```
      maprcli table replica resume -path mapr/sanfrancisco/
      customers -replica /mapr/newyork/customers
      ```

- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see Adding a Column Family to a Replica on page 1086
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See Table-Replication Alarms.

Setting Up Multi-Master Replication Manually

You can run `maprcli` commands to set up multi-master replication, first establishing replication in one direction, and then establishing it in the other direction.

- Verify that you have complete the steps to configure the clusters for table replication. For more information, see Preparing Clusters for Table Replication on page 1066.
- Run the `maprcli table info` command on the source table to verify that you have the following permissions:
  - `readperm`, which is required for reading from the table.
  - `replperm`, which is required for replicating from the table.
- Run the `maprcli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
  - `bulkload`, which is required for the initial copy of source data into the destination table.
  - `replperm`, which is required for receiving replicated updates from the source table.

1. For manual setup in one direction, follow these steps:

a) Create the replica manually with the `maprcli table create command`. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

```
maprcli table create -path <path to the replica> -copymetafrom <path
to the source table>
```

For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table create -path /mapr/newyork/customers -copymetafrom /
mapr/sanfrancisco/customers
```

b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica
<path to the replica> -paused true
```

For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table replica add -path /mapr/sanfrancisco/
customers -replica /mapr/newyork/customers -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step d.

last-updated: Apr 11, 2022

c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

To verify that the customers table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprcli table replica list -path /mapr/sanfrancisco/customers
```

d) Authorize replication between the tables by registering the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream
<path to the source table>
```

To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

```
maprcli table upstream add -path /mapr/newyork/customers -upstream /
mapr/sanfrancisco/customers
```

e) Verify that you specified the correct source table by running the `maprcli table upstream list` command.

```
maprcli table upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli table upstream list -path /mapr/newyork/customers
```

f) If you set `-paused` to `true` when adding the replica, follow these steps:

1. Load the replica with data from the source table by using the MapR Database CopyTable utility for binary tables or the MapR Database JSON CopyTable on page 5312 utility for JSON tables.
2. Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

```
maprcli table replica resume -path <path to the source
table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli table replica resume -path mapr/sanfrancisco/
customers -replica /mapr/newyork/customers
```

2. For manual setup in the other direction, follow these steps:

a) Log into both the source and destination clusters.

b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica
<path to the replica>
```

c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

d) Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream
<path to the source table>
```

- With multi-master replication, if one of the tables goes offline, direct client applications to the other table. For more information, see Multi-Master Replication on page 616.
- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see Adding a Column Family to a Replica on page 1086
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See Table-Replication Alarms.

Adding Table Replicas
Explains how to add table replicas using either the Control System, the CLI or the REST API.

You can register a MapR Database binary or JSON table as a replica of another MapR Database binary or JSON table using the Control System and the CLI. When you add a replica using the Control System, you can also setup and start replication between a source MapR Database Binary or JSON table to a replica MapR Database Binary or JSON table. Before you begin, complete the steps to prepare MapR clusters for table replication.

Adding Table Replica Using the Control System

To replicate a table:

1. Log in to the Control System and go to the **Replication** tab in the table information page.
2. Click **Add Replica** and follow the steps for:
   - Adding JSON Table Replicas on page 1076
   - Adding Binary Table Replicas on page 1078
3. Click **Add Replica**.

Adding Table Replica Using the CLI or the REST API

To add a replica, run the following command:

```
/opt/mapr/bin/maprcli table replica add -path <table path> -replica
<replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see `table replica add` on page 1851.

Note: You also have the option to setup table replication with `maprcli table replica autosetup` which will setup and start replication. For more information, see Setting Up Table Replication Using the CLI on page 1069.

Adding JSON Table Replicas
Explains how to add replicas of JSON tables using either the Control System, the CLI or the REST API.

You can register a MapR Database JSON table as a replica of another MapR Database JSON table using either the Control System or the CLI. When you add a replica using the Control System, you can also setup and start replication between a source MapR Database JSON table to a replica MapR Database JSON table. Before you begin, complete the steps to prepare MapR clusters for table replication.

Adding JSON Table Replica Using the Control System

To create a replica:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Replicas** tab.
   The list of replicas associated with the table displays.
3. Click **Add Replica**.
   The **Add Replica** page displays.
4. Specify the following settings:

Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst` **Note:** For replication to a table, the command will fail if the replica path you specify points to table that already exists.
Replication State	Specify whether or not to start replication by choosing one of the following: • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication.

	• Pause Replication — Registers the table on the destination cluster as a replica and adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. **Note:** Although visible, this option is not supported if the source or replica is on a remote secure cluster.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both the primary and secondary roles. Client applications update both tables and each table replicates updates to the other. See Multi-Master Replication on page 616. If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located. See Primary-Secondary Replication on page 611. **Note:** Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (**Yes**) or asynchronous (**No**). See Modes of replication on page 610 for more information.
Encrypt On Wire	Specify whether (**Yes**) or not (**No**) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:
   - **Replicate Entire Document**
   - **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
     "_id" : "ID",
     "a" :
```

```
            {
                 "b" :
                      {
                           "c" : "value",
                      },
                 "e" : "value"
            }
}
```

To replicate field `c`, you must specify `a.b.c` as the field path. Do not use quotation marks and do not include spaces after each dot. Click:

- **Add Field** to add another field to replicate.
- to remove a field.

By default, the entire document in the source table is replicated.

Note: If a field is added at a later date, replication for that field will start at that time.

7. Click **Add Replica**.
   A table with the specified fields is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding JSON Table Replica Using the CLI or the REST API

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see `table replica add` on page 1851.

Note: You also have the option to use `maprcli table replica autosetup` which will setup and start replication. For more information, see `table replica autosetup` on page 1854.

Adding Binary Table Replicas
Explains how to add replicas of binary tables using either the Control System or the CLI.

You can register a MapR Database Binary table as a replica of another MapR Database Binary table using the Control System and CLI. When you add a replica using the Control System, you can also setup and start replication between a source MapR Database Binary table to a replica MapR Database Binary table. Before you begin, complete the steps to prepare MapR clusters for table replication.

Adding Binary Table Replica Using the Control System

To create a replica:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Replicas** tab.
   The list of replicas associated with the table displays.

3. Click **Add Replica**.
   The **Add Replica** page displays.

4. Specify the following settings:

Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfracisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst` **Note:** For replication to a table, the command will fail if the replica path you specify points to table that already exists.
Replication State	Specify whether or not to start replication by choosing one of the following: • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. • Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. **Note:** Although visible, this option is not supported if the source or replica is on a remote secure cluster.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other. See Multi-Master Replication on page 616. If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located. See Primary-Secondary Replication on page 611. **Note:** Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (**Yes**) or asynchronous (**No**). See Modes of replication on page 610 for more information.

last-updated: Apr 11, 2022

Encrypt On Wire	Specify whether (**Yes**) or not (**No**) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:
   - **Replicate all column families**
   - **Replicate Selected Column Families** — Specify the column family name and select:
     - **Include All Columns** — to replicate all the columns associated with the column family.
     - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

   By default, all columns in the source table are replicated.

   Note: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If a column is added at a later date, replication for that column will start at that time.

7. Click **Add Replica**.
   A table with the specified column families is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding Binary Table Replica Using the CLI or the REST API

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see `table replica add` on page 1851.

Note: You also have the option to use `maprcli table replica autosetup` which will setup and start replication. For more information, see `table replica autosetup` on page 1854.

Displaying the List of Table Replicas
Describes how to view information on the table replicas using the Control System or the CLI.

last-updated: Apr 11, 2022

Displaying the List of Table Replicas Using the Control System

To view table replicas:

1. Log in to the Control System and go to the table information page.
2. Click **Replication**.
   The page displays all the replicas and for each replica, the pane displays the following statistics:

Column Name	Column Description
Paused	Whether replication is paused.
Destination Cluster	The cluster on which the replica resides.
Destination Path	The path to the destination.
Up to Date	Whether replica is up-to-date. Data may not be up-to-date for the following reasons: • Data Pending — Indicates the amount of data that is yet to be replicated to the replica. • Puts Pending — Indicates the number of puts that are yet to be replicated to the replica. • Bytes Pending — Indicates the number of bytes that are yet to be replicated to the replica.
Earliest	The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica.
Latest	The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica.
Errors	Error () information, if any.
Compression Type	The type of on-wire compression.
Synchronous	Whether replication is synchronous or asynchronous.
Throttled	Whether replication is throttled.
Encrypted	Whether replication is encrypted.

Retrieving List of Table Replicas Using the CLI or the REST API

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see `table replica list` on page 1863

Modifying Table Replica

Explains how to edit the properties of a replica using the Control System and the CLI.

Modifying a Table Replica Using the Control System

To modify the properties of a table replica:

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Replicas** to go to that tab.
3. Click  associated with the replica to modify.

last-updated: Apr 11, 2022

The **Edit Replica** page displays.

4. Make changes to the following as desired:

Path to Replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst` **Note:** For replication to a table, the command will fail if the replica path you specify points to a table that already exists.
Replication State	Specify whether or not to start replication by choosing one of the following: • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and start replication. • Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other. See Primary-Secondary Replication on page 611. If this is not selected, table replication will be basic primary-secondary topology, which is the default. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located. See Primary-Secondary Replication on page 611. **Note:** Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (**Yes**) or asynchronous (**No**).
Encrypt On Wire	Specify whether (**Yes**) or not (**No**) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.

last-updated: Apr 11, 2022

Compress On Wire	The type of on-wire compression. Choose one of the following: • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:
   - For JSON table replica:
     - **Replicate Entire Document**
     - **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" : "value",
                    },
               "e" : "value"
          }
}
```

       To replicate field `c`, you must specify `a.b.c` as the field path. Do not use quotation marks and do not include spaces after each dot. Click:
       - **Add Field** to add another field to replicate.
       - ⛔ to remove a field.
   - For Binary table replica:
     - **Replicate All Column Families**
     - **Replicate Selected Column Families** — Specify the column family name and select:
       - **Include All Columns** — to replicate all columns associated with the column family.
       - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.
7. Click **Edit Replica** for the changes to take effect.

Modifying a Table Replica Using the CLI or REST API

The basic command to modify a table replica is:

```
maprcli table replica edit -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume

last-updated: Apr 11, 2022

- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica edit` on page 1859.

Removing Table Replicas
Explains how to un-register one or more replicas using either the Control System or the CLI.
Removing Replication Using the Control System

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Replication** to go to that tab.
3. Select the replicas to remove by clicking the associated checkbox.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Remove Replica(s)** from the **Actions** drop-down menu.
   The **Remove Replica(s)** confirmation window displays.
5. Verify the list of replicas to remove and click **Remove Replica**.
   If necessary, click ✕ to remove a replica.
   The selected replicas are no longer replicas of the source table and will no longer receive updates from the source table. You must also remove upstream source to remove the association between the source table and the replica table. For more information, see Removing Upstream Sources.

Removing Replication Using the CLI or REST API

The un-register a replica, run the following command:

```
maprcli table replica remove -path <table path> -replica <replica table
path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica remove` on page 1867.

Pausing Table Replication
Explains how to pause table replication of data from a source MapR Database binary or JSON table to a replica MapR Database binary or JSON table respectively using either the Control System or the CLI.
Pausing Table Replication Using the Control System

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Replicas** to go to that tab.
3. Select the replicas to pause by clicking the associated checkbox.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.

4. Select **Pause Replication** from the **Actions** drop-down menu.
   The **Pause Replication** confirmation window displays.
5. Verify the list of replicas to pause and click **Pause Replication** to pause replication on the selected replicas.
   If necessary, click ✕ to remove a replica from being paused.

Pausing Table Replication Using the CLI or REST API

The pause replication, run the following command:

```
maprcli table replica pause -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica pause` on page 1866.

Resuming Table Replication
Explains how to resume replication between a source MapR Database binary or JSON table and a replica of that table when the replication state is set to paused from the Control System or by the `maprcli table replica add` or the `maprcli table replica pause` command.
Resuming Replication Using the Control System

1. Go to the table information page.
   See Viewing Table Information on page 1032.
2. Click **Replicas** to go to that tab.
3. Select the replicas in paused state by clicking the associated checkbox.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Resume Replication** from the **Actions** drop-down menu.
   The **Resume Replication** confirmation window displays.
5. Verify the list of replicas for which to resume replication and click **Resume Replication**.
   If necessary, click ✕ to leave the replica in paused state.

Resuming Replication Using the CLI or REST API

The resume replication, run the following command:

```
maprcli table replica resume -path <table path> -replica <replica table
path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica resume` on page 1869.

Adding a Column Family to a Replica
Changes to the structure of a source table are not automatically replicated to replica table. You must complete the following steps to add a column family to a replica.

When an entire table is being replicated, new column families are not automatically created at the replica. However, once you add the new column family to the replica then updates to the new column family will immediately start being replicated.

When you are replicating a subset of column families and columns, you must add the new column family to the replica and also run the copytable utility to initially populate the new column family in the replica table.

1. Pause replication by running the `maprcli table replica pause` command.
2. Add the new column family to the replica by running the `maprcli table replica edit` command.
3. If the replica includes a subset of column families and columns from the source table, copy the data from the new column family from the source table into the replica by using the CopyTable utility. Use the `-columns` parameter to specify the name of the column family.
4. Resume replication by running the `maprcli table replica resume` command.

Viewing Active Table Replication Alarms
Describes how to view active table replication alarms using the Control System and the CLI.

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

- Log in to the Control System and click **Data** > **Tables** to view table replication alarms in the **Active Alarms** pane.

  You can:

  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Table-Replication Alarms on page 2237 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 1545.

Viewing Table Replication Alarms in the Log Files

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Managing Upstream Source for Table Replicas

You can set up a table to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Setting Table as Upstream Source for a Replica
Explains how to set up the current table as the upstream source for a replica if the replica was not configured to automatically re-sync with the current table.
Setting Up Current Table as Upstream Source for a Replica Using the Control System

To set up a table as the upstream source for replicas:

1. Go to the **Replication** tab in the table information page.
2. Select the checkbox beside the replicas that do not have the current table configured as upstream source for automatic re-sync.
   Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Table as Upstream Source** from the **Actions** drop-down menu.
   The **Set Current Table as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
   The current table will automatically send updates to the replica(s).

Setting Up Table as Upstream Source for a Replica Using the CLI or REST API

The basic command to set a table as the upstream source for a replica is:

```
maprcli table upstream add -path <replica table path> -upstream <source
table path>
```

See `table upstream add` on page 1870 for complete reference information.

Adding Upstream Source for Table
Describes how to add an upstream source for a table using either the Control System or the CLI.
Adding Upstream Source Using the Control System

To add an upstream source for the current table:

1. Log in to the Control System and go to the **Replication** tab in the table information page.
2. Click **Add Upstream Source Table** in the **Upstream Sources** pane.
   The **Add Upstream Source Table** window displays.
3. Enter the path to the upstream source table.
   - For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under `volume1` which has a mount point at `/volume1`, specify the following path: `/volume1/testsrc`
   - For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customersrc`
4. Click **Add Upstream Source Table**.

Adding Upstream Source Using the CLI or the REST API

The basic command to add upstream source is:

```
maprcli table upstream add -path <table path> -upstream <upstream table
path>
```

See `table upstream add` on page 1870 for complete reference information.

Listing all Upstream Sources for a Table
Explains how to retrieve and view the list of upstream sources for a table using either the Control System, or the CLI.
Viewing Upstream Sources Using the Control System

To view the list of upstream sources:

- Log in to the Control System and go to the **Replication** tab in the table information page.
  The list of upstream sources for the table displays in the **Upstream Source** pane. For each upstream source, the pane displays the following:

Column Name	Column Description
IDX	The index number of the replica table.
Upstream Source Cluster	The cluster on which the upstream table resides.
Upstream Source Path	The path to the upstream source table.
UUID	The replica table's universally unique identifier.

  Selecting the checkbox beside an upstream source makes the **Remove Upstream Source(s)** button available. You can:

  - Add an upstream source table
  - Remove an upstream source table

Retrieving Upstream Sources Using the CLI or the REST API

The basic command to retrieving the list of upstream sources for a table is:

```
maprcli table upstream list -path <table path>
```

See `table upstream list` on page 1871 for complete reference information.

Removing Upstream Source
Explains how to remove a table as an upstream source using either the Control System or the CLI.
Removing Upstream Source Using the Control System

To remove upstream source:

1. Log in to the Control System and go to the **Replication** tab in the table information page.
   See Viewing Table Information on page 1032.
2. Select the upstream sources to remove in the **Upstream Source** pane by clicking the associated checkbox.
3. Click **Remove Upstream Source Table** in the **Upstream Source** pane.
   The **Remove Upstream Source Table** confirmation dialog displays.
4. Verify the list of upstream sources to remove and click **Remove Upstream Source Table**.

Removing Upstream Source Using the CLI or the REST API

The basic command to remove upstream source is:

```
maprcli table upstream remove -path <table path> -upstream <upstream table
path>
```

See `table upstream remove` on page 1873 for complete reference information.

Managing Secondary Indexes

Describes how to manage secondary indexes, including adding, deleting, and listing indexes, setting up your cluster for querying, and troubleshooting index usage.

You can add and manage secondary indexes using either the `maprcli table index` commands or the Control System. The `maprcli table index` commands are also available using the REST API. The following diagram provides links to information about managing indexes.

1. Describes the tasks needed to prepare your environment so you can query MapR Database JSON tables using secondary indexes.
2. Describes how to add secondary indexes on MapR Database JSON tables.
3. Describes how to view information about secondary indexes. This includes information about whether an index is lagging its parent JSON table.
4. Describes how to use the MapR Database shell to examine the contents of a secondary index. This includes displaying information about errors encountered inserting into the index.
5. Describes how to verify that the data in a secondary index is consistent with its JSON table.
6. This topic describes how to remove secondary indexes that are no longer needed.
7. Describes how to debug and troubleshoot usage of secondary indexes.

The following permissions are required to add, remove, and list indexes. Indexes share the same volume and topology as its JSON table, so the applicable permissions are on the volume and JSON table path.

- `readAce` on the volume
- `lookupdir` on directories in the table path

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Also, to add or remove an index, the user must be the creator of the table or a user with `indexperm` permission.

Preparing Clusters for Querying using Secondary Indexes on JSON Tables

Describes the tasks needed to prepare your environment so you can query MapR Database JSON tables using secondary indexes.

Installing with the MapR Installer

To install MapR using the MapR installer, follow the steps outlined at Installing with the MapR Installer on page 141.

last-updated: Apr 11, 2022

Starting with MapR 6.0.1, you do not have to enable a separate query service to use secondary indexes. The **Operational Applications with MapR Database** template installs and configures the replication gateways needed to update secondary indexes in MapR Database JSON and includes the components needed to run OJAI queries.

You must enable the OJAI Distributed Query Service on page 505 to use certain features. The following table summarizes the differences in the functionality of OJAI queries when you do and do not have the service enabled:

Service Not Enabled	Service Enabled
• Can run queries that use a single secondary index • Can sort data in your queries up to a configurable limit	• Can run queries that use multiple secondary indexes • Can sort data in your queries without any limit • Can run queries in parallel

Selecting any of the following templates enables the OJAI Distributed Query Service:

- **Operational Applications with MapR Database and Distributed Query Service**
- **MapR Converged Cluster: Batch, interactive and real-time analytics**
- **Analytics with MapR Database**

You can also explicitly enable the OJAI Distributed Query Service by selecting the service in the **Custom Services** template.

For more information about installer templates, see Auto-Provisioning Templates on page 5448.

For more information about how secondary index selection and execution works in MapR Database JSON, see Selection and Execution of Secondary Indexes on page 582.

Note: The **OJAI Query Service** has been renamed to the **OJAI Distributed Query Service** in MapR 6.0.1. All information about the OJAI Distributed Query Service applies to the OJAI Query Service, except where noted.

Installing without the MapR Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the MapR installer. Generally, you need to perform the following steps:

1. Install software.

   To install MapR without using the MapR installer, follow the steps outlined at Installing without the MapR Installer on page 141. In addition to installing MapR core packages, you also need to install MapR Drill if you want advanced secondary index selection, sorts on large data sets, and parallel query execution. When installing Drill, make sure to Configure the OJAI Distributed Query Service on page 182.

2. Install and configure replication gateways.

   Updates are propagated from the JSON tables using the Gateways for Replicating MapR Database Tables on page 621. You need to install the replication gateways. Since the source JSON table and the secondary index are on the same volume within a cluster, configure an intracluster gateway. In this type of gateway, the source and destination clusters are the same.

   If your gateways are running on the same nodes as CLDB, then no additional configuration steps are required. See Configuring Gateways for Table and Stream Replication on page 1152 for details about this scenario and other options for configuring your gateways.

Upgrades

Other sections of the documentation describe the detailed steps for upgrades. Generally, you need to perform the following steps:

1. Upgrade your MapR software by following the instructions at Upgrading MapR Core or EEP Components on page 284.
2. Install MapR Drill, if you have not already done so and want to sort large data sets and run queries in parallel.
3. When installing Drill, make sure to Configure the OJAI Distributed Query Service on page 182.
4. If you are upgrading without the MapR installer, follow step 2 in the previous section to install and configure replication gateways.
5. Enable the replication support needed to propagate index updates by running the following command:

   ```
   maprcli cluster feature enable -name mfs.feature.db.streams.v6.support
   ```

   See Step 4: Enable New Features on page 330 for further details.

Important: If you are using a Manual Rolling Upgrade Description on page 319, you must upgrade all nodes running replication gateways before performing updates on tables with indexes. Otherwise, the index updates will hang.

Adding Secondary Indexes on JSON Tables

Describes how to add secondary indexes on MapR Database JSON tables.

You can add secondary indexes using the Control System, or the `maprcli table index` commands.

If you are adding an index on a large table, particularly if it contains complex data, you should consider modifying the `mfs.db.parallel.copyregions` parameter using the maprcli config save command. The parameter controls the degree of parallel processing in your MapR cluster. Increasing parallelism can improve the index build time by optimizing the build's intermediate copy operation.

Permissions

You need the following permissions to add an index:

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table

If you created the table in version 6.0 or later, you automatically have `indexperm` permission. For tables created before 6.0, even if you are the owner of the table, you must explicitly add `indexperm` permission.

Note: The mapr user is not treated as a superuser. MapR Database does not allow the mapr user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

See Restrictions on Secondary Indexes on page 565 for information about other restrictions.

Adding Indexes Using the Control System

1. Log in to the Control System and go to the **Indexes** tab in the table information page.
2. Click **Add Index** to display the **Add Index** page.
3. Specify the following settings:

last-updated: Apr 11, 2022

a) Specify the name of the index in the **Index Name** field.

b) Specify whether (**Yes**) or not (**No**) the index is hashed in the **Hashed** field. If **Yes**, specify the number of hash index partitions for distributing the keys.

See Hashed Indexes on page 555 for information about whether you should create a hashed index.

4. Specify the list of indexed fields under **FIELDS INDEXED**.
   a) Specify the name of the indexed field in the **Field Name** text field.

   b) Select the ordering (**Ascending** or **Descending**) for the field from the **Order** drop-down menu.

   c) Select the function of the field from the **Function** drop-down menu.

   Before defining an index that specifies index keys with CAST functions, see Using Casts in Secondary Indexes on page 557 for more information on creating indexes using CAST functions.

   Tip: To add more indexed fields, click **Add Another** and repeat step 4.

5. Specify the names of the included fields under **INCLUDED FIELDS**.
   For more information, see Covering Indexes on page 560.

   Tip: To add additional included fields, click **Add Another** and repeat step 5.

6. Click **Add Index** to create the index.

Adding Indexes Using the CLI

The following is the basic command for adding a secondary index on a JSON table.

```
maprcli table index add
  -path <path>
  -index <index name>
  -indexedfields < indexed field names >
```

See `table index add` on page 1827 for a description of the complete syntax.

Troubleshooting Secondary Indexes
Describes how to debug and troubleshoot usage of secondary indexes.

The following table lists problems you may encounter when using secondary indexes. Based on the symptoms listed in the first column, refer to the section in the third column to further troubleshoot the issue.

Symptom	Possible Cause	Troubleshooting Steps
Query performance is slow	Query is not using secondary indexes	1. Determining the Query Execution Path for OJAI Queries on page 1097 2. Determining Secondary Index Usage on page 1098
	Non-optimal OJAI query plan chosen	Examining the OJAI Query Plan on page 1098
	Non-optimal query plan chosen by OJAI Distributed Query Service	Determining Index Use on page 3364

Symptom	Possible Cause	Troubleshooting Steps
Inconsistent query results	Secondary index update lag	Identifying Secondary Index Lag on page 1099
	Unresolved encoding errors	Troubleshooting Secondary Index Encoding Errors on page 1101
Query runs out of memory	Memory configuration in the OJAI Distributed Query Service set too low	Adjusting Memory Settings in the OJAI Distributed Query Service on page 1103

Secondary Index Restrictions

When troubleshooting secondary indexes, you should also keep in mind the following restrictions:

Name Restrictions

You cannot use the following characters in the index name and in the indexed fields:

```
< > ? % \
```

To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  "♥,"♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  '♦,'♦=#;{}&()/'
```

To use either the ' or the " character in the index name and in the indexed fields, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"'MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"♦●
♥,"LOTNo" -includedfields \
  "♦","♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'"MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "'●timestamp":desc,"●
```

```
🐰,"LOTNo" -includedfields \
  '🐰',"🍁=#;{}&()/"
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

  For example, you cannot create an index with the following indexed fields:

  ```
  a.b[].c, a.b.d
  ```

  Although subfield b appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

  See Composite Indexes and Container Field Paths on page 554 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

  If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (`INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG`).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.
- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:
  - The indexed field is a container field path:

    ```
    maprcli table index add -path /
    people \
       -index phoneNumberIdx \
       -indexedfields
    Phones[].Number \
       -includedfields
    Phones[].Number
    ```

- The field specifies a cast to another type.

  You can create an index in which the `score` field is an indexed field cast as a `double` type, and `score` is also an included field. The included field retains the original data type of the `score` field:

  ```
  maprcli table index add -path /
  castTable \
     -index castIdx1 \
     -indexedfields
  '$CAST(score@DOUBLE)' \
     -includedFields score
  ```

  You can create an index in which the `score` field is an indexed field, cast as a `double` type, and the `score` field is also another indexed field, cast as a `long` type:

  ```
  maprcli table index add -path /
  castTable \
     -index castIdx2 \
     -indexedfields
  '$CAST(score@DOUBLE)','$CAST(scor
  e@LONG)'
  ```

- You cannot use casts with included fields.
- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

  For example, suppose you have the following JSON table:

  ```
  {
       "_id" : "ID",
       "a" :
            {
                 "b" :
                      {
                           "c" :
  "value",
                           "d" :
  "value"
                      },
                 "e" : "value"
            }
  }
  ```

  If you create a column family at field c in the JSON path `a.b.c`, you cannot define field `a.b.c` as either an indexed or included field. You can define the fields a, `a.b`, and `a.b.d` as either indexed or included fields.

last-updated: Apr 11, 2022

- You cannot specify an included field in which the data in the field spans more than one column family.

  In the following example, the included field `sl1.sl2` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm  readperm
traverseperm  jsonfamilypath
writeperm  minversions
maxversions  compression
ttl         inmemory  cfname
memoryperm
u:root           u:root
u:root
u:root     0
1            lz4
2147483647  false     default
u:root
u:root           u:root
u:root         sl1
u:root     0
1            lz4
2147483647  false     cf1
u:root
u:root           u:root
u:root         sl1.sl2.sl3
u:root     0
1            lz4
2147483647  false     cf2
u:root
u:root           u:root
u:root         sl1.sl2.sl3.sl4
u:root     0
1            lz4
2147483647  false     cf3
u:root

maprcli table index add -path /
cftab -index i1 -indexedfields
sl1.sl2.sl3.sl4.l4a,
sl1.l1a -includedfields
sl1.sl2,sl1.sl2.sl3.sl4.sl5.l5b -js
on
{
        "timestamp":1507419777919,
        "timeofday":"2017-10-07
04:42:57.919 GMT-0700 PM",
        "status":"ERROR",
        "errors":[
                {
                        "id":22,

"desc":"Data for included field
sl1.sl2 may not span more than one
column family."
                }
         ]
}
```

- You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same.

  See Composite Indexes and Container Field Paths on page 554 for more details.

- You cannot specify a composite index with an indexed field that is a subfield of another indexed field.

  For example, you cannot create an index with the following indexed fields:

  ```
  a, a.b
  ```

  The indexed field `a.b` is a subfield of the indexed field `a`.

Option Restrictions

- As indexes are automatically split, you cannot disable splits when you create your index.

Index Use Restrictions

- Indexes do not optimize non-existence filter conditions.

Describes how to use the MapR Database JSON `verifyindex` command to verify that the data in a secondary index is consistent with its JSON table.

dbshell indexscan on page 5298

Determining the Query Execution Path for OJAI Queries

You can determine whether an OJAI query directly accesses MapR Database JSON or leverages the OJAI Distributed Query Service by enabling Java OJAI tracing. Java OJAI tracing logs information that enables you to determine which execution path your queries use.

Follow the instructions at Enable OJAI Tracing on page 2667 to output tracing messages that include query plans.

If the query does not use the OJAI Distributed Query Service, you will see tracing like the following:

```
2017-07-17 17:35:59 TRACE OjaiDocumentStore:132 -
Query Plan: '[{"streamName":"DBDocumentStream","parameters":
{"queryConditionPath":false,"indexName":"abc_Idx","projectionPath":
["c","b","a"],"primaryTable":"/tmp/test-728918932/ei_suffix_sort"}}]'
```

If a query uses the OJAI Distributed Query Service, you will see tracing like the following instead:

```
2017-07-17 18:51:13 TRACE OjaiDocumentStore:132 - Query
Plan:'[{"streamName":"DrillDocumentStream","parameters":{"sql":"select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC"}}]'
```

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
```

```
2692966d-0888-96e2-fa09-0d9befcd3173 ,sql string = select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC)
```

Note that the **Query Plan** in the second trace fragment above contains a **DrillDocumentStream** instead of a **DBDocumentStream**. The **sql** parameter in that stream shows a SQL query. This is also missing in the first trace fragment above. The presence of the SQL query indicates that OJAI passes the query to the OJAI Distributed Query Service, as noted in the third trace fragment.

For further information about OJAI query plans, see Examining the OJAI Query Plan on page 1098. For background information about different query execution paths, see OJAI Distributed Query Service on page 505.

Determining Secondary Index Usage
This section describes how to determine whether a query is using secondary indexes, depending on the query execution path used.

Determine whether your query uses the OJAI Distributed Query Service by following the steps outlined at Determining the Query Execution Path for OJAI Queries on page 1097. The following sections describe next steps depending on the execution path.

Simple OJAI Queries

Using the tracing described at Determining the Query Execution Path for OJAI Queries on page 1097, you will see the following in the log output:

```
2017-07-17 17:35:59 TRACE MapRDBTableImplHelper:703 - Scan on Index:
'testIndex', Primary Table is: '/tmp/testTable', Index Scan QueryCondition:
'((field < {"$numberLong":101}))',
Index Scan startRow: '\x0FZ', Index Scan stopRow: '\x0F\x89\xCA\x80\x00'
```

The "**Scan on Index**", highlighted in bold, indicates OJAI used a secondary index to process the query.

Queries Requiring the OJAI Distributed Query Service

The tracing output described at Determining the Query Execution Path for OJAI Queries on page 1097 contains a **queryId**, highlighted in bold:

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
2692966d-0888-96e2-fa09-0d9befcd3173 ,
sql string = select t.`$$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from
dfs.`/tmp/testTable` t where (t.`l0_a4_int` = -92) order by t.`l0_a4_int`
ASC,t.`_id` DESC)
```

Use this **queryId** to retrieve more information through the Drill Web Console, including the query plan selected by the OJAI Distributed Query Service. See Query Profile on page 3365 for details.

Examining the OJAI Query Plan
This section describes two ways to access a Java OJAI query plan and provides general information about how to interpret the query plan. You can examine the query plan to determine if the Java OJAI client chooses an appropriate execution path.

Using OJAI Tracing

After following the steps at Determining the Query Execution Path for OJAI Queries on page 1097, if you determine that your query directly accesses MapR Database JSON and does not use the OJAI Distributed Query Service, you can further examine the query plan in the trace output.

As noted in the referenced topic, to enable tracing, set the following property in your `log4j.properties` file, located in the `/opt/mapr/conf` directory:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

In the following logged output, the query plan uses an index named `i1_idx` and projects field `id1`. It also limits the result to two documents:

```
2017-10-18 11:29:32,876 TRACE
[main] com.mapr.ojai.store.impl.OjaiDocumentStore -
Query Plan: '[{"streamName":"DBDocumentStream","parameters":
{"queryConditionPath":false,"indexName":"i1_idx","projectionPath":
["id1"],"primaryTable":"/tmp/test-728918932/tab"}},
{"streamName":"LimitStream","parameters":{"limit":2}}]'
```

Calling `QueryResult.getQueryPlan`

Instead of using OJAI tracing, you can programmatically retrieve query plans by calling QueryResult.getQueryPlan. The method returns a JSON document that is a list of `Maps`. Each `Map` in the list represents a DocumentStream in the query plan, which corresponds to an operation. The order of the list represents the order the MapR Database client processes each operation. Each `Map` entry contains the name of the DocumentStream (`streamName`) and its parameters. You may see `Map` entries corresponding to the following `DocumentStreams` in a query plan:

- `DBDocumentStream` - Accesses MapR Database without the OJAI Distributed Query Service
- `DrillDocumentStream` - Uses the OJAI Distributed Query Service to process the query
- `LimitStream` - Limits the number of documents to return
- `OffsetStream` - Skips past specified number of documents before reading

Important: The `DocumentStream` names and their parameters are subject to change from one release to the next. Take that into consideration if you plan to write tools that interpret the contents of an OJAI query plan

Identifying Secondary Index Lag

This section describes the commands you use to determine if updates to a secondary index are lagging.

Secondary index lag can occur due to aysnchronous secondary index updates. Use maprcli table index list and mapr verifyindex to assess if there is update lag in an index and to see details on the updates that are lagging.

Run maprcli table index list

The `maprcli table index list` command lists information about indexes created on a table. To retrieve the most current status, specify the optional `refreshnow` parameter. Examine the values of the following fields to determine if an index is lagging:

- isUptodate - True if the index is up-to-date
- bytesPending - The number of bytes pending propagation to the index
- putsPending - The number of puts pending propagation to the index
- minPendingTS - The timestamp of the oldest put pending propagation to the index
- maxPendingTS - The timestamp of the most recent put pending propagation to the index

last-updated: Apr 11, 2022

In the sample output below, the index is up-to-date.

```
maprcli table index list -path /demo/business -json
{
        "timestamp":1506617667735,
        "timeofday":"2017-09-28 04:54:27.735 GMT+0000 PM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "cluster":"my.cluster.com",
                        "type":"maprdb.si",
                        "indexFid":"2049.93.10257820",
                        "indexName":"i1",
                        "hashed":false,
                        "indexState":"REPLICA_STATE_REPLICATING",
                        "idx":1,
                        "indexedFields":"a.b:ASC",
                        "isUptodate":true,
                        "minPendingTS":0,
                        "maxPendingTS":0,
                        "bytesPending":0,
                        "putsPending":0,
                        "bucketsPending":0,
                        "copyTableCompletionPercentage":100,
                        "numTablets":1,
                        "numRows":4,
                        "totalSize":24576
                }
        ]
}
```

Run mapr verifyindex

If `maprcli table index list` shows that an index is lagging, use the mapr verifyindex command to gather more information. The following example illustrates the output in the case where an index is lagging. The following updates have not yet propagated to the index:

- Document with _id=997 not yet inserted into the index.
- Update to the `city` field in document with _id=998 not yet propagated to the index.

```
// Display contents of parent JSON table
# mapr dbshell

maprdb root:> find /t1
{"_id":"1000","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"997","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"998","city":"city4","misc":{"a":"misc.a","b":2}}
{"_id":"999","city":"city3","misc":{"a":"misc.a","b":2}}
4 document(s) found.

// Display contents of an index that is lagging.
// Document with _id=997 is missing from the index and
// there is a mismatch in the index data for document with _id=998
maprdb root:> indexscan /t1 --indexname i2
{"_id":"1000","city":"city3"}
{"_id":"998","city":"city3"}
{"_id":"999","city":"city3"}
3 document(s) found.
maprdb root:> quit
```

last-updated: Apr 11, 2022

```
// Output of verifyindex
# mapr verifyindex -path /t1 -index i2

Missing Document in Index:
{"_id":"997","city":"city3"}

Mismatch Document Found!!
Table side-->{"_id":"998","city":"city4"}
Index side-->{"_id":"998","city":"city3"}

Number of rows in table but not in index: 1
Number of rows in index but not in table: 0
Mismatch row count: 1
```

Troubleshooting Secondary Index Encoding Errors

This section describes how to locate secondary index encoding errors in log files, and then resolve them.

Unresolved secondary index encoding errors can result in queries returning incomplete results. See Secondary Index Encoding Error on page 2240 for details.

To troubleshoot secondary index encoding errors, follow these steps:

1. Determine whether any table has index encoding alarms by using one of the following two options:
   - Run the following `grep` command, searching for the strings `index` and `encoding` in the `mfs.log-5` file:

     ```
     # grep -i "index.*encoding" /opt/mapr/logs/mfs.log-5
     2018-07-10 11:06:07,7042 INFO DB db/repl/araggregator.cc:524 Table
     2050.43.262440 hit index row-key encoding error
     2018-07-10 11:06:07,7042 INFO DB db/repl/araggregator.cc:914 Raising
     alarm VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR for volume 195503497
     ```

     The fid, `2050.43.262440`, in the sample output indicates the table corresponding to the alarm. If you are not sure which table this corresponds to, you can convert the fid to a table path by following the instructions at Converting fid and volid on page 2438.

   - Check for any table index encoding alarms in the MapR Control System, as described at Viewing Active Table Replication Alarms on page 1318.

     The alarm details indicate the table corresponding to the alarm.

2. Find the index on the table from step 1 that is causing the error.

   Run dbshell indexscan on page 5298 with `--mode` set to `err` on each index to see the index's error output. You need to run the command multiple times if a table has multiple indexes with errors.

   For example, if `table1` has three secondary indexes and all three secondary indexes have errors, you must run `indexscan` three times:

   ```
   indexscan /table1 --indexname index1 --mode err
   indexscan /table1 --indexname index2 --mode err
   indexscan /table1 --indexname index3 --mode err
   ```

   The following example shows error output from running the `dbshell indexscan` command:

   ```
   maprdb root:> indexscan /IndexEncodingErrorAlarmsTest1/tab1 --indexname
   idx1 --mode err
   {"_id":"100","$ERROR":"Index field 1: INVALID_CAST"}
   ```

last-updated: Apr 11, 2022

3. Address the identified errors by attempting the following suggested resolutions:

Error	Suggested Resolutions
KEY_TOO_LONG: The collective size of the index key is limited to less than 32 KB.	• Reinsert the row in the JSON table so the collective size of all the indexed fields is less than 32 KB. • Redesign the secondary index so fields with large values are included fields instead of indexed fields. • Reduce the number of indexed fields in the secondary index.
INVALID_CAST: An error was encountered applying the CAST function on an indexed field.	• Verify that you have specified the correct types when using the CAST function with indexed fields. • If the types are correct, reinsert the row in the JSON table so the values of indexed fields can be cast to the specified type. See Using Casts in Secondary Indexes on page 557.

Adjusting Memory Settings in the OJAI Distributed Query Service

This section describes how to verify, through log output, that your OJAI query is running out of memory due to memory limits in the OJAI Distributed Query Service. It then describes how to adjust the memory settings in the service.

1. Before adjusting the OJAI Distributed Query Service memory settings, first confirm that your query has run out of memory due to limits in the service.

   You should see output like the following in your client application log:

```
15:32:46.465 [Thread-21] - Error caused in scan Drill submissionFailed
for "select t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/
business` t where ((t.`city` = 'Currie') and (t.`state` = 'PA') and
(t.`review_count` > 5100)) limit 1
org.ojai.exceptions.OjaiException: Drill submissionFailed for "select
t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/business` t where
((t.`city` = 'Currie') and (t.`state` = 'PA') and (t.`review_count` >
5100)) limit 128" please ch

:1142)
        at
java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.jav
a:617)
        at java.lang.Thread.run(Thread.java:745)
Caused by: org.apache.drill.common.exceptions.UserRemoteException:
RESOURCE ERROR: One or more nodes ran out of memory while executing the
query.

Failure trying to allocate initial reservation for Allocator. Attempted
to allocate 5000000 bytes and received an outcome of FAILED_LOCAL.
Fragment 0:0
```

   In the OJAI Distributed Query Service, log files are in the `/opt/mapr/drill/<drill-version>/logs/drillbit.log` on each node where the Query Service is running.

   You should see output like the following:

```
2017-10-07 15:32:41,693 [BitServer-3] INFO
o.a.drill.exec.ops.FragmentContext - User Error Occurred: One or more
nodes ran out of memory while executing the query. (Failure trying to
allocate initial reservation for Allocator. Attempted
org.apache.drill.common.exceptions.UserException: RESOURCE ERROR: One or
more nodes ran out of memory while executing the query.

Failure trying to allocate initial reservation for Allocator. Attempted
to allocate 7000000 bytes and received an outcome of FAILED_LOCAL.
Fragment 1:1
```

2. After confirming, increase the Query Service memory settings by editing the `/opt/mapr/conf/conf.d/warden.drill-bits.conf` file on each Drillbit node. The file contains the following entries:

```
service.env=DRILL_HEAP=3072m,DRILL_MAX_DIRECT_MEMORY=1024m,DRILLBIT_CODE_
CACHE_SIZE=512m
service.heapsize.min=4608
service.heapsize.max=4608
```

   Perform the following steps on **each** Drillbit node:

   a) Modify `DRILL_HEAP` and `DRILL_MAX_DIRECT_MEMORY` in the `service.env` entry based on your requirements.

   b) Update `service.heapsize.min` and `service.heapsize.max` to reflect the updates you made. The numbers sum to the 3 memory settings in the `service.env` entry.

   c) Restart warden on the node by running the following command:

```
service mapr-warden restart
```

Listing Secondary Indexes

Describes how to list information about the secondary indexes created on MapR Database JSON tables.

You can view secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

Note: The mapr user is not treated as a superuser. MapR Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

- Log in to the Control System and go to the **Indexes** tab in the table information page.
  The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

Column Name	Column Description
Index Name	The name of the index
Fields Indexed	The number of fields on the JSON table that are indexed and used for ordering
Fields Covered	The number of fields on the JSON table that are indexed, but not used for ordering
State	The replication state of the index
Up to Date	Whether the index is up to date
Hashed	Whether the index is hashed
Size	The size of the index

To view more details on individual indexes, see Viewing Secondary Index Details on page 1105.

Listing Indexes Using the CLI

The following is basic command for listing secondary indexes.

```
maprcli table index list
            -path <path>
            -refreshnow < true | false >
```

See `table index list` on page 1834 for more information.

Viewing Secondary Index Details

Describes how to use the Control System to view more specific details on secondary indexes.

You can view secondary index details using the Control System.

1. Go to the **Indexes** tab in the table information page for the JSON table.
2. Click the name of the index to display the details.
   The page displays **Summary** and **Metrics** tabs.

Summary	The **Summary** tab displays the following:	
	Throughput - By Op Type	See Viewing Throughput by Operation Type Using the Control System on page 1303
	Region Distribution	See Viewing Region Distribution on page 1306.
	SETTINGS AND AUDITING	Displays the index name, whether or not the index is hashed and if hashed, the number of hashed partitions, the status of the index and if the index is current, and the number of bytes, puts, and buckets that are yet to be replicated to the index.
	INCLUDED FIELDS	The fields in the JSON table that are indexed, but not used for ordering.
	FIELDS INDEXED	The fields in the JSON table that are indexed and used for ordering.
Metrics	The **Summary** tab displays charts for the secondary index metrics. For more information, see Viewing Secondary Index Metrics on page 1305.	

Removing Secondary Indexes on JSON Tables

Describes how to remove secondary indexes that are no longer needed.

You can remove secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

last-updated: Apr 11, 2022

- `indexperm` permission on the table, if you did not create the table

Note: The mapr user is not treated as a superuser. MapR Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Removing Indexes Using the Control System

1. Log in to the Control System and go to the **Indexes** tab in the table information page.
2. Select the indexes to remove and click **Remove Index**.
   The **Remove Index** confirmation window displays.
3. Review the index(es) to remove and click **Remove Index**.

Removing Indexes Using the CLI

The following is the basic command for removing a secondary index on a JSON table.

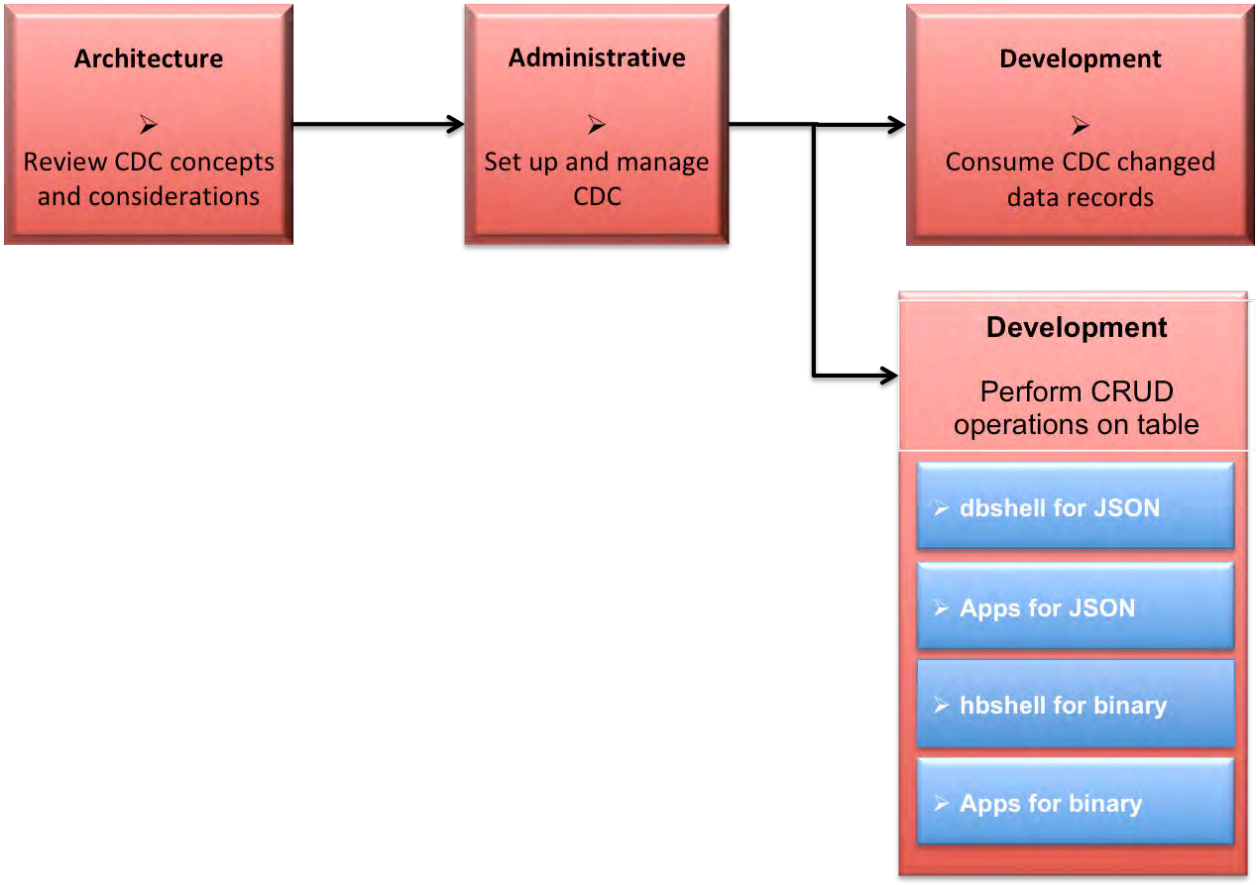
```
maprcli table index remove
  -path <path>
  -index <index name>
```

See `table index remove` on page 1837 for more information.

Administering Change Data Capture

This topic covers the Control System and `maprcli` tools for managing the Change Data Capture (CDC) feature.

The following topics provide information you need to understand the CDC feature, to setup and use CDC and the `maprcli` commands used to perform tasks.



1. Learning about CDC
2. Setting up the CDC environment
3. Consuming CDC changed data records
4. Using dbshell to perform CRUD operations on MapR Database JSON tables
5. Developing client applications for MapR Database JSON tables.
6. Using hbshell to perform CRUD operations on MapR Database binary tables.
7. Developing client applications for MapR Database binary tables.

Additional Information

- table changelog on page 1813: The `maprcli table changelog` commands for managing the changelog relationship between the source table and the destination stream topic.

Setting Up CDC

To set up the Change Data Capture (CDC) feature, the following must exist or be created: a MapR Database source table (JSON or binary), a MapR Event Store For Apache Kafka changelog stream, a MapR Event Store For Apache Kafka stream topic, and a MapR Database table changelog relationship between the source table and the destination stream topic.

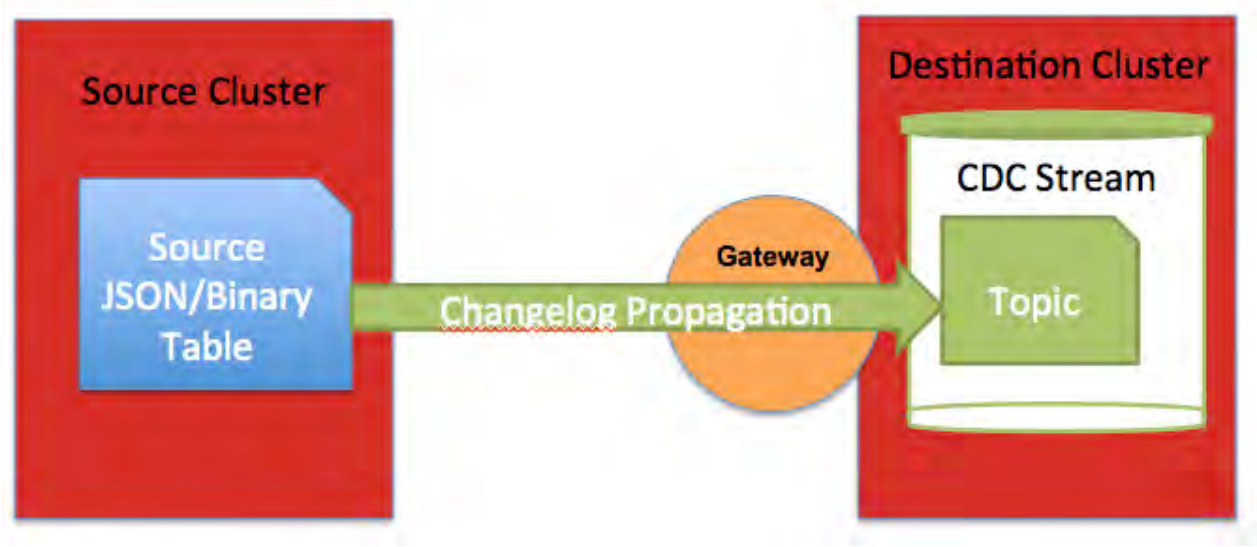
Before Setting Up CDC

The destination MapR Event Store For Apache Kafka stream can be in same cluster as the MapR Database source table or it can be on a remote MapR cluster. If you are propagating changed data from

a source table on a source cluster to a destination stream topic on a remote destination cluster, a gateway must be setup. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering MapR Gateways on page 1150 and Configuring Gateways for Table and Stream Replication on page 1152.

The following diagram shows a simple CDC data model, with one source table to one destination topic on one stream. Because this scenario has the destination stream topic on a remote destination cluster, a gateway must be setup and configured.

Note: More complex CDC scenarios can be implemented and multiple gateways can be setup. See Data Modeling and CDC on page 604 for more information about CDC data models.



Important: If you have a secure cluster, secure configuration must be setup. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.

Create Table

A MapR Database table (JSON or binary) must be established for the CDC data. You can create a new table and add data or use an existing table with data. See maprcli table create for creating a new table or use the Control System. Example code is provided for completing this task using either the maprcli or REST. Alternatively, depending on whether you are establishing JSON documents or binary files, you can use the following:

- mapr dbshell for MapR Database JSON documents
- hbshell for MapR Database binary data

Attention: Ensure that a volume exists and mounted for both tables and streams. Even though MapR Database tables and MapR Event Store For Apache Kafka stream can exist in the same volume, for organizational purposes, you could create separate volumes for both tables and streams.

The following code examples show how to:

- Create and mount a volume for a source table.
- Create a new binary table. The -tabletype parameter's default setting is binary so you don't need to specify this parameter.
- Create a new JSON table.

last-updated: Apr 11, 2022

CLI

```
// Create Volume for table
maprcli volume create -name
tableVolume -path /tableVolume

// Create Binary table
maprcli table create -path /
tableVolume/cdcTable

// Create JSON table
maprcli table create -path /
tableVolume/cdcTable -tabletype json
```

REST

```
// Create Volume for table
https://10.10.100.17:8443/rest/
volume/create?name=tableVolume&path=/
tableVolume

// Create Binary table
https://10.10.100.17:8443/rest/table/
create?path=/tableVolume/cdcTable

// Create JSON table
https://10.10.100.17:8443/rest/
table/create?path=/tableVolume/
cdcTable&tabletype=json
```

Create Stream

A MapR Event Store For Apache Kafka changelog stream must be created for the propagated changed data records using the `maprcli stream create -ischangelog` parameter. See maprcli stream create or use the Control System.

Note: Ensure that a volume exists and mounted for both tables and streams. Even though MapR Database tables and MapR Event Store For Apache Kafka stream can exist in the same volume, for organizational purposes, you could create separate volumes for tables and streams.

Important: The changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change.

- If the `stream topic create` command is used to create a stream topic, then the number of topic partitions can be set at creation time and then is *locked*.
- If the `table changelog add` command is used to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.

The following code examples show how to:

- Create and mount a volume for a changelog stream.
- Create a changelog stream using the default partitions value of one (1).
- Create a changelog stream changing the default partitions to three (3).

last-updated: Apr 11, 2022

CLI

```
// Create Volume for stream
maprcli volume create -name
streamVolume -path /streamVolume

// Create stream (default partitions:
1)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog true

// Create stream  (default
partitions: 3)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog
true -defaultpartitions 3
```

REST

```
// Create Volume for stream
https://10.10.100.17:8443/rest/volume/
create?name=streamVolume&path=/
streamVolume

// Create stream (default partitions:
1)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true

// Create stream (default partitions:
3)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true&defau
ltpartitions=3
```

Create Topic

A MapR Event Store For Apache Kafka stream topic must be created for the changed data records. This can be accomplished in a variety of ways:

- Use the maprcli table changelog add command. This command establishes a changelog relationsip between the source table and the destination stream topic.
- Use the maprcli stream topic create command. I
- Use the REST equivalent of the above maprcli commands.
- Use the Control System.

Important: Once a changelog relationship is established between the source table and the destination stream topic, the number of topic partitions is *locked*. (The `maprcli table changelog add` command is used to establish the changelog relationship.) The `stream topic edit` command can not be used to modify the topic's number of partitions.

The following describes when to create a stream topic a specific way.

- If the changelog stream's default partitions are acceptable for the stream topic (because the topic inherits the stream's default partitions), you can either:

last-updated: Apr 11, 2022

  - Go directly to adding the changelog relationship with the `maprcli table changelog add` command and create the topic there.
  - Create the topic with the `stream topic create` command and *not* specify the `-partitions` parameter.
- If you want to change the topic's partitions, create the topic with the `stream topic create` command and set the `-partitions` parameter.
- If you use the Control System, either of the above methods are available.

The following code examples show how to create a stream topic and change the default partition to five (5).

CLI

```
// Create topic (default partitions: 5
maprcli stream topic create -path /
streamVolume/changelogStream -topic
cdcTopic1 -partitions 5
```

REST

```
// Create topic (default partitions: 5
https://10.10.100.17:8443/rest/stream/
topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1&partit
ions=5
```

Add Changelog

A table changelog relationship must be added between the source table and the destination stream topic by using the maprcli table changelog add command or the Control System. By adding a table changelog relationship, you are creating an environment that propagates changed data records from a source table to a MapR Event Store For Apache Kafka stream topic.

- If you are creating a changelog relationship and the stream topic does not exist, you specify the stream path and topic.
- If you are creating a changelog relationship and the stream topic *does* exist, specify the stream path and topic plus the `-useexistingtopic` parameter. The `-useexistingtopic` parameter can only be used with a changelog stream's newly created topic or a previous changelog stream topic *for the same source table*.

Note: Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

Note: Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See table changelog resume on page 1820 for more information.

The following code examples show how to:

- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does not* exist.
- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does* exist.

last-updated: Apr 11, 2022

CLI	`maprcli table changelog add -path /tableVolume/cdcTable -changelog /streamVolume/changelogStream:cdcTopic1`
	
	`maprcli table changelog add -path /tableVolume/cdcTable -changelog /streamVolume/changelogStream:cdcTopic1 -useexistingtopic true`

REST	`https://10.10.100.17:8443/rest/table/changelog/add?path=/tableVolume/cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1`
	
	`https://10.10.100.17:8443/rest/table/changelog/add?path=/tableVolume/cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1&useexistingtopic=true`

The following example verifies that the table changelog relationship exists:

```
maprcli table changelog list -path /tableVolume/cdcTable
```

What's Next: Modifying and Consuming Data

To have CDC changed data records to consume, you need to perform inserts, updates, and deletes on the MapR Database table data. See CRUD operations on documents using mapr dbshell for JSON documents, mapr hbshell for binary data, Java applications for MapR Database JSON, C or Java applications for MapR Database Binary.

A MapR Event Store For Apache Kafka Kafka/OJAI consumer application subscribes to the topic and consumes the change data records. See Consuming CDC Records on page 2723 for more information.

Example: Setting Up CDC with Default Topic Partitions

This example creates the following: a volume for a MapR Database table, a MapR Database JSON table, a MapR Event Store For Apache Kafka changelog stream without changing the default partitions, creates a topic while adding a table changelog relationship from the source table to the destination stream topic and and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
   maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
   maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
   maprcli table create -path /tableVolume/cdcTable -tabletype json

// Creating a stream for CDC data
   maprcli stream create -path /streamVolume/changelogStream -ischangelog
true

// Creating a changelog relationship between the source table and the stream
   maprcli table changelog add -path /tableVolume/cdcTable -changelog /
```

```
streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
   maprcli table changelog info -changelog  /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
   https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
   https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
   https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true

// Creating a changelog relationship between the source table and the stream
   https://10.10.100.17:8443/rest/table/changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
   https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Example: Setting Up CDC with Non-default Topic Partitions
This example creates the following: a volume for a MapR Database table, a MapR Database JSON table, a MapR Event Store For Apache Kafka changelog stream with default partitions, a stream topic with custom partitions, a table changelog relationship from the source table to the destination stream topic, and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
   maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
   maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
   maprcli table create -path /tableVolume/cdcTable -tabletype json

// Creating a stream for CDC data
   maprcli stream create -path /streamVolume/changelogStream -ischangelog
true -defaultpartitions 3

// Creating a stream topic that overrides the stream's default partitions
   maprcli stream topic create -path /streamVolume/changelogStream -topic
cdcTopic1 -partitions 5

// Creating a changelog relationship between the source table and the
stream plus using an existing topic that has custom partitions
   maprcli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1  -useexistingtopic true

// Viewing the changelog information
```

```
   maprcli table changelog info -changelog  /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
   https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
   https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
   https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true&defaultpartitions=3

// Creating a stream topic that overrids the stream's default partitions
    https://10.10.100.17:8443/rest/stream/topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1amp;partitions=5

// Creating a changelog relationship between the source table and the
stream plus using an existing topic that has custom partitions
   https://10.10.100.17:8443/

Managing Table Changelogs
Describes how to manage CDC table changelogs through the Control System and maprcli.

Adding a Change Data Log
Explains how to add a change data log using the Control System and the CLI.

To add a change data log, you must have the following permissions:

- **Replication Access** (UI) or `replperm` (CLI) on the source table on the source cluster
- **Topic** (UI) or `topicperm` (CLI) on the destination stream in the destination cluster

If you are a normal user and want to create a changelog between your own MapR Database table and someone else's stream topic, you must have **Topic** (UI) permission or `topicperm` (CLI) on the destination stream.

Adding a Change Data Log Using the Control System

1. Log in to t he Control System and go to the **Change Data Capture** tab in the table information page.
2. Click **Add Change Log** to display the **Add Change Log** page.
3. Set values for the following.

Destination Cluster	(Required) The path to the cluster on which the changelog stream exists. If the destination stream is on a remote secure cluster, then a gateway and secure configuration must first be setup. For more information, see Table Replication on page 610, Administering MapR Gateways on page 1150, and Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.
Destination Stream Topic Name	(Required) The target of the changelog stream, specified as `<stream_path>:<topic_name>`, to which all change data records will be published. The stream must exist as a changelog stream or the operation fails.
Publish to Existing Topic	Whether (**Yes**) or not (**No**) to publish to existing topic. If value is **No** and the topic does not already exist, it will be created.
Publish Existing Data	Whether (**Yes**) or not (**No**) to initiate publishing of the existing data to the stream. If value is **No**, only new changes will be propagated.
Defer Publishing	Whether (**Yes**) or not (**No**) to pause propagation after creating the change log.
Throttle	Whether (**Yes**) or not (**No**) the data transfer to the stream for this change log must be throttled.
Synchronously	Whether (**Yes**) or not (**No**) to acknowledge the client writes to the table before the CDC gateway receives the data.
Encrypt on Wire	Whether (**Yes**) or not (**No**) the data transfer between MapR File System and gateway for this change log is encrypted.
Compress on Wire	The compression scheme of the data transfer between MapR File System and gateway for this change log instance.

4. Choose one of the following:
   - For JSON table:
     - **Publish Entire Document** — to publish the entire document to the stream topic.
     - **Publish Selected Field Path** — to specify the paths to the fields to publish to the stream topic.
   - For Binary table:
     - **Publish Entire Document** — to publish the entire document to the stream topic.
     - **Publish Selected Column Families** — to specify the column families to publish to the stream topic.
5. Click **Add Change Log**.

Adding a Change Data Log Using the CLI and REST API

The basic command to add a change data log to a table is:

```
maprcli table changelog add
```

For complete reference, see table changelog add on page 1813.

last-updated: Apr 11, 2022

Viewing the List of Change Logs
Explains how to view the list of change logs using the Control System or the CLI.
Viewing the List of Change Logs Using the Control System

- Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
  For each change log, the page displays the following:

Column Name	Column Description
Edit Change Log	Shortcut to the **Edit Change Log** window for editing a change log.
Paused	Specifies whether the change propagation is paused for the associated change log.
Destination Cluster	Specifies the destination cluster on which the stream exists.
Destination Stream Topic Name	Specifies the name of the stream associated with the change log.
Up to Date	Specifies whether (**Yes**) or not (**No**) the change log is up to date. If value is **No**, hover the cursor over the value to see the number of pending bytes, puts, and buckets.
Errors	Indicates whether there were any errors during change propagation.
Compression Type	The type of compression for data transfer between MapR File System and gateway for the associated change data log instance
Synchronous	Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data.
Throttle	Specifies whether data transfer to the stream for the associated change data log is throttled.
Encrypted	Specifies whether the data transfer between MapR File System and gateway for the associated change data log is encrypted.
Field Path	Specifies whether only specific field paths are being published to the stream topic.

Retrieving the List of Change Logs Using the CLI or REST API

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

For complete reference, see table changelog list on page 1816.

Viewing Change Log Information
Explains how to view information about a specific change log using the CLI.
Retrieving Change Log Information Using the CLI or REST API

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog info
```

For complete reference, see table changelog info on page 1815.

Editing a Change Log
Explains how to modify a change log associated with a table using either the Control System or the CLI.

Editing a Change Log Using the Control System

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Click  associated with the change log to modify.
   The **Edit Change Log** window displays.
3. Make the necessary changes to any of the following:

Throttle	Whether (**Yes**) or not (**No**) the data transfer must be throttled.
Synchronously	Whether (**Yes**) or not (**No**) to acknowledge the client writes to the table before the CDC gateway receives the data.
Encrypt on Wire	Whether (**Yes**) or not (**No**) the data transfer is encrypted.
Compress on Wire	The compression scheme of the data propagation.

4. Click **Save Changes** for the changes to take effect.

Editing a Change Log Using the CLI or REST API

The basic command to modify the change log is:

```
maprcli table changelog edit
```

For complete reference, see table changelog edit.

Pausing Data Propagation
Explains how to pause data propagation using either the Control System or the CLI.
Pausing Data Propagation Using the Control System

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Select the change log(s) to pause.
   Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Pause Data Propagation** from the **Actions** drop-down menu to display the **Pause Data Capture** confirmation dialog.
4. Review the change log(s) to pause and click **Pause Data Capture**.

Pausing Data Propagation Using the CLI or REST API

The basic command to pause change data propagation is:

```
maprcli table changelog pause
```

For complete reference, see table changelog pause.

Resuming Data Propagation
Explains how to resume a paused change log using either the Control System or the CLI.
Resuming Data Propagation Using the Control System

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Select the change log(s) to pause.
   Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.

last-updated: Apr 11, 2022

3. Select **Resume Data Propagation** from the **Actions** drop-down menu to display the **Resume Data Capture** confirmation dialog.
4. Review the change log(s) to resume and click **Resume Data Capture**.

Resuming Data Propagation Using the CLI or REST API

The basic command to resume change data propagation is:

```
maprcli table changelog resume
```

For complete reference, see table changelog resume.

Removing Change Logs
Describes how to remove change logs using either the Control System or the CLI.
Removing Change Logs Using the Control System

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Select the change log(s) to remove.
   Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Remove Change Logs** from the **Actions** drop-down menu to display the **Remove Change Log(s)** confirmation dialog.
4. Review the change log(s) to remove and click **Remove Change Logs**.

Removing Change Logs Using the CLI or REST API

The basic command to remove a change log is:

```
maprcli table changelog remove
```

For complete reference, see table changelog remove.

Troubleshooting Changelogs

checkandcreate topic failed with error 17

I'm getting a **checkandcreate topic** error while trying to edit a changelog topic.

Because the `maprcli table changelog add` command is an asynchronous command, the CDC relationship (same as replication relationship) involves storing information at both the source and destination sides. This results in the following behavior:

- When the `maprcli table changelog add` operation succeeds, it means that the add request is received. To check whether there is an error during the add operation, run the `maprcli table changelog list` operation.
- The `maprcli table changelog edit` operation only modifies the information on the source side, even if an error is display in the `maprcli table changelog list` output, the changelog can still be modified.

Troubleshooting methods:

- If the stream topic already exists in the destination and you are getting an error, delete the topic. The `maprcli table changelog add` operation automatically retries and finishes.
- If the error can not be fixed, delete the partial relationship from the source side with the `maprcli table changelog remove` operation and retry.

Enabling/Disabling Propagation

Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See table changelog resume on page 1820 for more information.

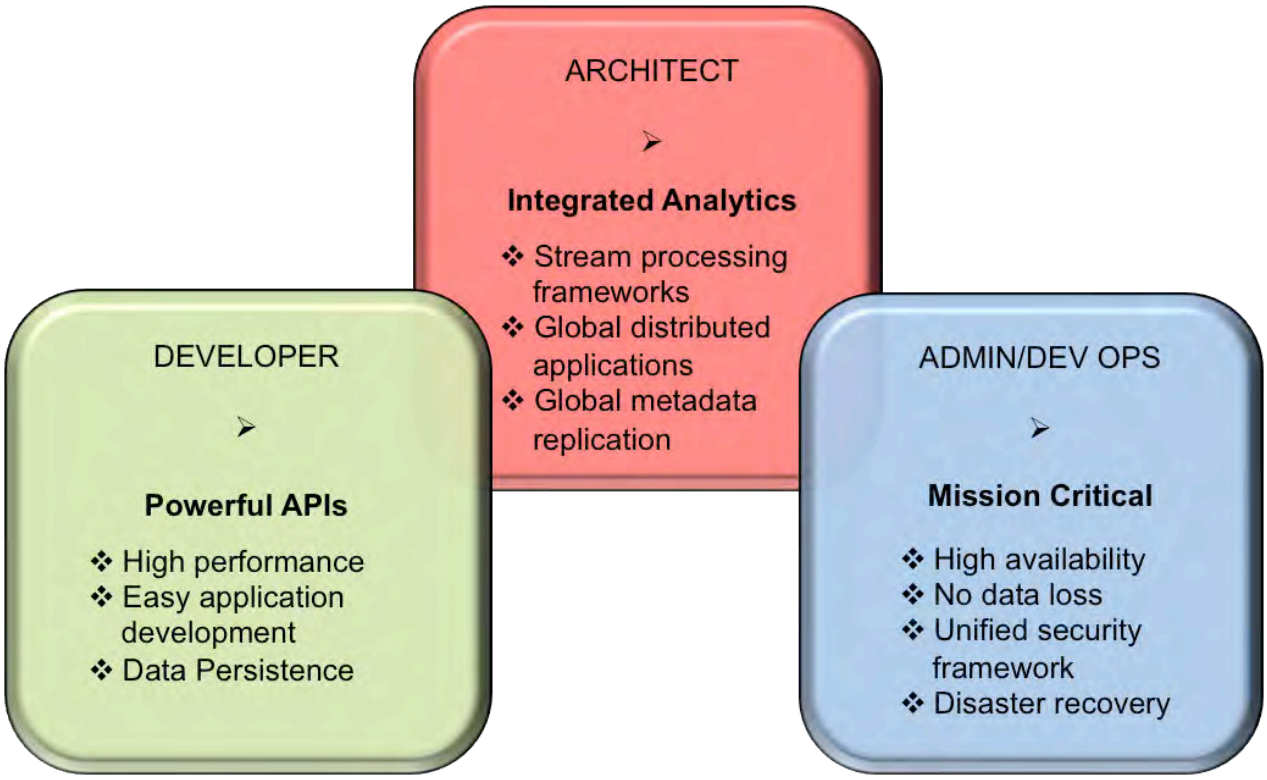
Indexing MapR Database Binary Tables with Elasticsearch

As of with MapR 6.0, MapR Database Elastic Search integration capability is deprecated and no longer available in the MapR Database product.

Attention: MapR Database Change Data Capture (CDC) framework can be used to integrate with latest versions of Elasticsearch. See Change Data Capture on page 597 for more information.

Administering Streams

MapR Event Store For Apache Kafka brings integrated publish and subscribe messaging to the MapR Data Platform. Producer applications can publish messages to topics, which are logical collections of messages, and Consumer applications can read those messages at their own pace. Topics are grouped into streams, for which administrators can apply security, retention, and replication policies.



1. The MapR Event Store For Apache Kafka and Apps section information and examples for developing Producer and Consumer applications.
2. The MapR Event Store For Apache Kafka section provides conceptual information.

last-updated: Apr 11, 2022

3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

Managing Streams

This topic provides information about managing streams in MapR Event Store For Apache Kafka.

Creating a Stream

Explains how to create a stream using the Control System and the CLI.

Your decision about what streams to create should take into account whatever topics you want to replicate. Replication is between streams, not individual topics.

For example, suppose that you plan to create the stream `pollution_monitors` to collect various measurements about pollution levels in cities in Europe. However, during a planning session, the representative from Amsterdam says that her country wants to perform analyses of the data for its cities, and would like your company to replicate the data to its own MapR cluster, where its own consumers can read the replicated messages.

You would create a separate stream of topics that contain data from only the pollution sensors in the cities in that country. You might even decide to do the same for each center, in case other centers eventually want to perform their own analyses, too. The streams you might decide to create could be `pollution_monitors_netherlands`, `pollution_monitors_sweden`, and so on.

Creating a Stream Using the Control System

To create a stream:

1. Log in to the Control System and click **Create Stream** under **Data** > **Streams**.

   Note: This option is not available in the Kubernetes version of the Control System.

   The **Create New Stream** page displays.

2. Specify the following properties.

Property	Description
Stream Path	The path and name of the stream to create. The path to the stream can include any character allowed by MapR. For example, `/my/path/with:/to/mystream:topic1` is valid, but `/my/path/with:/to/mystream:withcolon:topic1` is invalid. The name of the stream cannot include a colon (`:`) or a forward slash (`/`).
Time To Live	The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose: • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 637 for details.

last-updated: Apr 11, 2022

Property	Description
Compression	The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompresses it, and passes it to client applications. Choose one of the following: • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB
Auto Create Topics	Whether (**Yes**) or not (**No**) to create a topic automatically when a producer tries to write the first message to it.
Default Partitions	The default number of partitions to allocate to new topics in the stream. When deciding how many partitions to create by default for new topics in a stream, consider the expected volume of messages that will be published to the topics in the stream. High message volumes can be handled more efficiently by multiple consumers in consumer groups reading from multiple partitions than by individual consumers reading from a single partition.  **Note:** You can override the default and specify a different number of partitions for each topic in the stream at the time of creating the topic or after creating the topic.
Use for Change Log	Whether (**Yes**) or not (**No**) to create the stream for changed data records (as a result of inserts, updates, and deletes) in a MapR Database table.

3. Set up access to streams for users, groups, and roles.

   For each user, group, and/or role, you can grant (by selecting the associated check box) or block (by deselecting the associated checkbox) the following types of access:

Administer	Can modify the access-control expressions for the stream, set up replication from the stream, and modify attributes of the stream. This permission includes the topic permission.
Copy Stream	Can copy data from one MapR stream to another MapR stream (using the `mapr copystream` utility) and compare the message IDs, metadata, and data in two MapR streams (using the `mapr diffstreams` utility).
Topic	Can create, edit, or remove topics in the stream.
Producer	Can publish messages to topics in the stream.
Consumer	Can listen to topics in the stream.

last-updated: Apr 11, 2022

By default, all permissions are given to the user creating the stream. To grant or block access to other users, groups, and/or roles, choose one of the following:

- Basic Settings: Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

  Tip: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

  Click **Add Another** to add permissions for another user, group, or role.

- Advanced Settings: Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Alternatively, click associated with the type of access to use the **Create Access Control Expression** window to define access for public or users, group, and/or role.

Note: If you switch from Basic to Advanced, the basic settings, if any, will be carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings will be lost because the subexpressions and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add access control expressions for another user, group, or role, click **Add Another** and repeat this step.

4. Click **Create Stream** to create the stream.

Creating a Stream Using the CLI or REST API

The basic command to create a stream is:

```
maprcli stream create -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

For complete reference information, see `stream create` on page 1758.

Editing a Stream

Describes how to edit streams using the Control System and the CLI.

Editing a Stream Using the Control System

1. Log in to the Control System and go to the stream information page.
2. Click **Edit Stream**.

   The **Edit Stream** page displays.
3. Make necessary changes to one or more of the following:

last-updated: Apr 11, 2022

Property	Description
Time To Live	The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose: • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 637 for details.
Compression	The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompress it, and pass it to client applications. Choose from one of the following compression settings: • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB
Auto Create Topics	Whether (**Yes**) or not (**No**) to create a topic automatically when a producer tries to write the first message to it.
Default Partitions	The default number of partitions to allocate to new topics in the stream.
Compact	Enable (**Yes**) or disable (**No**) log compaction. If enabled, obsolete records from topics are detected and deleted. By default, this is disabled (**No**).

4. Add, modify, or remove access to streams for users, groups, and roles.

   For each user, group, and/or role, you can grant (by selecting the associated check box) or deny (by deselecting the associated checkbox) the following types of access:

Administer	Can modify the *ACE* for the stream, set up replication from the stream, and modify attributes of the stream. This permission includes the topic permission.
Copy Stream	Can copy data from one MapR stream to another MapR stream (using the `mapr copystream` utility) and compare the message IDs, metadata, and data in two MapR streams (using the `mapr diffstreams` utility).
Topic	Can create, edit, or remove topics in the stream.
Producer	Can publish messages to topics in the stream.
Consumer	Can listen to topics in the stream.

last-updated: Apr 11, 2022

To grant or deny access to users, groups, and/or roles, choose one of the following:

- Basic Settings: Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

  Tip: Click to create a copy of the associated *ACE* setting. Click to remove the associated *ACE*.

  Click **Add Another** to add permissions for another user, group, or role.

- Advanced Settings: Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:

  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information.

Note: If you switch from Basic to Advanced, the basic settings, if any, are carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings are lost because the subexpressions, and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

5. Click **Save Changes** for the changes to take effect.

Editing a Stream Using the CLI or REST API

The basic command to edit a stream is

```
/opt/mapr/bin/maprcli stream edit -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the stream

For complete reference information, see `stream edit` on page 1765.

Encrypting a Stream

Apply an additional layer of security to streams by encrypting them.

To set encryption on a stream:

1. Before encrypting a stream, ensure that wire-level security is enabled for the cluster. See Enabling Wire-level Security on page 1411.

2. Determine whether a directory or stream is encrypted by running the following command:

```
hadoop mfs -ls <path>
```

   Note: Streams inherit the value of the `-setnetworkencryption` setting from the directory in which they are created.

3. If the directory is not encrypted, set the encryption on the streams with the following command:

```
hadoop mfs -setnetworkencryption on <path of stream>
```

Example

Suppose that the streams that you want to encrypt are all in the `/test` directory. You run this command to discover whether the directory is encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z U U   - root root          0 2015-09-07 02:37  268435456 /test
           p 2049.43.131260  localhost:5660
```

The second flag U after the permissions indicates that the directory `test` is unencrypted. Because you want to encrypt your stream to enhance data security, you run this command, which encrypts the entire directory:

```
hadoop mfs -setnetworkencryption on /test
```

If you run the `-lsd` command again, you will see that the U is replaced by an E, indicating that the directory is now encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z E U   - root root          0 2015-09-07 02:40  268435456 /test
           p 2049.43.131260  localhost:5660
```

Defining ACEs

Indicates how to build access control expressions (ACEs) using the Expression Builder.

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.

   Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and/or role to access the volume.
Any	OR (|) operation	Indicates that any one of the conditions must be met for public or user, group, and/or role to access the volume.

last-updated: Apr 11, 2022

2. Click:

+	To add an expression.
( )	To add a subexpression.
x	To remove an expression or subexpression.

3. Select Public or User, Group, or Role from the drop-down menu and:
   a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
   b) Enter name of the user, group, or role.
4. Click **Save Changes** to create an Access Control Expression.

Setting Whole Volume ACEs Using the CLI

See Setting Whole Volume ACEs on page 1459.

Setting Table ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Setting Stream ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Removing Streams

Explains how to delete a stream using either the Control System or the CLI.

Deleted streams cannot be recovered unless they were replicated before deletion. After a stream is deleted, producers will not be able to publish messages to topics in the stream, and consumers will not be able to read messages from topics in the stream.

Removing a Stream Using the Control System

1. Log in to the Control System and go to the stream information page.
2. Click **Remove Stream** to display the **Remove Stream** confirmation dialog.
3. Confirm the action by clicking **Remove Stream**.

Removing a Stream Using the CLI or REST API

The command to delete a stream is:

```
stream delete -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

For complete reference, see stream delete on page 1764.

Viewing a List of Streams

Describes how to view the list of streams using the Control System.

Listing Streams in a Volume

1. Log in to the Control System and click **Data** > **Streams** to view all the volumes that you have access to.

   Note: This option is not available in the Kubernetes version of the Control System.

For each volume, the pane displays the following:

Column Name	Column Description
Name	The name of the volume.
Type	The type. Value can be: • — Volume • — Directory • — Stream
Owner	The name of the owner.
Last Modified	The last modification date and timestamp.

2. Click the name of the volume (to browse to the path to the stream) or enter the name of the volume in the text field.

   The streams in the selected volume display. If necessary, click to return to **All** volumes view.

Listing Streams by Stream Path

1. Log in to the Control System and click **Data** > **Streams**.

   Note: This option is not available in the Kubernetes version of the Control System.

2. Enter the path to the stream in the search field and click **GO**.

Viewing Stream Information

Explains how to view stream information including stream properties, topics, and replication settings using the Control System and the CLI.

Viewing Stream Information Using the Control System

To view stream information:

1. Log in to the Control System and click **Data** > **Streams**.

   Note: This option is not available in the Kubernetes version of the Control System.

2. Locate the stream (by searching or browsing the volumes or by entering the full path to the stream) and click on the stream name.

   The stream information page displays the following tabs:

   - Summary
   - Topics
   - Replication

   You can:

   - Modify the stream
   - Remove the stream

   The **Summary** tab displays:

   - The active and recent alarms in the **Alarms** pane.

last-updated: Apr 11, 2022

- The stream settings and permissions in the **Detail** pane.

Retrieving Stream Information Using the CLI or REST API

The basic command to retrieve stream information is:

```
maprcli stream info -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
`adminperm`	When a user with this permission runs the command, the output includes the access-control expressions for the `adminperm` and `topicperm` permissions.
`produceperm`, `consumeperm`, or `topicperm`	When a user with one of these permissions runs the command, the output does not include any access-control expressions.

For complete reference information, see `stream info` on page 1768.

Managing Topics

Topics are logical collections of messages. The following sections describe how to create and manage topics.

Adding a Topic to a Stream
Explains how to add a topic to a stream using either the Control System or the CLI.
Adding a Topic to a Stream Using the Control System

1. Log in to the Control System and go to the **Topics** tab in the stream information page.
2. Click **Add Topic** in the **All** topics pane.
3. Specify the name of the topic in the **Topic Name** field.
   A name can include alphanumeric characters and the following characters: `.` (dot), _ (underscore), and `-` (hyphen).
4. Specify the number of partitions to use for the topic.
   After you create the topic, you can increase the number of partitions, but you cannot reduce the number. If the topic is associated with a stream for change log, you cannot modify the partitions after you create the topic.
5. Click **Add Topic** to create the topic.

Adding a Topic to a Stream Using the CLI or the REST API

The basic command to create a topic is:

```
maprcli stream topic create -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see `stream topic create` on page 1781.

Removing Topics in a Stream
Describes how to delete one or more topics from the stream using either the Control System or the CLI.

Consumers do not have to stop consuming from a topic before the topic is deleted.

Removing Topics in a Stream Using the Control System

1. Log in to the Control System and the go to the **Topics** tab in the stream information page.
2. Select the topics to remove in the **All** topics pane and click **Remove Topic(s)**.
   The **Remove Topic(s)** confirmation window displays.
3. Verify the list of topics and click **Remove Topic**.
   The topic and the messages are immediately deleted.

Removing Topics in a Stream Using the CLI or REST API

The command to delete a topic is:

```
maprcli stream topic delete -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see `stream topic delete` on page 1783.

Viewing the List of Topics in a Stream

Explains how to view the list of topics in a stream using the Control System and the CLI.

Viewing the List of Topics in a Stream Using the Control System

- Log in to the Control System and go to the **Topics** tab in the stream information page.
  The All topics pane displays the list of topics in the stream and for each topic, the pane displays the following:

Column Name	Column Description
Topic Name	The name of the topic.
Maximum Lag	The consumer lag time (in milliseconds).
Partitions	The number of partitions in the topic.
Consumers	The number of consumers for the topic.
Physical Size	The physical size (in MB) of the topic.

  You can view a topic from the list of topics by entering the topic name in the search field. You can also:

  - Add a topic to the stream.
  - Remove one or more topics.
  - Modify the number of partitions for a topic.

Viewing the List of Topics in a Stream Using the CLI or REST API

The command to view the list of topics in a stream is:

```
stream topic list -path <Stream Path>
```

For complete reference information, see `stream topic list` on page 1787.

Modifying Topic Partitions

Explains how to modify the number of partitions using the Control System and the CLI.

Note: In general, you can increase the number of partitions, but you cannot reduce the number. However, if the topic is associated with a stream for change logs, you *cannot* modify the number of partitions.

last-updated: Apr 11, 2022

Modifying Topic Partitions Using the Control System

1. Log in to the Control System and go to the **Topics** tab in the stream information page.
2. Click in the **Partitions** column for the topic.
   The **Edit Partition** window displays.
3. Modify the number of partitions and click **Save Changes** for the changes to take effect.

Modifying Topic Partitions Using the CLI or REST API

The command to modify topic partitions is:

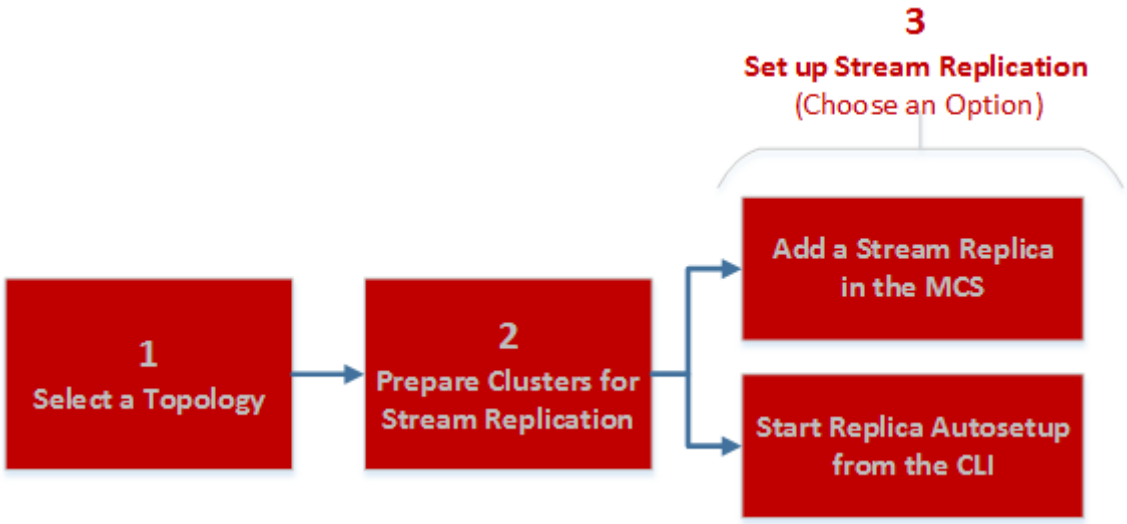
```
stream topic edit -path <stream path> -topic <topic name> -partitions
<number of partitions>
```

For complete reference information, see `stream topic edit` on page 1784.

Managing Stream Replication

This section contains topics about setting up stream replication and administering existing replicas.

The process to set up stream replication consists of 3



steps:

1. Stream Replication on page 656
2. Preparing Clusters for Stream Replication on page 1130
3. Adding Stream Replicas on page 1131
4. Setting Up Stream Replication Using the CLI on page 1133

After you set up replication, you can administer replicas using the Control System or the CLI. To view the replication status, run stream replica list on page 1775.

Preparing Clusters for Stream Replication

Configuring clusters for participation in the replication of MapR Event Store For Apache Kafka streams involves configuring two or more gateways on destination clusters and, if the clusters are secure, setting up secure communications between the clusters.

- Plan which replication topology you want to use: basic primary-secondary, multi-master, or a combination of these. For more information about replication topologies, see Stream Replication on page 656.

last-updated: Apr 11, 2022

- Ensure that you have administrative authority on the clusters that you plan to use.
- Replicating streams requires the installation of gateways. For more information about installation requirements, see Service Layout Guidelines for Replication on page 116

To configure clusters for replication between streams:

1. In the mapr-clusters.conf file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster.

   Note:

   This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See mapr-clusters.conf on page 2200 for the format to use for the entries.

2. Configure gateways on the destination clusters.

   See Configuring Gateways for Table and Stream Replication.

3. **For secure clusters:** Optionally, configure source clusters so that you can locally run maprcli commands that are executed on the destination cluster.

   See Configuring Secure Clusters for Running Commands Remotely.

4. **For secure clusters:** Add one cross-cluster ticket to each source cluster for each cluster that it replicates to.

   See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication.

5. Ensure that the user ID of the person who starts the replication process has the `readAce` permission on the volume where the source streams are located and the `writeAce` permission on the volumes where the replica streams are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Adding Stream Replicas

You can create stream replicas using the Control System and the CLI. When you add a replica using the Control System, you can also set up and start replication between a source and replica stream.

Before creating a replica:

1. Review the following:
   - Modes of Stream Replication on page 659
   - Security for Stream Replication on page 662
   - Preparing Clusters for Stream Replication on page 1130

Note:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In
  - Multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.

last-updated: Apr 11, 2022

- Many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

Adding a Replica Using the Control System

To add a replica using the Control System:

1. Log in to the Control System and go to the **Replication** tab in the Viewing Stream Information on page 1127.
2. Click **Add Replica**.
   The **Add Replica** page displays.
3. Specify the following settings.

Path to Source Stream	The path and name of the stream that you want to create a replica for.
Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path and name of the replica stream.
Replication State	Specify whether or not to start replication by choosing one of the following: • **Automatic Setup** — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, copies the content of the current stream into the replica, and starts replication. In this case, the replica stream starts empty and accumulates messages over time. • **Pause Replication** — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current stream, after which you can restart replication.  **Note:** If you are interested only in the messages that are published to the source stream after replication starts, then you do not need to pause replication initially. However, if you want the full set of messages from the source stream that have not yet been purged or marked for deletion, then pause replication initially.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each stream playing both the primary and secondary roles. Client applications update both streams and each stream replicates updates to the other. If this is not selected, stream replication will be basic primary-secondary topology. In this topology, you replicate in one direction. See Stream Replication on page 656 for more information.

4. Select values for the following optional settings.

last-updated: Apr 11, 2022

Throttle	Specifies whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled. Throttling has two effects, both of which allow MapR Event Store For Apache Kafka to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
Replicate Synchronously	Specifies whether replication is synchronous (**Yes**) or asynchronous (**No**). The default value is asynchronous replication.
Encrypt On Wire	Specifies whether (**Yes**) or not (**No**) to enable on-wire encryption. By default, this is disabled (**No**). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	Specifies the type of compression to use when replicating messages.

5. Click **Add Replica** to create the replica.

Adding a Replica Using the CLI or REST API

The basic command to create a replica is:

```
maprcli stream replica add -path <stream path> -replica <remote stream path>
```

To run this command, your user ID must have the following permissions on the:

- Source cluster:
  - `readAce` and `writeAce` on the volume
  - `lookupdir` on directories in the path
  - `adminperm` and `copyperm` permissions on the source stream
- Target cluster:
  - `readAce` and `writeAce` on the volume
  - `lookupdir` on directories in the path

For complete reference, see `stream replica add` on page 1770.

Note: You also have the option to set up replication with `maprcli table replica autosetup` which will set up and start replication. For more information, see Setting Up Stream Replication Using the CLI on page 1133.

Setting Up Stream Replication Using the CLI

Describes how to run the `maprcli stream replica autosetup` command to set up primary-secondary or multi-master replication from an existing source stream.

Note: This procedure describes how to use the maprcli to automatically set up stream replication. As an alternative, you can use the Control System to automatically set up table replication or use the `maprcli` command to manually set up primary-secondary replication.

Before you begin, review the following requirements:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.

last-updated: Apr 11, 2022

- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
- In many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

In general, you should store your streams on their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a stream in the promoted mirror lags behind the stream's replica. See Preparing Clusters for Table Replication on page 1066 for more details.

Set up replication automatically by following these steps:

1. Log into both the source and destination clusters.
2. Run the command `maprcli stream replica autosetup`:
   - For primary-secondary replication:

     ```
     maprcli stream replica autosetup -path <path to source
     stream> -replica <path to replica stream>
     ```

     For example, to set up primary-secondary replication from the `activity` stream in the `sanfrancisco` cluster to a new `activity` stream in the `newyork` cluster, you could use this command:

     ```
     maprcli stream replica autosetup -path
     /mapr/sanfrancisco/activity -replica /mapr/newyork/activity
     ```

   - For multi-master replication:

     ```
     maprcli stream replica autosetup -path <path to source
     stream> -replica <path to replica stream> -multimaster yes
     ```

     For example, to set up multi-master replication between the `activity` stream in the `sanfrancisco` cluster and a new `activity` stream in the `newyork` cluster, you could use this command:

     ```
     maprcli stream replica autosetup -path /mapr/sanfrancisco/activity
     -replica /mapr/newyork/activity -multimaster yes
     ```

     Note: The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

   Note: By default, `maprcli stream replica autosetup` sets up asynchronous replication. If you want to set up synchronous replication or use any of the other optional parameters, see `stream replica autosetup` on page 1771.

3. To check the replication status, run stream replica list on page 1775.

Setting Up Primary-Secondary Stream Replication Manually
Describes how to setup a primary-secondary stream replica that replicates in one direction.

Replica streams can be in a remote MapR cluster or in the MapR cluster where their source streams are located. All updates from a source stream arrive at a replica stream after having been authenticated at a gateway. Therefore, the `produceperm` access control expressions on the replica stream is irrelevant; gateways have the implicit authority to publish messages to topics in replica streams.

To set up primary-secondary replication of streams:

1. Create the replica manually with the `maprcli stream create` command. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source stream.

   ```
   maprcli stream create -path <path to replica>
   -copymetafrom <path to source stream>
   ```

   For example, to create the replica `activity` in the `newyork` cluster and use the metadata from the source stream in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli stream create -path /mapr/newyork/activity
   -copymetafrom /mapr/sanfrancisco/activity
   ```

2. Register the replica as a replica of the source stream by running the `maprcli stream replica add` command.

   ```
   maprcli stream replica add -path <path to source stream>
   -replica <path to replica> -paused true
   ```

   For example, to register the `activity` stream in the `newyork` cluster as a replica of the `activity` stream in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli stream replica add -path /mapr/sanfrancisco/activity
   -replica /mapr/newyork/activity -paused true
   ```

   The `-paused` parameter ensures that replication does not start immediately after you register the source stream as a source for this replica. You do this registration in step 4.

3. Verify that you specified the correct replica by running the `maprcli stream replica list` command.

   ```
   maprcli stream replica list -path <path to source stream>
   ```

   To verify that the `activity` stream in the `newyork` cluster is a replica of the `activity` stream in the `sanfrancisco` cluster, you could look at the output of this command:

   ```
   maprcli stream replica list -path /mapr/sanfrancisco/activity
   ```

4. Authorize replication between the streams by defining the source stream as the upstream stream for the replica by running the `maprcli stream upstream add` command.

   Definition of the upstream stream ensures that a stream cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two streams.

   ```
   maprcli stream upstream add -path <path to replica> -upstream
   <path to source stream>
   ```

   To add the `activity` stream in the `sanfrancisco` cluster as an upstream source for the `activity` stream in the `newyork` cluster:

   ```
   maprcli stream upstream add -path /mapr/newyork/activity -upstream
   /mapr/sanfrancisco/activity
   ```

5. Verify that you specified the correct source stream by running the `maprcli stream upstream list` command.

   ```
   maprcli stream upstream list -path <path to the replica>
   ```

   To verify this in our example scenario, you could use this command:

   ```
   maprcli stream upstream list -path /mapr/newyork/activity
   ```

6. Load the replica with data from the source stream by using the `mapr copystream` on page 5339 utility.

7. Start replication with the command `maprcli stream replica resume`.

   ```
   maprcli stream replica resume -path <path to the source stream>
   -replica <path to the replica>
   ```

   For our example scenario, you could use this command:

   ```
   maprcli stream replica resume -path mapr/sanfrancisco/activity
   -replica /mapr/newyork/activity
   ```

Viewing the List of Stream Replicas

Explains how to view the list of replicas for a stream using the Control System and the CLI.

Viewing the List of Stream Replicas Using the Control System

- Log in to the Control System and go to the **Replication** tab in the stream information page.

  The **Replicas** pane displays the the list of replicas for the selected stream and for each replica, the pane displays the following:

Column Name	Column Description
Paused	Specifies whether replication is paused.
Destination Cluster & Type	The cluster on which the replica stream resides.
Destination Path	Specifies the name and path of the replica stream.
Up to Date	Specifies whether or not the replica is up-to-date.
Earliest	The date of the oldest message that has yet to be replicated.

last-updated: Apr 11, 2022

Column Name	Column Description
Latest	The date of the newest message that has yet to be replicated.
Errors	Indicates if there were errors during replication.
Compression Type	The type of on-wire compression.
Synchronous	Specifies whether replication is synchronous.
Throttled	Specifies whether replication operations are throttled.
Encrypted	Specifies whether on-wire encryption is enabled.

Selecting the checkbox beside a replica makes the Actions drop-down menu available. You can:

- Add a replica
- Edit a replica
- Pause a replica
- Resume replication
- Un-register replica(s)
- Set current stream as an upstream source

Viewing the List of Stream Replicas Using the CLI or REST API

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream
path>
```

For complete reference information, see `stream replica pause` on page 1777.

Editing a Stream Replica
Explains how to edit a stream replica using the Control System and the CLI to modify the way in which messages are replicated from the source stream to the replica.
Editing a Stream Replica Using the Control System

To un-register one or more stream replicas from the Control System:

1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Click  associated with the replica to edit in the **Replicas** pane.
   The **Edit Replica** page displays.
3. Make necessary changes to any of the following properties.

Path to Replica	Specify path and name of the replica stream.
Throttle	Enable (**Yes**) or disable (**No**) throttling of replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled. Throttling has two effects, both of which allow MapR Event Store For Apache Kafka to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated.

last-updated: Apr 11, 2022

	• Throttling slows down the rate at which messages to be replicated are read from disk.
Replicate Synchronously	Set up synchronous (**Yes**) or asynchronous (**No**) replication.
Encrypt On Wire	Enable (**Yes**) or disable (**No**) on-wire encryption. By default, this is disabled (**No**). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	Specify type of compression to use when replicating messages.

4. Click **Save Changes** for the changes to take effect.

Editing a Stream Replica Using the CLI or REST API

The basic command to modify a replica is:

```
stream replica edit -path <stream path> -replica <remote stream path>
```

For complete reference information, see `stream replica edit` on page 1773.

Removing Stream Replicas

Explains how to unregister one or more replicas using the Control System and the CLI.

Removing Stream Replicas Using the Control System

To un-register one or more stream replicas from the Control System:

1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Select the replicas to remove in the **Replicas** pane.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Remove Replica(s)** from the **Actions** drop-down menu.
   The **Remove Replica(s)** confirmation window displays.
4. Verify the list of replicas to remove and click **Remove Replica**.
   This action un-registers the stream as the replica of the source stream.

Removing a Stream Replica Using the CLI or REST API

The command to remove a replica is:

```
stream replica remove -path <stream path> -replica <remote stream path>
```

For complete reference information, see `stream replica remove` on page 1778.

Pausing Stream Replication

Explains how to pause replication from a source stream to a replica stream using the Control System and the CLI.

Pausing Stream Replication Using the Control System

To pause one or more replications:

1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Select the replicas to pause in the **Replicas** pane.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.

3. Select **Pause Replication** from the **Actions** drop-down menu.
   The **Pause Replication** confirmation window displays.
4. Verify the list of replicas to pause and click **Pause Replication**.
   This action pauses replication from the source stream to the selected replica stream(s).

Pausing Stream Replication Using the CLI or REST API

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream
path>
```

For complete reference information, see stream replica pause on page 1777.

Resuming Stream Replication

Explains how to resume replication from one stream to another stream using either the Control System or the CLI.

Resuming Stream Replication Using the Control System

To resume one or more replications:

1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Select the replicas (in **Paused** state) in the **Replicas** pane.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Resume Replication** from the **Actions** drop-down menu.
   The **Resume Replication** confirmation window displays.
4. Verify the list of replicas to resume and click **Resume Replication**.
   This action resumes replication from the source stream to the selected replica stream(s).

Resuming Stream Replication Using the CLI or REST API

The command to resume a replication is:

```
maprcli stream replica resume -path <stream path> -replica <remote stream
path>
```

For complete reference information, see stream replica resume on page 1778.

Managing Upstream Sources for Stream Replicas

You can set up a stream to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Set up Stream as Upstream Source

Describes how to set up the current stream as the upstream source for a replica if the replica was not set up to automatically resync with the current stream.

Setting Up Current Stream as Upstream Source for a Replica Using the Control System

To set up a stream as the upstream source for a replica:

1. Go to the **Replication** tab in the stream information page
2. Select the checkbox beside the replica(s) that do not have the current stream configured as upstream source for automatic resync.
   Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.

3. Select **Set Current Stream as Upstream Source** from the **Actions** drop-down menu.
   The **Set Current Stream as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
   The current stream will automatically send updates to the replica(s).

Setting Up Stream as Upstream Source for a Replica Using the CLI or REST API

The basic command to set a table as the upstream souce for a replica is:

```
maprcli stream upstream add -path <replica stream path> -upstream <source
stream path>
```

See `stream upstream add` on page 1779 for complete reference information.

Adding Upstream Source for a Stream
Explains how to add an upstream source for a stream using either the Control Panel or the CLI.

You can register a stream as an upstream source for a stream using the Control System and the CLI. When you register a stream as an upstream source, the registered upstream source stream will send updates to the stream.

Adding Upstream Source for a Stream Using the Control System

To register a stream as an upstream source:

1. Log in to the Control System and go the stream information page.
2. Click **Add Upstream Source** in the **Upstream Sources** pane.
   The **Add Upstream Sources** window displays.
3. Specify the path and name of the source stream in the **Upstream Source** field.
4. Click **Add Upstream Source** to register the source stream as an upstream source for this stream.

Adding Upstream Source for a Stream Using the CLI or REST API

The command to add an upstream source is:

```
maprcli stream upstream add -path <stream path> -upstream <upstream stream
path>
```

For complete reference information, see `stream upstream add` on page 1779.

Listing all Upstream Sources for a Stream
Describes how to list all the upstream sources for a stream using the Control System and the CLI.
Listing all Upstream Sources for a Stream Using the Control System

- Log in to the Control System and go to the **Replication** tab in the stream information page.
  The **Upstream Sources** pane displays the list of upstream sources for the selected stream and for each upstream source, the pane displays the following:

Column Name	Column Description
IDX	The index number of the upstream stream.
Upstream Source Cluster	The name of the MapR cluster in which the upstream stream is located.
Upstream Source Path	The path and name of the upstream stream.
UUID	The upstream stream's universally unique identifier.

last-updated: Apr 11, 2022

You can add an upstream source and by selecting the checkbox beside a stream, you can decouple the selected upstream stream.

Listing all Upstream Sources for a Stream Using the CLI or REST API

The command to list all upstream sources for a stream is:

```
maprcli stream upstream list -path <stream path>
```

For complete reference information, see stream upstream list on page 1780.

Removing Upstream Sources for a Stream
Explains how to un-register a stream as an upstream source for a stream using either the Control System or the CLI.

When you remove a stream as an upstream source for a stream, the upstream source stream will stop sending updates to the stream.

Removing Upstream Sources for a Stream Using the Control System

1. Log in to the Control System and go the **Replication** tab in the stream information page.
2. Select the upstream sources to remove in the **Upstream Sources** pane and click **Remove Upstream Source(s)**.
   The **Remove Upstream Source(s)** confirmation window displays.
3. Verify the list and click **Remove Upstream Source**.
   This action un-registers the selected stream(s) as upstream source(s) for this stream.

Removing Upstream Sources for a Stream Using the CLI or REST API

The command to decouple upstream sources is:

```
maprcli stream upstream remove -path <stream path> -upstream <upstream
stream path>
```

For complete reference information, see stream upstream remove on page 1781.

Preparing Clusters for Log Compaction

Describes how to prepare your environment so you can use log compaction.

Installing with the MapR Installer

When you use the MapR Installer to install MapR Event Store For Apache Kafka, a local gateway is also locally installed so that log compaction can be implemented. To configure for log compaction, see maprcli stream create on page 1758 and stream edit on page 1765.

Installing without the MapR Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the MapR installer. Generally, you need to perform the following steps:

1. Install the MapR software.To install MapR without using the MapR installer, follow the steps outlined at Installing without the MapR Installer on page 141.
2. Install the MapR gateway on your local cluster. Since gateways for log compaction are installed on the local cluster, no configuration is needed. See Gateways and Stream Replication on page 662 for general information about gateways.

last-updated: Apr 11, 2022

Adding Gateways for Load Balancing

Since the number of gateways impacts the compaction process, you might want to increase the number of gateways on the cluster to improve the load distribution. To add gateways for log compaction, you install additional MapR gateways on your local cluster. See Gateways and Stream Replication on page 662 for general information about gateways.

Note: No configuration is required because the additional gateways are installed on the local clusster.

For More Information

See the following topics for more information:

- maprcli stream create on page 1758 and stream edit on page 1765
- MapR Event Store For Apache Kafka Java Applications on page 2754, MapR Event Store For Apache Kafka Java API Library on page 2756, and Enabling Log Compaction on page 2765

Mirroring Topics with Apache Kafka MirrorMaker

Use the Apache Kafka MirrorMaker utility either to mirror topics that are in Apache Kafka clusters to streams that are in MapR Data Platform clusters or to Mirror topics that are in MapR Data Platform clusters to Apache Kafka clusters.

Mirroring is a type of replication that takes place in this sequence of steps:

1. Messages that are published to topics in a source cluster are read by consumers that MirrorMaker manages.
2. These consumers send the messages to producers that MirrorMaker also manages.
3. The producers publish the messages in topics that are in the destination cluster.

Mirroring can continue indefinitely. Alternatively, you can mirror your data as a way of migrating it from Apache Kafka to MapR Event Store For Apache Kafka. If you use it for this purpose, you can stop mirroring after migrating your producers and consumers to use MapR Event Store For Apache Kafka, as described in Migrating Apache Kafka 0.9.0 Applications to MapR Event Store For Apache Kafka.

Attention: MirrorMaker does not provide the same reliability guarantees as the replication features in MapR Event Store For Apache Kafka. In particular, MirrorMaker does not replicate cursors or message positions, which makes disaster recovery much more difficult than with replication of MapR Event Store For Apache Kafka. Therefore, MapR Data Platform recommends MirrorMaker for use only for mirroring between MapR Event Store For Apache Kafka and Apache Kafka, not for replication of MapR Event Store For Apache Kafka.

Prerequisites

- Ensure that the destination stream in the MapR Data Platform cluster exists. To create a stream, run the command `maprcli stream create`.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the stream.

Command Syntax and Descriptions of Parameters

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
[--whitelist=<Java-style regular expression for specifying the topics to
```

```
mirror>]
[--blacklist=<Java-style regular expression for specifying the topics not
to mirror>]
```

Parameter	Description
`consumer.config`	The path and name of the file that lists the consumer properties. See the Consumer Properties and Descriptions on page 1143 section for detailed information.
`num.streams`	Use the --num.streams option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
`producer.config`	The path and name of the file that lists the producer properties. See the Producer Properties and Descriptions on page 1144 section for detailed information.
`whitelist`	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). If you use this parameter, do not use the `blacklist` parameter.
`blacklist`	A Java-style regular expression for specifying the topics not to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). If you use this parameter, do not use the `whitelist` parameter.

Consumer Properties and Descriptions

```
zookeeper.connect=<IP address>:<ZooKeeper port>
zookeeper.connection.timeout.ms=<Timeout value in milliseconds>
group.id=<ID>
bootstrap.servers=<IP address>:<port>
shallow.iterator.enable=false
```

Property	Description
`zookeeper.connect`	The IP address and port number of the ZooKeeper instance for the Apache Kafka cluster.
`zookeeper.connection.timeout.ms`	The max time that the client waits to establish a connection to zookeeper. If not set, the value in `zookeeper.session.timeout.ms` is used.
`group.id`	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using `subscribe(topic)` or the Kafka-based offset management strategy. If `group.id` is not set and the value of the `num.streams` option is > 1 , messages might go multiple times to a stream.

last-updated: Apr 11, 2022

Property	Description
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,....` Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).
`shallow.iterator.enable`	Set this value to `false`.

Producer Properties and Descriptions

```
key.serializer=<serializer class>
value.serializer=<serializer class>
streams.producer.default.stream=<Path and name of the stream to copy the
topics to>
auto.create.topics.enable=true
```

Property	Description
`key.serializer`	The name of the appropriate serialization class in the `org.apache.kafka.common.serialization` package or a class that implements the `Serializer` interface for serializing keys.
`value.serializer`	The class that implements the `Serializer` interface for serializing values.
`streams.producer.default.stream`	Specifies the path and name of stream that the topics will be copied to.
`auto.create.topics.enable`	Enables auto-creation of topics within the stream specifed with the `streams.producer.default.stream` parameter.

Mirroring Topics from an Apache Kafka Cluster to the MapR Cluster
You can use MirrorMaker to mirror data continuously from Apache Kafka clusters to streams in MapR Event Store For Apache Kafka clusters.

- Because this procedure requires that MirrorMaker be run from the MapR Data Platform cluster, ensure that the mapr-kafka package is installed on the node that you choose to run MirrorMaker from.
- Configure the node as a mapr client.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the destination stream.

Alternatively, you can stop mirroring after you migrate the consumers and producers for your applications from your Apache Kafka cluster to your data-fabric cluster where the stream is located. See in Migrating Apache Kafka 0.9.0 Applications to MapR Event Store For Apache Kafka for details. After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a Kafka cluster and a number of producers to write the messages from those topics into topics in MapR Event Store For Apache Kafka.

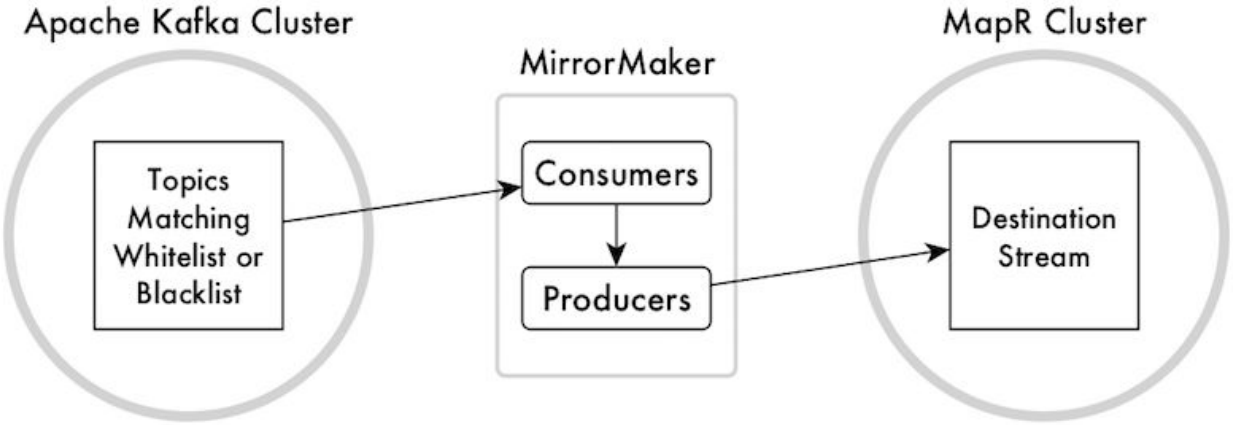


Figure 17: Mirroring from Apache Kafka to MapR Event Store For Apache Kafka

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the Apache Kafka cluster. You also create a file that contains the required configuration parameters for the producers that publish to the stream in the MapR Data Platform cluster. You point to these files in the MirrorMaker command.

You can specify the topics you want to mirror or the topics you do not want to mirror. To mirror topics, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want to mirror. To specify topics you do not want mirrored, use the `blacklist` parameter to provide a Java-style regular expression that matches the names of the topics that you do not want mirrored.

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

   The descriptions of these properties, except for the last, are taken from the documentation for Apache Kafka. The last property is not documented.

Property	Description
`zookeeper.connect`	The IP address and port number of the ZooKeeper instance for the Apache Kafka cluster.
`zookeeper.connection.timeout.ms`	The max time that the MirrorMaker waits to establish a connection to Zookeeper.
`group.id`	A unique string that identifies the consumer group the consumers started by MirrorMaker belong to.
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...`. Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

Property	Description
`streams.producer.default.stream`	Specifies the path and name of the stream in the MapR Data Platform cluster that the topics will be mirrored to.
`auto.create.topics.enable`	Set the value to `true`. The producers will therefore be able to create topics in the destination stream automatically.

3. Run MirrorMaker with this command to start mirroring topics from Apache Kafka to MapR Event Store For Apache Kafka:

   Syntax

```
/opt/mapr/kafka/kafka-0.9.0/bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
[--whitelist=<Java-style regular expression for specifying the topics to
mirror>]
[--blacklist=<Java-style regular expression for specifying the topics
not to mirror>]
```

Parameter	Description
`consumer.config`	The path and name of the file that lists the consumer properties and their values.
`num.streams`	Use this option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
`producer.config`	The path and name of the file that lists the producer properties and their values.
`whitelist`	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). If you use this parameter, do not use the `blacklist` parameter.
`blacklist`	A Java-style regular expression for specifying the topics not to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). If you use this parameter, do not use the `whitelist` parameter.

   Example

   In this example, the file that lists the properties and values for the consumers that will read messages from the topics in Apache Kafka is named `consumers.props`. It contains this list:

```
zookeeper.connection.timeout.ms=6000
group.id=cg1
```

last-updated: Apr 11, 2022

```
bootstrap.servers=10.10.100.87:9093
shallow.iterator.enable=false
```

The file that lists the properties and values for the producers that will publish messages to topics in MapR Event Store For Apache Kafka is named `producers.props`. It contains this list:

```
streams.producer.default.stream=/newStream
auto.create.topics.enable=true
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the `whitelist` parameter.

Here is the command:

```
bin/kafka-mirror-maker.sh --consumer.config consumers.props
--num.streams 2 --producer.config producers.props --whitelist="na_west.*"
```

Mirroring Topics from the MapR Cluster to an Apache Kafka Cluster
You can use MirrorMaker to mirror data continuously from streams in MapR Data Platform clusters to Apache Kafka clusters.

- This procedure requires MirrorMaker to run from the MapR Data Platform cluster. Verify that the mapr-kafka package is installed on the node that you choose to run MirrorMaker on.
- Configure the node as a `mapr` client.
- Ensure that the ID of the user who runs MirrorMaker has the `consumeperm` permission on the stream.

After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a stream in a MapR Data Platform cluster and a number of producers to write the messages from those topics into topics in an Apache Kafka cluster.

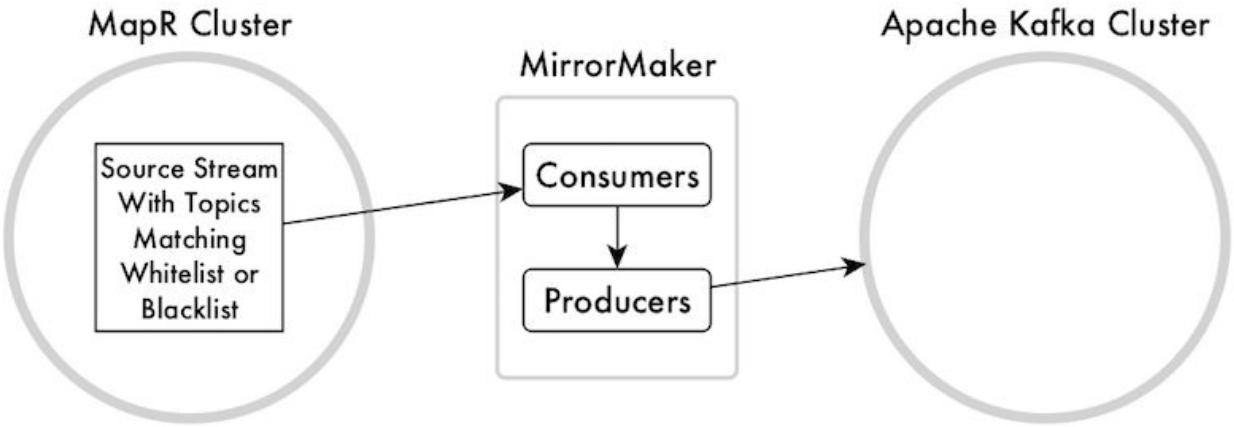

Figure 18: Mirroring from MapR Event Store For Apache Kafka to Apache Kafka

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the stream in the MapR Data Platform cluster. You also create a file that contains the required configuration parameters for the producers that publish to the Apache Kafka cluster. You point to these files in the MirrorMaker command.

You can specify the topics you want to mirror or the topics you do not want to mirror. To mirror topics, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want to mirror. To specify topics you do not want mirrored, use the `blacklist` parameter

last-updated: Apr 11, 2022

to provide a Java-style regular expression that matches the names of the topics that you do not want mirrored.

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

Property	Description
`streams.record.strip.streampath`	Set the value of this property to true. In messages that are written to streams, the names of topics include the paths and names of the streams in which those topics are located. Apache Kafka needs only the names of the topics. This parameter removes the path and name of the stream that the topics will be mirrored from.
`streams.consumer.default.stream`	Specifies the path and name of the stream that the topics will be mirrored from.
`group.id`	A unique string that identifies the consumer group the consumers started by MirroMaker belong to.

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

Property	Description
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The producers will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...`. Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).
`producer.type`	Specifies whether the messages are published asynchronously in batches or as data is received by producers. The values are `async` and `sync`.
`compression.codec`	Specifies the compression codec for all messages that are generated by producers. The possible values are `none`, `gzip`, `snappy`, and `lz4`.

3. Run MirrorMaker with this command to start mirroring topics from MapR Event Store For Apache Kafka to Apache Kafka:

   Syntax

```
bin/kafka-mirror-maker.sh

--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
[--whitelist=<Java-style regular expression for specifying the topics to
mirror>]
[--blacklist=<Java-style regular expression for specifying the topics
not to mirror>]
```

Parameter	Description
`consumer.config`	The path and name of the file that lists the consumer properties and their values.
`new.consumer`	Specifies to use consumers that use the Apache Kafka 0.90 API library.
`num.streams`	Use this parameter to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
`producer.config`	The path and name of the file that lists the producer properties and their values.
`whitelist`	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). If you use this parameter, do not use the `blacklist` parameter.
`blacklist`	A Java-style regular expression for specifying the topics not to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). If you use this parameter, do not use the `whitelist` parameter.

Example

In this example, the file that lists the properties and values for the consumer that will read messages from the topics in MapR Event Store For Apache Kafka is named `consumers.props`. It contains this list:

```
streams.record.strip.streampath=true
streams.consumer.default.stream=/myStream
group.id=cg1
```

The file that lists the properties and values for the producers that will publish messages to topics in Apache Kafka is named `producers.props`. It contains this list:

```
bootstrap.servers =10.10.83.93:9092
producer.type=sync
compression.codec=none
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the whitelist parameter.

```
bin/kafka-mirror-maker.sh --new.consumer
--consumer.config consumers.props --num.streams 2 --producer.config
producers.props
--whitelist="na_west.*"
```

last-updated: Apr 11, 2022

Administering MapR Gateways

A MapR gateway mediates one-way communication between a source MapR cluster and a destination cluster. You can replicate MapR Database tables (binary and JSON) and MapR Event Store For Apache Kafka streams. MapR gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

The initial task for setting up your gateways is to decide where you want to put them:

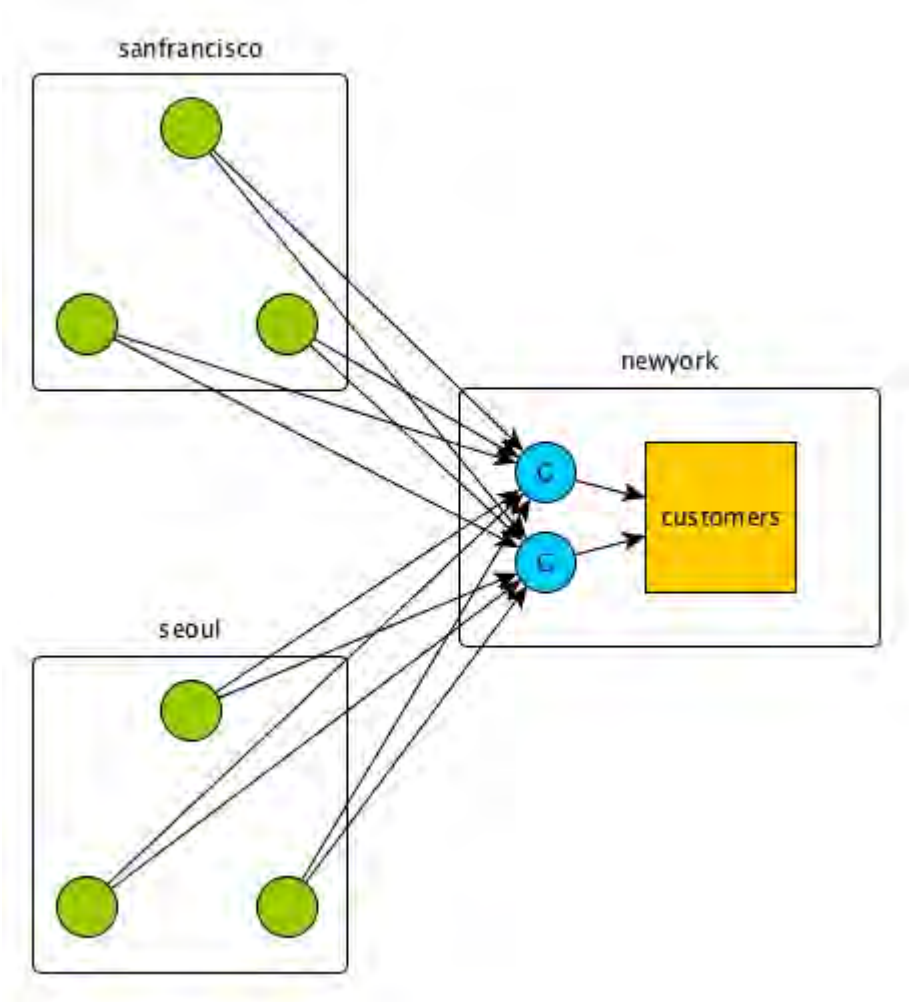
- If you are going to replicate MapR Database tables, see Gateways for Replicating MapR Database Tables on page 621.
- If you are going to replicate streams, see Gateways and Stream Replication on page 662.
- If your MapR Database JSON tables have secondary indexes, see Preparing Clusters for Querying using Secondary Indexes on JSON Tables on page 1089.
- If you are using CDC, see Getting Started with CDC on page 600.

Note: Gateways perform negligible disk I/O and use negligible amounts of memory, though gateways require significant CPU usage.

However, the resource that gateways use the most is network bytes. For example, if the peak network throughput for puts is about 40 MB per second per node, in a 10-node source cluster the peak network throughput will be about 400 MB per second. So, the aggregate network throughput required on the nodes running gateways will be 400 MB per second for both incoming and outgoing traffic. The aggregate network throughput for a 50 node cluster would be 2GB per second.

For another example, in the following diagram there are two source clusters of three nodes each and the clusters are replicating to one destination cluster. The peak traffic on the gateways will be 40MB per second per cluster node, which means that these gateways together will experience a peak network load of 240MB per second.

last-updated: Apr 11, 2022



Although the load is balanced across the two gateways, so that each gateway experiences a peak network load of 120MB per second, each gateway should be able to tolerate the full aggregate network load in case the other gateway fails unexpectedly.

Configuring Gateways for Table and Stream Replication

Configuring gateways involves installing the `mapr-gateway` package on nodes on a MapR destination cluster and then configuring the MapR source cluster to communicate with the destination cluster. The MapR source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

How Many Gateways to Configure?

Although it is possible to use a single gateway, the recommended practice is to configure at least two (2) gateways, so that replication can continue if one gateway fails. MapR source clusters distribute requests among the gateways in a round-robin fashion. See Gateways for Replicating MapR Database Tables on page 621, Table Replication on page 610, and Preparing Clusters for Stream Replication on page 1130 for more information about replication.

For more information about setting up cross-cluster security, including cross-cluster security for table and stream replication, see Setting Up Cross-Cluster Security on page 1482.

Default Gateway Configuration for Replication

If you do not perform any of these options, MapR Database uses the configuration from the `mapr-clusters.conf` file. It uses the cluster name specified in that file as the destination cluster, and the CLDB node addresses as the gateway nodes. You must have gateways running on these CLDB nodes.

Configuration Procedure

Tip: To list the current gateways, see cluster gateway get on page 1565.

1. On the destination cluster, install the `mapr-gateway` package on each node where you want to run a gateway. See Installing MapR Software.

   Note: On the gateway nodes in the destination cluster, when you run (or re-run) the `configure.sh` script (in addition to your regular parameters) be sure to specify the `-N` parameter with the name of the cluster to which the gateway belongs. For more information about `configure.sh` usage, options, and examples, see configure.sh on page 2053.

2. To change the port that a gateway uses (by default, gateways use port `7660`):

   a. On the node where the gateway is running, edit the `/opt/mapr/conf/gateway.conf` file, ensure that the line `#gateway.port=7660` is not commented, and change the port number. For more information about `gateway.conf` configuration properties, see gateway.conf on page 2197.

b. After saving the file, restart the gateway by running this command: `maprcli node services -name gateway -action restart`

3. On the source cluster, specify the destination cluster's name and gateway nodes by using one of the following methods:

- Run the `maprcli cluster gateway set` command:

```
maprcli cluster gateway set -dstcluster <cluster name> -gateways
"<space-delimited list of gateways>"
```

The following sample command sets two gateway nodes on the destination cluster `my.cluster.com`:

```
maprcli cluster gateway set -dstcluster my.cluster.com -gateways
"node1.com node2.com"
```

- Add a DNS record to your DNS server's zone file for your domain.

See Managing Gateways on page 1154 for more information about using these methods.

Managing Gateways

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

You can run the following commands to perform operations on your gateways.

Note: If you have configured an intra-cluster gateway, the source and destination clusters are the same.

- To see a list of the gateways for a particular destination cluster:

  Run the `maprcli cluster gateway get` command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To see a list of the gateways for all of the destination clusters to which the source cluster is replicating:

  Run the `maprcli cluster gateway list` command on the source cluster. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To remove the list of gateways that you specified for a destination cluster by using the `maprcli cluster gateway set` command:

  Run the `maprcli cluster gateway delete` command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To find out how MapR Database or MapR Event Store For Apache Kafka is finding gateways (for example, from DNS records, lists created by the `maprcli cluster gateway set` command or the `mapr-clusters.conf` file):

  Run the command `maprcli cluster gateway resolve` on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To stop and start one or more gateways:

  Run the `maprcli node services -name gateway -action stop|start` on the clusters where the gateways are running.

  ```
  /opt/mapr/bin/maprcli node services -name gateway -action stop -nodes
  <hostnames or IP addresses separated by spaces>
  ```

  ```
  /opt/mapr/bin/maprcli node services -name gateway -action start -nodes
  <hostnames or IP addresses separated by spaces>
  ```

- To check the status of a gateway service on a particular node:

  Run the command maprcli service list on the clusters where the gateways are running.

last-updated: Apr 11, 2022

Running the `maprcli cluster gateway set` command

The syntax of the `maprcli cluster gateway set` command is:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster <cluster
name> -gateways "<space-delimited list of gateways>"
```

To generate a list of the existing gateways in a MapR cluster, use the `maprcli cluster gateway list` command. You can then copy this list and paste it into the `maprcli cluster gateway set` command. Alternatively, to generate a list of the gateways on a local cluster, run the `maprcli cluster gateway local -format text` command. If you want to run the command from a different cluster and point to the cluster where the gateways are located, use the `-cluster` parameter to provide the name of that cluster.

For example, suppose that you are configuring table replication from the cluster `sanfrancisco` to the cluster `newyork`, and want to use two gateways. The nodes on which these gateways are located are named `gw1` and `gw2`.

The command that you run will be as follows:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster newyork -gateways
"gw1.bigcompany.com gw2.bigcompany.com"
```

Adding a DNS record to your DNS server's zone file for your domain

In your DNS server's zone file for your domain, you can add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you can copy into a DNS configuration file, run a `maprcli` command to generate the record, or create a record manually.

For details, see Specifying the Location of Gateways on page 782.

If a Gateway Fails

If a gateway fails, the warden service tries three (3) times to restart it automatically. After an interval, the warden tries again three times to start the gateway. You can configure the interval by using the parameter `services.retryinterval.time.sec` in the `warden.conf` file. The default is 30 minutes.

During the time that the gateway is down, source clusters will resend updates to other gateways. Source clusters will also ping the failed gateway with an exponentially increasing backoff.

If all of the gateways fail in a destination cluster, source clusters will ping the failed gateways in the same manner. Updates pending replication are stored on disk in an internal data structure until at least one gateway in the destination cluster comes back online. Therefore, you will see additional storage costs during a gateway outage. The Gateway Service Down alarm in the Control System will notify you when none of the gateways in a destination cluster can be reached.

If the additional storage becomes too costly, you can follow either of these procedures:

If you are replicating to a MapR Database binary table:

1. Run the `maprcli table replica remove` command to stop replicating to the replica. This action deletes the pending updates.
2. Resolve the gateway outage.
3. Recreate the replica and start replicating to it by running the `maprcli table replica autosetup` command.

If you are replicating to a MapR Event Store For Apache Kafka stream:

last-updated: Apr 11, 2022

1. Run the `maprcli stream replica remove` command to stop replicating to the replica stream. This action cancels the pending updates to the replica stream.
2. Resolve the gateway outage.
3. Run the command `maprcli stream replica autosetup` to recreate the replica stream and start replicating to it.

Troubleshooting

You can refer to two log files for each gateway when troubleshooting. Both these files are in the `/opt/mapr/logs` directory on the node where the gateway is running:

- `gateway.log`
- `gatewayinit.log`

MapR Database Lookup Order

MapR Database uses the following order to locate the gateways that are running in a destination cluster.

- Look up the destination cluster's name and gateway addresses in the information specified by the `maprcli cluster gateway set` command. If a list of gateways, then a DNS lookup is performed.
- Perform a DNS lookup of the destination cluster and the addresses of the gateways. If no DNS record for the destination cluster is found, then the lookup goes to the `mapr-clusters.conf` file.
- Look up the destination cluster's name and the CLDB node addresses in the `mapr-clusters.conf` file under the assumption that gateways are running on all of the CLDB nodes and only on those nodes.

Administering Services

The various topics in this section describe how to manage (start, stop, restart, etc.) the various services installed on the MapR cluster using the MapR Control System (click **Services**) and the CLI.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, MapR recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services
Explains how to view the list of services using either the Control System or the CLI.
Viewing the Services Installed on the Cluster Using the Control System

- Log in to the Control System and click **Services**.

  The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

Column Name	Column Description
Service	The name of the installed service.
Running Nodes	The number of nodes on which the associated service is running. The service can be stopped ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is running.
Standby Nodes	The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is in standby state.
Failed Nodes	The number of nodes on which the service has failed. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has failed.
Stopped Nodes	The number of nodes on which the associated service is stopped (and not running). The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has been stopped.
Config Path	The path to the configuration file for the service.
Log Viewer	(Displays only if Kibana is installed on a node) The link ( ) to the Kibana UI.

last-updated: Apr 11, 2022

You can filter the list of services displayed by:

- **EEP**, which includes services such as Hive, Drill, etc.
- **Core**, which includes services such as CLDB, Hoststats, File server, etc.
- **Monitoring**, which includes services such as Grafana, Kibana, etc.

Viewing the Services Running on a Node Using the Control System

1. Log in to the Control System and click **Nodes**.

   Note: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:
   - Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.
   - Go to the **Summary** tab in the node information page to view detailed information on the services installed on a node.

   In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

Column Name	Column Description
Service	The name of the service.
State	The current state of the service. Value can be: • Running • Stopped
Memory Allocated	The amount of system memory allocated to the service.
System Memory Utilized	The percentage of memory utilized by the service.
CPU Usage	The CPU used by the service.
Log Path	The path to the service log file.
Log Viewer	The link to the Kibana UI (only if Kibana is installed).

You can select the checkbox beside one or more services to take the following actions:

- Start Services
- Stop Services
- Restart Services

Note: If Kibana is installed, you can click to view the logs. See Kibana User Guide for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see service list on page 1746.

Enabling and Disabling a Service Using the CLI and REST API
Describes how to enable or disable a service using either the REST API or the CLI.

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

Disabling a Service Using the CLI or REST API

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action disable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=disable' --user mapr:mapr`

Note: When you disable a service, the service is stopped and the service is not automatically starrted/restarted when Warden is started/restarted.

See `node services` on page 1730 for more information.

Enabling a Service Using the CLI or REST API

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action enable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=enable' --user mapr:mapr`

Note: When you enable a service, the service is started/restarted when Warden is started/restarted.

See `node services` on page 1730 for more information.

Related tasks

Restarting the Services on page 831
Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services
Explains how to start services using either the Control System, the CLI or the REST API.

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See Enabling and Disabling a Service Using the CLI and REST API on page 828 for more information.

Starting the Services Running on the Nodes Using the Control System

To start the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

To start one or more services running on a node:

1. Go to the **Summary** tab in the node information page.
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
   The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click for the service to start.
   The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see `node services` on page 1730.

Stopping the Services

Describes how to stop services using either the Control System, the CLI or the REST API.

Stopping the Services Running on the Nodes Using the Control System

To stop the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   Note: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

To stop one or more services running on a node:

1. Go to the **Summary** tab in the node information page.
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
   The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop.
   The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see `node services` on page 1730.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

When a MapR system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

Note: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that MapR currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See Enabling and Disabling a Service Using the CLI and REST API on page 1159 for more information.

last-updated: Apr 11, 2022

Restarting the Services Running on the Nodes Using the Control System

To restart the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System

1. Go to the **Summary** tab in the node information page.
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
   The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click associated with the service to restart.
   The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see `node services` on page 1730.

Related tasks

Enabling and Disabling a Service Using the CLI and REST API on page 1159
Describes how to enable or disable a service using either the REST API or the CLI.

Viewing a Service Information Page

Describes how to view the information pages for the installed services using the Control System.

1. Log in to the Control System and click **Services**.

   Note: The **Services** page is not available on the Kubernetes version of the Control System.

   The **Services** pane displays the list of services that are installed on the cluster.
2. Click the name of the service from the list.
   The information page for the service displays.

Changing the User for MapR Services from the Command-Line

Explains how use the CLI to change the user that MapR services run as.

All services should run with the same uid/gid on all nodes in the cluster.

Running MapR Services as the Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`
4. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

5. Start Warden.

```
service mapr-warden start
```

Running MapR Services as a Non-Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.
4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.
6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing NODE_ALARM_MAPRUSER_MISMATCH alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Viewing the Service Log

Esplains how to view service logs using Kibana.

last-updated: Apr 11, 2022

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

1. Log in to the Control System and do one of the following:
   - Click **Services** to display the list of services installed on the cluster.
   - Go to the **Summary** tab in the service information page for the service.
2. Click  in the **Log Viewer** column to view the log for the associated service in the Kibana UI. See Kibana User Guide for more information.

Setting Up Central Configuration from the Command-Line

Describes the concept of a central location where customized MapR configuration files for MapR services are stored.

MapR provides a central location where you can place customized configuration files for all the services running on the MapR cluster. As a result, you do not have to edit the configuration files on each node individually.

Default configuration files for each service are stored locally under `/opt/mapr/`. You can edit these files to create customized versions of the configuration files. To push these changes to other nodes in the cluster, copy the customized files to the `mapr.configuration` volume in the MapR filesystem. When the `pullcentralconfig` script runs, it overwrites the local configuration file in `/opt/mapr` with the customized files on all nodes on which the change applies.

The `mapr.configuration` volume is mounted at `maprfs://var/mapr/configuration.`The `mapr.configuration` volume mount location is not configurable and is only used for central configuration.

Using Central Configuration

Lists the steps to configure and use central configuration of files.

MapR provides a central location where you can place customized configuration files for all the services running on the MapR cluster. As a result, you do not have to edit the configuration files on each node individually.

Default configuration files for each service are stored locally under `/opt/mapr/`. You can edit these files to create customized versions of the configuration files. To push these changes to other nodes in the cluster, copy the customized files to the `mapr.configuration` volume in the MapR File System. When the `pullcentralconfig` script runs, it overwrites the local configuration file in `/opt/mapr` with the customized files on all nodes to which the change applies.

The `mapr.configuration` volume is mounted at `maprfs://var/mapr/configuration.`The `mapr.configuration` volume mount location is not configurable and is only used for central configuration.

Complete the following steps to use the Central Configuration (`pullcentralconfig` script) to push a customized configuration file from the `mapr.configuration` volume in MapR File System to nodes in the cluster.

1. Customize a configuration file on any node in the cluster. See Listing the Configuration Files for Each Service to determine which files you can customize.

last-updated: Apr 11, 2022

2. Create the directory structure for the configuration file that is relative to $MAPR_HOME based on the number of nodes to which the file applies:

Scope	MapR File System Location
Use this file on all nodes that use the configuration file unless a node-specific file exists in the `mapr.configuration` volume.	`/var/mapr/configuration/default/<directory path to the configuration file>`
Use this file for a specific node.	`/var/mapr/configuration/nodes/<hostname>/<directory path to the configuration file>`

3. Copy the customized file to the `mapr.configuration` volume in the directory that you created. For example, to create a directory to update the web server configuration file, which is in `/opt/mapr/conf`, you would create directory path `/var/mapr/configuration/default/conf` and then copy the updated file to this directory.

4. Run the `pullcentralconfig` script or wait until the script acknowledges the update. For more information, see About the pullcentralconfig Script.

5. Restart the services associated with the updated configuration files to ensure that the latest version is used for each service.

Scenario

Lists an example scenario to demonstrate customized configuration for a 8-node cluster.

In the following example, you have a cluster with eight nodes, and five of them (host1, host2, host3, host4, and host5) are running the NodeManager service.

You want to create one customized configuration file (`mapred-site.xml`) that applies to host2 through host5 and assign a different customized configuration file to host1.

Hostname	Customized Configuration Files
host1	`/var/mapr/configuration/`**`nodes/host1`**`/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml`
host2	`/var/mapr/configuration/`**`default`**`/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml`
host3	`/var/mapr/configuration/`**`default`**`/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml`
host4	`/var/mapr/configuration/`**`default`**`/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml`
host5	`/var/mapr/configuration/`**`default`**`/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml`
host6	Not applicable. No customized configuration files are used.
host7	Not applicable. No customized configuration files are used.
host8	Not applicable. No customized configuration files are used.

last-updated: Apr 11, 2022

Warning: Do *not* change the name of the new configuration file - it must match the name of the original version.

Step 1. Create a customized configuration file and copy it to a volume
Use the CLI to create a customized configuration file and copy it to a volume.

Complete the following steps to create a customized configuration file for host2 through host5 and copy it to the mapr.configuration volume:

1. Make a copy of the existing default version of the `mapred-site.xml` file (so you can use it as a template), and store it in `/tmp`. You can perform this step on any node in the cluster that contains the configuration file.

```
cp /opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml /tmp/
mapred-site.xml
```

2. Edit the copy and put in the changes you want for host2 through host5.
3. Create the directories required to store the file under `/var/mapr/configuration/default`.

```
hadoop fs -mkdir -p /var/mapr/configuration/default/hadoop/
hadoop-2.7.0/etc/hadoop
```

4. Store the new configuration file in the `/var/mapr/configuration/default` directory.

```
hadoop fs -put /tmp/mapred-site.xml /var/mapr/configuration/default/
hadoop/hadoop-2.7.0/etc/hadoop
```

Step 2. Create a node-specific configuration file and copy it to a volume
Use the CLI to create a node-specific configuration file and copy it to a volume.

Complete the following steps to create a node-specific configuration file for host1 and copy it to the mapr.configuration volume:

1. Edit the `mapred-site.xml` configuration file in `/tmp` (or you could copy the default version into `/tmp` again and edit that) and create the node-specific configuration file for host1.
2. Create the directories required to store the file under `/var/mapr/configuration/nodes`:

```
hadoop fs -mkdir -p /var/mapr/configuration/nodes/host1/hadoop/
hadoop-2.7.0/etc/hadoop
```

3. Store the new configuration file for host1 in the node-specific directory you just created.

```
hadoop fs -put /tmp/mapred-site.xml /var/mapr/configuration/nodes/host1/
hadoop/hadoop-2.7.0/etc/hadoop
```

Step 3. Verify the changes
Explains the use of the `pullcentralconfig` script in verifying file changes.

Now that you have two separate customized configuration files for your NodeManager nodes, the `pullcentralconfig` script will detect the new files in `/var/mapr/configuration` the next time it is launched. It overwrites the local version in `/opt/mapr` with the appropriate customized version for each of the five NodeManager nodes.

1. To launch the `pullcentralconfig` script, perform one of the following operations:

- Run `pullcentralconfig` from the command line to overwrite the old files immediately.

```
/opt/mapr/server/pullcentralconfig
```

- Wait five minutes (the interval between successive checks for updated configuration files) for the script to run automatically.

2. Look at the information messages in `pullcentralconfig.log`. Whenever the timestamp comparison is `false`, an INFO message indicates that the older file under `/opt/mapr` is copied into a backup file (`.bkp`) and the newer version is copied to replace it. Sample log output is as follows:

```
cat pullcentralconfig.log
   Header: hostName: doc22.lab, Time Zone: Pacific Standard Time,
processName: CentralConfig, processId: 16701
   2017-07-17 13:13:01,842 INFO
com.mapr.centralconfig.CentralConfigCopyHelper [main]: Copied /var/mapr/
configuration/default///hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml
to /opt/mapr//hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xmlusing
maprexecute.
```

3. Restart the service.

About the pullcentralconfig Script
Provides a brief synopsis about the `pullcentralconfig` script.

The `pullcentralconfig` script runs on each node in the cluster. The `pullcentralconfig` script is launched automatically at specified intervals (the default interval is 300 seconds, which is five minutes). For each service listed in `/opt/mapr/roles`, the `pullcentralconfig` script searches for corresponding configuration files in the central configuration location, `/var/mapr/configuration`. If any configuration files are found, it compares the timestamp (`mtimes`) of the files in the central configuration location to the timestamp of the local version in `/opt/mapr`. If the central configuration version is newer, `pullcentralconfig` overwrites the local version with the central configuration file. To ensure that the newer version gets used, you need to restart the associated service.

Checking for Node-specific vs. Cluster-wide Configuration Files
Explains the order in which the `pullcentralconfig` script checks for central configuration files.

The `pullcentralconfig` script checks for central configuration files in this order:

1. Node-specific configuration files under `/var/mapr/configuration/nodes/<hostname>`. If configuration files are found here, `pullcentralconfig` does not check `/var/mapr/configuration/default`.

2. Cluster-wide configuration files under `/var/mapr/configuration/default`. The `pullcentralconfig` script only searches here if no node-specific configuration files are found.

If no configuration files are found in either location, the script finishes and no changes are made to the files in `/opt/mapr`.

Changing the Polling Frequency
Explains how to change the polling frequency of the `pullcentralconfig` script.

By default, the `pullcentralconfig` script polls the central configuration location every five minutes (300 seconds) to check for configuration files.

1. You can change the polling frequency by editing the following variable in `warden.conf`:

```
pollcentralconfig.interval.seconds
```

2. To make the change take effect, restart Warden:

```
root$> service mapr-warden restart
```

Listing the Configuration Files for Each Service
Explains how to use the CLI to list all the configuration files for each service.

Each service on a node has one or more configuration files associated with it. The default version of each configuration file can be used as a template that you can modify as needed.

Files in the following directory contain the list of configuration files for each installed service: `/opt/mapr/servicesconf/<service>`.

- Use the following command to display the configuration files or the directory that contains the configuration files for each service:

```
cat /opt/mapr/servicesconf/<service>
```

For example, the following command displays the configuration files for NodeManager:

```
cat /opt/mapr/servicesconf/nodemanager
    hadoop/hadoop-2.7.4/etc/hadoop
```

The following table contains the configuration files and configuration file directories available for Hadoop and Hbase:

Service	Pathnames of Configuration Files
cldb	`/opt/mapr/conf/BaseLicense.txt`
	`/opt/mapr/conf/cldb.conf`
	`/opt/mapr/hadoop/hadoop-xxx/etc/hadoop/hadoop-metrics.properties`
	`/opt/mapr/conf/log4j.cldb.properties`
	`/opt/mapr/conf/log4j.properties`
	`/opt/mapr/conf/MapRLicenseIssuerCert.der`
fileserver	`/opt/mapr/conf/mfs.conf`
historyserver	`/opt/mapr/conf/conf.d/warden.historyserver.conf` **Attention:** You can perform additional configuration of the historyserver in `/opt/mapr/hadoop/hadoop-xxx/etc/hadoop/yarn-site.xml`
nfs	`/opt/mapr/conf/nfsserver.conf`
	`/opt/mapr/conf/exports`
nodemanager	`/opt/mapr/conf/conf.d/warden.nodemanager.conf`
	`/opt/mapr/conf.new/hadoop_version`

Service	Pathnames of Configuration Files
resourcemanager	`/opt/mapr/conf/conf.d/warden.resourcemanager.conf` **Attention:** You can perform additional configuration of the resourcemanager in `/opt/mapr/hadoop/hadoop-xxx/etc/hadoop/yarn-site.xml`
webserver	`/opt/mapr/apiserver/conf/properties.cfg`

Preserving Multiple Versions of Configuration Files

- If you want to save multiple versions of customized configuration files, you can take snapshots of `mapr.configuration` to preserve each version you create.

  This maybe helpful if you want to try various versions of the configuration files on the cluster.

  Warning: Before a local configuration file is updated by the `pullcentralconfiguration` script, a backup of the current version is created. The file extension `.bkp` indicates the back-up configuration file.

Disabling Automatic Central Configuration

Explains how to stop automatic runs of the `pullcentralconfig` script.

1. Automatic central configuration is enabled by default. You can configure central configuration to stop automatic runs of the `pullcentralconfig` script by editing `warden.conf` and setting the following variable to *false*: `centralconfig.enabled=false`
2. To make the change take effect, restart Warden:

   ```
   root$> service mapr-warden restart
   ```

   Note: When automatic central configuration is disabled, you can still manually run the `pullcentralconfig` script to push the latest configuration files to nodes in the cluster.

Viewing CLDB Information

Describes how to view CLDB information from the CLDB page, and provides an explanation of each field that the page displays.

The CLDB page on the Control Panel provides information about the Container Location Database (CLDB). The CLDB is a management service that tracks container locations and the root of volumes.

To display the CLDB information page, log in to the Control System and go to the service information page for CLDB. Alternatively, you can use the following links to access the CLDB page:

- For a *secure* cluster, access the CLDB view at `https://<cldbmaster>:7443/cldb.jsp`.
- For an *non-secure* cluster, access the CLDB view at `http://<cldbmaster>:7221/cldb.jsp`.

The CLDB page displays the following information:

Container Location Database	*Description:* This section displays: • CLDB Mode: The CLDB node can be in one of the following modes: MASTER_READ_WRITE or SLAVE_READ_ONLY.

last-updated: Apr 11, 2022

	• CLDB BuildVersion: Lists the build version. • Master for CLDB volume ready: Indicates whether the CLDB volume is ready for use. • CLDB Status: The status of the CLDB node. • Cluster Capacity: The storage capacity for the cluster. • Cluster Used: The amount of storage in use. • Cluster Available: The amount of available storage. • Cluster Used Percentage: The percentage of storage in use.
Active FileServers	*Description:* Displays information about the File Servers in use: • ServerID (Hex): The server's ID in hexadecimal notation. • ServerId: The server's ID in decimal notation. • HostPort: The IP address of the file server. • HostName: The hostname assigned to the file server. • Network Location: The network topology for the file server. • Last Heartbeat (s) : The timestamp for the last received heartbeat. • State: Is the file server ACTIVE (in use at present) • Capacity (MB): Total storage capacity on the file server. • Used (MB): Storage used on the file server. • Available (MB): Storage available on the file server. • In Transit (MB): Amount of data in transit
Active NFSServers	*Description:* Displays information about the NFS Servers in use: • ServerID (Hex): The server's ID in hexadecimal notation. • ServerId: The server's ID in decimal notation. • HostPort: The IP address of the NFS server. • HostName: The hostname assigned to the NFS server. • Last Heartbeat (s) : The timestamp for the last received heartbeat. • State: Is the NFS server ACTIVE (in use at present)

last-updated: Apr 11, 2022

Volumes

Description: Displays information about the volumes on the container:

- Volume Name: The name of the volume. Click the name of the volume to view the containers of the volume (including the container ID, size (in MB), container primary location and container locations, and replication type, which can be S for sequential and C for cascading).
- Mount Point: The path in which the volume is mounted over NFS.
- Mounted: Specifies whether volume is mounted. Value can be Y or N.
- ReadOnly: Specifies whether volume is a read-only or read/write volume. Value can be Y (if volume is read-only) or N (if volume is read/write).
- Volume ID: The Volume ID.
- Volume Topology: The path describing the topology to which the volume is assigned.
- Quota: The total size of the volume's quota. A quota of 0 means no quota is assigned.
- Advisory Quota: The usage level that triggers a disk usage warning.
- Used: Total size of data written to the volume after compression.
- LogicalUsed: Actual size of data written to the volume.
- Root Container ID: The ID of the root container.
- Replication: The number of copies of the volume.
- Guaranteed Replication: The minimum number of copies of the volume.

Accountable Entities

Description: Displays information about users and groups:

- AE Name: The name of the accountable entity.
- AE Type: The type of accountable entity.
- AE Quota: The hard quota allocated to the accountable entity.
- AE Advisory Quota: The advisory quota limit for the accountable entity.
- AE Used: The amount of disk space used by the accountable entity.

Mirrors Information

Description: Contains a link to the Mirrors page, which displays information about volume mirrors:

- Mirror Volume Name: The name of the mirror volume.

last-updated: Apr 11, 2022

- Mirror ID: The ID of the mirror volume used for the last successful mirroring. This ID starts with 1 and is incremented by 1 after each mirroring.
- Mirror NextID: The ID to be used for the next mirroring operation.
- Mirror Status: The status of the mirroring operation.
- Last Successful Mirror Time: The date and time stamp from the last successful mirroring operation.
- Mirror SrcVolume: The source volume for the mirror volume.
- Mirror SrcRootContainerID: The source container ID for the mirror volume.
- Mirror SrcClusterName: The source cluster name for the mirror volume.
- Mirror SrcSnapshot: The source snapshot associated with the mirror volume.
- Mirror DataGenerator Volume: The first volume that generates data (RW Volume) in the mirror chain.

  For example, if the mirror chain is **A** > **B** > **C**, then at C, the Mirror DataGenerator volume is A while the source volume is B.
- Mirror DataGenerator snapshot time: The time at which the last snapshot for the Mirror DataGenerator Volume was generated.

Snapshots Information

Description: Contains a link to the Snapshots page, which displays information about snapshots:

- Snapshot ID: The ID of the snapshot.
- RW Volume ID: The ID of the standard (or read/write) volume associated with the snapshot.
- Snapshot Name: The name of the snapshot.
- Root Container ID: The ID of the container.
- Snapshot Size: The size of the snapshot.
- Snapshot InProgress: The status of the snapshot if it is currently in progress.

The page also displays a list of snapshot containers, and the following information about each:

- Snapshot Container ID: The unique ID of the container.
- Snapshot ID: The ID of the snapshot corresponding to the container.
- RW Container ID: The corresponding source container ID.

last-updated: Apr 11, 2022

	• Latest Epoch: The latest sequence number of the snapshot. Higher the number, the newest and most up-to-date is the snapshot. • SizeMB: The container size, in MB. • Container Master Location: The location of the container's primary replica. • Container Locations: The location of the data containers. • Inactive Locations: The location of inactive containers.
Storage Pools	*Description:* Displays information about storage pools: • SP: The ID of the storage pool. • ServerId: The ID of the server associated with the storage pool. • SpIdx: The index of the storage pool. • Last Heartbeat(s): TBD • Capacity: The total capacity of the storage pool. • Used: The amount of space used on the storage pool. • Disk Fullness Level (percentage): The percentage of disk space (associated with the storage pool) that is full. • InTransit: Indicates that some containers in the storage pool are being resynced. • OutTransit: Indicates that none of the containers in the storage pool are being resynced.
Active Container Moves	*Description:* Displays information about the containers being moved: • Container ID: The ID of the container being moved. • SizeMB: The size (in MB) of the container being moved. • From Location: The location from where the container is being moved. • From SP: The SP out of which the container is being moved. • To Location: The location to which the container is being moved. • To SP: The SP to which the container is being moved.

Managing Drill

Provides a short description on managing Drill services.

last-updated: Apr 11, 2022

You can install and run a Drillbit service on one node or on all of the nodes on a MapR cluster to form a distributed cluster environment. After you have installed Drill and configured connections to your data sources, you can view Drill metrics and manage Drillbits using the Control System.

Viewing Drill Information
Explains how to view Drill information using the Control System.
Viewing Drill Information Using the Control System

1. Log in to the Control System and click **Services**.

   Note: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Drill** in the **Services** pane.
   The **Drill** information page displays the following:

Summary

The **Summary** tab displays the following panes:

Information	Displays the number of Drillbits and the number of completed and in-progress queries.
Resource Utilization	The percentage of CPU, memory, and disk space utilized by Drill.
Running Fragments	The number of query fragments running in the Drillbit during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. For more information on fragments, see Drill Query Execution.
Memory Used	The amount of direct memory used by the JVM during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. To configure the amount of direct memory allocated to a Drillbit for query processing in a Drill cluster, see Configuring Drill Memory.
Queries	The number of queries during the selected time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

Drill Bits The **Drill Bits** tab displays the list of Drillbits. See Viewing the List of Drillbits on page 1175.

Viewing the List of Drillbits

Explains how to view the list of Drillbits using the Control System.

- Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.

  For each Drillbit, the pane displays the following:

Column Name	Column Description
Drill Bit ID	The ID of the Drillbit.
Node	The node on which the Drillbit is installed.
Service State	The status of the service. Value can be: • Running • Stopped
Queries in Progress	The number of queries currently in progress.
Resource Usage - Memory	The percentage of memory being used.
Resource Usage - CPU	The percentage of CPU being used.

  Select the checkbox beside one or more Drillbit IDs to:

  - **Stop the Service(s)**
  - **Start the Service(s)**
  - **Restart the Service(s)**

  For more information, see Stopping, Starting, and Restarting Drillbits on page 1175.

Stopping, Starting, and Restarting Drillbits

Explains how to stop, start and restart Drillbits using the Control System.

Stopping Drillbits

1. Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Stop Service(s)** to display the **Stop Service** confirmation dialog.

   You can only stop Drillbits that are currently in running state.
3. Review the list of Drillbits and click **Stop Service** to stop the Drillbits.

Starting Drillbits

1. Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.

last-updated: Apr 11, 2022

2. Select the checkbox associated with the Drillbit(s) and click **Start Service(s)** to display the **Start Service** confirmation dialog.

   You can only start Drillbits that are currently in stopped state.

3. Review the list of Drillbits and click **Start Service** to start the Drillbits.

Restarting Drillbits

1. Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Restart Service(s)** to display the **Restart Service** confirmation dialog.
3. Review the list of Drillbits and click **Restart Service** to restart the Drillbits.

Managing the MapR NFS Service

Provides an overview of managing the NFS service on a licensed cluster.

The MapR NFS service lets you access data on a licensed MapR cluster using the NFS protocol:

- Community Edition license: one NFS node allows you to access your cluster as a standard POSIX-compliant filesystem.
- Enterprise Edition or Enterprise Database Edition license: multiple NFS servers allow each node to mount its own MapR filesystem on NFS enabled with VIPs for high availability (HA) and load balancing.

You can mount the MapR cluster using NFS, and use standard shell scripting to read and write live data on the cluster. NFS access to cluster data can be faster than accessing the same data with the `hadoop` commands. To mount the cluster using NFS from a client machine, see Accessing Data with NFS v3.

Managing VIPs for NFS

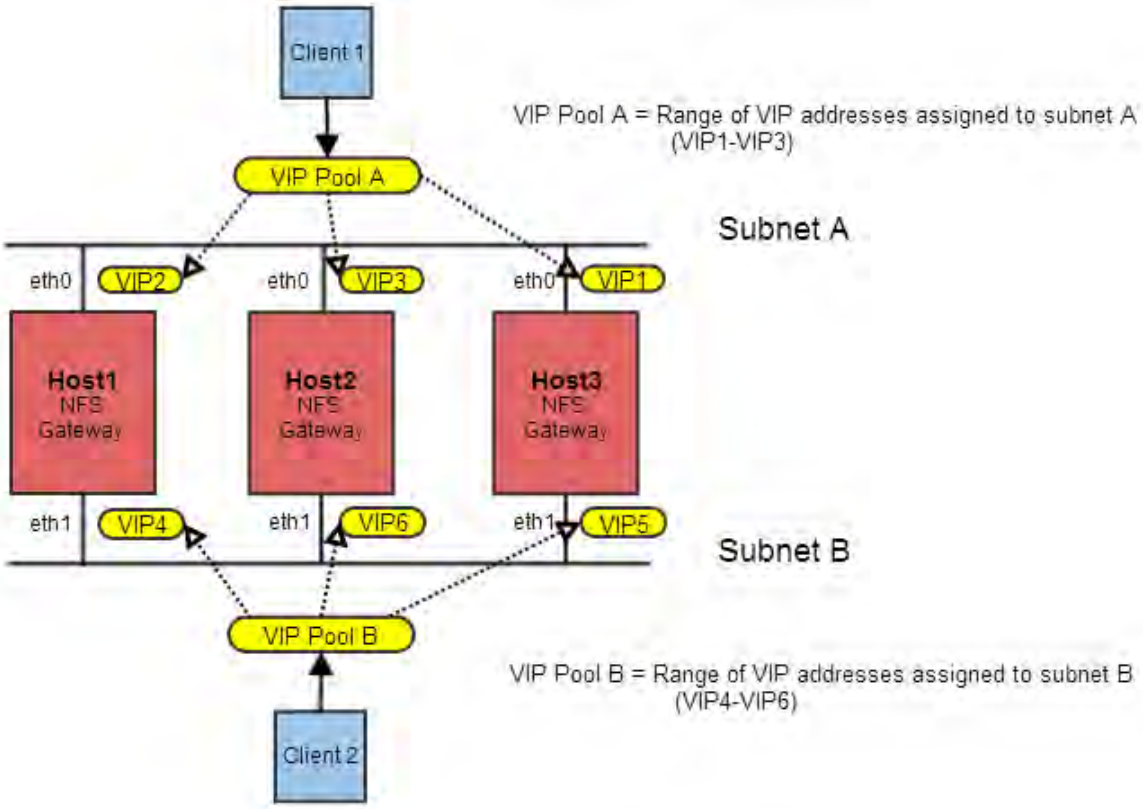
Explains how to use virtual IP addresses (VIPs) on NFS servers.

You can set up a pool of NFS servers on various nodes in your cluster and connect to them using virtual IP addresses (VIPs) to achieve High Availability (HA) with failover; if one node fails, the VIP will automatically be reassigned to another NFS node in the pool. If you do not specify a list of NFS nodes to form a pool, then MapR uses any available node running the MapR NFS Gateway service. VIPs are not assigned to any nodes that are not on the list, regardless of whether they are running NFS.

Note: To add a server to an NFS pool that is not divided into subnets, start the MapR NFS service on that server. The MapR cluster automatically detects it and adds it to the pool.

The following illustration shows three nodes (Host1, Host2, and Host3) acting as NFS servers. Each node has two NICs whose ports are labeled eth0 and eth1. The NICs are grouped into two subnets, called Subnet A and Subnet B. Clients can access any of the NFS servers through a pool (or range) of VIPs assigned to each subnet. MapR assigns each VIP address in the pool at random to a MAC address in the subnet (with its corresponding physical IP address).

last-updated: Apr 11, 2022



The initial VIP assignment shown above is summarized in the following table. If one NFS server becomes unavailable, the VIP assigned to that server is automatically assigned to another server on the same subnet.

Server	Subnet	VIPs (randomly assigned)
NFS1	A	VIP2
NFS2	A	VIP3
NFS3	A	VIP1
NFS1	B	VIP4
NFS2	B	VIP6
NFS3	B	VIP5

If the cluster's NFS nodes have multiple network interface cards (NICs) connected to different subnets, you should restrict VIP assignment to the NICs that are on the correct subnet: for each NFS server, choose whichever MAC address is on the subnet from which the cluster will be NFS-mounted, then add it to the list.

Warning: If you add a VIP that is not accessible on the subnet, then failover will not work. Also, do not use duplicate MAC addresses. For example, for bonding interfaces on the cluster nodes, do not use the same MAC address for bond0 and bond0.X, as then the failover of VIP might not work.

You can only set up VIPs for failover between network interfaces that are in the same subnet. In large clusters with multiple subnets, you can set up multiple groups of VIPs to provide NFS failover for the different subnets.

last-updated: Apr 11, 2022

VIPs are evenly distributed across NFS nodes. For example, if six VIP addresses are available for three NFS servers, two VIPs are assigned to each server. If the previous example did not have two separate subnets, the six VIP addresses might be assigned like this:

Server	VIPs (randomly assigned)
N/FS1	VIP1, VIP3
NFS2	VIP4, VIP5
NFS3	VIP2, VIP6

The following sections describe how to set up, edit, and remove VIPs using the Control System and the CLI.

Using Consistent Export Rules
Lists the default NFS export rules.

Export rules (stored in `conf/exports`) should be the same across all NFS nodes that are in the same VIP pool, and for nodes that are configured for the same VIP failover. The default version of `conf/exports` is as follows:

```
# Sample Exports file

# for non /mapr exports
# <Path>  <comma separated cldb addresses=host:port> <exports_control>

# for /mapr exports
# <Path> <exports_control>

#access_control -> order is specific to default
# list the hosts before specifying a default for all
#  a.b.c.d,1.2.3.4(ro) d.e.f.g(ro) (rw)
#  enforces ro for a.b.c.d & 1.2.3.4 and everybody else is rw

# special path to export clusters in mapr-clusters.conf. To disable
exporting,
# comment it out. to restrict access use the exports_control
#
/mapr (rw)

#to export only certain clusters, comment out the /mapr & uncomment.
# Note: this will cause /mapr to be unexported
#/mapr/clustername (rw)

#to export /mapr only to certain hosts (using exports_control)
#/mapr a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster1 rw to a.b.c.d & ro to e.f.g.h (denied for others)
#/mapr/cluster1 a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster2 only to e.f.g.h (denied for others)
#/mapr/cluster2 e.f.g.h(rw)

# export /mapr/cluster3 rw to e.f.g.h & ro to others
#/mapr/cluster2 e.f.g.h(rw) (ro)
```

Setting Up VIPs for NFSv3
Explains how to set up VIPs for NFS version 3 using either the Control System or the CLI.

last-updated: Apr 11, 2022

Note: The NFSv3 server (`mapr-nfsserver`) nodes cannot failover to NFSv4 server (`mapr-nfs4server`) nodes and vice versa. Ensure that different sets of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary when both NFSv3 and NFSv4 are going to be set up on the same cluster). The MACs should be mutually exclusive as both NFSv3 and NFSv4 servers cannot run on the same node.

Adding VIPs Using the Control System

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure:

- You have installed NFS on at least three nodes (recommended).
- You have started the NFS gateway service on the servers to which you plan to assign VIPs.

1. Log in to the Control System, click **Services**, and go to the NFS service information page where you can configure VIPs for NFSv3 nodes.

   Note: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.

   MapR distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.

   If you are assigning only one VIP, you can leave the field blank. MapR distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
5. Enter the Netmask for the VIP range in the **Netmask** field.

   For example: `255.255.255.0`. MapR assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
   - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.

     If additional NFS Gateway services are started, the network interfaces on their nodes will automatically become candidates for the VIPs in this range.
   - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:

     A list of available and selected node names, physical IP addresses, and MAC addresses displays. Select from the:
     - Available list and click ▶ to move selection to **Selected** VIPs.
     - Selected list and click ◀ to remove from selected list of VIPs.

last-updated: Apr 11, 2022

See Designating NICs for MapR on page 844.

8. Confirm the actual VIP assignment by clicking **Save Changes**.
   It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Adding VIPs Using the CLI and REST API

CLI

The basic command to set up VIPs is:

```
maprcli virtualip
add -netmask <netmask> -virtualip
<virtualip> -service nfs3 -json
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/virtualip/add?
service=nfs3&netmask=<netmask>&virtual
ip=<vip>' --user mapr:mapr
```

For the complete list of required and optional parameters, see `virtualip add` on page 1904.

Setting Up VIPs for NFSv4
Describes how to setup Virtual IPs (VIPs) for high availability of NFSv4 servers, using either the Control System or the CLI.

Virtual IP addresses (VIPs) allow you to achieve high availability with failover when the NFS servers use them to connect to your cluster. When configuring VIPs for NFSv4 servers, ensure that you select NFSv4 server nodes only. MapR does not support failing over between NFSv3 and NFSv4 servers.

Adding VIPs Using the Control System

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure that:

- You have installed NFS on at least three nodes (recommended).
- You have started the NFS gateway service on the servers to which you plan to assign VIPs.

1. Log in to the Control System and go to the NFS4 service information page where you can configure VIPs for NFSv4 nodes.
2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.
   MapR distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.
   If you are assigning only one VIP, you can leave the field blank. MapR distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
5. Enter the Netmask for the VIP range in the **Netmask** field.
   For example: `255.255.255.0`. MapR assigns this netmask to the network interfaces along with the VIPs.

6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
   - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.

     If additional NFS Gateway services are started, the network interfaces on their nodes automatically become candidates for the VIPs in this range.
   - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:

     The system displays a list of available and selected node names, physical IP addresses, and MAC addresses. Do one of the following:
     - Select from the available list and click ▶ to move the selection to **Selected** VIPs.
     - Choose from the selected list and click ◀ to remove the chosen entries from the selected list of VIPs.

     See Designating NICs for MapR on page 844.
8. Confirm the actual VIP assignment by clicking **Save Changes**.

   It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Setting up VIPs for NFSv4 Server from the Command-Line

To set up VIPs for NFSv4 server:

1. Add VIPs to the NFS server nodes in the cluster by running the `virtualip add` on page 1904 command.

   ```
   maprcli virtualip add -virtualip <vip> -virtualipend <vipend> -service
   nfs4 -netmask <netmask> -macs <mac>
   ```

   For example, for a range of virtual IPs use:

   ```
   maprcli virtualip add -virtualip 10.10.104.203 -virtualipend
       10.10.104.206 -service nfs4 -netmask 255.255.255.0 -macs
      "18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
   ```

   For a single virtual IP, do not include the `-virtualipend` parameter. For example:

   ```
   maprcli virtualip add -virtualip 10.10.104.203 -service nfs4 -netmask
   255.255.255.0 -macs
      "18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
   ```

   For the complete list of required and optional parameters, see `virtualip add` on page 1904.
2. Add the hostname for each VIP in the `/etc/hosts` file on all the nodes in the cluster.
3. Add the principal for each VIP and generate the keytab file. That is, repeat this step in the following order for each VIP:

   a) Add the principals for the following:
      - NFS server hostnames in the kerberos server.

- VIP hostname in the kerberos server.

b) Generate the keytab file, which contains entries for all the NFS server and VIP hostname principals.

4. Restart the `rpc.gssd` service on all the NFSv4 server nodes.
   To restart, run the following command:

```
service rpcgssd start
```

5. Mount the cluster.

Editing a VIP
Explains how to modify the Virtual IP (VIP) range using either the Control System or the CLI.
Editing a VIP Using the Control System

1. Log in to the Control System and go to the service information page for NFS.
2. Click the **VIP Range** to modify.
   The **Edit Virtual IP** page displays.
3. Modify changes to one or more of the following as needed.

Preferred MAC Address	The preferred MAC for this virtual IP. When an NFS server restarts, the MapR system attempts to move all of the virtual IP addresses that list a MAC address on this node as a preferred MAC to this node. If the new value is null, this field resets the preferred MAC value.
Select network interfaces	The list of MAC addresses that represent the NICs on the nodes to which the VIPs in the VIP range can be associated. Use this list to limit VIP assignment to NICs on a particular subnet when your NFS server is part of multiple subnets.

4. Click **Save Changes** for the changes to take effect.

Editing a VIP Using the CLI and REST API

CLI

The basic command to modify a VIP range is:

```
maprcli virtualip edit -netmask
<netmask> -virtualip <virtualip>
```

REST

Send a request of type POST. For example:

```
durl -k -X POST 'https://<host>:8443/
rest/virtualip/edit?
netmast<netmask>&virtualip=<vip>' --us
er mapr:mapr
```

For the complete list of required and optional parameters, see `virtualip edit` on page 1907.

Viewing the List of Virtual IPs
Explains how to view the list of VIPs using either the Control System or the CLI.
Viewing the List of VIPs Using the Control System

- Log in to the Control System and go to the service information page for NFS.
  The page displays the following:

Column Name	Column Description
VIP Range	The Virtual IP range.
Virtual IP	The VIP (in the range) of the associated node.
Node Name	The host name of the node.
Physical IP	The physical IP of the associated node.
MAC Address	The MAC address of the network interface that is assigned to the associated VIP.

You can add and remove VIPs.

Retrieving the List of VIPs Using the CLI and REST API

CLI

The basic command to retrieve a list of VIPs is:

```
maprcli virtualip list
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://<host>:8443/
rest/virtualip/list' --user mapr:mapr
```

For complete reference, see `virtualip list` on page 1908.

Removing a VIP

Explains how to remove a VIP range using either the Control System or the CLI.

Removing a VIP Range Using the Control System

1. Log in to the Control System and go the service information page for NFS.
2. Select the VIP range(s) to remove and click **Remove Virtual IP**.
   The **Remove Virtual IP** confirmation dialog displays.
3. Review the VIP range(s) to remove and click **Remove Virtual IP**.

Removing a VIP Range Using the CLI or REST API

The basic command to remove a VIP range is:

```
maprcli virtualip remove -virtualip <virtual IP>
```

For complete reference information, see `virtualip remove` on page 1912.

Accessing Data with NFS v3

Describes how MapR works with NFS v3.

Unlike other Hadoop distributions that only allow cluster data import or import as a batch operation, MapR lets you mount the cluster itself using NFS so that your applications can read and write data directly. MapR allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With a NFS-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS.

MapR exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v3 paths to the cluster will be the same. This makes it easy to work on the same files using NFS v3

last-updated: Apr 11, 2022

and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

Warning: MapR uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS v3.

You can mount the cluster on a Linux, Mac, or Windows client. Before you begin, make sure you know the hostname and directory of the NFS v3 share you plan to mount.

Starting, Stopping, and Restarting MapR NFSv3
Explains how to start, stop, and restart NFS version 3 using either the Control System or the CLI.
Starting, Stopping, and Restarting MapR NFSv3 Using the Control System

See:

- Starting the Services on the Cluster Using the Control System on page 830
- Stopping a Service on the Cluster Using the Control System on page 831
- Restarting the Services on the Cluster Using the Control System on page 832

Starting, Stopping, and Restarting MapR NFSv3 Using the CLI and REST API

NFSv3 Server	The command to stop, start, or restart MapR NFSv3 server is: `maprcli node services -nodes <node names> -nfs stop|start|restart`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<nodeNames>&nfs=stop|start|restart' -- user mapr:mapr`

Note: When NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers. For the complete list of parameters, see `node services` on page 1730.

Setting Up Aliases for NFS Exports

When provisioning MapR File System for various tenants, you can set up an alias for the path in MapR File System, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in MapR File System.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in MapR File System (`/mapr`). To set up an alias for a path in MapR File System:

1. Open the NFS exports file in `/opt/mapr/conf/` directory.
2. Specify the alias name for the mount path using the following syntax:

   ```
   <path in MFS> /<alias name> <options>
   ```

   Here:

`<path in MFS>`	Refers to the MapR File System mount path. If this points to a:

	• Volume, the user can access the snapshots associated with the volume. • Directory, the user cannot access the snapshots.
`/<alias name>`	Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in MapR File System will be exported.
`<options>`	The list of available/supported options.

For example, suppose a MapR File System mount path of `/mapr/samplecluster/samplevolume` for tenant samplecustomer. To set up an alias, add the following to the exports file:

```
/mapr/samplecluster/samplevolume /samplecustomer (rw)
```

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

Note: Only the alias will be visible/exposed to the NFS client.

3. Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprcli nfsmgmt refreshexports
```

4. Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Mounting NFS to MapR File System on a Cluster Node

You can *automatically* or *manually* mount NFS to the MapR File System on a cluster node.

Automatically Mount

Use this procedure to *automatically* mount NFS to MapR File System on the cluster *my.cluster.com* at the `/mapr` mount point.

1. Set up the mount point by creating the directory.

```
sudo mkdir /mapr
```

last-updated: Apr 11, 2022

2. Add the following line to `/opt/mapr/conf/mapr_fstab`:

```
<hostname>:/mapr /mapr hard,nolock
```

Note: The change to `/opt/mapr/conf/mapr_fstab` will not take effect until Warden is restarted.

Every time your system is rebooted, the mount point is automatically re-established according to the `mapr_fstab` configuration file.

Manually Mount

Use this procedure to *manually* mount NFS to MapR File System on the cluster *my.cluster.com* at the `/mapr` mount point.

1. Set up a mount point for a NFS share.

```
sudo mkdir /mapr
```

2. Mount the cluster via NFS.

```
sudo mount -o hard,nolock usa-node01:/mapr /mapr
```

Note: When you mount manually from the command line, the mount point does not persist after a reboot.

Mounting NFS on a Linux Client

Explains how to mount NFS on a Linux client either automatically at start up or manually.

You can *automatically* or *manually* mount NFS on a Linux client when your system starts up.

Automatically Mount

Use this procedure to *automatically* mount to NFS on a Linux client when your system starts up.

Add an NFS mount to `/etc/fstab`.

```
# device          mountpoint      fs-type      options      dump fsckorder
...
usa-node01:/mapr  /mapr_nfs/         nfs          rw           0    0
...
```

Manually Mount

Use this procedure to *manually* mount to NFS on a Linux client.

1. Install the NFS client.
   - `sudo yum install nfs-utils` (Red Hat or CentOS)
   - `sudo apt-get install nfs-common` (Ubuntu)
   - `sudo zypper install nfs-client` (SLES)

2. List the NFS shares exported on the server. For example:

```
showmount -e usa-node01
```

Note: If the NFS protocol is v4 only, the `showmount` command does not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

3. Set up a mount point for an NFS share. For example:

```
sudo mkdir /mapr_nfs/
```

4. Mount the cluster using NFS. Use the command as in the following example:

```
sudo mount -t nfs -o sec=mode vers=NFS_version usa-node01:/mapr /
mapr_nfs/
```

where mode is one of the following:

- krb5 for Kerberos version 5 authentication service.
- krb5i for Kerberos version 5 with integrity.
- krb5p for Kerberos version 5 with privacy.
- none for no authentication.

and NFS_version is either 3 or 4.

Restriction: You can use the `sec=mode` option only for NFS version 4. NFS version 3 does not support this option.

Tip: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs -o sec=krb5,vers=4.0 usa-node01:/mapr /mapr_nfs/
```

For NFS v3, use the command as in the following example:

```
mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
```

Note: The mount point does not persist after reboot when you mount manually from the command line.

5. List all mounted file systems to verify that the cluster is mounted. For example:

```
$ mount | grep nfs4
  usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
```

Mounting NFS on a Mac Client
Describes how to mount a NFS server on a Mac client.

last-updated: Apr 11, 2022

Use this procedure to mount to the cluster *manually* from the command line:

1. Open a terminal. For example, you can click on **Launchpad > Open terminal**.
2. At the command line, enter the following command to become the root user:
   `sudo bash`
3. List the NFS shares exported on the server. For example:
   ```
   showmount -e usa-node01
   ```
4. Set up a mount point for an NFS share. For example:
   ```
   sudo mkdir /mapr_nfs/
   ```
5. Mount the cluster using NFS. Use the command as in the following example:
   ```
   sudo mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
   ```
   Note: The mount point does not persist after reboot when you mount manually from the command line.
6. List all mounted file systems to verify that the cluster is mounted. For example:
   ```
   $ mount | grep nfs
   usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
   ```

Mounting NFS on a Windows Client
Describes how to mount an NFS share on a Windows client, and configure the relevant user and group IDs.

To set up the Windows NFS client, mount the cluster, map a network drive, and configure the user ID (UID) and group ID (GID). The Windows client must access NFS using a valid UID and GID from the Linux domain. Mismatched UID or GID results in permission problems when MapReduce jobs try to access files that were copied from Windows over an NFS share.

Due to Windows directory caching, the `.snapshot` directory may not appear in the root directory of each volume. As a workaround, you can force Windows to re-load the volume's root directory by updating its modification time (for example, by creating an empty file or directory in the volume's root directory).

With Windows NFS clients, use the `-o nolock` option on the NFS server to prevent the Linux NLM from registering with the portmapper. The native Linux NLM conflicts with the MapR NFS server.

Complete the following steps to mount NFS on a Windows client:

1. Mount the Cluster.

Windows 10 Enterprise	Complete the following steps for *Windows 10 Enterprise* **a.** Open **Start > Control Panel > Programs**. **b.** Select **Turn Windows features on or off**. **c.** Select **Services for NFS**. **d.** Click **OK**.

e. Enable write permissions for the anonymous user as the default options only grant read permissions when mounting a UNIX share using the anonymous user.

To grant write permissions, make a change to the Windows registry by performing the following steps:

1. Open `regedit` by typing it in the search box and pressing **Enter**.
2. Create a new **New DWORD (32-bit) Value** inside the `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default` folder named `AnonymousUid` and `AnonymousGid` and assign the UID and GID found on the UNIX directory as shared by the NFS system.

f. Restart the NFS client or reboot the machine to apply the changes.

g. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o anon usa-node01:/mapr z:
```

For more information, see step 2.

Windows 7 Enterprise

Complete the following steps for *Windows 7 Ultimate* or *Windows 7 Enterprise*

a. Open **Start > Control Panel > Programs**.

b. Select **Turn Windows features on or off**.

c. Select **Services for NFS**.

d. Click **OK**.

e. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr
z:
```

For more information, see step 2.

Other Versions of Windows

Complete the following steps for all other versions of Windows:

a. Download and install Microsoft Windows Services for Unix (SFU). You only need to install the NFS Client and the User Name Mapping.

last-updated: Apr 11, 2022

b. Configure the user authentication in SFU to match the authentication used by the cluster (LDAP or operating system users). You can map local Windows users to cluster Linux users, if desired.

c. Once SFU is installed and configured, mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr
z:
```

For more information, see step 2.

2. Map a network drive with the Map Network Drive tool.

a) Open **Start > My Computer**.

b) Select Tools > Map Network Drive.

c) In the Map Network Drive window, choose an unused drive letter from the **Drive** drop-down list.

d) Specify the folder by browsing for the MapR cluster, or by typing the hostname and directory into the text field.

e) Browse for the MapR cluster or type the name of the folder to map. This name must follow UNC. Alternatively, click **Browse…** to find the correct folder by browsing available network shares.

f) Select **Reconnect at login** to reconnect automatically to the MapR cluster whenever you log into the computer.

g) Click **Finish**.

3. Configure the UID and GID for NFS access.

System that is part of Active Directory Domain

For a system that is part of the Active Directory Domain, you must instruct the NFS client to access an AD server to get `uidNumber` and `gidNumber`.

a. Ensure that the AD Users schema has auxiliary class `posixAccount`.

b. Populate the AD `uidNumber` and `gidNumber` fields with the matching `uid` and `gid` from Linux.

c. Configure the NFS client to look up `uid` and `gid` in the AD DS store.

d. Refer to details here: `http://technet.microsoft.com/en-us/library/hh509016(v=ws.10).aspx`.

System not using Active Directory

For a standalone Windows 7 or Vista machine (not using Active Directory), Windows always uses its configured anonymous UID and GID for NFS access, which by default are `-2`. However, you can configure Windows to use specific values, which results in being able to access NFS using those values.

last-updated: Apr 11, 2022

The UID and GID values are set in the Windows Registry and are global on the Windows NFS client box. This solution might not work well if your Windows box has multiple users who each need access to NFS with their own permissions, but there is no obvious way to avoid this limitation.

The values are stored in the registry path `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default`. The two DWORD values are `AnonymousUid` and `AnonymousGid`. If they do not exist, you must create them.

Refer to details here: `https://docs.microsoft.com/en-us/archive/blogs/msdn/sfu/can-i-set-up-user-name-mapping-in-windows-vista`.

4. (Optional) Deactivate the `nlockmgr` service.

If the `nlockmgr` service is active on a Windows machine, attempts to mount a MapR NFS share fail with the following message:

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr / g:
Network Error - 53
Type 'NET HELPMSG 53' for more information.
```

a) Run the `rpcinfo` command to confirm that the `nlockmgr` service is active.

```
C:\Users\administrator.Client1>rpcinfo -p ClusterNode1
program version protocol     port
-------------------------------------------------
100000       4      tcp      111    portmapper
100024       1      udp    60588    status
100007       2      udp      817    ypbind
100021       1      udp    47016    nlockmgr
100021       3      udp    47016    nlockmgr
100021       4      udp    47016    nlockmgr
100021       1      tcp    34254    nlockmgr
100021       3      tcp    34254    nlockmgr
100021       4      tcp    34254    nlockmgr
```

b) Check the output for the presence of `nlockmgr`. To deregister `nlockmgr` services on the node, use the `-d` switch in `rpcinfo` on the MapR node.

```
rpcinfo -d 100021 1
rpcinfo -d 100021 2
rpcinfo -d 100021 3
rpcinfo -d 100021 4
```

c) Re-check `rpcinfo` output to verify that no `nlockmgr` services are registered. The NFS mount completes successfully at this point.

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr/ Z:
Z: is now successfully connected to ClusterNode1:/mapr/
The command completed successfully.
```

Configuring Access When ACES are set

Some NFS clients, such as the Microsoft native Windows NFSv3 client, check mode bits to determine if access is allowed even before contacting the NFS server. If *ACE*s are set on a directory or file, the client-side permission checks based solely on mode bits prevent the client from accessing the file or directory. You can set the value for the `WindowsAceSupport` property to `true` in the `nfsserver.conf` `on page 2207` file to allow the Windows client access to the file or directory. The default value for this property is `false`, and denies access to the client even before contacting the NFS server.

When the `WindowsAceSupport` property value is set to `true`, MapR returns mode bits 777 to the client if *ACE* is set on the file or directory, thus allowing the client to establish a connection to the server. However, when the client actually tries to read or write from the server, MapR performs permission checks against the mode bits and *ACE*s on the directory and/or file, ensuring proper access.

Note: When the `WindowsAceSupport` property value is set to `true`:

- Tools that visually display access information might show read/write access for users who do not have that access.
- Files that are not executables might appear executable.
- You cannot use the NFSv3 to access an NFSv4 server, because the NFSv4 server only supports the v4 protocol.

Configuring the Linux NFS Client

Describes how to set the optimal number of RPC requests to the NFS server.

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
```

2. To enable the configuration to take effect after you remount the NFS client to the NFS gateway, issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS gateway. For example, the following commands unmount and mount NFS assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

Note: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfsserver.log`:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

Tip: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Accessing Data with NFS v4

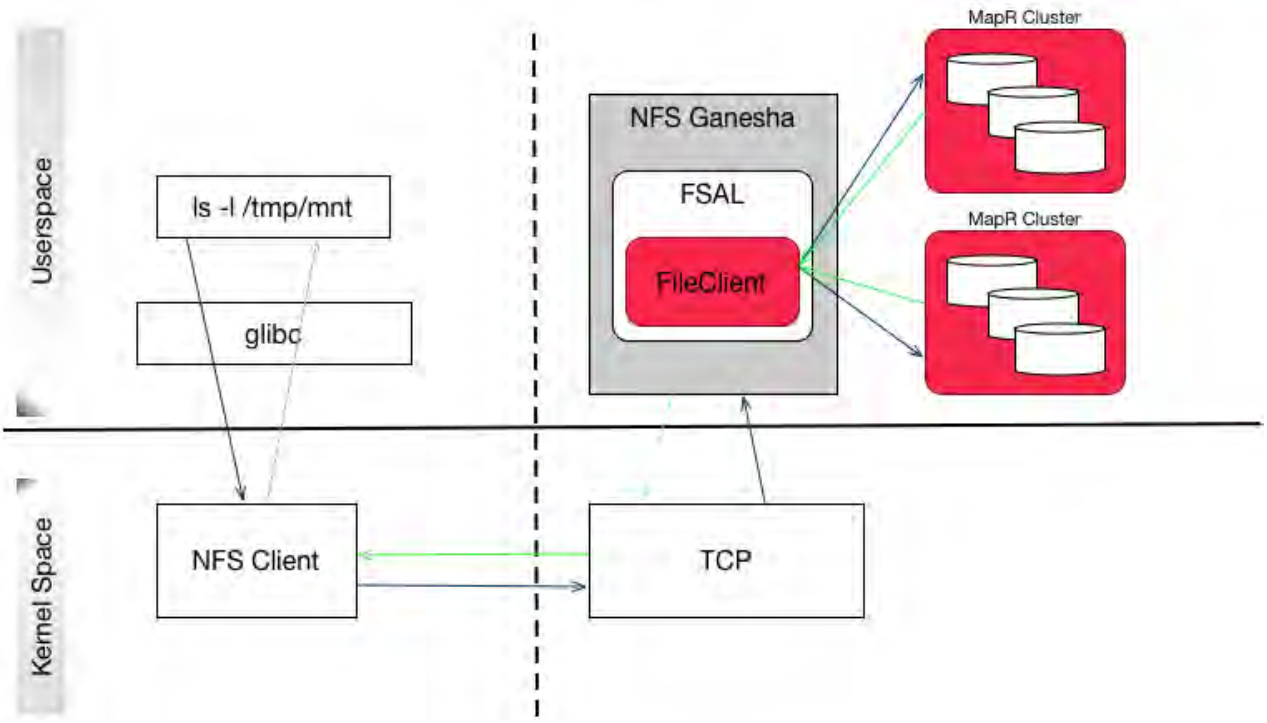
Describes how MapR works with the NFS v4 protocol. Presents an overview of the process flow to read and write MapR processes with NFS v4, and a list of NFS v4 features that MapR does not support.

MapR lets you mount the cluster using NFS v4 so that your applications can read and write data directly. MapR allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With an NFS v4-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS v4.

MapR uses NFS Ganesha for supporting NFS v4 features. NFS Ganesha is an Open Source userspace implementation of the NFS v4 server. MapR version 6.1 uses NFS Ganesha version 2.3, while HPE Ezmeral Data Fabric 6.2 uses an upgraded version 3.3 of NFS Ganesha.

The MapR NFS v4, running as a userspace process, registers callbacks with NFS Ganesha through the File System Abstraction Layer (FSAL), which is a shared library (`libfsalmapr.so`). NFS Ganesha loads and uses this library whenever the MapR File System is exported/mounted. The FSAL, in turn, uses FileClient (`libMapRClient.so`) to connect to the cluster.

The following diagram illustrates how the MapR processes read and write operations to the MapR cluster using NFS v4. When the user enters a command (such as `ls`), the NFS client submits the request over TCP to the MapR NFS v4 server. The NFS v4 server uses the MapR FileClient to perform the requested operation on the cluster and returns the response to the NFS v4 client over TCP.



MapR exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v4 paths to the cluster are the same. This makes it easy to work on the same files using NFS v4 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

For NFS v4, MapR also requires alias or pseudo-path, which when specified masks the mount path from the NFS v4 client. MapR's NFS v4 server provides a pseudo-filesystem where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. For more information, see NFS v4 RFC.

Unsupported NFS v4 Features

MapR does not currently support the following NFS v4 features:

- pNFS
- Delegations
- Mandatory locking
- Lock upgrades and downgrades
- Deny share
- *ACL*
- Namespaces
- Persistent reply cache
- Data retention

- Attributes such as time_access, FATTR4_ARCHIVE, FATTR4_FILES_AVAIL, FATTR4_FILES_FREE, FATTR4_FILES_TOTAL, FATTR4_FS_LOCATIONS, FATTR4_MIMETYPE, FATTR4_QUOTA_AVAIL_HARD, FATTR4_QUOTA_AVAIL_SOFT, FATTR4_QUOTA_USED, FATTR4_TIME_BACKUP, and FATTR4_ACL

Configuring NFSv4 Server

You can configure NFSv4 server by setting the values for the parameters in the `/opt/mapr/conf/nfs4server.conf` file. The configuration parameters are defined within blocks in the file. The following sections describe the blocks and required parameters (within each block) for the MapR NFSv4 server.

NFS_CORE_PARAM

Contains the general settings for the daemon. The parameters in this block should not be modified.

`Clustered`	The value is `false`. Do not modify this parameter.
`Plugins_Dir`	The directory for the FSAL libraries. The value is `/opt/mapr/lib`. Do not modify this parameter.
`DRC_TCP_Size`	The maximum number of results stored in the DRC. The default value is `16`.
`DRC_TCP_Recycle_Expire_S`	The amount of time after which to expire results stored in DRC. The default value is `60` seconds.
`Dirent_Entries_Track`	Specifies whether (`true`) or not (`false`) to monitor dirent entries. If `true`, the process restarts if the number of dirent entries exceeds limit.
`Num_Log_Files`	The maximum number of log files. The default value is `1`.
`Max_Logfile_Size`	The maximum amount of space for each log file. The default value is `1073741824`. The total amount of disk space for log files is calculated using the following: `Num_Log_Files * Max_LogFile_Size` For example, suppose `Num_Log_Files = 32` and `Max_LogFile_Size = 1GB`. Then, the total disk space for log files is 32GB.

`Enable_RQUOTA`	Specifies whether (`true`) or not (`false`) to enable support for remote quotas. The default value is `false`.
`NFS_Protocols`	The supported NFS protocols. The only supported value is 4.

NFSV4

Contains settings for NFSv4 protocol. The following parameter should not be modified.

`Delegations`	boolean	Specifies whether delegation is supported. The default value is `false` and should not be modified (cannot be set to `true`) as delegation is not supported.
`Dirent_Cache_Threshold`	128	The threshold for caching directory entries. If directory entries exceed threshold, the entries are not cached; caching is enabled only if entries are below this threshold. **Note:** This should be used only if `readdirplus` is `true`.

EXPORT_DEFAULTS

Contains default values for all subsequent EXPORT blocks. The settings in subsequent EXPORT blocks can override these default values on a per export basis.

`Anonymous_Uid`	The anonymous UID. The default value is `-2`, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled.

`Anonymous_Gid`	The anonymous GID. The default value is `-2`, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled.
`Protocols`	The supported NFS protocols. The default value is `4`. This cannot be changed.

EXPORT

Contains settings for exporting a filesystem.

`SecType`	The comma-separated list of supported authentication flavors for the export or the type of security. Value can be comma-separated list of: • krb5 — authentication • krb5i — integrity • krb5p — privacy  **Note:** This *must* be specified if you want the clients to use kerberos ticket for secure access.
`Path`	(Required) The (cluster) path to export via NFS. The path should have a leading slash. If just `/mapr` is specified as the path, all the clusters (listed in the `mapr-clusters.conf` file) will be visible. To export only a specific cluster, specify the complete path to the cluster to export.  **Note:** Exporting will not be successful if extra forward slash (`/`) characters are in the path. For example, the following path will not be exported because of the extra slash (shown in bold) in the path: `/mapr/Test3//ATS-VOLUME`

last-updated: Apr 11, 2022

`Pseudo`	(Required for NFSv4 protocol for every directory or volume to export) The pseudo path, which when specified, masks the mount path from the NFS client, for the NFSv4 exports. MapR's NFSv4 server provides a pseudo-filesystem where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. When mounting with NFSv4, use the pseudo path. Value can be the volume or directory path.
`Export_Id`	(Required) The tag used to set the ID for the export or the unique ID to associate with each export. Value should not be 0.  **Note:** The export ID associated with each export must be the same across all NFSv4 servers on the cluster.
`Clients`	The list of clients these export permissions apply to. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients.

`Squash`	Specifies whether to enable or disable root squashing. By default, root squashing is disabled. If root squash is enabled, the values substituted for the root user will be anonymous user (`Anonymous_Uid` and `Anonymouos_Gid`); that is, the UID and GID of a file created will not be `nfsnobody` because the default value of -2 is converted to a 32 bit unsigned integer (4294967294) instead of the 16 bit equivalent (65534), which is the value of nfsnobody.
`Access_Type`	(Required) The type of access on the mount point. Valid values include: • RO — for read-only mount point • RW — for read/write mount point • MDONLY — for read/write access to metadata only • MDONLY_RO — for read-only access to metadata only
FSAL	(Required) The filesystem to use. Value must be MAPR to use the MapR File System `libfsalmapr.so` library, which contains the shared library (`libMapRClient`) and the callbacks.

LOG

Contains configuration for logging. The default log level is INFO. Value can be one of the following:

- FATAL
- MAJ
- CRIT
- WARN
- EVENT
- INFO

last-updated: Apr 11, 2022

- DEBUG
- MID_DEBUG
- FULL_DEBUG

MAPRFS

Contains configurations for NFS gateway access to MapR filesystem.

Parameter	Default Value	Description
`log_path`	`/opt/mapr/logs/nfs4`	Path for the log files.
`ra_sessions`	`5`	Number of parallel read ahead sessions per client library (`libMapRClient.so`). Each open file acts as one read ahead session. For example, if value is set to `5`, up to `5` files can have read ahead sessions per client library (`libMapRClient.so`). To disable read ahead sessions, set value to `0`. **Note:** The number of client libraries is 3 by default and cannot be configured.

last-updated: Apr 11, 2022

Parameter	Default Value	Description
`flush_inline`	`true`	Specifies whether or not to flush all writes inline. Value can be: • `true` — flush all writes inline • `false` — disable inline flushing If enabled (default), writes are sent to server directly. If disabled, for all open files, the buffer is flushed automatically every 3 seconds or when it reaches 64KB.
`fast_local_directio`	`false`	Specifies whether to optimize or disable NFS client for local direct IO. Value can be: • `true` — optimize • `false` — disable
`nfs_track_memory`	`false`	Specifies whether to enable (`true`) or disable (`false`) memory tracking for NFS.

Parameter	Default Value	Description
`hb_interval`	`5`	The interval (in seconds) for sending heartbeat to CLDB to allow CLDB to determine whether server is running. The CLDB will declare the NFS gateway dead when it loses about 8 heartbeats in a row and will trigger a failover.
`req_threshold`	`5`	The amount of time (in seconds) for processing requests. If the threshold is exceeded, warnings will be logged.

Parameter	Default Value	Description
`client_lib_path`	`/tmp/nfs4`	The location for the client library (`libMapRClient`). **Note:** To install and use NFSv4 and FUSE-based POSIX client on the same node, ensure that the path for the client library for the NFSv4 and FUSE-based POSIX client is not `/tmp`. Specify a different location for the client libraries. For example, `/tmp/nfs4lib`.
`readdirplus`	`true`	Specifies whether (`true`) or not (`false`) to enable extended read from the directory. If enabled (`true`), each entry returns the name, the file ID, attributes (including the field), and file handle.

last-updated: Apr 11, 2022

Note:

- The `libnfsidmap` must be configured to use `nsswitch`, a translation mechanism for mapping names to IDs, in the `/etc/idmapd.conf` file.
- The NFSv3 (mapr-nfsserver) nodes cannot failover to NFSv4 server nodes and vice versa. Ensure that different set of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary if both NFSv3 and NFSv4 are going to be set up for same cluster). The MACs should be mutually exclusive as both NFSv4 and NFSv3 servers cannot run on the same node.

Sample Configurations

You can refer to the following sections, which contain blocks for the various required configurations using sample values.

Configuration for Supported NFS Protocols

To specify the supported NFS protocols, set the value for the `NFS_Protocols` parameter in the `/opt/mapr/conf/nfs4server.conf` file. For example, for NFSv4 protocol, in the `/opt/mapr/conf/nfs4server.conf` file, set the value for the `NFS_Protocols` parameter as shown (in bold) below.

```
NFS_CORE_PARAM
{
        Plugins_Dir = /opt/mapr/lib;
        NFS_Protocols = 4;
        Clustered = false;
}
```

Note: The only supported protocol is `4`.

For NFSv4, the `showmount` command does not return the list of exported NFS shares.

Configuration for Mounting the Cluster

Add the `MAPRFS` block in the `/opt/mapr/conf/nfs4server.conf` file as shown below.

```
MAPRFS
{
  #Directory path where nfsv4 logs should be stored
  log_path = /opt/mapr/logs/nfs4;

  #Set number of readahead sessions
  ra_sessions = 5;

  #Flush all writes inline
  flush_inline = true;

  #Optimize for local direct writes
  fast_local_directio = false;

  #Set security ticket file
  tkt_location = /tmp/maprticket_XXX;

  #Hearbeat interval for NFSv4 (in seconds)
  hb_interval = 5;

  #Request threshold, logs warning if any request takes more time (in
seconds)
```

```
  req_threshold = 5;
}
```

Configuration for Exporting the File System

Modify the EXPORT block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below. The following sample block shows a standard configuration where the exported path and the actual path are the same.

```
EXPORT
{
     # Export Id (mandatory, each EXPORT must have a unique Export_Id)
     Export_Id = 77;

     # Exported path (mandatory)
     Path = /mapr;

     # Pseudo Path (required for NFS v4)
     Pseudo = /mapr;
     Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
     Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
     SecType = krb5;

    # Exporting FSAL
      FSAL {
      Name = MAPR;
    }

}
```

Note: If you change anything in the export block, restart NFSv4 service and remount the path.

Configuration for Pseudo Path

To mask the path to the volume from the client, set the pseudo path. For the pseudo path, you can specify a value that is different from the path parameter to hide the true path name. To hide the full path to volumes and/or directories, specify the complete path in the EXPORT block.

For example, modify the EXPORT block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below to mask the path and show only the name of the volume to the client. Note that the following sample block shows a pseudo path that is different from the exported path.

```
EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /vol1;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
```

```
     Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
     SecType = krb5;

   # Exporting FSAL
      FSAL {
      Name = MAPR;
    }

}
```

Configuration for Security

The NFS client to NFS Server can be secured using Kerberos. Before configuring Kerberos to work with MapR, modify the `/opt/mapr/conf/nfs4server.conf` file to specify the security type. For example, modify the `EXPORT` block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below.

```
EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
      Pseudo = /vol1;
      Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
      Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
       FSAL {
        Name = MAPR;
      }

}
```

The NFSv4 server uses the ticket in `/opt/mapr/conf` directory, if it is present, to secure communication between the NFS server and the MapR cluster.

Configuration for Clients

You can add a client block to the NFSv4 server configuration specifying the list of clients to which the export permissions apply. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients. For example:

```
EXPORT
{
     # Export Id (mandatory, each EXPORT must have a unique Export_Id)
     Export_Id = 77;

     # Exported path (mandatory)
     Path = /mapr;
```

last-updated: Apr 11, 2022

```
     # Pseudo Path (required for NFS v4)
     Pseudo = /mapr;

    # Defining the clients who are allowed to export
      CLIENT
    {
     # Required for access (default is None)
     Clients=192.168.0.10, 192.168.1.0/8;
     Access_Type = RW;
     Squash = No_root_squash;
     SecType=krb5;
    }
     # Exporting FSAL
     FSAL{
         Name = MAPR;
     }
}
```

Configuration for NFS Ganesha Debug Logging

Add the following block in the `/opt/mapr/conf/nfs4server.conf` file.

```
LOG {
  COMPONENTS {
    ALL = DEBUG;
  }
}
```

Default NFSv4 Server Configuration File

The `nfs4server.conf` file is available in `/opt/mapr/conf` directory.

```
      LOG
{
  COMPONENTS {
    ALL = INFO;
  }

  FORMAT {
    EPOCH = false;
    CLIENTIP = true;
    HOSTNAME = false;
    PROGNAME = false;
    FILE_NAME = false;
    LINE_NUM = true;
    FUNCTION_NAME = true;
    COMPONENT = false;
    LEVEL = false;
    time_format = syslog_usec;
  }
}

NFSV4
{
  #Delegation is not supported.
  Delegations = false;

  #Dirent cache threshold. Use only when readdirplus is true
  #Dirent_Cache_Threshold = 128;
}
```

last-updated: Apr 11, 2022

  # Could use CLIENT blocks instead
  Access_Type = RW;

  # Security type (krb5,krb5i,krb5p)
  #SecType = krb5;

  # Exporting FSAL
  FSAL {
    Name = MAPR;
  }

  #SuperUser_Uid = 0;
}
```

Configuring NFSv4 Server for Kerberos
Describes how to configure and use NFSv4 on Kerberos.

You can configure MapR NFSv4 server to use Kerberos-based authentication. MapR supports configuration of NFSv4 server for Kerberos with Active Directory server and Kerberos with LDAP. You can also configure MapR NFSv4 server to work with other Kerberos installations. Before configuring MapR NFSv4 server for Kerberos, you must have performed the following:

- Installed packages for Kerberos server.
- Installed NFSv4 server. See Installing MapR NFS on page 386 for more information.
- Installed packages for Kerberos client.

Note: The steps in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

Configure NFSv4 Server for Kerberos with Active Directory Server

The following procedure describes how to configure the MapR NFSv4 server to work with the Kerberos available with Active Directory server. Before configuring the MapR NFSv4 server, ensure that Active

last-updated: Apr 11, 2022

Directory server is installed and all the nodes on the cluster have joined that Active Directory server. The following procedure requires the NFSv4 server to run under user `mapr` and group `maprgrp`.

1. In an Active Directory server environment, join the cluster nodes to the Active Directory server.

   Follow the sample procedure here or consult with your system administrator for assistance with installing and joining the nodes to Active Directory server.

2. Check if Kerberos tickets for host and NFS service principal are present, by running the following command:

```
# klist
klist: No credentials cache found (filename: /tmp/krb5cc_0)
```

3. Ensure host principal is available by checking to see if existing keys are present on the node.

   For example, when you run the following command, the output should look similar to the following output for `nfs4ad.com` domain:

```
# klist -kt
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp           Principal
---- ------------------- ------------------------------------------------------

   2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
   2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
   2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
   2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
   2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
   2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
   2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
   2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
   2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
   2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
```

4. Generate the host ticket by running the `kinit` command.

   For example:

```
[root@atsqa4-161 ~]# kinit -k ATSQA4-161$
[root@atsqa4-161 ~]# klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: ATSQA4-161$@NFS4AD.COM
Valid starting       Expires              Service principal
04/11/2018 03:04:38  04/11/2018 13:04:38  krbtgt/NFS4AD.COM@NFS4AD.COM
        renew until 04/18/2018 03:04:38
```

5. Add NFS service principal entry for the host in the AD server by running the `setspn` command.
   For example, for `nfs4ad.com` domain, run the following command:

```
C:\Users\Administrator>setspn -A nfs/atsqa4-161.nfs4ad.com mapr
Checking domain DC=nfs4ad,DC=com
Registering ServicePrincipalNames for CN=mapr,CN=Users,DC=nfs4ad,DC=com
        nfs/atsqa4-164.nfs4ad.com
Updated object
```

6. Get the latest service ticket for the host from the AD server by running the `kvno` command.
   For example:

```
# kvno nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM: kvno = 46
kvno nfs/qa108-43.nfs4ad.com@NFS4AD.COM
```

7. Add entry for NFS service principal key in the Kerberos keytab file, `/etc/krb5.keytab`:

```
# ktutil
ktutil:  addent -password -p nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM -k
46 -e RC4-HMAC
Ex: addent -password -p nfs/qa108-43.nfs4ad.com@NFS4AD.COM -k 46 -e
RC4-HMAC
Password for nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM:
( Give mapr user password i.e nfs4AD123 )
ktutil:  l
slot KVNO Principal
---- ---- ---------------------------------------------------------------------

   1   46      nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
ktutil:  wkt /etc/krb5.keytab
ktutil:  q
```

8. Verify that NFS service principal and host principal are in the `/etc/krb5.keytab` file by running the `klist` command.

   For example, for domain `nfs4ad.com`, run the following command and verify the entries in the file:

```
# klist -kt /etc/krb5.keytab
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp           Principal
---- ------------------- ------------------------------------------------------

   4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
   4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
   4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
   4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
   4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
   4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
   4 08/01/2018 00:29:21 ATSQA4-161$@NFS4AD.COM
   4 08/01/2018 00:29:21 ATSQA4-161$@NFS4AD.COM
   4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
   4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
   4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
  46 08/01/2018 02:58:01 nfs/atsqa4-161.nfs4ad.com@NFS4AD.COM
```

9. Ensure that `/etc/krb5.keytab` file is owned by user `mapr` and if necessary, change ownership to user `mapr`.

   For example:

```
[root@qa108-41 ~]# chown mapr:root /etc/krb5.keytab
[root@qa108-41 ~]# ls -l /etc/krb5.keytab
-rw------- 1 mapr root 4175 Jul 22 23:53 /etc/krb5.keytab
```

10. Restart the `rpcgssd` service on the host to establish GSS security contexts.

CentOS	`service rpcgssd start`
Ubuntu	`service gssd restart`

11. Enable security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.

    For example:

```
  # Security type (krb5,krb5i,krb5p)
  SecType = krb5;
```

12. Start the NFSv4 server.

    For more information, see Starting, Stopping, and Restarting MapR NFSv4 on page 1216.

13. List the shares exported on the server by running `showmount -e` command.

    If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

    ```
    /opt/mapr/server/nfs4mgr list-exports
    ```

14. Ensure that the `list-exports` command runs successfully.

    For example:

    ```
    #  maprcli nfs4mgmt list-exports
    Export Id     Path
    30            /mapr
    0             /
    ```

15. (Troubleshooting) Run the following command to restart the services if you see security-related issues.

    CentOS

    ```
    maprcli node services -nfs4
    stop -nodes `hostname` ; service
    rpcgssd restart; sleep 1; service
    rpcbind  restart ; sleep 1;
    service nfs restart ; service
    nfs stop ; sleep 2; maprcli
    node services -nfs4 start -nodes
    `hostname`
    ```

    Ubuntu

    ```
    maprcli node services -nfs4
    stop -nodes `hostname` ; service
    gssd restart; sleep 1; service
    rpcbind  restart ; sleep 1; service
    nfs-kernel-server restart ; service
    nfs-kernel-server stop ; sleep
    2; maprcli node services -nfs4
    start -nodes `hostname`
    ```

16. Set up VIPs for the NFSv4 servers:

    a) Add entries for IPs and names of VIPs in the `/etc/hosts` file on the NFSv4 server host first and then on the AD server host.

       For example:

       ```
       10.10.88.14 nfsvirtualip1
       10.10.88.15 nfsvirtualip2
       ```

    b) Add NFS service principal for the virtual IP by running the `setspn` command.

       For example:

       ```
       C:\Users\Administrator>setspn -A host/nfsvirtualip1 nfsserver
       C:\Users\Administrator>setspn -A nfs/nfsvirtualip1 nfsserver

       C:\Users\Administrator>setspn -A host/nfsvirtualip2 nfsserver
       C:\Users\Administrator>setspn -A nfs/nfsvirtualip2 nfsserver
       ```

last-updated: Apr 11, 2022

c) Restart the `rpcgssd` service on the host to re-establish GSS security contexts.
For example:

```
service rpcgssd restart
```

Configuring NFSv4 Server for Other Kerberos Installations

1. Configure NFS server for Kerberos.
Consult with your system administrator for assistance with the commands for configuring the NFS server for Kerberos-based authentication. For example, you must do the following:
   - Create a service principal with `nfs` as the service name.
   For example: `nfs/host.domain.com@REALM`
   - Generate a keytab for the NFS service principal, store it in the `/etc/krb5.keytab` file, and set correct permissions on the file.
2. Enable the security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.
For example:

```
# Security type (krb5,krb5i,krb5p)
SecType = krb5;
```

3. Start the NFSv4 server.
For more information, see Starting, Stopping, and Restarting MapR NFSv4 on page 1216.
4. List the shares exported on the server by running `showmount -e` command.
If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

5. Ensure that the `list-exports` command runs successfully.
For example:

```
#  maprcli nfs4mgmt list-exports
Export Id     Path
30            /mapr
0             /
```

Configuring NFSv4 Client

1. Ensure that NFS client has a `/etc/krb5.keytab` file with a valid principal similar to one of the following: `nfs/<client_fqdn>@<domain>@<REALM>`, `host/<client_fqdn>@<domain>@<REALM>`, or `<HOSTNAME>$@<REALM>`.
If the principal is not present, create the `keytab` file with the principal, which will be used to mount the share, for the OS (as mentioned in the OS vendor documentation).

2. Mount the cluster by running the `mount` command.
   For example:

   ```
   mount -t nfs4 -o sec=<security-type> <nfs4-server-hostname>:/
   <pseudo-path> <mount-point>
   ```

   For example:

   ```
   # mount -t nfs4 -o sec=krb5 <FQDN>:/mapr /mnt/nfs4mnt
   ```

3. Generate user ticket for the user to access the mount path.
   For example, for user `mapr` on domain `nfs4ad.com`, run one of the following commands to generate the ticket:

   - ```
     kinit mapr@NFS4AD.COM
     <Enter password>
     ```

   - ```
     echo usr2AD123 | kinit user2@NFS4AD.COM
     ```

   Note: You must renew the user ticket before it expires; otherwise, the mount path returns permissions denied error after the ticket expires.

4. (Troubleshooting) Restart the services and mount again to avoid security-related issues.

CentOS	`service rpcgssd restart; sleep 1;`
	`service rpcbind  restart ; sleep 1;`
	`service nfs stop`

Ubuntu	`service rpcgssd restart; sleep 1;`
	`service rpcbind  restart ; sleep 1;`
	`service nfs stop`

Troubleshooting: Any running IO on NFSv4 mount (with Kerberos) is stuck if the krb5 ticket expires for the current user. The mount point also hangs and becomes inaccessible.

Workaround: Restart the `rpcgssd` service with the new ticket to make the mount point accessible and re-trigger the IO to proceed.

Configuring NFSv4 Server Without Kerberos

To start using NFSv4 server without Kerberos, do the following:

1. Start the NFSv4 server.
   For more information, see Starting, Stopping, and Restarting MapR NFSv4 on page 1216.

last-updated: Apr 11, 2022

2. Verify that the list-exports command runs successfuly.
   For example:

```
#  maprcli nfs4mgmt list-exports
Export Id     Path
30            /mapr
0             /
```

3. Mount the cluster by running the `mount` command.
   For example:

```
mount -t nfs4 <nfs4-server-hostname>:/<pseudo-path> <mount-point>
```

Starting, Stopping, and Restarting MapR NFSv4
Describes how to start, stop and restart the NFS version 4 service using either the Control System, the CLI, or the REST API.
Starting, Stopping, and Restarting MapR NFSv4 Using the Control System

See:

- Starting the Services on the Cluster Using the Control System on page 830
- Stopping a Service on the Cluster Using the Control System on page 831
- Restarting the Services on the Cluster Using the Control System on page 832

Starting, Stopping, and Restarting MapR NFSv4 Using the CLI and REST API

Note: On Ubuntu 20, run the following commands before starting NFS4, Else, NFS fails to start as it cannot find the jemalloc library.

```
apt-get install libjemalloc2

ln /usr/lib/x86_64-linux-gnu/libjemalloc.so.2 /opt/mapr/lib/
libjemalloc.so.1
```

CLI	To stop, start, or restart the MapR NFSv4 server, run: `maprcli node services -nodes <node names> -nfs4 stop|start|restart`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<nodeNames>&nfs4=stop|start|restart' --user mapr:mapr`

Note: When the NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers.

For the complete list of parameters, see `node services` on page 1730.
Mounting NFS on a Linux Client
Describes how to mount a NFS server on a Linux client.

You can manually mount NFS on a Linux client when your system starts up.

Note: On nodes running CentOS, use the VIP for mounting because, by default, the mount command will use the physical IP of the node.

1. List the NFS shares exported on the server.

   For example, run the following command for NFS version 4 servers:

   ```
   /opt/mapr/server/nfs4mgr list-exports
   ```

   If the NFS protocol is not version 4 only, use the `showmount` command to retrieve the list of exported NFS shares. For example:

   ```
   showmount -e usa-node01
   ```

2. Mount the cluster using NFS.

   For example:

   ```
   mount -t nfs4 -o sec=krb5 usa-node01:/<psuedo_mapr> /mapr
   ```

   Tip: For the best performance, use NFS v4.0.

   Use the `vers=4.0` parameter in the mount command. For example:

   ```
   mount -t nfs4 -o sec=krb5,vers=4.0 usa-node01:/<psuedo_mapr> /mapr
   ```

Note: When you mount manually from the command line, the mount point does not persist after a reboot.

Configuring the Linux NFS Client
Describes how to set the optimal number of RPC requests to the NFS server.

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

   ```
   echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
   sunrpc.conf
   echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
   sunrpc.conf
   ```

2. To enable the configuration to take effect after you remount the NFS client to the NFS gateway, issue the following echo commands:

   ```
   echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
   echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
   ```

last-updated: Apr 11, 2022

3. Remount the NFS client to the NFS gateway. For example, the following commands unmount and mount NFS assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

Note: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfsserver.log`:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

Tip: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Advisory Locking in NFS v4

Explains NFS v4 support for Advisory Locking.

MapR NFS v4 service includes support for (advisory) file locking. MapR keeps track of the locks on a file in the NFS gateway, but does not prevent a client process from writing to a file that is locked by another process. The locks are not shared with other NFS gateways. Since the locks are enforced locally, it is the responsibility of the client process to check for write locks on a file before attempting to perform write operations on the file.

To ensure that a file is locked and not available for changes by other processes and to ensure that the lock on a file by a process is honored by other processes, add a program similar to the following for the process.

Sample Program Description	The following program demonstrates how to open a file, check if the file has a write lock, and wait if another process currently has locked the file. Before running this application, ensure that you have access to a cluster running MapR File System.
Opens a file	`if (argc > 1) { int fd = open(argv[1], O_WRONLY); if(fd == -1) { printf("Unable to open the file\n"); exit(1); }`
Checks if the file is locked for a write operation	`lock.l_type = F_WRLCK; lock.l_start = 0;`

```
lock.l_whence =
SEEK_SET;
    lock.l_len =
0;
    lock.l_pid =
getpid();
```

Gets lock, else waits

```
    int ret
= fcntl(fd,
F_SETLKW,
&amp;lock);

printf("Return
value of
fcntl:%d\n",ret);
    if(ret==0) {
      while (1) {

scanf("%c",
NULL);
      }
    }
```

Sample Program Code

```
#include <stdio.h>
#include <fcntl.h>

int main(int argc, char **argv) {
  if (argc > 1) {
    int fd = open(argv[1], O_WRONLY);
    if(fd == -1) {
      printf("Unable to open the
file\n");
      exit(1);
    }
    static struct flock lock;

    lock.l_type = F_WRLCK;
    lock.l_start = 0;
    lock.l_whence = SEEK_SET;
    lock.l_len = 0;
    lock.l_pid = getpid();

    int ret = fcntl(fd, F_SETLKW,
&lock);
    printf("Return value of
fcntl:%d\n",ret);
    if(ret==0) {
      while (1) {
        scanf("%c", NULL);
      }
    }
  }
}
```

NFSv4 Troubleshooting

Issues with listing the exports:

If `nfs4mgr list-exports` command returns the error, `Error org.freedesktop.DBus.Error.ServiceUnknow`

`n: The name org.ganesha.nfsd was not provided by any .service files`, do the following to resolve the error:

1. Open the `/etc/dbus-1/system.conf` file.
2. Find and replace the following in the file:
   a. Find:

```
<deny
send_destination="org.freedeskt
op.DBus"

send_interface="org.freedesktop
.DBus"

send_member="UpdateActivationEn
vironment"/>
```

   b. Replace with:

```
<!-- Allow anyone to talk to
the message bus -->
<allow
send_destination="org.freedeskt
op.DBus"/>
<!-- But disallow some
specific bus services -->
<allow send_interface="*"/>
<allow receive_interface="*"/>
<allow own="*"/>
```

3. Save and close the file.
4. Restart the messagebus and NFSv4 service.

   To restart the messagebus service, run the following command:

```
service messagebus restart
```

   To restart NFSv4 service, see Starting, Stopping, and Restarting MapR NFSv4 on page 1216.

Lock expires as a result of problems in node connection or node failover:

If the lock expires as a result of problems in node connection or node failover, all IOs from the application will fail with EIO message to prevent the file from getting corrupted. You can tune the kernel to reclaim lost locks and not fail writes on lock lease expiration. To tune the kernel, run the following command:

```
echo Y > /sys/module/nfs/parameters/
recover_lost_locks
```

Warning: This kernel tuning this might result in data corruption.

User ID mapping is not working when NFSv4 server and client are in two different sub-domains:

If user ID (with FQDN user names) mapping is not working with the installed `libnfsidmap` library (for

example, `libnfsidmap-0.25-19` on Centos), do the following:

1. Download the latest `libnfsidmap` library for the OS.

   For CentOS:

   a. Download the library source with the patches.

   b. Apply the patches till `libnfsidmap-0.25-dns-resolved.patch`.

   c. Build the new library.

2. Stop NFSv4 service and replace the old library with the new library.

3. Replace the old `nsswitch.so` file with the new `nsswitch.so` file that is compiled.

4. Restart rpcidmapd service and NFSv4 service.

NFS Ganesha crashes when unmounting the cluster:

NFS Ganesha crashes when unmounting the cluster as a non-root user. Download and install the following Kerberos 16 package:

- `sssd-krb5-common-1.16.0-19.el7.x86_64`
- `sssd-krb5-1.16.0-19.el7.x86_64`

Discover realm command fails:

If the `realm discover` command fails with following error: `realm: Couldn't connect to realm service: Error calling StartServiceByName for org.freedesktop.realmd: GDBus.Error:org.freedesktop.DBus.Error.TimedOut: Activation of org.freedesktop.realmd timed out`, reboot the node and add Active Directory information in the `/etc/resolv.conf` again. For example, your entry in the `/etc/resolv.conf` file should look similar to the following:

```
# cat /etc/resolv.conf
nameserver 10.10.111.41
domain nfs4ad.com
search nfs4ad.com lab qa.lab
scale.lab perf.lab ipmi.lab
```

Unable to start the service:

If you or the warden is unable to restart the NFS service, do the following:

1. Review the warden logs (in `$MAPR_HOME/logs/warden.log` file) to determine when the NFSv4 Service Alarm on page 2232 was raised.

last-updated: Apr 11, 2022

2. Review the following NFSv4 server logs in `$MAPR_HOME/logs/nfs4/nfs4server.log-0` and `$MAPR_HOME/logs/nfs4/fsal.log-0`, and other logs under `$MAPR_HOME/logs/nfs4` on the node where the service went down to determine the cause for the error.

   The following example logs show some common causes for NFSv4 service shutting down such as license not present or an issue in the configuration.

```

3. Take corrective action to rectify the cause for the error.

Viewing the List of NFS Servers

Explains how to view the list of NFS servers using the Control System.

- Log in to the Control System and go to the service information page for CLDB.
  The **Active NFS Servers** section displays the following:

Column Name	Column Description
Server ID-HEX	The server's ID in hexadecimal notation.
Server ID	The server's ID in decimal notation.
Host Port	The IP address of the NFS server host.
Hostname	The hostname of the NFS server host.
Last heartbeat	The timestamp for the last received heartbeat.

Column Name	Column Description
State	The status of the NFS server. Value can be: • Active

Handling Heavy Write Loads on Red Hat Enterprise Linux
Describes a fix to mitigate resource contention between NFS Clients and the NFS Server on Red Hat Linux.

If you are operating on RHEL and have a heavy NFS write load, you might experience resource contention between the NFS client and the NFS server. This resource contention can cause the NFS server to be unresponsive. To avoid this potential problem, try one of following approaches. These approaches work on all versions of Red Hat (5.x, 6.x and 7.x).

- Edit `/etc/sysctl.conf` and apply these settings on each NFS server:

  ```
  vm.dirty_ratio=10
  vm.dirty_background_ratio=5
  ```

  Reboot the server so the changes will take effect. To make the settings take effect immediately, issue the `echo` command as shown:

  ```
  % echo 10 > /proc/sys/vm/dirty_ratio
  % echo 5 > /proc/sys/vm/dirty_background_ratio
  ```

- Separate the NFS client from the NFS server so they do not compete for memory on the same system.

Configure NFS Write Performance
Describes how to set the optimal value for outstanding Remote Procedure Call (RPC) requests to the NFS server.

The default Remote Procedure Call (RPC) requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128, for optimal performance. The NFS client uses this value to determine when to send requests to the NFS server, along with the number of parallel requests to send.

- If the value is too small, the NFS client does not send many parallel requests. This scenario results in decreased performance.
- If the value is too high, the NFS client sends a lot of parallel requests, but the NFS server discards some requests, as it has a limit on the number of requests it can handle. This scenario causes the NFS client to resend the requests, and negatively affects performance.

The kernel tunable value `sunrpc.tcp_slot_table_entries` represents the number of simultaneous RPC requests. The default value of this tunable is 16 (on Red Hat versions prior to version 6.3). On Red Hat versions 6.3 and above, the default value of this tunable is set at 65536. Increasing or decreasing this value to 128 (depending on the Red Hat version in use), may improve write speeds. Use the command `sysctl -w sunrpc.tcp_slot_table_entries=128` to set the value. Add an entry to your `sysctl.conf` file to make the setting persist across reboots.

Perform the following steps as the root user, on each NFS client machine:

1. Issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration. These commands enable the configuration to persist after a reboot of the NFS client machine.

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >>  /etc/modprobe.d/
sunrpc.conf
```

2. Issue the following `echo` commands. These commands enable the configuration to take effect after you remount the NFS client to the NFS gateway.

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS gateway. Mount the MapR NFS server with a rsize and wsize of 128K, as this value significantly cuts down NFS server requests for a given transfer, and improves the overall performance. For example, the following commands unmount and mount the NFS server, assuming that the cluster is mounted at `/mapr`.

```
umount /mapr
mount -o nolock,rsize=131072,wsize=131072 <hostname>:/mapr /mapr
```

4. After rebooting the node, if the `/proc/sys/sunrpc` directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service, using the following command: `service rpcidmapd start`.

Failure to set this tunable to an optimum value, may result in the following error in the `/opt/mapr/logs/nfsserver.log` file:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot
allocate more OncRpcContexts: [numDropped=2556001] dropping connection from
nfsc=10.13.64.225:0
```

NFS write performance varies between different Linux distributions. The recommended value of this tunable may have no effect, or even a negative effect on your particular cluster.

Adjusting NFS Memory Settings

The memory allocated to each MapR service is specified in the `/opt/mapr/conf/warden.conf` file, which MapR automatically configures based on the physical memory available on the node. You can adjust the minimum and maximum memory used for NFS, as well as the percentage of the heap that it tries to use, by setting the `percent`, `max`, and `min` parameters in the `warden.conf` file on each NFS node. Example:

```
...
service.command.nfs.heapsize.percent=3
service.command.nfs.heapsize.max=1000
service.command.nfs.heapsize.min=64
...
```

The percentages need not add up to 100; in fact, you can use less than the full heap by setting the `heapsize.percent` parameters for all services to add up to less than 100% of the heap size. In general, you should not need to adjust the memory settings for individual services, unless you see specific memory-related problems occurring.

Running NFS on a Non-standard Port

1. To run NFS on an arbitrary port, modify the following line in `warden.conf`:

   ```
   service.command.nfs.start=/etc/init.d/mapr-nfsserver start
   ```

   Add `-p <portnumber>` to the end of the line, as in the following example:

   ```
   service.command.nfs.start=/etc/init.d/mapr-nfsserver start -p 12345
   ```

2. After modifying `warden.conf`, restart the MapR NFS server by issuing the following command:

   ```
   maprcli node services -nodes <nodename> -nfs restart
   ```

3. You can verify the port change with the `rpcinfo -p localhost` command.

   Warning: MapR uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS version 3.

Enabling Debug Logging for NFS Using the CLI

Debug-level logging is available to help you isolate and identify NFS-related issues.

Enabling Debug Logging for NFSv3

1. To enable logging at the debug level, enter this command at the command line:

   ```
   maprcli trace setlevel -port 9998 -level debug
   ```

   where `-port 9998` indicates NFS.

   Warning: The `debug` log level provides much more information than the default log level of `info`.

2. In default mode, information is logged to a buffer and dumped periodically. To display information immediately instead, enable `continuous` mode by entering:

```
maprcli trace setmode -port 9998 -mode continuous
```

Sample log output from an `ls` command is shown here:

From `/opt/mapr/logs/nfsserver.log`:

```

(sleep=0) ip= cldb=10.10.80.41:7222
```

The log shows every operation sent to and received from an NFS client.

3. To return to the default log level and log mode, enter:

```
maprcli trace setlevel -port 9998 -level default
maprcli trace setmode -mode default
```

Enable Debug Logging for NFSv4

1. Modify `core-site.xml` file to add the following:

```
<property>
   <name>fs.mapr.trace</name>
   <value>DEBUG</value>
   <description> </description>
</property>
```

2. Save and close the file.

Run the `/opt/mapr/server/nfs4mgr` command for debugging NFS Ganesha.

Unmounting the MapR Cluster from the Command-Line

- To unmount the MapR cluster, run the `umount` command.

  For example, to unmount the cluster in `/mapr`, run the following command:

  ```
  umount /mapr
  ```

  If a process is busy on the mount point, the umount command will fail. To unmount the cluster after the process completes, run the following command:

  ```
  umount -l /mapr
  ```

Managing MapR POSIX Clients

Provides a brief synopsis of MapR POSIX clients.

The MapR POSIX clients allow app servers, web servers, and other client nodes and apps to read and write data directly and securely to a MapR cluster. The following topics describe the steps for configuring and managing loopback NFS POSIX and FUSE-based POSIX clients.

Apart from the clients that are EOL, all others are supported. However, newer clients might have features that may not be supported in older clients.

Difference between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients

The following table summarizes the differences between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients:

	MapR POSIX Loopback NFS Client	MapR FUSE-based POSIX Basic/ Platinum Client
Throughput	• 500MB/s for remote read/write • 1G/s for local read/write	Greater than 2G/s for remote and local read/write
Client OS	Supported Linux and Ubuntu distributions only.	
Installs On Node Type	• Client node • Cluster node	
Access to Cluster	Must have direct network access to all MapR cluster nodes.	Must have direct network access to all MapR cluster nodes. However, each client only supports up to 16 clusters.
Connection to File System	• Proxied on host to regular MapR client traffic • Direct, no NFS gateway • No single point of failure	
Security	Fully secured.	
Caching	Buffered writes are cached in the kernel.	Buffered writes are cached (only in kernel >= 3.15) if writeback option is enabled.

last-updated: Apr 11, 2022

MapR loopbacknfs POSIX Client
Explains the differences between the MapR POSIX client and the Linux native NFS client.

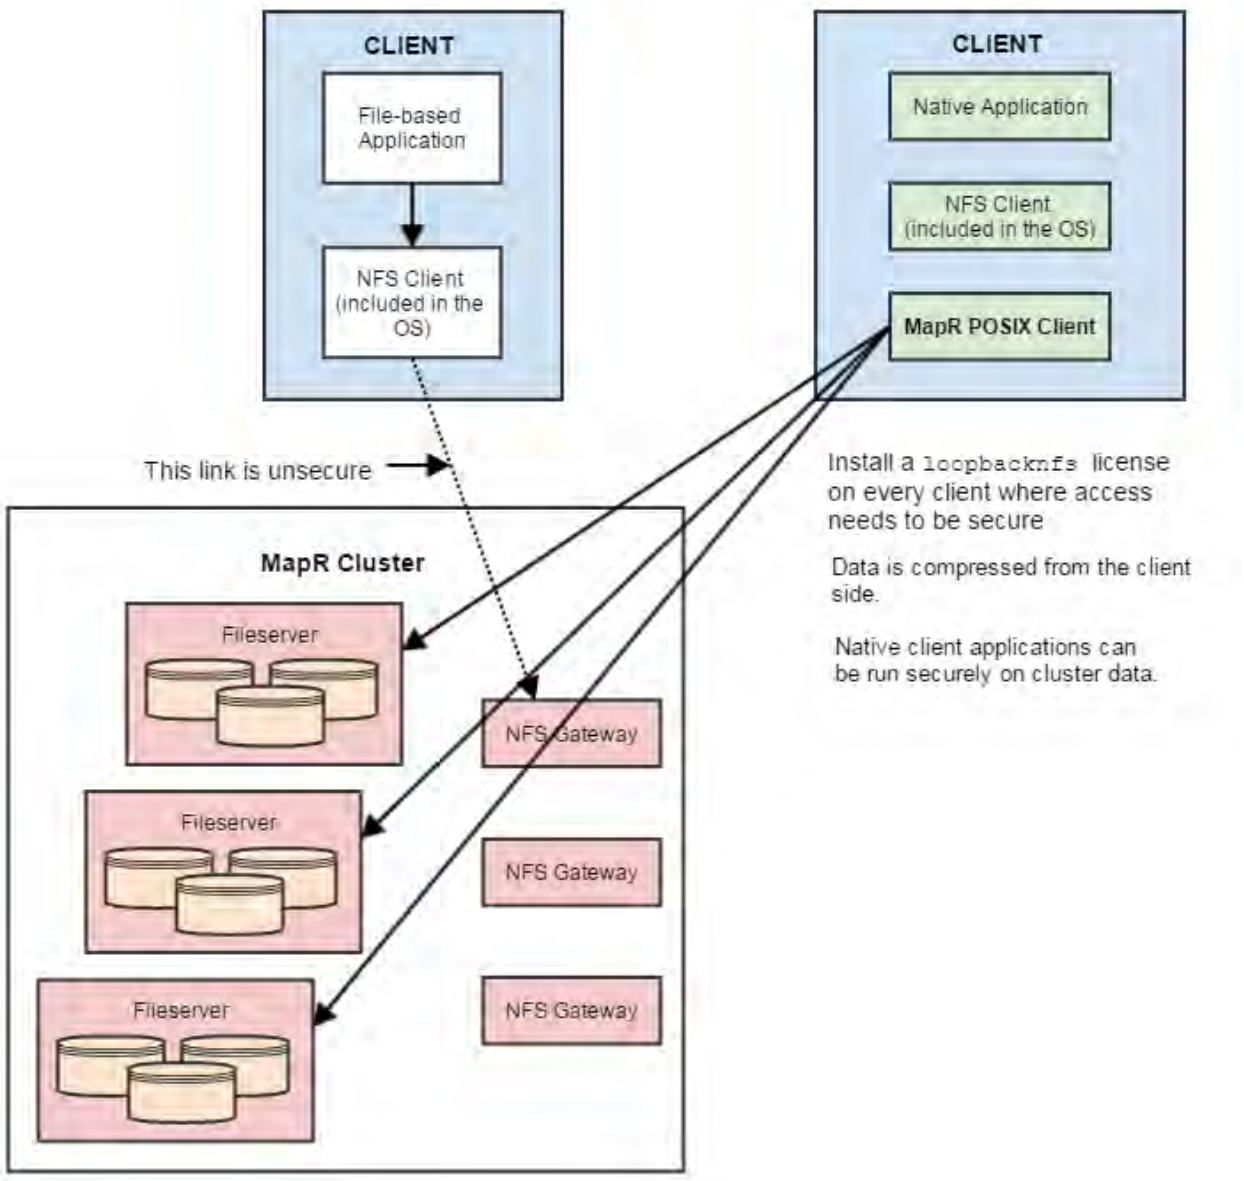
The MapR POSIX Client feature allows app servers, web servers, and other client nodes and apps to read and write directly to a MapR cluster. Starting with the 4.0.2 release, MapR provides single-user `loopbacknfs` licenses that give access to one or more clusters.

The table below summarizes the differences between the basic Linux OS NFS client and the MapR POSIX client:

	Linux OS Client	MapR POSIX Client
Client OS	• Supported Linux distributions and desktop systems (Mac OS X and Windows)	• Supported Linux distributions only • No version for Mac OS X
Installs On Node Type	• Client node - not part of the MapR cluster • No mapr-fileserver or other Hadoop services	• Client node • Cluster node
Access to Cluster	• Must have direct network access to NFS Gateways.	• Must have direct network access to all MapR cluster nodes
Supported Interfaces	• POSIX-NFS	• POSIX-NFS
Connection to File System	• Point to point • Via an NFS gateway • Single point of failure	• Proxied on host to regular MapR client traffic • Direct, no NFS gateway • No single point of failure
Security	• Link to NFS gateway is insecure	• Fully secured

The Linux OS NFS client must go through an NFS gateway, the link to the gateway is not secured, and transmitted data is not compressed.

The following diagram illustrates how the MapR POSIX client (`mapr-loopbacknfs`) works, in comparison with the Linux OS NFS client (left).



The instructions on this page are for the MapR POSIX client. For instructions on setting up NFS on a MapR cluster, see Managing the MapR NFS Service on page 1176.

The table below summarizes the differences in the MapR POSIX client deployment behavior when installed with a MapR cluster where security is disabled or enabled:

	Cluster Security Disabled	Cluster Security Enabled
Client Node	• MapR cluster looks exactly like network attached storage (NAS) • POSIX permissions are enforced	• Single-user authentication • Write access is supported only for applications with UID matching authenticated user
Cluster Node	• MapR cluster looks exactly like NAS • POSIX permissions are enforced	• Secure cluster access is key • Best Practice: Use ticket from *mapr* user

last-updated: Apr 11, 2022

Specifying Environment Variables

Explains how to set environment variables on a client node.

A subset of the environment variables defined on the servers for the MapR cluster must be defined, with the same values, on the client. You can add environment variables directly to the startup script, or create a local `env.sh` file in `/usr/local/mapr-loopbacknfs/conf`. You cannot simply copy the `env.sh` file from a server node in the cluster because the MAPR_HOME setting would be different.

Complete the following steps to specify environment variables:

1. On a server node in the MapR cluster, locate the `env.sh` and `env_override.sh` files in the `/opt/mapr/conf` directory. If the `env_override.sh` file is not present, use the `env.sh` file. For more information about these files, see About env_override.sh on page 2290.
2. Retrieve the MAPR_SUBNETS and JAVA_HOME settings from the server files and clone them to `/usr/local/mapr-loopbacknfs/conf/env.sh` on the client node.
3. (Optional) Set the `NFS_LOOPBACK_HONOUR_SUBNETS` environment variable to avoid re-registration whenever there is a change in any network interface. Value can be:
   - `true` to consider the `MAPR_SUBNETS` while registering with CLDB. If set to `true`, re-registration does not happen whenever there is a change in any network interface.
   - `false` to ignore the `MAPR_SUBNETS`. If set to `false`, re-registration happens whenever there is a change in any network interface.

   For example:

   ```
   # export NFS_LOOPBACK_HONOUR_SUBNETS=true
   # export MAPR_SUBNETS=10.10.104.0/24

   # env | grep SUBNET
   NFS_LOOPBACK_HONOUR_SUBNETS=true
   MAPR_SUBNETS=10.10.105.0/24,10.10.104.0/24
   ```
4. Change the JAVA_HOME setting to point to the location where Java is installed on the client.
5. Add the following lines to the client node `env.sh` file:

   ```
   export MAPR_HOME=/usr/local/mapr-loopbacknfs
   export MAPR_TICKETFILE_LOCATION=/usr/local/mapr-loopbacknfs/initscripts/
   mapr-loopbacknfs/longlived_ticket
   ```

   Note: To allow impersonation, set the value for `MAPR_TICKETFILE_LOCATION` to the path to the mapr user ticket.
6. Save and close the `env.sh` file.
7. Restart the loopbacknfs service for the changes to take effect.

Copying Configuration Files from a Server Node

Settings in the `nfsserver.conf` and `mapr-clusters.conf` files on server nodes in the MapR cluster are also needed by the POSIX client. Complete the following steps to copy configuration files from a server node:

1. On a server node in the MapR cluster, locate the `nfsserver.conf` and `mapr-clusters.conf` files in the `/opt/mapr/conf/` directory.

last-updated: Apr 11, 2022

2. Copy both of those files to the `/usr/local/mapr-loopbacknfs/conf/` directory on the client machine.

Starting the mapr-loopbacknfs Service to Access a Cluster
Describes the prerequisites and the process of starting the `mapr-loopbacknfs` service to access a secure cluster.

The following instructions explain how to start the loopbacknfs service so you can access either a non-secure or secure cluster.

To access multiple clusters, ensure that the first cluster that you configure is a MapR 4.0.2 or later cluster, with available POSIX client licenses.

Prerequisites for accessing a secure cluster:

- Ensure that the stock Linux NFS service is not running. Linux NFS and MapR NFS cannot run concurrently.
- Disable the lock manager (`nlockmgr`).
- Check that the `rpcbind` service is running on RHEL and CentOS v6.0 and higher. You can use the command `ps ax | grep rpcbind` to check.
- Check that the `portmapper` service is running on RHEL and CentOS v5.x and lower, and on Ubuntu and SLES. You can use the command `ps ax | grep portmap` to check.
- Make sure you have applied a Community Edition (M3) license or an Enterprise Edition (M5) license (paid or trial) to the cluster. See Adding a License on page 777.
- Enable security for the cluster. See Enabling Wire-level Security on page 1411 and Disabling Wire-level Security on page 1412 wire-level security.
- Generate a user ticket. See Generating a MapR User Ticket on page 1426 for instructions. If you do not already have a MapR user ticket, with full control *ACL* authorization on the cluster, you must have a cluster administrator do this for you.
  - In the MapR cluster, navigate to the server node to which you want to connect.
  - First, run `maprlogin password` to login. The user who logs in must be a privileged user, such as the `mapr` superuser.
  - Next, run `maprlogin generateticket -type service -user <user> -duration 365:0:0 -out <file>` to generate the user ticket. The <user> for whom the ticket is generated can be any user. If the service ticket expires, the POSIX client:
    - Automatically uses the renewed service ticket without requiring a restart, if the ticket is replaced before expiration (ticket expiry time + grace period of 55 minutes). If the ticket is replaced after expiration (which is ticket expiry time + grace period of 55 minutes), the POSIX loopbacknfs client does not refresh the ticket as the mount becomes stale.
    - Allows impersonation if a service ticket is replaced before ticket expiration (which is ticket expiry time + grace period of 55 minutes) with a `servicewithimpersonation` ticket.
    - Honor all changes in user/group IDs of the renewed ticket.
- Copy the user ticket file from the cluster server node where you generated it to the `/usr/local/mapr-loopbacknfs/conf` directory on the client machine where the MapR POSIX client runs.

last-updated: Apr 11, 2022

Note: Since the NFS server runs based on a single user's ticket, it can act on behalf of only one user. Therefore, the UID or GID associated with the ticket must match the UID or GID of any user who accesses the NFS server through the MapR POSIX Client.

Note: Securing the cluster so that only one user can have secure access provides tight control over cluster access, but it also means that any user on the client who is able to read the generated ticket has read access to all data in the cluster.

Start the mapr-loopbacknfs service and mount the volume

Complete the following steps from your client node, except where noted, to start the `mapr-loopbacknfs` service and mount the volume:

Note: If cluster security is enabled, the ticket that you generated using the preceding procedure, must be available or the NFS server does not start.

1. Start the `mapr-loopbacknfs` service from the command line.

```
service mapr-loopbacknfs start
```

2. Create a mount point at `/mapr` and mount the client node to it.

```
mkdir /mapr
mount localhost:/mapr /mapr
```

3. You can also automate the mounting of the volume with every launch of the `mapr-loopbacknfs` service. On the POSIX client node, create `/usr/local/mapr-loopbacknfs/conf/mapr_fstab` and add the following line:

```
localhost:/mapr /mapr hard,nolock
```

Securing the Mountpoint

POSIX permissions are the only limitation on read access by the MapR POSIX client, whether the cluster connected to has security enabled or disabled. By securing the mountpoint, you can limit access to a single user.

Complete the following steps to secure the mountpoint:

1. On the client system, create `/mapr/<clustername>`:

```
mkdir -p /mapr/<clustername>
```

2. Set ownership and permissions:

```
chown user1:<posix_user> /mapr
chmod 700 /mapr
```

3. Mount the cluster:

```
mount localhost:/mapr/<clustername>  /mapr/<clustername>
```

Now only the `<posix_user>` can access the cluster with the POSIX client.

Registering a POSIX Client with Additional Clusters

The first time you start the `loopbacknfs` service, you edit the `mapr-loopbacknfs` init script by defining the `CLUSTER_NAME` and `CLDB_IPS` variables, then run the script. These actions update the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file.

However, when you want to register a client with a new cluster or an additional cluster, you must add entries directly to the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file. Editing the `mapr-loopbacknfs` script and restarting the `loopbacknfs` service does not update the `mapr-clusters.conf` file.

Configuring the MapR POSIX Client

Explains how to set the number of RPC requests that POSIX clients send to a cluster.

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the cluster to be 128.

Perform the following steps as the root user on each POSIX client machine:

1. Issue the following commands to create the *sunrpc.conf* file under */etc/modprobe.d* with the recommended configuration:

   ```
   echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
   sunrpc.conf
   echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
   sunrpc.conf
   ```

   These commands enable the configuration to persist after a reboot of the NFS client machine.

2. Issue the following echo commands:

   ```
   echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
   echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
   ```

   The commands enable the configuration to take effect after you remount the POSIX client to the MapR cluster.

3. Remount the POSIX client to the MapR cluster. For example, the following commands unmount and mount the NFS assuming that the cluster is mounted at */mapr*:

   ```
   umount /mapr
   mount -o hard,nolock 127.0.0.1:/mapr /mapr
   ```

   Note: Failure to configure this property may result in the following error in */usr/local/mapr-loopbacknfs/log*: `ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot allocate more OncRpcContexts: [numDropped=2556001] dropping connection from nfsc=10.13.64.225:0`

   #### CentOS Troubleshooting Tip

   After the reboot of the node, if the */proc/sys/sunrpc* directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command: `service rpcidmapd start`.

Verifying MapR POSIX Client Licenses

Use the Control System, to check how many MapR POSIX client licenses are available and being used.

1. Log in to the Control System and click **Admin** > **Cluster Settings**.

last-updated: Apr 11, 2022

2. Look at the **LICENSES** pane for the number of POSIX Client nodes that are available and currently being used.

Managing the mapr-loopbacknfs Service
Explains how to start/stop and manage the `loopbacknfs` service from the command line.

To manually start or stop the service:

```
service mapr-loopbacknfs [start|stop]
```

To have the service start automatically when the OS starts up:

```
systemctl enable mapr-loopbacknfs
```

To monitor the service:

```
service mapr-loopbacknfs status
showmount -e localhost
```

The showmount command displays:

```
Export list for <host>
/mapr               127.0.0.1
/mapr/<clustername> 127.0.0.1
```

Setting Up Aliases for NFS Exports

When provisioning MapR File System for various tenants, you can set up an alias for the path in MapR File System, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in MapR File System.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in MapR File System (`/mapr`). To set up an alias for a path in MapR File System:

1. Open the NFS exports file in `/opt/mapr/conf/` directory.
2. Specify the alias name for the mount path using the following syntax:

   ```
   <path in MFS> /<alias name> <options>
   ```

   Here:

`<path in MFS>`	Refers to the MapR File System mount path. If this points to a: • Volume, the user can access the snapshots associated with the volume. • Directory, the user cannot access the snapshots.
`/<alias name>`	Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in MapR File System will be exported.
`<options>`	The list of available/supported options.

   For example, suppose a MapR File System mount path of `/mapr/samplecluster/samplevolume` for tenant samplecustomer. To set up an alias, add the following to the exports file:

   ```
   /mapr/samplecluster/samplevolume /samplecustomer (rw)
   ```

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

Note: Only the alias will be visible/exposed to the NFS client.

3. Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprcli nfsmgmt refreshexports
```

4. Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Troubleshooting mapr-loopbacknfs Service Issues

Describes solutions for mapr-loopbacknfs issues.

To debug authentication issues, follow these steps:

1. If you receive a standard error (stderr):
   - Make sure `rpcinfo/portmap` is installed and/or run service portmap start.
   - Run service `rpcbind restart`.
2. Examine the log files for error messages:

```
/usr/local/mapr-loopbacknfs/logs/loopbacknfs.log
/usr/local/mapr-loopbacknfs/logs/mount_local_fs.log
```

Error messages in `loopbacknfs.log` file:

Error Message	Solution
`Refresh User tickets failed as security layer could not be initialized with user ticket /tmp/maprticket_0`	`Unset MAPR_TICKETFILE_LOCATION in initscripts/mapr-loopbacknfs.`
`exiting: license only allows 10 NFS/mfs server(s), currently alive=10`	`If you have multiple clusters listed in the mapr-clusters.conf file on the client, make sure the first one listed is a MapR 4.0.2 or later cluster. If that is not the problem, you will probably need to purchase additional licenses, or reduce number of installations of the mapr-loopbacknfs service.`
`mount.nfs: Protocol not supported`	`The NFS directory with mapr-loopbacknfs is already mounted.`

3. Verify that settings in configuration files are correct.
   - For all clusters: `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf`

last-updated: Apr 11, 2022

- For secure clusters: `MAPR_TICKETFILE_LOCATION`

4. Check for “stale” mounts.
   - The `mount_local_fs.pl` script can cause the initscript wrapper to force unmounts of the mounted file systems.
   - Always check for stale mounts after stopping the service:
     - `df -k` should return instantly.
     - Use `umount -f <mount_point>` to force the unmount.
     - Use `ps -ef | grep mount_local` to confirm that the script is not stuck.

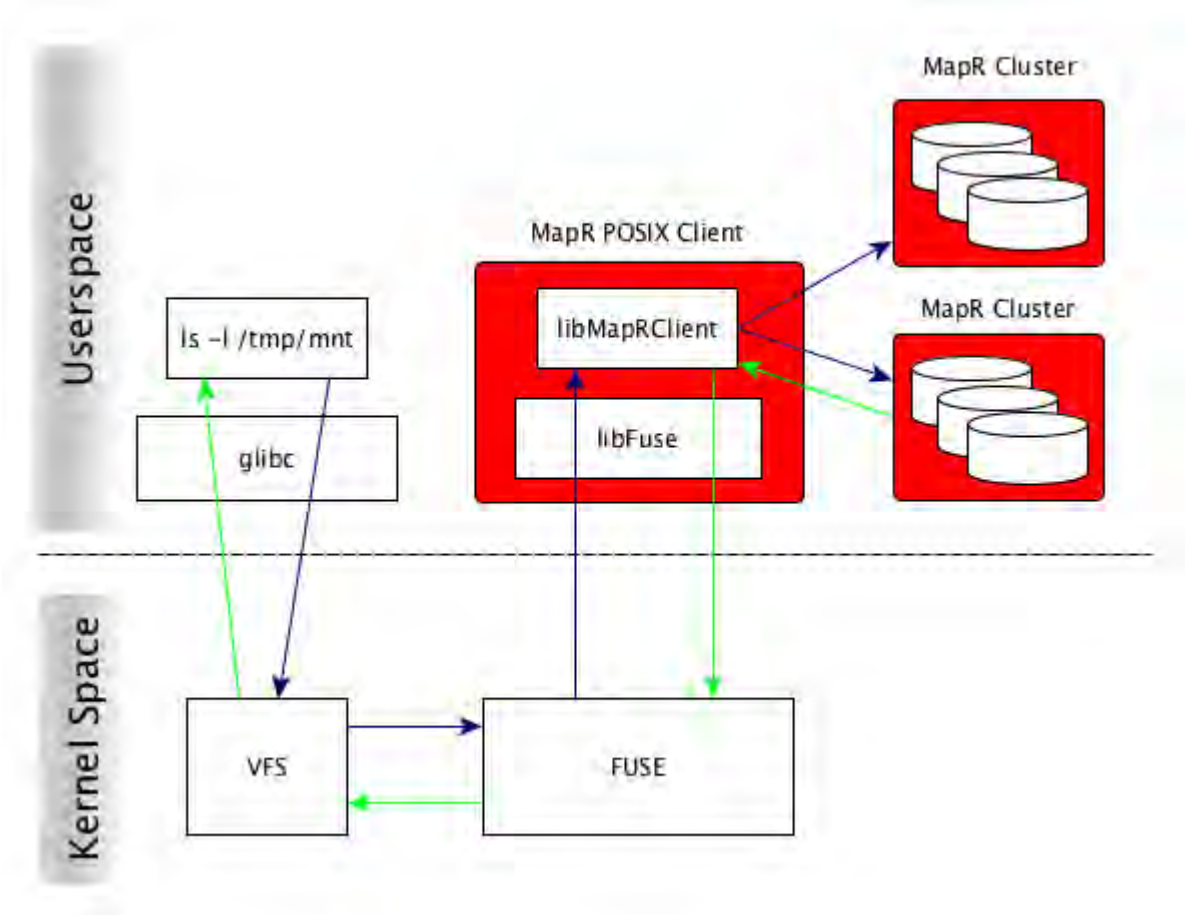
MapR FUSE-Based POSIX Client
Provides a brief description of the FUSE-based POSIX client.

The MapR FUSE-based POSIX client (either *mapr-posix-client-basic* or *mapr-posix-client-platinum*) allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a MapR cluster like a Linux filesystem.

The same MapR client can access both secure and nonsecure clusters; however, a MapR client that is configured to access a secure cluster can access a nonsecure cluster only if these conditions are met:

1. The secure cluster must be listed in the `mapr-clusters.conf` file.
2. A user must obtain a ticket for the secure cluster even if the user wants to access only the nonsecure cluster.

The FUSE-based MapR POSIX client runs as a userspace process to connect to one or more MapR clusters. The necessary FUSE (Filesystem in Userspace) library (`libfuse`) is bundled with the POSIX client package. With the installation of the POSIX client package, the MapR POSIX client performs operations such as read and write on the filesystem exposed by FUSE. The following diagram illustrates how the MapR FUSE-based POSIX client works.



Example of Mounting FUSE

This example shows you how to mount FUSE and perform operations as a regular user.

The following example is a quick introduction to mounting FUSE and accessing the mount point as a regular user.

Assume that you have a mount point */mapr* that you want to mount on FUSE and access as user *kate*.

Perform the following steps:

1. Create the user *kate*: Run

   ```
   adduser kate
   ```

2. Generate a ticket with impersonation as user *kate*. You will use this ticket to mount and access FUSE. Run:

   ```
   maprlogin generateticket -type servicewithimpersonation -user
   kate -out /var/tmp/sample_ticket
   ```

   Note: For more information on generating a ticket with impersonation, see How Impersonation Works on page 1478 and Generating a Service with Impersonation Ticket on page 1428

3. Edit the `/opt/mapr/conf/fuse.conf` file and set `fuse.ticketfile.location=/var/tmp/sample_ticket`

4. The mount point */mapr* is already set in the `fuse.conf` file.

   Note: Change `fuse.mount.point=/mapr` if your mount point is different from */mapr*.

5. Create the */mapr* directory. Run:

   ```
   mkdir /mapr
   ```

6. Start the MapR FUSE POSIX client, either *basic* or *platinum* as per your licence. For example:

   ```
   service mapr-posix-client-basic start
   ```

The */mapr* directory is now mounted on FUSE. You can perform all operations on */mapr/* as the user *kate*.

Configuring the MapR FUSE-Based POSIX Client
Lists FUSE configuration parameters.

FUSE Parameters

You can set the POSIX client configuration values in the `/opt/mapr/conf/fuse.conf` file. After installing the FUSE-based POSIX client, you can edit the configuration file to define the values for the following parameters and save the file.

To retrieve the list of configuration parameters, run the following command:

```
/opt/mapr/bin/posix-client-* --help
```

Here * refers to the basic or platinum client package installed on the system. If necessary, set the shared `LD_LIBRARY_PATH` environment variable to run the `help` option with the command. For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

Note: The MapR FUSE-based POSIX clients support only the configuration parameters in the `fuse.conf` file. All other FUSE configuration parameters are not supported. For more information on the non-mapr configuration parameters, refer to FUSE documentation.

`fuse.access.type`	*Default Value:* rw Sets the type of access on the mount point. Value can be: • `ro` — Read only • `rw` — Read and write
`fuse.affinity`	*Default Value:* 0 (Disabled)

Specifies whether to enable (`1`) or disable (`0`) NUMA affinity. If enabled, sets the NUMA affinity for the POSIX client.

`fuse.allow.other`

Default Value: 1

Allow other users to access the mount point. Value can be one of:

- `0` - do not allow other users
- `1` - allow other users

Set this to `1` if the `root` user starts the FUSE service. Set to `0` or comment out this parameter if a non-root user starts the FUSE service . If set to `1`, also add the `user_allow_other` parameter to the `/etc/fuse.conf` file.

`fuse.asyncdirect.io`

Default Value: 1

Specifies whether to enable asynchronous direct IO. Value can be one of:

- `0` - disable
- `1` - enable

`fuse.attr.timeout`

Default Value: 3.0

The timeout value in seconds for file/directory (regular) attributes (such as file size, UID, and GID, which are normally stored inside the inode) cache. This value is used to determine whether to use the cached attribute information (only if within the specified timeout window) or fetch attribute information again. The default is 3.0 seconds, which specifies that cached attribute information must be considered stale and refreshed after 3.0 seconds. You can assign fractions of a second as well (for example, `fuse.attr.timeout=2.8`).

Set the value for this parameter to `0` to compare POSIX (pjd) compliance with the ext3/4 file system. A value of 0 disables caching. For better performance, avoid disabling caching.

`fuse.auto.inval.data`

Default Value: 1

Specifies whether (1) or not (0) to automatically invalidate the kernel FUSE cache for any data change that causes mtime change, on the files. If set to 1, when the file is read, the correct file data is returned. If set to 0, the kernel cache of the data, which might not have the most current change, is returned.

`fuse.auto.unmount`

Default Value: 1

Specifies whether to automatically unmount the filesystem when the process is terminated. Value can be one of:

- `0` - disable
- `1` - enable

`fuse.big.writes`

Default Value: 1

Specifies whether to enable writes larger than 4KB. Value can be one of:

last-updated: Apr 11, 2022

- `0` - disable
- `1` - enable

Sets the size of the data/buffer that can be transferred from the kernel to the FUSE library, per request. If enabled, FUSE allows writes of 128KB from the kernel. If disabled, FUSE allows writes of 4KB from the kernel.

`fuse.client.lib.path`

Default Value: `/tmp`

Specifies the path to store the client libraries.

Note: To install and use FUSE-based POSIX client and NFS v4 on the same node, ensure that the path for both the client library for the FUSE-based POSIX client, and NFS v4 is not `/tmp`, which is the default. Specify a different location for the client libraries. For example, `/tmp/fuselib`.

`fuse.cluster.conf.location`

Default Value: `/opt/mapr/conf/mapr-clusters.conf`

The path to the configuration file to use.

`fuse.congestion.threshold`

Default Value: 10

Specifies the kernel's congestion threshold.

`fuse.disable.shardcache`

Default Value: 0 (false)

Specifies whether to disable shard cache, which is a cache of lookups. Value can be:

- `0` - false
- `1` - true

If true, more number of lookup calls are used. The FUSE client uses the shard cache to ensure that requests for data related to the same file are served by the same library. This is done using hash to improve performance. In very rare circumstances, it might make sense to disable this cache in conjunction with MapR support.

`fuse.disable.writeback`

Default Value: 0

Specifies whether (`1`) or not (`0`) to disable the writeback cache. This parameter is applicable only in kernel versions >= 3.15. By default, in kernel versions >= 3.15, writeback is enabled. To disable writeback cache, set the value for this parameter to `1`. If enabled, the writes are buffered in the kernel. However, when multiple FUSE clients work on the same file, writes to a file by one FUSE client might never be seen by other FUSE clients performing a read because the kernel does not update the attributes of the file unless the file is modified locally. You can disable the writeback cache to allow the kernel to perform a write through.

`fuse.enforce.core.pattern`

Default Value: false

Specifies whether (`true`) or not (`false`) to write to `/proc/sys/kernel/core_pattern` file when the FUSE-based POSIX starts. The default value is `false`. If `true`, the `core_pattern` file contains

an `/opt/cores/%e.core.%p.%h` entry and if `false`, the file is not touched.

`fuse.entry.timeout`

Default Value: 3

The timeout value in seconds for the name lookup cache. Use this parameter to determine whether to use the cached entry for the name lookup (if within the specified timeout window) or lookup the name again. The default is 3 seconds, which specifies that cached name lookup information must be considered stale and refreshed after 3 seconds. For this option, it is possible to give fractions of a second as well (for example, `fuse.entry.timeout=2.8`).

Set the value for this parameter to `0` to compare POSIX (pjd) compliance with the ext3/4 file system. Avoid retaining this value as 0 as it disables the cache, and impacts performance.

`fuse.evenly.spread.data`

Default Value: 0

Specifies whether (`1`) or not (`0`) to evenly spread writes across the nodes on the cluster. If set to `0`, writes are always sent to the local primary node, from where data is replicated on all the other nodes. If set to `1`, writes are distributed across different nodes. Set the value to `1` in case of reduced performance resulting from a large number of writes on the local primary node.

`fuse.export`

Default Value: `/mapr`

Denotes the fully-qualified cluster path to the volume or directory under the mount point.

When you do not specify a value, all clusters found in `mapr-clusters.conf` are mounted under the entity specified by the `fuse.mount.point` property (`/mapr` by default). If `mapr-clusters.conf` contains two clusters A and B, there are directories pointing to the root directories of those clusters, for example `/mapr/A` and `/mapr/B`.

When you specify a value, it overrides the default behavior, and causes exactly one path from one cluster to be exposed at the entity specified by the `fuse.mount.point` property. You can either fully expose a single cluster, or expose only a subset of a single cluster.

If you set `fuse.export` to the name of a cluster, enclosed within `/`, then that cluster is mounted at `/mapr`. For example if `fuse.export=/A/`, then the path `/mapr` shows the root directory of cluster A.

If you set `fuse.export` to a path within a cluster, then `/mapr` points to that path. For example, if `fuse.export=/A/var/`, then `/mapr` displays the directory contents of `/var` from the MapR cluster A.

Note: If the value is not a valid path to the name of a volume or directory, the FUSE service does not start. The value *cannot* be the path to a file.

`fuse.fast.local.directio`

Default Value: 0

Specifies whether to optimize (1) or disable (0) FUSE client for local direct IO. Value can be one of:

last-updated: Apr 11, 2022

- `0` - disable
- `1` - optimize

`fuse.flush.inline`

Default Value: 0

Specifies whether (1) or not (0) to flush all writes inline. Value can be one of:

- `0` - disable inline flushing
- `1` - flush all writes inline

If disabled, for all open files, by default, the buffer is flushed automatically every 3 seconds or when it reaches 64KB. If enabled, writes are sent to server directly.

`fuse.fsname`

Default Value: FUSE mount point

Specifies the filesystem source, which is the first field in the `/etc/mtab` file. The default value is the FUSE mount point that is denoted by the parameter `fuse.mount.point`.

`fuse.hb.interval`

Default Value: 5

Specifies the heartbeat interval (in seconds) for the FUSE-based POSIX client.

`fuse.log.debug_level`

Default Value: error

The FUSE-based POSIX client log level. The value can be one of:

- `fatal`
- `error`
- `warn`
- `info`
- `debug`

`fuse.log.path`

Default Value: `/opt/mapr/logs`

Specifies the path to store the log files.

`fuse.max.background`

Default Value: 64

Specifies the maximum number of asynchronous requests that can be submitted. IO requests beyond the maximum limit are blocked.

`fuse.max.cache.pages`

Default Value: 1048576 (1 Million pages)

Specifies the maximum number of pages (each page is 8KB) in the page cache that each MapR Client library in FUSE process can use when working with a large number of open files. This setting limits the amount of memory consumed by FUSE.

`fuse.max.read`

Default Value: 131072

Specifies the maximum size (in bytes) of read requests.

`fuse.max.readahead`

Default Value: 131072

Specifies the maximum number of bytes to read ahead.

`fuse.max.write`

Default Value: 131072

Specifies the maximum number of bytes that is allowed in a single write request.

`fuse.mount.point`

Default Value: `/mapr`

This parameter is mandatory. Specifies the mount point where the MapR filesystem must be mounted. Ensure that the specified mount point is empty before starting the service. Once mounted, the POSIX client has access to all the clusters specified in `/opt/mapr/conf/mapr-clusters.conf` file. The value should not be `/mapr` if you wish to mask MapR branding.

Note: If NFS server is also running on this node, ensure that the FUSE mount point is different from the NFS server mount point.

`fuse.mount.setuid`

Default Value: `0`

By default, FUSE mounts with the `nosuid` option. This prevents users other than root from running executable files with the SUID bit set, on FUSE. Enable this parameter (set to 1), to allow users other than root to run executable files with the SUID bit enabled, on the MapR Fuse FileSystem.

This parameter works in conjunction with the `allowreadforexecute` parameter in volume create on page 1931 and volume modify on page 2005 commands.

The following table describes how both parameters work together to permit running SUID binaries:

Table

fuse.mount.setuid	allowreadforexecute	Result
Disabled	Does not matter	SUID binaries cannot be executed by users other than *root*.
Enabled	Disabled	Users other than *root* can run the SUID binaries only when the binary has **both read and execute permissions**.
Enabled	Enabled	Users other than *root* can execute the SUID binaries either when the binary has **both read and execute permissions** OR **execute permission alone**.

last-updated: Apr 11, 2022

fuse.negative.timeout

Default Value: 3

Applicable for the Container, Basic, and Platinum POSIX clients.

Indicates the duration in seconds to cache negative lookup results.

Negative lookup results that are returned when a file does not exist (lookup retuned ENOENT), are cached for the specified number of seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

The default value of 3 indicates that negative lookup results are cached for 3 seconds.

Set this value to `0` to disable the negative lookup cache.

When patching or upgrading the client from an older release, this parameter is automatically applied. However, new parameters are not automatically written to `fuse.conf`. Make sure to copy this parameter from `fuse.conf.new` to `fuse.conf`, only if you want to change the default value, or disable this cache.

fuse.nonempty

Default Value: 0

Specifies whether FUSE can be mounted on a non-empty mount point (1) or on an empty mount point (0). Value can be:

- 0 - indicates that mount point should be empty
- 1 - indicates that mount point need not be empty

fuse.num.libs

Default Value:

- Container - 1
- Basic - 1
- Platinum - 5

Specifies the number of client libraries to run with. For:

- Container client, value must be 1.
- Basic client, value must be 1.
- Platinum client, default value is 5 and can be set to a value greater than 5.

More than one library allows for more than 1GB/sec throughput on remote operations as each additional library increases the throughput by sharding operations across libraries (for parallelism).

Note: Each additional library will consume additional memory and CPU.

fuse.num.threads

Default Value: 64

Specifies the number of FUSE threads in userspace per mount point. A higher number allows parallel processing of multiple operations. Recommended value is only up to 64.

fuse.ra.sessions

Default Value:

- Container - 1
- Basic - 1
- Platinum - 5

Specifies the number of parallel read ahead sessions per library. Each open file acts as one read ahead session. For example, for the default value of 5, up to 5 files can have read ahead sessions per library. If value is set to `0`, readahead is disabled.

Note: A greater value allows larger number of parallel read ahead sessions, which is useful if more number of files need to be opened simultaneously. However, each additional read ahead session consumes additional memory (512K per read ahead session) and threads.

`fuse.readdirplus`

Default Value: 1

Enables (1) or disables (0) `readdirplus` functionality for high latency networks. The `readdirplus` attribute returns the file handle and attribute information such as the name and the file ID, along with the directory entries, unlike the `readdir` attribute that requires the client to query the server separately for each directory entry. For the best performance, do not disable this parameter.

`fuse.sync.read`

Default Value: 0

Specifies whether to enable or disable synchronized reads. Value can be:

- `0` - disable
- `1` - enable

`fuse.ticketfile.location`

Default Value: `/opt/mapr/conf/maprfuseticket`

Specifies the ticket to use to start the service in secure mode. Generate the required ticket and place it in `/opt/mapr/conf/<maprfuseticket>`.

Note: To support impersonation, provide the mapr user ticket file location or the user's servicewithimpersonation ticket file location. You can use the mapr user ticket on the server node, and service with impersonation ticket on client node. The FUSE service must be started by the root user if servicewithimpersonation ticket is specified. In case of non-impersonated ticket, the ticket credentials becomes the identity for all the requests, no matter which user is accessing the fuse mount point.

See also: Setting up a Ticket for the POSIX Client.

`fuse.track.memory`

Default Value: false

Specifies whether to enable (`true`) or disable (`false`) memory tracking for FUSE.

`fuse.use.compressed.inode.format`

Default Value: 0

Specifies whether or not to use compressed inode format. When enabled, a 16-bit unique identifier is used to avoid inode cache collisions when multiple

last-updated: Apr 11, 2022

clients are modifying (creating, deleting, and similar operations) the same directories/files. The value can be one of:

- `0` — (default) do not use compressed inode format
- `1` — use compressed inode format including unique identifier

Note: Even when set to `1`, EBUSY errors are returned if client accesses more than 32k volumes at the same time.

Enabling this flag may not completely avoid inode cache collisions when too many modifications such as creation, and deletion are performed on the same directories or files. Give the kernel sufficient time to purge inode cache entries between modifications.

`fuse.xattr.enable`

Default Value: 0 (false)

Specifies whether (true) or not (false) to enable extended attributes through the FUSE client. Value can be one of:

- 0 - false
- 1 - true

The default value is 0 (false). This is disabled by default because if enabled, during operations, the kernel might make a lot of extended attribute calls for security checks resulting in performance degradation even when there are no extended attributes on the inode. When disabled, extended attributes can still be added using the `hadoop fs` command; however, this must be enabled to perform any operations on extended attributes using the FUSE-based POSIX client.

Note: Of the five types of extended attribute namespaces in Linux, system, trusted, user, raw, and security, only user namespace is supported. For all other namespaces, EINVAL is returned.

You must start/restart the FUSE-based POSIX client for the changes to take effect. See Starting and Stopping the POSIX Client for more information.

Configuration Backup When Installing/Upgrading POSIX Clients

When you install a patch, the `/opt/mapr/conf/fuse.conf.new` file contains the new settings. You can copy the new parameters (with default values) to your existing `fuse.conf` file and restart FUSE for the settings to take effect.

When you upgrade from a prior release, on all supported OS other than Ubuntu, the old `fuse.conf` file is backed up as `fuse.conf.backup`, before being overwritten with the new settings. This backup is available in the `/opt/mapr/conf` directory.

On Ubuntu, the upgrade process does not create a backup copy of the file. You need to manually backup the `fuse.conf` file before upgrading, as this file is overwritten with the new settings after upgrading.

last-updated: Apr 11, 2022

To continue using FUSE with your custom settings, and take advantage of the new settings, manually copy your custom settings in the `fuse.conf.backup` file to the `fuse.conf` file, set custom values for the new parameters in the `fuse.conf` file where necessary, and restart FUSE for the settings to take effect.

To restart FUSE, use one of the following commands depending on the POSIX client of your choice:

- For POSIX container: `service mapr-posix-client-container restart`
- For POSIX basic: `service mapr-posix-client-basic restart`
- For POSIX platinum: `service mapr-posix-client-platinum restart`

Optimizing FUSE performance when running the Flexible I/O tester (fio tool)

Performance Tips

- With Linux kernels prior to version 4.8, size extending writes are serialized by the kernel, and result in degraded write performance. For optimized write performance, ensure that the Linux kernel in use, is at least version 4.8.
- With kernel 4.8 and above, fio performance improves when using larger block sizes and larger number of jobs (numjobs). Keep numjobs constant and use larger blocksizes (>128k) for enhanced performance.

For example, for optimised performance, the `fio` command could be as follows:

```
fio --ioengine=libaio --direct=1 --gtod_reduce=1 --name=perftest --filename=
perfile
          --bs=16m --iodepth=64 --size=4G --rw=write --numjobs=4
```

Configuring Timeout for Inactive Connections
In cases where the file client connects infrequently to a remote CLDB node that is firewalled, TCP segments on the connection are silently dropped by the firewall due to the long idle time. However, the client keeps waiting for the response till RPC times out. To mitigate this scenario, you can now configure the timeout for inactive connections. Use the `fs.mapr.binding.inactive.threshold` parameter in the *core-site.xml* file to set this threshold in seconds. For example:

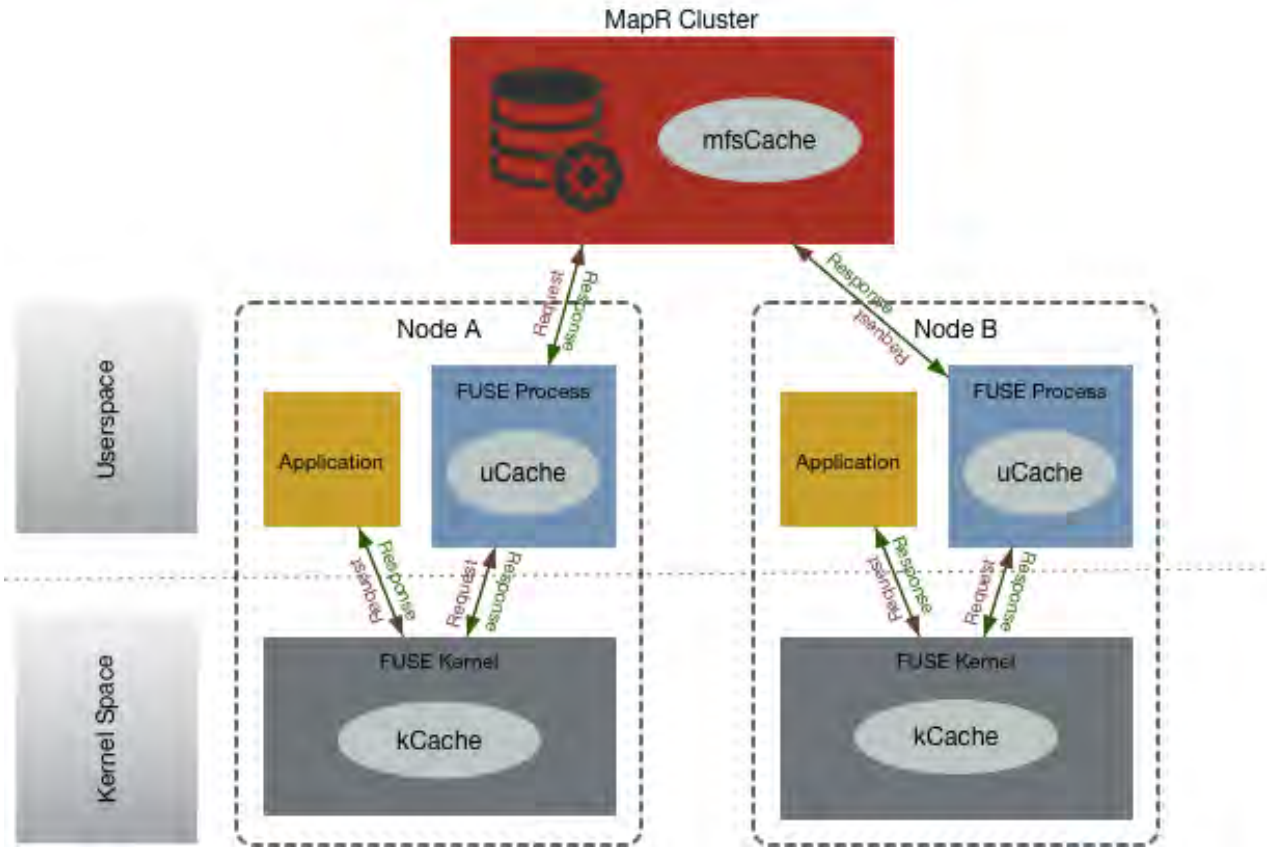
```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, that is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLBD to use for communication.

Tuning the Cache for FUSE-Based POSIX Clients
Describes performance tuning measures for FUSE clients.

The FUSE kernel and the FUSE userspace process caches both data and metadata. When an application performs a read of a file using the FUSE-based POSIX client, data is generally returned from the local FUSE kernel cache if that portion of the file resides in cache from a previous read or write operation. However, if the file has been modified on the MapR cluster by a different client, the data in the local kernel cache may be stale. The following illustration shows the layers of cache — FUSE kernel cache (referred to as kCache), the FUSE userspace cache (referred to as uCache), MapR filesystem cache (referred to as mfsCache) — and the following sections describe how these affect reads and writes and how the FUSE attributes can be used to tune the caching behavior.

last-updated: Apr 11, 2022



Inode Attribute Cache

Inode attributes are cached in the FUSE kernel cache (kCache) and in the userspace cache (uCache). When the same file is accessed from multiple FUSE clients, writes on the file through one mountpoint may not be seen by other applications performing a read on the file (through a different client). The inode attributes are cached in the kernel because of which another application modifying the file might not see the updates instantly. For example, the inode attributes, to name a few, such as size, or modification timestamp (mtime) of the file, in the kCache and uCache on Node A might be stale if the file is being modified concurrently by an application on Node B.

Tuning the attribute timeout in kCache	The FUSE kernel refreshes inode attributes from the userspace FUSE process once every 3 seconds by default. This can be tuned through the `fuse.attr.timeout` parameter in the `fuse.conf` file. The `fuse.attr.timeout` parameter specifies the interval of time at which to refresh the inode attributes in kernel and can be used to minimize the amount of time it takes to refresh the cache. Even if `fuse.attr.timeout` is set to `0`, Node A might still not see the latest writes from Node B because there is cached metadata in the userspace FUSE process on Node A; metadata can be served from the uCache and the application might not see current updates for attributes like size. To see the latest changes on a file, see Tuning the attribute timeout in uCache on page 1250.
Tuning the attribute timeout in uCache	The userspace FUSE process caches both data and metadata and refreshes the inode attributes from the MapR filesystem once every 3 seconds; *this is not tunable*. Even if the `fuse.attr.timeout` is set to 0, because there is cached data and metadata in

the userspace FUSE process (uCache), stale data or metadata can be served from the userspace FUSE process, which only refreshes inode attributes every 3 seconds. However, the userspace FUSE process updates the inode attributes every time a file is opened. To see the latest changes on a file, applications, especially readers on a file, that require to see updates on the file within 3 seconds can close and open the file to refresh the attributes and see instant updates.

Readdir Cache

Directory entries (files within a directory) are not cached in the uCache, but are cached in the kCache. The kCache can be stale on Node A if there are files being created in the directory by an application from the mountpoint on Node B. That is, a user listing directory entries on Node A for a directory (using a command like ls) might not see the files that were just created from Node B.

Tuning the entry timeout in kCache

The `fuse.entry.timeout` parameter specifies the interval of time at which to refresh the readdir (or lookup) cache in the kernel (kCache). The default value is 3 seconds and this can be configured in the `fuse.conf` file.

Data Cache

By default:

- Reads are buffered both in the kCache and the uCache.
- Writes are not buffered in the kCache, but are buffered in the uCache.

An application trying to read a file on Node A might not see the latest updates to the file (written from node B) for the following reasons:

- Reads on Node A might have been served either from the kCache or the uCache of Node A.

  See Tuning the cache for reads on page 1251 for information on invalidating the cache.

- The writes might have been buffered in the uCache of Node B.

  See Tuning the cache for writes on page 1252 for information on disabling buffering at a file level or altogether.

Tuning the cache for reads

Tuning the kCache

The `fuse.auto.inval.dat` a parameter specifies whether or not to automatically invalidate the kCache for any data change, which causes mtime change, on the files. If enabled, any mtime update on the file automatically invalidates the page cache of the file. The mtime is an inode attribute; for information on refreshing the cache for inode attributes, see Inode Attributes.

last-updated: Apr 11, 2022

	Tuning the uCache	Every read cache page is valid for 3 seconds. After 3 seconds, the read cache page is dropped from uCache. *This is not tunable*.
Tuning the cache for writes	**Tuning the kCache**	The `fuse.writeback.cache` parameter specifies whether to buffer writes in the kernel or to perform a write through. If enabled, the writes are buffered in the kernel. If disabled, writes are not buffered in the kernel and are directly sent to the FUSE process. By default, writeback caching is disabled; that is, the kernel sends all writes to the FUSE process directly. If an application does small writes, then the FUSE process might run out of CPU because of the overhead involved in small writes. To mitigate this, the FUSE kernel can be configured to enable caching in the kernel using the `fuse.writeback.cache` attribute. However, this can be enabled only on kernels running version >= 3.15.
	Tuning the uCache	The `fuse.flush.inline` attribute can be used to disable data buffering in the uCache. By default, the userspace FUSE process caches the writes locally. This parameter specifies whether to cache writes (for up to 3 seconds or 64KB in size) or write directly to server. This can be disabled at both the file and FUSE process levels. If the application does buffering before writing to filesystem, to avoid redundant buffering, you can disable buffering at the FUSE level by setting the

	`fuse.flush.inline` parameter value to `1` in the `fuse.conf` file. Caching can be disabled at a file-level by opening the file in `O_DIRECT` mode.

Caching Negative Lookup Results

FUSE issues thousands of lookup calls for the file, even when the initial lookup call has returned ENOENT, indicating that the file that does not exist, This behaviour is in contrast to NFS, which caches the lookup result for a specified time. For example, when running a `git clone` operation on the *mapr-core* repository, testing indicated that FUSE issued 870k calls, while NFS issued 82k calls, for files that are non-existent.

To reduce the number of negative lookups, and optimize performance, the FUSE configuration contains the `fuse.negative.timeout` parameter.

By default, this parameter is set to 3 seconds. Negative lookup results that are returned when a file does not exist (lookup retuned ENOENT), are cached for 3 seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

For more information on this parameter, check the FUSE configuration.

Configuring MapR FUSE-based POSIX Client for Tenant Environment
Explains the parameters to set to enable tenant user access to tenant shares from the FUSE-based POSIX client.

To enable tenant users to access the tenant share from the FUSE-based POSIX client, set the following configuration parameters in the `fuse.conf` file on the tenant host:

fuse.mount.point	Specifies the local mount path to where the cluster filesystem is going to mount. To mask the MapR branding from the tenant user, do not specify `/mapr` as the value for this parameter.
fuse.export	Specifies the path to the tenant volume mount path or directory under the tenant volume mount point. This is disabled by default, allowing users to access all the clusters specified in the `/opt/mapr/conf/mapr-clusters.conf` file. This must be set to enable the user on the tenant host to directly access only the specified volume or directory.
fuse.ticketfile.location	Specifies the path to the tenant ticket file to start the service in secure mode.

For more information on all other available and supported parameters, see Configuring the MapR FUSE-based POSIX Client.

Sample MapR FUSE-Based POSIX Client Configuration File

```
#Set path to the mount point
fuse.mount.point=/mapr

#Set path where logs shall be stored
fuse.log.path=/opt/mapr/logs

#Set path where client libraries shall be stored
fuse.client.lib.path=/tmp
```

last-updated: Apr 11, 2022

```
#Allow all users to access the filesystem
fuse.allow.other=1

#Enable larger than 4kB writes
fuse.big.writes=1

#Enable NUMA affinity
fuse.affinity=0

#Auto unmount on process termination
fuse.auto.unmount=1

#Set number of libMapRClient libraries to run with
#fuse.num.libs=DEFAULT_NUM_LIBS

#Set number of readahead sessions
#fuse.ra.sessions=1

#Enable/Disable memory tracking for fuse
fuse.track.memory=false

#Set number of FUSE threads
#fuse.num.threads=64

#Enable async direct io
fuse.asyncdirect.io=1

#Set the maximum size of read requests
#fuse.max.read=128

#Set the maximum bytes to readahead
#fuse.max.readahead=128k

#Set the maximum size in a single write request
#fuse.max.write=128

#Enable sync reads
#fuse.sync.read=0

#Set number of maximum background requests
fuse.max.background=64

#Set kernel's congestion threshold
#fuse.congestion.threshold=10

#Flush all writes inline
#fuse.flush.inline=0

#Optimize for local direct writes
#fuse.fast.local.directio=0

#Optimize by evenly distribute data across cluster
#fuse.evenly.spread.data=0

#Disable shard cache
#fuse.disable.shardcache=0

#Sets the filesystem  source  (first  field  in  /etc/mtab).
#The default is the mount program name.
#fuse.fsname=NAME

#Set fuse ticket file
fuse.ticketfile.location=/opt/mapr/conf/maprfuseticket
```

```
#fuse nonempty option to enable mounting at nonempty mount point
#fuse.nonempty=0

#by default, we support user namespace xattr.
#setting below option to 1 will enable the user xattr.
#fuse.xattr.enable=1

#Attribute timeout for inodes
#fuse.attr.timeout=3.0

#Entry timeout for inodes
#fuse.entry.timeout=3.0

#Hearbeat interval for FUSE in seconds
#fuse.hb.interval=5

#Disable writeback cache
#If multiple fuse servers are operating on the same file then enabling
#this option will break consistency among different fuse servers i.e.
#writes to file1 on server1 will not be seen by an application reading
#file1 on server2 forever.
fuse.disable.writeback=1

#Set cluster configuration file
#fuse.cluster.conf.location=/opt/mapr/conf/mapr-clusters.conf

#Sets client debug level, values are fatal, error, warn, info, debug
fuse.log.debug_level = error;

#Inode compressed format
fuse.use.compressed.inode.format=0
```

Managing the FUSE-Based POSIX Client
Describes how to use the FUSE-based POSIX client.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the MapR filesystem. You need to open the relevant ports for **TCP** connectivity from POSIX clients to the MapR file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports.

- CLDB - Ports 7222 and 7223.
- Filesystem Server - 5660, 5692, 5724, 5756, and 6660.

You can open additional CLDB ports for better performance. See Ports Used by MapR Software on page 2290 for more information.

When using Multi-MFS instances, open the relevant ports for these instances to work. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756 (5660+96), instance

1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. See Working with Multiple Instances of the File System on page 790 for more information.

Setting up a Ticket for the POSIX Client

The POSIX client can be accessed using user and service tickets. The service tickets have long lifetimes, by default, for ease of administration. This is useful for running application processes that should not be bounded by the CLDB duration (`cldb.security.user.ticket.duration.seconds`) and renewal (`cldb.security.user.ticket.max.duration.seconds`) properties, which limit the lifetime of user tickets. If you plan to use a user ticket, ensure that the user has read permissions on the ticket file.

Irrespective of the ticket type, after generating the ticket, set the `fuse.ticketfile.location` parameter value in the `fuse.conf` file to point to the ticket file to use.

For more information, see:

- Generating a MapR User Ticket on page 1426
- Generating a Service Ticket on page 1428

Note: If the UID/GID in the ticket (without impersonation capability) is different from the UID/GID of the logged-in user, all operations are performed using the UID/GID of the ticket and not that of the logged-in user.

Starting and Stopping the POSIX Client

To ensure that the service can be started and stopped and to run the help option, set the shared `LD_LIBRARY_PATH` environment variable. Update the shared library environment variable to include the paths to the following:

- Full path to the directory containing `libjvm.so` file
- `$MAPR_HOME/lib` (that is, `/opt/mapr/lib` directory)

For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

To allow a non-root user to start this service, as administrator or `root` user, run the following command:

```
chmod u+s /opt/mapr/bin/fusermount
```

Verify that permissions have been set for non-root user to start the service. For example:

```
ls -l /opt/mapr/bin/fusermount
```

Your output should look similar to the following:

```
-rwsr-xr-x 1 root root 39704 Feb 16 19:41 /opt/mapr/bin/fusermount
```

Ensure that the non-root user has full permissions on the mount point and log files.

To manually start or stop the service:

```
service mapr-posix-client-* [start|stop|status]
```

When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

Note: The POSIX client service cannot be stopped or restarted if any other process is accessing the mount point. With `systemd` (on CentOS/RH 7.x and SLES 12), the service will enter failed state (if you tried to stop) or activating state (if you tried to restart) and you must manually kill the client processes.

Running the POSIX Client in Secure Mode

The POSIX client reads the `mapr-clusters.conf` file to determine whether the process must start in secure or non-secure mode. If security is configured, the servicewithimpersonation ticket file must be present in the default `/tmp` directory. If the ticket file is not in the default `/tmp` directory, specify the location of the ticket file using the `fuse.ticketfile.location` configuration parameter in the `fuse.conf` file

Tip: See also: Enabling Impersonation for the MapR Superuser on page 1480 and Enabling Impersonation for any User on page 1480.

If the ticket expires after a connection has been established between the POSIX client and the cluster, the connection can stay alive for up to an hour. No new connections will be allowed. If the ticket was blacklisted, restart POSIX client to refresh the ticket.

Mounting the MapR File System

To mount the MapR filesystem at the mount point specified in the `/opt/mapr/conf/fuse.conf` file, create the mountpoint specified in the `fuse.conf` file and start the service. For example:

```
mkdir /mapr
service mapr-posix-client-* start
```

Note: When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

Attention: Remember the following points when using a FUSE mounted filesystem:

- When trying to open a FIFO on a FUSE mounted filesystem, permissions to perform the operation are not checked.
- Any user can set time using `touch -t` for any file on a FUSE mounted filesystem.

See also: Enabling Soft Mount and Setting the Timeout on page 420

Monitoring the POSIX Client

To determine whether the POSIX client is running, run the following command:

```
service mapr-posix-client-* status
```

Note: When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

Adding and Removing Users

Before you add and/or remove users using the POSIX client, make a note of the following:

- Invalid UID/GID cannot perform operations on the system.
- When you add or remove users, it may take up to 30 minutes for the changes to take effect.

last-updated: Apr 11, 2022

By default, the UID cache will expire in 30 minutes. To disable UID cache, set the value (in seconds) for `fs.mapr.uid.cache.timeout.seconds` parameter in the `core-site.xml` file. You can set the value to:

- `0` to fetch the GID information from the idstore directly
- `>0` to specify the amount of time to keep the UID information in cache

For example, your `core-site.xml` entry would look similar to the following for:

- Disabling cache:

```
<property>
   <name>fs.mapr.uid.cache.timeout.seconds</name>
   <value>0</value>
   <description>disable UID cache</description>
</property>
```

- Setting 3 minutes as the amount of time to keep the UID information in cache:

```
<property>
   <name>fs.mapr.uid.cache.timeout.seconds</name>
   <value>180</value>
   <description>UID cached for 3 minutes</description>
</property>
```

Registering POSIX Client with Additional Clusters

To register the POSIX client with additional clusters, you must add entries directly to the `/opt/mapr/conf/mapr-clusters.conf` file. The clusters will be visible after few minutes.

Note: Each client supports up to 16 clusters.

Configuring the FUSE Read Chunk Size

The POSIX FUSE platinum client can break large reads into multiple pieces to be handled in parallel, if you set the FUSE read chunk size of a file. This process is called sharding.

By default, the FUSE read chunk size is set to 2 MB. To change the chunk size used by the FUSE platinum client for parallel reads, set the value (in bytes) for the `fs.mapr.fuseshard.chunksize` configuration field in the `core-site.xml` file. To set the chunksize to 5 MB (5242880 bytes), use:

```
<property>
        <name>fs.mapr.fuseshard.chunksize</name>
        <value>5242880</value>
        <description>setting chunk size</description>
        </property>
```

For example, if the FUSE read chunk size is set to 1 MB, and the FUSE platinum client is configured with 5 libraries, then the platinum client reads 5 MB in parallel.

Unmounting the FUSE Mount

To unmount the mountpoint and kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

Note: When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

Troubleshooting the FUSE-Based POSIX Client
Explains how to enable and collect the stack trace to troubleshoot POSIX client issues.

This section contains information for troubleshooting the FUSE-based POSIX client.

Enabling Traces

To enable traces at system startup, set the property `fs.mapr.trace` in the `core-site.xml` file. For example:

```
<property>
   <name>fs.mapr.trace</name>
   <value>DEBUG | INFO | WARN | ERROR | CRITICAL | OFF</value>
   <description> </description>
</property>
```

Collecting the Stack Trace

If the mountpoint is not responding or if the filesystem operations are taking too much time, collect the stack trace of all the threads to debug. To collect the stack trace of all threads, run the following command:

```
gstack <fuse-process-id> > ./gstack.log
```

If the filesystem commands fail, repeat the filesystem command with `strace` and collect the log file:

```
strace <filesystem command> > ./strace.log
```

Managing the MAST Gateway

You can start, stop, and restart the MAST Gateway using the MapR Control System and the CLI. You can also configure how frequently MapR runs the load balancer to balance the load on the MAST Gateway.

Configuring the MAST Gateway Service

After installing MAST Gateway service, perform the following steps on the node if MapR File System is not installed on the node. If MapR File System is (also) installed on the node, start at step 4:

1. Run `configure.sh` on page 2053 utility.
   For example:

   ```
   /opt/mapr/server/configure.sh -C <CLDB nodes> -Z <Zookeeper nodes> -N
   <ClusterName>
   ```

2. Start Warden if it is already not running.

   ```
   service mapr-warden start
   ```

3. Run `jps` or `/etc/init.d/mapr-mastgateway status` to check whether MAST Gateway is running on the node.

4. Open the `/opt/mapr/conf/mastgateway.conf` file and set values for the following parameters:

last-updated: Apr 11, 2022

Parameter	Default Value	Description
`mastgateway.port`	8660	The port on which the MAST Gateway process runs. Default value is 8660.
`mastgateway.worker.numthreads`	16	The number of threads to execute tiered data operations such as read and modify part of the offloaded data. The default value is 16. You can modify this based on the machine's configuration.
`mastgateway.cntr.worker.numthreads`	16	The number of threads to use to execute container-based tiered data operations such as offload and recall of file-level and volume-level data in parallel. The default value is 16. **Tip:** For faster offload, modify this value based on the machine's configuration.
`mastgateway.logfile.size.mb`	1024	The maximum size (in MB) of the MAST Gateway log file. When the size limit is reached, the logs get rolled over.

Note: If you modify the `mastgateway.conf` file, you must restart the MAST Gateway for the changes to take effect.

5. (Optional) Add the following parameters in the `/opt/mapr/conf/mastgateway.conf` file only if you wish to customize libcurl.

   The MAST Gateway uses libcurl to perform tiering-related operations. The following table lists the customizable libcurl options and their default values. If these are not set in the `mastgateway.conf` file, the default values are used.

   Note: In the `mastgateway.conf` file, add only the parameters that you wish to customize.

Parameter	Default Value	Description
`mastgateway.curl.timeout`	300000	Timeout for the entire request.
`mastgateway.curl.connecttimeout`	60000	Timeout for the connection phase.
`mastgateway.curl.nosignal`	0	Do not install signal handlers.
`mastgateway.curl.followlocation`	0	Follow HTTP redirects.
`mastgateway.curl.maxsendspeed`	0	Limit on data upload speed.
`mastgateway.curl.maxrecvspeed`	0	Limit on data download speed.
`mastgateway.curl.maxconnects`	5	Maximum number of connections in the connection pool.
`mastgateway.curl.dnsservers`	null	Preferred DNS servers.
`mastgateway.curl.interface`	null	Bind connection locally to this.

Parameter	Default Value	Description
mastgateway.curl.verifypeer	1	Verify the SSL certificate.
mastgateway.curl.verifyhost	2	Verify the host name in the SSL certificate.
mastgateway.curl.cainfo	null	CA cert bundle.
mastgateway.curl.issuercert	null	Issuer certificate.
mastgateway.curl.sslcert	null	Client cert.
mastgateway.curl.sslcerttype	null	Client cert type.
mastgateway.curl.sslkey	null	Client key.
mastgateway.curl.sslkeytype	null	Client key type.
mastgateway.curl.sslkeypasswd	null	Client key password.
mastgateway.curl.proxy	null	Proxy to use. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.preproxy	null	Socks proxy to use.
mastgateway.curl.proxyport	0	Proxy port to use. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.proxytype	0	Proxy type. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.httpproxytunnel	0	Tunnel through the HTTP proxy. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
mastgateway.curl.proxyuser	null	Proxy user name. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.

last-updated: Apr 11, 2022

Parameter	Default Value	Description
`mastgateway.curl.proxypasswd`	null	Proxy password. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.proxyauth`	1	HTTP proxy authentication methods. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.proxyverifypeer`	1	Verify the proxy's SSL certificate.
`mastgateway.curl.proxyverifyhost`	2	Verify the proxy certificate's name against host.
`mastgateway.curl.proxycainfo`	null	Path to proxy Certificate Authority (CA) bundle.
`mastgateway.curl.proxysslcert`	null	SSL proxy client certificate.
`mastgateway.curl.proxysslcerttype`	null	Type of the proxy client SSL certificate.
`mastgateway.curl.proxysslkey`	null	Private keyfile for TLS and SSL proxy client cert.
`mastgateway.curl.proxysslkeytype`	null	Type of proxy private key file.
`mastgateway.curl.proxysslkeypasswd`	null	Passphrase for proxy private key.

For example, to configure the MAST Gateway for proxy server, your `mastgateway.conf` file settings for proxy server should look similar to the following:

```
mastgateway.curl.proxy=10.20.30.140

mastgateway.curl.preproxy=null

mastgateway.curl.proxyport=3128

mastgateway.curl.proxytype=0

mastgateway.curl.httpproxytunnel=0

mastgateway.curl.proxyuser=proxyuser

mastgateway.curl.proxypasswd=proxyuserpwd
```

```
mastgateway.curl.proxyauth=1
```

6. Save and close the `/opt/mapr/conf/mastgateway.conf` file.
7. (Optional) Configure memory for the MAST Gateway in the `/opt/mapr/conf/conf.d/warden.mastgateway.conf` file by setting values for the following parameters:

Parameter	Default Value	Description
`service.heapsize.min`	2048	The minimum amount of node memory (in MB) to allocate.
`service.heapsize.max`	20480	The maximum amount of node memory (in MB) allocate.
`service.heapsize.percent`	10	The percentage of node memory to allocate.

   By default, 10% of the node memory or 20GB, whichever is lower, is allocated to MAST Gateway. If the MAST Gateway is processing jobs for both warm and cold tiers, memory consumption can increase up to 7GB or more. If you see high memory alarms for small memory consumption also, tune the percentage of memory allocated for MAST Gateway. Ensure that the percentage of memory allocated through `service.heapsize.percent` is available for MAST Gateway.

8. (Optional) Set the value for `fs.mapr.pool.queue.max_size` parameter to 20000 in the `/opt/mapr/conf/dbclient.conf` file.

   If compression is enabled on the data in a tiering-enabled volume, tiering jobs can fail and return errors because of the large number of operations sent to the DB (where metadata for offloaded data is stored). To prevent errors, add the `fs.mapr.pool.queue.max_size` parameter to the `/opt/mapr/conf/dbclient.conf` file and set the value for this parameter to a large number, such as 20000. For example, your entry in the `/opt/mapr/conf/dbclient.conf` file should look similar to the following:

   ```
   fs.mapr.pool.queue.max_size = 20000
   ```

9. Restart the MAST Gateway for the changes to take effect.

   See Starting, Stopping, and Restarting the MAST Gateway on page 1263 for more information.

Configuring Secure Access

If the MapR cluster is a secure cluster and the MAST Gateway is installed on a cluster node, no additional configuration is needed for the MAST Gateway to access data. On the other hand, if the MapR cluster is a secure cluster and if MAST Gateway is installed on an edge node, to enable the MAST Gateway to communicate with the secure MapR cluster, do the following:

1. Copy the `/opt/mapr/conf/maprserverticket`, `/opt/mapr/conf/ssl_keystore`, and `/opt/mapr/conf/ssl_truststore` files on the CLDB node to the `/opt/mapr/conf` directory on the edge node.
2. Run `configure.sh` as shown below:

   ```
   /opt/mapr/server/configure.sh -C <cldb-node-IP-addresses> -Z
   <zookeeper-node-IP-addresses> -secure -N <cluster-name>
   ```

   See `configure.sh` on page 2053 for more information.

Starting, Stopping, and Restarting the MAST Gateway

You can start, stop, and restart the MAST Gateway using the Control System and the CLI.

Starting, Stopping, and Restarting the MAST Gateway Using the Control System

See:

- Starting the Services on the Cluster Using the Control System on page 830
- Stopping a Service on the Cluster Using the Control System on page 831
- Restarting the Services on the Cluster Using the Control System on page 832

Starting, Stopping, and Restarting the MAST Gateway Using the CLI

- Run the following command to:
  - Start the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action start
```

  - Stop the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action stop
```

  - Restart the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action restart
```

Balancing Gateway Load

Explains how CLDB balances MAST Gateway loads.

CLDB assigns volumes to MAST Gateways so that any tiering-related operation for a volume is performed by the MAST Gateway assigned to the volume. This assignment is sticky and the volume remains assigned to the same gateway across CLDB, MAST Gateway, and cluster restarts. When a MAST Gateway goes down, volumes assigned to the MAST Gateway are not re-assigned immediately. Instead, when a tiering operation needs to be run and the assigned MAST Gateway is down, CLDB assigns a new MAST Gateway to the volume, and the operation is performed using the newly assigned MAST Gateway.

Volumes are assigned to gateways with the lowest load (or lowest number of volumes currently assigned to it) to ensure equal distribution. Whenever a volume is created or removed or whenever a MAST Gateway is added or removed, the load on the gateways require rebalancing. MapR automatically balances the load on the gateways after a certain (configurable) amount of time since the occurrence of the event that necessitates a rebalance. The delay after which MapR tries to rebalance varies based on the type of event that necessitates a rebalance. See Configuring the Delay After Which Load Balancer runs for Events on page 1265 for more information.

Each volume in the cluster is assigned a weight, which is 1 for all volumes. The load on a gateway is the sum of weights of all the volumes that are assigned to the gateway. Load balancer tries to ensure that the load on a gateway is at least the average weight.

```
avg weight = (sum(weight of all tiered vols) + num active gws - 1) / num
active gws
```

When the balancer needs to pick volumes from a gateway for reassignment, it first picks the volume with max weight and one that currently has no activity (volume level offload, recall, or compaction). To minimize the interruptions in gateway activity, the balancer first considers idle volumes and picks volumes with active

tasks after. However, any balancing and/or reassignment is skipped if there is already assignment related flux in the cluster (such as volumes with gateway assignment currently in progress). If this happens, load balancer runs again with a shorter time delay of 10 minutes.

MapR performs load balancing in batches of 5 volumes per run. That is, it assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). MapR figures out the next batch of volumes by re-evaluating the current assignment state. When the load on the gateway is balanced, the balancer is disabled and the load balancer is run again only by any of the 4 events.

Configuring Interval Between Load Balancer Runs

- MapR assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). Run the following command to configure the interval between runs:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.recheck":"<time-in-seconds>"}
```

Configuring the Delay After Which Load Balancer runs for Events

MapR runs the load balancer automatically for any of the following events. You can configure the delay after which MapR runs the load balancer.

Create Volume	When you create a tiering-enabled volume, it is assigned the gateway with the lowest load. If gateways are not available for the volume at the time of creation, the volume might stay unassigned. To ensure that the volume has an associated gateway for handling the tiering operations, MapR runs the gateway load balancer after a delay of 2 hours (7200 seconds) by default for this event. To configure the delay, set the value for `cldb.tier.gw.balance.delay.vol.create` property (in seconds) using the `config save` on page 1586 command. For example: `maprcli config save -values {"cldb.tier.gw.balance.delay.vol.create":"<time-in-seconds>"}`
Remove Volume	When you remove a volume, the distribution of volumes across gateways can become uneven, and the balancer must be run to redistribute the volumes. For this event, MapR runs the load balancer to redistribute the volumes and rebalance the gateways after a delay of 2 hours (7200 seconds) by default for this event. To configure the delay, set the value for the `cldb.tier.gw.balance.delay.vol.delete` property (in seconds) using the `config save` on page 1586 command. For example: `maprcli config save -values {"cldb.tier.gw.balance.delay.vol.delete":"<time-in-seconds>"}`
Add Gateway	When you install a new gateway on a cluster, volumes are assigned to the new gateway only if a new volume is created or an existing volume has a pending

last-updated: Apr 11, 2022

	task, but no active assigned gateway. Volumes that have active gateways are not re-assigned by default. For this event, MapR runs the load balancer to re-distribute the volumes and rebalance the gateway load after a delay of 2 hours (7200 seconds) by default. To configure the delay, set the value for the `cldb.tier.gw.balance.delay.new.gw` property (in seconds) using the `config save` on page 1586 command. For example: `maprcli config save -values {"cldb.tier.gw.balance.delay.new.gw":"<time-in-seconds>"}`
Remove Gateway	When you remove a gateway or when a gateway goes down, all the volumes assigned to the gateway are not re-assigned by default; only volumes with pending tasks are assigned to new gateways. For this event, MapR runs the load balancer to re-distribute the volumes after 6 hours (21600 seconds) by default. To configure the delay, set the value for the `cldb.tier.gw.balance.delay.dead.gw` property (in seconds) using the `config save` on page 1586 command. For example: `maprcli config save -values {"cldb.tier.gw.balance.delay.dead.gw":"<time-in-seconds>"}`

Determining the Volumes Assigned to MAST Gateways

- Run one of the following commands to determine the volumes that are assigned to MAST Gateways:
  - `/opt/mapr/server/mrconfig info mastgateway`
  - `/opt/mapr/server/mrconfig info volume mastgateway`

  For more information, see `mrconfig info` on page 2152.

Enabling Debug Logging for MAST Gateway

The MAST Gateway service log file contains alarm messages, error codes, and information on the errors. When the `mastgateway.log` file reaches `mastgateway.logfile.size.mb/5`, a roll over happens and the `mastgateway.log` file is renamed as `mastgateway.log.1`; also, a new `mastgateway.log` file is created. When the newly created `mastgateway.log` reaches `mastgateway.logfile.size.mb/5`, a roll over happens again and:

- The `mastgateway.log.1` is renamed as `mastgateway.log.2`
- The `mastgateway.log` is renamed as `mastgateway.log.1`
- A new `mastgateway.log` is created

This process continues and up to 5 files, whose size is `mastgateway.logfile.size.mb/5`, are created before the oldest log file, `mastgateway.log.4`, is deleted.

- Run the following command to enable debug logging for MAST Gateway:

```
maprcli trace setlevel -module MASTGateway -level Debug -port 8660
```

Configuring NodeManager Restart

NodeManager restart is enabled by default. Active containers will keep running in the event that the NodeManager shuts down.

When the NodeManager restart is enabled, it stores the container state of active containers in a recovery directory;when the NodeManager restarts, it retrieves the container state from the recovery directory.

If you disable NodeManager restart, active containers are shut down when the NodeManager shuts down and containers need to be reallocated when the NodeManager starts again.

To configure NodeManager restart, enable the NodeManager recovery and also specify a port that can be dedicated to run the NodeManager service.

1. Add the following parameters to the `yarn-site.xml` on each NodeManager node:
   a) Set `yarn.nodemanager.recovery.enabled` to true.
   b) Set `yarn.nodemanager.address` to include a port that is dedicated to run the NodeManager on this node.
   c) Optionally, set `yarn.nodemanager.recovery.dir` to a different recovery directory for this node.
      By default, the recovery directory is set to`$hadoop.tmp.dir/yarn-nm-recovery` which resolves to `tmp/hadoop-mapr/nm-local-dir/yarn-nm-recovery`. See the following example configuration:

```
<property>
  <name>yarn.nodemanager.recovery.enabled</name>
  <value>true</value>
</property>
<property>
  <name>yarn.nodemanager.address</name>
  <value>0.0.0.0:8099</value>
</property>
```

2. Restart the NodeManager Service.
   For more information, see Managing Services on page 827.

Managing Jobs and Applications

If you have used Hadoop in the past to run MapReduce applications, then running jobs on the MapR Data Platform platform will be very familiar to you. MapR Data Platform is a full Hadoop distribution, API-compatible with all versions of Hadoop. MapR Data Platform provides additional capabilities not present in any other Hadoop distribution.

You can perform the following procedures to manage applications in a MapR Data Platform cluster:

Job Scheduling

You can use job scheduling to prioritize the YARN applications that run on your MapR cluster.

The MapReduce system supports a minimum of one queue, named `default`. Hence, this parameter's value should always contain the string `default`. Some job schedulers, like the Capacity Scheduler, support multiple queues.

last-updated: Apr 11, 2022

The default job scheduler is the Fair Scheduler, which is designed for a production environment with multiple users or groups that compete for cluster resources.

The MapR Converged Data Platform supports these job schedulers:

- **FIFO queue-based scheduler**: The FIFO queue scheduler runs jobs based on the order in which the jobs were submitted. You can prioritize a job by changing the value of the `mapred.job.priority` property or by calling the `setJobPriority()` method.
- **Fair Scheduler**: This is the default scheduler. The Fair Scheduler allocates a share of cluster capacity to each user over time. The design goal of the Fair Scheduler is to assign resources to jobs so that each job receives an equal share of resources over time. The Fair Scheduler enforces fair sharing within each queue. Running jobs share the queue's resources.
- **Capacity Scheduler**: The Capacity Scheduler enables users or organizations to simulate an individual hadoop cluster with FIFO scheduling for each user or organization. You can define organizations using *queues*.

The following sections provide more information about job scheduling:

Hadoop 2.x Fair Scheduler

The FairScheduler is a pluggable scheduler for Hadoop that allows YARN applications to share resources in a large cluster fairly. Fair scheduling is a method of assigning resources to applications such that all applications get, on average, an equal share of resources over time. Hadoop 2.x is capable of scheduling multiple resource types.

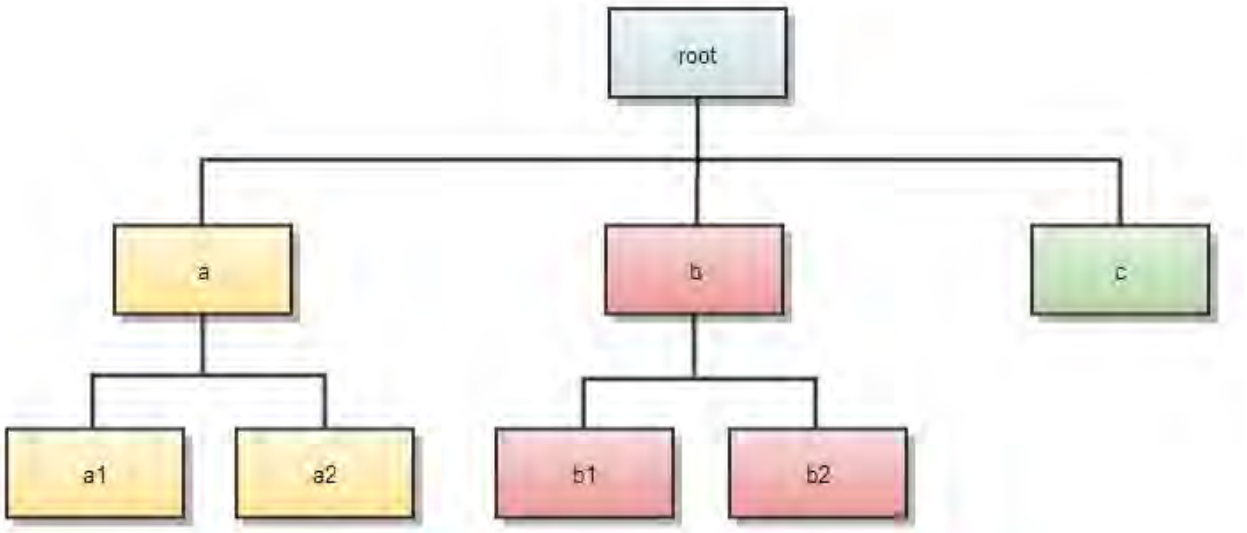
By default, the Fair Scheduler bases scheduling fairness decisions only on memory. It can be configured to schedule resources based on memory, CPU, and disk usage. When only one application is running, that application uses the entire cluster. When other applications are submitted, resources that free up are assigned to the new applications, so that each application eventually gets approximately the same amount of resources. Unlike the default Hadoop scheduler, which forms a queue of applications, this lets short applications finish in reasonable time while not starving long-lived applications. It is also a reasonable way to share a cluster between a number of users. Finally, fair sharing also uses priorities applied as weights to determine the fraction of total resources that each application should get.

For additional information about Hadoop Fair Scheduler, you can also refer to the open source documentation.

Scheduling Queues

The scheduler organizes applications further into *queues*, and shares resources fairly between these queues. By default, all users share a single queue, named `default`. If an application specifically lists a queue in a container resource request, the request is submitted to that queue. You can also assign queues based on the user name included with the request through configuration. Within each queue, a scheduling policy is used to share resources between the running applications. The default is memory-based fair sharing, but FIFO and multi-resource with Dominant Resource Fairness can also be configured.

Queues can be arranged in a hierarchy to divide resources, and they can be configured with weights to share the cluster in specific proportions. The Fair Scheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root.* The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:



In addition to providing fair sharing, the Fair Scheduler allows assigning guaranteed minimum shares to queues, which is useful for ensuring that certain users, groups or production applications always get sufficient resources. When a queue contains apps, it gets at least its minimum share, but when the queue does not need its full guaranteed share, the excess is split between other running apps. This lets the scheduler guarantee capacity for queues while utilizing resources efficiently when these queues do not contain applications.

Configuring the Fair Scheduler

The Fair Scheduler lets all applications run by default, but you can also limit the number of running applications per user and per queue through the configuration file. This can be useful when a user must submit hundreds of applications at once, or in general to improve performance if running too many applications at once would cause too much intermediate data to be created or too much context-switching. Limiting the applications does not cause any subsequently submitted applications to fail; it only causes them to wait in the scheduler's queue until earlier applications finish.

To customize the Fair Scheduler, set the configuration properties in `yarn-site.xml` and update the allocation file to list existing queues and their respective weights and capacities. The allocation file is automatically created during MapR installation in the following directory:

```
{$MAPR_HOME}/hadoop/hadoop-2.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

Specifying Fair Scheduler Configuration Properties in yarn-site.xml
Lists the properties in the *yarn-site.xml* file for Fair Scheduler.

The `yarn-site.xml` file contains the following parameters that determine scheduler-wide options.

yarn.scheduler.fair.allocation.file	*Default Value*: `fair-scheduler.xml` *Description*: Specifies the path to the allocation file. If a relative path is given, the file is searched for on the classpath.
yarn.scheduler.fair.user-as-default-queue	*Default Value*: `true` *Description*: Determines whether to use the username associated with the allocation file as the default queue name, if a queue name is not specified.

last-updated: Apr 11, 2022

	Note: If a queue placement policy is given in the allocations file, this property is ignored.
yarn.scheduler.fair.preemption	*Default Value*: `false` *Description*: Indicates whether to use preemption. **Note:** Do not use preemption when `FairScheduler DominantResourceFairness` is in use and node labels are present.
yarn.scheduler.fair.sizebasedweight	*Default Value*: `false` *Description*: Indicates whether to assign shares to individual applications based on their size, rather than providing an equal share to all applications regardless of size. When set to `true`, applications are weighted by *(ln 1 + <application's total requested memory>)/ ln 2*.
yarn.scheduler.fair.assignmultiple	*Default Value*: `false` *Description*: Indicates whether to allow multiple container assignments in one heartbeat.
yarn.scheduler.fair.resources-based-on-labels-enabled	*Default Value*: `false` *Description*: Indicates whether to allow container allocation on all nodes by recomputing fair shares based on labels.
yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled	*Default Value*: `false` *Description*: Indicates whether to enable/disable preemption of the threshold per-label.

Fair Scheduler Allocation File
Describes an allocation file and the entities within an allocation file.

An allocation file is an XML manifest that describes queues and their properties, as well as certain policy defaults. The allocation file is automatically created during MapR installation in the following directory:

```
{$MAPR_HOME}/hadoop/hadoop-2.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

The allocation file contains the following types of elements:

Queue Elements

Queue elements represent queues and can contain the following elements:

- `minResources`
- `maxResources`
- `maxRunningApps`

  Tip: The `queueMaxAppsDefault` value is used for any parent queue that does not set a value for the `maxRunningApps` element.

- `weight`

last-updated: Apr 11, 2022

- `schedulingPolicy`
- `aclSubmitApps`
- `aclAdministerApps`
- `minSharePreemptionTimeout`
- `maxContainerAllocation`

  Tip: The `maxContainerAllocation` property sets a limit on the resources a queue can allocate for a single container. The value cannot exceed `maxResources`. If you do not set `maxContainerAllocation`, the value is inherited from a parent queue. The default values are set through the `yarn.scheduler.maximum-allocation-mb`, `yarn.scheduler.maximum-allocation-vcores`, and `yarn.scheduler.maximum-allocation-disks` properties, which you can modify in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`. The `maxContainerAllocation` element is not valid for the root queue.

For more information on these elements, see Hadoop: Fair Scheduler.

User Elements

User elements represent settings that govern the behavior of individual users. They can contain a single property, `maxRunningApps`, which limits the number of running applications for a particular user. It contains the following elements:

- `userMaxAppsDefault`
- `queueMaxAppsDefault`
- `fairSharePreemptionTimeout`
- `defaultQueueSchedulingPolicy`
- `queuePlacementPolicy`

For more information on these elements, see Hadoop: Fair Scheduler.

Tip: If you set a value for `queueMaxAppsDefault` and do not set a value for `maxRunningApps` for the root queue, the value of `queueMaxAppsDefault` sets the application limit for all queues under the root queue hierarchy.

Example Allocation File

See example allocation file in Hadoop: Fair Scheduler.

Queue Access Control Lists

Queue Access Control Lists (*ACL*s) allow administrators to control who may take actions on particular queues. They are configured with the `aclSubmitApps` and `aclAdministerApps` properties, which can be set per queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as user1,user2 group1,group2 or group1,group2. An action on a queue is permitted if its user or group is in the *ACL* of that queue or in the *ACL* of any of that queue's ancestors. Therefore, if queue2 is inside queue1, and user1 is in queue1's *ACL*, and user2 is in queue2's *ACL*, then both users may submit to queue2.

last-updated: Apr 11, 2022

For more information, see Hadoop: Fair Scheduler.

The `yarn.admin.acl and yarn.acl.enable` Properties	By default, on a secure cluster, users cannot kill jobs that do not belong to them.
	On a secure cluster, you do not need to set the `yarn.acl` or the `yarn.admin.acl` properties. By default, they are set as follows. On unsecured clusters, these properties are not set by default.
	`<property>`
	`<name>yarn.acl.enable</name> >`
	`<value>true</value> >`
	`</property>`
	`<property>`
	`<name>yarn.admin.acl</name> >`
	`<value> </value> >`
	`</property>`
	The `yarn.admin.acl` property is set by default to " ", meaning that an administrator is not specified on a cluster.
	To allow users to kill jobs that do not belong to them, or to get access to their logs, you need to set the `yarn.admin.acl` property with the user or group name.

Fair and Capacity scheduler root queue admins	For both the Fair scheduler and Capacity scheduler, the default value of the administrators for the root queues is " " .

Hadoop 2.x Capacity Scheduler

The `CapacityScheduler` is a pluggable scheduler for Hadoop that allows multiple tenants to securely share a large cluster. Resources are allocated to each tenant's applications in a way that fully utilizes the cluster, governed by the constraints of allocated capacities.

Queues are typically set up by administrators to reflect the economics of the shared cluster. The Capacity Scheduler supports hierarchical queues to ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources.

The following sections provide more information about the CapacityScheduler:

Capacity Scheduler Features

The CapacityScheduler supports these features:

- **Hierarchical Queues** Hierarchical queues ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources, thereby providing more control and predictability.
- **Capacity Guarantees** Queues are allocated a fraction of the capacity of the grid, which means that a certain capacity of resources are at their disposal. All applications submitted to a queue have access to the capacity allocated to the queue. Administrators can configure soft limits and optional hard limits on the capacity allocated to each queue.
- **Security** Each queue has strict Access Control Lists (ACLs). The ACLs control which users can submit applications to individual queues. Also, safeguards ensure that users cannot view or modify applications from other users. Per-queue and system administrator roles are also supported.

- **Elasticity** Free resources can be allocated to any queue beyond its capacity allocation. As tasks scheduled on these resources complete, the resources become available to be reassigned to applications on queues running below their capacity. (Note that pre-emption is not supported.) This ensures that resources are available in a predictable and elastic manner to queues, thus preventing artificial silos of resources in the cluster and improving cluster utilization.
- **Multi-tenancy** A comprehensive set of limits is provided to prevent a single application, user, or queue from monopolizing resources of the queue or the cluster as a whole. This ensures that the cluster is not overwhelmed.
- **Operability**
  - **Runtime Configuration** The queue definitions and properties, such as capacity or ACLs, can be changed in a secure manner by administrators at runtime, which minimizes disruption to users. Also, a console is provided for users and administrators to view the current allocation of resources to various queues in the system. Administrators can add queues at runtime, but queues cannot be deleted at runtime.
  - **Drain applications** Administrators can stop queues at runtime to ensure that while existing applications run to completion, no new applications can be submitted. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. Existing applications continue to completion, so the queue can be drained gracefully. Administrators can also start the stopped queues.
- **Resource-based Scheduling** Support for resource-intensive applications, where an application can optionally specify higher resource requirements than the default, thereby accommodating applications with differing resource requirements. Currently, *memory* is the only supported resource requirement.

Setting Up ResourceManager to Use CapacityScheduler

To configure the ResourceManager to use the CapacityScheduler, set the following property in the `yarn-site.xml` file:

Property Name	Value
`yarn.resourcemanager.scheduler.class`	`org.apache.hadoop.yarn.server.resourcemanager.scheduler.capacity. CapacityScheduler`

Setting Up Queues

The ResourceManager uses the configuration file `capacity-scheduler.xml`, where you can configure various scheduling parameters related to queues. These parameters include:

- the short queue name
- the full queue path name
- a list of associated child queues and applications
- the guaranteed capacity (expressed as a percentage of total resources in the cluster) available to the jobs in the queue
- the maximum capacity of the queue
- a list of active users and their resource allocation limits
- the state of the queue (running or stopped)
- access control lists that determine who can access the queue

The CapacityScheduler has a pre-defined queue called *root*. All queues in the system are children of the `root` queue. Further queues can be set up by configuring `yarn.scheduler.capacity.root.queues` with a list of comma-separated child queues.

Queue Properties

The `capacity-scheduler.xml` file includes three types of queue properties:

Resource Allocation Properties

The following table lists resource allocation properties:

Property	Description
`yarn.scheduler.capacity.<queue-path>.capacity`	Queue *capacity* in percentage (%) expressed as a float (for example, 12.5). The sum of capacities for all queues, at each level, must equal 100. Applications in the queue may consume more resources than the queue's capacity if there are free resources, which provides elasticity.
`yarn.scheduler.capacity.<queue-path>.maximum-capacity`	Maximum queue capacity in percentage (%) expressed as a float. This property limits the elasticity for applications in the queue. The default is -1 which disables it.
`yarn.scheduler.capacity.<queue-path>.minimum-user-limit-percent`	Sets the minimum value, expressed as an integer, on the percentage of resources allocated to a user, if there is a demand for resources. A value of 100 implies no user limits are imposed. The default is 100. The maximum value depends on the number of users who have submitted applications. For example, if this property is set to 25 and two users have submitted applications to a queue, the maximum percent of queue resources for each user is 50%. If a third user submits an application, no single user can use more than 33% of the queue resources. With four or more users, no user can use more than 25% of the queue resources.
`yarn.scheduler.capacity.<queue-path>.user-limit-factor`	The multiple of the queue capacity that can be configured to allow a single user to acquire more resources. Value is specified as a float. The default is 1, which ensures that a single user can never take more than the queue's configured capacity no matter how idle the cluster is.

last-updated: Apr 11, 2022

Property	Description
`yarn.scheduler.capacity.resource-calculator`	Specifies the `ResourceCalculator` implementation to be used to compare resources in the scheduler. The default value is `DiskBasedResourceCalculator`, which uses memory, CPU and disk. Other values for this parameter include: • `DefaultResourceCalculator`, which uses memory only • `DominantResourceCalculator`, which uses dominant-resource to compare multi-dimensional resources such as memory and CPU • `DiskBasedDominantResourceCalculator`, which uses dominant-resource to compare multi-dimensional resources, such as memory, CPU and disk

Running and Pending Application Limits

Applications are considered active if they are either running or pending. The following table lists properties that specify running and pending application limits:

Property	Description
`yarn.scheduler.capacity.maximum-applications`	Maximum number of applications in the system that can be concurrently active, both running and pending. Limits on each queue are directly proportional to their queue capacities and user limits. This is a hard limit; any applications submitted when this limit is reached will be rejected. The default is 10000. This applies to all queues.
`yarn.scheduler.capacity.<queue-path>.maximum-applications`	Overrides `yarn.scheduler.capacity.maximum-applications` on a per queue basis.
`yarn.scheduler.capacity.maximum-am-resource-percent`	Maximum percent of resources in the cluster that can be used to run application masters - controls the number of concurrent active applications. Limits on each queue are directly proportional to their queue capacities and user limits. Specified as a float. For example, 0.5 = 50%. The default is 0.1. This can be set for all queues with yarn.scheduler.capacity.maximum-am-resource-percent
`yarn.scheduler.capacity.<queue-path>.maximum-am-resource-percent`	Overrides `yarn.scheduler.capacity.maximum-am-resource-percent` on a per queue basis.

Queue Administration and Permissions

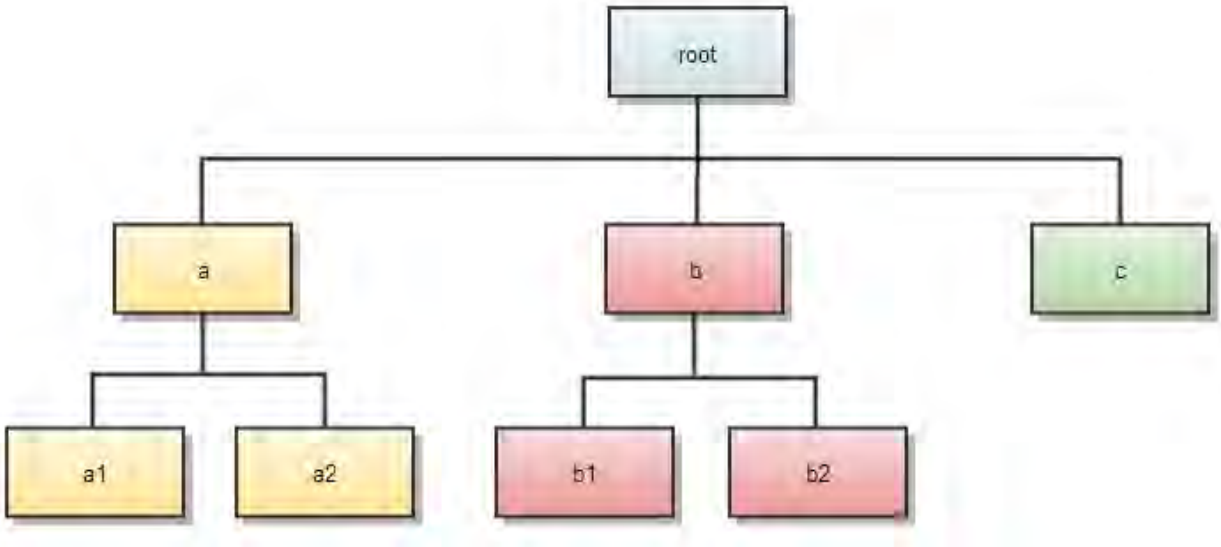
The following table lists queue administration and permission properties:

last-updated: Apr 11, 2022

Property	Description
`yarn.scheduler.capacity.<queue-path>.state`	The *state* of the queue. Possible values are RUNNING or STOPPED. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. If the *root* queue is STOPPED, no applications can be submitted to the entire cluster. Existing applications continue to completion, so the queue can be *drained* gracefully.
`yarn.scheduler.capacity.root.<queue-path>.acl_submit_applications`	The *ACL* that controls who can *submit* applications to the given queue. If the given user/group belongs to the *ACL* on a given queue or one of the parent queues in the hierarchy, they can submit applications. *ACLs* for this property *are* inherited from the parent queue if not specified.
`yarn.scheduler.capacity.root.<queue-path>.acl_administer_queue`	The *ACL* that controls who can *administer* applications on the given queue. If the given user/group has the necessary ACLs on the given queue or one of the parent queues in the hierarchy, they can administer applications. *ACLs* for this property *are* inherited from the parent queue if not specified.

Setting Up a Hierarchy of Queues

CapacityScheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root.* The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:



Queue paths are defined for each level under the `root` queue. A queue's children are defined with the parameter `yarn.scheduler.capacity.<queue-path>.queues`, where `<queue-path>` takes the form `root.<child>`, `root.<child>.<child>`, and so on. For example, the queue path to a2 is designated as `root.a.a2`.

Warning:

Children do not inherit properties directly from the parent unless otherwise noted.

last-updated: Apr 11, 2022

The corresponding queue definition block of the `capacity-scheduler.xml` file is shown below.

```
<property>
  <name>yarn.scheduler.capacity.root.queues</name>
  <value>a,b,c</value>
  <description>The queues at this level (root is the root queue).
  </description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.a.queues</name>
  <value>a1,a2</value>
  <description>The queues at this level (root is the root queue).
  </description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.b.queues</name>
  <value>b1,b2,b3</value>
  <description>The queues at this level (root is the root queue).
  </description>
</property>
```

Changing Queue Configuration

You can change queue properties and add new queues by editing `capacity-scheduler.xml`. Make sure that the updated queue configuration is valid and that the queue-capacity at each level equals 100%.

For the changes to take effect, run the following command:

```
yarn rmadmin -refreshQueues
```

Warning:

Queues cannot be deleted, only added.

Queue Access Control Lists
Describes how to restrict access to queues using Access Control Lists (ACLs).

Queue *ACL*s allow administrators to control who may take actions on particular queues. They are configured with the following properties:

```
yarn.scheduler.capacity.root.support.acl_submit_applications
yarn.scheduler.capacity.root.support.acl_administer_queue
```

You can set these properties for each queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as `user1,user2 group1,group2` or `group1,group2`. An action on a queue is permitted if its user or group is in the *ACL* of that queue, or in the *ACL* of any of that queue's ancestors. So if queue2 is inside queue1, and user1 is in queue1's *ACL*, and user2 is in queue2's *ACL*, then both users may submit to queue2.

The root queue's *ACL*s are "*" by default. Since *ACL* are passed down, by default, everyone may submit to, and kill applications from every queue. To restrict access, change the root queue's *ACL*s to something other than `*`.

last-updated: Apr 11, 2022

By default, the yarn.admin.acl property in yarn-site.xml is also set to *, which means that any user can be the administrator. If queue *ACL*s are enabled, you also need to set the yarn.admin.acl property to the correct admin user for the YARN cluster. For example:

```
<property>
<name>yarn.admin.acl</name> >
<value>mapr</value> >
</property>
```

If you do not set this property correctly, users can kill YARN jobs even when they do not have access to the queues for those jobs.

Label-based Scheduling

Label-based scheduling provides a way to allocate shared cluster resources on particular nodes in a cluster. First, you assign node labels in a text file. The node labels map to one or more nodes. Next, you can create queue labels and job labels based on the node labels.

When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label). This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

The following sections provide more information about label-based scheduling:

Label-based Scheduling for YARN Applications

Label-based scheduling provides job placement control on a multi-tenant hadoop cluster. Using label-based scheduling, an administrator can control exactly which nodes are chosen to run jobs submitted by different users and groups. This is useful for data locality and multi-tenancy use cases.

To use label-based scheduling, an administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label).

This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

YARN Resource Calculation Based on Labels

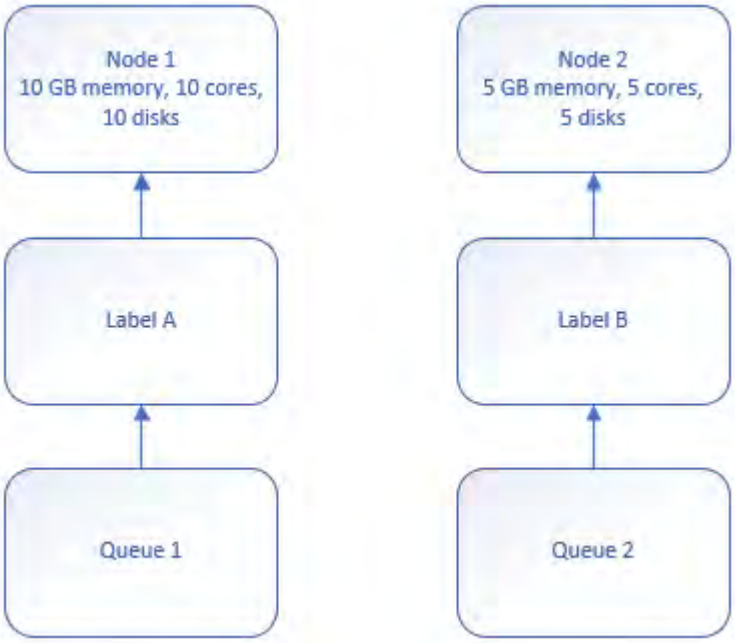
MapR 6.1.0 implements correct steady/instantaneous Fair Scheduler shares, headroom, and maximum resource calculation for queues with label-based scheduling (LBS).

This new approach to YARN resource allocation enables the cluster LBS configuration to compute the resources that are allowed for each queue. It also uses LBS to assign containers to the correct queues to preempt containers, and to prevent resource overuse. The LBS approach to YARN resource allocation relies on:

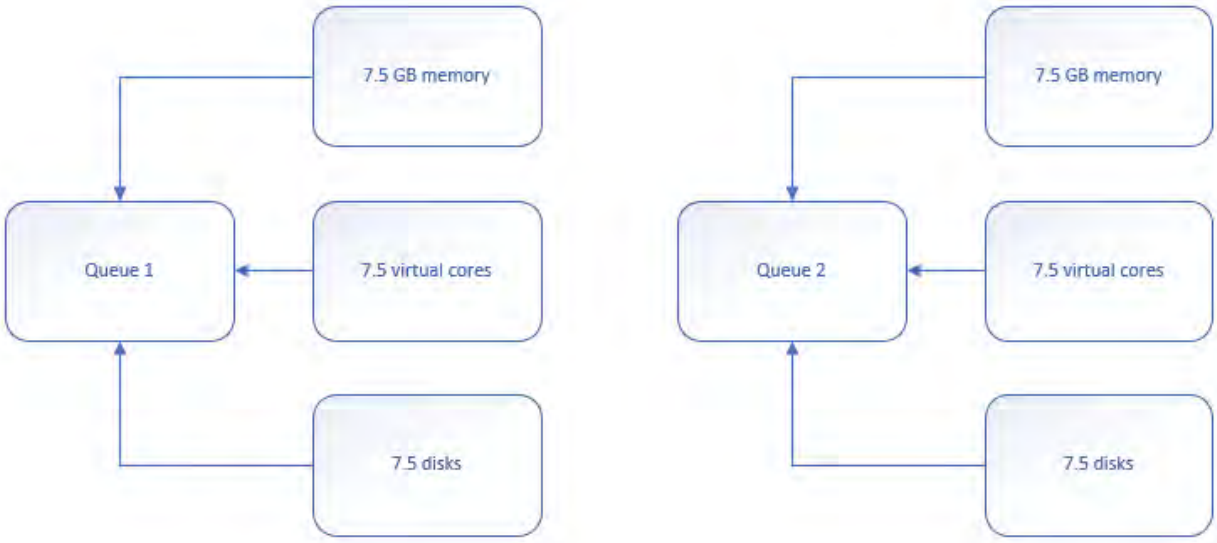
1. Resource computation (memory, CPU, disks) based on labels for each queue.
2. Per-label preemption threshold.

Example of LBS Resource Computation

For example, imagine that you have the following resources:

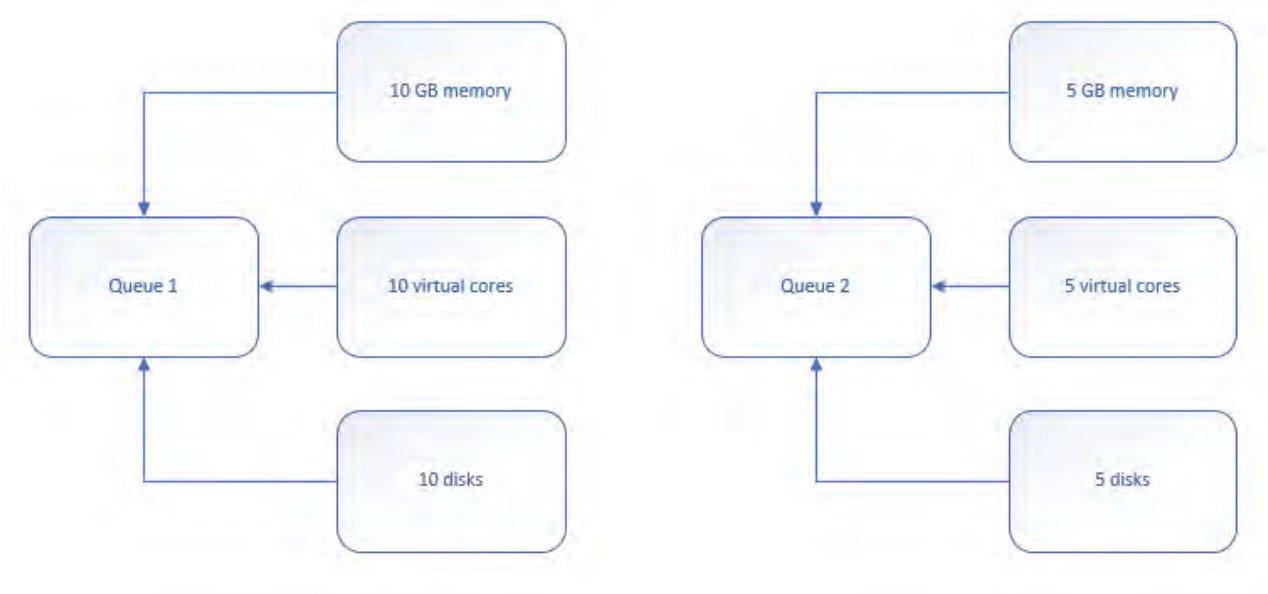


Using the former fair-share resource distribution results in the following:



Using the new LBS resource distribution results in the following:

last-updated: Apr 11, 2022



Understanding LBS preemption thresholds

Before LBS, preemption occurred by default when an entire cluster became 80% full (`yarn.scheduler.fair.preemption.cluster-utilization-threshold=0.8f`). With LBS, preemption occurs per labeled resource, as that resource becomes 80% full.

Descriptions of New Properties When Using LBS

- `defaultQueueLabel`

  Assigned to all new queues and existing queues that do not have a label (excluding the `root` queue).

  For example, `root.%username%` queue is created if you submit a new job without queue information and property `yarn.scheduler.fair.user-as-default-queue` is true.

  You can specify this property in `fair-scheduler.xml`:

```
<allocations>
  <defaultQueueLabel>LabelA</defaultQueueLabel>
  <queue name="root">
          ...
  <queue name="queue1">
  </queue>
  <queue name="queue2">
    <label>LabelB</label>
   </queue>
          ...
  </queue>
</allocations>
```

  See Specifying Fair Scheduler Configuration Properties in yarn-site.xml on page 1269 for more information.

- `yarn.scheduler.fair.resources-based-on-labels-enabled`

  Used to enable or disable recomputing of fair shares based on labels. It allows container allocation on all nodes.

  You can specify this property in `yarn-site.xml`:

  ```
  <property>
    <name>yarn.scheduler.fair.resources-based-on-labels-enabled</name>
    <value>false</value>
  </property>
  ```

- `yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled`

  Allows enabling or disabling (default) preemption of the threshold per-label. To overcome the default and start container preemption when the threshold of the label is exceeded, change this property to `true`.

  You can specify this property in `yarn-site.xml`:

  ```
  <property>

  <name>yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled</name>
    <value>false</value>
  </property>
  ```

See Specifying Fair Scheduler Configuration Properties in yarn-site.xml on page 1269 for more information.

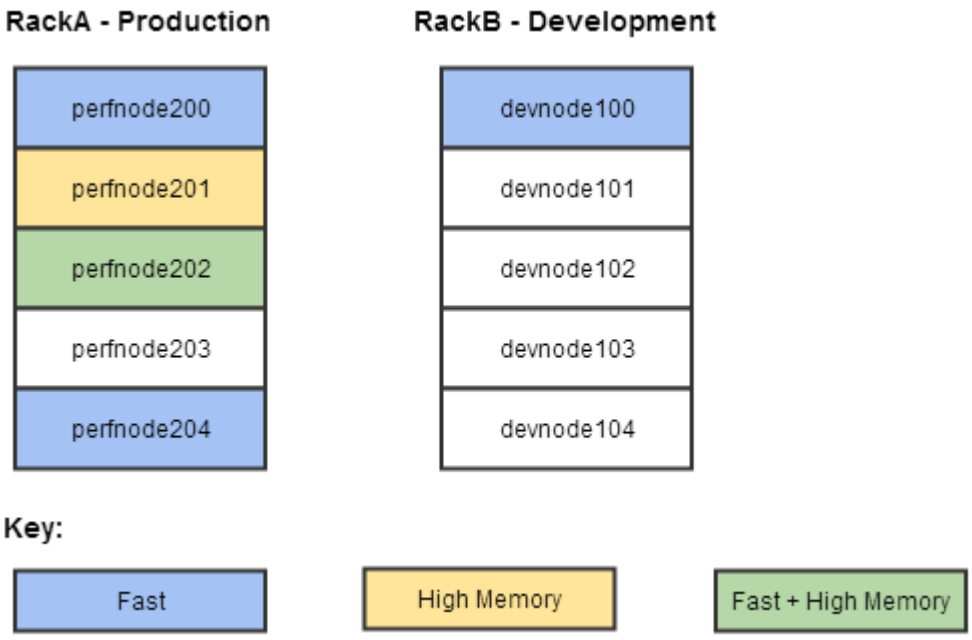
LBS Requirements and Restrictions?

Before you adopt LBS, you should be aware of two issues:

- Multiple labels for a node and label expression at the queue level are not supported.
- Except for `root`, all queues including the default, must be labeled, either independent or through inheritance.

Sample Cluster Configuration

To illustrate the concept of label-based scheduling, consider a cluster with two racks: RackA and RackB. The nodes in RackA are dedicated to the Production group, and the nodes in RackB are dedicated to the Development group. In addition, some nodes are configured with a fast CPU, one node is configured with high memory, and one node is configured with both a fast CPU and high memory. The following diagram illustrates the cluster configuration:



Creating a Node Labels File

The node labels file is a text file stored in MapR filesystem that maps labels to nodes. A node label applies a name to a cluster node, to identify it for the purpose of specifying where to run MapReduce YARN applications (MRv2).

Syntax for Node Labels File

Each line in the node labels file consists of an identifier (a regular expression that identifies one or more nodes), whitespace to separate the identifier from the labels, then one or more labels (separated by commas, whitespace, or both) to apply to the specified nodes. If a label contains two or more words (such as "High Memory"), enclose the name in single or double quotation marks so the whitespace will not be interpreted as a delimiter between two labels.

```
<identifier> <label1>[,<label2>,...,<labeln>]
```

Warning:

Labels must *not* start with a digit.

The identifier specifies nodes by matching the node names or IP addresses in one of two ways:

- Unix-style glob which supports the ? and * wildcards
- Java regular expressions (refer to http://docs.oracle.com/javase/6/docs/api/java/util/regex/Pattern.html for more information)

Warning:

The identifier *must* match the fully qualified domain name (FQDN). To determine the FQDN, run the command `hostname --fqdn`.

Sample Node Labels File

last-updated: Apr 11, 2022

The following node labels file is written for the sample cluster configuration and uses glob identifiers. Note that the FQDNs include the realm `company.com`.

```
perfnode20*.company.com RackA
perfnode200.company.com Fast
perfnode201.company.com 'High Memory'
perfnode202.company.com Fast
perfnode204.company.com Fast

devnode10*.company.com RackB
devnode100.company.com Fast
```

Using Node Labels to Schedule YARN Applications

To set up node labels for the purpose of scheduling YARN applications (including MapReduce applications) on a specific node or group of nodes:

1. Create a text file and specify the labels you want to use for the nodes in your cluster. In this example, the file is named `node.labels`.
2. Copy the file to a location on MapR filesystem where it will not be modified or deleted, such as `/var/mapr`.

   ```
   hadoop fs -put ~/node.labels /var/mapr
   ```

3. Edit `yarn-site.xml` on all ResourceManager nodes and set the `node.labels.file` parameter and the optional `node.labels.monitor.interval` parameter as shown:

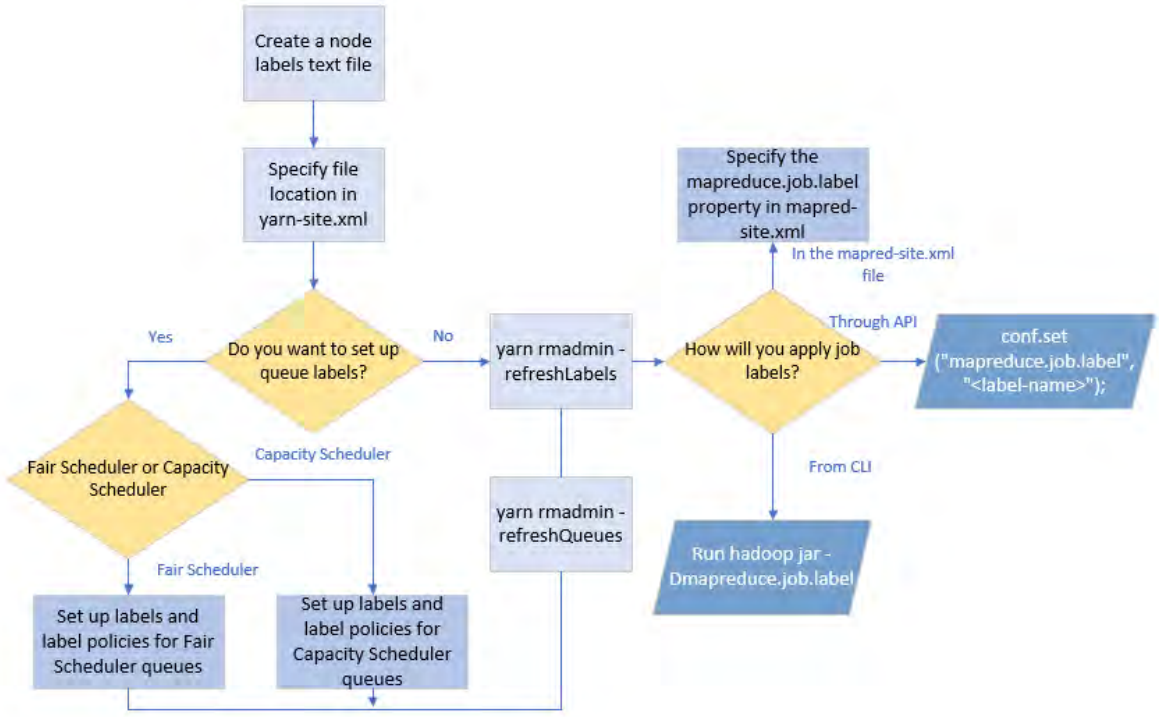
   ```
   <property>
      <name>node.labels.file</name>
      <value>/var/mapr/node.labels</value>
      <description>The path to the node labels file.</description>
   </property>

   <property>
      <name>node.labels.monitor.interval</name>
      <value>120000</value>
      <description>Interval for checking the labels file for updates
   (default is 120000 ms)</description>
   </property>
   ```

4. For this and subsequent changes to take effect, issue either of the following commands to manually tell the ResourceManager to reload the node labels file:
   - For any YARN applications, including MapReduce applications, enter `yarn rmadmin -refreshLabels`
   - For MapReduce applications, enter `mapred job -refreshLabels`
5. Verify that labels are implemented correctly by running either of the following commands:

   ```
   yarn rmadmin -showLabels
   mapred job -showlabels
   ```

The following flowchart summarizes these steps. In addition, the flowchart introduces the concept of queue labels for the Fair Scheduler and the Capacity Scheduler.



Creating Queue Labels

Queue labels are optional with label-based scheduling. You can use queue labels to determine which nodes an application or job can run on (subject to the queue label policy). A queue label is created from node labels as explained below.

Defining Queue Labels for Fair Scheduler

Explains how to customize the Fair Scheduler.

By default, all users share a single queue, named *default*.

To customize the Fair Scheduler, create an allocation file that lists existing queues and their respective weights and capacities, as explained in Hadoop 2.x Fair Scheduler. In the allocation file, add the following property within the `queue` section:

```
<label>labelname</label>
```

For example:

```
<queue name="Customer Data Analysis">
   <weight>2.0</weight>
   <label>Fast</label>
</queue>
```

For a hierarchical queue, note that labels and label policies can be defined on any level of the queue. If a child queue does not have its own labels or label policies, the labels and label policies of the closest level are used.

Defining Queue Labels for Capacity Scheduler

The Capacity Scheduler has a pre-defined queue called *root*. All queues in the system are children of the root queue. Further queues can be set up by configuring `yarn.scheduler.capacity.root.queues` with a list of comma-separated child queues.

If a parent queue has child queues, this is how labels and label policies are applied to the child queues:

last-updated: Apr 11, 2022

- If the child queues have their own labels or label policies, they are used.
- If the child queues do not have their own labels or label policies, the parent queue's labels and label policies apply.

To use label-based scheduling with the Capacity Scheduler, add the following property to the `capacity-scheduler.xml` file:

```
yarn.scheduler.capacity.root.<queue-name>.label
```

For example, for a queue named `alpha`, the label could be defined like this:

```
<property>
   <name>yarn.scheduler.capacity.root.alpha.label</name>
   <value>Fast||Development</value>
</property>
```

When you make changes to queue labels or queue policies, remember to refresh them by running the following command:

```
yarn rmadmin -refreshQueues
```

Defining a Queue Label Policy

A queue label policy determines whether an application label or a queue label prevails when there is a conflict between the two. For YARN applications, you can set the following queue label policies:

- PREFER_QUEUE — always use label set on queue
- PREFER_APP — always use label set on application
- AND (default) — application label AND queue label
- OR — application label OR queue label

See the following sections for directions on setting the queue label policy for Fair Scheduler and Capacity Scheduler.

Setting Queue Label Policies for Fair Scheduler

To set a queue label policy for a Fair Scheduler queue, specify the label policy in the corresponding `queue` section of the allocation file, as shown here:

```
<queue name="CustomerDataAnalysis">
      <weight>2.0</weight>
      <labelPolicy>OR</labelPolicy>
      <label>Fast</label>
</queue>
```

Setting Queue Label Policies for Capacity Scheduler

To set a queue label policy for a capacity queue, add the following property to the `capacity-scheduler.xml` file:

```
yarn.scheduler.capacity.root.<queue-name>.label-policy
```

For example:

```
<property>
  <name>yarn.scheduler.capacity.root.alpha.label-policy</name>
```

```
  <value>PREFER_APP</value>
</property>
```

Examples of Queue Policy Behavior

The following examples show the job placement policy behavior in various scenarios, based on the sample node labels file:

Application Label	Queue Label	Queue Policy	Outcome
Fast	High Memory	PREFER_APP	The job runs on nodes labeled **Fast** (hostnames match perfnode200, perfnode202, perfnode204, or devnode100)
Fast	High Memory	PREFER_QUEUE	The job runs on nodes labeled **High Memory** (hostnames match perfnode201 or perfnode202)
Fast	High Memory	AND	The job runs on nodes only if they are labeled both **Fast** *and* **High Memory** (hostname matches perfnode202)
Fast	High Memory	OR	The job runs on nodes if they are labeled either **Fast** *or* **High Memory** (hostnames match perfnode200, perfnode201, perfnode202, perfnode204, or devnode100)

Creating Job Labels

Explains the use of job labels to place jobs on particular nodes.

To place an individual job on a particular node, use a *job label*. You can apply job labels in three ways:

- Use set() from the Hadoop configuration API in your Java application. For example:

```
conf.set("mapreduce.job.label","Production");
```

- At the command line, pass the label in `-Dmapreduce.job.label` when you run the job with the hadoop jar command. For example:

```
hadoop jar /opt/mapr/hadoop/hadoop-2.4.1/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.4.1-mapr-4.0.1-20140804.191359-4.jar \
teragen -Dmapreduce.job.label=Production 100000000 /teragen
```

- Set the `mapreduce.job.label` parameter in `mapred-site.xml`. For example, to configure an application label expression for a MapReduce application that can run on any Development node or Fast node (including a Fast node from the Production rack), set the `mapreduce.job.label` parameter as shown:

```
<property>
   <name>mapreduce.job.label</name>
   <value>Development || Fast</value>
   <description>Label expression for MapReduce application</description>
</property>
```

Warning:

If an application is submitted with a label that does not correspond to any nodes, the application will run as though no label had been specified. Consult the ResourceManager log for more information (look for '`invalid label`' error messages).

Submitting Jobs and Applications to the Cluster

You can submit YARN applications (MapReduce version 2 and other applications that run on YARN) to the same cluster. An application can be submitted to the cluster in the following ways:

- The `hadoop jar` command submits an MRv2 application.
- The `yarn jar` command submits an application.
- An external application submits an application.
- An ecosystem component generates and submits an application.
- The `hadoop job` command submits an MRv2 application.
- The `mapred job` command submits an MRv2 application.

When you submit a non-MapReduce application to the cluster, such a Spark application, it is automatically processed using `yarn` mode (ResourceManager, NodeManager, and MapReduce ApplicationMaster).

Note: The method to submit Hadoop commands from a Windows or Mac client is different, For details, see Setting Up the Client.

Configuration Files for Jobs and Applications

Lists the locations of the MapReduce configuration files.

To override the MapReduce default configuration, use the following MapReduce configuration files:

MapReduce Version	Configuration File Locations
MapReduce Version 2	• `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/mapred-site.xml` • `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`

To override the default configuration for applications, use the `yarn-site.xml` file that is present in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

YARN Container Resources

Provides an overview of YARN.

last-updated: Apr 11, 2022

A YARN application can be a MapReduce version 2 (MRv2) application or a non-MapReduce application. The Warden on each node calculates the resources that can be allocated to process YARN applications. Each application has an ApplicationMaster that negotiates YARN container resources. For MapReduce applications, YARN processes each map or reduce task in a container. The ApplicationMaster requests resources from the ResourceManager based on memory, CPU, and disk requirements for the YARN containers. For YARN containers that process MRv2 tasks, there are additional considerations. See YARN Container Resources for MapReduce Version 2 Applications on page 1289 for details.

The ApplicationMaster requests YARN container resources based on the values of the following parameters:

yarn.scheduler.minimum-allocation-mb

Default: 1024

Description: Defines the minimum memory allocation available for a container in MB.

To change the value, edit the yarn-site.xml file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.

yarn.scheduler.maximum-allocation-mb

Default: 8192

Description: Defines the maximum memory allocation available for a container in MB.

To change the value, edit the yarn-site.xml file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.

yarn.nodemanager.resource.memory-mb

Default: Variable. This value is calculated by Warden.

Description: Defines the memory available to processing Yarn containers on the node in MB.

Warden uses the following formula to calculate this value: `[total physical memory on node] - [memory required by the operating system, MapR File System, and MapR services installed on the node]`.

To determine the value, go to the ResourceManager UI and view the memory available for that node.

yarn.nodemanager.resource.cpu-vcores

Default: Variable. This value is calculated by Warden.

Description: Defines the number of CPUs available to process YARN containers on this node.

Warden uses the following formula to calculate this value: `[Number of CPU cores on node] - [Number of CPU cores assigned to MapR File System]`.

To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the number of CPUs available for that node.

To change the value, edit the yarn-site.xml file for the node, assign the new value to this property, then restart the NodeManager.

yarn.nodemanager.resource.io-spindles

Default: Variable. This value is calculated by Warden.

Description: Defines the number of disks available to process YARN containers. Warden uses the following formula to calculate this value: `[Number of of disks on the node]`.

last-updated: Apr 11, 2022

	To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the disk information for this node.

YARN Container Resources for MapReduce Version 2 Applications

In addition to the YARN container resource allocation parameters, the MapReduce ApplicationMaster also considers the following container requirements when it sends requests to the ResourceManager for containers to run MapReduce applications:

Parameter	Default	Description
`mapreduce.map.memory.mb`	1024	Defines the container size for map tasks in MB.
`mapreduce.reduce.memory.mb`	3072	Defines the container size for reduce tasks in MB.
`mapreduce.reduce.java.opts`	-Xmx2560m	Java options for reduce tasks.
`mapreduce.map.java.opts`	-Xmx900m	Java options for map tasks.
`mapreduce.map.disk`	0.5	Defines the number of disks a map task requires. For example, a node with 4 disks can run 8 map tasks at a time. **Note:** If I/O intensive tasks do not run on the node, you may want to change this value.
`mapreduce.reduce.disk`	1.33	Defines the number of disks that a reduce task requires. For example, a node with 4 disks can run 3 reduce tasks at a time. **Note:** If I/O intensive tasks do not run on the node, you might want to change this value.

You can use one of the following methods to change the default configuration:

- Provide updated values in the `mapred-site.xml` file on the node that runs the job. You can use central configuration to change this value on each node that runs the NodeManager in the cluster. Then, restart NodeManager on each node in the cluster. The `mapred-site.xml` file for MapReduce ve applications is located in the following directory: `opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`
- Override the default values from the command line for each application that requires a non-default value.

Monitoring the Cluster

This section describes how to monitor the health and performance of a MapR cluster.

Monitoring Using the Control System and the CLI

Describes the Overview page in the Control System, which displays information about the cluster.

The **Overview** displays a summary of information about the cluster in six panes including information on cluster health, activity, and usage.

Note: During installation using the MapR Installer, you can configure metrics and logging using settings on the **Monitoring** page of the MapR Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the **Overview** page. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the **Overview** page. If you want, you can install metrics collection or logging at any time by selecting the feature during an Incremental Install.

The following sections provide information about each pane.

Setting the Refresh Rate on the Control System
Explains how to configure how frequently you want to refresh the graphs and data in the panes.

To set the refresh rate:

1. Log in to the Control System and click **Settings** from the drop-down menu.
2. Enter the refresh rate in seconds for the following.
   - Data refresh rate
   - Metrics and charts refresh rate

   The default refresh rate is 30 seconds. The minimum refresh rate is:
   - 5 seconds for data.
   - 30 seconds for metrics and charts.
3. Set the User Session Inactivity Timer in minutes. The user is logged out from the Control System after the specified number of minutes if there is no activity on the Control System. The default value is 30 minutes.
4. Click **Save Changes** for the changes to take effect.

Customizing the List of Metric Charts and Columns on the Control System
Explains how to customize the list of metric charts and columns on the Control System.

You can customize the list of table metric charts and columns that you see on the Control System.

Adding and Removing Charts from the Charts View

1. Log in to the Control System and go to one of the following pages:
   - **Metrics** tab of the node details page.
   - **Metrics** tab in the **Data** > **Tables** page.
   - **Metrics** tab of the table information page.
   - **Metrics** tab of the secondary index details page.
2. Click to display the **Customize Active Charts** window.
   In the **Customize Active Charts** window, the:
   - **Available** list displays the charts available, but currently not displayed.
   - **Selected** list displays the charts currently displayed in the page.
3. Select the charts from the:
   a) Selected list of charts and click to remove selected charts.
   b) Available list of charts and click to move selection to **Selected** charts to display on page.

You can select up to six charts to display at a time on the page. For the list of charts that can be viewed, see Viewing Table Metrics in the Control System on page 1306.

4. (Optional) Click ^ and/or down v arrows to sort the order of charts.
5. Click **Save** to view the selected charts.

Adding and Removing Columns from the List View

1. Log in to the Control System and do one of the following:
   - Go to the **Metrics** tab of the node details page and select **Activity by Tables** from the drop-down menu to view the metrics for all table-related activities on the node.
   - Go to the **Metrics** tab of the table information page and select:
     - **Activity by Nodes** (default selection) from the drop-down menu to view the metrics for table activity across nodes.
     - **Activity by Indexes** from the drop-down menu to view metrics for all index-related activity on the table.
   - Go to the **Metrics** tab of the secondary index details page and select **Activity by Nodes** to view metrics for index-related activity across nodes.
2. Click  to switch to a list view.
3. Click  to display the **Customize Columns** window.
   In the **Customize Columns** window, the:
   - **Available** list displays the columns available, but currently not displayed.
   - **Selected** list displays the columns currently displayed in the page.
4. Select the columns from the:
   a) Selected list of columns and click < to remove selected columns from the view.
   b) Available list of columns and click > to move selection to **Selected** columns (for display).
   For the list of metrics that can be viewed in the columns, see Viewing Table Metrics in the Control System on page 1306
5. (Optional) Click ^ and/or down v arrows to sort the order of columns.
6. Click **Save** to view the selected columns.

Monitoring the Cluster

Explains how to view the cluster health, disk, memory, CPU utilization metrics, and alarms on the cluster using either the Control System or the CLI.

Monitoring Cluster Health Using the Control System

- Log in to the Control System and click **Overview**.
  The **Overview** page displays the following panes:
  - Node Health — the health of the nodes on the cluster, by service (default) or topology
  - Active Alarms — a summary of active alarms for the cluster
  - Cluster Utilization — CPU, memory, and disk space usage

last-updated: Apr 11, 2022

- Yarn — the number of running and queued applications, number of Node Managers, and percent of memory and CPU's used relative to the amount configured

Note: During installation using the MapR Installer, you can configure metrics and logging using settings on the **Monitoring** page of the MapR Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the panes. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the various panes. If you want, you can install metrics collection or logging by selecting the feature during an Incremental Install.

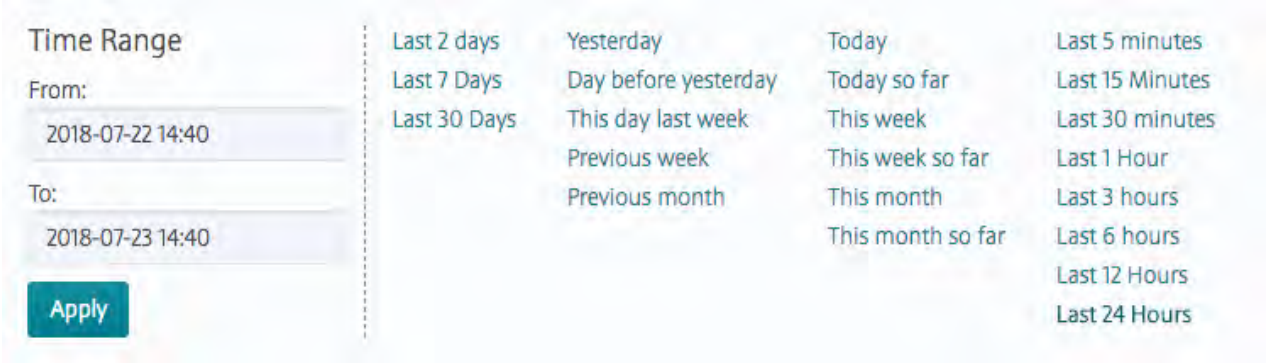
Viewing Cluster Utilization Information on the Control System

The **Cluster Utilization** pane in the **Overview** page displays the following for:

- CPU — Percentage of cores currently utilized and total cores
- Memory — Percentage of memory (in GB) currently utlized and total memory (in GB)
- Disk — Percentage of space (in GB) currently utilized and total disk space (in GB)

The **Cluster Utilization** pane also shows the amount of raw data and the savings (in percentage) after compression.

The **Utilization Trend** pane shows CPU, memory, and disk usage trend for the last 24 hours by default. You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot).



You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view. If there were any alarms during the selected date/time range, the **Alarms** pane above shows:

- When the alarm was raised
- The severity of the alarm
  - — an error
  - — a warning
  - — information

Monitoring Cluster Alarms on the Control System

See Viewing Active Cluster Alarms on page 1316 for more information.

Retrieving Cluster Information Using the CLI or REST API

The basic command to retrieve cluster health and disk space information is:

```
maprcli dashboard info -cluster <cluster>
```

The `utilization` field in the output shows the total and utilized amount of disk space, memory, and CPU for the cluster, which can also be visualized on the Control System. For example:

```
# /opt/mapr/bin/maprcli dashboard info -json
{
    "timestamp":1525230746268,
    "timeofday":"2018-05-01 08:12:26.268 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            ...
            "utilization":{
                "cpu":{
                    "util":7,
                    "total":8,
                    "active":0
                },
                "memory":{
                    "total":15886,
                    "active":11281
                },
                "disk_space":{
                    "total":273,
                    "active":0
                },
                "compression":{
                    "compressed":0,
                    "uncompressed":0
                },
                "tiering":{
                    "logicalUsed":0,
                    "replicatedLogicalUsed":0,
                    "replicatedTotalUsed":0,
                    "ecTotalUsed":0,
                    "cvTotalUsed":0,
                    "offloaded":0,
                    "recalled":0
                }
            },
            ...
        }
    ]
}
```

For information on all the fields returned by this command, see `dashboard info` on page 1587.

Monitoring Nodes

Explains how to monitor nodes using either the Control System or the CLI.

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

Note: The metrics collection infrastructure must be installed during installation to visualize the graphs and charts. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

last-updated: Apr 11, 2022

Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

To monitor the health of nodes:

1. Log in to the Control System and click:
   - **Overview** to view the health of the nodes in the **Node Health** pane.
   - **Nodes** to view the health of the nodes in the **Node Health** pane.
2. Select one of the following from the drop-down menu in the **Node Health** pane.
   - **By Service** to organize the display of nodes by services.

     This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running ( ) and is down ( ).

     Note: The color of the node (which reflects the status of the service) is even when a service is stopped (not running) on the node.
   - **By Topology** to view the display of nodes by topology.

     This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

	Indicates the node is healthy.
	Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: • There is no heartbeat from the MapR filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node.
	Indicates the node is in maintenance mode.
	Indicates critical issue(s) on the node. A node is considered to be in critical state if: • There is no heartbeat from the node for more than 5 minutes. • All MapR files system disks on the node are dead or are offline. • All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour. • File server is dead/inactive because there is no heartbeat for a long time. • NFS server on node is dead. • MapR install directory is full. • Node reported high MapR filesystem memory usage.

Monitoring Node Resource Utilization from the Control System

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

last-updated: Apr 11, 2022

Monitoring Active Node Alarms from the Control System

See Viewing Active Node Alarms on page 1317 for more information.

Monitoring Node Health Using the CLI or REST API

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see `node heatmap` on page 1702.

Viewing Node Metrics

Explains how to view node metrics using the Control System.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to visualize the metrics that are desribed in the following section.

Monitoring Node Metrics Using the Control System

- Log in to the Control System and go to the **Metrics** tab in the node information page.

  By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

  You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

  - to shift time window forwards.
  - to shift time window backwards.

  Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

  Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

Metric	Charts
CPU Usage	• Node Active CPU Usage • Node CPU Usage** • Node CPU Usage IDLE • Node CPU Usage NICE • Node CPU Usage SYSTEM • Node CPU Usage USER • Node CPU Usage WAIT • MFS CPU Usage • Allocated vs Available CPU Cores • MapR Process CPU Usage • MAST Gateway CPU Usage • DB Gateway CPU Usage • Data Access Gateway CPU Usage
Memory Usage	• Node Free Memory • Node Utilized Memory*** • Node Memory Free vs Used* • MFS Process Memory Usage • MapR Process Memory Usage
SWAP Space	• Node Swap Free • Node Swap Used • Node Swap Space Available vs Used* • Node Swap IO
Node IOs	• Node Network IO* • Node Network Interface Input • Node Network Interface Output • Node Network Interface Error Input • Node Network Interface Error Output
System Disk Throughput	• Disk Read Ops • Disk Write Ops • Disk Reads and Writes*

Metric	Charts
System Disk Latency	• Disk Avg Read Latency • Disk Avg Write Latency • Disk Read and Write Times
MFS Throughput	• MFS Read Throughput • MFS Write Throughput • MFS Read and Write Throughput • MFS System Disk Activity in Bytes*

* This metric is diplayed in the default chart view for a node.

** This metric is diplayed in the default chart view for a node and in the default list view for a table.

*** This metric is diplayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see Viewing Per Node Metrics for Table Activities on page 1297.
- All stream activities on a node, see Monitoring Streams Operations Using the Control System on page 1313.

Viewing Per Node Metrics for Table Activities
Describes how to view per node metrics for table activities using the Control System and Grafana.

This section describes how to view the metrics as charts and lists in the Control System. For information on visualizing the metrics in the Grafana UI, see Metric Visualization on page 1381

Note: The metrics collection infrastructure must be installed to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to visualize the metrics as described below.

1. Log in to the Control System and go the **Metrics** tab in the node information page.
2. Select **Activity by Tables** from the drop-down menu.

   By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

   You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

   - › to shift time window forwards.

last-updated: Apr 11, 2022

- to shift time window backwards.

The charts show metrics for the node across tables. Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window, where you can select charts to display and remove from the **Available** and **Selected** lists. You can view up to 6 charts at a time in the page.

You can switch to the list view by clicking . In the list view, you can:

- Click the table name to go to the metrics page for the table.
- Select one or more tables and switch to charts view (by clicking) to visualize metrics for the selected tables only.

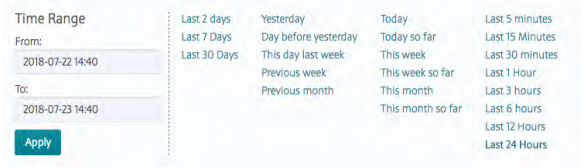
For the complete list of metrics that you can view at both the node and table levels, see Viewing Table Metrics in the Control System on page 1306.

Monitoring YARN

- Log in to the MapR Control System and:
  - Click **Overview** to view the following in the **YARN** pane:
    - Number of node managers, running applications, and queued jobs.
    - Memory and CPU utilization metrics.
  - Go to the service information page for YARN. The YARN information page displays the following panes:

Summary	Displays: • Total number of nodes and number of active and unhealthy nodes. • Allocated, pending, and reserved number of Resource Manager containers.
Top Queues by CPU Utilization	Displays the queues that utilize the most CPU (in percentage).
Top Queues by Memory Consumption	Displays the queues that consume the most memory (in percentage).
Applications	Displays the number of submitted, completed, running, pending, and failed applications during a selected date and time range. You can select a preset or specify a custom time range.  You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.
Resource Manager (CPU)	The number of cores allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.

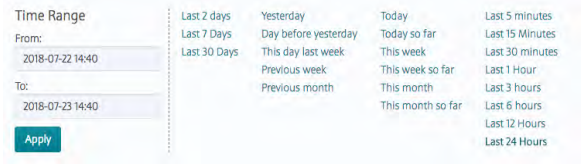
last-updated: Apr 11, 2022



You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Resource Manager (Memory)

The amount (in MB) of memory allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.



You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

Monitoring Volumes

Explains how to monitor volume parameters using the Control System.

You can monitor volume:

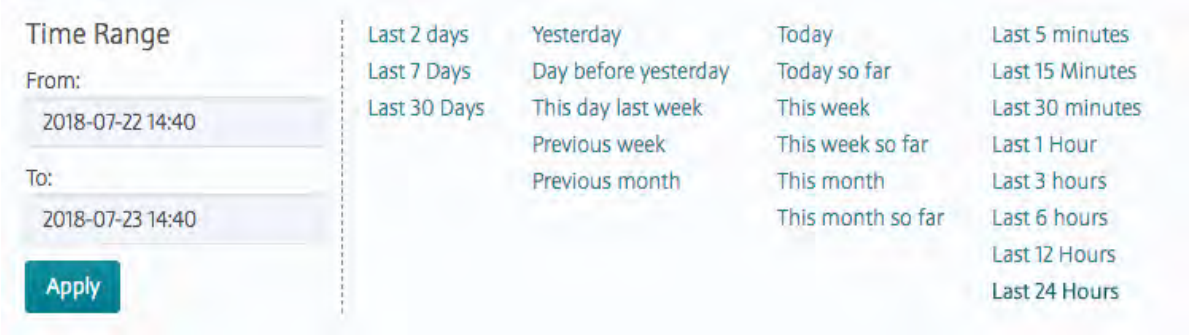
- Disk usage
- Alarms

Monitoring Volume Disk Usage Using the Control System

- You can view:
  - Volumes that use the most amount of allocated disk space in the **Top Volume Utilization** pane under **Data** > **Volumes**.

    Note: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

  - Disk usage trend for a volume in the **Usage Trends** pane in the **Summary** tab of the volume information page. You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot).



You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view.

last-updated: Apr 11, 2022

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to view the charts described here.

Monitoring Volume Alarms in the Control System

See Viewing Active Volume Alarms on page 1317.

Monitoring Local and Remote Storage for Volumes

You can view the following storage utilization metrics for tiered volumes in the **Data** > **Volumes** > **Local & Remote Usage** pane.

Note: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

- Local — The total disk space (in GB) used (before compression) for the volumes in the MapR cluster. This value does not include erasure-coded backend volumes and cache-volumes because their logical usage is already accounted for by the front-end and parent volumes respectively.
- Cold Offloaded — The total physical data (in GB) offloaded to the cold tier. This is calculated using the following: *amount of data purged from the hot tier (MapR cluster) + amount of data recalled to the hot tier (MapR cluster)*.
- Warm Offloaded — The total physical data (in GB) offloaded to the erasure coded volume (warm tier). This is calculated using the following: *amount of data purged from the hot tier (MapR cluster) + amount of data recalled to the hot tier (MapR cluster)*.

Collecting Volume Metrics

Describes how to enable and collect operational metrics for volumes.

You can collect the following volume metrics on MapR File System after you enable metrics collection as described in Enabling Volume Metric Collection on page 1301:

Read I/Os	Number of reads
Write I/Os	Number of writes
Read throughput	Amount of data read
Write throughput	Amount of data written
Read latency	Time taken by read operations
Write latency	Time taken by write operations

If you enable metrics collection on a volume, for each MapR File System instance, on every node where the volume containers reside, metrics for the volume (for a day) are captured every 10 seconds and logged to files in a local volume, which is two way replicated. The metrics log file, `Metrics.log-<date>-<n>.json`, is available at `/var/mapr/local/<hostname>/audit/<mfs-port>` directory. Here:

- `mfs-port` is the port on which the MapR File System instance listens.
- `date` is the record date in the format yyyy-mm-dd. A new file is created at the beginning of each day.
- n is the iteration of the log file represented by 3 digits. A new file is created every time Warden is restarted on the node. For the first file, <n> is 001 and <n> is incremented every time warden restarts. For example: `Metrics.log-2017-08-18-001.json` and `Metrics.log-2017-08-18-002.json` When a new file is created, the old file is purged based on the CLDB audit log retention period, which is 30 days by default.

Each record in the file looks similar to the following:

```
{
 "ts":1503048590000,
  "vid":35211529,
  "RDT":0.0,
  "RDL":0.0,
  "RDO":0.0,
  "WRT":308085.8,
  "WRL":2434.0,
  "WRO":2192.0
}
```

Here:

- `ts` — timestamp in milliseconds
- `vid` — volume ID
- `RDT` — read throughput in KB (cumulative for 10 seconds)
- `RDL` — amount of time taken by read operations (average for 10 seconds)
- `RDO` — number of read operations (cumulative for 10 seconds)
- `WRT` — write throughput in KB (cumulative for 10 seconds)
- `WRL` — amount of time taken by write operations (average for 10 seconds)
- `WRO` — number of write operations (cumulative for 10 seconds)

The `collectd` service reads up to 16 MB of data every ten seconds from each file, then aggregates and writes one minute worth of data to OpenTSDB. When reading the file, the `collectd` service stores offsets (as to how much has been read) as extended attributes (`trusted.disptachedOffset`) on the file. In addition to the default tags assigned to each metric when collectd writes metrics to OpenTSDB, the following tags are assigned to volume metrics:

- `mapr.volmetrics.[read_|write_][throughput|latency|ops]` — Displays the type of metric
- `volume_name` — Displays the name of the volume

For more information on the default tags, see Metric Collection on page 1334.

For each metrics file, MapR also creates a file, `Vollist_metrics.log-<date>-<n>`, in the `/var/mapr/local/<hostname>/audit/<mfs-port>/` directory. This file is purged based on the CLDB audit log retention period, which is 30 days by default. This file contains a comma separated list of volume name and volume ID (for volumes for which metrics are captured) and is associated with the `Metrics.log-<date><n>.json` file. For example, the record in the file looks similar to the following:

```
<volumeid>,<volume name>,<volumeid>,<volume name>,...
```

You can visualize the metrics in the dashboards on Grafana. See Metric Visualization on page 1381 for more information.

Enabling Volume Metric Collection
Describes how to enable metric collection for a volume, and gather volume statistics.

On all new installations, this feature is enabled by default and you only need to enable metrics collection for each volume. If you are upgrading from a version prior to MapR version 6.0, to start collecting volume

last-updated: Apr 11, 2022

metrics that you can then visualize in Grafana, you must enable the metrics collection feature and then enable metrics collection for each volume.

You can enable metrics collection from the command-line and using the Control System.

Enabling the Metric Collection Feature

- Enable the feature by running the following command:

```
/opt/mapr/bin/maprcli cluster feature enable -name
mfs.feature.metrics.support
```

Enabling Metric Collection for New Volumes Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Volume** to display the **Create New Volume** page.
3. Enter values for the required settings and move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.

   For more information, see Creating a Volume on page 864.
4. Click **Create Volume** to create the volume.

Enabling Metric Collection for Existing Volumes Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the **Volumes** to edit and **Edit Volume** from the **Actions** drop-down menu or go the volume info page and click **Edit Volume**.
3. Move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.

   For more information, see Creating a Volume on page 864.
4. Click **Save Changes** for the changes to take effect.

Enabling Metric Collection for Volumes Using the CLI

- Enable metrics collection on:
  - A new volume by running the following command:

    ```
    /opt/mapr/bin/maprcli volume create -name <volume-name> -path
    <volume-mount-path> -type <volume-type> -metricsenabled true
    ```

    For more information, see `volume create` on page 1931.
  - An existing volume by running the following command:

    ```
    /opt/mapr/bin/maprcli volume modify -name <volume-name> -metricsenabled
    true
    ```

    For more information, see `volume modify` on page 2005.

- All volumes that do not have mapr in the name by running the following script:

```
for i in `/opt/mapr/bin/maprcli volume list -columns n | grep -v
mapr | grep -v volumename`; do echo $i; /opt/mapr/bin/maprcli volume
modify -name $i -metricsenabled true; done
```

Monitoring Tables
Explains how to monitor table alarms and view table metrics in the Control System.
Monitoring Table Alarms in the Control System

See Viewing Active Table Replication Alarms on page 1318.

Viewing Throughput by Operation Type Using the Control System

- Log in to the Control System and do one of the following:
  - Go to the **Summary** tab in the table information page.

    The **Throughput - By Op Type** pane displays a graph for the following operations on the table in the last hour:
    - Gets
    - Puts
    - Scans
    - Increments
    - Appends
    - Checks and Puts
    - Updates and Gets
  - Go to the **Summary** tab in the index details page.

    The **Throughput - By Op Type** pane displays a graph for the following operations on the index in the last hour:
    - Puts
    - Scans

  You can move the cursor over the graph to view the number of operations on the table (across nodes).

Visualizing Table Metrics in the Control System

In the Control System, you can visualize node-level metrics for table operations on a node. You can view charts that show metrics for all tables across all nodes, metrics per table aggregated across nodes, metrics per table per node, and metrics per node across tables. In addition, you can view metrics for activity by indexes and for the table and its secondary indexes.

For the full list of metrics (and associated charts/columns) that you can view in the Control System, see Viewing Table Metrics in the Control System on page 1306.

- Log in to the Control System and do one of the following to view table metrics:
  - Go to the **Metrics** tab in the node information page and select **Activity by Tables** from the drop-down menu.

    In this tab, you can view charts/columns that show metrics for all table operations on the node, operations on streams, and other node metrics described here.

- Go to the **Metrics** tab in the **Data** > **Tables** page.

  In this tab, you can view charts/columns that show metrics per node for all tables.

- Go to the **Metrics** tab in the table information page.

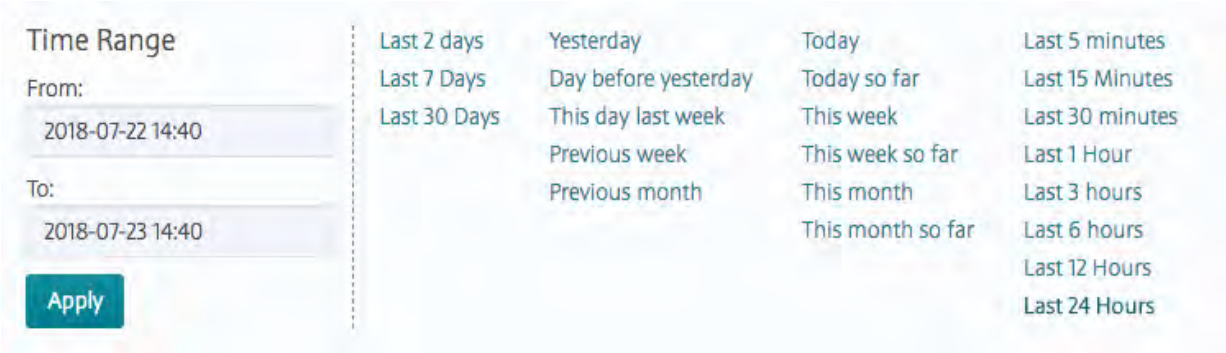
  In this tab, you can view charts/columns that show operations on the table and its secondary indexes across nodes.

- Go to the **Metrics** tab in the index details page and select **Activity by Nodes** from the drop-down menu.

  In this tab, you can view charts that show all index operations and index operations per node.

You can select the charts to view by clicking . See Adding and Removing Charts from the Charts View on page 1290 for more information.

The charts on the page show the metrics for the last 24 hours by default. You can select a preset or specify a custom time range.



You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

Note: When you select a granular view, the chart might not show the most accurate data because of the difference between the interval at which the metrics are logged and the downsampling (lowering the sampling rate) for the interval being viewed.

You can switch to a list view, where available, by clicking . In this view, you can select metrics to view by clicking . See Adding and Removing Columns from the List View on page 1291 for more information.

In the list view, you can:

- Filter the list by clicking .
- Click the node name to go to the node-level metrics page.
- Select one or more nodes and switch to charts view by clicking to visualize metrics for the selected nodes only. The legends for the charts reflect the selected nodes.

Note: Certain grouping of metrics, available in the charts view, are not available in the list view. All the metric grouping available in the list view are available in the charts view as well. When you switch from charts to list view and vice versa, your selection of metrics in one view is not carried over to the other view.

last-updated: Apr 11, 2022

The chart and list views allow you to detect and diagnose bottlenecks and performance issues on individual tables and nodes. You can use the charts for measuring the throughput and latency of different RPC operations on a table and for determining which operations on a table are slow or which tables are most frequently accessed.

For example:

- Suppose your node is busy and you are noticing intermittent latency spikes on your table. You can compare throughput and latency in the **Metrics** tab of the table information page and investigate if the latency spike is due to node being very busy or node having high CPU utilization by switching to the list view from where you can navigate to the **Metrics** tab of the node details page.
- Suppose your index queries take minutes instead of seconds to complete. You can compare the get latency percentile with the scan read/response in the **Metrics** tab of the table information page by zooming in to the area where you see the spike. Switch to **Activity by Index** to view the index vs primary table scans where you can determine whether excessive scan load went to the primary table.
- Suppose you are noticing latency spikes on one of your table as a result of a lot of activity on another table. Observe the get latency percentile spikes in the **Metrics** tab of the table information page and switch to **Activity by Node** list view to identify the nodes with high overall aggregate table RPC load and node IOps. Select the saturated nodes in the list view and switch to the chart view. Go back to the list view and click the saturated node to navigate to the **Metrics** tab of the node details page. Switch to **Activity by Tables** to determine the most active table.

Viewing Secondary Index Metrics

You can visualize the secondary index metrics in the Control System.

- Log in to the Control System and do one of the following:
  - Go to the **Metrics** tab in the table information page and select **Activity by Indexes** from the drop-down menu to view all index-related activity on the table.
  - Go to the **Metrics** tab in the secondary index page to view metrics for index-related activity across tables or per node.

  By default, the page displays metrics for the last 24 hours. You can select a preset or specify a custom time range.

  You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

  - > to shift time window forwards.
  - < to shift time window backwards.

last-updated: Apr 11, 2022

The page displays charts by default. When viewing activity by nodes, you can switch to a list view by clicking and return to charts view by clicking .

Charts view	You can select the charts to view by clicking . See Adding and Removing Charts from the Charts View on page 1290 for more information. Click the associated with the chart to view information about the graph.
List view	The list view shows the metrics in the columns. You can customize the columns by clicking . See Adding and Removing Columns from the List View on page 1291 for more information. In addition, you can: • Click the column name to sort the table by that column. • Click the node name to go to the metrics page for the node. • Click one or more checkboxes next to the node name and switch to the charts view to visualize metrics for the secondary index activities on those nodes only.

You can use the charts to diagnose and troubleshoot bottlenecks and performance issues. For the complete list of metrics that you can view for secondary indexes, see Viewing Table Metrics in the Control System on page 1306.

Viewing Region Distribution

- Log in to the Control System and go to one of the following pages:
  - **Summary** tab in the table information page to view the region distribution for a table.
  - **Summary** tab in the index details page to view the region distribution for a secondary index.

  The **Region distribution** pane shows the distribution of the table or secondary index regions across the nodes in the cluster. The shade of the node reflects the sum of the physical size of data on the node with the darker shade indicating increased resource utilization on the node. You can move the cursor over a node to view the following:
  - Hostname of the node
  - Number of regions on the node
  - Total size of data (across regions) on the node

  You can click a node to go to the node information page.

Viewing Table Metrics in the Control System

Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

- View these metrics in the Control System, see Monitoring Tables on page 1303.
- Customize the charts you see on the page, see Adding and Removing Charts from the Charts View on page 1290.

last-updated: Apr 11, 2022

- Customize columns you see on the page, see Adding and Removing Columns from the List View on page 1291.

Chart/Column Name	Metric	Description
Table Bytes Read Per Node	Throughput - bytes read	The number of bytes read from the primary table per node for all RPC types.
Table and Index Bytes Read		The number of bytes read across a primary table and its secondary indexes for all RPC types.
Table Bytes Written Per Node	Throughput - bytes written	The number of bytes written to the primary table per node for all RPC types.
Table and Index Bytes Written		The number of bytes written across a primary table and its secondary indexes for all RPC types.
Table Rows Read Per Node	Throughput - rowCount read	The number of rows read from the primary table per node for all RPC types.
Table and Index Rows Read		The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Table Rows Written Per Node	Throughput - rowCount written	The number of rows written to the primary table per node for all RPC types.
Table and Index Rows Written		The number of rows written across a primary table and its secondary indexes for all RPC types.
All Tables Written Rows Throughput		Number of rows written by RPC operation type.
Table Rows Responded Per Node	Throughput - rowCount returned	The number of rows returned from the primary table per node for all RPC types.
Table and Index Rows Responded		The number of rows returned across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Scan Throughput		Compares the scan throughput for rows read versus rows returned. This is displayed in the default chart view for a node and for a table.

last-updated: Apr 11, 2022

Chart/Column Name	Metric	Description
All Tables Throughput	Throughput - rpcCount/second	Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables.
Throughput by Rpc Type		The combined RPC load for the primary table and its indexes.
All Tables RPC Byte Throughput		The number of bytes processed by RPC operation type.
All Tables Read Rows Throughput		Number of rows processed by RPC operation type.
All Tables Returned Rows Throughput		Number of rows returned by RPC operation type.
Put and Append Operation Throughput		Number of put and append RPC operations for the table, including its indexes.
Table Check and Put Ops Per Node		The number of check and put operations completed for a primary table and for a node.
Table Update and Get Ops Per Node		The number of update and get operations completed for a primary table and for a node.
Table Get and Index Scans		The number of get and index scans completed for a primary table and for a node.
Table Write and Index Maintenance Activity		The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index.
Table Get Ops Per Node		The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Get Throughput Per Node		The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table.
Table Increment Ops Per Node		The number of increment operations completed for a primary table and for a node.
Table Put Ops Per Node		The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Scan Ops Per Node		The number of scan operations completed for a primary table and for a node.
Table Append Ops Per Node		The number of append operations completed for a primary table and for a node.
Table Write Throughput Per Node		The number of put and append

Chart/Column Name	Metric	Description
Table and Index Scan Latency	Latency	The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index.
Table and Index Scan Latency Per node		The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency.
Table Append Latency Per Node		The 99th percentile latency of append operations on the primary table per node.
Table Increment Latency Per Node		The 99th percentile latency of increment operations on the primary table per node.
Table Put Latency Per Node		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Get Latency Per Node		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Scan Latency Per Node		The 99th percentile latency of scan operations on the primary table per node.
Table Get Latency Percentiles*		The get operation latency by percentile for the primary table and its secondary indexes.
Primary Table Put & Append Latency Percentiles*		The pure write operation latency by percentile for the primary table and its secondary indexes.
Table Write Throughput Latency Percentiles		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Get Throughput Latency Percentiles		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Check and Put Latency Per Node		The 99th percentile latency of check and put operations on the primary table per node.
Table Update and Get Latency Per Node		The 99th percentile latency of update and get operations on the primary table per node.
Index Put Latency		The 99th percentile latency of put operations per secondary index of the

Chart/Column Name	Metric	Description
All Tables Replication Sent Bytes	Replication - rows/bytes sent	The number of bytes of replication data sent.
All Tables Replication Pending Bytes	Replication - rows/bytes pending	The number of bytes of replication data not yet sent.
All Tables Replication Activity	Replication - rows/bytes sent/pending	Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables.
Index Throughput by RPC Type	Index - Throughput	The combined RPC load for the primary table and its secondary indexes.
Index Put Ops		The number of put operations completed per secondary index of the primary table.
Index Put Ops Per Node		The number of put operations completed per secondary index of the primary table per node.
Index Scan Ops		The number of scan operations completed per secondary index of the primary table.
Index Scan Ops Per Node		The number of scan operations completed per secondary index of the primary table per node.
Index Bytes Read	Index - rows/bytes read	The number of bytes read per secondary index of the primary table for all RPC types.
Index Bytes Read Per Node		The number of bytes read per secondary index of the primary table per node for all RPC types.
Index Bytes Written Per Node		The number of bytes written per secondary index of the primary table per node for all RPC types.
Index Rows Read		The number of rows read per secondary index of the primary table for all RPC types.
Index Rows Read Per Node		The number of rows read per secondary index of the primary table per node for all RPC types.
Index Rows Responded	Index - rows/bytes returned	The number of rows returned per secondary index of the primary table for all RPC types.
Index Rows Responded Per Node		The number of rows returned per secondary index of the primary table per node for all RPC types.
Index Scan Read vs Returned Rows	Index - rows/bytes read	The number of secondary index rows that were read versus returned.

last-updated: Apr 11, 2022

Chart/Column Name	Metric	Description
Index Bytes Written	Index - rows/bytes write	The number of bytes written per secondary index of the primary table for all RPC types.
Index Rows Written		The number of rows written per secondary index of the primary table for all RPC types.
Index Rows Written Per Node		The number of rows written per secondary index of the primary table per node for all RPC types.
All Tables Index Sent Bytes	Index - rows/bytes sent	The number of bytes sent for secondary index updates.
All Tables Index Pending Bytes	Index - rows/bytes pending	The number of bytes of secondary index data remaining to be sent.
All Index Maintenance Activity		Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Tables CDC Sent Bytes	CDC - rows/bytes sent	The number of bytes of CDC data sent.
All Tables CDC Pending Bytes	CDC - rows/bytes pending	The number of bytes of CDC data per node not yet sent.
All Tables CDC Propagation Activity		The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Streams Producer Ops	Streams Throughput, RPCs	The number of Streams producer RPCs.
All Streams Consumer Ops		The number of Streams consumer RPCs.
All Streams Producer Messages	Streams Throughput, messages	The number of Streams messages produced.
All Streams Consumer Messages		The number of Streams messages read by consumers.
Table Value Cache All Lookups	Value Cache Lookups	All operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups		The number of get operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups Per Index		The number of get operations for a primary table and for a node that performed a cache lookup.

last-updated: Apr 11, 2022

Chart/Column Name	Metric	Description
Table and Index Value Cache All Lookups	Value Cache Hits	All operations across the primary table and its secondary indexes that performed a cache lookup.
Table and Index Value Cache Lookups Per Index		The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index.
Table and Index Value Cache Lookups		The number of get operations across the primary table and its secondary indexes that performed a cache lookup.
Table Value Cache All Hits		All operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits Per Index		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table and Index Value Cache All Hits		All operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits Per Index		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index.
Value Cache Utilization	Value Cache	Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table.
All Tables Flushes	Bucket Flushes	The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables.
All Tables Flushes		The number of total table flushes that were manually versus automatically triggered.
All Tables Force Flushes	Bucket Force Flushes	The number of table flushes that were not automatically triggered.

last-updated: Apr 11, 2022

Chart/Column Name	Metric	Description
All Tables Compactions	Compaction	Number of table compactions. Compactions combine multiple MapR Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables.
All Tables Full Compactions		Number of full compactions. Compactions combine multiple MapR Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, MapR Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
All Tables Mini Compactions		Number of partial compactions. Compactions combine multiple MapR Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, MapR Database needs to read only two spill files.
All Tables TTL Compactions		Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families.
All Tables Free Index Memory	Memindex Usage	The number of available MB in the in-memory bucket file cache.

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Monitoring Streams
Explains how to monitor streams using either the Control System or the CLI.

The speed at which messages flow from producers to partitions, and from partitions to consumers depends on the performance of your producers, the cluster nodes hosting partitions, and your consumers.

Monitoring Streams Operations Using the Control System

- Log in to the Control System and go to the **Metrics** tab in the node information page to select the charts that show the following when you filter the list of charts by table activities:
  - **All Streams Producer Messages**: The number of Streams messages produced on the node
  - **All Streams Consumer Messages**: The number of Streams messages on the node read by consumers
  - **All Streams Producer Ops**: The number of Streams producer RPCs on the node
  - **All Streams Consumer Ops**: The number of Streams consumer RPCs on the node

  For more information, see Adding and Removing Charts from the Charts View on page 1290.

last-updated: Apr 11, 2022

Monitoring Active Stream Alarms

See Viewing Active Stream Alarms on page 1318.

Monitoring Cluster Nodes that Host Partitions

You can find out which nodes in a MapR cluster are being used for topics in a stream by running the command `maprcli stream topic info`. The nodes are listed in the `servers` field.

The `guts` utility can show you whether there are any I/O bottlenecks on these nodes. This utility can also show you whether there is any capacity on other nodes in the cluster that you can take advantage of by creating additional partitions for topics.

To run this utility, issue this command after logging into the MapR cluster that you want statistics for:

```
/opt/mapr/bin/guts
```

You can also use the `guts` utility to show only these statistics from MapR Event Store For Apache Kafka:

Table

Name	Description
`mpr`	The number of RPCs from MapR Event Store For Apache Kafka producers to the server.
`mpm`	The number of messages that have been published to the server.
`mpMB`	The total size in MB of the messages that have been published to the server.
`mlr`	The number of RPCs from MapR Event Store For Apache Kafka consumers to the server.
`mlm`	The number of messages that have been read from the server.
`mcl`	The number of concurrent RPCs from consumers to the server.
`mlMB`	The total size in MB of the messages that have been read from the server.

To see these statistics, run this command:

```
/opt/mapr/bin/guts streams:all
```

Note: These statistics are for the most recent sample period at the time the command is run, and are not cumulative. Sample periods are one second.

Monitoring Producers

To get a sense of how quickly producers are sending messages to the producer client library, you can run the command `stream topic info` at intervals.

Doing so will show you changes over time in the rate at which the values for `maxoffset` and `maxtimestamp` increase for the partitions in the topics that your producers are publishing to.

For example, if you have a script that runs the command at intervals of 10 seconds, the change per second would be `(Value at first run - Value at second run)/10`.

This is an indirect measure of the speed of the producers because the producer client library batches messages before publishing them to partitions. The faster the producers send messages to the client, the faster the client publishes message batches, and the greater the change per second.

last-updated: Apr 11, 2022

If producers do not seem to be sending messages quickly enough, and this problem is not caused by server-side I/O bottlenecks, you can spawn more producer threads.

See `stream topic info` for the syntax of this command.

Monitoring Consumers
There are two commands that you can run at intervals to get a sense of how far behind a consumer is in a partition. The consumer must belong to a consumer group, even if the consumer is the only member of that group.

To find the lag in milliseconds between the timestamp of the most recently published message in a stream, topic, or partition and the timestamp of a consumer's most recently committed cursor, run the command `stream cursor list`. The lag is the value of the `consumerlagmillis` parameter.

To find the timestamp of the most recently committed cursor for the consumer that is furthest back in a partition compared to all other consumers reading from the same partition, run the command `stream topic info`. This timestamp is the value of the `mintimestampacrossconsumers` parameter. Use this timestamp together with the values of the following parameters to get a sense of where this cursor is in the partition:

`mintimestamp`	This parameter shows the timestamp of the oldest message in the partition.
`maxtimestamp`	This parameter shows the timestamp of the most recently published message in the partition.

If a consumer's configuration for cursor commits is the default (the configuration parameter `enable.auto.commit` is set to `true` and `auto.commit.interval.ms` is set to 1000 milliseconds), the consumer will be only about one second ahead of the offset and timestamp reported for the consumer's most recently committed cursor.

If it seems that consumers are falling behind and that this problem is not caused by server-side I/O bottlenecks, you can start more consumer threads.

If the current number of consumers in a consumer group is equal to the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, add a partition to this topic before adding a consumer. The consumer client library dynamically reassigns the existing partitions in the topic to the consumers in the consumer group, as well as assigning the new partition to a consumer.

If the current number of consumers in a consumer group is less than the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, you don't need to add any partitions before adding a consumer.

Monitoring Alarms
Provides an overview of how to monitor alarms using the Control Panel and the CLI.

On a cluster with an Enterprise Edition or Enterprise Database Edition license, MapR raises alarms to alert you to information about the cluster:

- Cluster health, including disk failures
- Volumes that are under-replicated or over quota
- Services not running

You can see any currently raised alarms in the **Active Alarms** pane and the **Alarm Summary** page of the Control System (click  in the Control System) or using the `alarm list on page 1545` command. For a list of all alarms, see the Alarms Reference.

When you click  , the **Alarm Summary** page displays all active alarms and for each alarm, the **All** active alarms pane displays the following:

last-updated: Apr 11, 2022

Column Name	Column Description
Severity	The severity of the alarm. Value can be: • — Critical • — Warning • — Information
Status	The status of the alarm. Value can be: • Active • Muted
Time	The date and time stamp from when the alarm was raised.
Name	The name of the alarm.
Info	The notes associated with the alarm, which contains description of the alarm and the recommended action to take.
Entity	The entity on which the alarm was raised.
Type	The type of alarm. Value can be: • CLUSTER • NODE • VOLUME • USER/GROUP

You can select the checkbox beside one or more alarms to:

- Dismiss the alarms
- Mute the alarms

Viewing Active Cluster Alarms
Describes how to view cluster alarms using the Control System and the CLI.

You can view cluster alarms using the Control System and the CLI.

Viewing Active Cluster Alarms in the Control System

- Log in to the Control System and click:
  - **Overview** to view all the alarms on the cluster in the **Active Alarms** pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **Active Alarms** pane.
  - (Alarm Summary) to view all the alarms on the cluster in the **All** alarms pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **All** alarms pane.

  You can:
  - View alarm information
  - Dismiss an alarm

last-updated: Apr 11, 2022

- Mute an alarm

Retrieving Cluster Alarms Using the CLI or REST API

The basic command to retrieve the alarms for a cluster is:

```
maprcli alarm list -cluster <cluster name> -type cluster
```

For complete reference information, see `alarm list` on page 1545.

Viewing Active Node Alarms
Describes how to view active node alarms using the Control System and the CLI.
Viewing Active Node Alarms in the Control System

- **Note:** The **Nodes** page is not available in the Kubernetes version of the Control System.

  Log in to the Control System and:

  - Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
  - Go to the node information page to view alarms in the **Alarms** pane for the selected node.
  - Click (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
  - Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

  You can:

  - View alarm notes
  - Mute an alarm
  - Dismiss an alarm

Retrieving Active Node Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

For complete reference information, see `alarm list` on page 1545.

Viewing Active Volume Alarms
Describes how to view volume alarms using the Control System and the CLI.

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

- Log in to the Control System and:
  - Click **Data** > **Volumes** to view all active volume alarms in the **Active Alarms** pane.

    Note: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

  - Go to the **Summary** tab in the volume information page to view the recent and active alarms for the selected volume in the **Alarms** pane.

last-updated: Apr 11, 2022

- Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
- Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

You can:

- View information related to the alarm.
- Dismiss an alarm.
- Mute an alarm.

See Volume Alarms on page 2240 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 1545.

Viewing Active Table Replication Alarms
Describes how to view active table replication alarms using the Control System and the CLI.

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

- Log in to the Control System and click **Data** > **Tables** to view table replication alarms in the **Active Alarms** pane.

  You can:

  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Table-Replication Alarms on page 2237 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 1545.

Viewing Table Replication Alarms in the Log Files

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Viewing Active Stream Alarms
Describes how to view active stream alarms using the Control System and the CLI.

You can view stream alarms using the Control System and the CLI.

Viewing Active Stream Alarms in the Control System

- Log in to the Control System and:
  - Click **Data** > **Streams** to view all stream alarms in the **Active Alarms** pane.
  - Go to the **Summary** tab in the stream information page to view the recent and active alarms for the selected stream in the **Active Alarms** pane.

  You can:
  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Alarms Reference on page 2221 for more information on the stream alarms.

Retrieving Active Stream Alarms Using the CLI or REST API

The basic command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 1545.

Monitoring Errors
Explains how to monitor errors using the Control System.

To view the errors on the cluster:

1. Log in to the Control System and click  to display the **Recent Errors** window.
   The **Recent Errors** window displays only if there are any errors. For each error, the window displays the following:

Column Name	Column Description
Name	The name of the error.
Type	The type of error.
Action	The type of operation during which the error occurred.
Date & Time	The date and time when the error occurred.
Description	A brief description of the error.

2. Choose one of the following from the drop-down menu to filter the list of errors by a specific type:
   - All Types — to display all types of errors.
   - Data — to display errors related to data
   - Disk Usage — to display errors related to disk usage
   - Nodes — to display errors on nodes
   - Schedules — to display errors related to schedules
   - Services — to display service-related errors
   - Snapshots — to display errors during snapshot

last-updated: Apr 11, 2022

- Volumes — to display errors on volumes
- Tables — to display errors on tables

Metering
The Control System includes a metering feature that can be used to collect cluster storage and compute usage details for consumption-based billing, for actual monthly storage and computations.

Understanding MapR Metering

The metering feature relies on collecting data for cluster storage and compute usage to produce reports. The metering reporting process is secure, reliable, and auditable.

The metrics are collected every 15 minutes and output in JSON format. This JSON file is written to `/var/mapr/metering/` with READ-ONLY permission. For archival and audit purposes, the metering files are saved in MapR filesystem, `/var/mapr/metering/zips` and `/var/mapr/metering/sent`. It is recommended to keep these files for a period of at least 2 years.

For a description of each metric collected by default, see Metering Data Descriptions on page 1322.

For install instructions, see Installing Metering on page 283.

Note: If more than one API server is running on your cluster, the Control System automatically turns on High Availability (HA) for your cluster.

Enabling or Disabling Upload to MapR Server
You can agree to (enable) or turn off (disable) automatic upload of metrics to the MapR server using the Control System and the CLI.

If the cluster is connected to the internet, automatic upload of metrics is enabled by default. If the cluster is not connected to the Internet, disable automatic upload of data and follow the steps to upload metering data manually.
Enabling or Disabling Using the Control System

1. Log in to the Control System and go to the **Auditing and Metering** tab in the **Admin** > **Cluster Settings** page.
2. Move the slider to **Yes** to enable or **No** to disable in the **Send Metering Metrics to MapR** section.

Enabling or Disabling Using the CLI

- Set the value for `mcs.metering.upload.data` to `0` to disable and `1` to enable by running the following command.

```
maprcli config save -values '{"mcs.metering.upload.data":"1"}'
```

Uploading Metering Measurement Results to MapR Server
You can choose to automatically send metrics to MapR server or upload metrics manually, depending on whether your cluster has internet connectivity.
Uploading Automatically While Connected to the Internet

If the cluster is connected to the internet, automatic upload of metrics is enabled by default. To disable automatic upload, see Enabling or Disabling Upload to MapR Server on page 1320.

Uploading Manually While Connected to the Internet

If you do not want to send your metrics every 30 minutes and instead want to send metrics on demand, perform the following steps:

1. Disable automatic upload of metrics in the MapR Control System web interface.
   See Enabling or Disabling Upload to MapR Server on page 1320 for the steps.

last-updated: Apr 11, 2022

2. Run the following command in the MapR CLI to create a .zip file of the metrics:

```
mapr-apiserver-cli.sh --prepareForOfflineSend
```

   The .zip file is stored in the `/var/mapr/metering/zips/` directory.

3. Download the following `tar` or `zip` file:

Linux and MAC	`https://package.mapr.com/releases/metering/mapr-apiserver-utils/mapr-apiserver-utils-1.0.201809050108.tar`
Windows	`https://package.mapr.com/releases/metering/mapr-apiserver-utils/mapr-apiserver-utils-1.0.201809050108.zip`

4. Untar the file into any target directory and `cd` into the that directory:

```
$ tar -xvf mapr-apiserver-utils-1.0.201809050108.tar -C <TARGET_DIR>
$ cd <TARGET_DIR>
```

5. Change directory into `./mapr-apiserver-utils/bin`:

```
$ cd ./mapr-apiserver-utils/bin/
```

6. Run the upload command:

```
$ ./uploadMetrics.sh -u -z <ZIP>
```

Uploading Using a Standalone Utility on an Internet-Connected Computer

You must transfer the metrics file to an internet-connected computer and then upload manually when your cluster is not connected to the internet.

1. Run the following command to create a .zip file of the metrics:

```
mapr-apiserver-cli.sh --prepareForOfflineSend
```

   The .zip file is stored in the `/var/mapr/metering/zips/` directory.

2. Copy the .zip file from the MapR cluster onto an internet-connected computer:

```
$ hadoop fs -copyToLocal /var/mapr/metering/zips/<ZIP>
```

3. On the internet-connected computer, download the following `tar` or `zip` file:

Linux and MAC	`https://package.mapr.com/releases/metering/mapr-apiserver-utils/mapr-apiserver-utils-1.0.201809050108.tar`

last-updated: Apr 11, 2022

Windows	`https://package.mapr.com/releases/metering/mapr-apiserver-utils/mapr-apiserver-utils-1.0.201809050108.zip`

4. Untar the file into any target directory and `cd` into the that directory:

```
$ tar -xvf mapr-apiserver-utils-1.0.201809050108.tar -C <TARGET_DIR>
$ cd <TARGET_DIR>
```

5. Change directory into `./mapr-apiserver-utils/bin`:

```
$ cd ./mapr-apiserver-utils/bin/
```

6. Run the upload command:

Linux	`$ ./uploadMetrics.sh -u -z <ZIP>`
Windows	`$ ./uploadMetrics.bat -u -z <ZIP>`

Calculating Metering Metrics

The metering metrics of tiered data is based on collection of total gigabytes of data offloaded with object tiering to cloud storage and the total amount of data (without replication) sitting in the cold tier.

- Total gigabytes of data offloaded with object tiering to cloud storage.

  This metric is computed by picking the "offloaded" value, in gigabytes, in the collected dashboard info on page 1587 stats from the tiering section. At any time, it gives the total amount of data offloaded to cold tiers for that cluster in gigabytes. The dashboard information is collected every 15 mins by the metering daemon.

- Total amount of data (without replication) sitting in the cold tier.

  This metric is also computed from the same series of collected dashboard info on page 1587 stats from the tiering section. It is the difference between consecutive values of "offloaded" in the series, ignoring negative values, and summing the series of positive values over the billing period.

Metering Data Descriptions

This table lists the metrics collected by the metering feature.

Table

JSON Field Name	Description
clusterId	Randomly generated ID created when the cluster is installed
collectionDate	Epoch timestamp for the latest metric collection
mapRCoreBuildVersion	MapR core software build version
signature	Digital signature of the metering JSON file
version	Version of the metering program used to capture this JSON result

Table (Continued)

JSON Field Name	Description
isSecure	Identifies whether the cluster is secure or not Options: `true` or `false`.
numberOfNodes	Number of nodes in the cluster
clusterDiskCapacityInGB	Total data in the cluster at that time
clusterDiskCapacityUsedInGB	Total data consumed in the cluster at that time
totalAmountOfDataOffloadedToColdTiersInGB	Data offloaded to the cloud, using Object Tiering You can display this metric using the `maprcli dashboard info` command.
cpuCoreInSeconds	CPU core hours consumed by all MapR Services across all nodes Also, CPU core-hours used by all Apache ecosystem components, as well as MapR File System, CLDB, API servers, REST gateways, replication gateways, and so on.
clients	Number of active instances at that moment
numberOfactiveUniquePlatinumPosixClients	Number of monthly active unique Platinum POSIX clients You can display this metric using the `maprcli node list -clientsonly` command.
numberOfactiveUniqueDSROrPACCInstances	Number of monthly active unique DSR instances, using Gold POSIX clients

Sample JSON File for Metering

A sample metering JSON file for an 8-node cluster with no workloads enabled.

Using MapR Data Platform Monitoring (Spyglass Initiative)

MapR Data Platform Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

Metric Monitoring

Administrators can monitor the current status of the cluster and anticipate future cluster requirements with dashboards. For example, you can use metrics dashboards to visualize the following:

Storage Utilization	Use metrics dashboards to monitor storage trends. For example, you can compare the volume of MapR File System usage at different times to the MapR File System capacity and then allocate resources to the MapR File System accordingly.
Node Utilization	Use metrics dashboards to check for node overload. For example, if the CPU usage is high on a few nodes, you may want to distribute the load across more nodes for better performance and efficiency.
MapR Database Operational Trends	Use metrics dashboards to display historical trends for MapR Database operations. For example, if a user

	reports MapR Database slowness, the historical trends associated with row scans, get, and put operations can be used to identify the node(s) on which the performance degradation occurs.

Log Monitoring

Administrators can use dashboards to visualize, search, and review logs when troubleshooting issues. For example, you can use log dashboards to troubleshoot the following issues:

Service Failures	When metrics indicate that one or more services are down, use log dashboards to check the logs for each failed service and drill-down to each associated node.
Application Failures	When an application or job fails, use log dashboard to identify possible bottlenecks. For example, you can search the logs for a given application ID across all the nodes in the cluster.
MapR File System Performance	When users experience MapR File System or NFS slowness, use log dashboards to search the MapR filesystem logs for service errors or application issues.

Related Information

- Using MapR Data Platform Monitoring (Spyglass Initiative) on page 1330
- MapR Monitoring Storage Options on page 116
- Step 8: Install Metrics Monitoring on page 162
- Step 9: Install Log Monitoring on page 165

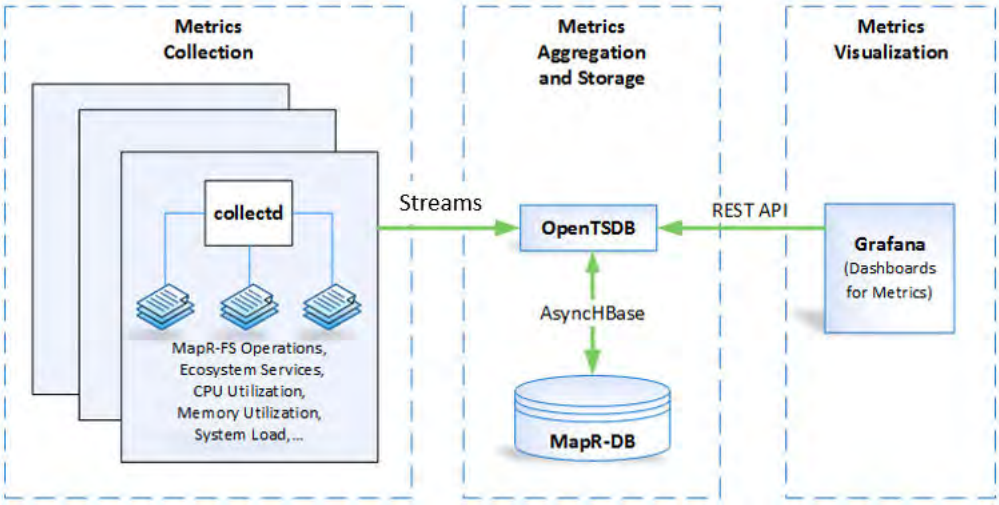
MapR Monitoring Architecture

MapR Monitoring integrates with open-source components to collect, aggregate, store, and visualize metrics and logs.

Note: The MapR Monitoring architecture is designed for use on MapR cluster nodes. Installing monitoring components on client nodes or edge nodes is not supported.

Metric Monitoring Architecture

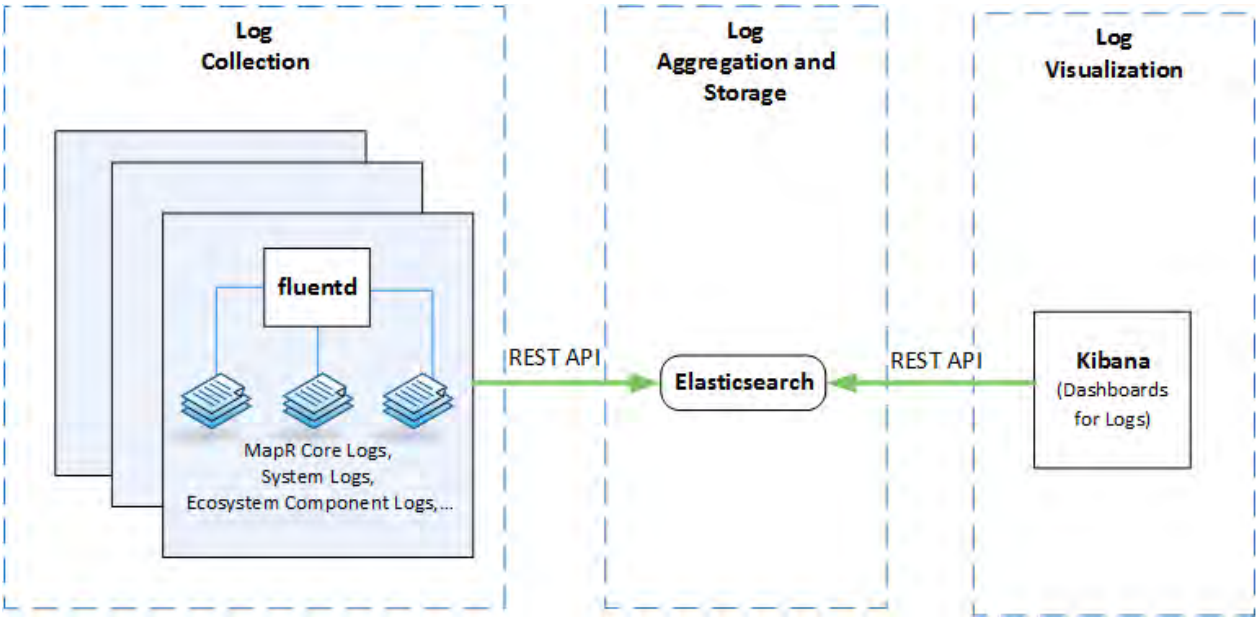
To visualize cluster metrics, MapR Monitoring integrates with the following components:



collectd	The collectd service runs on each node in the cluster to collect metrics. It uses streams to send the metrics to opentsdb. For more information, see Metric Collection on page 1334.
OpenTSDB	OpenTSDB aggregates the metrics and runs as the time-series database on top of MapR Database, the metrics data store. Based on your cluster requirements, it runs on one or more nodes in the cluster.
Grafana	Grafana uses REST API to access metrics data from OpenTSDB. Using a single instance of Grafana, users can build custom dashboards or use sample dashboards to visualize the metric. For more information about dashboards, see Metric Visualization on page 1381.

Log Monitoring Architecture

To visualize logs, MapR Monitoring integrates with the following components:



fluentd	fluentd runs on each node in the cluster to collect and parse logs. It uses REST API to send the logs to ElasticSearch. For more information, see Log Collection on page 1386.
Elasticsearch	Elasticsearch indexes the logs so that they are easily accessed and searchable. Based on your cluster requirements, it runs on one or more nodes in the cluster. For more information, see Log Aggregation and Storage on page 1391.
Kibana	Kibana uses REST API to access and search the logs available in Elasticsearch. Using a single instance of Kibana, users can create visualizations and dashboards to analyze their logs. For more information, see Log Visualization on page 1396.

Spyglass on Streams

Release 6.0 of the MapR Data Platform introduced Spyglass on Streams. When you install release 6.0 or later, Streams is the default mechanism through which metrics flow from the Collectd service to

OpenTSDB. Moving metrics through streams secures the data and provides a mechanism to perform real-time data analytics.

Note: Currently, Spyglass on Streams is not available for logs. Fluentd continues to use the REST API to send logs to ElasticSearch for the indexing of logs.

The Flow of Metrics via Streams

The Collectd service collects node-level and service-level metrics from each node in the cluster. The Collectd service hashes metrics to a stream and writes the metrics into topics in that stream.

In release 6.1.0 and later, Collectd creates one stream per cluster: `/var/mapr/mapr.monitoring/metricstreams/0`. Topic names use the format `<hostname>`. For example: `mfs81.qa.lab`.

The Streams server distributes metrics to the available OpenTSDB nodes, and OpenTSDB consumes the metrics.

Note: Writing to an external OpenTSDB is not supported from release 6.0 onwards. In addition, inserting non-MapR data into the provided OpenTSDB is not supported. Any custom data added to the provided OpenTSDB will be removed by the purge script (`tsdb_cluster_mgmt.sh`) that runs periodically.

Determining How Many OpenTSDB Nodes to Install

Having multiple OpenTSDB nodes in the cluster distributes the workload. The number of partitions and OpenTSDB nodes determines the level of parallelism for consumption.

Each OpenTSDB node can consume one partition at a time. By default, metrics data is divided across 12 partitions in each topic and optimal parallelism is reached if there are five OpenTSDB nodes to consume the partitions. See Parallelism When Consuming Messages. Note that the term “consumer” in the topic equates to an OpenTSDB node in Spyglass on Streams.

A general guideline for the minimum number of OpenTSDB nodes in a cluster is one for every 10x increase in nodes beyond 10, for example:

- Three OpenTSDB nodes in a 10-node cluster
- Four OpenTSDB nodes in a 100-node cluster
- Five OpenTSDB nodes in a 1000-node cluster

If your cluster has 10 or more nodes, at least three OpenTSDB nodes should be available to consume metrics. Typically, for every 10x increase in nodes, you should add another OpenTSDB node. For example, if your cluster reaches a size of 100 nodes, have four OpenTSDB nodes available for consumption.

These guidelines do not guarantee optimal performance. Evaluate the performance of the streams to determine if your cluster would benefit from additional OpenTSDB nodes.

Note: If all configured OpenTSDB nodes have been offline for several hours, you may notice an initial spike in memory and CPU usage by OpenTSDB processes as they aggressively try to keep up with the metrics. You can reduce the number of AsynchHBase threads to reduce the CPU and memory usage. By default, AsynchHBase runs 128 threads. To modify the number of threads, add or modify the following property in the `/opt/mapr/asynchbase/asynchbase-<version>/conf/asynchbase.conf` file on the OpenTSDB nodes:

```
"fs.mapr.async.worker.threads=<value>"
```

last-updated: Apr 11, 2022

Increasing the Number of Streams

For release 6.1 and later, the default setting for the number of streams is one. Even if your cluster grows to 1000 nodes or more, you do not need to increase the number of streams. For release 6.0.x, increasing the number of streams is recommended as you add more nodes (see the release 6.0 documentation), but this practice is not required in release 6.1 and later.

Changing the Automatic Stream Cursor Commits

You can adjust the frequency of automatic stream cursor commits for OpenTSDB. Modify the `tsd.streams.autocommit.interval` in `opentsdb.conf` The unit is thousands of seconds. The default value is '60000' which is 60 secs. For a system with heavy loads, consider changing the value to something like 5 minutes.

Metric Collection

Metrics are collected from each node in the cluster so that administrators can use the data to monitor the cluster. In general, the `collectd` service collects metrics every 10 seconds. The exception is volume metrics which are collected every 10 minutes.

When `collectd` writes metrics to streams, tags are assigned to each metric so that administrators can filter metric data to create dashboards that are specific to their needs.

By default, each metric contains the following tags:

- `fqdn`: Displays values for a specified node.
- `clusterid`: Displays values for a specific cluster.
- `clustername`: As of EEP 3.0, displays values for a specific cluster.

However, many metrics have additional tags that you can use to filter metric data.

Streams store metrics in OpenTSDB with the following schema:

```
<metrictype.name> <fqdn:fqdnvalue> <clusterid:clusteridvalue>
<clustername:clusternamevalue>[<AdditionalTagA:AdditionalTagAvalue>
<AdditionalTagB:AdditionalTagBvalue>...] <metricvalue> <timestamp>
```

Note: A negative value shown in the metrics indicates that the maximum value configured for that metric is exceeded. The maximum value for GUT metrics is int32 (2^31-1).

For more information on using tags and dashboards, see Metric Visualization on page 1381.

Configure Metric Retention

By default, OpenTSDB stores two weeks of metrics. Based on your requirements, you can change metric retention period.

The following cron job runs each day to purge metrics based on the retention period.

```
$min $hour * * * $OTSDB_HOME/bin/tsdb_cluster_mgmt.sh -purgeData >>
$OTSDB_HOME/var/log/opentsdb/purgeData.log 2>&1
```

Complete the following steps to edit the metric retention period:

1. Open the `/opt/mapr/opentsdb/opentsdb-<version>/bin/tsdb_cluster_mgmt.sh` file.

2. In the following line, update the value of `'2 weeks ago'` to the new retention period.

```
$OT_HOME/bin/tsdb scan --delete 2000/01/01 $(date --date='2 weeks ago'
+'%Y/%m/%d') sum $metric
```

For example, to delete metrics from 1/1/2000 to [current date - 2 days]:

```
$OT_HOME/bin/tsdb scan --delete 2000/01/01 $(date --date='2 days ago'
+'%Y/%m/%d') sum $metric
```

Warning: MapR monitoring uses 2 MB disk space per minute per node when MapR Event Store For Apache Kafka metrics is enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with a 3X replication. This stream metrics data is automatically deleted every 30 days.

Note: For more information, see the OpenTSDB scan command documentation.

Configure Queue Filters for `mapr.rm.<value>` Metrics

The YARN application metrics that are collected by JMX have the metric name syntax `mapr.rm.<metric_name>` and the metric values are aggregated among all the queues in the default queue. However, you can configure collectd to create a filter for each queue. As an alternative, you can use the REST API queue metrics (`mapr.rm_queue.<metric_name>`) which are by default set up for filtering by queue.

To configure collectd to create queue filters for `mapr.rm.*` metrics, define each queue that you want to create filters for in the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file. You can configure collectd to generate filters for every queue or only for specific queues. Changes that you make to the collectd.conf file only apply to metrics collected after you restart the collectd service.

1. Open the collectd.conf file and locate the MBean "QueueMetrics" block.

```
<MBean "QueueMetrics">
      ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "default-queue"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "default-queue"
      </Value>

      ...
    </MBean>
```

This block specifies that there is one queue named `root` and that the filter for this queue is named `default-queue`.

2. Create copy of the MBean "QueueMetrics" block.

3. Configure the ObjectName option in the MBean "QueueMetrics" block copy, with the queue path for the queue that you want to create a filter for.

last-updated: Apr 11, 2022

- To define the a child queue named `alpha` under the `root` queue:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
```

- To define a child queue named beta which is under a child queue named alpha:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=b
eta"
```

4. For each Value block within the MBean "QueueMetrics" block you are defining, replace `default-queue` with the queue name that you want to create a filter for.
   - To define filter value `alpha` for the rm_queue tag, set the InstancePrefix to `alpha:`

```
 <MBean "QueueMetrics">
      ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
      InstancePrefix "rm"
<Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "alpha"
      </Value>
<Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "alpha"
      </Value>
...
    </MBean>
```

   - To define a filter value `beta` for the rm_queue tag, set the InstancePrefix to `beta:`:

```
 <MBean "QueueMetrics">
      ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=b
eta"
      InstancePrefix "rm"
<Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "beta"
      </Value>
<Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "beta"
      </Value>
...
    </MBean>
```

5. Repeat steps 2 and 3 for each queue that you want to create a filter value for.
6. Save the collectd.conf file.
7. Repeat steps 1 through 6 on each ResourceManager node.

8. Restart the collectd service.

```
maprcli node services -name collectd -nodes <space separated list of
ResourceManager Nodes> -action restart
```

In the following example, rm_queue tag will have the following filter values: `alpha` , `beta` (child of alpha), and `highpriority` (child of root):

```
<MBean "QueueMetrics">
      ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "alpha"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "alpha"
      </Value>
      ...
      <Value "ReservedVCores">
        Type "reserved_vcores"
        InstancePrefix "alpha"
      </Value>
    </MBean>

<MBean "QueueMetrics">
      ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha q2=beta"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "beta"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "beta"
      </Value>
      ...
      <Value "ReservedVCores">
        Type "reserved_vcores"
        InstancePrefix "beta"
      </Value>
    </MBean>

<MBean "QueueMetrics">
      ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=highpriority"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "highpriority"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
```

last-updated: Apr 11, 2022

```
        InstancePrefix "highpriority"
      </Value>
      ...
      <Value "ReservedVCores">
        Type "reserved_vcores"
        InstancePrefix "highpriority"
      </Value>
    </MBean>
```

Configure the Collectd Service Heap Size

The `collectd` service uses an embedded JVM when it gathers metrics from the CLDB, Node Manager, Resource Manager, and Drill. You can edit the Plugin Java section of *collectd.conf* to configure limits to the collectd virtual memory footprint.

Note: The Plugin Java section of the collectd.conf file may be commented or uncommented. The configure.sh utility will uncomment the Plugin Java section when `collectd` runs on a node that requires an embedded JVM. Therefore, when you update the file, do not add or remove comment symbols (#) in the Plugin java section

Complete the following steps on each `collectd` node:

1. Open the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file.
2. Look for the following section:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
 <Plugin java>
JVMArg "-Djava.class.path=......
```

3. Update `Xms` and `Xmx` options in the Plugin java section.

   `Xms` defines the amount of memory allocated to the service when it starts. `Xmx` defines the maximum amount of memory allocated to the service.

   If the <Plugin java> section is not commented out, the configuration may look like this:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
<Plugin java>
JVMArg "-Djava.class.path=......
JVMArg "-Xms32m"
JVMArg "-Xmx128m"
```

   If the <Plugin java> section is commented out, the configuration may look like this:

```
### **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
#<Plugin java>
# JVMArg "-Djava.class.path=......
# JVMArg "-Xms32m"
# JVMArg "-Xmx128m"
```

4. Restart the `collectd` service.

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

CPU Metrics

Every 10 seconds, the collectd service uses the cpu plugin to gather the following CPU metrics on each node in the cluster.

Name	Description	Additional Tag(s)
`cpu.percent`	The aggregate percentage of all CPUs.	• `cpu_core`: Display values specified core. Core values: 0,1, and 2 • `cpu_class`: Display values for a specified class of CPU. CPU class values: idle, user, nice, system.
`thread.cpu_usage`	The percentage of CPU used by each thread.	• `thread_name`: Indicates if thread belongs to RPC, MapR Database, MapR File System, or an instance of MapR File System.

Disk Free Metrics

Every 10 seconds, the collectd service uses the df plugin to gather the following disk free metrics on each node in the cluster.

Name	Description	Additional Tag(s)
df.df_complex	The aggregate number of bytes for disk partitions.	• `df_partition`: Display values for a specified disk. Disk values: dev or boot. • `df_type`: Display values for a certain type. Type values: free, reserved, and used.
df.percent_bytes	The aggregated percentage of disk partitions.	• `df_partition`: Display values for a specified disk. Disk values: dev or boot. • `df_type`: Display value for a certain type. Type values: free, reserved, and used.

Disk Metrics

Every 10 seconds, the collectd service uses the disk plugin to gather the following disk metrics on each node in the cluster.

Name	Description	Additional Tag(s)
disk.disk_await	The average time in milliseconds to complete I/O requests. This includes the time request are waiting in queue and the time spent processing the request. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specified disk.
disk.disk_avg_requests_size	The average size in kilobytes for I/O requests issued to the disk. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specified disk.
disk.disk_avg_queue_size	The average number of requests issued to the disk. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specified disk.

last-updated: Apr 11, 2022

Name	Description	Additional Tag(s)
disk.disk_io_time.io_time	The disk I/O time in milliseconds (ms).	• `disk_name`: Display values for a specified disk.
disk.disk_io_time.weighted_io_time	The aggregate time in milliseconds (ms) spent on I/O operations that are either in progress or have completed	• `disk_name`: Display values for a specified disk.
disk.disk_merged.read	The number of physical read operations.	• `disk_name`: Display values for a specified disk.
disk.disk_merged.write	The number of physical write operations.	• `disk_name`: Display values for a specified disk.
disk.disk_octets.read	The number of bytes read from disk.	• `disk_name`: Display values for a specified disk.
disk.disk_octets.write	The number of bytes written to disk.	• `disk_name`: Display values for a specified disk.
disk.disk_ops.read	The number of completed read operations.	• `disk_name`: Display values for a specified disk.
disk.disk_ops.write	The number of completed write operations.	• `disk_name`: Display values for a specified disk.
disk.disk_time.read	The average time in milliseconds(ms) to read from disk.	• `disk_name`: Display values for a specified disk.
disk.disk_time.write	The average time in milliseconds(ms) to write to disk.	• `disk_name`: Display values for a specific disk.
disk.disk_utilization	The disk utilization percentage. This metric is available as of EEP 3.0.	• `disk_name`: Display values for a specific disk.
disk.pending_operations	The number of pending disk operations.	• `disk_name`: Display values for a specific disk.

Drill Metrics

Every 10 seconds, the collectd service uses the plugin to gather the following Drill metrics on each node in the cluster.

Name	Description
mapr.drill.allocator_root_used	The amount of memory used in bytes by the internal memory allocator.
mapr.drill.allocator_root_peak	The peak amount of memory used in bytes by the internal memory allocator.
mapr.drill.blocked_count	The number of threads that are blocked because they are waiting for a monitor lock.
mapr.drill.count	The number of live threads (including both daemon and non-daemon threads).
mapr.drill.fd_usage	The ratio of used to total file descriptors.

last-updated: Apr 11, 2022

Name	Description
mapr.drill.fragments_running	The number of query fragments currently running in the drillbit.
mapr.drill.heap_used	The amount of heap memory used in bytes by the JVM.
mapr.drill.non_heap_used	The amount of non-heap memory used in bytes by the JVM.
mapr.drill.queries_completed	The number of completed, canceled or failed queries for which this drillbit is the foreman.
mapr.drill.queries_running	The number of running queries for which this drillbit is the foreman.
mapr.drill.runnable_count	The number of threads executing in the JVM.
mapr.drill.waiting_count	The number of threads that are waiting to be executed. This can occur when a thread must wait for another thread to perform an action before proceeding.

Hive JMX Metrics

Every 10 seconds, the `collectd` service uses the Hive plug-in to gather the following Hive JMX metrics on each node in the cluster. Descriptions for the Hive metrics are not currently available.

Metric Collection

Metrics collected in Hive relate specifically to the HiveServer2 and Hive metastore processes. Each process runs in a separate JVM, and the JVMs provide values for the metrics.

Starting in EEP 6.3.2 and EEP 7.0.1, the `hive.exec.submit.local.task.via.child` option (in hive-site.xml) is set to `true`, by default, and enables HiveServer2 to spawn local tasks (typically mapjoin hashtable generation phase) in child JVMs. The system does not collect metrics for the child JVMs. The system only collects metrics for the HiveServer2 and Hive metastore processes.

Hive Metastore Metrics

The following are the JMX metrics provided for the Hive metastore:

- mapr.hivemetastore.hivemetastore_buffers_direct_capacity
- mapr.hivemetastore.hivemetastore_buffers_direct_count
- mapr.hivemetastore.hivemetastore_buffers_direct_used
- mapr.hivemetastore.hivemetastore_buffers_mapped_capacity
- mapr.hivemetastore.hivemetastore_buffers_mapped_count
- mapr.hivemetastore.hivemetastore_buffers_mapped_used
- mapr.hivemetastore.hivemetastore_class_loading_loaded
- mapr.hivemetastore.hivemetastore_class_loading_unloaded
- mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_count
- mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_time
- mapr.hivemetastore.hivemetastore_gc_ps_scavenge_count
- mapr.hivemetastore.hivemetastore_gc_ps_scavenge_time

last-updated: Apr 11, 2022

HiveServer2 Metrics

The following are the JMX metrics provided for HiveServer2 (hs2):

- mapr.hiveserver2.hiveserver2_buffers_direct_capacity
- mapr.hiveserver2.hiveserver2_buffers_direct_count
- mapr.hiveserver2.hiveserver2_buffers_direct_used
- mapr.hiveserver2.hiveserver2_buffers_mapped_capacity
- mapr.hiveserver2.hiveserver2_buffers_mapped_count
- mapr.hiveserver2.hiveserver2_buffers_mapped_used
- mapr.hiveserver2.hiveserver2_class_loading_loaded
- mapr.hiveserver2.hiveserver2_class_loading_unloaded
- mapr.hiveserver2.hiveserver2_exec_async_pool_size
- mapr.hiveserver2.hiveserver2_exec_async_queue_size
- mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_count
- mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_time
- mapr.hiveserver2.hiveserver2_gc_ps_scavenge_count
- mapr.hiveserver2.hiveserver2_gc_ps_scavenge_time
- mapr.hiveserver2.hiveserver2_active_sessions
- mapr.hiveserver2.hiveserver2_open_sessions
- mapr.hiveserver2.hiveserver2_init_total_count_dbs
- mapr.hiveserver2.hiveserver2_init_total_count_partitions
- mapr.hiveserver2.hiveserver2_init_total_count_tables
- mapr.hiveserver2.hiveserver2_memory_heap_committed
- mapr.hiveserver2.hiveserver2_memory_heap_init

- mapr.hiveserver2.hiveserver2_memory_heap_max
- mapr.hiveserver2.hiveserver2_memory_heap_usage
- mapr.hiveserver2.hiveserver2_memory_heap_used
- mapr.hiveserver2.hiveserver2_memory_non_heap_committed
- mapr.hiveserver2.hiveserver2_memory_non_heap_init
- mapr.hiveserver2.hiveserver2_memory_non_heap_max
- mapr.hiveserver2.hiveserver2_memory_non_heap_usage
- mapr.hiveserver2.hiveserver2_memory_non_heap_used
- mapr.hiveserver2.hiveserver2_memory_pools_code_cache_usage
- mapr.hiveserver2.hiveserver2_memory_pools_compressed_class_space_usage
- mapr.hiveserver2.hiveserver2_memory_pools_metaspace_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_eden_space_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_old_gen_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_survivor_space_usage
- mapr.hiveserver2.hiveserver2_memory_total_committed
- mapr.hiveserver2.hiveserver2_memory_total_init
- mapr.hiveserver2.hiveserver2_memory_total_max
- mapr.hiveserver2.hiveserver2_memory_total_used
- mapr.hiveserver2.hiveserver2_threads_blocked_count
- mapr.hiveserver2.hiveserver2_threads_count
- mapr.hiveserver2.hiveserver2_threads_daemon_count
- mapr.hiveserver2.hiveserver2_threads_deadlock_count
- mapr.hiveserver2.hiveserver2_threads_deadlocks
- mapr.hiveserver2.hiveserver2_threads_new_count
- mapr.hiveserver2.hiveserver2_threads_runnable_count
- mapr.hiveserver2.hiveserver2_threads_terminated_count
- mapr.hiveserver2.hiveserver2_threads_timed_waiting_count
- mapr.hiveserver2.hiveserver2_threads_waiting_count
- mapr.hiveserver2.hiveserver2_active_calls_api_get_all_databases
- mapr.hiveserver2.hiveserver2_active_calls_api_get_all_functions
- mapr.hiveserver2.hiveserver2_active_calls_api_get_all_tables

last-updated: Apr 11, 2022

Load Metrics
Every 10 seconds, the collectd service uses the load plugin to gather the following load metrics on each node in the cluster.

Name	Description
load.load.longterm	The number of tasks running on the node every 15 minutes.
load.load.midterm	The number of tasks running on the node every 10 minutes.
load.load.shortterm	The number of tasks running on the node every minute.

MapR Alarm Metrics
Every 10 seconds, the collectd service uses a plugin to gather the cluster alarms.

Name	Description	Additional Tag(s)
mapr.alarms.alarm_raised	The number of alarms raised. The timestamp for each alarm is based on the time that MapR raised the alarm, not the time when the collectd service gathered the alarm data.	• `alarm_name:` Display values for a specified alarm name. • `alarm_entity:.` Display values for a specified volume, node, user, or group.

MapR Cache Metrics
Every 10 seconds, the collectd service uses a plugin to gather the following MapR filesystem cache metrics on each node in the cluster.

Name	Description
mapr.cache.lookups_data	The number of cache lookups in the block cache.
mapr.cache.lookups_dir	The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages.
mapr.cache.lookups_inode	The number of cache lookups in the inode cache.
mapr.cache.lookups_largefile	The number of cache lookups in the large file LRU cache. The large file LRU is used for storing files with size greater than 64K and also MapR Database data pages.
mapr.cache.lookups_meta	The number of cache lookups on the meta LRU cache. The meta LRU is used for storing internal B-Tree pages.
mapr.cache.lookups_smallfile	The number of cache lookups on the small file LRU cache. This LRU is used for storing files with size less than 64K and also MapR Database index pages.
mapr.cache.lookups_table	The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages.
mapr.cache.misses_data	The number of cache misses in the block cache.
mapr.cache.misses_dir	The number of cache misses on the table LRU cache.
mapr.cache.misses_inode	The number of cache misses in the inode cache.

Name	Description
mapr.cache.misses_largefile	The number of cache misses on the large file LRU cache.
mapr.cache.misses_meta	The number of cache misses on the meta LRU cache.
mapr.cache.misses_smallfile	The number of cache misses on the small file LRU cache.
mapr.cache.misses_table	The number of cache misses on the table LRU cache.

MapR CLDB Metrics

Every 10 seconds, the collectd service uses a MapR plugin to gather the following CLDB metrics on the primary CLDB node in the cluster.

Name	Description
mapr.cldb.cluster_cpu_total	The number of physical CPUs in the cluster.
mapr.cldb.cluster_cpubusy_percent	The aggregate percentage of busy CPUs in the cluster.
mapr.cldb.cluster_disk_capacity	The storage capacity for MapR disks in GB.
mapr.cldb.cluster_diskspace_used	The amount of MapR disks used in GB.
mapr.cldb.cluster_memory_capacity	The memory capacity in MB.
mapr.cldb.cluster_memory_used	The amount of used memory in MB.
mapr.cldb.containers	The number of containers currently in the cluster.
mapr.cldb.containers_created	The cumulative number of containers created in the cluster. This value includes containers that have been deleted.
mapr.cldb.containers_unusable	The number of containers that are no longer usable. The CLDB marks a container as unusable when the node that stores the container is offline for 1 hour or more.
mapr.cldb.disk_space_available	The amount of disk space available in GB.
mapr.cldb.nodes_in_cluster	The number of nodes in the cluster.
mapr.cldb.nodes_offline	The number of nodes in the cluster that are offline.
mapr.cldb.rpc_received	The number of RPCs received.
mapr.cldb.rpcs_failed	The number of RPCs failed.
mapr.cldb.storage_pools_cluster	The number of storage pools.
mapr.cldb.storage_pools_offline	The number of offline storage pools.
mapr.cldb.volumes	The number of volumes created, including system volumes.

MapR Database Metrics

Every 10 seconds, the collectd service uses a plugin to gather MapR Database metrics on each node in the cluster. MapR Database provides both node and table metrics.

Node metrics capture data for operations across a MapR node. You can use them to assess the performance of individual nodes in your MapR cluster.

Starting in MapR 6.1, MapR Database supports table metrics. Table metrics provide more granular metrics. They allow you detect and diagnose bottlenecks and performance issues that are specific to individual tables. For example, suppose a node metric shows a spike in a particular RPC. Knowing this, you can use the corresponding table metric to determine if the spike originates from a single table.

Examples of other use cases that benefit from table metrics are the following:

last-updated: Apr 11, 2022

- You want to measure the latency of different RPC operations on a table
- You want to determine which operations on a table are slow
- You want to determine which tables are most frequently accessed

MapR Database Node Metrics
This section describes the available MapR Database node metrics.

The following table lists MapR Database node metrics:

Metric Category	Name	Description
Throughput - RPC counts	`mapr.db.append_rpcs`	The number of MapR Database append RPCs completed
	`mapr.db.checkandput_rpcs` [1]	The number of MapR Database check and put RPCs completed
	`mapr.db.get_currpcs`	The number of MapR Database get RPCs in progress
	`mapr.db.get_rpcrows`	The number of get rows completed. Each get RPC can include multiple get rows.
	`mapr.db.get_rpcs`	The number of MapR Database get RPCs completed
	`mapr.db.increment_rpcs` [1]	The number of MapR Database increment RPCs completed
	`mapr.db.put_currpcs`	The number of MapR Database put RPCs in progress
	`mapr.db.put_rpcs`	The number of MapR Database put RPCs completed
	`mapr.db.scan_currpcs`	The number of MapR Database scan RPCs in progress
	`mapr.db.scan_rpcrows`	The number of scan rows completed. Each scan RPC can include multiple scan rows.
	`mapr.db.scan_rpcs`	The number of MapR Database scan RPCs completed
	`mapr.db.updateandget_rpcs`	The number of MapR Database update and get RPCs completed
Throughput - Row count written	`mapr.db.append_rpcrows` [1]	The number of rows written by append RPCs
	`mapr.db.checkandput_rpcrows` [1]	The number of rows written by check and put RPCs
	`mapr.db.increment_rpcrows` [1]	The number of rows written by increment RPCs
	`mapr.db.put_rpcrows`	The number of rows written by put RPCs. Each MapR Database put RPC can include multiple put rows.
	`mapr.db.updateandget_rpcrows` [1]	The number of rows written by update and get RPCs
Throughput - Rows returned	`mapr.db.get_resprows` [1]	The number of rows returned from get RPCs
	`mapr.db.scan_resprows` [1]	The number of rows returned from scan RPCs

last-updated: Apr 11, 2022

Metric Category	Name	Description
Throughput - Row count read	`mapr.db.get_readrows` [1]	The number of rows read by get RPCs
	`mapr.db.put_readrows` [1]	The number of rows read by put RPCs
	`mapr.db.scan_readrows` [1]	The number of rows read by scan RPCs
Throughput - Bytes written	`mapr.db.append_bytes` [1]	The number of bytes written by append RPCs
	`mapr.db.checkandput_bytes` [1]	The number of bytes written by check and put RPCs
	`mapr.db.put_bytes`	The number of bytes written by put RPCs
	`mapr.db.increment_bytes` [1]	The number of bytes written by increment RPCs
	`mapr.db.updateandget_bytes` [1]	The number of bytes written by update and get RPCs
Throughput - Bytes read	`mapr.db.get_bytes` [1]	The number of bytes read by get RPCs
	`mapr.db.scan_bytes` [1]	The number of bytes read by scan RPCs
Value cache usage	`mapr.db.valuecache_hits`	The number of MapR Database operations that utilized the MapR Database value cache
	`mapr.db.valuecache_lookups`	The number of MapR Database operations that performed a lookup on the MapR Database value cache
	`mapr.db.valuecache_usedSize`	The MapR Database value cache size in MB
Compactions	`mapr.db.fullcompacts` [1]	The number of compactions that combine multiple MapR Database data files containing sorted data (known as spills) into a single spill file. MapR Database creates a spill file each time it flushes files containing unsorted data (known as buckets). Full compactions improve read performance because after compaction, MapR Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
	`mapr.db.minicompacts` [1]	The number of compactions that combine multiple small data files containing sorted data (known as spills) into a single spill file. MapR Database creates a spill file each time it flushes files containing unsorted data (known as buckets). After a mini compaction, MapR Database needs to read only two spill files.
	`mapr.db.ttlcompacts` [1]	The number of compactions that result in reclamation of disk space due to removal of stale data. You can configure the TTL for a table if it has only a default column family. See table cf edit on page 1806 for details.

Metric Category	Name	Description
Table flushes	`mapr.db.flushes` [1]	The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold
	`mapr.db.forceflushes` [1]	The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the in-memory bucket file cache fills up
CDC - Data sent	`mapr.db.cdc.sent_bytes` [1]	The number of bytes of CDC data sent
	`mapr.db.cdc.sent_rows` [1]	The number of rows of CDC data sent
Secondary indexes - Data sent	`mapr.db.index.sent_bytes` [1]	The number of bytes sent for secondary index updates
	`mapr.db.index.sent_rows` [1]	The number of rows sent for secondary index updates
Replication - Data sent	`mapr.db.repl.sent_bytes` [1]	The number of bytes sent to replicate data
	`mapr.db.repl.sent_rows` [1]	The number of rows sent to replicate data
CDC - Data pending	`mapr.db.cdc.pending_bytes` [1]	The number of bytes of CDC data remaining to be sent
	`mapr.db.cdc.pending_rows` [1]	The number of rows of CDC data remaining to be sent
Secondary indexes - Data pending	`mapr.db.index.pending_bytes` [1]	The number of bytes of secondary index data remaining to be sent
	`mapr.db.index.pending_rows` [1]	The number of rows of secondary index data remaining to be sent
Replication - Data pending	`mapr.db.repl.pending_bytes` [1]	The number of bytes of replication data remaining to be sent
	`mapr.db.repl.pending_rows` [1]	The number of rows of replication data remaining to be sent

[1] Available starting in MapR 6.1

MapR Database Table Metrics

Starting in MapR 6.1, MapR Database supports table metrics. This section describes the available MapR Database table metrics. It also describes how to configure metrics per table, disable them in your cluster, and how to filter them by operation and table.

Table metrics are collected per node. By default, these metrics are written to OpenTSDB every minute. Pre-existing tables in your MapR cluster inherit this default setting. You can change this default per table using either the table create on page 1788 or table edit on page 1822 command. Secondary indexes inherit their metric configuration from their parent table.

You cannot disable metrics on individual tables. During installation, you can disable table metrics across your entire cluster. If you are using the MapR installer, select the minimum metrics collection configuration option. If you are doing a manual install, see Installing Metering Using Manual Steps on page 284.

The following table lists MapR Database table metrics:

mapr.db.table.latency	The latency of RPC operations on tables, represented as a histogram. Endpoints identify histogram bucket boundaries.

Note: Put latency metrics for indexes reflect only the index update time. They do not include lag time due to asynchronous index updates.

mapr.db.table.read_bytes	The number of bytes read from tables.
mapr.db.table.read_rows	The number of rows read from tables.
mapr.db.table.resp_rows	The number of rows returned from tables.
mapr.db.table.rpcs	The number of RPC calls completed on tables.
mapr.db.table.value_cache_hits	The number of MapR Database operations on tables that utilized the MapR Database value cache.
mapr.db.table.value_cache_lookups	The number of MapR Database operations on tables that performed a lookup on the MapR Database value cache.
mapr.db.table.write_rows	The number of rows written to tables.
mapr.db.table.write_bytes	The number of bytes written to tables.

Tags for Table Metrics

Each table metric collects data across all operations on tables and secondary indexes in a MapR node. To view metrics for a particular RPC operation on a specific table, you must filter the metric by RPC type and table path, as described in the following list:

rpc_type	The name of the RPC: • `append` • `check_and_put` • `get` • `increment` • `put` • `scan` • `update_and_get`
table_path	The path of the MapR Database table. OpenTSDB supports only the following characters: • Alphanumeric characters • Dot (.) • Underscore (_) • Dash (-) • Slash (/) • Space ( )

- Unicode letters

If a table path contains characters that are not in this list, MapR cannot collect those table metrics.

index

The name of the secondary index defined on the table specified in `table_path`, if you want to filter on a specific index. When you specify this tag, you cannot specify the `noindex` tag.

Note: You can use regular expressions when specifying the index name to filter for a group of indexes.

noindex

Set to `"//primary"` if you want to filter metrics for only the primary table and exclude metrics for secondary indexes defined on the table. When you specify this tag, you cannot specify the `index` tag.

The following list shows examples of the table-specific tags to use to filter different table metrics:

mapr.db.table.write_rows

Tag Name: `table_path`

Tag Value: `/var/mapr/mapr.monitoring/tsdb-meta`

Description: The number of rows written to a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, including writes to its secondary indexes.

mapr.db.table.rpcs

- *Tag Name*: `rpc_type`
  - *Tag Value*: `get`
- *Tag Name*: `table_path`
  - *Tag Value*: `/var/mapr/mapr.monitoring/tsdb-meta`
- *Tag Name*: `noindex`
  - *Tag Value*: `//primary`

Description: The number of completed *get* RPCs for a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, excluding metrics on the table's secondary indexes.

mapr.db.table.read_rows

- *Tag Name*: `table_path`
  - *Tag Value*: `/var/mapr/mapr.monitoring/tsdb-meta`
- *Tag Name*: `index`
  - *Tag Value*: `tsdbIdx`

Description: The number of rows read from a secondary index named `tsdbIdx`, defined on the table in the path `/var/mapr/mapr.monitoring/tsdb-meta`.

last-updated: Apr 11, 2022

Note: In addition to these table-specific tags, Metric Collection on page 1334 describes other available tags.

MapR Event Store For Apache Kafka Metrics
Every 10 seconds, the collectd service uses a plugin to gather the following Streams metrics on each node in the cluster.

Warning: MapR monitoring uses 2 MB disk space per minute per node when MapR Event Store For Apache Kafka metrics is enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with a 3X replication. This stream metrics data is automatically deleted every 3 days.

Name	Description
mapr.streams.produce_rpcs	The number of Streams producer RPCs. This metric is available as of EEP 2.0.
mapr.streams.produce_msgs	The number of Streams messages produced. This metric is available as of EEP 2.0.
mapr.streams.produce_bytes	The number of megabytes produced by Streams messages. This metric is available as of EEP 2.0.
mapr.streams.listen_rpcs	The number of Streams consumer RPCs. This metric is available as of EEP 2.0.
mapr.streams.listen_msgs	The number of Streams messages read by the consumer. This metric is available as of EEP 4.0. **Note:** If you upgrade to EEP 4.0, all Streams messages are consumed, however this metric only reports a count on messages that were produced in EEP 4.0. Messages produced prior to EEP 4.0 are consumed, but not counted. In this scenario, the metric reports a partial count or a zero count if all messages were produced prior to EEP 4.0.
mapr.streams.listen_currpcs	The number of concurrent Stream consumer RPCs. This metric is available as of EEP 2.0.
mapr.streams.listen_bytes	The number of megabytes consumed by Streams messages. This metric is available as of EEP 2.0.

MapR File System Metrics
Every 10 seconds, the collectd service uses a MapR plugin to gather the following MapR File System metrics on each node in the cluster.

Name	Description
mapr.fs.bulk_writes	The number of bulk-write operations. Bulk-write operations occur when the primary MapR File System container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes.
mapr.fs.bulk_writesbytes	The amount of MB written by bulk-write operations. Bulk-write operations occur when the primary MapR File System container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes.
mapr.fs.kvstore_delete	The number of delete operations on key-value store files which are used by the CLDB and MapR Database.

last-updated: Apr 11, 2022

Name	Description
mapr.fs.kvstore_insert	The number of insert operations on key-value store files which are used by the CLDB and MapR Database.
mapr.fs.kvstore_lookup	The number of lookup operations on key-value store files which are used by the CLDB and MapR Database.
mapr.fs.kvstore_scan	The number of scan operations on key-value store files which are used by the CLDB and MapR Database.
mapr.fs.local_readbytes	The amount of MB read by applications that are running on the MapR File System node where the data resides.
mapr.fs.local_reads	The number of file read operations by applications that are running on the MapR File System node where the data resides.
mapr.fs.local_writebytes	The amount of MB written by applications that are running on the MapR File System node where the data resides.
mapr.fs.local_writes	The number of file write operations by applications that are running on the MapR File System node where the data resides.
mapr.fs.read_bytes	The amount of data (in MB) read remotely.
mapr.fs.read_cachehits	The number of cache hits for file reads. This value includes pages that MapR File System populates using the readahead mechanism.
mapr.fs.read_cachemisses	The number of cache misses for file read operations.
mapr.fs.reads	The number of remote reads.
mapr.fs.statstype_create	The number of file create operations.
mapr.fs.statstype_lookup	The number of lookup operations.
mapr.fs.statstype_read	The number of file read operations.
mapr.fs.statstype_write	The number of file write operations.
mapr.fs.write_bytes	The amount of data (in MB) written remotely.
mapr.fs.writes	The number of remote writes.

MapR Process Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following MapR process metrics on each node in the cluster.

Name	Description	Additional Tag(s)
mapr.process.context_switch_involuntary	The number of involuntary context switches for MapR processes. An involuntary context switch occurs when a process consumes more CPU time than what it was allocated by the kernel. When an involuntary context switch occurs, the kernel stops a process to provide resources to another process.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.

Name	Description	Additional Tag(s)
mapr.process.context_switch_voluntary	The number of voluntary context switches for MapR processes. A voluntary context switch occurs when a process does not require the entire CPU time it was allocated by the kernel or when a process is suspended. When a voluntary context switch occurs, the kernel provides CPU resources to another process.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.cpu_percent	The percentage of CPU used for MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.cpu_time.syst	The amount of time, measured in seconds, that the process has been in kernel mode.	
mapr.process.cpu_time.user	The amount of time, measured in seconds, that the process has been in user mode	
mapr.process.data	The amount memory, in MB, used by the data segments of MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.disk_octets.read	The number of bytes read from disk for MapR processes.	
mapr.process.disk_octets.write	The number of bytes written to disk for MapR processes.	
mapr.process.disk_ops.read	The number of read operations for MapR processes.	
mapr.process.disk_ops.write	The number of write operations for MapR processes.	
mapr.process.mem_percent	The percentage of total system memory (not capped by MapR processes) used for MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.page_faults.majflt	The number of major MapR process faults that required loading a memory page from disk.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.page_faults.minflt	The number of minor MapR process faults that required loading a memory page from disk.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.rss	The actual amount of memory, in MB, used by MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.vm	The amount of virtual memory, in MB, used by MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.

MapR I/O Metrics
Every 10 seconds, the collectd service uses a plugin to gather the following MapR I/O metrics on each node in the cluster.

Name	Description
mapr.io.read_bytes	The number of MB read from disk.
mapr.io.reads	The number of MapR File System disk read operations.
mapr.io.write_bytes	The number of MB written to disk.
mapr.io.writes	The number of MapR File System disk write operations.

MapR RPC Metric
Every 10 seconds, the collectd service uses a plugin to gather the following MapR RPC metrics on each node in the cluster.

Name	Description
mapr.rpc.bytes_recd	The number of bytes received by the MapR File System over RPC.
mapr.rpc.bytes_sent	The number of bytes sent by the MapR File System over RPC.
mapr.rpc.calls_recd	The number of RPC calls received by the MapR File System.

Spark JMX Metrics
Every 10 seconds, the `collectd` service gathers the following Spark JMX metrics on each node in the cluster.

For detailed information about Spark metrics, see the Apache Spark documentation.

MapR Topology Metrics

Every 60 seconds, the collectd service uses a plugin to gather the following topology metrics on each node in the cluster. Use these metrics to understand disk utilization across a topology or rack. By default, these metrics include all racks and topologies associated with the cluster. However, you can use tags to specify which rack(s) or topologies(s) to include. **Note:** Racks and topologies can span multiple nodes and one rack can be associated with multiple topologies.

Name	Description	Tag
mapr.topology.disks_total_capacity	The disk capacity in gigabytes. This metric is available as of EEP 3.0.	• `rack_name:` Display values for a specified rack. • `topology_name`: Display values for a specified topology. Provide the full topology path.
mapr.topology.disks_used_capacity	The amount disk space used in gigabytes. This metric is available as of EEP 3.0.	• `rack_name:` Display values for a specified rack. • `topology_name`: Display values for a specified topology. Provide the full topology path.
mapr.topology.utilization	The aggregate percentage of CPU utilization. This metric is available as of EEP 3.0.	• `rack_name:` Display values for a specified rack. • `topology_name`: Display values for a specified topology. Provide the full topology path.

MapR Volume Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following MapR volume metrics on each CLDB node in the cluster.

For volumes prefixed with `mapr.internal*`, the reported volume metrics are not meaningful.

Name	Description	Tag(s)
mapr.volume.logical_used	The number of MBs used for logical volumes before compression is applied to the files.	• `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.
mapr.volume.snapshot_used	The number of MBs used for snapshots.	• `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.
mapr.volume.total_used	The number of MB used for volumes and snapshots.	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.

last-updated: Apr 11, 2022

Name	Description	Tag(s)
mapr.volume.used	The number of MB used for volumes after compression is applied to the files.	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.
mapr.volume.quota	The number of megabytes(MB) used for volume quota.	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.

Every 10 seconds, the collectd service uses a plugin to gather the following MapR volume metrics on each CLDB node in the cluster.

Name	Description	Tag(s)
mapr.volmetrics.read_throughput	The per volume read throughput in KB	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.write_throughput	The per volume write throughput in KB	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.read_latency	The per volume read latency in milliseconds	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.

last-updated: Apr 11, 2022

Name	Description	Tag(s)
mapr.volmetrics.write_latency	The per volume write latency in milliseconds	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.read_ops	A count of the read operations per volume	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.write_ops	A count of the write operations per volume	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.

Virtual Memory Metrics

Every 10 seconds, the collectd service uses the vmem plugin to gather the following memory metrics on each node in the cluster.

Name	Description
vmem.vmpage_faults.majflt	The number of major page faults. Major page faults require pages to be accessed from disk.
vmem.vmpage_faults.minflt	The number of minor page faults. Minor page faults can be resolved by sharing pages that are already in memory.

Memory Metrics

Every 10 seconds, the collectd service uses the memory and swap plugins to gather the following memory metrics on each node in the cluster.

Name	Description	Additional Tag(s)
memory.memory	The amount of physical memory in bytes.	• `memory_type`: Display values for a specified memory type. Memory type values: free, used, buffered, etc.

last-updated: Apr 11, 2022

Name	Description	Additional Tag(s)
swap.swap	The amount of swap space in bytes.	• `swap_type`: Display values for a specified swap type. Swap type values: used and free.
swap.swap_io	The amount of swap I/O in bytes.	

Network Metrics
Every 10 seconds, the collectd service uses the interface plugin to gather network metrics on each node in the cluster.

Name	Description	Additional Tag(s)
interface.if_errors.rx	The number of network errors received.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_errors.tx	The number of network errors transmitted.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_octets.rx	The number of bytes received over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_octets.tx	The number of bytes transmitted over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_packets.rx	The number of packets received over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_packets.tx	The number of packets transmitted over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.

Node Manager Metrics
Every 10 seconds, the collectd service uses a plugin to gather the following Node Manager metrics on each node in the cluster.

Name	Description
mapr.nm.allocated_GB	The amount of memory allocated to the Node Manager in GB.
mapr.nm.allocated_containers	The number of containers allocated to the Node Manager.
mapr.nm.allocated_vcores	The number of CPUs allocated to the Node Manager.
mapr.nm.available_vcores	The number of CPUs available to the Node Manager.
mapr.nm.available_GB	The amount of memory available to the Node Manager in GB.
mapr.nm.containers_completed	The number of containers that have completed.
mapr.nm.containers_failed	The number of containers that have failed.

Name	Description
mapr.nm.containers_initing	The number of containers that are initializing.
mapr.nm.containers_killed	The number of containers that have been killed by the Node Manager.
mapr.nm.containers_running	The number of containers that are running.
mapr.nm.containers_launched	The number of containers started by the Node Manager.
mapr.nm.jvm.gc_count	The number of garbage collections.
mapr.nm.jvm.gc_count_ps_mark_sweep	The number of parallel scavenge mark sweep collections.
mapr.nm.jvm.gc_count_ps_scavenge	The number of parallel scavenge collections.
mapr.nm.jvm.gc_time_millis	The amount of time spent on garbage collection in milliseconds.
mapr.nm.jvm.gc_time_millis_ps_mark_sweep	The amount of time spent on parallel scavenge mark sweep collection in milliseconds.
mapr.nm.jvm.gc_time_millis_ps_scavenge	The amount of time in milliseconds spent on parallel scavenge collection.
mapr.nm.jvm.log_error	The total number of ERROR logs.
mapr.nm.jvm.log_fatal	The total number of FATAL logs.
mapr.nm.jvm.log_info	The total number of INFO logs
mapr.nm.jvm.log_warn	The total number of WARN logs.
mapr.nm.jvm.mem_heap_committed_m	The amount of heap memory committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_heap_max_m	The maximum amount of heap memory that can be committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_heap_used_m	The amount of heap memory used by the Node Manager in megabytes.
mapr.nm.jvm.mem_max_m	The maximum amount of memory that can be committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_non_heap_committed_m	The amount of non-heap memory committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_non_heap_max_m	The maximum amount of non-heap memory that can be committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_non_heap_used_m	The maximum amount of non-heap memory that can be used by the Node Manager in megabytes.
mapr.nm.jvm.threads_blocked	The number of Node Manager threads in BLOCKED state.
mapr.nm.jvm.threads_new	The number of Node Manager threads in NEW state.
mapr.nm.jvm.threads_runnable	The number of Node Manager threads in RUNNABLE state.
mapr.nm.jvm.threads_terminated	The number of Node Manager threads in TERMINATED state.
mapr.nm.jvm.threads_time_waiting	The number of Node Manager threads in TIMED_WAITING state.
mapr.nm.jvm.threads_waiting	The number of Node Manager threads in WAITING state.
mapr.nm.shuffle.shuffle_connection	The number of Node Manager shuffle connections.

last-updated: Apr 11, 2022

Name	Description
mapr.nm.shuffle.shuffle_output_bytes	The amount of Node Manager shuffle output in bytes.
mapr.nm.shuffle.shuffle_outputs_failed	The number of failed Node Manager shuffle outputs.
mapr.nm.shuffle.shuffle_outputs_ok	The number of completed Node Manager shuffle outputs.
mapr.nm.ugi.get_groups_avg_time	The average amount of time spent by Node Manager on group resolution.
mapr.nm.ugi.get_groups_num_ops	The number of group resolutions completed by the Node Manager.
mapr.nm.ugi.login_failure_avg_time	The average amount of time spent by Node Manager on failed login attempts.
mapr.nm.ugi.login_failure_num_ops	The number of failed login attempts by the Node Manager.
mapr.nm.ugi.login_success_avg_time	The average amount of time spent by Node Manager to successfully login.
mapr.nm.ugi.login_success_num_ops	The number of successful logins by the Node Manager.

Resource Manager Metrics

Every 10 seconds, the `collectd` service uses a MapR plugin to gather Resource Manager metrics on the active Resource Manager. `Collectd` gathers metrics on the Resource Manager JVM process, YARN applications, and nodes that are managed by the Resource Manager. The method used to gather the metrics differs based on the metric type.

YARN Application Metrics

`Collectd` gathers YARN application metrics via JMX and REST API. The application metrics that are collected by JMX have the metric name `mapr.rm.<metric_name>`. Application metrics collected via REST API have the metric name `mapr.rm_queue.<metric_name>`.

Metrics Collected Using JMX

The following metrics are collected using JMX. To filter these metrics by queue using the *rm_queue* tag, see Configure Queue Filters for mapr.rm.<value> Metrics on page 1335.

mapr.rm.active_applications

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of active applications.

mapr.rm.active_users

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of users with active applications.

mapr.rm.aggregate_containers_allocated

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of allocated containers.

mapr.rm.aggregate_containers_released

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of released containers.

mapr.rm.allocated_MB

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The amount of memory allocated to the Resource Manager in MB.

mapr.rm.allocated_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs allocated to the Resource Manager.
mapr.rm.apps_completed	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of completed applications.
mapr.rm.apps_failed	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of failed applications.
mapr.rm.apps_killed	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of killed applications.
mapr.rm.apps_pending	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of pending applications.
mapr.rm.apps_running	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of running applications.
mapr.rm.apps_submitted	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of submitted applications.
mapr.rm.available_MB	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory available to the Resource Manager in MB.
mapr.rm.available_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of disks available to the Resource Manager.
mapr.rm.available_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs available to the Resource Manager.
mapr.rm.pending_MB	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory, in MB, waiting to be allocated by the Resource Manager.
mapr.rm.pending_containers	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of containers waiting to be allocated by the Resource Manager.
mapr.rm.pending_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue.

	Description: The number of disks waiting to be allocated by the Resource Manager.
mapr.rm.pending_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs waiting to be allocated by the Resource Manager.
mapr.rm.reserved_MB	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory reserved by the Resource Manager in MB.
mapr.rm.reserved_containers	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of containers reserved by the Resource Manager.
mapr.rm.reserved_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of disks reserved by the Resource Manager.
mapr.rm.reserved_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs reserved by the Resource Manager.

Metrics Collected Using REST API

The following YARN application metrics are collected using REST API.

mapr.rm_queue.aggregate_containers_allocated	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of containers allocated for applications in the default and custom queues.
mapr.rm_queue.appmaster_used_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks used by the Application Master for applications in the default and custom queues.
mapr.rm_queue.appmaster_used_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, used by the Application Master for applications in the default and custom queues.
mapr.rm_queue.appmaster_used_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the Application Master for applications in the default and custom queues.

mapr.rm_queue.apps_pending	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of pending applications in the default and custom queues.
mapr.rm_queue.apps_running	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of applications running in the default and custom queues.
mapr.rm_queue.fairshare_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter is the number of disks allocated to default and custom queues.
mapr.rm_queue.fairshare_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the amount of memory, in MB, allocated to default and custom queues.
mapr.rm_queue.fairshare_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the number of CPUs used by applications in the default and custom queues.
mapr.rm_queue.used_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of disks used by applications in the default and custom queues.
mapr.rm_queue.used_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory, in MB, used by applications in the default and custom queues.
mapr.rm_queue.used_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs used by applications in the default and custom queues.
mapr.rm_queue.max_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum number of disks available to default and custom queues.
mapr.rm_queue.max_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum amount of memory, in MB, available to default and custom queues.

last-updated: Apr 11, 2022

mapr.rm_queue.max_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum number of CPUs available to default and custom queues.
mapr.rm_queue.user_allocated_disks	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks allocated to the queues.
mapr.rm_queue.user_allocated_memory	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, allocated to the queues.
mapr.rm_queue.user_allocated_vcores	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs allocated to queues.
mapr.rm_queue.user_appmaster_used_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks used by the queues.
mapr.rm_queue.appmaster_used_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory used by the queues.
mapr.rm_queue.appmaster_used_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the queues.
mapr.rm_queue.user_apps_pending	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of applications pending in the queues.

last-updated: Apr 11, 2022

mapr.rm_queue.user_apps_running	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of applications running in the queues.
mapr.rm_queue.user_used_disks	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of number of disks used by the queues.
mapr.rm_queue.user_used_memory	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, used by the queues.
mapr.rm_queue.user_used_vcores	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the queues.

Resource Manager Node Metrics

The following are the Node metrics:

mapr.rm_cluster.active_nodes	The number of nodes in the cluster where containers are running.
mapr.rm_cluster.total_nodes	The number of nodes in the cluster.
mapr.rm_cluster.unhealthy_nodes	The number of nodes in the cluster that are unable to accept applications.

Resource Manager JVM Metrics

The following Resource Manager metrics are collected using JMX:

mapr.rm.jvm.gc_count	The number of garbage collections.
mapr.rm.jvm.gc_count_ps_mark_sweep	The number of parallel scavenge mark sweep collections.
mapr.rm.jvm.gc_count_ps_scavenge	The number of parallel scavenge collections.

mapr.rm.jvm.gc_time_millis	The amount of time, in milliseconds, spent on garbage collection.
mapr.rm.jvm.gc_time_millis_ps_mark_sweep	The amount of time, in milliseconds, spent on parallel scavenge mark sweep collection.
mapr.rm.jvm.gc_time_millis_ps_scavenge	The amount of time, in milliseconds, spent on parallel scavenge collection.
mapr.rm.jvm.log_error	The total number of ERROR logs.
mapr.rm.jvm.log_fatal	The total number of FATAL logs.
mapr.rm.jvm.log_info	The total number of INFO logs.
mapr.rm.jvm.log_warn	The total number of WARN logs.
mapr.rm.jvm.mem_heap_committed_m	The amount of heap memory, in megabytes, committed to the Resource Manager.
mapr.rm.jvm.mem_heap_max_m	The maximum amount of heap memory, in megabytes, that can be committed to the Resource Manager.
mapr.rm.jvm.mem_heap_used_m	The amount of heap memory, in megabytes, used by the Resource Manager.
mapr.rm.jvm.mem_max_m	The maximum amount of memory, in megabytes, that can be committed to the Resource Manager.
mapr.rm.jvm.mem_non_heap_committed_m	The amount of non-heap memory, in megabytes, committed to the Resource Manager.
mapr.rm.jvm.mem_non_heap_max_m	The maximum amount of non-heap memory, in megabytes, that can be committed to the Resource Manager.
mapr.rm.jvm.mem_non_heap_used_m	The maximum amount of non-heap memory, in megabytes, that can be used by the Resource Manager.
mapr.rm.jvm.threads_blocked	The number of Resource Manager threads in BLOCKED state.
mapr.rm.jvm.threads_new	The number of Resource Manager threads in NEW state.
mapr.rm.jvm.threads_runnable	The number of Resource Manager threads in RUNNABLE state.
mapr.rm.jvm.threads_terminated	The number of Resource Manager threads in TERMINATED state.
mapr.rm.jvm.threads_time_waiting	The number of Resource Manager threads in TIMED_WAITING state.
mapr.rm.jvm.threads_waiting	The number of Resource Manager threads in WAITING state.

Configure the OpenTSDB Service Heap Size

By default, the OpenTSDB service is configured to use a default heap size of 6 gigabytes. The default heap size can be adjusted by modifying certain configuration files.

last-updated: Apr 11, 2022

In EEPs 6.0.1 and later, the OpenTSDB service is configured to use a default heap size of 6 GB. In earlier EEPs, the default was configured to be 2 GB. If you configure a custom value for the OpenTSDB service heap size and then upgrade to EEPs 6.0.1 or later, you will see the 6-GB default implemented in the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file.

To change the heap size to a different setting, edit the configuration files on all OpenTSDB nodes as follows. The following steps change the heap size from 2 GB to 6 GB. The default heap size might need further adjustment if your cluster grows to a large number of nodes. If the 6-GB heap size is insufficient, you can use these same steps to adjust it:

1. Edit the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file to change:

   ```
   service.heapsize.max=2000
   service.heapsize.min=2000
   ```

   to

   ```
   service.heapsize.max=6000
   service.heapsize.min=6000
   ```

2. Edit the `/opt/mapr/opentsdb/opentsdb-*/etc/init.d/opentsdb` file to change:

   Note: Step 2 is not required for EEPs 6.0.1 and later, which contain logic to edit the `opentsdb` file automatically.

   ```
   $
   {JVMXMX:=-Xmx2000m -Xss1m -XX:MaxMetaspaceSize=128m}
   ```

   to

   ```
   $
   {JVMXMX:=-Xmx6000m -Xss1m -XX:MaxMetaspaceSize=128m}
   ```

3. Restart the OpenTSDB service:

   ```
   maprcli node services -name opentsdb -nodes <space-separated list of
   OpenTSDB nodes> -action restart
   ```

Metric Visualization
Use dashboards to visualize metrics across multiple nodes and clusters.

You can use a single dashboard to visualize metrics for multiple nodes in the cluster, for an entire cluster, or for multiple clusters. In a dashboard, you can use metric tags to filter the type of data that you want to see. To learn more about the tags available for each metric, see Metric Collection on page 1334.

Before you start visualizing metrics, review the following notes:

Sample Dashboards

As of EEP 1.1, the Grafana UI includes sample CLDB, node, and volume dashboards. For more information, see Sample Dashboards in Grafana on page 1384.

Grafana Documentation

For information about creating and using dashboards, see the Grafana documentation.

The Embedded Grafana Database

Grafana uses an embedded database to store configuration data such as users, data sources, and dashboards. When used with the MapR Data Platform, Grafana uses SQLite for its embedded database. Other databases, such as MySQL and PostgreSQL, are not supported for use with the MapR implementation of Grafana.

Note also that in a data-fabric cluster, each instance of Grafana has its own embedded SQLite database. Therefore, if you make a change to the Grafana configuration data (for example, if you add a new user) on one node, you must repeat the change on all other nodes where Grafana is installed.

Access the Grafana UI

You can launch the Grafana UI from the Control System or directly from a web browser.

1. Use one of the following methods to launch the Grafana UI:
   - In the Control System, go to the **Services** page and click **Grafana** to launch the Grafana UI in another tab.
   - From a web browser, launch the following URL: `http://<IPaddressOfGrafanaNode>:3000`
2. Provide user credentials. See Logging on to Grafana on page 1382.
3. Click **Log in**.

Logging on to Grafana

This page describes the credentials needed to log on to Grafana for secure and nonsecure clusters for MapR 6.0 and later.

EEP 5.0.0 and MapR Installer 1.9.0 implemented some changes in security that affect the user IDs and passwords you need to log on to Grafana. Beginning with EEP 5.0.0, Grafana no longer uses its own database to authenticate on secure MapR clusters. On secure clusters, when you enter your user name and password into the browser, the Grafana server sends the user name and password to the CLDB, and the CLDB authenticates using the Pluggable Authentication Module (PAM) and HTTPS. Grafana still relies on its database for some user information. However, because authentication relies on the CLDB, any new user that you add to Grafana must also exist on the MapR cluster.

EEP 4.x.x (Grafana 4.4.2) and Earlier

To log on, enter the default Grafana `admin` user and password:

- **User:** `admin`
- **Password:** `admin`

EEP 5.x.x (Grafana 4.6.1) and Later

To log on, specify the user and password as follows:

	Secure Cluster	Nonsecure Cluster
User	Type the MapR cluster admin user ID. **Note:** If the cluster admin user has no password or is not able to log in, see Logging on to Grafana Without Using the Cluster Admin on page 1383.	Type the Grafana `admin` user ID.
Password	Type the MapR cluster admin password that you specified during cluster installation.	Type the password for the Grafana `admin` user that you specified during cluster installation. (During cluster installation,

	Secure Cluster	Nonsecure Cluster
		the MapR Installer web interface asks you to provide this password. You can also provide the password by using `configure.sh` during a manual installation.)

For More Information

To change the Grafana password, see Changing the Password for Grafana on page 1383.

For more information about the Grafana versions supported by each EEP, see EEP Components and OS Support on page 5536.

For information about the EEPs supported by different MapR Core versions, see EEP Support and Lifecycle Status on page 5531.

Logging on to Grafana Without Using the Cluster Admin
In secure Grafana installations where the cluster admin (typically `mapr`) has no password and is not allowed to log in as a user, special steps are required to enable login with a user other than the cluster admin.

Use this procedure only if the cluster admin has no password. After an upgrade or a new installation of Grafana, perform these steps on the Grafana nodes:

1. Remove the old Grafana database. You will be able to access the Grafana database later using the new Grafana admin user:

   ```
   cd /opt/mapr/grafana/grafana-<version>/var/lib/grafana
   mv grafana.db grafana.db.sv
   ```

2. Use the `export` command to specify the new Grafana admin user:

   ```
   export GRAFANA_ADMIN_ID=<username>
   ```

3. Run `configure.sh` with the `-R` option:

   ```
   configure.sh -R
   ```

4. Restart Grafana.

Changing the Password for Grafana
Describes how to change the Grafana password for secure and nonsecure clusters.

Secure Clusters

To change the Grafana password for a secure cluster, you must change the password for the MapR cluster admin user. The security implementation determines how you change the password. For example, if your security implementation is PAM and LDAP, you need to use LDAP to change the cluster admin password.

Note: If the cluster is secure, attempting to change the Grafana password using the Grafana interface has no effect.

Nonsecure Clusters

For a nonsecure cluster:

1. Log in to the interface using the `admin` user ID and the password that you specified for the `admin` user ID when you installed the cluster.
2. Select **Home > Admin > Profile**.
3. On the **User Profile** screen, click **Change Password**, located near the bottom of the screen.
4. Enter and save the new password.

Adding a New Grafana User to a Secure MapR Cluster
In a secure MapR cluster, adding a new Grafana user requires an extra step to ensure that the user can be authenticated through the CLDB.

Beginning with EEP 5.0.0, Grafana no longer uses its own database to authenticate on secure MapR clusters. On secure clusters, when you enter your user name and password into the browser, the Grafana server sends the user name and password to the CLDB, and the CLDB authenticates using the Pluggable Authentication Module (PAM) and HTTPS.

Because authentication relies on the CLDB, any new user that you add to Grafana must also exist on the MapR cluster. Therefore, to add a new Grafana user in a secure MapR cluster:

1. Add the user to the Linux system first. This user must have the same Linux UID and GID on every node in the MapR cluster.
2. Add the same user to Grafana, making sure that you use the user ID you added to the Linux system. In Grafana: **Settings > ServerAdmin > Users > Add new user**.

Sample Dashboards in Grafana
Use the sample dashboards to get familiar with the types of graphs you can create. As of EEP 1.1, sample dashboards are available by default in Grafana.

Displaying the Sample Dashboards

For Grafana 4.x, 5.x, and 6.x, navigate to the **Welcome to Grafana** page, and click the **Home** drop-down menu to display the sample dashboards. Once you select a dashboard, it displays in the **Recently viewed dashboards** list on the Home page.

In Grafana 7.5.x and later, use these steps to display the dashboards:

1. Navigate to the **Welcome to Grafana** page.
2. On the left-side icon menu, click **Dashboard > Manage**. The list of dashboards is displayed.
3. Click a dashboard in the list to load the dashboard. The **General / Node Dashboard** page is displayed.
4. Loading the dashboard adds the dashboard to the **Recently viewed dashboards** list on the **General / Home** page.

Sample Dashboard Descriptions

CLDB Dashboard	The CLDB dashboard provides a high-level view of the MapR cluster. It displays the following information about the cluster: number of nodes, status of nodes, number of volumes, container information, disk capacity, and the utilization of CPU, memory, and disks across the cluster.
Node Dashboard	The Node dashboard provides node-specific information. It displays the following information for the selected node: CPU, memory, network I/O, MapR File System I/O, MapR Database operations, and Node Manager metrics. All the metrics are tagged with node

	hostname and the `fqdn` drop-down menu on the top left can be used to switch between nodes.
Volume Dashboard	The Volume dashboard provides volume-specific information. It displays the following information for the selected volume: raw data size, snapshot size, total size (including the snapshot size), volume utilization trends, read/write latency, number of reads/writes, and read/write throughput. All the metrics are tagged with volume name. Use the `VolumeName` drop-down menu on the top left to switch between volumes.

Troubleshooting Sample Dashboards

The sample dashboards should display metrics automatically. However, with certain EEPs, some manual configuration may be required to view sample dashboard metrics.

Configure the ClusterID in the CLDB dashboard	When the `ClusterID` drop-down menu on the CLDB dashboard is set to `None`, you must manually enter the ClusterID. You can determine the ClusterID from the Manage Licenses page on the Control System. ClusterID is usually an eighteen digit number.
Configure the Hostname in the Node dashboards	When the `fqdn` drop-down menu on the Node dashboard is set to `None`, you must manually enter the hostname for the node that you want to view metrics for.
Configure the Volume in the Volume dashboard	When the `VolumeName` drop-down menu on the Volume dashboard is set to `None`, you must manually enter the volume name for the volume that you want to view metrics for. The Volumes page on the Control System lists the volume names in the format required by the field. For example, you can enter `mapr.cluster.root` in the `VolumeName` drop-down menu.

Note: You must apply the manual configuration each time you view a dashboard.

Update the OpenTSDB Data Source For Grafana

Grafana connects to a single OpenTSDB node to read metrics. If Grafana cannot read the metrics because an OpenTSDB node has failed, you must configure Grafana to connect to a different OpenTSDB node.

Note: The OpenTSDB node that Grafana connects to by default is determined by the first OpenTSDB node that was specified when the cluster was configured to use MapR monitoring.

1. Use one of the following methods to launch the Grafana user interface:
   - From the Control System, select the **Grafana** view. After you select the **Grafana** view, you might also need to select the **Pop-out page into a tab** option.
   - From a web browser, launch the following URL: `http://<IPaddressOfGrafanaNode>:3000`
2. Click the Grafana icon in the upper left corner to toggle the side-menu bar.
3. Select **Data Sources** from the menu.
4. Click the **MapRMonitoringOpenTSDB** data source.
5. In the **Http setting** section, update the **Url** field to point to an active OpenTSDB node.
6. Click **Save & Test**.

last-updated: Apr 11, 2022

Log Collection

Fluentd collects log events from each node in the cluster and stores them in a centralized location so that administrators can search the logs when troubleshooting issues in the cluster. The process that fluentd uses to parse and send log events to Elasticsearch differs based on the formatting of log events in each log file.

Fluentd uses one or both of the following mechanisms to parse logs:

multi-line matching	Using the log time stamp as a delimiter, multi-line matching uses the `tail` plugin to read logs and determine the end of a log event. Each log event is sent to Elasticsearch when the next log event is written to the log file. This mechanism is often used when each log event starts with a timestamp and then includes a stack trace.
multi-pattern matching	Multi-pattern matching uses the `grok` plugin to parse logs events using complex expressions. This mechanism is often used to parse logs events that have non-uniform log formatting.

Before Fluentd sends the log entries to Elasticsearch, Fluentd assigns the following columns to each log event:

Tag	Description
level	The message level of the log entry. For example, info, warning, or error.
class	Java or C++ process name associated with the log entry.
message	The log message.
event_time	The time, with millisecond precision, when the log entry was written to the log file.
service_name	The name of the service that generated the log entry.
@timestamp	The time, with second precision, when fluentd read the message.
fqdn	The node on which the log entry was written.
clusterid	The clusterid of the cluster on which the log was written.

Note: The log event contents differs based on the service that logs it and the type of log. Therefore, the log events sent to Elasticsearch may include empty columns.

For more information about Elasticsearch, see the Elasticsearch website.

Configure Logs to Index

Edit the *fluentd.conf* file (`/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf`) to enable or disable the indexing of a specific log.

The *fluentd.conf* file includes a source parameter for each log file that it indexes.

1. To disable the indexing of a log, comment all lines for the associated source parameter.
2. To enable the indexing of a log, for example syslogs, uncomment the lines for the associated source parameter.

last-updated: Apr 11, 2022

3. Restart `fluentd` on each node in the cluster which is impacted by changes to the index configuration. For example, if you disable the indexing of Kibana logs, restart `fluentd` on the node that runs Kibana.

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> \
 -action restart
```

For example, in this excerpt of the *fluentd.conf* file, NodeManager error logs are disabled and ResourceManager logs are enabled:

```
# yarn nodemanager log
# <source>
#  @type tail
#  @id yarn_nodemanager_input
#  format multiline
#  format_firstline /\d{4}-\d{1,2}-\d{1,2}/
#  format1 /^(?<my_event_time>[^ ]* [^ ]*) (?<level>[^ ]*) (?<class>[^:]*):
(?<message>.*)$/
#  time_key my_event_time
#  keep_time_key true
#  path /opt/mapr/hadoop/hadoop-*/logs/yarn-*-nodemanager-*.log
#  tag nodemanager
#  pos_file /opt/mapr/fluentd/fluentd-0.14.00/var/log/fluentd/tmp/
nodemanager.pos
# </source>

# yarn resourcemanager log
<source>
  @type tail
  @id yarn_resourcemanager_input
  format multiline
  format_firstline /\d{4}-\d{1,2}-\d{1,2}/
  format1 /^(?<my_event_time>[^ ]* [^ ]*) (?<level>[^ ]*) (?<class>[^:]*):
(?<message>.*)$/
  time_key my_event_time
  keep_time_key true
  path /opt/mapr/hadoop/hadoop-*/logs/yarn-*-resourcemanager-*.log
  tag resourcemanager
  pos_file /opt/mapr/fluentd/fluentd-0.14.00/var/log/fluentd/tmp/
resourcemanager.pos
</source>
```

Forward Logs to Syslog Server

You can configure `fluentd` to send logs to a syslog server in addition to Elasticsearch. This topic provides instructions for configuring `fluentd` to send logs to syslog compatible collectors. However, it only provides guidelines for the syslog configuration, as syslog parameters differ by version. Knowledge of how to configure a syslog compatible collector is required to complete this configuration.

Complete the following steps:

1. Configure `fluentd` to send logs to the syslog server.
2. Configure `syslog` server to accept logs from `fluentd`.

Step 1: Configure fluentd to send logs to the syslog server

Complete the following steps on each `fluentd` node.

1. Open the `fluentd.conf` file (*/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf*).

last-updated: Apr 11, 2022

2. Remove the # to uncomment the following store section:

```
# <store>
# @type remote_syslog
# host 10.10.100.92
# port 51400
# severity debug
# tag fluentd
# </store>
```

3. Update the `host` parameter to the hostname/IP address of the receiving `syslog` server.
4. Update the `port` parameter to match the port that the receiving `syslog` server is expecting remote logging information on.
5. Restart the `fluentd` service:

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

Note: You can run this command after completing the steps on a node or run this command with a list of nodes once you have configured each `fluentd` node.

Step 2: Configure syslog to accept logs from fluentd

In general, you need to perform the following steps on the `syslog` collection server:

- Configure `syslogd` to listen for logs outside of the `syslog` node.
- Set up rules for how `syslog` handles the logs once it receives it.

1. In */etc/rsyslog.d/listen.conf*, comment out the following parameter:

```
$SystemLogSocketName /run/systemd/journal/syslog
```

2. In */etc/rsyslog.conf*, uncomment the following properties:

```
#$ModLoad imudp
#$UDPServerRun 514
```

3. In */etc/rsyslog.conf*, update the UDPServerRun to a value above 1000 that matches the port you configured in *fluentd.conf*. For example: `Set UDPServerRun` to 51400
4. In */etc/rsyslog.conf*, configure rules for handling logs. For example, add the following before the RULES section to route messages from the `fluentd` node to a log file named *qa-node91.log*.

```
if $fromhost-ip == '10.10.100.91' then /var/log/qa-node91.log
& ~
```

Note: In this example, the IP address must match the IP address of the `fluentd` node.

MapR Core Logs

The `fluentd` component reads and parses the following MapR Core log files on each node in the cluster.

Service Name	Parsing Method	Description
adminuiapp	Multi-line	Control System logs from `/opt/mapr/apiserver/logs/apiserver.log`.
cldb	Multi-line	CLDB server logs from `$MAPR_HOME/logs/cldb.log`.
cldbfssummary	Multi-line	Summary of the CLDB server logs from `$MAPR_HOME/logs/cldbfssummary.log`
mfs_maprdb	Multi-line	MapR Database logs from `$MAPR_HOME/logs/mfs.log-5`. **Note:** If nodes in the cluster run two filesystem instances, Fluentd only reads and parses logs from primary fileserver instance. Therefore, logs from the secondary fileserver instance will not be indexed by Elasticsearch.
mfs	Multi-line	MapR filesystem logs from `$MAPR_HOME/logs/mfs.log-3`. **Note:** If nodes in the cluster run two filesystem instances, Fluentd only reads and parses logs from primary fileserver instance. Therefore, logs from the secondary fileserver instance will not be indexed by Elasticsearch.
nfsserver	Multi-line and Multi-pattern	NFS server log from `$MAPR_HOME/logs/nfsserver.log`
nodemanager	Multi-line	Node Manager logs from `$MAPR_HOME/hadoop/hadoop-*/logs/yarn-*-nodemanager-*.log`.
resourcemanager	Multi-line	ResourceManager logs from `$MAPR_HOME/hadoop/hadoop-*/logs/yarn-*-resourcemanager-*.log`
warden	Multi-line and Multipattern	Warden logs from `$MAPR_HOME/logs/warden.log`.
zookeeper	Multi-line	Zookeeper logs from `$MAPR_HOME/zookeeper/zookeeper-*/logs/zookeeper.log`

MapR Ecosystem Logs

The `fluentd` component reads and parses the following MapR ecosystem component logs on each node in the cluster.

Service Name	Parsing Method	Description
drill	Multi-line	Drill logs from `$MARP_HOME/drill-*/logs/drillbit.log`.

last-updated: Apr 11, 2022

Service Name	Parsing Method	Description
drillbitsSqlline	Multi-line	Drill SQL query logs from `$MAPR_HOME/drill/drill-*/logs/sqlline.log`.
hbaserest	Multi-line and Multipattern	HBase REST Server logs from `$MAPR_HOME/hbase/hbase-*/logs/hbase-*-rest-*.log`.
hbasethriftserver	Multi-line	Hbase Thrift Server logs from `$MAPR_HOME/hbase/hbase-*/logs/hbase-*-thrift-*.log`.
hive	Multi-line	HiveServer logs from `$MAPR_HOME/hive/hive-*/logs/root/hive.log`.
httpfs	Multi-line	HttpFS logs from `$MAPR_HOME/httpfs/httpfs-*/logs/httpfs.log`.
hue	Multi-line	Hue logs from `$MAPR_HOME/hue/hue-*/logs/hue-mapr-runcpserver-*.out`.
oozie	Multi-line	Oozie logs from `$MAPR_HOME/oozie/oozie-*/logs/oozie.log` .
oozieOps	Multi-line	Oozie operation logs from `$MAPR_HOME/oozie/oozie-*/logs/oozie-ops.log`.
oozieCatalina	Multi-line and Multipattern	Oozie Catalina logs from `$MAPR_HOME/oozie/oozie-*/logs/catalina.out`.
sparkhistory	Multi-line	Spark HistoryServer logs from `$MAPR_HOME/spark/spark-*/logs/spark-mapr-org.apache.spark.deploy.history.HistoryServer-1-*.out`.

System Logs

The `fluentd` component does not collect the following system logs by default because they require the configuration of additional permissions for the *$MAPR_USER*.

Service name	Parsing Method	Description
kernlog	Multi-line	Kernel logs from `/var/log/kern.log`.
syslog	Multi-line	System logs from `/var/log/syslog` and `/var/log/messages`.
mysql_errors	Multi-line	MySQL errors from `/var/log/mysql/error.log`.

last-updated: Apr 11, 2022

Note: To enable `fluentd` to read and parse these logs, see Configure Logs to Index on page 1386 and also perform the following:

- On Ubuntu and RHEL/CentOS, add *$MAPR_USER* to the `admin` group.
- On RHEL/CentOS, change the ownership of the log file so that it is owned by both the `root` user and the `admin` group.

MapR Monitoring Logs
The `fluentd` component reads and parses the following MapR Monitoring component logs on each node in the cluster.

Service Name	Parsing Method	Description
collectd	Multi-line	The collectd component logs from `$MAPR_HOME/collectd/collectd-*/var/log/collectd/collectd_daemon.log`
fluentd	Multi-line	The fluentd component logs from `$MAPR_HOME/fluentd/fluentd-*/var/log/fluentd/fluentd.log`,
grafana	Multi-line	Grafana logs from `$MAPR_HOME/grafana/grafana-*/var/log/grafana/grafana.log`.
kibana	Multi-line	Kibana logs from `$MAPR_HOME/kibana/kibana-*/var/log/kibana/kibana.log`.

Log Aggregation and Storage
`Fluentd` uses a round-robin approach when writing logs to Elasticsearch nodes. If an Elasticsearch node in unavailable, `Fluentd` can fail over log storage to another Elasticsearch node.

Each `Fluentd` service connects to each Elasticsearch node that you configure to aggregate and store logs. The Elasticsearch nodes are set when you configure MapR Monitoring with the MapR Installer or when you run configure.sh with the `-ES` parameter.

The Elasticsearch index directory is shared among all the Elasticsearch nodes in the cluster. When you use the MapR Installer to install Elasticsearch, each Elasticsearch node writes index data to `/opt/mapr/es_db`, unless you specified a different location during the installation. When you manually install Elasticsearch, each Elasticsearch node writes index data to `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/`, unless you specified a different location using the `configure.sh -ESDB` option. For a cluster with one Elasticsearch node, the index directory is allocated 5 shards. For clusters with 2 or more Elasticsearch nodes, the index directory is allocated a number of shards equal to 3 times the number of Elasticsearch nodes in the cluster.

`Fluentd` does not require additional configuration to enable automatic failover to an available Elasticsearch node. However, it is important that at least three Elasticsearch nodes are configured to aggregate and store logs so that failure of one node does not prevent logs from being used for monitoring purposes. Based on your environment, more Elasticsearch nodes may be required. Service Layout Guidelines for Large Clusters on page 115.

For more information about Elasticsearch, see the Elastic website.

Configure Log Retention
By default, Elasticsearch indexes 2 days of logs. Based on your requirements, you can configure a different retention period for Elasticsearch.

The following cron job runs each day to purge logs based on the retention period.

```
$min $hour * * * $ES_HOME/bin/curator --config $ES_HOME/etc/elasticsearch/
curator.yml \
 $ES_HOME/etc/elasticsearch/curator_actions/delete_indices.yml >>
$ES_HOME/var/log/elasticsearch/purgeData.log 2>&1 "
```

Log Retention for Elasticsearch

Complete the following steps to edit the log retention period for Elasticsearch:

1. Open the `/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator_actions/delete_indices.yml` file.
2. Update the `unit` and `unit_count` to the new retention period.

unit	The unit of measure for the retention period. Valid parameter values: `days` and `weeks`.
unit_count	The number of days or weeks.

For example, this version of the *delete_indices.yml* file retains logs for 2 days.

```
actions:
  1:
    action: delete_indices
    description: >-
      Delete indices older than 2 days (based on index name), for
mapr_monitoring-
      prefixed indices. Ignore the error if the filter does not result
in an
      actionable list of indices (ignore_empty_list) and exit cleanly.
    options:
      ignore_empty_list: True
      timeout_override:
      continue_if_exception: False
      disable_action: False
    filters:
    - filtertype: pattern
      kind: prefix
      value: mapr_monitoring-
      exclude:
    - filtertype: age
      source: name
      direction: older
      timestring: '%Y.%m.%d'
      unit: days
      unit_count: 2
      exclude:
```

Log Retention for Kibana

Each time you start Kibana, it logs data to its log file. You cannot delete the log file while Kibana is running.

To purge the log files:

1. Restart Kibana so that a new log file is created.

```
maprcli node services -name kibana -nodes <kibana hostname/
IPaddress> -action restart
```

2. Delete all the old log files (`kibana.*.<#>`) from the following location: `/opt/mapr/kibana/kibana-<version>/var/log/kibana/`.

Configure Purge Duration
Based on your requirements, you can configure a purge duration for Elasticsearch.

To update the purge duration on node with installed Elasticsearch 6.5.3, run the following command:

```
/opt/mapr/elasticsearch/elasticsearch-<Version>/usr/share/elasticsearch/bin/es_cluster_mgmt.sh --purgeAge <newValue>
```

This command will automatically update the `delete_indices.yml` file. This change updates only the `unit_count` value to `newValue`, without changing the unit value.

Configure Log Rotation Policies for MapR Monitoring Services
New log files are created based on the log rotation policy. By default, each MapR Monitoring service has a log rotation policy. In most cases, you can change the policy based on your requirements.

OpenTSDB Log Rotation Policy

By default, OpenTSDB creates a new log file when each log file reaches the maximum file size of 128MB. After 4 log files are generated, it deletes the oldest log file.

To change the log rotation policy, edit the following file: `/opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/logback.xml`. For more information, see the OpenTSDB Logging documentation.

Fluentd and CollectD Log Rotation Policy

By default, `Fluentd` and `Collectd` create a new log file each day and they both retain 30 log files. Log rotation for `Fluentd` and `Collectd` logs is managed by `logrotate`.

To change the log rotation policies, edit the following files: `/etc/logrotate.d/fluentd` and `etc/logrotate.d/collectd`. For details on how to update the log rotation policy, see the logrotate documentation.

Elasticsearch Log Rotation Policy

By default, Elasticsearch creates a new log file each day and it retains 7 days of logs.

To change the log rotation policy, edit the following file `/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/logging.yml`. For details on how to update logging.yml, see the Elasticsearch documentation.

Grafana Log Rotation Policy

By default, Grafana creates a new log file whenever the current log file exceeds the 256MB. It retains log files that were generated in the last 7 days.

To change the log rotation policy, edit the `[log]` section of the following file: `/opt/mapr/grafana/grafana-<version>/etc/grafana/grafana.ini`. For details on how to update the grafana.ini, see the Grafana documentation.

Kibana Log Rotation Policy

Each time you start Kibana, it logs data to its log file and it does not automatically delete old log files. A new log file is created when you restart Kibana. To purge the log files, see Configure Log Retention on page 1391.

Configure the Elasticsearch Service Heap Size

The Elasticsearch service is memory-intensive. By default, the Elasticsearch service is configured to use a minimum and maximum heap size of 2 GB. You can override these default values by making changes in the Elasticsearch Warden configuration file and the `jvm.options` file. Restart Elasticsearch after you modify the settings.

Configuring Memory in the Warden Configuration File

You can enable memory settings in the ElasticSearch Warden configuration file, located in the `/opt/mapr/conf/conf.d/warden.elasticsearch.conf` directory. Modify the `service.heapsize.min` and `service.heapsize.max` values set in `warden.elasticsearch.conf`, as shown:

```
service.heapsize.min=2000
service.heapsize.max=2000
```

The `service.heapsize.min` and `service.heapsize.max` values are set in megabytes as an integer. For older EEPs, you must make sure that the `-Xms` and `-Xmx` values in the jvm.options file match the settings in the Warden configuration file.

About the jvm.options File

The `jvm.options` file centralizes arguments to the Java Virtual Machine to simplify the management of the JVM options. You can no longer set the JVM options through the ES_MIN_MEM, ES_MAX_MEM, ES_HEAP_SIZE, ES_HEAP_NEWSIZE, ES_DIRECT_SIZE, ES_USE_IPV4,ES_GC_OPTS, ES_GC_LOG_FILE, and JAVA_OPTS environment variables.

If you installed the Elasticsearch service from the TAR or ZIP distributions, you can locate the `jvm.options` file in `config/jvm.options`. If you installed ElasticSearch from the Debian or RPM packages, you can locate the `jvm.options` file in the `$ES_HOME/etc/elasticsearch/jvm.options` directory, for example:

```
/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch
```

To specify an alternative location, set the ES_JVM_OPTIONS environment variable to the file path.

Configuring Memory in the jvm.options File

Note: If you configured Elasticsearch memory in the Warden configuration file, configuring memory in the `jvm.options` file is not required for EEPs 6.2.0, 6.1.1, 6.0.2 and later, which contain logic to edit the `jvm.options` file automatically. For other EEPs, you must ensure that memory-configuration changes are made *both* in the Warden configuration file and in the`jvm.options` file.

The `-Xms` and `-Xmx` values in the `jvm.options` file set the Elasticsearch heap size, as shown:

```
-Xms2g
-Xmx2g
```

The `-Xms` parameter sets the minimum heap size in gigabytes. The `-Xmx` parameter sets the maximum heap size in gigabytes. Elasticsearch recommends that both parameters have the same value.

Restarting the Elasticsearch Service

After you modify memory settings, issue the following command to restart the Elasticsearch service:

```
maprcli node services -name elasticsearch -nodes <space separated list of
Elasticsearch nodes> -action restart
```

Tip:

- On a production cluster, you can lock Elasticsearch memory to improve performance. To lock Elasticsearch memory, set the `bootstrap.mlockall: true` option in `$ES_HOME/etc/elasticsearch/elasticsearch.yml`.
- If Elasticsearch uses more than 75% of the configured heap size, you may want to increase the maximum heapsize value.

  For more information, see the Elasticsearch documentation.

Configure Fluentd Services to Write to Elasticsearch Nodes on the Same Rack
On clusters with high-density racks, ensure you have at least one Elasticsearch server per rack and configure each Fluentd service to write to Elasticsearch nodes that run on the same rack as the Fluentd service. This configuration minimizes the impact of log aggregation on other processes that run on the cluster and in particular, minimizes the amount of backbone bandwidth used by the log aggregation.

Complete the following steps on each node that runs the Fluentd service.

1. Open the `/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/es_config.conf` file.
2. Edit the `hosts` property to only include Elasticsearch nodes that are on the same rack as the Fluentd service.
   Example:

   ```
   hosts qa-node90:9200,qa-node91.qa.lab:9200,qa-node92.qa.lab:9200
   ```

3. Restart Fluentd.

   ```
   maprcli node services -name fluentd -nodes <space separated list of
   fluentd nodes> -action restart
   ```

Warning: Changes to the es_config.conf files are overridden by configure.sh. Therefore, you will need reconfigure the hosts property in the es_config.conf file after configure.sh is run on Fluentd nodes.

60-mapr_elasticsearch.conf

The `/etc/sysctl.d/60-mapr_elasticsearch.conf` file is created when you install Elasticsearch. This file specifies a Docker host setting for Elasticsearch.

The `vm.max_map_count` setting is a tuning parameter that limits the number of discrete mapped memory areas for the Linux VM:

Example

```
vm.max_map_count=262144
```

For more information about the `max_map_count` parameter, see the Linux Kernel documentation.

60-mapr_fluentd.conf

The `/etc/sysctl.d/60-mapr_fluentd.conf` file is created when you install Fluentd. This file contains Linux kernel tuning parameters.

The `tcp_tw_reuse` parameter allows you to reuse sockets in the TIME_WAIT state for new connections.

The `ip_local_port_range` parameter defines the local port range that is used by TCP and UDP to choose the local port.

last-updated: Apr 11, 2022

Example

```
net.ipv4.tcp_tw_reuse = 1
net.ipv4.ip_local_port_range = 10240    65535
```

Log Visualization
Use dashboards to visualize the logs across multiple nodes and clusters.

For information about creating and using dashboards, see the Kibana documentation.

Access the Kibana UI
You can launch the Kibana UI from the Control System or directly from a web browser.

1. Use one of the following method to launch the Kibana UI:
   - In the Control System, go to **Services** and click **Kibana** to launch the Kibana UI in another tab.
   - From a web browser, launch the following URL: `http://<IPaddressOfKibanaNode>:5601`
2. Log on as needed. See Logging on to Kibana on page 1396.

Logging on to Kibana
This page describes the credentials needed to log on to Kibana for secure and nonsecure clusters for MapR 6.0 and later.

Elasticsearch has its own user database, which also serves Kibana. EEP 5.0.0 and MapR Installer 1.9.0 implemented some changes in security that affect the user IDs and passwords you need to log on to Kibana.

EEP 4.x.x

To log on, specify the user and password as follows:

	Secure Cluster	Nonsecure Cluster
User	Type the Kibana `admin` user.	No logon required.
Password	Type `admin`.	No logon required.

EEP 5.0.0 and Later

To log on, specify the user and password as follows:

	Secure Cluster	Nonsecure Cluster
User	Type the Kibana `admin` user ID.	No logon required.
Password	Type the ElasticSearch/Kibana password that you specified during cluster installation.	No logon required.

For More Information

To change the Elasticsearch/Kibana password, see Changing the Password for Elasticsearch and Kibana on page 1397.

For more information about the Grafana versions supported by each EEP, see EEP Components and OS Support on page 5536.

For information about the EEPs supported by different MapR Core versions, see EEP Support and Lifecycle Status on page 5531.

Changing the Password for Elasticsearch and Kibana
Describes how to change the password for Elasticsearch / Kibana.

Kibana gets its password from Elasticseach. To change the password for the `admin` user for Elasticsearch and Kibana:

1. On one of the Elasticsearch nodes, run these commands:

```
ESHOME=/opt/mapr/elasticsearch/elasticsearch-<es_version>
cd $ESHOME/usr/share/elasticsearch/usr/share/elasticsearch/plugins/
search-guard-6
bash tools/hash.sh -p "NewPasswordYouWantForAdmin"
  $2a$12$6ASxMQEBKYPyGUc10RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq
```

   The es_version depends on the EEP that you have installed. To determine the `es_version`, use the following table, or refer to Component Versions for Released EEPs on page 5586:

Core Version	EEP Version	<es_version>
6.2.0	8.0.0	6.8.8
6.2.0	7.1.1	6.8.8
6.2.0	7.1.0	6.8.8
6.2.0	7.0.1	6.8.8
6.2.0	7.0.0	6.8.8
6.1.1	6.3.5	6.8.8
6.1.1 or 6.1.0	6.3.4	6.8.8
6.1.1 or 6.1.0	6.3.3	6.8.8
6.1.0	6.3.2	6.8.8
6.1.0	6.3.1	6.8.8
6.1.0	6.3.0	6.5.3
6.1.0	6.2.0	6.5.3
6.1.0	6.1.1	6.5.3
6.1.0	6.1.0	6.5.3
6.1.0	6.0.2	6.2.3
6.1.0	6.0.1	6.2.3
6.1.0	6.0.0	6.2.3

2. Using the hash generated in step 1, edit the `sgconfig/sg_internal_users.yml` file. Change this:

```
admin:
hash: $2a$12$VcCDgh2NDk07JGN0rjGbM.Ad41qVR/YFJcgHp0UGns5JDymv..TOG
#password is: <PasswordSpecifiedAtClusterInstallation>
```

   to this:

```
admin:
hash: $2a$12$6ASxMQEBKYPyGUc10RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq
#password is: <NewPasswordYouWantForAdmin>
#hash: $2a$12$VcCDgh2NDk07JGN0rjGbM.Ad41qVR/YFJcgHp0UGns5JDymv..TOG
#password is: <PasswordSpecifiedAtClusterInstallation>
```

3. Save the file.

4. Load the new users database into Elasticsearch:

```
KSPW=$(cat $ESHOME/etc/elasticsearch/.keystore_password)
./tools/sgadmin.sh -h <esHostname> -f sgconfig/sg_internal_users.yml -t
internalusers -ks
../../../../../etc/elasticsearch/keystores/
admin-usr-keystore.jks -kspass $KSPW -ts
../../../../../etc/elasticsearch/keystores/truststore.jks -tspass
$KSPW -cn MaprMonitoring
```

Related concepts

Checking the EEP Version on page 5413
Some MapR Installer operations require you to know the version of the currently installed MapR Ecosystem Pack (EEP). You can check the EEP version easily from within the MapR Installer user interface or derive the EEP version from your repository information.

Related tasks

Checking the MapR Installer Version on page 5412
Some MapR Installer features require you to use the latest version of the Installer. You can check the MapR Installer version easily from within the user interface.

Display Logs Chronologically

To display logs chronologically in Kibana, sort the log events by the event_time column.

@timestamp indicates the time with second precision and is not as precise as event_time which indicates the time with millisecond precision. Therefore, if you want to display logs chronologically in Kibana, sort the log events by the event_time column, not the @timestamp column.

Update the Elasticsearch URL for Kibana

Kibana connects to a single Elasticsearch node to read logs. In the event that Kibana is unable to read logs due to the failure of an Elasticsearch node, configure Kibana to connect to an available Elasticsearch node.

Note: The Elasticsearch node that Kibana connects to by default is determined by the first Elasticsearch node that was specified when the cluster was configured to use MapR Monitoring

1. Open `/opt/mapr/kibana/kibana-<version>/config/kibana.yml`.

2. Update the `elasticsearch.url` parameter to point to an available Elasticsearch node.

   Tip: If you want to configure Kibana to work even if the Elasticsearch node is unavailable, see the Kibana documentation for the steps to configure Kibana to load balance across multiple Elasticsearch nodes.

MapR Monitoring Tips and Troubleshooting

Lists the nuances of monitoring clusters.

Monitoring a Secure Cluster

After regenerating the MapR user ticket, service failures occur for `collectd` and OpenTSDB

If you delete or regenerate the MapR user ticket, the running `collectd` and OpenTSDB services will fail. After updating the MapR user ticket, restart `collectd` and OpenTSDB services.

Monitoring Logs

I notice a sudden increase in `fluentd` logs. What can I do?

A sudden increase in the log file for `fluentd` could mean that a feedback loop is occurring where `fluentd` logs an error in the log file for a `fluentd` issue and that log entry causes yet another error when `fluentd` tries to parse it. In this case, consider disabling the index of `fluentd` logs. See Configure Logs to Index on page 1386.

I see "400 - Rejected by Elasticsearch" messages in the fluentd logs. What can I do?

Messages such as the following can accumulate in the `fluentd` log when a process does not produce logs with valid UTF-8 output:

```
2019-04-25 17:00:11 -0700 [warn]: #0
dump an error event:
error_class=Fluent::Plugin::Elasticsea
rch
ErrorHandler::ElasticsearchError
error="400 - Rejected by
Elasticsearch" location=nil
after setting this option in
es_config.conf
```

In a message such as the following, you might see invalid characters represented as a diamond with a question mark:  . The `"service_name":"collectd"` part of the message indicates that `collectd` is generating the invalid UTF-8 output:

```
[2019-04-30T19:06:29,495][DEBUG]
[o.e.a.b.TransportShardBulkAction]
[mfs73] [mapr_monitoring-2019.05.01]
[4] failed
to execute bulk item (index) index
{[mapr_monitoring-2019.05.01]
[mapr_monitoringv1]
[taQkcWoBCeW3tMAsn1cW],
source[{"my_event_time":"2019-04-30

ctd"}]}
org.elasticsearch.index.mapper.MapperP
arsingException: failed to parse
field [message] of type [text]
Caused by:
com.fasterxml.jackson.core.JsonParseEx
ception: Invalid UTF-8 middle byte
0x5c
```

One workaround is to comment out the log producing the invalid character. You can do this in the `fluentd.conf` file. For more information, see Configure Logs to Index on page 1386.

Another workaround is to fix the application that produces the error message. If the log file is produced by an application that you control, change the output of the log producing the invalid character.

Monitoring Metrics

Where should I store the Elasticsearch index?

Elasticsearch requires a lot of disk space. Also, when you upgrade Elasticsearch, the default index directory is removed along with the package update. Therefore, it is recommended to configure a separate filesystem for the index data. It is not recommended to store index data under the `/` or the `/var` filesystem.

Note: If you store the Elasticsearch index on a filesystem that is locally hosted, you will be able to access logs in the event that the MapR cluster is not available.

For more information about the Elasticsearch index and the default index directory, see Log Aggregation and Storage on page 1391.

I see a "Bad Request" error message for my MapR Database metrics? What can I do?

If you have more than 1000 active tables in MapR Database and the MapR monitoring request size to OpenTSDB is more than 4 KB, you may see the following error message:

```
"Sorry but your request was rejected
as being invalid.
The reason provided was: Chunked
request not supported."
```

You can increase the maximum request size of OpenTSDB to up to 64 KB by setting the following parameters in the `opentsdb.conf` file:

```
tsd.http.request.enable_chunked=true
tsd.http.request.max_chunk=65536
```

For more information, see the OpenTSDB configuration guide.

Installation and Configuration Errors

See Troubleshoot MapR Monitoring Installation Errors on page 172

Reconfiguring MapR Monitoring

Changes to an existing cluster, such as the addition of services, may require additional steps to enable the collection of metrics and logs.

Configure Monitoring for Additional Services

When you add services to a cluster where MapR Monitoring is already configured, you must restart collectd and Fluentd services to enable the collection of logs and metrics for the newly added services.

1. Restart the collectd service on each node that runs the service that was added to the cluster.

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

2. Restart the Fluentd service on each node that runs the service that was added to the cluster.

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

Update the Monitoring Storage Nodes

You must reconfigure MapR Monitoring when you add additional OpenTSDB or Elasticsearch nodes, or when you change the OpenTSDB or Elasticsearch node locations.

1. Run configure.sh on each node in the MapR cluster with the `-R`, `-ES`, and `-OT` parameters. Optionally, you can include the `-ESDB` parameter.

```
/opt/mapr/server/configure.sh -R -ES <comma-separate list of
Elasticsearch nodes> \
 -OT <comma-separate list of OpenTSDB nodes> [-ESDB <filepath>]
```

   For the entire list of available `configure.sh` parameters, see configure.sh

   If you encounter any errors after running `configure.sh`, see Troubleshoot MapR Monitoring Installation Errors on page 172

2. If you updated the list of Elasticsearch nodes, restart the all the Fluentd, Elasticsearch, and Kibana services.

```
maprcli node services -name fluentd -nodes <space separated list of
Fluentd nodes> -action restart
```

```
maprcli node services -name elasticsearch -nodes <space separated list
of Elasticsearch nodes> -action restart
```

```
maprcli node services -name kibana -nodes <space separated list of
Kibana nodes> -action restart
```

last-updated: Apr 11, 2022

3. If you updated the list of OpenTSDB nodes, restart the collectd, OpenTSDB, and Grafana services.

```
maprcli node services -name opentsdb -nodes <space separated list of
OpenTSDB nodes> -action restart
```

```
maprcli node services -name collectd -nodes <space separated list of
collectd nodes> -action restart
```

```
maprcli node services -name grafana -nodes <space separated list of
Grafana nodes> -action restart
```

Configuring Security

Describes how to configure security and manage secure clusters.

Configuring Data-Fabric Security

Provides usage information for frequently used security functionality, including Access Control Lists (ACLs), Access Control Expressions (ACEs), file permissions, and subnet whitelisting.

Note: Release 6.1 makes it easier to secure new data-fabric installations. See Using the Enable MapR Secure Cluster Option on page 5427 in the MapR Installer on page 5395.

Wired encryption and authentication (including impersonation) for the data-fabric platform and for all supported ecosystem products are enabled on all new installations through MapR Installer on page 5395 and through manual installation by running the `configure.sh on page 2053` command with the `-secure` option.

You can enable security features at any time, but additional configuration is required for the individual components to work with security enabled. This section discusses initial configuration of a secure cluster as well as other forms of security.

The following access control elements are available irrespective of whether you have enabled security features for your cluster. Additionally, once security features are enabled, these elements benefit from encrypted traffic within the cluster and strong authentication to the cluster.

- Access Control Lists (ACLs) for the cluster, the volumes in the cluster, and the MapReduce application queue
- *ACE*s control user permissions for directories, files, and MapR Database tables that are stored natively
- File permissions for objects in the MapR File System layer
- Subnet whitelisting restricts access to the cluster's FileServer service

On clusters with security features enabled, ecosystem components may require additional configuration. For example, Hive functionality has different security requirements depending on the interaction between the HiveServer2 component, the Hive command-line interface, and the Hive metastore.

See the MapR Security Support Matrix on page 5602 for more information about supported security options for Ecosystem components. See the specific Ecosystem component in Ecosystem Components on page 3174 for information on security configuration.

See Security Vulnerabilities on page 6569 for a list of known vulnerabilities.

Verifying if Files Needed for Security are Present

When you run `configure.sh` with the `-secure` option, the following files are automatically created in the `/opt/mapr/conf` directory. To ensure that security is properly configured, navigate to the `/opt/mapr/conf` directory and verify that the files are present.

Master value controlling the cluster secure or non-secure state	*File or command:* `/opt/mapr/conf/mapr-clusters.conf` `maprcli dashboard info -cluster <clusterName> -json | grep secure` *Default secure setting:* `secure=true` *Alternate possible values/notes:* `secure=false` disables security on restarting the cluster.
Data-fabric service account	*File or command:* `sudo passwd -S mapr` *Default secure setting:* Site Specific Password *Alternate possible values/notes:* No password. Use `su` to access.
CLDB key file	*File or command:* `/opt/mapr/conf/cldb.key` *Default secure setting:* Created at install, do not change *Alternate possible values/notes:* Must exist on all CLDB nodes and be identical.
Server ticket	*File or command:* `/opt/mapr/conf/maprserverticket` *Default secure setting:* Created at install, do not change *Alternate possible values/notes:* Must exist on all cluster nodes and be identical.
User ticket	*File or command:* `/opt/mapr/conf/maprusertickets` *Default secure setting:* Created at install, do not change *Alternate possible values/notes:* Must exist on all cluster nodes and be identical. This ticket is owned and used by the service account as needed.
SSL keys	*File or command:* `/opt/mapr/conf/ssl_truststore` `/opt/mapr/conf/ssl_keystore` *Default secure setting:* Created at install, and should rarely change. These keys are used by web and REST HTTPS interfaces. *Alternate possible values/notes:* Add site specific certificates with the keytool utility.
Java (JAAS) authentication service settings	*File or command:* `/opt/mapr/conf/mapr.login.conf` *Default secure setting:* Created at install, do not change *Alternate possible values/notes:* Must exist on all cluster nodes and be identical.

last-updated: Apr 11, 2022

Roles for use with ACEs	*File or command:* `/opt/mapr/conf/m7_permissions_roles_refimpl.conf` *Default secure setting:* Specific roles defined using automation *Alternate possible values/notes:* Use should be deprecated. Linux groups are a much better method, centralized and consistent with enterprise standards.
Default security settings for some data-fabric services	*File or command:* `/opt/mapr/conf/env.sh` *Default secure setting:* Created at install, do not change *Alternate possible values/notes:* Must exist on all cluster nodes and be identical. You can view the list of settings by using this command: `grep -i secure env.sh`
ZooKeeper security setting	*File or command:* `/opt/mapr/zookeeper/zookeeper-$zkver/conf/zoo.cfg` *Default secure setting:* `authMech=MAPR-SECURITYauthProvider.1=org.apache.zookeeper.server.auth.SASLAuthenticationProvide` *Alternate possible values/notes:* `authMech=SIMPLE-SECURITY`
JMX remote access (debug and metrics monitoring)	*File or command:* `/opt/mapr/conf/jmxremote.{access,password}` *Default secure setting:* `read-only` and with the password limited to the data-fabric service account. *Alternate possible values/notes:* `read-write` but is not recommended

Determining if Wire-Level Security is Enabled Using the CLI

When you run `configure.sh` with the `-secure` option, wire-level security is automatically enabled at the cluster level. You can, optionally, disable wire-level security at the individual volume-level. To determine if wire-level security is enabled for a volume, run the following command:

```
/opt/mapr/bin/maprcli volume list -json |grep wire
```

This command returns the value of `wireSecurity` as `1` if wire-level security is enabled for the volume; `0` otherwise.

Enabling Cluster Wide Data Access Auditing

To enable auditing data access operations at a cluster level, run:

```
/opt/mapr/bin/maprcli audit data -enabled
```

Determining if per Volume Data Access Auditing is Enabled

To determine if auditing data access operations is enabled for a volume, run:

```
/opt/mapr/bin/maprcli volume info -name <volume_name> -json | grep -i
'audited\|coalesce'
```

This command returns the value of `audited` as `1` if data access auditing is enabled for the volume; `0` otherwise.

Getting Started with MapR Security
Describes quick implementation of security.

MapR 6.1 introduced enhanced security settings that simplify the process of creating secure clusters. For a brief introduction, see Security. To learn how to secure a cluster, see this course.

To set up a secure cluster:

1. Enable cluster security, authentication, and wire-level encryption by running configure.sh if you performed a manual installation.

   See Enabling Security on page 1405 for more information.

   

   Note: If you selected the Using the Enable MapR Secure Cluster Option on page 5427 when installing with the MapR Installer on page 5395, you can proceed to the next step.

2. Generate MapR user tickets to authenticate with your username and password.

   See Generating a MapR User Ticket on page 1426 for more information.

3. Configure each Ecosystem component, where necessary, for security.

   See Security and Ecosystem Components on page 703 for more information.

4. (Optional) Enable encryption of data at rest at the cluster level and selectively for volumes as well.

   See Enabling Encryption of Data at Rest on page 1413 for more information.

5. (Optional) Turn on auditing for the cluster and for directories that contain sensitive data.

   See Enabling and Disabling Auditing of Cluster Administration on page 758 and Enabling and Disabling Auditing of Data Access Operations on page 758 for more information.

6. (Optional) Enable authorization using ACEs for files, tables, streams, or volumes and ACLs for administrative activities that can be performed on the cluster.

   See Managing Access Control Expressions on page 1448 and Managing Access Control Lists on page 1445 for more information.

Tip: After you enable security, review the System Behavior Changes After Enabling Security on page 1410.

Enabling Security
Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

The following steps enable:

- Security for the cluster nodes
- Wire-level encryption for the platform and ecosystem components
- Authentication for all network-based connections
- (Optional) Data-at-rest encryption on the cluster

When you set up a cluster, you must run the `configure.sh on page 2053` script on each node that you want to add to the cluster. After you enable security, review the System Behavior Changes After Enabling Security on page 1410.

last-updated: Apr 11, 2022

Basic Procedure

To enable security for the cluster, follow these steps in order:

1. If the cluster is running, shut it down.
2. Delete the `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files on a machine where wire-level security is not enabled, as the `configure.sh` script fails if you already have these files in the directory.

   Note: The `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files are generated during installation of the Web server even if you did not enable security.

   For example, to delete the files, run the following commands:

   ```
   cd /opt/mapr/conf
   /bin/rm -f ssl_keystore ssl_keystore.p12 ssl_keystore.pem ssl_truststore
   ssl_truststore.p12 ssl_truststore.pem
   ```

   If you are re-running the script due to an invocation error from a previous run, the `cldb.key` and `maprserverticket` files may have already been created. Delete these files, as the script fails if you already have these files in the directory. For example, run the following command to delete these files:

   ```
   cd /opt/mapr/conf
   /bin/rm -f cldb.key maprserverticket ssl_keystore ssl_keystore.p12
   ssl_keystore.pem ssl_truststore ssl_truststore.p12 ssl_truststore.pem
   ```

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

   ```
   /opt/mapr/server/configure.sh -secure -dare -genkeys -Z
   <Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
   ```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify a fully-qualified domain name (FQDN) as described in Connectivity on page 133. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

   Important: You must run `configure.sh -dare -genkeys` only *once* on one CLDB node, since the resulting files must be copied to other nodes.

   This command generates the following files in the `/opt/mapr/conf` directory:

   - `cldb.key`
   - `dare.master.key`
   - `maprserverticket`
   - `ssl_keystore`
   - `ssl_keystore.p12`
   - `ssl_keystore.pem`
   - `ssl_truststore`

last-updated: Apr 11, 2022

- `ssl_truststore.p12`
- `ssl_truststore.pem`

Note: The `dare.master.key` file is generated only if data at rest encryption is enabled on the cluster.

Tip: A comprehensive listing of the Trust and Key Store files is at: Understanding the Key Store and Trust Store Files on page 1408.

4. Copy the `cldb.key` to any node with the CLDB or Zookeeper service installed, and copy the `dare.master.key` to any node with the CLDB service installed.

   Note: Copy the `dare.master.key` file only if you are enabling data at rest encryption on the cluster.

5. Verify that the files `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` are owned by the user that runs cluster services. This user is `mapr` by default. Also, the `maprserverticket`, `ssl_keystore`, `ssl_keystore.p12`, and `ssl_keystore.pem` files must have their UNIX permission-mode bits set to `400`, and the `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files must be readable to all users.

6. Copy the `maprserverticket`, `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files to the `/opt/mapr/conf` directory of *every* node in the cluster.

7. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

   ```
   /opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
   <CLDB_node_list> -N <cluster_name>
   ```

   The `-secure` option indicates that security must be enabled on the node where the command is run and the `-dare` option indicates that data at rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

   Important: You must also do this on any nodes that you add to the cluster in the future.

8. Copy the `ssl_truststore`, `ssl_truststore.p12`,and `ssl_truststore.pem` files to any client nodes outside the cluster.

   Important: If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

9. Optionally, enable encrypted quorum ZooKeeper communication. See zoo.cfg on page 2220 for more information.

10. Log in as the `mapr` superuser using the maprlogin command: `maprlogin password` (in this command, `password` is literal text).

11. If clients will connect to multiple secure clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. See Setting Up the Client for more information on MapR clients.

last-updated: Apr 11, 2022

Advanced Procedure

In certain situations, you may opt for variant of the basic procedure. Such situations include, but are not limited to the following:

- You are running the script on a host that is configured without a domain name.
- You have a cluster where all the machines do not have the same domain name.
- You wish to import your own custom certificates instead of the self-signed certificates generated by the `configure.sh` utility.

Running on Hosts with no Configured Domain Name

When used without the `-certdomain` argument, the `configure.sh` script discovers the domain name of the node on which it is being executed using the `hostname -d` command and then creates a 100-year self-signed certificate using the PKCS#1 v1.5 with SHA-512 hash function (SHA512withRSA) with a wildcard certificate with the common name `(CN) *.<domain>`. For example, if `hostname -d` returns the domain name `mycompany.com`, then the CN of the certificate is `*.mycompany.com`. This certificate works for all machines within the `mycompany.com` domain and can therefore be copied to all cluster nodes as specified in Step 5 in the Basic Procedure.

Certificate generation fails if the host that you are running the script from is configured without a domain name. To fix this, modify your machine configuration so that `hostname -d` returns a non-empty string and then run the `configure.sh` script.

Alternatively, re-run the script with the `-certdomain` option as shown in Step 3 of the Basic Procedure:

```
/opt/mapr/server/configure.sh -secure -genkeys -certdomain <domain_name> -Z
<Zookeeper_node_list> -C <CLDB_node_list> [ -N <cluster_name> ]
```

Securing Clusters with Multiple Domain Names

Generally, all machines within a cluster should belong to the same domain. In the unusual case where you have a cluster with different machines belonging to different domains, applications that perform hostname verification can fail if you run the `configure.sh` script (as described in Step 3 of the Basic Procedure on page 1406) to generate a single-domain wildcard certificate. In this case, you must provide your own multi-domain wildcard certificate and import the custom certificate into the keystore as described in Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster.

Using Custom Certificates

To import your own custom certificates into the keystore instead of using the self-signed certificates, see Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster.

zoo.cfg on page 2220
Lists the ZooKeeper configuration file.

Understanding the Key Store and Trust Store Files
Provides a comprehensive listing of the key store and trust store files.

Key Stores and Trust Stores in Release 6.1.0

The following files are generated by running `configure.sh -dare -genkeys` on a CLDB node. Alternatively, you can generate them by running the manageSSLKeys.sh on page 2120 script. The `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files are also generated during installation of the Web server, even if you did not enable security. For more information, see Enabling Security on page 1405.

cldb.key *Location:* `/opt/mapr/conf`

	Description: The CLDB key file. This file must exist on all CLDB nodes and be identical.
dare.master.key	*Location:* `/opt/mapr/conf`
	Description: The key file that enables data-at-rest encryption. The `dare.master.key` file is generated only if data at rest encryption is enabled on the cluster. This file must be copied to all the nodes with the CLDB service installed.
maprserverticket	*Location:* `/opt/mapr/conf`
	Description: The server ticket. This file must exist on all cluster nodes and be identical.
ssl-client.xml	*Location (symlink):* `/opt/mapr/conf`
	Location (file): `${MAPR_HOME}/hadoop/hadoop-<version>/etc/hadoop/ssl-client.xml`
	Description: Contains the SSL configuration for the client in XML format.
ssl_keystore	*Location:* `/opt/mapr/conf`
	Description: This file is needed on all nodes where the webserver is running.
ssl_keystore.p12	*Location:* `/opt/mapr/conf`
	Description: When upgrading from MapR Core 5.2.2 or Core 6.0.x to MapR 6.1 or later, create the `ssl_keystore.p12` and `ssl_truststore.p12` files, and copy them to the `/opt/mapr/conf` directory on all nodes in the cluster.The `.p12` files are required to generate the `.pem` files needed by Grafana and the Data Access Gateway. This step is necessary only for manual upgrades.
ssl_keystore.pem	*Location:* `/opt/mapr/conf`
	Description: When upgrading from MapR Core 5.2.2 or Core 6.0.x to MapR 6.1 or later, create the `ssl_truststore.pem` and `ssl_keystore.pem` files, and copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The Data Access Gateway, Grafana, and Hue components use these files. This step is necessary only for manual upgrades.
ssl-server.xml	*Location (symlink):* `/opt/mapr/conf`
	Location (file): `${MAPR_HOME}/hadoop/hadoop-<version>/etc/hadoop/ssl-server.xml`
	Description: Contains the SSL configuration for the server in XML format.
ssl_truststore	*Location:* `/opt/mapr/conf`
	Description: contains the certificates required by nodes initiating communication over TLS.
ssl_truststore.p12	*Location:* `/opt/mapr/conf`
	Description: When upgrading from MapR Core 5.2.2 or Core 6.0.x to MapR 6.1 or later, create the `ssl_keystore.p12` and `ssl_truststore.p12` files, and copy them to the `/opt/mapr/conf` directory on all nodes in the cluster.The `.p12` files are required to generate the `.pem` files needed by Grafana

last-updated: Apr 11, 2022

	and the Data Access Gateway. This step is necessary only for manual upgrades.
ssl_truststore.pem	*Location:* `/opt/mapr/conf` *Description:* When upgrading from MapR Core 5.2.2 or Core 6.0.x to MapR 6.1 or later, create the `ssl_truststore.pem` and `ssl_keystore.pem` files, and copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The Data Access Gateway, Grafana, and Hue components use these files. This step is necessary only for manual upgrades.

Disabling Security

To disable security features for your cluster:

1. If the cluster is running, shut it down.
2. On all nodes, run the `configure.sh` on page 2053 script with the `-unsecure` option and specify the CLDB and ZooKeeper nodes.

   ```
   configure.sh -unsecure -C <CLDB_Node> -Z <ZK_Node> -N <cluster_name>
   ```

3. Start the cluster.

System Behavior Changes After Enabling Security

After enabling security features for your cluster, the following behaviors change:

- Users must authenticate with the `maprlogin` utility.
- Components that have web UIs, such as the Control System, Hive, and Oozie, require authentication.

  Warning: Note that you must also complete the PAM configuration to set up user authentication for the Control System logins.
- Several components that communicate over HTTP use HTTPS instead.
- Encryption is used for network traffic.
- Access to a cluster using URIs that use the CLDB node's name or IP address, instead of the cluster name, is no longer supported, as in the following examples. The following URIs no longer work after enabling security:

  ```
  http://cldb1.cluster.com:7222/f1
  ```

  ```
  http://10.10.20.10:7221/f1
  ```

  The following URIs work after enabling security:

  ```
  http:///f1 <access f1 in default cluster>
  ```

  ```
  http://my.cluster.com/f1
  ```

Managing Encryption for MapR Core

Provides information that allows you to use encryption across the MapR platform.

This section describes how to enable security for data at rest and on the wire as well as general security components and system changes.

last-updated: Apr 11, 2022

Enabling Wire-level Security

Wire-level security encrypts data transmission between the nodes in your cluster.

You can enable encryption for data on the wire at the volume level only if security is enabled at the cluster level. If necessary, refer to Determining if a Cluster is Secure Using the CLI and REST API on page 1421 to determine if the cluster is secure before enabling wire-level encryption on a volume. If your cluster is enabled for security, wire-level security is enabled by default on all new volumes and no additional steps are required. This section describes how to enable wire-level security on new and existing volumes (if the volume is already not enabled for wire-level security).

Enabling Wire-level Security for a Volume Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page or go to the Edit Volume page.
3. Set the value for the **Data on Wire Encryption** property to **Yes** (to enable).
   See Creating a Volume on page 864 or Modifying a Volume on page 892 for more information.
4. Complete the steps to create or modify the volume.
   See Creating a Volume on page 864 or Modifying a Volume on page 892 for more information.

Enabling Wire-Level Security for a Volume Using the CLI and REST API

CLI

Set the value for the `wiresecurityenabled` parameter to `true` when you:

- Create the volume. For example:

```
maprcli volume create -name
<volName> -path
<volMountPath> -wiresecurityenabled
 true
```

- Modify the volume. For example:

```
maprcli volume modify -name
<volName> -wiresecurityenabled true
```

REST

Send a request of type POST and set the value for the `wiresecurityenabled` parameter to `true` when you:

- Create the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
wiresecurityenabled=true' --user
mapr:mapr
```

- Modify the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=<volName>&wiresecurityenabled=
true' --user mapr:mapr
```

last-updated: Apr 11, 2022

See `volume create` on page 1931 and `volume modify` on page 2005 for more information.

Disabling Wire-level Security

You can disable wire encryption for a volume using the Control System, the CLI, and REST API.

Disabling Wire-level Security for a Volume Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page or go to the Edit Volume page.
3. Set the value for the **Data on Wire Encryption** property to **No** (to disable).
   See Creating a Volume on page 864 or Modifying a Volume on page 892 for more information.
4. Complete the steps to create or modify the volume.
   See Creating a Volume on page 864 or Modifying a Volume on page 892 for more information.

Disabling Wire-Level Security for a Volume Using the CLI and REST API

You can disable encryption of data on wire at the volume level.

CLI

Set the value for the `wiresecurityenabled` parameter to `false` when you:

- Create the volume. For example:

```
maprcli volume create -name
<volName> -path
<volMountPath> -wiresecurityenabled
 false
```

- Modify the volume. For example:

```
maprcli volume modify -name
<volName> -wiresecurityenabled
false
```

REST

Send a request of type POST and set the value for the `wiresecurityenabled` parameter to `false` when you:

- Create the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
wiresecurityenabled=false' --user
mapr:mapr
```

- Modify the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=<volName>&wiresecurityenabled=
false' --user mapr:mapr
```

See `volume create` on page 1931 and `volume modify` on page 2005 for more information.

Enabling Encryption of Data at Rest

You can enable or disable data at rest encryption at the volume level using the Control System, CLI, and REST API if encryption of data at rest is enabled at the cluster level. If you installed using the MapR Installer on page 5395 and selected the **Enable DARE** option, the cluster is automatically enabled for data at rest encryption during installation. If you are upgrading or if you did not enable data at rest encryption at the time of installation, you can enable encryption of data at rest at the cluster level if the cluster is a secure cluster. See Enabling Data at Rest Encryption at the Cluster Level from the Command-Line on page 1413 below for more information.

If encryption is enabled at the cluster level, data at rest encryption is also enabled at the volume level by default through the `mapr.volume.dare.default` configuration parameter. If you do not wish to encrypt data at rest in a volume, you can disable encryption when you create a volume; you cannot modify data at rest encryption setting on a volume after the volume is created. See Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System on page 1414 or Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API on page 1415 below for more information.

Standard volumes inherit the data at rest encryption setting from a volume by default if the `inherit` property is specified. If you create a mirror volume for a (source) volume enabled for data at rest encryption, the mirror volume:

- Inherits the data at rest encryption setting from the source volume if the mirror volume is in the same cluster as the source volume or if the mirror volume is on a remote cluster enabled for encryption of data at rest.
- Does not inherit the data at rest encryption setting from the source volume if the mirror volume is on an unsecure cluster or if the mirror volume is on secure cluster that is not enabled for encryption of data at rest.

Note: If you want to create a mirror volume enabled for data at rest encryption for a source volume not enabled for data at rest encryption, set the value to `true` for `dare` property when creating the mirror volume.

This section describes how to enable data at rest encryption at the cluster and volume levels.

Enabling Data at Rest Encryption at the Cluster Level from the Command-Line

To enable encryption at the cluster level:

1. Run `configure.sh` on page 2053 with the `-dare` and `-genkeys` option on a CLDB node.

   For example:

   ```
   /opt/mapr/server/configure.sh -N
   <cluster-name> -secure -dare -genkeys -C <CLDB-node-list> -Z
   <ZK-node-list>
   ```

   The Master Key is generated and stored in a master key file at `/opt/mapr/conf/dare.master.key`. When CLDB comes up, it sets the value for the following CLDB configuration properties to `1` to allow encryption of data at the volume level:

   - `mfs.enable.dare`
   - `mapr.volume.dare.default`

   You can verify that these parameter values are correctly set by running the `config load` on page 1585 command. For example:

   ```
   # maprcli config load -json
   {
   ```

last-updated: Apr 11, 2022

```
    "timestamp":1524669009979,
    "timeofday":"2018-04-25 08:10:09.979 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "bulk.container.create.support":"1",
            "cldb.accept.unknown.replica.delay.mins":"5",
            ...,
            "mapr.volume.dare.default":"1",
            ...,
            "mfs.enforce.dare":"1",
            ....,
            "pernode.numcntrs.alarm.thr":"50000"
        }
    ]
}
```

Note: An informational alarm, reminding you to create a copy of the master key, is raised on the CLDB node. This is because, the loss of the master key can be catastrophic and irreversible. Loss of this key might result in loss of data. Before clearing the alarm, it is strongly recommended to create a copy of this file in other location(s) for backup purposes.

2. Copy the master key file (generated in step 1 above) to `/opt/mapr/conf` directory on all the other CLDB nodes in the cluster.
3. Run `configure.sh` on page 2053 on all the nodes, except the node on which the command was run to generate the master key (in step 1), with the `-dare` option.

   For example:

```
/opt/mapr/server/configure.sh -N <cluster-name> -secure -dare -C
<CLDB-node-list> -Z <ZK-node-list>
```

If this is a new installation, no additional steps are needed. You have enabled data at rest encryption at the cluster level and, by default, all new volumes are enabled for data at rest encryption. You can, however, still create volumes that are not enabled for encryption of data at rest. See Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System on page 1414 or Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API on page 1415 for more information.

Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System

You can enable data at rest encryption at the volume level only if data at rest encryption is enabled at the cluster level. If necessary, refer to Determining if a Secure Cluster is Enabled for Encryption Using the Control System on page 1421 to determine if the cluster is enabled for encryption of data at rest before enabling data at rest encryption on a volume.

Note: If you do not wish to encrypt data-at-rest in a volume, you can disable encryption when you create a volume; you cannot modify data-at-rest encryption setting on a volume after the volume is created.

To enable or disable data-at-rest encryption for a new volume using the Control System:

1. Log in to the Control System and click **Data** > **Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page.
3. Select volume type, specify values for required and optional properties, and set the value for the **Data at Rest Encryption** property to **Yes** (to enable) or **No** (to disable).

   See Creating a Volume on page 864 for more information.

4. Click **Create Volume** to create a volume enabled for encryption of data at rest.

Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API

You can enable DARE at the volume level only if data at rest encryption is enabled at the cluster level. If necessary, refer to Determining if a Secure Cluster is Enabled for Encryption of Data at Rest Using the CLI and REST API on page 1422 to determine if the cluster is enabled for encryption of data at rest before enabling a volume for data at rest encryption.

Note: If you do not wish to encrypt data-at-rest in a volume, you can disable encryption when you create a volume; you cannot modify data-at-rest encryption setting on a volume after the volume is created.

CLI

Set the value for the `dare` parameter to one of the following when you create the volume:

- `true` to enable data-at-rest encryption.

  Note: This is the default value.

  For example:

```
maprcli volume create -name
<volName> -path <volMountPath>
[-dare true]
```

- `false` to disable data-at-rest encryption.

  For example:

```
maprcli volume
create -name <volName> -path
<volMountPath> -dare false
```

REST

Send a request of type POST and set the value for the `dare` parameter to one of the following when you create the volume:

- `true` to enable data-at-rest encryption.

  Note: This is the default value.

  For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>[
&dare=true]' --user mapr:mapr
```

- `false` to disable data-at-rest encryption.

  For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
dare=false' --user mapr:mapr
```

See `volume create` on page 1931 for more information.

Converting to Cluster Enabled for Data at Rest Encryption

Enable Data-At-Rest Encryption for a Cluster.

last-updated: Apr 11, 2022

MapR's data-at-rest encryption allows you to protect the data in the event a disk is compromised. Using the MapR Installer on page 5395, you can select the **Enable MapR DARE** option during an incremental install after upgrading. You can also convert a cluster not enabled for encryption at rest to a cluster enabled for encryption at rest from the command-line during a Manual Rolling Upgrade Description on page 319 or after an Offline and Manual Upgrade Procedure on page 316.

Note: Encryption of data at rest can only be enabled on a secure cluster.

To convert:

1. Perform the following steps on a CLDB node to generate the master key for encryption of data at rest:
   a) Stop Warden on a CLDB node by running the following command:
   ```
   /bin/systemctl stop mapr-warden
   ```
   b) Install MapR v6.1 packages if this is a rolling upgrade.
   See Upgrading MapR Core Without the MapR Installer on page 309. You can skip this step if you have already installed the MapR v6.1 packages.
   c) Run the `configure.sh on page 2053` command as follows:
   ```
   /opt/mapr/server/configure.sh -genkeys -nocerts -dare  -R
   ```
   When you run the `configure.sh on page 2053` command with the `genkeys` and `dare` options, a MasterKey file is generated and stored in `/opt/mapr/conf/dare.master.key`.
   Important: You must create a copy of this file in other location(s) for backup purposes. Loss of this key will result in loss of cluster.
   d) Start Warden by running the following command:
   ```
   /bin/systemctl start mapr-warden
   ```
2. Copy the data at rest encryption master key file (generated above) to the `/opt/mapr/conf` directory on all the other CLDB nodes on the cluster.
3. Perform the following steps on all the nodes, one node at a time if you are doing a rolling upgrade, in the cluster:
   a) Stop Warden by running the following command:
   ```
   /bin/systemctl stop mapr-warden
   ```
   b) Install MapR v6.1 packages if this is a rolling upgrade.
   See Upgrading MapR Core Without the MapR Installer on page 309. You can skip this step if you have already installed the MapR v6.1 packages.
   c) Run the `configure.sh on page 2053` command as follows:
   ```
   /opt/mapr/server/configure.sh -dare -R
   ```
   d) Start Warden by running the following command:
   ```
   /bin/systemctl start mapr-warden
   ```

4. Enable encryption of data at rest through the `mfs.feature.dare` property, and optionally enable other features, if they are not yet enabled.

   Run `maprcli cluster feature enable -name mfs.feature.dare` to enable encryption of data at rest.

   See Step 4: Enable New Features on page 330 for information on enabling other features.

5. Specify whether (`1`) or not (`0`) to convert all existing volumes not enabled for encryption of data at rest to volumes enabled for encryption of data at rest by setting the value for the `cldb.enforce.old.volumes.dare` property using the `config save` on page 1586 command.

   By default, all existing volumes are converted to volumes enabled for data at rest encryption because the default value for `cldb.enforce.old.volumes.dare` property is `1`. To not convert all existing volumes to volumes enabled for data at rest encryption, run the following command:

   ```
   maprcli config save -values '{"cldb.enforce.old.volumes.dare":"0"}'
   ```

6. Format the storage pools (SPs) on the nodes for data at rest encryption, one node and one SP at a time. That is:

   a) Decommission the node.

      See Decommissioning a Node for Enabling Encryption of Data at Rest on page 1417 for more information.

   b) Format the SPs on the node.

      See Formatting a Storage Pool for Encryption of Data at Rest on page 1418 for more information.

   c) Move the node back to the original topology.

      See Changing the Topology of one or more Nodes on page 805 for more information.

      CAUTION: Wait for few minutes and make sure that the Under Replicated Alarm is cleared for all the Volumes on a SP, before formatting the next SP.

7. Enable encryption of data at rest at the cluster-level by running the following command:

   ```
   maprcli config save -values '{"mfs.enforce.dare":"1"}'
   ```

8. Verify that encryption of data at rest is enabled at the cluster-level by running the following command:

   ```
   maprcli config load -json | grep dare
   ```

   Your output should look similar to the following:

   ```
   "cldb.enforce.old.volumes.dare":"1",
   "mapr.default.dare.alarm.pending":"0",
   "mapr.volume.dare.default":"1",
   "mfs.enforce.dare":"1",
   "mfs.feature.dare":"1",
   ```

Encryption of data at rest is enabled by default for all new volumes on the cluster. You can disable data at rest encryption for volumes that do not require encryption of data at rest. See Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System on page 1414 or Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API on page 1415.

Decommissioning a Node for Enabling Encryption of Data at Rest

Decommission Node to Enable DARE.

last-updated: Apr 11, 2022

Use the following procedure to decommission a node for preparing the node for data at rest encryption.

1. Drain the node of data by moving the node to the `/decommissioned` physical topology.
   See Changing the Topology of one or more Nodes on page 805 for more information. By default, all the data on a node in the `/decommissioned` topology is migrated to volumes and nodes in the `/data` topology.
2. Run the following command to check if volumes are present on the node:
   ```
   maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
   ```
   Note: Run this command for each non-local volume in your cluster to verify that the node being decommissioned is not storing any volume data.
3. Stop Warden on the node as the root user or use `sudo`.
   For example, run the following command to stop Warden using sudo: `sudo /bin/systemctl stop mapr-warden`
4. Run `configure.sh` on page 2053 utility with the `-C` and `-Z` options on all the other nodes if the node you moved is a CLDB or ZooKeeper node.
5. Remove the node.
   See Removing One or More Nodes on page 810 for more information.
6. Verify that the SPs associated with the node (that you removed in the previous step) are not displayed in the list of storage pools in the CLDB service information page.
   See Viewing CLDB Information on page 1169 for more information.

Formatting a Storage Pool for Encryption of Data at Rest

This section describes how to reformat a storage pool for data at rest encryption and determine if a storage pool is enabled for data at rest encryption.

Formatting a Storage Pool on a Node for Encryption of Data at Rest

1. Determine the number of SPs on the node by running the following command:
   ```
   /opt/mapr/server/mrconfig sp list
   ```
2. Select the SP to reformat and run the following command:
   ```
   mrconfig sp offline <sp path>
   ```
3. Wait for the Data Under-Replicated on page 2241 alarm to clear and ensure that there are no Data Unavailable on page 2240 alarms.
4. Remove the disk from MapR File System.
   See Removing Disks from the File System on page 838 for more information.
5. Format the disk on the node.
   See Formatting Disks on a Node From the Command-line on page 840 for more information.
6. Add disk to MapR File System.
   See Adding Disks to MapR File System on page 837 for more information.

Determining if a Storage Pool is Enabled for Data at Rest Encryption

- Run the following command to determine if an SP is enabled for data-at-rest encryption:

```
/opt/mapr/server/mrconfig sp list -v
ListSPs resp: status 0:2
No. of SPs (2), totalsize 3518339 MB, totalfree 691937 MB

SP 0: name SP1, Online, size 1761217 MB, free 377127 MB, path /dev/
sdb, log 200 MB, port 5660, guid 9dd586829e179476005b0ce23f0dae3c,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sdb /dev/
sdd, dare 1
SP 1: name SP2, Online, size 1757121 MB, free 314809 MB, path /dev/
sde, log 200 MB, port 5660, guid daa5916af8909118005b0ce2430d6d54,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sde /dev/
sdf, dare 1
```

  If enabled, the value for `dare` in the output is `1` (as shown in bold in the above sample command output) and if disabled, the value is `0`.

Managing SSL Certificates

This section decribes how to manage certificates and keystores such as when encryption is initially not enabled or when a custom certificate is used.

Re-running configure.sh after Configuration

If the `configure.sh` script is initially run without the `-genkeys` option, the script generates a `ssl_keystore` file for use by the web server for the Control System.

Then if the `configure.sh` script is re-run with the `-genkeys` option, the system detects the existing `ssl_*` files and exits with an error to prevent inadvertent deletion or reuse of the `ssl_keystore` file.

Note: For general information on certificates, see SSL Certificates on page 689.

To re-run `configure.sh` on clusters without security features enabled:

1. Manually delete the `ssl_keystore` file on each node.
2. Run the `configure.sh -genkeys -R` command.

Note: The contents of the `ssl_keystore` file are unique to each node.

To re-run `configure.sh` on clusters where the contents of the `ssl_keystore` file are customized:

1. Run the `configure.sh -genkeys -nocerts -R` command to preserve your customizations.

SSL Keys Error Message

The error message will look similar to the following example:

```
/opt/mapr/server/configure.sh
        -secure -genkeys -C $CLDB_GRP -Z $ZK_GRP -RM $RM -HS
        $HISTORYSERVER
        <hostname1>: Configuring Hadoop-2.x at
        /opt/mapr/hadoop/hadoop-2.x
        <hostname1>: Done configuring Hadoop
        <hostname1>: CLDB node list:
        <hostname1>:7222,<hostname2>:7222,<hostname3>:7222

        <hostname1>: Zookeeper node
        list: <hostname1>:5181,<hostname2>:5181,<hostname3>:5181

        <hostname1>: Node setup configuration: cldb fileserver
```

```
        historyserver nfs nodemanager resourcemanager webserver
        zookeeper
        <hostname1>: Log can be found at:
        /opt/mapr/logs/configure.log
        <hostname1>: /opt/mapr/conf/ssl_keystore already exists
        <hostname1>: ERROR: could not generate ssl keys. See log file
        for more details
        clush: <hostname1>: exited with exit code 1
```

General Security for Ecosystem Components

Ecosystem components in the MapR Converged Data Platform use the Java Authentication and Authorization Service (JAAS) for security configuration.

- **`/opt/mapr/conf/mapr.login.conf`** file-defines JAAS configurations
- **`MAPR_ECOSYSTEM_LOGIN_OPTS`** environment variable in the `/opt/mapr/conf/env.sh` file-specifies the JAAS configuration used by installed Ecosystem components

Note: See the Ecosystem Guide for component-specific security configuration information.

When security is enabled, the value of the `MAPR_ECOSYSTEM_LOGIN_OPTS` is modified to include the `hybrid` JVM option for `hadoop.login`. This is equivalent to setting the `-Dhadoop.login=hybrid` flag at the command line. This setting specifies a mixed security environment using Kerberos and MapR tickets.

The `mapr.login.conf` file has two stanzas for hybrid security:

```
 /**
 * authenticate using hybrid of kerberos and MapR
 * maprticket must already exist on filesystem as MapR login module
 * cannot get kerberos identity from subject for implicit login.
 */

hadoop_hybrid {
  org.apache.hadoop.security.login.KerberosBugWorkAroundLoginModule optional
      useTicketCache=true
      renewTGT=true
      doNotPrompt=true;
  com.mapr.security.maprsasl.MaprSecurityLoginModule required
      checkUGI=false;
  org.apache.hadoop.security.login.GenericOSLoginModule required;
  org.apache.hadoop.security.login.HadoopLoginModule required
      principalPriority=com.mapr.security.MapRPrincipal;
};

hadoop_hybrid_keytab {
  org.apache.hadoop.security.login.KerberosBugWorkAroundLoginModule optional
      refreshKrb5Config=true
      doNotPrompt=true
      useKeyTab=true
      storeKey=true;
  com.mapr.security.maprsasl.MaprSecurityLoginModule required
      checkUGI=false
      useServerKey=true;
  org.apache.hadoop.security.login.GenericOSLoginModule required;
  org.apache.hadoop.security.login.HadoopLoginModule required
      principalPriority=com.mapr.security.MapRPrincipal;
};
```

Determining if a Cluster is Secure and Enabled for Encryption
Explains how to use the Control System, the CLI, and the REST API to determine whether or not a cluster is secure and whether or not on-wire encryption and data at rest encryption are enabled at the cluster and volume levels.

Determining if a Cluster is Secure Using the Control System

- Log in to the Control System and click to display the **Security** page.
  The **Security** page contains information for determining whether or not the cluster is secure and enabled for on-wire encryption and/or data-at-rest encryption.

Determining if a Secure Cluster is Enabled for Encryption Using the Control System

- Log in to the Control System on a secure cluster and click to display the **Security** page.
  The page displays the following:
  - **Cluster-level Settings** — whether or not on-wire encryption and authentication, and data-at-rest encryption is enabled at the cluster-level. The pane shows:
    - — if enabled
    - — if disabled
  - **Volume Settings** — the number of volumes that are not enabled for:
    - Data on Wire Encryption
    - Data at Rest Encryption

    You can click the number associated with Data on Wire Encryption or Data at Rest Encryption to display the list of volumes filtered by Data on Wire Encryption or Data at Rest Encryption respectively.

Determining if a Cluster is Secure Using the CLI and REST API

CLI

Run the following command to determine if a cluster is secure or unsecure:

```
/opt/mapr/bin/maprcli dashboard
info -cluster <clusterName> -json |
grep secure
```

The value for `secure` is `true` if secure and `false` if unsecure in the command output.

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
10.10.82.24:8443/rest/dashboard/
info' --user mapr:mapr
{"timestamp":1525198793701,"timeofday"
:"2018-05-01 11:19:53.701 GMT-0700
AM","status":"OK","total":1,"data":
[{"version":"6.1.0.20180501072815.GA",
"cluster":
{"name":"ksTest","secure":true,"dare":
true,"ip":"10.10.82.24","id":"60002141
79272613712","nodesUsed":1,"totalNodes
Allowed":-1},"volumes":{"mounted":
{"total":17,"size":0},"unmounted":

_vcores":0,"used_disks":0}}]}
```

The value for `secure` is `true` if secure and `false` if unsecure.

If the value for `secure` is `true`, your cluster is enabled for on-wire encryption. See `dashboard info` on `page 1587` for more information.

Determining if a Secure Cluster is Enabled for Encryption of Data at Rest Using the CLI and REST API

CLI

Run the following command to determine if a cluster is enabled or disabled for data at rest encryption:

```
/opt/mapr/bin/maprcli dashboard
info -name <clusterName> -json | grep
dare
```

The value for `dare` is `true` if enabled and `false` if disabled in the command output.

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
10.10.82.24:8443/rest/dashboard/
info' --user mapr:mapr
{"timestamp":1525198793701,"timeofday"

```

The value for `dare` is `true` if enabled and `false` if disabled.

See `dashboard info` on `page 1587` for more information.

Configuring Authentication
Provides information about MapR ticket, Kerberos, Pluggable Authentication Module (PAM) authentication.

Robust authentication prevents third parties from representing themselves as legitimate users. The core component of user authentication in MapR is the *ticket*. A ticket is an object that contains specific information about a user, an expiration time, and a key. Tickets uniquely identify a user and are encrypted to protect their contents. Tickets are used to establish sessions between a user and the cluster.

MapR supports two methods of authenticating a user and generating a ticket:

- Kerberos
- Username/password pairing with PAM

Both of these methods are mediated by the maprlogin on page 2130 utility. When you authenticate with a username/password pair, the system verifies credentials using Pluggable Authentication Modules (PAM). You can configure the cluster to use any registry that has a PAM module.

Managing Tickets
Introduces authentication using tickets for users and MapR servers.

MapR implements authentication with tickets. *Tickets* contain keys, and are used to authenticate users and MapR servers. In addition, *certificates* are used to implement server authentication. Every user who wants to access a cluster must have a MapR user ticket (`maprticket_<uid>`) and every node in the cluster must have a MapR server ticket (`maprserverticket`).

A ticket is an object that contains specific information about a user and a key. A ticket authenticates a user to the cluster. Tickets are encrypted to protect their contents. The following table describes the tickets used by MapR for internal cluster operations, the user who can generate the ticket, and the command used to generate the ticket. This type of ticket should only be placed on cluster nodes.

Ticket Type	Description	Permissions/Command to Generate Ticket
maprserver	For (internal) cluster operations. This type of ticket can be long lasting.	user root using the `configure.sh` on page 2053 utility
crosscluster	For (internal) cross-cluster operations such as mirroring and replication. This type of ticket can be long lasting.	user mapr using the `maprlogin` on page 2130 utility. The UID of the ticket (mapr) is always used as the identity of the entity using this ticket.

The following table describes the type of tickets supported by MapR for users and services and whether the ticket can be used to impersonate another user. All these tickets, except the user ticket, can only be generated by the cluster administrator using the `maprlogin` on page 2130 utility; the user ticket can be generated by any valid user using the `maprlogin` on page 2130 utility. These type of tickets can be placed on both cluster and client nodes and support (FUSE-based and loopbacknfs) POSIX clients and HDFS APIs.

Ticket Type	Description	Impersonation support	Notes
user	For granting access to individual users. This type of ticket has a short duration.	N/A*	The UID of the ticket (implicit or explicit value of the `-user` parameter to `maprlogin` command) is used as the identity of the entity using this ticket, except for the exceptions noted here for user `root` and user `mapr`.

Ticket Type	Description	Impersonation support	Notes
service	For accessing services running on client nodes. This type of ticket can have long duration.	N/A*	The UID of the ticket (explicit value of the `-user` parameter to `maprlogin` command) is used as the identity of the entity using this ticket, except for the exceptions noted here for user `root` and user `mapr`.
servicewithimpersonation (not scoped)	For accessing services running on client nodes to run jobs on behalf of any user (except user `mapr`). This type of ticket can have long duration.	Yes	The ticket cannot be used to impersonate user `root` or user `mapr`.
servicewithimpersonation (scoped)	For accessing services running on client nodes to run jobs on behalf of the users (except user `root` and user `mapr`) specified in the ticket. This type of ticket can have long duration.	Yes	At ticket generation time, you cannot specify UID/GID of user `root` or user `mapr` to impersonate user root or user mapr respectively. **Note:** In release 6.0.1, scoped impersonation works with FUSE-based POSIX clients; scoped impersonation cannot be used with NFS and loopbacknfs POSIX clients. To use scoped impersonation in release 6.0.1, obtain the 6.0.1 EBF patch for RPM or DEB-based distributions from MapR Support, and install the patch.
tenant	For tenant user(s) to access tenant volume(s) in a multi-tenant environment. This type of ticket can have long duration.	Yes	The ticket can be used to impersonate user `root` but cannot be used to impersonate user `mapr`.

* Exceptions:

- User `mapr` can impersonate other users (including user `root`)
- User `root` can impersonate other users (excluding user `mapr`)

Important: The identity of the user that authenticates with the `maprlogin` utility is independent from the identity of the user of the client OS.

MapR tickets contain the following information:

- UID (generated from the UNIX user ID)
- GIDs (group IDs for each group the user belongs to)

last-updated: Apr 11, 2022

- ticket creation time
- ticket expiration time (initial duration of the ticket)
- renewal expiration time (maximum lifetime of the ticket)
- Whether user can (true) or cannot (false) impersonate another user

Since a ticket contains the GIDs for a user at the time the ticket is generated, a user must re-generate their ticket after changing group memberships.

Syntax and Examples of Creating and Managing User Tickets

For complete syntax, see The maprlogin Utility. For examples of creating and managing user tickets, see maprlogin Command Examples on page 2134

How Tickets Work
Explains the concept of tickets and their working.

When an authenticated user runs a client, the client uses that user's ticket to communicate securely with the server. After Enabling Wire-level Security on page 1411, supported communications channels between client and server are encrypted.

Nodes use tickets to identify themselves to one another in order to prevent *spoofing*, a condition where an untrusted machine presents itself as a trusted machine to gain access to the cluster.

User Blocking

System administrators can use the command line interface to *block* a user. The command to block invalidates all of a user's tickets. Once a block command is received by the CLDB, the name of the blocked user is sent to all FileServer nodes, which reject any request sent by that user that has a ticket older than the block time stamp. Due to the nature of this check, there is no explicit removal of a blocked user. Issuing a new ticket with a time stamp more recent than the block time stamp implicitly permits the user. To permanently prevent a user from logging in again, revoke the user's credentials in the PAM registry.

What Blocking Affects

A blocked user cannot access the MapR filesystem or the CLDB, but since blocking only revokes a user's *existing valid tickets*, be aware of the following interactions:

- Blocking has no effect on Oozie's cached credentials in `~/.oozie-auth-token`, and has no effect on Oozie in general, even after a restart.
- Blocking does not affect a new authentication with user ID and password or with existing Kerberos credentials.
- Since NFS does not use MapR tickets, blocking does not affect NFS access.
- Blocked users can still be impersonated as impersonation does not check whether a user is blocked or not.
- Blocking has no effect on ZooKeeper. Blocked users can still connect to the ZooKeeper server and execute commands. The workaround to resolve this issue is to delete the ticket file.

Generating a MapR User Ticket
Describes what a user ticket is, and how to generate a user ticket.

A user ticket file is stored in `/tmp` and can only be read by that user. To generate a MapR user ticket, run the following command:

```
maprlogin password
```

This command prompts for the user's password, then generates a MapR user ticket associated with the UNIX user ID. By default, tickets on Linux systems are generated in the `/tmp` directory and are named in the form `maprticket_<UID>` . Tickets on Windows systems are generated in the `%TEMP%/` directory and are named in the form `maprticket_<username>` . To change the default location, change the value of the `MAPR_TICKETFILE_LOCATION` environment variable.

Note: The `mapr` user can impersonate any user, including user `root`.

Note: There are no notifications to indicate that a ticket is about to expire. Use the `maprlogin print` command, with the ticket file, to see when the ticket expires. You can renew the ticket until the renewal date mentioned.

To illustrate a typical work flow, suppose a user wants to access two clusters, cluster1 and cluster2. During this session, a user logs in as `root` to cluster1, gets a MapR user ticket, and displays the ticket contents with the `maprlogin print` command.

```
root@qa-node113:~/SecurityInstall# maprlogin password
[Password for user 'root' at cluster 'cluster1': ]
MapR credentials of user 'root' for cluster 'cluster1' are written to '/tmp/
maprticket_0'
root@qa-node113:~/SecurityInstall#
```

First Ticket for Cluster 1

```
root@qa-node113:~/SecurityInstall# maprlogin print
Opening keyfile /tmp/maprticket_0
qasecurity1: user = root, created = 'Wed Sep 11 14:19:02 PDT 2013', expires
= 'Wed Sep 25 14:19:02 PDT 2013', RenewalTill = 'Fri Oct 11 14:19:02 PDT
2013', uid = 0, gids = 0, 42
root@qa-node113:~/SecurityInstall#
```

Now the `root` user logs in to cluster2. The `maprlogin` command returns a ticket for cluster2. This ticket is stored in the common ticket file. Commands now have access to both tickets.

```
root@qa-node113:/opt/mapr/conf# maprlogin password -cluster cluster2
[Password for user 'root' at cluster 'cluster2': ]
MapR credentials of user 'root' for cluster 'cluster2' are written to '/tmp/
maprticket_0'
```

Showing Tickets for both Clusters

```
root@qa-node113:/opt/mapr/conf# maprlogin print
Opening keyfile /tmp/maprticket_0
qasecurity1: user = root, created = 'Thu Sep 12 11:07:54 PDT 2013', expires
= 'Thu Sep 26 11:07:54 PDT 2013', RenewalTill = 'Sat Oct 12 11:07:54 PDT
2013', uid = 0, gids = 0, 42
qasecurity2: user = root, created = 'Thu Sep 12 15:20:49 PDT 2013', expires
= 'Thu Sep 26 15:20:49 PDT 2013', RenewalTill = 'Sat Oct 12 15:20:49 PDT
2013', uid = 0, gids = 0, 500
root@qa-node113:/opt/mapr/conf#
```

Generating a Service Ticket

Applications may have service processes that run outside the MapR cluster but need to access the cluster to run MapR commands. For security reasons, you may not want to run these services as the mapr user. Instead, you can use the maprlogin utility to generate a "service ticket" that can be used to access the cluster for the user account that runs the service. The maprlogin utility uses the current user's ticket (the user running the maprlogin command) to send an authenticated request for a newly generated service ticket.

This type of ticket has a specified duration (expiration), a renewal period (maximum lifetime), and a designated location where the ticket is safely stored. The service process that uses the ticket can access it based on the definition of the `MAPR_TICKETFILE_LOCATION` environment variable, which points to the location of the ticket and should be set for the service process when it starts. Short duration and renewal values may be used for security reasons, but much longer lifetimes are supported for ease of administration.

For example:

```
# maprlogin generateticket -type service -out /tmp/
longlived_ticket -duration 30:0:0 -renewal 90:0:0 -user mapr
MapR credentials of user 'mapr' for cluster 'xxxx' are written to '/tmp/
longlived_ticket'
```

This command generates a service ticket that expires after 30 days and is stored in `/tmp/longlived_ticket`. The ticket may be renewed at any time before the 30 days pass, extending its lifetime to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Note: This type of ticket can only be generated by a user with full control on a cluster's Access Control List (ACL).

Generating a Service with Impersonation Ticket

Impersonation allows a user to access data and submit jobs on behalf of another user. You may want to allow users, other than the mapr user, to impersonate other users. You can use the `maprlogin` utility to generate a "servicewithimpersonation ticket" that can be used to access a secure cluster impersonating another user. That is, the servicewithimpersonation ticket provides the user the ability to impersonate other users (except the mapr user) in addition to the ability to access a secure cluster. This type of ticket can only be generated by a user with full control on a cluster's Access Control List (ACL).

If this type of ticket is generated and saved in the location specified with the `-out` option, after generating the ticket, do the following:

1. Reset the permissions on the ticket to grant the user, for whom the ticket was generated, read permissions on the ticket.
2. Set the `MAPR_TICKETFILE_LOCATION` environmental variable to point to the ticket file location if the path specified for the `-out` option was not `/tmp/maprticket_<uid>`.

This type of ticket, similar to a service ticket, has a specified duration (expiration), a renewal period (maximum lifetime), and a location where the ticket is safely stored. It grants the specified user the ability to impersonate other users, except the mapr user.

The default duration for this type of ticket is LIFETIME and the duration is not bounded by the CLDB duration properties. Short duration and renewal values may be used for security reasons, but much longer lifetimes are supported for ease of administration.

last-updated: Apr 11, 2022

For example:

```
# maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration 30:0:0 -renewal
90:0:0
```

The above command generates a service with impersonation ticket that expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time before the 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires. The ticket allows the user to impersonate all users on the cluster.

To allow a user to impersonate only specific users and/or groups, use the `impersonateduids` and/or `impersonatedgids` options with the `maprlogin` command. For example:

```
# maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration
30:0:0 -impersonateduids 1002,1003 -impersonatedgids 1005,1006 -renewal
90:0:0
```

The above command generates a service with impersonation ticket. The ticket holder can impersonate users whose UIDs are 1002 and 1003 and users in the groups with GIDs 1005 and 1006. The ticket expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time before the 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Generating a Ticket for a Tenant
Explains what tenant tickets are and how to generate a tenant ticket.

Tenant tickets allow tenant users to access the tenant volume on the cluster (when you have a multi-tenant environment on MapR File System). Generate the tenant ticket on the cluster and copy it to the tenant host(s) to grant tenant users access to the provisioned storage.

- To generate a tenant ticket, run one of the following commands on the cluster:

  ```
  maprlogin generateticket -type tenant -cluster <cluster_name> -user
  <tenant_admin_user> \
  -duration <seconds> -out <ticket_file_path>.txt
  ```

  Note: For more information, see the `maprlogin` command.

  By default:

  - Tenant ticket is stored in `/tmp` and can only be read by that user. To change the default location, specify the path to the desired location with the `out` parameter.
  - Tenant ticket has no expiration. To change the expiration time, specify `duration` for the ticket with the command.

  In the tenant tickets, the value for `CanImpersonate` and `tenant` will always be `true`. For example, when you run the `maprlogin print` command, your output should look similar to the following:

  ```
  Opening keyfile /user/clstrAdmin/tenant_user_ticket.txt
  tenantHost: user = tenant_user, created = 'Mon Jul 11 07:14:53 UTC 2016',
  expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11
  07:14:53 UTC 12016',
  uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
  ```

  To grant access to tenant users, the tenant ticket must be copied over to the tenant hosts.

After generating the ticket, do the following:

1. Reset the permissions on the ticket to grant the tenant admin read permissions on the ticket.
2. Move the ticket out of the default `/tmp` directory to a secure location on the tenant host(s).

Generating a MapRTicket from a Kerberos Ticket

On clusters that use Kerberos for authentication, a MapR ticket is implicitly obtained for a user that runs a MapR command without first using the `maprlogin` utility.

If you want to use a Kerberos ticket to generate a `maprticket`, follow these steps:

1. Obtain a Kerberos identity by running `kinit` or by another mechanism.
2. Run `maprlogin kerberos` to indicate that you have an existing Kerberos ticket. You can also specify these options: `[ -cluster ]` The name of the cluster. `[ -duration ]` The ticket duration in seconds.

Configuring MapR PAM Authenticator

The MapR Converged Data Platform supports Pluggable Authentication Modules (PAM) in the UNIX authentication stack. MapRMapR Data Platform provides a PAM Authenticator module that generates MapRMapR Data Platform tickets in conjunction with the `maprlogin` utility. After you install the MapR Converged Data Platform, the PAM Authenticator module is located at *`$INSTALL_DIR`*`/lib/libmapr_pam.so`. Configuration files for PAM are located in the `/etc/pam.d` directory, and each UNIX operation, such as `su`, `login`, or `ssh`, has a specific PAM configuration file in that directory.

Configure the PAM Authenticator on Ubuntu or SLES

To configure the MapR PAM Authenticator, append the following line to the end of the `/etc/pam.d/common-auth` file:

```
auth optional /opt/mapr/lib/libmapr_pam.so # MapR PAM module
```

Warning: An absolute path to the location of the `libmapr_pam.so` file is required. By default, this location is `$MAPR_HOME/lib/libmapr_pam.so`.

Configure the PAM Authenticator on Red Hat or CentOS

1. Insert the following line in the `/etc/pam.d/system-auth` file immediately before the first module that uses the `auth sufficient` configuration:

```
auth optional libmapr_pam.so # MapR PAM module
```

2. Append the string `try_first_pass` to the end of the module that uses `auth sufficient`, as in this example:

   Before modification:

   ```
   auth required pam_env.so
   auth sufficient pam_unix.so nullok
   auth requisite pam_succeed_if.so uid >= 500 quiet
   auth required pam_deny.so
   ```

   After modification, changes in **bold**:

   ```
   auth required pam_env.so
   auth optional libmapr_pam.so # MapR PAM module
   auth sufficient pam_unix.so nullok try_first_pass
   auth requisite pam_succeed_if.so uid >= 500 quiet
   auth required pam_deny.so
   ```

Enable Debugging for PAM

To enable debugging for the client traffic used by the `maprlogin` utility, update the `/opt/mapr/conf/log4j.properties` file with the following line:

`log4j.logger.com.mapr.login=DEBUG`

After updating the `log4j.properties` file, trace the `com.mapr.login` package at the DEBUG level.

Be sure to update the correct instance of the `log4j.properties` file. Traffic specific to MapRMapR Data Platform, such as `maprlogin` and Control System traffic, uses the instance in the `/opt/mapr/conf` directory. Hadoop applications use the `log4j.properties` file in the `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop` directory.

To perform the same tracing activity on the server side, modify the appropriate instance of the `log4j.properties` file on the server, or specify the page `com.mapr.login` in the Control System UI's tracing/logger settings. To trace PAM activity from the server, add the following line to the server's `log4j.properties` instance:

```
log4j.logger.net.sf.jpam=DEBUG
```

After modifying this setting, the server log will contain a message similar to the following:

`2013-07-23 16:05:25,200 DEBUG Pam [1068409264@qtp-874242484-3]: Debug mode active.`

Detailed information about PAM activity is written to the `/opt/mapr/logs/pam.log` file.

Other Packages

The following packages are not directly related to PAM, but can provide useful insights for subtler errors.

- `org.apache.hadoop.security` - This package contains Apache security code, including MapRMapR Data Platform enhancements. Tracing this package can provide information about what login configuration is in use.
- `com.mapr.fs.cldb.http.login` - This package contains code that the CLDB uses to validate `maprlogin` calls.

Common Issues

The Linux Documentation Project's HOWTO on LDAP Implementation has a section on PAM and NSS that may prove helpful.

If a user's credentials appear valid, for example in a case where the `su` and `ssh` commands work normally, but PAM does not correctly authenticate, the issue may relate specifically to MapRMapR Data Platform's use of PAM as a normal user, compared to the usual case where PAM consumers run as the root user, causing permissions issues. The two most common issues relating to this condition are:

- The `/etc/shadow` directory is not readable to the `mapr` user. This directory is made readable to the `mapr` user during install, but some secure environments and configuration management tools undo these changes.
- A Kerberos PAM module is attempting to create and change the ownership of a kerberos ticket file. This attempt fails, since these changes require root privileges. Different Kerberos PAM modules can report errors differently, leading to difficulty tracking down root causes of errors. To address permissions problems with Kerberos PAM modules, configure the Kerberos PAM module to skip creating a ticket file, using the KDC only to validate the password. PAM configuration information is located in the `/etc/pam.d` directory. MapRMapR Data Platform can use a custom PAM configuration specified in the `web.conf` file.

Configuring Kerberos
Describes how Kerberos works with MapR tickets.

MapR does not directly support Kerberos. However, Kerberos is indirectly supported through the MapR login utility, which is used to generate MapR tickets. This topic describes how Kerberos works with MapR tickets.

Kerberos Compatibility with RHEL 8

When you install Kerberos out of the box with RHEL 8, it uses the new default Kerberos Cache Manager (KCM) credentials cache type, which fails to work with the `maprlogin kerberos` command. To resolve this issue, disable KCM.

Open the file `/etc/krb5.conf.d/kcm_default_ccache` and comment out the following lines:

```
[libdefaults]
        default_ccache_name = KCM:
```

Alternatively, remove this file.

Configuring Kerberos for Authentication Using MapR Tickets

To use Kerberos to generate MapR tickets for users, enable Kerberos on CLDB by creating a Kerberos identity on the Kerberos server used by the cluster and distributing that identity to the other CLDB nodes in the cluster.

Note: You must enable wire-level security on your clusters before using Kerberos. See Enabling Wire-level Security.

MapR clusters do not provide Kerberos infrastructure. This section assumes you have a functioning Kerberos realm and your systems have the Kerberos client installed. The tips in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

Important: If you are using strong encryption with Kerberos with the Oracle JDK, you will require a new Java Cryptography Extension (JCE) policy file.

Creating a Kerberos Identity for the CLDB

The CLDB requires a Kerberos server identity, but no other nodes do. By default, this identity takes the form `mapr/<cluster name>`. You can use `configure.sh` on page 2053 or edit the

last-updated: Apr 11, 2022

`mapr-clusters.conf` file to change this default. Use the following commands in a Linux-based Kerberos environment to set up the identity:

```
kadmin
        : addprinc -randkey mapr/my.cluster.com
        : ktadd -k /opt/mapr/conf/mapr.keytab mapr/my.cluster.com
```

Copy the resulting `mapr.keytab` file to the same location on every CLDB node. The `mapr.keytab` file must be owned and readable only by the `mapr` user. You can specify the location of the `mapr.keytab` file in the `conf/mapr.login.conf` file. The default location for `mapr.keytab` is `/opt/mapr/conf`.

Updating the keytab File

You can use the `kadmin` tool to update the server keys that are stored in the keytab file. Because the server tickets used to authenticate to the CLDB use the new keys immediately, you must copy the new keytab file to all the CLDB servers in the cluster immediately after updating the server keys.

To update the keytab file with a new key, run the following command:

```
kadmin
        : ktadd -k /opt/mapr/conf/mapr.keytab mapr/my.cluster.com
```

The CLDB automatically detects changes to the keytab file on systems that use Java 7 or later. Systems that use Java 6 require a CLDB restart to detect changes to the keytab file.

Note: Starting with the 4.0.1 release of the MapR software, Java 6 is deprecated in favor of Java 7 and Java 8.

Running configure.sh

After a Kerberos principal is created for the CLDB, that principal is added to the `mapr.keytab` file, and the `mapr.keytab` file is copied to all the CLDB servers, Kerberos user authentication is fully enabled for the MapR cluster.

Two `configure.sh` parameters are important for Kerberos:

- `-K|-kerberosEnable` — lets the rest of the cluster know that Kerberos is enabled, so that clients can auto detect Kerberos tickets and use them to get MapR tickets.
- `-P "<cldbPrincipal>"` — specifies the Kerberos instance which is used to form the CLDB Kerberos principal in the form of `mapr/<instance-name>@<realm-name>`. Enclose this value in quotes (").

Run `configure.sh` on each MapR cluster node, and on each MapR client node that will communicate with one or more clusters. For more information, see `configure.sh` on page 2053.

```
configure.sh -K -P "<cldbPrincipal>"
```

Running `configure.sh` on each node enters the Kerberos information into the local `clusters.conf` file, so that the following command is all that is required for the client to access the cluster:

```
hadoop fs -ls
```

If you do not run `configure.sh` on each node, the following two commands are required from the client:

```
maprlogin kerberos
hadoop fs -ls
```

last-updated: Apr 11, 2022

Kerberos Command Summary

- **kinit**: Creates a Kerberos ticket. Prompts the user for userid and password. After validating, Kerberos creates a ticket file in `/tmp` that is owned by the user. Use the `-R` option to renew an existing ticket. Kerberos credentials expire in 8-10 hours. Expired credentials must be renewed or replaced. By default, tickets can be renewed for up to 24 hours.
- **klist**: Lists the contents of the user's ticket file.
- **kdestroy**: Destroys the contents of the user's ticket file. The user is no longer authenticated.
- **kadmin**: Used to administer Kerberos. The login for this command is implicitly `<userid>/admin`, since administrator IDs typically end in `/admin`.
- **ktutil**: Kerberos keytab maintenance utility. Used to combine, or alter Kerberos keytabs.

Disabling Replay Detection for Kerberos Authentication

You can set an option in `mapr-clusters.conf` file to disable replay detection for Kerberos runtime authentication.

```
disableReplayDetection=true
```

By default, this parameter is set to `false`, meaning that MapR clients enable Kerberos replay detection. Typically, replay detection is enabled to prevent potential attacks such as the replay of Kerberos packets or multiple login attempts with the same user ID. Set this parameter to `true` only if you want MapR clients not to enforce this detection.

This parameter applies when users attempt an implicit or explicit `maprlogin`, such as by using the `maprlogin kerberos` command or by submitting jobs and other operations with `kerberosEnable=true` set in the `mapr-clusters.conf` file.

This parameter is used when applications connect to the cluster using Kerberos; `mapr-clusters.conf` only needs to be updated when it is used by such applications. If all Kerberos access to the cluster is from clients outside the cluster, only the `mapr-clusters.conf` file on those client machines has to be updated. If Kerberos is used from applications running on the cluster, `mapr-clusters.conf` file should be updated there as well.

Configuring YARN with Kerberos
Lists the process to use YARN with Kerberos.

Make sure that the following tasks are already completed, as directed in earlier sections of this guide:

- Enabling Wire-level Security on page 1411 by running `configure.sh` with the security options.
- Configuring Kerberos on page 1432 by creating a Kerberos principle and keytab file.

Note: To enable YARN REST SPNEGO, see Configuring SPNEGO on MapR on page 1436.

Now complete the following tasks.

Configure the yarn-site.xml File

Add the following properties to the `yarn-site.xml` file on every node in the cluster.

```
/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml
```

Note: You need to use `/opt/mapr/conf/mapr.keytab` for the `keytab` property and `mapr` instead of `yarn` for the `principal` property.

```
<!-- ResourceManager security configs -->
<property>
 <name>yarn.resourcemanager.keytab</name>
 <value>/opt/mapr/conf/mapr.keytab</value>    <!-- path to the YARN
keytab -->

</property>
<property>
 <name>yarn.resourcemanager.principal</name>
 <value>mapr/clustername@YOUR-REALM.COM</value>
</property>

<!-- NodeManager security configs -->
<property>
 <name>yarn.nodemanager.keytab</name>
<value>/opt/mapr/conf/mapr.keytab</value>    <!-- path to the YARN
keytab -->

</property>
<property>
 <name>yarn.nodemanager.principal</name>
 <value>mapr/clustername@YOUR-REALM.COM</value>
</property>
<property>
 <name>yarn.nodemanager.container-executor.class</name>
 <value>org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor</
value>
</property>
<property>
 <name>yarn.nodemanager.linux-container-executor.group</name>
 <value>mapr</value>
</property>
```

Configure the mapred-site.xml File

Add the following properties to the `mapred-site.xml` file on every node in the cluster.

```
/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml
```

Note that you need to use `/opt/mapr/conf/mapr.keytab` for the `keytab` property and `mapr` instead of `yarn` for the `principal` property.

```
<!-- MapReduce Job History Server security configs -->
<property>
  <name>mapreduce.jobhistory.address</name>
  <value>host:port</value> <!-- Host and port of the MapReduce Job History
Server; default port is 10020  -->
</property>
<property>
  <name>mapreduce.jobhistory.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value><!-- path to the YARN
keytab -->
</property>
<property>
  <name>mapreduce.jobhistory.principal</name>
  <value>mapr/clustername@YOUR-REALM.COM</value>
</property>
```

last-updated: Apr 11, 2022

Modifying the env_override.sh File

Either the `/opt/mapr/conf/env.sh` file or the `/opt/mapr/conf/env_override.sh` file contains a setting for MapR login option that defaults to the value `maprsasl`. Change this value to `hybrid`, which includes Kerberos and other security protocols. For more information about the `env_override.sh` file, see About env_override.sh on page 2290.

The new line (after the change) should be as follows:

```
MAPR_LOGIN_OPTS="-Dhadoop.login=hybrid ${MAPR_JAAS_CONFIG_OPTS} $
{MAPR_ZOOKEEPER_OPTS}"
```

Restart ResourceManager, NodeManager, and JobHistoryServer

Restart the NodeManager, ResourceManager, and JobHistoryServer services, using either the `maprcli node services` command (with the `name` option) or the Control System. After restarting the services, make sure you can run simple Hadoop jobs by running:

```
hadoop jar /opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/
hadoop-mapreduce-examples-<version>.jar pi
```

Configuring SPNEGO on MapR

MapR uses the Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO) to secure several Web UIs in a secure cluster, as well as the REST calls to the Control System.

Configuring SPNEGO for the Web Server Nodes on Secure Clusters

The following procedure configures SPNEGO support for the apiserver nodes on your secure cluster.

1. Generate a Kerberos principal with the user name HTTP, of the form `HTTP/<webserver name>` on each node in the secure cluster that will receive inbound SPNEGO traffic.

   Use the fully qualified domain name (FQDN) as the name in the principal. Although you could also use a short name or the IP address for the principal name, using the FQDN keeps the name consistent with principal names that `configure.sh` generates and includes in the `mapr.login.conf` file.

   Whatever you use as the principal name is what users will have to match exactly in a browser to access the web pages that are protected.

   Note: Several services and components in a MapR cluster handle SPNEGO traffic, including the Control System. You can name the keytab file `mapr.keytab` if that file does not already exist. If the `mapr.keytab` file already exists, generate the new principal to a different file name and merge it to the `mapr.keytab` file using the `ktutil` tool. For example:

   ```
   kadmin
    : addprinc -randkey HTTP/<webserver name>
    : ktadd -k /opt/mapr/conf/mapr.keytab HTTP/<webserver name>
   ```

2. Verify that the `/opt/mapr/conf/mapr.login.conf` file lists the correct principal in the `MAPR_WEBSERVER_KERBEROS` section.

   To enable SPNEGO for the Control System Web UI or for the Control System REST calls, on all nodes with the webserver role, add the following line to the `/opt/mapr/apiserver/conf/properties.cfg` file. For example:

   ```
   mapr.rest.auth.methods=kerberos,basic
   ```

   Important: The `mapr.rest.auth.methods=kerberos,basic` option, which is shown above, is valid only on a secure cluster. If a cluster is not secure, only basic authentication (`WWW-Authenticate: Basic`) is available to clients.

3. Restart the Control System for the changes to take effect.

Testing SPNEGO With curl

This example tests that the Control System is using GSS for REST calls made with `curl`.

Use the following command to verify that your version of `curl` supports SPNEGO. Under the **Features** header, output of the command should show either **GSS-Negotiate** or SPNEGO. For example:

```
# curl --versioncurl 7.22.0 (x86_64-pc-linux-gnu) libcurl/7.22.0
OpenSSL/1.0.1 zlib/1.2.3.4 libidn/1.23 librtmp/2.3Protocols:
dict file ftp ftps gopher http https imap imaps ldap pop3 pop3s rtmp rtsp
smtp smtps telnet tftp
Features: GSS-Negotiate IDN IPv6 Largefile NTLM NTLM_WB SSL libz TLS-SRP
```

Verify that you have a valid Kerberos ticket-granting-ticket (TGT) with the `kinit -p <user>` command,. Then, test `curl` with the following command:

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt
https://<web server node>:8443/rest/<API call> -k -v
```

This command returns HTTP/1.1 200 OK when `curl` is working correctly with SPNEGO.

Configuring Browsers for SPNEGO

Use the following processes to configure browsers for SPNEGO connections.

Firefox

The process below configures your Firefox browser for SPNEGO connections.

Note: These instructions are specific for Firefox version 40.0.3xj. The details may differ slightly if you are using a different version.

1. Open the Firefox configuration page by navigating to the address `about:config`.
2. In the **Search** text field, enter `network.negotiate-auth.trusted-uris` to bring up that property.
3. Right-click on `network.negotiate-auth.trusted-uris` and select **Modify** to edit the property and enter the hostnames of the web server nodes in your cluster as a comma-separated list.
4. Click **OK**.

Chromium on Ubuntu

last-updated: Apr 11, 2022

To configure the Chromium browser on Ubuntu for SPNEGO, edit the `/etc/chromium-browser/default` file and add the following property:

```
CHROMIUM_FLAGS="--user-data-dir --auth-server-whitelist=<web server host
names>"
```

The `--user-data-dir` flag enables the root user to launch the browser.
The `--auth-server-whitelist` flag specifies the web servers that support SPNEGO authentication.

Troubleshooting Kerberos

Java errors from Kerberos problems can be obscure and difficult to interpret. To see the Kerberos error messages, enable Kerberos debugging by adding these settings to your JVM:

```
-Dsun.security.krb5.debug=true -Dsun.security.spnego.debug=true -Djavax.net.
debug=all
```

You can also enable Kerberos debugging for the MapR-provided `maprcli` and Hadoop clients by adding the following line to the `/opt/mapr/conf/env_override.sh` shell script:

```
#MAPRLOGIN_OPTS="$
{MAPRLOGIN_OPTS} -Dsun.security.krb5.debug=true -Dsun.security.spnego.debug=
true -Djavax.net.debug=all"
```

The `env.sh` script reads this file as part of its execution. For more information, see About env_override.sh on page 2290.

Capture the Kerberos error to research the issue.

The following sections list common Kerberos error conditions:

Incorrect JVM

Nodes often have multiple Java Virtual Machines (JVM) installed. The MapR `env.sh` script automatically configures a JVM to use. To change the automatically configured JVM, set the value of the `JAVA_HOME` environment variable in the `/opt/mapr/conf/env_override.sh` file. The `env.sh` script reads this file as part of its execution. For more information, see About env_override.sh on page 2290.

Incorrect Server Name

The following error message is caused by an incorrect CLDB server name in the `mapr.login.conf` file. The error message mentions passwords, but the error condition is unrelated to password authentication.

```
2018-04-25 16:46:02,324 ERROR MapRLoginServlet [185087767@qtp-648535353-2]:

Invalid or missing keytab file

The `keytab` file must be consistent with the key versions of the Kerberos principal. The following example shows an inconsistent keytab file:

```
kadmin:  getprinc mapr/realm1
        Principal: mapr/realm1@mapr
        Expiration date: [never]
        Last password change: Thu May 23 15:36:01 PDT 2013
        Password expiration date: [none]
        Maximum ticket life: 0 days 10:00:00
        Maximum renewable life: 7 days 00:00:00
        Last modified: Thu May 23 15:36:01 PDT 2013 (mapr/admin@mapr)
        Last successful authentication: Thu May 23 19:31:59 PDT 2013
        Last failed authentication: Thu May 23 15:35:41 PDT 2013
        Failed password attempts: 0
        Number of keys: 8
        Key: vno 15, aes256-cts-hmac-sha1-96, no salt
        Key: vno 15, arcfour-hmac, no salt
        Key: vno 15, des3-cbc-sha1, no salt
        Key: vno 15, des-cbc-crc, no salt
        Key: vno 15, des-cbc-md5, Version 4
        Key: vno 15, des-cbc-md5, Version 5 - No Realm
        Key: vno 15, des-cbc-md5, Version 5 - Realm Only
        Key: vno 15, des-cbc-md5, AFS version 3
        MKey: vno 1

        ktutil:  rkt mapr.keytab
        ktutil:  l
        slot KVNO Principal

 ---- ---- ---------------------------------------------------------------------

        1   14            mapr/realm1@mapr
        2   14            mapr/realm1@mapr
        3   14            mapr/realm1@mapr
        4   14            mapr/realm1@mapr
        ktutil:  q
```

Note that the key versions in the Kerberos principal `/realm1` are 15, and the versions in the `keytab` file are 14. This mismatch can result in errors about missing keys or mismatched encryption.

Note:

This error state can also be caused by the `/opt/mapr/conf/mapr.keytab` file not being owned by the user `mapr` or not being present. The `keytab` file is owned by `root` at generation. Be sure to use the `chown` command to set the `mapr` user as the owner:

```
$ chown mapr:mapr /opt/mapr/conf/mapr.keytab
```

Incompatible encryption on Java runtime

Incompatible cryptography between the KDC and the JDK results in failed handshakes, leading to errors similar to the following:

```
Caused by: javax.security.auth.login.LoginException: Unable to obtain
Principal Name for authentication
```

With debugging active, the following message is displayed:

```
>>>DEBUG <CCacheInputStream>  client principal is username@hostname
        >>>DEBUG <CCacheInputStream> server principal is X-CACHECONF:/
krb5_ccache_conf_data/fast_avail/krbtgt/user@hostname
        >>>DEBUG <CCacheInputStream> key type: 0
        >>>DEBUG <CCacheInputStream> auth time: Wed Dec 31 16:00:00 PST 1969
        >>>DEBUG <CCacheInputStream> start time: null
        >>>DEBUG <CCacheInputStream> end time: Wed Dec 31 16:00:00 PST 1969
        >>>DEBUG <CCacheInputStream> renew_till time: null
        >>> CCacheInputStream: readFlags()
        >>> unsupported key type found the default TGT: 18
        Negotiate support not initiated, will fallback to other scheme if
allowed. Reason:
```

This debug message indicates that the problem is an unsupported key type.

Incompatible encryption errors can occur due to a `keytab` file that is not present or contains outdated keys.

Be sure to update the Java jurisdiction policy file. Jurisdiction policy files are available from Oracle.

A persistent encryption incompatibility problem may require you to edit the `krb5.conf` file to ensure compatible algorithms between Java and Kerberos.

Bugs in Java

The following error occurs in Java version 1.6.0_25. Upgrade to 1.6.0_45 to resolve the error.

Note:

Starting with the 4.0.1 release of the MapR software, Java 6 is deprecated in favor of Java 7 and Java 8.

Kerberos and PAM validation

Standard Kerberos implementations are predicated on access to elevated user privileges that are not present on secure MapR clusters. In a MapR cluster, the Control System console and other components call PAM as an ordinary user process. This discrepancy in expected and actual privileges can cause a variety of obscure file permisson errors. Since different Kerberos PAM modules are available, error reports can vary.

To diagnose this issue, attempt starting the Control System as the root user, or clear out the `/tmp` folder. If there are no problems when starting the Control System as root, or if clearing out the `/tmp` folder enables a single login before errors appear again, the problem may lie in the Kerberos PAM configuration.

To resolve this condition, prevent Kerberos from creating a ticket file. MapR security does not use Kerberos tickets. The Kerberos KDC is used to validate passwords. Typically the configuration file for PAM is in the `/etc/pam.d` directory. See the documentation for your specific Kerberos PAM module for more information.

Configuring PAM
Describes how PAM works with MapR.

MapR uses Pluggable Authentication Modules (PAM) for password verification in a variety of places. Make sure PAM is installed and configured on the node running the `mapr-apiserver`, or other components that will use PAM to verify passwords.

There are typically several PAM modules (profiles), configurable via configuration files in the `/etc/pam.d/` directory. Any component verifying user passwords tries the following three profiles in order:

1. sudo (`/etc/pam.d/sudo`)
2. sshd (`/etc/pam.d/sshd`)
3. mapr-admin (If you have created the `/etc/pam.d/mapr-admin` profile and the component checks beyond the first two profiles.)

The profile configuration file (for example, `/etc/pam.d/sudo`) should contain an entry corresponding to the authentication scheme used by your system. For example, if you are using the simplest form of local OS authentication, check for an entry similar to the following - consult with your Unix system administrator if you are uncertain:

```
auth    sufficient      pam_unix.so  # For local OS Auth
```

Component-specific PAM Configurations

Some ecosystem components have unique requirements that require setup of a component-specific PAM configuration. See the Ecosystem Guide for the specific Ecosystem component.

Configuring PAM for the Control System and the REST API
Describes how to create a custom PAM profile and use a specific PAM file for authentication.

Starting in MapRMapR Data Platform v6.0, no additional configuration is needed to use PAM files for authentication. The apiserver supports PAM and automatically loads the following PAM files, if they exist, in the following order for authentication:

```
/etc/pam.d/mapr-admin
/etc/pam.d/sudo
/etc/pam.d/sshd
/etc/pam.d/chkpasswd
/etc/pam.d/passwd
```

However, you can create a custom PAM profile and set the admin server property to point to a specific PAM file to use for authentication:

1. Open the `/opt/mapr/apiserver/conf/properties.cfg` file and set the PAM file as the value for the `authentication.pam.service` property.

   For example, to set `mapr-admin` as the file to use for authentication, your entry in the file should look similar to the following:

   ```
   ojai.cache.size=64
   mapr.webui.https.port=8443
   doc.url=https://docs.datafabric.hpe.com/home
   proxy.zkservices=elasticsearch,opentsdb
   authentication.pam.service=mapr-admin
   ```

2. Save and close the file.

Configuring PAM to use LDAP

For instructions, refer to your operating system vendor documentation.

last-updated: Apr 11, 2022

Configuring PAM to use Kerberos

To configure PAM with Kerberos:

1. Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
2. Install the appropriate PAM packages:
   - On Redhat/Centos, `sudo yum install pam_krb5`
   - On Ubuntu, `sudo apt-get install -krb5`

Creating a Custom PAM Profile

If you wish to ensure that MapR uses a MapR-unique PAM configuration, you can:

- Leave the `/etc/pam.d/sudo` file as is - MapR strongly recommends against manually editing the `/etc/pam.d/sudo` file.
- Create your own PAM profile in `/etc/pam.d`, naming it `mapr-admin`.
- Manually edit `mapr.login.conf` and other ecosystem component configuration files to use `mapr-admin` only.

Example /etc/pam.d/mapr-admin File

Below are some simple examples of what might work in the PAM profile by editing `mapr-admin` or a different PAM profile.

Note: Be sure to consult with your Linux administrator before modifying PAM profiles.

```
account     required      pam_unix.so
account     sufficient    pam_succeed_if.so uid < 1000 quiet
account     [default=bad success=ok user_unknown=ignore] pam_ldap.so
account     required      pam_permit.so

auth    sufficient      pam_unix.so nullok_secure
auth    requisite       pam_succeed_if.so uid >= 1000 quiet
auth    sufficient      pam_ldap.so use_first_pass
auth    required        pam_deny.so

password    sufficient    pam_unix.so md5 obscure min=4 max=8 nullok
try_first_pass
password    sufficient    pam_ldap.so
password    required      pam_deny.so

session     required      pam_limits.so
session     required      pam_unix.so
session     optional      pam_ldap.so
```

Note: The file `/etc/pam.d/sudo` should be modified only with care and only when absolutely necessary.

last-updated: Apr 11, 2022

Example for Hue

- In Hue, you can set which PAM profiles to use by modifying `pam_service` option in the `<HUE_HOME>/desktop/conf/hue.ini` file:

```
[desktop]
  ...
# Configuration options for user authentication into the web application
# ------------------------------------------------------------------------
 [[auth]]
# Authentication backend...
backend=desktop.auth.backend.PamBackend
  ...
# The service to use when querying PAM.
## pam_service=sudo sshd login
```

Note: The `mapr-admin` profile is not used in the default Hue configuration.

Note: Hue respects only `auth` section from the PAM profiles.

Example for Livy

- With Livy you can authenticate users with PAM only by using MapR MultiMechs authentication, so it uses the configuration from `/opt/mapr/conf/mapr.login.conf`.

Managing Access Controls
Describes how to create, enable, and use ACLs and ACEs.

ACLs specify users or system processes that can perform specific actions on an object. ACEs are Boolean expressions that defines a combination of users, groups, or roles that have access to an object.

Managing Access Control Lists
Defines and describes how to create ACLs.

An access control list (ACL) specifies users or system processes that can perform specific actions on an object.

Creating Cluster-level ACLs

A cluster-level Access Control List (ACL) determines who has access to a cluster and which actions they are allowed to perform. ACLs on a secure MapR cluster are predicated on a locally managed OS registry.

Important: Before you create an ACL that applies to a particular group, you must create that group and assign users to it.

For example, the Red Hat Linux commands for creating a group called `developers` and adding a user named `jsmith` on a locally managed OS registry are:

```
groupadd developers
useradd -g developers jsmith
```

Once users and groups have been defined, an administrator can create a cluster-level ACL using the Control System and the CLI.

Creating an ACL from the Control System

1. Click **Admin** > **User Settings** > **Permissions**.
2. Follow steps for Adding Cluster Permissions on page 755.

   Each allowed action has a permission code associated with it. The codes are explained below.

last-updated: Apr 11, 2022

Permission Code	Allowed Action
login	Log in to the MapR Control System, use the API and command-line interface, read access on cluster and volumes. **Note:** Read access allows you to only view the MapR objects that already exist. You cannot create volumes, policies, schedules, snapshots, nor any other MapR objects.
ss	Start/stop services
cv	Create volumes
cp	Create security policies
a	Administrative access to cluster ACLs. Grants no other permissions.
fc	Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster ACLs.

Creating an ACL from the Command Line

To create an ACL at the command line, use the `acl set` command. Include spaces between multiple entries, such as a list of usernames and their associated permission levels (or *actions*).

The syntax is:

```
maprcli acl set -type volume -name <volume name>
                [-group <groupname>:<action> -user <username>:<action>]
```

Note: The `acl set` command *removes* previously set permissions if they are not explicitly called out in the command line.

Other ACL commands include:

- acl edit - to modify permissions in an ACL (use this command instead of `acl set` to change some permissions while leaving others intact)
- acl show - to display permissions in an ACL

Example

To create an ACL for a cluster named `my.cluster.com` that allows administration of cluster ACLs to user `root` and control over all other aspects of the cluster to all users in the `developers` group, enter this command:

```
maprcli acl set -type cluster -cluster my.cluster.com -user root:a -group
developers:fc
```

Now suppose you want to change the `developers` group permissions so they can only log in and start or stop services. Use the `acl edit` command as shown:

```
maprcli acl edit -type cluster -cluster my.cluster.com -group
developers:login,ss
```

Note that only the `developers` group's permissions change, while the user named `root` retains control over the cluster's ACL settings.

last-updated: Apr 11, 2022

Creating Job Queue ACLs

A job queue ACL controls who can submit jobs to a queue, kill jobs, or modify their priority. The default behavior is that any user can submit a job, and jobs can only be seen and killed by the administrator or the user that submitted those jobs.

To create a job queue ACL, specify the following parameters in the `mapred-queue-acls.xml` file:

Parameter	What it does
`mapred.queue.names` *`queue1,queue2,...`*	Names the queues to which jobs can be submitted.
`mapred.acls.enabled=true`	Indicates that ACLs will be checked whenever a user or group submits a job, tries to kill a job, or tries to change its priority. This parameter is set to true by default when security features for your cluster are enabled.
`mapred.queue.<queue-name>.acl-submit-job` *`user1,user2,... group1,group2,...`*	Identifies the users and groups that can submit jobs to the specified *queue-name*.
`mapred.queue.<queue-name>.acl-administer-job` *`user1,user2,... group1,group2,...`*	Identifies the users and groups that can change the priority or kill jobs submitted to the specified *queue-name*. Note that the job owner can always kill his own job or change its priority.

For information on configuring queue properties, see Configuring Properties for Queues. You can also set job initialization parameters for a queue.

Creating Volume-level ACLs

MapR provides volumes as a way to organize data and manage cluster performance. For example, you might want to create a volume for each user, department, or project. You can then create a volume-level ACL that controls which users and groups have access to that volume, and what actions they may perform.

You can create volume-level ACLs from the Control System or from the command line.

Creating Volume-level ACLs from the Control System

- For:
  - New volumes, see Creating a Volume on page 864 to set volume-level ACLs.
  - Existing volumes, see Modifying a Volume on page 892 to modify volume-level ACLs.

Creating Volume-level ACLs from the Command Line

To create an ACL at the command line, use the `acl set` command to specify a list of authorized users (or groups) and the actions they are allowed to perform.

The syntax is:

```
maprcli acl set -type volume -name <volume name> [-user
<username>:<action> -group <groupname>:<action>]
```

Include spaces between multiple entries, such as a list of usernames and their associated permission levels (or *actions*). Each allowed action has a permission code associated with it. The codes are explained below.

Permission Code	Allowed Action
dump	Dump or back up the volume
restore	Restore or mirror the volume
m	Modify the volume's properties
d	Delete the volume

last-updated: Apr 11, 2022

Permission Code	Allowed Action
a	Administrator (can edit and view ACLs, but cannot perform volume operations)
fc	Full control over the volume (this enables all volume-related administrative options with the exception of changing the volume ACLs)

Example

This example shows how to create an ACL for a volume named `test-volume` that allows full control over volume ACLs for user `rjones`. In addition, all users in the `developers` group are given permission to dump, restore, and modify volume properties.

```
maprcli acl set -type volume -name test-volume -user rjones:fc
-group developers:dump,restore,m
```

Managing Access Control Expressions
Defines and describes how to create, enable, and use ACEs.

Access Control Expressions (ACEs) are defined by a combination of user, group, or role definitions.

ACE Syntax
Describes how to construct access control expressions (ACEs).

An *ACE* is defined by a combination of user, group, or *role* definitions. You can combine these definitions using the following syntax:

Operator	Description
u	Username or user ID, as they appear in `/etc/passwd`, of a specific user. Usage: `u:<username or user ID>`
g	Group name or group ID, as they appear in /etc/group, of a specific group. Usage: `g:<group name or group ID>`
r	Name of a specific role. Usage: `r:<role name>`.
p	Public. Specifies that this operation is available to the public without restriction. Cannot be combined with any other operator. API request or CLI command to save such settings will return an error.
!	Negation operator. Usage: `!<operator>`.
&	AND operation.
|	OR operation
()	Delimiters for subexpressions.
""	The empty string indicates that no user has the specified permission.

An example definition is `u:1001 | r:engineering`, which restricts access to the user with ID 1001 or to any user with the role `engineering`.

In this next example, members of the group `admin` are given access, and so are members of the group `qa`:

```
g:admin | g:qa
```

For another example, suppose that you have this list of groups to which you want to give read permissions:

- The `admin` group as a whole, but not the admins for a particular cluster (which is named `cl3`).

last-updated: Apr 11, 2022

- Members of the `qa` group who are responsible for testing the two applications (named `app2` and `app3`).
- The business analysts (group `ba`) in department 7A (group `dept_7a`)
- All of the data scientists (group `ds`) in the company.

To grant the read permission, you construct this boolean expression:

```
u:cfkane | (g:admin & !g:cl3) | (g:qa & (g:app2 | g:app3)) | (g:ba &
g:dept_7a) | g:ds
```

This expression is made up of five subexpressions which are separated by OR operators.

- • The first subexpression `u:cfkane` grants the read permission to the username `cfkane`.
  - The subexpression `(g:admin & !g:cl3)` grants the read permission to the admins for all clusters except cluster `cl3`. The operator `g` is the group operator, the value `admin` is the name of the group of all admins. The `&` operator limits the number of administrators who have read permission because only those administrators who meet the additional condition will have it.

    The condition `!g:cl3` is a limiting condition. The operator `!` is the NOT operator. Combined with the group operator, this operator means that this group is excluded and does not receive the read permission.

    Warning: Be careful when using the NOT operator. You might exclude fewer people than you intended. For example, suppose that you do not want anyone in the group `group_a` to have access. You therefore define this *ACE*: `!g:group_a` You might think that the data is now protected because members of `group_a` do not have access to it. However, you have not restricted access for anyone else except the members of `group_a`. The rest of the world can access the data. You should not define *ACE*s through exclusion by using the NOT operator. You should define them by inclusion and use the NOT operator to limit further the access of the groups or roles that you have included.

    In the subexpression `(g:admin & !g:cl3)`, the NOT operator limits the number of members within the admin group who have access. The `admin` group is included, and all users who are also part of the `cl3` group are excluded.

- The subexpression `(g:qa & (g:app2 | g:app3))` demonstrates that you can use a subexpression within a subexpression. The larger subexpression means that only members of group `qa` who are also members of group `app2` or `app3` have read access to the data. The smaller subexpression limits the number of people who have this permission in the `qa` group.
- • The next two subexpressions -- `(g:ba & g:dept_7a)` and `g:ds` -- grant the read permission to the members of group `ba` who are also in the group `dept_7a`. It also grants permission to the members of the group `ds`.

Creating User Roles for ACEs
Describes how to create and use roles for access control.

Note: MapR recommends that you use Unix Groups over Roles whenever possible, for centralized maintenance. Use Roles only when you are unable to modify LDAP or AD groups easily.

A role is a label attached to a set of users, which defines a common task, or set of behaviors for those users. Roles enable you to use functionality similar to Unix groups for your users, without requiring you to alter the existing group hierarchy of your system. Role names can be up to 64 characters long, and cannot use the `:`, `&`, `|`, or `!` characters.

Standard Reference Implementation
User Information

The standard reference implementation is a library called `libmapr_roles_refimpl.so`. This library is located at `/opt/mapr/server/permissions`. This library opens a configuration file named `m7_permissions_roles_refimpl.conf`, which should contain a list of all the roles, and the users associated with those given roles. This configuration file is located at `/opt/mapr/conf`, and should be identical across all clusters.

The structure of the configuration file is as follows. Roles end with `:`, while user names are written on each subsequent line. For example:

```
Role_1:
            user_a
            user_b
```

```
Role_2:
            user_b
            user_c
            user_d
            #comment
```

This example file states that there are two roles to choose from when assigning permissions - `Role_1` and `Role_2`. The users located under `Role_1` are `user_a`and `user_b`. `Role_2` contains `user_b`, `user_c`, and `user_d`. Blank lines, and lines beginning with # are ignored.

Assume a table has permissions `r:Role_2`. `user_b` has access to this table, while `user_a` does not have access.

After adding a new role to the `m7_permissions_roles_refimpl.conf` file, you must issue the following command to enable the MapR File System layer to pick up the new role: `$ /opt/mapr/server/mrconfig dbrolescache invalidate`

Run this command on all the nodes, whenever there is a change in the roles configuration file.

Developer Information

The functions that the `libmapr_roles_refimpl.so` exposes, are found in the extensibility implementation. When the library is called initially through `GetSecurityMembership`, it parses the `m7_permissions_roles_refimpl.conf` file, and loads it into memory. All user names are read, and parsed into user IDs (uid_t). If a user ID is not found, the ID is skipped.

The library uses a HashTable. The roles are the keys. The values are a Binary Tree of user IDs.

Each call checks the given user ID and role. The HashTable keys off the role, and then searches the Binary Tree for the user ID. If the HashTable finds a user ID, it sets the boolean value of that role to `true`. If the HashTable does not find a user ID, or if any errors occur, such as `Role not found`, it sets the boolean value to `false`.

There is also a cleanup method which frees the memory allocated to the HashTable, along with all of its children. If the `GetSecurityMembership` method is called again, the library reloads the configuration file, and loads all the values into memory.

Extensible Implementation

If users decide not to use the reference implementation, they can replace the shared library with their own. In the `mfs.conf` file, add a parameter that specifies the name of the file. If the name of the file is changed, then MFS searches `/opt/mapr/server/permissions` for the new file. If the file is found, it is loaded into memory. If not, then all roles evaluate to `false`.

The user's shared library should contain two functions specified under the `mapr::fs` namespace:

```
extern "C"
            void GetSecurityMembership(uid_t uid, const char *roles[], int
numRoles, bool truthValue[]) {
            }
```

```
extern "C"
            void cleanup() {
            }
```

`GetSecurityMembership` takes the given user ID along with a list of all the roles, the amount of roles in the array, and an array of all the results, as booleans.

Users must code their own implementation of populating the `truthValue` array with either `true` or `false`. The `truthValue` array has the same length as `numRoles`, and is initialized. Do not modify any other variables.

Use the `cleanup` method to reset the shared library to an initialized state. This method resets all values, and frees memory, since the shared library is not closed, till the class calling it, gets destructed.

Invoke Shared Library from MFS

The `TablePermissions` class handles opening, and closing the shared library. During class initialization, the name of the shared library that is read from the `mfs.conf`, file, is passed to the constructor. The constructor loads the shared library into memory, using the `LoadSO` method from `filterutils.cc`. The constructor also loads the `GetSecurityMembership` method, along with the `cleanup` method, as variables that can be called.

`TablePermissions` contains two methods that can be called, to access the shared library:

- The `GetSecurityMembership` method takes 3 arguments - the user ID, the array of roles, and the amount of roles in the array. This method returns a `RolePermission` structure, which contains all the same data, as well as the boolean of the successful roles for that given user ID. To evaluate the user roles, pass this `RolePermission` structure to the `TablePermission::checkTablePermissions` method.
- The `cleanup` method calls the `cleanup` method in the shared library. This method takes no arguments.

The entity that allocates the `RolePermission` structure into memory, also needs to deallocate this structure.

Deallocating the `TablePermissions` class, calls the `cleanup` method, and closes the shared library.

Shared Library Security

The `/opt/mapr/server/permissions` folder is initialized with `755` permissions. This implies that only the user who installed MapR has access to writing to that folder. These permissions prevent a user from replacing a shared library with a malicious file.

The `m7_permissions_roles_refimpl.conf` file has `755` permission, which means that only an administrator can make changes to this file.

The Roles Library Shared Object and Access Control Expressions

When you access an object that is secured by an *ACE* , the MapR File System layer calls the roles library shared object, and checks the permissions of the entity requesting access against the contents of the roles file. The roles library shared object reads the roles file every 600 seconds. You can specify your own roles

last-updated: Apr 11, 2022

library shared object, and specify the location of that object, using the parameter `mfs.dbroles.sopath` in the `/opt/mapr/conf/mfs.conf` file.

Enabling Volume, Directory, and File Authorizations with ACEs
Describes how to set access control expressions for volumes, directories and files.

*ACE*s allow you to define whitelists (to grant access) and blacklists (to deny access) for a combination of users, roles, and groups. You can grant different permissions to multiple users, groups, and roles for MapR File System files, directories, and whole volume data using boolean expressions and subexpressions.

ACEs for Files, Directories, and Whole Volume

An *ACE* is defined by a combination of user, group, and/or role definitions. You can combine these definitions using the supported syntax. For more information, see Syntax of Access Control Expressions.

The examples in the following table demonstrate how *ACE*s can be used to create whitelists to grant access, and blacklists to deny access.

This Access Control Expression...	Grants access to...	Denies access to...
`(u:u1&g:g1)`	only user 'u1', if user 'u1' is a member of group 'g1'	users who are not 'u1' and members of group 'g1'
`(g:g1&g:g2)|r:r1`	only users who are in both the groups 'g1' and 'g2', or users who are assigned role 'r1'	users who are not in both the groups 'g1' and 'g2', and users who are not assigned role 'r1'
`(g:g1&!g:g2)`	only users who are in group 'g1' and not in group 'g2'	users who are in group 'g2', even if they are in group 'g1', and all other users
`(g:g1|g:g2)`	users who are in groups 'g1' or 'g2' only	users who are not in groups 'g1' or 'g2'
`(g:g1|g:g2)&!r:r1`	only users in groups 'g1' or 'g2' and who are not assigned role 'r1'	users who are not members of groups 'g1' or 'g2', users who are assigned role 'r1', even if they are in group 'g1' or 'g2', and all other users
`(p)`	everyone	none
`(!g:g1&!g:g2&!g:g3)`	users who are not in groups 'g1', 'g2', and 'g3'	only users who are in groups 'g1', 'g2', or 'g3'
`((u:u1|u:u2|u:u3)&g:g1&g:g2)&!r:r1`	only users 'u1', 'u2', or 'u3', who are also members in groups 'g1' and 'g2', but not assigned role 'r1'	users who are not 'u1', 'u2', or 'u3' and members of groups 'g1' and 'g2', and users who are assigned role 'r1'
`(u:u1|u:u2|u:u3)&g:g1|g:g2`	only users who are 'u1', 'u2', or 'u3' and who are members in groups 'g1' or 'g2'	users who are not 'u1', 'u2', or 'u3' and members of groups 'g1' or 'g2'

Note: The entities — user, group, role, and public — must be the same for MapR File System and MapR Database *ACE*s.

Managing File and Directory ACEs
Describes the implications of setting access control expressions on files and directories.

File *ACE* allows you to define access (whitelist and blacklist) to files and directories for a combination of users, groups, and roles. If *ACE*s are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set *ACE*s, MapR sets or resets the corresponding POSIX mode bits to match the permissions granted through *ACE*s. For more information, see Setting/Modifying File and Directory ACEs.

last-updated: Apr 11, 2022

- If both *ACE*s and POSIX mode bits are set, access is granted if access is allowed through *ACE*s or POSIX mode bits.
- If *ACE*s are not set, POSIX mode bits are used to grant access.
- If neither *ACE*s nor POSIX mode bits are set, access is denied.

The owner of the file or directory (and mapr and root users) can set, modify, and remove *ACE*s for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files using the `hadoop mfs` command or the FileACE Java APIs on page 1457 and FileACE C APIs on page 1457. Specifically, the following access types are supported.

Access Type		Description
Command-Line	**Java API (Enum)**	
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.

For more information, see `hadoop mfs`, FileACE Java APIs on page 1457, and FileACE C APIs on page 1457.

Directory ACEs

You can set the same *ACE*s on directories as for files. In addition, directory *ACE*s support permissions to list, add child, delete child, and lookup directories using `hadoop mfs` command. Specifically, the following access types are supported.

Access Type		Description
Command-Line	**Java API (Enum)**	
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.
`-readdir`	`READDIR`	List the contents of a directory. This access is required to write and/or execute files in the directory.
`-lookupdir`	`LOOKUPDIR`	Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory.
`-addchild`	`ADDCHILD`	Add a file or subdirectory.
`-deletechild`	`DELETECHILD`	Delete a file or subdirectory.

Although you can set both file and directory *ACE*s on directories, only the directory *ACE*s are used for determining access to the directory. The file *ACE* on the directory is used as the default *ACE* setting for new files under that directory.

By default, when you set *ACE*s on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.

last-updated: Apr 11, 2022

- New files under that parent inherit the file *ACE*s and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default *ACE*, the empty string (""), which indicates that no one has permissions to read, write, or execute the file; POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file *ACE*s and corresponding POSIX mode bits from the parent directory.

Note: When accessing files and directories, the *ACE*s on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACES are set on an executable file

When *ACE*s are set on any file, mode bits are cleared. However, for a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with *ACE*s set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRAces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set access control expressions (ACEs) for files and directories.

For files and directories, run the `hadoop mfs` command to set *ACE*s. When *ACE*s are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding *ACE*s. POSIX mode bits for others is set only if `"p"` is given as the value for an *ACE*.

The following table lists the POSIX mode bits that correspond to the access types.

	ACE	POSIX Mode Bits
File	`readfile`	r
	`writefile`	w
	`executefile`	x
Directory	`readdir`	r
	`addchild`	w
	`deletechild`	w
	`lookupdir`	x

The POSIX mode bit granting write (`w`) access to directory is set only if user, role, or group is granted permission for both (`addchild` and `deletechild`) access types.

The `hadoop` command, by default, sets the POSIX mode bits corresponding to the given *ACE*s, and:

- Overwrites existing *ACE* values with new values, if specified, for access types that were previously set.
- Sets *ACE* values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, whether or not they were previously set.

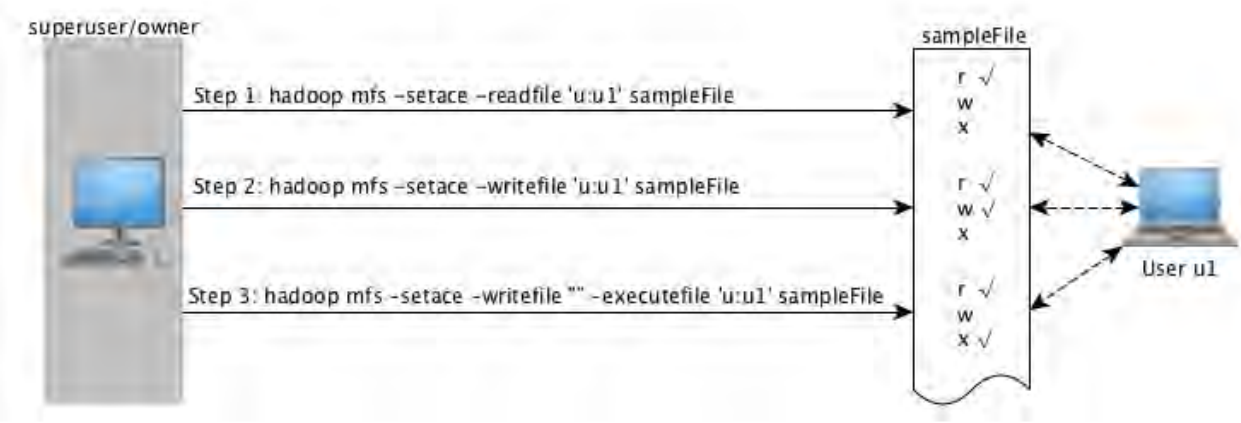
last-updated: Apr 11, 2022

Warning: Changing the POSIX mode bits using `chmod` does not change the corresponding *ACE* setting and may result in different, conflicting permissions to files and directories.

File ACE Example

Illustrates setting access control expressions for files.

Suppose the following sequence of file *ACE* settings (and corresponding POSIX mode bits) are set for user u1.



As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, `sampleFile`.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (write and execute) access types.

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

Note: When the empty string ("") is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`).

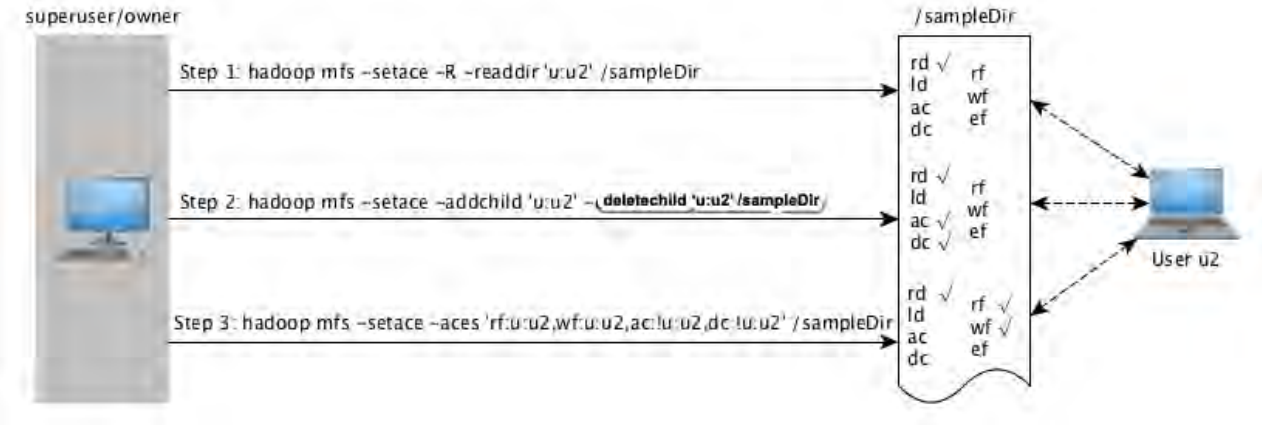
last-updated: Apr 11, 2022

There is no change in *ACE*s or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory *ACE* settings for user u2:



As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory, and sampleDir, while all other directory/file *ACE*s are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (`r`) is set to u2 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.

Step 2:

User u2 is granted permission only to add and delete child directories, while all other directory/file *ACE*s are not specified.

After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (`w`) to the directory for owner/user is set to u2 because user u2 is granted access for both (`addchild` and `deletechild`) access types.

If user u2 creates child directories, the child directories, by default, inherit the *ACE* settings of the parent directory.

There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.

Step 3:

User u2's permissions are modified to grant access to read and write to files in the directory, user u2's permissions for adding and deleting child directories are removed (using the negation operator), and all other directory/file *ACE*s are not specified.

After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add

last-updated: Apr 11, 2022

and delete child directories. The POSIX mode bits for directory write access (`w`) is set to 0 for owner/user.

Although, at the directory level, user u2 has permissions to read and write to files in the directory, for existing files, the file level *ACE*s or the POSIX mode bits for the file are used to determine access. However, by default, user u2 gets read and write permissions to all new files created under the directory. If user u2 creates new files under the directory, the files inherit the file *ACE*s from the parent directory by default and the POSIX mode bits for read (`r`) and write (`w`) access are set to u2 for owner/user.

There is no change in *ACE*s or POSIX mode bits for all other (`lookupdir` and `executefile`) access types.

Deleting File and Directory ACEs
: Describes how to delete file and directory ACEs using the CLI.

  You can remove all *ACE* associated with a file or directory using the `hadoop mfs -delace` command. When you delete all the *ACE*s, the system sets the *ACE* for the file or directory to the default value, which is the empty string (""). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

  You cannot remove specific access types that have been set; instead, use the empty string to deny specific types of access. When the empty string ("") is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`). If you use the empty string ("") or the negation operation (`!`) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the *ACE* setting.

FileACE Java APIs
: Contains the path to the Java FileACE APIs.

  The Java FileACE APIs are located at File ACE APIs.

FileACE C APIs
: Describes the C FileACE APIs.

  The FileACE C APIs are defined in the header file `hdfs.h` and are as follows:

  hdfsSetAces

  Sets the ACEs for a file or directory.

  Syntax

```
int hdfsSetAces(hdfsFS fs, const char *path, hdfsFileAces *faces, int
isSet, int isRecursive);
```

  Parameters

  - fs: The configured filesystem handle
  - path: The path to the file or directory for which the ACEs need to be set.
  - faces: The ACEs to set
  - isSet: Set to 0 to merge with any existing ACEs, or set to 1 to replace all existing ACEs.
  - isRecursive: Set to 1 to apply ACEs recursively when setting on a directory.

  Return Value

0 on success, else an error code.

hdfsGetAces

Gets the ACEs from a file or directory.

Syntax

```
int hdfsGetAces(hdfsFS fs, const char *path, void *aceBuf, int bufLen,
hdfsFileAces *faces);
```

Parameters

- fs: The configured filesystem handle
- path: The path to the file or directory from which the ACEs need to be fetched.
- aceBuf: The buffer to hold the ACEs.
- bufLen: Length of the ACE buffer (*aceBuf*)
- faces: The structure that contains the returned ACEs.

Return Value

0 on success, else error ERANGE, which indicates that the buffer is too small to hold the ACE entries.

hdfsDeleteAces

Deletes all ACEs from a file or directory.

Syntax

```
int hdfsDeleteAces(hdfsFS fs, const char *path);
```

Parameters

- fs: The configured filesystem handle
- path: The path to the file or directory from which the ACEs need to be deleted.

Return Value

0 on success, else an appropriate error.

Managing Whole Volume ACEs

Describes how to grant permissions to users, groups, and roles for the volume data using whole volume access control expressions (ACEs).

Whole volume *ACE*s allow you to define whitelists to grant access, and blacklists to deny access, for files and tables within a volume.

Volume administrators and mapr user can set and modify whole volume *ACE*s. By default, *ACE*s grant everyone access to read and write to files and tables in the volume at the volume-level; however, inside the volume, to determine access for:

- Files, the file *ACE*s or POSIX mode bits are used.
- Tables, the table *ACE*s are used.

Supported Access Types

At the volume level, the following access types are supported:

Access Type	Description
`-readAce`	Read files, MapR Database binary tables, MapR Database JSON tables, and MapR streams in the volume. By default, this is set to p to grant all users this permission.
`-writeAce`	Write to files, MapR Database binary tables, MapR Database JSON tables, and MapR streams in the volume. By default, this is set to p to grant all users this permission.

ACE Behavior on Snapshots and Mirrors

Volume Snapshots

Volume snapshots reflect the *ACE*s of the volume at that point in time. Changes in volume *ACE*s:

- Are carried over to a new snapshot of the volume.
- Do not propagate to older snapshots of the volume.

Volume Mirrors

*ACE*s of a volume are propagated to mirror volumes. After each mirroring operation, mirror volumes reflect the current *ACE* setting of their source volume. After a mirror volume is promoted to a read-write volume, you can modify the *ACE*s on the mirror volume from the command line. *ACE*s on the promoted mirror volume can be different from the source volume.

Setting Whole Volume ACEs

Describes how to set ACE expressions when creating or modifying volumes.

You can set *ACE*s at the time of volume creation using the `volume create` on page 1931 command and modify them at a later time using the `volume modify` on page 2005 command. When you run the command to set or modify *ACE*s, the command does the following:

- Overwrites existing values with new values, if specified, for access types that were previously set.
- Sets values for access types that have not yet been set, if specified.
- Does not modify access types that were not specified with the command, whether they were previously set or are unset.

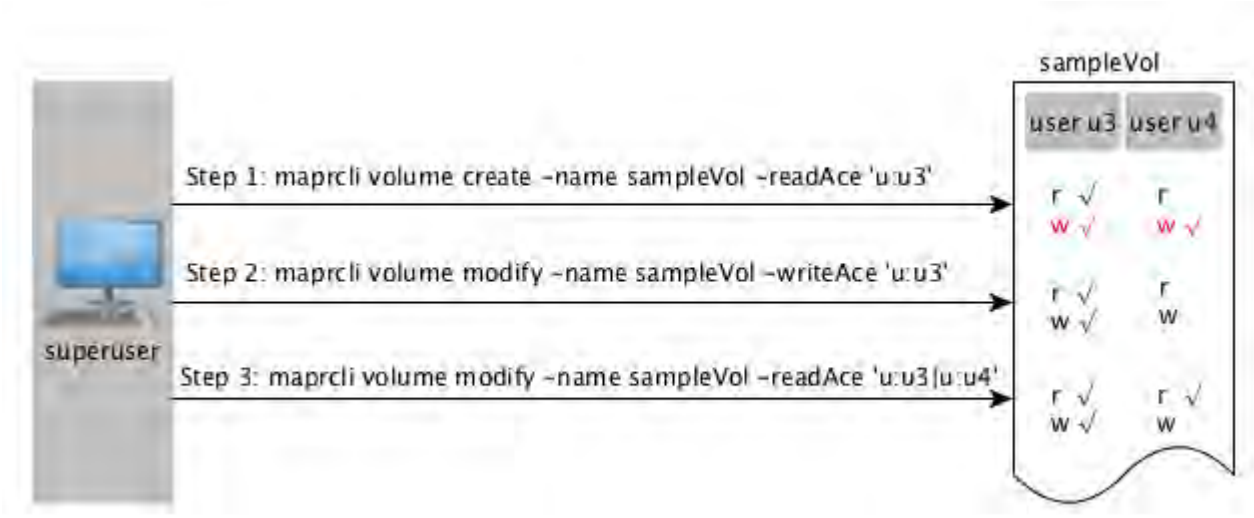
When you set whole volume *ACE*s, permissions on files and tables under that volume remain unchanged. Also, new files and tables in the volume do not inherit the whole volume *ACE*s of that volume. Instead, whole volume *ACE*s, if set, are used to determine volume level access to tables and files within the volume. To gain access to volume data, the user must have access at both the volume and file/table levels.

Whole Volume *ACE* Example

For example, suppose the following sequence of whole volume *ACE* settings for users u3 and u4 is as follows.

Note: In the following illustration, default *ACE* values are shown in red.

last-updated: Apr 11, 2022



As shown in the illustration above, in:

Step 1:

User u3 is granted permissions to read.

User u3: User u3 has permissions to read files and tables at the volume level and by default, user u3 has write permission (shown in red) at the volume level. However, for:

- Files in the volume, file *ACE* or POSIX mode bits are used to determine read and write access for user u3.
- Tables in the volume, table *ACE*s are used to determine read and write access for user u3.

User u4: User u4 cannot read files and tables within the volume because the *ACE* for the volume does not explicitly grant access to user u4. Although user u4 has write permission by default, user u4 cannot write to files/tables in the volume because user u4 does not have read permission.

Step 2:

User u3 is granted permissions to write.

User u3: User u3's read access remains unchanged and although user u3 has permissions to write to files and tables, for:

- Files in the volume, file *ACE* or POSIX mode bits are used to determine write access for user u3.
- Tables in the volume, table *ACE*s are used to determine write access for user u3.

User u4: User u4 cannot write to files/tables in the volume.

Step 3

User u4 is granted read access.

User u3: User u3's read and write access remains unchanged.

User u4: User u4 has permissions to read files and tables at the volume-level; however, for:

last-updated: Apr 11, 2022

- Files in the volume, file *ACE* or POSIX mode bits are used to determine read access for user u4.
- Tables in the volume, table *ACE*s are used to determine read access for user u4.

Deleting Whole Volume ACEs

You cannot remove ACEs that have been set; instead, if necessary, use the empty string (`""`) to deny specific types of access. If the empty string is used to deny a specific type of access, that type of access is denied to all users. To deny access to specific users only, use the negation operator (`!`).

Enabling Table and Stream Authorizations with ACEs

Permissions for MapR tables, column families, and columns are defined by Access Control Expressions (ACEs). You can set permissions for tables when you create or edit tables. You can set default permissions for column families when you create or edit tables, and you can override these defaults when you create column families.

For the syntax to use when creating Access Control Expressions, see ACE Syntax on page 1448.

When a user, group, or role requests to read data from, write data to, or append data to a column, MapR Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. MapR Database checks whether this user has write permission on `cf1` AND `col1` AND `col2`. If the user does not have all three permissions, MapR Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, MapR Database would simply not return the data. If the user tried to read from those two columns and additional columns on which he had read permissions, the results would contain the data for those additional columns but exclude the data for `col1` and `col2`.

Note: Table Permissions for Older Releases: Because MapR tables are stored at the file-system level, you can also set permissions for MapR Database tables directly in the file system, if your version of MapR does not support Access Control Expressions (ACEs). Support for ACEs was introduced in version 3.1.

To set permissions directly in the filesystem, see Performing File System Operations on MapR Database Tables on page 1041.

Setting Table ACEs Using the CLI

You can set ACEs with the following commands:

- `table create` on page 1788 — Creates a new MapR table.
- `table edit` on page 1822 — Edits a MapR table.
- `table cf create` on page 1799 — Creates a column family for a MapR table.
- `table cf edit` on page 1806 — Edits a column-family definition.
- `table cf colperm set` on page 1795 — Set Access Control Expressions (ACEs) for a specified column.

Setting Stream ACEs Using the CLI

You can set ACEs with the following commands:

- `stream create` on page 1758 — Creates a new MapR stream.
- `stream edit` on page 1765 — Edits a MapR stream.

Permission Types for Fields and Column Families in JSON Tables

By using access-control expressions (ACEs), you can grant or deny access to fields and column families that are in JSON tables.

For an explanation of the syntax of ACEs, see ACE Syntax.

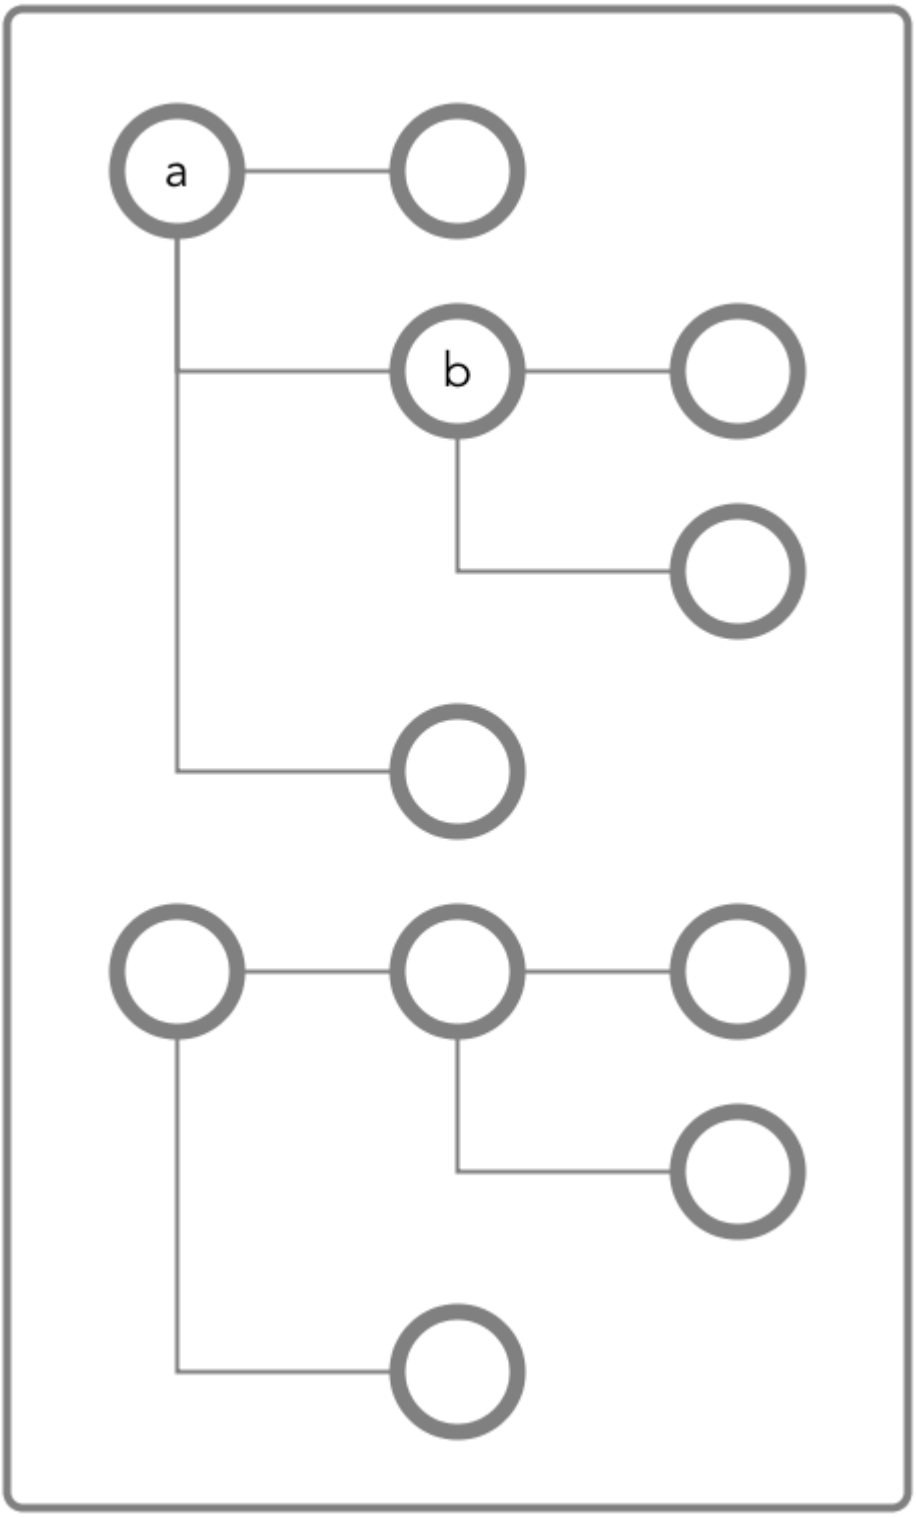
There are three types of permission:

- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access the fields that the grantee has write or read permission on.

For example, suppose that a user has read and write access only on field b in this document.

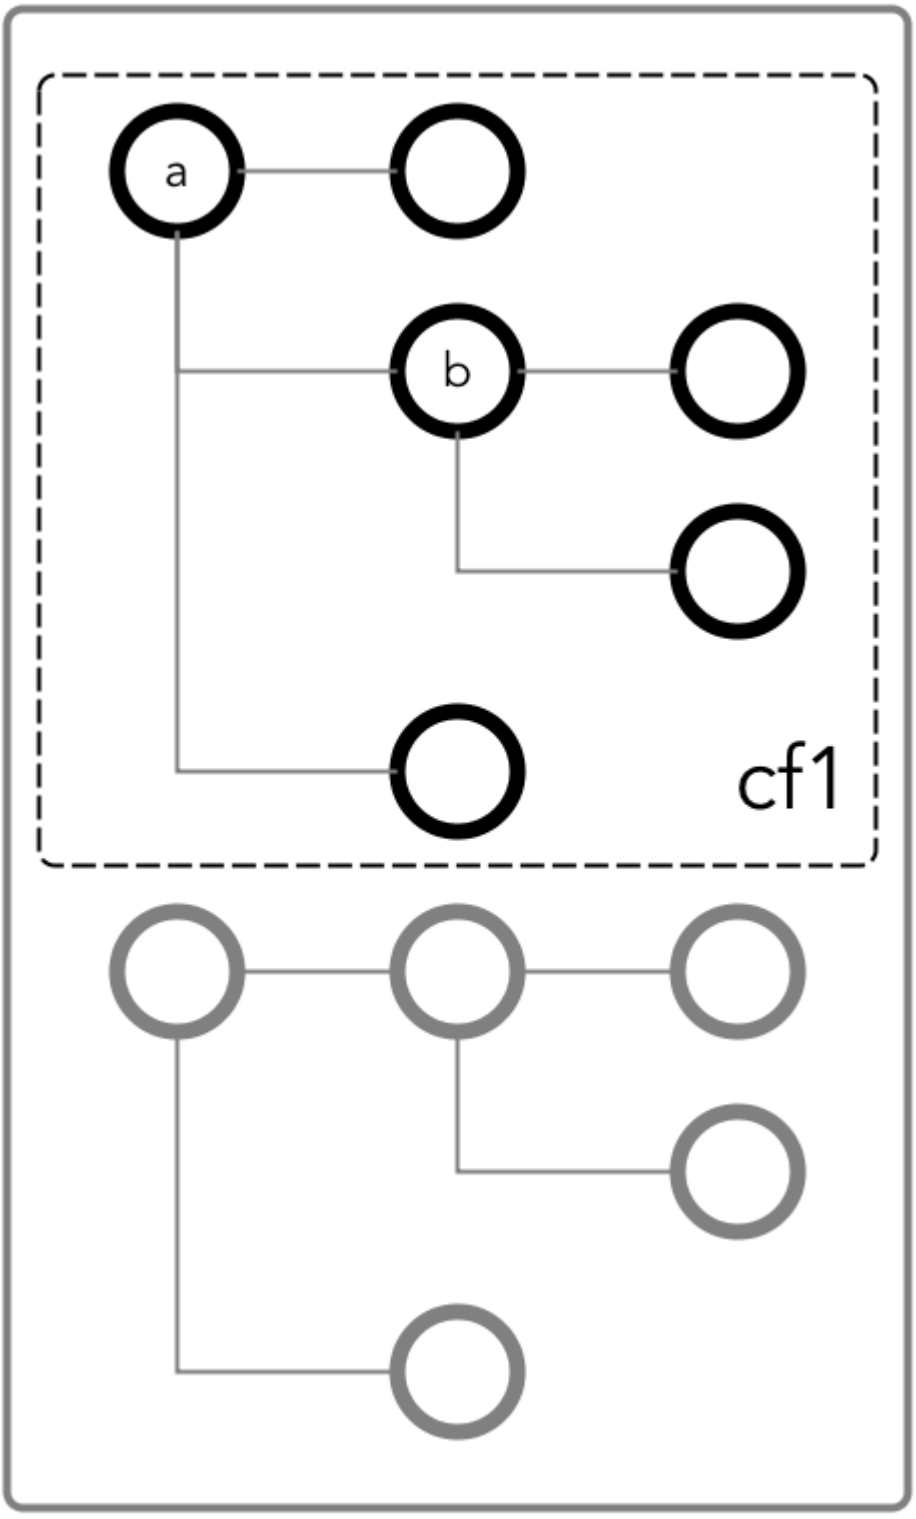


To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If traverse permission on the default column family were denied the user, it would not be possible for the user to access field b. Granting traverse permission on field a in this case would have no effect.

last-updated: Apr 11, 2022

In the next example, field a is a column family named `cf1`.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

Read (`readperm`)

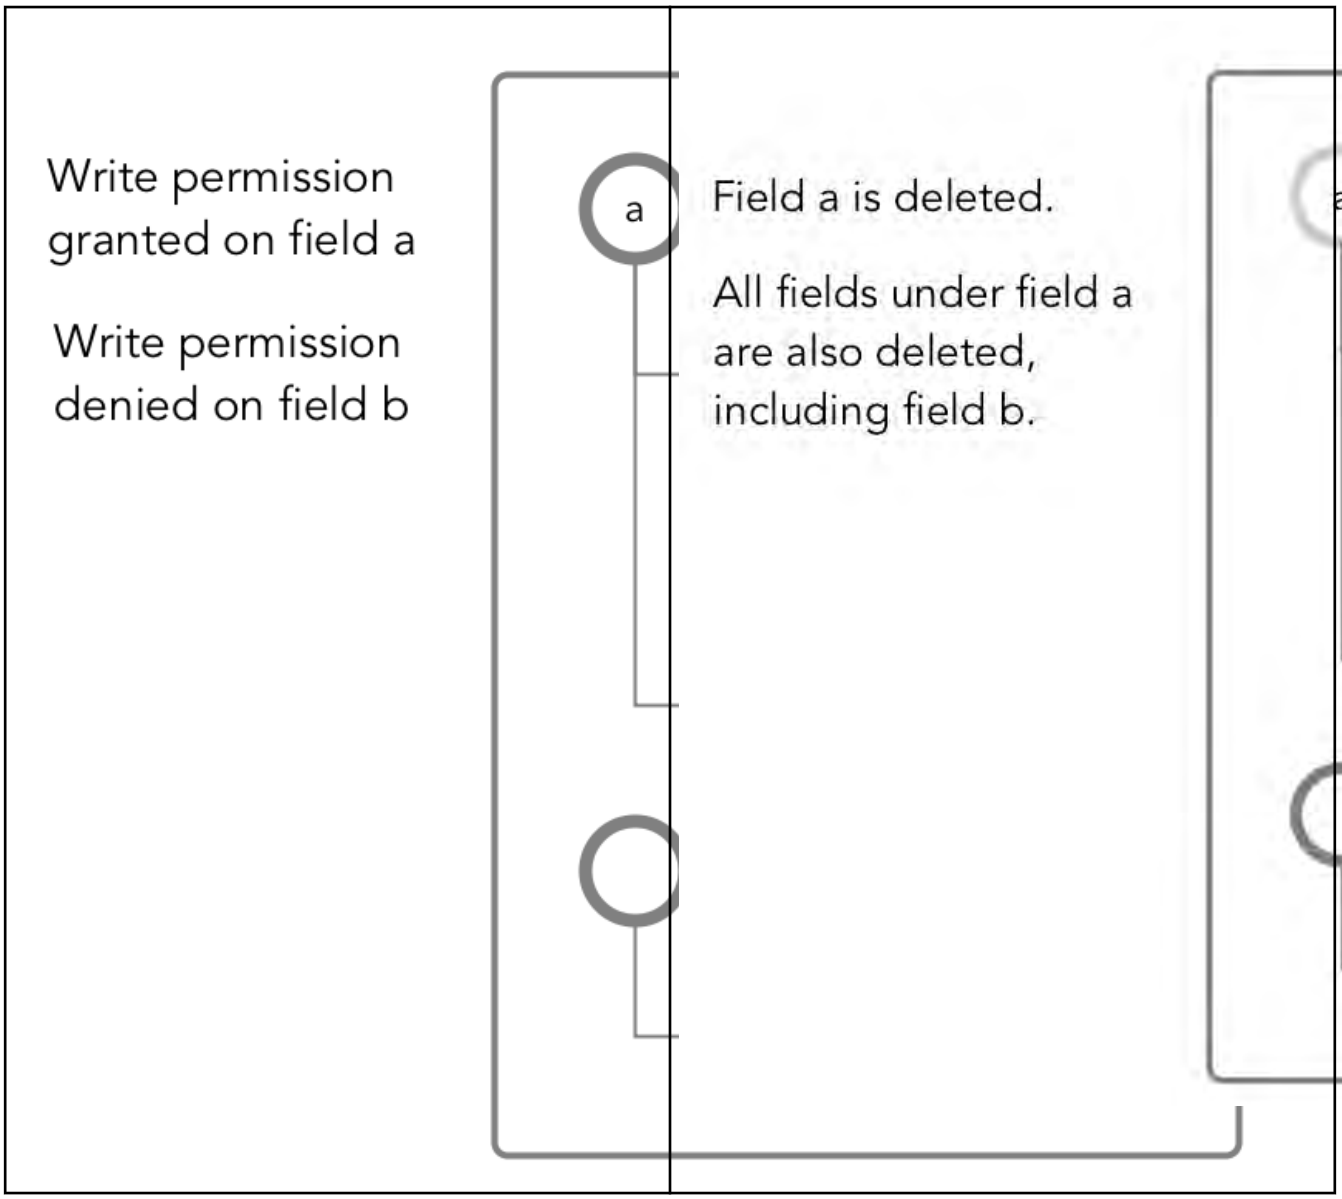
This permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field that the permission was granted on. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite a field's value.

As illustrated in the following two diagrams, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Obtaining `readperm` and `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

last-updated: Apr 11, 2022

When the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

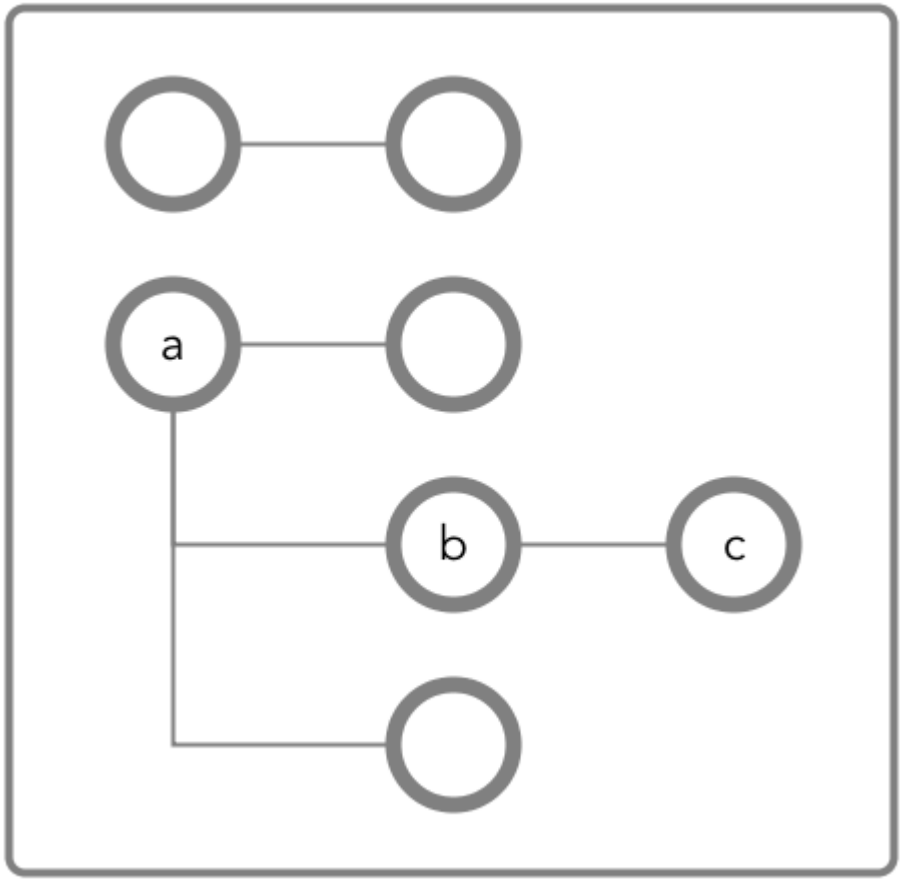


Figure 19: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field c.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of MapR Database's native JSON support. For information about them, see Column Families in JSON table.

In the following document, you want to perform an operation on field c, which is in the column family `cf1` that is defined at field b with the path `a.b`.

last-updated: Apr 11, 2022

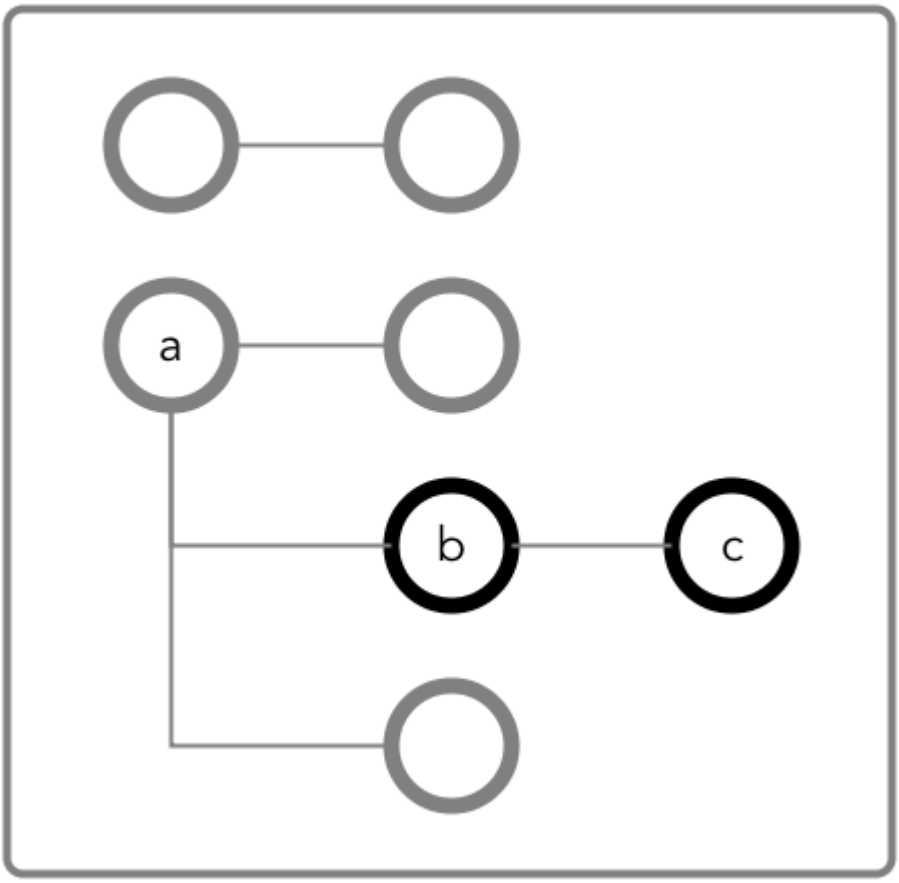

Figure 20: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`	You need `traverseperm` on field b and both `readperm` and `writeperm` on field c. You can be granted these permissions with commands similar to these:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field> -writeperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have `readperm` and `writeperm` on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Obtaining `readperm` or `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the following document, you want to perform an operation on field `c`, which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

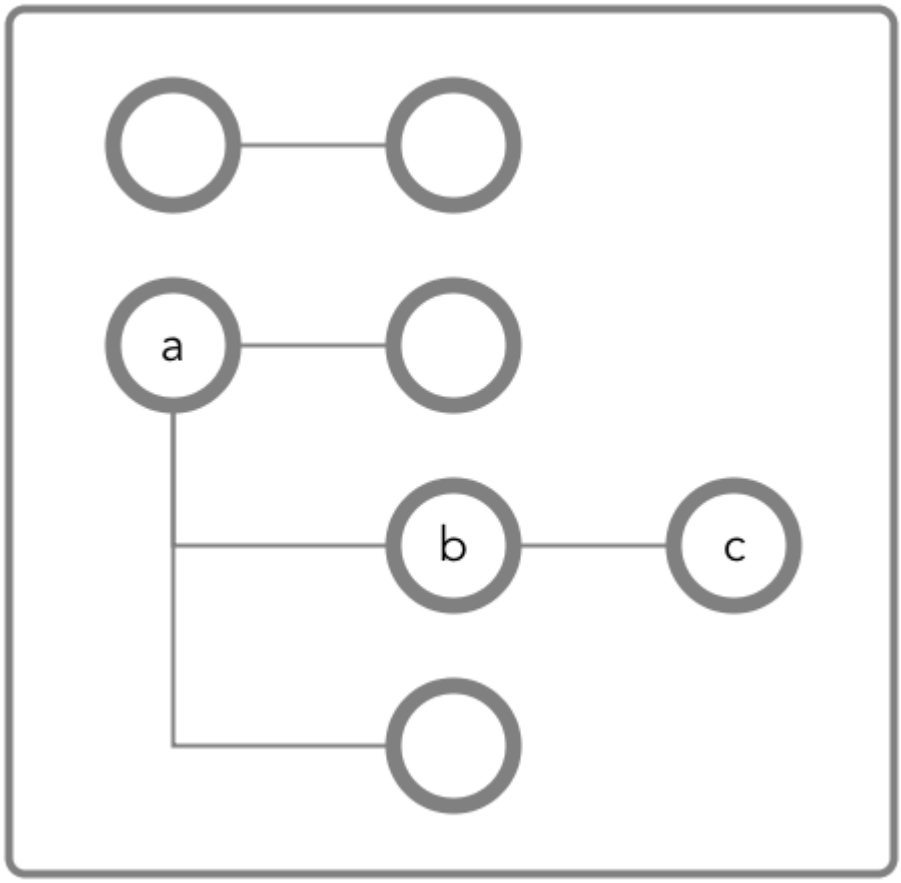

Figure 21: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family

In this case, field `c` inherits the permission, assuming that the permission was not denied on field `a` or `b`.

If you do not have `readperm` or `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b -traverseperm
```

```
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of MapR Database's native JSON support. For information about them, see Column Families in JSON Tables.

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field `b` with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

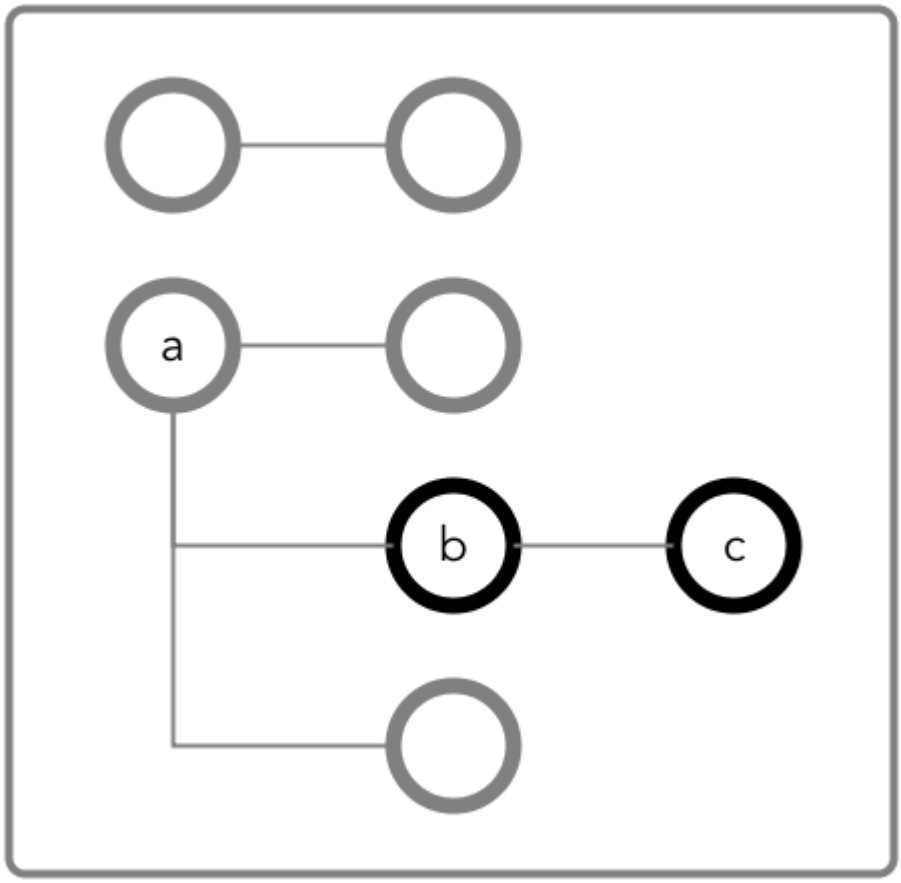

Figure 22: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`	You need `traverseperm` on field b, and you need `readperm` or `writeperm` granted to you explicitly on field c.
	Example commands to grant these permissions:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Setting Permissions on Arrays

When granting permissions on a field, if the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

Note: This topic describes the behavior of permissions in MapR Database version 6.1 and later, regardless of the MapR version you used to grant the permissions. To understand how permissions on arrays behave in earlier releases, see Operational Changes (MapR 6.1.0) - Permissions on Arrays in MapR Database JSON.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person`, to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents, for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

last-updated: Apr 11, 2022

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables

This page summarizes the default access-control expressions for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	`-defaultreadperm -defaulttraversepe rm -defaultwriteperm`	`u:<ID of the process>`
	`maprcli table create`		`u:<user ID of table creator>`
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	`maprcli table edit`		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	`maprcli table cf create`	`-readperm -traverseperm -writeperm -indexperm`	ACEs for `-defaultreadperm`, `-defaulttraverseperm`, and `-defaultwriteperm`
	Control System		
Set permissions on a column family when editing the column family.	`maprcli table cf edit`		Current ACEs
	Control System		
Set permissions on individual fields.	`maprcli table cf colperm set`		Inherited from column family or parent field
	Control System		

Defining ACEs

Indicates how to build access control expressions (ACEs) using the Expression Builder.

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.

   Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and/or role to access the volume.
Any	OR (|) operation	Indicates that any one of the conditions must be met for public or user, group, and/or role to access the volume.

last-updated: Apr 11, 2022

2. Click:

+	To add an expression.
( )	To add a subexpression.
x	To remove an expression or subexpression.

3. Select Public or User, Group, or Role from the drop-down menu and:
   a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
   b) Enter name of the user, group, or role.
4. Click **Save Changes** to create an Access Control Expression.

Setting Whole Volume ACEs Using the CLI

See Setting Whole Volume ACEs on page 1459.

Setting Table ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Setting Stream ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Creating Subnet Whitelists

Provides the procedure necessary to restrict access to cluster data.

To provide additional cluster security, you can limit cluster data access to a whitelist of trusted subnets. The `mfs.subnets.whitelist` parameter in `mfs.conf` accepts a comma-separated list of subnets in CIDR notation. When this parameter is set, the FileServer service only accepts requests from the specified subnets.

1. Edit `/opt/mapr/conf/mfs.conf` and modify the `mfs.subnets.whitelist` parameter.
2. Add a comma-separated list of subnets in CIDR notation.
3. Restart the FileServer.

Customizing Security in MapR

Describes the `.customSecure` file and how MapR 6.x handles custom security settings.

This topic contains the following subsections:

Note: Implementing custom security is not recommended unless your installation demands it. Using the custom security option means that MapR software does not ensure that your system is secure by default, and that you need to manually perform all security configuration.

In MapR 6.x, the configure.sh script detects that a cluster is in one of three security states:

Secure	The cluster is configured with the default MapR security settings.
Unsecure	No security settings are configured for the cluster.
Custom secure	The cluster has a mixture of MapR security settings and custom settings.

Understanding how `configure.sh` handles custom security settings is important when you upgrade a cluster, add services, add nodes, or change security settings.

What is Custom Security?

Any change to the default MapR configuration for authentication, authorization, or encryption represents a "custom security" change. Users who make such changes are encouraged to create a `.customSecure` file to ensure that `configure.sh` does not remove these changes. Custom security changes include any change to the keystore or truststore passwords or the number of keys in those files or the names of the keys.

Other examples of custom security changes include:

- Implementing Kerberos security
- Changing the Hive authorization model
- Changing the Oozie authorization model

Identifying the Current Security State of the Cluster

If the current security state of the cluster (secure, unsecure, or custom secure) is unknown, you can use one of these checks to identify which state the cluster is in:

- Check the security value in the `/opt/mapr/conf/mapr-clusters.conf` file. For example:

  ```
  <clustername1> secure=true <CLDB> <CLDB> … <CLDB>
  ```

  For more information, see mapr-clusters.conf on page 2200.

- Check for the presence of the `.customSecure` file:

  ```
  /opt/mapr/conf/.customSecure
  ```

  If the file is present, `configure.sh` treats the cluster as custom secure.

About the .customSecure File

If you customized the security settings for your cluster and you want to ensure that `configure.sh` does not change any of the settings, you can create a `.customSecure` file. Create the file in the following location on every node:

```
/opt/mapr/conf/.customSecure
```

The `.customSecure` file does not contain any information. The presence of the file tells `configure.sh` that the cluster has security settings that must not be changed by `configure.sh`.

Typically, you create the `.customSecure` file manually. However, in some cases, `configure.sh` creates or removes the `.customSecure` file for you. For example, if `configure.sh` detects that it is being run after an upgrade from a MapR 5.x secure cluster, it creates the `.customSecure` file automatically. If you use the `-forceSecurityDefaults` option and `-secure` or `-unsecure` with `configure.sh`, the script removes the `.customSecure` file because you are forcing the removal of custom security settings.

last-updated: Apr 11, 2022

Forcing a Change to the Security Configuration

If your MapR 6.x cluster has custom security settings (the `.customSecure` file is present), and you want to change to the default MapR secure or non-secure settings, you can use the `-forceSecurityDefaults` option of `configure.sh` to make the change. Note these considerations:

- Using the `-forceSecurityDefaults` option removes the `.customSecure` file. You must specify the `-secure` or `-unsecure` option with `-forceSecurityDefaults`. Otherwise, the command will have no effect.
- The `-forceSecurityDefaults` option might not remove all of your custom settings. Some manual editing might be necessary to return the cluster to a usable state.
- When forcing a custom-secured cluster to be MapR secure, you still need to include other `configure.sh` options that are required for security. And you need to perform any steps required to add security. For example, see Enabling Wire-level Security on page 1411.

Custom Security and the MapR Installer

Using the MapR Installer or MapR Installer Stanzas is not supported on clusters with custom security or customized configurations.

Adding a Node to a Cluster with Custom Security

Adding a node to a cluster with custom security is similar to adding a node to a cluster with MapR security, but there are some additional steps:

1. Add the node with default MapR security as described in Adding Nodes to a Cluster on page 807.
2. To support your custom security mode, copy any custom resources or settings as needed from existing nodes to the added node.
3. Create the `/opt/mapr/conf/.customSecure` file on the added node:

   ```
   /usr/bin/touch /opt/mapr/conf/.customSecure
   ```

Adding a Service to a Cluster with Custom Security

If you add a new service (ecosystem component) to a secure or custom-secure cluster, `configure.sh` configures the service for MapR security automatically. If the cluster is custom secure, you need to change the security settings for the service to be compatible with the current cluster settings and restart the service. Any subsequent use of `configure.sh -R` will leave the customization in place.

Managing Impersonation

Provides instructions for enabling and using MapR impersonation features.

Impersonation, also known as identity assertion, is one user accessing data and submitting jobs on behalf of another user. Impersonation in MapR allows centralized control of access to resources in the MapR File System and MapR Database.

Example: Access Control and Impersonation

As an example of impersonation, consider user Bob and a generic Service X:

1. Bob launches a client for the service and may or may not provide credentials.
2. Service X authenticates Bob and establishes a connection for him to use.

3. Bob issues a command to the service that will produce a query.
4. The service uses any user's servicewithimpersonation ticket to authenticate with the datastore - MapR File System/MapR Database.
5. The datastore authenticates the user with the impersonation ticket - the service can now proceed.
6. The service sends the datastore a query, as user Bob.
7. The datastore checks permissions for Bob on the assets that the query will access.
8. If Bob has permissions, the datastore returns the query results to the service, which relays the results to the client, and the query succeeds.
9. If Bob does not have permissions, the datastore sends an access error to the service, which relays the error to the client, and the query fails.

When you use impersonation in MapR:

- The datastore permissions are authoritative.
- The process has end-to-end security.
- Users can do nothing more and nothing less than what they are authorized to do.
- This control is independent of remote authentication and security mechanisms that control user access to application features.
- Any permissions set up within applications, or within the UNIX filesystem permissions on servers where MapR components reside, have no effect on user access to MapR resources.
- The mapr superuser is allowed to impersonate any MapR user in any group, connecting from any host. Other users with impersonation capability can impersonate any MapR user in any group, except the mapr superuser and the root user.

Using Impersonation without Security

Although it is possible to enable impersonation in a non-secure MapR installation, MapR strongly recommends against doing this. The implementation rules are different, and setting up the MapR environment with impersonation operating under those rules makes it very difficult to enable security at a later date. Disabling security in a secure MapR installation is easy, if the need arises.

If you choose to implement impersonation in a non-secure MapR cluster, see Configuring Impersonation when Cluster Security is not Enabled.

Using Impersonation with Security

In general, this documentation assumes that security is enabled in your MapR installation. See Enabling Wire-level Security on page 1411 and Enabling Encryption of Data at Rest on page 1413.

You can use the `maprlogin` utility to generate a **servicewithimpersonation** ticket that can be used to access a secure cluster impersonating another user. That is, the **servicewithimpersonation** ticket provides the user the ability to impersonate other users (except the mapr user) in addition to the ability to access a secure cluster. The servicewithimpersonation ticket generated with the list of `impersonatedgids` and `impersonateduids` cannot be used to impersonate user root or user mapr. If the user is other than root or mapr, CLDB resolves the username to UID locally and then checks if the resolved UID can be impersonated (i.e., if it is a part of the ticket's `impersonateduids`) or at least one of the GIDs of the resolved UID can be impersonated (i.e., if at least one of the GIDs should be part of the ticket's `impersonatedgids`). The servicewithimpersonation ticket can only be generated by a user with full control on a cluster's Access Control List (ACL).

If you are setting up user impersonation in a secure cluster, you need to generation an impersonation ticket. See the *Generating and Printing Service with Impersonation Ticket* section in the maprlogin Command Examples on page 2134 topic and Generating a Service with Impersonation Ticket on page 1428 for information on generating an impersonation ticket.

After generating the ticket:

1. Ensure that mapruser1 has read permissions on the ticket.
2. If you moved the ticketfile to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable.

How Impersonation Works
Introduces impersonation functionality, limitations, and core requirements.

When a user attempts to impersonate another user to the MapR File System or MapR Database systems and the configuration parameters for resolving the UID and GIDs on the server (see Resolving Username with UID and GIDs During Impersonation) are disabled:

1. The MapR client looks for that user name in the local operating system registry.
2. If the user name is:
   - Found, MapR sends the user's UID and GID to the server for impersonation.
   - Not found in the local operating system registry, the user action is not processed.

When a user attempts to impersonate another user to the MapR File System or MapR Database systems and if the configuration parameters for resolving the UID and GIDs on the server (see Resolving Username with UID and GIDs During Impersonation) are enabled:

1. The MapR client asks CLDB to look for that user name and resolve the UID and GIDs for that user on the server.
2. If the user name is:
   - Found on the server, the server allows the user to proceed with the impersonation.
   - Not found, the user action is not processed.

Note: If the configuration property for resolving the username is set on the client and the configuration property for resolving the username is not set on CLDB, the operation will fail with an error.

Limitations on Impersonation
Service with impersonation tickets cannot be used to impersonate user mapr or user root. A scoped service with impersonation ticket cannot contain the UID of user root or user mapr (in the impersonated UIDs) and the GID of user root or user mapr (in the impersonated GIDs). User mapr can impersonate any user, including user root.

Core Requirements for Impersonation

The mapr superuser is allowed to access to the MapR File System and MapR Database systems. The following conditions must be met in order for the mapr superuser to be able to impersonate another MapR user:

1. The `hadoop.proxyuser.mapr.groups` and `hadoop.proxyuser.mapr.hosts` parameters must be set correctly in the `core-site.xml` file.

   See Enabling Impersonation for the mapr Superuser.

   These settings are not always required. The hadoop proxy user functionality is only applicable to ecosystem components included in the MapR distribution for Apache Hadoop. If the MapR client accesses an ecosystem component, such as HiveServer2, these settings may be required. These settings are never needed when the MapR client accesses MapR File System or MapR Database directly. Enabling impersonation here ensures that the correct settings are in place if they are needed.

2. The name of the MapR user that you want the mapr superuser to be able to impersonate must appear in the local operating system registry where the MapR client is running if server-side resolution of UID and GIDs is not enabled.

3. The UID and GUID of the user name under which the MapR client is running must match exactly the UID and GUID for that user name on the server.

Note: The user mapr can impersonate any user, including user root.

For all other users with access to the MapR File System and MapR Database systems, the following conditions must be met for the user to impersonate another user.

1. A valid servicewithimpersonation ticket must be present for the user who intends to impersonate on the system.

2. The name of the MapR user to impersonate must appear in the local operating system registry where the MapR client is running if server-side resolution of UID and GIDs is not enabled.

3. The UID and GUID of the user name under which the MapR client is running must match exactly the UID and GUID for that user name on the server.

Note: If a user is not authorized to impersonate, then the operations will proceed as the user, not the target user, and some operations will succeed, and some will not even if the user has all the permissions for these operations. Also, if a user with full access and impersonating capability tries to impersonate another user, the operations will succeed only if the target user has permissions on the directory.

Component Requirements for Impersonation

Some MapR ecosystem components have additional requirements to enable impersonation.

The following components must have settings that support impersonation in the configuration files indicated, on each node where the component resides:

- **Drill**: Edit the `drill-env.sh` file. See Configuring User Impersonation in the Apache Drill documentation.
- **Flume**: Edit the `flume.conf` file. See Configure User Impersonation for Flume.
- **HBase**: Edit the `hbasesite.xml` file. See Impersonation via the HBase REST Gateway.
- **HiveServer2**: Edit the `hive-site.xml` file. See Hive User Impersonation.
- **Hue**: Edit the `hue.ini` file. See Configure Hue with Impala.
- **Impala**: Does not support impersonation.
- **Oozie**: Edit the `oozie-site.xml` file. See User Impersonation for Oozie.

- **Spark**: No special settings are required for Spark in MapReduce 2 (YARN) mode, since Spark automatically inherits the correct behavior from YARN. When running standalone, Spark cannot perform impersonation and should not be used if security is important.

Application Development Requirements

You can set up impersonation in an application programmatically.

- **C/C++**: Use `hb_connection_create_as_user()`. See the “C API for impersonation” section of Creating C Apps - Binary Tables on page 2453 and Impersonation Example on page 2456..
- **Java**: Use `UserGroupInformation.doAs()`. See Class UserGroupInformation in the Hadoop documentation.

Enabling Impersonation for the MapR Superuser

Provides a procedure necessary to implement superuser impersonation.

To enable impersonation in your MapR installation:

1. Open the following file in a text editor:

   ```
   /opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml
   ```

2. Add the following `hadoop.proxyuser` properties:

   ```
   <property>
           <name>hadoop.proxyuser.mapr.hosts</name>
           <value>*</value>
   </property><property>
           <name>hadoop.proxyuser.mapr.groups</name>
           <value>*</value>
   </property>
   ```

   The `hosts` setting (`*`) allows the `mapr` superuser to connect from any host to impersonate a user.

   The `groups` setting (`*`) allows the `mapr` superuser to impersonate any user in any group.

   Note: Do not use anything other than a single asterisk here. Other parts of MapR ignore the values here and treat them as if each is set to a single asterisk.

3. Close the file, saving any changes that you made.

Enabling Impersonation for any User

Provides a procedure necessary to implement impersonation for any MapR user.

To enable impersonation for any MapR user:

1. Log in to the system as root, mapr user, or any user with full control.

last-updated: Apr 11, 2022

2. Generate a servicewithimpersonation ticket for the MapR user.

   For example:

   ```
   $ maprlogin generateticket -type servicewithimpersonation -user
   mapruser1 -out /var/tmp/sample_ticket
   ```

   Warning: The `mapr` user ticket can be used to impersonate any user, including user root.

   You can generate a scoped servicewithimpersonation ticket for the user. The scoped impersonation tickets allows the user using the ticket to impersonate only the UIDs and or GIDs specified in the ticket. For example:

   ```
   $ maprlogin generateticket -type servicewithimpersonation -user
   mapruser1 -impersonateduids 550 -impersonatedgids 500 -out /var/tmp/
   sample_ticket
   ```

   Note: When generating a scoped impersonation ticket, the impersonated UIDs cannot contain the UID of user `root` or user `mapr`, and the impersonated GIDs cannot contain the GID of user `root` or user `mapr`.

   For more information, see `maprlogin` on page 2130.

3. Move the ticket to a secure location and share the ticket with the user (for whom this ticket was generated).

4. (Optional) Copy the file to a permanent directory.

Configuring Impersonation without Cluster Security
Describes how to use impersonation on a non-secure cluster.

To configure impersonation without enabling cluster security, perform the following steps on the client:

1. Enable impersonation for each ecosystem component you will use that supports impersonation. See *Component Requirements for Impersonation* in How Impersonation Works.

2. Enable impersonation for the data-fabric core components. See Enabling Impersonation for the mapr Superuser.

3. On each client system from which you wish to be able to use impersonation:
   a) Set a `MAPR_IMPERSONATION_ENABLED` environment variable with the value `true`. This value must be set in the environment of any process you start that does impersonation.

   b) Create a file in `/opt/mapr/conf/proxy/` that has the name of the data-fabric superuser or any other user. For the data-fabric superuser, the default file name would be `mapr`. For all other users, you can use their username for the proxy file.

   If the data-fabric superuser has a different name in your cluster, use that name for the proxy file. To verify the data-fabric superuser name, check the `mapr.daemon.user=` line in the `/opt/mapr/conf/daemon.conf` file on a data-fabric cluster server.

Resolving Username with UID and GIDs During Impersonation
Lists parameters for configuring impersonation.

To resolve username with UID and GIDs on the server (and not the local operating system registry) during impersonation, you can set the following configuration parameters on the client and CLDB:

last-updated: Apr 11, 2022

Parameter	Description
`fs.mapr.server.resolve.user`	Must be set in `core-site.xml` file on the client machine. Value can be one of the following: • `true` - enable • `false` - disable By default, this is disabled. If enabled, client will request CLDB to resolve user with UID/GIDs. For example, to enable this property, your entry in `core-site.xml` file should be as shown below: `<configuration> <property> <name>fs.mapr.server.resolve.user</ name> <value>true</value> </property> </configuration>`
`cldb.security.resolve.user`	Must be set using the `config` command. Value can be one of the following: • `0` - disable • `1` - enable By default, this is disabled. If enabled, CLDB will resolve the user with UID/GIDs for all incoming client requests. For example, to enable this property, run the following command: `maprcli config save -values {cldb.security.resolve.user:1}`

Note: Both the configuration parameters must be set to enable support for UID/GID resolution on the server. If the configuration parameter is set on the client to resolve on the server, and if the configuration parameter is not set on CLDB, the operation will fail with an error.

Managing Secure Clusters

Provides procedures that will enable you to use MapR clusters securely.

Administrative topics such as configuring cross-cluster security, managing mirror volumes in secure clusters, running commands on remote secure clusters are discussed. In addition, access scenarios for secure and non-secure MapR clusters and HDFS clusters are described.

Setting Up Cross-Cluster Security

Provides an overview of the `configure-crosscluster.sh` utility that is used to set up security between two clusters.

When all local and remote CLDB nodes are reachable from the local node, you can run the `configure-crosscluster.sh` on page 2065 utility on any CLDB node to automatically set up a trust relationship between clusters.

For two or more MapRMapR Data Platform clusters to communicate with one another, a secure trust relationship must exist between the clusters. A secure trust relationship between clusters is required for

running commands remotely, creating remote replicas and mirror copies of volumes, and accessing data using NFS on the other cluster. The following sections describe the quick way to configure both the clusters for mirroring, replication, and remote access, and the advanced manual way to configure the clusters for mirroring, replication, remote access, and/or NFS server access.

Quick Configuration

You can run the `configure-crosscluster.sh` on page 2065 utility on any CLDB node in a cluster to automatically set up a trust relationship between the cluster and another cluster. To automatically configure two clusters for remote access, mirroring, and replication in both directions:

1. Log in to the CLDB node on a cluster.
2. Run the `configure-crosscluster.sh` on page 2065 utility with the `all` parameter.
   For example:

   ```
   # /opt/mapr/server/configure-crosscluster.sh create all -remoteip
   <remote_node_IP>
   ```

   When the utility runs, it performs the following actions on all the clusters:

   a. Updates the `/opt/mapr/conf/mapr-clusters.conf` file to include the first entry from the `/opt/mapr/conf/mapr-clusters.conf` file on the other cluster.

   b. Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.

   c. Generates a cross-cluster ticket for the other cluster, copies the ticket to the CLDB node on the other cluster, merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node in the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all other CLDB nodes on the other cluster.

   For more information on the arguments, syntax, and options, see the `configure-crosscluster.sh` on page 2065 utility.
3. Verify access to the remote cluster by:
   - Running remote commands on a node in either cluster.
   - Creating mirror volumes on any node in the destination cluster.
   - Setting up table and stream replication on tables and streams in the source cluster.

   To configure access over NFS, see Configuring Secure Clusters for Cross-Cluster NFS Access on page 1490.

Advanced Configuration

Using the `configure-crosscluster.sh` on page 2065 utility with the default configuration works only when all local and remote CLDB nodes are reachable from the local node. It does not work, for example, if you set up multi-homed clusters as documented in the MAPR_SUBNETS section in Designating NICs for MapR on page 844, because the `configure-crosscluster.sh` on page 2065 utility cannot traverse between local and remote IPs (for example, from the external IP 23.21.203.95 to internal IP 10.10.100.100). In such environments, run the `configure-crosscluster.sh` on page 2065 utility with the `-remotehosts` parameter.

You can configure the clusters manually for unidirectional or bidirectional remote access, mirroring, or replication only. The following sections describe the manual steps for:

Configuring Secure Clusters for Running Commands Remotely
Describes how to configure secure clusters to access them all from a single cluster and run commands remotely on them.

You can configure a number of secure clusters to access them all from one cluster. You need not log into each secure cluster separately and run `maprcli` commands locally on them.

For example, suppose you need to manage two secure clusters, clusterA and clusterB. One method is to log into each cluster separately and run commands locally on each. However, it is possible to log into clusterA only and manage both clusters from clusterA, running commands locally for clusterA and remotely for clusterB. When you type the `maprcli` commands, you must use the `-cluster` parameter in those commands to specify the cluster on which you want the commands to run.

You can configure the secure clusters for remote access manually (as described in the following section) or automatically by running the `configure-crosscluster.sh` utility. If you run the `configure-crosscluster.sh` utility, the utility configures the clusters for running commands remotely in both directions. See `configure-crosscluster.sh` on page 2065 for more information.

Prerequisite

Ensure that you have the relevant ports open for secure cluster communication.

Setting Up Secure Clusters Manually for Cross-Cluster Access

To manually configure two secure clusters for remote access:

1. Log in to the secure cluster from which you want to run commands.
   In the rest of this procedure, this cluster is referred to as clusterA and the remote cluster is referred to as clusterB.

2. Configure clusterA for communicating with the other clusters by editing `mapr-clusters.conf` file on each node clusterA to specify the hostname or IP address of the CLDB nodes on the other clusters.

   For example, suppose:

   - clusterA's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

     ```
     clusterA.cluster.com secure=true perfnode50.lab:7222
     ```

   - clusterB's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

     ```
     clusterB.cluster.com secure=true perfnode100.lab:7222
     ```

   Perform the following steps to configure the nodes on the clusters:

   a) On any node in clusterA, append the first entry from clusterB's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of clusterA's `mapr-clusters.conf` file.
      Note that clusterA's entry must be the first line of the `mapr-clusters.conf` file:

      ```
      clusterA.cluster.com secure=true perfnode50.lab:7222
      clusterB.cluster.com secure=true perfnode100.lab:7222
      ```

      The clusterA's `mapr-clusters.conf` file now contains two entries.

   b) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the other nodes in clusterA.

c) On any node in clusterB, append the first entry from clusterA's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of the remote cluster's `mapr-clusters.conf` file.

Note that clusterB's entry must be the first line of mapr-clusters.conf file:

```
clusterB.cluster.com secure=true perfnode100.lab:7222
clusterA.cluster.com secure=true perfnode50.lab:7222
```

The clusterB's `mapr-clusters.conf` file now contains two entries.

d) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the nodes in clusterB.

See mapr-clusters.conf on page 2200.

3. Perform the following steps on clusterA to ensure that the `ssl_truststore` file has signers for all the clusters:

a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterB into a temporary directory on clusterA.

For example:

```
# scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterB_ssl_truststore
```

b) Merge the `ssl_truststore` of clusterB with the `ssl_truststore` of clusterA using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterB as `/tmp/clusterB_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterB_ssl_truststore /opt/mapr/conf/ssl_truststore
```

c) Copy the merged `ssl_truststore` file to every node on clusterA.

4. Perform the following steps on clusterB *only* if you want to set up access to clusterA from clusterB:

a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterA into a temporary directory on clusterB.

For example:

```
# scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterA_ssl_truststore
```

b) Merge the `ssl_truststore` of clusterB with the `ssl_truststore` of clusterA using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterA as `/tmp/clusterA_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterA_ssl_truststore /opt/mapr/conf/ssl_truststore
```

c) Copy the merged `ssl_truststore` file to every node on clusterB.

5. For crossclusters to work using the Control System, place the mapruserticket of the remote cluster into the local cluster.
   a) Generate a mapruserticket for the remote cluster as `mapr` user:

```
maprlogin password -cluster demo
[Password for user 'mapr' at cluster 'demo': ]
MapR credentials of user 'mapr' for cluster 'demo' are written to
'/tmp/maprticket_5000'
```

   b) Merge the generated maprticket:

```
cat /tmp/maprticket_5000 >>/opt/mapr/conf/
maprusertickets
```

6. Verify access by running remote commands on clusterA.
   See Verifying Access to run Remote Commands on page 1486.

Verifying Access to run Remote Commands

1. Log in to any node on clusterA and run the `maprlogin` on page 2130 utility from clusterA to obtain user ticket for accessing the remote cluster.
   For example, to obtain tickets for managing the remote cluster from clusterA, run the following command::

```
# /opt/mapr/bin/maprlogin password -cluster clusterB.cluster.com
```

2. Verify access by running remote commands on clusterA.
   For example, the following command, executed from a node in clusterA, lists the volumes on clusterB:

```
# /opt/mapr/bin/maprcli volume list -cluster clusterB.cluster.com
```

Configuring Secure Clusters for Cross-Cluster Mirroring and Replication
Describes configuring clusters for cross-cluster operations such as mirroring and replication.

Cross-cluster tickets are required on secure clusters that need to pull data from another secure cluster and on secure clusters that need to push data to another secure cluster. For example:

- Volume mirroring is a pull operation. The volume data is pulled by the destination cluster from the source cluster. Since the destination cluster performs the operation, the destination cluster receives a ticket that is generated on the source cluster.
- Table and streams replication is a push operation. The table or stream data is pushed from the source cluster to the destination cluster. Since the source cluster performs the operation, the source cluster receives a ticket that is generated on the destination cluster.

You can configure secure clusters for cross-cluster mirroring and replication manually (as described in Setting up Secure Clusters Manually for Cross-Cluster Mirroring on page 1487 and Setting up Secure Clusters Manually for Cross-Cluster Replication on page 1489). You can configure secure clusters automatically, by running the `configure-crosscluster.sh` utility. This utility configures the clusters for both mirroring and replication in both directions. For more information, see `configure-crosscluster.sh` on page 2065.

Setting up Secure Clusters Manually for Cross-Cluster Mirroring

To set up secure clusters for cross-cluster mirroring:

1. Verify that the user for whom you are configuring access, exists in the registry on both the clusters and has the following permissions:
   - Permissions to create volumes on the source cluster.
   - Permissions to mirror volumes on the destination cluster.

   You can set up access for the *mapr* user, who already has permissions to create volumes and mirror volumes.
2. Configure clusterA for communicating with the other clusters by editing `mapr-clusters.conf` file on each node clusterA to specify the hostname or IP address of the CLDB nodes on the other clusters.

   For example, suppose:
   - clusterA's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

     ```
     clusterA.cluster.com secure=true perfnode50.lab:7222
     ```
   - clusterB's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

     ```
     clusterB.cluster.com secure=true perfnode100.lab:7222
     ```

   Perform the following steps to configure the nodes on the clusters:

   a) On any node in clusterA, append the first entry from clusterB's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of clusterA's `mapr-clusters.conf` file.

   Note that clusterA's entry must be the first line of the `mapr-clusters.conf` file:

   ```
   clusterA.cluster.com secure=true perfnode50.lab:7222
   clusterB.cluster.com secure=true perfnode100.lab:7222
   ```

   The clusterA's `mapr-clusters.conf` file now contains two entries.

   b) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the other nodes in clusterA.

   c) On any node in clusterB, append the first entry from clusterA's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of the remote cluster's `mapr-clusters.conf` file.

   Note that clusterB's entry must be the first line of mapr-clusters.conf file:

   ```
   clusterB.cluster.com secure=true perfnode100.lab:7222
   clusterA.cluster.com secure=true perfnode50.lab:7222
   ```

   The clusterB's `mapr-clusters.conf` file now contains two entries.

   d) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the nodes in clusterB.

   See `mapr-clusters.conf` on page 2200.
3. Log in to any node on the source cluster (ClusterA) and perform the following steps:

last-updated: Apr 11, 2022

a) Generate a cross-cluster ticket for the destination cluster for this user.

For example, to generate a cross-cluster for destination cluster, run the following command on the source cluster:

```
source$ /opt/mapr/bin/maprlogin generateticket -type
crosscluster -out /tmp/crossclusterticket -user destinationclusteruser
```

b) Copy the cross-cluster ticket file to any node on the destination cluster (clusterB).

For example:

```
source$ scp /tmp/crossclusterticket mapr@<dest-ip>:/tmp/
sourceClusterTicketFile
```

4. Log in to the node on the destination cluster (clusterB) where the cross-cluster ticket was copied, and perform the following steps:

a) Merge the cross-cluster ticket file with the `/opt/mapr/conf/maprserverticket` file on the node.

For example, to merge, run the following command:

```
dest$ cat /tmp/sourceClusterTicketFile >> /opt/mapr/conf/
maprserverticket
```

b) Copy the `/opt/mapr/conf/maprserverticket` file to the CLDB nodes on the destination cluster.

5. Perform the following steps on clusterB to ensure that the `ssl_truststore` file has signers for all the clusters:

a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterA into a temporary directory on clusterB.

For example:

```
# scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterA_ssl_truststore
```

b) Merge the `ssl_truststore` of clusterA with the `ssl_truststore` of clusterB using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterA as `/tmp/clusterA_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterA_ssl_truststore /opt/mapr/conf/ssl_truststore
```

c) Copy the merged `ssl_truststore` file to every node on clusterB.

6.

7. Perform the steps to verify configuration for mirroring.

You can now create mirror volumes on the destination cluster and set up a schedule to pull data from the volumes on the source cluster. However, you cannot create volumes on the source cluster that pull data from volumes in the destination cluster, because the setup described above is unidirectional. To configure

the clusters for bidirectional mirroring, repeat the steps above, by switching the source and destination clusters.

For example, suppose there are two clusters, clusterA and clusterB, and you performed the steps above for clusterA as the source cluster and clusterB as the destination cluster. After you complete the steps above, your destination cluster, clusterB can pull data from volumes on clusterA. For clusterA to mirror data on clusterB, perform the steps above with clusterB as the source cluster and clusterA as the destination cluster.

Setting up Secure Clusters Manually for Cross-Cluster Replication

To set up secure clusters for cross-cluster replication:

1. Verify that the user, for whom you are configuring access, exists in the registry on the destination cluster.
2. Log in to any node on the destination cluster and perform the following steps:
   a) Generate a cross-cluster ticket for the source cluster.
      For example, to generate a cross-cluster for the source cluster, run the following command on the destination cluster:
      ```
      dest$ /opt/mapr/bin/maprlogin generateticket -type
      crosscluster -out /tmp/crossclusterticket -user destinationclusteruser
      ```
   b) Copy the cross-cluster ticket file to any node on the source cluster.
      For example:
      ```
      dest$ scp /tmp/crossclusterticket mapr@<source-ip>:/tmp/
      sourceClusterTicketFile
      ```
3. Log in to the node in the source cluster where the cross-cluster ticket was copied, and perform the following steps:
   a) Merge the cross-cluster ticket file with the `/opt/mapr/conf/maprserverticket` file on the node.
      For example, to merge, run the following command:
      ```
      cat /tmp/destinationClusterTicketFile >> /opt/mapr/conf/
      maprserverticket
      ```
   b) Copy the `/opt/mapr/conf/maprserverticket` file to all the nodes on the source cluster.
4. Configure the Gateway for table and streams replication.
   See Configuring Gateways for Table and Stream Replication on page 1152 for more information.
5. Perform the steps to verify configuration for replication.

You can now set up volumes on the source cluster to push data to replicas on the destination cluster. However, you cannot create replicas on the source cluster that get data from volumes in the destination cluster because the setup described above is unidirectional. To configure the clusters for bidirectional replication, repeat the steps above by switching the source and destination clusters.

For example, suppose there are two clusters, clusterA and clusterB, and you performed the steps above for clusterA as the source cluster and clusterB as the destination cluster. After you complete the steps above, your source cluster, clusterA can push data to replicas on clusterB. For clusterB to replicate data on clusterA, perform the steps above with clusterB as the source cluster, and clusterA as the destination cluster.

Verifying Cross-Cluster Configuration for Mirroring and Replication

You can verify the cross-cluster configuration for:

1. Mirroring by logging in to a node on the destination cluster as the user for whom access was configured, and creating a mirror volume on the destination cluster for a volume on the source cluster.

   You can create mirror volumes using the Control System and/or the CLI.

2. Replication by logging in to a node on the source cluster as the user for whom access was configured and creating a replica in the destination cluster for a volume, table, and stream on the source cluster.

   You can create replicas using the Control System and the CLI. To set up replication on secure clusters for:

   - Tables, refer to the documentation for the Control System and/or the CLI.
   - Streams, refer to the documentation for the Control System and/or the CLI.

Configuring Secure Clusters for Cross-Cluster NFS Access

Describes how to manually set up cross-cluster NFS access.

MapR-NFS offers many usability and interoperability advantages to the customer, and makes big data radically easier and less expensive to use. In a secure environment, however, you must configure NFS carefully because the NFS protocol is inherently insecure. Running the NFS server on any cluster node might expose the filesystem to be world readable and writeable to any machine that knows the IP address of the cluster node running the NFS server and has access to the network, regardless of the permissions, passwords and other security mechanisms. At the minimum, you should configure iptables firewall rules for all the cluster nodes where the NFS server is running, to restrict incoming NFS traffic to authorized client IP addresses.

Configuring cross-cluster NFS access might expose the entire filesystem of the other cluster to be world readable and writeable as well. Therefore, automated configuration for cross-cluster NFS access is not available with the `configure-crosscluster.sh` on page 2065 utility. You should manually configure cross-cluster NFS access only if you are fully aware of the security risks, and taken appropriate steps to mitigate the risks by securing both your NFS gateway, and incoming client traffic.

This section describes the manual configuration process on a secure cluster for accessing another secure cluster using NFS. There are two methods by which an NFS client can access file systems from multiple clusters:

1. Run the NFS server on one cluster.

   For this method, configure cross-cluster NFS security for the NFS gateway on one cluster, so that the NFS client can mount the mapr filesystem once from the NFS gateway, and then access the file systems for both clusters.

2. Run the NFS server on both clusters.

   For this method, cross-cluster NFS configuration is not needed. The NFS client can mount the MapR filesystem individually for each cluster. This method requires that the NFS gateway to be run on each cluster, and the client performs one NFS mount for each NFS filesystem to be accessed.

The following procedure describes how to setup NFS for the first method:

1. Log in to any node on the secure cluster where the NFS server is running.

   In the rest of this procedure, this cluster is referred to as clusterA.cluster.com and the remote cluster is referred to as clusterB.cluster.com.

2. Set up the `/opt/mapr/conf/maprserverticket` file on clusterA.cluster.com to include the server ticket from clusterB.cluster.com. To set up:

   a) Copy the `/opt/mapr/conf/maprserverticket` file from any node on clusterB.cluster.com to any directory on the node you are logged into on clusterA.cluster.com.

last-updated: Apr 11, 2022

b) Append maprserverticket entry in the `maprserverticket` file from clusterB.cluster.com to the `/opt/mapr/conf/maprserverticket` file on the node you are logged into on clusterA.cluster.com.

Note: If you configured cross-cluster security either automatically using the `configure-crosscluster.sh` on page 2065 utility or manually before, there can be multiple entries in the `maprserverticket` file; copy the first entry with the alias matching the remote cluster name.

For example, to add maprserverticket of clusterB.cluster.com into the `/opt/mapr/conf/maprserverticket` file of clusterA.cluster.com, run the following command:

```
cat /tmp/remoteclusterticketfile | grep B.cluster.com |
head --lines=+1 >> /opt/mapr/conf/maprserverticket
```

c) Copy the `/opt/mapr/conf/maprserverticket` file (on the node you are logged into in clusterA.cluster.com) to all the other nodes running NFS server on clusterA.cluster.com.

3. Verify data access on both clusters using NFS.

   Users with access to the NFS servers must be able to access data in both clusters by providing the correct path. For example, users with NFS server access can verify access by running commands similar to the following:

```
# ls /mapr
clusterA.cluster.com  clusterB.cluster.com
# ls /mapr/clusterB.cluster.com/
apps  file  CLUSTERB hbase  opt  tmp  user  var
```

Accessing External HDFS Clusters

Outlines how to use protocols to connect to other clusters.

MapR clusters can access an external HDFS cluster with the `webhdfs://` protocols.

Prerequisites

Before you begin, verify the following:

- The MapR node accessing the HDFS cluster must have the `mapr-core` or `mapr-client` package installed.
- The HDFS cluster is installed and configured according to the vendor's specifications.
- To use the `hdfs://` protocol, edit the `fs.hdfs.impl` property in the `$HADOOP_HOME/conf/core-site.xml` file to include the value `org.apache.hadoop.hdfs.DistributedFileSystem`.

The following cases provide information about MapR and accessing HDFS clusters.

Configuring Access Between Non-Secure MapR and HDFS Clusters

If the MapR and HDFS clusters are both non-secure, verify that the `fs.hdfs.impl` property in the `$HADOOP_HOME/conf/core-site.xml` file has the following value:

```
org.apache.hadoop.hdfs.DistributedFileSystem
```

No additional configuration is required.

last-updated: Apr 11, 2022

Verifying access to HDFS cluster

Use the following commands to verify access to the remote HDFS cluster from the MapR cluster.

CDH3 Only

```
hadoop fs -ls hdfs://<namenode_host:port>/
```

Other HDFS Versions

```
hadoop fs -ls webhdfs://<namenode_host_running_webhdfs_service>/
```

Using Java Applications with Secure Clusters

Describes ramifications associated with using Java applications in a MapR secure environment.

A secure computing environment places additional requirements on the Java Virtual Machine (JVM) properties of Java clients. The JVMs launched by MapR with scripts, such as those used by the `maprcli`, `hadoop`, or `hbase` commands, have those properties automatically set by the MapR software. The MapR software attempts to set useful values for these properties.

When a JVM is used or launched directly, such as when you write a stand-alone Java program, any Java code that sets values for the following properties may cause issues on your cluster.

Property	Default Value	Description
java.security.auth.login.config	`/opt/mapr/conf/mapr.login.conf`	Path to the file that specifies JAAS configurations used by MapR.
javax.net.ssl.trustStore	`/opt/mapr/conf/ssl_truststore`	Controls the truststore used by MapR clients for HTTPS connections.
http.auth.preference	`basic`	The default setting disables JVM's default handling of SPNEGO, enabling MapR's Hadoop code to handle SPNEGO authentication.
zookeeper.saslprovider	`com.mapr.security.maprsasl.MaprSaslProvider`	Enables ZooKeeper security.
hadoop.login	`hadoop_default`	Controls the JAAS configuration used by MapR security.

Administering the MapR Data Access Gateway

The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Installing the Data Access Gateway Service

The MapR Data Access Gateway is installed when you install the MapR Database using the MapR Installer. To manually install the service, see Installing MapR Data Access Gateway on page 203. For conceptual information, see Understanding the MapR Data Access Gateway on page 750.

Shutting Down and Upgrading the Data Access Gateway Service

When the Data Access Gateway receives a shutdown request, it stops accepting new requests and returns an error to the client. Any in-progress requests are allowed to complete before shutting down the service. This allows you to perform rolling upgrades.

Modifying Configuration Settings for the Data Access Gateway Service

Logging Properties

The MapR Data Access Gateway uses standard Log4J configuration to control its logging. The log4j properties are in the `/opt/mapr/data-access-gateway/conf/log4j2.xml` file on nodes where you have installed the service. After modifying any properties on a node, restart the service. For details, see Administering the Data Access Gateway Service on page 1495.

Log data is stored in the `/opt/mapr/data-access-gateway/logs/data-access-gateway.log` file.

Application Properties

To configure MapR Data Access Gateway properties, modify `/opt/mapr/data-access-gateway/conf/properties.cfg` on nodes where you have installed the service.

The following table lists the properties you can configure:

auth.token.expiration	*Default*: 1800 seconds *Description*: Expiration time (in seconds) for the authentication token.
grpc.service.max-message-size	*Default*: 32MB *Description*: The maximum message size that the gRPC service accepts. The default is set to 32MB, as this is the default maximum document size for MapR Database JSON tables. This property is available in Data Access Gateway 2.0.202104302209 and later or 3.0.0.0.202104302219 and later.
grpc.service.ojai.query.result-limit	*Default*: 5000 *Description*: Limit on the number of documents returned in retrieval requests using the Node.js and Python OJAI clients.
grpc.service.port	*Default*: 5678 *Description*: Port number gRPC clients use to connect to the Data Access Gateway. The Node.js and Python OJAI clients are gRPC clients.
grpc.service.ssl.enabled	*Default*: cluster *Description*: Controls whether TLS is enabled for the gRPC Service. Values: `cluster`|`true`|`false` If set to `cluster`: • TLS is enabled if your MapR cluster is secure. • TLS is disabled if your MapR cluster is not secure. When TLS is enabled, the SSL provider is OpenSSL.
rest.https.port	*Default*:8243 *Description*: Port number used to connect to the Data Access Gateway using HTTPS.

last-updated: Apr 11, 2022

rest.result.limit	*Default*:5000 *Description*: Limit the number of documents returned in retrieval requests using the MapR Database JSON REST API.

There is also a configuration file `/opt/mapr/data-access-gateway/conf/ojai-config.json` for parameters used by Data Access Gateway clients:

- MapR Database JSON REST API
- Node.js OJAI
- Python OJAI
- C# OJAI
- Go OJAI
- Java OJAI Thin Client

A parameter you can modify is the client sort limit:

```
{
    "ojai": {
        "mapr": {
            "query": {
                "max-client-sort-limit": 6000
            }
        }
    }
}
```

To understand why you might want to modify this parameter, see Comparisons and Sorts in OJAI Queries on page 2586.

After modifying any parameters on a node, restart the service as described in Administering the Data Access Gateway Service on page 1495.

Warden Configuration

The Warden configuration for the MapR Data Access Gateway is in the `/opt/mapr/data-access-gateway/conf/warden.data-access-gateway.conf` file on nodes where you have installed the Data Access Gateway. To control the amount of memory allocated to the service, modify the following settings:

service.heapsize.max	*Default*:3000 *Description*: Defines the maximum heap size (in MB) for the service.
service.heapsize.min	*Default*:3000 *Description*: Defines the minimum heap size (in MB) for the service.

After modifying the warden configuration file on a node, run `configure.sh -R`, and restart the service:

```
/opt/mapr/server/configure.sh -R
maprcli node services -nodes <node name> -name data-access-gateway -action
restart
```

Administering the Data Access Gateway Service

The MapR Data Access Gateway is a service that you administer in the same manner as other MapR services. The name of the service is `data-access-gateway`.

To restart the service through the CLI, run the following command:

```
maprcli node services -nodes <node name> -name data-access-gateway -action
restart
```

For details about other operations you can perform on the service, see Managing Services on page 827.

Related concepts

Understanding the MapR Data Access Gateway on page 750
The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster.

Using the MapR Database JSON REST API on page 2696
Starting in the EEP 5.0 release, you can use a REST API to access MapR Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on MapR Database JSON tables.

Using the Node.js OJAI Client on page 2673
Starting with EEP 6.0, you can use the Node.js OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON from middleware components, and add, update, and query documents in a MapR Database JSON table.

Using the Python OJAI Client on page 2678
Starting with EEP 6.0, you can use the Python OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Using the C# OJAI Client on page 2688
Starting with EEP 6.1.0, you can use the C# OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Using the Go OJAI Client on page 2692
Starting with EEP 6.0.0, you can use the Go OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Using the Java OJAI Thin Client on page 2670
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write MapR Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

L3/L4 Load Balancing with the MapR Data Access Gateway

You can use `haproxy` for L3/L4 load balancing of clients that use the MapR Data Access Gateway. This topic describes how to install, configure, and run `haproxy`, and how to set your client connection string to connect to the load balancing service.

Determine the server where you want to run the load balancing service. The server must be reachable by the clients using the Data Access Gateway. It also must be able to connect to the Data Access Gateway.

1. Install the `haproxy` service on the server you have identified:

CentOS	`sudo yum install haproxy`

last-updated: Apr 11, 2022

Ubuntu	`sudo add-apt-repository ppa:vbernat/haproxy-1.7`
	`sudo apt update`
	`sudo apt install haproxy`

SLES	`sudo zypper install haproxy`

2. Configure the `haproxy` service by setting the following parameters in the configuration file at `/etc/haproxy/haproxy.cfg`:
   a) Create a `frontend` section with the following parameters:

```
frontend <section_name>
   mode tcp
   bind *:<port_to_use_in_the_client_connection_string>
   default_backend <backend_section_name>
```

   b) Create a `backend` section with one `server` entry for each Data Access Gateway server:

```
backend <backend_section_name>
   mode tcp
   server <DAG_server_name1> <DAG_server_host1>:<DAG_server_port1>
   server <DAG_server_name2> <DAG_server_host2>:<DAG_server_port2>
   ...
   server <DAG_server_nameN> <DAG_server_hostN>:<DAG_server_portN>
```

   The <*backend_section_name*> is the parameter you specified in Step 2a.

3. Restart the `haproxy` service:

```
sudo service haproxy restart
```

Setting Your Client Connection String

Assume you have the following `haproxy` configuration settings and you have installed `haproxy` on `node1.cluster.com`:

```
frontend connection_input
  mode tcp
  bind *:8553
  default_backend maprdb_servers

backend maprdb_servers
  mode tcp
  server srv01 node1.cluster.com:5678
  server srv02 node2.cluster.com:5678
```

You can use the following client connection string with this sample configuration:

DAG with HTTPS | TLS	`node1.cluster.com:8553?auth=basic;user=mapr;password=mapr;ssl=true;sslCA=/opt/mapr/conf/ssl_truststore.pem;sslTargetNameOverride=node1.cluster.com`

DAG with HTTP

```
node1.cluster.com:8553?
auth=basic;user=mapr;password=mapr;ssl
=false
```

L7 Load Balancing with the Data Access Gateway

You can use `nginx` for L7 load balancing of clients that use the Data Access Gateway. This topic describes how to install, configure, and run `nginx`, and how to set your client connection string to connect to the load balancing service.

Determine the server where you want to run the load balancing service. The server must be reachable by the clients using the Data Access Gateway. It also must be able to connect to the Data Access Gateway.

1. Install the `nginx` service on the server you have identified:

   CentOS

   ```
   sudo yum install nginx
   ```

   Ubuntu

   ```
   sudo apt install nginx
   ```

   SLES

   ```
   sudo zypper install nginx
   ```

2. Configure the `nginx` service by setting the following parameters in the configuration file at `/etc/nginx/nginx.conf`:
   a) In the `http` section, create an `upstream` block with one `server` entry for each Data Access Gateway server:

   ```
   upstream <upstream_name> {
       server <DAG_server_host1>:<DAG_server_port1>;
       server <DAG_server_host2>:<DAG_server_port2>;
       ...
       server <DAG_server_hostN>:<DAG_server_portN>
       }
   ```

   b) Create (or modify) the `server` block, depending on whether your cluster is secure or nonsecure:

   Secure Cluster

   For a secure cluster, you must specify the following SSL parameters:

   - Listen port and protocol
   - Path to the SSL certificate
   - Path to the SSL key
   - Path to the file containing the SSL password

   ```
   server {
       listen 80 ssl http2;
       listen [::]:80;

       ssl_certificate
   <path_to_certificate>;
       ssl_certificate_key
   <path_to_key>;
       ssl_password_file
   ```

last-updated: Apr 11, 2022

```
<path_to_password_file>;

    access_log logs/access.log
main;

    location / {
            grpc_pass grpcs://
<upstream_name>;
    }
}
```

Nonsecure Cluster

```
server {
    listen 80 http2;
    listen [::]:80;

    access_log logs/access.log
main;

    location / {
        grpc_pass grpc://
<upstream_name>;
    }
}
```

The <*upstream_name*> is the parameter you specified in Step 2a.

3. Restart the `nginx` service:

```
sudo service nginx restart
```

Setting Your Client Connection String

Assume you have the following `nginx` configuration settings and you have installed `nginx` on `node1.cluster.com`:

Secure Cluster

```
user mapr;
worker_processes 1;
error_log /var/log/nginx/error.log
warn;
pid /var/run/nginx.pid;
events {
    worker_connections  1024;
}
http {
    log_format  main  '$remote_addr -
$remote_user [$time_local] "$request"'
                      '$status
$body_bytes_sent "$http_referer"'

'"$http_user_agent"';
    upstream servers {
        server node1.cluster.com:5678;
        server node2.cluster.com:5678;
    }
    server {
        listen 80 ssl http2;
        listen [::]:80;
```

```
        ssl_certificate /opt/mapr/
conf/ssl_keystore.pem;
        ssl_certificate_key /opt/mapr/
conf/ssl_keystore.pem;
        ssl_password_file /root/
passwd;

        access_log logs/access.log
main;

        location / {
            grpc_pass grpcs://servers;
        }
    }
}
```

You can use the following client connection string with this sample configuration:

```
node1.cluster.com:80?
auth=basic;user=mapr;password=mapr;ssl
=true;sslCA=/opt/mapr/conf/
ssl_truststore.pem;sslTargetNameOverri
de=node1.cluster.com
```

Nonsecure Cluster

```
user mapr;
worker_processes 1;
error_log /var/log/nginx/error.log
warn;
pid /var/run/nginx.pid;
events {
    worker_connections  1024;
}
http {
    log_format  main  '$remote_addr -
$remote_user [$time_local] "$request"'
                      '$status
$body_bytes_sent "$http_referer"'

'"$http_user_agent"';
    upstream servers {
        server node1.cluster.com:5678;
        server node2.cluster.com:5678;
    }
    server {
        listen 80 http2;
        listen [::]:80;

        access_log logs/access.log
main;

        location / {
            grpc_pass grpc://servers;
        }
    }
}
```

You can use the following client connection string with this sample configuration:

```
node1.cluster.com:80?
auth=basic;user=mapr;password=mapr;ssl
=false
```

Planning for High Availability

Configuring a cluster for HA (High Availability) involves running redundant instances of specific services, and configuring NFS properly. When properly licensed and configured for HA, the MapR cluster provides *automatic failover* for continuity throughout the stack.

The following table provides the minimum number of instances of each core service required for HA:

Service	Minimum Number of Instances	Comments
CLDB	2	
ZooKeeper	3	At least 3 are needed to maintain a quorum in case one instance fails.
NFS	2	NFS can be configured for HA using virtual IP addresses (VIPs).
ResourceManager	2	

In HA clusters, it is appropriate to run more than one instance of the WebServer with a load balancer to provide failover. NFS can be configured for HA using VIPs.

The following sections provide information about HA planning:

CLDB Failover

Explains the concept of CLDB failover, and its advantages.

The CLDB service automatically replicates its data to other nodes in the cluster, preserving at least two (and generally three) copies of the CLDB data. If the CLDB process dies, it is automatically restarted on the node. All jobs and processes wait for the CLDB to return, and resume from where they left off, with no data or job loss.

If the node itself fails, the CLDB data is still safe, and the cluster can continue normally as soon as the CLDB is started on another node. In an Enterprise Edition-licensed cluster, a failed CLDB node automatically fails over to another CLDB node without user intervention, and without data loss. It is possible to recover from a failed CLDB node on a Community Edition cluster, but the procedure is different.

Complete the following steps to recover from a failed CLDB node on a community edition cluster:

1. Restore ZooKeeper

If the CLDB node that failed was also running ZooKeeper, install ZooKeeper on another node to maintain the minimum required number of ZooKeeper nodes. Before installing ZooKeeper on another node, ensure that the ZooKeeper role is deleted on the failed node. See Removing ZooKeeper Role for more information.

2. Locate the CLDB Data

After restoring the ZooKeeper service on the MapR cluster, use the `maprcli dump zkinfo` command to identify the latest epoch of the CLDB, identify the nodes where replicates of the CLDB are stored, and select one of those nodes to serve the new CLDB node.

Secure cluster must first be converted to non-secure cluster before running the `maprcli dump zkinfo` command. Perform the following steps as root or use sudo:

last-updated: Apr 11, 2022

Note: For non-secure clusters, skip to step 4.

1. On the ZooKeeper nodes, stop Warden and ZooKeeper by running the following commands:

```
service mapr-warden stop
service mapr-zookeeper stop
```

2. Convert the secure cluster to non-secure cluster by running the following command on the ZooKeeper nodes:

   Note: The script `configure.sh` takes comma-separated lists of cluster names and ZooKeeper host names (and optionally ports) or IP addresses.

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>:
[<port>]...]|<IP>[,<IP>...] -Z <host>[:<port>][,<host>:[<port>]...]|
<IP>[,<IP>...] -unsecure -R
```

3. Restart ZooKeeper:

```
service mapr-zookeeper restart
```

4. Issue the `maprcli dump zkinfo` command using the `-json` flag.

```
maprcli dump zkinfo -zkconnect localhost:5181 -json | grep -i "Container
ID"
```

   The output displays the ZooKeeper znodes. For example:

```
maprcli dump zkinfo -zkconnect localhost:5181 -json |grep -i "Container
ID" | more
   "/datacenter/controlnodes/cldb/epoch/1/KvStoreContainerInfo":"
Container ID:1
   VolumeId:1 Master:10.10.104.34:5660-10.10.105.34:5660--9-VALID
Servers:
   10.10.104.34:5660-10.10.105.34:5660--9-VALID
   10.10.104.33:5660-10.10.105.33:5660--9-VALID
   10.10.104.32:5660-10.10.105.32:5660--9-VALID
   Inactive Servers:  Unused Servers:  Latest epoch:9"
```

   In the above example output, the latest epoch is *9*.

5. In the `/datacenter/controlnodes/cldb/epoch/1` directory, locate the CLDB with the latest epoch.

   The Latest Epoch field identifies the current epoch of the CLDB data.

6. Select a CLDB from among the copies at the latest epoch. For example, `10.10.105.32:5660--9-VALID` indicates that the node has a copy at epoch 9 (the latest epoch).

You can now install a new CLDB on the selected node.

To convert the non-secure cluster to a secure cluster, run the the following command:

last-updated: Apr 11, 2022

Note: The script `configure.sh` takes comma-separated lists of cluster names and ZooKeeper host names (and optionally ports) or IP addresses.

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>:
[<port>]...]|<IP>[,<IP>...] -Z <host>[:<port>][,<host>:[<port>]...]|
<IP>[,<IP>...] -secure -R
```

3. Stop the Selected Node

Perform the following steps on the node you have selected for installation of the CLDB:

1. Change to the root user (or use sudo for the following commands).
2. Stop the Warden:

```
service mapr-warden stop
```

4. Remove the CLDB Role on the Failed Node

To remove the CLDB role on the failed node, perform the following steps:

1. Stop Warden on the node.

```
service mapr-warden stop
```

2. Purge the CLDB package mapr-cldb with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.

5. Install the CLDB on the Selected Node

Perform the following steps on the node you have selected for installation of the CLDB:

1. Login as `root` or use `sudo` for the following commands.
2. Install the CLDB service on the node:
   - RHEL/CentOS: `yum install mapr-cldb`
   - Ubuntu: `apt-get install mapr-cldb`

6. Configure the Selected Node

The script configure.sh configures a node to be part of a MapR cluster, or modifies services running on an existing node in the cluster. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run configure.sh, make sure you have a list of the hostname of the ZooKeeper nodes. You can optionally specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222
ZooKeeper	5181

The script configure.sh takes an optional cluster name and log file, the CLDB hostname, and comma-separated list of ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>] -Z <host>[:<port>]
[,<host>[:<port>]...] \
 [-L <logfile>][-N <cluster name>]
```

Note: Each time you specify the `-Z <host>[:<port>]` option, you must use the *same order* for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example

```
/opt/mapr/server/configure.sh -C r1n1.sj.us:7222 \
-Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5
181 -N MyCluster
```

7. Start the Nodes

Perform the following steps on the node you have selected for installation of the CLDB:

Start the Warden:

```
service mapr-warden start
```

After the CLDB restarts, there is a 15-minute delay before replication resumes, in order to allow all nodes to register and heartbeat. This delay can be configured using the `config save` command to set the `cldb.replication.manager.start.mins` parameter.

8. Restart All Nodes

To restart all nodes in the cluster, stop each node, configure the node with the new CLDB and ZooKeeper addresses, and start the node.

Complete the following steps on each node in the cluster:

1. Stop the node.
   a. Change to the root user (or use sudo for the following commands).
   b. Stop the Warden:

      ```
      service mapr-warden stop
      ```

2. Configure all the nodes with the new CLDB and ZooKeeper addresses.

   The script `configure.sh` configures a node to be part of a MapR cluster, or modifies services running on an existing node in the cluster. You must run this script to configure a node. The script creates (or updates) configuration files related to the cluster and the services running on the node.

   Before you run `configure.sh`, make sure you have the hostname of the CLDB node and the hostnames of the ZooKeeper nodes. You can, optionally, specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222

last-updated: Apr 11, 2022

Service	Default Port #
ZooKeeper	5181

The script `configure.sh` takes an optional cluster name and log file, the CLDB hostname, and comma-separated list of ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>] -Z <host>[:<port>]
[,<host>[:<port>]...] [-L <logfile>][-N <cluster name>]
```

Note: Each time you specify the `-Z <host>[:<port>]` option, you must use the same order for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example:

```
/opt/mapr/server/configure.sh -C r1n1.sj.us:7222 -Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.u
s:5181 -N MyCluster
```

3. Start Warden.

```
service mapr-warden start
```

Best Practices for Running a Highly Available Cluster

Lists high availability cluster replication types, and the best practices for running such a cluster.

MapR runs a wide variety of concurrent applications in a highly available fashion. Node failures do not have cluster-wide impact, and activities on other nodes in the cluster can continue normally. In parallel, MapR components detect failures and automatically recover from them. During the recovery process, clients may experience latency, the duration of which depends on the nature of the failure.

Node Shutdown Instances

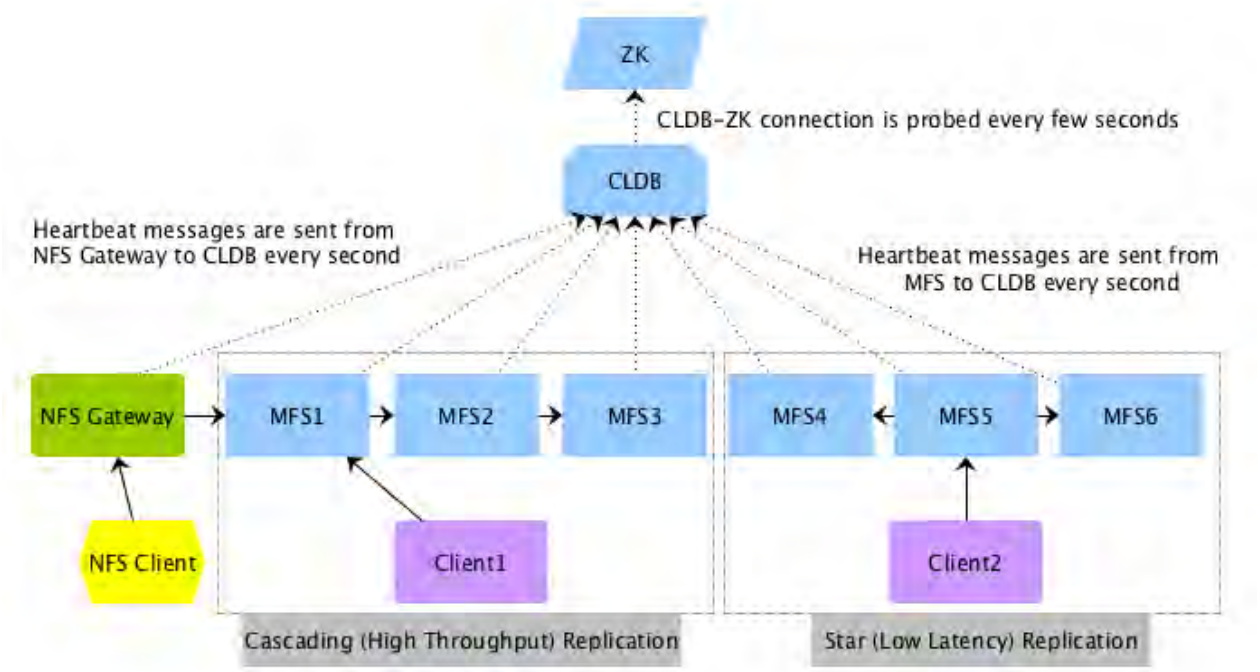
The cause of a service failure can be one of the following:

Planned shutdown	A planned/controlled failure. In this case, MapR is informed that a file server will be stopped. MapR services use this information to improve recovery behavior.
Unexpected shutdown	MapR services (MapR File System, NFS server etc.,) are stopped. However, the host operating system continues to run and failure detection is fast.
Hard unplanned shutdown	A power off, network down, or some other kind of unplanned stop. A node is stopped in a way that it is no longer reachable. Packets sent to this node do not get an error response and failure is detected through network layer's timeout mechanism. This results in longer failure detection times.

In all of these instances, the recovery process typically involves detecting that a node is unreachable, and contacting another available node for the same piece of information (either for reads, writes, or administrative operations).

How MapR File System and Associated Services Work

Let's review how MapR File System and associated services typically work, using the following illustration.



High-throughput or Cascading Replication Type: As shown in the illustration, the client, Client1, writes to a MapR filesystem, MFS1, which in turn talks to MFS2, which in turn talks to MFS3 for cascading (high throughput) replication. The replication is inline and synchronous, which means MFS1 replies to the client only after it receives a response from MFS2. MFS2, in turn, only responds to MFS1 after MFS3 has replied to it. Client1 can read from any MFS, but write only to MFS1.

Low-latency or Star Replication Type: As shown in the illustration, the client, Client2, writes to MFS5. This illustration shows an example of star (low latency) replication where MFS5 replicates to both MFS4 and MFS6 in parallel. Again, the replication is inline and synchronous, which means that MFS5 responds to Client2 only after it has received responses from both MFS4 and MFS6.

Recommended Settings for Running a Cluster with Low Latency and Fast Failover Characteristics

A well designed cluster provides automatic failover for continuity throughout the stack. For an example of a large, high-availability Enterprise Edition cluster, see Example Cluster Designs on page 118. On a large cluster designed for high availability, services should be assigned according to the service layout guidelines. For more information, see Service Layout Guidelines for Large Clusters on page 115. In general, services, specifically CLDB and ZooKeeper, should be installed on separate nodes to prevent the failure of multiple services at the same time and to enable the cluster to recover quickly.

Recommended Settings to Recover from Unplanned Shutdown

Latencies as a result of unplanned or unexpected failures/shutdowns can be improved by performing the following:

Enabling Fast Failover of Services

Describes the Fast Failover feature that allows a cluster to rapidly detect and recover from network failures.

For running a cluster with Fast Failover characteristics, enable the Fast Failover feature:

```
/opt/mapr/bin/maprcli config save -values {mfs.feature.fastfailover:1}
```

last-updated: Apr 11, 2022

If you have enabled the fast failover feature, when the MapR File System detects a failed node, it very quickly declares the node as being down. Clients experience a short latency period while the failure is being detected. Once MapR detects the failure, MapR redirects clients of the failed node to an alternate location (a replica container) for the data. If you have not enabled the fast failover feature, the MapR File System repeatedly contacts the failed node.

This feature is enabled on all new installations. For upgrade installations, this feature is not enabled by default. You need to evaluate whether this feature works well with your existing infrastructure, before enabling it. You cannot turn this feature off after turning it on.

Tuning the TCP for Fast Failure Detection
Describes how to tune the TCP stack to detect node or network failures rapidly.

An unplanned failure chiefly takes the form of a node failure or a network failure. In both instances, the network layer retries to connect to the failed node. The number of retry attempts is dictated by the TCP parameter `/proc/sys/net/ipv4/tcp_syn_retries`. The default value of that parameter is 5 (in Linux), resulting in a latency of more than a minute to detect the node failure. The problem is compounded when the same failed node is contacted repeatedly in the context of a long operation, such as when a client accesses multiple data objects present on that node.

The MapR stack solves the problem by remembering (caching) the information about a node's failure, and by not contacting that node for subsequent operations on data objects present on that node. Since all form of data is replicated, MapR services find alternative locations for a data object. This feature is in-built into the current software and does not have to be enabled explicitly. Hence, the communication between a client and a recently failed node incurs a one-time long-duration latency. As mentioned before, that latency is governed by the number of retries at the TCP level. Hence, to further improve the one-time longer latency of an operation between a pair of nodes, it is recommended that the number of TCP retries be decreased from 5 to 4, resulting in a latency of about 30 seconds.

Setting the Timeout for TCP Connections

To set the TCP retry count, set the value of `tcp_syn_retries` to 4 in the `/proc/sys/net/ipv4/` directory (for IPv4 connections). For example:

```
echo 4 > /proc/sys/net/ipv4/tcp_syn_retries
```

Similarly for IPv6 connections, set:

```
echo 4 > /proc/sys/net/ipv6/tcp_syn_retries
```

This TCP setting of 4 ensures that the TCP stack takes about 30 seconds to detect failure of a remote node. To ensure that this setting is persistent across system reboots, set this value in the `/etc/sysctl.conf` file.

Warning: This setting impacts all TCP connections to and from a node. Hence, caution must be exercised when lowering this further. Also, in some instances, reducing this further may result in a node being incorrectly flagged as unavailable.

Reducing Failure Detection Time for File Clients
Describes how to set the time for Hadoop and POSIX clients to detect node failures.

To reduce the amount of time it takes (Hadoop and FUSE-based POSIX) clients to detect (CLDB and data node) failure, define the property, `fs.mapr.connect.timeout`, in the `core-site.xml` file. The value for this property can be set in 100 milliseconds and will be rounded up to the nearest 100 milliseconds. The minimum value for this property is 100 milliseconds, which can be incremented only by units of 100 milliseconds. Suppose a value of 260 milliseconds is specified, by default, the value will automatically be rounded up to 300 milliseconds. The default value for this property is `0`, which means that the Linux TCP timeout setting will be used for connections if this property is not set.

Your entry in `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.connect.timeout</name>
  <value>200</value>
  <description>file client wait time of 200 milliseconds</description>
</property>
```

This setting (for hadoop and FUSE-based POSIX clients) ensures that the clients wait only for the specified amount of time to establish a connection. That is, it is used only for the first request sent to CLDB or a data node before or after a failure. For subsequent requests, the default system connection timeout value is used. In the event of a failure after a connection has been established, the client will wait for the connection to timeout (based on the system timeout value) before it contacts the next (CLDB or data) node to process the request.

For example, suppose the value for this parameter is 100 milliseconds and the Linux TCP connection timeout value is 30 seconds. When a hadoop or FUSE-based POSIX client contacts CLDB or a data node for the first time to establish a connection, the client will wait for 100 milliseconds before trying the next CLDB or data node. After a connection is established, for subsequent requests, the client will wait for 30 seconds for a response. If the node goes down after a connection has been established, the client will wait for 30 seconds before trying the next node. If the client contacts a recovered node for the first time, it will wait for 100 milliseconds to establish the connection.

Note: MapR filesystem does not use this property internally; it is used by Hadoop and FUSE-based POSIX clients only. This setting is not applicable to NFS gateway and loopbacknfs POSIX clients.

Detecting CLDB failures

When a connection with CLDB is established, CLDB returns the list of reachable and unreachable CLDB nodes on the cluster.

Populating the cache

The client stores information about the unreachable CLDB nodes in `/tmp/cldbinfo/unreachableCldbs` file on the client host. The format of this file is the same as the `mapr-clusters.conf` file (i.e., "`clustername ip:port`"). For example:

```
cat /tmp/cldbinfo/unreachableCldbs
  object_pools 10.10.104.33:7222
10.10.104.34:7222
```

The client reads the `mapr-clusters.conf` file and the `unreachableCldbs` file to determine the CLDB to connect to. It then tries to reach the available CLDB nodes first; it tries the unreachable CLDB nodes only if the available CLDB is unable to service its request.

Invalidating the cache

If the available CLDB is unable to service the client request, the client tries the unreachable CLDB. If an unreachable CLDB becomes reachable again, it is removed from the `/tmp/cldbinfo/unreachableCldbs` file, making it reachable for all subsequent IOs and if a reachable CLDB becomes unreachable, it is added to the `/tmp/cldbinfo/unreachableCldbs` file.

Recommended Settings for Planned Shutdown

Explains the modalities of a planned shutdown.

last-updated: Apr 11, 2022

The MapR stack improves the latencies for planned shutdowns by implementing a fast failover mechanism where different services respond to the intimation of a failure.

Notifying CLDB to Allow Fast Failover

When planning to shutdown a node, notifying CLDB of an impending shutdown allows CLDB to update the replication chain such that primary and intermediate containers, if any, are not on the node and re-assign VIPs on the node when the node actually goes down. This, in turn, allows clients to continue activities on available nodes.

MapR (v5.1) includes an argument, `node failover`, to the `maprcli` command that notifies CLDB of impending node shutdown so that CLDB can ensure that the specified node does not have any primary containers and intermediate containers (in a cascaded chain), and VIPs are re-assigned.

Shutting Down a Node

To notify CLDB of a planned shutdown of a node:

1. Enable the fast failover behavior.

   Refer to Enabling Fast Failover for more information.

2. Reset the value of tcp_syn_retries parameter.

   Refer to Tuning TCP for more information.

3. (Optional) Get the hostname of the node to put in maintenance mode by running the following command:

   ```
   /opt/mapr/bin/maprcli node list -columns hostname
   ```

4. Run the `failover` command for that node.

   For example:

   ```
   /opt/mapr/bin/maprcli node failover -nodes <node-hostname>
   ```

   Wait for few minutes (to allow containers to failover) before proceeding to the next step.

5. Stop warden on that node by running the following command:

   ```
   service mapr-warden stop
   ```

6. Notify MapR that the node is in maintenance mode and when the maintenance task is complete, remove the node from maintenance mode.

   See Performing Maintenance on a Node for the commands to run to put and take a node out of maintenance mode.

Warning: Shut down only one node at a time. Do not take down multiple nodes for maintenance at the same time.

ResourceManager High Availability

Provides an overview of how high availability for Resource Manager works.

The ResourceManager service tracks a cluster's resources and schedules YARN applications. Configure high availability for the ResourceManager so that the failure of the ResourceManager service is not a single point of failure for the cluster. The high availability of ResourceManager is based on the cluster configuration of the restart, recovery, and failover features.

last-updated: Apr 11, 2022

Restart

By default, the Warden attempts to restart a failed service three times. You can configure the frequency that Warden attempts to restart failed services before initializing failover in the warden.conf file. For more information, see warden.conf.

Recovery

When a ResourceManager restarts or fails over, the active ResourceManager can recover the state of the previously running ResourceManager. By default, ResourceManager recovery is enabled and it uses the `FileSystemRMStateStore` implementation to store the ResourceManager state in the MapR File System. You can configure the ResourceManager to have no recovery or you can enable the recovery. You can also configure the state store implementation that you want to use. For more information, see Recovery for the ResourceManager.

Failover

When a ResourceManager fails, the cluster can fail over the ResourceManager process to another node. To configure failover, the cluster must have one or more nodes with the ResourceManager role.

Note:

Starting in Version 4.0.2, zero configuration failover provides automatic failover without requiring that you specify the ResourceManager nodes when you run configure.sh. It also does not require any further configuration to yarn-site.xml.

Upgrade any client nodes to the 4.0.2 client to ensure proper communication with the ResourceManager service. Earlier versions of the MapR client do not support the zero configuration feature.

You can select one of the following failover implementations when you use the configure.sh utility to configure each node:

- **Zero Configuration Failover.** With zero configuration failover, the ResourceManager process only runs on one node in the cluster. When the active ResourceManager fails, one of the standby ResourceManager nodes automatically loads the working state from the state store and continues providing services to the cluster. Zero configuration failover is the default, recommended setting for the following reasons:
  - **Only one ResourceManager process consumes cluster resources.** With the manual or automatic failover option, the active and standby ResourceManagers consume cluster resources.
  - **Warden initiates failover automatically.** With the manual failover, you need to manually run the yarn rmadmin command for failover to occur.
  - **Simplified clients connectivity.** Clients identify the active ResourceManager with a single request to the Zookeeper. With the manual or automatic failover option, ResourceManager clients connect to each ResourceManager in a round-robin fashion until they locate the active ResourceManager; this results in delays when launching or querying jobs.
  - **Consistent Configuration.** All cluster nodes and clients can use the same yarn-site.xml configuration file. With manual or automatic failover, you must maintain a customized yarn-site.xml file for each node that runs the ResourceManager.

  For more information, see Zero Configuration Failover for the ResourceManager.

last-updated: Apr 11, 2022

- **Manual or Automatic Failover.** With manual failover or automatic failover, one active ResourceManager and one or more standby Resource Managers run in the cluster. The standby ResourceManager nodes run the ResourceManager process without loading the working state. When the active ResourceManager fails, one of the standby ResourceManager nodes can load the working state from the state store and continue providing services to the cluster. For more information, see Manual or Automatic Failover for the ResourceManager.

You can perform the following procedures to manage ResourceManager:

Manual or Automatic Failover for the ResourceManager

With manual or automatic failover, an active ResourceManager and two standby ResourceManager processes run in the cluster. The standby ResourceManager nodes run the ResourceManager process without loading the working state. When the active ResourceManager fails, one of the standby ResourceManager nodes can load the working state from the ZooKeeper and continue providing services to the cluster.

ResourceManager clients (MapR client nodes, ApplicationMaster processes, and NodeManager nodes) attempt connections to the ResourceManager nodes in a round-robin fashion until they hit an active ResourceManager node. If the active ResourceManager node is down, ResourceManager clients resume round-robin polling until an active ResourceManager node is detected.

For web requests, including REST API requests, standby ResourceManager nodes automatically redirect web requests to the active ResourceManager node.

The difference between manual and automatic failover is how the transition from standby to active occurs for the ResourceManager process.

- With manual failover, you manually invoke the transition of the ResourceManager from standby to active with the yarn rmadmin command.
- With automatic failover, the ResourceManager processes have an embedded ZooKeeper-based ActiveStandbyElector, which chooses the active ResourceManager. This ActiveStandbyElector also detects failures in the currently active ResourceManager and automatically transitions one of the standby ResourceManagers to an active state.

If you specify multiple ResourceManagers when you run configure.sh, automatic failover is configured. However, you can edit the yarn-site.xml file to enable manual failover instead.

Automatic Failover Administration

The Zookeeper-based ActiveStandbyElector on each ResourceManager node detects failures in the currently active ResourceManager and automatically transitions one of the standby ResourceManagers to an active state. Therefore, `rmadmin -transitionToStandby` and `-transitionToActive` are disabled.

Configuring Automatic Failover for the ResourceManager

To use automatic failover, specify multiple ResourceManagers when you run configure.sh on each node in the cluster.

The following configure.sh script syntax configures three ResourceManager nodes (one active and two standby) and one HistoryServer node:

```
/opt/mapr/server/configure.sh -C <CLDB node list> -Z <ZK node list> -RM
<hostname1,hostname2,hostname3> -HS <hostname1> [additional parameters]
```

Note: After you run configure.sh, each ResourceManager node contains a different value for the `yarn.resourcemanager.ha.id` property in the yarn-site.xml.

last-updated: Apr 11, 2022

Example yarn-site.xml file

The following configure.sh syntax specifies three ResourceManager nodes (nodeA, nodeB, and nodeC) and a HistoryServer node (nodeA):

```
/opt/mapr/server/configure.sh -C node1,node2,node3 -Z node1,node2,node3 -RM
nodeA,nodeB,nodeC -HS nodeA [additional parameters]
```

```

Manual Failover Administration

Configure manual failover for the ResourceManager if you want to manually transition the state of ResourceManagers in the cluster. In the event of a ResourceManager failure, you use `rmadmin` commands to check the status of each ResourceManager and then transition a standby ResourceManager to the active state.

Configuring Manual Failover for the ResourceManager

To configure manual failover, specify multiple ResourceManagers when you run `configure.sh` on each node in the cluster and then edit `yarn-site.xml` to disable automatic failover.

1. Specify multiple ResourceManagers when you run configure.sh on each cluster and client node. The following the `configure.sh` script syntax configures three ResourceManager nodes (one active and two standby):

   ```
   /opt/mapr/server/configure.sh -C <CLDB node list> -Z <ZK node list> -RM
   <hostname1,hostname2,hostname3> -HS <hostname1> [additional parameters]
   ```

   Note: After you run `configure.sh`, each ResourceManager node contains a different value for the `yarn.resourcemanager.ha.id` property in the `yarn-site.xml`.

2. Disable the following automatic failover properties in the `yarn-site.xml` on each node with the ResourceManager role:
   - `yarn.resourcemanager.ha.automatic-failover.enabled`
   - `yarn.resourcemanager.ha.automatic-failover.embedded`
3. Restart the ResourceManager service. For more information, see Restarting the Services on page 831.

Transitioning a Standby ResourceManager to Active

The `yarn rmadmin` command includes options to manage high availability for the ResourceManager, including transitioning a ResourceManager node between active and standby modes. These commands take the ResourceManager service ID as an argument and can be run on any node in the cluster. The *serviceID* of a ResourceManager is set in the `yarn.resourcemanager.ha.rm-ids` property of the *yarn-site.xml* file.

Transition a standby ResourceManager to the active state when the active ResourceManager process has failed or the node that runs the process is no longer accessible.

1. Determine if an active ResourceManager is running in the cluster. See Checking the ResourceManager State.
2. Run the following command to set the current active ResourceManager to standby:

   ```
   yarn rmadmin -transitionToStandby <serviceID>
   ```

3. Run the following command to transition the standby ResourceManager to the active state:

```
yarn rmadmin -transitionToActive <serviceID>
```

Checking the ResourceManager State

When you configure manual or automatic failover, the ResourceManager is either in active or standby state. Each ResourceManager has a serviceID that identifies the service.

- To check the state of a ResourceManager, run the following command with the serviceID:

```
yarn rmadmin -getServiceState <serviceID>
```

  The command returns `active` or `standby` based on the state of the ResourceManager associated with the serviceID that you provide.

  Note: Tip To determine the serviceIDs associated with the ResourceManagers in the cluster, run `hadoop conf | grep yarn.resourcemanager.ha.rm-ids`

Using Central Configuration with Manual and Automatic Failover

When you configure manual or automatic failover for the ResourceManager, the contents of the *yarn-site.xml* configuration file are slightly different on each ResourceManager node as the value of the `yarn.resourcemanager.ha.id` property is distinct for each ResourceManager node. If your cluster is using the central configuration feature, configure central configuration overrides for each ResourceManager node:

1. Keep a central copy of the file at */var/mapr/configuration/default/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml*.

2. Configure central configuration overrides in the following manner:
   `/var/mapr/configuration/nodes/<HOSTNAME FOR RM 1>/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml` `/var/mapr/configuration/nodes/<HOSTNAME FOR RM 2>/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml` `/var/mapr/configuration/nodes/<HOSTNAME FOR RM 3>/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml`

Zero Configuration Failover for the ResourceManager

As of MapR 4.0.2, you can use zero configuration failover. With zero configuration failover, the ResourceManager role is installed on two or more nodes but the ResourceManager process only runs on one node in the cluster.

If the node running the ResourceManager process fails and the Warden on that node is unable to restart it, the Warden on each node and Zookeeper work together to start a ResourceManager process on the cluster. ResourceManager clients connect to the Zookeeper to determine which ResourceManager node is active. Therefore, when failover occurs, the Resource Manager clients are not affected as they automatically connect to the active ResourceManager.

Note: When you run `maprcli service list` command, the state of the active ResourceManager process displays as 2 (running) but the other ResourceManagers displays as 5 (stand by).

Enabling Zero Configuration Failover for the ResourceManager

To enable zero configuration failover, do not specify the -RM parameter when you run configure.sh on each node in the cluster. However, for failover to occur, at least two nodes in the cluster must have the ResourceManager role.

last-updated: Apr 11, 2022

For example, if the cluster includes multiple nodes with the ResourceManager role, you can run the following configure.sh command on each cluster node and no further configuration is required:

```
/opt/mapr/server/configure.sh -N mycluster -C centos21 -Z centos21 -HS
centos22 -F /tmp/disks.txt -disk-opts F
```

configure.sh automatically populates yarn-site.xml with the following configuration:

```
<configuration>
<!-- Resource Manager MapR HA Configs -->
<property>
        <name>yarn.resourcemanager.ha.custom-ha-enabled</name>
        <value>true</value>
        <description>MapR Zookeeper based RM Reconnect Enabled.
If this is true, set the failover proxy to be the class
MapRZKBasedRMFailoverProxyProvider</description>
</property>
<property>
        <name>yarn.client.failover-proxy-provider</name>

<value>org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider</
value>
        <description>Zookeeper based reconnect proxy provider. Should
be set if and only if mapr-ha-enabled property is true.</description>
</property>
<property>
        <name>yarn.resourcemanager.recovery.enabled</name>
        <value>true</value>
        <description>RM Recovery Enabled</description>
</property>
<!-- :::CAUTION::: DO NOT EDIT ANYTHING ON OR ABOVE THIS LINE -->
</configuration>
```

For more information about the ResourceManager properties in yarn-site.xml, see ResourceManager Configuration Properties.

Updating ResourceManager Ports

To simplify the failover configurations in the *yarn-site.xml* file, Warden maintains the list of ResourceManager ports in the *warden.resourcemanager.conf* file. For a list of the default port numbers, see Ports Used by MapR Software on page 2290. If you want to edit the default ResourceManager ports, edit the *warden.resourcemanager.conf* file and the *yarn-site.xml* file on each ResourceManager node.

Note: If each node requires different ResourceManager ports, you must maintain a separate *yarn-site.xml* file for each node. Therefore, to you use Central Configuration, you must create a customized configuration file for each ResourceManager node in the cluster.

To update the port numbers, edit the values in the *warden.resourcemanager.conf* file and add the values in the *yarn-site.xml* file.

1. Open the warden.resourcemanager.conf file (`/opt/mapr/conf/conf.d/warden.resourcemanager.conf`).

last-updated: Apr 11, 2022

2. Edit the port numbers, which are listed using the following format: `service.extinfo.<port>=<port number>`

Port Name	Property Name in warden.resourcemanager.conf
ResourceManager Scheduler RPC (for ApplicationMasters)	service.extinfo.SCHEDULER_PORT
ResourceManager Resource Tracker RPC (for NodeManagers)	service.extinfo.RESOURCETRACKER_PORT
ResourceManager Client RPC	service.port
ResourceManager Admin RPC	service.extinfo.ADMIN_PORT
ResourceManager Web UI (HTTP)	service.extinfo.WEBAPP_PORT
ResourceManager Web UI (HTTPS)	service.extinfo.WEBAPP_HTTPS_PORT

3. Open the *yarn-site.xml* file (`/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`).

4. For each port that you edited, add the associated property to the *yarn-site.xml* file:

Port Name	Property Name in yarn-site.xml
ResourceManager Scheduler RPC (for ApplicationMasters)	yarn.resourcemanager.scheduler.address
ResourceManager Resource Tracker RPC (for NodeManagers)	yarn.resourcemanager.resource-tracker.address
ResourceManager Client RPC	yarn.resourcemanager.address
ResourceManager Admin RPC	yarn.resourcemanager.admin.address
ResourceManager Web UI (HTTP)	yarn.resourcemanager.webapp.address
ResourceManager Web UI (HTTPS)	yarn.resourcemanager.webapp.https.address

   For example, to update the port number for the ADMIN_PORT to 9000 on each node, enter the following in the *yarn-site.xml* file on each node:

```
<property>
   <name>yarn.resourcemanager.adminaddress</name>
   <value>10.10.30.140:9000</value>
</property>
```

5. Restart the Warden and the ResourceManager services.

Switching from Zero Configuration to Manual or Automatic Failover

You can change your ResourceManager failover implementation from zero configuration to manual or automatic failover by re-configuring all the cluster and client nodes.

For more information, see Configuring Manual Failover for the Resource Manager or Configuring Automatic Failover for the Resource Manager.

Recovery for the ResourceManager

After a restart or failover, the active ResourceManager recovers the ResourceManager state based on the checkpoints provided in the ResourceManager state store. During recovery, the ResourceManager resumes applications and tasks that were running prior to the failover but were not completed.

Two implementations of the ResourceManager state store are available:

- **FileSystemRMStateStore.** Enables implicit write access to a single ResourceManager node. MapR File System provides fencing implicitly and its state store implementation provides better scalability and failover performance than the ZKRMStateStore. The state store is also naturally protected by MapR File System replication. By default, FileSystemRMStateStore is the state store implementation for the ResourceManager and the ResourceManager state store is maintained in the following MapR filesystem volume: `/var/mapr/cluster/yarn/rm/system`.
- **ZKRMStateStore.** Enables implicit write access to a single ResourceManager node. This is usually recommended for HA implementations where YARN is running on HDFS. However, FileSystemRMStateStore is recommended in a MapR cluster.

Note: For recovery to occur,all ResourceManager nodes must have access to the ResourceManager state store.

ResourceManager Recovery Administration

To change the default behavior, update the ResourceManager configuration in the yarn-site.xml files and restart the ResourceManager(s). The yarn-site.xml is located in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`

You may want to perform the following tasks:

Disabling the restart of applications after failover

You can configure the ResourceManager to not recover its state after a restart or failover occurs.

- Set the value of `yarn.resourcemanager.recovery.enabled` to `false` in `yarn-site.xml` on each ResourceManager node.

Configuring Maximum Attempts for Applications
Describes how to set the maximum number of restart attempts for all applications run by the MapR ResourceManager and the ApplicationMaster.

When an ApplicationMaster fails, the ResourceManager restarts the ApplicationMaster as long as the number of restart attempts does not exceed the max-attempt values set at the ResourceManager and ApplicationMaster level . By default, the maximum attempt value is set to 2.

- To configure the maximum number of ApplicationMaster attempt retries for all applications run by the ResourceManager:

  Set the value of `yarn.resourcemanager.am.max-attempts` in the `yarn-site.xml` file. The value defaults to 2.

- To configure the number of ApplicationMaster attempts allowed for the MapReduce ApplicationMaster:

  Set the value of `mapreduce.am.max-attempts` in the `mapred-site.xml` file. The value defaults to 2.

Configuring the MapR File System State Store
Describes the configuration of the MapR state store.

By default, the Resource Manager stores its state in the MapR filesystem. However, you can change the values for the following properties related to the MapR filesystem state store:

- To configure the URI to the state store location:

  Set the value of `yarn.resourcemanager.fs.state-store.uri` in the `yarn-site.xml` file. The value defaults to the ResourceManager volume (`/var/mapr/cluster/yarn/rm/system`).

- To configure the retry policy used by the state store client to connect with MapR file system:

  Set the value of `yarn.resourcemanager.fs.state-store.retry-policy-spec` in the `yarn-site.xml` file. The value defaults to (2000,500).

- To configure the number of completed applications retained by the state store:

  Set the value of `yarn.resourcemanager.state-store.max-completed-applications` in the `yarn-site.xml` file. The value defaults to 10000.

Enabling ZooKeeper Based State Store

By default, the Resource Manager stores its state in the MapR File System. However, you can use the Zookeeper based state store instead. To configure the ResourceManager to use the Zookeeper state store:

- Set the value of `yarn.resourcemanager.store.class` to `org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore` in the yarn-site.xml.
- Set the value of `yarn.resourcemanager.zk-address` to a comma-separated list of host:port pairs for each ZooKeeper server used by the ResourceManager. This property needs to be set in yarn-site.xml.

ResourceManager Configuration Properties

The following sections describe the properties that you can configure for the ResourceManager. The default values for these properties are defined in the yarn-default.xml or by MapR. You can configure overrides to the default by adding to or editing the properties in yarn-site.xml.

The following sections provide information about ResourceManager failover and recovery properties:

ResourceManager Failover Properties

The following table describes the configuration properties for ResourceManager failover:

Property	Description
yarn.resourcemanager.ha.custom-ha-enabled	When yarn.client.failover-proxy-provider is set to org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider, this property must `true`. The default, set by configure.sh in yarn-site.xml when the cluster uses zero configuration failover for the ResourceManager, is `true`.
yarn.resourcemanager.ha.enabled	Enables high availability for the ResourceManager. The default, set by MapR in the yarn-site.xml, is `true`. This property must be set to `true` for failover to occur.
yarn.resourcemanager.ha.automatic-failover.enabled	When yarn.resourcemanager.ha.enabled is true, this property enables the ResourceManager to automatically failover. The default, set in yarn-default.xml, is `true`.
yarn.resourcemanager.ha.automatic-failover.embedded	When yarn.resourcemanager.ha.enabled is true, this property enables the ResourceManager to use the embedded automatic failover. The default, set in yarn-default.xml, is `true`.
yarn.resourcemanager.cluster-id	Specifies the cluster that the ResourceManager belongs to. This value is originally set by configure.sh in the yarn-site.xml and the value is required for failover to occur.
yarn.resourcemanager.ha.rm-ids	The ResourceManager service ID. Configure.sh adds this property to each node with the ResourceManager role.

Property	Description
yarn.resourcemanager.ha.id	Specifies the serviceID of the ResourceManager on the current node.
yarn.resourcemanager.zk-address	Specifies the zookeeper quorum that the ResourceManager belongs to. This value is originally set by configure.sh in the yarn-site.xml when you configure failover.
yarn.client.failover-proxy-provider	Specifies the ResourceManager failover implementation used by clients, ApplicationMasters, and NodeManagers. configure.sh sets this value based on the type of failover that you configure. • For automatic or manual failover, configure.sh sets this value to org.apache.hadoop.yarn.client.ConfiguredRMFailoverProxyProvider • For zero configuration failover, configure.sh sets this value to org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider This value is set by configure.sh in yarn-site.xml when you configure failover. Otherwise, the default, set in yarn-default.xml is org.apache.hadoop.yarn.client.DefaultFailoverProxyProvider.
yarn.resourcemanager.scheduler.address[.<serviceID>]	The address of the scheduler interface This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.resource-tracker.address[.<serviceID>]	The address of the resource tracker interface. ResourceManager listens for container requests and heartbeats from the NodeManagers on this port. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.address[.<serviceID>]	The address of the client interface. The ResourceManager listens for client requests on this port. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.

last-updated: Apr 11, 2022

Property	Description
yarn.resourcemanager.admin.address[.<serviceID>]	The address of the administrative interface. ResourceManager listens for administrative requests from the yarn rmadmin command on this port. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.webapp.address[.<serviceID>]	The address of the ResourceManager web UI. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.webapp.https.address[.<serviceID>]	The address of the secure ResourceManager web UI. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.client.failover-max-attempts	The max number of times FailoverProxyProvider should attempt failover. The default is -1.
yarn.client.failover-sleep-base-ms	The sleep base (in milliseconds) to be used for calculating the exponential delay between failovers. The value defaults to the value set by yarn.resourcemanager.connect.retry-interval.ms, which is 30000 ms.
yarn.client.failover-sleep-max-ms	The maximum sleep time (in milliseconds) between failovers. The value defaults to the value set by yarn.resourcemanager.connect.retry-interval.ms, which is 30000 ms.
yarn.client.failover-retries	The number of times a client attempts to reconnect to a ResourceManager. The default, set in yarn-default.xml, is 0 (infinite).
yarn.client.failover-retries-on-socket-timeouts	The number of times a client attempts to reconnect to a ResourceManager on socket timeouts. The default, set in yarn-default.xml, is 0 (infinite).

ResourceManager Recovery Properties

The following table describes the configuration properties for ResourceManager recovery:

last-updated: Apr 11, 2022

Property	Description
yarn.resourcemanager.recovery.enabled	Enables the Resourcemanager to recovery based on the information in the ResourceManager state store. The default, set by configure.sh, is `true`.
yarn.resourcemanager.am.max-attempts	The maximum number of application attempts. This is a global setting for all ApplicationMaster nodes. You can configure an individual maximum number of application attempts for each ApplicationMaster node, but this property sets a global upper bound that overrides the individual node configuration. The default, set in yarn-default.xml, is 2.
mapreduce.am.max-attempts	The maximum number of MapReduce application attempts. If this value is larger than the value set by the ResourceManager, the ResourceManager value will override this value. The default number is set to 2, to allow at least one retry for AM. This property is set in mapred-default.xml.
yarn.resourcemanager.fs.state-store.uri	URI pointing to the location of the FileSystem path where the ResourceManager state is stored. The default value is configured to the path for the ResourceManager volume (`/var/mapr/cluster/yarn/rm/system`). If the FileSystem name is not provided, the system uses the value specified in the `fs.default.name` specified in the `core-site.xml` file.
yarn.resourcemanager.fs.state-store.retry-policy-spec	Specifies the retry policy for the MapR File System client. This policy is specified in pairs of values for the sleep time, in milliseconds, and number of retries. Each pair is enclosed in parentheses, such as `(1000,20), (2000,30)`. The previous example sleeps for 1000 milliseconds for twenty retries, then thirty more retries 2000 milliseconds apart. The default, set in yarn-default.xml, is `(2000,500)`.
yarn.resourcemanager.store.class	The class name of the state-store to be used for saving application/attempt state and the credentials. The available state-store implementations are `org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore`, a ZooKeeper based state-store implementation, and `org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore`, a state-store implementation based on MapR File System. The default, yarn-default.xml, is `org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore`.

Property	Description
yarn.resourcemanager.state-store.max-completed-applications	The maximum number of completed applications that the state store retains, which is a number less than or equal to ${yarn.resourcemanager.max-completed-applications}. The default value is 10000. This setting ensures that the applications kept in the state store are consistent with the applications in ResourceManager memory. Any value larger than ${yarn.resourcemanager.max-completed-applications} is reset to the default. The value of this property affects ResourceManager recovery performance.Typically, a smaller value optimizes performance for recovery.
yarn.resourcemanager.zk-address	A comma-separated list of Host:Port pairs. Each corresponds to a ZooKeeper server, such as 127.0.0.1:5181,127.0.0.1:5181,127.0.0.1:5181. These hosts are used by the ResourceManager to store state.
yarn.resourcemanager.zk-state-store.parent-path	The full path of the root znode where ResourceManager state is stored. The default value is/rmstore.
yarn.resourcemanager.zk-num-retries	Number of times the ResourceManager tries to connect to the ZooKeeper server when the connection is lost. The default value is 500.
yarn.resourcemanager.zk-retry-interval-ms	The interval between retries, in milliseconds, when connecting to a ZooKeeper server. The default value is 2000.
yarn.resourcemanager.zk-timeout-ms	The ZooKeeper session timeout in milliseconds. The ZooKeeper server uses this configuration to determine session expiration. Sessions expire when the server does not receive a heartbeat from the client within the session timeout period. The default value is 10000.
yarn.resourcemanager.zk-acl	ACLs that set permissions on ZooKeeper znodes. The default value is world:anyone:rwcda

Administrator's Reference

This section contains in-depth reference information for the administrator.

maprcli and REST API Syntax

This section provides information about the MapR command API. Most commands can be run on the command-line interface (CLI), or by making REST requests programmatically or in a browser.

To run CLI commands, use an ssh connection to any node in the cluster. To use the REST interface, make HTTP requests to a node that is running the WebServer service.

last-updated: Apr 11, 2022

Overview
Each command reference page includes the command syntax, a table that describes the parameters, and examples of command usage.

In each parameter table, required parameters are in **bold** text. For output commands, the reference pages include tables that describe the output fields. Values that do not apply to particular combinations are marked **NA**.

REST API Syntax
Describes the MapR REST API syntax format.

MapR REST calls use the following format:

```
https://<host>:<port>/rest/<command>[/<subcommand>...]?<parameters>
```

Construct the `<parameters>` list from the required and optional parameters, in the format `<parameter>=<value>` separated by the ampersand (&) character. Example:

```
https://r1n1.qa.sj.ca.us:8443/rest/volume/mount?name=test-volume&path=/test
```

Values in REST API calls must be URL-encoded. For readability, the values in this document use the actual characters, rather than the URL-encoded versions.

Authentication

To make REST calls using `curl` or `wget`, provide the username and password. To configure PAM for REST API, see PAM Configuration.

Curl Syntax

```
curl -k -u <username> https://<host>:<port>/rest/<command>...
```

Warning: To keep your password secure, do not provide it on the command line. Curl will prompt you for your password, and you can enter it securely.

Wget Syntax

```
wget --no-check-certificate --user <username> --ask-password https://
<host>:<port>/rest/<command>...
```

Warning: To keep your password secure, do not provide it on the command line. Use the `--ask-password` option instead; then wget will prompt you for your password and you can enter it securely.

To authenticate to the REST interface, use basic authentication or SPNEGO.

Basic Authentication

To authenticate using basic authentication, send a request with a basic authorization header, which has a user ID and password. For example, to authenticate using basic authentication, run the following command:

```
curl https://
<webserver-hostname>:8443/login -d
'username=root&password=mapr'
```

On the other hand, if you do not wish to reauthenticate with every request, you can save the cookie and send the cookie with every subsequent request. For example, to authenticate and save the cookie in a text

last-updated: Apr 11, 2022

file named `cookiejar.txt` in `/tmp` directory, run the following command:

```
curl -X POST -c /tmp/
cookiejar.txt "https://
<webserver-hostname>:8443/login -d"
'username=<name>&password=<pwd>'
```

To send the cookie with subsequent requests, for example to retrieve the list of nodes on the cluster, you can submit a request similar to the following:

```
curl -L -b /tmp/cookiejar.txt
"https://<webser-hostname>:8443/rest/
node/list/"
```

SPNEGO

To authenticate using SPNEGO, ensure that the apiserver nodes are configured for SPNEGO. After configuring, send a negotiate authorization header. For example, to authenticate with the SPNEGO token and save the cookie in a text file named `cookiejar.txt` in your home directory, run the following command:

```
curl --negotiate -u : -b ~/
cookiejar.txt -c ~/cookiejar.txt
https://<web server node>:8443/rest/
<API call> -k -v
```

The contents of the cookie is something similar to the following:

```
cat /tmp/cookiejar.txt
# Netscape HTTP Cookie File
# https://curl.haxx.se/docs/http-cookies.html
# This file was generated by libcurl! Edit at your own risk.

#HttpOnly_<webserver-hostname>  FALSE  /  TRUE   1509486224
MAPR.APISERVER.JSESSIONID  node014ukard563rhu1ns8umn2s6uft3709.node0
#HttpOnly_<webserver-hostname>  FALSE  /  FALSE  0
MAPR.APISERVER.SESSIONID   HZA9C20D084E614E36AA567F47FC9105A4
```

REST API Calls to Remote Cluster

If you have secure clusters and you wish to make REST API calls to a remote secure cluster, you can specify the `cluster` parameter in the request if you have your environment configured for remote access. To set up your environment for API calls to remote secure cluster:

1. Follow the steps for configuring secure clusters for running commands remotely.
2. Verify access to run remote commands.
3. Rename the ticket file generated using the `maprlogin password` command to `maprusertickt` and move the file to `/opt/mapr/conf` directory.

Command-Line Interface

Describes how the MapR CLI command syntax is documented.

The MapR CLI commands are documented using the following conventions:

- `[Square brackets]` indicate an optional parameter

last-updated: Apr 11, 2022

- `<Angle brackets>` indicate a value to enter

The following syntax example shows that the `volume mount` command requires the `-name` parameter, for which you must enter a list of volumes, and all other parameters are optional:

```
maprcli volume mount
      [ -cluster <cluster> ]
      -name <volume list>
      [ -path <path list> ]
```

For clarity, the syntax examples show each parameter on a separate line; in practical usage, the command and all parameters and options are typed on a single line. Example:

```
maprcli volume mount -name test-volume -path /test
```

Common Parameters
Describes parameters that are available for many commands.

The following parameters are available for many commands in both the REST and command-line contexts.

Parameter	Description
cluster	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
zkconnect	A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: `'<host>[:<port>][,<host>[:<port>]...]'` Default: `'localhost:5181'` In most cases the ZooKeeper connect string can be omitted, but it is useful in certain cases when the CLDB is not running.

Common Options
Describes options that are available for many commands.

The following options are available for most commands in the command-line context.

Option	Description
-noheader	When displaying tabular output from a command, omits the header row.
-long	Shows the entire value. This is useful when the command response contains complex information. When -long is omitted, complex information is displayed as an ellipsis (...).
-json	Displays command output in JSON format. When -json is omitted, the command output is displayed in tabular format.

Option	Description
-cli.loglevel	Specifies a log level for API output. Legal values for this option are: • DEBUG • INFO • ERROR • WARN • TRACE • FATAL

Filters
Describes the use of filters with MapR CLI commands.

Some MapR CLI commands use *filters*, which let you specify large numbers of nodes or volumes by matching specified values in specified fields rather than by typing each name explicitly.

Filters use the following format:

```
[<field><operator>"<value>"]<and>[<field><operator>"<value>"] ...
```

field	Field on which to filter. The field depends on the command with which the filter is used.
operator	An operator for that field: • == - Exact match • `!=` - Does not match • > - Greater than • < - Less than • >= - Greater than or equal to • <= - Less than or equal to
value	Value on which to filter. Wildcards (using *) are allowed for operators == and `!=`. There is a special value `all` that matches all values.

You can use the wildcard (*) for partial matches. For example, you can display all volumes whose owner is `root` and whose name begins with `test` as follows:

```
maprcli volume list -filter [n=="test*"]and[on=="root"]
```

Note: maprcli commands and REST APIs do not support OR conditions.

Response
Describes the different return responses.

The commands return responses in JSON or in a tabular format. When you run commands from the command line, the response is returned in tabular format unless you specify JSON using the -json option; when you run commands through the REST interface, the response is returned in JSON.

last-updated: Apr 11, 2022

Note: The columns returned by operations such as `get`, `list`, `info`, and so on are not sorted in any particular order.

Success

On a successful call, each command returns the error code zero (OK) and any data requested. When JSON output is specified, the data is returned as an array of records along with the status code and the total number of records. In the tabular format, the data is returned as a sequence of rows, each of which contains the fields in the record separated by tabs.

JSON

```
{
              "status":"OK",
              "total":<number of
records>,
              "data":[
              {
              <record>
              }
              ...
              ]
              }
```

Tabular

```
status
              0
```

Or

```
<heading>   <heading>   <heading> ...
              <field>     <field>
<field> ...
              ...
```

Error

When an error occurs, the command returns the error code and descriptive message.

JSON

```
{
            "status":"ERROR",
            "errors":[
            {
            "id":<error code>,
            "desc":"<command>: <error
message>"
            }
            ]
            }
```

Tabular

```
ERROR (<error code>) -  <command>:
<error message>
```

acerole validate
Verifies given user roles for ACEs exists in the `/opt/mapr/conf/m7_permissions_roles_refimpl.conf` file.

last-updated: Apr 11, 2022

This command returns `true` if role exists in the `/opt/mapr/conf/m7_permissions_roles_refimpl.conf` file and `false` if given role is not in the file. If the `MAPR_ROLES_LIB_ENABLE_TRACE` environment variable is set to `TRUE`, the command returns also the number of users assigned to the specified role and the number of roles in the file.

Syntax

```
/opt/mapr/bin/maprcli acerole validate -role <role to validate>
```

Parameters

Parameter	Description
`role`	The role to validate.

Examples

Verifies whether given role exists when the `MAPR_ROLES_LIB_ENABLE_TRACE` environment variable is not set:

```
$ maprcli acerole validate -role Role_1
maprcli acerole validate command returned : true
```

Verifies whether given role exists when the `MAPR_ROLES_LIB_ENABLE_TRACE` environment variable is set:

```
$ export MAPR_ROLES_LIB_ENABLE_TRACE=TRUE
$ echo $MAPR_ROLES_LIB_ENABLE_TRACE
TRUE
$ maprcli acerole validate -role Role_1
RoleMap: Added user 500 with role 'Role_1'
RoleMap: Added user 1000 with role 'Role_1'
RoleMap: found 2 users and 2 roles.
maprcli acerole validate command returned : true
```

acl
Describes the acl commands used to access control lists (ACLs).

Specifying Permissions

Specify permissions for a user or group with a string that lists the permissions for that user or group. To specify permissions for multiple users or groups, use a string for each, separated by spaces. The format is as follows:

- Users -

  ```
  <user>:<action>[,<action>...][<user>:<action>[,<action...]]
  ```

- Groups -

  ```
  <group>:<action>[,<action>...][<group>:<action>[,<action...]]
  ```

To use the `acl edit` command, you must have full control (`fc`) permission on the cluster or volume for which you are running the command.

The following tables list the permission codes used by the `acl` commands.

Cluster Permission Codes

Permission Code	Allowed Action
login	Log in to the MapR Control System, use the API and command-line interface, read access on cluster and volumes.
ss	Start/stop services.
cv	Create volumes.
a	Administrative access to cluster ACLs. Grants no other permissions.
fc	Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster ACLs.

Volume Permission Codes

Code	Allowed Action
dump	Dump the volume.
restore	Mirror or restore the volume.
m	Modify volume properties, create and delete snapshots.
d	Delete a volume.
a	Administrative access to volume ACLs.
fc	Full control (admin access and permission to change volume ACL).

Security Policy Permission Codes

Code	Allowed Action
a (admin)	View and modify the permissions on a security policy; cannot view or modify the security policy.
fc (full control)	View and modify the security policy, including data access ACEs; cannot view or modify the permissions on a security policy.
r (read)	View all parts of a security policy; cannot modify the security policy.

acl edit
Modifies a specific user's access to a cluster, volume, or security policy.

Permissions Required

The `acl edit` command grants one or more specific volume or cluster permissions to a user. To use the `acl edit` command, you must have administrative (a) permissions on the volume and cluster for which

last-updated: Apr 11, 2022

you are running the command. The permissions are specified as a comma-separated list of permission codes. See acl on page 1528.

Syntax

CLI

```
/opt/mapr/bin/maprcli acl edit
    [ -cluster <cluster name> ]
    [ -group <group> ]
    [ -name <name> ]
    -type cluster|volume|
    [ -user <user> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/acl/edit?<parameters>`

Parameters

Parameter	Description
cluster	The cluster on which to run the command.
group	Groups and allowed actions for each group. See acl on page 1528. Format: `<group>:<action>[,<action>...] [ <group>:<action>[,<action...]]`. You must specify either a `user` or a `group`.
name	The object name. For a volume, specify the name of the volume in this parameter.
type	The object type (`cluster` or `volume`). When the type is `volume`, specify a volume name using the `name` parameter.
user	Users and allowed actions for each user. See acl on page 1528. Format: `<user>:<action>[,<action>...] [ <user>:<action>[,<action...]].` You must specify either a `user` or a `group`.

Examples

Give the user jsmith dump, restore, and delete permissions for "test-volume":

CLI

```
/opt/mapr/bin/maprcli acl edit -type
volume -name test-volume -user
jsmith:dump,restore,d
```

REST

```
https://10.10.82.22:8443/rest/acl/
edit?
```

last-updated: Apr 11, 2022

```
type=volume&name=test-volume&user=jsmi
th%3Adump,restore,d
```

acl set
Modifies the Access Control List (ACL) for a cluster, volume, or security policy.

The `acl set` command specifies the *ACL* for a cluster or volume. Any previous permissions are overwritten by the new values, and any permissions omitted are removed. To use the `acl set` command, you must have administrative (a) permissions on the volume and cluster for which you are running the command. The ACL permissions are specified as a comma-separated list of permission codes. See acl on page 1528. You must specify either a `user` or a `group`. When the `type` is `volume`, you must specify a volume name using the `name` parameter.

The `acl set` command removes any previous *ACL* values. To preserve some of the permissions, you should either use the `acl edit` command instead of `acl set`, or use `acl show` to list the values before overwriting them.

Syntax

CLI

```
/opt/mapr/bin/maprcli acl set
    [ -cluster <cluster name> ]
    [ -group <group> ]
    [ -name <name> ]
    -type cluster|volume|
    [ -user <user> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/acl/set?<parameters>`

Parameters

Parameter	Description
cluster	The cluster on which to run the command.
group	Groups and allowed actions for each group. See acl on page 1528. Format: `<group>:<action>[,<action>...] [ <group>:<action>[,<action...]]`
name	The object name. For a volume, specify the name of the volume in this parameter.
type	The object type (`cluster` or `volume`).
user	Users and allowed actions for each user. See acl on page 1528. Format: `<user>:<action>[,<action>...] [ <user>:<action>[,<action...]]`

last-updated: Apr 11, 2022

Examples

Give the user `root` full control of the `my.cluster.com` cluster and remove all permissions for all other users:

CLI

```
/opt/mapr/bin/maprcli acl set -type
cluster -user user10:fc
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/acl/set?
type=cluster&user=user10%3Afc' --user
mapr:mapr
{"timestamp":1525462091620,"timeofday"
:"2018-05-04 12:28:11.620 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

Usage Example

```
# /opt/mapr/bin/maprcli acl show -type cluster
Allowed actions           Principal
[login, ss, cv, a, fc, cp] User mapr
[login, ss, cv, a, fc, cp] User root
[login, cp]  User fuser1

# /opt/mapr/bin/maprcli acl set -type cluster -cluster my.cluster.com -user
root:fc
# /opt/mapr/bin/maprcli acl show -type cluster
Principal  Allowed actions
User root  [login, ss, cv, a, fc, cp]
```

Warning: Notice that the specified permissions have overwritten the existing *ACL*.

Give multiple users specific permissions for the `egVol1` volume and remove all permissions for all other users:

CLI

```
# /opt/mapr/bin/maprcli acl
set -type volume -name
egVol1 -user m7user5:dump,restore,m
m7user4:fc -json
{
    "timestamp":1525462647371,
    "timeofday":"2018-05-04
12:37:27.371 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
# curl -k -X POST 'https://
10.10.82.24:8443/rest/acl/set?
type=volume&name=egVol1&user=m7user5%3
Adump,restore,m%20m7user4%3Afc' --user
 mapr:mapr
{"timestamp":1525463080941,"timeofday"
:"2018-05-04 12:44:40.941 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

last-updated: Apr 11, 2022

acl show
Displays the ACL associated with an object (cluster or a volume).

Syntax

An ACL contains the list of users who can perform specific actions.

CLI

```
/opt/mapr/bin/maprcli acl show
     -type object type [cluster|
volume|securitypolicy]
    [ -name name ]
    [ -cluster cluster name ]
    [ -user userName whose ACL is
queried ]
    [ -group groupName whose ACL is
queried ]
    [ -output output format short|
long|terse (default short). default:
short ]
    [ -perm list of available
permissions Parameter takes no
value  ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/acl/show?<parameters>`

Parameters

Parameter	Description
cluster	The name of the cluster on which to run the command.
group	The group for which to display permissions.
name	The cluster or volume name.
output	The output format: • long • short • terse The default format is `short`.
perm	When you specify this option, `acl show` displays the permissions available for the object type specified in the `type` parameter.
type	Value can be one of `cluster` or `volume`. If type is `volume`, the volume `name` is required.
user	The user for whom to display permissions.

last-updated: Apr 11, 2022

Output

The actions that each user or group is allowed to perform on the cluster or the specified volume. For information about each allowed action, see acl on page 1528.

```
Principal   Allowed actions
User root   [login, ss, cv, a, fc]
Group root  [login, ss, cv, a, fc]
All users   [login]
```

Examples

Show the ACL for the cluster:

CLI

```
# /opt/mapr/bin/maprcli acl
show -type cluster -json
{
    "timestamp":1555494572399,
    "timeofday":"2019-04-17
02:49:32.399 GMT-0700 AM",
    "status":"OK",
    "total":2,
    "data":[
        {
            "Principal":"User mapr",
            "Allowed
actions":"[login, ss, cv, a, fc, cp]"
        },
        {
            "Principal":"User root",
            "Allowed
actions":"[login, ss, cv, a, fc, cp]"
        }
    ]
}
```

REST

```
curl -u mapr:mapr -X GET -k "https://
host:8443/rest/acl/show?type=cluster"
{"timestamp":1555494852652,"timeofday"
:"2019-04-17 02:54:12.652 GMT-0700
AM","status":"OK","total":2,"data":
[{"Principal":"User mapr","Allowed
actions":"[login, ss, cv, a, fc,
cp]"},{"Principal":"User
root","Allowed actions":"[login, ss,
cv, a, fc, cp]"}]}
```

Show the ACL for "test-volume":

CLI

```
# /opt/mapr/bin/maprcli acl
show -type volume -name sampleVol1
Allowed actions
Principal
[dump, restore, m, a, d, fc]  User
mapr
[dump, restore, m, d, fc]     User
foo
[dump, restore, a]            User
```

```
bar
[m, d]                          User abc
```

REST

```
# curl -u mapr:mapr -X GET -k
"https://host:8443/rest/acl/show?
type=volume&name=sampleVol1"
{"timestamp":1525461068100,"timeofday"
:"2018-05-04 12:11:08.100 GMT-0700
PM","status":"OK","total":4,"data":
[{"Principal":"User mapr","Allowed
actions":"[dump, restore, m, a, d,
fc]"},{"Principal":"User
foo","Allowed actions":"[dump,
restore, m, d, fc]"},
{"Principal":"User bar","Allowed
actions":"[dump, restore, a]"},
{"Principal":"User abc","Allowed
actions":"[m, d]"}]}
```

Show the permissions that can be set on a cluster:

CLI

```
# /opt/mapr/bin/maprcli acl
show -type cluster -perm
Permissions
Description
login        Login
access
ss           Start/stop services in
the cluster
cv           Create
volumes
a
Administrator
fc           Full
control
cp           Create security policies
```

REST

```
# curl -u mapr:mapr -X GET -k
"https://host:8443/rest/acl/show?
type=cluster&perm"
{"timestamp":1555497261931,"timeofday"
:"2019-04-17 03:34:21.931 GMT-0700
AM","status":"OK","total":6,"data":
[{"Permissions":"login","Description":
"Login access"},
{"Permissions":"ss","Description":"Sta
rt/stop services in the cluster"},
{"Permissions":"cv","Description":"Cre
ate volumes"},
{"Permissions":"a","Description":"Admi
nistrator"},
{"Permissions":"fc","Description":"Ful
l control"},
{"Permissions":"cp","Description":"Cre
ate security policies"}]}
```

alarm
Describes the alarm commands that perform functions related to system alarms.

Alarm Notification Fields

The following fields specify the configuration of alarm notifications.

Field	Description
alarm	The named alarm.
individual	Specifies whether individual alarm notifications are sent to the default email address for the alarm type: • 0 - do not send notifications to the default email address for the alarm type • 1 - send notifications to the default email address for the alarm type
email	A custom email address for notifications about this alarm type. If specified, alarm notifications are sent to this email address, regardless of whether they are sent to the default email address.

Alarm Types

See Alarms Reference.

Alarm History

To see a history of alarms that have been raised, look at the file `/opt/mapr/logs/cldb.log` on the master CLDB node. Example:

```
grep ALARM /opt/mapr/logs/cldb.log
```

alarm clear
Clears one or more alarms. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli alarm clear
    -alarm <alarm>
    [ -cluster <cluster> ]
    [ -entity entity (hostname OR
volume name OR Ae name) ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/alarm/clear?<parameters>`

last-updated: Apr 11, 2022

Parameters

Parameter	Description
alarm	The named alarm to clear. See Alarm Types.
cluster	The cluster on which to run the command.
entity	The entity on which to clear the alarm.

Examples
Clear a specific alarm:

CLI

```
maprcli alarm clear -alarm
NODE_ALARM_DEBUG_LOGGING
```

REST

```
https://abc.sj.us:8443/rest/alarm/
clear?alarm=NODE_ALARM_DEBUG_LOGGING
```

alarm clearmulti
Clears all alarm occurences of specified multiple alarm types. Permissions required: fc or a.

Syntax

CLI

```
maprcli alarm clearmulti
   [ -cluster cluster_name ]
   -alarm alarm[:entity][:aetype]
<comma seperated alarms>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/alarm/clearmulti?<parameters>`

Parameters

Parameter	Description
alarm	Comma seperated list of alarm types to clear.
cluster	The cluster on which to run the command. Default is the current cluster.

Examples
Clear a specific alarm:

CLI

```
maprcli alarm clear -alarm
NODE_ALARM_DEBUG_LOGGING,VOLUME_ALARM_
COMPACTION_FAILURE
```

last-updated: Apr 11, 2022

REST

```
https://abc.sj.us:8443/rest/alarm/
clear?
alarm=NODE_ALARM_DEBUG_LOGGING,VOLUME_
ALARM_COMPACTION_FAILURE
```

alarm clearall
Clears all alarms. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli alarm clearall
    [ -cluster <cluster> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/alarm/clearall?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.

Examples
Clear all alarms:

CLI

```
maprcli alarm clearall
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
clearall
```

alarm config load
Displays the configuration of alarm notifications. Permission required: `login`

Syntax

CLI

```
maprcli alarm config load
    [ -cluster <cluster> ]
    [ -output terse|verbose ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/alarm/config/load?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`output`	Whether the output should be terse or verbose.

Output

A list of configuration values for alarm notifications.

Output Fields

See Alarm Notification Fields.

Sample output

```

```

Examples

Display the alarm notification configuration:

CLI

```
maprcli alarm config load
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
config/load
```

alarm config save

Sets notification preferences for alarms. Permissions required: `fc` or `a`.

Alarm notifications can be sent to the default email address and a specific email address for each named alarm. If `individual` is set to `1` for a specific alarm, then notifications for that alarm are sent to the default email address for the alarm type. If a custom email address is provided, notifications are sent there regardless of whether they are also sent to the default email address.

Syntax

CLI

```
maprcli alarm config save
    [ -cluster <cluster> ]
    -values <values>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/alarm/config/save?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`values`	A comma-separated list of configuration values for one or more alarms, in the following format: `<alarm>,<individual>,<email>` See Alarm Notification Fields.

Examples

Send alert emails for the AE_ALARM_AEQUOTA_EXCEEDED alarm to the default email address and a custom email address:

CLI

```
maprcli alarm config save -values
"AE_ALARM_AEQUOTA_EXCEEDED,1,test@exam
ple.com"
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
config/save?
values=AE_ALARM_AEQUOTA_EXCEEDED,1,tes
t@example.com
```

alarm group

Alarm groups are groups of alarms for which email addresses of users/groups can be set (to send alert to when an alarm is raised) and removed.

Permissions required: fc or a

alarm group addalarms

Add alarms to a group.

Syntax

CLI

```
maprcli alarm group addalarms
    -groupname <group name>
    -alarms <alarm name>
```

REST API N/A

Parameters

Parameter	Description
groupname	The name of the alarm group to create. If necessary, run listGroup to retrieve the list of alarm groups.
alarms	The comma-separated list of alarms to add to the group.

last-updated: Apr 11, 2022

Examples

Add alarms to alarm group:

```
maprcli alarm group addAlarms
    -groupname cldb.alarm.group.info
    -alarms NODE_ALARM_HB_PROCESSING_SLOW,CLUSTER_ALARM_CLUSTER_ALMOST_FULL
```

alarm group addemails

Adds the email addresses of users/groups to send alert to when an alarm is raised.

Syntax

CLI

```
maprcli alarm group addEmails
    [ -cluster <cluster_name> ]
    -groupname <group name>
    -emails <email addresses>
```

REST API

N/A

Parameters

Parameter	Description
cluster	The cluster on which to run the command.
groupname	The name of the alarm group to add the email addresses to. When an alarm in the group is raised, an alert email will be sent to the users/groups. If necessary, run listgroup to retrieve the list of alarm groups.
emails	The comma-separated list of email addresses of users to send alert emails to when an alarm is raised.

Examples

Add email addresses to `cldb.alarm.group.error` group.

```
maprcli alarm group addEmails -groupname cldb.alarm.group.error -emails
abc@gmail.com,xyz@gmail.com
```

alarm group deletealarms

Delete alarms in an alarm group.

Syntax

CLI

```
maprcli alarm group deletealarms
    -groupname <group name>
    -alarms <alarm name>
```

REST API

N/A

Parameters

Parameter	Description
groupname	The name of the alarm group to remove alarms from.

Parameter	Description
alarms	The comma-separated list of alarms to remove from the group.

Examples

Delete NODE_ALARM_HB_PROCESSING_SLOW and CLUSTER_ALARM_CLUSTER_ALMOST_FULL alarms in the `cldb.alarm.group.info` group:

```
maprcli alarm group deleteAlarms
    -groupname cldb.alarm.group.info
    -alarms NODE_ALARM_HB_PROCESSING_SLOW,CLUSTER_ALARM_CLUSTER_ALMOST_FULL
```

alarm group deleteemails

Deletes the email addresses of users/groups.

Syntax

CLI

```
maprcli alarm group deleteEmails
    [ -cluster <cluster_name> ]
    -groupname <group name>
    -emails <email addresses>
```

REST API N/A

Parameters

Parameter	Description
cluster	The cluster on which to run the command.
groupname	The name of the alarm group to remove the email addresses from. If necessary, run listgroup to retrieve the list of alarm groups.
emails	The comma-separated list of email addresses of users/groups to remove.

Examples

Delete the given emails associated with the `cldb.alarm.group.error` group:

```
maprcli alarm group deleteEmails -groupname cldb.alarm.group.error -emails
xyz@gmail.com,abc@gmail.com
```

alarm group listgroup

Lists the alarm groups.

Note: The three dots in the output indicate multiple alarms in the group. Use `-json` to format the output.

Syntax

CLI

```
maprcli alarm group listGroup
    [ -cluster <cluster_name> ]
```

last-updated: Apr 11, 2022

```
    [ -start ]
    [ -limit ]
    [ -output <verbose> ]
```

REST API N/A

Parameters

Parameter	Description
cluster	The cluster on which to run the command.
start	The list offset at which to start. Default: 0
limit	The number of records to retrieve. Default value is 2147483647.
output	The output format: • terse • verbose Default value is verbose.

Examples

Return the list of alarms and associated email addresses.

```
# maprcli alarm group listGroup
alarm name emails group name
... abc@mapr.com cldb.alarm.group.error
... cldb.alarm.group.info
... cldb.alarm.group.warn
```

Return the list of alarms and associated email addresses in JSON format.

```
root@saradaqa4:~# maprcli alarm group listGroup -json
{
    "timestamp":1495018857252,
     "timeofday":"2017-05-17 11:00:57.252 GMT+0000",
     "status":"OK",
     "total":3,
     "data":[
  {
     "group name":"cldb.alarm.group.error",
     "emails":"abc@mapr.com",
     "alarm name":[
        "NODE_ALARM_DISK_FAILURE",
        "CLUSTER_ALARM_LICENSE_EXPIRED",
        "CLUSTER_ALARM_CLUSTER_FULL",
        "NODE_ALARM_NO_DISK_ATTACHED",
        "VOLUME_ALARM_SNAPSHOT_FAILURE",
        "VOLUME_ALARM_MIRROR_FAILURE",
        "NODE_ALARM_CORE_PRESENT",
        "NODE_ALARM_HIGH_MFS_MEMORY",
        "VOLUME_ALARM_DATA_UNAVAILABLE",
        "NODE_ALARM_MAPRUSER_MISMATCH",
        "VOLUME_ALARM_NO_NODES_IN_TOPOLOGY",
        "VOLUME_ALARM_TABLE_REPL_ERROR",
        "NODE_ALARM_NO_HEARTBEAT",
        "VOLUME_ALARM_QUOTA_EXCEEDED",
```

```
        "VOLUME_ALARM_TOPOLOGY_FULL",
        "NODE_ALARM_PAM_MISCONFIGURED",
        "NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED",
        "NODE_ALARM_TOO_MANY_CONTAINERS",
        "NODE_ALARM_NUM_INSTANCES_MISMATCH",
        "AE_ALARM_AEQUOTA_EXCEEDED"
    ]
}
```

alarm list
Lists alarms in the system. Permissions required: `login`.

You can list all alarms, alarms by type (Cluster, Node or Volume), or alarms on a particular node or volume. To retrieve a count of all alarm types, pass `1` in the `summary` parameter. You can specify the alarms to return by filtering on type and entity. Use `start` and `limit` to retrieve only a specified window of data.

Syntax

CLI

```
maprcli alarm list
    [ -alarm alarm name ]
    [ -all list all raised alarms
including the ones which are muted
Parameter takes no value  ]
    [ -cluster cluster_name ]
    [ -entity entity (hostname OR
volume name OR Ae name) ]
   [ -entitylimit entitylimit ]
    [ -filter none. default: none ]

    [ -history list cleared up alarms
only Parameter takes no value  ]
    [ -limit limit. default:
2147483647 ]
    [ -muted list alarms configured
to be mute Parameter takes no value  ]
    [ -output output. default:
verbose ]
    [ -sortby <alarmname|
alarmdescription|alarmtype|alarmstate|
alarmraised|alarmcleared|alarmentity|
alarmmutetime|alarmmuteupto|
alarmmuteduration|alarmgroups> ]

    [ -start start. default: 0 ]
    [ -summary summary ]

    [ -type type (CLUSTER
OR NODE OR VOLUME OR AE) ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/alarm/list?<parameters>`

Parameters

Parameter	Description
`alarm`	The alarm name for which to return information.
`all`	The list of all raised and muted alarms.
`cluster`	The cluster on which to list alarms.
`entity`	The name of the cluster, node, volume, user, or group to check for alarms.
`entitylimit`	The number of alarm occurrences to return per alarm type. For example, if there are 10 alarms of type VOLUME_ALARM_COMPACTION_FAILURE and the entity limit is set to 4, then only the four latest alarm occurrences of type VOLUME_ALARM_COMPACTION_FAILURE are listed.
`filter`	A filter specifying alarms to list. See Filters for more information. Default: `none`
`history`	The list of all alarms cleared in the last 30 days. Muted alarms are not displayed in the output.
`limit`	The number of records to retrieve. Default: 2147483647
`muted`	The list of alarms that are muted.
`output`	Indicates whether the output should be `terse` or `verbose`. Default: `verbose`
`sortby`	Specifies one of the following attributes by which to sort the list of alarms: `alarmname`, `alarmdescripton`, `alarmtype`, `alarmstate`, `alarmraised`, `alarmcleared`, `alarmentity`, `alarmmutetime`, `alarmmuteupto`, `alarmmuteduration`, `alarmgroups`. By default, the list of alarms is sorted by `alarmtype`.
`start`	The list offset at which to start. Default: `0`
`summary`	Specifies the type of data to return: • `1` = count by alarm type • `0` = List of alarms Default: false (0)
`type`	The entity type: • `cluster` • `node` • `volume` • `ae`

Output

Information about one or more named alarms on the cluster, or for a specified node, volume, user, or group.

Output Fields

last-updated: Apr 11, 2022

Field	Description
alarm state	State of the alarm: • 0 = Clear • 1 = Raised
description	A description of the condition that raised the alarm.
entity	The name of the volume, node, user, or group.
alarm name	The name of the alarm.
alarm statechange time	The date and time when the alarm was most recently raised.

Sample Output

```
alarm state
description
entity                                alarm name
alarm statechange time
1            Volume desired replication is 1, current

```

REST API

```
https://r1n1.sj.us:8443/rest/alarm/
list?muted
```

alarm mute
Mutes an active alarm for the specified amount of time.

Syntax

CLI

```
maprcli alarm mute
     -alarm alarm[:entity][:aetype]
[:mute_duration] <comma seperated
alarms>
     [ -cluster cluster_name ]
     [ -muteminutes <mute_period> ]
```

REST API

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/alarm/mute?<parameters>`

Parameters

Parameter	Description
`alarm`	The comma-separated list of the active alarms to mute. To mute an active alarm associated with an entity (such as volume, node, etc.) or type of accountable entity, you must also specify the name of the entity or the type of accountable entity separated by a colon (`:`).
`cluster`	The cluster on which to run the command.

Parameter	Description
`muteminutes`	The amount of time, in minutes, to mute the alarm. This can be specified separately or specified after the colon (`:<mute_period>`) immediately following the alarm name. For example, if multiple alarms are being muted for different periods of time, use colon (`:<mute_period>`) to specify the mute period for each alarm. Specifying this separately is optional if colon (`:<mute_period>`) is used to specify the amount of time to mute an alarm. For example, when specifying a list of alarms to mute, use this parameter to specify the amount of time to mute the alarm for which no time period is specified using colon (`:<mute_period>`). **Note:** Either the value for this parameter or colon (`:<mute_period>`) is required to specify the amount of time for which to mute the alarm.

Examples

Mute an active alarm for 10 minutes using one of the following:

```
maprcli alarm mute -alarm CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION:10
```

```
maprcli alarm mute -alarm
CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION -muteminutes 10
```

Mute an active volume alarm on volume1 for 10 minutes using one of the following:

```
maprcli alarm mute -alarm VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1:10
```

```
maprcli alarm mute -alarm
VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1 -muteminutes 10
```

Mute active volume alarm on volume1 for 10 minutes, active cluster alarm for 20 minutes, and active volume alarm on volume2 for 30 minutes using one of the following:

```
maprcli alarm mute -alarm
        VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1:10,
        CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION:20,
        VOLUME_ALARM_DATA_UNDER_REPLICATED:volume2:30
```

```
maprcli alarm mute -alarm
        VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1:10,
        CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION:20,
        VOLUME_ALARM_DATA_UNDER_REPLICATED:volume2
        -muteminutes 30
```

alarm names
Displays a list of alarm names. Permissions required: `login`

Syntax

CLI

```
maprcli alarm names
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/alarm/names`

Output

Attention: The list of alarms depends on the ecosystem components installed. Your output may vary depending on the ecosystem components that you have installed.

```
https://r1n1.sj.us:8443/rest/alarm/
names
```

alarm raise
Raises a specified alarm or alarms. Permissions required: `fc` or `a`.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli alarm raise
     -alarm <alarm>
    [ -cluster <cluster> ]
    [ -description <description> ]
    [ -entity <cluster, entity, host,
node, or volume> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/alarm/raise?<parameters>`

Parameters

Parameter	Description
`alarm`	The alarm type to raise. See Alarm Types.
`cluster`	The cluster on which to run the command.
`description`	A brief description.
`entity`	The entity on which to raise alarms.

Examples

Raise a specific alarm:

CLI

```
maprcli alarm raise -alarm
NODE_ALARM_DEBUG_LOGGING
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
raise?alarm=NODE_ALARM_DEBUG_LOGGING
```

alarm unmute
Unmute a muted alarm.

Syntax

CLI

```
maprcli alarm unmute
   -alarm [<alarm
name>[:<entity>[:<aetype>]]]+
   [ -cluster cluster_name ]
```

REST API

Request Type	POST

Request URL	`http[s]://<host>:<port>/rest/alarm/unmute?<parameters>`

Parameters

Parameter	Description
`alarm`	The comma-separated list of the muted alarms to unmute. To unmute an alarm associated with an entity (such as volume, node, etc.) or type of accountable entity, you can specify also the name of the entity or the type of accountable entity separated by a colon (:).
`cluster`	The name of the cluster on which to run the command.

audit
Describes commands used to audit operations related to cluster management and data access.

audit cluster
Enables and disables auditing of operations that are related to the administration of a MapR cluster.

Only the `mapr` user for the cluster can run this command. For more information about the `mapr` user, see Managing Users and Groups.

For information about auditing cluster-administration operations, see Auditing of Activity Related to Cluster Administration.

Syntax

CLI

```
maprcli audit cluster
   -enabled <true | false>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/audit/cluster?<parameters>`

Parameters

Parameter	Description
`enabled`	The value `true` enables auditing, the value `false` disables it.

audit data
Enables and disables auditing of filesystem and table operations.

For a list of these operations, see Auditing of Filesystem Operations and Table Operations.

All administrative users for the cluster can run this command. For more information, see Managing Users and Groups on page 752.

Syntax

CLI

```
maprcli audit data
[ -cluster <cluster name> ]
[ -enabled <true | false> ]
[ -maxsize <GB> ]
[ -retention <number of days> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/audit/data?<parameters>`

Parameters

Parameter	Description
`cluster`	The path and name of a remote MapR cluster.
`enabled`	The value `true` enables auditing, the value `false` disables it.
`maxsize`	The size in GB at which an alarm is sent to the dashboard in the MapR Control Service. The alarm is to notify the cluster administrator that the audit log is becoming large enough that the administrator might want to take action. For more information about this parameter, the alarm, and possible actions to take, see Managing Audit Logs for Filesystem and Table Operations. The audit log continues to grow until the administrator takes action or until the retention period ends. The default value is 32.
`retention`	The period of time in days for which to keep the data in the audit log for the data access. After this period elapses, the content of the file is deleted and new entries are added to the file until the next retention period elapses.

audit info

Displays whether auditing of cluster-management operations and auditing data-access operations are enabled. Also, displays the maxSize and retention values for these two levels of auditing.

Only the `mapr` user for the cluster can run this command. For more information about the `mapr` user, see Managing Users and Groups.

Syntax

CLI

```
maprcli audit info
[ -cluster <cluster_name> ]
-json
```

REST

Request Type	POST

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/audit/info?<parameters>`

Parameter

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`json`	Displays command output in JSON format. When `-json` is omitted, there is no output.

Example Output

This output shows that auditing of operations on data and auditing of cluster-level operations are both enabled. For descriptions of `maxSizeGB` and `retentionDays`, see the commands maprcli audit cluster and maprcli audit data.

```
]# maprcli audit info -json
{
        "timestamp":1434458923034,
        "timeofday":"2015-06-16 12:48:43.034 GMT+0000",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "data":{
                                "enabled":"1",
                                "maxSizeGB":"32",
                                "retentionDays":"30"
                        },
                        "cluster":{
                                "enabled":"1",
                                "maxSizeGB":"NA",
                                "retentionDays":"NA"
                        }
                }
        ]
}
```

blacklist
Describes commands used to blacklist and to list blacklisted users.

blacklist user
Blocks a user on a specific cluster.

This action cancels all existing tickets for the specified user. There is no REST equivalent command. For information about blocking, see How Tickets Work.

Syntax

CLI

```
maprcli blacklist user
    -name <user name>
   [ -blacklisttime <millis from
```

```
epoch> or <MM/DD/YYYY> ]
   [ -cluster <cluster name> ]
```

REST N/A

Parameters

Parameter	Description
name	Username to block.
blacklisttime	Invalidates all user's tickets that were raised prior to the specified date (in the format <MM/DD/YYYY>). Alternatively, you can specify the time in milliseconds from epoch time (the number of milliseconds that have elapsed since Jan 1, 1970 midnight UTC).
cluster	Name of the cluster from which to block the user.

Example

Block the *rogueuser* user name from the cluster my.cluster.com:

CLI

```
maprcli blacklist user -name
rogueuser -cluster my.cluster.com
```

Block the *rogueuser* user's tickets that were raised prior to 1st September 2020 from the cluster my.cluster.com:

CLI

```
maprcli blacklist
user -name rogueuser -cluster
my.cluster.com -blacklisttime
09/01/2020
```

Block the *rogueuser* user's tickets that were raised prior to 1605418200155 milliseconds from epoch, from the cluster my.cluster.com:

CLI

```
maprcli blacklist
user -name rogueuser -cluster
my.cluster.com -blacklisttime
1605418200155
```

The value `1605418200155` corresponds to the time November 15th 2020, 11:00:00 am IST+05:30. Therefore, all *rogueuser* tickets that were raised prior to November 15th 2020, 11:00:00 am IST+05:30 are blocked.

Related Log File

The log file `/opt/mapr/logs/cldbaudit.log.json` contains the log of the block operation including the updated block time. For example:

```
{"timestamp":
{"$date":"2020-11-13T08:37:36.524Z"},"resource":"mapruser4","operation":"bla
cklist",
```

```
"username":"root","uid":0,"clientip":"10.10.50.42","properties":

[{"property":"blacklisttime","oldvalue":"1605254599376","newvalue":"16058757
66173"}],
             "status":0}{"timestamp":
{"$date":"2020-11-13T08:37:45.020Z"},"resource":"cluster",
             "operation":"listBlacklist","username":"root","uid":0,
             "clientip":"10.10.50.42","status":0}
```

Here the old block list time was *1605254599376* milliseconds (November 13, 2020 1:33:19 PM IST) and is now updated to *1605875766173* milliseconds (Friday, November 20, 2020 6:06:06 PM IST).

blacklist listusers
Lists blocked users on a specific cluster.

By default, this command lists users that have been blocked from the cluster where the command is run. There is no REST equivalent command. For information about blocking, see How Tickets Work.

Syntax

CLI

```
maprcli blacklist listusers
      [ -cluster <cluster name> ]
```

REST

N/A

Parameters

Parameter	Description
cluster	Name of the cluster for which the blocked users must be listed.

Examples

Show blocked users for the cluster my.cluster.com:

CLI

```
maprcli blacklist listusers -cluster
my.cluster.com
```

cluster
Manages cluster features, gateways, and cluster-wide settings.
cluster feature enable
Allows features to be enabled. Used after upgrading.

Note: Run `cluster feature list` on page 1558 command to retrieve the list of features that can be enabled.

Syntax

CLI

```
maprcli cluster feature enable
  [ -name <feature name >]
  [ -force ]
  [ -all ]
```

REST

```
N/A
```

Parameters

Parameter	Description
`name`	Name of the feature.
`force`	Forces the enabled and disabled dependency features. No value is taken.
`all`	Enables all of the features. No value is taken.

Note: Once a feature is enabled, it can not be disabled.

Examples

To enable all features, use the `cluster feature enable -all` command.

```
maprcli cluster feature enable -all
```

To enable a specific feature, use the `cluster feature enable -name` command. For example:

```
maprcli cluster feature enable -name mfs.feature.audit.support
```

cluster feature list
Allows features to be listed. Used after upgrading.

Syntax

CLI

```
maprcli cluster feature list
              [ -name <Feature name >]
              [ -enabled ]
              [ -disabled ]
```

REST

```
N/A
```

Parameters

Parameter	Description
`name`	Lists the named feature. Displays whether the feature is enabled or disabled along with the feature name.
`enabled`	Lists only the enabled features. No value is taken.
`disabled`	Lists only the disabled features. No value is taken.

Tip: The three dots in the output indicate multiple entries. Use `-json` to format the output.

Examples

Lists the disabled features.

```
maprcli cluster feature list -disabled
dependency
name
description    enabled

mfs.feature.audit.support
     false
```

Lists all the features.

```
maprcli cluster feature list

dependency

name

Tip: Use `-json` to format the output.

cluster gateway delete

Deletes the list of MapR gateways from a source MapR cluster.

Source MapR clusters can use such lists to locate the gateways that enable replication of table data to a particular MapR cluster or indexing of table data in a particular Elasticsearch cluster. You create lists of gateways by running the `cluster gateway set` on page 1573 command.

There are three methods of specifying the location of gateways to a MapR cluster that is a source for table replication or indexing in Elasticsearch. If a source MapR cluster relies on DNS records to find out where gateways are located, or the cluster relies on the `mapr-clusters.conf` file to locate gateways, there is no list for the `cluster gateway delete` command to delete.

Note: Deleting a list of gateways with the `maprcli cluster gateway delete` command does not uninstall the listed gateways from the MapR cluster where they are located.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
delete
    [ -cluster <cluster on which
command needs to be run> ]
     -dstcluster <cluster name>
```

REST

```
http[s]://<host>:<port>/rest/cluster/
gateway/delete?dstcluster=<path>
```

Parameters

Parameter	Description
`cluster`	If you are not on the source cluster, provide the name of the source cluster on which this command should be run.
`dstcluster`	The name of the cluster on which the gateways are located. If you are replicating table data to another MapR cluster, specify the name of that destination cluster. This destination cluster could be the source cluster if you are performing intra-cluster replication. If you are indexing table data in an Elasticsearch cluster, specify the name of the source MapR cluster because that is where the gateways are located.

Example

Deletes a list of gateways that is stored on a source MapR cluster. The gateways are being used for table replication are located in the destination MapR cluster `newyork`.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
delete -dstcluster newyork
```

last-updated: Apr 11, 2022

REST

```
https://<host>:<port>/rest/cluster/
gateway/delete?dstcluster=newyork
```

Related concepts

Administering MapR Gateways on page 1150
A MapR gateway mediates one-way communication between a source MapR cluster and a destination cluster. You can replicate MapR Database tables (binary and JSON) and MapR Event Store For Apache Kafka streams. MapR gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1152
Configuring gateways involves installing the `mapr-gateway` package on nodes on a MapR destination cluster and then configuring the MapR source cluster to communicate with the destination cluster. The MapR source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

gateway.conf on page 2197

Gateways for Replicating MapR Database Tables on page 621
In MapR Database table replication, MapR Database replicates updates to tables (binary and JSON) on source MapR clusters to replicas of those tables on destination MapR clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Related tasks

Specifying the Location of Gateways on page 782
Describes how to set the location of the MapR gateways using either the Control System or the CLI.

Lists the MapR gateways that a source MapR cluster is using.

cluster gateway list on page 1567
Lists all of the gateways that a source MapR cluster is using.

cluster gateway local on page 1569
Lists the gateways that are configured on the MapR cluster where this command is run.

cluster gateway resolve on page 1571
Lists the gateways configured on a MapR cluster that are up and running at the time that the command is issued.

cluster gateway set on page 1573
Specifies the locations of the MapR gateways that a source MapR cluster can use for table replication to a destination MapR cluster, or for indexing table data in an Elasticsearch cluster.

Related information

Managing Gateways on page 1154
Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

cluster gateway get

Lists the MapR gateways that a source MapR cluster is using.

The source MapR cluster could be using the MapR gateways either for replication of table data to a destination MapR cluster or for the indexing of data in an Elasticsearch cluster.

This list of gateways is created by the `cluster gateway set on page 1573` command.

last-updated: Apr 11, 2022

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
get
    [ -cluster <sourceCluster> ]
    -dstcluster
<destinationCluster>
```

REST

```
http[s]://<host>:<port>/
rest/cluster/gateway/get?
dstcluster=<path>&cluster=<path>
```

Parameters

Parameter	Description
`cluster`	If you are not on the source cluster, provide the name of the source cluster on which this command should run.
`dstcluster`	The name of the cluster on which the gateways are located. If you are replicating table data to another MapR cluster, specify the name of that destination cluster. This destination cluster could be the source cluster if you are performing intra-cluster replication. If you are indexing table data in an Elasticsearch cluster, specify the name of the source MapR cluster because that is where the gateways are located.

Example

Gets the list of gateways that is stored on a source MapR cluster. The gateways are being used for table replication and are located in the destination MapR cluster `sfcluster`.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
get -dstcluster sfcluster
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/get?dstcluster=sfcluster
```

Example Output

```
cluster gatewayConfig
sfcluster gw1 gw2
```

cluster gateway list

Lists all of the gateways that a source MapR cluster is using.

The source MapR cluster is using gateways either for replication of table data to destination MapR clusters or for the indexing of table data in Elasticsearch clusters.

This list is created by the `cluster gateway set` on page 1573 command.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
list
    [ -cluster <sourceCluster> ]
```

REST

```
http[s]://<host>:<port>/rest/cluster/
gateway/list
```

Parameters

Parameter	Description
`cluster`	If you are not on the source cluster, provide the name of the source cluster on which this command should run.

Example

Lists all the gateways that a source MapR cluster can use when replicating table data in MapR clusters or indexing data in Elasticsearch clusters. In this example, assuming `newyork` to be the name of a MapR cluster that is a destination for table replication, the output shows two gateways that are available for replicating to this cluster.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
list
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/list
```

Example Output

```
cluster gatewayConfig
newyork gw1 gw2
```

Related concepts

Administering MapR Gateways on page 1150
A MapR gateway mediates one-way communication between a source MapR cluster and a destination cluster. You can replicate MapR Database tables (binary and JSON) and MapR Event Store For Apache Kafka streams. MapR gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1152
Configuring gateways involves installing the `mapr-gateway` package on nodes on a MapR destination cluster and then configuring the MapR source cluster to communicate with the destination cluster. The MapR source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

gateway.conf on page 2197

Gateways for Replicating MapR Database Tables on page 621
In MapR Database table replication, MapR Database replicates updates to tables (binary and JSON) on source MapR clusters to replicas of those tables on destination MapR clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Related tasks

Specifying the Location of Gateways on page 782
Describes how to set the location of the MapR gateways using either the Control System or the CLI.

Related reference

cluster gateway delete on page 1564
Deletes the list of MapR gateways from a source MapR cluster.

cluster gateway get on page 1565
Lists the MapR gateways that a source MapR cluster is using.

cluster gateway local on page 1569
Lists the gateways that are configured on the MapR cluster where this command is run.

cluster gateway resolve on page 1571
Lists the gateways configured on a MapR cluster that are up and running at the time that the command is issued.

cluster gateway set on page 1573
Specifies the locations of the MapR gateways that a source MapR cluster can use for table replication to a destination MapR cluster, or for indexing table data in an Elasticsearch cluster.

Related information

Managing Gateways on page 1154

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

cluster gateway local
Lists the gateways that are configured on the MapR cluster where this command is run.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
local
        [ -cluster cluster on which
command to be run ]
        [ -format dns/text. default:
text ]
```

REST

```
http[s]://<host>:<port>/rest/cluster/
gateway/local
```

Parameters

Parameter	Description
`format`	The output format. Value types: `dns` or `text`. Default: `text`. **Note:** • If the output is formatted as DNS, you can copy and paste the output into a DNS record in the zone file for your domain. The source MapR cluster can then locate the gateways by doing a DNS lookup. • If the output is formatted as text, you can copy and paste that text into the `-gateways` parameter of the `maprcli cluster gateway set` command. Running this command is an alternative way of specifying the location of these gateways to the source MapR cluster.
`cluster`	If you are not on a MapR cluster where one or more gateways are configured, provide the name of the cluster. • When replicating MapR Database table data to one or more replicas on this cluster, then the cluster is a destination MapR cluster. • When indexing MapR Database table data in one or more Elasticsearch cluster, then the current cluster is a source MapR cluster where the tables being indexed are located.

Example

This example shows text output of the list of gateways that are configured on a MapR cluster:

last-updated: Apr 11, 2022

CLI	`/opt/mapr/bin/maprcli cluster gateway local`
REST	`https://<host>:<port>/rest/cluster/gateway/local`
Example Output	`gatewayinfo centos23 centos22`

This example shows DNS output of the list of gateways that are configured on a MapR cluster:

CLI	`/opt/mapr/bin/maprcli cluster gateway local -format dns`
REST	`https://<host>:<port>/rest/cluster/gateway/local?format=dns`
Example Output	`gatewaydnsinfo ; TXT Record addresses gateway.mycluster IN TXT "centos23 centos22"`

cluster gateway resolve

Lists the gateways configured on a MapR cluster that are up and running at the time that the command is issued.

Run this command on a source MapR cluster to find out how many gateways are available for table replication to a destination MapR cluster, or for indexing table data in an Elasticsearch cluster.

This command uses the following criteria to get the list:

- If you specified the locations of the gateways with the `cluster gateway set` on page 1573 command, the `maprcli cluster gateway resolve` command returns the list of the gateways.
- If you specified the locations of the gateways only with a DNS record, this command performs a DNS lookup for gateways on the specified MapR cluster and returns the list that it finds.
- If you did not specify the locations of the gateways using the previously listed methods, this command assumes that gateways are located on the CLDB nodes configured in the `mapr-clusters.conf` file on the MapR cluster where the command is run.

Note: Unresponsive gateways are not included in the list.

For more information about gateways, see MapR Gateways.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
resolve
    [ -cluster <cluster on which the
command is to be run> ]
    -dstcluster <destination cluster
name>
```

REST

```
http[s]://<host>:<port>/rest/
cluster/gateway/resolve?
dstcluster=<clustername>
```

Parameters

Parameter	Description
`cluster`	If you are not on the source MapR cluster, provide the name of the source cluster on which this command should run.

last-updated: Apr 11, 2022

Parameter	Description
`dstcluster`	The name of the cluster for which you want to list the available gateways. If you are replicating table data to another MapR cluster, specify the name of that destination cluster. This destination cluster can be the source cluster if you are performing intra-cluster replication. If you are indexing table data in an Elasticsearch cluster, specify the name of the source MapR cluster because that is where the gateways are located.

Example

This example shows that only one gateway is up and running on the MapR cluster `cluster1`. The IP address of this gateway was found in a DNS record, as indicated by the `Source` field.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
resolve -dstcluster cluster1 -json
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/resolve?dstcluster=cluster1
```

Example Output

```
{
        "timestamp":1424266395862,
        "timeofday":"2015-02-18
01:33:15.862 GMT+0000",
        "status":"OK",
        "total":1,
        "data":[
                {

"GatewayHosts":"10.10.20.12:7660",
                        "Source":"DNS"

                }
        ]
}
```

cluster gateway set

Specifies the locations of the MapR gateways that a source MapR cluster can use for table replication to a destination MapR cluster, or for indexing table data in an Elasticsearch cluster.

In addition to this method, there are two other methods that you can use to specify the locations of gateways that a source MapR cluster can use when replicating to a particular MapR cluster or when indexing in an Elasticsearch cluster. See Configuring Gateways for Table and Stream Replication for details about them.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
set
   [ -cluster <cluster on which
command to be run> ]
   -dstcluster <cluster name>
   -gateways <space-separated list of
hostnames>
```

REST

```
http[s]://<host>:<port>/
rest/cluster/gateway/set?
dstcluster=<path>&gateways=<list
of gateways>
```

Parameters

Parameter	Description
`cluster`	If you are not on the source MapR cluster, provide the name of that cluster.

last-updated: Apr 11, 2022

Parameter	Description
`dstcluster`	The name of the MapR cluster in which the gateways are located. If you are replicating table data to another MapR cluster, specify the name of that destination cluster. This destination cluster could be the source cluster if you are performing intra-cluster replication. If you are indexing table data in an Elasticsearch cluster, specify the name of the source MapR cluster because that is where the gateways are located.
`gateways`	A space-delimited list of gateway hostnames or IP addresses. Place double quotation marks around the list of gateways, as in this example: `-gateways "gateway1 gateway2"`

Example

This example specifies the hostnames of two gateways that are in the MapR cluster `newyork . This command could be used in any of these situations:`

- The cluster `newyork` is the destination cluster for table replication from the source MapR cluster.
- The cluster `newyork` is both a source and destination cluster for intra-cluster table replication.
- The cluster `newyork` is a source MapR cluster that contains tables being indexed in one or more Elasticsearch clusters.

CLI

```
/opt/mapr/bin/maprcli cluster
gateway set -dstcluster
newyork -gateways "gw1.bigcompany.com
gw2.bigcompany.com"
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/set?
dstcluster=newyork&gateways=gw1.bigcom
pany.com%20gw2.bigcompany.com
```

cluster info

Returns minimum and maximum values for the following attributes:

- `VolumeSize` — The size of the volume.
- `VolumeQuotaSize` — The hard quota (disk space) for the volume.
- `VolumeAdvisoryQuota` — The advisory quota (disk space) for the volume.
- `VolumeLogicalUsedSize` — The logical size used by the volume.
- `VolumeNumContainers` — The number of replicas for the volume.
- `VolumeGuranteedNumContainers` — The number of guaranteed replicas for the volume.
- `VolumeNumNamespaceContainers` — The number of replicas for the name container associated with the volume.
- `VolumeGuranteedNumNamespaceContainers` — The number of guaranteed replicas for the name container associated with the volume.
- `VolumeNumSnapshots` — The number of snapshots of the volume.
- `VolumeCoalesceInterval` — The coalesce interval setting for the volume.
- `VolumeMaxInodesAlarmThreshold` — The threshold for triggering the VOLUME_ALARM_INODES_EXCEEDED alarm.
- `VolumeMaxNsSizeMbAlarmThreshold` — The threshold for triggering the VOLUME_ALARM_INODES_EXCEEDED alarm.
- `VolumeReReplicationTimeOut` — The timeout value for re-replication.
- `StoragePoolCapacitySize` — The total amount of disk space on the storage pool.

- `StoargePoolUsedSize` — The amount of used space on the storage pool.
- `StoragePoolAvailableSize` — The amount of available space on the storage pool.

Syntax

CLI	`maprcli cluster info -getminmax <attributes>`
REST API	N/A

Parameters

Parameter	Description
`getminmax`	The comma-separated list of attributes to return minimum and maximum values for. To retrieve the minimum and maximum values for all the attributes, use the keyword `all`.

Examples

Retrieve the minimum and maximum values for all the attributes:

```
maprcli cluster info -getminmax all
```

Output

```
# maprcli cluster info -getminmax all
min     unit max     name
1804262 MB   2703486 StoragePoolAvailableSize
0       MB   32768   VolumeAdvisoryQuota
2       Num  6       VolumeNumContainers
0       MB   47152   VolumeLogicalUsedSize
60      Min  60      VolumeCoalesceInterval
0       MB   0       VolumeMaxNsSizeMbAlarmThreshold
0       MB   0       VolumeSharedSize
1826966 MB   2738572 StoragePoolCapacitySize
2       Num  6       VolumeNumNamespaceContainers
0       MB   6020    VolumeOwnedSize
22704   MB   35086   StoragePoolUsedSize
0       Num  0       VolumeNumSnapshots
0       Sec  0       VolumeReReplicationTimeOut
0       MB   6020    VolumeSize
1       Num  2       VolumeGuranteedNumNamespaceContainers
0       Sec  5       VolumeMaxInodesAlarmThreshold
1       Num  2       VolumeGuranteedNumContainers
0       MB   0       VolumeQuotaSize
```

Retrieve the minimum and maximum values for the given attributes:

```
# maprcli cluster info
    -getminmax
VolumeNumContainers,VolumeGuranteedNumContainers,VolumeGuranteedNumNamespace
Containers,VolumeNumNamespaceContainers
```

Output

```
# maprcli cluster info -getminmax
VolumeNumContainers,VolumeGuranteedNumContainers,VolumeGuranteedNumNamespace
Containers,VolumeNumNamespaceContainers
min unit max name
1   Num  2   VolumeGuranteedNumNamespaceContainers
2   Num  6   VolumeNumContainers
2   Num  6   VolumeNumNamespaceContainers
1   Num  2   VolumeGuranteedNumContainers
```

cluster mapreduce get
Displays the cluster-wide default for the MapReduce mode.

Warning: This command is deprecated alongside MapReduce v1.

Syntax

CLI

```
maprcli cluster mapreduce get
```

REST

```
http[s]://<host>:<port>/rest/cluster/
mapreduce/get
```

Output Fields

Field	Description
`default_mode`	Displays either `yarn` or `classic`.
`mapreduce_version`	Displays the hadoop version associated with the default_mode.

Sample Output

```
default_mode  mapreduce_version
classic       0.20.2
```

Examples

CLI

```
maprcli cluster mapreduce get
```

REST

```
https://r1n1.sj.us:8443/rest/cluster/
mapreduce/get
```

cluster mapreduce set
Sets the cluster-wide MapReduce mode.

Warning: This command is deprecated alongside MapReduce v1.

Syntax

CLI

```
maprcli cluster mapreduce set -mode
yarn
```

REST

```
http[s]://<host>:<port>/rest/cluster/
mapreduce/set?<parameters>
```

Parameters

Parameter	Description
`mode`	The MapReduce mode of the cluster. Enter `yarn` to use Resource Manager and Node Manager to run MapReduce jobs or applications.

Examples

Sets the MapReduce mode for the cluster to classic.

CLI

```
maprcli cluster mapreduce set -mode
yarn
```

REST

```
https://r1n1.sj.us:8443/rest/cluster/
mapreduce/set?mode=yarn
```

cluster queryservice
Describes the commands to enable/disable and view the settings for the OJAI Distributed Query Service.

Enable the OJAI Distributed Query Service on page 505 if you want the following functionality when querying MapR Database JSON tables:

- Advanced secondary index selection
- Sorts of large data sets
- Parallel query execution

Permissions Required

If you enable the OJAI Distributed Query Service during installation, then you must be user 'mapr' to run these commands. If you disable the service, and later re-enable it, then the command needs to be run by the user that re-enabled the service.

cluster queryservice getconfig
Retrieves the configuration of the OJAI Distributed Query Service.

Permissions Required

Only the user that enabled the OJAI Distributed Query Service can run this command. If the service was enabled during installation, user 'mapr' must run the command.

Syntax

CLI

```
maprcli cluster queryservice
getconfig -cluster < cluster-name >
```

REST

Not available

Parameters

Parameter	Description
cluster	(Optional) Name of the cluster that is using secondary indexes to query MapR Database JSON table

Example

```
maprcli cluster queryservice getconfig -cluster my.cluster.com
```

cluster queryservice setconfig
Enables or disables the OJAI Distributed Query Service. When enabling the service, you can specify the configuration of the service.

Permissions Required

Only the user that enabled the OJAI Distributed Query Service can run this command. If the service was enabled during installation, user 'mapr' must run the command.

Syntax

CLI

```
maprcli cluster queryservice
setconfig
              [ -cluster <
cluster-name > ]
              -enabled < true | false
>
              -clusterid < cluster-id
of MapR Drill cluster >
              -storageplugin < Name
of MapR Drill Storage plug-in >
              -znode < Root Zookeeper
node user by MapR Drill cluster >
```

REST

Not available

Parameters

Parameter	Description
cluster	(Optional) Name of the cluster that is using secondary indexes to query MapR Database JSON tables
enabled	(Required) Whether the OJAI Distributed Query Service is enabled Values: true or false

Parameter	Description
clusterid	(Required) Cluster ID of your MapR Drill cluster Refer to the value of the `cluster-id` parameter in the `drill-distrib.conf` file. You can find this file in the `/opt/mapr/drill/drill-<version number>/conf` directory.
storageplugin	(Required) Name of the MapR Drill Storage plug-in instance used to run OJAI queries (usually **dfs**)
znode	(Required) Name of the root Zookeeper node used by the MapR Drill cluster (usually **/drill**)

Example

```
maprcli cluster queryservice setconfig \
   -enabled true \
   -clusterid mycluster \
   -storageplugin dfs \
   -znode /drill
```

config
Lists configuration values for the MapR cluster.

Configuration Fields

The following fields are configurable.

`cldb.balancer.disk.max.switches.in.nodes.percentage`
Default Value: 10

The maximum number of containers that can be balanced in parallel by the disk balancer. The value is a percentage of the number of nodes in the system.

`cldb.disk.balancer.enable`
Default Value: 1 (Disk Balancer is enabled)

Enables (1) or disables (0) the Disk Balancer.

`cldb.balancer.disk.sleep.interval.sec`
Default Value: 120

The sleep interval (in seconds) between two successive runs of the Disk Balancer.

`cldb.balancer.disk.threshold.percentage`
Default Value: 70

Percentage of used space that causes containers in a storage pool to be distributed across other less used storage pools.

`cldb.balancer.logging`
Default Value: 0

Disables (0) or enables (1) the logging of messages in the Disk Balancer and Role Balancer.

`cldb.balancer.role.max.switches.in.nodes.percentage`
Default Value: 10

The percentage (of the number of nodes in the system) to use to determine the maximum number of containers whose roles (Masters and Tails) are balanced in parallel by the Role Balancer.

For example, suppose there are 500 nodes and the value of this parameter is 10(%). The number of containers whose roles are balanced in parallel is (10/100)*500=50.

cldb.balancer.role.paused

Default Value: 1

Enables (0) or Disables (1) the Role Balancer.

cldb.balancer.role.sleep.interval.sec

Default Value: 900

The sleep interval (in seconds) between two successive runs of the Role Balancer.

cldb.balancer.startup.interval.sec

Default Value: 1800

The initial startup delay (in seconds) of the Role Balancer for existing clusters.

cldb.cluster.almost.full.percentage

Default Value: 90

The percentage at which the `CLUSTER_ALARM_CLUSTER_ALMOST_FULL` alarm is triggered.

cldb.container.alloc.selector.algo

Default Value: 0

The allocation algorithm to use when creating new containers. The value can be one of:

- 0 - indicates Round Robin algorithm if the number of nodes is less than or equal to 100, Randomized algorithm otherwise.
- 1 - indicates Round Robin algorithm. If selected, containers are allocated across nodes in a topology in a round robin fashion.
- 2 - indicates Randomized algorithm. If selected, containers are allocated across nodes in a randomized way.

cldb.container.assign.buffer.sizemb

Default Value: 1024

The size of the container (in MB) that should be used as a buffer. When allocating a new container, this size is deducted from the maximum container size.

Note: When you modify the value of `cldb.container.sizemb`, check and update the value of `cldb.container.assign.buffer.sizemb` to prevent new containers from being created when existing containers are not full.

cldb.container.create.diskfull.threshold

Default Value: 85

The percentage of space on a file server to use to classify the file server as full.

cldb.container.sizemb

Default Value: 32768

The maximum size for containers (in MB). This is a soft limit.

Note: When `cldb.container.sizemb` value is modified, check and update the value of `cldb.container.assign.buffer.sizemb` to prevent new containers from being created when existing containers are not full.

cldb.default.chunk.sizemb

Default Value: 256

The size of each chunk (in MB) that make up a file in the MapR filesystem.

cldb.default.volume.topology

Default Value: /data

last-updated: Apr 11, 2022

	The default topology for new volumes.
cldb.dialhome.metrics.file.rotation.period	*Default Value:* 365 The retention period of the files (in days) that is used to record Dialhome metrics. Files that are past their retention period are automatically deleted.
cldb.disable.alarm.history	*Default Value:* 0 (false) Set this to 1 (true) to disable CLDB alarm history, as tracking and fetching the alarm history can degrade the performance of CLDB on large clusters.
cldb.fs.mark.rereplicate.sec	*Default Value:* 3600 The number of seconds that a node can fail to heartbeat before it is considered dead. Once a node is considered dead, the CLDB re-replicates any data contained on the node.
cldb.fs.reregistration.wait.time	*Default Value:* 15 The amount of time (in minutes) to wait before checking for inactive nodes. **Note:** Reduce the value to raise the No Heartbeat Alarm on page 2233 without delay, after CLDB failover. To avoid spurious alarms, do not reduce this value below 5 (minutes).
cldb.log.fileserver.timeskew.interval.mins	*Default Value:* 60 The frequency (in minutes) at which CLDB should log messages about the time skew on the file server.
cldb.max.parallel.resyncs.star	*Default Value:* 3 The number of container replicas that can resync in parallel from the source for low-latency (star-replicated) volumes.
cldb.mfs.heartbeat.timeout.multiple	*Default Value:* 10 Specifies a multiple heartbeat timeout. For small clusters, the heartbeat interval is 1 second and the multiple is 10 by default, which makes the heartbeat timeout 10 seconds.
cldb.min.fileservers	*Default Value:* 1 The number of file servers hosting the CLDB volume that is required for the master CLDB to complete the bootstrap process.
cldb.replication.manager.critical.paused	*Default Value:* 0 Disables (0) or enables (1) the processing of critically under-replicated containers. If enabled, the critically under-replicated containers are processed on a priority basis to increase the number of copies.
cldb.replication.manager.max.resyncs.in.nodes.percentage	*Default Value:* 1200 The number of containers that can be replicated in parallel, expressed as a percentage of the number of active nodes. If the value is 1200, the number of containers that can be replicated is 12 times the number of active nodes.
cldb.replication.manager.over.paused	*Default Value:* 0 Disables (0) or enables (1) the processing of over-replicated containers. Over-replicated containers are processed to delete extra copies, which is when

	the number of copies is more than the desired replication factor.
cldb.replication.manager.start.mins	*Default Value:* 15 The delay (in minutes) between CLDB startup and replication manager startup, to allow all nodes to register and heartbeat.
cldb.replication.max.in.transit.containers.per.sp	*Default Value:* 4 The maximum number of containers that can be in transit on a storage pool (SP). Containers that serve either as the source or destination of a resync operation are considered as being in 'transit'.
cldb.replication.sleep.interval.sec	*Default Value:* 15 The sleep duration (in seconds) between consecutive runs of the Replication Manager.
cldb.replication.tablescan.interval.sec	*Default Value:* 120 The sleep duration (in seconds) between consecutive runs of the Replication Scanner. While the Replication Scanner classifies containers into different buckets, the Manager thread either replicates or removes additional copies.
cldb.rm.wait.rack.violated.fork.copy.mins	*Default Value:* 720 The buffer time (in minutes) after which all container copies found on the same rack are fixed.
cldb.rm.wait.fork.on.same.rack.mins	*Default Value:* 180 The time (in minutes) to defer creating containers on the same rack, for critically under-replicated containers, if there are at least two copies of the containers.
cldb.security.user.ticket.duration.seconds	*Default Value:* 1209600 The length of time (in seconds) before the user ticket (generated using the `maprlogin password` command) expires.
cldb.security.user.ticket.max.duration.seconds	*Default Value:* 2592000 The maximum amount of time (in seconds) allowed for the user ticket (generated using the `maprlogin password` command).
cldb.security.user.ticket.renew.duration.seconds	*Default Value:* 2592000 The length of time (in seconds) to renew the user ticket (generated using the `maprlogin password` command).
cldb.security.user.ticket.renew.max.duration.seconds	*Default Value:* 7776000 The maximum duration allowed for a user ticket (generated using `maprlogin password` command) renewal.
cldb.topology.almost.full.percentage	*Default Value:* 90 The threshold percentage that is used to raise alarms when the used space on the nodes of a topology exceed a certain percentage of total space.
cldb.volume.epoch	*Default Value:* Not Applicable The starting epoch of a new Container. Epoch is used internally in the selection of the master container.

last-updated: Apr 11, 2022

cldb.volumes.namespace.default.min.replication	*Default Value:* 2 The minimum replication factor for the name container. Containers with fewer copies than this value are replicated on a priority basis. **Note:** To modify, run the `maprli volume modify -name <volume name> -nsminreplication <replication factor>` command.
cldb.volumes.namespace.default.replication	*Default Value:* 3 The desired replication factor for the name container. **Note:** To modify, run the `maprli volume modify -name <volume name> -nsreplication <replication factor>` command.
mapr.fs.nocompression	*Default Value:* "bz2,gz,tgz,tbz2, zip,z,Z,mp3,jpg, jpeg,mpg,mpeg,avi, gif,png,lzo,jar" The file types that should not be compressed. See File Extensions of Compressed Files on page 989.
mapr.fs.permissions.supergroup	*Default Value:* root The *super group* of the MapR filesystem layer.
mapr.fs.permissions.superuser	*Default Value:* mapr The *super user* of the MapR filesystem layer.
mapr.targetversion	*Default Value:* Not Applicable The configuration variable to set the current version of the MapR distribution. Failing to set this variable on an upgrade causes alarms to be missed when all the nodes in a cluster are not at the same version of the software.
mfs.db.parallel.copyregions	*Default Value:* Not Applicable The number of parallel copy regions per MFS instance. Setting this field to a larger value increases the parallelism for data transfers during index updates, CDC propagation, and table replication. A larger value increases the transfer rate and reduces the initial synchronization time, but uses more system resources. The latter may impact the response time and performance of applications that read data from the same nodes.
mfs.high.memory.alarm.threshold	*Default Value:* 110 (percentage of allocated memory) On initialization, the MapR filesystem is allocated a certain amount of memory. There is some additional headroom that can be used if the MapR filesystem is under memory pressure. However, if the MapR filesystem exceeds the high memory threshold (default 10% over the allocated memory, that is 110%), the High FileServer Memory Alarm on page 2230 is raised. This threshold can be 8% to 30% over the allocated memory (that is 108% to 130%) .
mfs.feature.db.json.support	*Default Value:* • 1 for new MapR installations • 0 for upgraded MapR installations

last-updated: Apr 11, 2022

	Disables (0) or enables (1) MapR streams and support in MapR Database for JSON documents and tables..
mfs.feature.devicefile.support	*Default Value:* 1 Disables (0) or enables (1) usage of Named Pipes over NFS.
pernode.numcntrs.alarm.thr	*Default Value:* 50000 The maximum number of Read/Write (RW) containers on each node beyond which performance may not be optimal. The optimal number for RW and snapshot containers combined is 10 times the value of this parameter.

config load
Displays information about the cluster configuration.

Syntax

CLI

```
maprcli config load
    [ -cluster <cluster> ]
    [ -keys <keys> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/config/load?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster for which to display values.
`keys`	This parameter is used to specify which information to display. Comma-separated fields are used to display values; see the Configuration Fields table.

Output

Information about the cluster configuration. See the Configuration Fields table.

Sample Output

```
{
        "status":"OK",
        "total":1,
        "data":[
                {
                        "mapr.webui.http.port":"8080",
                        "mapr.fs.permissions.superuser":"root",
                        "mapr.smtp.port":"25",
                        "mapr.fs.permissions.supergroup":"supergroup"
                }
        ]
}
```

last-updated: Apr 11, 2022

Examples

Display several keys:

CLI

```
/opt/mapr/bin/maprcli config
load -keys
mapr.webui.http.port,mapr.webui.https.
port,mapr.webui.https.keystorepath,map
r.webui.https.keystorepassword,mapr.we
bui.https.keypassword,mapr.webui.timeo
ut
```

REST

```
https://abc.sj.us:8443/rest/config/
load?
keys=mapr.webui.http.port,mapr.webui.h
ttps.port,mapr.webui.https.keystorepat
h,mapr.webui.https.keystorepassword,ma
pr.webui.https.keypassword,mapr.webui.
timeout
```

config save

Saves configuration information, specified as key/value pairs. Permissions required: `fc` or `a`.

See the Configuration Fields table.

Warning: Changing cluster configuration may have an impact on the way the cluster functions. Make sure you understand the change well or else make the change under the guidance of MapR support.

Syntax

CLI

```
maprcli config save
         [ -cluster cluster name ]
         -test test only. default: 0
         -values JSON Object to
comprise all config properties to save
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/config/save?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`values`	A JSON object containing configuration fields; see the Configuration Fields table.
`test`	Set this to 1 to test SMTP configuration without actually saving the values. The system sends a test email to check if the configuration is correct. This parameter is applicable only for SMTP configuration.

last-updated: Apr 11, 2022

Examples

Configure MapR SMTP settings:

CLI

```
/opt/mapr/bin/maprcli config
save -values
'{"mapr.smtp.provider":"gmail","mapr.s
mtp.server":"smtp.gmail.com","mapr.smt
p.sslrequired":"true","mapr.smtp.port"
:"465","mapr.smtp.sender.fullname":"Ab

Cd","mapr.smtp.sender.email":"xxx@gmai
l.com","mapr.smtp.sender.username":"xx
x@gmail.com","mapr.smtp.sender.passwor
d":"abc"}'
```

REST

```
https://abc.sj.us:8443/rest/config/
save?
values={"mapr.smtp.provider":"gmail","
mapr.smtp.server":"smtp.gmail.com","ma
pr.smtp.sslrequired":"true","mapr.smtp
.port":"465","mapr.smtp.sender.fullnam
e":"Ab
Cd","mapr.smtp.sender.email":"xxx@gmai
l.com","mapr.smtp.sender.username":"xx
x@gmail.com","mapr.smtp.sender.passwor
d":"abc"}
```

Note: The maximunm number of volumes that can be balanced at a time is 1000.

Related concepts

config on page 1580
Lists configuration values for the MapR cluster.

dashboard info

Displays a summary of information about the cluster.

Syntax

CLI

```
/opt/mapr/bin/maprcli dashboard info
    [ -cluster <cluster name> ]
    [ -multi_cluster_info true|false]
    [ -version true|false ]
    [ -zkconnect <ZooKeeper connect
string> ]
    -json
```

Note: The `-json` option is required.

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/dashboard/info[?<parameters>]`

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. By default, the cluster is the local cluster.
`multi_cluster_info`	Specifies whether to display cluster information from multiple clusters. Values: `true` or `false`. Default: `false`.
`version`	Specifies whether to display the version. Values: `true` or `false`. Default: `false`.
`zkconnect`	Common Parameters on page 1525
`json`	Formats the output.

Output

A summary of information about the services, volumes, MapReduce applications, health, and utilization of the cluster.

Output Fields

Field	Description
timestamp	The time at which the `dashboard info` data was retrieved, expressed as a Unix epoch time.
timeofday	The local time and date of the query.
status	The success status of the `dashboard info` command.
total	The number of clusters for which data was queried in the `dashboard info` command.
version	The MapR software version running on the cluster.
cluster	Determines the following information about the cluster: • `name` — the cluster name • `secure` — whether the cluster is secure or not. Value: `true` (if enabled) or `false` (if disabled) • `dare` — whether the cluster is enabled for data at rest encryption or not. Value: `true` (if enabled) or `false` (if disabled) • • `ip` — the IP address of the active CLDB • `id` — the cluster ID • `nodesUsed` — number of nodes in the cluster • `totalNodesAllowed` — number of allowed nodes

last-updated: Apr 11, 2022

Field	Description
volumes	The number and size (in GB) of volumes that are: • Mounted • Unmounted

last-updated: Apr 11, 2022

Field	Description

utilization	The following utilization information:
	• CPU — utilization, total and active. CPU utilization % is calculated as (100% - idle%) on each node and then averaged across all nodes where hoststats is running.
	• Memory — total and active in MB.
	• Disk space — total and active in GB.
	• Compression — compressed and uncompressed data size
	• Tiering — following cluster level tiering information:
	  • `logicalUsed` — The total gigabytes of disk space used (before compression) for the tiered volumes in the cluster.
	  This value does not include erasure-coded backend volumes and cache-volumes.
	  • `replicatedLogicalUsed` — The logical size in gigabytes, of disk used by the tiered volumes and all associated replicas.
	  This value is calculated as follows: *disk space (before compression) used by volume * number of replicas*. This value does not include erasure-coded backend volumes and cache-volumes.
	  • `replicatedTotalUsed` — The total space after compression (in GB) used by tiered volumes and associated snapshots and replicas.
	  This value is calculated as follows: *total space used by volume * number of replicas*. This value does not include EC-backend volumes and cache-volumes since their `replicatedTotalUsed` is already accounted for by the front-end and parent volumes respectively.
	  • `metaDBUsedMB` — The disk space (in MB) used by the metadata volume associated with the tier.
	  • `replicatedMetaDBUsedMB` — The disk space (in MB) used by the replicas of the metadata volume associated with the tier.
	  • `offloaded` — The total physical data (in GB) offloaded to the cold tier.
	  This value is calculated as follows: *amount of data purged from the hot tier (MapR cluster) + amount of data recalled to the hot tier (MapR cluster)*.
	  • `recalled` — The total physical data (in GB) recalled from the cold tier.
	  This value is calculated as follows: *amount of data recalled to the hot tier (MapR cluster) + total amount of disk space used by the cache-volume*.
	  • `cvTotalUsed` — The total disk space (in GB) used by all the cache-volumes. At the volume level, for mirror volumes, this is the total size of the cache volume and its replicas.
	  • `replicatedCvTotalUsed` — The total disk space (in GB) used by all the cache-volumes and associated replicas.

Field	Description
clusterReplication	The following cluster replication information: • `bytesReceived` • `bytesSend`
streamThroughput	The following stream throughput information: • `bytesProduced` • `bytesConsumed`
label_stats	Information about the labels registered and assigned.
services	The number of active, stopped, failed, and total installed services on the cluster, for example: • API server • CLDB • Fileserver • File Migrate • ResourceManager • NodeManager • NFSv4 • hoststats • MAST Gateway
yarn	The following mapreduce information: • Running applications • Queued applications • Number of NodeManagers • Total memory • Total VCores • Total disks • Used memory • Used VCores • Used disks

Examples

Display dashboard information:

dialhome

The `dialhome` commands are used to change the Dial Home status of the cluster:

dialhome ackdial
Acknowledges the most recent Dial Home on the cluster. Permissions required: login

Syntax

CLI

```
maprcli dialhome ackdial
    [ -forDay <date> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/dialhome/ackdial[?<parameters>]`

Parameters

Parameter	Description
`forDay`	Date for which the recorded metrics were successfully dialed home. Accepted values: UTC timestamp or a UTC date in MM/DD/YY format. Default: yesterday

Sample Output

```
# maprcli dialhome ackdial -forDate 5/26/15
dialhome ackdial
     -forDay Date for which the recorded metrics were successfully dialed
home. Accepted values: UTC timestamp in millisecond or a UTC date in
MM/DD/YY format. default: 5/31/15
```

Examples

Acknowledge Dial Home:

CLI

```
maprcli dialhome ackdial
```

last-updated: Apr 11, 2022

REST

```
https://abc.sj.us:8443/rest/dialhome/
ackdial
```

dialhome enable
Enables Dial Home on the cluster. Permissions required: `fc` or a

Syntax

CLI

```
maprcli dialhome enable
    -enable 0|1
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/dialhome/enable`

Parameters

Parameter	Description
`enable`	Specifies whether to enable or disable Dial Home: • 0 - Disable • 1 - Enable

Output

A success or failure message.

Sample output

```
# maprcli dialhome enable -enable 1
enabled
1

# maprcli dialhome status
enabled
1
```

Examples

Enable Dial Home:

CLI

```
maprcli dialhome enable -enable 1
```

REST

```
https://abc.sj.us:8443/rest/dialhome/
enable?enable=1
```

dialhome lastdialed
Displays the date of the last successful Dial Home call. Permissions required: `fc` or a.

Syntax

CLI

```
maprcli dialhome lastdialed
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/dialhome/lastdialed`

Output

The date of the last successful Dial Home call.

Sample output

```
$ maprcli dialhome lastdialed
date
1322438400000
```

Examples

Show the date of the most recent Dial Home:

CLI

```
maprcli dialhome lastdialed
```

REST

```
https://abc.sj.us:8443/rest/dialhome/lastdialed
```

dialhome metrics

Returns a compressed metrics object. Permissions required: login.

Syntax

CLI

```
maprcli dialhome metrics [ -forDay <date> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/dialhome/metrics`

Parameters

Parameter	Description
`forDay`	Date for which the recorded metrics were successfully dialed home. Accepted values: UTC timestamp or a UTC date in MM/DD/YY format. Default: yesterday

last-updated: Apr 11, 2022

Output

Sample output

```
$ maprcli dialhome metrics
metrics
[B@48067064
```

Examples

Show the Dial Home metrics:

CLI

```
maprcli dialhome metrics
```

REST

```
https://abc.sj.us:8443/rest/dialhome/
metrics
```

dialhome status
Displays the Dial Home status. Permissions required: login.

Syntax

CLI

```
maprcli dialhome status
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/dialhome/status`

Output

The current Dial Home status.

Sample output

```
$ maprcli dialhome status
enabled
1
```

Examples

Display the Dial Home status:

CLI

```
maprcli dialhome status
```

REST

```
https://abc.sj.us:8443/rest/dialhome/
status
```

disk
Lists disk parameters.

Disk Fields

The following table shows the fields displayed in the output of the disk list and disk listall commands. You can choose which fields (columns) to display and sort in ascending or descending order by any single field.

availablespace	Terse Name: dsa Description: Disk space available, in MB.
diskname	Terse Name: n Description: Name of the disk or partition
error	Terse Name: err Description: Disk error message, in English. Only sent if **status** is `1`.  **Note:** This message is **not** translated.
failuretime	Terse Name: ft Description: Disk failure time, This field is applicable only for MapR disks. Only sent if **status** is `1`.
firmwareversion	Terse Name: fw Description: Firmware version
fstype	Terse Name: fs Description: File system type
hostname	Terse Name: hn Description: Hostname of the node that owns this disk/partition
modelnum	Terse Name: mn Description: The model number of the disk
mount	Terse Name: mt Description: Disk mount status • `0` = unmounted • `1` = mounted
powerstatus	Terse Name: pst Description: Disk power status: • `0` = Active/idle (normal operation) • `1` = Standby (low power mode) • `2` = Sleeping (lowest power mode, drive is completely shut down)
serialnum	Terse Name: sn Description: Serial number of the disk
status	Terse Name: st Description: Disk status: • `0` = Good • `1` = Bad disk

last-updated: Apr 11, 2022

	• 2 = Offline disk
totalspace	Terse Name: dst Description: Total disk space, in MB
usedspace	Terse Name: dsu Description: Disk space used, in MB
vendor	Terse Name: ven Description: Name of the disk vendor

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

node list on page 1705
Lists nodes in the cluster.

dump volumeinfo on page 1637
Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

disk add

Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli disk add
    -disks <disk names>
    -host <host>
  [ -cluster <cluster> ]

  [ -stripeWidth <stripe-width> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/disk/add?<parameters>`

Parameters

Parameter: `cluster`	*Default Value*: No default value Possible Values: Any valid cluster.

	Description: The cluster on which to add disks. If not specified, the default is the current cluster.
Parameter: `disks`	*Default Value*: No default value Possible Values: Any valid disk names Description: A comma-separated list of disk names. Examples: • /dev/sdc • /dev/sdd,/dev/sde,/dev/sdf
Parameter: `host`	*Default Value*: No default value Possible Values: Any valid host or IP Description: The hostname or IP address of the machine on which to add the disk.
Parameter: `stripeWidth`	*Default Value*: No default value Possible Values: Any integer Description: The number of disks per storage pool.

Output

Output Fields

Field	Description
`ip`	The IP address of the machine that owns the disk(s).
`disk`	The name of a disk or partition. Example **sca** or **sca/sca1**
`all`	The string `all`, meaning all unmounted disks for this node.

Examples

Add a disk:

CLI

```
maprcli disk add -disks /dev/
sda1 -host 10.250.1.79
```

REST

```
https://abc.sj.us:8443/rest/disk/add?
disks=["/dev/sda1"]&host="10.250.1.79"
```

configure.sh on page 2053

last-updated: Apr 11, 2022

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

disk list
Lists the disks on a node.

Syntax

CLI

```
maprcli disk list
  -host name/ip
  [ -system 1/0 ]
  [ -output <terse|verbose>. default:
verbose ]

  [ -sortby <hostname|diskname|
mount|vendor|modelnum|serialnum|
firmwareversion|totalspace|usedspace|
            availablespace|
fstype|powerstatus|status|errormsg|
storagepoolid|failuretime> ]
  [ -sortorder <asc|desc> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/disk/list?<parameters>`

Parameters

Parameter	Description
`host`	The node on which to list the disks.
`output`	Whether the output should be `terse` or `verbose`. Default is `verbose`.
`sortby`	Specifies one of the following attributes to sort the list of disks by: `hostname`, `diskname`, `mount`, `vendor`, `modelnum`, `serialnum`, `firmwareversion`, `totalspace`, `usedspace`, `availablespace`, `fstype`, `powerstatus`, `status`, `errormsg`, `storagepoolid`, `failuretime`
`sortorder`	The order to sort the results by. Value can be: • `asc` - for ascending order • `desc` - for descending order

Parameter	Description
`system`	Show only operating system disks: • 0 - shows only MapR File System disks • 1 - shows only operating system disks • Not specified - shows both MapR File System and operating system disks

Output

Information about the specified disks. See the Disk Fields table.

Sample Output

```
# maprcli disk list -host 10.10.82.23 -output terse
mn            pst      sp  fw   mt  fs       dsu  n          st  dsa

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

disk listall
Lists all disks.

Syntax

CLI

```
maprcli disk listall
    [ -cluster <cluster> ]
    [ -limit <limit>]
    [ -output terse|verbose ]
    [ -start <offset>]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/disk/listall[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`limit`	The number of rows to return, beginning at start. Default: 0
`output`	Always the string `terse`.
`start`	The offset from the starting row according to sort. Default: 0

Output

Information about all disks. See the Disk Fields table.

Sample Output

```
# maprcli disk listall -output terse
mn            pst      sp  fw   mt  fs       dsu  n          st  dsa

8016    centos29.lab
```

Examples

List all disks:

CLI

```
maprcli disk listall
```

REST

```
https://abc.sj.us:8443/rest/disk/
listall
```

disk remove

Removes a disk from MapR File System. Permissions required: `fc` or `a`.

The `disk remove` command does not remove a disk containing unreplicated data, unless forced. To force disk removal, specify `-force` with the value `1` or `true`.

Note:

- Use the `-force 1`, or the equivalent `-force true` option only if you are sure that you do not need the data on the disk. This option removes the disk without regard to the replication factor or other data protection mechanisms, and may result in permanent data loss.
- Removing a disk in the storage pool that contains Container ID 1 stops the cluster. Container ID 1 contains CLDB data for the master CLDB. Run `disk remove` without the `-force 1`, or the equivalent `-force true` option first, and examine the warning messages to make sure that you are not removing the disk with Container ID 1. If you try to remove a disk associated with the storage pool that contains Container ID 1, you receive an error message similar to the following:

```
ERROR (151) -  Failed operation for disk /dev/sdb, Operation may
bring
down cluster due to loss of cluster meta-data.
```

Tip: If necessary, run the following command for information on the disk associated with the storage pool that contains Container ID 1:

```
/opt/mapr/server/mrconfig info dumpcontainers  | grep cid:1
```

The command output may look similar to the following:

```
cid:1 volid:1 sp:SP1:/dev/sdb
spid:82380c287085486f0058112ecf016b76
prev:0 next:0 issnap:0 isclone:0 deleteinprog:0 fixedbyfsck:0
stale:0
querycldb:0 resyncinprog:0 shared:0 owned:206 logical:206
snapusage:0
snapusageupdated:1 ismirror:0 isrwmirrorcapable:0 role:1
maxUniq:2100150
isResyncSnapshot:0 snapId:0 port:5660
```

To safely remove such a disk, first perform a CLDB Failover to make one of the other CLDB nodes the primary CLDB, and then remove the disk as normal.

Syntax

CLI

```
/opt/mapr/bin/maprcli disk remove
    -host name/ip
    -disks comma-separated list of
disks
    [ -force <true|false OR 1|0>.
Required to remove the disk when
errors have been reported; otherwise,
the command behaves like a test
remove when errors are reported.
If -force is set to false and there
are no errors, the disk is removed.
Default: false ]
    [ -cluster cluster_name ]
```

REST

Request Type	POST

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/disk/remove?<parameters>`

Parameters

Parameter	Description
`host`	The hostname or ip address of the node from which to remove the disk.
`disks`	A list of disks in the form: `["disk"]or["disk","disk","disk"...]or[]`
`force`	Whether to force disk removal. • `0` or `false` (default) - do not remove the disk or disks if there is unreplicated data on the disk • `1` or `true` - remove the disk or disks regardless of data loss, or other consequences
`cluster`	The cluster on which to run the command.

Output

Output Fields

Field	Description
`disk`	The name of a disk or partition. Example: `sca` or `sca/sca1`
`all`	The string `all`, meaning all unmounted disks attached to the node.
`disks`	A comma-separated list of disks which have non-replicated volumes. For example, "sca" or "sca/sca1,scb"

Examples

Remove a disk:

CLI

```
/opt/mapr/bin/maprcli disk
remove -disks /dev/sda
```

REST

```
https://abc.sj.us:8443/rest/disk/
remove?disks=/dev/sda
```

dump
Returns key information about volumes, containers, storage pools, and MapR cluster services for debugging and troubleshooting.

dump balancerinfo

Returns detailed information about the storage pools on a cluster. If there are any active container moves, the command returns information about the source and destination storage pools.

The `maprcli dump balancerinfo` command enables you to see how much space is used in storage pools and to track active container moves. For best results, use the `-json` option when running `dump balancerinfo` from the command line.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between storage pools. Whenever a storage pool is over 70% full (or a threshold defined by the `cldb.balancer.disk.threshold.percentage` parameter), the disk space balancer distributes containers to other storage pools that have lower utilization than the average for that cluster. The disk space balancer aims to ensure that the percentage of space used on all the disks in the node is similar. For more information, see Disk Space Balancer.

Syntax

CLI

```
maprcli dump balancerinfo
    [-cluster <cluster name>]
```

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.

Output

The `maprcli dump balancerinfo` command returns detailed information about the storage pools on a cluster. If there are any active container moves, the command returns information about the source and destination storage pools.

```
# maprcli dump balancerinfo -cluster my.cluster.com -json

                },
```

Output fields

Field	Description
spid	The unique ID number of the storage pool.
fsid	The unique ID number of the file server. The FSID identifies an MapR File System instance or a node that has MapR File System running in the cluster. Typically, each node has a group of storage pools, so the same FSID will correspond to multiple SPIDs.
ip:port	The host IP address and MapR File System port.
capacityMB	The total capacity of the storage pool (in MB).
usedMB	The amount of space used on the storage pool (in MB).
percentage	The percentage of the storage pool currently utilized. A ratio of the space used (*usedMB*) to the total capacity (*capacityMB*) of the storage pool.
fullnessLevel	The fullness of the storage pool relative to the fullness of the rest of the cluster. Possible values are *OverUsed*, *AboveAverage*, *Average*, *BelowAverage*, and *UnderUsed*. For more information, see Monitoring storage pool space usage below.
inTransitMB	The amount of data (in MB) that the disk space balancer is currently moving into a storage pool.
outTransitMB	The amount of data (in MB) that the disk space balancer is currently moving out of a storage pool.

The following fields are returned only if the disk space balancer is actively moving one or more containers at the time the command is run.

Field	Description
containerid	The unique ID number of the container.
sizeMB	The amount of data (in MB) being moved.
From fsid	The FSID (file server ID number) of the source file server.
From IP:Port	The IP address and port number of the source node.
From SP	The SPID (storage pool ID) of the source storage pool.
To fsid	The FSID (file server ID number) of the destination file server.
To IP:Port	The IP address and port number of the destination node.
To SP	The SPID (storage pool ID number) of the destination storage pool.

Examples

Monitoring storage pool space usage

You can use the `maprcli dump balancerinfo` command to monitor space usage on storage pools.

```
# maprcli dump balancerinfo -json

....
{
                        "spid":"4bc329ce06752062004fa1a537abcefg",
                        "fsid":5410063549464613987,
                        "ip:port":"10.50.60.72:5660-",
                        "capacityMB":1585096,
                        "usedMB":1118099,
                        "percentage":70,
                        "fullnessLevel":"AboveAverage",
                        "inTransitMB":0,
                        "outTransitMB":31874
                },
```

Tracking active container moves

Using the `maprcli dump balancerinfo` command you can monitor the activity of the disk space balancer. Whenever there are active container moves, the command returns information about the source and destination storage pools.

```
# maprcli dump balancerinfo -json
      ....
      {
           "containerid":7840,
           "sizeMB":15634,
           "From fsid":8081858704500413174,
           "From IP:Port":"10.50.60.64:5660-",
           "From SP":"9e649bf0ac6fb9f7004fa19d20rstuvw",
           "To fsid":3770844641152008527,
           "To IP:Port":"10.50.60.73:5660-",
           "To SP":"fefcc342475f0286004fad963flmnopq"
       }
```

last-updated: Apr 11, 2022

The example shows that a container (7840) is being moved from a storage pool on node 10.50.60.64 to a storage pool on node 10.50.60.73.

> **Tip:** You can use the storage pool IDs (SPIDs) to search the CLDB and MapR File System logs for activity (balancer moves, container moves, creates, deletes, etc.) related to specific storage pools.

dump balancermetrics
Returns a cumulative count of container moves and MB of data moved between storage pools.

The `maprcli dump balancermetrics` command returns a cumulative count of container moves and MB of data moved between storage pools. You can run this command periodically to determine how much data has been moved by the disk space balancer between two intervals. For best results, use the `-json` option when running `dump balancermetrics` from the command line.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between storage pools. Whenever a storage pool is over 70% full (or it reaches a threshold defined by the `cldb.balancer.disk.threshold.percentage` parameter), the disk space balancer distributes containers to other storage pools that have lower utilization than the average for that cluster. The disk space balancer aims to ensure that the percentage of space used on all the disks in the node is similar. For more information, see Disk Space Balancer.

Syntax

CLI

```
maprcli dump balancermetrics
    [-cluster <cluster name>]
```

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.

Output

The `maprcli dump balancermetrics` command returns a cumulative count of container moves and MB of data moved between storage pools since the current CLDB became the master CLDB.

```
# maprcli dump balancermetrics -json
{
    "timestamp":1337770325979,
    "status":"OK",
    "total":1,
    "data":[
        {
            "numContainersMoved":10090,
            "numMBMoved":3147147,
            "timeOfLastMove": "Wed May 23 03:51:44 PDT 2012"
        }
    ]
}
```

Output fields

Field	Description
numContainersMoved	The number of containers moved between storage pools by the disk space balancer.
numMBMoved	The total MB of data moved between storage pools on the cluster.
timeOfLastMove	The date and time of most recent container move.

Example

CLI

```
maprcli dump balancermetrics -cluster
10.10.82.23 -json
```

dump cldbnodes

Lists the nodes that contain *container location database* (CLDB) data.

The CLDB is a service running on one or more MapR nodes that maintains the location of cluster containers, services, and other information. The CLDB automatically replicates its data to other nodes in the cluster, preserving at least two (and generally three) copies of the CLDB data. If the CLDB process dies, it is automatically restarted on the node.

Syntax

CLI

```
maprcli dump cldbnodes
    [-cluster <cluster name>]
    -zkconnect <ZooKeeper Connect
String>
    -json | -long
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`zkconnect`	A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: '<host>[:<port>][,<host>[:<port>]...]'. To obtain zookeeper connection strings, use the `maprcli node listzookeepers` command.
`json | long`	This command returns multiple levels of data. You need to specify either JSON format or "long" format to see the full output.

last-updated: Apr 11, 2022

Output

The `maprcli dump cldbnodes` command returns the IP address and port number of the CLDB nodes on the cluster.

```
$ maprcli dump cldbnodes -zkconnect centos23.lab:5181 -json
{
    "timestamp":1433270634424,
    "timeofday":"2015-06-02 06:43:54.424 GMT+0000",
    "status":"OK",
    "total":1,
    "data":[
        {
            "valid":[
                "10.10.82.23:5660-",
                "10.10.82.28:5660-",
                "10.10.82.29:5660-",
                "10.10.82.22:5660-"
            ]
        }
    ]
}
```

Example

CLI

```
maprcli dump cldbnodes -zkconnect
centos23.lab:5181 -json
```

dump containerinfo
Returns detailed information about one or more specified containers.

A *container* is a unit of sharded storage in a MapR cluster. Every container in a MapR volume is either a *name container* or a *data container*.

> **Tip:** For an explanation of sharding, see the Configuring the Chunk Size topic.

The name container is the first container in a volume and holds that volume's namespace and file chunk locations. Depending on its replication role, a name container may be either a *master container* (part of the original copy of the volume) or a *replica container* (one of the replicas in the replication chain).

Every data container is either a *master container*, an *intermediate container*, or a *tail container*.

Syntax

CLI

```
maprcli dump containerinfo
    [-cluster <cluster name>]
    -ids <id1,id2,id3 ...>
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`ids`	Specifies one or more container IDs. Container IDs are comma separated. The `maprcli dump containers` command provides the container ID required for `-ids` parameter.

Output

The `maprcli dump containerinfo` command returns information about one or more containers.

```
# maprcli dump containerinfo -ids 1  -json
{
        "timestamp":1507024362685,
        "timeofday":"2017-10-03 02:52:42.685 GMT-0700 AM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "ContainerId":1,
                        "Epoch":9,
                        "Master":"10.10.105.35:5660--9-VALID",
                        "ActiveServers":{
                                "IP":[

                                        "10.10.105.35:5660--9-VALID",
                                        "10.10.105.36:5660--9-VALID",
                                        "10.10.105.37:5660--9-VALID"
                                ],

                        "VolumeMounted":false,
                        "AccessTime":"September 29, 2017"
                }
        ]
}
```

Output fields

Field	Description
ContainerID	The unique ID number for the container.
Epoch	A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container.
Master	The physical IP address and port number of the *master copy*. The master copy is part of the original copy of the volume.
ActiveServers	The physical IP address and port number of each active node on which the container resides.
InactiveServers	The physical IP address and port number of each inactive node on which the container resides.
UnusedServers	The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time.
OwnedSizeMB	The size on disk (in MB) dedicated to the container.
SharedSizeMB	The size on disk (in MB) shared by the container.
LogicalSizeMB	The logical size on disk (in MB) of the container.
TotalSizeMB	The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size.
Mtime	The time of the last modification to the contents of the container.
NameContainer	Indicates if the container is the *name container* for the volume. If `true`, the container holds the volume's namespace information and file chunk locations.
VolumeName	The name of the volume.
VolumeId	The unique ID number of the volume.
VolumeReplication	The *replication factor*, the number of copies of a volume excluding the original.
VolumeMounted	Indicates whether the volume is mounted. If `true`, the volume is currently mounted. If `false`, the volume is not mounted.

last-updated: Apr 11, 2022

Example

CLI

```
maprcli dump containerinfo -ids
2049  -json
```

dump cldbmetainfo

Prints metadata from the *container location database* (CLDB) tables.

Syntax

CLI

```
maprcli dump cldbmetainfo
    -json
```

Note: For formatted results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`json`	Returns formatted output

Output

The `maprcli dump cldmetainfo` command lists meta information from the CLDB tables, For an explanation of the output fields, see fid stat on page 1657.

```
$ maprcli dump cldbmetainfo -json
{
    "timestamp":1433270634424,
    "timeofday":"2020-06-02 06:43:54.424 GMT+0000",
    "status":"OK",
    "total":2,

                        "version":1048603,
                        "networkencryption":false,
                        "diskflush":false,
                        "nlevels":0
                }
        ]
}
```

Example

CLI

```
maprcli dump cldbmetainfo -json
```

dump containers
Returns information about containers in a cluster.

This command provides information about containers based on the following `-type` criteria:

- offline - Returns information about containers that have no valid copies online. This command is useful when you need to find out exactly what data is offline (for example, when a "volume data unavailable" alarm is raised).
- resync - Returns information about containers that are resynchronizing.
- bm - Returns information about containers that are becoming master but are not yet master.
- unused - Returns information about containers that are unused.
- waiting - Returns information about containers that are waiting for a role.

A *container* is a unit of sharded storage in a MapRMapR Data Platform cluster. Every container in a MapRMapR Data Platform volume is either a *name container* or a *data container*. The name container is the first container in a volume and holds that volume's namespace and file chunk locations. Depending on its replication role, a name container may be either a *master container* (part of the original copy of the volume) or a *replica container* (one of the replicas in the replication chain).

Every data container is either a *master container*, an *intermediate container*, or a *tail container*.

Syntax

CLI

```
maprcli dump containers
    [ -cluster <cluster_name> ]
     -type offline|resync|bm|waiting|
unused
```

Note: For best results, use the `-json` option from the command line.

REST N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`type`	Specifies the type of information that is returned about the containers: • `offline` - Returns information about containers that have no valid copies online. • `resync` - Returns information about containers that are resynchronizing. • `bm` - Returns information about containers that are becoming master but are not yet master. • `unused` - Returns information about containers that are unused. • `waiting` - Returns information about containers that are waiting for a role.

Output fields

Field	Description
ContainerID	The unique ID number for the container.
Epoch	A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container.
Master	The physical IP address and port number of the *primary copy*. The primary copy is part of the original copy of the volume.
ActiveServers	The physical IP address and port number of each active node on which the container resides.
InactiveServers	The physical IP address and port number of each inactive node on which the container resides.
UnusedServers	The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time.
OwnedSizeMB	The size on disk (in MB) dedicated to the container.

last-updated: Apr 11, 2022

Field	Description
SharedSizeMB	The size on disk (in MB) shared by the container.
LogicalSizeMB	The logical size on disk (in MB) of the container.
TotalSizeMB	The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size.
Mtime	The time of the last modification to the contents of the container.
NameContainer	Indicates if the container is the *name container* for the volume. If `true`, the container holds the volume's namespace information and file chunk locations.
VolumeName	The name of the volume.
VolumeId	The unique ID number of the volume.
VolumeReplication	The *replication factor*, the number of copies of a volume excluding the original.
VolumeMounted	Indicates whether the volume is mounted. If `true`, the volume is currently mounted. If `false`, the volume is not mounted.

Example

CLI

```
maprcli dump containers -type
offline -cluster my.cluster -json
```

Output Samples

The following `maprcli dump containers -type offline` command returns information about all offline containers.

```
# maprcli dump containers -type offline -json
{
        "timestamp":1348174731389,
        "status":"OK",
        "total":11,
        "data":[
                {
                        "ContainerId":2060,
                        "Epoch":3,
                        "Master":"unknown ip (0)-0-VALID",
                        "ActiveServers":{

                        },
                        "InactiveServers":{

                        },
                        "UnusedServers":{
                                "IP:Port":"10.10.20.39:5660--3"
                        },
                        "OwnedSizeMB":"0 MB",
                        "SharedSizeMB":"0 MB",
```

```
                        "LogicalSizeMB":"0 MB",
                        "TotalSizeMB":"0 MB",
                        "NameContainer":"true"
                },
                {
                        "ContainerId":2185,
                        "Epoch":3,
                        "Master":"unknown ip (0)-0-VALID",
                        "ActiveServers":{

                        },
                        "InactiveServers":{

                        },
                        "UnusedServers":{
                                "IP:Port":"10.10.20.39:5660--3"
                        },
                        "OwnedSizeMB":"0 MB",
                        "SharedSizeMB":"0 MB",
                        "LogicalSizeMB":"0 MB",
                        "TotalSizeMB":"0 MB",
                        "NameContainer":"false"
                },
...
```

The following `maprcli dump containers -type resync` command returns information about containers that are resyncronizing.

```
# maprcli dump containers -type resync -json
{
        "timestamp":1438666159569,
        "timeofday":"2015-08-03 10:29:19.569 GMT-0700",

dump replicationmanagerinfo

Returns information about which containers are under or over replicated in a specified volume.

For each container, the command displays the current state of that container.

Syntax

CLI

```
maprcli dump replicationmanagerinfo
     [-cluster <cluster name>]
     -volumename <volume name>
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`volumename`	Specifies the name of the volume. To obtain a volume name, use the `maprcli volume list` command.

Output

The `maprcli dump replicationmanagerinfo` returns information about volumes and the containers on those volumes including the nodes on which the containers have been replicated and the space allocated to each container. If replication activity is not underway when the maprcli command is executed, no container information is included. If replication activity is underway, details of containers are listed.

```
# maprcli dump replicationmanagerinfo -volumename mapr.metrics  -json
{
    "timestamp":1433449934381,
    "timeofday":"2015-06-04 08:32:14.381 GMT+0000",
    "status":"OK",
    "total":1,
    "data":[
        {
            "VolumeName":"mapr.metrics",
            "VolumeId":54955151,
            "VolumeTopology":"/data",
            "VolumeUsedSizeMB":0,
            "VolumeReplication":3,
            "VolumeMinReplication":2,
            "MirrorThrottle":true,
            "AccessTime":"Thu Jun 04 16:57:58 UTC 2015",
            "limitSpread":true
        },
                {
                        "ContainerId":2053,

                        },
                        "InactiveServers":{

                        },
                        "UnusedServers":{

                        },
                        "OwnedSizeMB":"1 MB",
                        "SharedSizeMB":"0 MB",
                        "LogicalSizeMB":"1 MB",
                        "Mtime":"Mon Apr 30 16:40:41 PDT 2012",
                        "NameContainer":"true"
                }
        ]
}
```

Output fields

Field	Description
VolumeName	Indicates the name of the volume.
VolumeId	Indicates the ID number of the volume.
VolumeTopology	The volume topology corresponds to the node topology of the rack or nodes where the volume resides. By default, new volumes are created with a topology of / (root directory). For more information, see Volume Topology.
VolumeUsedSizeMB	The size on disk (in MB) of the volume.
VolumeReplication	The desired replication factor, the number of copies of a volume excluding the original. The default value is *3*.
VolumeMinReplication	The minimum replication factor, the number of copies of a volume (excluding the original) that should be maintained by the MapR cluster for normal operation. When the replication factor falls below this minimum, writes to the volume are disabled. The default value is *2*.
MirrorThrottle	Specifies whether mirror throttling is enabled (true) or disabled (false). Throttling is set on the source volume and applies to all its mirrors. This property was introduced in version 4.0.2.
AccessTime	A value that can be used to determine which volumes are accessed regularly. This value is updated every 6 hours with the last time that an operation occurred on the volume. The access time is not updated for changes to volume properties, creation of a snapshot, or synchronization between a volume and a mirror. However, the volume access time is updated the first time you upgrade to a MapR version that includes this property. This property was introduced in version 4.0.2.

Field	Description
limitSpread	An internal flag for MapR volumes to control the growth of volume in terms of number of containers. When this flag is set, cldb tries to limit the number of new containers created depending on the present size of volume. If volume size (data in volume) is small, cldb tries to reuse space in existing containers to avoid the creation of new containers. This helps reduce the wasting of containers IDs in an environment that has small volumes.
ContainerId	The unique ID number for the container.
Epoch	A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container.
Master	The physical IP address and port number of the *master copy*. The master copy is part of the original copy of the volume.
ActiveServers	The physical IP address and port number of each active node on which the container resides.
InactiveServers	The physical IP address and port number of each inactive node on which the container resides.
UnusedServers	The physical IP address and port number of each on which the container does not reside.
OwnedSizeMB	The size on disk (in MB) dedicated to the container.
SharedSizeMB	The size on disk (in MB) shared by the container.
LogicalSizeMB	The logical size on disk (in MB) of the container.
Mtime	Indicates the time of the last modification to the container's contents.
NameContainer	Indicates if the container is the *name container* for the volume. If `true`, the container is the volume's first container and replication occurs simultaneously from the master to the intermediate and tail containers.

Example

CLI

```
maprcli dump
replicationmanagerinfo -cluster
docs41cluster -volumename
mapr.metrics  -json
```

dump replicationmanagerqueueinfo
Returns information that enables you to check the status of containers in various replication manager queues like under-replicated containers, and over-replicated containers, etc.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli dump
replicationmanagerqueueinfo
    [-cluster <cluster name>]
    -queue <queue>
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
queue	The name of the queue. Valid values are *0*, *1*, *2*, or *5*. Queue 0 includes containers that have copies below the minimum replication factor for the volume. Queue 1 includes containers that have copies below the replication for the volume, but above the minimum replication factor. Queue 2 includes containers that are over-replicated. Queue 5 includes containers which are not rack aware.

Output

The `maprcli dump replicationmanagerqueueinfo` command returns information about one of these queues: 0, 1, 2, or 5. Depending on the queue value entered, the command displays information about containers that are under-replicated or over-replicated. You can use this information to decide if you need to change the replication factor for that volume.

```
# maprcli dump replicationmanagerqueueinfo -queue 0
Mtime                        LogicalSizeMB  UnusedServers  ActiveServers
TotalSizeMB  NameContainer  InactiveServers  ContainerId

Output fields

Field	Description
ContainerID	The unique ID number of the container.
Epoch	A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container.
Master	The physical IP address and port number of the *master copy*. The master copy is part of the original copy of the volume.
ActiveServers	The physical IP address and port number of each active node on which the container resides.
InactiveServers	The physical IP address and port number of each inactive node on which the container resides.
UnusedServers	The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time.
OwnedSizeMB	The size on disk (in MB) dedicated to the container.
SharedSizeMB	The size on disk (in MB) shared by the container.
LogicalSizeMB	The logical size on disk (in MB) of the container.
TotalSizeMB	The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size.
Mtime	The time of the last modification to the contents of the container.
NameContainer	Indicates if the container is the *name container* for the volume. If `true`, the container holds the volume's namespace information and file chunk locations.

Example

CLI

```
maprcli dump
replicationmanagerqueueinfo -queue
0 -json
```

dump rereplicationinfo
Returns information about the ongoing re-replication of replica containers.

This information includes the destination IP address and port number, the ID number of the destination file server, and the ID number of the destination storage pool.

Re-replication occurs whenever the number of available replica containers drops below the number prescribed by that volume's replication factor. Re-replication may occur for a variety of reasons including replica container corruption, node unavailability, hard disk failure, or an increase in replication factor.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli dump rereplicationinfo
    [-cluster <cluster name>]
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.

Output

The `maprcli dump rereplicationinfo` command returns information about the ongoing re-replication of replica containers including the destination IP address and port number, the ID number of the destination file server, and the ID number of the destination storage pool.

```
# maprcli dump rereplicationinfo -json
{
        "timestamp":1338222709331,
        "status":"OK",

                }
        ]

}
```

Output fields

Field	Description
sizeMB	The amount of data (in MB) being moved.
To fsid	The ID number (FSID) of the destination file server.
To IP:Port	The IP address and port number of the destination node.
To SP	The ID number (SPID) of the destination storage pool.

Example

CLI

```
maprcli dump rereplicationinfo -json
```

dump rereplicationmetrics
Displays information about containers that were copied by the replication manager.

This command displays the following fields :

- `numContainersCopied` - The number of containers that were copied by the replication manager to maintain the volume's replication factor or topology since the current CLDB was the master.
- `numMBCopied` -The cumulative size of the containers that were copied by the replication manager to maintain the volume's replication factor or topology since the current CLDB was the master.

Syntax

CLI

```
maprcli dump rereplicationmetrics
  [-cluster <cluster name>]
```

REST

N/A

Parameters

Parameter	Description
`cluster`	Cluster name.

Example

CLI maprcli dump rereplicationmetrics

Example Output

```
# maprcli dump rereplicationmetrics
numContainersCopied  numMBCopied
0                    0
```

dump rolebalancerinfo
Returns information about active replication role switches.

Use the `dump rolebalancerinfo` command to see if the replication role balancer is currently switching the replication roles of any containers in a cluster. For example, if too many data containers with the master or intermediate roles exist within a storage pool, the replication role balancer switches the role of some of these containers to the tail role to evenly spread the load across nodes during the replication process. If the role balancer is not currently switching the roles of any containers, the command returns a message stating that there are no active role switches.

You can include some additional parameters with the `dump rolebalancerinfo` command, such as the `volumeinfo` parameter, which provides information about how the replication role balancer balanced container roles across each storage pool in a particular volume.

See Replication Role Balancer for more information about how the replication role balancer works.

For the best readability, use the `-json` option at the end of the command.

Syntax

CLI

```
maprcli dump rolebalancerinfo
        [ -cluster cluster_name ]
        [ -namecntrinfo Get
NameContainers Info Parameter takes
no value  ]
        [ -stats Gets RoleBalancer
AcitveSwitches Info Parameter takes
no value  ]
        [ -volumeinfo Gets Balancing
Info for Volumes(s) Parameter takes
no value  ]
        [ -volumename Specifies the
name of the volumes ]
```

REST N/A

Parameters

Parameter	Description
cluster	The cluster on which to run the command. When you omit this parameter, the command runs on the same cluster where it is issued. In a multi-cluster environment, use this parameter to specify a particular cluster.

stats	Provides a list of active switches for the role balancer. The command returns the same information with or without this parameter.
volumeinfo	Provides the volume balancing information and details how the container roles are balanced across each storage pool in a volume. Requires the `volumename` parameter.
volumename	The name of the volume. To obtain volume names, use the `maprcli volume list` command.
namecntrinfo	Provides information about how the name containers are distributed across the storage pools in the cluster, including how many name containers are master and tail containers. Useful when the replication role balancer is configured to balance container roles by count instead of size.

Output

The following example shows the output of the `dump rolebalancerinfo` command when the replication role balancer switches a container to the tail role:

```
# maprcli dump rolebalancerinfo -json
{
      "timestamp":1452150159265,
      "timeofday":"2016-01-07 07:02:39.265 GMT+0000",
      "status":"OK",
      "total":1,
      "data":[
             {
                   "containerid":57482,
                   "Tail IP:Port":"10.10.104.37:5660-10.10.105.37:5660-",
                   "Updates blocked Since":"Thu Jan 07 07:02:24 UTC 2016"
             }
        ]
   }
```

The following example shows the `dump rolebalancerinfo -volumeinfo -volumename` command:

```
# maprcli dump rolebalancerinfo -volumeinfo -volumename vol2 -json
{
    "timestamp":1452218225547,
    "timeofday":"2016-01-08 01:57:05.547 GMT+0000",
    "status":"OK",
    "total":1,
    "data":[
        {
            "VolumeBalancingInfo":{
                "Volume":"vol2",
                "Assign Cache Containers Count":60,
                "Assign Cache Containers Size":951171,
                "Zero Size Containers Count":5,
                "Storage Pools":[

                    },
                    {
                        "SpId":"ca379b6cfc888270005669428c02c6e3",
                        "HostAddress":"10.10.104.32(2)",
                        "NumContainers":5,
                        "NumMasters":0,
                        "NumTails":2,
                        "SizeOfContainers":107549,
                        "SizeOfMasters":0,
                        "DesiredSizeOfMasters":35849,
                        "SizeOfTails":48267,
                        "DesiredSizeOfTails":35849,
                        "Assign Cache Containers Count":0,
                        "Assign Cache Containers Size":0
                    }

                ]
            }
        }
    ]
}
```

Output

Field	Description
containerID	The unique ID number of the container.
Tail IP:Port	The IP address and port number of the tail container node.
Updates blocked Since	During a replication role switch, updates to that container are blocked during the date and time indicated.
Volume	Name of the volume.
Assign Cache Containers Count	The total number of containers in the assign cache. The assign cache is a list of containers that the CLDB has reserved on a particular file server node. The CLDB allocates containers from the cache when it receives a request from the file server for more containers.
Assign Cache Containers Size	The total size of the containers in the assigned cache. The assign cache is a list of containers that the CLDB has reserved on a particular file server node. The CLDB allocates containers from the cache when it receives a request from the file server for more containers.
Zero Size Containers Count	The number of empty cache containers.
Storage Pools	The list of storage pools in the specified volume.

SpId	The ID of the storage pool located within the specified volume.
HostAddress	The server on which the storage pool resides.
NumContainers	The total number of containers that reside on the storage pool in the specified volume.
NumMasters	The total number of master containers that reside on the storage pool in the specified volume.
NumTails	The total number of tail containers that reside on the storage pool in the specified volume.
SizeOfContainers	The total size of the containers that reside on the storage pool in the specified volume.
SizeOfMasters	The total size of the master containers that reside on the storage pool in the specified volume.
DesiredSizeOfMasters	The cumulative size of master replicas on a specific storage pool within a volume. Typically, this is 1/ReplicationFactor of all containers on a storage pool for a particular volume. For example, if the replication factor is set to 3, then ⅓ of all containers on a storage pool should have the master container role.
SizeOfTails	The total size of the tail containers that reside on the storage pool in the specified volume.
DesiredSizeOfTails	The cumulative size of tail replicas on a specific storage pool within a volume. Typically, this is 1/ReplicationFactor of all containers on a storage pool for a particular volume. For example, if the replication factor is set to 3, then ⅓ of all containers on a storage pool should have the tail container role.

Example

CLI

```
maprcli dump rolebalancerinfo -json
```

dump rolebalancermetrics

Returns the cumulative number of times that the replication role balancer has switched the replication role of name containers and data containers on the cluster.

The `maprcli dump rolebalancermetrics` command enables you to view the number of times that the replication role balancer has switched the replication role of the name containers and data containers to ensure that containers are balanced across the nodes in the cluster. For best results, use the `-json` option when running `dump rolebalancermetrics` from the command line.

The *replication role balancer* is a tool that switches the replication roles of containers to ensure that every node has an equal share of master and replica containers (for name containers) and an equal share of master, intermediate, and tail containers (for data containers).

The replication role balancer changes the replication role of the containers in a cluster so that network bandwidth is spread evenly across all nodes during the replication process. A container's replication role determines how it is replicated to the other nodes in the cluster. For *name containers* (the volume's first container), replication occurs simultaneously from the master to all replica containers. For *data containers*, replication proceeds from the master to the intermediate container(s) until it reaches the tail containers. For more information, see Replication Role Balancer.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli dump rolebalancermetrics
    [-cluster <cluster name>]
```

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.

Output

The `maprcli dump rolebalancerinfo` command returns the cumulative number of times that the replication role balancer has switched the replication role of name containers and data containers on the cluster.

```
# maprcli dump rolebalancermetrics -json
{
        "timestamp":1433372048169,
    "timeofday":"2015-06-03 10:54:08.169 GMT+0000",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "numNameContainerSwitches":60,
                        "numDataContainerSwitches":28,
                        "timeOfLastMove":"Wed May 23 05:48:00 PDT 2015"
                }
        ]
}
```

Output fields

Field	Description
numNameContainerSwitches	The number of times that the replication role balancer has switched the replication role of name containers.
numDataContainerSwitches	The number of times that the replication role balancer has switched the replication role of data containers.
timeOfLastMove	The date and time of the last replication role change.

Example

CLI

```
maprcli dump rolebalancermetrics -json
```

dump supportdump
Collects logs and other information about the node to help troubleshoot issues.

Syntax

CLI

```
maprcli dump supportdump [ -cluster
<cluster name> ] [ -nodes <node
names> ] [ -params <parameter
string> ] [ -zkconnect <ZK connect
string> ]
```

REST

N/A

Parameters

Parameter	Description
cluster	Cluster name.
nodes	Node names for which support dump is needed. Space separated. Default: all
params	Parameter string to create a dump.
zkconnect	ZK connection string.

Output

```
# maprcli dump supportdump
node
centos29.lab
centos23.lab
centos28.lab
centos22.lab
```

Example

CLI

maprcli dump supportdump

dump volumeinfo

Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

A *volume* is a logical unit that allows you to apply policies to a set of files, directories, and sub-volumes. Using volumes, you can enforce disk usage limits, set replication levels, establish ownership and accountability, and measure the cost generated by different projects or departments. For more information, see Administering Volumes on page 856.

Syntax

CLI

```
maprcli dump volumeinfo
    [-cluster <cluster name>]
    -volumename <volume name>
```

REST

N/A

Parameters

cluster

The cluster on which to run the command. If this parameter is omitted, the command is run on the

last-updated: Apr 11, 2022

	cluster on which it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
volumename	The name of the volume. To obtain volume names, use the volume list on page 1979 `maprcli volume list` command. This parameter is mandatory.

Output

The `maprcli volume info` returns information about the volume and the containers associated with that volume. Volume information includes the ID, volume name, and replication factor. For each container on the specified volume, the command returns information about nodes and storage. See the following Example on page 1640 for sample output.

AccessTime	Indicates the volumes that are accessed regularly. This value is updated every 6 hours with the last time that an operation occurred on the volume. The access time is not updated for changes to volume properties, creation of a snapshot, or synchronization between a volume and a mirror. However, the volume access time is updated the first time you upgrade to a MapR version that includes this property. This property was introduced in MapR version 4.0.2.
ActiveServers	The IP address and port number of each active node on which the container resides.
allowGrant	Indicates whether (`true`) or not (`false`) a parent volume grants permission for a child volume to inherit its properties.
Audited	Indicates whether (`1`) or not (`0`) auditing is enabled for the volume.
AuditVolume	Indicates whether (`1`) or not (`0`) the volume accommodates audit logs.
CoalesceInterval	The interval of time to elapse after the first instance of an operation on a node is recorded in audit logs, if auditing is enabled. Subsequent identical operations performed on the same node from the same client are ignored during the interval.
ContainerId	The unique ID number of the container.
CreatorContainerId	The container ID of the read-write container. The container ID is retained in all mirrors of those containers (in all mirrors of the volume). The container ID enables the identification of the correct containers to source from, when mirror sources are changed in a mirror chain.
CreatorVolumeUuid	A randomly generated unique ID that is shared by all mirrors of a volume, and all containers of them. You can use this ID to avoid undesirable chaining of containers when mirror sources are changed in a mirror chain.
dareEnabled	Indicates whether (`1`) or not (`0`) data-at-rest encryption (DARE) is enabled for the volume.
DisabledDataAuditOperations	The list of operations excluded from auditing.
EnabledDataAuditOperations	The list of operations selected for auditing.
enforcementMode	The data access enforcement mode.

Epoch	A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container.
fixCreatorId	An internal flag for MapR volumes to fix the creator container ID.
ForceAudit	Indicates whether (`1`) or not (`0`) to force audit of operations on all files, tables, and streams in the volume.
InactiveServers	The IP address and port number of each inactive node on which the container resides.
limitSpread	An internal flag for MapR volumes to control the growth of a volume in terms of number of containers. When this flag is set, CLDB tries to limit the number of new containers created, depending on the present size of a volume. If a volume size (data in volume) is small, CLDB tries to reuse space in existing containers to avoid the creation of new containers. This reuse helps reduce wastage of containers IDs in an environment that has small volumes.
LogicalSizeMB	The logical size on disk (in MB) of the container.
Master	The IP address and port number of the *master copy*. The master copy is part of the original copy of the volume.
MetricsEnabled	Indicates whether (`1`) or not (`0`) metrics collection is enabled for the volume.
MirrorThrottle	Specifies whether mirror throttling is enabled (true) or disabled (false). Throttling is set on the source volume and applies to all its mirrors. This property was introduced in MapR version 4.0.2.
Mtime	Indicates the time when the last modification was made to the contents of the container.
NameContainer	Indicates if the container is the *name container* for the volume. If `true`, the container is the first container of the volume. Replication then occurs simultaneously from the master to the intermediate and tail containers.
NameSpaceMinReplication	The minimum replication factor or the number of copies of the name container associated with the volume that should be maintained by the MapR cluster for normal operation. When the replication factor falls below this minimum value, writes to the volume are disabled. The default value is *2*.
NameSpaceReplication	The desired replication factor or the number of copies of the name container associated with the volume. The default value is *3*. The maximum value is *6*.
NumInodesInUse	Indicates the uumber of inodes used by the container.
OwnedSizeMB	The size on disk (in MB) dedicated to the container.
ReReplicationTimeOutSec	The timeout (in seconds) period until CLDB starts re-replicating the containers on the node of the volume, when CLDB stops receiving a heartbeat from the node.
securityPolicyTags	The list of security policy tags to be associated with this volume.
SharedSizeMB	The size on disk (in MB) shared by the container.

last-updated: Apr 11, 2022

TenantUser	Displays the name of the tenant user, if any.
TotalSizeMB	The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size.
UnusedServers	The IP address and port number of servers from which no "heartbeat" has been received for quite some time.
VolumeId	The unique ID number of the volume.
VolumeMinReplication	The minimum replication factor. Indicates the number of copies of a volume (including the original) that should be maintained by the MapR cluster for normal operation. When the replication factor falls below this minimum value, writes to the volume are disabled. The default value is *2*. A replication factor of 2 indicates that the number of copies of a volume is 2 (original +1 copy). A replication factor of 3 indicates that the number of copies of a volume is 3 (original + 2 copies).
VolumeName	The name of the volume.
VolumeReplication	The desired replication factor. Indicates the number of copies of a volume. The default value is *3*. The maximum value is *6*.
VolumeTopology	The volume topology corresponds to the node topology of the rack or nodes where the volume resides. By default, new volumes are created with a topology of `/` (root directory). For more information, see Setting Up Node Topology on page 805.
VolumeUsedSizeMB	The size on disk (in MB) of the volume.
WireSecurityEnabled	Indicates whether (`1`) or not (`0`) wire-level security is enabled.

Example
Dump volume information

CLI

```
# /opt/mapr/bin/maprcli dump
volumeinfo -cluster
docs41cluster -volumename
sampleVol  -json
{
    "timestamp":1435363982346,

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

node list on page 1705
Lists nodes in the cluster.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

dump volumenodes
Returns information about the nodes on a volume.

Syntax

CLI

```
maprcli dump volumenodes
    [-cluster <cluster name>]
    -volumename <volume name>
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`volumename`	The name of the volume. To obtain volume names, use the `maprcli volume list` command.

Output

The `maprcli dump volumenodes` command returns the IP address and port number of volume nodes.

```
# maprcli dump volumenodes -volumename mapr.hbase -json
{
    "timestamp":1433372931725,
    "timeofday":"2015-06-03 11:08:51.725 GMT+0000",
    "status":"OK",
    "total":1,
    "data":[
        {
            "Servers":{
                "IP:Port":[
                    "10.10.82.23:5660--3-VALID",
                    "10.10.82.28:5660--3-VALID",
                    "10.10.82.29:5660--3-VALID"
                ]
            }
```

last-updated: Apr 11, 2022

```
        }
    ]
}
```

Output fields

Field	Description
IP:Port	The IP address and MapR File System port.

Example

CLI

```
maprcli dump volumenodes -volumename
mapr.hbase -json
```

dump zkinfo
Returns the ZooKeeper znodes.

Note: This command is used by the `mapr-support-collect.sh` script to gather cluster diagnostics for troubleshooting.

This command enables you to view a snapshot of the data stored in Zookeeper as a result of cluster operations

ZooKeeper prevents service coordination conflicts by enforcing a rigid set of rules and conditions, provides cluster-wide information about running services and their configuration, and provides a mechanism for almost instantaneous service failover. Warden will not start any services unless ZooKeeper is reachable and more than half of the configured ZooKeeper nodes are live.

The `mapr-support-collect.sh` script calls the `maprcli dump supportdump` command to gather cluster diagnostics for troubleshooting. For more information, see mapr-support-collect.sh.

Syntax

CLI

```
maprcli dump zkinfo
    [-cluster <cluster name>]
    [-zkconnect <connect string>]
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`zkconnect`	A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: '<host>[:<port>][,<host>[:<port>]...]'. To obtain zookeeper connection strings, use the `maprcli node listzookeepers` command.

Output

The `maprcli dump zkinfo` command is run as part of support dump tools to view the current state of the Zookeeper service. The command should always be run using the `-json` option, since output in the default tabular format is not useful. Command output displays the data stored in the ZooKeeper hierarchical tree of znodes.

```
# maprcli dump zkinfo -json
{
        "timestamp":1335825202157,
        "status":"OK",
        "total":1,
        "data":[
                {
                "/_Stats":"\ncZxid = 0,ctime = Wed Dec 31 16:00:00 PST
1969,mZxid = 0,mtime = Wed Dec 31 16:00:00 PST 1969,pZxid = 516,cversion
= 12,dataVersion = 0,aclVersion = 0,ephemeralOwner = 0,dataLength =
0,numChildren = 13",
                        "/":[
                                {
                                    ....
                                }
        ]
}
```

Output fields

You can use the `maprcli dump zkinfo` command as you would use a database snapshot. The `/services`, `/services_config`, `/servers`, and `/*_locks` znodes are used by Warden to store and exchange information.

Field	Description
services	The `/services` directory is used by Warden to store and exchange information about services.
datacenter	The `/datacenter` directory contains CLDB "vital signs" that you can use to identify the CLDB master, the most recent epoch, and other key data. For more information, see Moving CLDB Data.
services_config	The `/services_config` directory is used by Warden to store and exchange information.
zookeeper	The `/zookeeper` directory stores information about the ZooKeeper service.
servers	The `/servers` directory is used by Warden to store and exchange information.
nodes	The `/nodes` directory (znode) stores key information about the nodes.

Moving CLDB Data
Describes how to move CLDB data to another node.

In a Community Edition-licensed cluster, CLDB data must be recovered from a failed CLDB node and installed on another node. The cluster can continue normally as soon as the CLDB is started on another node.

For more information, see CLDB Failover on page 1500.

Use the `maprcli dump zkinfo` command to identify the latest epoch of the CLDB, identify the nodes where replicates of the CLDB are stored, and select one of those nodes to serve the new CLDB node. Perform the following steps on any cluster node:

1. Log in as `root` or use `sudo` for the following commands.
2. Issue the `maprcli dump zkinfo` command using the `-json` flag.
   `# maprcli dump zkinfo -json`
   The output displays the ZooKeeper znodes.
3. In the `/datacenter/controlnodes/cldb/epoch/1` directory, locate the CLDB with the latest epoch.

   ```
   { "/datacenter/controlnodes/cldb/epoch/1/KvStoreContainerInfo":"
   Container ID:1 VolumeId:1
   Master:10.250.1.15:5660-172.16.122.1:5660-192.168.115.1:5660--13-VALID
   Servers: 10.250.1.15:5660-172.16.122.1:5660-192.168.115.1:5660--13-VALID
   Inactive Servers: Unused Servers: Latest epoch:13" }
   ```

   The Latest Epoch field identifies the current epoch of the CLDB data. In this example, the latest epoch is *13*.
4. Select a CLDB from among the copies at the latest epoch. For example, `10.250.2.41:5660--13-VALID` indicates that the node has a copy at epoch 13 (the latest epoch).

entity
Manages *entities* (users and groups).
entity info
Displays information about an entity.

Syntax

CLI

```
maprcli entity info
    [ -cluster <cluster> ]
    -name <entity name>
    [ -output terse|verbose ]
    -type <type>
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/entity/info?<parameters>`

Parameters

Parameter	Description
cluster	The cluster on which to run the command.
name	The *entity* name. Obtain the entity name by running the `maprcli entity list` command.
output	Whether to display terse or verbose output.

Parameter	Description
type	The entity type. Obtain the entity type by running the `maprcli entity list` command.

Output

Sample Output

```
DiskUsage  EntityQuota  EntityType  EntityName  VolumeCount
EntityAdvisoryquota  EntityId
864415     0            0           root        208
0                   0
```

Output Fields

Field	Short Name	Description
DiskUsage	dsu	Disk space used by the user or group
EntityQuota	qta	The user or group quota
EntityType	t	The entity type
EntityName	n	The entity name
VolumeCount	vct	The number of volumes associated with the user or group
EntityAdvisoryquota	aqt	The user or group advisory quota
EntityId	id	The ID of the user or group

Examples

Display information for the user 'root':

CLI

```
maprcli entity info -type 0 -name root
```

REST

```
https://abc.sj.us:8443/rest/entity/
info?type=0&name=root
```

entity list
Lists and displays information about entities.

Syntax

CLI

```
maprcli entity list
    [ -alarmedentities true|false ]
    [ -cluster <cluster> ]
    [ -columns <columns> ]
    [ -filter <filter> ]
    [ -limit <rows> ]
    [ -output terse|verbose ]
    [ -sortby ]
    [ -start <start> ]
```

REST

Request Type	GET

Request URL	`http[s]://<host>:<port>/rest/entity/list[?<parameters>]`

Parameters

Parameter	Description
`alarmedentities`	Specifies whether to list only entities that have exceeded a quota or advisory quota.
`cluster`	The cluster on which to run the command.
`columns`	A comma-separated list of fields to return in the query. See the Fields table below.
`filter`	A filter specifying entities to display. See Filters for more information.
`limit`	The number of rows to return, beginning at start. Default: 0
`output`	Specifies whether output should be `terse` or `verbose`.
`sortby`	Specifies one of the following attributes to sort the list of entities by: `entityname`, `entitytype`, `entityid`, `entityemail`, `entityquota`, `entityadvisoryquota`, `entitydiskusage`, `entityvolumecount`. By default, the list of entities sorted by `entityname`.
`start`	The offset from the starting row according to sort. Default: 0

Output

Information about the users and groups. Only users and groups with associated volumes are returned in the output.

Table

Field	Short Name	Description
EntityType	t	Entity type • `0` = User • `1` = Group
EntityName	n	User or Group name
EntityId	id	User or Group id
EntityQuota	qta	Quota, in MB. `0` = no quota.
EntityAdvisoryquota	aqt	Advisory quota, in MB. `0` = no advisory quota.
VolumeCount	vct	The number of volumes this entity owns.
DiskUsage	dsu	Disk space used for all entity's volumes, in MB.

last-updated: Apr 11, 2022

Sample Output

```
DiskUsage  EntityQuota  EntityType  EntityName  VolumeCount
EntityAdvisoryquota  EntityId
5859220    0            0           root        209
0                   0
```

Examples

List all entities:

CLI

```
maprcli entity list
```

REST

```
https://abc.sj.us:8443/rest/entity/
list
```

Filter entities by entity name:

CLI

```
maprcli entity list -filter
"[EntityName==mapr]"
```

REST

```
https://abc.sj.us:8443/rest/entity/
list?filter=[EntityName%3D%3Dmapr]
```

entity modify

Modifies a user or group quota or email address. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli entity modify
    [ -advisoryquota <advisory quota>
    [ -cluster <cluster> ]
    [ -email <email>]
    [ -entities <entities> ]
    -name <entityname>
    [ -quota <quota> ]
    -type <type>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/entity/modify?<parameters>`

Parameters

Parameter	Description
`advisoryquota`	The advisory quota.
`cluster`	The cluster on which to run the command.

Parameter	Description
`email`	Email address.
`entities`	A comma-separated list of entities, in the format `<type>:<name>`. Example: `0:<user1>,0:<user2>,1:<group1>,1:<group2>...`
`name`	The *entity* name.
`quota`	The quota for the entity.
`type`	The entity type: • 0=user • 1-group

Examples

Modify the email address for the user 'root':

CLI

```
maprcli entity modify -name
root -type 0 -email test@example.com
```

REST

```
https://abc.sj.us:8443/rest/entity/
modify?
name=root&type=0&email=test@example.co
m
```

Related tasks

Setting Quota Defaults for Users and Groups on page 781
Explains how to set disk space quotas for users and groups.

Related reference

rlimit set on page 1736
Sets the resource usage limit for the cluster's disk resource.

entity remove

Removes an entity (specified by name and type).

Note: Entity can be removed only when there are no resources associated with the entity.

Syntax

CLI

```
maprcli entity remove
    -name <entity name>
    -type <type>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/entity/remove?<parameters>`

Parameters

Parameter	Description
`name`	The *entity* name. Obtain the entity name by running the `maprcli entity list` command.
`type`	The entity type. Value can be: • `0` - for user • `1` - for group If necessary, obtain the entity type by running the `maprcli entity list` command.

Example

Remove an entity by name and type:

```
maprcli entity remove -name mapruser1 -type 1
```

fid
Displays information about MapR Database or file-system components that are identified by a FID.
fid dump
Displays detailed information for MapR Database or file-system components that are identified by an FID.

Note: Only the root user and the MAPR_USER user (user under which MapRMapR Data Platform services runs) have permissions to run this command.

Syntax

CLI

```
maprcli fid dump
   [ -cluster <cluster_name> ]
   -fid <file identified for the
element>
```

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`fid`	The file identifier for the element (region, kvstore, etc.) for which you want detailed information. The output of `maprcli table region list` lists the FIDs for the table's regions.

Note: You can run this command on any FID available on the MapRMapR Data Platform filesystem.

Tablet Map
Displays output for a tablet map includes the key for each tablet and its corresponding FID.

last-updated: Apr 11, 2022

Each tablet contains a range of data starting with the key associated with the tablet and ending before the key associated with the next tablet

FID for a Tablet Map

Describes how to determine the FID for a tablet map.

To determine the FID for a tablet map:

1. Run `hadoop mfs -ls <table path>` to determine the table FID. The table FID is the FID that displays after the "p."
   Example:

```
[mapr@hostname ~]$ hadoop mfs -ls /testdst
                        Found 1 items
                        tr-------- Z U 3 mapr mapr 2 2015-02-18 15:24 0 /
testdst
                        p 2049.49.131220 hostname:5660
                        r 2061.32.131258 hostname:5660
```

2. Run maprcli fid dump on the table FID to determine the tablet map FID.
   Example:

```
                        [mapr@hostname ~]$ maprcli fid dump -fid
2049.49.131220
                        value key
                        {"value":{"fid":"<parentCID>.51.131224"}} schema
                        {"value":{"fid":"<parentCID>.50.131222"}}
tabletmap
```

3. Construct the tablet map FID for the maprcli fid dump command by replacing <parentCID> with the set of numbers before the first period four numbers in the table FID.
   Example: `2049.50.131222`

Output Example for a Tablet Map

Example command and output.

```
maprcli fid dump -fid 2049.50.131222 -json
{
 "timestamp":1425579595296,

}
```

Tablet
Describes output for a tablet.

The `maprcli fid dump` output for a tablet includes key and value pairs for the following:

- **startkey.** The first key value in the tablet.
- **pmap.** Each partition.
- **endkey.** The last key value in the tablet.

Output Fields for a Tablet

This table describes a majority of the output values for each partition (pmap) in the tablet.

Field	Description
`key`	The partition key.
`segfid`	The FID of the segment map associated with this partition.
`isFrozen`	A Boolean value that indicates if a partition is in a frozen state or not. Internally, a partition is sometimes temporarily marked as frozen in order for certain operations to complete.
`inSplit`	A Boolean value that indicates if a partition split is in progress for this partition.
`useBucketDesc`	This property is for internal use only.
`lastFlushedBucketFid`	The FID of the bucket file (WAL) which was last flushed for this partition.
`numLogicalBlocks`	The number of logical blocks (8K) for this partition.
`numPhysicalBLocks`	The number of physical blocks (8K) for this partition.
`numRows`	The number of rows stored in this partition.
`numRowsWithDelete`	The number of rows which are marked for delete in this partition.
`numRemoteBlocks`	The number of disk blocks which are not local to this partition. When a region splits, a partition moves from one node to another and it is possible to temporarily have some remote blocks.
`numSpills`	The number of spills.
`numSegments`	The number of segments.

Output Example for a Tablet

```
maprcli fid dump -fid 2116.59.131462 -json
{
    "timestamp":1425579636931,
    "timeofday":"2015-03-05 06:20:36.931 GMT+0000",
    "status":"OK",
    "total":6,
    "data":[
        {
            "key":"endkey.user3155781742051747178",
            "value":{

            }
        },
        {
            "key":"pmap.",
            "value":{
                "segfid":"<parentCID>.1065.133486",
                "isFrozen":false,
                "inSplit":false,
                "useBucketDesc":true,
                "lastFlushedBucketFid":"2116.901.133158",
                "numLogicalBlocks":34921,
                "numPhysicalBlocks":21976,
                "numRows":9332,
                "numRowsWithDelete":0,
                "numRemoteBlocks":0,
                "numSpills":137,
                "numSegments":74
            }
        },
        {
            "key":"pmap.user1523186274532578170",
            "value":{
                "segfid":"<parentCID>.1066.133488",
                "isFrozen":false,

                "lastFlushedBucketFid":"2116.902.133160",
                "numLogicalBlocks":37011,
                "numPhysicalBlocks":23260,
                "numRows":9868,
                "numRowsWithDelete":0,
                "numRemoteBlocks":168,
                "numSpills":147,
                "numSegments":78
            }
        },
        {
            "key":"pmap.user2078250355776544396",
            "value":{
                "segfid":"<parentCID>.445.132238",
                "isFrozen":false,
                "inSplit":false,
                "useBucketDesc":true,
                "lastFlushedBucketFid":"2116.447.132242",
                "numLogicalBlocks":71124,
                "numPhysicalBlocks":44797,
                "numRows":18991,
                "numRowsWithDelete":0,
                "numRemoteBlocks":172,
                "numSpills":300,
```

```
                "numSegments":152
            }
        },
        {
            "key":"postSplitCopy",
            "value":{
                "raw":"dummy"
            }
        },
        {
            "key":"startkey.",
            "value":{
            }
        }
    ]
}
```

Note: The postSpitCopy key and value are for internal use only.

Segment Map
Describes output of a segment map.

The `maprcli fid dump` output of a segment map includes a map of row keys and the corresponding segment FID.

Output Fields for a Segment Map

Field	Description
key	The row key
value	The FID corresponding to the segment associated with this key.

Output Example for a Segment Map

```
maprcli fid dump -fid 2116.1065.133486 -json

{
    "timestamp":1425579702407,
    "timeofday":"2015-03-05 06:21:42.407 GMT+0000",
    "status":"OK",
    "total":74,
    "data":[
        {
            "key":"",
            "value":{
                "fid":"<parentCID>.943.133242"
            }
        },
        {
            "key":"user1006417450462802131",
            "value":{
                "fid":"<parentCID>.945.133246"
            }
        },
…
    ]
}
```

Segment
Describes output for a segment.

The output of `maprcli fid dump` for a segment includes details about each spill.

Output Fields for a Segment

Field	Description
`key`	The index of the spill.
`numRemoteBlocks`	The number of remote blocks.
`numspills`	The number of spills.
`value`	The property contains the following values: • fid: The FID of the spill containing row and value data. • smeSize: The spill map entry size. • keyIdxOffset: The offsets and length inside the spill for the index • keyIdxLength: The length inside the spill for the index • ldbIdxLength: The length of the index portion in the spill. • bloomBitsPerKey: The number of bits used in the bloom filter per key. • numLogicalBlocks. The number of logical blocks in the spill. • numPhysicalBlocks: The number of physical blocks in the spill. • numRows: The number of rows in the spill. • numRowsWithDelete: The number of rows which are marked for delete in the spill. • families:Information about the location of different column family data in the spill and the time range of that data.

Output Example for a Segment

```
maprcli fid dump -fid  2116.945.133246  -json
{
    "timestamp":1425579733821,
    "timeofday":"2015-03-05 06:22:13.821 GMT+0000",
    "status":"OK",
    "total":1,
    "data":[
        {
            "key":0,
            "numRemoteBlocks":0,
            "numSpills":0,
            "numSegments":0,
            "value":{
                "fid":"<parentCID>.946.133248",
                "smeSize":55,
                "keyIdxOffset":12,
                "keyIdxLength":3587,
                "ldbIdxLength":20,
```

```
                "bloomBitsPerKey":80,
                "numLogicalBlocks":369,
                "numPhysicalBlocks":232,
                "numRows":99,
                "numRowsWithDelete":0,
                "families":{
                    "id":1,
                    "offset":524288,
                    "length":2976835,
                    "minTimeStamp":1425578650850,
                    "maxTimeStamp":1425578856492
                }
            }
        }
    ]
}
```

fid stat

Displays statistics for MapR Database or filesystem components that are identified by a FID.

Only the root user and the MAPR_USER user (user name under which MapR services runs) have permissions to run this command.

Note: This command is similar to the UNIX `stat` command.

Syntax

CLI

```
/opt/mapr/bin/maprcli fid stat
   [ -cluster <cluster name> ]
   -fid <file identifier for the
element>
```

REST

N/A

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`fid`	The file identifier for the element (region, kvstore, etc.) for which you want detailed information. The output of the `maprcli table region list` command lists the FIDs for the regions of the table.

Output Fields

Columns	Description
compression	The compression setting, either `on` or `off`. If `on`, this parameter displays the compression type.
deleteFlags	An internal delete flag that is set on the FID for transactions involving multiple nodes. If deleted, this parameter denotes the deletion type, either `self` or `recursive delete`.

last-updated: Apr 11, 2022

Columns	Description
diskflush	Indicates whether persistent flush is enabled (`true`) or not (`false`) for this inode.
gid	The group ID
lblocks	Number of logical B-Tree blocks
mode	The UNIX style permission mode bits for the FID
mtime	Last modification time
nblocks	Total number of B-Tree blocks used
networkencryption	Indicates whether wire encryption is enabled or disabled
nlevels	Number of B-Tree levels
nlink	Number of links to this inode
parent	The parent FID
size	The size of the FID. Depending on the type of FID, it can be the actual size (in bytes), or the number of entries
subtype	The subtype of the FID
type	The type of the FID. For example, regular file, dir, filelet, kvstore, fidmap etc.
uid	The user ID of the owner
version	The current version of the FID.
xattrInum	The extended attribute of the FID

Example

Displays statistics for a specified FID:

```
[user@hostname ~]$ maprcli fid stat -fid 2062.32.131252  -json
{
        "timestamp":1586935733623,
        "timeofday":"2020-04-15 12:28:53.623 GMT-0700 AM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "type":"FTDirectory",
                        "subtype":"FSTInval",
                        "parent":"<parentCID>.35.131200",
                        "size":1,
                        "nblocks":1,
                        "lblocks":0,
                        "compression":"off",
                        "deleteFlags":"DeleteTypeNone",

                        "mtime":1583751630,
                        "mode":"755",
                        "uid":1000,
                        "gid":1000,
                        "nlink":3,
                        "xattrInum":0,
                        "version":1048589,
                        "networkencryption":true,
                        "diskflush":false,
```

```
                        "nlevels":1
                }
        ]
}
```

file
Lets you perform tiering operations at the file level.

file offload
Initiates offload of a file using a MAST Gateway.

Permissions Required

The user running the command must have (mode bit or *ACE*) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file offload
       -name <file_name>
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/file/offload?<parameters>`

Parameters

Parameter	Description
`name`	The name (including the path) of the file to offload.

Error Message

The OP_TIMEOUT message that indicates that the operation timed out, is returned if the connection to the gateway is lost.

Example

Offload file named `test1` in volume named `vol1`:

CLI

```
/opt/mapr/bin/maprcli file
offload -name /vol1/test1
 {
    "timestamp":1520277246831,
    "timeofday":"2018-03-05
07:14:06.831 GMT+0000",
    "status":"OK",
    "total":1,
    "data":[
        {
            "status":12,
            "message":"File transfer
request queued.",
```

```
"gateway":"10.10.88.200:8660",

"jobid":"0x37d7c7738cd0991f.0xe35d5f0e
5b24cda.0x4"
        }
    ]
 }
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/file/offload?
name=/vol1/test1' --user mapr:mapr

{"timestamp":1520277246831,"timeofday"
:"2018-03-05 07:14:06.831
GMT+0000","status":"OK","total":1,
   "data":
[{"status":12,"message":"File
transfer request
queued.","gateway":"10.10.88.200:8660"
,

"jobid":"0x37d7c7738cd0991f.0xe35d5f0e
5b24cda.0x4"}]}
```

Offload a file named `mfs` in volume named `vol1`:

CLI

```
/opt/mapr/bin/maprcli file
offload -name /vol1/mfs -json
  {
    "timestamp":1534141379576,
    "timeofday":"2018-08-12
11:22:59.576 GMT-0700 PM",
    "status":"ERROR",
    "errors":[
        {
            "id":6,
            "desc":"Lost connection
to gateway."
        }
    ]
  }
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/
tierjobstatus?name=/vol1/mfs' --user
mapr:mapr

{"timestamp":1534141379576,"timeofday"
:"2018-08-12 11:22:59.576 GMT-0700
PM","status":"ERROR",
   "errors":[{"id":6,"desc":"Lost
connection to gateway."}]}
```

file recall
Initiates recall of a file from a storage tier using a MAST Gateway.

Permissions Required

The user running the command must have (mode bit or *ACE*) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file recall
     -name <file_name>
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/file/recall?<parameters>`

Parameters

Parameter	Description
`name`	The name (including the path) of the file to recall.

Example

Recall file named file1 in volume named vol1:

CLI

```
/opt/mapr/bin/maprcli file
recall -name /vol1/test1 -json
{
  "timestamp":1516337242973,
  "timeofday":"2018-01-19
04:47:22.973 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[{
       "status":12,
       "message":"File transfer
request queued.",
       "gateway":"10.10.88.198:8660",

"jobid":"0xb76f872c64fe4677.0x3673092f
759a500d.0x1"
  }]
}
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/recall?
<parameters>' --user mapr:mapr
{"timestamp":1516337242973,"timeofday"
:"2018-01-19 04:47:22.973
GMT+0000","status":"OK","total":1,"dat
a":[{"status":12,"message":"File
transfer request
queued.","gateway":"10.10.88.198:8660"
,"jobid":"0xb76f872c64fe4677.0x3673092
f759a500d.0x1"}]}
```

last-updated: Apr 11, 2022

file tierjobabort

Initiates abort of an ongoing offload or recall operation.

Permissions Required

The user running the command must have (mode bit or *ACE*) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file
tierjobabort
    -name <file_name>
    [ -job <jobID> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/file/tierjobabort?<parameters>`

Parameters

Parameter	Description
`name`	The name (including the path) of the file being offloaded/recalled.
`job`	The ID of the job, which was specified with the offload or recall command, to abort. This must be specified to ensure that the correct offload or recall task is aborted. If this is not specified, the command picks a job to abort in the following order: **1.** Job that is in “already aborting progress” status. **2.** Job that is in “running jobs with latest jobid” status. If there are no jobs in progress, the command returns “no active transfer in progress” error.

Examples

CLI

```
/opt/mapr/bin/maprcli file
tierjobabort -name /c1/file5G -json
{
  "timestamp":1557734728770,
  "timeofday":"2019-05-13
01:05:28.770 GMT-0700 AM",
   "status":"OK",
   "total":1,
    "data":[
              {
               "status":10,
               "message":"File
transfer being aborted.",

"gateway":"10.10.103.79:8660",
```

last-updated: Apr 11, 2022

```
"jobid":"0x140dea11228a3211.0x18565bc5
d5e4e4fe.0x2"
             }
            ]
}
```

REST

```
curl -k -X POST 'https://host:port/
rest/file/tierjobabort?name=/c1/
file5G' --user mapr:mapr
{"timestamp":1557738947905,"timeofday"
:"2019-05-13 02:15:47.905 GMT-0700
AM","status":"OK","total":1,"data":
[{"status":10,"message":"File
transfer being
aborted.","gateway":"host:port","jobid
":"0x140dea11228a3211.0x18565bc5d5e4e4
fe.0x3"}]}
```

file tierjobstatus

Checks the status of a previous offload or recall operation.

Permissions Required

The user running the command must have (mode bit or *ACE*) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file
tierjobstatus
            -name <file_name>
            [ -job <jobID> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/file/tierjobstatus?<parameters>`

Parameters

Parameter	Description
`name`	The name (including the path) of the file.
`job`	The ID of the job specified with the offload or recall command.

Output

The command returns ***one*** of the following messages:

FTOS_SUCCESS

Indicates that the file tiering operation was successful. For example:

last-updated: Apr 11, 2022

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus  -n
ame /v5/

```

FTOS_JOB_NOT_AVAILABLE

Indicates that the job ID associated with the specified file tiering operation is not available or is invalid. For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /v5/
nfile2 -json
 {

"timestamp":15338
41993320,

"timeofday":"201
8-08-09
12:13:13.320
GMT-0700 PM",

"status":"ERROR",
   "errors":[
```

```
              {

"id":13,

"desc":"File has
no active
transfer in
progress."
              }
            ]
 }
```

REST

```
curl -k -X GET
'https://

   "errors":
[{"id":14,"desc":
"File transfer
request
permission
denied."}]}
```

file tierstatus
Checks the status of the file offload operation and returns information on whether or not the file has any local data.

This command does not require a MAST Gateway.

Syntax

CLI

```
maprcli file tierstatus
         -name <file_name>
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/file/tierstatus?<parameters>`

Parameters

Parameter	Description
`name`	The name (including the path) of the file.

Output

The output of this command varies based on whether or not data is local, was offloaded, or was recalled. The output returns *one* of the following messages:

- Data was completely offloaded:

```
File does not have local data
```

- Data could not be completely offloaded or data was recalled:

```
File has local data
```

- File is not configured for tiering:

```
File is not on a tiered volume
```

Examples

Retrieve the status of file named new2test4 in volume name testvol2:

CLI

```
maprcli file tierstatus -name /
testvol2/new2test4 -json
 File does not have local data.
  {
        "timestamp":1514877988773,
        "timeofday":"2018-01-01
11:26:28.773 GMT-0800",
        "status":"OK",
        "total":1,
        "data":[
                {
                    "status":1,
                    "message":"File
does not have local data."
                }
        ]
  }
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/tierstatus?
name=/testvol2/new2test4' --user
mapr:mapr

{"timestamp":1514877988773,"timeofday"
:"2018-01-01 11:26:28.773
GMT-0800","status":"OK","total":1,
  "data":[{"status":1,"message":"File
does not have local data."}]}
```

Retrieve the status of file named new2test3 in volume named testvol2:

CLI

```
maprcli file tierstatus -name /
testvol2/new2test3 -json
 File has local data.
```

last-updated: Apr 11, 2022

```
  {
        "timestamp":1514878021374,
        "timeofday":"2018-01-01
11:27:01.374 GMT-0800",
        "status":"OK",
        "total":1,
        "data":[
                {
                    "status":0,
                    "message":"File
has local data."
                }
        ]
  }
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/tierstatus?
name=/testvol2/new2test3' --user
mapr:mapr

{"timestamp":1514878021374,"timeofday"
:"2018-01-01 11:27:01.374
GMT-0800","status":"OK","total":1,
  "data":[{"status":0,"message":"File
has local data."}]}
```

Retrieve the status of file named file0 in volume named dir1 inside a volume called std_volume:

CLI

```
/opt/mapr/bin/maprcli
file tierstatus -name /std_volume/
dir1/file0 -json
  File is not on a tiered volume.
 {
  "timestamp":1609831337961,
  "timeofday":"2021-01-04
11:22:17.961 GMT-0800 PM",
  "status":"ERROR",
  "errors":[
           {
            "id":4,
            "desc":"File is not on a
tiered volume."
           }
          ]
 }
```

REST

Send a request of type GET. For example:

```
curl -k -X
GET 'https://abc.sj.us:8443/rest/
file/tierstatus?name=/std_volume/dir1/
file0' --user mapr:mapr
```

job
Manages Hadoop jobs running on the cluster.

job linklogs

Creates symbolic links to all the logs relating to the activity of a specific job.

The `maprcli job linklogs` command works with the Centralized Logging to provide a job-centric view or an application-centric view of all log files generated during job or application execution.

The output of `job linklogs` is a directory populated with symbolic links to all log files related to the specified job(s) or to the application. The command can be performed during or after a job or application is processed.

Syntax

CLI

```
maprcli job linklogs
    -jobid <jobPattern>
    -todir <desinationDirectory>
    [-jobconf <pathToJobXml>]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/job/linklogs?<parameters>`

Parameters

Parameter	Description
`jobid`	For MapReduce version 2, specify the application ID.
`todir`	The target directory for the symbolic links to the log files.
`jobconf`	For MapReduce version 2, this parameter is not applicable.

Output

For MapReduce version 2, the following directory will be created in the location specified by `todir` for the application ID that you specify for the `jobid` parameter:

- `<applicationId>/hosts/<host>/` contains symbolic links to log directories of tasks executed for <applicationId> on <host>

Examples

Link logs for all jobs named "wordcount1" and dump output to /myvolume/joblogviewdir:

CLI

```
maprcli job linklogs -jobid
job_*_wordcount1 -todir /myvolume/
joblogviewdir
```

REST

```
https://abc.sj.us:8443/
rest/job/linklogs?
jobid=job_*_wordcount1&todir=/
myvolume/joblogviewdir
```

last-updated: Apr 11, 2022

license
Manages MapR licenses.
license add
Adds a license. Permissions required: `fc` or `a`.

You can specify the license either by passing the license string itself to `license add`, or by specifying a file containing the license string. In a multinode cluster, add the license to one node (any node). Adding the same license to more than one node returns an error.

Syntax

CLI

```
maprcli license add
    [ -cluster cluster name ]
    [ -is_file true|false. default:
false ]
    -license long_license_string
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/license/add?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`is_file`	Specifies whether the `license` specifies a file. If `false`, the `license` parameter contains a long license string.
`license`	The license to add to the cluster. If `-is_file` is true, `license` specifies the file name of a license file. Otherwise, `license` contains the license string itself.

Examples

Note: After obtaining a valid license file from your MapR sale representative, copy the license file to a cluster node, for example in the path `/tmp/license.txt`.

To add a license from a file:

CLI

```
maprcli license add -is_file
true -license /tmp/license.txt
```

REST

```
https://abc.sj.us:8443/rest/license/
add?
is_file=true&license=%2Ftmp%2Flicense.
txt
```

Related concepts

Upgrading and Your License on page 295

If you are upgrading from MapR version 5.0 or earlier, the Base License file must be manually updated on all nodes in your cluster.

license addcrl

Adds a certificate revocation list (CRL). Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli license addcrl
    [ -cluster <cluster> ]
    -crl <crlstring>
    [ -is_file true|false. default:
false ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/license/addcrl?<parameters>`

Parameters

Parameter	Description
cluster	The cluster on which to run the command.

Parameter	Description
crl	The CRL to add to the cluster. If file is set, `crl` specifies the filename of a CRL file. Otherwise, `crl` contains the CRL string itself.
is_file	Specifies whether the license is contained in a file.

Examples

CLI

```
maprcli license addcrl
   -crl crl.txt
   -is_file true
```

REST

```
https://centos26.lab:8443/
rest/license/addcrl?
crl=crl.txt&is_file=true
```

Displays the cluster ID for use when creating a new license. Permissions required: `login`.

license list

Lists licenses on the cluster. Permissions required: `login`. For best results, use the `-json` option when running the command.

Syntax

CLI

```
maprcli license list
[ -cluster <cluster> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/license/list[?<parameters>]`

Parameters

Parameter	Description
cluster	The cluster on which to run the command.

Note: If you use the `-json` option with this command, and you pipe the output into another program, you may find that the result cannot be parsed by certain JSON libraries, such as the JSON library for Python. To work around this problem, you can replace the single-escape characters (\) in the JSON output that the `license list` command returns, with double-escape characters (\\).

Output

Sample Output

```
# maprcli license list -json
{
    "timestamp":1433543033194,
    "timeofday":"2015-06-05 10:23:53.194 GMT+0000",

Removes a license. Permissions required: `fc` or `a`.

nfsmgmt
Refreshes NFS exports and server cache.
nfsmgmt refreshexports
Refreshes the list of clusters and mount points available to mount with NFS. Permissions required: `fc` or `a`.

Syntax

CLI

```
[ -nfshost <ip or hostname>  ]
[ -nfsport <port> ]
[ -isusermode <true | false> ]
```

REST N/A

Parameters

Parameter	Description
`nfshost`	The hostname of the node that is running the MapR NFS server. Default: 127.0.0.1
`nfsport`	The port to use. Default: 9998
`isusermode`	Specifies whether the mode for creating the ticket for NFS is in user mode or not. Options: True or False. The ticket can not be created for nfs in user mode. Default: false

Example

CLI

```
maprcli nfsmgmt refreshexports -nfshost
10.10.82.29 -nfsport 9998
```

nfsmgmt refreshgidcache
Deletes the GID list (`uidGidCache_` entries) in NFS server cache. Permissions required: `fc` or `a`.

Useful for immediately reflecting the groups update.

Syntax

CLI

```
    [ -nfshost <ip or hostname>  ]
    [ -nfsport <port> ]
    [ -isusermode <true | false> ]
```

REST

N/A

Parameters

Parameter	Description
nfshost	The hostname of the node that is running the MapR NFS server. Default: 127.0.0.1
nfsport	The port to use. Default: 9998
isusermode	Specifies whether the mode for nfs is in user mode or not. Options: True or False. The ticket can not be created for nfs in user mode. Default: false

Example

CLI

```
maprcli nfsmgmt refreshgidcache -nfshost
10.10.82.29 -nfsport 9998
```

nfs4mgmt
Manages NFSv4 server.

nfs4mgmt add-export
Adds an export.

Syntax

CLI

```
/opt/mapr/bin/maprcli nfs4mgmt
add-export
       [ -nfshost ip/hostname.
default: 127.0.0.1 ]
       [ -nfsport port. default:
9995 ]
       -exportid export id. default:
0
       -conffile conf file path
```

REST

N/A

Parameters

Parameter	Description
conffile	The path to the NFSv4 configuration file.
exportid	The export ID as specified in the configuration file. The default value is 0.
nfshost	The NFS server host. Value can be the IP address or the hostname of the NFS server host. The default value is 127.0.0.1.

last-updated: Apr 11, 2022

Parameter	Description
`nfsport`	The NFS server port. The default value is 9995.

Examples

nfs4mgmt list-exports
Returns the list of exports.

Syntax

CLI

```
/opt/mapr/bin/maprcli nfs4mgmt
list-exports
        [ -nfshost ip/hostname.
default: 127.0.0.1 ]
        [ -nfsport port. default:
9995 ]
```

REST

N/A

Parameters

Parameter	Description
`nfshost`	The NFS server host. Value can be the IP address or the hostname of the NFS server host. The default value is 127.0.0.1.
`nfsport`	The NFS server port. The default value is 9995.

Output

Example

Troubleshooting

Issue

Sometimes, you might see the following error when you run the `list-exports` command:

```
Error
org.freedesktop.DBus.Error.ServiceUnkn
own: The name org.ganesha.nfsd was
not provided by any .service files
```

Resolution

Modify the `/etc/dbus-1/system.conf file` as follows:

last-updated: Apr 11, 2022

1. Remove the following:

```
<deny
send_destination="org.freedesktop.D
Bus"

send_interface="org.freedesktop.DBu
s"

send_member="UpdateActivationEnviro
nment"/>
```

2. Add the following:

```
<allow send_interface="*"/>
<allow receive_interface="*"/>
<allow own="*"/>
```

nfs4mgmt remove-export
Removes an export.

Syntax

CLI

```
/opt/mapr/bin/maprcli mfs4mgmt
remove-export
       [ -nfshost ip/hostname.
default: 127.0.0.1 ]
       [ -nfsport port. default:
9995 ]
       -exportid export id. default:
0
```

REST

N/A

Parameters

Parameter	Description
`exportid`	The export ID to remove as specified in the configuration file. The default value is 0.
`nfshost`	The NFS server host. Value can be the IP address or the hostname of the NFS server host. The default value is 127.0.0.1.
`nfsport`	The NFS server port. The default value is 9995.

Examples

nfs4mgmt update-export
Updates an export based on configuration changes.

Syntax

CLI

```
/opt/mapr/bin/maprcli mfs4mgmt
update-export
```

```
        [ -nfshost ip/hostname.
default: 127.0.0.1 ]
        [ -nfsport port. default:
9995 ]
        -exportid export id. default:
0
        -conffile conf file path
```

REST N/A

Parameters

Parameter	Description
`conffile`	The path to the NFSv4 configuration file.
`exportid`	The export ID to update as specified in the configuration file. The default value is 0.
`nfshost`	The NFS server host. Value can be the IP address or the hostname of the NFS server host. The default value is 127.0.0.1.
`nfsport`	The NFS server port. The default value is 9995.

Examples

node
Manages nodes in the cluster

Fields

The following table lists the data fields that provide information about each node. Each field has two names:

- Field name - displayed in the output of the `node list` command
- Short name - used to specify the columns displayed using the `columns` parameter

The short name is also used when specifying rows with a filter, for example when specifying nodes on which to perform an action with the `node services` command.

Field Name	Short Name	Description
blockMovesIn	bmi	Block moves in.
blockMovesOut	bmo	Block moves out.
bytesReceived	br	Bytes received by the node since the last CLDB heartbeat.
bytesSent	bs	Bytes sent by the node since the last CLDB heartbeat.
clienthealth	clhealth	The status of the client. Value can be one of the following: • Active • Inactive

Field Name	Short Name	Description
clienttype	cltype	The type of client. For example, posixclientgold, posixclientbasic, posixclientplatinum, LOOPBACK_NFS, NFS_V3, NFS_V4.
configuredservice	csvc	Services that are configured as roles on the node.
CorePresentAlarm	ncp	Timestamp when the Core Present alarm was raised.
cpus	cpc	The total number of CPUs on the node.
davail	dsa	Disk space available on the node, in GB.
DiskFailureAlarm	fda	Timestamp when Disk Failure on page 2226 alarm was raised.
disks	dsc	Total number of disks on the node.
dreadK	drk	Disk Kbytes read since the last heartbeat.
dreads	dro	Disk read operations since the last heartbeat.
DRILLDOWNALARM	nadrill	Timestamp when "Drill Service Down" alarm was raised.
dtotal	dst	Total disk space on the node, in GB.
dused	dsu	Disk space used on the node, in GB.
dwriteK	dwk	Disk Kbytes written since the last heartbeat.
dwrites	dwo	Disk write ops since the last heartbeat.
ESServerDown	naes	Timestamp when "Elasticsearch Server Down" alarm was raised.
faileddisks	nfd	Number of failed MapR File System disks on the node. • 0 = Clear • 1 = Raised
fs-heartbeat	fhb	Time since the last heartbeat to the CLDB, in seconds.
GatewayServiceDown	nagwsd	Timestamp when "Gateway Service Down" alarm was raised.
HbaseThriftServiceDown	hbasethrift	Timestamp when "HBase Thrift Service Down" alarm was raised.
HbProcessingSlow	hbpsa	Timestamp when Heartbeat Processing Slow on page 2227 alarm was raised.

last-updated: Apr 11, 2022

Field Name	Short Name	Description
health	h	Overall node health, calculated from various alarm states: • 0 = Healthy • 1 = Needs attention • 2 = Degraded • 3 = Maintenance • 4 = Critical
healthDesc	hd	The health description.
HighMfsMemoryAlarm	nhmm	Timestamp when MapR File System High Memory alarm was raised.
HomeMapRFullAlarm	hmf	Timestamp when Installation Directory Full alarm was raised.
hostname	hn	The host name. In the output for the `clientsonly` option, this is the hostname where the client is running.
id	id	The node ID.
IncorrectTopologyAlarm	ita	Timestamp when Incorrect Topology alarm was raised.
InstanceMismatch	nanim	Timestamp when Instance Mismatch alarm was raised.
Insufficient memory for buckets	tbwarning	Timestamp when Tiny Bucket Flush alarm was raised.
ip	ip	A list of IP addresses associated with the node. In the output for the `clientsonly` option, this is the IP address of the host where the client is running.
JobHistoryServerDown	nasjhsd	Timestamp when "Job History Server Down" alarm was raised.
jt-heartbeat	jhb	Time since the last heartbeat to the JobTracker, in seconds.
lasthb	lhb	Time since the last heartbeat from the client host.
LogLevelAlarm	lla	Timestamp when Excess Logs alarm was raised.
MapRfs disks	nmd	Number of disks for use by MapR File System
MemoryAllocationAlarm	maa	Timestamp when Memory Allocation alarm was raised.
MemorySwapping	nams	Timestamp when Memory Usage alarm was raised.
mtotal	mt	Total memory, in MB.
mused	mu	Memory used, in MB.

last-updated: Apr 11, 2022

Field Name	Short Name	Description
NodeDuplicateHostIdAlarm	ndh	Timestamp when Duplicate Host ID on page 2226 alarm was raised.
NodeManagerDown	nanmd	Timestamp when "Node Manager Down" alarm was raised.
NodeMaprUserMismatchAlarm	nma	Timestamp when MapR User Mismatch on page 2230 alarm was raised.
NodeNoHeartbeatAlarm	nha	Timestamp when No Heartbeat alarm was raised.
NodeTooManyContainersAlarm	nmc	Timestamp when Node Too Many Containers on page 2234 alarm was raised.
NoDiskAttached	nanda	Timestamp when No Disk Attached alarm was raised.
numInstances	ni	Number of configured MapR File System instances.
numReportedInstances	nri	The number of running instances reported by MapR File System to CLDB.
numResyncSlots	nrs	The number of resync slots.
numGetsInLastTenSeconds	ngl10s	Number of table get operations in last 10 seconds.
numGetsInLastMinute	ngl1m	Number of table get operations in last 1 minute.
numGetsInLastFiveMinutes	ngl5m	Number of table get operations in last 5 minutes.
numGetsInLastFifteenMinutes	ngl15m	Number of table get operations in last 15 minutes.
numPutsInLastTenSeconds	npl10s	Number of table put operations in last 10 seconds.
numPutsInLastMinute	npl1m	Number of table put operations in last 1 minute.
numPutsInLastFiveMinutes	npl5m	Number of table put operations in last 5 minutes
numPutsInLastFifteenMinutes	npl15m	Number of table put operations in last 15 minutes.
numScansInLastTenSeconds	nsl10s	Number of table scan operations in last 10 seconds.
numScansInLastMinute	nsl1m	Number of table scan operations in last 1 minute.
numScansInLastFiveMinutes	nsl5m	Number of table scan operations in last 5 minutes.
numScansInLastFifteenMinutes	nsl15m	Number of table scan operations in last 15 minutes.

last-updated: Apr 11, 2022

Field Name	Short Name	Description
PamMisconfiguredAlarm	pma	PAM misconfigured alarm (NODE_ALARM_PAM_MISCONFIGURED): • 0 = Clear • 1 = Raised
ResourceManagerDown	narmd	Timestamp when "Resource Manager Down" alarm is raised.
RootPartitionFullAlarm	rpf	Timestamp when Root Partition Full alarm was raised.
rpcin	rpi	RPC bytes received since the last heartbeat.
rpcout	rpo	RPC bytes sent since the last heartbeat.
rpcs	rpc	Number of RPCs since the last heartbeat.
service	svc	A comma-separated list of services running on the node: • cldb - CLDB • fileserver - MapR File System • nfs - NFS Gateway Example: "cldb,fileserver,nfs"
ServiceBeeswaxDownNotRunningAlarm	sbwa	Timestamp when "Beeswax Service Down" alarm was raised.
ServiceCLDBDownNotRunningAlarm	sca	Timestamp when CLDB alarm was raised.
ServiceFileserverDownNotRunningAlarm	sfsa	Timestamp when Fileserver alarm was raised.
ServiceHiveDownNotRunningAlarm	shsma	Timestamp when HiveMeta Service Down alarm was raised.
ServiceHoststatsDownNotRunningAlarm	sha	Timestamp when Hoststats alarm was raised.
ServiceHs2DownNotRunningAlarm	shsa	Timestamp when HS2 Service Down alarm was raised.
ServiceHttpfsDownNotRunningAlarm	shfsa	Timestamp when "Httpfs Service Down" alarm is raised.
ServiceHueDownNotRunningAlarm	shuea	Timestamp when "Hue Service Down" alarm was raised.
ServiceNFSDownNotRunningAlarm	sna	Timestamp when NFS alarm was raised.
ServiceOozieDownNotRunningAlarm	sooza	Timestamp when Oozie Service Down alarm was raised.
ServicesWebserverDownNotRunningAlarm	swa	Timestamp when Webserver alarm was raised.

last-updated: Apr 11, 2022

Field Name	Short Name	Description
spsPerInstance	nsp	Number of storage pools per file server instance.
TimeSkewAlarm	tsa	Timestamp when Time Skew alarm was raised.
racktopo	rp	The rack path.
uptime	cpt	Date when the node came up.
utilization	cpu	CPU use percentage since the last heartbeat.
VersionMismatchAlarm	vma	Timestamp when Version alarm was raised.
vip	vip	The virtuap IP address

Creates a volume.

node list on page 1705
Lists nodes in the cluster.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

node allow-into-cluster

Allows host IDs to join the cluster after duplicates have been resolved.

When the CLDB detects duplicate nodes with the same host ID, all nodes with that host ID are removed from the cluster and prevented from joining it again. After making sure that all nodes have unique host IDs, you can use the `node allow-into-cluster` command to un-ban the host ID that was previously duplicated among several nodes.

Syntax

CLI

```
maprcli node allow-into-cluster
    [ -hostids <host IDs> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/node/allow-into-cluster[?<parameters>]`

Parameters

Parameter	Description
hostids	A comma-separated list of host IDs.

Examples

Allow former duplicate host IDs node1 and node2 to join the cluster:

CLI

```
maprcli node
allow-into-cluster -hostids
node1,node2
```

REST

```
https://abc.sj.us:8443/rest/node/
allow-into-cluster?hostids=node1,node2
```

node cldbmaster
Returns the address of the master CLDB node.

The `node cldbmaster` API returns the server ID and hostname of the node serving as the CLDB master node.

Syntax

CLI

```
maprcli node cldbmaster
    [ -cluster <cluster name> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/cldbmaster[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The name of the cluster for which to return the CLDB master node information.

Examples

Return the CLDB master node information for the cluster my.cluster.com:

CLI

```
maprcli node cldbmaster -cluster
my.cluster.com
```

```
{
        "timestamp":1622099062802,
        "timeofday":"2021-05-27
```

```
07:04:22.802 GMT+0000 AM",
        "status":"OK",
        "total":1,
        "data":[
                {

"cldbmaster":"ServerID:
3523090783455785824 HostName:
m2-mapreng-vmm167214.xxxx"
                }
        ]
}
```

REST

```
curl -k -X
POST 'https://10.163.167.214:8443/
rest/node/cldbmaster?
cluster=my.cluster.com' --user
mapr:mapr
```

```
{"timestamp":1622099484367,"timeofday"
:"2021-05-27 07:11:24.367 GMT+0000
AM","status":"OK","total":1,"data":
[{"cldbmaster":"ServerID:
3523090783455785824 HostName:
m2-mapreng-vmm167214.mip.xxx"}]}
```

node failover
Fails over master containers and VIPs to another node.

When this command runs, all master and intermediate containers are moved off the node and VIPs are re-assigned.

Syntax

CLI

```
maprcli node failover
            [ -nodes <node hostname> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/node/failover[?<parameters>]`

Parameters

Parameter	Description
nodes	The hostname of the node going down.

Examples

Notify CLDB of the node, exampleHost, going down:

CLI

```
maprcli node failover -nodes
exampleHost
```

REST

```
https://abc.sj.us:8443/rest/node/
failover?nodes=exampleHost
```

node heatmap

Displays a heatmap for the specified nodes.

Syntax

CLI

```
maprcli node heatmap
    [ -cluster <cluster> ]
    [ -filter <filter> ]
    [ -view <view> ]
    -json | -long
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/heatmap[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`filter`	A filter specifying snapshots to preserve. See Filters for more information.

Parameter	Description

`view`	Name of the heatmap view to show:
	• `status` = Node status (the default view):
	  • `0` = Healthy
	  • `1` = Needs attention
	  • `2` = Degraded
	  • `3` = Maintenance
	  • `4` = Critical
	• `cpu` = CPU utilization, as a percent from 0-100.
	• `memory` = Memory utilization, as a percent from 0-100.
	• `diskspace` = MapR filesystem disk space utilization, as a percent from 0-100.
	• `NODE_*` = Status of various alarms: `0` if clear, `1` if raised. For example: `NODE_ALARM_DISK_FAILURE` or `NODE_ALARM_SERVICE_CLDB_DOWN`. You can return a complete list of supported alarm parameters by running:
	`maprcli node heatmap -view`
	See the lists of parameters below this table.

`-json` | `-long`	This command returns multiple levels of data. You must specify either JSON format or "long" format to see the full output.

Alarm Parameters

You can view the status of a number of different alarms, including the status of alarms for services down and alarms for other conditions on the cluster.

Service Down Alarms

`NODE_ALARM_SERVICE_CLDB_DOWN` `NODE_ALARM_SERVICE_FILESERVER_DOWN`
`NODE_ALARM_SERVICE_JT_DOWN` `NODE_ALARM_SERVICE_TT_DOWN`
`NODE_ALARM_SERVICE_HBMASTER_DOWN` `NODE_ALARM_SERVICE_HBREGION_DOWN`
`NODE_ALARM_SERVICE_WEBSERVER_DOWN` `NODE_ALARM_SERVICE_NFS_DOWN`
`NODE_ALARM_SERVICE_HOSTSTATS_DOWN` `NODE_ALARM_SERVICE_OOZIE_DOWN`
`NODE_ALARM_SERVICE_HUE_DOWN` `NODE_ALARM_SERVICE_HTTPFS_DOWN`
`NODE_ALARM_SERVICE_BEESWAX_DOWN` `NODE_ALARM_SERVICE_HIVEMETA_DOWN`
`NODE_ALARM_SERVICE_HS2_DOWN`

Other Alarms

`NODE_ALARM_DEBUG_LOGGING` `NODE_ALARM_DISK_FAILURE` `NODE_ALARM_VERSION_MISMATCH`
`NODE_ALARM_TIME_SKEW` `NODE_ALARM_ROOT_PARTITION_FULL`
`NODE_ALARM_OPT_MAPR_FULL` `NODE_ALARM_CORE_PRESENT` `NODE_ALARM_HIGH_MFS_MEMORY`
`NODE_ALARM_PAM_MISCONFIGURED` `NODE_ALARM_TT_LOCALDIR_FULL`
`NODE_ALARM_NO_HEARTBEAT` `NODE_ALARM_MAPRUSER_MISMATCH`
`NODE_ALARM_DUPLICATE_HOSTID` `NODE_ALARM_METRICS_WRITE_PROBLEM`
`NODE_ALARM_TOO_MANY_CONTAINERS`

Output

In general, the heatmap output looks like this (in JSON format).

```
{
            status:"OK",
            data: [{
            "{{rackTopology}}" : {
            "{{nodeName}}" : {{heatmapValue}},
            "{{nodeName}}" : {{heatmapValue}},
            "{{nodeName}}" : {{heatmapValue}},
            ...
            },
            "{{rackTopology}}" : {
            "{{nodeName}}" : {{heatmapValue}},
            "{{nodeName}}" : {{heatmapValue}},
            "{{nodeName}}" : {{heatmapValue}},
            ...
            },
            ...
            }]
            }
```

Table

Field	Description
rackTopology	The topology for a particular rack.
nodeName	The name of the node in question.
heatmapValue	The value of the metric specified in the view parameter for this node, as an integer.

Examples

Display a heat map with the node status (default view) for the default rack:

```
maprcli node heatmap -json
            {
            "timestamp":1422567293873,
            "timeofday":"2015-01-29 01:34:53.873 GMT-0800",
            "status":"OK",
            "total":1,
            "data":[
            {"/data/default-rack":{
            "centos24":2}
            }]
            }
```

The equivalent REST API command would be:

```
https://r1n1.sj.us:8443/rest/node/heatmap
```

Display memory usage for the default rack:

```
maprcli node heatmap -view memory -json
            {
            "timestamp":1422585976631,
            "timeofday":"2015-01-29 06:46:16.631 GMT-0800",
            "status":"OK",
```

last-updated: Apr 11, 2022

```
            "total":1,
            "data":[
            {"/data/default-rack":{
            "centos24":71}
            }]
            }
```

The equivalent REST API command would be:

```
https://r1n1.sj.us:8443/rest/node/heatmap?view=memory
```

Display the value of NODE_ALARM_DISK_FAILURE for the default rack:

```
maprcli node heatmap -view NODE_ALARM_DISK_FAILURE -long
            /data/default-rack
            {"centos24":0}
```

node list
Lists nodes in the cluster.

You can retrieve information for a set of nodes in several ways:

- To list only nodes with raised alarms, set `alarmednodes` to `1`.
- To list only NFS nodes, set `nfsnodes` to `1`.
- To view only a few nodes from the list, use the `start` and `limit` options to select only a portion of the results.
- To list nodes that match certain criteria, pass a filter to the `filter` parameter. See the node on page 1694 table for the filter options. See the Filters on page 1526 page for information on filters.

Using the `node list` command without the `-clientsonly true` or the `-nfsnodes true` option, does not list edge nodes. To include edge nodes, use the `-nfsnodes true` or the `-clientsonly true` option.

Syntax

CLI

```
/opt/mapr/bin/maprcli node list
    [ -alarmednodes 0|1 ]
    [ -cluster <cluster> ]
    [ -clientsonly true|false ]
    [ -columns <columns>|all]
    [ -filter <filter> ]
    [ -limit <limit> ]
    [ -nfsnodes true|false ]
    [ -output terse|verbose ]
    [ -sortby <attribute> ]
    [ -sortorder asc|desc ]
    [ -start <offset> ]
    [ -zkconnect <ZooKeeper Connect
String> ]
```

REST

Request Type	GET

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/node/list[?<parameters>]`

Parameters

Parameter	Description
`alarmednodes`	When set to `1`, displays only nodes with raised alarms. You cannot use this parameter if `nfsnodes` is set.
`cluster`	The cluster on which to run the command.
`clientsonly`	Set this parameter to `true` to return the list of nodes running unique platinum FUSE-based POSIX clients, and NFSv3, and NFSv4 services. The command returns the following fields: `clienttype`, `clienthealth`, `hostname`, `ip`, `lasthb`, `id`. For more information, see the fields table. If you set this parameter to `false`, which is the default value, this parameter returns node-level information for all the services running on each node.
`columns`	A comma-separated list of fields to return in the query, specified by the short names. When specifying this option, the `ip` and `hostname` columns are always returned in the query.
`filter`	A filter specifying nodes on which to start or stop services. See the Fields table on the node page for the fields available to filter. See the maprcli and REST API Syntax page for information on filters.
`limit`	The number of rows to return, beginning at start. Default: 0
`nfsnodes`	Set this to `true` to display POSIX (edge) nodes. When set to `false`, edge nodes are not displayed. Cannot be used if `alarmednodes` is set. When you set the `cldb.ignore.posix.only.hb.alarm` parameter to `1`, dead edge nodes are displayed for 4 minutes from the time they went down, as CLDB removes all the dead edge nodes after 4 minutes. However, when you set `cldb.ignore.posix.only.hb.alarm` parameter to `0`, dead edge nodes are displayed for 24 hours.
`output`	Specifies whether the output should be terse or verbose.

Parameter	Description
sortby	Specifies one of the following attributes by which to sort the list of nodes: nodeid, nodeip, nodehostname, noderackpath, nodeswitchpath, nodestatus, nodeservices, nodefshb, nodejthb, nodedisktotal, nodediskused, nodediskavail, noderpc, noderpcin, noderpcout, nodediskcount, nodediskreadops, nodediskreadkbytes, nodediskwriteops, nodediskwritekbytes, nodecpucount, nodecpuutil, nodememtotal, nodememused, nodefaileddisks, nodevirtualip, nodevirtualipend, nodenetmaskvnodemacaddress, nodegateway, nodebytesreceived, nodebytessent, nodecpuuptime, nodemaprdiskcount, nodestatusdesc, nodeblockmovesout, nodeblockmovesinvnodemaxcontainersthreshold, nodenuminstances, nodenumspsperinstance, nodenfsstate, nodeisposixclient, nodeisloopbacknfs, nodeisloopbacknfsrunning
start	The offset from the starting row according to sort. Default: 0
zkconnect	ZooKeeper Connect String

Output

Information about the nodes. See the fields for more information.

Sample Output

```
# /opt/mapr/bin/maprcli node list -json
{
    "timestamp":1555342212112,
    "timeofday":"2019-04-15 08:30:12.112 GMT-0700 AM",

```

Fields

For definitions of the output fields, and short names for use with filters, see the fields table.

Examples

List all nodes:

For neatly formatted results, use the `-json` option when listing all nodes or a large subset of node information.

CLI

```
/opt/mapr/bin/maprcli node list -json
{
    "timestamp":1555342212112,
    "timeofday":"2019-04-15
08:30:12.112 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
        {

"id":"7146221175287263104",
            "ip":[
                "10.10.82.29",
                "172.17.0.1"
            ],
            "hostname":"doc29.lab",
            "racktopo":"/data/
default-rack/doc29.lab",
            "health":2,
            "healthDesc":"One or more
services is down",

REST

```
curl -u mapr:mapr -X GET -k "https://
host:8443/rest/node/list"
```

List the health and configured service of all nodes:

The following examples show the use of short forms for the `column` parameter.

CLI

```
/opt/mapr/bin/maprcli node
list -columns
service,health,configuredservice -json
/opt/mapr/bin/maprcli node
list -columns svc,h,csvc -json
{
    "timestamp":1555343115082,
    "timeofday":"2019-04-15
08:45:15.082 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ip":[
                "10.10.82.29",
                "172.17.0.1"
            ],
            "hostname":"doc29.lab",
            "health":2,

"service":"resourcemanager,fileserver,

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

dump volumeinfo on page 1637
Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

node listcldbs

Returns the hostnames of the nodes in the cluster that are running the CLDB service.

Syntax

CLI

```
maprcli node listcldbs
    [ -cluster <cluster name> ]
    [ -cldb  <cldb hostname|ip:port> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/listcldbs[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The name of the cluster for which to return the list of CLDB node hostnames.
`cldb`	The hostname or IP address and port number of a CLDB node.

Examples

Return the list of CLDB nodes for the cluster my.cluster.com:

CLI

```
# maprcli node listcldbs -cluster
my.cluster.com -json
{
    "timestamp":1529445021408,
    "timeofday":"2018-06-19
02:50:21.408 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {

"CLDBs":"in111-22.qa.lab,in111-24.qa.l
ab,in111-21.qa.lab"
        }
    ]
}
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/node/listcldbs?
cluster=my.cluster.com' --user
mapr:mapr
{"timestamp":1529445190525,"timeofday"
:"2018-06-19 02:53:10.525 GMT-0700
PM","status":"OK","total":1,"data":
[{"CLDBs":"in111-22.qa.lab,in111-24.qa
.lab,in111-21.qa.lab"}]}
```

last-updated: Apr 11, 2022

node listcldbzks
Returns the hostnames of the nodes in the cluster that are running the CLDB service and the IP addresses and port numbers for the nodes in the cluster that are running the ZooKeeper service.

Syntax

CLI

```
maprcli node listcldbzks
    [ -cluster <cluster name> ]
    [ -cldb  <cldb hostname|ip:port> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/listcldbzks[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The name of the cluster for which to return the CLDB and ZooKeeper information.
`cldb`	The hostname or IP address and port number of a CLDB node.

Examples

Return CLDB and ZooKeeper node information for the cluster my.cluster.com:

CLI

```
maprcli node listcldbzks -cluster
my.cluster.com
{
    "timestamp":1529445399193,
    "timeofday":"2018-06-19
02:56:39.193 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {

"CLDBs":"in111-22.qa.lab,in111-24.qa.l
ab,in111-21.qa.lab",

"Zookeepers":"in111-21.qa.lab:5181,in1
11-22.qa.lab:5181,in111-24.qa.lab:5181
"
        }
    ]
}
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/node/listcldbzks?
cluster=my.cluster.com' --user
```

```
mapr:mapr
{"timestamp":1529445324540,"timeofday"
:"2018-06-19 02:55:24.540 GMT-0700
PM","status":"OK","total":1,"data":
[{"CLDBs":"in111-22.qa.lab,in111-24.qa
.lab,in111-21.qa.lab","Zookeepers":"in
111-21.qa.lab:5181,in111-22.qa.lab:518
1,in111-24.qa.lab:5181"}]}
```

node listzookeepers
Returns the hostnames of the nodes in the cluster that are running the ZooKeeper service.

Syntax

CLI

```
maprcli node listzookeepers
    [ -cluster <cluster name> ]
    [ -cldb  <cldb hostname|ip:port> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/listzookeepers[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The name of the cluster for which to return the list of zookeeper node hostnames.
`cldb`	The hostname or IP address and port number of a valid CLDB node. The other CLDB nodes and zookeeper nodes can be discovered from this node.

Examples

Return the list of zookeeper nodes for the cluster my.cluster.com

If you know that the CLDB service is running on a node with hostname `host1`, you can enter:

CLI

```
maprcli node listzookeepers -cluster
my.cluster.com -cldb host1 -json
{
    "timestamp":1529451245796,
    "timeofday":"2018-06-19
04:34:05.796 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {

"Zookeepers":"in111-21.qa.lab:5181,in1
```

```
11-22.qa.lab:5181,in111-24.qa.lab:5181
"
        }
    ]
}
```

REST

```
https://abc.sj.us:8443/rest/node/
listzookeepers?
cluster=my.cluster.com&cldb=host1
{"timestamp":1529451245796,"timeofday"
:"2018-06-19 04:34:05.796 GMT-0700
PM","status":"OK","total":1,"data":
[{"Zookeepers":"in111-21.qa.lab:5181,i
n111-22.qa.lab:5181,in111-24.qa.lab:51
81"}]}
```

node maintenance

Places a node into a maintenance mode for a specified duration.

Important: Stop CLDB if it is running on the node, before putting that node in maintenance mode. Else, the maintenance mode operation is not permitted. Run: `maprcli node services -name cldb -action stop -nodes mapr-<node>`

Note: You cannot put a master CLDB node in Maintenance mode.

For the duration of the maintenance mode, the cluster's CLDB does not consider the data of this node as lost and does not trigger a resync of the data on this node. See Administering Nodes on page 797 for more information.

Syntax

CLI

```
/opt/mapr/bin/maprcli node maintenance
    [ -cluster <cluster> ]
    [ -serverids <serverids> ]
    -nodes <node names>
    -timeoutminutes <timeout in
minutes>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/node/maintenance?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`serverids`	List of server IDs
`nodes`	List of nodes, space separated.

last-updated: Apr 11, 2022

Parameter	Description
`timeoutminutes`	Duration of the maintenance mode in minutes

Examples

CLI

```
/opt/mapr/bin/maprcli
node maintenance -nodes
centos22.lab -timeoutminutes 20
```

REST

```
curl -u mapr:mapr -X POST -k 'https://
abc.sj.us:8443/rest/node/maintenance?
nodes=centos22.lab&timeoutminutes=20'
```

node metrics

Retrieves metrics information for nodes in a cluster.

Warning: This command is deprecated. See Using MapR Data Platform Monitoring (Spyglass Initiative) on page 1330 for information about viewing metrics and logs for nodes, services, and applications.

This command retrieves and displays various metrics related to the operation of nodes. The data displayed comes from the files that each node updates periodically that are stored in the node local volume on each node in the cluster.

Syntax

CLI

```
maprcli node metrics
         -nodes <hostname>
         -start <start time>
         -end <end time>
        [ -interval <interval
timestamp> ]
        [ -events true|false ]
        [ -columns <column names> ]
        [ -cluster <cluster name> ]
```

Parameters

Parameter	Description
nodes	A space-separated list of host names. The host name must be either the specific hostname (use the `maprcli node list -columns hostname` command to obtain the hostname value) or the name "hostname" if using the command line on the actual node. The IP address and "localhost" can not be used.
start	The start of the time range. Can be a UTC timestamp (in this case, a Java millisecond timestamp) or a UTC date in MM/DD/YY or MM/DD/YYYY format.
end	The end of the time range. Can be a UTC timestamp (in this case, a Java millisecond timestamp) or a UTC date in MM/DD/YY or MM/DD/YYYY format.

last-updated: Apr 11, 2022

Parameter	Description
interval	Data measurement interval in seconds. The minimum value is 10 seconds.
events	Specify TRUE to return node events only. The default value of this parameter is FALSE.
columns	Comma-separated list of column names to return.
cluster	Cluster name.

Column Name Parameters

The `node metrics` API always returns the `NODE` (node name) and `TIMESTAMP` (integer timestamp) columns. Use the `-columns` flag to specify a comma-separated list of column names to return.

Warning: The `CPUNICE`, `CPUUSER`, and `CPUSYSTEM` parameters return information in *jiffies*. This unit measures one tick of the system timer interrupt and is usually equivalent to 10 milliseconds, but may vary depending on your particular node configuration. The reporting interval is the maximum possible value. In addition, the CPU* parameters accumulate and do not reset from report to report. Call `sysconf(_SC_CLK_TCK)` to determine the exact value for your node.

`CPUNICE`	Amount of CPU time used by processes with a positive nice value.	
`CPUUSER`	Amount of CPU time used by user processes.	
`CPUSYSTEM`	Amount of CPU time used by system processes.	
`LOAD5PERCENT`	Percentage of time this node spent at load 5 or below	
`LOAD1PERCENT`	Percentage of time this node spent at load 1 or below	
`MEMORYCACHED`	Memory cache size in bytes	
`MEMORYSHARED`	Shared memory size in bytes	
`MEMORYBUFFERS`	Memory buffer size in bytes	
`MEMORYUSED`	Memory used in megabytes	
`PROCRUN`	Number of processes running	
`RPCCOUNT`	Number of MapR RPC calls	
`RPCINBYTES`	Number of bytes passed in by MapR RPC calls	
`RPCOUTBYTES`	Number of bytes passed out by MapR RPC calls	
`SERVAVAILSIZEMB`	Server storage available in megabytes	

last-updated: Apr 11, 2022

SERVUSEDSIZEMB	Server storage used in megabytes	
SWAPFREE	Free swap space in bytes	
TTMAPUSED	Number of TaskTracker slots used for map tasks	
TTREDUCEUSED	Number of TaskTracker slots used for reduce tasks	

Three column name parameters return data that is too granular to display in a standard table. Use the `-json` option to return this information as a JSON object.

Parameter	Description	Metrics Returned
CPUS	Activity on this node's CPUs. Each CPU on the node is numbered from zero, `cpu0` to `cpuN`. Metrics returned are for each CPU.	`CPUIDLE`: Amount of CPU time spent idle. Reported as *jiffies*. `CPUIOWAIT`: Amount of CPU time spent waiting for I/O operations. Reported as *jiffies*. `CPUTOTAL`: Total amount of CPU time. Reported as *jiffies*.
DISKS	Activity on this node's disks. Metrics returned are for each partition.	`READOPS`: Number of read operations. `READKB`: Number of kilobytes read. `WRITEOPS`: Number of write operations. `WRITEKB`: Number of kilobytes written.
NETWORK	Activity on this node's network interfaces. Metrics returned are for each interface.	`BYTESIN`: Number of bytes received. `BYTESOUT`: Number of bytes sent. `PKTSIN`: Number of packets received. `PKTSOUT`: Number of packets sent.

Examples

Retrieving the percentage of time that a node spent at the 1 and 5 load levels between dates

```
$ maprcli node metrics
        -nodes centos24.lab
        -start 08/02/15
        -end 08/03/15
        -interval 7200
        -columns LOAD5PERCENT,LOAD1PERCENT
```

Sample Output

```
NODE          LOAD5PERCENT  LOAD1PERCENT  TIMESTAMPSTR
TIMESTAMP
centos24.lab  15            9             Sat Aug 01 17:00:08 PDT 2015

}
```

node move
Moves one or more nodes to a different topology. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli node move
    [ -cluster <cluster> ]
     -serverids <server IDs>
     -topology <topology>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/node/move?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`serverids`	The comma-separated list of server IDs of the nodes to move. If you insert spaces between server IDs, the command only operates on the first server ID in the list.
`topology`	The new topology.

To obtain existing topology, run

```
maprcli node topo
```

To obtain the server ID, run

```
maprcli node list -columns id
```

Sample output from `maprcli node list -columns id` is shown below. The resulting server ID(s) can be copied and pasted into the `maprcli node move` command.

```
id                   hostname     ip
547819249997313015   node-34.lab  10.10.40.34,10.10.88.34
2130988050310536949  node-36.lab  10.10.40.36,10.10.88.36
8683110801227243688  node-37.lab  10.10.40.37,10.10.88.37
5056865595028557458  node-38.lab  10.10.40.38,10.10.88.38
3111141192171195352  node-39.lab  10.10.40.39,10.10.88.39
```

Examples

CLI

```
maprcli node move
   -topology /newData
   -serverids 547819249997313015
```

REST

```
https://abc.sj.us:8443/rest/node/move?
topology=%2FnewData&serverids=54781924
9997313015
```

node remove

Removes one or more server nodes from the system. Permissions required: `fc` or `a`.

After issuing the `node remove` command, wait several minutes to ensure that the node has been properly and completely removed.

Syntax

CLI

```
maprcli node remove
    [ -filter "<filter>" ]
    [ -hostids <host IDs> ]
    [ -nodes <node names> ]
    [ -service <fileserver or
nfsserver> ]
    [ -zkconnect <ZooKeeper Connect
String> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/node/remove[?<parameters>]`

Parameters

Parameter	Description
`filter`	A filter specifying nodes on which to start or stop services. See Filters for more information.
`hostids`	A list of host IDs, separated by spaces.

last-updated: Apr 11, 2022

Parameter	Description
`nodes`	A list of node names, separated by spaces.
`service`	Service to be removed. Either fileserver or nfsserver.
`zkconnect`	ZooKeeper Connect String. Example: 'host:port,host:port,host:port,...'. To obtain zookeeper connection strings, use the `maprcli node listzookeepers` command. Default: localhost:5181

Examples

CLI

```
maprcli node remove -nodes 10.20.30.40
```

REST

```
https://abc.sj.us:8443/rest/node/
remove?nodes=10.20.30.40
```

node services

Starts, stops, or restarts services on one or more server nodes. Permissions required: `ss`, `fc` or `a`.

To start or stop services, you must specify the service name, the action (start, stop, or restart), and the nodes on which to perform the action. You can specify the nodes in one of two ways:

- Use the `nodes` parameter to specify a space-delimited list of node names.
- Use the `filter` parameter to specify all nodes that match a certain pattern. See Filters for more information.

Syntax

CLI

```
/opt/mapr/bin/maprcli node services
    [ -action start|stop|restart|
enable|disable ]
    [ -apiserver start|stop|restart|
enable|disable ]
    [ -cldb start|stop|restart|enable|
disable ]
    [ -cluster <cluster> ]
    [ -fileserver start|stop|restart|
enable|disable ]
    [ -filter <filter> ]

    [ -name <service> ]
    [ -nfs start|stop|restart|enable|
disable ]
    [ -nfs4 start|stop|restart|enable|
disable ]
    [ -nodes <node names> ]

    [ -zkconnect <ZooKeeper Connect
String> ]
```

REST

Request Type	POST

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/node/services[?<parameters>]`

Parameters

To perform an action on a service, on a particular set of nodes, you must specify the following three parameters:

- `action`- the action to perform:
  - Start, stop, restart a service.
  - Disable a service to prevent it from starting when Warden restarts and enable a service to allow the service to start when Warden restarts.

  Note: Suspend and resume are not supported.
- `node` or `filter` - the nodes on which to perform the action; either a list of nodes, or a filter that matches a set of nodes
- `name` - the service on which to perform the action

The following table lists the parameters available with the `node services` command.

Parameter	Description
`action`	An action to perform on a service specified in the `name` parameter: Values: start, stop, suspend, resume, restart, enable, or disable
`apiserver`	Starts, stops, or restarts the apiserver. Values: start, stop, restart, enable, or disable
`cldb`	Starts, stops, or restarts the cldb service. Values: start, stop, suspend, resume, restart, enable, or disable
`cluster`	The cluster on which to run the command.
`fileserver`	Starts, stops, or restarts the fileserver service. Values: start, stop, suspend, resume, restart, enable, or disable
`filter`	A filter specifying nodes on which to start or stop services. For fields to use with the filter, see the node on page 1694 table. See Filters on page 1526 for more information about filters. **Note:** You must specify either the `filter` parameter or the `nodes` parameter.
`name`	A service on which to perform an action specified by the `action` parameter. Any service can be specified with this option, but the following services can be specified only with the `name` option: `collectd`, `elasticsearch`, `fluentd`, `grafana`, `historyserver`, `hivemeta`, `hoststats`, `hs2`, `httpfs`, `hue`, `kibana`, `nodemanager`, `opentsdb`, `oozie`, and `resourcemanager`.

last-updated: Apr 11, 2022

Parameter	Description
`nfs`	Starts, stops, or restarts the nfs service. Values: start, stop, suspend, resume, restart, enable, or disable
`nfs4`	Starts, stops, or restarts the NFSv4 service. Values: start, stop, restart, enable, or disable
`nodes`	A list of node names, separated by spaces.  **Note:** Either this or `filter` is required.
`zkconnect`	The ZooKeeper Connect String.

Examples

Start the NodeManager Service

```
/opt/mapr/bin/maprcli node services -name nodemanager -nodes
abc.sj.us -action start
```

Stop the ResourceManager Service

```
/opt/mapr/bin/maprcli node services -name resourcemanager -nodes
abc.sj.us -action stop
```

Stop the ResourceManager Service

```
/opt/mapr/bin/maprcli node services -name resourcemanager -nodes
abc.sj.us -action restart
```

Restart NFS server

```
/opt/mapr/bin/maprcli node services -nodes abc.sj.us -nfs restart
```

Restart NFS server using a filter

Using a filter is common, especially in HBase environments, where full restarts of region and master servers are needed.

```
/opt/mapr/bin/maprcli node services -filter ["csvc==nfs"] -nfs restart
```

Start the Hue Service

```
/opt/mapr/bin/maprcli node services -name hue -action start -nodes <node n>
```

Restart the hoststats service

Restart the hoststats service after making changes to the MapRMapR Data Platform Metrics database. You do not need to restart warden.

```
/opt/mapr/bin/maprcli node services -name hoststats -action restart -nodes
<nodes>

OR

/opt/mapr/bin/maprcli node services -name hoststats -action restart -filter
'[csvc==hoststats]'
```

node topo
Lists cluster topology information.

Lists internal nodes only (switches/racks/etc) and not leaf nodes (server nodes).

Syntax

CLI

```
maprcli node topo
    [ -cluster <cluster> ]
    [ -path <path> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/topo?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`path`	The path on which to list node topology.

Output

Node topology information.

Sample output

```
{
    "timestamp":1433545849048,
    "timeofday":"2015-06-05 11:10:49.048 GMT+0000",
    "status":"OK",
    "total":4,
    "data":[
        {
            "path":"/"
        },
        {
            "path":"/data"
        },
        {
            "path":"/data/default-rack"
        },
        {
            "path":"/default-rack"
        }
    ]
}
```

Output Fields

Field	Description
path	The physical topology path to the node.

last-updated: Apr 11, 2022

Examples

CLI

```
# maprcli node topo
path
/
/data
/data/default-rack
/default-rack
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/node/topo' --user
mapr:mapr
{"timestamp":1529382835319,"timeofday"
:"2018-06-18 09:33:55.319 GMT-0700
PM","status":"OK","total":4,"data":
[{"path":"/"},{"path":"/data"},
{"path":"/data/default-rack"},
{"path":"/default-rack"}]}
```

node toposize
Lists disk space utilization for each topology.

Syntax

CLI

```
maprcli node toposize
    [ -cluster <cluster> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/node/toposize[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.

Output

Field	Description
`AvailableSpace`	The amount of available disk space (in GB).
`path`	The cluster rack path to the node (or topology of the node).
`TotalSpace`	The amount of total disk space (in GB).
`UsedSpace`	The amount of utilized disk space (in GB).

Example

Retrieve topology-based disk utilization information:

last-updated: Apr 11, 2022

CLI

```
# maprcli node toposize
path
TotalSpace(GB)  UsedSpace(GB)
AvailableSpace(GB)
/
1584            18              1563

```

rlimit
Manages resource usage limits for the cluster.
rlimit get
Returns the resource usage limit for the cluster's disk resource.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli rlimit get
    -resource disk
    [ -cluster <cluster name> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/rlimit/get?<parameters>`

Parameters

Parameter	Description
`resource`	The type of resource to get the usage limit for. Currently only the value `disk` is supported.
`cluster`	The name of the cluster whose usage limit is being queried.

Examples

Return the disk usage limit for the cluster my.cluster.com:

CLI

```
# maprcli rlimit get -resource
disk -cluster ksTest -json
{
    "timestamp":1529382231966,
    "timeofday":"2018-06-18
09:23:51.966 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "limit":"251947MB",
            "clusterSize":"279942MB",
            "currentUsage":"3MB"
        }
    ]
}
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/rlimit/get?
cluster=ksTest' --user mapr:mapr
{"timestamp":1529382231966,"timeofday"
:"2018-06-18 09:23:51.966 GMT-0700
PM","status":"OK","total":1,"data":
[{"limit":"251947MB","clusterSize":"27
9942MB","currentUsage":"3MB"}]}
```

rlimit set

Sets the resource usage limit for the cluster's disk resource.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli rlimit set
    -resource disk
    [ -cluster <cluster name> ]
    -value <limit>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/rlimit/set?<parameters>`

Parameters

Parameter	Description
`resource`	The type of resource for which to set the usage limit. Currently `disk` is the only value that is supported.
`cluster`	The name of the cluster whose usage limit is being set.
`value`	The value of the limit being set. You can express the value as KB, MB, GB, or TB.

Examples

Set the disk usage limit for the cluster my.cluster.com to 80TB:

CLI

```
maprcli rlimit set -resource
disk -cluster my.cluster.com -value
80TB
```

REST

```
https://abc.sj.us:8443/rest/rlimit/
get?
resource=disk&cluster=my.cluster.com&v
alue=80TB
```

schedule
Manages schedules.

Schedule Fields

The schedule object contains the following fields:

last-updated: Apr 11, 2022

Field	Value
id	The ID of the schedule.
name	The name of the schedule.
inuse	Indicates whether the schedule is associated with an action.
rules	An array of JSON objects specifying how often the scheduled action occurs. See Rule Fields below.

Rule Fields

The following table shows the fields to use when creating a rules object.

Field	Values
frequency	How often to perform the action: • `once` - Once • `yearly` - Yearly • `monthly` - Monthly • `weekly` - Weekly • `daily` - Daily • `hourly` - Hourly • `semihourly` - Every 30 minutes • `quarterhourly` - Every 15 minutes • `fiveminutes` - Every 5 minutes • `minute` - Every minute
retain	How long to retain the data resulting from the action. For example, if the schedule creates a snapshot, the retain field sets the snapshot's expiration. The retain field consists of an integer and one of the following units of time: • mi - minutes • h - hours • d - days • w - weeks • m - months • y - years **Note:** For offload schedule, set the value for this to `0`.

last-updated: Apr 11, 2022

Field	Values
time	The time of day to perform the action, in 24-hour format: HH
date	The date on which to perform the action: • For single occurrences, specify month, day and year: MM/DD/YYYY • For yearly occurrences, specify the month and day: MM/DD • For monthly occurrences occurrences, specify the day: DD Daily and hourly occurrences do not require the date field.

Example

The following example JSON shows a schedule called "snapshot," with three rules.

```
     {
            "id":8,
            "name":"snapshot",
            "inuse":0,
            "rules":[
                {
                    "frequency":"monthly",
                    "date":"8",
                    "time":14,
                    "retain":"1m"
                },
                {
                    "frequency":"weekly",
                    "date":"sat",
                    "time":14,
                    "retain":"2w"
                },
                {
                    "frequency":"hourly",
                    "retain":"1d"
                }
            ]
        }
```

schedule create

Creates a schedule. Permissions required: `fc` or `a`.

A schedule can be associated with a volume to automate mirror syncing, snapshot creation, and data offload. See volume create and volume modify.

Syntax

CLI

```
maprcli schedule create
    [ -cluster <cluster> ]
    -schedule <JSON>
```

REST

Request Type	POST

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/schedule/create?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`schedule`	A JSON object describing the schedule. See Schedule Objects for more information.

Examples

Scheduling a Single Occurrence

CLI

```
maprcli schedule create -schedule
'{"name":"Schedule-1","rules":
[{"frequency":"once","retain":"1w","ti
me":13,"date":"12/5/2010"}]}'
```

REST

```
https://abc.sj.us:8443/rest/schedule/
create?
schedule={"name":"Schedule-1","rules":
[{"frequency":"once","retain":"1w","ti
me":13,"date":"12/5/2010"}]}
```

A Schedule with Several Rules

CLI

```
maprcli schedule create -schedule
'{"name":"Schedule-2","rules":
[{"frequency":"weekly","date":"sun","t
ime":7,"retain":"2w"},
{"frequency":"daily","time":14,"retain
":"1w"},
{"frequency":"hourly","retain":"1w"},
{"frequency":"yearly","date":"11/5","t
ime":14,"retain":"1w"}]}'
```

REST

```
https://abc.sj.us:8443/rest/schedule/
create?
schedule={"name":"Schedule-1","rules":
[{"frequency":"weekly","date":"sun","t
ime":7,"retain":"2w"},
{"frequency":"daily","time":14,"retain
":"1w"},
{"frequency":"hourly","retain":"1w"},
{"frequency":"yearly","date":"11/5","t
ime":14,"retain":"1w"}]}
```

schedule list

Lists the schedules on the cluster.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli schedule list
    [ -cluster <cluster> ]
    [ -output terse|verbose ]
    [ -sortby ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/schedule/list[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`output`	Specifies whether the output should be terse or verbose.
`sortby`	Specifies one of the following attributes to sort the list of schedules by: `scheduleid`, `schedulename`, `schedulerulefrequency`, `scheduleruledate`, `scheduleruletime`, `scheduleruleminutes`, `scheduleruleretaintime`, `scheduleinuse`. By default, the list of schedules sorted by `schedulename`.

Output

A list of all schedules on the cluster. See Schedule Objects for more information.

Sample Output

```
# maprcli schedule list
id  name            inuse  rules
1   Critical data   0      ...
2   Important data  0      ...
3   Normal data     0      ...
```

Examples

List schedules:

CLI

```
# maprcli schedule list -json
{
    "timestamp":1531004445284,
    "timeofday":"2018-07-07
04:00:45.284 GMT-0700 PM",
    "status":"OK",
    "total":4,
    "data":[
        {
            "id":4,
            "name":"Automatic Tiering
Scheduler",
```

last-updated: Apr 11, 2022

```
            "inuse":0,
            "description":"Automatic
Scheduler for EC and Cold Tier: It
uses internal policies to schedule
the task",
            "rules":{

            }
        },
        {
            "id":1,
            "name":"Critical data",
            "inuse":0,
            "rules":[
                {

"frequency":"hourly",
                    "retain":"24h"
                },
                {

"frequency":"daily",
                    "time":0,
                    "retain":"7d"
                },
                {

"frequency":"weekly",
                    "date":"sun",
                    "time":0,
                    "retain":"12w"
                }
            ]
        },
        {
            "id":2,
            "name":"Important data",
            "inuse":0,
            "rules":[
                {

```

schedule modify
Modifies an existing schedule, specified by ID. Permissions required: `fc` or `a`.

To find a schedule's ID:

1. Use the schedule list command to list the schedules.
2. Select the schedule to modify.
3. Pass the selected schedule's ID in the -id parameter to the `schedule modify` command.

Syntax

CLI

```
maprcli schedule modify
    [ -cluster <cluster> ]
    -id <schedule ID>
    [ -name <schedule name> ]
    [ -rules <JSON>]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/schedule/modify?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`id`	The ID of the schedule to modify.
`name`	The new name of the schedule.
`rules`	A JSON object describing the rules for the schedule. If specified, replaces the entire existing rules object in the schedule. For information about the fields to use in the JSON object, see Rule Fields.

Examples

Modify a schedule

CLI

```
maprcli schedule modify -id 0 -name
Newname -rules
'[{"frequency":"weekly","date":"sun","
time":7,"retain":"2w"},
{"frequency":"daily","time":14,"retain
":"1w"}]'
```

REST

```
https://abc.sj.us:8443/rest/schedule/
modify?
id=0&name=Newname&rules=[{"frequency":
"weekly","date":"sun","time":7,"retain
":"2w"},
{"frequency":"daily","time":14,"retain
":"1w"}]
```

schedule remove
Removes a schedule.

A schedule can only be removed if it is not associated with any volumes. See volume modify.

Syntax

CLI

```
maprcli schedule remove
    [ -cluster <cluster> ]
    -id <schedule ID>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/schedule/remove?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.

last-updated: Apr 11, 2022

Parameter	Description
`id`	The ID of the schedule to remove.

Examples

Remove schedule with ID 0:

CLI

```
maprcli schedule remove -id 0
```

REST

```
https://abc.sj.us:8443/rest/schedule/
remove?id=0
```

security

Configures security options.

genkey
Generates keys and certificates.

This command is for internal use only. You must use `configure.sh` with the `genkeys` option instead.

genticket
Generates tickets.

This command is for internal use only. You must use the maprlogin utility instead.

service list
Lists all services on the specified node, the memory allocated for each service, the state of each service, and log path for each service.

Syntax

CLI

```
/opt/mapr/bin/maprcli service list
    -node <node name>
    [ -cluster <cluster name> ]
    [ -zkconnect <ZooKeeper connect
string> ]
    [ -output terse|verbose ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/service/list?<parameters>`

Parameters

Parameter	Description
cluster	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.

last-updated: Apr 11, 2022

Parameter	Description
node	The node for which to list services. Default: localhost. If this is not specified, the `/etc/hosts` file must include the IP address or hostname for the localhost.
output	Whether the output should be terse or verbose. Default: verbose.
zkconnect	A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: '<host>[:<port>][,<host>[:<port>]...]'. To obtain zookeeper connection strings, use the `maprcli node listzookeepers` command.

Output Fields

Field	Description
memallocated	The amount of system memory allocated to the service.
name	Service name.
state	Current state of the service. See Service States on page 1747.
logpath	Path to the log files for the service.
displayname	Display name of the service in the Control System.

Service States

The following table lists the service states with their descriptions:

State	Description
0	Not configured. The package for the service is not installed and/or the service is not configured (`configure.sh` has not run). This state is also returned for all the services if you run the command without specifying a node.
1	Configured. The package for the service is installed and configured.
2	Running. The service is installed, started by the warden, and is currently running.
3	Stopped. The service is installed and `configure.sh` has run, but the service is not running.
4	Failed. The service is installed and configured, but not running.
5	Stand by. The service is installed and is in standby mode, waiting to take over in case of failure of another instance.

Examples

CLI Example

The following output is an example of the service information returned when you run the `service list` command without specifying the node:

```
# /opt/mapr/bin/maprcli service list -json
{
```

{"name":"hoststats","state":0,"logpath":"/opt/mapr/
logs/hoststats.log","displayname":"HostStats"},
{"name":"apiserver","state":0,"logpath":"/opt/mapr/apiserver/logs/
apiserver.log","displayname":"APIServer"}]}
```

Note: When you configure high availability for the ResourceManager, the status of the standby ResourceManager service differs based on the selected failover implementation. When the cluster uses manual or automatic failover for the ResourceManager, standby ResourceManagers have a state equal to 2 (running). When the cluster uses zero configuration failover for the ResourceManager, standby ResourceManagers have a state equal to 5 (stand by).

setloglevel
Sets log level on individual services.
setloglevel cldb
Sets the log level on the CLDB service. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli setloglevel cldb
    -classname <class>
    -loglevel DEBUG|ERROR|FATAL|INFO|
TRACE|WARN
    -node <node>
    -port <port>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/setloglevel/cldb?<parameters>`

Parameters

Parameter	Description
`classname`	The name of the class for which to set the log level. The class can be at the package level or a specific class. Contact MapR Support for this parameter.

Parameter	Description
loglevel	The log level to set. Default: INFO • DEBUG • ERROR • FATAL • INFO • TRACE • WARN
node	The node on which to set the log level.
port	The CLDB port. Default: 7222

Examples

CLI

```
maprcli setloglevel cldb
    -classname
com.mapr.fs.cldb.CLDBServer
    -loglevel debug
    -node abc.sj.us
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/setloglevel/cldb?
classname=com.mapr.fs.cldb.CLDBServer&
loglevel=debug&node=abc.sj.us' --user
mapr:mapr
{"timestamp":1529380341288,"timeofday"
:"2018-06-18 08:52:21.288 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

setloglevel fileserver

Sets the log level on the FileServer service. Permissions required: fc or a.

Syntax

CLI

```
maprcli setloglevel fileserver
    -classname <class>
    -loglevel DEBUG|ERROR|FATAL|INFO|
TRACE|WARN
    -node <node>
    -port <port>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/setloglevel/fileserver?<parameters>`

Parameters

Parameter	Description
classname	The name of the class for which to set the log level. The classname is listed under the `maprcli trace info` command. Contact MapR Support for this parameter.
loglevel	The log level to set. Default: INFO • DEBUG • ERROR • FATAL • INFO • TRACE • WARN
node	The node on which to set the log level.
port	The MapR File System port. Default: 5660

Examples

CLI

```
maprcli setloglevel fileserver
    -classname FileServer
    -loglevel debug
    -node centos26.lab
```

REST

```
https://abc.sj.us:8443/rest/
setloglevel/fileserver?
classname=FileServer&loglevel=debug&no
de=centos26.lab
```

setloglevel hbmaster

Sets the log level on the HBase Master service. Permissions required: `fc` or a.

Syntax

CLI

```
maprcli setloglevel hbmaster
    -classname <class>
    -loglevel DEBUG|ERROR|FATAL|INFO|
TRACE|WARN
    -node <node>
    -port <port>
```

REST

```
http[s]://<host>:<port>/rest/
setloglevel/hbmaster?<parameters>
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
classname	The name of the class for which to set the log level. The class can be specified at the package level or for a specific class. Contact MapR Support for this parameter.
loglevel	The log level to set. Default: INFO • DEBUG • ERROR • FATAL • INFO • TRACE • WARN
node	The node on which to set the log level.
port	The HBase Master webserver port. Default: 16000 (16010 for the WebUI)

Examples

CLI

```
maprcli setloglevel hbmaster
    -classname
org.apache.hadoop.hbase.master
    -loglevel debug
    -node centos26.lab
    -port 16000
```

REST

```
https://centos26.lab:8443/rest/
setloglevel/hbmaster?
classname=org.apache.hadoop.hbase.mast
er&loglevel=debug&node=centos26.lab&po
rt=16000
```

setloglevel hbregionserver

Sets the log level on the HBase RegionServer service. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli setloglevel hbregionserver
    -classname <class>
    -loglevel DEBUG|ERROR|FATAL|INFO|
TRACE|WARN
    -node <node>
    -port <port>
```

REST

```
http[s]://<host>:<port>/rest/
setloglevel/hbregionserver?
<parameters>
```

Parameters

Parameter	Description
classname	The name of the class for which to set the log level. The class can be specified at the package level or for a specific class. Contact MapR Support for this parameter.
loglevel	The log level to set. Default: INFO • DEBUG • ERROR • FATAL • INFO • TRACE • WARN
node	The node on which to set the log level.
port	The HBase Region Server webserver port. Default: 16020 (16030 for the WebUI)

Examples

CLI

```
maprcli setloglevel hbregionserver
    -classname
org.apache.hadoop.hbase.regionserver
    -loglevel debug
    -node centos26.lab
    -port 16020
```

REST

```
https://centos26.lab:8443/rest/
setloglevel/hbregionserver?
classname=org.apache.hadoop.hbase.regi
onserver&loglevel=debug&node=centos26.
lab&port=16020
```

setloglevel nfs

Sets the log level on the NFS service. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli setloglevel nfs
    -classname <class>
    -loglevel DEBUG|ERROR|FATAL|INFO|
TRACE|WARN
```

last-updated: Apr 11, 2022

```
    -node <node>
    -port <port>
    -isusermode <TRUE|FALSE>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/setloglevel/nfs?<parameters>`

Parameters

Parameter	Description
classname	The name of the class for which to set the log level. The classname is listed under the `maprcli trace info` command. Contact MapR Support for this parameter.
loglevel	The log level to set. Default: INFO • DEBUG • ERROR • FATAL • INFO • TRACE • WARN
node	The node on which to set the log level.
port	The NFS port. Default: 9998
isusermode	Whether or not is the request is for user mode.

Examples

CLI

```
maprcli setloglevel nfs
    -classname NFSD
    -loglevel debug
    -node centos26.lab
```

REST

```
https://abc.sj.us:8443/rest/
setloglevel/nfs?
classname=NFSD&loglevel=debug&node=cen
tos26.lab
```

stream
Manages stream functionality.
stream assign list
For the given stream, lists consumers and the topics and partitions that the consumers are reading messages from.

Permissions Required
To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminperm`, `consumeperm`, `produceperm`, or `topicperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream assign list -path <Stream Path > [ -consumergroup <Consumer Group ID> ] [ -topic <Topic Name> ] [ -partition <Partition ID> ] [ -detail <Detail Parameter takes no value>  ]`
REST	`http[s]://<host>:<port>/rest/stream/assign/list?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream.
`consumergroup`	Specifies the ID of a particular consumer group that you want to list the consumers for.
`topic`	The name of a topic to list the consumers for. If you also specify the `-partition` parameter, only the consumers that are reading from the indicated partition are listed.
`partition`	The ID of a specific partition. If you specify this ID, you must also use the `-topic` parameter.
`detail`	Includes the values of additional parameters in the output. These parameters are used internally.

Sample Output
With the `-detail` parameter:

```
# maprcli stream assign list -path /s1 -json -detail
{
    "timestamp":1441965109585,
    "timeofday":"2015-09-11 02:51:49.585 GMT-0700",
    "status":"OK",
    "total":1,
    "data":[
        {
            "consumergroup":"xyzt1",
            "topic":"topic1",
            "assignseqnum":1,
            "consumerguid":"F3693413-2600-0876-CC91-052FA4F25500",
            "consumer":"ravindra.perf",
            "consumerip":"10.10.30.200",
```

last-updated: Apr 11, 2022

```
            "consumerpid":"30768",
            "assignment":"0,1,2,3"
        }
    ]
}
```

Without the `-detail` parameter:

```
# maprcli stream assign list -path /s1 -json
{
    "timestamp":1441965116100,
    "timeofday":"2015-09-11 02:51:56.100 GMT-0700",
    "status":"OK",
    "total":1,
    "data":[
        {
            "consumergroup":"xyzt1",
            "topic":"topic1",
            "consumer":"ravindra.perf",
            "consumerip":"10.10.30.200",
            "consumerpid":"30768",
            "assignment":"0,1,2,3"
        }
    ]
}
```

Field Descriptions

consumergroup	The name of the consumer group that is reading messages from this topic partition.
topic	The name of the topic.
assignseqnum	The sequence number of the current assignment of this partition. This value is used internally.
consumerguid	The globally unique identifer for the consumer. This value is used internally.
consumer	The ID of the consumer. This value is set with the client.id configuration parameter.
consumerip	The IP address of the consumer.
consumerpid	The process ID of the consumer.
assignment	The index numbers of the partitions that are assigned to this consumer.

`stream create`

Creates a new stream.

After you create a stream, you can edit the values of its parameters with the command `maprcli stream edit`.

To see the value of a stream's parameters, use the command `maprcli stream info`.

To run this command, your user ID must have write permission on the directory in which you want to create a stream.

Permissions Required

To run this command, your user ID must have the following permissions:

- readAce and writeAce on the volume

- lookupdir on directories in the path

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream create -path <Stream Path> [-ttl <Time to live in second> default:604800] [-autocreate <Auto create topics> default:true] [-defaultpartitions <Default partitions per topic> default:1] [-compression off|lz4|lzf|zlib. default: inherit from parent directory] [-produceperm <Producer access control expression> default u:creator] [-consumeperm <Consumer access control expression> default u:creator] [-topicperm <Topic CRUD access control expression> default u:creator] [-copyperm <Stream copy access control expression> default u:creator] [-adminperm <Stream administration access control expression> default u:creator] [-copymetafrom <Stream to copy attributes from> default:none] [-ischangelog <true|false> default: false] [-defaulttimestamptype timestamp type: createtime | logappendtime. default: createtime] [-pidexpirysecs <Producer ID expiry time in seconds. Default: 6048000>] [-mincompactionlag <Set time in melliseconds for which a message remains uncompacted. Default: 0>] [-deleteretention <Set the time in milliseconds for which delete records are retained. Default: 86400000>]`
REST	`http[s]://<host>:<port>/rest/stream/create?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream to create. The path to the stream can include any character allowed by MapR. For example, `/my/path/with:/to/mystream` is valid, but `/my/path/with:/to/mystream:withcolon` is invalid. The name of the stream cannot include a colon (:) or a forward slash (/).

last-updated: Apr 11, 2022

Parameter	Description
`ttl`	Specifies the number of seconds to elapse between the publication of a message in a topic in this stream and the expiration of that message. Consumers do not see messages that have expired. Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages for details. A value of 0 causes messages to be retained indefinitely.
`autocreate`	Specifies whether to create a topic automatically when a producer tries to write the first message to it. Values are `true` and `false`. The default is `true`.
`defaultpartitions`	Specifies the default number of partitions to allocate to new topics in the stream.
`compression`	Specifies the compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompresses it, and passes it to client applications. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is the type of compression that is set for the directory in which the stream is located. For more information, see Compression.
`produceperm`	Specifies the access-control expression that controls who can publish messages to topics in the stream. See ACE Syntax.
`consumeperm`	Specifies the access-control expression that controls who can who can listen to topics in the stream. See ACE Syntax.
`topicperm`	Specifies the access-control expression that controls who can create, edit, or remove topics in the stream. See ACE Syntax.
`copyperm`	Specifies the access-control expression that controls who can use `mapr copystream` or `mapr diffstreams` on the stream. See ACE Syntax.
`adminperm`	Determines which users can modify ACEs for a stream, set up replication of a stream, and modify other attributes of a stream. **Important:** By default, only the stream owner can modify this setting; however, a patch is available that changes this behavior. After applying the patch, both the stream owner and the MAPR user can modify this setting. The patch works with MapR Core-6.1.0. To install patches, see Applying a Patch. See ACE Syntax. This permission includes the `topicperm` permission.

last-updated: Apr 11, 2022

Parameter	Description
`copymetafrom`	If you plan to replicate messages to this stream from another stream, specify the path to that other stream. The metadata from that stream will be copied to the new stream when the new stream is created.
`ischangelog`	Specifies whether the stream is for the Change Data Capture feature's changed data records. Value: true|false. Default: false. • If you want to use a non-default partition value (Default: 1) for the topic, use the `maprcli stream create -path </mypath/stream:topic> -ischangelog true -defaultpartitions < value other than 1 >` command to create the stream and then create the topic with the `maprcli streams topic create` command. • If you want to use the default partitions value (1) for the Change Data Capture feature, use the `maprcli stream create -path </mypath/stream> -ischangelog true` command to create the stream and then use the `maprcli table changelog add -path <mypath/stream:topic` command to set up the Change Data Capture feature and create the topic.
`defaulttimestamptype`	Specifies the type of timestamp stored in the topic's message. Value: createtime | logappendtime Default: createtime. The topic inherits the default value from the stream unless the topic sets the timestamp type to a different value. A `createtime` value is the time defined by the user or application (when creating the message). If user or application does not define this value (or passes null), the client uses the current system timestamp. A `logappendtime` value is the time when the message (log) was appended to the server.
`pidexpirysecs`	Specifies the expiration time for the Producer ID. This parameter fixes the lifetime for the Producer ID. Default: 604800
`mincompactionlag`	Sets the **minimum** delay (in milliseconds) before which messages are **not** compacted. It is the **minimum** time that the messages are available for consumption. Beyond this time period, the messages **may** be compacted. Default: 0 The lag is calculated from the time that a message was produced to the stream topic-partition. **Note:** Compaction is set only when you edit the stream. See stream edit on page 1765.
`deleteretention`	Sets the **minimum** time (in milliseconds) before which deleted records are removed. It is the **minimum** time that the deleted records are still available. Beyone this time period, the deleted messages **may** be removed. Default: 86400000 Used with log compaction.

last-updated: Apr 11, 2022

`stream cursor delete`

Deletes committed cursors that are in the partitions in a stream.

Note: Deleting the committed cursors for active consumers has no effect on the consumers. Consumers use read cursors to keep track of where they currently are in partitions.

For example, the consumer `consumer1` continues reading the messages in a partition from the position of the consumer's read cursor even after the consumer's committed cursor is deleted. However, if `consumer1` goes offline and the partition is reassigned to another consumer (`consumer2`) in the same consumer group before `consumer1` creates another committed cursor, `consumer2` starts reading the partition at the most recent message.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` or `consumeperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream cursor delete -path <Stream Path> [ -consumergroup <Consumer Group ID> ] [ -topic <Topic Name> ] [ -partition <Partition ID> ]`
REST	`http[s]://<host>:<port>/rest/stream/cursor/delete?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream in which the committed cursors are located.
`consumergroup`	Specifies the ID of a particular consumer group that you want to delete the committed cursors for.
`topic`	The name of a topic to delete committed cursors from. If you also specify the `-partition` parameter, only the committed cursors in the indicated partition are deleted.
`partition`	The ID of the partition where the committed cursors that you want to delete is located. If you specify this ID, you must also use the `-topic` parameter.

`stream cursor list`

Lists the cursors for the consumers of a stream.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminperm`, `consumeperm`, `produceperm`, or `topicperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream cursor list -path <Stream Path> [ -consumergroup <Consumer Group ID> ] [ -topic <Topic Name> ] [ -partition <Partition ID> ]`
REST	`http[s]://<host>:<port>/rest/stream/cursor/list?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream in which the cursors are located.
`consumergroup`	Specifies the ID of a particular consumer group that you want to list the cursors for.
`topic`	The name of a topic to list committed cursors from. If you also specify the `-partition` parameter, only the committed cursors in the indicated partition are listed.
`partition`	The ID of the partition where the particular cursor that you want to list is located. If you specify this ID, you must also use the `-topic` parameter.

Sample Output

```
# maprcli stream cursor list -path /s1 -topic topic0 -json
{
    "timestamp":1441883091373,
    "timeofday":"2015-09-10 04:04:51.373 GMT-0700",
    "status":"OK",
    "total":4,
    "data":[

            "committedoffset":"113214511",
            "producertimestamp":"2015-09-10T03:48:14.082-0700",
            "consumertimestamp":"2015-09-10T03:48:07.769-0700",
            "consumerlagmillis":"6313"
        },
    ]
}
```

Field Descriptions

consumergroup	The ID of the consumer group to which belongs the consumer that owns the committed cursor.
committedoffset	The last offset that was committed by the consumer that is reading from the listed partition and that belongs to the listed consumer group.
consumerlagmillis	The difference in milliseconds between the timestamp of the last published message and the timestamp of the last message consumed by the consumer.
consumertimestamp	The timestamp of the most recent message that the consumer has consumed.
partitionid	The index number of the partition within the topic. The first partition in a topic has an index of 0, the next partition an index of 1, and so on.
produceroffset	The maximum offset produced for this partition.
topic	The name of the topic that the cursor corresponds to.

stream delete

Deletes the specified stream. Deleted streams cannot be recovered unless they were previously replicated.

Producers are no longer able to publish messages to topics in the stream, and consumers are no longer able to read messages from topics in the stream.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume

last-updated: Apr 11, 2022

- `lookupdir` on directories in the path

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream delete -path <Stream Path>`
REST	`http[s]://<host>:<port>/rest/stream/delete?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream to delete.

`stream edit`

Edits the values of parameters for the specified stream.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Syntax

CLI	`maprcli stream edit -path Stream Path [-ttl <Time to live in seconds>] [-autocreate true|false] [-defaultpartitions <Default partitions per topic>] [-compression off|lz4|lzf|zlib] [-produceperm <Producer access control expression> default u:creator] [-consumeperm <Consumer access control expression> default u:creator] [-topicperm <Topic CRUD access control expression> default u:creator] [-copyperm <Stream copy access control expression> default u:creator] [-adminperm <Stream administration access control expression> default u:creator] [-defaulttimestamptype timestamp type: createtime | logappendtime. default: createtime] [-compact <Sets log compaction for a stream. Value: true | false default: false>] [-pidexpirysecs <Producer ID expiry time in seconds. Default: 604800>] [-mincompactionlag <Sets time in milliseconds for which a message remains uncompacted. default: 0>] [-deleteretention <Sets the time in milliseconds for which delete records are retained. Default: 86400000>] [-force <When used with -compact, forces enabling log compaction on a stream. Parameter takes no value.>]`
REST	`http[s]://<host>:<port>/rest/stream/edit?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream to create.
`ttl`	Specifies the number of seconds to elapse between the publication of a message in a topic in this stream and the expiration of that message. Consumers do not see messages that have expired. Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages for details. A value of 0 causes messages to be retained indefinitely.
`autocreate`	Specifies whether to create a topic automatically when a producer tries to write the first message to it. Values are `true` and `false`. The default is `true`.
`defaultpartitions`	Specifies the default number of partitions to allocate to new topics in the stream.

Parameter	Description
`compression`	Specifies the compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompresses it, and passes it to client applications. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is the type of compression that is set for the directory in which the stream is located. For more information, see Compression.
`produceperm`	Specifies the access-control expression that controls who can publish messages to topics in the stream. See ACE Syntax.
`consumeperm`	Specifies the access-control expression that controls who can who can listen to topics in the stream. See ACE Syntax.
`topicperm`	Specifies the access-control expression that controls who can create, edit, or remove topics in the stream. See ACE Syntax.
`copyperm`	Specifies the access-control expression that controls who can use `mapr copystream` or `mapr diffstreams` on the stream. See ACE Syntax.
`adminperm`	Determines which users can modify ACEs for a stream, set up replication of a stream, and modify other attributes of a stream. **Important:** By default, only the stream owner can modify this setting; however, a patch is available that changes this behavior. After applying the patch, both the stream owner and the MAPR user can modify this setting. The patch works with MapR Core-6.1.0. To install patches, see Applying a Patch. See ACE Syntax. This permission includes the `topicperm` permission.
`defaulttimestamptype`	Specifies the type of timestamp stored in the topic's message. Value: createtime | logappendtime Default: createtime. The topic inherits the default value from the stream unless the topic sets the timestamp type to a different value. A `createtime` value is the time defined by the user or application (when creating the message). If user or application does not define this value (or passes null), the client uses the current system timestamp. A `logappendtime` value is the time when the message (log) was appended to the server.
`pidexpirysecs`	Specifies the expiration time for the Producer ID. This parameter fixes the lifetime for the Producer ID. Default: 604800
`compact`	Sets log compaction for stream. When set to true, enables log compaction. When set to false, disables log compaction. Value: true|false Default: false **Note:** A license is required to run the `-compact` option; otherwise, the command hangs. See Adding a License on page 777.

Parameter	Description
`mincompactionlag`	Sets the **minimum** delay (in milliseconds) before which messages are **not** compacted. It is the **minimum** time that the messages are available for consumption. Beyond this time period, the messages **may** be compacted. Default: 0 The lag is calculated from the time that a message was produced to the stream topic-partition.
`deleteretention`	Sets the **minimum** time (in milliseconds) before which deleted records are removed. It is the **minimum** time that the deleted records are still available. Beyone this time period, the deleted messages **may** be removed. Default: 86400000
`force`	Used with the `-compact` parameter to force log compaction on a stream parameter. No values are passed. Used for backward compatibility.

`stream info`

Displays the values of the parameters of the specified stream.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
`adminperm`	When a user with this permission runs the command, the output includes the access-control expressions for the `adminperm` and `topicperm` permissions.
`produceperm`, `consumeperm`, or `topicperm`	When a user with one of these permissions runs the command, the output does not include any access-control expressions.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream info -path <Stream Path>`
REST	`http[s]://<host>:<port>/rest/stream/info?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to see information about.

Sample Output

```
maprcli stream info -path /streamVol/stream1 -json
{
    "timestamp":1521233326943,
    "timeofday":"2018-03-16 01:48:46.943 GMT-0700 PM",
```

```
    "status":"OK",
    "total":1,
    "data":[
        {
            "path":"/streamVol/stream1",
            "physicalsize":57344,
            "logicalsize":32768,
            "numtopics":1,
            "defaultpartitions":1,
            "ttl":604800,
            "compression":"lz4",
            "autocreate":true,
            "produceperm":"u:root",
            "consumeperm":"u:root",
            "topicperm":"u:root",
            "copyperm":"u:root",
            "adminperm":"u:root",
            "ischangelog":false,
            "timestamptype":"createtime"
        }
    ]
}
```

`stream purge`
Runs the purge process, removing messages that are marked for deletion and reclaiming disk space.

For information about the purge process, see Time-to-Live for Messages.

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Permissions Required
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream purge -path <Stream Path>`
REST	`http[s]://<host>:<port>/rest/stream/purge?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream to reclaim disk space from.

last-updated: Apr 11, 2022

`stream replica add`

Registers an existing stream as a replica of the specified stream.

Note: A license is required to run this command. Running this command without a license can cause the command to hang. See Adding a License on page 777.

Permissions Required at the Source Cluster

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` and `copyperm` permissions on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Permissions Required at the Target Cluster

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

Syntax

CLI	`maprcli stream replica add -path <stream path> -replica <remote stream path> [-paused <start replication in paused state> default: false] [-throttle <throttle replication operations under load> default: false] [-networkencryption <enable on-wire encryption> default: false] [-synchronous <replicate to remote stream before acknowledging producers> default: false] [-networkcompression <on-wire compression type: off|lz4|lzf|zlib> default: compression setting on stream]`
REST	`http[s]://<host>:<port>/rest/stream/replica/add?path=<path>&replica=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to create a replica for.
`replica`	The path and name of the stream that you want to create as a replica of the stream that you specified with the `-path` parameter.

last-updated: Apr 11, 2022

Parameter	Description
`paused`	A boolean value that specifies whether to pause the replication so that it does not start immediately. The replication can be resumed using the replica resume command at a later time. The values are `true` or `false`. The default is `false`. Set `-paused` to `true` if you want to run `mapr copystream` to load the replica stream before starting replication. If it is not paused, replication starts immediately after you run the commands `maprcli stream replica add` and `maprcli stream upstream add`, in which case the replica stream starts empty and accumulates messages over time. If you are interested only in the messages that are published to the source stream after replication starts, then you do not need to pause replication initially. However, if you want the full set of messages from the source stream that have not yet been purged or marked for deletion, then pause replication initially.
`throttle`	A boolean value that specifies whether to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. The values are `true` or `false`. The default is `false`. Throttling has two effects, both of which allow MapR Event Store For Apache Kafka to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
`networkencryption`	A boolean value that specifies whether or not to enable on-wire encryption. The values are `true` or `false`. The default is `false`. If you set the value to `true`, the local cluster and any other cluster that is part of the replication process must be enabled for security.
`synchronous`	A boolean value that specifies whether replication is synchronous or asynchronous. The values are `true` or `false`. The default is `false` and specifies asynchronous replication.
`networkcompression`	Specifies the type of compression to use when replicating messages. For more information, see Managing Compression.

`stream replica autosetup`
Sets up and starts replication between a source stream and replica stream.

The `maprcli stream replica autosetup` command performs the following steps to set up replication:

1. Creates a stream in the destination cluster.
2. Declares the new stream to be a replica of the source stream and ensures that replication does not begin immediately after the next step.
3. Declares the source stream as the original of the replica stream.

last-updated: Apr 11, 2022

4. Runs the `mapr copystream` utility to load a copy of the source data into the replica.
5. For multi-master replication, it declares the source stream to be a replica of the new stream and then declares the new stream to be an upstream source for the source stream.
6. Clears the paused replication state to start replication.

For more information about the automatic setup process, see Replica Autosetup for Streams on page 659.

Note: Before you set up replication for a stream, verify that the cluster is setup for replication. For more information, see Preparing Clusters for Stream Replication on page 1130.

Permissions Required at the Source Cluster
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` and `copyperm` permissions on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Permissions Required at the Target Cluster
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

Syntax

CLI	`maprcli stream replica autosetup -path <stream path> -replica <remote stream path> [-synchronous <replicate to remote stream before acknowledging producers> default: false] [-multimaster <set up bi-directional replication> default: false] [-throttle <throttle replication operations under load> default: false] [-networkencryption <enable on-wire encryption> default: false] [-networkcompression <on-wire compression type: off|lz4|lzf|zlib> default: compression setting on stream] [-directcopy enable directcopy. default: true] [-useexistingreplica use existing replica table if present. default: false]`
REST	`http[s]://<host>:<port>/rest/stream/replica/autosetup?path=<path>&replica=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to create a replica for.
`replica`	The path and name of the stream that you want to create as a replica of the stream that you specified with the `-path` parameter.
`synchronous`	A boolean value that specifies whether replication is synchronous or asynchronous. The values are `true` or `false`. The default is `false` and specifies asynchronous replication.
`multimaster`	A boolean value that specifies whether or not to set up a multi-master topology. The values are `true` or `false`. The default is `false` and specifies to use the basic primary-secondary topology, rather than the multi-master topology.
`throttle`	A boolean value that specifies whether to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. The values are `true` or `false`. The default is `false`. Throttling has two effects, both of which allow MapR Event Store For Apache Kafka to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
`networkencryption`	A boolean value that specifies whether or not to enable on-wire encryption. The values are `true` or `false`. The default is `false`. If you set the value to `true`, the local cluster and any other cluster that is part of the replication process must be enabled for security.
`networkcompression`	Specifies the type of compression to use when replicating messages. For more information, see Managing Compression.
directcopy	A Boolean value that specifies whether or not autosetup will use the directcopy option . The values are `true` or `false.` Autosetup with direct copy (`true`) is the default. If you set this parameter to `false`, the cluster will run autosetup without the directcopy option. For more information, see Replica Autosetup for Streams on page 659.
useexistingreplica	When the directcopy parameter is set to `true` (default), this Boolean value specifies whether or not an existing stream can be used as the replica stream. The values for this parameter are `true` or `false`. No reuse of existing tables (`false`) is the default. If a stream exists with the specified name, and this parameter is set to false, the create stream operation will fail.

`stream replica edit`

Modifies the way in which messages are replicated from one stream to another.

last-updated: Apr 11, 2022

Permissions Required at the Source Cluster
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Permissions Required at the Target Cluster
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

Syntax

CLI	`maprcli stream replica edit`
	`-path <stream path>`
	`-replica <remote stream path>`
	`[ -newreplica <renamed stream path> ]`
	`[ -throttle <throttle replication operations under load> ]`
	`[ -networkencryption <enable on-wire encryption> ]`
	`[ -synchronous <replicate to remote stream before acknowledging producers> ]`
	`[ -networkcompression <on-wire compression type: off|lz4|lzf|zlib> ]`

REST	`http[s]://<host>:<port>/rest/stream/replica/edit?path=<path>&replica=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to create a replica for.
`replica`	The path and name of the stream that you want to create as a replica of the stream that you specified with the `-path` parameter.
`newreplica`	Specifies a new name to give to the replica stream.

Parameter	Description
`throttle`	A boolean value that specifies whether to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. The values are `true` or `false`. The default is `false`. Throttling has two effects, both of which allow MapR Event Store For Apache Kafka to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
`networkencryption`	A boolean value that specifies whether or not to enable on-wire encryption. The values are `true` or `false`. The default is `false`. If you set the value to `true`, the local cluster and any other cluster that is part of the replication process must be enabled for security.
`synchronous`	A boolean value that specifies whether replication is synchronous or asynchronous. The values are `true` or `false`. The default is `false` and specifies asynchronous replication.
`networkcompression`	Specifies the type of compression to use when replicating messages. For more information, see Managing Compression.

`stream replica list`
Lists the replicas of a given stream.

Permissions Required on the Source Cluster
To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream replica list`
	`-path <stream path>`
	`[ -refreshnow <immediately refresh replication statistics>`
	`default: false ]`

REST	`http[s]://<host>:<port>/rest/stream/replica/list?path=<path>`

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to list the replicas of.
`refreshnow`	A boolean value that specifies whether to trigger an immediate update of the replica statistics. The values are `true` or `false`. By default, the value is `false` and the command lists the current version of the replica statistics, which could be a maximum of five minutes old.

Sample with Output

```
# maprcli stream replica list -path /srcVol/srcStream -json
{
    "timestamp":1507758209755,
    "timeofday":"2017-10-11 02:43:29.755 GMT-0700",
    "status":"OK",
    "total":1,
    "data":[
        {
            "cluster":"my.cluster.com",
            "stream":"/destVol",
            "type":"MapRStream",
            "replicaPath":"/destVol",
            "replicaState":"REPLICA_STATE_CREATE_SCHEDULE",
            "paused":false,
            "throttle":false,
            "idx":1,
            "networkencryption":false,
            "synchronous":false,
            "networkcompression":"lz4",
            "propagateExistingData":false,
            "isUptodate":true,
            "minPendingTS":0,
            "maxPendingTS":0,
            "bytesPending":0,
            "bucketsPending":0,
            "copyTableCompletionPercentage":0,
        }
    ]
}
```

Data Fields

Data Fields	Description
cluster	The cluster on which the replica stream resides.
stream	The path of the replica stream.
type	Identifies the type of table: MapR Database table or MapR Event Store For Apache Kafka stream.
replicaPath	The replica location of the source stream.
replicaState	The replication state indicates when stream replication is in progress and it also displays the status of operations related to replica autosetup with directcopy.
paused	A Boolean values that specifies if replication is paused.
throttle	A Boolean value that specifies if replication is throttled.

Data Fields	Description
idx	The index number of the replica stream.
networkencryption	A Boolean value that specifies if replication is encrypted.
synchronous	A Boolean value that specifies whether replication is synchronous or asynchronous.
networkcompression	The type of on-wire compression.
propagateExistingData	Used to identify whether existing data in a CDC table is propagated to stream topic.
isUptodate	A Boolean value that specifies if the replica is up-to-date.
minPendingTS	The epoch time in milliseconds of the oldest message that has yet to be replicated.
maxPendingTS	The epoch time in milliseconds of the newest message that has yet to be replicated.
bytesPending	The number of bytes that have yet to be replicated.
bucketsPending	The number of buckets that have yet to be replicated.
copyTableCompletionPercentage	The percentage of data replication completed from the source stream to the destination stream. **Note:** When replicating MapR Database data, the copyTablePercentageCompletion data may re-adjust to a lower rate. This depends on table region (also referred to as tablets) splits and merges as well as the rate of incoming data to replicating data.

`stream replica pause`

Pauses replication from a *source* stream to a *replica* stream during autosetup and replication phases.

Permissions Required on the Source Cluster

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream replica pause -path <stream path> -replica <remote stream path>`
REST	`http[s]://<host>:<port>/rest/stream/replica/pause?path=<path>&replica=<name>`

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`path`	The path and name of the stream that is the source for the replica that you want to pause replication to.
`replica`	The path and name of the stream replica that you want to pause replication to.

`stream replica remove`

Unregisters a stream as the replica of another stream.

Permissions Required on the Source Cluster

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream replica remove -path <stream path> -replica <remote stream path>`
REST	`http[s]://<host>:<port>/rest/stream/replica/remove?path=<path>&replica=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that is the source for the replica that you want to remove.
`replica`	The path and name of the stream replica that you want to remove.

`stream replica resume`

Resumes replication from one stream to another stream Replication can be paused during autosetup and replication phases. When replication resumes, it continues from where it left off.

Permissions Required on the Source Cluster

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream replica resume -path <stream path> -replica <remote stream path>`
REST	`http[s]://<host>:<port>/rest/stream/replica/resume?path=<path>&replica=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that is the source for the replica that you want to resume replicating to.
`replica`	The path and name of the stream replica that you want to resume replicating to.

`stream upstream add`

Registers a stream as an upstream source for a given stream. For example, if you wanted to replicate messages from `Stream_A` to `Stream_B`, `Stream_A` would be the upstream source for `Stream_B`.

Permissions Required on the Target Cluster

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream upstream add -path <stream path> -upstream <upstream stream path>`
REST	`http[s]://<host>:<port>/rest/stream/upstream/add?path=<path>&upstream=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to specify a source stream for.

last-updated: Apr 11, 2022

Parameter	Description
`upstream`	The path and name of the stream that you want to use as a source for the stream that you specified with the `-path` parameter.

`stream upstream list`
Lists all of the streams that are replicating to a given stream.

Permissions Required on the Target Cluster
To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream upstream list -path <Stream Path>`
REST	`http[s]://<host>:<port>/rest/stream/upstream/list?path=<path>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to list the source streams for.

Sample Output

```
# maprcli stream upstream list -path /dst -json
{
    "timestamp":1437992841303,
    "timeofday":"2015-07-27 03:27:21.303 GMT-0700",
    "status":"OK",
    "total":1,
    "data":[
        {
            "cluster":"my.cluster.com",
            "stream":"/src",
            "idx":1,
            "uuid":"3e98ee93-d88a-f3d6-bc80-001b02b65500"
        }
    ]
}
```

last-updated: Apr 11, 2022

Field Descriptions

`cluster`	The name of the MapR cluster in which the upstream stream is located.
`stream`	The name of the upstream stream.
`idx`	The index number of the upstream stream.
`uuid`	The upstream stream's universally unique identifier.

`stream upstream remove`
Unregisters a stream as an upstream source for a given stream.

Permissions Required on the Target Cluster
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the source stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream upstream remove -path <stream path> -upstream <upstream stream path>`
REST	`http[s]://<host>:<port>/rest/stream/upstream/remove?path=<path>&upstream=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream that you want to remove a source stream from.
`upstream`	The path and name of the stream that you want to remove as a source for the stream that you specified with the `-path` parameter.

`stream topic create`
Creates a topic in the specified stream.

Permissions Required
To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `topicperm` permission on the stream

last-updated: Apr 11, 2022

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream topic create -path <Stream Path> -topic <Topic Name> [ -partitions <Number of partitions> default: attribute defaultpartitions on the stream ] [ -timestamptype Timestamp type: createtime | logappendtime default: createtime ]`
REST	`http[s]://<host>:<port>/rest/stream/topic/create?path=<path>&topic=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream in which to create the topic.
`topic`	The name of the topic to create. A name can include alphanumeric characters and the period, underscore, and dash characters.
`partitions`	The number of partitions to use for the topic. After you create the topic, you can increase the number of partitions, but you cannot reduce the number. The default number of partitions for new topics is set by the defaultpartitions parameter in the commands maprcli stream create and maprcli stream edit. **Important:** A CDC changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change. • If the `stream topic create` command is used to create a stream topic, then the number of topic partitions can be set at creation time and then is *locked*. • If the table changelog add on page 1813 command is used to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.

Parameter	Description
`timestamptype`	Specifies the type of timestamp stored in the topic's message. Value: createtime | logappendtime Default: createtime. The topic inherits the default value from the stream unless the topic sets the timestamp type to a different value. A `createtime` value is the time defined by the user or application (when creating the message). If user or application does not define this value (or passes null), the client uses the current system timestamp. A `logappendtime` value is the time when the message (log) was appended to the server.

`stream topic delete`

Deletes the specified topic from the specified stream.

Consumers do not have to stop consuming from a topic before the topic is deleted.

The deletion of the topic and the messages is immediate. However, the command also starts a background process for the purging the topic and messages to reclaim disk space.

If the parameter `-autocreate` for the stream is set to `true`, a topic with the same name is created if a producer writes a message to a topic of the same name. For example, if you delete the topic `Topic_A` and then a producer writes a message to the topic `Topic_A`, MapR Event Store For Apache Kafka creates a topic that is named `Topic_A`. Aside from the name, the new topic `Topic_A` shares nothing with the deleted topic `Topic_A`.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `topicperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream topic delete`
	`-path <Stream Path>`
	`-topic <Topic Name>`

REST	`http[s]://<host>:<port>/rest/stream/topic/delete?path=<path>&topic=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream from which to delete the topic.
`topic`	The name of the topic to delete.

last-updated: Apr 11, 2022

`stream topic edit`

Allows you to increase the number of partitions that are in the specified topic.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `topicperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream topic edit -path <Stream Path> -topic <Topic Name> [ -partitions <Number of partitions> ] [ -timestamptype Timestamp type: createtime | logappendtime default: createtime ]`
REST	`http[s]://<host>:<port>/rest/stream/topic/edit?path=<path>&topic=<name>&partitions=<number>`

Parameters

Parameter	Description
`path`	The path and name of the stream in which the topic is located.
`topic`	The name of the topic to edit.

Parameter	Description
`partitions`	The number of partitions to use for the topic. You cannot reduce the number of partitions. To find out how many partitions a topic is currently using, run the command `maprcli stream topic info.` **Important:** A CDC changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change and the `stream topic edit` command can not modify the topic's partition number. • If the `stream topic create` command is used to create a stream topic, then the number of topic partitions can be set at creation time and then is *locked*. • If the table changelog add on page 1813 command is used to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.
`timestamptype`	Specifies the type of timestamp stored in the topic's message. Value: createtime | logappendtime Default: createtime. The topic inherits the default value from the stream unless the topic sets the timestamp type to a different value. A `createtime` value is the time defined by the user or application (when creating the message). If user or application does not define this value (or passes null), the client uses the current system timestamp. A `logappendtime` value is the time when the message (log) was appended to the server.

`stream topic info`
Lists information about a stream's topic, grouped by partition ID.

Permissions Required
To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminperm`, `consumeperm`, `produceperm`, or `topicperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Syntax

CLI	`maprcli stream topic info -path <Stream Path> -topic <Topic Name>`
REST	`http[s]://<host>:<port>/rest/stream/topic/info?path=<path>&topic=<name>`

Parameters

Parameter	Description
`path`	The path and name of the stream for which you want to display information about topics.
`topic`	The name of the topic for which you want to display information.

Sample Output

```
maprcli stream topic info -path /streamVol/stream1 -topic topic1 -json
{
    "timestamp":1521232252550,
    "timeofday":"2018-03-16 01:30:52.550 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "partitionid":0,
            "physicalsize":0,
            "logicalsize":0,
            "maxoffset":-1,
            "minoffsetacrossconsumers":0,
            "mintimestamp":"1969-12-31T04:00:00.000-0800 PM",
            "maxtimestamp":"1969-12-31T04:00:00.000-0800 PM",
            "mintimestampacrossconsumers":"1969-12-31T04:00:00.000-0800 PM",
            "fid":"2113.32.131400",
            "master":"doc24.lab:5660",
            "servers":"doc24.lab:5660",
            "timestamptype":"createtime",

"logcompactionlaststarted":"1969-12-31T04:00:00.000-0800 PM",

"logcompactionlastcompleted":"1969-12-31T04:00:00.000-0800 PM",
                    "logcompactionstatus":"not started"
        }
    ]
}
```

Field Descriptions

`partitionid`	The index number of the partition within the topic. The first partition in a topic has an index of 0, the next partition an index of 1, and so on.
`physicalsize`	The physical size (in bytes) of the stream topic with data compression.
`logicalsize`	The logical size (in bytes) of the stream topic without data compression.

maxoffset	The maximum offset for this partition.
minoffsetacrossconsumers	All known consumers for this partition have consumed messages at least up to this offset.
mintimestamp	The timestamp of oldest message in the partition.
maxtimestamp	The timestamp of newest message in the partition.
mintimestampacrossconsumers	All known consumers for this partition have consumed messages older than this timestamp.
fid	The inode hosting the head of the partition.
master	*For use by MapR support:* The master server that is hosting the head of the partition.
servers	*For use by MapR support:* Lists all of the servers that are hosting the head of the partition.
timestamptype	The type of timestamp stored in the topic's message. Possible values: createtime (default) and logappendtime.
logcompactionlaststarted	Displays the last time log compaction was started if log compaction was enabled. The value is displayed in epoch time. This field displays when there is a change in the value for this field.
logcompactionlastcompleted	Displays the last time log compaction completed if log compaction was enabled. The value is displayed in epoch time. This field displays when there is a change in the value for this field
logcompactionstatus	Displays whether log compaction was started or completed.

stream topic list
Lists the topics that are in a stream, as well as the number of partitions in each topic.

Permissions Required
To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminperm`, `consumeperm`, `produceperm`, or `topicperm` permission on the stream

Note: The `mapr` user is not treated as a superuser. MapR Event Store For Apache Kafka does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI	`maprcli stream topic list -path <Stream Path>`
REST	`http[s]://<host>:<port>/rest/stream/topic/list?path=<path>`

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`path`	The path and name of the stream for which you want to list the topics.

Sample Output

```
# maprcli stream topic list -path /s1 -json
{
    "timestamp":1441882201851,
    "timeofday":"2015-09-10 03:50:01.851 GMT-0700",
    "status":"OK",
    "total":2,
    "data":[
        {
            "topic":"topic0",
            "partitions":4,
            "consumers":8,
            "physicalsize":148373504,
            "logicalsize":1009713152,
            "maxlag":6314
        },
        {
            "topic":"topic1",
            "partitions":4,
            "consumers":8,
            "physicalsize":148373504,
            "logicalsize":1009713152,
            "maxlag":6385
        }
    ]
}
```

`table`
Performs functions related to MapR Database tables.
`table create`
Creates a MapR binary or JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
/opt/mapr/bin/maprcli table create
  -path <path>
  [ -copymetafrom <path to source
table> ]
  [ -copymetatype all|cfs|aces|splits|
attrs ]
  [ -regionsizemb <region size in MB> ]
  [ -autosplit true|false ]
  [ -bulkload true|false ]

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/table/
create?path=<path>&<parameters>'
  -u <username>:<password>
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description

path	The path to the new MapR table.
	• For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
	• For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
	  **Note:** You cannot use the following characters in the table name:
	`< > ? % \`
	To use the following characters in the table name, enclose them either in single or double quotes:
	`; | ( ) /`
	For example:
	`maprcli table create -path "/♦=#; {}&()/" (or) maprcli table create -path '/♦=#; {}&()/'`
	To use either the **'** or the **"** character in the table name, enclose:
	• the **'** character within double quotes (")
	• the **"** character within single quote (')
	For example:
	`maprcli table create -path "/'♦=#; {}&()/" (or) maprcli table create -path '/"♦=#; {}&()/'`

Parameter	Description
copymetafrom	The path to a table that contains the metadata that should be used to create the table. • For a path on the local cluster, start the path at the volume mount point. For example, if you want to copymetadata from a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, if you want to copymetadata from a table named test under volume1 in the sanfrancisco cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`
copymetatype	The type of metadata to copy from the table identified in the `copymetafrom` parameter. You can specify one or more of the following options in a comma separated list: • `all`. Copy all metadata. This is the default. • `cfs`. Copy column family metadata. • `aces`. Copy ACE permissions. • `splits`. Copy split keys. • `attrs`. Copy table attributes.
regionsizemb	The average size of the regions into which MapR tries to split the table as the table grows. The default is 4096 MB. This value is ignored if `autosplit` is set to `false`. If `autosplit` is set to `true`, MapR splits a region when the size of the region exceeds 150% of the average value. For example, if the average value is 4096 MB, MapR splits a region that is larger than 6144 MB. Although splits are automatic, merges are not. For example, if the value of `regionsizemb` is changed from 8 GB to 4 GB, all regions that are eligible are split automatically, if `autosplit` is set to `true`. However, if the value of `regionsizemb` is changed from 2 GB to 4 GB, regions smaller than 4 GB are not automatically merged. **Note:** When a table has less than 4 regions, MapR ignores the `regionsizemb` parameter and splits regions at a lower threshold.
autosplit	A Boolean value that specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the `regionsizemb` parameter. The default value is `true`. If you set the value to `false`, you can manually split tables into regions by using the `table region split` command.

last-updated: Apr 11, 2022

Parameter	Description
bulkload	A Boolean value that specifies whether to allow a full bulk load of the table. The default is `false`. For more information, see Loading Data into Binary Tables on page 1040 and Loading Documents into JSON Tables on page 1036.
audit	Specifies whether to turn auditing on for the table. If auditing is also enabled at the cluster level with the `maprcli audit data` command and enabled for the current volume, setting this value to true causes auditing to start for the table.
tabletype	Specifies whether the table will be a binary table or a JSON table. The values are `binary` and `json`. The default is `binary`.
packperm	The *ACE* that controls who can pack table regions. By default, permission is given to the user ID that is used to create the table.
bulkloadperm	The *ACE* that controls who can load this table with bulk loads if the table was created with bulk load support. By default, permission is given to the user ID that is used to create the table.
splitmergeperm	The *ACE* that controls who can take the following actions: • Run the `table region split` and `table region merge` commands to split the table into regions or to merge regions of the table together. • Change the value of `regionsizemb`. By default, permission is given to the user ID that is used to create the table.
createrenamefamilyperm	The *ACE* that controls who can create column families for this table or rename existing column families. By default, permission is given to the user ID that is used to create the table.
deletefamilyperm	The *ACE* that defines access to delete column families for this table. Delimit the expression with single-quotation marks. By default, permission is given to the user ID that is used to create the table.
adminaccessperm	The *ACE* that controls who can view and edit the permissions for this table. By default, permission is given to the user ID that is used to create the table.
replperm	The *ACE* that controls who can set up replication either to or from a table. By default, permission is given to the user ID that is used to create the table
indexperm	The secondary index Admin permissions setting that controls who can create an index associated with this table. By default, permission is given to the user ID that is used to create the table.

Parameter	Description
defaultversionperm	The default *ACE* for the version permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `versionperm` in the `table cf create` and `table cf edit` commands overrides this value. **Note:** This permission is not applicable to JSON tables. Versioning is not supported for JSON documents.
defaultcompressionperm	**Applies to binary tables only:** The default *ACE* for the compression permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `compressionperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultmemoryperm	The default *ACE* for the memory permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `memoryperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultreadperm	The default *ACE* for the read permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `readperm` in the `table cf create` and `table cf edit` commands overrides this value. See table cf create on page 1799 and table cf edit on page 1806
defaultwriteperm	The default *ACE* for the write permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `writeperm` in the `table cf create` and `table cf edit` commands overrides this value. See table cf create on page 1799 and table cf edit on page 1806
defaulttraverseperm	**Applies to JSON tables only:** The default Access Control Expression for the traverse permission on new column families. For more information about this permission, see Permission Types for Fields and Column Families in JSON Tables on page 1462.
defaultappendperm	**Applies to binary tables only:** The default *ACE* for the append permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `appendperm` in the `table cf create` and `table cf edit` commands overrides this value.

Parameter	Description
metricsinterval	The metrics collection interval, in seconds, for the table. Possible values: 10, 60, 600 Default: 60 seconds When configured to 10 seconds, under normal workloads, the metrics are available in OpenTSDB in about 30 seconds. At an interval of 60 seconds, the metrics are available in about 90 seconds. **Note:** You cannot disable metrics collection for a table by setting the interval to 0.

Example

Creates a MapR table named `newtable` in `volume1`:

CLI	`/opt/mapr/bin/maprcli table create -path /volume1/newtable`
REST	`curl -k -X POST \ 'https://r1n1.sj.us:8443/rest/table/create?path=%2Fvolume1%2Fnewtable' \ -u mapr:mapr`

`table cf`
Manages column families for MapR Database tables.
`table cf colperm get`
Lists the Access Control Expressions (ACEs) for a specified column.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table cf colperm get
  -path <path>
  -cfname <column-family name>
  [ -name <column name> ]
  [ -json | -long ]
```

last-updated: Apr 11, 2022

REST

```
curl -k -X GET
  'http[s]://<host>:<port>/rest/
table/cf/colperm/get?
path=<path>&cfname=<name>&name=<name>'

  -u <username>:<password>
```

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
cfname	The name of the column family in which the column is located.
name	The name of the column that you want to list the ACEs for. If you do not specify the column name, the ACEs for all of the columns in the family are listed.
json	This command returns multiple levels of data. You must specify to display the output either in JSON or the "long" format to see the full set of information.
long	This command returns multiple levels of data. You must specify to display the output either in JSON or the "long" format to see the full set of information.

Example

Lists ACEs for column `col1` in table `mytable` and column family `cf1`:

CLI

```
maprcli table cf colperm get -path /
mytable -cfname cf1 -name col1 -long
```

REST

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/
rest/table/cf/colperm/get?
path=%2Fmytable&cfname=cf1&name=col1'
\
  -u mapr:mapr
```

`table cf colperm set`
Sets access control expressions (ACEs) for a specified column.

last-updated: Apr 11, 2022

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
/opt/mapr/bin/maprcli table cf
colperm set
  -path <path>
  -cfname <column-family name>
  -name <column name>
  [ -appendperm <Access Control
Expression for column appends> ]
  [ -readperm <Access Control
Expression for column reads> ]
  [ -writeperm <Access Control
Expression for column writes> ]
  [ -traverseperm <Access Control
Expression for column traversals in
JSON tables> ]
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/
table/cf/colperm/set?
path=<path>&cfname=<name>&name=<name>&
<parameters>'
  -u <username>:<password>
```

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

last-updated: Apr 11, 2022

Parameter	Description
cfname	The name of the column family in which the column is located.
name	**For binary tables:** The name of the column for which you want to set the *ACE*. **For JSON tables:** The fieldpath of the field on which you want to set permissions. For example, if you wanted to grant `readperm` to a user on field `b` in the following document. the fieldpath would be `a.b`. `{ "a" : { "b" : "value_b" } }`
appendperm	**Applies to binary tables only:** The *ACE* for column appends. Use single quotation marks around the *ACE*. Column appends require permission both at the column-family level and at the column level.
readperm	The *ACE* for column reads. Use single quotation marks around the *ACE*. Reads require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family.
writeperm	The *ACE* for column writes (puts and deletes). Use single quotation marks around the *ACE*. Writes require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family.
traverseperm	**Applies to JSON tables only:** The Access Control Expressions that specifies who has permission to pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user `sjohnson` has read permission on `a.b`, but not on `a`. For `sjohnson` to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family. By default, this permission is given to the value of defaulttraverseperm for the JSON table.

last-updated: Apr 11, 2022

Example

Sets `readperm` ACE for column `col1` in table `mytable` and column family `cf1` :

CLI

```
/opt/mapr/bin/maprcli table cf
colperm set -path /mytable -cfname
cf1 -name col1 -readperm 'g:group1'
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/
table/cf/colperm/set?
path=%2Fmytable&cfname=cf1&name=col1&r
eadperm="g:group1"' \
  -u mapr:mapr
```

`table cf colperm delete`
Deletes the Access Control Expressions (ACEs) for a specified column. Deletion cannot be undone.

Note: When a user, group, or role requests to read data from, write data to, or append data to a column, MapR Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. For example, suppose user `i_montoya` tries to write data to columns `col1` and `col2` in column family `cf1`. MapR Database checks whether `i_montoya` has write permission on `cf1` AND `col1` AND `col2`. If `i_montoya` does not have all three permissions, MapR Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, MapR Database would simply not return the data. If the user tried to read from those two columns and additional columns on which he had read permissions, the results would contain the data for those additional columns but exclude the data for `col1` and `col2`.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table cf colperm delete
  -path <path>
  -cfname <column-family name>
  -name <column name>
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/
```

```
rest/table/cf/colperm/delete?
path=<path>&cfname=<name>&name=<name>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
cfname	The name of the column family in which the column is located.
name	The name of the column that you want to delete the ACEs for.

Example

Deletes ACEs for column `col1` in table `mytable` and column family `cf1`:

CLI

```
maprcli table cf
colperm delete -path /mytable -cfname
cf1 -name col1
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/
rest/table/cf/colperm/delete?
path=%2Fmytable&cfname=cf1&name=col1'
\
  -u mapr:mapr
```

`table cf create`
Creates a column family for a HPE Ezmeral Data Fabric binary or JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

last-updated: Apr 11, 2022

- `createrenamefamilyperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
/opt/mapr/bin/maprcli table cf create
  -path <Table path >
  -cfname <Column family name >
  [ -minversions <Min versions to
keep> Default: 0 ]
  [ -maxversions <Max versions to
keep> Default: 1 ]
  [ -ttl <Time to live> Enter 0 for
forever, otherwise, enter time in
seconds. Default: 0 ]
  [ -inmemory <In-memory> Default:
false ]
  [ -compression <off|lzf|lz4|zlib>
Default: table's compression setting
is applied. ]
  [ -versionperm <Version
Permissions> ]
  [ -compressionperm <Compression
Permissions> ]
  [ -memoryperm <Memory Permissions> ]
  [ -readperm <Read Permissions> ]
  [ -writeperm <Write Permissions> ]
  [ -appendperm <Append
Permissions> ]

  [ -jsonpath Json <Family Path -
needed for JSON column family, like
a.b.c> ]
  [ -force <Force create non-default
column family for json tabletype>
Default: false ]
  [ -traverseperm <Traverse
Permissions> ]
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/
table/cf/create?
path=<path>&cfname=<name>&<parameters>
'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
cfname	The name of the column family to create.
minversions	**Applies to binary tables only:** Minimum number of versions of column values to keep. The default is zero.
maxversions	**Applies to binary tables only:** Maximum number of versions of column values to keep. The default is one.
ttl	Time to live in seconds. When the age of the data in this column family exceeds the value of the `ttl` parameter, the data is purged. Setting the value of `ttl` to 0 is equivalent to allowing data to remain indefinitely. Default: 0  **Note:** If the value of `-ttl` for an existing column family in a JSON table is not 0, you cannot add another column family. You also cannot set the TTL for a JSON table if it has secondary indexes. See Setting TTL for Data.

last-updated: Apr 11, 2022

Parameter	Description
inmemory	Boolean. Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if its `inmemory` parameter is set to `false`, but preference will be given to column families where this parameter is set to `true`. A column family can have more than 32 bytes stored inline if its `inmemory` parameter is set to `true`. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have the `inmemory` parameter set to `true`. **Note:** All of the data for a column family are either stored in-line with the row key, or not stored at all. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, then data is not stored in-line for that column family. The default value for the `inmemory` parameter is `false`.
compression	The compression setting to use for the column family. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is equal to the compression setting for the directory in which the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 990.
versionperm	**Applies to binary tables only:** *ACE* for changing the value of the `maxversions` and `minversions` parameters. By default, permission is given to the value of `defaultversionperm` for the table.
compressionperm	**Applies to binary tables only:** *ACE* for changing the value of the `compression` parameter. By default, permission is given to the value of `defaultcompressionperm` for the table.
memoryperm	The *ACE* for changing the value of the `inmemory` parameter. Use single quotation marks around the *ACE*. By default, permission is given to the value of `defaultmemoryperm` for the table.

Parameter	Description
readperm	The *ACE* for column reads. Use single quotation marks around the *ACE*. Reads require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family. By default, permission is given to the value of `defaultreadperm` for the table.
writeperm	The *ACE* for column writes (puts and deletes). Use single quotation marks around the *ACE*. Writes require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family. By default, permission is given to the value of `defaultwriteperm` for the table.
appendperm	**Applies to binary tables only:** The *ACE* for column appends. Use single quotation marks around the *ACE*. Column appends require permission both at the column-family level and at the column level. By default, permission is given to the value of `defaultappendperm` for the table.
jsonpath	**Applies to JSON tables only:** Specifies the path to the column family. The path is in dotted notation. For example, suppose the table contained JSON documents that were of this general structure: `{ "_id" : "ID", "a" : { "b" : { "c" : "value", }, "e" : "value" } }` You want to create a column family at the field `d` in the new path `a.b.d` because you plan to store image files in fields in that column family. **Important:** Ensure that the field at which you want to create the column family does not yet exist. Also ensure that there are no secondary indexes defined on the field. If the field does exist or is a field in an index, the data in the field could become inaccessible after you create the column family. **Restriction:** As of MapR 6.0, a column family cannot be deleted from a JSON table.

last-updated: Apr 11, 2022

Parameter	Description
force	**Applies to JSON tables only:** By default, every time you try to create a non-default column family in a JSON table, this command fails and returns a warning message that you should ensure there is no existing data at the specified path. Set this parameter to true if you want to override this warning mechanism and create a column family.
traverseperm	**Applies to JSON tables only:** The Access Control Expressions that specifies who has permission to pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user `sjohnson` has read permission on `a.b`, but not on `a`. For `sjohnson` to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family. By default, this permission is given to the value of defaulttraverseperm for the JSON table.

Note: If a field is specified as a column family JSON path name, that field cannot be defined as either an indexed or included field when creating an index. For example, suppose you have the following JSON table:

```
{
    "_id" : "ID",
    "a" :
        {
            "b" :
                {
                    "c" : "value",
                    "d" : "value"
                },
            "e" : "value"
        }
}
```

If you created a column family at field `c` in the JSON path `a.b.c`, when creating an index, field `a.b.c` cannot be defined as an indexed or included field. However, you can define, as either an indexed or included field, fields `a`, `a.b`, `a.b.d`.

Example

Creates a new column family `mynewcf` for table `mytable`, keeping four versions in memory:

last-updated: Apr 11, 2022

CLI

```
/opt/mapr/bin/maprcli table cf
create -path /volume1/mytable -cfname
mynewcf \
  -maxversions 4 -inmemory true
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/
table/cf/create?
path=%2Fvolume1%2Fmytable&cfname=mynew
cf&maxversions=4&inmemory=true' \
  -u mapr:mapr
```

`table cf delete`
Deletes a column family from a MapR Database binary table or JSON table. Deletion cannot be undone.

Important: As of MapR 6.0, a column family cannot be deleted from a JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `deletefamilyperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table cf delete
  -path <path>
  -cfname <name>
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/cf/delete?
path=<path>&cfname=<name>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
cfname	The name of the column family to delete. **Note:** In JSON tables, it is not possible to delete column families in addition to the default column family.

Example

Deletes a column family `mycf` from table `thetable`:

CLI

```
maprcli table cf delete -path /
volume1/thetable -cfname mycf
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/
table/cf/delete?
path=%2Fvolume1%2Fthetable&cfname=mycf
' \
  -u mapr:mapr
```

`table cf edit`
Edits a column family in a binary table or JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
/opt/mapr/bin/maprcli table cf edit
  -path <Table path >
  -cfname <Column family name>
  [ -newcfname <New column family
name> ]
  [ -minversions <Min versions to
keep> ]
  [ -maxversions <Max versions to
keep> ]
  [ -ttl <Time to live> Enter 0 for
forever, otherwise, enter time in
seconds. Default: 0 ]
  [ -inmemory <In-memory> ]
  [ -compression <off|lzf|lz4|zlib> ]
  [ -versionperm <Version
Permissions> ]
  [ -compressionperm <Compression
Permissions> ]
  [ -memoryperm <Memory Permissions> ]
  [ -readperm <Read Permissions> ]
  [ -writeperm <Write Permissions> ]
  [ -appendperm <Append Permissions> ]
  [ -traverseperm <Traverse
Permissions> ]
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/
table/cf/edit?
path=<path>&cfname=<name>&<parameters>
'
  -u mapr:mapr
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
cfname	The name of the column family to edit.

last-updated: Apr 11, 2022

Parameter	Description
newcfname	The new name to give to the column family.
minversions	**Applies to binary tables only:** Minimum number of versions of column values to keep. The default is zero.
maxversions	**Applies to binary tables only:** Maximum number of versions of column values to keep. The default is one.
ttl	Time to live in seconds. When the age of the data in this column family exceeds the value of the `ttl` parameter, the data is purged. Setting the value of `ttl` to 0 is equivalent to allowing data to remain indefinitely. Default: 0 **Note:** If the value of `-ttl` for an existing column family in a JSON table is not 0, you cannot add another column family. You also cannot set the TTL for a JSON table if it has secondary indexes. See Setting TTL for Data.
inmemory	Boolean. Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if its `inmemory` parameter is set to `false`, but preference will be given to column families where this parameter is set to `true`. A column family can have more than 32 bytes stored inline if its `inmemory` parameter is set to `true`. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have the `inmemory` parameter set to `true`. **Note:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data at all will be stored in-line for that column family. The default value for the `inmemory` parameter is `false`.
compression	The compression setting to use for the column family. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is equal to the compression setting for the directory in which the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 990.
versionperm	**Applies to binary tables only:** *ACE* for changing the value of the `maxversions` and `minversions` parameters. By default, permission is given to the value of `defaultversionperm` for the table.

last-updated: Apr 11, 2022

Parameter	Description
compressionperm	**Applies to binary tables only:** *ACE* for changing the value of the `compression` parameter. By default, permission is given to the value of `defaultcompressionperm` for the table.
memoryperm	*ACE* for changing the value of the `inmemory` parameter. Use single quotation marks around the *ACE*. By default, permission is given to the value of `defaultmemoryperm` for the table.
readperm	The *ACE* for column reads. Use single quotation marks around the *ACE*. Reads require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family. By default, permission is given to the value of `defaultreadperm` for the table.
writeperm	The *ACE* for column writes (puts and deletes). Use single quotation marks around the *ACE*. Writes require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family. By default, permission is given to the value of `defaultwriteperm` for the table.
appendperm	**Applies to binary tables only:** *ACE* for column appends. Use single quotation marks around the *ACE*. Column appends require permission both at the column-family level and at the column level. By default, permission is given to the value of `defaultappendperm` for the table.
traverseperm	**Applies to JSON tables only:** The Access Control Expressions that specifies who has permission to pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user `sjohnson` has read permission on `a.b`, but not on `a`. For `sjohnson` to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family. By default, this permission is given to the value of defaulttraverseperm for the JSON table.

last-updated: Apr 11, 2022

Note: If a field is specified as a column family JSON path name, that field cannot be defined as either an indexed or included field when creating an index. For example, suppose you have the following JSON table:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                   {
                       "c" : "value",
                       "d" : "value"
                   },
               "e" : "value"
          }
}
```

If you created a column family at field c in the JSON path `a.b.c`, when creating an index, field `a.b.c` cannot be defined as an indexed or included field. However, you can define, as either an indexed or included field, fields `a`, `a.b`, `a.b.d`.

Example

Changes the name of a column family in table `mytable` from `mycf` to `mynewcfname`. Also changes the time to live setting.

CLI

```
/opt/mapr/bin/maprcli table
cf edit -path /my.cluster.com/volume1/
mytable -cfname mycf \
  -newcfname mynewcfname -ttl 86400
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/
table/cf/edit?
path=%2Fmy.cluster.com%2Fvolume1%2Fmyt
able&cfname=mycf&newcfname=mynewcfname
&ttl=86400' \
  -u mapr:mapr
```

`table cf list`
Lists the column families for a MapR table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli table cf list
  -path <path>
  [ -cfname <name>]
```

REST

```
curl -k -X GET \
  'http[s]://<host>:<port>/rest/
table/cf/list? \
   path=<path>&cfname=<name>' \
  -u <username>:<password>
```

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
cfname	The name of the column family.
showcol	Set to `false` by default. If set to `true`, then all column-level attributes for this column family are displayed.

Output Fields

Verbose Field Name	Terse Field Name	Field Value
inmemory	inmem	Whether or not this column value resides in memory
cfname	n	The column family name
maxversions	vmax	Maximum number of versions for this column family
minversions	vmin	Minimum number of versions for this column family
compression	comp	Compression scheme used for this column family
ttl	ttl	Time to live for this column family

last-updated: Apr 11, 2022

Verbose Field Name	Terse Field Name	Field Value
compressionperm	pcomp	**Applies to binary tables only:** *ACE* for changing the value of the `compression` parameter. By default, permission is given to the value of `defaultcompressionperm` for the table.
memoryperm	pmem	*ACE* for changing the value of the `inmemory` parameter. Use single quotation marks around the *ACE*. By default, permission is given to the value of `defaultmemoryperm` for the table.
readperm	pread	The *ACE* for column reads. Use single quotation marks around the *ACE*. Reads require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family. By default, permission is given to the value of `defaultreadperm` for the table.
traverseperm	ptraverse	**Applies to JSON tables only:** The Access Control Expressions that specifies who has permission to pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user `sjohnson` has read permission on `a.b`, but not on `a`. For `sjohnson` to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family. By default, this permission is given to the value of defaulttraverseperm for the JSON table.

Verbose Field Name	Terse Field Name	Field Value
writeperm	pwrite	The *ACE* for column writes (puts and deletes). Use single quotation marks around the *ACE*. Writes require permission both at the column-family level and at the column level (for binary tables) or field level (for JSON tables). In JSON tables, this permission is inherited by fields within the column family. By default, permission is given to the value of `defaultwriteperm` for the table.

Example

This example lists all column families for the table `newtable`.

CLI

```
maprcli table cf list -path /
my.cluster.com/volume1/newtable
```

REST

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/rest/
table/cf/list?
path=%2Fmy.cluster.com%2Fvolume1%2Fnew
table' \
  -u mapr:mapr
```

Example Output

```
[user@node]# maprcli table cf list -path /mapr/default/user/user/newtable
comp  inmem  vmax  n           ttl         vmin
lz4   false  3     dine        2147483647  0
lz4   false  3     nahashchid  2147483647  0
lz4   false  3     wollachee   2147483647  0
```

table changelog

These maprcli commands are used to create and manage Change Data Capture (CDC) changelogs. A changelog is used to establish a relationship between a MapR Database source table (JSON or binary) and a MapR Event Store For Apache Kafka stream topic and to manage the propagation process.
table changelog add

Description

Creates a changelog and creates a stream topic if one does not already exist. A changelog establishes a relationship between a MapR Database source table (JSON or binary) and a MapR Event Store For Apache Kafka stream topic.

Syntax

Table

CLI	`maprcli table changelog add -path <source table path> -changelog <destination stream path>:<topic name>`

last-updated: Apr 11, 2022

Table (Continued)

REST	`http://<ipaddress>:8443/rest/table/changelog/add?path=<source-table-path>&changelog=<destination stream path>:<topic name>`

Parameters

Table

Parameter	Description
path	(Required) Path of the source table.
changelog	(Required) Target of the change log, specified as <stream_path>:<topic_name>, to which all change data records will be published. The stream must exist, otherwise, the command fails. If the topic does not already exist, `maprcli table changelog add` creates it. To propagate to an existing topic, specify `-useexistingtopic`. **Note:** The `maprcli stream create` command is used to create the changelog stream. **Important:** A CDC changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change. When using the `table changelog add` command to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.
useexistingtopic	If true, allows propagation to an existing topic. Default: false.
propagateexistingdata	If true, initiates propagation of the existing data to the stream topic, otherwise, only new changes are propagated. Default: true
columns	For MapR Database JSON, a comma separated list of field paths to be propagated. For MapR Database Binary, a comma separated list of column family names, for example, <family>[:<column>] to be propagated. Default: All fields are propagated.
throttle	If true, data transfers to the specified sink are throttled. Default: false
pause	If true, pauses propagation after the changlog is created. Default: false
synchronous	If true, acknowledges the client writes to the table before the internal CDC gateway receives the data. Default: false
networkencryption	Specifies whether the data transfer between MapR filesystem and the internal gateway is encrypted. If true, data propagation is encrypted on-wire. Default: false
networkcompression	Specifies the compression scheme (off|lzf|lz4|zlib) of the data transfer on-wire. Default: lz4

Example

```
maprcli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1
```

```
https://ip.address:8443/rest/table/changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1
```

table changelog edit

Description

Changes changelog specifications.

Syntax

Table

CLI	`maprcli table changelog edit -path <source table path> -changelog <destination stream path>:<topic name>`
REST	`http://<ipaddress>:8443/rest/table/changelog/edit?path=<source-table-path>&changelog=<destination-stream-path>:<topic-name>`

Parameters

Table

Parameters	Description
path	(Required) Path of the MapR Database source table
changelog	(Required) Target of this changelog.
throttle	If true, data propation is throttled. Default: false
synchronous	If true, acknowledges the client writes to the table before the internal CDC gateway receives the data. Default: false
networkencryption	If true, data propagation is encrypted on-wire. Default: false
networkcompression	Specifies the compression scheme (off|lzf|lz4|zlib) of the data propagation on-wire. Default: lz4

Example

```
maprcli table changelog edit -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1
```

```
https://10.10.100.17:8443/rest/table/changelog/edit?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1
```

table changelog info

Description

Displays changelog source table information.

Syntax

Table

CLI	`maprcli table changelog info -path <destination stream path>:<topic name>`
REST	`http://<ipaddress>:8443/rest/table/changelog/info?path=<destination stream path>:<topic name>`

Parameters

Table

Parameters	Description
path	(Required) Path to the stream with topic. Specified in the format: `pathToStream:streamTopic`

Example

```
maprcli table changelog info -changelog  /streamVolume/
changelogStream:cdcTopic1 -json
https://10.10.100.17:8443/rest/table/changelog/info?changelog=/streamVolume/
changelogStream:cdcTopic1
```

Output

```
{
"timestamp":1498526974087,
"timeofday":"2017-06-26 06:29:34.087 GMT-0700",
"status":"OK",
"total":1,
"data":[
{
"cluster":"clst185",
"changelog":"/streamVolume/changelogStream/cdcTopic1",
"idx":0,
"uuid":"59bf0064-97a1-c417-b6d7-0a6681515900"
}
]
}
```

table changelog list

Description

Lists changelog information.

Syntax

Table

CLI	`maprcli table changelog list -path <source table path>`
REST	`http://<ipaddress>:8443/rest/table/changelog/list?path=<source-table-path>`

Parameters

Table

Parameters	Description
path	(Required) Path of the source table in the MapR Database cluster.
refreshnow	Specifies if the user wants to trigger an immediate update of the sink statistics.

Example

```
// CLI example
maprcli table changelog list -path /tableVolume/cdcTable -json

// REST example
https://10.10.100.17:8443/rest/table/changelog/list?path=/tableVolume/
cdcTable
```

Output

```
{
    "timestamp":1505779365019,
    "timeofday":"2017-09-18 05:02:45.019 GMT-0700",
    "status":"OK",
    "total":1,
    "data":[
        {
            "cluster":"my.cluster.com",
            "changelog":"/streamVolume/changelogStream:cdcTopic1",
            "changelogStream":"/streamVolume/changelogStream",
            "replicaState":"REPLICA_STATE_REPLICATING",
            "paused":false,
            "throttle":false,
            "idx":1,
            "networkencryption":false,
            "synchronous":false,
            "networkcompression":"lz4",
            "propagateExistingData":true,
            "isUptodate":true,
            "minPendingTS":0,
            "maxPendingTS":0,
            "bytesPending":0,
            "putsPending":0,
            "bucketsPending":0,
            "uuid":"76a3efd3-6357-8cd6-092f-0fca5dc05900",
            "copyTableCompletionPercentage":100
        }
```

last-updated: Apr 11, 2022

```
    ]
}
```

Output Data Fields

The following fields display for each replica.

Field	Description
cluster	The cluster on which the replica resides.
changelog	Identifies the destination stream topic for the changelog.
changelogstream	Identifies the destination stream for the changelog.
replicaState	The replication state. For information about the replication states, see Table Replication States on page 625.
paused	A Boolean values that specifies if replication is paused.
throttle	A Boolean value that specifies if replication is throttled.
idx	The internal index value.
networkencryption	A Boolean value that specifies if replication is encrypted.
synchronous	A Boolean value that specifies whether replication is synchronous or asynchronous.
networkcompression	The type of on-wire compression.
propagateExistingData	Identifies whether existing data in the source table is propagated to the destination stream topic.
isUptodate	A Boolean value that specifies if the replica is up-to-date.
minPendingTS	The epoch time in milliseconds of the oldest operation that has yet to be replicated to the replica.
maxPendingTS	The epoch time in milliseconds of the newest operation that has yet to be replicated to the replica.
bytesPending	The number of bytes that have yet to be replicated to the replica.
putsPending	The number of puts that have yet to be replicated to the replica.
bucketsPending	The number of buckets that have yet to be replicated to the replica.
uuid	The table UUID.
copyTableCompletionPercentage	When propagation of existing data is in progress, this value is the percentage of data from the source table that has been propagated to the destination stream topic. **Note:** When replicating MapR Database data, the copyTablePercentageCompletion data may re-adjust to a lower rate. This depends on table region (also referred to as tablets) splits and merges as well as the rate of incoming data to replicating data.
errors	If applicable, an error is displayed.

table changelog pause

last-updated: Apr 11, 2022

Description

Pauses the propagation of changed data records.

Syntax

Table

CLI	`maprcli table changelog pause -path <source table path> -changelog <destination stream path>:<topic name>`
REST	`http://<ipaddress>:8443/rest/table/changelog/pause?path=<source-table-path>&changelog=<destination stream path>:<topic_name>`

Parameters

Table

Parameters	Description
path	(Required) Path of the MapR Database source table
changelog	(Required) Target of this change log.

Example

```
maprcli table changelog pause -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1
```

```
https://10.10.100.17:8443/rest/table/changelog/pause?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1
```

table changelog remove

Description

Removes the changelog connection.

Syntax

Table

CLI	`maprcli table changelog remove -path <source table path> -changelog <destination stream path>:<topic name>`
REST	`http://<ipaddress>:8443/rest/table/changelog/remove?path=<source-table-path>&changelog=<destination stream path>:<topic_name>`

last-updated: Apr 11, 2022

Parameters

Table

Parameters	Description
path	(Required) Path of the source table in the MapR Database cluster.
changelog	(Required) Target of the change log.

Example

```
maprcli table changelog remove -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1
```

```
https://10.10.100.17:8443/rest/table/changelog/remove?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1
```

table changelog resume

Description

Resumes the propagation of changed data records after a pause.

Syntax

Table

CLI	`maprcli table changelog resume -path <source table path> -changelog <destination stream path>:<topic name>`
REST	`http://<ipaddress>:8443/rest/table/changelog/resume?path=<source-table-path>&changelog=<destination stream path>:<topic_name>`

Parameters

Table

Parameters	Description
path	(Required) Path of the MapR Database source table
changelog	(Required) Target of this change log.

Example

```
maprcli table changelog resume -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1
```

```
https://10.10.100.17:8443/rest/table/changelog/resume?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1
```

`table delete`
Deletes a MapR Database binary or JSON table.

last-updated: Apr 11, 2022

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table delete -path <path>
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/table/
delete?path=<path>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
`path`	Path to the MapR table to delete. • For a path on the local cluster, start the path at the volume mount point. For example, if you want to delete a table named `test` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, if you want to delete a table named `customer` under volume1 in the sanfrancisco cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Example

Deletes the table `table`:

CLI

```
maprcli table delete -path /mapr/
mycluster/volume1/table
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
delete?
```

last-updated: Apr 11, 2022

```
path=%2Fmapr%2Fmycluster%2Fvolume1%2Ft
able' \
  -u mapr:mapr
```

`table edit`

Edits the attributes of a MapR Database binary or JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table edit
  -path <path >
  [ -audit true|false ]
  [ -autosplit <Auto Split table> ]
  [ -regionsizemb <Region Size in
MB> ]
  [ -bulkload <Bulk load> ]
  [ -deletettl <delete TTL in secs> ]
  [ -packperm <Pack Permission
settings> ]
  [ -bulkloadperm <Bulk load
Permission settings> ]
  [ -splitmergeperm <Split and Merge
Permission settings>]
  [ -createrenamefamilyperm <Add/
Rename Family Permission settings> ]
  [ -deletefamilyperm <Delete Family
Permission settings> ]
  [ -adminaccessperm <Secondary Index
Admin Permission settings> ]
  [ -replperm <Replication Admin
Permission settings> ]
  [ -indexperm <Ace Admin Permission
settings> ]
  [ -defaultversionperm <CF Versions
Default Permission> ]
  [ -defaultcompressionperm <CF
Compression Default Permission> ]
  [ -defaultmemoryperm <CF Memory
Default Permission> ]
  [ -defaultreadperm <CF Read Default
Permission> ]
  [ -defaultwriteperm <CF Write
Default Permission> ]
  [ -defaulttraverseperm <CF Traverse
Default Permission> ]
```

```
  [ -defaultappendperm <CF Append
Default Permission> ]

  [ -metricsinterval <Metrics
collection interval, in seconds> ]
```

REST

```
curl -k -X POST \
  'http[s]://<host>:<port>/rest/table/
edit?path=<path>&<parameters>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named test under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
audit	Specifies whether to turn auditing on for the table. If auditing is also enabled at the cluster level with the `maprcli audit data` command and enabled for the current volume, setting this value to true causes auditing to start for the table. The possible values are `true` and `false`. By default, the value is `false`.
autosplit	A Boolean value that specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the `regionsizemb` parameter. The default value is `true`. If you set the value to `false`, you can manually split tables into regions by using the `table region split` command.

last-updated: Apr 11, 2022

Parameter	Description
regionsizemb	The average size of the regions into which MapR Database tries to split the table as the table grows. The default is 4096 MB. This value is ignored if `autosplit` is set to `false`. If `autosplit` is set to `true`, MapR Database splits a region when the size of the region exceeds **150%** of the average value. For example, if the average value is 4096 MB, MapR Database splits a region that is larger than 6144 MB. Although splits are automatic, merges are not. For example, if the value of `regionsizemb` is changed from 8 GB to 4 GB, all regions that are eligible are split automatically, if `autosplit` is set to `true`. However, if the value of `regionsizemb` is changed from 2 GB to 4 GB, regions smaller than 4 GB are not automatically merged. **Note:** When a table has less than 4 regions, MapR Database ignores the `regionsizemb` parameter and splits regions at a lower threshold.
bulkload	A Boolean value that specifies whether to allow a full bulk load of the table. The default is `false`. For more information, see Loading Data into Binary Tables on page 1040 and Loading Documents into JSON Tables on page 1036.
deletettl	The number of seconds to wait before purging the delete operations. The time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours for tables configured for replication. If the table is not configured for replication, the default is 0 hours.
packperm	The Access Control Expression that controls who can pack table regions. By default, permission is given to the user ID that was used to create the table.
bulkloadperm	The Access Control Expression that controls who can load this table with bulk loads if the table was created with bulk load support. By default, permission is given to the user ID that was used to create the table.
splitmergeperm	The Access Control Expression that controls who can take the following actions: • Run the `table region split` and `table region merge` commands to split the table into regions or to merge regions of the table together. • Change the value of `regionsizemb`. By default, permission is given to the user ID that was used to create the table.
createrenamefamilyperm	The Access Control Expression that controls who can create column families for this table or rename existing column families. By default, permission is given to the user ID that was used to create the table.

Parameter	Description
deletefamilyperm	The Access Control Expression that defines access to delete column families for this table. Delimit the expression with single-quotation marks. By default, permission is given to the user ID that was used to create the table.
adminaccessperm	The Access Control Expression that controls who can view and edit the permissions for this table. By default, permission is given to the user ID that was used to create the table.
replperm	The Access Control Expression that controls who can set up replication either to or from a table. By default, permission is given to the user ID that is used to create the table.
indexperm	The secondary index admin permission setting that controls who can create an index associated with this table. By default, permission is given to the user ID that is used to create the table.
defaultversionperm	The default Access Control Expression for the version permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `versionperm` in the `table cf create` and `table cf edit` commands overrides this value. **Note:** This permission is not applicable to JSON tables. Versioning is not supported for JSON documents.
defaultcompressionperm	**Applies to binary tables only:** The default Access Control Expression for the compression permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `compressionperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultmemoryperm	The default Access Control Expression for the memory permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `memoryperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultreadperm	The default Access Control Expression for the read permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `readperm` in the `table cf create` and `table cf edit` commands overrides this value. See table cf create on page 1799 and table cf edit on page 1806

last-updated: Apr 11, 2022

Parameter	Description
defaultwriteperm	The default Access Control Expression for the write permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `writeperm` in the `table cf create` and `table cf edit` commands overrides this value. See table cf create on page 1799 and table cf edit on page 1806
defaulttraverseperm	**Applies to JSON tables only:** The default Access Control Expression for the traverse permission on new column families. For more information about this permission, see Permission Types for Fields and Column Families in JSON Tables on page 1462.
defaultappendperm	**Applies to binary tables only:** The default Access Control Expression for the append permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `appendperm` in the `table cf create` and `table cf edit` commands overrides this value.
metricsinterval	The metrics collection interval, in seconds, for the table. Possible values: 10, 60, 600 Default: 60 seconds When configured to 10 seconds, under normal workloads, the metrics are available in OpenTSDB in about 30 seconds. At an interval of 60 seconds, the metrics are available in about 90 seconds. **Note:** You cannot disable metrics collection for a table by setting the interval to 0.

Example

Changes the value of `regionsizemb` for the table `mytable`:

CLI

```
maprcli table edit -path /volume1/
mytable -regionsizemb 8192
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
edit?
path=%2Fvolume1%2Fmytable&regionsizemb
=8192' \
  -u mapr:mapr
```

table index

Manages indexes for MapR Database JSON tables.

Permissions Required

To run this command, your user ID must have the following permissions:

- readAce on the volume

- lookupdir on directories in the table path

Note: The mapr user is not treated as a superuser. MapR Database does not allow the mapr user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

table index add
This topic describes how to add secondary indexes on MapR Database JSON tables.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table

If you created the table in version 6.0 or later, you automatically have `indexperm` permission. For tables created before 6.0, even if you are the owner of the table, you must explicitly add `indexperm` permission.

Note: The mapr user is not treated as a superuser. MapR Database does not allow the mapr user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table index add
  -path <path>
  -index <index name>
  -indexedfields < indexed field
names >
  [ -includedfields < included field
names > ]
  [ -hashed [ enable hashed index:
true | false> ]
  [ -numhashpartitions < number of
hash index partitions when hashed
index is enabled > ]
```

REST

```
curl -k -X POST \
  'http[s]://<host>:<port>/rest/table/
index/add?path=<path>&index=<index
name>&indexedfields=<indexed field
names>&<parameters>' \
  -u <username>:<password>
```

Parameters

Parameter	Description
path	(Required) Path to where the parent JSON table resides.
index	(Required) Name of the index.

last-updated: Apr 11, 2022

Parameter	Description

indexedfields	(Required) Names of the indexed fields. This is a comma separated list of the fields from the JSON table that are indexed and used for ordering the index. The sort ordering of each field can be specified separately. The syntax is as follows:
	`-indexedfields <fieldname>:<sort_order>,<fieldname>:<sort_order>,...`
	Important: Do not place a space between the commas and the field names.
	A sort_order of `asc`, `ASC`, or `1` denotes an ascending sort order. This is the default.
	A sort _order of `desc`, `DESC`, or `-1` denotes a descending sort order.
	The following example specifies two indexed fields. `fieldName1` has an ascending sort, while `fieldName2` is descending.
	`-indexedfields fieldName1:asc,fieldName2:desc`
	If an indexed field contains a colon (:) in the name, you need to escape the last colon in the name. In the example below, the indexed field names are the following:
	1. `field1`
	2. `field2`
	3. `colonField:X:Y`
	The following shows how to escape the last colon in the third indexed field.
	`-indexedfields field1,field2,colonField:X\\:Y`
	Note: The CAST function can be applied on indexed fields. You must enclose each CAST function call in single quotes. See the next section for details.

includedfields	(Optional) Names of the included fields. This is a comma separated list of the fields from the JSON table that are part of the index, but not used for ordering. The syntax is as follows: `-includedfields <fieldname>,<fieldname>,...` **Important:** Do not place a space between the commas and the included field names.
hashed	(Optional) True | False. Default: false

Parameter	Description
numhashpartitions	(Optional) Number of hash index partitions when the hashed index option is enabled. This parameter determines the number of logical partitions MapR Database distributes keys across. Incoming keys are hashed to 2 byte partition IDs. Default: 10

Applying CAST on Indexed Fields

Indexes can be defined with the CAST function applied to an indexed field.

The following statement queries a table named `lineitem` and casts the `L_LINENUMBER` and `L_ORDERKEY` fields to the `int` data type.

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE CAST(L_LINENUMBER as
int) = 1 AND CAST(L_ORDERKEY as int) = 550;
```

To optimize the previous statement, you can create an index on the `L_LINENUMBER` and `L_ORDERKEY` fields, and use the CAST function to map each field to a specific data type, as shown below:

```
maprcli table index add \
  -path /drill/testdata/qa/sf1/maprdb/json/lineitem \
  -index l_cast_comp_1 -indexedfields
'$CAST(L_LINENUMBER@INT)','$CAST(L_ORDERKEY@INT)' \
  -includedfields L_LINESTATUS,L_QUANTITY
```

The index stores the values of the `L_LINENUMBER` and `L_ORDERKEY` fields as the `int` data type. MapR Database can use the index for any subsequent queries that cast these fields to `int` instead of accessing data in the primary table and converting the values to `int`.

See Using Casts in Secondary Indexes on page 557 for more information.

Restrictions

The following restrictions apply to creating indexes.

Name Restrictions

You cannot use the following characters in the index name and in the indexed fields:

```
< > ? % \
```

To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  "♥,"♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "●timestamp":desc,"●
```

last-updated: Apr 11, 2022

```
●,"LOTNo" -includedfields \
  '●,'●=#;{}&()/'
```

To use either the ' or the " character in the index name and in the indexed fields, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"'MYTABLE1_ANALYSIS_1●=#;{}&()/" \
  -indexedfields "_●timestamp":desc,"●●
●,"LOTNo" -includedfields \
  "●","●=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'"MYTABLE1_ANALYSIS_1●=#;{}&()/' \
  -indexedfields "'_●timestamp":desc,"●
●,"LOTNo" -includedfields \
  '●','●=#;{}&()/"
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

  For example, you cannot create an index with the following indexed fields:

  ```
  a.b[].c, a.b.d
  ```

  Although subfield b appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

  See Composite Indexes and Container Field Paths on page 554 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

  If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (`INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG`).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.

- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:
  - The indexed field is a container field path:

    ```
    maprcli table index add -path /
    people \
       -index phoneNumberIdx \
       -indexedfields
    Phones[].Number \
       -includedfields
    Phones[].Number
    ```

  - The field specifies a cast to another type.

    You can create an index in which the `score` field is an indexed field cast as a `double` type, and `score` is also an included field. The included field retains the original data type of the `score` field:

    ```
    maprcli table index add -path /
    castTable \
       -index castIdx1 \
       -indexedfields
    '$CAST(score@DOUBLE)' \
       -includedFields score
    ```

    You can create an index in which the `score` field is an indexed field, cast as a `double` type, and the `score` field is also another indexed field, cast as a `long` type:

    ```
    maprcli table index add -path /
    castTable \
       -index castIdx2 \
       -indexedfields
    '$CAST(score@DOUBLE)','$CAST(scor
    e@LONG)'
    ```

- You cannot use casts with included fields.

- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

  For example, suppose you have the following JSON table:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" :
"value",
                         "d" :
"value"
                    },
               "e" : "value"
          }
}
```

  If you create a column family at field `c` in the JSON path `a.b.c`, you cannot define field `a.b.c` as either an indexed or included field. You can define the fields `a`, `a.b`, and `a.b.d` as either indexed or included fields.

last-updated: Apr 11, 2022

- You cannot specify an included field in which the data in the field spans more than one column family.

  In the following example, the included field `sl1.sl2` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm  readperm
traverseperm  jsonfamilypath
writeperm  minversions
maxversions  compression
ttl         inmemory  cfname
memoryperm
u:root           u:root
u:root
u:root     0
1            lz4
2147483647  false     default
u:root
u:root           u:root
u:root         sl1
u:root     0
1            lz4
2147483647  false     cf1
u:root
u:root           u:root
u:root         sl1.sl2.sl3
u:root     0
1            lz4
2147483647  false     cf2
u:root
u:root           u:root
u:root         sl1.sl2.sl3.sl4
u:root     0
1            lz4
2147483647  false     cf3
u:root

maprcli table index add -path /
cftab -index i1 -indexedfields
sl1.sl2.sl3.sl4.l4a,
sl1.l1a -includedfields
sl1.sl2,sl1.sl2.sl3.sl4.sl5.l5b -js
on
{
        "timestamp":1507419777919,
        "timeofday":"2017-10-07
04:42:57.919 GMT-0700 PM",
        "status":"ERROR",
        "errors":[
                {
                        "id":22,

"desc":"Data for included field
sl1.sl2 may not span more than one
column family."
                }
         ]
}
```

last-updated: Apr 11, 2022

- You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same.

  See Composite Indexes and Container Field Paths on page 554 for more details.

- You cannot specify a composite index with an indexed field that is a subfield of another indexed field.

  For example, you cannot create an index with the following indexed fields:

  ```
  a, a.b
  ```

  The indexed field `a.b` is a subfield of the indexed field `a`.

Option Restrictions

- As indexes are automatically split, you cannot disable splits when you create your index.

Index Use Restrictions

- Indexes do not optimize non-existence filter conditions.

Example

CLI

```
maprcli table index
add -path /demo/business -index
newIndex -indexedfields fieldName
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
index/add?
path=%2Fdemo%2Fbusiness&index=newIndex
&indexedfields=fieldName' \
  -u mapr:mapr
```

table index list

This topic describes how to list information about the secondary indexes created on MapR Database JSON tables.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the table path

Note: The mapr user is not treated as a superuser. MapR Database does not allow the mapr user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli table index list
  -path <path>
  [ -indexname <index name> ]
  [ -refreshnow < true | false > ]
```

REST

```
curl -k -X GET
  'http[s]://<host>:<port>/rest/table/
index/list?path=<path>&<parameters>'
  -u <username>:<password>
```

Parameters

Parameter	Description
path	(Required) Path to where the parent JSON table resides
indexname	(Optional) Name of the index for which to display information. If omitted, the output includes all indexes created on the table.
refreshnow	(Optional) Whether to fetch the current status of the index Default: False

Example

CLI

```
maprcli table index list -path /
my.cluster.com/volume1/table1
```

```
maprcli table index list -path /demo/
business -json
```

REST

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/rest/table/
index/list?
path=%my.cluster.com%2Fvolume1%2Ftable
1' \
  -u mapr:mapr
```

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/rest/table/
index/list?path=%2Fdemo%2Fbusiness' \
  -u mapr:mapr
```

Output Fields

Output Field	Description
cluster	The cluster on which the index resides
type	For indexes, this is always `maprdb.si`

last-updated: Apr 11, 2022

Output Field	Description
indexFid	A unique id used to identify the index in MapR File System
indexName	Name of the index
hashed	A boolean value that specifies whether the index is hashed
indexState	The replication state of the index. For information about the replication states, see Table Replication States on page 625.
idx	The index id. Unique per table.
indexedFields	The list of indexed fields with the sort order of each key
includedFields	The list of included fields in the index. Missing from output if there are no included fields.
isUptodate	A boolean value that specifies if the index is up-to-date
minPendingTS	The epoch time in milliseconds of the oldest operation that has yet to be replicated to the index
maxPendingTS	The epoch time in milliseconds of the newest operation that has yet to be replicated to the index
bytesPending	The number of bytes that have yet to be replicated to the index
putsPending	The number of puts that have yet to be replicated to the index
bucketsPending	The number of buckets that have yet to be replicated to the index
copyTableCompletionPercentage	The percentage of data from the source that has been copied to the index during the setup phase of replication. After replication setup completes, the value remains at 100. **Note:** When replicating data to the index, the `copyTableCompletionPercentage` value may decrease. This happens when splits or merges occur in the JSON table's regions, or the table receives new data.
numTablets	The number of tablets the index occupies
numRows	The number of rows in the index
totalSize	The total size of the index

Example Output

```
maprcli table index list -path /demo/business -json -indexname i1
{
        "timestamp":1506617667735,
        "timeofday":"2017-09-28 04:54:27.735 GMT+0000 PM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "cluster":"my.cluster.com",
                        "type":"maprdb.si",
                        "indexFid":"2049.93.10257820",
```

last-updated: Apr 11, 2022

```
                        "indexName":"i1",
                        "hashed":false,
                        "indexState":"REPLICA_STATE_REPLICATING",
                        "idx":1,
                        "indexedFields":"a.b:ASC",
                        "isUptodate":true,
                        "minPendingTS":0,
                        "maxPendingTS":0,

                        "putsPending":0,
                        "bucketsPending":0,
                        "copyTableCompletionPercentage":100,
                        "numTablets":1,
                        "numRows":4,
                        "totalSize":24576
                }
        ]
}
```

Troubleshooting Use Cases

Situations where you can use this command include the following:

- Examine the properties of an index.
- Determine if there is a lag in updates in an index.

See Troubleshooting Secondary Indexes on page 1092 for more information on these use cases.

table index remove
This topic describe how to remove secondary indexes that are no longer needed.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table, if you did not create the table

Note: The mapr user is not treated as a superuser. MapR Database does not allow the mapr user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table index remove
  -path <path>
  -index <index name>
```

REST

```
curl -k -X POST \
  'http[s]://<host>:<port>/rest/table/
index/remove?path=<path>&index=<index
name>'
  -u <username>:<password>
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
path	(Required) Path to where the parent JSON table resides
index	(Required) Name of the index

Example

CLI

```
maprcli table
index remove -path /my.cluster.com/
volume1/newtable -index testIndex
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
index/remove?
path=%2Fmy.cluster.com%2Fvolume1%2Fnew
table&index=testIndex' \
  -u mapr:mapr
```

`table info`

Displays information about a MapR Database binary or JSON table, or an index on a JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table info
  -path <path>
  [ -index <index name> ]
```

REST

```
curl -k -X GET \
  'http[s]://<host>:<port>/rest/table/
info?path=<path>&index=<index name>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Parameters

Parameter	Description
path	The path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
index	The name of the index for which to display information.

Example

Lists the information for a table named `mytable` in the JSON format, as described in Common Options on page 1525:

CLI

```
maprcli table info -path /mapr/
my.cluster.com/volume1/mytable -json
```

REST

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/rest/table/
info?
path=%2Fmapr%2Fmy.cluster.com%2Fvolume
1%2Fmytable' \
  -u mapr:mapr
```

Sample Output

```
# maprcli table info -path /mydirectory/mytable -json
{
    "timestamp":1444671479053,
    "timeofday":"2015-10-12 10:37:59.053 GMT-0700",

                        "uuid":"8fea24dc-6e56-6d56-6336-0e0408e15e00"
                }
```

```
        ]
}
```

Output Field	Description
path	The path to the MapR Database table • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
numregions	Number of regions in the table
totallogicalsize	Estimated size (in bytes) of uncompressed data stored in table (excluding replication)
totalphysicalsize	Estimated size (in bytes) of actual data stored in table (excluding replication). Includes internal metadata and reflects compressed data size when compression is enabled.
totalcopypendingsize	Total size (in bytes) of pending data for replication
totalrows	Estimated number of rows in a table
autosplit	A Boolean value that specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the `regionsizemb` parameter. The default value is `true`. If value is set to `false`, you can manually split tables into regions by using the `table region split` command.
bulkload	A Boolean value that specifies whether to allow a full bulk load of the table. The default is `false`. For more information, see Loading Data into Binary Tables on page 1040 and Loading Documents into JSON Tables on page 1036.
tabletype	Specifies whether the table will be a binary table or a JSON table. The values are `binary` and `json`. The default is `binary`.

Output Field	Description
regionsizemb	The average size of the regions into which MapR Database tries to split the table as the table grows. The default is 4096 MB. This value is ignored if `autosplit` is set to `false`. If `autosplit` is set to `true`, MapR Database splits a region when the size of the region exceeds 150% of the average value. For example, if the average value is 4096 MB, MapR Database splits a region that is larger than 6144 MB. Although splits are automatic, merges are not. For example, if the value of `regionsizemb` is changed from 8 GB to 4 GB, all regions that are eligible are split automatically, if `autosplit` is set to `true`. However, if the value of `regionsizemb` is changed from 2 GB to 4 GB, regions smaller than 4 GB are not automatically merged. **Note:** When a table has less than 4 regions, MapR Database ignores the `regionsizemb` parameter and splits regions at a lower threshold.
audit	Specifies whether to turn auditing on for the table. If auditing is also enabled at the cluster level with the `maprcli audit data` command and enabled for the current volume, setting this value to true causes auditing to start for the table.
metricsinterval	The table metrics collection interval, in seconds
maxvalueszinmemindex	The maximum value size to save in an in-memory index
adminaccessperm	The Access Control Expression that controls who can view and edit the permissions for this table. By default, permission is given to the user ID that is used to create the table.
createrenamefamilyperm	The Access Control Expression that controls who can create column families for this table or rename existing column families. By default, permission is given to the user ID that is used to create the table.
bulkloadperm	The Access Control Expression that controls who can load this table with bulk loads if the table was created with bulk load support. By default, permission is given to the user ID that is used to create the table.
indexperm	The secondary index Admin permissions setting that controls who can create an index associated with this table. By default, permission is given to the user ID that is used to create the table.
packperm	The Access Control Expression that controls who can pack table regions. By default, permission is given to the user ID that is used to create the table.
deletefamilyperm	The Access Control Expression that defines access to delete column families for this table. Delimit the expression with single-quotation marks. By default, permission is given to the user ID that is used to create the table.

last-updated: Apr 11, 2022

Output Field	Description
replperm	The Access Control Expression that controls who can set up replication either to or from a table. By default, permission is given to the user ID that is used to create the table
splitmergeperm	The Access Control Expression that controls who can take the following actions: • Run the `table region split` and `table region merge` commands to split the table into regions or to merge regions of the table together. • Change the value of `regionsizemb`. By default, permission is given to the user ID that is used to create the table.
defaultappendperm	**Applies to binary tables only:** The default Access Control Expression for the append permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `appendperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultcompressionperm	**Applies to binary tables only:** The default Access Control Expression for the compression permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `compressionperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultmemoryperm	The default Access Control Expression for the memory permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `memoryperm` in the `table cf create` and `table cf edit` commands overrides this value.
defaultreadperm	The default Access Control Expression for the read permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `readperm` in the `table cf create` and `table cf edit` commands overrides this value. See table cf create on page 1799 and table cf edit on page 1806
defaulttraverseperm	**Applies to JSON tables only:** The default Access Control Expression for the traverse permission on new column families. For more information about this permission, see Permission Types for Fields and Column Families in JSON Tables on page 1462.
defaultwriteperm	The default Access Control Expression for the write permission on new column families that are created in this table. If no value is specified, the default is `u:<username of the table creator>`. This value of the parameter `writeperm` in the `table cf create` and `table cf edit` commands overrides this value. See table cf create on page 1799 and table cf edit on page 1806.

last-updated: Apr 11, 2022

Output Field	Description
wireencryptionfrompolicies	The system automatically sets this field to true if at least one security policy has wire-level encryption enabled, false otherwise.

`table region`
Manages table regions for MapR Database binary and JSON tables.
`table region list`
Lists the regions that make up a specified table or index.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table region list
  -path <path>
  [ -start <offset from starting
region> ]
  [ -limit <number of regions to
return> ]
  [ -index <index name> ]
  [ -output terse | verbose ]
```

REST

```
curl -k -X GET \
  'http[s]://<host>:<port>/rest/table/
region/list?path=<path>&<parameters>'
  -u <username>:<password>
```

Parameters

Parameter	Description
path	Path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, if you want to list regions for a table named `test` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, if you want to list regions for a table named `test` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

Parameter	Description
start	The offset from the starting region. The default value is 0.
limit	The number of regions to return, counting from the starting region. The default value is 2147483647.
index	The name of the index for which to list region information.
output	Specifies whether the output should be `terse` or `verbose`. Default: `verbose`

Output Fields

Verbose Field Name	Terse Field Name	Field Value
primarymfs	pn	Host name and port of the primary node for this region
secondarymfs	sn	Host names and ports of the secondary nodes where this region is replicated
startkey	sk	Value of the start key for this region For the first region in a table, this value is exclusive. For all other regions, it is inclusive. See the example output.
endkey	ek	Value of the end key for this region This value is always exclusive. See the example output.
lastheartbeat	lhb	Time since last heartbeat from the region's primary node
fid	fid	The region's FID.
logicalsize	ls	The logical size (in bytes) of the region without data compression (excluding replication).
physicalsize	ps	The physical size (in bytes) of the region with data compression (excluding replication).
copypendingsize	cps	Amount of data remaining to be replicated
numberofrows	nr	Number of rows in the region
numberofrowswithdelete	nrd	Number of rows in the region, counting deleted rows
numberofspills	nsp	Number of spills for the region
numberofsegments	nsg	Number of segments in the region

Examples

Lists the Region Information for a Table

This example lists the region information for the table `newtable`.

CLI

```
maprcli table region list -path /
my.cluster.com/volume1/newtable
```

REST

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/rest/table/
region/list?
path=%2Fmy.cluster.com%2Fvolume1%2Fnew
table' \
  -u mapr:mapr
```

Example Output Using the -json Option

This example shows two table regions. The value of `endkey` for the first region is the value of `startkey` for the second region. The value of `endkey` is always exclusive. So, for the first region, `endkey` shows that the first region was split with the addition of the record with the key `5190414F2E44DB732547630A9A81452539749000`; for the second region, `startkey` shows that the region begins with that record.

        }
    ]
}
```

table region merge
Merges regions of a table together to reduce the number of regions that a table occupies.

This command merges the region that you specify with the region that contains the row keys that immediately follow the row keys of the specified region.

Note: Consider the table configuration when you decide to merge regions because it is possible that MapR Database might immediately split the regions after they are merged. If `autosplit` is set to true, MapR Database splits a region when the size of the region exceeds 150% of the average value (`regionsizemb`). For example, if the average value is 4096 MB, MapR Database splits a region that is larger than 6144 MB.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `splitmergeperm` permission on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table region merge
  -fid <regionFID>
  -path <table path>
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/
table/region/merge?fid=<region
FID>&path=<path>'
  -u <username>:<password>
```

Parameters

Parameter	Description
fid	The FID for the table region that you want to merge. The output of `maprcli table region list` lists the FIDs for the table.

Parameter	Description
path	The path to the table whose regions are being merged. • For a path on the local cluster, start the path at the volume mount point. For example, if you want to merge regions for table named `test` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on a remote, you must also specify the cluster name in the path. For example, if you want to merge regions for table named `test` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

Example

Merges the specified region:

CLI

```
maprcli table region merge -path /
user/test5 -fid 2086.32.131296
```

REST

```
curl -k -X POST \
  'https://myhost:8443/rest/table/
region/merge?
path=%2Fuser%2Ftest5&fid=2086.32.13129
6' \
  -u mapr:mapr
```

`table region pack`
Manually triggers the packing of regions.

MapR Database automatically compacts or packs regions and reclaims space when 25% of the data contained in the partitions (max of 3 per tablet) has expired; however, for a time series table, you **must** run this command to reclaim space used by expired rows and to avoid read amplification, if the old rows are never accessed.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `packperm` permission on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table region pack
  -path <table path>
```

```
  -fid <fid>|all
  [ -nthreads <number of threads> ]
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/region/pack?
path=<path>&fid=<fid>&<parameters>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	Specifies the path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, if you want to pack a table named `test` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on another cluster, you must also specify the cluster name in the path. For example, if you want to pack a table named `customer` under volume1 in the sanfrancisco cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`
fid	Specifies that you want to pack all table regions or a single table region that you identify with a FID. The output of maprcli table region list lists the FIDs for the table.
nthreads	Specifies the number of threads allocated to process the packing of table regions. Default:16

Example

Packs the specified region:

CLI

```
maprcli table region pack -path /user/
test5 -fid 2086.32.131296
```

REST

```
curl -k -X POST \
  'https://myhost:8443/rest/table/
region/pack?
path=%2Fuser%2Ftest5&fid=2086.32.13129
6' \
  -u mapr:mapr
```

`table region split`
Splits a region in a table.

last-updated: Apr 11, 2022

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `splitmergeperm` permission on the table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table region split
  -path <path>
  -fid <fid>
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/table/
region/split?path=<path>&fid=<fid>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	Path to the table. • For a path on the local cluster, start the path at the volume mount point. For example, if you want to split regions in a table named `test` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/test` • For a path on another cluster, you must also specify the cluster name in the path. For example, if you want to split regions in a table named `customer` under volume1 in the sanfrancisco cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`
fid	The FID of the region to split. The output of `maprcli table region list` lists the FIDs for the table's regions.

Example

This example splits a region in the table `newtable`.

last-updated: Apr 11, 2022

CLI

```
maprcli table region split -path /
my.cluster.com/volume1/newtable -fid
2086.32.131296
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
region/split?
path=%2Fmy.cluster.com%2Fvolume1%2Fnew
table&fid=2086.32.131296' \
  -u mapr:mapr
```

`table replica`
Performs functions related to replication of MapR Database binary and JSON tables. Replication occurs for binary-to-binary tables and JSON-to-JSON tables.
`table replica add`
Registers a table as a replica of another MapR Database binary or JSON table.

Note: You do not need to use this command if you use the `table replica autosetup` command.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

Note: The **mapr user** is not treated as a superuser. MapR Database does not allow the **mapr user** to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
/opt/mapr/bin/maprcli table replica
add
  -path <table path>
  -replica <replica table path>
  [ -columns <comma separated list of
<family>[:<column>]>  ]
  [ -paused <is replication paused>
default: false ]
  [ -throttle <throttle replication
ops> default: false> ]
  [ -networkencryption <enable
on-wire encryption> default: false> ]
  [ -synchronous <is synchronous
replication> default: false ]
  [ -networkcompression <on-wire
compression type: off|on|lzf|lz4|
zlib> default: on ]
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/table/
```

last-updated: Apr 11, 2022

```
replica/add?
path=<path>&replica=<name>&<parameters
>
  -u <username>:<password>
```

Note: The **mapr user** is not treated as a superuser. MapR Database does not allow the **mapr user** to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the source table that you want to replicate. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`
replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst` **Note:** For replication to a table, the command will fail if the table in the replica path does not exist.

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>columns</td><td>By default, all columns in the source table are replicated.

If you do not want to replicate all columns in the table, you can specify specific columns to replicate:

For binary tables

Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to replicate the column family purchases and the column stars in the reviews column family: <code>-columns purchases,reviews:stars</code>

Note: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If the column is added at a later date, replication for that column will start at that time.

For JSON tables

Provide a comma-delimited list of fields to replicate. Include the full field path for each field.

Example

Suppose your table contains documents that contain this general structure:

<pre>{
     "_id" : "ID",
     "a" :
          {
"b" :
  {
       "c" :
"value",
  },
"e" : "value"
          }
}</pre>
To replicate fields a, c, and e, you would specify these field paths:</td></tr>
</table>

Parameter	Description
paused	A Boolean value that specifies whether to pause the replication so that it does not start immediately. The replication can be resumed using the replica resume command at a later time. The values are `true` or false. Default: Not paused (`false`)
throttle	A Boolean value that specifies whether to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. The values are true or false. Default: No throttle (`false`)
networkencryption	A Boolean value that specifies whether or not to enable on-wire encryption. The values are `true` or `false`. If you set this to `true`, the local cluster and any other cluster that is part of the replication process must be enabled for security. Default: No encryption (false)
synchronous	A Boolean value that specifies whether replication is synchronous or asynchronous. The values are `true` or `false`. Default: Asynchronous (`false`)
networkcompression	The type of on-wire compression. Default: on The types are: • `off` • on (default) • `lzf` • `lz4` • `zlib` The default compression is lz4, which can be set by specifying on or `lz4` as value.

Example

Registers a table on the local cluster as a replica of another table on the local cluster:

CLI

```
/opt/mapr/bin/maprcli table
replica add -path /volume1/
custA -replica /volume2/custA
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/add?
path=%2Fvolume1%2FcustA&replica=%2Fvol
ume2%2FcustA' \
  -u mapr:mapr
```

`table replica autosetup`
Sets up and starts replication between a *source* MapR Database binary or JSON table to a *replica* MapR Database binary or JSON table.

The `maprcli table replica autosetup` command performs the following steps to set up replication:

1. Creates a new table with metadata from the source table in the destination cluster.
2. Declares the new table to be a replica of the source table and ensures that replication does not begin immediately after the next step.
3. Declares the source table as an upstream source for the replica.
4. For multi-master replication, replica autosetup declares the source table to be a replica of the new table and then declares the new table to be an upstream source for the source table.
5. Loads a copy of the source data into the replica(s).
6. Clears the paused replication state to start the replication stream.

For more information about the automatic setup process, see Replica Autosetup for MapR Database Tables on page 624.

Before you set up replication for a table, verify that the cluster is setup for replication. For more information, see Preparing Clusters for Table Replication on page 1066.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with *ACE*.

Syntax

CLI

```
/opt/mapr/bin/maprcli table replica
autosetup
  -path <table path>
  -replica <replica table path>
  [ -columns <comma separated list of
<family>[:<column>]> ]
  [ -synchronous <is synchronous
replication> default: false ]
  [ -multimaster <is multi master
replication> default: false ]
  [ -throttle <throttle replication
ops> default: false ]
  [ -networkencryption <enable
on-wire encryption> default: false ]
  [ -networkcompression <on-wire
compression type: off|on|lzf|lz4|
zlib> default: on ]
  [ -directcopy <enable directcopy>
default: true ]
  [ -useexistingreplica <use existing
replica table if present> default:
false ]
```

last-updated: Apr 11, 2022

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/table/
replica/autosetup?
path=<path>&replica=<path>&<parameters
>'
  -u <username>:<password>
```

Parameters

path	The path to the source table that you want to replicate. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`
replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under`volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`  **Note:** For replication to a table, the command will fail if the replica path you specify points to table that already exists.

last-updated: Apr 11, 2022

columns

By default, all columns in the source table are replicated.

If you do not want to replicate all columns in the table, you can specify specific columns to replicate:

For binary tables

Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to replicate the column family purchases and the column stars in the reviews column family: `-columns purchases,reviews:stars`

Note: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If the column is added at a later date, replication for that column will start at that time.

For JSON tables

Provide a comma-delimited list of fields to replicate. Include the full field path for each field.

Example

Suppose your table contains documents that contain this general structure:

```
{
     "_id" : "ID",
     "a" :
          {
"b" :
  {
       "c" :
"value",
  },
"e" : "value"
          }
}
```

To replicate fields a, c, and e, you would specify these field paths:

```
a,a.b.c,a.e
```

last-updated: Apr 11, 2022

synchronous	A Boolean value that specifies whether replication is synchronous or asynchronous. The value is either `true` or `false`. Asynchronous (`false`) is the default.
multimaster	A Boolean value that specifies whether or not to set up a multi-master topology. The value is either `true` or `false`. Basic primary-secondary topology (`false`) is the default.
throttle	A Boolean value that specifies whether or not to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. The value is either `true` or `false`. No throttle (`false`) is the default.
networkencryption	A Boolean value that specifies whether or not to enable on-wire encryption. The value is either `true` or `false`. No encryption (`false`) is the default. If you set this to `true`, the local cluster and any other cluster that is part of the replication process must be enabled for security.
networkcompression	The type of on-wire compression. The types are: • off • on (default) • `lzf` • `lz4` • `zlib` lz4 is the default compression which it set by parameter values `on` or `lz4`.
directcopy	A Boolean value that specifies whether or not autosetup will use the directcopy option . The value is either `true` or `false`. Autosetup with direct copy (`true`) is the default. If you set this parameter to `false`, the cluster will run autosetup without the directcopy option. For more information, see Replica Autosetup for MapR Database Tables on page 624. **Note:** If a table was originally created in MapR 5.x and the `maprcli table replica autosetup` command is specified with `directcopy=false`, then an error, “Copy Table failed for tables”, occurs. This is due to the introduction of new table meta information in 6.0. It is recommended that replication be setup using `directcopy=true` (which is the default). If the default method is not desired, then replication should be setup manually.
useexistingreplica	When the directcopy parameter is set to `true` (default), this Boolean value specifies whether or not an existing table can be used as the replica table. The value is either `true` or `false`. No reuse of existing tables (`false`) is the default. If a table exists with the specified name, and this parameter is set to false, the create table operation will fail.

last-updated: Apr 11, 2022

Example

CLI

```
/opt/mapr/bin/maprcli table
replica autosetup -path /volume1/
custBsrc -replica /volume2/custBdst
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/autosetup?
path=%2Fvolume2%2FcustBsrc&replica=%2F
volume2%2FcustBdst' \
  -u mapr:mapr
```

`table replica edit`
Edits the properties of a replica of a MapR Database binary or JSON table.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

Note: The **mapr user** is not treated as a superuser. MapR Database does not allow the **mapr user** to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table replica edit
  -path <table path>
  -replica <replica table path>
  [ -newreplica <renamed table path> ]
  [ -columns <comma separated list of
<family>[:<column>]> ]
  [ -throttle <throttle replication
ops> ]
  [ -networkencryption <enable
on-wire encryption> ]
  [ -synchronous <is synchronous
replication> ]
  [ -networkcompression <on-wire
compression type: off|on|lzf|lz4|
zlib> ]
```

REST

```
curl -k -X POST
  'http[s]://<host>:<port>/rest/table/
replica/edit?
path=<path>&replica=<path>&<parameters
>'
  -u <username>:<password>
```

Note: The **mapr user** is not treated as a superuser. MapR Database does not allow the **mapr user** to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the source table that you want to replicate. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`
replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`
newreplica	The updated replica path due to a renamed replica table, renamed cluster, or changed table path. The table specified in the `replica` parameter and the table specified in the `newreplica` parameter must have the same UUID.

last-updated: Apr 11, 2022

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>columns</td><td>By default, all columns in the source table are replicated.

If you do not want to replicate all columns in the table, you can specify specific columns to replicate:

For binary tables

Provide a comma-separated list of column families or columns from a certain column family (column family:qualifier). For example, use the following syntax to replicate the column family purchases and the column stars in the reviews column family: <code>-columns purchases,reviews:stars</code>

Note: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If the column is added at a later date, replication for that column will start at that time.

For JSON tables

Provide a comma-delimited list of fields to replicate. Include the full field path for each field.

Example

Suppose your table contains documents that contain this general structure:

<pre>{
     "_id" : "ID",
     "a" :
          {
"b" :
  {
       "c" :
"value",
  },
"e" : "value"
          }
}</pre>
To replicate fields a, c, and e, you would specify these field paths:</td></tr>
</table>

Parameter	Description
throttle	A Boolean value that specifies whether or not to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. The values are `true` or `false`. No throttle (`false`) is the default.
networkencryption	A Boolean value that specifies whether or not to enable on-wire encryption. The values are `true` or `false`. No encryption (`false`) is the default. If you set this to true, the local cluster and any other cluster that is part of the replication process must be enabled for security.
synchronous	A Boolean value that specifies whether replication is synchronous or asynchronous. The values are `true` or `false`. Asynchronous (`false`) is the default.
networkcompression	The type of on-wire compression. The types are: • off • on (default) • `lzf` • `lz4`. This is the default • `zlib` lz4 is the default compression which it set by parameter values on or lz4.

Examples

Changes the replica path to reflect that replica `t2dst` is renamed to `t2dst_new`:

CLI

```
maprcli table replica edit -path /
volume1/t1src -replica /volume1/t2dst
\
  -newreplica /volume1/t2dst_new
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/edit?
path=%2Fvolume1%2Ft1&replica=%2Fvolume
1%2Ft2&newreplica=%2Fvolume1%2Ft2_new'
 \
  -u mapr:mapr
```

Changes the column families to replicate:

CLI

```
maprcli table
replica edit -path /volume1/
custAsrc -replica /volume2/custAdst \
  -columns purchases, reviews, returns
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/edit?
path=%2Fvolume1%2FcustAsrc&replica=%2F
volume2%2FcustAdst&columns=purchases,r
eviews,returns' \
  -u mapr:mapr
```

table replica list
Lists replicas and the associated replica statistics for a specified MapR Database binary or JSON table. By default, replica statistics are updated every five minutes.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path

Note: The **mapr user** is not treated as a superuser. MapR Database does not allow the **mapr user** to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
/opt/mapr/bin/maprcli table replica
list
  -path <table path>
  [ -refreshnow true|false ]
```

REST

```
curl -k -X GET
  'http[s]://
<host>:<port>/rest/table/replica/list?
path=<path>&refreshnow=false'
  -u <username>:<password>
```

Parameters

Parameter	Description
path	The path to the table that you want to list replicas for. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfranciscocluster`, specify the following path: `/mapr/sanfrancisco/volume1/customer`

last-updated: Apr 11, 2022

Parameter	Description
refreshnow	A Boolean value that specifies if you want to trigger an immediate update of the replica statistics. The values are `true` or `false`. By default, the value is `false`; the command lists the current version of the replica statistics, which could be a maximum of five minutes old.

Output

Lists information about each replica for the specified table.

Output Data Fields

The following fields display for each replica.

Field	Description
cluster	The cluster on which the replica resides.
table	The table name for the replica.
type	The table type.
paused	A Boolean values that specifies if replication is paused.
replicaPath	The table replica path.
replicaState	The replication state. For information about the replication states, see Table Replication States on page 625.
throttle	A Boolean value that specifies if replication is throttled.
idx	The internal index value.
networkencryption	A Boolean value that specifies if replication is encrypted.
synchronous	A Boolean value that specifies whether replication is synchronous or asynchronous.
networkcompression	The type of on-wire compression.
isUptodate	A Boolean value that specifies if the replica is up-to-date.
minPendingTS	The epoch time in milliseconds of the oldest operation that has yet to be replicated to the replica.
maxPendingTS	The epoch time in milliseconds of the newest operation that has yet to be replicated to the replica.
bytesPending	The number of bytes that have yet to be replicated to the replica.
putsPending	The number of puts that have yet to be replicated to the replica.
bucketsPending	The number of buckets that have yet to be replicated to the replica.
uuid	The table UUID.

Field	Description
copyTableCompletionPercentage	When replica autosetup with directcopy is in progress, this value is the percentage of data from the source that has been copied to the replica. After replication is setup, the value remains at 100. **Note:** When replicating MapR Database data, the copyTablePercentageCompletion data may re-adjust to a lower rate. This depends on table region (also referred to as tablets) splits and merges as well as the rate of incoming data to replicating data.
errors	If applicable, an error is displayed.

Sample Output

```
{
  "timestamp":1485555420019,
  "timeofday":"2017-01-27 10:17:00.019 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"cluster",
      "table":"/dst",
      "type":"MapRDB",
      "replicaPath":"/dst",
      "replicaState":"REPLICA_STATE_REPLICATING",
      "paused":false,
      "throttle":false,
      "idx":1,
      "networkencryption":false,
      "synchronous":false,
      "networkcompression":"lz4",
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "uuid":"4164f38a-b4ed-0302-f929-0d8bc68b5800",
      "copyTableCompletionPercentage":100
    }
    ]
}
```

Example

Lists replicas for the `custA` table:

CLI

```
/opt/mapr/bin/maprcli table replica
list -path /volume1/custA
```

REST

```
curl -k -X GET \
  'https://r1n1.sj.us:8443/rest/table/
replica/list?path=%2Fvolume1%2FcustA'
\
  -u mapr:mapr
```

last-updated: Apr 11, 2022

table replica pause
Pauses the replication of data from a *source* MapR Database binary or JSON table to a *replica* MapR Database binary or JSON table during autosetup and replication phases.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `replperm` permissions on the source table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table replica pause
  -path <table path>
  -replica <replica table path>
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/replica/
pause?path=<path>&replica=<path>'
  -u <username>:<password>
```

Parameters

Parameter	Description
path	The path to the source table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`

last-updated: Apr 11, 2022

Parameter	Description
replica	The path to the replica that will receive updates from the source. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`

Example

Sets the replication state to paused:

CLI

```
maprcli table
replica pause -path /volume1/
custAsrc -replica /volume2/custAdst
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/pause?
path=%2Fvolume1%2FcustAsrc&replica=%2F
volume2%2FcustAdst' \
  -u mapr:mapr
```

`table replica remove`
De-registers the specified MapR Database binary or JSON table as a replica.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `replperm` permissions on the source table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

After running this command, the specified table or index is no longer a replica of the source table and will no longer receive updates from the source table.

In addition, run the `table upstream remove` command to remove the association between the source table and the replica table.

last-updated: Apr 11, 2022

Syntax

CLI

```
/opt/mapr/bin/maprcli table replica
remove
  -path <table path>
  -replica <replica table path>
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/replica/
remove?path=<path>&replica=<path>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the source table that is being replicated. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`
replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`

Example

De-registers table `custAdst` as a replica of table `custAsrc`:

CLI

```
/opt/mapr/bin/maprcli table
replica remove -path /volume1/
custAsrc -replica /volume2/custAdst
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/remove?
path=%2Fvolume1%2FcustAsrc&replica=%2F
volume2%2FcustAdst' \
  -u mapr:mapr
```

`table replica resume`
Resumes replication between a *source* MapR Database binary or JSON table and a *replica* of that table. Replication can be paused during autosetup and replication phases. When replication resumes, it continues from where it left off.

Permissions Required

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `replperm` permissions on the source table

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Syntax

CLI

```
maprcli table replica resume
  -path <table path>
  -replica <replica table path>
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/replica/
resume?path=<path>&replica=<path>'
  -u <username>:<password>
```

Parameters

Parameter	Description
path	The path to the table that will be replicated. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under a volume with a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customersrc`

last-updated: Apr 11, 2022

Parameter	Description
replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`

Example

CLI

```
maprcli table
replica resume -path /volume1/
custAsrc -replica /volume2/custAdst
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
replica/resume?
path=%2Fvolume1%2FcustAsrc&replica=%2F
volume2%2FcustAdst' \
  -u mapr:mapr
```

`table upstream`
Performs functions related to upstream sources for table replication.
`table upstream add`
Adds a binary table as upstream source for a replica.

Note: You do not need to use this command if you use the `table replica autosetup` command.

Syntax

CLI

```
maprcli table upstream add
  -path <table path>
  -upstream <upstream table
path>
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/upstream/add?
path=<path>&upstream=<name>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

last-updated: Apr 11, 2022

Parameters

Parameter	Description
path	The path to the replica. • For a path to a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/testdst` • For a path to a table on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under volume1 in the sanfrancisco cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`
upstream	The path to the source table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under volume1 which has a mount point at /volume1, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under volume1 in the sanfrancisco cluster, specify the following path: `/mapr/sanfrancisco/volume1/customersrc`

Example

Adds `company1src` as the upstream source for replica `company1dst`:

CLI

```
maprcli table
upstream add -path /volume2/
company1dst -upstream /volume1/
company1src
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
upstream/add?
path=%2Fvolume2%2Fcompany1dst&upstream
=%2Fvolume1%2Fcompany1src' \
  -u mapr:mapr
```

`table upstream list`
Lists the binary tables that replicate data to the specified replica binary table.

Syntax

CLI

```
maprcli table upstream list
  -path <table path>
```

last-updated: Apr 11, 2022

REST

```
curl -k -X GET
  'http[s]://<host>:<port>/rest/table/
upstream/list?path=<path>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the replica. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under `volume1` which has a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customerdst under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customerdst`

Sample Output

```
maprcli table upstream list -path /volume2/company1 -json
{
        "timestamp":1423162601288,
        "timeofday":"2015-02-05 10:56:41.288 GMT-0800",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "cluster":"mycluster",
                        "table":"/volume1/company1",
                        "idx":1,
                        "uuid":"P?\\x18\\xCC\\x17\\xB1&\\xA7i,\\x04\\xBB\
\xB8\\xD3T\\x00"
                }
        ]
}
```

Example

Lists sources that replicate data to the replica `/volume2/company1`:

CLI

```
maprcli table upstream list -path /
volume2/company1 -json
```

REST

```
curl -k -X GET \
  'https://
r1n1.sj.us:8443/rest/table/upstream/
```

```
list?path=%2Fvolume2%2Fcompany1' \
  -u mapr:mapr
```

`table upstream remove`
Un-registers a binary table as an upstream source for a replica.

Note: This step is separate from the `table replica remove` command, which stops replication updates to a replica.

Syntax

CLI

```
maprcli table upstream remove
  -path <table path>
  -upstream <upstream table path>
```

REST

```
curl -k -X POST
  'http[s]://
<host>:<port>/rest/table/upstream/
remove?path=<path>&upstream=<path>'
  -u <username>:<password>
```

Note: The `mapr` user is not treated as a superuser. MapR Database does not allow the `mapr` user to run this command unless that user is given the relevant permission or permissions with access-control expressions.

Parameters

Parameter	Description
path	The path to the replica. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under `volume1` which has a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`
upstream	The path to the source table. • For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under `volume1` which has a mount point at `/volume1`, specify the following path: `/volume1/testsrc` • For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customersrc`

last-updated: Apr 11, 2022

Example

Removes `company1src` as the upstream source for replica `company1dst`:

CLI

```
maprcli table upstream remove -path /
volume2/company1dst -upstream /
volume1/company1src
```

REST

```
curl -k -X POST \
  'https://r1n1.sj.us:8443/rest/table/
upstream/remove?
path=%2Fvolume2%2Fcompany1dst&upstream
=%2Fvolume1%2Fcompany1src' \
  -u mapr:mapr
```

tier
Lets you create, modify, remove, and retrieve list of tiers and tiering rules.

tier create
Creates a new tier.

Syntax

CLI

```
maprcli tier create
       -name <tier_name>
       -type cold|ectier
       [ -url <tier_url> ]
       [ -credential
<credentials_file_path> ]
       [ -tag <object_store_type> ]
       [ -credential_str
<tier_credentials> ]
       [ -dbtopology
<metadata_volume_path> ]
       [ -cluster <cluster_name> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/tier/create?<parameters>`

Usage

To create a warm tier:

```
maprcli tier create
          [ -cluster <cluster_name> ]
          -name <tier_name>
          -type ectier
          [ -dbtopology <path> ]
```

last-updated: Apr 11, 2022

To create a cold tier:

```
maprcli tier create
          [ -cluster <cluster_name> ]
          -name <tier_name>
          -type cold -url <tier_URL>
          -credential|credential_str <credential>
          [ -dbtopology <path> ]
          [ -tag S3-AWS|S3-GCS|S3-HDS|S3-IBM|Azure-Blobs|S3-Others ]
```

Note: The `-tag` parameter is required for Azure.

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`credential`	(For tier of type cold only) The path to the credentials file to use for accessing the tier. The credentials file must already exist on the node from where the tier is being created. For more information, see Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API on page 962. **Note:** Either this or `-credential_str` is required for creating a cold tier.
`credential_str`	(For tier of type `cold` only) The credentials, access key and secret key, bucket name, and region in JSON format. Either this or `-credential` is required for creating a cold tier.
`dbtopology`	The rack path to the volume where metadata is stored in DB tables. The default value is `/data`.
`name`	The name of the tier.
`tag`	(For tier of type `cold` only) The object store to connect to. Value can be one of the following: • S3-GCS (for Google Cloud Platform) • S3-HDS (for Hitachi HCP) • S3-IBM (for IBM Cloud Object Storage) • S3-AWS (for Amazon AWS) • Azure-Blobs (for Microsoft Azure) • S3-Others (for other all vendors) The MAST Gateway uses this to determine the connector library (such as libcurl, etc.) to use. See Specifying the Vendor/Object Store for a Cold Tier on page 964 for more information on the object store. **Note:** This parameter is required for Azure.

last-updated: Apr 11, 2022

Parameter	Description
`type`	The type of tier to create. Value can be: • `cold` — to offload to low-cost storage alternative on the cloud • `ectier` — to offload to low-cost storage alternative on the MapR cluster
`url`	(For tier of type `cold` only) The URL (or endpoint) of the tier in the following format: `<protocol>://<IP|hostname>.<domain>`. Fore more information, see Specifying the Vendor/Object Store for a Cold Tier on page 964. When specifying the URL (for S3), use double quotes. If the protocol is `https`, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold-tier storage does not support HTTPS, all tier related operations will fail. If the cold tier does not support HTTPS, set the protocol to `http`, which is the default.

Examples

Create a cold tier for offloading to S3:

CLI

```
# /opt/mapr/bin/maprcli
tier create -name
ksTestCold -type cold -url
"s3.amazonaws.com" -credential
credentials.txt -json
{
    "timestamp":1519669953410,
    "timeofday":"2018-02-26
10:32:33.410 GMT-0800 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created tier:
'ksTestCold'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=ksTestCold&type=cold&url=s3.amazo
naws.com&credential=/root/
credentials.txt' --user mapr:mapr
{"timestamp":1519679457859,"timeofday"
:"2018-02-26 01:10:57.859 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
tier: 'ksTestCold'"]}
```

Create a EC tier for offloading to a erasure coded volume on the MapR cluster:

last-updated: Apr 11, 2022

CLI

```
# /opt/mapr/bin/maprcli tier
create -name ksTestEC -type
ectier -json
{
    "timestamp":1519664750448,
    "timeofday":"2018-02-26
09:05:50.448 GMT-0800 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created tier:
'ksTestEC'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=ksTestEC&type=ectier' --user
mapr:mapr
{"timestamp":1519679884411,"timeofday"
:"2018-02-26 01:18:04.411 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
tier: 'ksTestEC'"]}
```

Create a cold tier by sending the credentials as a string:

CLI

```
# maprcli tier create -name
testCold -type cold -url
"s3.amazon.com" -credential_str
'{"bucketName":"testbucket","credentia
ls":
{"accessKey":"ABCDEFGHIJKLM","secretKe
y":"OPQRSTUVWXYZ"}}' -json
{
    "timestamp":1526406945863,
    "timeofday":"2018-05-15
10:55:45.863 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created tier:
'testCold'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=testCold&type=cold&url=s3.amazon.
com&credential_str=%7B%22bucketName%22
%3A%22testbucket%22%2C%22credentials%2
2%3A%7B%22accessKey%22%3A%ABCDEFGHIJKL
```

```
%22%2C%22secretKey%22%3A%22OPQRSTUVWXY
Z%22%7D%7D' --user mapr:mapr
{"timestamp":1526483636503,"timeofday"
:"2018-05-16 08:13:56.503 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully created
tier: 'testCold'"]}
```

tier info
Retrieves information about a tier.

Syntax

CLI

```
$ maprcli tier info
    -name <tier_name>
    [ -cluster <cluster_name> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/tier/info?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the tier.

Output

The command returns the following:

`volume`	The name of the volume associated with the tier.
`tiertype`	The type of tier. Value can be one of the following: • cold • ectier
`tierid`	The ID of the tier.
`dbtopology`	The topology of the volume associated with the tier.
`dbvolumeid`	The ID of the volume associated with the tier.
`tiername`	The name of the tier.
`bucketname`	The name of the bucket. The value is displayed for cold tiers only.
`region`	The region. The value is displayed for cold tiers only.

objectstoretype	The type of object store (for cold tiers only). Value can be one of the following: • S3-GCS • S3-HDS • S3-IBM • S3-Others • Azure-Blobs
url	The tier URL. The value is displayed for cold tiers only.

Examples

Retrieve information about a warm tier:

CLI

```
# maprcli tier info -name testWarm
volume
tiertype  dbtopology  dbvolumeid
tierid    tiername
mapr.internal.tier.testWarm
ectier    /data       201186661
74117928  testWarm
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/info?
name=testWarm' --user mapr:mapr
{"timestamp":1530987914127,"timeofday"
:"2018-07-07 11:25:14.127 GMT-0700
AM","status":"OK","total":1,"data":
[{"tierid":"74117928","tiername":"test
Warm","tiertype":"ectier","volume":"ma
pr.internal.tier.testWarm","dbtopology
":"/data","dbvolumeid":201186661}]}
```

Retrieve information about a cold tier:

CLI

```
# maprcli tier info -name testCold
volume
tiertype  dbtopology  dbvolumeid
tierid    tiername  bucketname
region     objectstoretype
url
mapr.internal.tier.testCold
cold      /data       13372843
49971858  testCold  testbucket
us-east-1  S3-AWS           http://
s3.amazon.com
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/info?
name=testCold' --user mapr:mapr
{"timestamp":1530987683808,"timeofday"
:"2018-07-07 11:21:23.808 GMT-0700
AM","status":"OK","total":1,"data":
```

```
[{"tierid":"49971858","tiername":"test
Cold","tiertype":"cold","url":"http://
s3.amazon.com","bucketname":"testbucke
t","region":"us-east-1","volume":"mapr
.internal.tier.testCold","dbtopology":
"/
data","dbvolumeid":13372843,"objectsto
retype":"S3-AWS"}]}
```

tier list
Lists the tiers on the cluster.

Syntax

CLI

```
maprcli tier list
    [ -cluster <cluster_name> ]
    [ -sortby <attribute> ]
    [ -sortorder asc|desc ]
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/tier/list?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`sortby`	Specifies one of the following attributes to sort the list of tiers by: `tierid`, `tiername`, `tiertype`, `url`, `throttling`, `bucketname`, `region`, `objectstoretype`, `volume`, `topology`
`sortorder`	The order to sort the results by. Value can be: • `asc` - for ascending order • `desc` - for descending order

Output

The command returns the following:

`volume`	The name of the tiered volume.
`tiertype`	The type of tier. Value can be one of the following: • cold • ectier
`dbtopology`	The topology of the metadata volume associated with the tier.
`dbvolumeid`	The ID of the metadata volume associated with the tier.

`tierid`	The ID of the tier.
`tiername`	The name of the tier.
`bucketname`	The name of the bucket. The value is displayed for cold tiers only.
`region`	The region. The value is displayed for cold tiers only.
`objectstoretype`	The type of object store (for cold tiers only). Value can be one of the following: • S3-AWS • S3-GCS • S3-HDS • S3-IBM • S3-Others • Azure-Blobs
`url`	The tier URL. The value is displayed for cold tiers only.

Example

Get the list of tiers:

CLI

```
# maprcli tier list
volume
tiertype  dbtopology  dbvolumeid
tierid     tiername    bucketname
region     objectstoretype
url
mapr.internal.tier.ksTestCold
cold      /data       135415553
30712925   ksTestCold  ksekhar-test
us-east-1  S3-AWS           http://
s3.amazonaws.com
mapr.internal.tier.testCold
cold      /data       192997092
189158428  testCold    testbucket
us-east-1  S3-AWS           http://
s3.amazon.com
mapr.internal.tier.ksTestEC
ectier    /data       87658196

```

tier modify
Modifies the credentials used to access tier.

Syntax

CLI

```
maprcli tier modify
     -name <tier_name>
     [ -credential
<path_to_credentials_file> ]
     [ -credential_str
<tier_credentials> ]
     [ -cluster <cluster_name> ]
     [ -force true|false ]
     [ -tag <object_store_type> ]
     [ -url <tier_url> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/tier/modify?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`credential`	(For cold tier only) The path to the credentials file to use to access the tier. **Note:** You cannot modify the bucket name in the credentials file after the tier is created; only the accesskey and the secretkey can be modified. For more information, see Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API on page 962.
`credential_str`	(For cold tier only) The region, bucket, and credentials, access key and secret key, specified in JSON format. Either this or `-credential` is required to connect to a cold tier.

Parameter	Description
`force`	Required to force a change of any of the following: • Bucket on the tier where data is offloaded. • Region where the bucket resides. • URL (or endpoint) of the tier. Value can be one of the following: • `true` — to force a change • `false` — to not change The default value is `false`.
`name`	The name of the tier.
`tag`	(For cold tier only) The tier to connect to. Value can be one of the following: • S3-GCS • S3-HDS • S3-IBM • S3-AWS • S3-Others • Azure-Blobs The MAST Gateway uses this to determine the connector library (such as libcurl, etc.) to use. **Note:** You must specify this parameter to connect to Azure.
`url`	(For cold tier only) The URL (or endpoint) of the tier. This can be modified only with the `-force` option. See Specifying the Vendor/Object Store for a Cold Tier on page 964 for information on the tier endpoints and supported authentication protocols. **Note:** If the credentials for the new URL are different, specify the new credentials through the credentials file or using the `credential_str` parameter.

Examples

Modify the credentials (credential file) used to access the tier:

CLI

```
# /opt/mapr/bin/maprcli tier
modify -name testCold -credential
credentials.txt -json
{
    "timestamp":1519670281090,
    "timeofday":"2018-02-26
10:38:01.090 GMT-0800 AM",
    "status":"OK",
    "total":0,
```

last-updated: Apr 11, 2022

```
    "data":[

    ],
    "messages":[
        "Successfully updated tier:
'ksTestCold'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
10.10.82.24:8443/rest/tier/modify?
name=testCold&credential=credentials.t
xt' --user mapr:mapr
{"timestamp":1526485277061,"timeofday"
:"2018-05-16 08:41:17.061 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
tier: 'testCold'"]}
```

Modify the tier by passing the credentials as a string:

CLI

```
# maprcli tier modify -name
testCold -credential_str
'{"bucketName":"testbucket","credentia
ls":
{"accessKey":"ABCDEFGHIJKL","secretKey
":"MNOPQRSTUVWXYZ"}}' -json
{
    "timestamp":1526484682668,
    "timeofday":"2018-05-16
08:31:22.668 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully updated tier:
'testCold'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/modify?
name=testCold&credential_str=%7B%22buc
k3A%22testbucket%22%2C%22credentials%2
2%3A%7B%22accessKey%22%3A%22ABCDEFGHIJ
KLMN%22%2C%22secretKey%22%3A%22OPQRSTU
VWXYZ%22%7D%7D' --user mapr:mapr
{"timestamp":1526485116177,"timeofday"
:"2018-05-16 08:38:36.177 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
tier: 'testCold'"]}
```

tier remove
Removes a tier.

Note: You cannot remove a tier currently associated with a volume.

Syntax

CLI

```
$ maprcli tier remove
    -name <tier_name>
    [ -cluster <cluster_name> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/tier/remove?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the tier to remove.

Examples

Remove a tier (specified by name):

CLI

```
# /opt/mapr/bin/maprcli tier
remove -name testCold -json
{
    "timestamp":1521064355911,
    "timeofday":"2018-03-14
02:52:35.911 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully deleted tier:
'testCold'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/remove?
name=testCold' --user mapr:mapr
{"timestamp":1526485963448,"timeofday"
:"2018-05-16 08:52:43.448 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully deleted
tier: 'testCold'"]}
```

tier rule create
Creates a rule for offloading data to a tier.

last-updated: Apr 11, 2022

Syntax

CLI

```
$ maprcli tier rule create
    -name <rule_name>
    -expr <regular_expression>
   [ -cluster <cluster_name> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/tier/rule/create?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.

last-updated: Apr 11, 2022

<table>
<tr><th>Parameter</th><th colspan="2">Description</th></tr>
<tr><td>expr</td><td colspan="2">The criteria for offloading data. The criteria can be defined using a combination of the following:</td></tr>
<tr><td></td><td>u</td><td>Username or user ID, as configured in the OS registry (such as /etc/passwd file, LDAP, etc.), of a specific user.
Usage: u:<username or user ID></td></tr>
<tr><td></td><td>g</td><td>Group name or group ID, as configured in the OS registry (such as /etc/group file, LDAP, etc.), of a specific group.
Usage: g:<groupname or group ID></td></tr>
<tr><td></td><td>m</td><td>(mtime) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending s to value and the number of days can be specified by appending d to the value.
Usage:
• "m:<value>s" — specifies mtime in seconds
• "m:<value>d" — specifies mtime in days
All files that are not modified since the specified amount of time, are offloaded.
Note: If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.</td></tr>
<tr><td></td><td>s</td><td>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.
Usage
• "s:<value>b" — specifies file size in bytes
• "s:<value>k" — specifies file size in KB
• "s:<value>m"</td></tr>
</table>

Parameter	Description
name	The name of the rule.

Examples

Create a rule to offload files older than a year:

CLI

```
/opt/mapr/bin/maprcli tier
rule create -name rule1 -expr
"m:365d" -json
{
    "timestamp":1519681290079,
    "timeofday":"2018-02-26
01:41:30.079 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created rule:
'rule1'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule1&expr=m:365d' --user
mapr:mapr
{"timestamp":1519681475025,"timeofday"
:"2018-02-26 01:44:35.025 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule1'"]}
```

Create a rule to offload files larger than 5 GB:

CLI

```
# /opt/mapr/bin/maprcli tier rule
create -name rule2 -expr "s:5g" -json
{
    "timestamp":1519681586774,
    "timeofday":"2018-02-26
01:46:26.774 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created rule:
'rule2'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
```

```
name=rule2&expr=s:5g' --user mapr:mapr
{"timestamp":1519681667766,"timeofday"
:"2018-02-26 01:47:47.766 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule2'"]}
```

Create rule to offload files whose owner is m7user1:

CLI

```
# /opt/mapr/bin/maprcli tier
rule create -name rule3 -expr
"u:m7user1" -json
{
    "timestamp":1519682014521,
    "timeofday":"2018-02-26
01:53:34.521 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created rule:
'rule3'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule3&expr=u:m7user1' --user
mapr:mapr
{"timestamp":1519682095080,"timeofday"
:"2018-02-26 01:54:55.080 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule3'"]}
```

Create rule to offload all files:

CLI

```
# /opt/mapr/bin/maprcli tier rule
create -name rule4 -expr "p" -json
{
    "timestamp":1519682694183,
    "timeofday":"2018-02-26
02:04:54.183 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created rule:
'rule4'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule4&expr=p' --user mapr:mapr
{"timestamp":1519682828031,"timeofday"
:"2018-02-26 02:07:08.031 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule4'"]}
```

Create rule to not offload any files:

```
# /opt/mapr/bin/maprcli tier rule create -name rule5 -expr "" -json
{
    "timestamp":1519682947271,
    "timeofday":"2018-02-26 02:09:07.271 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created rule: 'rule5'"
    ]
}
```

Create a rule, called testRule, for offloading all files owned by user m7user1 or for offloading files owned by user mapr and whose size is greater than 5 GB or whose file modification timestamp is greater than 365 (days):

CLI

```
# /opt/mapr/bin/maprcli tier
rule create -name testRule -expr
"u:m7user1 | (u:mapr & (s:5g |
m:365d))" -json
{
    "timestamp":1519683138305,
    "timeofday":"2018-02-26
02:12:18.305 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created rule:
'testRule'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
10.10.82.24:8443/rest/tier/rule/
create?
name=testRule&expr=u%3Am7user1%7C%28u%
3Amapr%26%28s%3A5g%20%7C%20m%3A365d%29
%29' --user mapr:mapr
{"timestamp":1526488621687,"timeofday"
:"2018-05-16 09:37:01.687 GMT-0700
AM","status":"OK","total":0,"data":
```

```
[],"messages":["Successfully created
rule: 'testRule'"]}
```

tier rule info
Retrieves information on a rule (specified by name).

Syntax

CLI

```
maprcli tier rule info
    -name <rule_name>
    [ -output verbose ]
    [ -cluster <cluster_name> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/tier/rule/info?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the rule.
`output`	The type of output. The default value is verbose.

Output

The command returns the following:

`expression`	The rules defined using a combination of expressions.
`inuse`	Whether (`true`) or not (`false`) the rule is associated with a volume.
`rulename`	The name of the rule.
`ruleid`	The ID of the rule.

Example

Retrieve information on the rule named testRule:

CLI

```
# maprcli tier rule info -name
testRule
expression
  inuse  rulename  ruleid
u:m7user1 | (u:mapr & (s:5g |
m:365d))  true   testRule  2
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/rule/info?
```

```
name=testRule' --user mapr:mapr
{"timestamp":1528147823598,"timeofday"
:"2018-06-04 02:30:23.598 GMT-0700
PM","status":"OK","total":1,"data":
[{"ruleid":"2","rulename":"testRule","
expression":"u:m7user1 | (u:mapr &
(s:5g | m:365d))","inuse":"true"}]}
```

tier rule list
Retrieves the list of rules for offloading data.

Syntax

CLI

```
$ maprcli tier rule list
    [ -output terse|verbose ]
    [ -cluster cluster_name ]
    [ -sortby <attribute> ]
    [ -sortorder <asc|desc> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host:port>/rest/tier/rule/list?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`output`	Specifies whether the output should be `terse` or `verbose`. Default: `verbose`.
`sortby`	The attributes by which to sort the list of tiers. Value can be one of the following: `ruleid`, `rulename`, `expression`
`sortorder`	The order to sort the results by. Value can be: • `asc` - for ascending order • `desc` - for descending order

Output

The command returns the following:

`expression`	The rules defined using a combination of expressions.
`rulename`	The name of the rule.
`ruleid`	The ID of the rule.

Example

Retrieve the list of tier rules:

CLI

```
# /opt/mapr/bin/maprcli tier rule list
expression
  rulename  ruleid
m:365d
  rule1     1
s:5g
  rule2     2
u:m7user1
  rule3     3
p
  rule4     4

  rule5     5
u:m7user1 | (u:mapr & (s:5g |
m:365d))  testRule  6
```

REST

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/rule/
list' --user mapr:mapr
{"timestamp":1519840839491,"timeofday"
:"2018-02-28 10:00:39.491 GMT-0800
AM","status":"OK","total":6,"data":
[{"ruleid":"1","rulename":"rule1","exp
ression":"m:365d"},
{"ruleid":"2","rulename":"rule2","expr
ession":"s:5g"},
{"ruleid":"3","rulename":"rule3","expr
ession":"u:m7user1"},
{"ruleid":"4","rulename":"rule4","expr
ession":"p"},
{"ruleid":"5","rulename":"rule5","expr
ession":""},
{"ruleid":"6","rulename":"testRule","e
xpression":"u:m7user1 | (u:mapr &
(s:5g | m:365d))"}]}
```

tier rule modify

Modifies the criteria in a tiering rule (specified by name).

Syntax

CLI

```
$ maprcli tier rule modify
    -name <rule_name>
    -expr <expression>
    [ -cluster <cluster_name> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/tier/rule/modify?<parameters>`

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`expr`	The criteria for offloading data. The criteria can be defined using a combination of the following: • `u` — the user who owns the file(s) to offload • `g` — the group that owns the file(s) to offload • `m` — the time since the file was modified • `s` — the size of the file to offload. Use `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. Or, use: • `p` — to offload all the files • `""` — empty string to not offload any files Use the following to string multiple criteria for offload: • `&` — to indicate all specified criteria must be met for offload • `|` — to indicate any of the specified criteria is adequate for offload • `( )` — to specify sub-expressions
`name`	The name of the rule.

Examples

Modify the criteria in the tiering rule, ksTestRule, to offload all files in the volume:

CLI

```
# /opt/mapr/bin/maprcli tier rule
modify -name ksTestRule -expr
"p" -json
{
    "timestamp":1516225073780,
    "timeofday":"2018-01-17
09:37:53.780 GMT+0000",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully updated rule:
'ksTestRule'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/modify?
name=ksTestRule&expr=p' --user
mapr:mapr
```

last-updated: Apr 11, 2022

```
{"timestamp":1526489124827,"timeofday"
:"2018-05-16 09:45:24.827 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
rule: 'ksTestRule'"]}
```

tier rule remove
Removes the rule for offloading data.

Note: You cannot remove a rule that is currently associated with a volume.

Syntax

CLI

```
$ maprcli tier rule remove
    -name <rule_name>
    [ -cluster <cluster_name> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host:port>/rest/tier/rule/remove?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the rule to remove.

Examples

Remove the rule named testRule:

CLI

```
# /opt/mapr/bin/maprcli tier rule
remove -name testRule -json
{
    "timestamp":1516225222172,
    "timeofday":"2018-01-17
09:40:22.172 GMT+0000",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully deleted rule:
'testRule'"
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
```

```
name=testRule' --user mapr:mapr
{"timestamp":1526488467571,"timeofday"
:"2018-05-16 09:34:27.571 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully deleted
rule: 'testRule'"]}
```

trace
Lets you view and modify the trace buffer, and the trace levels for the system modules.

The valid trace levels are:

- DEBUG
- INFO
- ERROR
- WARN
- FATAL

trace dump
Dumps the contents of the trace buffer into the MapR filesystem log.

Syntax

CLI

```
maprcli trace dump
    [ -host <host> ]
    [ -port <port> ]
```

REST

None.

Parameters

Parameter	Description
host	The IP address of the node from which to dump the trace buffer. Default: `localhost`
port	The port to use when dumping the trace buffer. Default: `5660`

Examples

Dump the trace buffer to the MapR filesystem log:

CLI

```
maprcli trace dump
```

trace info
Displays the trace level of each module.

Syntax

CLI

```
maprcli trace info
    [ -host <host> ]
    [ -port <port> ]
```

REST

None.

Parameters

Parameter	Description
host	The IP address of the node on which to display the trace level of each module. Default: `localhost`
port	The port to use. Default: `5660`

Output

A list of all modules and their trace levels.

Sample Output

```
RPC Client Initialize
**Trace is in DEFAULT mode.
**Allowed Trace Levels are:
FATAL
ERROR
WARN
INFO
DEBUG
**Trace buffer size: 2097152
**Modules and levels:

DONE
```

Examples

Display trace info:

CLI

```
maprcli trace info
```

trace print
Manually dumps the trace buffer to stdout.

Syntax

CLI

```
maprcli trace print
    [ -host <host> ]
    [ -port <port> ]
    -size <size>
```

REST

None.

Parameters

Parameter	Description
host	The IP address of the node from which to dump the trace buffer to stdout. Default: `localhost`
port	The port to use. Default: `5660`
size	The number of kilobytes of the trace buffer to print. Maximum: 64

Output

The most recent `<size>` bytes of the trace buffer.

```
-----------------------------------------------------
2010-10-04 13:59:31,0000 Program: mfs on Host: fakehost IP: 0.0.0.0, Port:
0, PID: 0

-----------------------------------------------------
DONE
```

Examples

Display the trace buffer:

last-updated: Apr 11, 2022

CLI

```
maprcli trace print
```

trace reset
Resets the in-memory trace buffer.

Syntax

CLI

```
maprcli trace reset
    [ -host <host> ]
    [ -port <port> ]
```

REST

None.

Parameters

Parameter	Description
host	The IP address of the node on which to reset the trace parameters. Default: `localhost`
port	The port to use. Default: `5660`

Examples

Reset trace parameters:

CLI

```
maprcli trace reset
```

trace resize
Resizes the trace buffer.

Syntax

CLI

```
maprcli trace resize
    [ -host <host> ]
    [ -port <port> ]
    -size <size>
```

REST

None.

Parameters

Parameter	Description
host	The IP address of the node on which to resize the trace buffer. Default: `localhost`
port	The port to use. Default: `5660`
size	The size of the trace buffer, in kilobytes. Default: `2097152` Minimum: `1`

last-updated: Apr 11, 2022

Examples

Resize the trace buffer to 1000

CLI

```
maprcli trace resize -size 1000
```

trace setlevel

Sets the trace level on one or more modules.

Syntax

CLI

```
/opt/mapr/bin/maprcli trace setlevel
    [ -host <host> ]
    -level <trace level>
    -module <module name>
    [ -port <port> ]
```

REST

None.

Parameters

Parameter	Description
host	The node on which to set the trace level. Default: `localhost`
module	The module on which to set the trace level. If set to `all`, sets each module to the specified trace level.

Parameter	Description
level	The new trace level. Set the level to `default`, to set the trace level of the specified module(s) to its default. If you do not set the level, then INFO is set as the level. You can find the existing trace level of each module, using the command: `/opt/mapr/bin/maprcli trace info` The current modules along with their default trace level are: • Global : INFO • RPC : ERROR • MessageQueue : ERROR • CacheMgr : INFO • IOMgr : INFO • Transaction : ERROR • Log : ERROR • Cleaner : INFO • Allocator : ERROR • BTreeMgr : ERROR • BTree : ERROR • BTreeDelete : ERROR • BTreeOwnership : INFO • MapServerFile : ERROR • MapServerDir : INFO • MFSReadAhead : INFO • Container : INFO • Snapshot : INFO • Util : ERROR • Replication : INFO • PunchHole : INFO • KvStore : INFO • Truncate : ERROR • Orphanage : INFO • FileServer : INFO • Heartbeat : ERROR • Defer : ERROR • ServerCommand : INFO • Write : ERROR • DB : INFO

last-updated: Apr 11, 2022

Parameter	Description
port	The port to use. Default: `5660`

Examples

Set the trace level of the Log module to INFO:

CLI

```
/opt/mapr/bin/maprcli trace
setlevel -module Log -level info
```

Set the trace level of the BTreeMgr module to FATAL:

CLI

```
/opt/mapr/bin/maprcli trace
setlevel -module BTreeMgr -level FATAL
```

Set the trace levels of all modules to their defaults:

CLI

```
/opt/mapr/bin/maprcli trace
setlevel -module all -level default
```

Set the trace levels of all modules to INFO:

CLI

```
/opt/mapr/bin/maprcli trace
setlevel -module all -level INFO
```

or equivalently:

```
/opt/mapr/bin/maprcli trace
setlevel -module all
```

trace setmode
Sets the trace mode.

There are two modes:

- Default
- Continuous

In default mode, all trace messages are saved in a memory buffer. If there is an error, the buffer is dumped to stdout. In continuous mode, every allowed trace message is dumped to stdout in real time.

Syntax

CLI

```
maprcli trace setmode
    [ -host <host> ]
    -mode default|continuous
    [ -port <port> ]
```

REST

None.

Parameters

Parameter	Description
host	The IP address of the host on which to set the trace mode
mode	The trace mode.
port	The port to use.

Examples

Set the trace mode to continuous:

CLI

```
maprcli trace setmode -mode continuous
```

urls
Displays the status page URL for the specified service.

Syntax

CLI

```
/opt/mapr/bin/maprcli urls
                      [ -cluster
<cluster name> ]
                      [ -zkconnect
<ZooKeeper Connect String:
'host:port,host:port,host:port,...'> ]
                      -name <name of
the service link is required for>
                      [ -validate
<Validate if URL is reachable or not.
default: true> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/urls/statuspage?<parameters>` If you submit the request without `statuspage` in the request URL, the return value contains a 404 error because the API requires a subcommand (empty or otherwise) to be present even though the subcommand is ignored.

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to save the configuration.

Parameter	Description
`name`	The name of the service for which to get the status page: • cldb
`validate`	Enables (`true`) or disables (`false`) validating whether the URL is reachable.
`zkconnect`	ZooKeeper Connect String

Examples

Display the URL of the status page for the CLDB service:

CLI

```
# /opt/mapr/bin/maprcli urls -name
cldb
url
https://abc.sj.us:7443/cldb.jsp
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/urls/statuspage?
name=cldb' --user mapr:mapr
{"timestamp":1544561148186,"timeofday"
:"2018-12-11 12:45:48.186 GMT-0800
PM","status":"OK","total":1,"data":
[{"url":"https://abc.sj.us:7443/
cldb.jsp"}]}
```

virtualip
Manages virtual IP addresses for NFS nodes.

Table

Field	Description
macaddress	The MAC address of the virtual IP.
netmask	The netmask of the virtual IP.
virtualipend	The virtual IP range end.

virtualip add
Adds a virtual IP address.

Permissions Required

`fc` or `a` on the cluster.

Syntax

CLI

```
maprcli virtualip add
    [ -cluster <cluster> ]
    [ -gateway <gateway> ]
    [ -macs <MAC address> ]
    -netmask <netmask>
    -virtualip <virtualip>
```

```
    [ -virtualipend <virtual IP range
end> ]
    [ -preferredmac <MAC address> ]
    [ -service nfs3|nfs4 ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/virtualip/add?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`gateway`	The NFS gateway IP or address
`macs`	A list of the MAC addresses that represent the NICs on the nodes that the VIPs in the VIP range can be associated with. Use this list to limit VIP assignment to NICs on a particular subnet when your NFS server is part of multiple subnets.
`netmask`	The netmask of the virtual IP.
`preferredmac`	The preferred MAC for this virtual IP. When an NFS server restarts, the MapR system attempts to move all of the virtual IP addresses that list a MAC address on this node as a preferred MAC to this node. If the new value is null, this parameter resets the preferred MAC value.
`service`	The service to assign VIPs to. Value can be one of the following: • `nfs3` — for NFSv3 • `nfs4` — for NFSv4 The default value is `nfs3`, which is used if this option is not specified. You must specify the MAC addresses (`macs`) with this option.
`virtualip`	The virtual IP, or the start of the virtual IP range.
`virtualipend`	The end of the virtual IP range.

Example

Add VIP for NFSv3 node:

CLI

```
maprcli virtualip add
        -cluster
mycluster.402.source
        -macs "09:0C:29:3C:47:AB
03:3C:34:76:CF:21 02:0E:22:71:AD:34"
        -netmask 255.255.255.0
        -virtualip  10.1.1.5
```

last-updated: Apr 11, 2022

```
        -preferredmac
"02:0E:22:71:AD:34"
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/virtualid/add?
cluster=mycluster.402.source&macs=%220
9%3A0C%3A29%3A3C%3A47%3AAB%2003%3A3C%3
A34%3A76%3ACF%3A21%2002%3A0E%3A22%3A71

rtualid=10.1.1.5&preferredmac=%2202%3A
0E%3A22%3A71%3AAD%3A34%22' --user
mapr:mapr
```

Add VIP range for NFSv3 nodes:

CLI

```
maprcli virtualip add
        -cluster
mycluster.402.source
        -service nfs3
        -macs "09:0C:29:3C:47:AB
03:3C:34:76:CF:21 02:0E:22:71:AD:34"
        -netmask 255.255.255.0
        -virtualip  10.1.1.5
        -virtualipend 10.1.1.7
        -preferredmac
"02:0E:22:71:AD:34"
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/virtualid/add?
cluster=mycluster.402.source&service=n
fs3&macs=%2209%3A0C%3A29%3A3C%3A47%3AA

pend=10.1.1.7&preferredmac=%2202%3A0E%
3A22%3A71%3AAD%3A34%22' --user
mapr:mapr
```

Add VIP for NFSv4 node:

CLI

```
maprcli virtualip add
        -cluster
mycluster.402.source
        -service nfs4
        -macs "09:0C:29:3C:47:AB
03:3C:34:76:CF:21 02:0E:22:71:AD:37"
        -netmask 255.255.255.0
        -virtualip  10.1.2.7
        -preferredmac
"02:0E:22:71:AD:37"
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/virtualid/add?

.255.255.0&virtualid=10.1.2.7&preferre
dmac=%2202%3A0E%3A22%3A71%3AAD%3A37%22
' --user mapr:mapr
```

virtualip edit
Edits a virtual IP (VIP) range. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli virtualip edit
    [ -cluster <cluster> ]
    [ -macs <MAC addresses> ]
    -netmask <netmask>
    -virtualip <virtualip>
    [ -virtualipend <virtual IP range
end> ]
    [ -preferredmac <MAC address> ]
    [ -service nfs3|nfs4 ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/virtualip/edit?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`macs`	A list of the MAC addresses that represent the NICs on the nodes to which the VIPs in the VIP range can be associated. Use this list to limit VIP assignment to NICs on a particular subnet when your NFS server is part of multiple subnets.
`netmask`	The netmask of the virtual IP.
`preferredmac`	The preferred MAC for this virtual IP. When a NFS server restarts, the MapR system attempts to move all of the virtual IP addresses that list a MAC address on this node as a preferred MAC to this node. If the new value is null, this parameter resets the preferred MAC value.
`service`	The service to which the VIPs need to be assigned. The Value can be one of the following: • `nfs3` — for NFSv3 • `nfs4` — for NFSv4 The default value is `nfs3`. You must specify the MAC addresses (`macs`) with this option.
`virtualip`	The virtual IP, or the start of the virtual IP range.

last-updated: Apr 11, 2022

Parameter	Description
`virtualipend`	The end of the virtual IP range.

Examples

Single virtual IP

CLI

```
maprcli virtualip edit
             -cluster
mycluster.402.source
             -macs
"09:0C:29:3C:47:AB
00:0c:29:9e:96:15"
             -netmask 255.255.255.0
             -virtualip 10.1.1.5
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/virtualip/remove?
cluster=mycluster.402.source&macs=%220

A29%3A9e%3A96%3A15%22&netmask=255.255.
255.0&virtualip=10.1.1.5' --user
mapr:mapr
```

Virtual IP range

CLI

```
maprcli virtualip edit
                     -cluster
mycluster.402.source
                     -macs
"09:0C:29:3C:47:AB
00:0c:29:9e:96:15"
                     -netmask
255.255.255.0
                     -virtualip
10.1.1.5
                     -virtualipend
10.1.1.8
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/virtualip/remove?
cluster=mycluster.402.source&macs=%220
9%3A0C%3A29%3A3C%3A47%3AAB%2000%3A0c%3
A29%3A9e%3A96%3A15%22&netmask=255.255.
255.0&virtualip=10.1.1.5&virtualipend=
10.1.1.8' --user mapr:mapr
```

virtualip list

Lists the virtual IP addresses in the cluster.

Syntax

CLI

```
maprcli virtualip list
    [ -cluster <cluster> ]
    [ -columns <columns> ]
    [ -filter <filter> ]
    [ -limit <limit> ]
    [ -nfsmacs <NFS macs> ]
```

```
    [ -output <output> ]
    [ -range <range> ]
    [ -sortby <attribute> ]
    [ -start <start> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/virtualip/list[?<parameters>]`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`columns`	The columns to display.  **Note:** • The `hostname` and `ip` fields are always returned in the query. • The value(s) for `assignables` are not returned as a column.
`filter`	A filter specifying VIPs to list. See Filters for more information.
`limit`	The number of records to return.
`nfsmacs`	Specifies whether (`1`) or not (`0`) to return the MAC addresses of servers running NFS. If value is `1`, the command returns the MAC addresses of the NFS servers.
`output`	Whether the output should be `terse` or `verbose`.
`range`	Specifies whether (`1`) or not (`0`) to return the VIP ranges. The default value is `0`, which returns all VIPs individually. If: • The value is `0`, the command returns the assignment of VIPs to hosts (specified by `hn`, `mac`, and `ip` in the output). • The value is `1`, the command returns the VIP ranges and the assignables, which is the group of nodes amongst which the VIP range (specified by `vip` and `vipe` in the output) must be distributed. If assignables is empty in the output, the range of VIPs (specified by `vip` and `vipe` in the output) can be assigned to any NFSv3 server.  **Note:** The `assignables` contains the list of MAC addresses only if the VIP assignment is restricted to a group of nodes. You must specify `-json` with the command to view the `assignables`.

last-updated: Apr 11, 2022

Parameter	Description
`sortby`	Specifies one of the following attributes to sort the list of virtual IP addresses by: `vipip`, `vipendip`, `vipnetmask`, `vipgateway`, `vipnumdevices`, `viphealth`, `vipassigneddevname`, `vipassigneddevip`, `vipassigneddevmac`, `vippreferredhostname`, `vippreferredip`, `vippreferredmac`.
`start`	The index of the first record to return.

Output

Field	Description
`assignables`	The group of nodes to assign the VIP range to. If empty, the range of VIPs can be assigned to any NFSv3 server. **Note:** You must specify `-json` with the command to view the `assignables`.
`hn`	The hostname.
`ip`	The IP address.
`mac`	The MAC address.
`nm`	The netmask.
`vip`	The virtual IP. If output contains VIP range, this is the start of the VIP range.
`vipe`	The end of the VIP range.

Examples

Return the list of VIPs:

CLI

```
# maprcli virtualip list
hn                      ip
vip          mac
nm
atsqa4-164.nfs4ad.com  10.10.88.164
10.10.88.10  0c:c4:7a:1f:91:a5

10.10.88.11  0c:c4:7a:1f:91:0a
255.255.255.0
```

REST

```
curl -k -X
GET 'https://abc.sj.us:8443/rest/
virtualip/list?limit=2' --user
mapr:mapr
```

Return a list of VIP ranges:

CLI

```
# maprcli virtualip list -range 1
assignables  vip
vipe         nm
...          10.10.88.10
10.10.88.13  255.255.255.0
...          10.10.88.14
10.10.88.15  255.255.255.0
...          10.10.88.17
10.10.88.18  255.255.255.0
```

REST

```
curl -k -X
GET 'https://abc.sj.us:8443/rest/
virtualip/list?range=1' --user
mapr:mapr
```

virtualip move

Reassigns a virtual IP or a range of virtual IP addresses to a specified Media Access Control (MAC) address.

Syntax

CLI

```
maprcli virtualip move
    [ -cluster <cluster name> ]
```

```
    -virtualip <virtualip>
    [ -virtualipend <virtualip end
range>
    -tomac <mac>
    [ -service nfs3|nfs4 ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/virtualip/move?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster where the virtual IP addresses are being moved.
`service`	The service to assign the VIPs to. Value can be one of the following: • `nfs3` — for NFSv3 • `nfs4` — for NFSv4 The default value is `nfs3`, which is used if this option is not specified.
`tomac`	The MAC address that the virtual IP addresses are being assigned.
`virtualip`	A virtual IP address. If you provide a value for `-virtualipend`, this virtual IP address defines the beginning of the range.
`virtualipend`	A virtual IP address that defines the end of a virtual IP address range.

Examples

Move a range of three virtual IP addresses to a MAC address for the cluster my.cluster.com:

CLI

```
maprcli virtualip move -cluster
my.cluster.com -virtualip
192.168.0.8 -virtualipend
192.168.0.10 -tomac 00:FE:ED:CA:FE:99
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/virtualip/move?
cluster=my.cluster.com&virtualip=192.1
68.0.8&virtualipend=192.168.0.10&tomac
=00%3AFE%3AED%3ACA%3AFE%3A99' --user
mapr:mapr
```

virtualip remove

Removes a virtual IP (VIP) or a VIP range. Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli virtualip remove
    [ -cluster <cluster> ]
    -virtualip <virtual IP>
    [ -virtualipend <Virtual IP Range
End> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/virtualip/remove?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`virtualip`	The virtual IP or the start of the VIP range to remove.
`virtualipend`	The end of the VIP range to remove.

Examples

CLI

```
maprcli virtualip remove -virtualip
10.1.1.5
```

```

volume

Manages volumes, snapshots and mirrors.

Fields

The following table lists the data fields that provide information about each volume. Each field has two names:

- Field name - displayed in the output of the `volume list` command and used to specify the columns displayed using the `columns` parameter
- Short name - used to specify the columns displayed using the `columns` parameter

The short name is also used when specifying rows with a filter, for example when specifying a set of volumes about which to get information.

Field Name	Short Name	Description
accesstime	va	A value that can be used to determine when this volume was accessed.

last-updated: Apr 11, 2022

actualreplication	arf	The actual current replication factor by percentage of the volume, as a zero-based array of integers from 0 to 100. For each position in the array, the value is the percentage of the volume that is replicated index number of times. Example: arf=5,10,85 means that 5% is not replicated, 10% is replicated once, 85% is replicated twice.
advisoryquota	aqt	The advisory quota for the volume, in MB. A value of `0` indicates there are no soft or advisory quotas for this volume.
AdvisoryQuotaExceededAlarm	aqa	Alarm raised if the volume size is more than the value configured for the advisory quota.
aename	aen	The *accounting entity (AE)* name.
aetype	aet	The type of *accounting entity (AE)*. Value can be: • `0` - user • `1` - group
allowGrant	ag	Specifies whether a parent volume grants permission for a child volume to inherit its properties. Value can be `true` or `false`.
AlmostFullTopologyAlarm	afta	Timestamp when Topology Almost Full on page 2244 alarm was raised.
audited	ea	Indicates whether `1` or not (`0`) auditing is enabled for the volume. See Enabling Auditing for the steps to enable auditing on a volume and on directories, files, and tables in that volume.
auditVolume	av	Indicates whether (`1`) or not volume accommodates audit logs.
BecomeMasterStuckAlarm	bms	Timestamp when the Volume Become Master Stuck on page 2245 alarm has been raised for the volume.
CannotMirrorAlarm	cma	Timestamp when the "Cannot Mirror" alarm was raised.
coalesceInterval	ci	The interval of time in minutes during which only the first instance of an operation on a node is recorded in audit logs, if auditing is enabled. Subsequent identical operations performed on the same node are ignored during the interval. Setting this field to a larger number helps prevent audit logs from growing quickly. **Note:** The default value is 60 minutes.

last-updated: Apr 11, 2022

CompactionFailureAlarm	cfa	Timestamp when the Compaction Failed on page 2240 alarm has been raised for the volume.
containerAllocationFactor	caf	Indicates the number of containers created for the volume.
ContainersNonLocalAlarm	cnla	Timestamp when the Local Volume containers non-local alarm was raised.
creationTime	ct	The volume creation time (epoch time in seconds). This is only available on volumes created using MapR v6.0.0 or later. For volumes created using older MapR versions, the `volume info` on page 1965 and `volume list` on page 1979 commands will return empty value for this field.
creator	on	Name of the user that created the volume.
creatorcontainerid	ccid	ID for the container.
creatorvolumeuuid	cvid	ID that supports the container chain identification for mirroring. The creatorcontainerid and creatorvolumeuuid fields combined form a unique identifier for the container chain.
CriticallyDegradedEcStripesAlarm	cea	Timestamp when the Data Under-Encoded on page 2242 alarm has been raised for the volume.
criticalReReplTimeOutSec	crto	The timeout (in seconds) before re-replicating critically under-replicated containers only.
cvtotalused		The total space used by the associated cache volume.
dareEnabled	de	Indicates whether (`1`) or not (`0`) data-at-rest encryption is enabled for the volume.
data-size-mirrored-mb	dsm	Indicates the amount of data (in MB) that has been mirrored to the volume.
data-size-to-mirror-mb	dstm	Indicates the amount of data (in MB) that is yet to be mirrored to the volume.
DataUnavailableAlarm	dua	Timestamp when the Data Unavailable on page 2240 alarm was raised.
DataUnderReplicatedAlarm	rfa	Timestamp when the Data Under-Replicated on page 2241alarm was raised.
dbindexlagsecalarmthresh	dilsat	Defines the lag time in seconds for updating secondary indexes after which the Secondary Index Encoding Error on page 2240 alarm is raised.

last-updated: Apr 11, 2022

dbrepllagsecalarmthresh	dlsat	Defines the lag time in seconds for replication after which the Table Replication Lag High on page 2238 alarm is raised.
DegradedEcStripesAlarm	dea	Timestamp when the Warm-Tier Data Node Down on page 2241 alarm has been raised for the volume.
disableddataauditoperations	ddao	The list of operations excluded from auditing. For more information, see Auditing Data Access Operations on page 698 and Selective Auditing of MapR File System, MapR Database Table, and MapR Event Store For Apache Kafka Operations Using the CLI on page 761.
ecscheme	ecs	The erasure coding scheme for the volume if the volume is enabled for warm tiering.
ecstorevolume	ecstore	The name of the backend volume or erasure coded volume associated with the tiering enabled front-end volume.
ecstripedepthmb	ecstripedepthmb	The stripe depth of the erasure coded volume. The default value is 4 MB.
ectopology	ectopo	The rack path to the erasure coded volume.
ectotalused	ecused	The total space, after compression, used by the erasure-coded volume. This includes the disk space used by the parity fragments.
enableddataauditoperations	edao	The list of operations selected for auditing. For more information, see Auditing Data Access Operations on page 698 and Selective Auditing of MapR File System, MapR Database Table, and MapR Event Store For Apache Kafka Operations Using the CLI on page 761.
enforceMinReplicationForIO	esmr	Indicates whether (`true`) or not (`false`) to enforce minimum number of replicas for the volume.
fixCreatorId	fcid	An internal flag for MapR volumes to fix the creator container ID.
forceAudit	fa	Indicates whether (`1`) or not (`0`) to force audit of operations on all files, tables, and streams in the volume.
FullTopologyAlarm	fta	Timestamp when the Topology Full Alarm on page 2244 was raised.
gateway	gwips	The hostname or IP address and port of the MAST Gateway associated with the volume.
InodesExceededAlarm	ia	Timestamp when the Inodes Exceeded alarm was raised.

LargeRowWarning	lrwarning	Timestamp when the Large Row on page 2243 alarm was raised.
lastSuccessfulMirrorTime	lmt	Last time when the mirror completed successfully.
limitspread	ls	An internal flag for MapR volumes to control the growth of volumes in terms of the number of containers. When this flag is set, CLDB tried to limit the number of new containers created depending on the present size of the volume. If the volume size (the data in the volume) is small, the CLDB tries to reuse space in existing containers thus avoiding the creation of new containers.
localpath	lp	Topology of the volume.
logicalUsed	dlu	Logical size of disk used by this volume in MB.
maxinodesalarmthreshold	miath	The threshold of inodes in use that set off the Inodes Limit Exceeded on page 2242 alarm.
maxnssizembalarmthreshold	mnsszath	The namespace container size, which when exceeded raises the INODES_EXCEEDED alarm.
metricsEnabled	me	Indicates whether (`1`) or not (`0`) metrics collection is enabled for the volume.
minreplicas	mrf	Minimum number of replicas before re-replication starts.
mirror-percent-complete	mpc	Percentage complete for the most recent or current mirror operation.
mirrorDataSrcCluster	mdc	Name of the cluster of the originator volume.
mirrorDataSrcVolume	mds	Name of the originator volume. This is used to identify the mirror family in cascaded mirroring.
mirrorDataSrcVolumeId	mdi	ID of the originator volume.
MirrorFailureAlarm	mfa	Timestamp when the Mirror Failure on page 2243 alarm was raised.
mirrorId	mid	Current mirror ID of the volume.
mirrorscheduleid	msid	ID of the schedule that determines when the volume needs to be mirrored.
mirrorSrcCluster	msc	Name of the source cluster from which the current mirroring will happen.
mirrorSrcVolume	src	Name of the source volume from which the current mirrroring will happen.
mirrorSrcVolumeId	msi	ID of the source volume from which the current mirroring will happen.

last-updated: Apr 11, 2022

mirrorstatus	mst	Status of the last mirror attempt.
mirrorthrottle	dt	Flag to determine if the throttling need to be done on mirroring. Value can be: • `0` - disabled • `1` - enabled
mirrortype	mrt	Determines the type of volume: • `0` - Read-write Volume • `1` - Mirror Volume • `2` - Mirror than can be converted to read-write • `3` - Read-write volume that can be converted to mirror
mountdir	p	The path the volume is mounted on.
mounted	mt	A value of `1` indicates the volume is mounted
nameContainerDataThresholdMB	ncdt	Maximum amount of data allowed in the name container.
nameContainerSizeMB	ncsmb	Size of the name container for this volume in MB.
nsMinReplicas	nsmr	Minimum replication level for the namespace container.
nsNumReplicas	nsnr	Replication level for the namespace container.
needsGfsck	nfsck	Indicates whether (`true`) or not (`false`) this volume requires a filesystem check.
nextMirrorId	nmid	Mirror ID that is assigned if the mirroring successfully completes the next time.
NoNodesInTopologyAlarm	nna	Timestamp when the No Nodes in Topology on page 2243 alarm was raised.
nsMinReplicas	nsmr	Indicates the minimum number of name space replicas configured for the volume.
nsNumRelicas	nsnr	Indicates the desired number of name space replicas configured for the volume.
numactivecgcontainers	numactivecgcntrs	The number of active CG containers for the volume.
numcontainers	nc	Number of containers that the volume has.
numreplicas	drf	Desired number of replicas. Containers with this amount of replicas are not re-replicated.

last-updated: Apr 11, 2022

OffloadRecallFailureAlarm	ora	Timestamp when the Offload/Recall Failed on page 2242 alarm has been raised for the volume.
partlyOutOfTopology	poot	A value of `1` indicates this volume is partly out of its topology
quota	qta	Quota for limiting disk size in MB. A value of `0` indicates there are no hard quotas for this volume
QuotaExceededAlarm	qa	Timestamp when the Volume Quota Alarm on page 2245 was raised.
rackpath	rp	The rack path for this volume.
readonly	ro	A value of `1` indicates the volume is read-only.
replicatedlogicalused	replused	Replicated logical used data of this volume
replicatedtotalused	replusedtotal	Replicated total used data of this volume
replicationtype	dcr	Replication type. Value can be `low_latency` (star replication) or `high_throughput` (chain replication).
ReplTypeConversionInProgress	rtip	Indicates whether (`1`) replication type conversion is currently happening.
reReplTimeOutSec	rto	Timeout (in seconds) before attempting re-replication of replica containers. This volume property defines the timeout period until CLDB starts re-replicating the containers on the node of the volume when CLDB stops receiving a heartbeat from the node.
scheduleid	sid	The ID of the schedule, if any, used by this volume.
schedulename	sn	The name of the schedule, if any, used by this volume.
skipWireSecuityForTierInternalOps	swsfti	Indicates whether the skip wire security tier internal ops got enabled for this volume.
snapshotcount	sc	The number of snapshots for this volume.
SnapshotFailureAlarm	sfa	Timestamp when the Snapshot Failure on page 2244 alarm was raised.
snapshotused	ssu	Total space used (in MB) by the data owned only by the snapshot and not present in the RW volume. Data shared between the snapshot and RW volume is not counted in this field.
TableIndexEncodingErrorAlarm	vatinee	Timestamp when the the VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR alarm has been raised for the volume.

last-updated: Apr 11, 2022

TableIndexErrorAlarm	vatinde	Timestamp when the VOLUME_ALARM_TABLE_INDEX_ERROR alarm has been raised for the volume.
TableIndexLagHighAlarm	vatindlh	Timestamp when the VOLUME_ALARM_TABLE_INDEX_LAG_HIGH alarm has been raised for the volume.
TableReplicationAsyncAlarm	vatrepa	Timestamp when the Table Replication Asynchronous on page 2238 alarm was raised.
TableReplicationErrorAlarm	vatrepe	Timestamp when the Table Replication Errors on page 2237 alarm was raised.
TableReplicationLagHighAlarm	vatreplh	Timestamp when the Table Replication Lag High on page 2238 alarm was raised.
tiercompactionoverheadthreshold	tcovr	The percentage of offloaded data that must have been deleted on the MapR cluster to qualify the data for compaction (or deletion from the tier).
tiercompactionscheduleid	tcsid	The ID of the schedule to use for running the compactor.
tierenable	tenb	Indicates whether (1) or not (0) staorage efficiency through tiering is enabled for the volume.
tierencryption	tenc	Indicates whether (`true`) or not (`false`) encryption of data on the tier is enabled.
tierid	tid	The ID of the tier.
tierjobendtime	tjetime	The date and time when the last tiering operation was completed.
tierjoboffloadavgthroughputmbps	tjospeed	The average throughput (MB per second) for offloaded data.
tierjobrecallavgthroughputmbps	tjrspeed	The average throughput (MB per second) for recalled data.
tierjobprogress	tjprog	The completion percentage of the currently running or last tiering operation.
tierjobstarttime	tjstime	The date and time when the currently running or last tiering operation was started.

tierjobstate	tjstatus	The status of the currently running or last tiering operation. Value can be one of the following: • Scheduled • Running • FailureFatal • FailureRetriable • Success • Aborted • AbortInProgress • AbortedInternal Fore more information on these, see Statuses on page 2040.
tierjobtotaloffloadsize	tjosize	The total amount of data offloaded to the tier during the last offload operation.
tierjobtype	tjtype	The type of tiering operation currently running or last performed on the volume.
tierLocal	tloc	The amount of (in MB) physical user data (including recalled data) on the volume in the cluster.
tiername	tname	The name of the tier.
tieroffloadscheduleid	tsid	The ID of the schedule for offloading data to the tier.
tierPurged	tpur	The amount (in MB) of physical user data that is offloaded to the tier.
tierRecall	trec	The amount of (in MB) physical user data that is recalled to the cluster.
tierrecallexpirytime	ret	The amount of time to keep recalled data on the MapR cluster before offloading (if there are changes) or purging (if there are no changes) the data.
tierruleid	rid	The ID of the rule or storage policy.
tiertype	ttype	The type of tier. Value can be either: • cold • ectier
totalused	tsu	Total space used for volume and snapshots, in MB.
used	dsu	Disk space used (in MB), not including snapshots.
volumeAces	vace	Displays the ACE values set for this volume.

last-updated: Apr 11, 2022

volumeid	id	The volume ID.
volumename	n	The name of the volume.
volumetype	t	The volume type (for backward-compatibility): • `0` - Read-write Volume • `1` - Mirror Volume
wireSecurity	ws	Indicates whether (`1`) or not (`0`) wire-level security is enabled.

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

node list on page 1705
Lists nodes in the cluster.

dump volumeinfo on page 1637
Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

`volume audit`

Enables or disables auditing on the specified volume.

You must have the `fc` permission on the cluster to use this command. See `acl` for details about this permission.

To learn how to determine whether auditing is enabled for a volume, see Checking Whether Auditing is Enabled for a Directory, File, or MapR Database Table.

Syntax

CLI

```
maprcli volume audit
   [ -cluster <cluster name> ]
   -name <volume name>
   [-dataauditops <+|-operations>]
   [ -enabled <true|false> ]
   [ -forceenable true|false ]
   [ -coalesce <interval in
minutes> ]
```

REST

Request Type	POST

Request URL	`http[s]://<host>:<port>/rest/volume/audit?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which the volume is located. This parameter is required if the volume is on a remote cluster. The remote cluster must be listed in the `mapr-clusters.conf` file for the cluster where you run the command.
coalesce	The interval of time during which READ, WRITE, or GETATTR operations on one file from one IP address or UID are logged only once for a particular operation, if auditing is enabled. For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged. Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading. The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly.

last-updated: Apr 11, 2022

Parameter	Description
`dataauditops`	The comma separated list of filesystem operations to include (specified with a preceding plus sign (+)) and/or exclude (specified with a preceding minus sign (-)) from auditing. **Note:** If the first operation in the list is to be excluded from auditing, it must be preceded by two minus (`--`) signs. Subsequent operations to exclude must be preceded by only a single minus (`-`) sign, whether or not the first operation was included (using a plus (+) sign) or excluded (using two minus (`--`) signs). If neither sign is specified, the given operation is included for auditing. The operations that can be included (+) and/or excluded (-) from auditing are listed here. You can, alternatively, group all the filesystem and table operations using the keyword `all`, which: • If included (+), cannot be specified with a list of other included operations. • If excluded (-), cannot be specified with a list of other excluded operations. **Note:** You can specify a mixed list of included and excluded operations. There are no changes to operations that are not specified with the command.
`enabled`	Enables or disables the auditing of operations within the volume. You must use either this parameter, the `-coalesce` parameter, or both. See Enabling Auditing for the steps to enable auditing on directories, files, and tables in a volume. When you set the value to false, auditing of operations within the volume ceases. None of the auditing settings are changed on the directories, files, and MapR Database tables within the volume. If you later run the `maprcli volume audit` command with `-enabled` set to `true`, auditing begins again on the objects that were already enabled for auditing.
`forceenable`	Enables or disables auditing of all directories, files, tables, and streams in the volume whether or not auditing is enabled at the individual file, table, and/or stream level.
`name`	The name of the volume.

Examples

Enable Auditing for a volume

The following example shows how to enable auditing for the volume “auditVolume”:

CLI

```
maprcli volume audit -name
auditVolume -enabled true
```

last-updated: Apr 11, 2022

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/audit?
name=auditVolume&enabled=true' --user
mapr:mapr
```

Modify the list of operations to audit

The following example shows how to specify the operations to audit. Here, `create` operation is included for auditing and `lookup` operation is excluded from auditing. There are no changes to operations that are not specified.

CLI

```
maprcli volume audit -name
sampleAuditVolume -dataauditops
+create,-lookup
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/audit?
name=sampleAuditVolume&dataauditops=%2
Bcreate%2C%2Dlookup' --user mapr:mapr
```

volume balancecontainers
Balances the containers, or stops the balancing of containers associated with the volume.

Syntax

CLI

```
maprcli volume balancecontainers
    [ -cluster cluster_name ]
      -name <volume name>
    [ -cancel <true|false>. default:
false ]
```

REST API N/A

Parameters

Parameter	Description
`cancel`	Stop the balancing of containers associated with the volume. Set this parameter to `true` to cancel balancing a volume.
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the volume.

Examples

Start balancing the containers associated with a volume:

```
maprcli volume balancecontainers -name sampleVol
```

Stop balancing the containers associated with a volume:

```
maprcli volume balancecontainers -name sampleVol -cancel true
```

volume balancinginfo
Fetch currently running or scheduled balancer information for one or more volumes.

Note: For best results, use the `-json` option when running the command.

Syntax

CLI

```
maprcli volume balancinginfo
    [ -cluster cluster_name ]
    [ -name <volume name> ]
```

REST API N/A

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the volume.

Output

The command returns the following fields:

Field	Description
`spId`	The ID of the storage pool.
`capacity`	The capacity/size of the storage pool in MB.
`usedSize`	The size of the storage pool that is consumed.
`desiredSize`	The total size of the containers of a volume that should be allocated on this storage pool.
`isUnderweight`	Value is `true` if the storage pool contains less than 50% of the `desiredSize` for this volume.
`isOverweight`	Value is `true` if the storage pool contains more than 1.5 times the `desiredSize` for this volume.

Examples

Fetch the list of volumes whose balancing is currently in progress or scheduled:

```
maprcli volume balancinginfo -json
```

Fetch the balancing information for a volume:

```
maprcli volume balancinginfo -name snapshotVolume1 -json
```

Output:

```
{
  "timestamp":1502529117881,
  "timeofday":"2017-08-12 09:11:57.881 GMT+0000",
  "status":"OK",
  "total":5,
  "data":[
    {
```

```
      "volumeName":"snapshotVolume1"
    },
    {
      "isBalancingInProgress":false
    },
    {
      "numContainers":15
    },
    {
      "volumeSize":384
    },
    {
      "spInfo":[
        {
          "spId":"f891ae9e6663fa2000598ec48808155c",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"bed92c0ecfaefc8b00598ec48b01cdfe",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false

          "capacity":157065,
          "usedSize":96,
          "desiredSize":97,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"7af11d5b9d223baa00598ec4850efb57",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        }
      ]
    }
  ]
}
```

volume compact
Runs the compactor to remove recalled data on the MapR cluster or stale data on the tier.

Permissions Required

The user running the command must have one of the following:

- Full control (fc) on the cluster or volume
- Volume edit permissions

last-updated: Apr 11, 2022

Syntax

CLI

```
maprcli volume compact
    [ -cluster <cluster_name> ]
     -name <vol_name>
     [ -forcerecallexpiry true|false ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/compact?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`forcerecallexpiry`	Specifies whether (`true`) or not (`false`) to purge recalled data on the MapR cluster. If the command is run with the value for this set to `true`, the compactor purges recalled data on the MapR cluster whether or not the expiry time for recalled data has been reached. If this is not specified or if the value for this is `false`, the compactor purges stale data on the tier and recalled data on the MapR cluster if the expiry time for recalled data has been reached or has passed. The default value is `false`.
`name`	The name of the volume.

Examples

Remove stale data on the tier for the volume named sampleVol:

CLI

```
# maprcli volume compact -name
sampleVol -json
{
    "timestamp":1528299575917,
    "timeofday":"2018-06-06
08:39:35.917 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully started
compaction."
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/compact?
name=sampleVol' --user mapr:mapr
```

last-updated: Apr 11, 2022

```
{"timestamp":1528299575917,"timeofday"
:"2018-06-06 08:39:35.917 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully started
compaction."]}
```

Remove recalled data immediately on the volume named sampleVol:

CLI

```
# maprcli volume compact -name
sampleVol -forcerecallexpiry
true -json
{
    "timestamp":1528299765110,
    "timeofday":"2018-06-06
08:42:45.110 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully started
compaction."
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/compact?
name=sampleVol&forcerecallexpiry=true'
 --user mapr:mapr
{"timestamp":1528299765110,"timeofday"
:"2018-06-06 08:42:45.110 GMT-0700
AM","status":"OK","total":0,"data":
[],"messages":["Successfully started
compaction."]}
```

volume container move

Moves a container. Permissions required: `fc` or `m` on the volume.

The volume container move command moves a specified container (`cid`) from a source file server (`fromfileserver`) to a destination file server (`tofileserver`). If the `tofileserver` parameter is not specified, a destination file server is chosen by the CLDB. If the `tofileserver` is specified but does not exist, the command fails with an error. If the `fromfileserver` does not exist or is down, the container move occurs once the source file server comes back up.

Syntax

CLI

```
volume container move
    -cid <cid>
    -fromfileserverid
<fromfileserverid>
    [ -tofileserverid
<tofileserverid> ]
```

REST

Request Type	POST

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/volume/container/move?<parameters>`

Parameters

Parameter	Description
`cid`	The container ID.
`fromfileserverid`	The ID of the file server on which the container to be moved currently resides. The ID is available from the `maprcli node list` command.
`tofileserverid`	The ID of the file server to which to move the container. If not specified, a file server is chosen by the CLDB. The ID is available from the `maprcli node list` command.

Examples

CLI

```
maprcli volume container
move -cid 2316 -fromfileserverid
5227152973904547710 -tofileserverid
875290643748357753
```

REST

```
curl -k -X POST 'https://abc.sj.us:8443/
rest/volume/container/move?
cid=2316&fromfileserverid=52271529739045
47710&tofileservicerid=87529064374835775
3' --user mapr:mapr
```

volume container switchmaster

Switches the master replica for a specified container to another replica in the replica chain.

This command fails if there is only one up-to-date replica for the container.

Note: Only the `root` and the MAPR_USER (user name under which MapR services run) user have permissions to run this command.

Syntax

CLI

```
maprcli volume container switchmaster
   [ -cluster <cluster_name> ]
   -cid <cid>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/container/switchmaster?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.
`cid`	The unique ID number for the container that you want to run the command on.

Example
Switches the master container for a specified container:

CLI

```
maprcli volume container
switchmaster -cid 2049
```

REST

```
https://abc.sj.us:8443/rest/volume/
container/switchmaster?cid=2049
```

volume create
Creates a volume.

Permissions Required

`cv` or `fc` on the cluster.

Note: See acl on page 1528 for more information.

Syntax

CLI

```
/opt/mapr/bin/maprcli volume create
   -name <volume name>
   [ -advisoryquota <advisory quota> ]
   [ -ae <accounting entity> ]
   [ -aetype <accounting entity

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/create?<parameters>`

Parameters

Parameter: `advisoryquota`

Default Value: No default value

Possible Values: 0 or any other integer value.

Description: The advisory quota for the volume as `integer` plus `unit. Example: quota=500G; Units: B`, `K`, `M`, `G`, `T`, `P`

Parameter: `ae`

Default Value: No default value

Possible Values: Name of the entity that owns the volume.

Description: The accounting entity that owns the volume.

Parameter: `aetype`

Default Value: No default value

Possible Values:

- `0=user`
- `1=group`

Description: Type of accounting entity.

Parameter: `allowgrant`

Default Value: false

Possible Values:

- `true`
- `false`

Description: Specifies whether the volume as a parent, grants permission for a child volume to inherit its properties.

Parameter: `allowinherit`

Default Value: true

last-updated: Apr 11, 2022

Possible Values:

- `true`
- `false`

Description: Specifies whether a new volume inherits properties from the parent mount point volume.

Parameter: `allowreadforexecute`

Default Value: false

Possible Values:

- `true`
- `false`

Description: Allows execution of SUID binaries with only their executable bit set, on a FUSE filesystem. This parameter works in conjunction with the `fuse.mount.setuid` FUSE option. For more information, see Configuring the MapR FUSE-Based POSIX Client on page 1240.

Parameter: `auditenabled`

Default Value: true

Possible Values:

- `true`
- `false`

Description: Specifies whether to turn on auditing for the volume. If you enable auditing at the cluster level with the `audit data on page 1553` command, setting this value to `true` causes auditing to start for any directories, files, tables, or streams that are already enabled for auditing. If none are yet enabled, enabling auditing on any of them causes auditing of them to start.

Set `auditenabled` to `true` to enable auditing on directories, files, tables, and streams in the volume.

You must have the `fc` permission on the cluster to use this parameter. See `acl` for details about this permission.

Parameter: `autooffloadthresholdgb`

Default Value: 1024 GB

Possible Values: Any positive integer.

Description: The size of the volume in GB (threshold). When this threshold is reached or exceeded, volume data is automatically offloaded by the Automatic Tiering Scheduler. To use the global size threshold (of 1024 GB), set the value to `0`.

Parameter: `cluster`

Default Value: No default value

Possible Values: Any valid cluster.

Description: The cluster on which to create the volume.

Parameter: *`coalesce`*

Default Value: 60 minutes

Possible Values: Set this parameter to a large number of minutes to prevent audit logs from growing quickly.

Description: The interval of time (in minutes) during which READ, WRITE, or GETATTR operations on one

last-updated: Apr 11, 2022

file from one IP address or UID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

Parameter: `compactionoverheadthreshold`

Default Value: 30%

Possible Values: 0-100%

Description: Specifies the percentage of offloaded data that must have been deleted on the MapR cluster to qualify the data for compaction (or deletion from the tier).

Parameter: `compactionschedule`

Default Value: Automatic Internal Schedule

Possible Values: Any valid schedule ID.

Set this parameter to `0` to disable the compactor.

Description: Specifies the schedule to use for running the compactor.

Parameter: `containerallocationfactor`

Default Value: 5

Recommended Value: 2* SP count in the volume topology.

Description: Specifies the number of containers to create when the first write from a remote client is sent to the volume. The pre-created containers are distributed equally across topologies, servers, MapR File System instances, and storage pools. CLDB also takes into consideration the load (IO/Space) when selecting target storage pools for containers. The value must be a positive integer.

Parameter: `createparent`

Default Value: 1

Possible Values:

- 0 - Do not create a parent directory
- 1 - Create a parent directory

Description: Specifies whether or not to create a parent directory to hold the volume link.

Parameter: `criticalrereplicationtimeoutsec`

Default Value: 0 (No timeout)

Possible Values: Any integer between 300 and 3600 (seconds)

Description: Timeout (in seconds) before re-replicating only the critically under-replicated containers . If you set both `rereplicationtimeoutsec` and `criticalrereplicationtimeoutsec`, and if the value of:

- `rereplicationtimeoutsec` is less than `criticalrereplicationtimeoutsec`, `rereplicationtimeoutsec` overrides the `criticalrereplicationtimeoutsec` setting for both under-replicated and critically under-replicated containers.
- `rereplicationtimeoutsec` is greater than `criticalrereplicationtimeoutsec`, `criticalrereplicationtimeoutsec` overrides the `rereplicationtimeoutsec` setting only for critically under-replicated containers; `rereplicationtimeoutsec` setting is still applicable for under-replicated containers.

Parameter: `dare`

Default Value: false

Possible Values:

- true
- false

Description: Specifies whether or not to enable data-at-rest encryption for volume. This setting takes effect only if the data-at-rest encryption feature is also enabled at the cluster level. Once enabled, this feature cannot be disabled.

Parameter: `dataauditops`

Default Value: Default enabled audit ops:
`setattr,chown,chperm,chgrp,getxattr,listxattr,setxattr,removexattr,read,write,create,delete,mkdir,readdir,rmdir,createsym,lookup,rename,createdev,truncate,tablecfcreate,tablecfdelete,tablecfmodify,tablecfScan,tableget,tableput,tablescan,tablecreate,tableinfo,tablemodify,getperm,getpathforfid,hardlink,filescan,fileoffload,filerecall,filetierjobstatus,filetierjobabort`

Possible Values: Any audit operations that you want to enable.

Description: The comma separated list of filesystem operations to include (specified with a preceding plus sign (+)) or exclude (specified with a preceding minus sign (-)) from auditing.

To exclude the first operation in the list (of operations) from auditing, precede it by two minus (`--`) signs. To exclude subsequent operations, precede them by only a single minus (`-`) sign, irrespective of whether the first operation was included (using a plus (+) sign) or excluded (using two minus (`--`) signs). If neither sign is specified, the given operation is included for auditing.

The operations that can be included (+) or excluded (-) from auditing are listed here. You can, alternatively, group all the operations using the keyword `all`, which:

- If included (+), cannot be specified with a list of other included operations.

- If excluded (`-`), cannot be specified with a list of other excluded operations.

You can specify a mixed list of included and excluded operations. There is no change to operations that are not specified with the command.

Note: If you specify only `setattr` as the audit operation to enable, `chown`, `chperm`, and `chgrp` are automatically added and enabled.

For more information, see Selective Auditing of Filesystem and Table Operations.

Parameter: `dbindexlagsecalarmthresh`

Default Value: 300 seconds

Possible Values: Any integer value.

Description: Specifies the threshold (in seconds) to raise an alarm for index update lag.

Parameter: `dbrepllagsecalarmthresh`

Default Value: 900 seconds

Possible Values: Any integer value.

Description: Specifies the threshold (in seconds) to raise an alarm for DB replication lag.

Parameter: `ecenable`

Default Value: false

Possible Values:

- `true`
- `false`

Description: Enable (`true`) or disable (`false`) warm tiering for the volume. Either this parameter or `tieringenable` is required to enable warm tiering. If you specify this parameter, you cannot specify `tiername`; when the command runs, a new tier is created for the volume. If you do not specify any rule, the default rule, which is all files (p), is associated with the volume.

Parameter: `ecscheme`

Default Value: 4+2

Possible Values: Any valid EC scheme.

Description:

Note: This parameter is applicable only for EC volumes, and only when you set the `ecenable` parameter to `true`.

The number of data chunks and the number of parity chunks separated by a plus (+) sign.

For schemes with local parity, the scheme is of the form `x+y+z`, where x is the number of data chunks, y is the number of local parity chunks, and z is the number of global parity chunks.

For information on the supported schemes, see Erasure Coding Scheme for Data Protection and Recovery on page 926.

Parameter: `ectopology`

Default Value: `/data/default-rack`

Possible Values: Any topology that exists in your environment.

last-updated: Apr 11, 2022

Description: Sets the topology to store the erasure coded volume. Once set, you cannot change the topology of an erasure coded volume using this command. To change the topology of an erasure coded volume, use `volume move` on page 2021.

Note:

1. This parameter is applicable only for EC volumes.
2. The specified EC topology needs to have sufficient nodes for the selected EC Scheme. For example, 6 nodes for 4+2, 5 nodes for 3+2 etc.

Parameter: `enforceminreplicationforio`

Default Value: false

Possible Values:

- `true`
- `false`

Description: Specifies whether (`true`) or not (`false`) to enforce minimum number of replicas for the (read-write) volume during IO. This flag ensures that further updates (writes) to volume are successful only when the minimum number of copies of the container are available. Setting this parameter to `true` ensures that if writes succeed, then it has been applied to at least the minimum number of copies; if writes fail, it may have been applied to zero or more copies.

Enabling this parameter, may stall `volume dump` and `volume snapshot create` operations, if the minimum number of copies of the container are not available.

If you do not set this parameter on a volume, or if you modified this parameter from `false` to `true`, then you need to restart all the nodes where the containers associated with the volume exist, for the changes to take effect.

This flag is ignored on mirror volumes. If there are more than five cluster nodes, this flag is set to `true`, by default, on the tier volume. If the number of cluster nodes is less than five, this flag is set to `false`, by default, on the tier volume.

Parameter: `forceauditenable`

Default Value: false

Possible Values:

- `true` - force audit of all content
- `false` - do not force audit

Description: Specifies whether (`true`) or not (`false`) to force audit of operations on all files, tables, and streams in the volume if auditing is enabled at the cluster and volume levels, irrespective of the audit setting on the individual directory, file, table, and stream.

Parameter: `group`

Default Value: No default value

last-updated: Apr 11, 2022

Possible Values: Any user with `Create Volume` privileges.

Description: Space-separated list of `group:permission` pairs. Use commas to separate permissions. For example: `group:permission,permission,...`

Parameter: `inherit`

Default Value: No default value

Possible Values: Any existing volume name

Description: Specifies the name of the volume from which the new volume inherits properties. When you specify `inherit`, you do not need to specify `allowgrant`. See the following section on Inheritance for more information.

Parameter: `localvolumehost`

Default Value: No default value

Possible Values: Any existing volume name

Description: Specifies the name of the local volume host.

Parameter: `localvolumeport`

Default Value: 5660

Possible Values: Any valid port number

Description: Specifies the port number of the local volume host.

Parameter: `maxinodesalarmthreshold`

Default Value: 50000000

Possible Values: Any positive integer.

Description: The number of inodes, which when exceeded raises the INODES_EXCEEDED alarm.

Parameter: `maxnssizembalarmthreshold`

Default Value: 500 GB

Possible Values: Any positive integer.

Description: The namespace container size, which when exceeded raises the INODES_EXCEEDED alarm.

Parameter: `metricsenabled`

Default Value: false

Possible Values:

- `true`
- `false`

Description: Specifies whether (`true`) or not (`false`) to enable metrics collection for a volume.

Parameter: `minreplication`

Default Value: 2

Possible Values: Can be any value that you desire based on the replication you need.

Description: The minimum replication level. When the replication factor falls below this minimum, re-replication occurs as aggressively as possible to restore the replication level. If any containers in the CLDB volume fall below the minimum replication factor, writes are disabled until aggressive re-replication restores the minimum level of replication.

> **Tip:** For more information, see Understanding Replication on page 454.

Parameter: `mirrorschedule`

Default Value: 0

last-updated: Apr 11, 2022

Possible Values: Any valid schedule ID.

Description: The schedule ID corresponding to the schedule to be used for mirroring. If you specify a mirror schedule ID, then the mirror volume automatically syncs with its source volume on the specified schedule. Pre-assigned IDs include 1 for critical data, 2 for important data, and 3 for normal data. Custom schedules are assigned ID numbers in sequence. To determine the ID number, use the `schedule list` command.

Parameter: `mirrorthrottle`

Default Value: true

Possible Values:

- `true`
- `false`

Description: Specifies whether mirror throttling is enabled (`true`) or disabled (`false`). Throttling is set on the source volume and applies to all its mirrors.

Parameter: `mount`

Default Value: true

Possible Values:

- `true`
- `false`

Description: Specifies whether to mount the volume (`true`) or not (`false`) after creating the volume.

Parameter: `name`

Default Value: No default value

Possible Values: Any valid name

Description: Specifies the name for the volume.

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

For tiering-enabled volumes, the volume name cannot exceed 98 characters. For regular volumes, the volume name should be a maximum of 128 characters.

Parameter: `namecontainerdatathreshold`

Default Value: 524288 MB

Possible Values: Any integer value. The value is interpreted as being in MB.

If you set this parameter to `0`, there is no limit on the size of user data that can be stored in the name container.

If chunk size is `0`, by default, all data is stored in the name container. However, if this property is set, all data is stored in a second container and only the meta data is stored in the name container once the threshold is reached. The size of the second container is not limited by this setting; you must ensure that the size does not grow too large, by limiting the amount of data in the volume.

Description: Limits the size of user data that can be placed in the name container. The value is interpreted as being in MB. If the user data size limit:

- Has not yet been reached, the first 64 KB of data is stored in name container, and the rest of the data is stored in data containers.
- Has already been reached, only meta data is stored in the name container, and the data is stored in data containers. For example, if you set the current name container size to 200GB and the limit to 100GB, then all new user data is stored in data containers.

Parameter: `nsminreplication`

Default Value: 2

Possible Values: Any integer value.

Description: A replication factor of the namespace container. When the replication factor falls below this value, re-replication occurs as aggressively as possible to restore the replication level. If any containers in the CLDB volume fall below the minimum replication factor, writes are disabled until aggressive re-replication restores the minimum level of replication.

When enabled, the CLDB manages the namespace container replication separate from the data container replication. You use this capability when you have low volume replication but want to have higher namespace replication.

Set the value to be the same or larger than the value of the equivalent data replication parameter, `minreplication`.

See also: Understanding Replication on page 454.

Parameter: `nsreplication`

Default Value: 3

Possible Values: Any integer value.

Description: A replication factor of the namespace container. When the number of copies fall below the desired replication factor, but remains equal to or above the minimum replication factor, re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter. This timeout is the time given for a node that is offline to come back online. After this timeout period, the CLDB takes action to restore the replication factor. When enabled, the CLDB manages the namespace container replication separate from the data container replication. This capability is used when you have low volume replication but want to have higher namespace replication. By default, the value of this parameter is the same or larger than the value of the equivalent data replication parameter. However, to set the value of this parameter lower than the replication value, first set `engg.manual.override` to `true` in `cldb.conf`. *See also: Understanding Replication on page 454*.

Parameter: `offloadschedule`

Default Value: No default value

Possible Values: Any valid schedule ID. To disable schedule-based offload, set this value to `0`.

Description: The ID of the schedule to associate with the volume for offloading volume data to the tier.

Note: This parameter is required only for Cold/EC tiered volumes.

last-updated: Apr 11, 2022

Parameter: `path`

Default Value: No default value

Possible Values: Any valid path.

Description: The path at which to mount the volume. The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).

Parameter: `quota`

Default Value: 0

Possible Values: Any integer value along with a unit.

Description: The quota for the volume as `integer` plus `unit. Example: quota=500G; Units: B`, `K`, `M`, `G`, `T`, `P`

Do not use two-letter abbreviations for quota units, such as `GB` and `MB`.

When you set a quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

Note that quotas for source and mirror volumes must match.

Parameter: `readAce`

Default Value: `p` (grant access to all users)

Possible Values: Any valid permissions.

Description: Specifies Access Control Expressions(ACEs) that grant permissions at the volume level to read files and tables in the volume. The default value is `p`, which grants access to all users.

See *ACE*s.

Parameter: `readonly`

Default Value: No default value

Possible Values:

- `0`
- `1`

Description: Specifies whether the volume is read-only.

- `0` - read/write
- `1` - read-only

Parameter: `recallexpirytime`

Default Value: 1 day

Possible Values: Any integer between `1` and `7500`.

Description: The amount of time (in days) to keep the recalled data before purging or offloading it.

Parameter: `replication`

Default Value: 3

Possible Values: Any integer starting at `0`.

Description: The desired replication level. When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, re-replication occurs after the timeout specified in the

`cldb.fs.mark.rereplicate.sec` parameter. Note that this timeout is the time given for a node that is offline to come back online. After this timeout period, the CLDB takes action to restore the replication factor.

> **Tip:** For more information, see Understanding Replication on page 454.

Parameter: `replicationtype`

Default Value: `high_throughput`

Possible Values:

- `low_latency` (star replication)
- `high_throughput` (chain replication)

Description: The desired replication type. The default setting is `high_throughput`.

Parameter: `rereplicationtimeoutsec`

Default Value: 3600 seconds (1 hour)

Possible Values: Any positive integer.

Description: Timeout (in seconds) before attempting re-replication of replica containers. This volume property defines the timeout period until CLDB starts re-replicating the containers on the node of the volume after CLDB stops receiving a heartbeat from the node.

When a node is down, CLDB gives the node an hour to come back online before it takes any action for the containers on this node. You can set this parameter on volumes to reduce the default value to a shorter time period. This option is provided mainly for local volumes, so that when the MapR File System is down, CLDB can give up quickly and decide that the container has no master. This forces the TT to give up on local containers, and take the appropriate recovery action of deleting the mapred volume and creating another one.

Parameter: `rootdirgroup`

Default Value: User who is running the command

Possible Values: Any valid group

Description: Group that owns the root directory

Parameter: `rootdirperms`

Default Value: `rwxr-xr-x`

Possible Values: Any valid permission

Description: Permissions on the volume root directory.

Parameter: `rootdiruser`

Default Value: User who is running the command

Possible Values: Any valid user

Description: User that owns the root directory.

Parameter: `schedule`

Default Value: 0

Possible Values: `0` or a valid schedule ID.

Description: The ID of a schedule. Use the `schedule list` command to find the ID of the named schedule that you want to apply to the volume.

To disable the schedule, set this parameter to `0`.

Parameter: `skipinherit`

Default Value: No default value

Possible Values:

last-updated: Apr 11, 2022

- `schedule`
- `tiername`

Description:Specifies not to inherit given properties associated with the:

- Parent volume (for other volumes)
- Source volume (for mirror volumes)

Value must be either or both:

- `schedule` to not inherit snapshot schedule settings
- `tiername` to not:
  - Inherit tiering properties like `tierid`, `tieroffloadscheduleid`, `ecshceme`, `ectopology`
  - Set default values for `compactionscheduleid` and `compactionoverheadthreshold`

Use comma to separate multiple values.

Parameter: `source`

Default Value: No default value

Possible Values: Any volume.

Description: The source volume from which a mirror volume receives updates, specified in the format `<volume>@<cluster>`.

Parameter: `tenant`

Default Value: No default value

Possible Values: Any valid tenant user.

Description: The tenant is the entity for which resources such as volumes are created. The tenant can be an organization, a department within an organization, or an individual.

This parameter indicates the tenant for whom the volume is being created. All resources within the created volume are owned by the specified tenant.

Parameter: `tierencryption`

Default Value: false

Possible Values:

- `true`
- `false`

Description: Specifies whether to enable (`true`) or disable (`false`) encryption of data on the object store. This parameter is applicable only for cold-tier volumes. If you enable this parameter, user data is encrypted before being written to the object, and the HTTPS protocol is used for communication with the object store to ensure that data is encrypted both on the wire and on the tier.

You can set this parameter only if you specify a tier name (see the `tiername` parameter) as well. You cannot modify this parameter after you set it.

If you set the value to `true`, you can also specify a custom key using the `tierkey` parameter. Once set to `true`, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold tier does not support HTTPS, all tier related operations fail. If the cold-tier does not support HTTPS, you must explicitly set the value for this to `false` at the time of associating a tier with the volume because the default value for this parameter is `true`.

> **Tip:** For warm tier, use `-dare` option on the front-end volume to enable or disable encryption of data-at-rest.

Parameter: `tieringenable`

Default Value: No default value

Possible Values:

- true
- false

Description: Enable (`true`) or disable (`false`) tiering for the volume. When you specify this parameter, you must also specify the `tiername`. For creating a tiering-enabled mirror volume, specify this parameter if the source volume is enabled for cold-tier; specify either this parameter or `ecenable`, if the source volume is enabled for warm-tier.

Parameter: `tieringrule`

Default Value: p (all files)

Possible Values: Name of any valid rule

Description: The name of the rule (referred to as storage policy in the Control System) to use for offloading data to the tier. If you do not specify a rule, the default rule, which is all files (p), is associated with the volume. See Creating a Rule in Creating a Storage Tier Policy on page 972 for more information.

Parameter: `tierkey`

Default Value: Auto generated

Possible Values:Any 32-character HEX string, or let CLDB auto-generate this string

Description: The 32-character HEX string to use for encryption only for cold tier volumes. If you do not specify a string, CLDB generates a 32 character HEX string to use for encrypting the data to offload to the tier.

Parameter: `tiername`

Default Value: No default value

Possible Values: Any

Description: The name of the tier to use for offloading data. You can set this name only once and cannot modify it.

For warm tiering, you cannot specify this parameter if `ecenable` is set to `true`.

Parameter: `topology`

Default Value: `/data`

Possible Values: Any

Description: The rack path to the volume.

To create a volume in a specific topology, you must have the Converged Enterprise Edition installed

last-updated: Apr 11, 2022

on your system. Without the Converged Enterprise Edition, when you run the `maprcli volume create` command with the `-topology` option, the following error message is returned:

```
ERROR (10010) -  Volume Creation
Failed: Setting topology on
                        a volume
requires data placement feature.
License not found for data placement.
```

Parameter: `type`

Default Value: 0

Possible Values:

- `mirror`
- `rw`
- `0`
- `1`

Description: The type of volume to create.

The following values are accepted:

- `mirror` - standard mirror (read-only) volume (promotable to standard read-write volume)
- `rw` - standard (read-write) volume (convertible to standard mirror volume)
- `0` - standard (read-write) volume (for backward compatibility)
- `1` - non-convertible mirror (read-only) volume (for backward compatibility)

Parameter: `user`

Default Value: All permissions (`dump, restore, m, a, d, fc`) for the administrator who created the volume

Possible Values: Any valid permissions

Description: Space-separated list of `user:permission` pairs.

Use comma to separate permissions. For example: `user:permission,permission,...`

Parameter: `wiresecurityenabled`

Default Value: true

Possible Values:

- `true`
- `false`

Description: Enables (`true`) or disables (`false`) on-wire encryption for all files, tables, and streams in the volume for secure clusters. This parameter is not supported on insecure clusters.

If `true`, this setting overrides all file, table, and stream level encryption settings (set using the `hadoop mfs` command) and enables on-wire encryption for all

files, tables, and streams. If you disable (`false`) this parameter at the volume level, but enable it at the file, table, or stream level, the file, table, or stream level encryption setting overrides this setting on those files, tables, and streams where it is enabled; for all other files, tables, and streams where encryption is not enabled at the file, table, or stream level, the on-wire encryption is disabled.

Parameter: `writeAce`

Default Value: p (grants access to all users)

Possible Values: Any valid permissions

Description: Specifies Access Control Expressions (ACEs) that grant permission at the volume level to write to files and tables in the volume. The default value is p, which grants access to all users.

See *ACE*s.

Inheritance

The following table shows the list of inheritable parameters that are (Yes) and are not (No) inherited by a:

- Mirror volume from the source volume on the same cluster
- Mirror volume from the source volume on a different cluster

Note: All (non-mirror) volumes inherit all the inheritable properties from the parent volume. For more information on the properties, refer to `volume create` parameters.

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
`advisoryquota`	Yes	Yes
`ae`	Yes	No
`aetype`	Yes	No
`allowgrant`	Yes	Yes
`allowinherit`	Yes	Yes
`auditenabled`	Yes	Yes
`coalesce`	Yes	Yes
`dare`	Yes	Yes[1], No[2]
`dataauditops`	Yes	Yes
`dbindexlagsecalarmthresh`	Yes	Yes
`dbrepllagsecalarmthresh`	Yes	Yes
`ecscheme`	Yes	No
`ectopology`	Yes	No
`group`	Yes	Yes
`inherit`	Yes	Yes
`localvolumehost`	No	No
`localvolumeport`	No	No

last-updated: Apr 11, 2022

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
`maxinodesalarmthreshold`	Yes	Yes
`minreplication`	Yes	Yes
`mirrorschedule`	Yes	No
`mirrorthrottle`	Yes	Yes
`nsminreplication`	Yes	Yes
`nsreplication`	Yes	Yes
`ofloadschedule`	Yes	No
`quota`	Yes	Yes
`readonly`	Yes	Yes
`recallexpirytime`	Yes	No
`replication`	Yes	Yes
`replicationtype`	Yes	Yes
`rereplicationtimeoutsec`	Yes	Yes
`rootdirperms`	Yes	Yes
`schedule`	Yes[3]	No
`source`	Yes	Yes
`tierencryption`	Yes	No
`tieringenable`	Yes	No
`tieringrule`	Yes	No
`tierkey`	Yes	No
`tiername`[4]	Yes	No
`topology`	Yes	No
`type`	Yes	Yes
`user`	Yes	Yes
`wiresecurityenabled`	Yes	Yes

- [1] If destination cluster is also enabled for data-at-rest encryption, `dare` setting is inherited by the mirror volume on the destination cluster.
- [2] If destination cluster is not enabled for data-at-rest encryption, `dare` setting is not inherited by the mirror volume on the destination cluster.
- [3] If `schedule` keyword is specified with the `skipinherit` parameter, schedule(s) are not inherited while inheriting volume properties from the source volume.
- [4] If `tiername` keyword is specified with the `skipinherit` parameter:
  - The tiering properties are not inherited by the mirror volume while inheriting volume properties from the tiering-enabled source volume.
  - For volumes enabled for warm-tier, the backend erasure-coded volume is not created.

last-updated: Apr 11, 2022

Examples

Create the volume "test-volume" mounted at "/test/test-volume"

CLI

```
/opt/mapr/bin/maprcli volume
create -name test-volume -path /test/
test-volume -type rw  -json
{
    "timestamp":1526522204072,
    "timeofday":"2020-05-16
06:56:44.072 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'test-volume'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=test-volume&path=/test/
test-volume&type=rw' --user mapr:mapr
{"timestamp":1526522305703,"timeofday"
:"2020-05-16 06:58:25.703 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'test-volume'"]}
```

Create Volume with a Quota and an Advisory Quota

This example creates a volume with the following parameters:

- advisoryquota: 100M
- name: volumename
- path: /volumepath
- quota: 500M
- replication: 3
- schedule: 2
- topology: /East Coast
- type: rw

CLI

```
/opt/mapr/bin/maprcli volume
create -name volumename -path /
volumepath -advisoryquota 100M -quota
500M -replication 3 -schedule
2 -topology "/East Coast" -type
rw -json
{
```

last-updated: Apr 11, 2022

```
    "timestamp":1526522474660,
    "timeofday":"2018-05-16
07:01:14.660 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'volumename'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=volumename&path=/
volumepath&advisoryquota=100M&quota=50
0M&replication=3&schedule=2&type=rw'
 --user mapr:mapr
{"timestamp":1526522622494,"timeofday"
:"2018-05-16 07:03:42.494 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'volumename'"]}
```

Create the mirror volume "test-volume.mirror" from source volume "test-volume" and mount at "/test/test-volume-mirror"

CLI

```
/opt/mapr/bin/maprcli
volume create -name
test-volume.mirror -source
test-volume@ksTest -path /test/
test-volume-mirror -type mirror -json
{
    "timestamp":1526524458615,
    "timeofday":"2018-05-16
07:34:18.615 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created
volume: 'test-volume.mirror'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=test-volume.mirror&path=/test/
test-volume-mirror&type=mirror&source=
test-volume@ksTest' --user mapr:mapr
{"timestamp":1526524637534,"timeofday"
:"2018-05-16 07:37:17.534 GMT-0700
PM","status":"OK","total":0,"data":
```

```
[],"messages":["Successfully created
volume: 'test-volume.mirror'"]}
```

Create volumes that inherit from a parent volume

When creating and mounting a volume, the location of the mount path is specified by the path parameter. Volumes can be mounted via the web console, the `maprcli` commands, or the REST commands. The `maprcli` commands include `volume create -path` command and the `maprcli volume mount -path` command if the volume was previously created. Sub-volumes (children) can inherit properties from their parent volume.

In the following example, a parent volume and two (2) child volumes are create where the child volume inherit properties from the parent. When the `inherit` flag is explicitly used, the `allowgrant` parameter for the parent volume is not required.

- For child volumes, c1 and c2, inheritance is explicit because the `inherit` option is specified. Thus, p1.c1 and p1.c2 volumes will inherit all properties from volume p1 (note that p1 is not a parent of p1.c1) regardless of whether the `allowgrant` option is set on p1 or not. In this case, there is an explicit inheritance ant the `allowgrant` flag is ignored and volume properties are inherited.
- For the child volume, c3, inheritance is implicit. Meaning, the child volume, p1.c3, inherits all properties from the parent volume, p1, only if the `allowgrant` option is set on p1.

CLI

```
/opt/mapr/bin/maprcli volume
create -name p1 -path /p1
/opt/mapr/bin/maprcli volume
create -name p1.c1 -inherit p1
/opt/mapr/bin/maprcli
volume create -name
p1.c2 -path /p1/c2 -inherit p1
/opt/mapr/bin/maprcli volume
create -name p1.c3 -path /p1/c3
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1&path=%2Fp1' --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1.c1&inherit=p1' --user
mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1.c2&path=%2Fp1%2Fc2&inherit=p1'
 --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1.c3&path=%2Fp1%2Fc3' --user
mapr:mapr
```

In the following example, the p1.child volume normally inherits from the p1 parent volume properties because p1.child is mounted under p1 and `allowgrant` option is set to `true` on the parent volume. However, if the child volume doesn't want to inherit properties, then set the `allowinherit` option to `false` (default: `true`).

CLI

```
/opt/mapr/bin/maprcli volume
create -name p1 -path /p1 -allowgrant
```

```
true
/opt/mapr/bin/maprcli volume
create -name p1.child -path /p1/
p1.child -allowinherit false
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1&path=%2Fp1&allowgrant=true'
 --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1.child&path=%2Fp1%2Fp1.child&al
lowinherit=false' --user mapr:mapr
```

Create a volume with namespace container replicas

CLI

```
/opt/mapr/bin/maprcli
volume create -name
testVol -nsminreplication
2 -nsreplication 3 -json
{
    "timestamp":1526525132522,
    "timeofday":"2018-05-16
07:45:32.522 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'testVol'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=testVol&path=/
testVol&nsminreplication=2&nsreplicati
on=3' --user mapr:mapr
{"timestamp":1526525257461,"timeofday"
:"2018-05-16 07:47:37.461 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'testVol'"]}
```

Create a volume and set ACEs

CLI

```
/opt/mapr/bin/maprcli volume
create -name testVol -readAce
p -writeAce 'g:group1&!u:user1' -json
{
    "timestamp":1526525429326,
    "timeofday":"2018-05-16
07:50:29.326 GMT-0700 PM",
    "status":"OK",
    "total":0,
```

```
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'testVol'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=testVol&readAce=p&writeAce=g%3Agr
oup1%26%21u%3Auser1' --user mapr:mapr
{"timestamp":1526525572035,"timeofday"
:"2018-05-16 07:52:52.035 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'testVol'"]}
```

Create a volume with auditing disabled for specific operations

CLI

```
/opt/mapr/bin/maprcli volume
create -name
test-volume -auditenabled
true -dataauditops --lookup,-read,-wri
te -json
{
    "timestamp":1526525720308,
    "timeofday":"2018-05-16
07:55:20.308 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'test-volume'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=test-volume&path=/test/
test-volume&auditenabled=true&dataaudi
tops=%2D%2Dlookup%2C%2Dread%2C%2Dwrite
' --user mapr:mapr
{"timestamp":1526525795017,"timeofday"
:"2018-05-16 07:56:35.017 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'test-volume'"]}
```

Create a volume and grant user permissions on the volume:

CLI Example 1

```
/opt/mapr/bin/maprcli volume
create -name testVol1 -path /
```

```
testVol1 -user user1:dump
user2:fc -json
{
    "timestamp":1521162402826,
    "timeofday":"2018-03-15
06:06:42.826 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[
    ],
    "messages":[
        "Successfully created volume:
'testVol1'"
    ]
}
```

REST

```
curl -k -X POST 'https://
10.10.82.24:8443/rest/volume/create?
name=testVol&path=/
testVol&user=user1%3Adump%20user2%3Afc
' --user mapr:mapr
{"timestamp":1526526072608,"timeofday"
:"2018-05-16 08:01:12.608 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'testVol'"]}
```

CLI Example 2

```
/opt/mapr/bin/maprcli volume
create -name testVol -path /
testVol2 -user user1:dump,restore
user2:a,fc -json
{
    "timestamp":1521162467485,
    "timeofday":"2018-03-15
06:07:47.485 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[
    ],
    "messages":[
        "Successfully created volume:
'testVol2'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=testVol2&path=/
testVol2&user=user1%3Adump%2Crestore%2
0user2%3Aa%2Cfc' --user mapr:mapr
{"timestamp":1526526256845,"timeofday"
:"2018-05-16 08:04:16.845 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'testVol2'"]}
```

Create a volume for a tenant

This example creates a volume for a tenant with the following parameters:

- `name`: volumename
- `path`: /volumepath
- `advisoryquota`: 500MB
- `quota`: 1GB
- `replication`: 3

CLI

```
/opt/mapr/bin/maprcli volume
create -name tenantVol -cluster
ksTest -path /egTenant -tenantuser
egTenant -advisoryquota 500M -quota
1G -replication 3 -json
{
    "timestamp":1526526462865,
    "timeofday":"2018-05-16
08:07:42.865 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'tenantVol'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=tenantVol&cluster=ksTest&path=/
egTenant&advisoryquota=500M&quota=1G&r
eplication=3' --user mapr:mapr
{"timestamp":1526526615167,"timeofday"
:"2018-05-16 08:10:15.167 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'tenantVol'"]}
```

Create a volume with on-wire encryption enabled for all files and tables in the volume:

CLI

```
/opt/mapr/bin/maprcli
volume create -name
test-Volume -path /testvolume -type
rw -wiresecurityenabled true -json
{
    "timestamp":1526526686905,
    "timeofday":"2018-05-16
08:11:26.905 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ],
```

```
    "messages":[
        "Successfully created volume:
'test-Volume'"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=test-volume&path=/
testVolume&type=rw&wiresecurityenabled
=true' --user mapr:mapr
{"timestamp":1526526748723,"timeofday"
:"2018-05-16 08:12:28.723 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'test-volume'"]}
```

Create a sub-volume and do not inherit schedules from the parent volume:

CLI

```
/opt/mapr/bin/maprcli volume
create -name p1.c2 -path /p1/
p1.c2 -skipinherit schedule -json
{
        "timestamp":1505196021575,
        "timeofday":"2017-09-11
11:00:21.575 GMT-0700",
        "status":"OK",
        "total":0,
        "data":[

        ],
        "messages":[
                "Successfully created
volume: 'p1.c2'"
        ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1.c2&path=/p1/
p1.c2&skipinherit=schedule' --user
mapr:mapr
{"timestamp":1526526980643,"timeofday"
:"2018-05-16 08:16:20.643 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'p1.c2'"]}
```

Create a mirror volume and do not inherit the schedule(s) from the source volume:

CLI

```
/opt/mapr/bin/maprcli volume
create -name p1.m2 -path /p1/
p1.m2 -type mirror -source
p1@ksTest -skipinherit schedule -json
{
        "timestamp":1505196450141,
        "timeofday":"2017-09-11
```

```
11:07:30.141 GMT-0700",
        "status":"OK",
        "total":0,
        "data":[

        ],
        "messages":[
                "Successfully created
volume: 'p1.m2'"
        ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=p1.m2&path=/p1/
p1.m2&type=mirror&source=p1@ksTest&ski
pinherit=schedule' --user mapr:mapr
{"timestamp":1526527151925,"timeofday"
:"2018-05-16 08:19:11.925 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'p1.m2'"]}
```

Create a volume and enable tiering, but do not specify the tier type and do not associate an offload rule or schedule:

CLI

```
/opt/mapr/bin/maprcli volume
create -name sampleVol -path /
sampleVol -tieringenable true -json
{
    "timestamp":1519922099117,
    "timeofday":"2018-03-01
08:34:59.117 GMT-0800 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'sampleVol'"
    ]
}
```

REST

```
curl -k -X POST 'https://
10.10.82.24:8443/rest/volume/create?
name=sampleVol&path=/
sampleVol&tieringenable=true' --user
mapr:mapr
{"timestamp":1519922181381,"timeofday"
:"2018-03-01 08:36:21.381 GMT-0800
AM","status":"OK","total":0,"data":
[],"messages":["Successfully created
volume: 'sampleVol'"]}
```

Create a volume, enable cold tiering, associate a rule and schedule for offloading data, and set the number of days to keep recalled data:

CLI

```
/opt/mapr/bin/maprcli volume
create -name sampleVol -path /
sampleVol -tieringenable
true -tiername
ksTestCold -tieringrule
rule1 -offloadschedule
2 -recallexpirytime 2 -json
{
    "timestamp":1519922642632,
    "timeofday":"2018-03-01
08:44:02.632 GMT-0800 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully created volume:
'sampleVol'"
    ]
}
```

REST

```
curl -k -X POST 'https://
10.10.82.24:8443/rest/volume/create?
name=sampleVol&path=/

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

node list on page 1705
Lists nodes in the cluster.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

volume dump create
Creates a volume *dump file* containing data from a volume for distribution or restoration.

Permissions Required

`dump` or `fc` on the volume.

Note: In a secure cluster, you must use the MapR user ID. Using `root` or any other user ID results in the system hanging.

Syntax

CLI

```
/opt/mapr/bin/maprcli volume dump
create
     [ -cluster cluster_name
     [-s startvolumepointname]
     [-e endvolumepointname]
     [-o (for dumpfile on stdout)]
     [-dumpfile dumpfilename (ignored
if -o is used)]
     -name volumename
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/dump/create?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`dumpfile`	The name of the dump file (ignored if `-o` is used).
`e`	The name of the state file to create for the end point of the dump.
`name`	A volume name.
`o`	This option dumps the volume to stdout instead of to a file.
`s`	The start point for an incremental dump.

Note: The data is not encrypted in the dump file created for a volume enabled for data at rest encryption.

Examples

Create a full dump:

CLI

```
/opt/mapr/bin/maprcli volume dump
create -e statefile1 -dumpfile
fulldump1 -name volume -n
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/dump/
create?
e=statefile1&dumpfile=fulldump1&name=v
olume&n' --user mapr:mapr
```

Create an incremental dump:

CLI

```
/opt/mapr/bin/maprcli volume
dump create -s statefile1 -e
statefile2 -name volume -dumpfile
incrdump1
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/dump/
create?
s=statefile1&e=statefile2&name=volume&
dumpfile=incrdump1' --user mapr:mapr
```

Create and Maintain Volume Dump File
Describes how to create full dump files and add incremental volume dump files.

You can use `volume dump create` to create two types of files:

- *full* dump files containing all data in a volume
- *incremental* dump files that contain changes to a volume between two points in time

A full dump file is useful for restoring a volume from scratch. An incremental dump file contains the changes necessary to take an existing (or restored) volume from one point in time to another. Along with the dump file, a full or incremental dump operation can produce a *state* file (specified by the ?-e parameter) that contains a table of the version number of every container in the volume at the time the dump file was created. This represents the *end point* of the dump file, which is used as the *start point* of the next incremental dump. The main difference between creating a full dump and creating an incremental dump is whether the -s parameter is specified; if -s is not specified, the volume create command includes all volume data and creates a full dump file. If you create a full dump followed by a series of incremental dumps, the result is a sequence of dump files and their accompanying state files:

dumpfile1 statefile1

dumpfile2 statefile2

dumpfile3 statefile3

Note: You can restore the volume from scratch, using the volume dump restore command with the full dump file, followed by each dump file in sequence.

When you create a dump file for a volume enabled for data at rest encryption, data in the dump file is not encrypted.

Note: In a secure cluster, you must use the MapR user ID. Using root or any other user ID results in the system hanging.

last-updated: Apr 11, 2022

To create and maintain an up-to-date dump of a volume:

1. Create a full dump file.
   Example:

```
maprcli volume dump create -name cli-created -dumpfile fulldump1 -e
statefile1
```

2. Periodically, add an incremental dump file.
   Examples:

```
maprcli volume dump create -s statefile1 -e statefile2 -name
cli-created -dumpfile incrdump1
maprcli volume dump create -s statefile2 -e statefile3 -name
cli-created -dumpfile incrdump2
maprcli volume dump create -s statefile3 -e statefile4 -name
cli-created -dumpfile incrdump3
```

   ...and so on.

volume dump restore
Restores or updates a volume from a dump file. Permissions required: `fc` or `restore` on the volume.

Syntax

CLI

```
maprcli volume dump restore
     [ -cluster cluster_name ]
     [-i (read dump from stdin)]
     [-n (create new volume if it
doesn't exist)]
     [-dumpfile dumpfilename (ignored
if -i is used)]
     [-full <true|false> (perform
full volume restore, default:false ]
     -name volumename
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/dump/restore?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`dumpfile`	The name of the dumpfile (ignored if `-i` is used).
`i`	This option reads the dump file from `stdin`.
`n`	This option creates a new volume if it doesn't exist.
`full`	Perform either a full volume restore or an incremental volume restore. The default restore is incremental.

Parameter	Description
`name`	A volume name, in the form `volumename`

Note: In a secure cluster, you must use the MapR user ID. Using `root` or any other user ID results in the system hanging.

Examples
Restore a volume from a full dump file:

CLI

```
maprcli volume dump restore -name
volume -dumpfile fulldump1 -full true
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/dump/
restore?
name=volume&dumpfile=fulldump1&full=tr
ue' --user mapr:mapr
```

Apply an incremental dump file to a volume:

CLI

```
maprcli volume dump restore -name
volume -dumpfile incrdump1
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/dump/
restore?
name=volume&dumpfile=incrdump1' --user
 mapr:mapr
```

Restore Volume From a Dump
Describes how to restore from full and incremental dump files.

There are two ways to use volume dump restore:

- With a full dump file, `volume dump restore` recreates a volume from scratch from volume data stored in the dump file.
- With an incremental dump file, `volume dump restore` updates a volume using incremental changes stored in the dump file.

The volume that results from a `volume dump restore` operation is a mirror volume whose source is the volume from which the dump was created. After the operation, this volume can perform mirroring from the source volume.

When you are updating a volume from an incremental dump file, you must specify an existing volume and an incremental dump file. To restore from a sequence of previous dump files would involve first restoring from the volume's full dump file, then applying each subsequent incremental dump file.

Note: In a secure cluster, you must use the MapR user ID. Using root or any other user ID results in the system hanging.

A restored volume may contain mount points that represent volumes that were mounted under the original source volume from which the dump was created. In the restored volume, these mount points have no meaning and do not provide access to any volumes that were mounted under the source volume. If the

last-updated: Apr 11, 2022

source volume still exists, then the mount points in the restored volume will work if the restored volume is associated with the source volume as a mirror.

To restore from a full dump plus a sequence of incremental dumps:

1. Restore from the full dump file, using the `-n` option to create a new mirror volume and the `-name` option to specify the name.
   Example:

   ```
   maprcli volume dump restore -dumpfile fulldump1 -name restore1 -n
   ```

2. Restore from each incremental dump file in order, specifying the same volume name.
   Examples:

   ```
   maprcli volume dump restore -dumpfile incrdump1 -name restore1 maprcli
                           volume dump restore -dumpfile incrdump2 -name
   restore1 maprcli volume dump restore
                           -dumpfile incrdump3 -name restore1
   ```

   ...and so on.

volume fixmountpath
Corrects the mount path of a volume. Permissions required: `fc` or `m` on the volume.

The CLDB maintains information about the mount path of every volume. If a directory in a volume's path is renamed (by a `hadoop fs` command, for example) the information in the CLDB will be out of date. The `volume fixmountpath` command does a reverse path walk from the volume and corrects the mount path information in the CLDB.

Syntax

CLI

```
maprcli volume fixmountpath
-name <name>
[ -cluster <clustername> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/fixmountpath?<parameters>`

Parameters

Parameter	Description
`name`	The volume name.
`cluster`	The cluster name

Examples

Fix the mount path of volume v1:

CLI

```
maprcli volume fixmountpath -name v1
```

REST

```
https://abc.sj.us:8443/rest/volume/
fixmountpath?name=v1
```

volume info
Displays information about the specified volume. For JSON formatted output, use the `-json` option when running the command.

Syntax

CLI

```
maprcli volume info
    [ -cluster <cluster name> ]
    [ -output verbose. default:
verbose ]
    [ -path <mount directory> ]
    [ -name <volume name> ]
    [ -columns comma separated list
of column names. default: all ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/volume/info?<parameters>`

Parameters

You must specify either name or path, but not both.

Parameter	Description
`cluster`	The cluster on which to run the command.
`columns`	A comma-separated list of fields to return in the query. See the Fields table on the `volume` command page. Default: `all`
`name`	The volume name for which to retrieve information. When issuing the `maprcli volume info -columns` and `marcli volume list -columns` commands, the column for the volume name is `volumename`.
`output`	Indicates whether the output should be terse or verbose. Default: verbose
`path`	The mount path of the volume for which to retrieve information.

Output

For definitions of the output fields, and short names for use with filters, see the Fields table on the `volume` command page.

Examples

Return information on standard volume named `test_vol`:

CLI

```
/opt/mapr/bin/maprcli volume
info -name test_vol -json
{
    "timestamp":1520275171388,

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

node list on page 1705
Lists nodes in the cluster.

dump volumeinfo on page 1637

Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

volume link create
Creates a link to a volume. Permissions required: `fc` or `m` on the volume.

Syntax

CLI

```
maprcli volume link create
    [ -cluster <clustername> ]
    -path <link path>
    -type <type>
    -volume <volume>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/link/create?<parameters>`

Parameters

Parameter	Description
`path`	The `-path` parameter specifies the link path: `/link` Example: `/home/abc/.rw`
`type`	The volume type: `writeable` or `mirror`.
`volume`	The volume name.
`cluster`	The cluster name.

Examples

Create a link to v1 at the path v1. mirror:

CLI

```
maprcli volume link create -volume
v1 -type mirror -path /v1.mirror
```

REST

```
https://abc.sj.us:8443/rest/
volume/link/create?path=/
v1.mirror&type=mirror&volume=v1
```

volume link remove
Removes the specified symbolic link. Permissions required: `fc` or `m` on the volume.

Syntax

CLI

```
maprcli volume link remove
    -path <path>
    [ -cluster <clustername> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/link/remove?<parameters>`

Parameters

Parameter	Description
`path`	The symbolic link to remove. The path parameter specifies the link path and other information about the symbolic link, using the following syntax: `/link/[maprfs::][volume::]<volume type>::<volume name>` • `link` - the symbolic link path *`maprfs` - a keyword to indicate a special MapR filesystem link • `volume` - a keyword to indicate a link to a volume • `volume type` - `writeable` or `mirror` • `volume name` - the name of the volume Example: `/abc/maprfs::mirror::abc`
`cluster`	The cluster name.

Examples

Remove the link /abc:

CLI

```
maprcli volume link remove -path /abc/
maprfs::mirror::abc
```

REST

```
https://abc.sj.us:8443/rest/
volume/link/remove?path=/abc/
maprfs::mirror::abc
```

volume list
Lists information about volumes specified by name, path, or filter.

See the Fields table on the volume on page 1913 page for the fields available to filter. See the Filters on page 1526 for more information.

last-updated: Apr 11, 2022

Syntax

CLI

```
/opt/mapr/bin/maprcli volume list
    [ -alarmedvolumes 0|1 ]

    [ -cluster <cluster> ]
    [ -columns <columns> ]

    [ -filter <filter> ]
    [ -limit <limit> ]
    [ -nodes <nodes> ]
    [ -output terse | verbose ]

    [ -sortby <attribute> ]
    [ -start <offset> ]
```

Note: For JSON formatted output, use the `-json` option when running `volume list` from the command line.

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/volume/list[?<parameters>]`

Parameters

Parameter	Description
`alarmedvolumes`	Specifies whether (1) or not (0) to list alarmed volumes only. Default: 0
`cluster`	The cluster name on which to run the command.
`columns`	A comma-separated list of fields to return in the query. See the volume on page 1913 table on the volume page. When issuing the `maprcli volume info -columns` and `marcli volume list -columns` commands, the column for the volume name is `volumename`.
`filter`	A filter specifying volumes to list. See Filters on page 1526 for more information. Default: none
`limit`	The number of rows to return, beginning at start. Default: 2147483647
`nodes`	A list of nodes. If specified, `volume list` only lists volumes on the specified nodes.
`output`	Specifies whether the output should be `terse` or `verbose`. Default: verbose
`sortby`	Specifies one of the following attributes to sort the list of volumes by: `volumeowner`, `volumenumreplicas`, `volumeminreplicas`, `volumerackpath`, `volumemountdir`, `volumename`, `volumequota`, `volumeused`, `volumequotaadvisory`, `volumeaename`, `volumeaetype`, `volumeschedule`, `volumetype`, `volumemirrorpercentcomplete`, `volumesnapshotcount`, `volumeid`, `volumenamecontainersize`, `volumelocalpath`, `volumesnapshotused`, `volumetotalused`, `volumelogicalused`, `volumecontainercount`, `volumemirrorschedule`, `volumeaccesstime`, `volumenamespacecontainernumreplicas`, `volumenamespacecontainerminreplicas`, `volumerereplicationtimeoutsec`, `volumecriticalrereplicationtimeoutsec`, `volumecreatetime`, `volumedareenabled`

Parameter	Description
`start`	The offset from the starting row according to sort. Default: 0

Output

Information about the specified volumes.

For standard and mirror volumes (not enabled for tiering), the output looks similar to the following:

```

Fields

For definitions of the output fields, and short names for use with filters, see the Fields table on the `volume` command page.

Examples

List all volumes

CLI

```
/opt/mapr/bin/maprcli volume
list -json
```

REST

```
https://10.10.82.23:8443/rest/volume/
list
```

List the first ten volumes

The `start` and `limit` parameters are useful for windowing the results. You can list the first ten volumes, then the next ten, and so on.

CLI

```
/opt/mapr/bin/maprcli volume
list -start 0 -limit 10 -json
```

REST

```
curl -k -X
GET 'https://abc.sj.us:8443/rest/
node/list?start=0&limit=10' --user
mapr:mapr
```

Filter by aename

CLI

```
maprcli volume list -filter
'[aename==mapr]' -columns volumeid
volumeid
```

last-updated: Apr 11, 2022

```

volume mirror push

Pushes the changes in a volume to all of its mirror volumes in the same cluster, and waits for each mirroring operation to complete.

Use this command when you need to push recent changes.

Syntax

CLI

```
maprcli volume mirror push
    [ -cluster <cluster> ]
    -name <volume name>
    [ -verbose true|false ]
```

REST

None.

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`name`	The volume to push.
`verbose`	Specifies whether the command output should be verbose. Default: true

Output

Sample Output

```
Starting mirroring of volume mirror1
Mirroring complete for volume mirror1
Successfully completed mirror push to all local mirrors of volume volume1
```

Examples

Push changes from the volume "volume1" to its local mirror volumes:

CLI

```
maprcli volume mirror push -name
volume1 -cluster mycluster
```

volume mirror start
Starts mirroring on the specified volume from its source volume.

- License required: Enterprise Edition
- Permissions required: `fc` or `restore` on the volume

When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The `volume mirror start` command does not wait for mirror completion, but returns immediately. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

To provide rollback capability for the mirror volume, the mirroring process creates a snapshot of the mirror volume before starting the mirror, with the following naming format: `<volume>.mirrorsnap.<date>.<time>`.

Normally, the mirroring operation transfers only deltas from the last successful mirror. Under certain conditions (mirroring a volume repaired by `fsck`, for example), the source and mirror volumes can become out of sync. In such cases, it is impossible to transfer deltas, because the state is not the same for both volumes. Use the `-full` option to force the mirroring operation to transfer all data to bring the volumes back in sync.

Syntax

CLI

```
maprcli volume mirror start
    [ -cluster <cluster> ]
    [ -full true|false ]
    -name <volume name>
```

REST

Request Type	POST

last-updated: Apr 11, 2022

Request URL	`http[s]://<host>:<port>/rest/volume/mirror/start?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`full`	Specifies whether to perform a full copy of all data. If false, only the deltas are copied.
`name`	The volume for which to start the mirror.

Output

Sample Output

```
messages
Started mirror operation for volumes 'testMirror'
```

Examples

Start mirroring the mirror volume "testMirror":

CLI

```
maprcli volume mirror start -name
testMirror
```

REST

```
https://abc.sj.us:8443/rest/volume/
mirror/start?name=testMirror
```

volume mirror status
Displays the status of the mirroring operation in progress. Use this command to examine the progress of mirroring.

- License required: Enterprise Edition
- Permissions required: `fc` or `restore` on the volume

The `status` command displays the statstics of the mirroring operation including the total number of container IDs to resync, the current status of the mirroring, the number of indoes in use for the mirror, the container ID information for the source and destination volumes, and the error code if any, to name a few.

Syntax

CLI

```
maprcli volume mirror status
    [ -cluster cluster_name ]
    -name name
    [ -start start. default: 1 ]
    [ -limit limit. default:
2147483647 ]
    [ -verbose <true/false> if true,
```

```
will displayed detailed container
information. default: true ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/mirror/status?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`name`	The volume for which to determine the mirror status.
`start`	The container to start with.
`limit`	The number of containers for which to display status.
`verbose`	Whether to display a terse output or display full statistics.

Examples

Check the status of the mirroring on mirror volume "testvol":

CLI

```
maprcli volume mirror status -name
testvol -json

**** Displays mirroring statistics.
****
***  Here, it is resyncing
destination containers ****

REST

```
https://abc.sj.us:8443/rest/volume/
mirror/status?name=testvol
```

volume mirror stop
Stops mirroring on the specified volume.

- License required: Enterprise Edition
- Permissions required: `fc` or `restore` on the volume

The `volume mirror stop` command lets you stop mirroring (for example, during a network outage). You can use the `volume mirror start` command to resume mirroring.

Syntax

CLI

```
maprcli volume mirror stop
    [ -cluster <cluster> ]
    -name <volume name>
```

REST

Request Type	POST

Request URL	`http[s]://<host>:<port>/rest/volume/mirror/stop?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`name`	The volume for which to stop the mirror.

Output

Sample Output

```
messages
Stopped mirror operation for volumes 'testMirror'
```

Examples

Stop mirroring the mirror volume "testMirror":

CLI

```
maprcli volume mirror stop -name
testMirror
```

REST

```
https://abc.sj.us:8443/rest/volume/
mirror/stop?name=testMirror
```

volume modify

Modifies an existing volume. Permissions required: `m` or `fc` on the volume.

An error occurs if the name or path refers to a non-existent volume, or cannot be resolved.

Syntax

CLI

```
/opt/mapr/bin/maprcli volume modify
    [ -cluster <cluster name> ]
    -name <volume name>
    [ -advisoryquota <advisory
quota> ]
    [ -ae <accounting entity> ]

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/modify?<parameters>`

Parameters

Parameter: `advisoryquota`

Possible Values: 0 or any other integer value.

Description: The advisory quota for the volume as `integer` plus `unit. Example: quota=500G; Units: B`, `K`, `M`, `G`, `T`, `P`

Parameter: `ae`

Possible Values: Name of the entity that owns the volume.

Description: The accounting entity that owns the volume.

Parameter: `aetype`

Possible Values:

- `0=user`
- `1=group`

Description: Type of accounting entity.

Parameter: `allowgrant`

Possible Values:

- `truetrue`
- `false`

Description: Specifies whether the volume as a parent, grants permission for a child volume to inherit its properties.

Parameter: `allowreadforexecute`

Possible Values:

- `true`
- `false`

Description: Allows execution of SUID binaries with only their executable bit set, on a FUSE filesystem. This parameter works in conjunction with the `fuse.mount.setuid` FUSE option. For more information, see Configuring the MapR FUSE-Based POSIX Client on page 1240.

Parameter: `auditenabled`

Possible Values:

- `true`
- `false`

Description: Specifies whether to turn on auditing for the volume. If you enable auditing at the cluster level

	with the audit data on page 1553 command, setting this value to `true` causes auditing to start for any directories, files, tables, or streams that are already enabled for auditing. If none are yet enabled, enabling auditing on any of them causes auditing of them to start. Set `auditenabled` to `true` to enable auditing on directories, files, tables, and streams in the volume. You must have the `fc` permission on the cluster to use this parameter. See `acl` for details about this permission.
Parameter: `autooffloadthresholdgb`	Possible Values: Any positive integer. Description: The size of the volume in GB (threshold). When this threshold is reached or exceeded, volume data is automatically offloaded by the Automatic Tiering Scheduler. To use the global size threshold (of 1024 GB), set the value to `0`.
Parameter: `cluster`	Possible Values: Any valid cluster. Description: The cluster on which to run the command.
Parameter: ***`coalesce`***	Possible Values: Set this parameter to a large number of minutes to prevent audit logs from growing quickly. Description: The interval of time (in minutes) during which READ, WRITE, or GETATTR operations on one file from one IP address or UID are logged only once for a particular operation, if auditing is enabled. For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged. Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.
Parameter: `compactionoverheadthreshold`	Possible Values: 0-100% Description: Specifies the percentage of offloaded data that must have been deleted on the MapR cluster to qualify the data for compaction (or deletion from the tier).
Parameter: `compactionschedule`	Possible Values: Any valid schedule ID. Set this parameter to `0` to disable the compactor. Description: Specifies the schedule to use for running the compactor. By default, the compactor runs on an automatic internal schedule.
Parameter: `containerallocationfactor`	Recommended value: 2* SP count in the volume topology. Description: Specifies the number of containers to create when the first write from a remote client is sent to the volume. The pre-created containers are distributed equally across topologies, servers, MapR File System instances, and storage pools. CLDB also

takes into consideration the load (IO/Space) when selecting target storage pools for containers. The value must be a positive integer.

Parameter: `criticalrereplicationtimeoutsec`

Possible Values: Any integer between 300 and 3600 (seconds)

Description: Timeout (in seconds) before re-replicating only the critically under-replicated containers . If you set both `rereplicationtimeoutsec` and `criticalrereplicationtimeoutsec`, and if the value of:

- `rereplicationtimeoutsec` is less than `criticalrereplicationtimeoutsec`, `rereplicationtimeoutsec` overrides the `criticalrereplicationtimeoutsec` setting for both under-replicated and critically under-replicated containers.
- `rereplicationtimeoutsec` is greater than `criticalrereplicationtimeoutsec`, `criticalrereplicationtimeoutsec` overrides the `rereplicationtimeoutsec` setting only for critically under-replicated containers; `rereplicationtimeoutsec` setting is still applicable for under-replicated containers.

Parameter: `dataauditops`

Possible Values: Any audit operations that you want to enable.

Description: The comma separated list of filesystem operations to include (specified with a preceding plus sign (+)) or exclude (specified with a preceding minus sign (-)) from auditing.

To exclude the first operation in the list (of operations) from auditing, precede it by two minus (`--`) signs. To exclude subsequent operations, precede them by only a single minus (`-`) sign, irrespective of whether the first operation was included (using a plus (+) sign) or excluded (using two minus (`--`) signs). If neither sign is specified, the given operation is included for auditing.

The operations that can be included (+) or excluded (`-`) from auditing are listed here. You can, alternatively, group all the operations using the keyword `all`, which:

- If included (+), cannot be specified with a list of other included operations.
- If excluded (`-`), cannot be specified with a list of other excluded operations.

You can specify a mixed list of included and excluded operations. There is no change to operations that are not specified with the command.

> **Tip:** For more information, see Selective Auditing of Filesystem and Table Operations.

Parameter: `disableddataauditops`

Possible Values: Any audit operations that you want to disable.

Description: The comma-separated list of disabled filesystem audit operations to set. This parameter is an alternate way of setting audit operations as compared

last-updated: Apr 11, 2022

to the `dataauditops` option. Plus (+) or minus signs (-) are not allowed for this option. Any audit operation that is specified with this option replaces any existing disabled audit operations configured for this security policy, while any audit operations that are not specified, are enabled.

Merging of the specified audit operations with existing audit operations is not performed, as with the `dataauditops` option.

Parameter: `dbindexlagsecalarmthresh`

Possible Values: Any integer value.

Description: Specifies the threshold (in seconds) to raise an alarm for index update lag.

Parameter: `dbrepllagsecalarmthresh`

Possible Values: Any integer value.

Description: Specifies the threshold (in seconds) to raise an alarm for DB replication lag.

Parameter: `ecenable`

Possible Values:

- `true`
- `false`

Description: Enable (`true`) warm tiering for the volume only if it is already not enabled. When specified, you cannot specify `tiername` to use an existing warm-tier; when the command runs, a new tier and rule are automatically created for the volume.

`ecenable` works only if you have set `tieringenable` to `true` at the time of volume creation.

When modifying volumes, `ecenable` does not automatically set `tieringenable` to `true` as in the case of volume creation.

Setting this parameter to `false` is the same as not specifying this parameter, and does nothing.

Parameter: `ecscheme`

Possible Values: Any valid EC scheme.

Description: The number of data chunks and the number of parity chunks separated by a plus (+) sign. The default scheme is `4+2`. For information on the supported schemes, see Erasure Coding Scheme for Data Protection and Recovery on page 926.

Note: This parameter is applicable only for EC volumes, and only when you set the `ecenable` parameter to `true`.

Parameter: `ectopology`

Possible Values: Any topology that exists in your environment.

Description: Sets the topology of the erasure coded volume if it is not set.

Note: This parameter is applicable only for EC volumes.

Once set, you cannot change the topology of an erasure coded volume using this command. To change the topology of an erasure coded volume, use `volume move` on page 2021

last-updated: Apr 11, 2022

Parameter: `enforceminreplicationforio`	Possible Values: • `true` • `false` Description: Specifies whether (`true`) or not (`false`) to enforce minimum number of replicas for the (read-write) volume during IO. This flag ensures that further updates (writes) to volume are successful only when the minimum number of copies of the container are available. Setting this parameter to `true` ensures that if writes succeed, then it has been applied to at least the minimum number of copies; if writes fail, it may have been applied to zero or more copies. Enabling this parameter, may stall `volume dump` and `volume snapshot create` operations, if the minimum number of copies of the container are not available. If you do not set this parameter on a volume, or if you modified this parameter from `false` to `true`, then you need to restart all the nodes where the containers associated with the volume exist, for the changes to take effect. This flag is ignored on mirror volumes.
Parameter: `forceauditenable`	Possible Values: • `true` • `false` Description: Specifies whether (`true`) or not (`false`) to force audit of operations on all files, tables, and streams in the volume if auditing is enabled at the cluster and volume levels, irrespective of the audit setting on the individual directory, file, table, and stream.
Parameter: `group`	Possible Values: Any user with `Create Volume` privileges. Description: Space-separated list of `group:permission` pairs.
Parameter: `maxinodesalarmthreshold`	Possible Values: Any positive integer. Description: The number of inodes, which when exceeded raises the INODES_EXCEEDED alarm.
Parameter: `maxnssizembalarmthreshold`	Possible Values: Any positive integer. Description: The namespace container size, which when exceeded raises the INODES_EXCEEDED alarm.
Parameter: `metricsenabled`	Possible Values: • `true` • `false` Description: Specifies whether (`true`) or not (`false`) to enable metrics collection for a volume.
Parameter: `minreplication`	Possible Values: Can be any value that you desire based on the replication you need.

last-updated: Apr 11, 2022

Description: The minimum replication level. When the replication factor falls below this minimum, re-replication occurs as aggressively as possible to restore the replication level. If any containers in the CLDB volume fall below the minimum replication factor, writes are disabled until aggressive re-replication restores the minimum level of replication.

> **Tip:** For more information, see Understanding Replication on page 454.

Parameter: `mirrorschedule`

Possible Values: `0` or a valid schedule ID.

Description: The schedule ID corresponding to the schedule to be used for mirroring. If you specify a mirror schedule ID, the mirror volume automatically syncs with its source volume on the specified schedule. Pre-assigned IDs include `1` for critical data, `2` for important data, and `3` for normal data. Custom schedules are assigned ID numbers in sequence. To determine the ID number, use the `schedule list` command. To disable the schedule, set this parameter to `0`.

Parameter: `mirrorthrottle`

Possible Values:

- `true`
- `false`

Description: Specifies whether mirror throttling is enabled (`true`) or disabled (`false`). Throttling is set on the source volume and applies to all its mirrors.

Parameter: `namecontainerdatathreshold`

Possible Values: Any integer value.

If you set this parameter to `0`, there is no limit on the size of user data that can be stored in the name container.

Description: Limits the size of user data that can be placed in the name container. The value is interpreted as being in MB. If the user data size limit:

- Has not yet been reached, the first 64 KB of data is stored in name container, and the rest of the data is stored in data containers.
- Has already been reached, only meta data is stored in the name container, and the data is stored in data containers. For example, if you set the current name container size to 200GB and the limit to 100GB, then all new user data is stored in data containers.

Parameter: `nsminreplication`

Possible Values: Any integer value.

Description: When the replication factor falls below this value, re-replication occurs as aggressively as possible to restore the replication level. If any containers in the CLDB volume fall below the minimum replication factor, writes are disabled until aggressive re-replication restores the minimum level of replication.

When enabled, the CLDB manages the namespace container replication separate from the data container replication. You use this capability when you have low volume replication but want to have higher namespace replication.

Set the value to be the same or larger than the value of the equivalent data replication parameter, `minreplication`.

See also: Understanding Replication on page 454.

Parameter: `nsreplication`

Possible Values: Any integer value.

Description: The desired namespace container replication level.

When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter. This timeout is the time given for a node that is down to come back online. After this timeout period, the CLDB takes the action required to restore the replication factor.

When enabled, the CLDB manages the namespace container replication separate from the data container replication. Use this capability when you have low volume replication but want to have higher namespace replication.

By default, the value of this parameter is the same or larger than the value of the equivalent data replication parameter, `replication`. However, to set the value of this parameter lower than the `replication` value, first set `engg.manual.override` to `true` in `cldb.conf`.

See also: Understanding Replication on page 454.

Parameter: `name`

Possible Values: Not Applicable.

Description: The name of the volume to modify.

Parameter: `offloadschedule`

Possible Values: Any valid schedule ID. To disable schedule-based offload, set this value to `0`.

Description: The ID of the schedule to associate with the volume for offloading volume data to the tier.

Note: This parameter is required only for Cold/EC tiered volumes.

Parameter: `quota`

Possible Values: Any integer value along with a unit.

Description: The quota for the volume as `integer` plus `unit. Example: quota=500G; Units: B`, `K`, `M`, `G`, `T`, `P`

Do not use two-letter abbreviations for quota units, such as `GB` and `MB`.

When you set a quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

Note that quotas for source and mirror volumes must match.

Parameter: `readAce`

Possible Values: Any valid permissions.

Description: Specifies Access Control Expressions(ACEs) that grant permissions at the volume level to read files and tables in the volume. The default value is `p`, which grants access to all users.

See *ACE*s.

Parameter: `readonly`

Possible Values:

- `0`
- `1`

Description: Specifies whether the volume is read-only.

- `0` - read/write
- `1` - read-only

Parameter: `recallexpirytime`

Possible Values: Any integer between `1` and `7500`.

Description: The amount of time (in days) to keep the recalled data before purging or offloading it.

Parameter: `replication`

Possible Values: Any integer starting at `0`.

Description: The desired replication level. When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter. Note that this timeout is the time given for a node that is offline to come back online. After this timeout period, the CLDB takes action to restore the replication factor.

> **Tip:** For more information, see Understanding Replication on page 454.

Parameter: `rereplicationtimeoutsec`

Possible Values: Any positive integer.

Description: Timeout (in seconds) before attempting re-replication of replica containers. This volume property defines the timeout period until CLDB starts re-replicating the containers on the node of the volume after CLDB stops receiving a heartbeat from the node.

When a node is down, CLDB gives the node an hour to come back online before it takes any action for the containers on this node. You can set this parameter on volumes to reduce the default 1 hour to a shorter time period. This option is provided mainly for local volumes, so that when the MapR File System is down, CLDB can give up quickly and decide that the container has no master. This forces the TT to give up on local containers, and take the appropriate recovery action of deleting the mapred volume and creating another one.

Parameter: `schedule`

Possible Values: `0` or a valid schedule ID.

Description: The ID of a schedule. Use the `schedule list` command to find the ID of the named schedule that you want to apply to the volume.

To disable the schedule, set this parameter to `0`.

Parameter: `skipwiresecurityfortierinternalops`

Possible Values:

- `true`
- `false`

Description: Skips wire security for internal operations.

Parameter: `source`

Possible Values: Any volume.

Description: The source volume from which a mirror volume receives updates, specified in the format `<volume>@<cluster>`.

Parameter: `tierencryption`

Possible Values:

- `true`
- `false`

Description: Specifies whether to enable (`true`) or disable (`false`) encryption of data on the object store. This parameter is applicable only for cold-tier volumes. If you enable this parameter, user data is encrypted before being written to the object, and the HTTPS protocol is used for communication with the object store to ensure that data is encrypted both on the wire and on the tier.

You can set this parameter only if you specify a tier name (see the `tiername` parameter) as well. You cannot modify this parameter after you set it.

If you set the value to `true`, you can also specify a custom key using the `tierkey` parameter. Once set to `true`, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold tier does not support HTTPS, all tier related operations fail. If the cold-tier does not support HTTPS, you must explicitly set the value for this to `false` at the time of associating a tier with the volume because the default value for this parameter is `true`.

> **Tip:** For warm tier, use `-dare` option on the front-end volume to enable or disable encryption of data-at-rest.

Parameter: `tieringrule`

Possible Values: Name of any valid rule

Description: The name of the rule (referred to as storage policy in the Control System) to use for offloading data to the tier. If you do not specify a rule, the default rule, which is all files (p), is associated with the volume. See Creating a Rule in Creating a Storage Tier Policy on page 972 for more information.

Parameter: `tierkey`

Possible Values:Any 32-character HEX string, or let CLDB auto-generate this string

Description: The 32-character HEX string to use for encryption only for cold tier volumes. If you do not specify a string, CLDB generates a 32 character HEX string to use for encrypting the data to offload to the tier.

Restriction: You cannot modify the tierkey that is already associated with the volume.

Parameter: `tiername`

Possible Values: Not Applicable

last-updated: Apr 11, 2022

Description: The name of the tier to use for offloading data. You can set this name only once and cannot modify it.

For warm tiering, you cannot specify this parameter if `ecenable` is set to `true`.

Parameter: `type`

Possible Values:

- `mirror`
- `rw`
- `0`
- `1`

Description: The type of volume to create.

The following values are accepted:

- `mirror` - standard mirror (read-only) volume (promotable to standard read-write volume)
- `rw` - standard (read-write) volume (convertible to standard mirror volume)
- `0` - standard (read-write) volume (for backward compatibility)
- `1` - non-convertible mirror (read-only) volume (for backward compatibility)

Parameter: `user`

Possible Values: Any valid permissions

Description: Space-separated list of `user:permission` pairs.

Use comma to separate permissions. For example: `user:permission,permission,...`

Parameter: `wiresecurityenabled`

Default Value: true

Possible Values:

- `true`
- `false`

Description: Enables (`true`) or disables (`false`) on-wire encryption for all files, tables, and streams in the volume for secure clusters. This parameter is not supported on insecure clusters.

If `true`, this setting overrides all file, table, and stream level encryption settings (set using the `hadoop mfs` command) and enables on-wire encryption for all files, tables, and streams. If you disable (`false`) this parameter at the volume level, but enable it at the file, table, or stream level, the file, table, or stream level encryption setting overrides this setting on those files, tables, and streams where it is enabled; for all other files, tables, and streams where encryption is not enabled at the file, table, or stream level, the on-wire encryption is disabled.

Parameter: `writeAce`

Possible Values: Any valid permissions

Description: Specifies Access Control Expressions (ACEs) that grant permission at the volume level to write to files and tables in the volume. The default value is p, which grants access to all users.

See *ACE*s.

Examples

Change the source volume of the mirror "test-mirror":

CLI

```
/opt/mapr/bin/maprcli volume
modify -name test-mirror -source
volume-2@my-cluster
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=test-mirror&source=volume-2@my-cl
uster&' --user mapr:mapr
```

Create a volume with namespace container replicas

CLI

```
/opt/mapr/bin/maprcli
volume modify -name
testVol -nsminreplication
2 -nsreplication 4 -json
{
    "timestamp":1526528489360,
    "timeofday":"2018-05-16
08:41:29.360 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=testVol&nsminreplication=2&nsrepl
ication=4' --user mapr:mapr
{"timestamp":1526528556748,"timeofday"
:"2018-05-16 08:42:36.748 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

Modify a volume to allow inheritance by a child volume

Sub-volumes (children) can inherit properties from their parent volume. The `maprcli volume create` and `volume modify` commands provide parameters for setting the inheritance feature. For a child volume to inherit from a parent volume, the parent volume must grant permission, and the child volume must be created specifying the volume name of the parent. In the following example, the parent volume, parentVol, grants inheritance to child volumes.

CLI

```
/opt/mapr/bin/maprcli volume
modify -name parentVol -allowgrant
true
```

REST

```
curl -k -X
POST 'https://abc.sj.us:8443/
rest/volume/modify?name=parentVol?
allowgrant=true' --user mapr:mapr
```

Set and modify ACEs on a volume

In the following example, the command sets and modifies access (defined using ACEs) to the volume data. When the command runs, new values:

- Overwrite existing values for access types that were previously set.
- Are set for access types that were not set.

Note: There is no change to the readAce access type, which is not specified with the command, irrespective of whether it is set or not.

CLI

```
/opt/mapr/bin/maprcli volume
modify -name testVol -writeAce
'g:group1&(!u:user1|!r:role1)'
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=testVol&writeAce=g%3Agroup1%26%28
%21u%3Auser1%7C%21r%3Arole1%29' --user
 mapr:mapr
```

Modify the list of operations that are audited

In the following example, the `create` operation is included for auditing and the `lookup` operation is excluded from auditing. There are no changes to operations that are not specified.

CLI

```
/opt/mapr/bin/maprcli volume
modify -name parentVol -dataauditops
+create,-lookup
```

RETST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=p1&dataauditops=%2Bcreate%2C-look
up' --user mapr:mapr
```

Modify an existing volume to enable on-wire encryption:

CLI

```
/opt/mapr/bin/maprcli
volume modify -name
local2 -wiresecurityenabled true -json
{
        "timestamp":1505205889697,
        "timeofday":"2017-09-12
```

```
01:44:49.697 GMT-0700",
        "status":"OK",
        "total":0,
        "data":[

        ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=p1&wiresecurityenabled=true' --us
er mapr:mapr
{"timestamp":1526569299139,"timeofday"
:"2018-05-17 08:01:39.139 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

Associate an offload rule with a tiering-enabled volume:

CLI

```
/opt/mapr/bin/maprcli volume
modify -name sampleVol -tieringrule
ksTestRule -json
{
    "timestamp":1526569498559,
    "timeofday":"2018-05-17
08:04:58.559 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=sampleVol&tieringrule=ksTestRule'
 --user mapr:mapr
{"timestamp":1526569554743,"timeofday"
:"2018-05-17 08:05:54.743 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

Modify a volume to set a schedule for data offload and set number of days to three days to keep recalled data:

CLI

```
/opt/mapr/bin/maprcli
volume modify -name
sampleVol -offloadschedule
3 -recallexpirytime 3 -json
{
    "timestamp":1526569615285,
    "timeofday":"2018-05-17
08:06:55.285 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[
```

```
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=sampleVol&offloadschedule=3&recal
lexpirytime=3' --user mapr:mapr
{"timestamp":1526569653267,"timeofday"
:"2018-05-17 08:07:33.267 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

Disable scheduled snapshot creation

To disable a schedule, set the `schedule` parameter to `0`.

For example:

CLI

```
/opt/mapr/bin/maprcli volume
modify -name mapr.apps  -schedule 0
/opt/mapr/bin/maprcli volume
info -name mapr.apps  -json | grep
schedule

"scheduleid":"0",

"schedulename":"",

"mirrorscheduleid":"0"
```

Remove file filter from a volume

To remove a file filter use the special filefilter "" .

For example:

CLI

```
/opt/mapr/bin/maprcli volume
modify -name noexec -filefilter ""
```

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

volume mount
Mounts one or more specified volumes. Permissions required: fc or `m` on the volume.

Syntax

CLI

```
maprcli volume mount
    [ -cluster <cluster> ]
    -name <volume list>
    -path <path list>
    [ -createparent 0|1 ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/mount?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`name`	The name of the volume to mount.
`path`	The path at which to mount the volume. The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).
`createparent`	Specifies whether or not to create a parent volume: • `0` = Do not create a parent volume. • `1` = Create a parent volume.

Examples

Mount the volume "test-volume" at the path "/test":

CLI

```
maprcli volume mount -name
test-volume -path /test
{
    "timestamp":1537804971391,
    "timeofday":"2018-09-24
09:02:51.391 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/mount?
name=test-volume&path=/test' --user
mapr:mapr
{"timestamp":1537804971391,"timeofday"
:"2018-09-24 09:02:51.391 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

volume move

Moves the specified volume or mirror to a different topology. Permissions required: `m` or `fc` on the volume.

Syntax

CLI

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/move?<parameters>`

Parameters

Parameter: `cluster`

Possible Values: Any valid cluster.

Description: The cluster on which to create the volume.

Parameter: `ectopology`

Possible Values: Any topology that exists in your environment.

Description: The new rack path for the erasure-coded volume if you are moving an erasure-coded volume.

Note: This parameter is applicable only for EC volumes.

Parameter: `label`

Possible Values: Any label.

Description: The label to use for the storage pool. See for more information on labels.

The label should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

Tip: Use the special label named `anywhere` to let a volume reside on any storage pool. Not setting a label, causes a volume to reside only on a storage pool without a label.

Parameter: `name`

Possible Values: Any valid name

Description: The name of the volume to move. For moving:

- An erasure coded volume, specify the name of the front-end volume.
- The metadata volume associated with a tier, specify the name of the metadata volume.

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

For tiering-enabled volumes, the volume name cannot exceed ninety-eight characters.

Parameter: `nslabel`

Possible Values: Any value.

Description: The label to use for the namespace container. See for more information on labels.

The label should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

Parameter: `topology`	Possible Values: Any Description: The new rack path for the: • Regular or tiered standard volume, if you are moving a regular or tiered standard volume. • Regular or tiered mirror volume, if you are moving a regular or tiered mirror volume. • Metadata volume, if you are moving a metadata volume associated with a tier. This parameter is not required, if you are moving an erasure-coded volume.

Advisory Note on Storage Labels

When the volume of a label is changed, replicas cannot be migrated within the file server, from one SP with the old label to another SP with the desired label. If there no other SPs, all old copies will not be fully migrated to the new desired label.

Examples

CLI

```
maprcli volume move -name
testVolume -topology /newPath
```

REST

```
curl -k -X 'https://abc.sj.us:8443/
rest/volume/move?
name=testVolume&topology=%2FnewPath'
 --user mapr:mapr
```

Related concepts

node on page 1694
Manages nodes in the cluster

Related reference

disk add on page 1602
Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

volume create on page 1931
Creates a volume.

node list on page 1705
Lists nodes in the cluster.

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

volume offload
Offloads data in the volume to the tier.

Permissions Required

The user running the command must have one of the following:

- Full control (fc) on the cluster or volume
- Volume edit permissions

Syntax

CLI

```
maprcli volume offload
   [ -cluster cluster_name ]
   [ -ignorerule <true|false> ]
   -name <volume_name>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/offload?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`ignorerule`	Specify whether (`true`) or not (`false`) to ignore existing rules associated with the volume for offloading data. If value is: • `true`, all data in the volume is offloaded and rules associated with the volume for offload are ignored. • `false`, data is offloaded based on the rules set up for offloading data. Default value is `false`.
`name`	The name of the volume.

Example

Offload a volume:

CLI

```
# /opt/mapr/bin/maprcli volume
offload -name sampleVol -json
{
    "timestamp":1501104289006,
    "timeofday":"2017-07-26
02:24:49.006 GMT-0700",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully started
offload."
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/offload?
```

```
name=sampleVol' --user mapr:mapr
{"timestamp":1519947659597,"timeofday"
:"2018-03-01 03:40:59.597 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully started
offload."]}
```

volume recall
Recalls the offloaded data for the specified volume.

Permissions Required

The user running the command must have one of the following:

- Full control (fc) on the cluster or volume
- Volume edit permissions

Syntax

CLI

```
maprcli volume recall
        [ -cluster cluster_name ]
         -name <volume_name>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/recall?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the volume.

Example

Recall a volume:

CLI

```
# /opt/mapr/bin/maprcli volume
recall -name sampleVol -json
{
    "timestamp":1520007453541,
    "timeofday":"2018-03-02
08:17:33.541 GMT-0800 AM",
    "status":"OK",
    "total":0,
    "data":[

    ],
    "messages":[
        "Successfully started recall."
```

```
    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/recall?
name=sampleVol' --user mapr:mapr
{"timestamp":1520007538784,"timeofday"
:"2018-03-02 08:18:58.784 GMT-0800
AM","status":"OK","total":0,"data":
[],"messages":["Successfully started
recall."]}
```

volume remove
Removes the specified volume or mirror. Permissions required: d or fc on the volume.

Syntax

CLI

```
maprcli volume remove
    [ -cluster <cluster> ]
    [ -force true|false ]
    [ -filter <filter> ]
    -name <volume name>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/remove?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`force`	Forces the removal of the volume, even if there are dependencies.
`name`	The volume name.
`filter`	All volumes with names that match the filter are removed.

Examples

CLI

```
maprcli volume remove -name testVolume
```

REST

```
https://abc.sj.us:8443/rest/volume/
remove?name=testVolume
```

volume rename
Renames the specified volume or mirror. Permissions required: `fc` or `d` on the volume.

Note: If you rename a volume, you must unmount and re-mount the volume to allow applications and/or users to continue accessing the volume.

Syntax

CLI

```
maprcli volume rename
    [ -cluster <cluster> ]
    -name <volume name>
    -newname <new volume name>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/rename?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`name`	The volume name.
`newname`	The new volume name. For tiering-enabled volumes, volume name cannot exceed ninety-eight characters.

Examples

Rename a standard volume:

CLI

```
# maprcli volume
rename -name testVolume -newname
newVolumeName -json
{
    "timestamp":1537994815889,
    "timeofday":"2018-09-26
01:46:55.889 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/rename?
name=testVolume&newname=newVolumeName'
 --user mapr:mapr
{"timestamp":1537994918599,"timeofday"
:"2018-09-26 01:48:38.599 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

volume showmounts
Returns a list of mount points for the specified volume.

last-updated: Apr 11, 2022

Note: The three dots in the output indicate hierarchical mounts within a volume. Use `-json` to format the output.

Syntax

CLI

```
maprcli volume showmounts
    [ -cluster <cluster name> ]
    -name <volume name>
    -json
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/volume/showmounts?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster hosting the volume.
`json`	(Required) Returns the output in JSON format.
`name`	The name of the volume to return a list of mount points for.

Examples

Return the mount points for volume mapr.user.volume for the cluster my.cluster.com:

CLI

```
maprcli volume showmounts -cluster
my.cluster.com -name
mapr.user.volume -json
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/volume/showmounts?
cluster=my.cluster.com&name=mapr.user.
volume' --user mapr:mapr
```

volume snapshot create

Creates a snapshot of the specified volume, using the specified snapshot name.

- License required: Enterprise Edition
- Permissions required: `fc` or `m` on the volume

Syntax

CLI

```
maprcli volume snapshot create
    [ -cluster <cluster> ]
    [ -retain <positive_integer>mi|h|
```

last-updated: Apr 11, 2022

```
d|w|m|y ]
    -snapshotname <snapshot>
    -volume <volume>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/snapshot/create?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`retain`	Specifies how long to retain the snapshot data. Value can be specified in: • Minutes by appending `mi` to the integer. For example, `30mi` can be specified as the value for this parameter to retain snapshot data for 30 minutes. • Hours by appending `h` to the integer. For example, `1h` can be specified as the value for this parameter to retain snapshot data for 1 hour. • Days by appending `d` to the integer. For example, `2d` can be specified as the value for this parameter to retain snapshot data for 2 days. • Weeks by appending `w` to the integer. For example, `4w` can be specified as the value for this parameter to retain snapshot data for 4 weeks. • Months by appending `m` to the integer. For example, `10m` can be specified as the value for this parameter to retain snapshot data for 10 months. • Years by appending `y` to the integer. For example, `7y` can be specified as the value for this parameter to retain snapshot data for 7 years. If this is not specified, snapshot data will never expire.
`snapshotname`	The name of the snapshot to create.
`volume`	The volume for which to create a snapshot.

Examples

Create a snapshot called "test-snapshot" for volume "test-volume":

CLI

```
maprcli volume
snapshot create -snapshotname
test-snapshot -volume test-volume
{
    "timestamp":1537805380237,
    "timeofday":"2018-09-24
```

```
09:09:40.237 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/snapshot/
create?
volume=test-volume&snapshotname=test-s
napshot' --user mapr:mapr
{"timestamp":1537805548885,"timeofday"
:"2018-09-24 09:12:28.885 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

volume snapshot list
Displays info about a set of snapshots.

You can specify the snapshots by volumes or paths, or by specifying a filter to select volumes with certain characteristics.

Syntax

CLI

```
/opt/mapr/bin/maprcli volume snapshot
list
    [ -cluster <cluster name> ]
    [ -columns <fields> ]
    ( -filter <filter> ]
    [ -path <volume path list> ]
    [ -volume <volume list> ]
    [ -limit <rows> ]
    [ -output (terse|verbose) ]
    [ -start <offset> ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/volume/snapshot/list[?<parameters>]`

Parameters

Either `volume` or `path` can be used if you wish the specify the snapshots. In addition, `filter` can be used with `volume` and `path`, or independently.

Parameter	Description
`cluster`	The cluster on which to run the command.
`columns`	A comma-separated list of fields to return in the query. See the Fields on page 2031 table below. Default: none
`filter`	A filter specifying snapshots to list. See Filters on page 1526 for more information.

Parameter	Description
`limit`	The number of rows to return, beginning at start. Default: `2147483647`
`output`	Specifies whether the output should be `terse` or `verbose`. Default: `verbose`
`path`	A comma-separated list of paths for which to list snapshots.
`start`	The offset from the starting row. Default: `0`
`volume`	A comma-separated list of volumes for which to list snapshots.

Fields

The following table lists the fields used in the `columns` parameter, and returned as output.

Field Name	Short Name	Description
`snapshotid`	`id`	Unique snapshot ID.
`sharedSize`	shSz	Size of data (in MB) that the snapshot shares with previous snapshots.
`volumename`	`vn`	Name of the read-write volume associated with the snapshot.
`ownername`	`on`	Owner (user or group) associated with the volume.
`cumulativeReclaimSizeMB`	`cs`	Disk space (in MB) used/owned by the snapshot
`snapshotname`	`n`	Snapshot name.
`ownedsize`	owSz	Size of data (in MB) owned by a snapshot, as opposed to sharedSize (owned by previous snapshots).
`ownertype`	`ot`	Owner type for the owner of the volume: • `0=user` • `1=group`
`volumeid`	`vid`	ID of the volume associated with the snapshot.
`creationtime`	`ct`	Snapshot creation time. Date time string (verbose output) or milliseconds since 1970 (terse output).
`volumepath`	`vp`	Path to the volume associated with the snapshot.
`expirytime`	`et`	The time until which the snapshot should be maintained. Expired snapshots are purged (deleted) periodically. Date time string (verbose output), or milliseconds since 1970 (terse output); 0 = never expires.

last-updated: Apr 11, 2022

Field Name	Short Name	Description
volumeSnapshotAces	N/A	*ACE* permissions for read and write on the volume snapshot. Use `-json` to view the *ACE* permissions.

Output

This sample output is based on using the following code to create a snapshot called `uservolume` for the volume named `users`.

```
/opt/mapr/bin/maprcli volume snapshot create -snapshotname
uservolsnap -volume users
```

Sample Output

```
# maprcli volume snapshot list
snapshotid  ownedsize  sharedSize  volumename
ownername  ownertype  cumulativeReclaimSizeMB  volumeid
snapshotname    creationtime                  volumepath
volumeSnapshotAces
256000051   0          0           users       mapr       1
0                      212450174  uservolsnap     Wed Sep 26 10:45:27 PDT
2018  /user       ...
```

Examples

List all snapshots:

CLI

```
# maprcli volume snapshot list
snapshotid  ownedsize
sharedSize  volumename  ownername
ownertype  cumulativeReclaimSizeMB
volumeid   snapshotname
creationtime
volumepath  volumeSnapshotAces
256000049   0          0
egVol       mapr       1
0                        29379677

    ]
}
```

volume snapshot preserve
Preserves one or more snapshots from expiration.

Specify the snapshots by volumes, paths, filter, or IDs.

- License required: Enterprise Edition
- Permissions required: `fc` or `m` on the volume

Syntax

CLI

```
maprcli volume snapshot preserve
    [ -cluster <cluster> ]
    ( -filter <filter> | -path
<volume path list> | -snapshots
<snapshot list> | -volume <volume
list> )
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/snapshot/preserve[?<parameters>]`

Parameters

Specify exactly one of the following parameters: volume, path, filter, or snapshots.

Parameter	Description
`cluster`	The cluster on which to run the command.
`filter`	A filter specifying snapshots to preserve. See Filters on page 1526 for more information.
`path`	A comma-separated list of paths for which to preserve snapshots.
`snapshots`	A comma-separated list of snapshot IDs to preserve.
`volume`	A comma-separated list of volumes for which to preserve snapshots.

Examples

Preserve two snapshots by ID:

First, use `volume snapshot list` to get the IDs of the snapshots you wish to preserve. Example:

```
# maprcli volume snapshot list
snapshotid  ownedsize  sharedSize  volumename  ownername
ownertype  cumulativeReclaimSizeMB  volumeid   snapshotname
creationtime                  volumepath  volumeSnapshotAces
256000049   0          0           egVol       mapr       1
0                       29379677   egVol-snapshot  Wed Sep 26 10:42:52 PDT
2018  /egVol      ...
256000051   0          0           users       mapr       1
0                       212450174  uservolsnap     Wed Sep 26 10:45:27 PDT
2018  /user       ...
256000050   0          0           egVol       mapr       1
0                       29379677   egVolSnapshot   Wed Sep 26 10:43:12 PDT
2018  /egVol      ...
```

Use the IDs in the `volume snapshot preserve` command. For example, to preserve the first two snapshots in the above list, run the commands as follows:

CLI

```
maprcli volume
snapshot preserve -snapshots
256000049,256000051 -json
{
    "timestamp":1537986060505,
    "timeofday":"2018-09-26
11:21:00.505 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/snapshot/
preserve?
snapshots=256000049,256000051' --user
mapr:mapr
{"timestamp":1537986132998,"timeofday"
```

```
:"2018-09-26 11:22:12.998 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

volume snapshot remove
Removes one or more snapshots.

- License required: Enterprise Edition
- Permissions required: `fc` or `m` on the volume

Syntax

CLI

```
maprcli volume snapshot remove
    [ -cluster <cluster> ]
    ( -snapshotname <snapshot name> ]
    [ -snapshots <snapshots> ]
    [ -volume <volume name> ]
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/snapshot/remove[?<parameters>]`

Parameters

Specify both snapshot name and volume, or just snapshot ID.

Parameter	Description
`cluster`	The cluster on which to run the command.
`snapshotname`	The name of the snapshot to remove. You must also specify the volume name using the `volume` parameter.
`snapshots`	A comma-separated list of IDs of snapshots to remove.
`volume`	The name of the volume from which to remove the snapshot. This is required if you are removing snapshot by specifying the snapshot name (using `snapshotname` parameter).

Examples

Remove the snapshot named "test-snapshot" associated with volume named "test-volume":

CLI

```
maprcli volume
snapshot remove -snapshotname
test-snapshot -volume test-volume
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/api/volume/snapshot/
remove?
snapshotname=test-snapshot&volume=tes
t-volume' --user mapr:mapr
```

Remove two snapshots by ID:

First, use `volume snapshot list` to get the IDs of the snapshots you wish to remove. Example:

```
# maprcli volume snapshot list
snapshotid  ownedsize  sharedSize  volumename  ownername
ownertype  cumulativeReclaimSizeMB  volumeid   snapshotname
creationtime                  volumepath  volumeSnapshotAces
256000049   0          0           egVol       mapr       1
0                       29379677   egVol-snapshot  Wed Sep 26 10:42:52 PDT
2018  /egVol      ...
256000051   0          0           users       mapr       1
0                       212450174  uservolsnap     Wed Sep 26 10:45:27 PDT
2018  /user       ...
256000050   0          0           egVol       mapr       1
0                       29379677   egVolSnapshot   Wed Sep 26 10:43:12 PDT
2018  /egVol      ...
```

Use the IDs in the `volume snapshot remove` command. For example, to remove the first two snapshots in the above list, run the commands as follows:

CLI

```
maprcli volume snapshot
remove -snapshots 256000049,256000051
{
    "timestamp":1537986405764,
    "timeofday":"2018-09-26
11:26:45.764 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/snapshot/
remove?
snapshots=256000049,256000051' --user
mapr:mapr
{"timestamp":1537987406574,"timeofday"
:"2018-09-26 11:43:26.574 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

volume tierjobabort
Terminates an ongoing offload or recall operation for a volume (specified by name).

Permissions Required

The user running the command must have one of the following:

- Full control (fc) on the cluster or volume
- Volume edit permissions

Syntax

CLI

```
maprcli volume tierjobabort
    [ -cluster cluster_name ]
     -name name
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/tierjobabort?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the volume.

Example

Stop offloading data to the tier:

CLI

```
/opt/mapr/bin/maprcli volume
tierjobabort -name sampleVol -json
{
        "timestamp":1503504450211,
        "timeofday":"2017-08-23
04:07:30.211 GMT+0000",
        "status":"OK",
        "total":0,
        "data":[

        ],
        "messages":[
                "Successfully started
to abort."
        ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/
tierjobabort?name=sampleVol' --user
mapr:mapr
{"timestamp":1503504450211,"timeofday"
:"2017-08-23 04:07:30.211
GMT+0000","status":"OK","total":0,"dat
a":[],"messages":["Successfully
started to abort."]}
```

volume tierjobstatus

Retrieves the status of the currently running operation (such as offload, recall, or terminate) for a volume.

Permissions Required

The user running the command must have one of the following:

- Full control (fc) on the cluster or volume
- Volume edit permissions

Syntax

CLI

```
maprcli volume tierjobstatus
     [ -cluster <cluster_name> ]
     -name <volume_name>
     [ -verbose true|false ]
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/volume/tierjobstatus?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the volume.
`verbose`	Specifies whether the command output should be verbose. The value for this must be `true` to retrieve the status of a compaction operation. The default value is `false`.

Output

The command returns the following:

`state`	The status of the offload, recall, or terminate operation. See Statuses on page 2040 below for more information.
`offloadedDataSize`	The amount of data offloaded. This is returned only when returning the status of an offload operation.
`progress`	The percentage of containers that have been processed so far.
`recalledDataSize`	The amount of data recalled. This is returned only when returning the status of a recall operation.
`reclaimedDataSize`	The amount of data purged. This is returned only when returning the status of a compaction job.
`startTime`	The date and timestamp for when the offload operation started.
`endTime`	The date and timestamp for when the offload operation completed.

last-updated: Apr 11, 2022

`gateway`	The IP address of the MAST Gateway used for the tiering operation.

Statuses

The value for the `state` field (statuses) can be one of the following:

State	Description

Scheduled	Indicates the job request has reached CLDB, but has not yet been forwarded to any MAST Gateway service. For example:
	CLI
	`{ "timestamp":1532093619983, "timeofday":"2018-07-20 06:33:39.983 GMT-0700 AM", "status":"OK", "total":1, "data":[ { "compaction":{ "state":"Scheduled", "scheduleTime":"2018-07-20 06:33:38.953 GMT-0700", "gateway":"10.10.108.116:8660" } } ] }`
	REST
	`{"timestamp":1532093619983,"timeofday":"2018-07-20 06:33:39.983 GMT-0700 AM","status":"OK","total":1,"data":[{"compaction":{"state":"Scheduled","scheduleTime":"2018-07-20 06:33:38.953 GMT-0700","gateway":"10.10.108.116:8660"}}]}`

<table>
<tr><th>State</th><th>Description</th></tr>
<tr><td>Running</td><td>Indicates the offload or recall job has been forwarded to MAST Gateway service. The MAST Gateway service can either still be waiting for resources to run the job or is actually performing the requested job. For example:

CLI

<pre>{
"timestamp":1532095481297,
"timeofday":"2018-07-20 07:04:41.297 GMT-0700 AM",
"status":"OK",
"total":1,
"data":[
{
"offload":{
"state":"Running",
"progress":"61%",
"startTime":"2018-07-20 07:00:02.277 GMT-0700",
"gateway":"10.10.108.115:8660"
},
"compaction":{
"state":"Success",
"progress":"100%",
"startTime":"2018-07-20 06:34:06.628 GMT-0700",
"endTime":"2018-07-20 06:40:25.334 GMT-0700",
"reclaimedDataSize":"0 MB",
"gateway":"10.10.108.115:8660"
}
}
]
}</pre>
REST

<pre>{"timestamp":1532095481297,"timeofday":"2018-07-20 07:04:41.297 GMT-0700 AM","status":"OK","total":1,"data":[{"offload":</pre></td></tr>
</table>

State	Description

FailureFatal	Indicates the job has failed with non-retriable error. You must resolve the issue and retry the operation. For example:
	CLI
	{
	"timestamp":1531778057385,
	"timeofday":"2018-07-16 09:54:17.385 GMT+0000 PM",
	"status":"OK",
	"total":1,
	"data":[
	{
	"offload":{
	"state":"FailureFatal",
	"progress":"50%",
	"startTime":"2018-07-16 21:54:01.779 GMT+0000",
	"endTime":"2018-07-16 21:54:05.339 GMT+0000",
	"offloadedDataSize":"0 MB",
	"gateway":"10.10.88.198:8660"
	}
	}
	]
	}
	REST
	{"timestamp":1531778057385,"timeofday":"2018-07-16 09:54:17.385 GMT+0000 PM","status":"OK","total":1,"data":[{"offload":{"state":"FailureFatal","progress":"50%","startTime":"2018-07-16 21:54:01.779 GMT+0000","endTime":"2018-07-16 21:54:05.339 GMT+0000","offloadedDataSize":"0 MB","gateway":"10.10.88.198:8660"}}]
	}

State	Description

FailureRetriable	Indicates the job has failed with an error for which CLDB will retry the job based on the configuration parameters, `cldb.gateway.retry.count` and `cldb.gateway.retry.waittime`. But if the job is restarted manually or terminated, CLDB will not retry. For example:
	CLI
	{
	"timestamp":1532624516372,
	"timeofday":"2018-07-26 10:01:56.372 GMT-0700 AM",
	"status":"OK",
	"total":1,
	"data":[
	{
	"offload":{
	"state":"FailureRetry, RetryCount: 5",
	"progress":"50%",
	"startTime":"2018-07-25 17:43:27.924 GMT-0700",
	"endTime":"2018-07-25 17:43:59.108 GMT-0700",
	"offloadedDataSize":"0 MB",
	"gateway":"10.10.25.29:8660"
	}
	}
	]
	}
	REST
	{"timestamp":1532624656640,"timeofday":"2018-07-26 10:04:16.640 GMT-0700 AM","status":"OK","total":1,"data":[{"offload":{"state":"FailureRetry, RetryCount: 5","progress":"50%","startTime":"2018-07-25 17:43:27.924 GMT-0700","endTime":"2018-07-25 17:43:59.108 GMT-0700","offloadedDataSize":"0

<table>
<tr><th>State</th><th>Description</th></tr>
<tr><td>Success</td><td>Indicates the job has been successfully completed. For example:
CLI
<pre>{

```

volume tierstats
Retrieves statistics on the offload and recall operation.

Permissions Required

The user running the command must have one of the following:

- Full control (fc) on the cluster or volume
- Volume edit permissions

Syntax

CLI

```
maprcli volume tierstats
            [ -cluster cluster_name ]
            -name <volume_name>
```

REST

Request Type	GET
Request URL	`http[s]://<host>:<port>/rest/volume/tierstats?<parameters>`

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`name`	The name of the volume.

Output

The command returns the following:

`offloadThroughput`	The amount of data (in MB) offloaded per second.
`totalTierDataSize`	The total size of tiered data (in MB).
`totalTierReclaimableSize`	The size of deleted data (in MB) that is under the compaction operation threshold.
`recallThroughput`	The amount of data (in MB) recalled per second.

Example

Retrieve statistics for a volume specified by name:

CLI

```
# /opt/mapr/bin/maprcli volume
tierstats -name sampleVol -json
{
    "timestamp":1520275614872,
    "timeofday":"2018-03-05
06:46:54.872 GMT+0000",
    "status":"OK",
    "total":1,
```

```
    "data":[
        {

"totalTierDataSize":"404.323 MB",

"offloadThroughput":"17.063 MB/s",

"recallThroughput":"14.071 MB/s"
        }
    ]
}
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/volume/tierstats?
name=sampleVol' --user marp:mapr
{"timestamp":1520275614872,"timeofday"
:"2018-03-05 06:46:54.872
GMT+0000","status":"OK","total":1,"dat
a":[{"totalTierDataSize":"404.323
MB","offloadThroughput":"17.063 MB/
s","recallThroughput":"14.071 MB/s"}]}
```

Retrieve statistics for a volume after a compaction operation:

CLI

```
# maprcli volume tierstats -name
test1 -json
{
        "timestamp":1527048672887,
        "timeofday":"2018-05-23
04:11:12.887 GMT+0000 AM",
        "status":"OK",
        "total":1,
        "data":[
                {

"totalTierDataSize":"3001.926 MB",

"totalTierReclaimableSize":"100 MB",

"offloadThroughput":"31.064 MB/s"
                }
        ]
}
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/volume/tierstatus?
name=test1' --user mapr:mapr
{"timestamp":1527048672887,"timeofday"
:"2018-05-23 04:11:12.887 GMT+0000
AM","status":"OK","total":1,"data":
[{"totalTierDataSize":"3001.926
MB","totalTierReclaimableSize":"100
MB","offloadThroughput":"31.064 MB/
s"}]}
```

volume unmount

Unmounts one or more mounted volumes. Permissions required: `fc` or `m` on the volume.

Syntax

CLI

```
maprcli volume unmount
    [ -cluster <cluster> ]
    [ -force 0|1 ]
    -name <volume name>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/unmount?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`force`	Specifies whether (1) or not (0) to force the volume to unmount.
`name`	The name of the volume to unmount.

Examples

Unmount the volume "test-volume":

CLI

```
maprcli volume unmount -name
test-volume
{
    "timestamp":1537804903335,
    "timeofday":"2018-09-24
09:01:43.335 GMT-0700 AM",
    "status":"OK",
    "total":0,
    "data":[

    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/unmount?
name=test-volume' --user mapr:mapr
{"timestamp":1537805053854,"timeofday"
:"2018-09-24 09:01:43.335 GMT-0700
AM","status":"OK","total":0,"data":[]}
```

volume upgradeformat
Upgrades and old-type volume to a new-type volume, which can in turn be used as a promotable mirror volume. Permissions required: `m` or `fc` on the volume.

Syntax

CLI

```
maprcli volume upgradeformat
    [ -cluster <cluster> ]
    -name <volume name>
```

REST

Request Type	POST
Request URL	`http[s]://<host>:<port>/rest/volume/upgradeformat?<parameters>`

Parameters

Parameter	Description
`cluster`	The cluster on which to run the command.
`name`	The volume name.

Examples

CLI

```
maprcli volume upgradeformat -name
vol999 -json
```

REST

```
https://abc.sj.us:8443/rest/volume/
upgradeformat?name=vol999
```

Utilities

Contains information about various scripts and utilities, that help setup, maintain, and monitor clusters.

The following scripts and utilities help you configure clusters, setup cross cluster security, setup storage pools, monitor CLDB activity, perform consistency checks and repair errors on volumes and snapshots, and maintain clusters with ease.

Script or Utility	Description
Cluster Configuration	
configure.sh on page 2053	Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks, including setting up MapR client nodes, and configuring services for a node.
configure-crosscluster.sh on page 2065	Sets up cross-cluster security between two clusters.
disksetup on page 2092	Formats specified disks for use by MapR storage, and adds those disks to the disktab file.
mrconfig on page 2138	Lets you create, remove, and manage storage pools, disk groups, and disks; and provides information about containers.

last-updated: Apr 11, 2022

Script or Utility	Description
pullcentralconfig on page 2180	Pulls master configuration files from `/var/mapr/configuration` on the cluster to the local disk, on each node.
fcdebug on page 2098	Dynamically sets the loglevel to debug a library.
Auditing and Monitoring	
cldbguts on page 2080	Monitors CLDB activity. This utility prints information about the CLDB service that is running on the node from which you run the utility.
ectool on page 2094	Dumps or checks the validity of the stripelets in the backend volume that is associated with the volume configured for warm tiering.
expandaudit on page 2096	Expands IDs captured in the audit logs to their corresponding names.
fsck on page 2100	Detects and fixes inconsistencies in the filesystem.
gfsck on page 2102	Performs consistency checks and appropriate repairs on a volume, or a volume snapshot.
mapr-support-collect.sh on page 2121	Collects information about a cluster's recent activity, to help MapR Support diagnose problems.
mapr-support-dump.sh on page 2127	Collects node and cluster-level information for the node on which you invoke the script.
mrdirectorystats on page 2177	Prints the space usage for each directory, for a container.
mrfscmd on page 2179	Returns the path to the file specified by ID (fid).
stubfuse on page 2181	Determines the read and write performance of a FUSE mount point.
Authentication	
maprlogin on page 2130	Authenticates logins to secure MapR clusters.

configure.sh
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

Note: The `configure.sh` script must always be run as `root`.

You run `configure.sh` to set up a MapR cluster node, or to set up a MapR client node for communication with one or more clusters. You can also run `configure.sh` to update the configuration of a node. For example, you can use `configure.sh` to change the services running on a node, or specify the user that runs MapR services.

Attention: On a Windows client, the `configure.sh` script is named `configure.bat`. The script requires the `-c` parameter and does not accept the `-Z` parameter, but otherwise works similarly as on a Linux client.

Steps Performed by configure.sh
`configure.sh` performs the following steps, each time you run it:

- **Updates /opt/mapr/conf/mapr-clusters.conf with the cluster name.** It creates or modifies a line in `/opt/mapr/conf/mapr-clusters.conf` containing a cluster name followed by a list of CLDB nodes. New entries are added to `mapr-clusters.conf` when the cluster name passed to the `-N` parameter is different from the existing cluster name in that file.

last-updated: Apr 11, 2022

- **Checks that the node has at least 4GB of RAM, and that the /tmp and /opt partitions each have at least 1 GB of free space.** If these conditions are not met, the script asks for confirmation before continuing.
- **Disables standard NFS daemons.** If the node has the `mapr-nfs` role, the script disables the standard Linux NFS daemon, since both NFS processes cannot run on the same node.
- **Updates additional *.conf and *.xml files related to the cluster and the services running on the node.** For example, `yarn-site.xml`, `warden.conf`, and `cldb.conf` may be updated based on input to `configure.sh`.
- **On cluster nodes, it creates a group named *shadow*, adds the MapR user to this group, and then enables members of the *shadow* group to view the */etc/shadow* file.** Read access to the `/etc/shadow` file enables MapR users to authenticate with the MapR cluster.
- **Starts newly installed services.** Automatically starts new services, if Warden is running at the time you run `configure.sh`.
- **All changes to configuration options or system files are logged to /opt/mapr/logs/configure.log.** You can use the `-L` parameter to specify a different log file name.

When you include disk-setup options (`-D` or `-F`) on nodes with the `mapr-fileserver` role, the script performs the following additional steps:

- **Runs disksetup to create the disktab file.** `configure.sh` takes the values that you specify in the `-disk-opts` option, and passes the value to disksetup. For example, if you include `-disk-opts FW5` when you run `configure.sh`, `configure.sh` runs `disksteup -F -W5`. If disksetup fails, `configure.sh` exits with an error.
- **Starts Zookeeper and Warden.** When the `configure.sh` script starts services, the message `starting <servicename>` is echoed to the standard output to enable the user to see which services are starting. When Warden starts, the Warden and ZooKeeper services are added to the `inittab` file as the first available `inittab` IDs, enabling these services to restart automatically on failure.

  You can specify the `-no-autostart` option to prevent the script from starting Zookeeper or Warden when you run `configure.sh` with the `-F` or `-D` options.

Syntax

```
/opt/mapr/server/configure.sh
        -C <cldb_list>
        -Z <zookeeper_list>
        -EZ <ext_zookeeper_list>
        [<parameters>]
```

```
/opt/mapr/server/configure.sh
        -C <cldb_list>
        [ -M <cldb_mh_list ...> ]
        -Z <zookeeper_list>
        [<parameters>]
```

```
/opt/mapr/server/configure.sh
        -c
```

```
        [ -R ]
        [<parameters>]
```

```
/opt/mapr/server/configure.sh
        -R
        [ -c ]
        [<parameters>]
```

Options

-C

Use the `-C` option for CLDB servers that only have a single IP address. This option takes a comma-separated list of the CLDB nodes that this machine uses to connect to the MapR cluster. The list is in the following format:

```
hostname[:port_no]
[,hostname[:port_no]...]
```

-c

Specifies client setup. The `-C` option is required, while the `-Z` option is optional. See set up a MapR client node for communication with one or more clusters.

-EZ

The `-EZ` option is optional when configuring the cluster, and is not applicable when configuring a client. This option takes a comma-separated list of the external IP addresses of the ZooKeeper nodes in the cluster. The list is in the following format:

```
hostname[:port_no]
[,hostname[:port_no] ...]
```

-M

Use the `-M` option only for multihomed CLDB servers that have more than one IP address. This option takes a comma-separated list of the multihomed CLDB nodes that this machine uses to connect to the MapR cluster. The list is in the following format:

```
hostname[:port_no][,
[hostname[:port_no]...]]
```

-R

After initial node configuration, specifies that `configure.sh` should use the previously configured ZooKeeper and CLDB nodes. The `-C` and `-Z` parameters are not required when you specify `-R`. When `-R` is specified, the CLDB credentials are read from `mapr-clusters.conf`, while the ZooKeeper credentials are read from `warden.conf`. Use the `-R` option when you make changes to the services configured on a node without changing the CLDB and ZooKeeper nodes. Specify the `--noRecalcMem` parameter to skip recalculating memory settings when refreshing roles.

last-updated: Apr 11, 2022

Note: This parameter impacts the JMX parameters in `/opt/mapr/conf/env_override.sh` in the following ways:

- When you set `MAPR_JMXLOCALBINDING` to `true`, running `/opt/mapr/server/configure.sh -R` sets `MAPR_JMXAUTH` to `false`, since JMX is only accessible from the local machine and does not require authentication.
- When you set `MAPR_JMXLOCALBINDING` to `false` but set `MAPR_JMXLOCALHOST` to `true`, running `/opt/mapr/server/configure.sh -R` sets `MAPR_JMXAUTH` to `true` and `MAPR_JMXSSL` to `false`, since JMX is only accessible from the local network and does not require secure authentication.
- When you set `MAPR_JMXLOCALBINDING` to `false` but set `MAPR_JMXREMOTEHOST` to `true`, running `/opt/mapr/server/configure.sh -R` sets `MAPR_JMXAUTH` to `true` and `MAPR_JMXSSL` to `true`, since JMX is now accessible remotely and requires secure authentication.

-Z

The `-Z` option is required unless you specify the `-c` (lowercase), or the `-R` option. The `-Z` option takes a comma-separated list of the ZooKeeper nodes in the cluster. The list is in the following format:

```
hostname[:port_no]
[,hostname[:port_no]...]
```

Parameters

-certdomain

Specifies a DNS domain for generated SSL wildcard certificates. This domain overrides the default DNS domain.

--create-user | -a

Creates a local user to run MapR services, using the user specified either with the `-u` parameter, or from the environment variable $MAPR_USER.

-D
