For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure MapR cluster. The ticket for the POSIX client can be generated on the MapR cluster using the `maprlogin on page 2130` utility.

last-updated: Apr 11, 2022

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the `CONTAINER_TICKET` field in the ticket Secret example.

Parameter	Notes
`CONTAINER_TICKET`	Base64-encoded ticket value. See Converting a String to Base64 on page 3169.

To create the secret:

1. Run the following command to create the Secret file:

   ```
   kubectl create -f <secret-file-name>.yaml
   ```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

   See Converting a String to Base64 on page 3169.

3. Add the base64 representation of sensitive data in the Secret file.

   For more information about the format of the Secret files, see REST Secrets on page 3168 and Ticket Secrets on page 3168 earlier in this section.

4. Deploy the secret on the pod by running the following command:

   ```
   kubectl apply -f <secret-file-name>.yaml
   ```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name `mapr` is `bWFwcg==`.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTXOqsXYPTnqRJl6/
mlWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRUOtKBG9gp65bsZN9Kphnr/
Wp15z8D3O2go951CANes/
7QQllYVP7l2BOpGR6I1zIrC3XGwI8OQWT61qpsjSVZv8zO5oQ5GDYQTkPttI/yAk/
```

last-updated: Apr 11, 2022

YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

Note: Another method for converting values to base64 is to use an Internet tool such as https://www.base64encode.org to encode or decode data.

Best Practices for Using Tickets

When using secure MapR clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see How Impersonation Works on page 1478 and maprlogin on page 2130.
- Match the security context `runAsUser:` ID and `fsGroup:` group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

Troubleshooting the MapR Data Fabric for Kubernetes FlexVolume Driver
This section describes how to resolve common problems you might encounter when using the MapR Data Fabric for Kubernetes FlexVolume driver.

Shared Memory Lock Causes POSIX Failure

Problem	On an upgrade from a previous version of the volume plug-in, POSIX can fail with the following error in the POSIX log file: `Create/Attach to stats shared memory failed.`
Possible Cause	A shared-memory segment lock can prevent the mount from becoming available to the requested pod.
Resolution	Follow the steps in Troubleshooting MapR loopbacknfs POSIX Client Upgrades on page 329 to remove the lock. Then retry the operation.

Unable to Access MapR File System

Problem	Storage is not mounted and no errors are generated in the plugin or provisioner logs.
Possible Cause	The fusermount symlink might be broken.
Resolution	If the symlink points to a location other than `/opt/mapr/k8s/bin/fusermount`, unlink it using the following command from the command line on the host: `unlink /bin/fusermount` Then re-create the Kubernetes Pod.

Pod Container Stuck in Container Creation State During Installation

Problem	During installation, the Pod container can become stuck in the container creation state on a node, and the`/opt/mapr/k8s` directory is not created. As a result, the plug-in does not get copied to the node.
Possible Cause	Unknown.
Resolution	Check the installation logs for an indication that the installation is not completed or the `/opt/mapr/k8s` directory is not created. Restart the kubelet service in the node: `systemctl restart kubelet`

Logs for the MapR Data Fabric for Kubernetes FlexVolume Driver

Logs for the MapR Data Fabric for Kubernetes can be found in:

```
/opt/mapr/logs
```

Log File	Description	Which Nodes
`install-k8s-plugin.log`	Captures events related to the copying of files from the plug-in container to each Kubernetes host node.	All Kubernetes nodes.
`plugin-k8s.log`	Captures events from the FlexVolume plug-in.	All Kubernetes nodes. **Note:** In Azure deployments, this log is hidden in the container. See Azure AKS Considerations on page 245.
`provisioner-k8s.log`	Captures events from the provisioner.	The Kubernetes node where the provisioner Pod is running.

Useful Troubleshooting Commands

The following Kubernetes commands can help you gather information about the resources used by the MapR Data Fabric for Kubernetes:

last-updated: Apr 11, 2022

- `kubectl describe <resourcetype> <resource> -n <namespace>`
- `kubectl get <resourcetype> <resource> -n <namespace> -o yaml`
- `kubectl logs <pod-name> -n <namespace>`
- `journalctl -u kubelet -r` (on the relevant node)

kubectl describe command

In this example, the `kubectl describe` command displays information about the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod. Note that the `kubectl describe` output includes an event section.

```
kubectl describe pod mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
Name:         mapr-kdfprovisioner-5dff68656-ln6vh
Namespace:    mapr-system
Node:         qa101-139/10.10.101.139
Start Time:   Fri, 09 Feb 2018 12:58:36 -0800
Labels:       app=mapr-kdfprovisioner
              pod-template-hash=189924212
Annotations:  openshift.ix/scc-maprkdf-scc

  Normal  Pulled                 8m    kubelet, qa101-139 Successfully
pulled image "maprtech/kdf-provisioner:1.0.0.006_centos7"
  Normal  Created                8m    kubelet, qa101-139 Created container
  Normal  Started                8m    kubelet, qa101-139 Started container
```

kubectl get command

In this example, the `kubectl get` returns the `.yaml` parameters for the `test-secure-provisioner86` Pod:

```
kubectl get pods test-secure-provisioner86 -n mapr-examples -o yaml
apiVersion: v1
kind: Pod
metadata:
  creationTimestamp: 2018-02-09T00:42:06Z
  name: test-secure-provisioner86
  namespace: mapr-examples
  resourceVersion: "721689"
  selfLink: /api/v1/namespaces/mapr-examples/pods/test-secure-provisioner86
```

```
  uid: 0dd21274-0d32-11e8-bdd6-84a9c4fbf7cb
spec:
  containers:
  - args:
    - sleep
    - "1000000"
    image: busybox
    imagePullPolicy: Always
    name: busybox
    resources: {}
    terminationMessagePath: /dev/termination-log
    terminationMessagePolicy: file
    volumeMounts:
    - mountPath: /dynvolume
      name: maprfs-pvc
    - mountPath: /var/run/secrets/kubernetes.io/serviceaccount
      name: default-token-zpv69
      readOnly: true
  dnsPolicy: ClusterFirst
  nodeName: qa108-165.qa.lab
  restartPolicy: Never
  schedulerName: default-scheduler
  securityContext: {}
  serviceAccount: default
  serviceAccountName: default
  terminationGracePeriodSeconds: 30
  tolerations:
  - effect: NoExecute
    key:node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
  volumes:
  -name: maprfs-pvc
```

Running the `kubectl get` command without the `-o yaml` parameter generates less output:

```
kubectl get pods test-secure-provisioner86 -n mapr-examples
NAME                        READY    STATUS   RESTARTS   AGE
test-secure-provisioner86  1/1      Running  0          14m
```

kubectl logs command

In this example, the `kubectl logs` command returns logged output for the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod:

```
kubectl logs mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
I0209 12:58:39.956822    1 controller.go:407] Starting provisioner
controller 013d58b3-0ddc-11e8-b0dd-0242acl10003!
```

journalctl -u command

In this example, the `journalctl` command returns events for the kubelet service for the node:

```
journalctl -u kubelet -r
-- Logs begin at Thu 2017-12-28 06:24:47 PST, end at Thu 2018-02-08
17:01:49 PST. --
Feb 08 17:01:49 k8s-master kubelet[26521]: E0206 17:01:49,047595  26521
```

last-updated: Apr 11, 2022

Ecosystem Components

The following sections provide information about each open-source project that is supported by the MapR Data Platform.

This section contains documentation for each open-source project. You can learn how to configure, use, and integrate each project within the context of a MapR cluster.

Documentation Covers All Component Versions

Unless noted, the ecosystem-component information in this content hierarchy applies to all component versions included in EEPs that are supported on the core software. For a list of the supported EEPs, see EEP Support and Lifecycle Status on page 5531.

MapR Ecosystem Packs

A MapR Ecosystem Pack (EEP) provides a set of ecosystem components that work together on one or more MapR cluster versions. Each EEP contains only one version of an ecosystem component. For example, each EEP supports only one version of Hive and one version of Spark.

HPE creates a new EEP version when a new ecosystem component is available or a patch is applied to an ecosystem component that is already in a released EEP.

A single version of core can support multiple EEPs, but only one at a time. For detailed information about each EEP, see MapR Ecosystem Pack (EEP) Reference on page 6504. For a list of currently supported EEPs, see EEP Support and Lifecycle Status on page 5531.

Hadoop Ecosystem and Monitoring Components

Hadoop ecosystem components within an EEP undergo extensive interoperability testing to validate that the components can work together. Examples of Hadoop ecosystem components include Hive, Pig, Spark, and Oozie.

The following open-source components are included in the EEP for monitoring and logging use cases, but NOT for third-party use cases:

- Collectd
- Elasticsearch
- Fluentd
- Grafana
- Kibana

- OpenTSDB

Note: Developer previews for fast-moving ecosystem components continue to be available in addition to EEPs. However, developer preview releases of ecosystem components are not tested for production environments, and they do not undergo the same interoperability testing.

For more information, see the EEP Release Notes on page 5658.

AsyncHBase

MapR provides a version of AsyncHBase that is modified to work with MapR Database binary tables. The MapR version of AsyncHBase is based on the AsyncHBase library provides asynchronous Java APIs to access MapR Database binary tables. The HBase Client version is based on the current EEP and MapR version you are running. For more information, see the Interoperability Matrices on page 5519.

Configuring the Default Database for AsyncHBase

For AsynchHBase 1.7 and later, you can configure whether AsyncHBase accesses HBase tables or MapR-DB tables by default. If this value is not configured, AsyncHBase will determine the table type.

You can configure the default database in the `asynchbase.conf` file and the client application. A default database setting in the client application overrides the default database configuration in the `aynchbase.conf` file.

The process that AsyncHBase uses to access tables differs based on the default database configuration.

- When the default database is HBase, AsyncHBase accesses the table using the HBase port that was used to initialize the AsyncHBase client and the table name provided to the application.
- When the default database is MapR-DB, the table name provided to the application is translated to the MapR-DB table path, and then AsyncHBase accesses the table.
- When a default database is not configured, AsyncHBase first tries to access the table as a MapR-DB table. If that fails, it tries to access the table as an HBase table.

Set the Default Database using asynchbase.conf

To specify if AsyncHBase accesses HBase tables or MapR-DB tables:

1. Add the `mapr.hbase.default.db` parameter in the `asynchbase.conf` (`/opt/mapr/asynchbase/asynchbase-<version>/conf/asynchbase.conf`) file.
2. Set the value of `mapr.hbase.default.db` to one of the following values which will indicate the default database:
   - `hbase`
   - `maprdb`

Set the Default Database in the Client Application

Based on the database that you want as the default, add the following code in the client application:

- To access MapR-DB tables:

```
Config config = new Config();
String dbString = "maprdb";
config.overrideConfig(HBaseClient.CONFIG_PARAM_DEFAULT_DB,dbString);
HBaseClient client = new
HBaseClient(config);
```

last-updated: Apr 11, 2022

- To access HBase tables:

```
Config config = new Config();
String dbString = "hbase";
config.overrideConfig(HBaseClient.CONFIG_PARAM_DEFAULT_DB,dbString);
HBaseClient client = new
HBaseClient(config);
```

Compiling and Running AsyncHBase Applications

When you compile or run AsyncHBase applications, you need to include the required AsyncHBase libraries.

To compile the application:

```
javac -cp `asynchbase
classpath`:$APP_CLASSPATH
<ProgramName>
```

To run the application, use one of the following commands:

- ```
  java -cp `asynchbase
  classpath`:$APP_CLASSPATH
  <ProgramName>
  ```

- ```
  asynchbase $APP_CLASSPATH
  <ProgramName>
  ```

To include the AsyncHBase library in your maven project:

1. Add MapR's maven repository to the list of repositories in your project's pom.xml:

   ```
   <repository>
   <id>mapr-releases</id>
   <url>https://repository.mapr.com/
   maven/</url>
   <snapshots><enabled>true</
   enabled></snapshots>
   <releases><enabled>true</enabled></
   releases>
   </repository>
   ```

2. Add the following dependency to the list of dependencies:

   ```
   <dependency> <groupId>org.hbase</
   groupId>
   <artifactId>asynchbase</
   artifactId>
   <version><AsyncHBaseVersion>-mapr-<
   MapREcoVersion></version> </
   dependency>
   ```

   Note: For example, if you are using AsyncHBase 1.7-1603, configure the following for the version dependency: `<version>1.7.0-mapr-1603</version>`

AsyncHBase Script

MapR provides an AsyncHBase script that you can use to run applications and generate the AsyncHBase classpath.

The asynchbase script has the following syntax:

```
asynchbase <command> [<args>]
Commands:
classpath Dump AsyncHBase CLASSPATH
CLASSNAME Run the class named CLASSNAME
```

Parameters	Description
classpath	Dumps the AsyncHBase classpath. For example, you can use `aynchbase classpath` when you compile an application: `javac -cp `asynchbase classpath`:$APP_CLASSPATH <ProgramName>`
CLASSNAME	Runs the named class. For example: `asynchbase <path to application> CLASSNAME`

AsyncHBase Behavior with MapR Database Binary Tables

After you install AsyncHBase, you can use the AsyncHBase libraries to provide asynchronous access to MapR Database binary tables. However, it is important to note the behavior that is specific to using AsyncHBase with MapR Database.

The `Scanner.setMaxNumKeyValues` method, when run against MapR Database binary tables, does not behave as documented.	According to the AsyncHBase documentation, this method sets "the maximum number of KeyValues the server is allowed to return in a single RPC response." When you use this method with MapR Database binary tables, the value for the maximum number of key values is ignored and the full set of KeyValues is always returned.
List<RegionClientStats> regionStats() is not supported	As of AsyncHBase 1.7-1603, `List<RegionClientStats> regionStats()` is not supported and when it is used the API does not return statistics.
MapR Database ignores HBase configurations in the asynchbase.conf file	As of AsyncHBase 1.7-1603, the conf object can be used to override Hbase properties that were previously only configured in the asynchbase.conf file. The asynchbase.conf file is located in the asynchbase installation directory. MapR Database does not use these Hbase configurations and therefore they are ignored by MapR Database

Using OpenTSDB with AsyncHBase

OpenTSDB can use MapR's AsyncHBase to perform time-series data-plots on MapR Database binary tables.

The OpenTSDB software package provides a time-series database that collects user-specified data.

To use OpenTSDB with AsyncHBase, install and configure OpenTSBD from source files or from a package.

Installing OpenTSDB from Source Files
The following steps describe how to install OpenTSDB from source files.

Be sure to install the OpenTSDB version that is required for your AsyncHBase version. AsyncHBase 1.6 requires OpenTSDB 2.0. AsyncHBase 1.7 requires OpenTSDB 2.2.

1. Clone the opentsdb.git project and check out the OpenTSDB branch that you require.

   Note:

   For example:

   ```
   $ git clone https://github.com/OpenTSDB/opentsdb.git
   Cloning into 'opentsdb'...
   remote: Counting objects: 5625, done.
   remote: Compressing objects: 100% (76/76), done.
   remote: Total 5625 (delta 51), reused 64 (delta 30)
   Receiving objects: 100% (5625/5625), 27.15 MiB | 2.67 MiB/s, done.
   Resolving deltas: 100% (3755/3755), done.
   Checking connectivity... done.
   $ cd opentsdb
   $ git tag -l
   mapr-1.1.0-release+5
   v1.0.0
   v2.0.0
   ...
   $ git checkout v2.0.0
   Switched to a new branch 'v2.0.0'
   ```

2. Install dependencies for graph generation:

   ```
   $ yum install autoconf automake gnuplot
   ```

3. Replace the `asynchbase.jar` file with the MapR version of that file:

   ```
   $ yum install mapr-asynchbase
   ```

4. Run the build script:

   ```
   ./build.sh
   ```

5. If you want to use OpenTSDB with MapR Database tables, open the create_table.sh file (<OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh) and add "/" before the table names so that MapR recognizes them as MapR Database tables: See Example: create_table.sh on page 3179.

6. Create tables:

   ```
   env COMPRESSION=NONE;HBASE_HOME=/opt/mapr/hbase/hbase-<version>
   <OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh
   ```

7. Run the following command to verify that the tables are created successfully:

   ```
   hadoop fs -ls /
   ```

8. Create a simple metric to store, such as “sys.cpu.user”:

```
./build/tsdb mkmetric sys.cpu.user --table=/tsdb --uidtable=/tsdb-uid
```

9. Run the OpenTSDB daemon (tsd).

```
./build/tsdb tsd --port=4242 --staticroot=build/staticroot
--cachedir=/tmp/opentsdb_tmp --zkquorum=10.10.101.50:5181 --table=/tsdb
--uidtable=/tsdb-uid
```

Note: Instead of providing these options on command line, you can configure the values in the opentsdb.conf file. This file must be in the root folder so the option settings are read when tsd is run. Also note that the staticroot argument points to the static UI files. You do not need to create cachedir because openstdb creates it automatically. Specifying the destination cachedir argument is enough. You do need to explicitly specify tsdb tables (tsdb, tsdb-uid) and Zookeeper quorum nodes.

10. Log into the web UI: `http://<TSD_Installed_Node_IP>:<Port>`
    For example: `http://10.10.10.230:4242/`

11. Run a simple test program that generates data and sends repeated puts for the metric over a socket connection: <UI-IP>:<UI-Port> . See Data Generator Program on page 3180.

12. Check the plot in the UI.
    a) Select **From date** and check **autoreload**.
    b) Fill in the metric (in this case, `sys.cpu.user`) and the Tag keys (`cpu, host`) values (`webserver 0, webserver 1`). You should see a graph with a random plot.

Example: create_table.sh
create_table.sh is used to set up MapR Database to accepts `puts` from OpenTSDB. This example create_table.sh script was updated to work with MapR Database tables.

Note the changed sections for the `*_TABLE` variables.

```
#!/bin/sh
# Small script to setup the HBase tables used by OpenTSDB.

test -n "$HBASE_HOME" || {
  echo >&2 'The environment variable HBASE_HOME must be set'
  exit 1
}
test -d "$HBASE_HOME" || {
  echo >&2 "No such directory: HBASE_HOME=$HBASE_HOME"
  exit 1
}

TSDB_TABLE=${TSDB_TABLE-'/tsdb'}
UID_TABLE=${UID_TABLE-'/tsdb-uid'}
TREE_TABLE=${TREE_TABLE-'/tsdb-tree'}
META_TABLE=${META_TABLE-'/tsdb-meta'}
BLOOMFILTER=${BLOOMFILTER-'ROW'}
# LZO requires lzo2 64bit to be installed + the hadoop-gpl-compression jar.
COMPRESSION=${COMPRESSION-'LZO'}
# All compression codec names are upper case (NONE, LZO, SNAPPY, etc).
COMPRESSION=`echo "$COMPRESSION" | tr a-z A-Z`

case $COMPRESSION in
```

```
  (NONE|LZO|GZIP|SNAPPY)  :;;  # Known good.
  (*)
    echo >&2 "warning: compression codec '$COMPRESSION' might not be
supported."
    ;;
esac

# HBase scripts also use a variable named `HBASE_HOME', and having this
# variable in the environment with a value somewhat different from what
# they expect can confuse them in some cases.  So rename the variable.
hbh=$HBASE_HOME
unset HBASE_HOME

'$BLOOMFILTER'}
EOF
```

Data Generator Program

This simple test program generates data and sends repeated puts for the metric over a socket connection.

```
import java.io.PrintWriter;
import java.net.Socket;
import java.util.Date;
import java.util.Random;

public class TestOpenTsdbAPI {
   public static Random random = new Random();
   public static long timeStamp = new Date().getTime()/1000; //in secs
   public static void testTSDBConnection() throws Exception {
       Socket sock = null;
       PrintWriter pw = null;
       String hostname = "10.10.10.230";
       int port = 4242;
       int count=1;
       while(true) {
           if(null==sock) {
               sock = new Socket(hostname, port);
               pw = new PrintWriter(sock.getOutputStream(), true);
           }
           pw.println(dataGen(0, 0, count));
           pw.flush();
           pw.println(dataGen(0, 1, count));
           pw.flush();
           pw.println(dataGen(1, 0, count));
           pw.flush();
           pw.println(dataGen(1, 1, count));
           pw.flush();
```

```
            if(++count==Integer.MAX_VALUE) break;
            Thread.sleep(60000);
        }
    }
    public static void main(String [] args) {
        try {
            testTSDBConnection();
        } catch(Exception ex) {
            ex.printStackTrace();
        }
    }

    public static String dataGen(int web, int cpu, int count) {
        int Low = 1;
        int High = 99;
        int val = random.nextInt(High-Low) + Low;
        long timeStamp1 = new Date().getTime()/1000;
        String dat = "put sys.cpu.user "+(timeStamp1)+" "+val+"
host=webserver"+ web +" cpu="+cpu;//(timeStamp+count)
        System.out.println(dat);
        return dat;
    }
}
```

For example, this program tries to put metrics for 2 hosts (webserver 0 and webserver 1). Each host has 2 CPUs (cpu 0 and cpu 1). Sample puts look like this:

```
put sys.cpu.user 1415300810 87 host=webserver0 cpu=0
put sys.cpu.user 1415300810 66 host=webserver0 cpu=1
put sys.cpu.user 1415300810 18 host=webserver1 cpu=0
put sys.cpu.user 1415300810 26 host=webserver1 cpu=1

put <metric> <timestamp> <value> <tag1>=<> <tag2>=<>
```

When you run the program, you should see entries that indicate that the tags for the metric were created, and they should auto-complete on the UI.

```
UniqueId: Creating an ID for kind='tagv' name='webserver0'
```

You can also verify this from command line instead of the UI:

```
<OpenTSDB-Root>/build/tsdb query 1y-ago sum sys.cpu.user
```

Installing OpenTSDB with a Package

The following steps describe how to install OpenTSDB from a package.

Be sure to install the OpenTSDB version that is required for your AsyncHBase version. AsyncHBase 1.6 requires OpenTSDB 2.0. AsyncHBase 1.7 requires OpenTSDB 2.2.

1. Install the OpenTSDB RPM:
   a) `mkdir /root/opentsdbrpm`

   b) `cd /root/opentsdbrpm`

   c) Download the version of OpenTSDB that you required.

      For OpenTSDB 2.0: `wget` https://github.com/OpenTSDB/opentsdb/releases/download/v2.0.0/opentsdb-2.0.0.noarch.rpm `-O opentsdb-2.0.0.noarch.rpm`

      For OpenTSDB 2.2: `wget`https://github.com/OpenTSDB/opentsdb/releases/download/v2.2.0/opentsdb-2.2.0.noarch.rpm`-o opentsdb-2.2.0.noarch.rpm`

d) `rpm -ivh opentsdb-<version>.noarch.rpm`

2. Configure OpenTSDB to work with MapR:

a) Edit the following `tsdb` scripts to cover MapR-specific dependencies: `/usr/share/opentsdb/bin/tsdb` and `/usr/bin/tsdb`

```
# Base of MapR installation
BASEMAPR=${MAPR_HOME:-/opt/mapr}

# Add MapR hadoop jars to classpath
if test -d "$BASEMAPR/hadoop/hadoop-0.20.2/lib"; then
 # hadoop conf directory to beginning of classpath (for core-site.xml)
 CLASSPATH="$BASEMAPR/hadoop/hadoop-0.20.2/conf:$CLASSPATH"

 for jar in "$BASEMAPR"/hadoop/hadoop-0.20.2/lib/*.jar; do
   if [ "`echo $jar | grep slf4j`" != "" ]; then
     continue
   fi
   CLASSPATH="$CLASSPATH:$jar"
 done
fi
```

b) Replace the asynchbase jar file (provide the current jar file name in the `cp` command):

```
cp
/opt/mapr/asynchbase/asynchbase-<version>/
asynchbase-<version>-mapr-*.jar
/usr/share/opentsdb/lib/
rm -f /usr/share/opentsdb/lib/asynchbase-<previous_version>.jar
```

c) Configure the `opentsdb.conf` files: These files must have the following settings:

```
/usr/share/opentsdb/etc/opentsdb/opentsdb.conf
/etc/opentsdb/opentsdb.conf
```

```
tsd.network.port = 4242
tsd.http.staticroot = /usr/share/opentsdb/static/
tsd.core.auto_create_metrics = false (for testing purposes only)
tsd.storage.hbase.data_table = /tsdb
tsd.storage.hbase.uid_table = /tsdb-uid
tsd.storage.hbase.zk_quorum = <zookeeperNode>:<zookeeperP>
```

d) Edit the `<OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh` file and add "/" before the table names so that MapR recognizes them as MapR Database tables. Then, create tables in MapR Database: .

```
export COMPRESSION=NONE; export HBASE_HOME=/opt/mapr/hbase/
hbase-<version>; /usr/share/opentsdb/tools/create_table.sh
```

See Example: create_table.sh on page 3179

e) Confirm that the tables are created:

```
hadoop fs -ls /
tr--------   3 root root            2 2014-12-12 01:47 /tsdb
tr--------   3 root root            2 2014-12-12 01:47 /tsdb-meta
tr--------   3 root root            2 2014-12-12 01:47 /tsdb-tree
tr--------   3 root root            2 2014-12-12 01:47 /tsdb-uid
```

3. Start the `tsd` daemon. You can give executable permissions to the tsdb script in `/usr/share/opentsdb/bin`, or you can directly use `tsdb` (because of the dependencies you added earlier).

```
chmod +x /usr/share/opentsdb/bin/tsdb
/usr/share/opentsdb/bin/tsdb tsd --port=4242
--staticroot="/usr/share/opentsdb/static/"
--cachedir="/tmp/opentsdb" --auto-metric
```

4. Create a metric: `/usr/share/opentsdb/bin/tsdb mkmetric mymetric.stock`

5. Test the metric:
   a) Run a Test Program for OpenTSDB on page 3184 that reads from the tmp_input on page 3183 file and sends put requests to opentsdb, which saves the data to a MapR Database table (tsdb/tsdb-uid).

   b) Run aggregation queries (such as SUM) from the command line: `/usr/share/opentsdb/bin/tsdb query 1y-ago sum mymetric.stock` or `tsdb query 1y-ago sum mymetric.stock`

   c) When you run the SUM command, the results should look like the following:

```
====
mymetric.stock 1407165399000 680.500015 {}
mymetric.stock 1407165401000 904.625000 {}
mymetric.stock 1407165402000 904.612495 {}
mymetric.stock 1407165403000 904.599991 {}
mymetric.stock 1407165404000 904.599991 {}
mymetric.stock 1407165405000 904.599991 {}
mymetric.stock 1407165406000 904.599991 {}
mymetric.stock 1407165407000 904.599991 {}
mymetric.stock 1407165408000 904.599991 {}
mymetric.stock 1407165409000 904.599991 {}
mymetric.stock 1407165410000 904.599991 {}
mymetric.stock 1407165411000 904.599991 {}
mymetric.stock 1407165412000 904.599991 {}
mymetric.stock 1407165413000 904.599991 {}
mymetric.stock 1407165414000 904.599991 {}
mymetric.stock 1407165415000 904.599991 {}
mymetric.stock 1407165416000 904.599991 {}
mymetric.stock 1407165417000 904.599991 {}
mymetric.stock 1407165418000 904.599991 {}
mymetric.stock 1407165419000 904.599991 {}
mymetric.stock 1407165422000 904.678749 {}
mymetric.stock 1407165423000 484.255005 {}
====
```

```

Test Program for OpenTSDB

```
public static void testTSDBConnection() throws Exception {
       Socket sock = null;
       PrintWriter pw = null;
       String hostname = "10.10.10.220"; //replace with the node where tsd
runs
       int port = 4242; //replace with your port
       sock = new Socket(hostname, port);
       pw = new PrintWriter(sock.getOutputStream(), true);
       File dir = new File(".");
       File fin = new File(dir.getCanonicalPath() + File.separator +
"tmp_input");
       BufferedReader br = new BufferedReader(new FileReader(fin));
String line = null;
while ((line = br.readLine()) != null) {
           System.out.println(line);
           pw.println(line);
           pw.flush();
}
br.close();
}
```

GetRequest API

MapR includes an additional constructor for the GetRequest class which takes an extra qualifier.

This additional constructor allows you to use one GetRequest to retrieve the key and value for tables that consist of multiple column families with different qualifiers:

```
public GetRequest(final byte[] table,
                  final byte[] key,
                  final byte[][] families,
                  final byte[][][] qualifiers) {
    super(table, key);
```

```
    this.families(families);
    this.qualifiers(qualifiers);
  }
```

Cascading

Cascading™ is a Java application framework produced by Concurrent, Inc. that enables developers to quickly and easily build rich enterprise-grade Data Processing and Machine Learning applications that can be deployed and managed across private or cloud-based Hadoop clusters.

Note: Cascading is ***not*** part of the MapR Data Platform distribution and not supported by HPE. However, like many other open source technologies, it can be used with MapR Data Platform. The following information provides relevant details about using Cascading with MapR Data Platform.

The `mt` command is the wrapper around Cascading. Multitool, a command line tool for processing large text files and datasets (like sed and grep on unix). The `mt` command is located in the `/opt/mapr/contrib/multitool/bin` directory.

For information about working with Cascading, see:

- Cascading project at Concurrent, Inc.
- Forum posts related to Cascading
- Search HPE Blog for Cascading topics

Apache Drill

Drill is a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data. Inspired by Google's Dremel, Drill is designed to scale to several thousands of nodes and query petabytes of data at interactive speeds that BI/Analytics environments require.

Drill includes a distributed environment, purpose built for large-scale data processing. At the core of Drill is the "Drillbit" service which is responsible for accepting requests from the client, processing the queries, and returning results to the client.

Installing Drill

You can install Drill on one node or multiple nodes in a cluster. When Drill runs on each data node in a cluster, Drill can maximize data locality without moving data over the network or between nodes. Drill uses ZooKeeper to maintain cluster membership and health check information.

last-updated: Apr 11, 2022

See Installing Drill on page 177 for instructions and additional information.

Configuring Data Source Connections

Drill connects to data sources through storage plugins. Drill can connect to several types of data sources including databases, local or distributed filesystems, and Hive metastores.

See Connecting Drill to Data Sources on page 3251 and Connect a Data Source for instructions and additional information.

Accessing Drill

After you install Drill and configure connections to your data sources, you can access Drill from any of the following user interfaces:

- Drill shell (SQLLine)
- Drill Web Console
- ODBC
- JDBC
- C++ API
- REST API

Additional Resources

Drill documentation is accessible from following the locations:

- Drill Release Notes on page 5747
- Apache Drill

Drill Tutorial

Drill is included as part of the Hadoop distribution. The sandbox with Drill is a fully functional single-node cluster that simulates Drill in a Hadoop environment. Business and technical analysts, product managers, and developers can use the sandbox environment to get a feel for the power and capabilities of Drill by performing various types of queries. Refer to the Drill web site and Drill documentation for more details.

Hadoop is not a prerequisite for Drill and users can start learning Drill by running SQL queries directly on the local filesystem.

To complete the tutorial on the sandbox with Drill, work through lessons in following order:

Installing the Drill Sandbox

Prerequisites

The sandbox with Drill runs on VMware Player and VirtualBox (**recommended**), free desktop applications that you can use to run a virtual machine on a Windows, Mac, or Linux PC.

Before you install the sandbox with Drill, verify that the host system meets the following prerequisites:

- VMware Player or VirtualBox is installed.
- At least 20 GB free hard disk space, at least 4 physical cores, and 8 GB of RAM is available. Performance increases with more RAM and free hard disk space.
- Uses one of the following 64-bit x86 architectures:

last-updated: Apr 11, 2022

- • A 1.3 GHz or faster AMD CPU with segment-limit support in long mode
  - A 1.3 GHz or faster Intel CPU with VT-x support
- If you have an Intel CPU with VT-x support, verify that VT-x support is enabled in the host system BIOS. The BIOS settings that must be enabled for VT-x support vary depending on the system vendor. See the VMware knowledge base article at http://kb.vmware.com/kb/1003944 for information about how to determine if VT-x support is enabled.

VM Player Downloads

For Linux, Mac, or Windows, download the free VMware Player or VirtualBox. Optionally, you can purchase VMware Fusion for Mac.

VM Player Installation

The following list provides links to the virtual machine installation instructions:

- To install the VMware Player, see the VMware documentation. Use of VMware Player is subject to the VMware Player end user license terms. VMware does not provide support for VMware Player. For self-help resources, see the VMware Player FAQ.
- To install VirtualBox, see the Oracle VM VirtualBox User Manual. By downloading VirtualBox, you agree to the terms and conditions of the respective license.

Warning:

The sandbox for Drill on VirtualBox comes with NAT port forwarding enabled. The sandbox for Drill on VMware Player supports NAT, but does not support port forwards.

Click the link appropriate for the virtual machine player running on your machine:

Installing the MapR Sandbox with Drill on VMware Player/VMware Fusion
Download the MapR sandbox for Drill and import the virtual machine into VirtualBox. Configure the network setting, and start the MapR sandbox for Drill.

Complete the following steps to install the MapR sandbox with Drill on VMware Player or VMware Fusion:

1. Download the MapR sandbox for Drill file to a directory on your machine. To access the file, go to https://package.mapr.hpe.com/releases/, and select the directory for the latest release. The file is located in the `sandbox/` directory for the release, as shown:
   ```
   https://package.mapr.com/releases/v6.1.0/sandbox/
   MapR-Sandbox-For-Apache-Drill-1.14.0-6.1.0-vmware.ova
   ```
2. Open the virtual machine player, and select the **Open a Virtual Machine** option. If you are running VMware Fusion, select **Import**.
3. Navigate to the directory where you downloaded the MapR sandbox with Drill file, and select `MapR-Sandbox-For-Apache-Drill-<version>-vmware.ova`. The *Import Virtual Machine* dialog appears.
4. Click **Import**. The virtual machine player imports the sandbox.
5. Select **Edit virtual machine settings** and then select the **Network Adapter** option.

   Note: The correct setting depends on your network connectivity when you run the sandbox. In general, if you are going to use a wired Ethernet connection, select **NAT**. If you use ODBC or JDBC on a remote host, select **Bridged Adapter**. If you are going to use a wireless network, select **Host-only**.

last-updated: Apr 11, 2022

6. Click **OK** to save the settings.
7. Select `MapR-Sandbox-For-Apache-Drill-<version>_VM`, and click **Play virtual** machine.
8. When you see the `maprdemo login:_` prompt, enter `mapr` and then enter `mapr` as the password.
   The message, *Welcome to your Demo virtual machine,* appears.
9. The client must be able to resolve the actual hostname of the Drill node(s) with the IP(s). Verify that a DNS entry was created on the client machine for the Drill node(s). If a DNS entry does not exist, create the entry for the Drill node(s).
   - For Windows, create the entry in %WINDIR%\system32\drivers\etc\hosts.
   - For Linux and Mac, create the entry in /etc/hosts.

   Example: `127.0.1.1 maprdemo`
10. Go to `http://localhost:8047` or `http://127.0.0.1:8047` to experience the Drill Web Console.

    Note: If you used a bridged adapter, the network generates and assigns an IP to the sandbox that you use in place of 127.0.0.1 or localhost. To get the IP address, enter `root` as the username and `mapr` as the password from the sandbox command line. Run the `ifconfig` command to get the sandbox IP address. The IP address is located in the inet address field. You can access the Drill Web Console using the IP address and port 8047, as shown in the following example:

    ```
    http://10.250.56.216:8047
    ```

    You can access the command line on the virtual machine by pressing Alt+F2 on Windows or Option+F5 on Mac. You can access the sandbox via SSH, as described in Getting to Know the Drill Sandbox

After downloading and installing the sandbox, continue with the tutorial by Getting to Know the Drill Setup.
Installing the MapR Sandbox with Drill on VirtualBox
Download the MapR sandbox for Drill and import the virtual machine into VirtualBox. Configure the network setting, and start the MapR Sandbox for Drill.

Note: The MapR sandbox for Drill on VirtualBox comes with NAT port forwarding enabled, which allows you to access the sandbox using localhost as the hostname.

Complete the following steps to install the MapR sandbox with Drill:

1. Download the MapR sandbox for Drill file to a directory on your machine. To access the file, go to https://package.mapr.hpe.com/releases/, and select the directory for the latest MapR release. The file is located in the `sandbox/` directory for the release, as shown:
   `https://package.mapr.com/releases/v6.1.0/sandbox/MapR-Sandbox-For-Apache-Drill-1.14.0-6.1.0.ova`
2. Open VirtualBox, and select **File** > **Import Appliance**. The *Import Appliance* window appears.
3. Go to the directory where you downloaded the MapR sandbox for Drill file, select the `MapR-Sandbox-For-Apache-Drill-<version>.ova` file, and click **Next**. The *Import Virtual Appliance* window appears.
4. In the *Import Virtual Appliance* window, select the option to **Reinitialize the MAC address of all network cards** and then click **Import**. The Import Appliance imports the sandbox.

5. When the import completes, select the MapR sandbox for Drill and then click **Settings**. The *Settings* window appears.

6. In the *Settings* window, select **Network**. The correct setting depends on your network connectivity when you run the sandbox. In general, if you are going to use a wired Ethernet connection, use the default, **NAT**. If you use ODBC or JDBC on a remote host, select **Bridged Adapter**. If you are going to use a wireless network, select **Host-only Adapter** or **Bridged Adapter** with the **Intel(R) Dual Band Wireless-AC 8260** option.

7. Click **OK** to continue.

8. Select the `MapR-Sandbox-For-Apache-Drill-<version>` in VirtualBox, and click **Start**.

9. When you see `maprdemo login:_` prompt, enter `mapr` and then enter `mapr` as the password.

   The message, *Welcome to your Demo virtual machine,* appears.

10. The client must be able to resolve the actual hostname of the Drill node(s) with the IP(s). Verify that a DNS entry was created on the client machine for the Drill node(s). If a DNS entry does not exist, create the entry for the Drill node(s).

    - For Windows, create the entry in %WINDIR%\system32\drivers\etc\hosts.
    - For Linux and Mac, create the entry in /etc/hosts.

    Example: `127.0.0.1 maprdemo`

11. Go to http://localhost:8047 or http://127.0.0.1:8047 to experience the Drill Web Console, and enter `mapr` as the username and password.

    Note: If you used a bridged adapter, the network generates and assigns an IP to the sandbox that you use in place of localhost or 127.0.0.1. To get the IP address, run `ifconfig` from the sandbox command line to get the sandbox IP address. The IP address is located in the inet address field. You can access the Drill Web Console using the IP address and port 8047, as shown in the following example:

    ```
    http://10.250.56.216:8047
    ```

    You can access the command line on the virtual machine by pressing Alt+F2 on Windows or Option+F5 on Mac. You can access the sandbox via SSH, as described in Getting to Know the Drill Sandbox.

After downloading and installing the sandbox, continue with the tutorial by Getting to Know the Drill Setup.

Getting to Know the Drill Setup

This section describes the configuration of the Drill system that you have installed and introduces the overall use case for the tutorial.

Storage Plugins Overview

The Hadoop cluster within the sandbox is set up with MapR File System, MapR Database, and Hive, which all serve as data sources for Drill in this tutorial. Before you can run queries against these data sources, you need to connect to the data source through an interface called a storage plugin. A storage plugin defines interfaces to read/write and get metadata from the data source. Each storage plugin also exposes optimization rules for Drill to leverage for efficient query execution.

Jump directly to the queries in Lesson 1: Learn About the Data Set, or first, get some important background information about pre-configured storage plugins by following these steps:

1. Start the Drill Web Console.

last-updated: Apr 11, 2022

2. Go to the Storage tab.
3. Open the configured storage plugins one at a time by clicking Update. You will see the following plugins configured.

dfs

This is a storage plugin configuration for the MapR File System in the sandbox. The connection attribute indicates the type of distributed filesystem: in this case, MapR File System. Drill can work with any distributed system, including HDFS, S3, and so on.

The configuration also includes a set of workspaces; each one represents a location in MapR File System:

- root: access to the root filesystem location
- clicks: access to nested JSON log data
- logs: access to flat (non-nested) JSON log data in the logs directory and its subdirectories
- views: a workspace for creating views

A workspace in Drill is a location where users can easily access a specific set of data and collaborate with each other by sharing artifacts. Users can create as many workspaces as they need within Drill.

Each workspace can also be configured as “writable” or not, which indicates whether users can write data to this location and defines the storage format in which the data will be written (parquet, csv, json). These attributes become relevant when you explore Drill SQL commands, especially CREATE TABLE AS (CTAS) and CREATE VIEW.

Drill can query files and directories directly and can detect the file formats based on the file extension or the first few bits of data within the file. However, additional information around formats is required for Drill, such as delimiters for text files, which are specified in the “formats” section as follows.

```
{
 "type": "file",
 "enabled": true,
 "connection": "maprfs:///",
 "workspaces": {
   "root": {
     "location": "/mapr/demo.mapr.com/data",
     "writable": false,
     "storageformat": null
   },
   "clicks": {
     "location": "/mapr/demo.mapr.com/data/nested",
     "writable": true,
     "storageformat": "parquet"
   },
   "logs": {
     "location": "/mapr/demo.mapr.com/data/flat",
     "writable": true,
     "storageformat": "parquet"
   },
   "views": {
     "location": "/mapr/demo.mapr.com/data/views",
     "writable": true,
     "storageformat": "parquet"
 },
 "formats": {
   "psv": {
     "type": "text",
     "extensions": [
       "tbl"
```

last-updated: Apr 11, 2022

```
      ],
      "delimiter": "|"
    },
    "csv": {
      "type": "text",
      "extensions": [
        "csv"
      ],
      "delimiter": ","
    },
    "tsv": {
      "type": "text",
      "extensions": [
        "tsv"
      ],
      "delimiter": "\t"
    },
    "parquet": {
      "type": "parquet"
    },
    "json": {
      "type": "json"
    }
  }
}
```

hive

A storage plugin configuration for a Hive data warehouse within the sandbox. Drill connects to the Hive metastore by using the configured metastore thrift URI. Metadata for Hive tables is automatically available for users to query.

```
{
 "type": "hive",
 "enabled": true,
 "configProps": {
   "hive.metastore.uris": "thrift://localhost:9083",
   "hive.metastore.sasl.enabled": "false"
 }
}
```

Client Application Interfaces

Drill also provides additional application interfaces for the client tools to connect and access from Drill. The interfaces include the following.

ODBC/JDBC drivers

Drill provides ODBC/JDBC drivers to connect from BI tools such as Tableau, MicroStrategy, SQUirrel, and Jaspersoft; refer to Drill Interfaces Introduction to learn more.

SQLLine

SQLLine is a JDBC application that comes packaged with Drill. In order to start working with it, you can use the command line on the demo cluster to log in as root, then enter `sqlline`. Use `mapr` as the login password. For example:

```
$ ssh root@localhost -p 2222
Password:
Last login: Mon Sep 15 13:46:08 2014 from 10.250.0.28
Welcome to your Mapr Demo virtual machine.
```

last-updated: Apr 11, 2022

```
[root@maprdemo ~]# sqlline
sqlline version 1.1.6
0: jdbc:drill:>
```

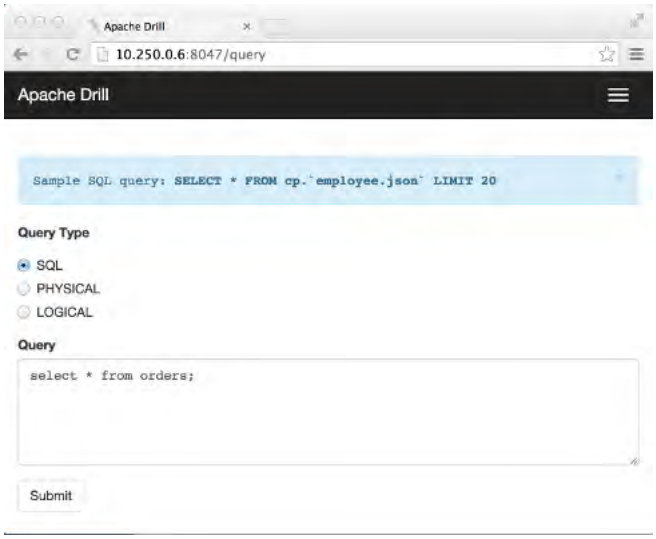
Drill Web UI

The Drill Web UI is a simple user interface for configuring and manage Drill. This UI can be launched from any of the nodes in the Drill cluster. The configuration for Drill includes setting up storage plugins that represent the data sources on which Drill performs queries. The sandbox comes with storage plugins configured for Hive, MapR Database binary tables, MapR File System, and local filesystem.

Users and developers can get the necessary information for tuning and performing diagnostics on queries, such as the list of queries executed in a session and detailed query plan profiles for each.

Detailed configuration and management of Drill is out of scope for this tutorial.

The following Web Console for Drill also provides a query UI where users can submit queries to Drill and observe results.



What's Next

Start running queries by going to Lesson 1: Learn About the Data Set.

Lesson 1: Learn About the Data Set

Goal

This lesson is simply about discovering what data is available, in what format, using simple SQL SELECT statements. Drill is capable of analyzing data without prior knowledge or definition of its schema. This means that you can start querying data immediately (and even as it changes), regardless of its format.

The data set for the tutorial consists of:

- Transactional data: stored as a Hive table
- Product catalog and primary customer data: stored as MapR Database binary tables
- Clickstream and logs data: stored in the MapR File System as JSON files

Queries in This Lesson

This lesson consists of select * queries on each data source.

Before You Begin

Start sqlline

If sqlline is not already started, use a Terminal or Command window to log into the demo VM as root, then enter `sqlline`:

```
$ ssh root@10.250.0.6
Password:
Last login: Mon Sep 15 13:46:08 2014 from 10.250.0.28
Welcome to your Mapr Demo virtual machine.
[root@maprdemo ~]# sqlline
sqlline version 1.1.6
0: jdbc:drill:>
```

You can run queries from this prompt to complete the tutorial. To exit from `sqlline`, type:

```
0: jdbc:drill:> !quit
```

Note that though this tutorial demonstrates the queries using SQLLine, you can also execute queries using the Drill Web UI.

Enable the DECIMAL Data Type

This tutorial uses the DECIMAL data type in some examples. The DECIMAL data type is disabled by default in this release, so enable the DECIMAL data type before proceeding:

```
alter session set `planner.enable_decimal_data_type`=true;

+-------+--------------------------------------------+
|  ok   |                  summary                   |
+-------+--------------------------------------------+
| true  | planner.enable_decimal_data_type updated.  |
+-------+--------------------------------------------+
1 row selected
```

List the available workspaces and databases:

```
0: jdbc:drill:> show databases;
+-------------+
| SCHEMA_NAME |
+-------------+
| hive.default |
| dfs.default |
| dfs.logs    |
| dfs.root    |
| dfs.views   |
| dfs.clicks  |
| dfs.data    |
| dfs.tmp     |
| sys         |
| maprdb      |
| cp.default  |
| INFORMATION_SCHEMA |
+-------------+
12 rows selected
```

Note that this command exposes all the metadata available from the storage plugins configured with Drill as a set of schemas. This includes the Hive and MapR Database databases as well as the workspaces configured in the filesystem. As you run queries in the tutorial, you will switch among these schemas

last-updated: Apr 11, 2022

by submitting the USE command. This behavior resembles the ability to use different database schemas (namespaces) in a relational database system.

Query Hive Tables

The orders table is a six-column Hive table defined in the Hive metastore. This is a Hive external table pointing to the data stored in flat files on the MapR File System. The orders table contains 122,000 rows.

Set the schema to hive:

```
0: jdbc:drill:> use hive;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'hive' |
+------------+------------+
```

You will run the USE command throughout this tutorial. The USE command sets the schema for the current session.

Describe the table:

You can use the DESCRIBE command to show the columns and data types for a Hive table:

```
0: jdbc:drill:> describe orders;
+-------------+------------+-------------+
| COLUMN_NAME | DATA_TYPE  | IS_NULLABLE |
+-------------+------------+-------------+
| order_id    | BIGINT     | YES         |
| month       | VARCHAR    | YES         |
| cust_id     | BIGINT     | YES         |
| state       | VARCHAR    | YES         |
| prod_id     | BIGINT     | YES         |
| order_total | INTEGER    | YES         |
+-------------+------------+-------------+
```

The DESCRIBE command returns complete schema information for Hive tables based on the metadata available in the Hive metastore.

Select 5 rows from the orders table:

```
0: jdbc:drill:> select * from orders limit 5;
+------------+------------+------------+------------+------------+-------------+

| order_id | month | cust_id | state | prod_id | order_total |
+------------+------------+------------+------------+------------+-------------+

| 67212 | June | 10001 | ca | 909 | 13 |
| 70302 | June | 10004 | ga | 420 | 11 |
| 69090 | June | 10011 | fl | 44 | 76 |
| 68834 | June | 10012 | ar | 0 | 81 |
| 71220 | June | 10018 | az | 411 | 24 |
+------------+------------+------------+------------+------------+-------------+
```

Because orders is a Hive table, you can query the data in the same way that you would query the columns in a relational database table. Note the use of the standard LIMIT clause, which limits the result set to the specified number of rows. You can use LIMIT with or without an ORDER BY clause.

Drill provides seamless integration with Hive by allowing queries on Hive tables defined in the metastore with no extra configuration. Note that Hive is not a prerequisite for Drill, but simply serves as a storage

plugin or data source for Drill. Drill also lets users query all Hive file formats (including custom serdes). Additionally, any UDFs defined in Hive can be leveraged as part of Drill queries.

Because Drill has its own low-latency SQL query execution engine, you can query Hive tables with high performance and support for interactive and ad-hoc data exploration.

Query MapR Database Binary Tables

The customers and products tables are MapR Database binary tables. MapR Database is an enterprise in-Hadoop NoSQL database. It exposes the HBase API to support application development. Every MapR Database binary table has a row_key, in addition to one or more column families. Each column family contains one or more specific columns. The row_key value is a primary key that uniquely identifies each row.

Drill allows direct queries on MapR Database binary tables. Unlike other SQL on Hadoop options, Drill requires no overlay schema definitions in Hive to work with this data. Think about a MapR Database table with thousands of columns, such as a time-series database, and the pain of having to management duplicate schemas for it in Hive!

Products Table

The products table has two column families.

Column Family	Columns
details	name category
pricing	price

The products table contains 965 rows.

Customers Table

The Customers table has three column families.

Column Family	Columns
address	state
loyalty	agg_rev membership
personal	age gender

The customers table contains 993 rows.

Set the workspace to maprdb:

```
0: jdbc:drill:> use maprdb;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'maprdb' |
+------------+------------+
```

last-updated: Apr 11, 2022

Describe the tables:

```
0: jdbc:drill:> describe customers;
+-------------+------------+-------------+
| COLUMN_NAME | DATA_TYPE  | IS_NULLABLE |
+-------------+------------+-------------+
| row_key     | ANY        | NO          |
| address     | (VARCHAR(1), ANY) MAP | NO          |
| loyalty     | (VARCHAR(1), ANY) MAP | NO          |
| personal    | (VARCHAR(1), ANY) MAP | NO          |
+-------------+------------+-------------+

0: jdbc:drill:> describe products;
+-------------+------------+-------------+
| COLUMN_NAME | DATA_TYPE  | IS_NULLABLE |
+-------------+------------+-------------+
| row_key     | ANY        | NO          |
| details     | (VARCHAR(1), ANY) MAP | NO          |
| pricing     | (VARCHAR(1), ANY) MAP | NO          |
+-------------+------------+-------------+
```

Unlike the Hive example, the DESCRIBE command does not return the full schema up to the column level. Column-oriented NoSQL databases such as MapR Database can be schema-less by design; every row has its own set of column name-value pairs in a given column family, and the column value can be of any data type, as determined by the application inserting the data.

A “MAP” complex type in Drill represents this variable column name-value structure, and “ANY” represents the fact that the column value can be of any data type. Observe the row_key, which is also simply bytes and has the type ANY.

Select 5 rows from the products table:

```
0: jdbc:drill:> select * from products limit 5;
+------------+------------+------------+
| row_key | details | pricing |
+------------+------------+------------+
| [B@a1a3e25 | {"category":"bGFwdG9w","name":"IlNvbnkgbm90ZWJvb2si"} |
{"price":"OTU5"} |
| [B@103a43af |
{"category":"RW52ZWxvcGVz","name":"IzEwLTQgMS84IHggOSAxLzIgUHJlbWl1bSBEaWFnb
25hbCBTZWFtIEVudmVsb3Blcw=="} | {"price":"MT |
| [B@61319e7b |
{"category":"U3RvcmFnZSAmIE9yZ2FuaXphdGlvbg==","name":"MjQgQ2FwYWNpdHkgTWF4a
SBEYXRhIEJpbmRlciBSYWNrc1BlYXJs"} | {"price" |
| [B@9bcf17 | {"category":"TGFiZWxz","name":"QXZlcnkgNDk4"} |
{"price":"Mw=="} |
| [B@7538ef50 | {"category":"TGFiZWxz","name":"QXZlcnkgNDk="} |
{"price":"Mw=="} |
```

Given that Drill requires no up front schema definitions indicating data types, the query returns the raw byte arrays for column values, just as they are stored in MapR Database. Observe that the column families (details and pricing) have the map data type and appear as JSON strings.

In Lesson 2, you will use CAST functions to return typed data for each column.

Select 5 rows from the customers table:

```
0: jdbc:drill:> select * from customers limit 5;
+------------+------------+------------+------------+
| row_key | address | loyalty | personal |
+------------+------------+------------+------------+
```

```
| [B@284bae62 | {"state":"Imt5Ig=="} |
{"agg_rev":"IjEwMDEtMzAwMCI=","membership":"ImJhc2ljIg=="} |
{"age":"IjI2LTM1Ig==","gender":"Ik1B |
| [B@7ffa4523 | {"state":"ImNhIg=="}
| {"agg_rev":"IjAtMTAwIg==","membership":"ImdvbGQi"} |
{"age":"IjI2LTM1Ig==","gender":"IkZFTUFMRSI= |
| [B@7d13e79 | {"state":"Im9rIg=="} |
{"agg_rev":"IjUwMS0xMDAwIg==","membership":"InNpbHZlciI="} |
{"age":"IjI2LTM1Ig==","gender":"IkZFT |
| [B@3a5c7df1 | {"state":"ImtzIg=="} |
{"agg_rev":"IjMwMDEtMTAwMDAwIg==","membership":"ImdvbGQi"} |
{"age":"IjUxLTEwMCI=","gender":"IkZF |
| [B@e507726 | {"state":"Im5qIg=="}
| {"agg_rev":"IjAtMTAwIg==","membership":"ImJhc2ljIg=="} |
{"age":"IjIxLTI1Ig==","gender":"Ik1BTEUi" |
+------------+------------+------------+------------+
```

Again the table returns byte data that needs to be cast to readable data types.

Query the File System

Along with querying a data source with full schemas (such as Hive) and partial schemas (such as MapR Database), Drill offers the unique capability to perform SQL queries directly on filesystem. The filesystem could be a local filesystem, or a distributed filesystem such as MapR File System, HDFS, or S3.

In the context of Drill, a file or a directory is considered as synonymous to a relational database “table.” Therefore, you can perform SQL operations directly on files and directories without the need for up-front schema definitions or schema management for any model changes. The schema is discovered on the fly based on the query. Drill supports queries on a variety of file formats including text, CSV, Parquet, and JSON in the 0.5 release.

In this example, the clickstream data coming from the mobile/web applications is in JSON format. The JSON files have the following structure:

```
{"trans_id":31920,"date":"2014-04-26","time":"12:17:12","user_info":
{"cust_id":22526,"device":"IOS5","state":"il"},"trans_info":{"prod_id":
[174,2],"purch_flag":"false"}}
{"trans_id":31026,"date":"2014-04-20","time":"13:50:29","user_info":
{"cust_id":16368,"device":"AOS4.2","state":"nc"},"trans_info":{"prod_id":
[],"purch_flag":"false"}}
{"trans_id":33848,"date":"2014-04-10","time":"04:44:42","user_info":
{"cust_id":21449,"device":"IOS6","state":"oh"},"trans_info":{"prod_id":
[582],"purch_flag":"false"}}
```

The clicks.json and clicks.campaign.json files contain metadata as part of the data itself (referred to as “self-describing” data). Also note that the data elements are complex, or nested. The initial queries below do not show how to unpack the nested data, but they show that easy access to the data requires no setup beyond the definition of a workspace.

Query nested clickstream data

Set the workspace to dfs.clicks:

```
 0: jdbc:drill:> use dfs.clicks;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.clicks' |
+------------+------------+
```

last-updated: Apr 11, 2022

In this case, setting the workspace is a mechanism for making queries easier to write. When you specify a filesystem workspace, you can shorten references to files in the FROM clause of your queries. Instead of having to provide the complete path to a file, you can provide the path relative to a directory location specified in the workspace. For example:

```
"location": "/mapr/demo.mapr.com/data/nested"
```

Any file or directory that you want to query in this path can be referenced relative to this path. The clicks directory referred to in the following query is directly below the nested directory.

Select 2 rows from the clicks.json file:

```
0: jdbc:drill:> select * from `clicks/clicks.json` limit 2;
+------------+------------+------------+------------+------------+
|  trans_id  |    date    |    time    | user_info  | trans_info |
+------------+------------+------------+------------+------------+
| 31920      | 2014-04-26 | 12:17:12
| {"cust_id":22526,"device":"IOS5","state":"il"} | {"prod_id":
[174,2],"purch_flag":"false"} |
| 31026      | 2014-04-20 | 13:50:29
| {"cust_id":16368,"device":"AOS4.2","state":"nc"} | {"prod_id":
[],"purch_flag":"false"} |
+------------+------------+------------+------------+------------+
2 rows selected
```

Note that the FROM clause reference points to a specific file. Drill expands the traditional concept of a “table reference” in a standard SQL FROM clause to refer to a file in a local or distributed filesystem.

The only special requirement is the use of back ticks to enclose the file path. This is necessary whenever the file path contains Drill reserved words or characters.

Select 2 rows from the campaign.json file:

```
0: jdbc:drill:> select * from `clicks/clicks.campaign.json` limit 2;
+------------+------------+------------+------------+------------+------------+

|  trans_id  |    date    |    time    | user_info  |  ad_info   |
trans_info |
+------------+------------+------------+------------+------------+------------+

| 35232      | 2014-05-10 | 00:13:03   |
{"cust_id":18520,"device":"AOS4.3","state":"tx"} | {"camp_id":"null"} |
{"prod_id":[7,7],"purch_flag":"true"} |
| 31995      | 2014-05-22 | 16:06:38   |
{"cust_id":17182,"device":"IOS6","state":"fl"} | {"camp_id":"null"} |
{"prod_id":[],"purch_flag":"false"} |
+------------+------------+------------+------------+------------+------------+

2 rows selected
```

Notice that with a select * query, any complex data types such as maps and arrays return as JSON strings. You will see how to unpack this data using various SQL functions and operators in the next lesson.

Query Logs Data

Unlike the previous example where we performed queries against clicks data in one file, logs data is stored as partitioned directories on the filesystem. The logs directory has three subdirectories:

- 2012

last-updated: Apr 11, 2022

- 2013
- 2014

Each of these year directories fans out to a set of numbered month directories, and each month directory contains a JSON file with log records for that month. The total number of records in all log files is 48000.

The files in the logs directory and its subdirectories are JSON files. There are many of these files, but you can use Drill to query them all as a single data source, or to query a subset of the files.

Set the workspace to dfs.logs:

```
 0: jdbc:drill:> use dfs.logs;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.logs' |
+------------+------------+
```

Select 2 rows from the logs directory:

```
0: jdbc:drill:> select * from logs limit 2;
+------------+------------+------------+------------+------------+------------+------------+---------
| dir0 | dir1 | trans_id | date | time | cust_id | device | state | camp_id
| keywords | prod_id | purch_fl |
+------------+------------+------------+------------+------------+------------+------------+---------
| 2014 | 8 | 24181 | 08/02/2014 | 09:23:52 | 0 | IOS5 | il | 2 | wait | 128
| false |
| 2014 | 8 | 24195 | 08/02/2014 | 07:58:19 | 243 | IOS5 | mo | 6 | hmm |
107 | false |
+------------+------------+------------+------------+------------+------------+------------+---------
```

Note that this is flat JSON data. The dfs.clicks workspace location property points to a directory that contains the logs directory, making the FROM clause reference for this query very simple. You do not have to refer to the complete directory path on the file system.

The column names dir0 and dir1 are special Drill variables that identify subdirectories below the logs directory. In Lesson 3, you will do more complex queries that leverage these dynamic variables.

Find the total number of rows in the logs directory (all files):

```
0: jdbc:drill:> select count(*) from logs;
+------------+
| EXPR$0 |
+------------+
| 48000 |
+------------+
```

This query traverses all of the files in the logs directory and its subdirectories to return the total number of rows in those files.

What's Next

Go to Lesson 2: Run Queries with ANSI SQL.

last-updated: Apr 11, 2022

Lesson 2: Run Queries with ANSI SQL

Goal

This lesson shows how to do some standard SQL analysis in Drill: for example, summarizing data by using simple aggregate functions and connecting data sources by using joins. Note that Drill provides ANSI SQL support, not a “SQL-like” interface.

Queries in This Lesson

Now that you know what the data sources look like in their raw form, using select * queries, try running some simple but more useful queries on each data source. These queries demonstrate how Drill supports ANSI SQL constructs and also how you can combine data from different data sources in a single SELECT statement.

- Show an aggregate query on a single file or table. Use GROUP BY, WHERE, HAVING, and ORDER BY clauses.
- Perform joins between Hive, MapR Database, and filesystem data sources.
- Use table and column aliases.
- Create a Drill view.

Aggregation

Set the schema to hive:

```
0: jdbc:drill:> use hive;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'hive' |
+------------+------------+
1 row selected
```

Return sales totals by month:

```
0: jdbc:drill:> select `month`, sum(order_total)
from orders group by `month` order by 2 desc;
+------------+------------+
| month | EXPR$1 |
+------------+------------+
| June | 950481 |
| May | 947796 |
| March | 836809 |
| April | 807291 |
| July | 757395 |
| October | 676236 |
| August | 572269 |
| February | 532901 |
| September | 373100 |
| January | 346536 |
+------------+------------+
```

Drill supports SQL aggregate functions such as SUM, MAX, AVG, and MIN. Standard SQL clauses work in the same way in Drill queries as in relational database queries.

Note that back ticks are required for the “month” column only because “month” is a reserved word in SQL.

last-updated: Apr 11, 2022

Return the top 20 sales totals by month and state:

```
0: jdbc:drill:> select `month`, state, sum(order_total) as sales from
orders group by `month`, state
order by 3 desc limit 20;
+------------+------------+------------+
|   month    |   state    |   sales    |
+------------+------------+------------+
| May        | ca         | 119586     |
| June       | ca         | 116322     |
| April      | ca         | 101363     |
| March      | ca         | 99540      |
| July       | ca         | 90285      |
| October    | ca         | 80090      |
| June       | tx         | 78363      |
| May        | tx         | 77247      |
| March      | tx         | 73815      |
| August     | ca         | 71255      |
| April      | tx         | 68385      |
| July       | tx         | 63858      |
| February   | ca         | 63527      |
| June       | fl         | 62199      |
| June       | ny         | 62052      |
| May        | fl         | 61651      |
| May        | ny         | 59369      |
| October    | tx         | 55076      |
| March      | fl         | 54867      |
| March      | ny         | 52101      |
+------------+------------+------------+
20 rows selected
```

Note the alias for the result of the SUM function. Drill supports column aliases and table aliases.

HAVING Clause

This query uses the HAVING clause to constrain an aggregate result.

Set the workspace to dfs.clicks

```
0: jdbc:drill:> use dfs.clicks;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'dfs.clicks' |
+------------+------------+
1 row selected
```

Return total number of clicks for devices that indicate high click-throughs:

```
0: jdbc:drill:> select t.user_info.device, count(*) from `clicks/
clicks.json` t
group by t.user_info.device
having count(*) > 1000;
+------------+------------+
|   EXPR$0   |   EXPR$1   |
+------------+------------+
| IOS5       | 11814      |
| AOS4.2     | 5986       |
| IOS6       | 4464       |
| IOS7       | 3135       |
| AOS4.4     | 1562       |
```

last-updated: Apr 11, 2022

```
| AOS4.3     | 3039       |
+------------+------------+
```

The aggregate is a count of the records for each different mobile device in the clickstream data. Only the activity for the devices that registered more than 1000 transactions qualify for the result set.

UNION Operator

Use the same workspace as before (dfs.clicks).

Combine clicks activity from before and after the marketing campaign

```
0: jdbc:drill:> select t.trans_id transaction, t.user_info.cust_id customer
from `clicks/clicks.campaign.json` t
union all
select u.trans_id, u.user_info.cust_id  from `clicks/clicks.json` u limit 5;
+-------------+------------+
| transaction |  customer  |
+-------------+------------+
| 35232       | 18520      |
| 31995       | 17182      |
| 35760       | 18228      |
| 37090       | 17015      |
| 37838       | 18737      |
+-------------+------------+
```

This UNION ALL query returns rows that exist in two files (and includes any duplicate rows from those files): `clicks.campaign.json` and `clicks.json`.

Subqueries

Set the workspace to hive:

```
0: jdbc:drill:> use hive;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'hive' |
+------------+------------+
```

Compare order totals across states:

```
0: jdbc:drill:> select ny_sales.cust_id, ny_sales.total_orders,
ca_sales.total_orders
    from
    (select o.cust_id, sum(o.order_total) as total_orders
    from hive.orders o where state = 'ny' group by o.cust_id) ny_sales
    left outer join
    (select o.cust_id, sum(o.order_total) as total_orders
    from
    hive.orders o where state = 'ca' group by o.cust_id) ca_sales
    on ny_sales.cust_id = ca_sales.cust_id
    order by ny_sales.cust_id
    limit 20;
+------------+------------+------------+
|  cust_id   |  ny_sales  |  ca_sales  |
+------------+------------+------------+
| 1001       | 72         | 47         |
| 1002       | 108        | 198        |
```

last-updated: Apr 11, 2022

```
| 1003       | 83         | null       |
| 1004       | 86         | 210        |
| 1005       | 168        | 153        |
| 1006       | 29         | 326        |
| 1008       | 105        | 168        |
| 1009       | 443        | 127        |
| 1010       | 75         | 18         |
| 1012       | 110        | null       |
| 1013       | 19         | null       |
| 1014       | 106        | 162        |
| 1015       | 220        | 153        |
| 1016       | 85         | 159        |
| 1017       | 82         | 56         |
| 1019       | 37         | 196        |
| 1020       | 193        | 165        |
| 1022       | 124        | null       |
| 1023       | 166        | 149        |
| 1024       | 233        | null       |
+------------+------------+------------+
```

This example demonstrates Drill support for correlated subqueries. This query uses a subquery in the select list and correlates the result of the subquery with the outer query, using the cust_id column reference. The subquery returns the sum of order totals for California, and the outer query returns the equivalent sum, for the same cust_id, for New York.

The result set is sorted by the cust_id and presents the sales totals side by side for easy comparison. Null values indicate customer IDs that did not register any sales in that state.

CAST Function

Use the maprdb workspace:

```
0: jdbc:drill:> use maprdb;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'maprdb' |
+------------+------------+
1 row selected
```

Return customer data with appropriate data types

```
0: jdbc:drill:> select cast(row_key as int) as cust_id,
cast(t.personal.name as varchar(20)) as name,
cast(t.personal.gender as varchar(10)) as gender, cast(t.personal.age as
varchar(10)) as age,
cast(t.address.state as varchar(4)) as state, cast(t.loyalty.agg_rev as
dec(7,2)) as agg_rev,
cast(t.loyalty.membership as varchar(20)) as membership
from customers t limit 5;
+------------+------------+------------+------------+------------+------------+---------

|  cust_id   |    name    |   gender   |    age     |   state    |
agg_rev   | membership |
+------------+------------+------------+------------+------------+------------+---------

| 10001      | "Corrine Mecham" | "FEMALE"   | "15-20"    | "va"       |
197.00     | "silver"   |
| 10005      | "Brittany Park" | "MALE"     | "26-35"    | "in"       |
230.00     | "silver"   |
| 10006      | "Rose Lokey" | "MALE"     | "26-35"    | "ca"       |
```

last-updated: Apr 11, 2022

```
250.00     | "silver"   |
| 10007      | "James Fowler" | "FEMALE"   | "51-100"   | "me"       |
263.00     | "silver"   |
| 10010      | "Guillermo Koehler" | "OTHER"    | "51-100"   | "mn"       |
202.00     | "silver"   |
+------------+------------+------------+------------+------------+------------+---------

5 rows selected
```

Note the following features of this query:

- The CAST function is required for every column in the table. This function returns the MapR Database/HBase binary data as readable integers and strings. Depending on what encoding is used while populating the MapR Database binary tables/HBase tables, you might have to use CONVERT_TO/CONVERT_FROM functions to decode them.
- The row_key column functions as the primary key of the table (a customer ID in this case).
- The table alias t is required; otherwise the column family names would be parsed as table names and the query would return an error.

Remove the quotes from the strings:

You can use the regexp_replace function to remove the quotes around the strings in the query results. For example, to return a state name va instead of “va”:

```
0: jdbc:drill:> select cast(row_key as int),
regexp_replace(cast(t.address.state as varchar(10)),'"','')
from customers t limit 1;
+------------+------------+
|   EXPR$0   |   EXPR$1   |
+------------+------------+
| 10001      | va         |
+------------+------------+
1 row selected
```

CREATE VIEW Command

Use a mutable workspace:

```
0: jdbc:drill:> use dfs.views;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.views' |
+------------+------------+
```

A mutable (or writable) workspace is a workspace that is enabled for “write” operations. This attribute is part of the storage plugin configuration. You can create Drill views and tables in mutable workspaces.

Create a view on a MapR Database binary table

```
0: jdbc:drill:> create or replace view custview as select cast(row_key as
int) as cust_id,
cast(t.personal.name as varchar(20)) as name,
cast(t.personal.gender as varchar(10)) as gender,
cast(t.personal.age as varchar(10)) as age,
cast(t.address.state as varchar(4)) as state,
cast(t.loyalty.agg_rev as dec(7,2)) as agg_rev,
cast(t.loyalty.membership as varchar(20)) as membership
```

```
from maprdb.customers t;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | View 'custview' replaced successfully in 'dfs.views' schema |
+------------+------------+
1 row selected
```

Drill provides CREATE OR REPLACE VIEW syntax similar to relational databases to create views. Use the OR REPLACE option to make it easier to update the view later without having to remove it first. Note that the FROM clause in this example must refer to maprdb.customers. The MapR Database binary tables are not directly visible to the dfs.views workspace.

Unlike a traditional database where views typically are DBA/developer-driven operations, filesystem-based views in Drill are very lightweight. A view is simply a special file with a specific extension (.drill). You can store views even in your local filesystem or point to a specific workspace. You can specify any query against any Drill data source in the body of the CREATE VIEW statement.

Dril provides a decentralized metadata model. Drill is able to query metadata defined in data sources such as Hive, HBase, and the filesystem. Drill also supports the creation of metadata in the filesystem.

Query data from the view:

```
0: jdbc:drill:> select * from custview limit 1;
+------------+------------+------------+------------+------------+------------+---------

|  cust_id   |    name    |   gender   |    age     |   state    |
agg_rev   | membership |
+------------+------------+------------+------------+------------+------------+---------

| 10001      | "Corrine Mecham" | "FEMALE"   | "15-20"    | "va"       |
197.00     | "silver"   |
+------------+------------+------------+------------+------------+------------+---------
```

Once the users know what data is available by exploring it directly from the file system, views can be used as a way to read the data into downstream tools such as Tableau and MicroStrategy for analysis and visualization. For these tools, a view appears simply as a “table” with selectable “columns” in it.

Query Across Data Sources

Continue using dfs.views for this query.

Join the customers view and the orders table:

```
0: jdbc:drill:> select membership, sum(order_total) as sales from
hive.orders, custview
where orders.cust_id=custview.cust_id
group by membership order by 2;
+------------+------------+
| membership |   sales    |
+------------+------------+
| "basic"    | 380665     |
| "silver"   | 708438     |
| "gold"     | 2787682    |
+------------+------------+
3 rows selected
```

In this query, we are reading data from a MapR Database binary table (represented by custview) and combining it with the order information in Hive. When doing cross data source queries such as this, you need to use fully qualified table/view names. For example, the orders table is prefixed by “hive,” which

is the storage plugin name registered with Drill. We are not using any prefix for “custview” because we explicitly switched the dfs.views workspace where custview is stored.

Note: Note: If the results of any of your queries appear to be truncated because the rows are wide, set the maximum width of the display to 10000:

```
0: jdbc:drill:> !set maxwidth 10000
```

Do not use a semicolon for this SET command.

Join the customers, orders, and clickstream data:

```
0: jdbc:drill:> select custview.membership, sum(orders.order_total) as
sales from hive.orders, custview,
dfs.`/mapr/demo.mapr.com/data/nested/clicks/clicks.json` c
where orders.cust_id=custview.cust_id and
orders.cust_id=c.user_info.cust_id
group by custview.membership order by 2;
+------------+------------+
| membership |   sales    |
+------------+------------+
| "basic"    | 372866     |
| "silver"   | 728424     |
| "gold"     | 7050198    |
+------------+------------+
3 rows selected
```

This three-way join selects from three different data sources in one query:

- hive.orders table
- custview (a view of the HBase customers table)
- clicks.json file

The join column for both sets of join conditions is the cust_id column. The views workspace is used for this query so that custview can be accessed. The hive.orders table is also visible to the query.

However, note that the JSON file is not directly visible from the views workspace, so the query specifies the full path to the file:

```
dfs.`/mapr/demo.mapr.com/data/nested/clicks/clicks.json`
```

What's Next

Go to Lesson 3: Run Queries on Complex Data Types

Lesson 3: Run Queries on Complex Data Types

Goal

This lesson focuses on queries that exercise functions and operators on self-describing data and complex data types. Drill offers intuitive SQL extensions to work with such data and offers high query performance with an architecture built from the ground up for complex data.

Queries in This Lesson

Now that you have run ANSI SQL queries against different tables and files with relational data, you can try some examples including complex types.

- Access directories and subdirectories of files in a single SELECT statement.
- Demonstrate simple ways to access complex data in JSON files.
- Demonstrate the repeated_count function to aggregate values in an array.

Query Partitioned Directories

You can use special variables in Drill to refer to subdirectories in your workspace path:

- dir0
- dir1
- …

Note that these variables are dynamically determined based on the partitioning of the file system. No up-front definitions are required on what partitions exist.

Set workspace to dfs.logs

```
0: jdbc:drill:> use dfs.logs;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.logs' |
+------------+------------+
```

Query logs data for a specific year

```
0: jdbc:drill:> select * from logs where dir0='2013' limit 10;
+------------+------------+------------+------------+------------+------------+--------

| dir0 | dir1 | trans_id | date | time | cust_id | device | state | camp_id
| keywords | prod_id | purch_flag |
+------------+------------+------------+------------+------------+------------+--------

| 2013 | 11 | 12119 | 11/09/2013 | 02:24:51 | 262 | IOS5 | ny | 0 | chamber
| 198 | false |
| 2013 | 11 | 12120 | 11/19/2013 | 09:37:43 | 0 | AOS4.4 | il | 2 | outside
| 511 | false |
| 2013 | 11 | 12134 | 11/10/2013 | 23:42:47 | 60343 | IOS5 | ma | 4 | and |
421 | false |
| 2013 | 11 | 12135 | 11/16/2013 | 01:42:13 | 46762 | AOS4.3 | ca | 4 |
here's | 349 | false |
| 2013 | 11 | 12165 | 11/26/2013 | 21:58:09 | 41987 | AOS4.2 | mn | 4 | he
| 271 | false |
| 2013 | 11 | 12168 | 11/09/2013 | 23:41:48 | 8600 | IOS5 | in | 6 | i |
459 | false |
| 2013 | 11 | 12196 | 11/20/2013 | 02:23:06 | 15603 | IOS5 | tn | 1 | like
| 324 | false |
| 2013 | 11 | 12203 | 11/25/2013 | 23:50:29 | 221 | IOS6 | tx | 10 | if |
323 | false |
| 2013 | 11 | 12206 | 11/09/2013 | 23:53:01 | 2488 | AOS4.2 | tx | 14 |
unlike | 296 | false |
| 2013 | 11 | 12217 | 11/06/2013 | 23:51:56 | 0 | AOS4.2 | tx | 9 | can't |
54 | false |
+------------+------------+------------+------------+------------+------------+--------
```

This query constrains files inside the subdirectory named 2013. The variable dir0 refers to the first level down from logs, dir1 to the next level, and so on. So this query returned 10 of the rows for February 2013.

last-updated: Apr 11, 2022

Further constrain the results using multiple predicates in the query

```
0: jdbc:drill:> select dir0 as yr, dir1 as mth, cust_id from logs
where dir0='2013' and dir1='8' and device='IOS5' and purch_flag='true'
order by `date`;
+------------+------------+------------+
| yr | mth | cust_id |
+------------+------------+------------+
| 2013 | 8 | 4 |
| 2013 | 8 | 521 |
| 2013 | 8 | 1 |
| 2013 | 8 | 2 |
| 2013 | 8 | 4 |
| 2013 | 8 | 549 |
| 2013 | 8 | 72827 |
| 2013 | 8 | 38127 |
...
```

This query returns a list of customer IDs for people who made a purchase via an IOS5 device in August 2013.

Return monthly counts per customer for a given year

```
0: jdbc:drill:> select cust_id, dir1 month_no, count(*) month_count from
logs
where dir0=2014 group by cust_id, dir1 order by cust_id, month_no limit 10;
+------------+------------+-------------+
|  cust_id   |  month_no  | month_count |
+------------+------------+-------------+
| 0          | 1          | 143         |
| 0          | 2          | 118         |
| 0          | 3          | 117         |
| 0          | 4          | 115         |
| 0          | 5          | 137         |
| 0          | 6          | 117         |
| 0          | 7          | 142         |
| 0          | 8          | 19          |
| 1          | 1          | 66          |
| 1          | 2          | 59          |
+------------+------------+-------------+
10 rows selected
```

This query groups the aggregate function by customer ID and month for one year: 2014.

Query Complex Data

Drill provides some specialized operators and functions that you can use to analyze nested data natively without transformation. If you are familiar with JavaScript notation, you will already know how some of these extensions work.

Set the workspace to dfs.clicks

```
0: jdbc:drill:> use dfs.clicks;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.clicks' |
+------------+------------+
```

Explore clickstream data

```
0: jdbc:drill:> select * from `clicks/clicks.json` limit 5;
+------------+------------+------------+------------+------------+
| trans_id | date | time | user_info | trans_info |
+------------+------------+------------+------------+------------+
| 31920 | 2014-04-26 | 12:17:12
| {"cust_id":22526,"device":"IOS5","state":"il"} | {"prod_id":
[174,2],"purch_flag":"false"} |
| 31026 | 2014-04-20 | 13:50:29
| {"cust_id":16368,"device":"AOS4.2","state":"nc"} | {"prod_id":
[],"purch_flag":"false"} |
| 33848 | 2014-04-10 | 04:44:42
| {"cust_id":21449,"device":"IOS6","state":"oh"} | {"prod_id":
[582],"purch_flag":"false"} |
| 32383 | 2014-04-18 | 06:27:47
| {"cust_id":20323,"device":"IOS5","state":"oh"} | {"prod_id":
[710,47],"purch_flag":"false"} |
| 32359 | 2014-04-19 | 23:13:25 |
{"cust_id":15360,"device":"IOS5","state":"ca"} | {"prod_id":
[0,8,170,173,1,124,46,764,30,711,0,3,25],"purch_flag":"true"} |
+------------+------------+------------+------------+------------+
```

Note that the user_info and trans_info columns contain nested data: arrays and arrays within arrays. The following queries show how to access this complex data.

Unpack the user_info column

```
0: jdbc:drill:> select t.user_info.cust_id as custid, t.user_info.device as
device,
t.user_info.state as state
from `clicks/clicks.json` t limit 5;
+------------+------------+------------+
| custid | device | state |
+------------+------------+------------+
| 22526 | IOS5 | il |
| 16368 | AOS4.2 | nc |
| 21449 | IOS6 | oh |
| 20323 | IOS5 | oh |
| 15360 | IOS5 | ca |
+------------+------------+------------+
```

This query uses a simple table.column.column notation to extract nested column data. For example:

```
t.user_info.cust_id
```

where `t` is the table alias provided in the query, `user_info` is a top-level column name, and `cust_id` is a nested column name.

The table alias is required; otherwise column names such as `user_info` are parsed as table names by the SQL parser.

Unpack the trans_info column

```
0: jdbc:drill:> select t.trans_info.prod_id as prodid,
t.trans_info.purch_flag as
purchased
from `clicks/clicks.json` t limit 5;
+------------+------------+
| prodid | purchased |
+------------+------------+
```

```
| [174,2] | false |
| [] | false |
| [582] | false |
| [710,47] | false |
| [0,8,170,173,1,124,46,764,30,711,0,3,25] | true |
+------------+------------+
5 rows selected
```

Note that this result reveals that the prod_id column contains an array of IDs (one or more product ID values per row, separated by commas). The next step shows how you to access this kind of data.

Query Arrays

Now use the [n] notation, where n is the position of the value in an array, starting from position 0 (not 1) for the first value. You can use this notation to write interesting queries against nested array data.

For example:

`trans_info.prod_id[0]`

refers to the first value in the nested prod_id column and

`trans_info.prod_id[20]`

refers to the 21st value, assuming one exists.

Find the first product that is searched for in each transaction:

```
0: jdbc:drill:> select t.trans_id, t.trans_info.prod_id[0] from `clicks/
clicks.json` t limit 5;
+------------+------------+
|  trans_id  |   EXPR$1   |
+------------+------------+
| 31920      | 174        |
| 31026      | null       |
| 33848      | 582        |
| 32383      | 710        |
| 32359      | 0          |
+------------+------------+
5 rows selected
```

For which transactions did customers search on at least 21 products?

```
0: jdbc:drill:> select t.trans_id, t.trans_info.prod_id[20]
from `clicks/clicks.json` t
where t.trans_info.prod_id[20] is not null
order by trans_id limit 5;
+------------+------------+
|  trans_id  |   EXPR$1   |
+------------+------------+
| 10328      | 0          |
| 10380      | 23         |
| 10701      | 1          |
| 11100      | 0          |
| 11219      | 46         |
+------------+------------+
5 rows selected
```

This query returns transaction IDs and product IDs for records that contain a non-null product ID at the 21st position in the array.

last-updated: Apr 11, 2022

Return clicks for a specific product range:

```
0: jdbc:drill:> select * from (select t.trans_id, t.trans_info.prod_id[0]
as prodid,
t.trans_info.purch_flag as purchased
from `clicks/clicks.json` t) sq
where sq.prodid between 700 and 750 and sq.purchased='true' order by
sq.prodid;
+------------+------------+------------+
| trans_id | prodid | purchased |
+------------+------------+------------+
| 21886 | 704 | true |
| 20674 | 708 | true |
| 22158 | 709 | true |
| 34089 | 714 | true |
| 22545 | 714 | true |
| 37500 | 717 | true |
| 36595 | 718 | true |
...
```

This query assumes that there is some meaning to the array (that it is an ordered list of products purchased rather than a random list).

Perform Operations on Arrays

Rank successful click conversions and count product searches for each session:

```
0: jdbc:drill:> select t.trans_id, t.`date` as session_date,
t.user_info.cust_id as
cust_id, t.user_info.device as device, repeated_count(t.trans_info.prod_id)
as
prod_count, t.trans_info.purch_flag as purch_flag
from `clicks/clicks.json` t
where t.trans_info.purch_flag = 'true' order by prod_count desc;
+------------+--------------+------------+------------+------------+------------+

| trans_id | session_date | cust_id | device | prod_count | purch_flag |
+------------+--------------+------------+------------+------------+------------+

| 37426 | 2014-04-06 | 18709 | IOS5 | 34 | true |
| 31589 | 2014-04-16 | 18576 | IOS6 | 31 | true |
| 11600 | 2014-04-07 | 4260 | AOS4.2 | 28 | true |
| 35074 | 2014-04-03 | 16697 | AOS4.3 | 27 | true |
| 17192 | 2014-04-22 | 2501 | AOS4.2 | 26 | true |
...
```

This query uses a Drill SQL extension, the repeated_count function, to get an aggregated count of the array values. The query returns the number of products searched for each session that converted into a purchase and ranks the counts in descending order. Only clicks that have resulted in a purchase are counted.

Store a Result Set in a Table for Reuse and Analysis

To facilitate additional analysis on this result set, you can easily and quickly create a Drill table from the results of the query.

Continue to use the dfs.clicks workspace

```
0: jdbc:drill:> use dfs.clicks;
+------------+------------+
```

last-updated: Apr 11, 2022

```
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.clicks' |
+------------+------------+
```

Return product searches for high-value customers:

```
0: jdbc:drill:> 0: jdbc:drill:> select o.cust_id, o.order_total,
t.trans_info.prod_id[0] as prod_id
from
hive.orders as o
join `clicks/clicks.json` t
on o.cust_id=t.user_info.cust_id
where o.order_total > (select avg(inord.order_total)
                       from hive.orders inord
                       where inord.state = o.state);
+----------+-------------+----------+
| cust_id  | order_total  | prod_id  |
+----------+-------------+----------+
| 1328     | 73           | 26       |
| 1328     | 146          | 26       |
| 1328     | 56           | 26       |
| 1328     | 91           | 26       |
| 1328     | 74           | 26       |
...
+----------+-------------+----------+
107,482 rows selected (14.863 seconds)
```

This query returns a list of products that are being searched for by customers who have made transactions that are above the average in their states.

Materialize the result of the previous query:

```
0: jdbc:drill:> 0: jdbc:drill:> create table product_search as select
o.cust_id, o.order_total, t.trans_info.prod_id[0] as prod_id
from
hive.orders as o
join `clicks/clicks.json` t
on o.cust_id=t.user_info.cust_id
where o.order_total > (select avg(inord.order_total)
                       from hive.orders inord
                       where inord.state = o.state);
+-----------+----------------------------+
| Fragment  | Number of records written  |
+-----------+----------------------------+
| 0_0       | 107482                     |
+-----------+----------------------------+
1 row selected
```

This example uses a CTAS statement to create a table based on a correlated subquery that you ran previously. This table contains all of the rows that the query returns (107,482) and stores them in the format specified by the storage plugin (Parquet format in this example). You can create tables that store data in csv, parquet, and json formats.

Query the new table to verify the row count

```
0: jdbc:drill:> select count(*) from product_search;
+------------+
|   EXPR$0   |
+------------+
```

```
| 107482     |
+------------+
1 row selected
```

This example simply checks that the CTAS statement worked by verifying the number of rows in the table.

Find the storage file for the table

```
[root@maprdemo product_search]# cd /mapr/demo.mapr.com/data/nested/
product_search
[root@maprdemo product_search]# ls -la
total 451
drwxr-xr-x. 2 mapr mapr      1 Sep 15 13:41 .
drwxr-xr-x. 4 root root      2 Sep 15 13:41 ..
-rwxr-xr-x. 1 mapr mapr 460715 Sep 15 13:41 0_0_0.parquet
```

Note that the table is stored in a file called `0_0_0.parquet`. This file is stored in the location defined by the `dfs.clicks` workspace:

```
"location": "/mapr/demo.mapr.com/data/nested"
```

with a subdirectory that has the same name as the table you created.

Summary

This tutorial introduced Drill and its ability to run ANSI SQL queries against various data sources, including Hive tables, MapR Database binary tables, and filesystem directories. The tutorial also showed how to work with and manipulate complex and multi-structured data commonly found in Hadoop/NoSQL systems.

Now that you are familiar with different ways to access the sample data with Drill, you can try writing your own queries against your own data sources. Refer to the Apache Drill documentation for more information.

Drill-on-YARN

You can install and run Drill under Warden or you can install and run Drill under YARN. YARN (Yet Another Resource Negotiator) is a cluster management tool that automates the resource sharing process in a cluster.

Note: The MapR default security feature introduced in 6.0 is not supported with Drill-on-YARN.

The following sections provide information about Drill-on-YARN, including overview material, installation and configuration instructions, and additional information related to Drill-on-YARN:

Drill-on-YARN Overview

Running Drill as a YARN application (Drill-on-YARN) enables Drill to work alongside other applications, such as Hadoop and Spark, in a YARN-managed cluster. If you are currently running Drill under Warden, you can upgrade Drill and continue to run Drill under Warden, or you can migrate Drill to run under YARN. See Migrate Drill to Run Under YARN for instructions.

YARN assigns resources, such as memory and CPU, to applications in the cluster and eliminates the manual steps associated with installation and resource allocation for stand-alone applications in a multi-tenant environment. YARN automatically deploys (localizes) the Drill software onto each Drill node and manages the Drill cluster. Drill becomes a long-running application with YARN. You can monitor the Drill-on-YARN cluster using the Application Master web UI.

Resource Usage

By design, Drill aggressively uses all of the resources available to run queries at optimal speed. When Drill runs under YARN, you must inform YARN of the resources that Drill needs. The resource settings are descriptive, not proscriptive. Drill does not limit itself to the YARN settings, instead the YARN settings

last-updated: Apr 11, 2022

inform YARN of the resources that Drill will consume so that YARN does not over-allocate those resources to other tasks.

YARN manages CPU, memory, and disks. YARN calls settings for memory and CPU “vcores." You configure Drill’s memory and then inform YARN of the Drill configuration. Drill uses all available disk I/O and CPU.

Components

Several software components work together to run Drill as a YARN application. Drill, YARN, and the Drill-on-YARN application collectively provide the components required to run Drill under YARN.

The following table lists the software components with their descriptions:

Software	Component	Description
YARN	Resource Manager	The Resource Manager manages the set of applications running on the cluster. Each cluster must have one Resource Manager.
	Node Manager	The Node Manager manages the application tasks running on a particular node. Each node in a cluster must have one Node Manager.
Drill	Drillbit	A Drillbit is the Drill daemon software that YARN runs on each node in the cluster. SeeDrill Query Execution. The Drillbit process on the node acts as the application task.
	Client	A client, such as JDBC, ODBC, or SQLLine sends queries to a Drillbit. The client uses ZooKeeper to discover a Drillbit that the client treats as the Foreman. SeeDrill Clients.
	Drill distribution archive	The Drill distribution archive is a Drill distribution .tar.gz file included with the Drill installation. Drill-on-YARN uploads this archive to the distributed filesystem (DFS). YARN downloads (localizes) the file to each worker node.
ZooKeeper	ZooKeeper	ZooKeeper is the service that tracks the available set of Drillbit processes. The Foreman for a query uses ZooKeeper to identify the set of available drill nodes that can run the query. SeeDrill Query Execution.
Drill-on-YARN Application	Application Master (AM)	The Application Manager requests containers from the Resource Manager and launches Drillbits using those containers. The AM monitors Drillbits, detects failures, and restarts failed Drillbits. The AM also provides a web UI to manage the Drill cluster.

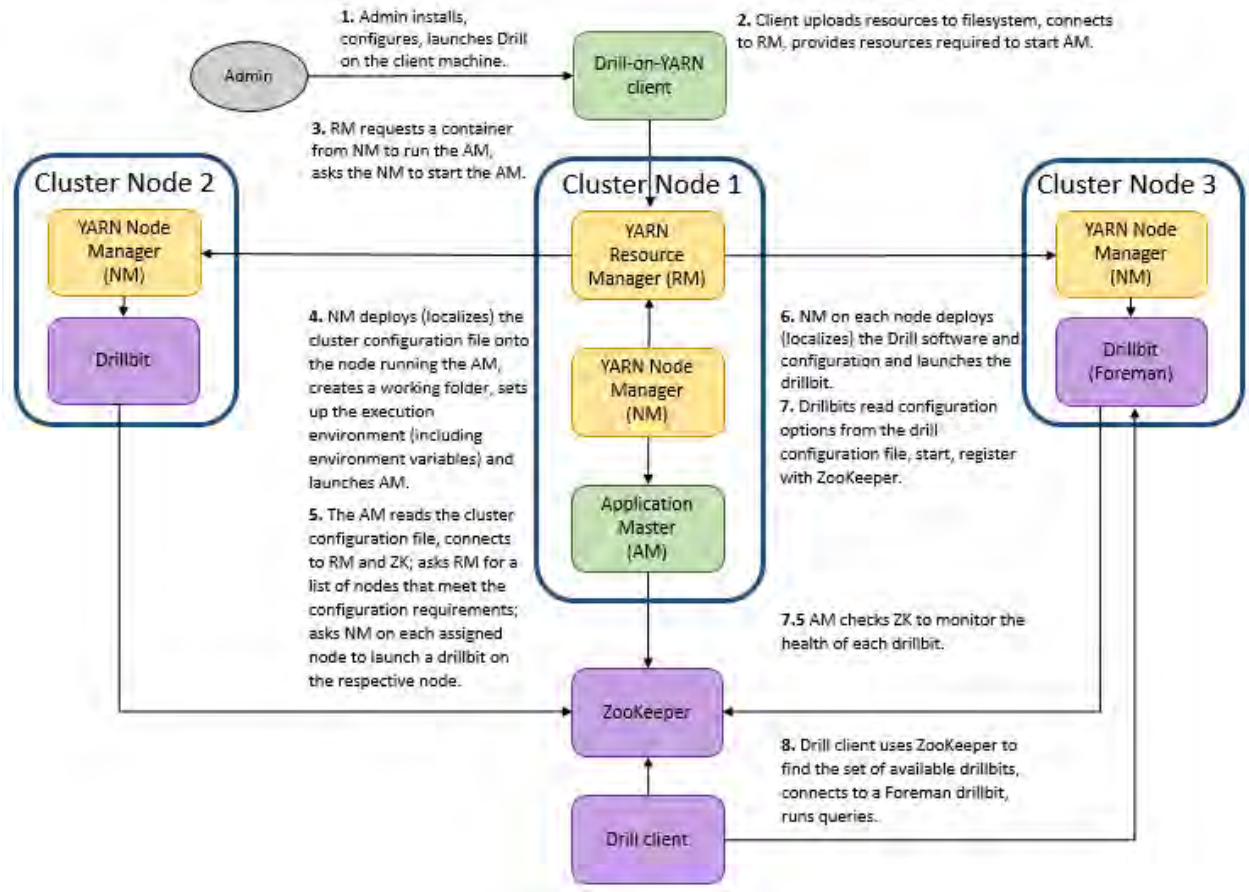
last-updated: Apr 11, 2022

	Drill-on-YARN client	The Drill-on-YARN client is a command-line program that starts, stops, and monitors the Drill cluster. The client provides the information that YARN needs to start the Application Master. The client can run on any machine that has both the Drill and YARN client software. The client does not have to be part of the YARN cluster.
	drill-on-yarn.conf	The drill-on-yarn.conf configuration file provides the information that Drill-on-YARN needs to manage the Drill cluster. This file is separate from the configuration files for Drill itself.

Component Workflow

Running Drill as a YARN application is mostly an automated process carried out by the Drill and YARN components. After an administrator installs, configures, and launches Drill from the Drill-on-YARN client, YARN deploys (localizes) Drill on to designated nodes and starts the Drill process on each node.

The following diagram shows the workflow between the components in a cluster with the steps that Drill and YARN complete to deploy and run Drill as a YARN application:



Configuring Drill to Run Under YARN

To run Drill under YARN, you must have the YARN version of Drill installed on the node designated as the Drill-on-YARN client. If you have not already planned your cluster and installed the YARN-ready version of

Drill, see Install Drill to Run Under YARN and then return to this topic to configure Drill to run as a YARN application.

Configuring Drill to run under YARN requires modifications to Drill, Drill-on-YARN, and YARN configuration files. The following sections provide the information needed to make the changes to the configuration files, as well as information about how to launch Drill under YARN and validate the cluster configuration and status of the Drill nodes.

Complete the following steps to configure Drill to run under YARN, launch Drill as a YARN application, and validate the cluster:

Step 1: Configure Drill

Drill configuration under Drill-on-YARN differs from Drill configuration under Warden. You must create a site directory to contain the site-specific files for Drill. Drill-on-YARN copies the site directory to every node so that each node has the configuration settings. Having a site directory also simplifies upgrades because you can just delete the old Drill distribution and install the new one while the site-specific files remain unchanged in the site directory.

The drill-env.sh file contains only custom configurations. MapR-specific configuration settings reside in distrib-env.sh, a file separate from the site-specific settings. When you migrate an existing Drill installation to run under YARN, you must modify the drill-env.sh to remove the Drill and settings, leaving only your site-specific settings.

When you finish configuring Drill, use the site directory to test Drill, including starting, checking status, and stopping Drill.

Note: If you installed the mapr-drill-yarn package on nodes other than the Drill-on-YARN client in order to make SQLLine accessible to users, the site directory must be accessible from all nodes. You can copy the configurations across all the nodes, as you did when you ran Drill under the Warden service. Alternatively, you can put the site directory in a shared filesystem nfs mount to extend the configuration. When users launch SQLLine, they should provide the ZooKeeper connection string to launch Drill.

Create the Site Directory

To create the `site` directory, complete the following steps as the user that installed Drill and will run the Drill-on-YARN client application:

1. Create the site directory and an environment variable for the directory:

```
export DRILL_SITE=/opt/mapr/drill/site
mkdir $DRILL_SITE
```

Note: The variable is not required. It is used for convenience in the documentation.

last-updated: Apr 11, 2022

2. Copy the drill-env.sh, drill-override.conf, drill-on-yarn.conf, and distrib-env.sh files from $DRILL_HOME/conf/ into the `site` directory. In the following example, $DRILL_HOME is the location of the new Drill installation (usually /opt/mapr/drill/drill-<version>).

```
cp $DRILL_HOME/conf/drill-override.conf $DRILL_SITE
cp $DRILL_HOME/conf/drill-env.sh $DRILL_SITE
cp $DRILL_HOME/conf/drill-on-yarn.conf $DRILL_SITE
cp $DRILL_HOME/conf/distrib-env.sh $DRILL_SITE
```

Note: Copy any configuration changes from drill-env.sh file in the previous Drill installation over to the drill-env.sh file in the `site` directory. Do not include the memory settings when you copy over your previous configurations. These changes must be made in the drill-on-yarn.conf file described in Step 3: Configure YARN to Run Drill.

Note: Never modify `distrib-env.sh`. The `distrib-env.sh` script contains MapR settings that you should not change. You copy this file to the `site` directory because it often contains values set during Drill installation. When you upgrade Drill, replace the file with the latest version from $DRILL_HOME/conf.

3. If you developed custom code (data sources or user-defined functions), place the Java JAR files in $DRILL_SITE/jars. If you have code from your prior Drill installation, copy the JAR files from $PREV_DRILL/jars/3rdparty to $DRILL_SITE/jars.

```
cp $PREV_DRILL/jars/3rdparty/yourJarName.jar $DRILL_SITE/jars
```

Note: Only copy the JAR files that you added. Do not copy JAR files that shipped with the prior Drill version.

4. Add native libraries to the `site` directory. If you used a native library, such as the JPAM library in prior versions of Drill, place the native libraries in $DRILL_SITE/lib to enable YARN to automatically copy (localize) them to each node that runs Drill.

```
cp native_libraries $DRILL_SITE/lib
```

Modify the drill-env.sh File

Copy any configuration changes from the drill-env.sh file in the previous Drill installation over to the drill-env.sh file in the `site` directory. Memory settings under Drill-on-YARN are now part of the drill-on-yarn.conf file. Modify the memory settings in $DRILL_SITE/drill-env.sh, as shown below, to ensure that the Drill memory settings match the amount of memory that Drill-on-YARN requires.

To modify drill-env.sh, complete the following steps:

1. Review each line in $PREV_DRILL/conf/drill-env.sh for settings you added, and copy them into the new $DRILL_SITE/drill-env.sh file.

Note: If you do not recall whether you customized settings, you can compare your file with the original version of drill-env.sh that shipped with the prior Drill version.

last-updated: Apr 11, 2022

2. Locate the following lines in `drill-env.sh` and note the values:

```
DRILL_MAX_DIRECT_MEMORY="<value>"
DRILL_HEAP="<value>"
```

Replace those lines with the following lines, substituting the values in the new lines with the values from the old lines:

```
export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"<value>"}
export DRILL_HEAP=${DRILL_HEAP:-"<value>"}
```

Note: If you do not intend to run Drill outside of YARN, you can remove the two lines shown above from drill-env.sh.

Note: If you do not make this change, Drill ignores the memory settings in the drill-on-yarn.conf file. If you are installing Drill fresh, and do not have an existing file, you can skip this step. Files in Drill 1.8 and later have the correct format.

Note: When you install Drill, the MapR Installer automatically adds the HADOOP_HOME variable, which points the current MapR-provided Hadoop to your distrib-env.sh. If HADOOP_HOME is located elsewhere, change this location in drill-env.sh

Use the Site Directory to Test Drill

You will use the `site` directory each time you start Drill using the `--site` or `--config` option. Use the option to verify that the configuration works by starting Drill as a stand-alone service on a single node.

```
drillbit.sh --site $DRILL_SITE start
```

Wait a few seconds and then verify that Drill continues to run:

```
drillbit.sh --site $DRILL_SITE status
```

You can also use the Drill Web Console for the Drillbit to verify that Drill has the proper settings. Once satisfied that the configuration is connect, stop Drill:

```
drillbit.sh --site $DRILL_SITE stop
```

Note: If you run a Drilbit with the `--site` (`--config`) option and you want to use SQLLine, you must add the option to SQLLine:

```
sqlline --site $DRILL_SITE
```

Tip: If you find that specifying the `--site` option becomes tedious, you can set the DRILL_CONF_DIR variable in your environment:

```
export DRILL_CONF_DIR="$DRILL_SITE"
drillbit.sh start
```

Step 2: Configure Drill-on-YARN

To configure Drill to run as a YARN application, modify the $DRILL_SITE/drill-on-yarn.conf cluster configuration file to suit the needs of your cluster. This file is a “starter” configuration file that corresponds to the simplest Drill cluster. The drill-on-yarn.conf file is in the same HOCON format as drill-override.conf.

last-updated: Apr 11, 2022

Consult the $DRILL_HOME/conf/drill-on-yarn-example.conf file as an example. However, do not just copy the example file. Instead, copy only the specific configuration settings that you need; the others will automatically take the Drill-defined default values.

Note: Make sure that resources can accommodate the Drill memory, CPU, and disk requirements.

The following sections list the configuration settings required to run Drill under YARN:

Drill Memory Settings

The following configuration sets the Java heap size and amount of direct memory the node can allocate to Drill:

```
drillbit: { heap: "<value>" max-direct-memory: "<value>" }
```

When you add the configuration, use the same values set in the following parameters of the `drill-env.sh` file, if you did not remove these lines when you modified `drill-env.sh`:

```
export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"<value>"}
export DRILL_HEAP=${DRILL_HEAP:-"<value>"}
```

Drill-on-YARN copies these values into the environment variables when launching each Drillbit. Drill also uses additional JVM memory. For example, Drill uses a code cache to hold classes generated at runtime. The default size of the cache is 1 GB:

```
drillbit: { code-cache: "1G" }
```

Typically, you do not need to change the code cache size, but you must account for it when computing the YARN container size.

YARN Container Size

The following configuration sets the YARN container size required to run Drill as a YARN application.

```
drillbit: {
   memory-mb: 14336
 }
```

The default value is 14GB. Typically, this size is the sum of the heap and direct memory. However, if you use custom libraries that perform their own memory allocation, or launch sub-processes, you must account for that memory usage as well. Note that YARN memory is expressed in MB. To compute the container size, start with the values used for the heap, direct memory, and code cache settings, as shown in the following example:

```
drillbit: {
    heap: "4G"
    max-direct-memory: "8G"
    code-cache: "1G"
    memory-mb: 14336
  }
```

The values shown above are the Drill defaults. You may use larger values. Although the three values account for the bulk of Drill memory, the JVM itself also has a certain overhead. Assume that the overhead is about 1 GB, though the amount varies depending on the workload.

Add the four values together to get a memory requirement in GB.

```
Total memory = 8G + 4G + 1G + 1G = 14G
```

last-updated: Apr 11, 2022

YARN sizes containers in megabytes. Convert GB to MB:

```
Container size = 14G * 1024 = 14336 MB
```

Set this size in drill-on-yarn.conf:

```
drillbit: { memory-mb: 14336 }
```

CPU

The following configuration sets the CPU to allocate to Drill:

```
drillbit: { vcores: <value> }
```

Drill is a CPU-intensive operation and greatly benefits from each additional core. YARN does not limit the number of cores used by an application. Rather, this number reports to YARN the average CPU usage of Drill so that YARN can use the number when deciding how many other applications to run on the same node.

Drillbit Cluster Configuration

The following configuration sets the cluster group:

```
cluster: [ { name: "drillbits" type: "basic" count: 1 } ]
```

Drill-on-YARN uses the concept of a “cluster group” of Drillbits to describe the set of drillbits to launch. Currently, only the “basic” type of group is supported. A basic group launches drillbits anywhere in the YARN cluster where a container is available. For a basic group, specify the group type and the number of drillbits to launch.

Note: The syntax says that cluster is a list that contains cluster group objects contained in braces. Drill currently supports just one group.

The name is optional. It appears in the Application Master web UI. Type must be set to “basic.” Set the count to the number of hosts on which Drill is to run at launch time. You can resize the Drill cluster after the cluster is launched.

YARN Queue Labels

The following configuration sets the YARN queue labels that identify the cluster nodes that run Drill:

```
yarn: { queue: "<queue_name>" }
```

The MapR distribution of YARN provides queue labels for assigning YARN applications to specific queues. See Label-Based Scheduling for YARN Applications. You can use queue labels with Drill to identify the YARN queue that should run Drill.

To use queue labels, complete the following steps:

1. Create a node label.
2. Assign the label to the nodes that are to run Drill.
3. Create a Drill-specific queue that uses the node label.
4. Configure Drill-on-YARN to use the queue.

last-updated: Apr 11, 2022

Suppose you create a queue called “drill.” Setting the following configuration causes Drill-on-YARN to launch through the drill queue:

```
yarn: { queue: "drill" }
```

Set queue to the name a name of your choice. When Drill-on-YARN launches, both the Application Master and drillbits run only on nodes with the same node label as the queue.

DFS Location

The following configuration sets the dfs location:

```
dfs: { app-dir: "/user/drill" }
```

Drill copies the archive in to the MapR filesystem in a location you provide. The default is /user/drill, however you can specify a different location. You do not have to specify the MapR File System connection information; MapR defines this automatically.

Step 3: Configure YARN to Run Drill

YARN default settings are optimized for MapReduce applications. MapReduce applications use a limited amount of memory; however, Drill is long-running and consumes a significant amount of resources. Adjust the YARN memory configuration to allow YARN to allocate containers large enough to run Drill. Exclude the YARN container directory from `systemd-tmpfiles` to prevent `systemd-tmpfiles` from removing Drill’s container files while Drill runs.

Increase Maximum Container Size

YARN provides a number of parameters to control the amount of resources available to applications. The MapR distribution of YARN sets most of these parameters automatically, except for the maximum container size, which is left at the Apache YARN default of 8 GB. Typical Drill configurations use significantly more memory. Therefore, you must increase the YARN maximum container size on each node to suit the needs of Drill. You can use the YARN Resource Manager web UI to determine the amount of memory available on each node.

Note: YARN resource requirements match the Drill resource requirements.

To increase the maximum container size, determine the required container size from the Drill setting in `drill-on-yarn.conf`, which you previously set in step 2:

```
drillbit: {
   memory-mb: 14336
 }
```

Use this number to set the `yarn.scheduler.maximum-allocation-mb` parameter in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop.<version>`, substituting the number of the version you have installed.

Edit `yarn-site.xml` to add the following:

```
<property>
   <name>yarn.scheduler.maximum-allocation-mb</name>
   <value>14336</value>
   <description>Set to allow Drill containers 14G.</description>
 </property>
```

Note: You must update this configuration on every YARN node.

Restart the YARN Resource Manager to pick up change, and use the YARN Resource Manager UI to verify that the maximum container size shows the new value.

Exclude the YARN Container Directory from systemd-tmpfiles

The system puts the YARN Node Manager container files in the `/tmp` directory. Most system administrators configure `systemd-tmpfiles` to periodically remove files in `/tmp`. Since Drill-on-YARN is a long-running YARN application, `systemd-tmpfiles` can remove Drill's container files while Drill runs. If this occurs, you must manually shut down the Drill cluster because `systemd-tmpfiles` will have removed the `pid` file that YARN needs to manage Drill.

You can prevent `systemd-tmpfiles` from cleaning up Drill's container files by adding a new configuration file to `/etc/tmpfiles.d/`, for example `/etc/tmpfiles.d/exclude-nm-local-dir.conf`, with the following configuration:

```
x /tmp/hadoop-mapr/nm-local-dir/*
```

Note: This configuration prevents `systemd-tmpfiles` from cleaning the `/nm-local-dir` directory when cleaning `/tmp`.

Example

```
$ cat /etc/tmpfiles.d/exclude-nm-local-dir.conf
x /tmp/hadoop-mapr/nm-local-dir/*
```

Step 4: Launch Drill Under YARN

Now that the Drill and YARN configuration is complete, you can issue the `start` command from the Drill-on-YARN client to launch Drill under YARN. Launching Drill-on-YARN from the client starts Drill and brings Drill up on other nodes.

Issuing the start command starts the YARN Application Master, which then works with YARN to start the Drillbits. The Application Master provides a web UI to monitor the cluster.

Note: To simplify debugging, you can set the cluster size to a single node. Once you confirm that a single node works, increase the node count.

Launch Drill under YARN as the `mapr` user. For example, if you installed Drill as `mapr` launch Drill as the `mapr` user.

Note: If you launch Drill as `root` and the system returns an error failing the launch attempt, launch Drill as a user with permissions, such as `mapr`.

Issue the following command to start Drill under YARN:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE start
```

Note: To run SQLLine, you must also add the `--site` option:

```
$DRILL_HOME/bin/sqlline --site $DRILL_SITE
```

Tip: To avoid typing the `site` argument each time you launch Drill under YARN, set an environment variable:

```
export DRILL_CONF_DIR=$DRILL_SITE
$DRILL_HOME/bin/drill-on-yarn.sh start
```

After you issue the start command, a number of lines describing the start-up process print. The tool automatically archives and uploads the site directory, which YARN copies (along with the Drill software) onto each node. A URL that includes both the host and the port number displays. Enter the URL in a web browser to access the Application Master web UI.

Note: When you launch Drill from the Drill-on-YARN client, the Application Master can come up on any node. Save the provided URL to share with other users so they can also access the Application Master. Alternatively, you can run the `status` command to see the URL or go to the YARN Resource Manager UI to get the link.

See Drill-on-YARN Command Line Tool for additional commands, including stop, status, and resize. See Application Master Web UI for cluster monitoring information.

Step 5: Validate Cluster Configuration and Status

The Drill-on-YARN command line tool prints a URL, for the Drill Application Master process, that you can use to monitor the cluster. The Drillbits should be up and running, unless the upload or launch failed.

Failed upload	If the upload fails, the most likely reason is that the HADOOP_HOME variable is not set, or the user launching Drill-on-YARN does not have permission to create or write to the DFS location set in the Drill-on-YARN configuration file.
Failed launch	If the launch fails, verify that the YARN maximum container size was set to be at least as large as the Drill container size and that YARN can provide the number of vcores and disks you have requested for Drill.

Monitor Cluster Activity

When the cluster launches successfully, you can verify the status of the components in the Drill cluster from the command line or you can copy the Application Master URL into your browser to use the Application Master web UI.

To check the status from the command line, issue the following command:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE status
```

- Verify that the Drillbits are in the Running state (or transition to that state after a few moments.) If the Drillbits remain in the Requesting state, the likely cause is that YARN cannot provide a container of the requested size. You can access this information on the Drillbits page in the Application Master web UI.
- Verify that the Application Master has correctly picked up the YARN-related configuration from drill-override.conf and drill-on-yarn.conf. You can access this information on the Configuration page in the Application Master web UI.
- Verify that the Application Master is running. The Drill Application Master uses ZooKeeper to verify that only one Application Master runs per Drill cluster. The Application Master fails if ZooKeeper is down, is configured incorrectly in drill-override.conf, or if another Application Master is running for the same cluster.
- Verify that that the configurations in are correct in drill-override.conf if there are Drillbit failures. Drill-on-YARN detects Drillbit failures and retries each Drillbit a few times. If the Drillbit continues to fail, the node is black-listed for that run of Drill-on-YARN. You can see failures in the History page of the web UI. If your Drillbits fail, the most likely reason is misconfiguration within drill-override.conf. Use YARN to locate and view the Drill logs for the failed container.

last-updated: Apr 11, 2022

Resize the Cluster

If the cluster works well for a single node, you can increase the number of nodes.

Note: In the Drill 1.8 release, adding nodes can be done while users run queries. However, removing nodes from the cluster causes queries to fail, and so should only be done when the cluster is idle.

To make a permanent change, modify the cluster size in drill-on-yarn.conf:

```
cluster: [
   {
     ...
     count: 5
   }
 ]
```

You can also resize the cluster dynamically. To add two nodes from the command line:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize +2
```

To set the cluster size to a total of five nodes:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize 5
```

To remove one of the nodes:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize -1
```

You can also resize your cluster using the Manage page of the Application Master web UI, by entering the number of desired nodes and clicking **Go**.

Stop the Cluster

You can stop the cluster from the command line or from the Manage page in the Application Master web UI.

To stop the cluster from the command line, issue the following command:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE stop
```

Migrate Drill to Run Under YARN

Explains how to migrate Drill to run under YARN instead of the MapR Warden service.

When you migrate Drill to run under YARN, you must back up configurations, including files and storage plugins, shutdown the Drill cluster running under Warden, and uninstall Drill on all Drill nodes in the cluster. You may also want to determine which system settings have been changed from the Drill defaults.

Note: Drill-on-YARN is an advanced feature used to manage a production Drill cluster. Only skilled Drill and MapR administrators, familiar with YARN, should configure Drill to run under YARN. If you are new to Drill, consider running Drill under the MapR Warden service until you are familiar with Drill and Drill cluster management.

The sections below provide the tasks required to migrate Drill under YARN:

Tasks

Complete the following tasks when you want to migrate Drill to run under YARN:

Backup configurations and UDFs	Back up configuration files, storage plugin configurations, and UDFs (user-defined functions) or

last-updated: Apr 11, 2022

custom JAR files. Back up the configuration files located in `/opt/mapr/drill/drill-<version>/conf`, including `drill-override.conf` and `drill-env.sh`, to preserve your ZooKeeper configuration and any options or custom configurations specified in the files. Also back up `logback.xml` if you configured the file for the Lilith software.

- To back up configuration files, go to `/opt/mapr/drill/drill-<version>/conf`, and copy the files to a location outside of the Drill installation directory.

  ```
  cp <file_name> drill-env.sh /
  path/to/directory
  ```

- To back up custom JARs or UDFs, go to `/opt/mapr/drill/drill-<version>/jars/3rdparty` and copy the JARs or UDFs to a location outside of the Drill installation directory.
- To back up storage plugin configurations, complete the following steps:
  1. Start the Web Console. The Drill node that you use to access the Web Console must be a node that is currently running the Drillbit process.
  2. Click **Storage**.
  3. Click **Update** next to a storage plugin.
  4. Copy the configuration to a text file, and save the file.
  5. Repeat steps 3 and 4 for each storage plugin configuration that you want to save.

Verify system option settings

Drill should save set system options when you migrate Drill. However, you may want to verify which system options were changed from the default settings beforehand. You can run the following query to see which system options were changed from the defaults:

```
select * from sys.options where
status = 'CHANGED';
```

Example:

```
select * from sys.options where
status = 'CHANGED';
+-------------------------------------+----------+

|                name
|   kind   |  type   |  status  |
num_val  | string_val  | bool_val  |
float_val  |
+-------------------------------------+----------+

| exec.errors.verbose
| BOOLEAN  | SYSTEM  | CHANGED  |
null     | null        | true      |
```

last-updated: Apr 11, 2022

```
null       |
| new_view_default_permissions
| STRING   | SYSTEM  | CHANGED  |
null     | 777         | null      |
null       |
| planner.enable_decimal_data_type
| BOOLEAN  | SYSTEM  | CHANGED  |
null     | null        | true      |
null       |
| planner.enable_limit0_optimization
| BOOLEAN  | SYSTEM  | CHANGED  |
null     | null        | true      |
null       |
+------------------------------------+----------+

4 rows selected (0.541 seconds)
```

After you migrate, run the query again to verify that the system options are still set. If not, set the options.

Shutdown the Drill cluster

Issue the following command to shutdown the existing Warden-managed Drill cluster:

```
maprcli node services -name
drill-bits -action stop -nodes <node
host names separated by a space>
```

Note: Do not shutdown nodes when queries are in progress.

Verify that Drillbits stopped

Run the following command to verify that the Drillbit service is no longer running on each node:

```
ps -ef | grep -i drill
```

No Drill processes should print to screen when you run this command.

You can also log in to the Control System at `https://<host name>:8443` to verify the status of the Drillbit service. You should not see Drillbit as a listed service.

Uninstall Drill

Uninstall Drill and then run `configure.sh -R` to refresh the configuration.

Issue the command appropriate for your system as root or using sudo to uninstall the mapr-drill package:

Operating System	Command
RedHat/CentOS	`yum remove mapr-drill`
Ubuntu	`apt-get remove mapr-drill`

Note: Verify that Drillbit processes stopped.

Additional Drill-on-YARN Configuration Options

You can include additional configuration options in the `$DRILL_SITE/drill-on-yarn.conf` file for specialized cases. For example, you can customize the Application Master web UI port or Application Master settings.

last-updated: Apr 11, 2022

Refer to the `drill-on-yarn-example.conf` file in $DRILL_HOME/conf to see examples of the additional options. Do not use the example file.

The following list describes the changes that you can make for several of the Drill-on-YARN components:

Application Name

You can customize the application name that appears when starting or stopping the Drill cluster and in the Drill-on-YARN web UI. Change the value of the following option to a name you prefer:

```
app-name: "My Drill Cluster"
```

Application Master Web UI Port

If you run multiple Drill clusters in a YARN cluster, YARN may assign two Drill Application Master processes on the same node. To avoid port conflicts, change the HTTP port for one or both of the Drill clusters. Change the value of the following option to a different port number:

```
drill.yarn:
 http: {
   port: 12345
 }
}
```

Application Master Settings

You can customize certain Application Master properties. All of the Application Master properties are prefixed with `drill.yarn.am`, for example `drill.yarn.am.heap`.

The following table lists the Application Master properties with their default settings:

Name	Description	Default
memory-mb	Memory, in MB, to allocate to the Application Master.	14336
vcores	Number of CPUS to allocate to the Application Master.	1
heap	Java heap for the Application Master.	450M

Drillbit

You can customize certain properties that control the Drillbit processes. All of the Drillbit properties are prefixed with `drill.yarn.drillbit`, for example `drill.yarn.drillbit.disks`.

Note: You can specify Drill disk usage to YARN, however Drill uses all disks regardless of the setting.

The following table lists the Drillbit properties with their default settings:

Name	Description	Default

last-updated: Apr 11, 2022

code-cache	Code cache that holds classes generated at runtime.	1G
memory-mb	Memory, in MB, to allocate to the Drillbit.	13000
vcores	Number of CPUS to allocate to the AM.	4
disks	Number of disk equivalents consumed by Drill (on versions of YARN that support disk resources.)	1
heap	Java heap memory.	4G
max-direct-memory	Direct (off-heap) memory for the Drillbit.	4G
log-gc	Enables Java garbage collector logging.	false
class-path	Additional class-path entries.	blank

Mapping of drill-env.sh to drill-on-yarn.conf Options

When you run Drill as a standalone application, you set startup options, such as Drillbit memory, in the $DRILL_HOME/conf/drill-env.sh start up script. Under YARN, Drill still reads $DRILL_SITE/drill-env.sh for configuration options, however Drill-on-YARN provides the $DRILL_SITE/drill-on-yarn.conf file to configure options that were formerly set in drill-env.sh.

The following table maps the drill-env.sh environment variables to their equivalent configuration parameters in drill-on-yarn.conf:

drill-env.sh Environment Variable	**drill-on-yarn.conf Configuration Parameter**
DRILL_MAX_DIRECT_MEMORY *	drill.yarn.drillbit.max-direct-memory
DRILL_HEAP *	drill.yarn.drillbit.heap
DRILL_JAVA_OPTS	drill.yarn.drillbit.vm-args (Added to those in drill-env.sh.)
SERVER_GC_OPTS (to add GC logging)	Drill.yarn.drillbit.log-gc (To enable GC logging)
DRILL_HOME	Set automatically when files are localized (drill.yarn.drill-install. localize is true), else drill.yarn.drill-install. drill-home.
DRILL_CONF_DIR	Set automatically when files are localized, else uses the normal defaults.

DRILL_LOG_DIR	Set automatically to point to YARN's log directory unless disabled by setting drill.yarn.drillbit. disable-yarn-logs to false. If disabled, uses the normal Drill defaults.
DRILL_CLASSPATH_PREFIX *	Drill.yarn.drillbit. prefix-class-path
HADOOP_CLASSPATH *	drill.yarn.hadoop.class-path (or, better drill.yarn.drillbit. extn-class-path.)
HBASE_CLASSPATH *	Drill.yarn.hadoop. hbase-class-path (or, better drill.yarn.drillbit. extn-class-path.)
EXTN_CLASSPATH * (New in Drill 1.8.)	Drill.yarn.drillbit. extn-class-path
DRILL_CLASSPATH *	drill.yarn.drillbit.class-path

Multiple Drill Clusters within YARN

You can define multiple Drill clusters within a single YARN cluster. Each Drill cluster is a collection of Drillbits that work as an independent unit. For example, you might define one test Drill cluster that consists of a few machines on the same physical cluster that runs larger Drill clusters for development and marketing.

You must assign each Drill cluster a distinct ZooKeeper entry. Drill uses ZooKeeper to coordinate activities. Each Drill cluster also needs a distinct set of ports because YARN may launch Drillbits from different clusters on the same physical node.

The following steps summarize the process for defining multiple Drill clusters on a single YARN cluster:

1. Create a new site directory.
2. Configure Drill.
3. Configure Drill-on-YARN.
4. Start the cluster.

The following task provides instructions for each of the steps required to configure and run multiple Drill clusters under YARN:

Defining Multiple Drill Clusters within YARN

Complete the following steps to define multiple Drill clusters under YARN:

1. Create a new "site" directory under $DRILL_HOME, and create an environment variable for the directory.

   ```
   mkdir $DRILL_HOME/<site_name>
   export $<SITE_NAME>_SITE=$DRILL_HOME/<site_name>
   ```

2. Copy the following configuration files from the existing "site" directory into the new "site" directory:
   - drill-override.conf
   - drill-env.sh
   - drill-on-yarn.conf
   - distrib-env.sh

3. Modify the settings in the `drill.exec` section of `$DRILL_SITE/drill-override.conf` to configure the new Drill cluster to act independently of the other Drill cluster(s), or share settings, such as storage plugin configurations. For the new Drill cluster to act independently, give `zk.root` a distinct name from the existing clusters. In the more advanced scenario where the clusters share configurations, give `zk.root` the same name as the existing Drill clusters. When the clusters share the same root, they must have distinct cluster-id values. The user, bit, and http ports must have values distinct from all the other Drill clusters.

   The following example shows a number 1 added to the first digit of the default port numbers, however you can choose any available ports.

   ```
   drill.exec: {
    cluster-id: "drillbits",
    zk: {
      root: "<site_name>"
      connect: "zk-host:5181"
    }

    rpc {
      user.server.port: 41010
      bit.server.port: 41011
    }
    http.port: 9047
   }
   ```

4. Modify the `drill-on-yarn.conf` configuration file for the new cluster. The new cluster must have a distinct name, a distinct upload directory in the filesystem, and a distinct port number.

   The following settings in the `drill.yarn` section must have distinct values for the new cluster:

   ```
   drill.yarn: {
    app-name: "Distinct Cluster Name"

    dfs: {
      app-dir: "/upload/directory"
    }

    http : {
      port: <distinct port number>
    }
   }
   ```

5. Start the new cluster from the "site" directory that correlates with the new cluster.

   ```
   $DRILL_HOME/bin/drill-on-yarn.sh --site $NEW_SITE start
   ```

Drill-on-YARN Command Line Tool

Run the Drill-on-YARN command line tool from the Drill-on-YARN client and use it to start, stop, resize, and check the status of the Drill cluster. When you launch Drill from the command line, the tool automatically archives and uploads the “site” directory, which YARN deploys (along with Drill) onto each node.

You can access the Drill-on-YARN command line tool in the following directory:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE command
```

where *command* is the operation you want to perform, such as `start`.

To avoid having to type the site argument for each command, set an environment variable:

```
export DRILL_CONF_DIR=$DRILL_SITE
```

The following example shows the start command after setting the environment variable:

```
$DRILL_HOME/bin/drill-on-yarn.sh start
```

Command Summary

The following table lists the commands and provides a brief summary for each:

Command	Description
start	Starts the Drill cluster. Prints the startup status followed by a summary of the application.
status	Retrieves basic information about the Drill cluster.
stop	Stops the Drill cluster.
resize <value> resize + <increase_node_count_by> resize - <decrease_ node_count_by>	Adds or removes nodes in the Drill cluster while the cluster runs. You can specify the exact number of nodes you want to run, or you can use +/- to increase or decrease the current node count by a certain amount.
clean	Removes the cached Drill archive from the designated DFS directory.

Commands

The following sections provide detailed information and examples for each of the commands listed in the command summary:

start

The start command launches Drill and provides a startup status followed by a summary of the application.

The first line in the summary displays the cluster name from the configuration file to confirm which cluster is starting.

```
Launching Drill-on-YARN...
```

The next line shows the YARN application ID and tracks the job status from Accepted to Running.

```
Application ID:
application_1462842354064_0001
Application State: ACCEPTED
Starting......
Application State: RUNNING
```

Once the job starts, you see the YARN job tracking URL with the Drill-on-YARN web UI URL.

```
Application Master URL: http://
<YARN_Job_Tracking_URL>:8048/
```

last-updated: Apr 11, 2022

Once the application starts, the Drill-on-YARN writes an “appid” file into the Drill installation directory:

```
ls /opt/mapr/drill/drill-<version>
…
drillbits1.appid
```

The file name is the same as the Drill cluster ID. The file contains the ID of the Drill-on-YARN application. The other commands use this ID. You can run only one Drill application at a time. If you attempt to start a second from the same client machine on which you started the first, the client command complains that the appid file already exists. If you attempt to start the cluster from a different node, the second application detects a conflict and shuts down again.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh start

Launching Drill-on-YARN...
Application ID:
application_1462842354064_0001
Application State: ACCEPTED
Starting......
Application State: RUNNING
Tracking
URL: http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Application Master URL: http://
10.250.50.31:8048/
```

status

The status command retrieves basic information about the Drill cluster and provides a status summary.

The first several lines of the status summary provide information about the state of YARN, which includes the application ID, the application state, and YARN’s tracking URL for the application.

```
Application ID:
application_1462842354064_0001
Application State: RUNNING
Host: yosemite/10.250.50.31
Tracking URL:
```

Following the state of YARN information is the host on which the Drill application is running, the queue on which the application was placed, and the user who submitted the application. The start time tells you when YARN started the application.

```
http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Queue: default
User: drilluser
Start Time: 2016-05-09 16:56:40
```

The next few lines are specific to Drill, including the name of the application (which you configured in the drill-on-yarn.conf configuration file), the Drill

Application Master URL, the number of Drillbits you requested to run, and the number actually running.

```
Application Name: Drill-on-YARN
AM State: LIVE
Target Drillbit Count: 1
Live Drillbit Count: 1
```

Finally, the last line provides the URL for the Drill-on-YARN web UI.

```
For more information, visit: http://
10.250.50.31:8048/
```

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh
status

Application ID:
application_1462842354064_0001
Application State: RUNNING
Host: yosemite/10.250.50.31
Tracking
URL: http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Queue: default
User: drilluser
Start Time: 2016-05-09 16:56:40
Application Name: Drill-on-YARN
AM State: LIVE
Target Drillbit Count: 1
Live Drillbit Count: 1
For more information, visit: http://
10.250.50.31:8048/
```

stop

The stop command stops the Drill cluster. This command is forceful and kills any in-flight queries. The output tracks the shutdown and displays the final YARN application status.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh stop

Stopping Application ID:
application_1462842354064_0001
Stopping...
Stopped.
Final status: SUCCEEDED
```

resize

The resize command changes the number of nodes in the cluster. You can use this command to add or remove nodes in the Drill cluster as it runs. You can specify the change either by giving the number of nodes you want to run, or by using the + or - to specify the change in node count.

Drill adds nodes only if additional nodes are available from YARN. If you request to stop more nodes than are running, Drill stops all of the running nodes.

last-updated: Apr 11, 2022

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh
resize 10
$DRILL_HOME/bin/drill-on-yarn.sh
resize +2
$DRILL_HOME/bin/drill-on-yarn.sh
resize -3
```

clean

The clean command removes the cached Drill archive from the designated DFS directory. If you run Drill-on-YARN for a temporary cluster, Drill leaves the Drill software archive in your designated DFS directory. Specifically, the first start uploads the Drill archive to DFS. Stop leaves the archive in DFS. Subsequent start commands reuse the cached archive if it is the same size as the version on the local disk. Clean removes the cached file, forcing Drill to upload a fresh copy if you again restart the Drill cluster.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh clean
```

Application Master Web UI

Drill, running as a YARN application, provides the Drill-on-YARN Application Master (AM) process to manage the Drill cluster. The Drill AM provides a web UI where you can monitor cluster status and perform simple operations, such as increasing or decreasing cluster size, or stopping the cluster.

When you launch Drill using the Drill-on-YARN command line tool, the tool signals YARN to launch the AM, which in turn launches the Drillbits in the cluster. When Drill starts, you can access the web UI using the URL provided at startup.

The following sections describe the information that the Application Master web UI provides:

Main

The main page provides the following information about the Drill cluster:

Drill Cluster Status

The Drill cluster status show the state of the Drill cluster, which is one of the following:

- LIVE: This is the normal state and shows that the Drill cluster is running.
- ENDING: The cluster is in the process of shutting down

There is no “ENDED.” state. When the cluster shuts down, the web UI is no longer available.

Target Drillbit Count

The target Drillbit count is the number of Drillbits to run in the cluster. The actual number may be less if Drillbits have not yet started, or if YARN cannot allocate enough containers.

Live Drillbit Count

The live Drillbit count is the number of Drillbits that are ready for use. These have successfully started, have registered with ZooKeeper, and are ready for use. You can see the detail of all Drillbits (including those in the process of starting or stopping) using the Drillbits page. Each Drillbit must run on a separate node, so

last-updated: Apr 11, 2022

	this is also the number of nodes in the cluster running Drill.
Total Drillbit Memory and Virtual Cores	The total number of YARN resources currently allocated to running Drillbits.
YARN Node Count, Memory, and Virtual Cores	Reports general information about YARN itself including the number of nodes, the total cluster memory, and total number of virtual cores.
Groups	Lists the cluster groups defined in the configuration file (only one is currently supported), along with the target and actual number of Drillbits in that group.

Configuration

The configuration page shows the complete set of configuration values used for the current run. The values come from the configurations you set and the Drill-provided defaults. Use this page to diagnose configuration-related issues. Names are shown in fully-expanded form. That is the name “drill.yarn.http.port” refers to the parameter defined, as follows, in your configuration file:

```
drill.yarn:
 http: {
   port: 8048
 }
}
```

Drillbits

The Drillbits page provides the following information about each of the Drillbits:

ID	A sequential number assigned to each new Drillbit. Numbers may not start with 1 if you have previously shut down some Drillbits.
Group	The cluster group that started the Drillbit. Cluster groups configured in drill-on-yarn.conf.
Host	The host name or IP address on which the Drillbit runs. If the Drillbit is in a normal operating state, this field is also a hyperlink to the Web UI for the Drillbit.
State	The operating state of the Drillbit. The normal state is “Running.” The Drillbit passes through a number of states as YARN allocates a container and launches a process, as the AM waits for the Drillbit to become registered in ZooKeeper, and so on. Similarly, the Drillbit passes through a different set of states during shutdown. Use this value to diagnose problems. If the Drillbit is in a live state, this field shows an “[X]” link that you can use to kill this particular Drillbit. Use this if the Drillbit has startup problems or seems unresponsive. During the shut-down process, the kill link disappears and is replaced with a “Cancelled” note.
ZK State	The ZooKeeper handshake state. Normal state is “START_ACK”, meaning that the Drillbit has registered with ZooKeeper. This state is useful when diagnosing problems.
Container ID	The YARN-assigned container ID for the Drillbit task. The ID is a link that takes you to the YARN Node Manager UI for the Drillbit task.

last-updated: Apr 11, 2022

Memory and Virtual Cores (vcores)	The amount of resources actually allocated to the Drillbit by YARN.
Start Time	The date and time (in your local time-zone, displayed in ISO format) when the Drillbit launch started. This page also displays unmanaged Drillbits, if present. An unmanage Drillbit is one that is running, has registered with ZooKeeper, but was not started by the Application Master. Likely, the Drillbit was launched using the Drillbit.sh script directly. Use the host name to locate the machine running the Drillbit if you want to convert the Drillbit to run under YARN.

Manage

The Manage page provides options to resize or stop the Drill cluster. You can resize the cluster by adding or removing Drillbits or setting the cluster to a specific size.

Drill is a long-running application. Typically, Drill runs indefinitely, and you would only shut down the Drill cluster to perform an upgrade of the Drill software or to change configuration options. When you terminate the Drill cluster, any in-progress queries fail. Therefore, best practice is to perform the shutdown with users so that Drill is not processing any queries at the time of the shut-down.

When removing or shutting-down the cluster, you receive a confirmation page asking if you really do want to stop Drillbit processes. Click **Confirm** to continue.

History

The History page lists all failed, killed, and restarted Drillbits. You can detect failures and diagnose problems using the information on this page. Use the YARN container ID listed on this page to locate the log files for the Drillbit.

Enabling Application Master Web UI Security
By default, the Application Master Web UI is not secure and open to everyone. You can configure user authentication or implement a simple, predefined user name and password to secure the UI. Modify the drill-on-yarn.conf configuration file to enable Drill-on-YARN security.

The following sections describe how to enable security for the Application Master web UI.

User Authentication

You must enable user authentication in Drill if you want Drill-on-YARN to use this feature for security purposes. When user authentication is enabled, the user name and password must match that of the user that started the Drill-on-YARN application.

To secure the Application Master web UI by way of user authentication, modify `drill-on-yarn.conf` to include the following section with the `auth-type` set to `drill`:

```
drill.yarn.http: {
   auth-type: "drill"
}
```

Simple Security

Define a username and password in `drill-on-yarn.conf` and then restart the Drill-on-YARN Application Master to implement simple security for the Application Master web UI.

last-updated: Apr 11, 2022

Modify the `drill-on-yarn.conf` configuration file to include the following section, replacing the user-name and password settings with yours, and then restar the Drill-on-YARN Application Master:

```
drill.yarn.http: {
   auth-type: "simple"
   user-name: "tsmith"
   password: "secret"
}
```

When you visit the web UI, a login page prompts you for the username and password that you configured. These are the only valid credentials.

Drill-on-YARN Limitations

Drill-on-YARN has the following limitations:

Hanging requests	Drill-on-YARN and YARN “hang” if YARN cannot fulfill a container request. YARN provides no information about why a request “hangs.”
/tmp directory	The default MapR YARN settings cause Drillbits to become unmanaged within a short amount of time due to a /tmp directory issue. See the Exclude the YARN Container Directory from tmpwatch section in Step 3: Configure YARN to Run Drill for information on how to resolve the issue.
Container size	The default MapRYARN settings do not allow a default Drill cluster to run due to the default YARN container size. See the Increase Maximum Container Size section in Step 3: Configure YARN to Run Drill for information on how to resolve the issue.
Drill disk usage	You can specify Drill disk usage to YARN, but Drill will use all disks regardless of the setting. There is no effective way to manage a Drill cluster that: • resizes based on load. • is rack-aware in its smaller state. YARN chooses arbitrary nodes perhaps resulting in large network reads. (MD-1028, MD-1089)
Node Labels	Although the Apache YARN documentation states that you can associate node labels with YARN container requests, some people have noticed that the feature does not work in practice. While Drill-on-YARN configuration has settings to associate Drillbit container requests with node labels, doing so is not supported. To use node labels, associate node labels with YARN queues as described in the YARN configuration step in the Migrate Drill to Run Under YARN documenation.

Configuring Drill

Lists the MapR-specific configuration for Drill.

Drill is highly configurable. This document focuses on MapR-related configurations and refers to the open source Apache Drill documentation for generic information. Key things to configure are:

Drill memory	Determine the amount of heap and direct memory allocated to a Drillbit for query processing in a Drill cluster. See Configuring Drill Memory on page 3239.

last-updated: Apr 11, 2022

Parquet block size	Change the Parquet block size to match the MapR filesystem chunk size. See Configuring the Parquet Block Size on page 3241.
Resources for a shared Drillbit	Configure queues and parallelization for supporting multiple users sharing a Drillbit. Support separate Drillbits running on different nodes in the cluster. See Configuring Resources for a Shared Drillbit.
Multitenancy	Configure a multitenant cluster to account for resources required for Drill. See Configuring a Multitenant Cluster on page 3246.
User Impersonation	Configure impersonation to allow a service to act on behalf of a client while performing the action requested by the client. See User Impersonation on page 3280.
User authentication and encryption	Configure user authentication when you want the identity of a user, before permitting the user access to a process running on a system. See MapR Security (Tickets) on page 3292 .
SSL/TLS for Encryption	Enable and configure SSL/TLS for encryption when you need to use Plain authentication. See SSL/TLS for Encryption on page 3312.
Drill impersonation with Hive authorization	Configure Drill impersonation to work with Hive impersonation to authorize access to metadata in the Hive metastore repository and data in the Hive warehouse. See User Impersonation with Hive on page 3286.
Volumes to use for spooling	Use the drill.exec.spill.directories option to set MapReduce volumes or local volumes for spooling to improve performance and stripe data across as many disks as possible.
Persistent configuration storage	See Persistent Configuration Storage and Configuring the ZooKeeper PStore Location on page 3247.
Access rights	Configure access rights if you have 777 file-level permissions to a table, and a query returns no results. See Configuring Access Rights.

Drill typically runs along side other workloads, including the following:

- MapReduce
- Yarn
- Hive and Pig
- Spark

You need to plan and configure these resources for use with Drill and other workloads:

- Memory
- CPU
- Disk

Configuring Access Rights

If the security in your organization limits access to MapR Database tables, you might experience a problem querying the tables. If you have 777 file-level permissions to a table, yet a query returns no results, you might need to add your user name to the maprcli *ACL*.

last-updated: Apr 11, 2022

Adding a Drill Node to a Cluster

To add a new node to a MapR cluster that provides the Drillbit service, add the node to the cluster first, and then install Drill on the new node. If you install Drill first, and then add the node to the cluster, the cluster cannot detect ZooKeeper information and the cluster is misnamed. These problems require some work to resolve. You need to edit the drill-override.conf file in the `mapr/drill` directory and modify the name of the cluster. Avoid this extra work, and install Drill only after adding the node to the cluster by performing steps in the following order:

1. Follow instructions for adding a node to a cluster.
2. Reconfigure the cluster as described in the same instructions.
3. Verify that the new node is up and running.
4. Stop Warden, as shown:

   ```
   $ service mapr-warden stop
   ```

5. Stop ZooKeeper service, as shown:

   ```
   $ service mapr-zookeeper stop
   ```

6. Configure the repository to add the ecosystem repository.
7. Install Drill on the new node.
8. Reconfigure the node.

   ```
   $ /opt/mapr/server/configure.sh -R
   ```

9. Start ZooKeeper if the node is a ZooKeeper node.
10. Start warden to make configuration changes effective.

Verify that the Drillbit service is running on the node. It might take a minute or so for the Drillbit to start after starting warden.

Configuring Drill Memory

A system administrator can modify the amount of system memory that Warden allocates to the Drill service on each node in the `warden.drill-bits.conf` file. Drill users, with file permissions, can modify the amount of heap and direct memory allocated to the Drill service on each node in the `drill-env.sh` file.

Note: The cumulative memory allocation in `drill-env.sh` cannot exceed the memory allocation in `warden.drill-bits.conf`.

After modifying `drill-env.sh`, restart Drill:

```
$ maprcli node services -name drill-bits -action restart -nodes
<space-separated-list-of-drill-hostnames>
```

After modifying `warden.drill-bits.conf`, run the configuration script, configure.sh, to update the node configuration and then restart Drill:

```
/opt/mapr/server/configure.sh -R
$ maprcli node services -name drill-bits -action restart -nodes
<space-separated-list-of-drill-hostnames>
```

last-updated: Apr 11, 2022

The following sections describe the `warden.drill-bits.conf` and `drill-env.sh` files in detail.

Drill Memory Allocation in a Warden-Managed Cluster

If you install and run Drill under the Warden service, Warden manages the amount of system memory that Drill can use. By default, Warden allocates 20% of the system memory on a node to the Drill service. For example, if a node has 50GB of memory, Warden allocates 10GB (20% of 50GB) to the Drill service.

A system administrator can define the amount of memory that Warden allocates to Drill by changing the value of the `DRILLBIT_MAX_PROC_MEM` variable in `/opt/mapr/drill/drill-<version>/conf/warden.drill-bits.conf`.

When starting, Drill verifies that the amount of memory configured in `drill-env.sh` does not exceed the limit set by the `service.env=DRILLBIT_MAX_PROC_MEM` variable in `warden.drill-bits.conf`. If the settings in `drill-env.sh` exceed the setting in Warden, the system prints a message stating the issue; Warden does not start the Drill service on the node.

The `warden.drill-bits.conf` file contains the following settings:

Note: Drill automatically configures the `service.heapsize` parameters. Do not modify them.

```
#Default Drill Mem Distrib: 20% of System memory
service.env=DRILLBIT_MAX_PROC_MEM=20%
//Specifies the maximum amount of memory that Warden will allocate to the
Drill service on the node. You can set this value as a percentage of system
memory or as an absolute value in GB. Memory configured in drill-env.sh
cannot exceed this memory setting.

service.heapsize.min=5120
//Minimum heap size. Do not change this value. The value is auto-populated
and represents the minimum memory that the Drillbit process will take.

service.heapsize.max=13312
//Maximum heap size. Do not change this value. The value is auto-populated
and represents the maximum memory that the Drillbit process will take.

#Warden will allocate 20% of memory for Drill
service.heapsize.percent=20
//Do not change this value. Total heap size available based on the value
set for the DRILLBIT_MAX_PROC_MEM variable. If the variable is defined in
absolute values, it is represented as a percent of the system memory.
```

Drill Memory Allocation in drill-env.sh

You can configure the amount of heap and direct memory allocated to Drill on each node in the`/opt/mapr/conf/conf.d/drill-env.sh` file. If you do not manually configure the heap and direct memory, Drill calculates these values based on the amount of system memory that Warden allocates to Drill and auto-populates the settings for the variables.

The cumulative amount of memory allocated to Drill in `drill-env.sh` cannot exceed the amount of memory that Warden allocates to Drill, which is set by the `DRILLBIT_MAX_PROC_MEM` variable in `warden.drill-bits.conf`.

Note: The values in `drill-env.sh`, such as 13G, are examples and do not indicate the default memory limits for Drill. By default, Warden allocates 20% of the system memory on a node to Drill.

The `drill-env.sh` file contains the following memory variables that you can uncomment and modify:

```
#export DRILLBIT_MAX_PROC_MEM=${DRILLBIT_MAX_PROC_MEM:-"13G"}
//Specifies the maximum amount of system memory that the Drill service
```

last-updated: Apr 11, 2022

```
can use on a node. Must be equal to or less than the value set for
DRILLBIT_MAX_PROC_MEM in warden.drill-bits.conf. You can set this value as
a percentage of system memory or as an absolute value in GB. If you define
this variable, without defining the heap and direct memory variables, Drill
automatically calculates the heap and direct memory values.

#export DRILL_HEAP=${DRILL_HEAP:-"4G"}
//Maximum theoretical heap limit for the JVM per node.

#export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"8G"}
//Java direct memory limit per node.

#export DRILLBIT_CODE_CACHE_SIZE=${DRILLBIT_CODE_CACHE_SIZE:-"1G"}
//The memory limit for the compiled code generated by the JVM JIT compiler.
Do not modify. The value for this parameter is auto-computed based on the
heap size and cannot exceed 1GB.
```

Note: If performance is an issue, add -Dbounds=false, as shown:

```
export DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dbounds=false"
```

Configuring the Parquet Block Size

The default value for the `store.parquet.block-size` parameter is 268435456 (256 MB), the same size as MapR filesystem chunk sizes. In previous versions of Drill, the default value was 536870912 (512 MB).

If you change the MapR filesystem chunk size, change the Parquet block size to match using the ALTER SYSTEM or SET commands, as shown:

```
ALTER SYSTEM SET `store.parquet.block-size` = <value>;
[ALTER SESSION] SET `store.parquet.block-size` = <value>
```

Alternatively, you can override the default setting in the `<DRILL_HOME>/conf/drill-override.conf` file, as shown:

```
drill.exec: {
  ...
  options.store.parquet.block-size = 268435456
}
```

For information about setting the MapR filesystem chunk size, see Setting Chunk Size.

Configuring Multiple Drill Clusters and Designating One Cluster as an OJAI Distributed Query Service

As of MapR 6.0 and Drill 1.11, you can run operational queries through the OJAI Distributed Query Service, as well as analytical queries through Drill. If you want to run operational and analytical workloads in your MapR cluster, you must configure multiple Drill clusters within the MapR cluster and then configure a Drill cluster as the OJAI Distributed Query Service. Restricting each workload to its own cluster improves query performance.

Note: Installing Drill and the OJAI Distributed Query Service together through the MapR Installer is not currently supported. Only one of these services running in the cluster is supported unless you manually install and configure multiple Drill clusters, as instructed here.

Data Distribution

If you install both Drill and the OJAI Distributed Query Service through the MapR Installer, both workloads get processed across the entire MapR cluster. When both services run together in the cluster, the system

replicates data across the entire cluster, causing remote reads and impairing performance, which can lead to missed SLAs and memory issues.

Memory Allocation

The amount of memory allocated to Drill and the OJAI Distributed Query Service differ. By default, when you install Drill, 13 GB of memory is allocated to the Drillbit service running on a node:

- 8 GB direct
- 4 GB heap
- 1 GB core cache

The OJAI Distributed Query Service less memory than Drill. By default, the OJAI Distributed Query Service is allocated ~ 5 GB of memory:

- 1 GB direct
- 3 GB heap
- 512 MB core cache

If you use the MapR Installer and select both Drill and the OJAI Distributed Query Service, memory is configured for Drill. If you only run operational queries, which do not use as much memory as analytical queries, you unnecessarily lose an additional 8 GB of memory.

How to Run Drill and the OJAI Distributed Query Service Together in a MapR Cluster

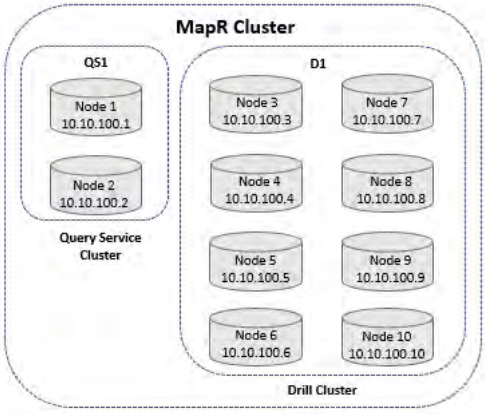
You can manually install Drill on several nodes and divide the nodes into multiple topologies (Drill clusters). For each of the topologies, create and mount a volume. Then, create directories within each volume to store your data. Configure these directories as workspaces in the Drill dsf storage plugin. Finally, configure a Drill cluster to run as an OJAI Distributed Query Service.

The following topics provide instructions for each of the required steps:

Step 1: Plan the Clusters
Decide which nodes in the MapR cluster you want to run Drill and which nodes you want to run the OJAI Distributed Query Service.

The nodes you select to run Drill can form one or more Drill clusters, while the nodes you select to run the OJAI Distributed Query Service can form another Drill cluster. You can configure multiple Drill clusters.

For example, if you have a ten node MapR cluster, you can configure one Drill cluster to run analytical queries and one OJAI Distributed Query Service cluster to run OJAI operational queries, as shown:



last-updated: Apr 11, 2022

Track the nodes that you want to group into a cluster, as this information is needed to configure node topology and volumes. Also note the memory requirements of each service. Only non-overlapping Drill clusters are supported. You cannot install more than one Drillbit on a MapR server node.

Step 2: Manually Install Drill on All Nodes
Manually install Drill on all nodes, including the nodes designated to run the OJAI Distributed Query Service.

For Drill installation instructions, see Installing Drill. You can install Drill to run under Warden or YARN, as described in the following following topics:

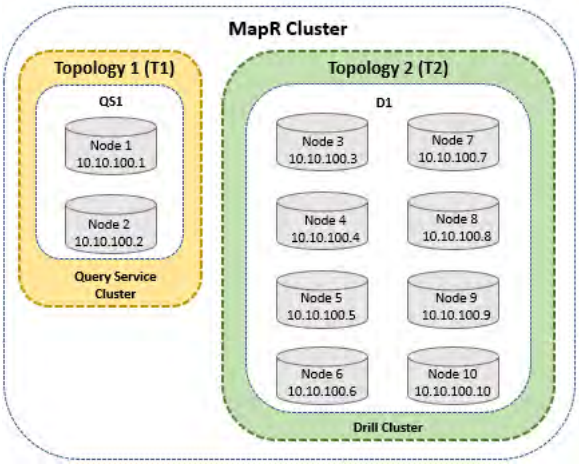
- Install Drill to Run Under Warden
- Install Drill to Run Under YARN

Step 3: Define Node Topologies
Node topologies restrict data to a designated set of nodes.

When you define a topology, data is only replicated on the nodes within the topology. Node topologies improve query performance because data is localized to the nodes specified in the topology instead of being distributed across the entireMapR cluster.

You can create node topologies for the Drill clusters in the UI or from the CLI. See Changing Topology for One or More Nodes for instructions.

When you create a topology, you define the nodes that form a Drill cluster, as shown in the following image:



The image shows two node topologies, T1 and T2. T1 is the Drill cluster to be configured as the OJAI Distributed Query Service. T2 is the Drill cluster that will remain a Drill service cluster.

Step 4: Create Volumes
Volumes organize data and manage cluster performance. Create and mount a volume to each of the topologies (Drill clusters) you created.

For example, you can create a volume named "operational" and mount it to the T1 topology and then create a volume named "analytical" and mount it to the T2 topology.

See Administering Volumes for volume information and Creating a Volume on page 864 for instructions.

Once you create the volumes, you have a place where you can create directories and store data. For example, you can create and store operational data in the `/operational/data/here` directory and analytical data in the `/analytical/data/here` directory.

Use these directories to configure the workspaces in the Drill dfs storage plugin configuration.

last-updated: Apr 11, 2022

Step 5: Configure Multiple Drill Clusters
Update the /opt/mapr/drill/drill-<version>/conf/drill-override.conf file on each Drill node that is part of a cluster with the cluster ID and a ZooKeeper entry to define the Drill cluster. Each Drill cluster should have a unique cluster ID and ZooKeeper entry to separate the clusters.

Note: Each Drill node in a cluster must have the same configuration.

The Drillbit process reads the configuration file and communicates with ZooKeeper to see if the cluster it belongs to exists. If the cluster exists, ZooKeeper says to join the cluster. If the cluster does not exist, the Drillbit initiates a new Drill cluster based on the cluster ID.

The following table provides an example of unique cluster IDs and ZooKeeper entries based on the topologies in the image shown in step 3, Define Node Topologies:

Cluster	Nodes	Cluster ID	ZooKeeper Entry
QS1	10.10.100.1 10.10.100.2	cluster-id: "drillbits"	zk.root: "drill"
D1	10.10.100.3 10.10.100.4 10.10.100.5 10.10.100.6 10.10.100.7 10.10.100.8 10.10.100.9 10.10.100.10	cluster-id: "drillbits2"	zk.root: "drill2"

For QS1, drill-override.conf must include the following configuration:

```
drill.exec: {
  zk.root: "drill",
  cluster-id: "drillbits",
  zk.connect: "<zk-node-ip-address>:5181",
}
```

For D1, drill-override.conf must include the following configuration:

```
drill.exec: {
  zk.root: "drill2",
  cluster-id: "drillbits2",
  zk.connect: "<zk-node-ip-address>:5181",
}
```

Note: If you installed Drill to run under YARN, follow the steps in Defining Multiple Drill Clusters Under YARN for each Drill node. Drill running under YARN requires some additional steps, such changing ZooKeeper ports.

Step 6: Configure Workspaces
You must configure a workspace on one Drill node in each Drill cluster that points to the volume directory where data is stored. When you create a workspace, you must include the volume mount point.

last-updated: Apr 11, 2022

For example, if you created a volume with the mount point `/operational` for the OJAI Distributed Query Service cluster and stored your data in `/data/here/` within that volume, you would configure the workspace, as shown:

```
 {
     "type": "file",
     "enabled": true,
     "connection": "file:///",
     "workspaces": {
       "root": {
         "location": "/",
         "writable": false,
         "defaultInputFormat": null
       },
       "tmp": {
         "location": "/tmp",
         "writable": true,
         "defaultInputFormat": null
       },
       "operational": {
           "location": "/operational/data/here",
           "writable": true,
           "defaultInputFormat": null
          }
     }
```

Likewise, if you also created a volume with a mount point `/analytical` for the other Drill cluster that runs analytical queries and stored your data in `/data/here/` within that volume, you would configure the workspace, as shown:

```
{
     "type": "file",
     "enabled": true,
     "connection": "file:///",
     "workspaces": {
       "root": {
         "location": "/",
         "writable": false,
         "defaultInputFormat": null
       },
       "tmp": {
         "location": "/tmp",
         "writable": true,
         "defaultInputFormat": null
       },
       "analytical": {
         "location": "/analytical/data/here",
         "writable": true,
         "defaultInputFormat": null
        }
     }
```

You can define a workspace in the Drill dfs storage plugin configuration on the Storage page in the Drill Web UI at `https://<drill-node-ip-address>:8047`. You only need to configure the workspace on one Drill node in each Drill cluster.

See Plugin Configuration Basics and Workspaces for more information.

Step 7: Register a Drill Cluster as an OJAI Distributed Query Service
You can select any of the configured Drill clusters to act as the OJAI Distributed Query Service provider for operational queries, by running the `queryservice setconfig` command.

last-updated: Apr 11, 2022

When you register the Drill cluster as the OJAI Distributed Query Service, adjust the memory setting on each node. The default Drill memory setting of 13 GB is unnecessarily high for the OJAI Distributed Query Service, which only requires ~ 5 GB. You must restart the Drillbits after you update the memory settings.

Registering a Drill Cluster as the OJAI Distributed Query Service

To register a Drill Cluster as an OJAI Distributed Query Service, run the following command:

```
maprcli cluster queryservice setconfig -enabled true -clusterid
<name_of_cluster> -storageplugin dfs -znode <zk_setting>
```

For example, drillbits2 and drill2 are the cluster ID and ZooKeeper settings used in examples in previous steps. For these configurations, the command is:

```
maprcli cluster queryservice setconfig -enabled true -clusterid
drillbits2 -storageplugin dfs -znode drill2
```

See queryservice setconfig for more information about the command.

Configuring Memory for the OJAI Distributed Query Service

Modify the memory settings on each node in the OJAI Distributed Query Service cluster and then restart Drill. See Configuring Drill Memory on page 3239 for instructions.

Configuring a Multitenant Cluster

Drill operations are memory and CPU-intensive. Currently, Drill resources are managed outside of any cluster management service, such as the MapR Warden service. In a multi-tenant or any other type of cluster, YARN-enabled or not, you configure memory and memory usage limits for Drill by modifying `drill-env.sh` as described in the section, "Configuring Drill Memory" in Apache Drill documentation.

Configure a multitenant cluster to account for resources required for Drill. For example, on a MapR cluster, ensure warden accounts for resources required for Drill. Configuring `drill-env.sh` allocates resources for Drill to use during query execution, while configuring the following properties in `warden-drill-bits.conf` prevents warden from committing the resources to other processes.

```
service.heapsize.min=<some value in MB>
service.heapsize.max=<some value in MB>
service.heapsize.percent=<a whole number>
```

Set the `service.heapsize` properties in `warden.drill-bits.conf` regardless of whether you changed defaults in `drill-env.sh` or not.

"Configuring Drill in a YARN-enabled MapR Cluster" shows an example of setting the `service.heapsize` properties. The `service.heapsize.percent` is the percentage of memory for the service bounded by minimum and maximum values. Typically, users change `service.heapsize.percent` because using a percentage setting increases or decreases resources according to different node configurations. For more information about the `service.heapsize` properties, see the section, "warden.<servicename>.conf."

You need to statically partition the cluster to designate which partition handles which workload. To configure resources for Drill in a MapR cluster, modify one or more of the files created by the installation process in `/opt/mapr/conf/conf.d:`

```
warden.drill-bits.conf
warden.nodemanager.conf
warden.resourcemanager.conf
```

Configure Drill memory by modifying `warden.drill-bits.conf` in YARN and non-YARN clusters. Configure other resources by modifying `warden.nodemanager.conf` and `warden.resourcemanager.conf` in a YARN-enabled cluster.

Configuring Drill in a YARN-enabled MapR Cluster

To add Drill to a YARN-enabled cluster, change memory resources to suit your application. For example, you have 120G of available memory that you allocate to following workloads in a Yarn-enabled cluster:

File system = 20G Yarn = 20G OS = 8G

If Yarn does most of the work, give Drill 20G, for example, and give Yarn 60G. If you expect a heavy query load, give Drill 60G and Yarn 20G.

YARN consists of two main services:

- ResourceManager: There is at least one instance in a cluster, more if you configure high availability.
- NodeManager: There is one instance per node.

The `warden.resourcemanager.conf` and `warden.nodemanager.conf` files set ResourceManager and NodeManager memory to the following defaults:

```
service.heapsize.min=64
service.heapsize.max=325
service.heapsize.percent=2
```

Change these settings for NodeManager and ResourceManager to reconfigure the total memory required for YARN services to run. If you want to place an upper limit on memory, set the YARN_NODEMANAGER_HEAPSIZE or YARN_RESOURCEMANAGER_HEAPSIZE environment variable in

```
/opt/mapr/hadoop/hadoop-2.5.1/etc/hadoop/yarn-env.sh
```

You do not set the `-Xmx` option, allowing memory to grow as needed.

MapReduce Version 2 and other Resources

You configure memory for each service by setting three values in `warden.conf`.

```
service.command.<servicename>.heapsize.percent
service.command.<servicename>.heapsize.max
service.command.<servicename>.heapsize.min
```

Configure memory for other services in the same manner. For more information about managing memory in a MapR cluster, see the following sections:

- Memory Allocation for Nodes
- Cluster Resource Allocation

How to Manage Drill CPU Resources

Currently, you do not manage CPU resources within Drill. Use Linux cgroups to manage the CPU resources.

Configuring the ZooKeeper PStore Location

By default, the ZooKeeper PStore offloads query profile data to `maprfs:///apps/drill/profiles`. You can override the default location in the `drill-override.conf` file.

last-updated: Apr 11, 2022

When query profile data is stored on a distributed system, like the MapR filesystem, you can see a global query list (view of query profiles coordinated by all Drill nodes in one Web UI).

To change the ZooKeeper PStore location, update the `drill.exec` block in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf with the following` configuration, as shown:

```
drill.exec: {
    cluster-id: "my_cluster_com-drillbits",
    zk.connect: "<zkhostname>:5181",
    sys.store.provider.zk.blobroot: "maprfs:///new/storage/location/"
   }
```

Note: By default, the MapR filesystem replicates the data three times. If you are concerned about storage consumption, you can create a new volume specifically for query profile data, and set the replication value to 1 for that volume. After you create the volume, update `sys.store.provider.zk.blobroot` to point to the volume. See Creating a Volume on page 864 for additional information.

After you modify `drill-override.conf`, restart Drill:

```
maprcli node services -name drill-bits -action restart -nodes
<drill-hostnames-separated-by-a-space>
```

Configuring cgroups to Control CPU Usage
Starting in Drill 1.13, you can configure a Linux cgroup (control group) to enforce CPU limits on the Drillbit service running on a node. Linux cgroups enable you to limit system resources to defined user groups or processes. You can use the cgconfig service to configure a Drill cgroup to control CPU usage and then set the CPU limits for the Drill cgroup on each Drill node in the `/etc/cgconfig.conf` file.

Note: Cgroups V2 is recommended.

Before You Begin

Each Drill node must have the `libcgroup` package installed to configure CPU limits for a Drill cgroup. The `libcgroup` package installs the cgconfig service required to configure and manage the Drill cgroup.

Install the `libcgroup` package using the `yum install` command, as shown:

```
yum install libcgroup
```

Enable Drill to Directly Manage CPU Resources

Starting in Drill 1.14, Drill can directly manage CPU resources through the start-up script, `drill-env.sh`, which means that you no longer have to manually add the PID (Drill process ID) to the `cgroup.procs` file each time a Drillbit restarts. This step occurs automatically upon restart. The start-up script checks for the specified cgroup, such as drillcpu, and then applies the cgroup to the launched Drillbit JVM. The Drillbit CPU resource usage is then managed under the cgroup, drillcpu.

For Drill to directly manage CPU resources, you must enable (uncomment) the following variables in the `drill-env.sh` script:

Variable	Description
export DRILLBIT_CGROUP=${DRILLBIT_CGROUP:-"drillcpu"}	Sets the cgroup to which the Drillbit belongs when running as a daemon using drillbit.sh start. Drill uses the cgroup for CPU enforcement only.

export SYS_CGROUP_DIR=${SYS_CGROUP_DIR:-"/sys/fs/cgroup"}	Drill assumes the default cgroup mount location set by systemd (the system and service manager for Linux operating systems). If your cgroup mount location is in a different location, change the setting to match your location.
export DRILL_PID_DIR=${DRILL_PID_DIR:-$DRILL_HOME}	The location of the Drillbit PID file when Drill is running as a daemon using drillbit.sh start. By default, this location is set to $DRILL_HOME.

Important: If you have Drill 1.13 running on the node, or you have Drill 1.14 running on the node and you do not want to enable Drill to directly manage the CPU resources through `drill-env.sh`, you must manually update the `/cgroup/cpu/drillcpu/cgroup.procs` file with the PID (Drill process ID), as shown, each time a Drillbit restarts to enforce the CPU limit for the Drillbit service:

```
echo 25809 > /cgroup/cpu/drillcpu/cgroup.procs
```

Set the CPU Limit for the Drillbit Service

You can set the CPU limit as a soft or hard limit, or both. You set the limits with parameters in the `/etc/cgconfig.conf` file. The hard limit takes precedence over the soft limit. When Drill hits the hard limit, in-progress queries may not complete. Review the following sections that describe the soft and hard limit parameters and then configure CPU limits.

Soft Limit Parameter

You set the soft limit with the `cpu.shares` parameter. This parameter takes an integer value, which specifies a relative share of CPU time available to the tasks in a cgroup. For example, if there are two tasks and `cpu.shares` is set to 100, each task receives half of the CPU time. The value must be 2 or greater. When you set a soft limit, Drill can exceed the CPU allocated if extra CPU is available for use on the system. Drill can continue to use CPU until there is contention with other processes over the CPU or Drill hits the hard limit.

Hard Limit Parameters

You set the hard limit on the amount of CPU time that the Drill process can use through the `cpu.cfs_period_us` and `cpu.cfs_quota_us` parameters.

- `cpu.cfs_period_us`

  Specifies a period in microseconds (represented by `us` for µs) to indicate how often a cgroup's access to CPU resources should be reallocated. For example, if you want tasks in a cgroup to have access to a single CPU for 0.2 seconds in a 1 second window, set `cpu.cfs_quota_us` to 200000 and `cpu.cfs_period_us` to 1000000. The upper limit of the `cpu.cfs_quota_us` parameter is 1 second and the lower limit is 1000 microseconds.

- `cpu.cfs_quota_us`

  Specifies the total amount of runtime in microseconds (represented by `us` for µs), for which all tasks in the Drill cgroup can run during one period (as defined by `cpu.cfs_period_us`). When tasks in the Drill cgroup use up all the time specified by the quota, the tasks are throttled for the remainder of the time specified by the period and they cannot run until the next period. For example, if tasks in the Drill cgroup can access a single CPU for 0.2 seconds out of every 1 second, set `cpu.cfs_quota_us` to 200000 and `cpu.cfs_period_us` to 1000000. Setting the `cpu.cfs_quota_us` value to -1 indicates that the group does not have any restrictions on CPU. This is the default value for every cgroup, except for the root cgroup.

Configuring CPU Limits

Complete the following steps to set a hard and/or soft CPU limit for the Drill process running on the node:

1. Start the cgconfig service:

```
service cgconfig start
```

2. Add a cgroup for Drill in the `/etc/cgconfig.conf` file:

```
group drillcpu {
                     cpu {
                            cpu.shares = 320;
                            cpu.cfs_quota_us = 400000;
                            cpu.cfs_period_us = 100000;
                            }
                     }
```

In the configuration example above, the `cpu.shares` parameter sets the soft limit. The other two parameters, `cpu.cfs_quota_us` and `cpu.cfs_period_us`, set the hard limit. If you prefer to set only one type of limit, remove the parameters that do not apply. When setting a soft limit, allocate a specific number of CPU shares to the Drill cgroup in the configuration. Calculate the CPU shares as:

```
1024 (CPU allocated to Drill/Total available CPU)
```

In the example, CPU shares is calculated as:

```
1024 (10/32) = 320
```

When setting a hard limit, add limits to the `cpu.cfs_quota_us` and `cpu.cfs_period_us` parameters. In the example, the Drill process can fully utilize 4 CPU.

Tip:

The hard limit parameter settings persist after each cgroup service restart. Alternatively, you can set the parameters at the session level using the following commands:

```
echo 400000 > /cgroup/cpu/drillcpu/cpu.cfs_quota_us
       echo 100000 > /cgroup/cpu/drillcpu/cpu.cfs_period_us
```

3. (Optional) If you want the cgconfig service to automatically restart upon system reboots, run the following command:

```
chkconfig cgconfig on
```

Working with Drill

For general information about working with Drill, refer to the following key topics:

Connecting Drill to Data Sources
Choose and configure storage plugins to enable Drill to connect to a data source.

Drill serves as a query layer that connects to data sources through storage plugins. A storage plugin is a software module for connecting Drill to data sources. A storage plugin typically optimizes execution of Drill queries, provides the location of the data, and configures the workspace and file formats for reading data.

What you can do with Storage Plugins

Several storage plugins are installed with Drill that you can configure to suit your environment. Through a storage plugin, Drill connects to a data source, such as a database, a file on a local or distributed filesystem, or a Hive metastore. See the Drill Storage and Format Plugin Support Matrix.

You can modify the default configuration of a storage plugin and give the new configuration a unique name. This document refers to Y as a different storage plugin, although it is actually just a reconfiguration of original interface.

On the Storage tab of the Web Console, you can view and reconfigure a storage plugin if you have permission. You can access each node running a Drillbit by starting the Drill Web Console. The way you start the Drill Web Console depends on your security setup.

When you install Drill using the `mapr-drill` package, storage plugin configurations are available for the following data sources:

- MapR File System
- MapR Database

  Note: To access MapR Database tables, use the dfs storage plugin with the maprdb format plugin.
- Hive
- Kafka

Connecting Drill to HBase

As of the MapR 6.0 and Drill 1.11, HBase is no longer supported, therefore the communication path between Drill and HBase is also not supported. If you have an hbase storage plugin configured in Drill, you should disable it.

Default Storage Plugin Configurations

The Drill documentation describes the attributes and definitions that you can configure for storage plugins, except for the MapR Database format. See MapR Database Format Plugin for Drill.

The Drill Web Console includes some default storage plugin configurations. The following table lists the default configurations and their descriptions:

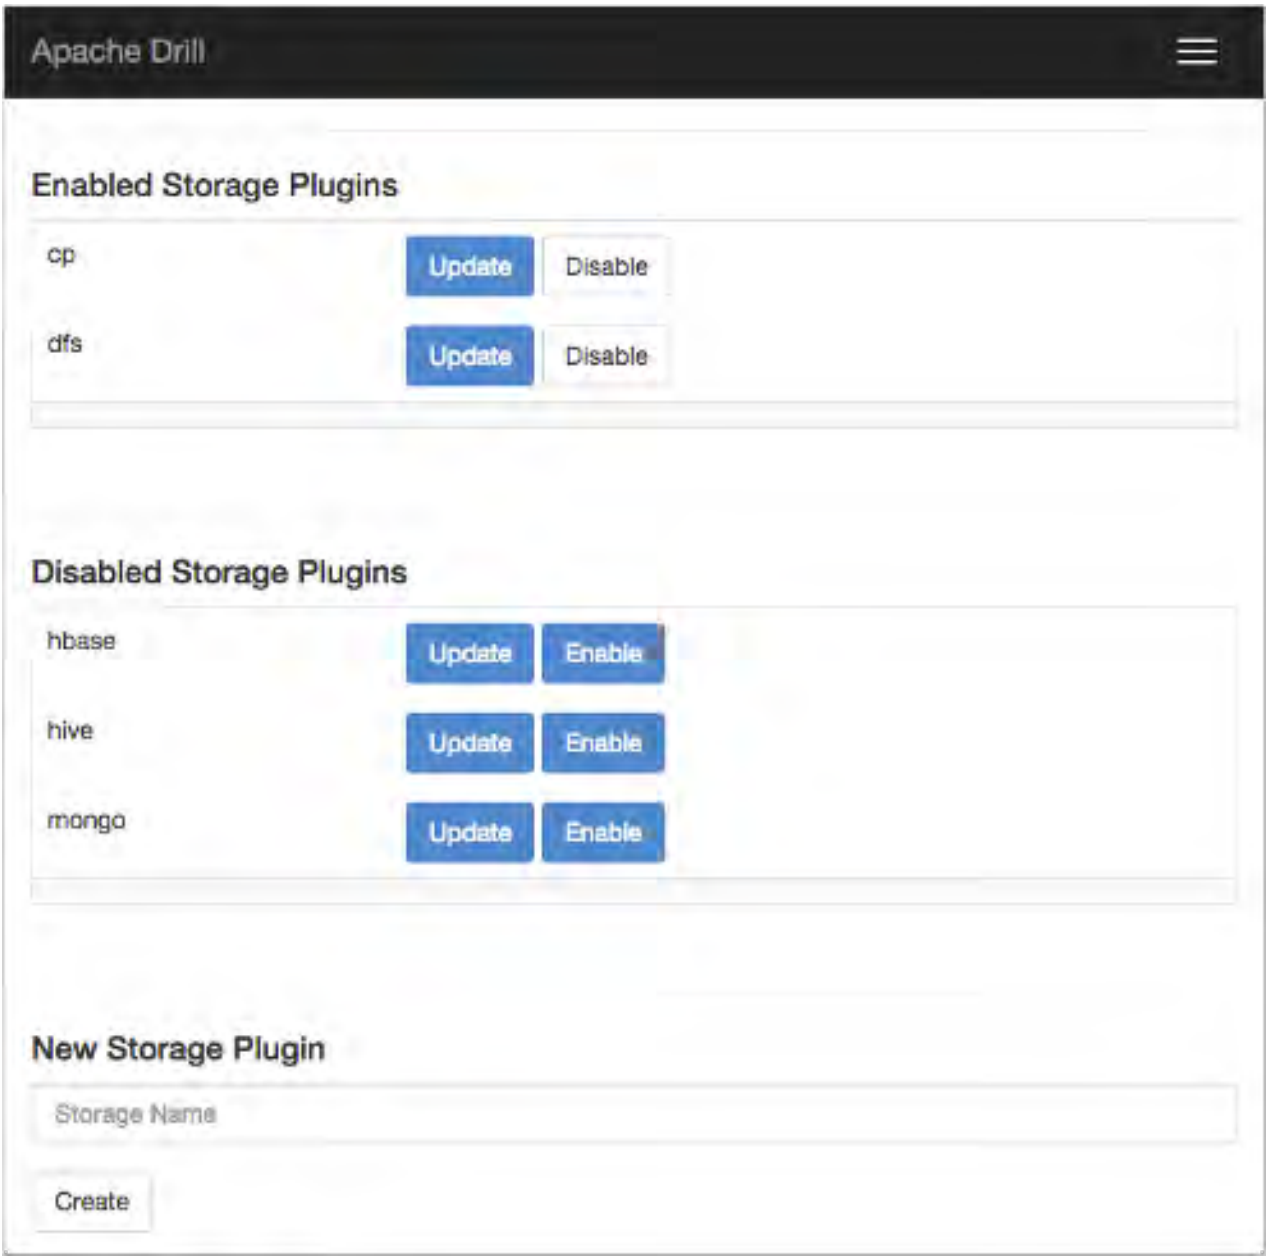
last-updated: Apr 11, 2022

Instance	Description
cp	Points to a JAR file in the Drill classpath that contains the Transaction Processing Performance Council (TPC) benchmark schema TPC-H that you can query.
dfs	Points to MapR File System by default. Drill automatically configures this instance when you install Drill in a the MapR cluster. Includes a maprdb format plugin for MapR Database.
hive	Integrates Drill with the Hive metadata abstraction of files, MapR Database, and libraries to read data and operate on SerDes and UDFs.

When you add or update a storage plugin configuration on one Drill node in a Drill cluster, Drill broadcasts the information to all of the other Drill nodes. All nodes have identical storage plugin configurations. You do not need to restart any Drillbits when you add or update a storage plugin configuration.h

Configuring Storage Plugin Instances

You can add, remove, or update Drill storage plugin configurations using the Web Console. The following image shows the default storage plugin configurations in the Drill Web UI:



If you click **Update** next to `dfs`, the following default configuration appears :

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs:///",
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": null
    },
    "tmp": {
      "location": "/tmp",
      "writable": true,
      "defaultInputFormat": null
    }
  },
```

last-updated: Apr 11, 2022

```
  "formats": {
    "psv": {
      "type": "text",
      "extensions": [
        "tbl"
      ],
      "delimiter": "|"
    },
    "csv": {
      "type": "text",
      "extensions": [
        "csv"
      ],
      "delimiter": ","
    },
    "tsv": {
      "type": "text",
      "extensions": [
        "tsv"
      ],
      "delimiter": "\t"
    },
    "parquet": {
      "type": "parquet"
    },
    "json": {
      "type": "json"
    },
    "maprdb": {
      "type": "maprdb"
    }
  }
}
```

The `dfs` configuration includes the storage plugin type, connection information, default workspaces, and file formats that the data source supports. You can add and remove workspaces and file formats.

Changing the Connection Attribute

You can also change the connection if you want the configuration to point to a different cluster.

By default, Drill connects to the cluster that the Drill node belongs to. You do not need to modify the connection unless you want to connect Drill to a different cluster. To connect to a different cluster, edit the connection to include the name of the cluster that you want to connect to.

Example:

```
"connection": "maprfs://<cluster_name>/"
```

Drill Storage and Format Plugin Support Matrix

You can deploy Drill without Hadoop in a standalone configuration on a single node, however multi-node standalone cluster deployments of Drill are not supported. Note that Drill itself does not require Hadoop.

The following table lists the supported and unsupported data sources and formats in Drill:

Data Source	Storage Plugin Type	Formats	Supported
MapR File System	dfs	Text (CSV, TSV, PSV)	Yes
		Parquet	Yes
		JSON	Yes

		Avro	No
MapR Database	dfs	Binary	Yes
		JSON	Yes
HBase	hbase	Binary	No (as of Drill 1.11 and MapR 6.0)
Hive	hive	Text (CSV, TSV, PSV)	Yes
		Parquet	Yes
		JSON	Yes
		Avro	Yes
		Other Hive built-in SerDes	Yes (Not recommended due to the memory overhead and performance implications.)
S3	s3	Supports the same formats as the dfs storage plugin.	Yes
MongoDB	mongodb	N/A	No
RDBMS	jdbc	N/A	No
Kudu	kudu	N/A	No
Kafka	kafka	JSON	No  **Note:** The kafka storage plugin on the MapR Streams is in the Alpha testing phase and not officially supported. See Configuring the Kafka Storage Plugin for more information.
OpenTSDB	openTSDB	N/A	 **Note:** The openTSDB storage plugin is not officially supported. See OpenTSDB Storage Plugin for more information.

 **Note:** As of the MapR 6.0 and Drill 1.11, HBase is no longer supported, therefore the communication path between Drill and HBase is also not supported. If you have an hbase storage plugin configured in Drill, you should disable it.

maprdb Format Plugin for Drill
Drill supports access to MapR Database JSON and binary tables through the maprdb format plugin.

When you install Drill, the maprdb format is automatically defined within the default dfs storage plugin configuration to make MapR Database a consumable data source for Drill. You can access the dfs storage plugin configuration from the Storage page in the Drill Web UI.

When you install Drill, you will see some options specific to the maprdb format plugin that you can change or configure. You can modify these options in the following places:

- dfs storage plugin configuration

last-updated: Apr 11, 2022

- drill-override.conf file
- SET command

For additional information about storage plugins, see Plugin Configuration Basics.

Modifying the maprdb Format Settings within the dfs Storage Plugin Configuration

You can add or modify certain maprdb format plugin settings within the dfs storage plugin configuration on the Storage page in the Drill Web UI.

The following table lists the maprdb format options that you can set within the dfs storage plugin configuration:

Option	Description	Value
allTextMode	When enabled, Drill reads all values as type varchar. Useful when the underlying data set has type values of mixed scalar types, such as integers, floating point, varchars, date, time, and timestamp. Disabled by default.	true|false
disableCountOptimization	When enabled, this option disables optimization for queries with the COUNT (*) aggregate function. Disabled by default.	true|false
enablePushdown	When enabled, Drill pushes down filters to MapR Database. Disabling this option is not recommended unless you intend to use it for troubleshooting purposes. Enabled by default.	true|false
ignoreSchemaChange	When enabled, Drill ignores schema changes. Disabled by default.	true|false
nonExistentColumnsProjection	When enabled, Drill can distinguish between null and non-existent fields. Disabled by default.	true|false
readNumbersAsDouble	When enabled, Drill reads all numeric values as type double. Useful when the underlying data set has type values of mixed numeric types, such as integers and floating point. Disabled by default.	true|false

The following example configuration shows you how to include the options in the maprdb format configuration within the dfs storage plugin configuration:

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs:///",
  "config": null,
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": "maprdb",
      "allowAccessOutsideWorkspace": false
    },
  "formats": {
    "maprdb": {
```

last-updated: Apr 11, 2022

```
      "type": "maprdb",
      "allTextMode": true,
      "disableCountOptimization": true,
      "enablePushdown": false
    },
    "parquet": {
      "type": "parquet"
    },
    "json": {
      "type": "json",
      "extensions": [
        "json"
      ]
    }
  }
}
```

See Plugin Configuration Basics and File System Storage Plugin for more information.

Overriding Default maprdb Format Plugin Settings in drill-override.conf

You can override the default maprdb format plugin settings that control the level of parallelism in Drill and the media type in the `drill-override.conf` file.

To override the default maprdb format plugin settings, add the options to the `format-maprdb.json` configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```
format-maprdb: {
                json: {
                    scanSizeMB: 512,
                    restrictedScanSizeMB: 4096
                    mediaType: HDD
                    }
                }
```

The following sections describe how to modify the options in the configuration shown above:

Configuring the Level of Parallelism in Drill

The size of data chunks and number of minor fragments affect the level of parallelism in Drill. When querying JSON tables, Drill creates minor fragments that scan the chunks of data that MapR Database passes to Drill. Minor fragments are logical units of work that determine the level of parallelism in Drill. The level of parallelism increases with the number of minor fragments. See Drill Query Execution for more information about how Drill executes a query.

Modifying the Size of Data Chunks

The `format-maprdb.json.scanSizeMB` option changes the size of data chunks that MapR Database passes to Drill when querying JSON tables. Drill creates approximately one minor fragment per data chunk when querying JSON tables. For example, if a table has 4 GB of data and the chunk size is set to 128 MB, Drill creates approximately 32 minor fragments to scan the data chunks.

The default setting for data chunks is 128 MB, however you can override this default in the drill-override.conf file. The value of the `format-maprdb.json.scanSizeMB` option can range from 32 MB to 8192 MB (8 GB). Adjust the setting based on the size of your tables. Use a higher setting for larger tables and a lower setting for smaller tables. The right setting can reduce latency and increase throughput.

Modifying the Number of Minor Fragments Created

The `format-maprdb.json.restrictedScanSizeMB` option determines the number of minor fragments that Drill creates to scan the data and do the join-back to a JSON table when executing a non-covering index plan.

last-updated: Apr 11, 2022

The default setting for this option is 4096 MB, however you can override this setting in the drill-override.conf file. The value of this option can range from 32 MB to 8192 MB (8 GB). Adjust the setting based on the size of your tables, keeping in mind that due to the random I/O nature of the join-back, a smaller setting (increased parallelism) may not necessarily increase throughput.

Note: The `planner.slice_target` option in Drill determines the number of minor fragments that can run in parallel. See Modifying Query Planning Options for more information.

Configuring the Media Type

Drill is optimized for SSDs, however MapR Database and Drill can run on HDDs. If you run Drill and MapR Database on HDDs, use the mediaType option in the `drill-override.conf` file to override the default setting. The `mediaType` option accepts HDD or SSD (default) as the value. Specify SSD or HDD in upper case as the value in the `drill-override.conf` file.

Drill Options for the maprdb Format Plugin

You can enable certain Drill options for the maprdb format plugin from the Options page in the Drill Web UI or from the command line using the SET and ALTER SYSTEM commands.

To enable the options from the Drill Web UI, go to `http(s)://<drill-hostname-or-ip-address>:8047`, and select **Options** in the menu bar. Alternatively, enable options from the command line using the SET or ALTER SYSTEM commands, as shown:

```
SET `store.hive.maprdb_json.optimize_scan_with_native_reader` = true;
```

You can enable the following Drill options for the maprdb format plugin:

store.hive.maprdb_json.optimize_scan_with_native_reader	Starting in Drill 1.14 (EEP 6.0), enable the `store.hive.maprdb_json.optimize_scan_with_native_reader` option if you want Drill to use the native Drill reader to read Hive MapR-DB JSON tables. When you enable the native Drill reader, Drill typically performs faster reads of data and applies filter pushdown optimizations.
store.hive.maprdb_json.read_timestamp_with_timezone_offset	Starting in Drill 1.16, you can enable Drill to read timestamp values with a timezone offset when the hive plugin is used and the Drill native MaprDB JSON reader is enabled through the `store.hive.maprdb_json.optimize_scan_with_native_reader` option.

last-updated: Apr 11, 2022

Important: Internally, Drill stores timestamp values in UTC format, for example 2018-01-01T20:12:12.123Z. When you enable the timezone offset option, select on a table returns different timestamp values. If you filter on timestamp values when this option is enabled, you must include the new timestamp value in the filter condition. For example, look at the timestamp values when the store.hive.maprdb_json.read_timestamp_with_timezone_offset option is disabled (set to 'false'):

```
select * from dfs.`/tmp/timestamp`;
----------------------------------------------------------
_id        datestring              datetimestamp
----------------------------------------------------------
1    2018-01-01 12:12:12.123    2018-01-01 20:12:12.123
2    9999-12-31 23:59:59.999    10000-01-01 07:59:59.999
----------------------------------------------------------
```

When the option is enabled (set to 'true'), you can see the difference in the timestamp values returned:

```
select * from dfs.`/tmp/timestamp`;
----------------------------------------------------------
_id     datestring            datetimestamp
----------------------------------------------------------
1    2018-01-01 12:12:12.123    2018-01-01 12:12:12.123
2    9999-12-31 23:59:59.999    9999-12-31 23:59:59.999
----------------------------------------------------------
```

When the option is enabled, queries that filter on timestamp values must include the new timestamp value in the filter condition, as shown:

```
select * from dfs.`/tmp/timestamp` where datetimestamp=timestamp
'2018-01-01 12:12:12.123';
----------------------------------------------------------
_id    datestring             datetimestamp
----------------------------------------------------------
1    2018-01-01 12:12:12.123   2018-01-01 12:12:12.123
----------------------------------------------------------
```

Notice that the WHERE clause uses the `2018-01-01 12:12:12.123` format versus the `2018-01-01 20:12:12.123` format.

MapR Database Tables

The `maprdb` format plugin enables you to query binary and JSON tables like you would query files in a file system because MapR Database and the MapR File System share the same namespace.

Binary tables differ from JSON tables in that they store a multi-dimensional map in which both keys and values are a sequence of bytes. JSON tables store OJAI documents. JSON tables support rich data types, including complex and repeated types, that enable database servers to evaluate filter conditions for optimized query execution. Binary tables can pose performance limitations because the table columns do not contain the necessary type information.

You can query tables stored in any directory in MapR Database using the same syntax that you use to select from files in the MapR File System. Instead of including the path of a file in a query, you include the table path. The user running the query must have read permission to access the table.

last-updated: Apr 11, 2022

Note: MapR Database is a case sensitive data source. To ensure that your queries return results, use the case that corresponds to the column names in the JSON tables and views that you query. For example, if you query the “age” column in a JSON table, the query must reference the column as “age” and cannot reference the column as “AGE” or the query will not return results. If you have a dataset where a column name has mixed cases, such as “age” and “AGE,” cleanse the data set so column names consist of one case and then reimport the data into the table to ensure a complete result set when you query the column.

The following sections describe the types of tables that MapR Database supports, provide examples of Drill queries on each type of table, and show you how to load data into a JSON table from JSON files.

JSON Tables

A JSON table is a collection of JSON documents stored in an optimized format in MapR Database. JSON tables support complex schema, like JSON files including nested and repeated types, but with additional support for more data types.

JSON tables leverage the OJAI API to natively support Drill data types making it possible for MapR Database to recognize, store, and interpret each of the Drill data types. This alleviates the need to encode data when an application writes to tables or use conversion functions when running queries against tables. For example, if a number or date is stored in a JSON table, you do not need to use the CAST or CONVERT functions for the query to return the actual values.

MapR Database's native support for Drill data types enables Drill to push down filters and projections to MapR Database which optimizes performance.

Querying a JSON Table

Querying JSON tables is simpler than querying binary tables because you do not have to include conversion functions in the queries to change the byte sequences into specific data types, and you do not have to include column families.

The following query examples show query results on a JSON table named “students” in MapR Database. Note that Drill returns human readable values without having to include the CAST or CONVERT functions in the queries.

Example 1

```
SELECT * FROM dfs.`/user/root/json/students`;
```

```
+-----------+-------------+--------+--------+-------------------+----------+
|    _id    |    date     |  name  | state  |      street       | zipcode  |
+-----------+-------------+--------+--------+-------------------+----------+
| student1  | 2016-01-15  | Alice  | CA     | 123 Ballmer Av    | 12345    |
| student2  | 2016-03-08  | Bob    | CA     | 1 Infinite Loop   | 12345    |
| student3  | 2015-12-22  | Frank  | CA     | 435 Walker Ct     | 12345    |
| student4  | 2015-09-15  | Mary   | CA     | 56 Southern Pkwy  | 12345    |
+-----------+-------------+--------+--------+-------------------+----------+
4 rows selected (0.233 seconds)
```

Example 2

```
SELECT _id, `date`, name, state, street, zipcode FROM dfs.`/user/root/json/
students`;
```

```
+-----------+-------------+--------+--------+-------------------+----------+
|    _id    |    date     |  name  | state  |      street       | zipcode  |
+-----------+-------------+--------+--------+-------------------+----------+
| student1  | 2016-01-15  | Alice  | CA     | 123 Ballmer Av    | 12345.0  |
| student2  | 2016-03-08  | Bob    | CA     | 1 Infinite Loop   | 12345.0  |
| student3  | 2015-12-22  | Frank  | CA     | 435 Walker Ct     | 12345.0  |
| student4  | 2015-09-15  | Mary   | CA     | 56 Southern Pkwy  | 12345.0  |
```

last-updated: Apr 11, 2022

```
+----------+-------------+--------+--------+------------------+----------+

Loading JSON Documents into a MapR Database Table with dbshell Commands

You can use the INSERT command in the `mapr dbshell` to load JSON documents into a MapR Database table.

The INSERT command is useful when inserting a small number of JSON documents into a JSON table.

Note: Alternatively, you can put JSON documents in a flat text file and use the `mapr importJSON` command to import the JSON documents into a table. The `mapr importJSON` command is useful when you need to insert many documents into a table. Refer to MapR Database JSON ImportJSON on page 5322 for instruction.

Note: The examples in this document use the student data in theQuerying HBase Tutorial to recreate the binary “students” table as a JSON table in MapR Database.

To load JSON documents into a MapR Database table through the `mapr dbshell`, complete the following steps:

1. Run the following command to start the `mapr dbshell`:

   ```
   mapr dbshell
   ```

2. Run the following command to create a table:

   ```
   create <table-name>

   Example:
    create students
   ```

   Note: By default, the table is stored in the default directory. The default directory is the current directory on the MapR Filesystem, which is set to the user’s home directory when the `mapr dbshell` starts. Include a file path, as shown, if you do not want the table stored in the default directory:

   ```
   create /file/path/table-name
   ```

3. Load the JSON documents into the table using the INSERT command, as shown:

   ```
   insert <table-name> --value '{JSON-document}'

   Example:
   insert students --value '{"_id":"student1", "name":"Alice",
   "street":"123 Ballmer Av", "zipcode":12345, "state":"CA"}'
   insert students --value '{"_id":"student2", "name":"Bob", "street":"1
   Infinite Loop", "zipcode":12345, "state":"CA"}'
   insert students --value '{"_id":"student3", "name":"Frank",
   "street":"435 Walker Ct", "zipcode":12345, "state":"CA"}'
   insert students --value '{"_id":"student4", "name":"Mary", "street":"56
   Southern Pkwy", "zipcode":12345, "state":"CA"}'
   ```

4. Run the following command to verify that the table was created:

```
find <table-name>

Example:
find students
```

5. Run the following command to close the `mapr dbshell`:

```
exit
```

6. If you need to start or restart Drill, run the following command:

```
maprcli node services -name drill-bits -action start|restart -nodes
<space-separated-list-of-drill-hostnames>
```

7. Run the following command to start the Drill shell (SQLLine):

```
sqlline
```

You can query the MapR Database JSON table from the Drill shell. If you did not include a file path when you created the table, the table was created in the current directory on the MapR Filesystem, which is set to the user's home directory. For example, the following query specifies the default directory if the root user created the table without indicating a file path:

```
SELECT * FROM dfs.`/user/root/table-name`;

Example:
SELECT * FROM dfs.`/user/root/students`;
```

If the user created the table in a specific directory, the query must include the directory in which the table was created, as shown:

```
SELECT * FROM dfs.`/file/path/table-name`;
```

Binary Tables

Binary tables store data in a flat table structure where the table consists of columns and column values. Every field in a binary table is stored as a sequence of bytes.

Binary tables do not store data type information. You manage the encoding for binary tables when storing data and then convert the sequence of bytes into a specific data type using the CAST or CONVERT functions when you run queries against the tables.

For example, if a string is stored in binary format, such as a UTF-8 encoded string, you must use the CAST function for the query to return a string type. If an integer is stored in binary format, such as 4-byte little endian encoding, you must use the CONVERT function for the query to return the integer value instead of the 4-byte sequence.

Querying a Binary Table

The following examples, from the Querying HBase Tutorial, display query results when the binary table "/user/root/binary/students" with two column families, "account" and "address," is queried without using a conversion function to convert the binary table data into specific data types.

Example 1

```
SELECT * FROM `/user/root/binary/students` students;
```

```
+--------------+-------------------------------------------------+-----------------------
|   row_key    |                    account                      |
address                                  |
+--------------+-------------------------------------------------+-----------------------

| [B@78dfa1ed  | {"date":"MjAxNi0wMS0xNQ==","name":"QWxpY2U="}  |
{"state":"Q0E=","street":"MTIzIEJhbGxtZXIgQXY=","zipcode":"MTIzNDU="}      |
| [B@22000c9a  | {"date":"MjAxNi0wMy0wOA==","name":"Qm9i"}       |
{"state":"Q0E=","street":"MSBJbmZpbml0ZSBMb29w","zipcode":"MTIzNDU="}      |
| [B@313b63e6  | {"date":"MjAxNS0xMi0yMg==","name":"RnJhbms="}  |
{"state":"Q0E=","street":"NDM1IFdhbGtlciBDdA==","zipcode":"MTIzNDU="}      |
| [B@321baa4a  | {"date":"MjAxNS0wOS0xNQ==","name":"TWFyeQ=="}  |
{"state":"Q0E=","street":"NTYgU291dGhlcm4gUGt3eQ==","zipcode":"MTIzNDU="}  |
+--------------+-------------------------------------------------+-----------------------

4 rows selected (0.612 seconds)
```

In example 2, using the CONVERT_FROM and CAST functions in a query on the same table converts the binary table data to typed data.

Example 2

```
SELECT CONVERT_FROM(row_key, 'UTF8') AS studentid,
CONVERT_FROM(students.account.name, 'UTF8') AS name,
CONVERT_FROM(students.address.state, 'UTF8') AS state,
CONVERT_FROM(students.address.street, 'UTF8') AS street,
CONVERT_FROM(students.address.zipcode, 'UTF8') AS zipcode,
CAST(students.account.`date` as date) AS `date` FROM dfs.`/user/root/binary/
students` students;
```

```
+------------+--------+--------+-------------------+----------+-------------+
| studentid  |  name  | state  |      street       | zipcode  |    date
|
+------------+--------+--------+-------------------+----------+-------------+

| student1   | Alice  | CA     | 123 Ballmer Av    | 12345    | 2016-01-15
|
| student2   | Bob    | CA     | 1 Infinite Loop   | 12345    | 2016-03-08
|
| student3   | Frank  | CA     | 435 Walker Ct     | 12345    | 2015-12-22
|
| student4   | Mary   | CA     | 56 Southern Pkwy  | 12345    | 2015-09-15
|
+------------+--------+--------+-------------------+----------+-------------+

```

Configuring the Hive Storage Plugin

You can connect Drill to a Hive data source through the hive storage plugin configuration in the Drill Web UI. Once configured, you can use Drill to query data stored in Hive.

Drill can work with only one version of Hive in a given cluster. To access Hive tables using custom SerDes or InputFormat/OutputFormat, all nodes running Drill must have the SerDes or InputFormat/OutputFormat JAR files in the following location: `<drill_installation_directory>/jars/3rdparty`.

To query across multiple versions of Hive, install each version of Hive on a separate Drill cluster. You must define separate storage plugins, each corresponding to the specific Hive version of the metastore.

Note: In EEP 6.0, Drill requires Hive version 2.3.3-mapr or later to successfully query Hive data sources.

Note: You can update the hive storage plugin configuration through the configuration script, configure.sh. If the hive storage plugin is disabled, and the configuration in the Drill Web UI displays "null," you must rerun configure.sh with the `-hiveMetastoreHost` argument. See configure.sh for details.

Configuring a Hive Remote Metastore

A remote Hive metastore configuration runs as a separate service outside of Hive. The metastore service communicates with the Hive database over JDBC. Point Drill to the Hive metastore service address, and provide the connection parameters in the hive storage plugin configuration to configure a connection to Drill. The hive storage plugin (located on the Storage tab in the Drill Web UI) has the following default configuration when you install Drill:

```
{
 "type": "hive",
 "enabled": true,
 "configProps": {
  "hive.metastore.uris": "",
  "javax.jdo.option.ConnectionURL": "jdbc:derby:;databaseName=../
sample-data/drill_hive_db;create=true",
  "hive.metastore.warehouse.dir": "/tmp/drill_hive_wh",
  "fs.default.name": "file:///",
  "hive.metastore.sasl.enabled": "false",
  "datanucleus.schema.autoCreateAll": "true"
 }
}
```

Complete the following steps to modify the default hive storage plugin configuration for your MapR File System environment:

1. Verify that Hive is running.
2. Issue the following command to start the Hive metastore service on the system specified in the `hive.metastore.uris`: `hive --service metastore`
3. Start the Drill Web UI.
4. Select the **Storage** tab. If Web UI security is enabled, you must have administrator privileges to perform this step.
5. In the list of disabled storage plugins in the Drill Web UI, click **Update** next to hive.
6. Update the following hive storage plugin parameters to match the system environment:
   - `"hive.metstore.uris"`
   - `"jdbc:<database>://<host:port>/<metastore database>"`
   - Change the default location of files to suit your environment. For example, change `"fs.default.name": "file:///"` to the MapR File System location: `maprfs:///`
   - To run Drill and Hive in a secure MapR cluster, change the `"hive.metastore.sasl.enabled"` parameter to `"true"`.
   - Change the `"datanucleus.schema.autoCreateAll"` property setting for your system environment. When enabled, `"datanucleus.schema.autoCreateAll"` initializes the Hive metastore schema.

last-updated: Apr 11, 2022

- In a production environment, remove the `"datanucleus.schema.autoCreateAll"` property from the hive storage plugin configuration; the property is not required because the preferred schema information is already created for the Hive metastore service.
- In a test environment with an embedded Hive metastore, you can disable (set to false) this property after the first query on the Hive data source that you submit from Drill. Alternatively, use the Hive schema tool to initialize or upgrade the Hive metastore schema. Using the Hive schema tool is recommended for queries on transactional tables. Run the `schematool` command as an initialization step, as shown:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType
<databaseType> -initSchema
```

7. Click **Enable** in the Web UI to enable the Hive storage plugin configuration.

Configuring the Kafka Storage Plugin
The Kafka storage plugin is not officially supported for Drill; however, if you choose to configure Kafka as a data source in Drill, you must update the `<drill_home>/jars/3rdParty` directory such that it contains the required JAR files and then restart Drill before you configure the `kafka` storage plugin in the Drill Web UI.

Verify that the nodes in your cluster meet the requirements and then complete the steps listed.

Requirements

The Kafka storage plugin requires:

- A MapR 6.1 cluster.
- Drill 1.14 installed on nodes.
- The MapR Kafka client package (kafka-1.1.1) installed on at least one node. The Kafka client installation provides the following kafka JAR files that you copy into the `<drill_home>/jars/3rdParty` directory (step 4):
  - kafka_2.11-1.1.1-mapr-1808.jar
  - kafka-clients-1.1.1-mapr-1808.jar

Steps

Complete the following steps to query Kafka Streams from Drill:

Note: Do not perform step 2 if you installed Drill using the MapR RPM or Debian packages. Step 2 is only required if you installed Drill using a TAR file.

1. Remove the specified JAR files from the `<drill_home>/jars/3rdParty` directory based on the Drill installation method:
   - If you installed Drill using MapR RPM or Debian packages, only remove JAR files that start with kafka, such as `kafka-clients-<version>.jar` and `kafka_<version>.jar`, from the `<drill_home>/jars/3rdParty` directory.
   - If you installed Drill using a TAR file, remove all the JAR files that start with `mapr` and `kafka`, such as `maprdb-<version>-mapr.jar, maprfs-<version>-mapr.jar`, `kafka_<version>-mapr.jar`, and `kafka-clients-<version>.jar`, from the `<drill_home>/jars/3rdParty` directory.

2. (Only perform this step if you installed Drill using a TAR file.) Copy the following JAR files from the `/opt/mapr/lib directory` into `<drill_home>/jars/3rdParty` directory:
   - `maprdb-6.1.0-mapr.jar`
   - `maprdb-6.1.0-mapr-tests.jar`
   - `maprfs-6.1.0-mapr.jar`
   - `maprfs-6.1.0-mapr-tests.jar`
   - `mapr-hbase-6.1.0-mapr.jar`
   - `mapr-hbase-6.1.0-mapr-tests.jar`
   - `mapr-streams-6.1.0-mapr.jar`
3. Copy the `mapr-streams-6.1.0-mapr.jar` file from the `/opt/mapr/lib` directory into the `<drill_home>/jars/3rdParty` directory.
4. Copy the following kafka JAR files from the `/opt/mapr/kafka/kafka-1.1.1/libs` directory into the `<drill_home>/jars/3rdParty` directory:
   - `kafka_2.11-1.1.1-mapr-1808.jar`
   - `kafka-clients-1.1.1-mapr-1808.jar`
5. Issue the following command to restart Drill:

   ```
   $ maprcli node services -name drill-bits -action restart -nodes <node
   hostnames separated by a space>
   ```

6. Log in to the Drill Web UI, and configure the kafka storage plugin. See Kafka Storage Plugin for instructions.

   Note: When configuring the kafka storage plugin, you must also include the following parameter in the storage plugin configuration:

   ```
   "streams.consumer.default.stream": "<path-to-stream>"
   ```

Usage Example

This example shows a Drill query on a MaR Streams data set made accessible to Drill through the kafka storage plugin.

For this example, tables that contain Yelp stream topics reside in a directory named /YelpStream. The kakfa storage plugin is configured with the "streams.consumer.default.stream" parameter pointing to the /YelpStream directory, as shown:

```
"streams.consumer.default.stream": "/YelpStream"
```

The USE command tells Drill to access data from only the kafka data source:

```
use kafka;
+-----+-----------------------------------+
| ok | summary |
+-----+-----------------------------------+
```

```
| true | Default schema changed to [kafka] |
+-----+-----------------------------------+
```

The SHOW TABLES command lists the tables in the /YelpStream directory configured for the kafka data source:

```
show tables;
+-------------+--------------------------+
| TABLE_SCHEMA | TABLE_NAME |
+-------------+--------------------------+
| kafka | /YelpStream:UserTable |
| kafka | /YelpStream:ReviewTable |
| kafka | /YelpStream:BusinessTable |
+-------------+--------------------------+
```

The query selects all the data from the BusinessTable in the `/YelpStream` directory, limiting the results to one row data:

```
select * from `/YelpStream:BusinessTable` limit 1;
+---+---------+----------+---------+----+-----------+-----+--------+---------+----+-

| _id | attributes | business_id | categories | city | full_address | hours
| latitude | longitude | name | neighborhoods | open | review_count | stars
| state | type | kafkaTopic | kafkaPartitionId | kafkaMsgOffset |
kafkaMsgTimestamp | kafkaMsgKey |
+---+---------+----------+---------+----+-----------+-----+--------+---------+----+-

Start the Drill Web UI

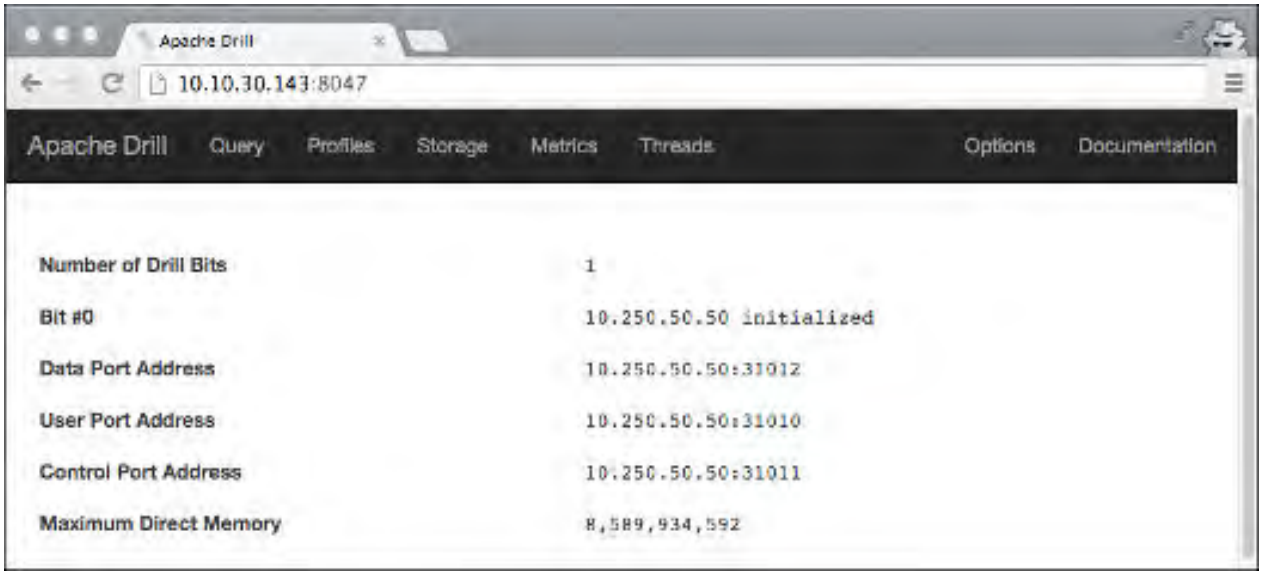
The Drill Web UI is one of several client interfaces that you can use to access Drill.

Accessing the Drill Web UI

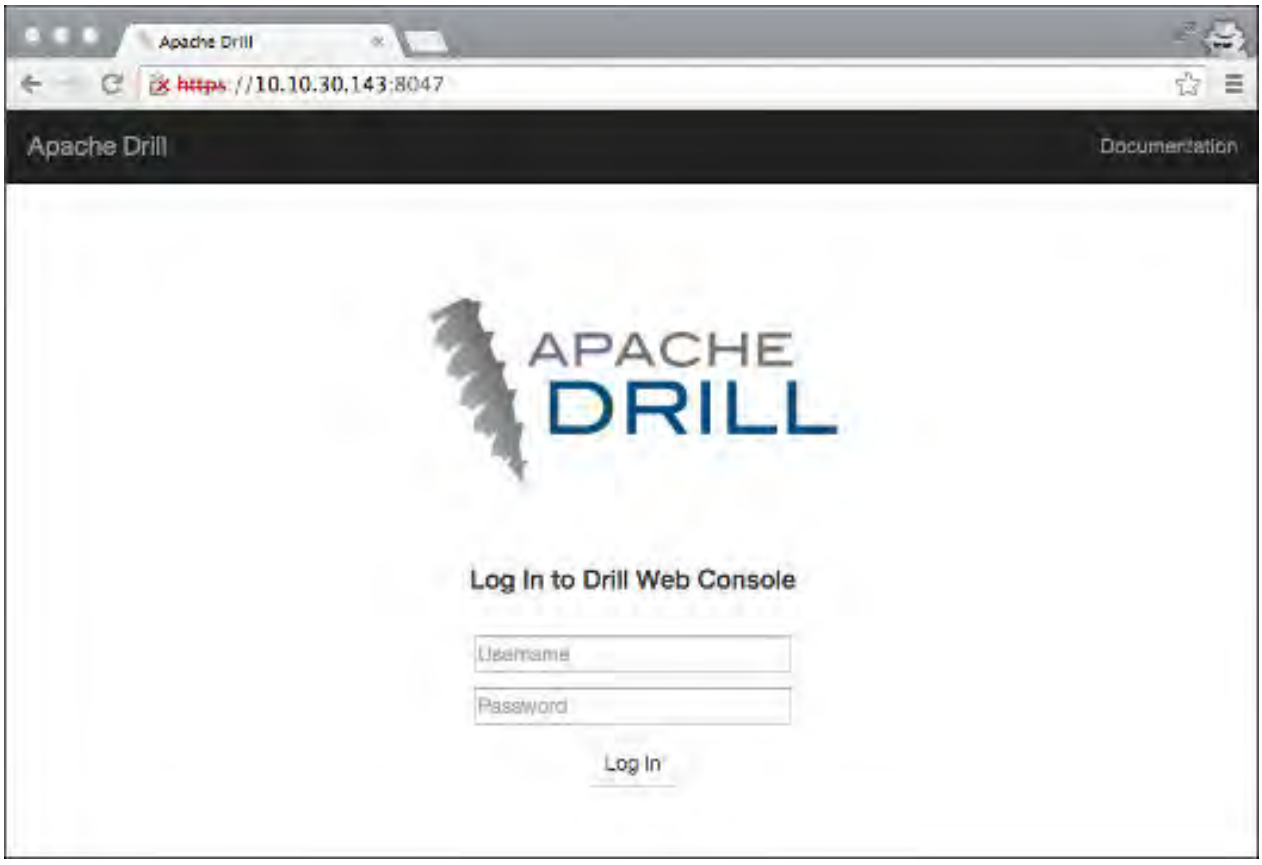
To open the Drill Web UI, launch a web browser, and go to one of the following URLs:

- If HTTPS support is disabled, use the default URL: http://<IP address or host name>:8047
- If HTTPS support is enabled, use this URL: https://<IP address or host name>:8047

If user authentication is *not* enabled, all the Drill Web UI controls appear to users and administrators, including Query, Profiles, Storage, Metrics, and Threads:

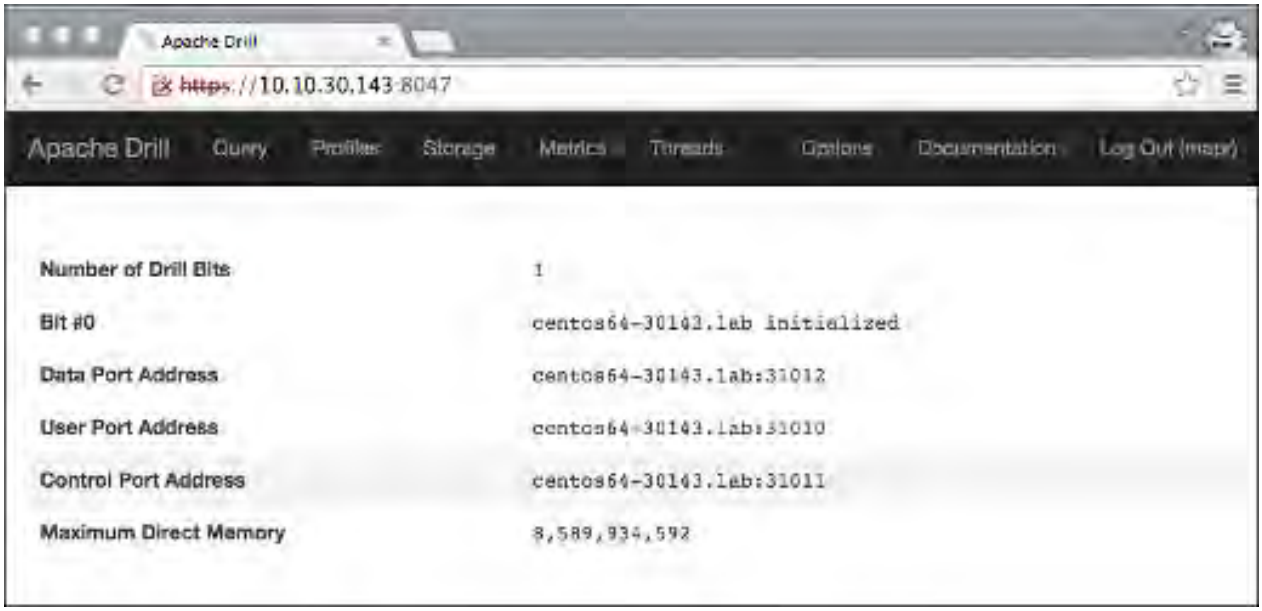


If user authentication is enabled, Drill prompts you for a user name and password:



If an administrator logs in, all the Drill Web UI controls appear, including Query, Profiles, Storage, Metrics, Threads, and Options. For administrators, the Profiles page contains the profiles of all queries executed on a cluster. Only administrators can see and use the Storage tab to view, update, or add a new storage plugin configuration. Only administrators can see and use the Threads tab, which provides information about threads running in Drill.

last-updated: Apr 11, 2022



If a non-administrative user logs in, the Drill Web UI controls are limited to Query, Metrics, and Profiles. The Profiles tab for a non-administrative user contains the profiles of all queries the user issued either through ODBC, JDBC, or the Drill Web UI.

Start the Drill Shell (SQLLine)
SQLLine is a JDBC application packaged with Drill that serves as the Drill shell. When you issue queries from the SQLLine, the SQLLine client sends the queries to the connected Drillbit (Drill node).

You can connect to Drill through SQLLine directly or through a connection-property file. If want to avoid exposing credentials, connecting through the connection-property file is recommended.

A JDBC connection string supplies the connection information to a Drill node or ZooKeeper cluster. When connecting to a ZooKeeper cluster, ZooKeeper selects the Drillbit that SQLLine connects to.

JDBC Connection String

This is an example of a JDBC connection string that connects SQLLine to drillnode1:

```
jdbc:drill:drillbit=drillnode1:31010
```

The default port on any Drill node is 31010.

Starting SQLLine

You start SQLLine from the Drill installation directory, as shown in the following example where SQLLine connects directly to a Drill node named `drillnode1`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
jdbc:drill:drillbit=drillnode1:31010
```

Connection Parameters

You can include SQLLine connection parameters in the connection string and run various shell commands, as described in Configuring the Drill Shell.

In the following example, -u is the connection parameter for the JDBC connection string, -n is the parameter for the username, and –p is the parameter for the password:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=drillnode1:31010" -n mapr -p mapr
```

In the following example, the `!connect` shell command is used to hide the password when making an authenticated connection:

```
//From /opt/mapr/drill/drill-<version>/, run:

bin/sqlline

//The sqlline prompt appears. At the prompt, provide the connection string
with the !connect property:

sqlline> !connect jdbc:drill:drillbit=drillnode1:31010
//The system prompts you for the username and password.
Enter username for jdbc:drill:drillbit=drillnode1:31010: mapr
Enter password for jdbc:drill:drillbit=drillnode1:31010: ********
```

Notice: In Drill 1.15, the SQLLine `!connect` command incorrectly requests a username and password when connecting to a secure cluster via MAPRSASL or KERBEROS authentication:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL

//!connect usage: connect <url> <username> <password> [driver]
//Driver is optional. Driver is the Apache Drill driver class,
org.apache.drill.jdbc.Driver.
```

To workaround this issue, provide your username when you connect and press Enter when prompted for the password:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL
mapr
Enter password for jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL:
```

Alternatively, you can use an empty quote in place of a username:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL ""
```

Configuration Options

You can also include configuration options, such as `schema` and `auth` (if authentication is enabled):

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs;auth=MAPRSASL"
```

Schema	The `schema` is the name of a storage plugin configuration to use as the default for queries. If you indicate the schema in the connection string, you do not have to run the `USE <schema>;` query to switch to the schema you want to use. All queries run against the schema indicated in the JDBC connection string.
Authentication	If authentication is enabled (Plain, MAPRSASL, Kerberos), include the `auth` option in the connection string. If Drill is installed on a cluster secured by the default security, set `auth=MAPRSASL`. If using Plain authentication, include the username and password, as shown: `/opt/mapr/drill/drill-<version>/bin/ sqlline -u "jdbc:drill:drillbit drillnode1:31010;schema=dfs;auth=MAPRSASL"`

Connecting to a Specific Drill Node

Indicate which Drill node you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:drillbit=<host>:<port>
```

Note that properties are case-sensitive. The `host` is the DNS or IP address of the server (Drill node). The default connection port is 31010.

Example

last-updated: Apr 11, 2022

The following example shows you how to start SQLLine with a JDBC connection string that includes the username, password, and auth parameters to authenticate to the server with Plain authentication:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=<ip-address>:<port>;auth=PLAIN" -n <username> -p
<password>
```

If you installed Drill on a a cluster secured by default security, set the `auth` type to `maprsasl`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=<ip-address>:<port>;auth=MAPRSASL"
```

Connecting to ZooKeeper

When you include the ZooKeeper nodes in the JDBC connection string, ZooKeeper selects an available Drill node for SQLLine to connect to.

Indicate the ZooKeeper cluster you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:zk=<zk-server-list>/drill/<clustername>
```

The `zk-server-list` is a comma-separated list of the ZooKeeper nodes in the cluster. The `clustername` is the unique name of the Drillbit cluster that you want to connect to.

You can locate the name of the Drillbit cluster in `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf`. The default name of the Drillbit cluster is `drillbits1`. The name is set by the `cluster-id` property. If you have multiple Drill clusters, you may want to override the Drillbit cluster name in `drill-override.conf`. However, first back-up your storage plugin configurations, as they may reset to the defaults when you change the cluster name. Restart Drill after you edit `drill-override.conf`.

Example

The following example shows you how to configure the JDBC connection string to connect SQLLine to the ZooKeeper cluster:

```
/opt/mapr/drill/drill-<version>/bin/sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-ip>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=PLAIN -n <username> -p <password>
```

The default port for ZooKeeper nodes is 5181.

If you installed Drill on a secure cluster, set the `auth` type to `MAPRSASL`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-ip>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=MAPRSASL
```

Using a Connection-Property File with SQLLine

Make sure you restrict access to the connection-property file to specific users.

Create a connection-property file named `login.properties`, as shown:

```
url:<jdbc-connection-url>
user:<username>
password:<password>

//Example
cat login.properties
```

```
url:jdbc:drill:schema=dfs;drillbit=drill-lab-node01
user:drilluser
password:letsdrill
```

To connect to Drill, run SQLLine as shown:

```
sqlline <sqlline args> <path/to/login.properties file>
```

The following examples show you how you can use the connection-property file to connect to Drill:

Example 1: Connecting to Drill via the connection-property file

Run SQLLine from `/opt/mapr/drill/drill-<version>/bin`:

```
sqlline login.properties

//List the active connection:
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01

//Exit SQLLine:
0: jdbc:drill:schema=dfs>!q
```

Example 2: Submitting a query when connecting to Drill via the connection-property file

Run SQLLine from `/opt/mapr/drill/drill-<version>/bin`:

```
sqlline -q "SELECT version FROM
sys.version" login.properties

//Run query:
0: jdbc:drill:schema=dfs> select
version from sys.version;
+----------+
| version  |
+----------+
| 1.16.0   |
+----------+
1 row selected (0.295 seconds)
```

Example 3: Use the properties command to connect to Drill via the connection-property

Run SQLLine from `/opt/mapr/drill/drill-<version>/bin`:

```
sqlline

//At sqlline the prompt, run:
sqlline> !properties /home/drilluser/
login.properties
0: jdbc:drill:schema=dfs>
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01
0: jdbc:drill:schema=dfs>
```

last-updated: Apr 11, 2022

Verify that Login Details are Secure

Run the following command to verify that login details are not exposed to other users:

```
ps -ef | grep sqlline

org.apache.drill.jdbc.Driver --maxWidt
h=10000 --color=true login.properties
drilluser     20119  1691  0 14:14
pts/1    00:00:00 grep sqlline
```

Exit SQLLine

To exit SQLLine, run `!quit`.

Start|Stop the Drill Process

You can start|stop|restart the Drill process on one or more nodes using the Control System or the following command:

```
maprcli node services -name drill-bits -action start|restart|stop -nodes
<node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

Related concepts

Drill Drivers on page 3333
HPE Ezmeral Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

Drill JDBC Drivers on page 3333
Download the Drill JDBC driver and use it on all platforms to connect BI tools, such as SQuirreL and Spotfire, to Drill. Drill also includes an embedded, open-source JDBC driver.

Hive to Drill Type Mapping

Using Drill you can read tables created in Hive that use data types in the Hive-to-Drill type mapping table. Currently, the Apache Hive version used by Drill does not support the timestamp in Unix Epoch format. The workaround is to use the JDBC format for the timestamp, which Hive accepts and Drill uses, as shown in the type mapping example.

For more information about connecting Drill to data sources, refer to Connect to Data Sources on the Apache Drill documentation web site. For information about workspaces, refer to Workspaces.

last-updated: Apr 11, 2022

Securing Drill

An administrator can install Drill with the default security configuration or manually configure custom security for Drill.

Drill supports several security features that secure the communication paths between Drill clients (such as ODBC/JDBC) and Drillbits and also between Drillbits. The following sections briefly describe the security configuration options for Drill and provide links to additional information and instructions.

MapR Default Security Configuration

Starting in MapR 6.0 and Drill 1.11 (EEP 4.0), Drill is automatically secured when you install Drill on a MapR cluster that was installed with the default MapR security configuration. The default MapR security configuration provides authentication, authorization, and encryption through the MapR-SASL mechanism, except for HTTPS, which uses SSL/TLS with form-based authentication. See Drill Default Security and SSL/TLS for Encryption for more information. You may also want to reference the following topics:

- Installing Drill, which describes some Drill installation security scenarios.
- Drill Drivers on page 3333, where you can access the JDBC and ODBC driver information and downloads required to connect to Drill when using the default security configuration.

Note: The default MapR security configuration does not include Kerberos or Plain authentication; however, you can manually configure these security mechanisms in addition to the default MapR security configuration.

Security Features Supported in a Custom Configuration

Drill supports several security features that an administrator can manually configure to secure the communication paths between the Drill client and Drillbit and also between Drillbits.

The following table lists the security features and mechanisms supported by Drill, as well as the communication paths secured by each mechanism:

Note: In the following table, Drill client refers to the Drill ODBC and JDBC clients. See Drill Drivers for ODBC and JDBC driver information.

Security Features	Supported Mechanisms	Communication Paths Secured
Authentication	MapR Security (MapR-SASL/Tickets)	• Drill client to Drillbit • Drillbit to Drillbit • Drillbit to ZooKeeper **Note:** The Drillbit creates znodes, for which ZooKeeper ACLs provide security. See Security Between ZooKeeper and Drillbits for more information.
	Kerberos	• Drill client to Drillbit • Drillbit to Drillbit
	Plain (username and password)	• Drill client to Drillbit

last-updated: Apr 11, 2022

Security Features	Supported Mechanisms	Communication Paths Secured
	Form-based	• Web client/REST API to Drillbit  **Note:** You can configure SSL/TLS for encryption.
	SPNEGO for HTTP	• Web client/REST API to Drillbit  **Note:** You can configure SSL/TLS for encryption.
Encryption	MapR Security (MapR/ Tickets)	• Drill client to Drillbit • Drillbit to Drillbit
	Kerberos	• Drill client to Drillbit • Drillbit to Drillbit
	SSL/TLS	• Drill client to Drillbit • Web client/REST API to Drillbit
Authorization	Based on filesystem permissions.	• Drill client to Drillbit
Impersonation	User Impersonation	• Drill client to Drillbit  **Note:** Drill supports user impersonation, inbound impersonation, and user impersonation with Hive authorization.
	Inbound impersonation	• Drill client to Drillbit  **Note:** Supports setting inbound impersonation policies, which are used to verify whether the user (set as the DelegationUID parameter passed in the client connection URL) can be impersonated by the connection user or not.

Views and File ACEs

In addition to the listed security features, you can create views on data to limit access to the data. You can also create file ACEs on the view definition files to protect the views.

Related concepts

Drill Drivers on page 3333
HPE Ezmeral Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

Start the Drill Shell (SQLLine) on page 3270
SQLLine is a JDBC application packaged with Drill that serves as the Drill shell. When you issue queries from the SQLLine, the SQLLine client sends the queries to the connected Drillbit (Drill node).

Connection URLs for Kerberos using JDBC Drivers to connect via SQLLine on page 3304

last-updated: Apr 11, 2022

You can use client-side connection URL parameters for Kerberos authentication in multiple combinations to authenticate a client with Drill.

Connection URL for Plain Authentication using the Apache JDBC Driver to connect via SQLLine on page 3311
When Plain authentication is enabled, each user that accesses the Drillbit process through a client, must provide username and password credentials for access.

SSL/TLS for Encryption on page 3312
You can enable SSL for Drill in a secure or unsecure cluster. SSL (Secure Sockets Layer), more recently called TLS, is a security mechanism that encrypts data passed between the Drill client and Drillbit (server). SSL also provides one-way authentication through which the Drill client verifies the identity of the Drillbit.

Configuring Drill Web UI and Web API Security on page 3323
The Drill web client and web API communicate with web browsers or web tools, like curl, through the HTTP or HTTPS. Drill uses HTTP by default.

SPNEGO for HTTP Authentication on page 3328
Drill 1.13 and later supports the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) to extend the Kerberos-based single sign-on authentication mechanism to HTTP. An administrator configures the web server (Drillbit) to use SPNEGO for authentication. Depending on the system, either the administrator or the user configures the client (web browser or web client tool) to use SPNEGO for authentication.

Roles and Privileges

Drill has USER and ADMIN roles. Each role can perform different functions in Drill.

Access in the Drill Web UI differs between users and administrators. Certain pages are exposed based on privilege. For example, only administrators can see the Storage tab and edit a storage plugin configuration.

The following sections describe a few additional differences between a user and an administrator in Drill.

USER Role

The following list notes the functions that a user can perform in Drill:

- Users can run queries on data to which they have access.
- Users can view and cancel their own queries in the Profiles tab of the Drill Web UI.
- Users can create views on data to provide granular access to that data.

Note: Each data source manages the read/write permissions.

ADMIN Role

When authentication is enabled, only Drill users assigned the administrator (ADMIN) role can perform the following tasks:

- Change system-level options by issuing the ALTER SYSTEM command or through the options tab in the Drill Web UI.
- Update a storage plugin configuration through the REST API or Drill Web UI.
- View the profiles of all queries run by all users.
- Cancel running queries that were launched by any user in the cluster.
- Shut down the Drillbit in the Drill Web UI.

Configuring USER and ADMIN Roles

You can define administrative users through the `security.admin.user_groups` and `security.admin.users` options.

The default value for `admin.users` is the `drill_process_user`. The default value for `admin.user_groups` is `drill_process_user_groups`. These options accept a comma-separated list of users or user groups.

To edit these options, use the SET command, as shown in the following examples:

```
ALTER SYSTEM SET `security.admin.user_groups` = 'drill,
%drill_process_user_groups%';
ALTER SYSTEM SET `security.admin.users` = 'user1, %drill_process_user%';
ALTER SYSTEM SET `security.admin.users` = 'user1, user2';
```

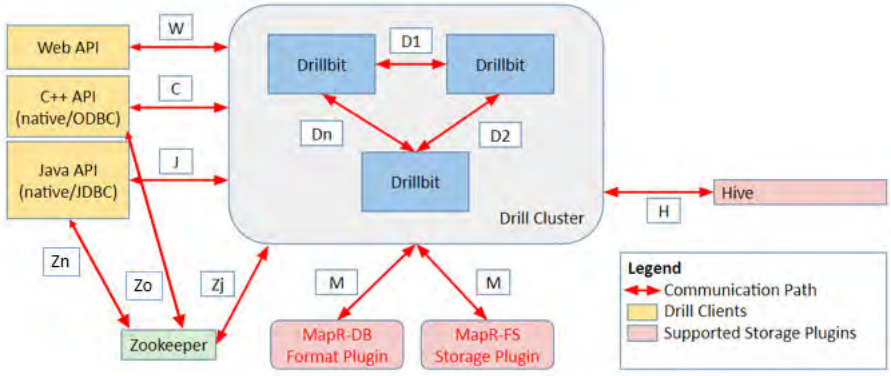
Drill Default Security

The default security configuration uses MapR-SASL (tickets) for authentication, authorization, and encryption to automatically secure the MapR cluster and ecosystem components when you install them manually or using the MapR Installer.

The default security configuration automatically secures all Drill communication paths with the following exceptions:

- The path between the web client and web server (W) uses SSL/TLS with form-based authentication.
- The path between the ODBC/JDBC client and ZooKeeper (Zn, Zo) is unsecure.

The following diagram shows the secured communication paths:



The following table describes the security support for each communication path in the diagram, along with the components involved in the communication:

Type of Security Supported	Communication Path	Component Communication
Authentication and encryption using MapR-SASL (tickets)	C	ODBC client/C++ API to Drillbits
	J	JDBC client/Java API to Drillbits
	D1, D2, Dn	Drillbit to Drillbit
	M	Drillbit to MapR Database/MapR File System

last-updated: Apr 11, 2022

	H	Drillbit to Hive **Note:** The Hive storage plugin is not secured by default and requires that you manually modify the configuration to enable security. See Configuring the Hive Storage Plugin on page 3263.
Plain authentication with SSL encryption (HTTPS enabled)	W	Web client/Web API to Web server **Note:** The HTTPS channel (Web client) uses Plain authentication to authenticate a Web client with SSL/TLS for encryption. This is configured by default in a secure 6.x cluster with Drill 1.11 or later installed. Plain authentication does not support encryption. You must enable SSL to encrypt the communication channels when using Plain authentication. See Configuring Drill Web UI and Web API Security on page 3323.
Authentication with MapR security (no encryption)	Zj	Drillbit to ZooKeeper **Note:** The Drillbit creates znodes, for which ZooKeeper *ACL*s provide security. See Security Between ZooKeeper and Drillbits on page 3322 for more information.
No security support	Zo, Zn	ODBC/JDBC client to ZooKeeper **Note:** Only znodes created for Drillbit endpoints in Zookeeper are readable by the client. All other znodes (not required by the client) are secured using ZooKeeper *ACL*s, and are only readable by Drillbits.

Note the following information:

- Kerberos and Plain authentication are not enabled or configured as part of the default security configuration. However, you can manually configure these security mechanisms in addition to the defaults. If you enable Plain authentication, you must use SSL/TLS for encryption.
- Drill clients running Drill 1.10 and earlier do not support encryption and cannot connect to Drillbits installed with the default MapR security configuration.

Connecting Drill

See Drill Drivers on page 3333. Alternatively, you can use SQLLine, the Drill shell, as shown:

Disabling Security

You can turn off the default MapR security configuration across the entire MapR cluster.

Note: If you unsecure a cluster, you must backup the Drill znodes. After the switch to unsecured, update the ACL on the Drill znodes so that Drill in an unsecured cluster can access all Drill znodes. See Security Between ZooKeeper and Drillbits on page 3322 for more information.

last-updated: Apr 11, 2022

To disable the default security configuration across an entire MapR cluster, run `configure.sh` with the `-unsecure` parameter, as shown:

```
/opt/mapr/server/configure.sh -forceSecurityDefaults [ -unsecure | -secure ]
 -C <CLDB_node> -Z <ZK_node>
```

Alternatively, you can enable security across an entire MapR cluster with the `-secure` parameter.

See Installing Drill on page 177 and configure.sh on page 2053 for more information.

Additional Notes

Performance	The default security configuration enables encryption for all network channels, which can affect Drill performance. If performance is your highest priority, install MapR and Drill without security enabled and have your security expert manually configure cluster security. Alternatively, you can install MapR and Drill with security enabled, and then disable individual Drill security settings. For example, you can edit the `drill-override.conf` file and disable encryption, leaving authentication enabled. **Note:** Manually configuring security settings when default security is enabled is not recommended.
Drill Configuration Files	The default security configuration introduces new Drill configuration files. In addition to drill-override.conf, distrib-env.sh, and drill-env.sh, Drill includes a drill-distrib.conf file. See Drill Configuration Files on page 3346 for more information. Note that modifying drill distribution-specific files is highly discouraged. To customize any Drill configuration, use `drill-override.conf` and `drill-env.sh`.
HBase	As of MapR 6.0 and Drill 1.11, HBase is no longer supported; therefore, the communication path between Drill and HBase is also not supported.

User Impersonation

Impersonation allows a service to act on behalf of a client while performing the action requested by the client. By default, user impersonation is disabled in Drill. You can configure user impersonation in the `/opt/mapr/drill/drill-<version>/drill-override.conf` file.

When you enable impersonation, Drill executes all the client requests as the user logged in to the client. Drill passes the user credentials to the filesystem, and the filesystem checks to see if the user has permission to access the data. When you enable authentication, Drill uses the pluggable authentication module (PAM) to authenticate a user's identity before the user can access the Drillbit process.

If impersonation is disabled, Drill executes all of the client requests against the file system as the user that started the Drillbit service on the node. This is typically a privileged user. The filesystem verifies that the system user has permission to access the data.

User Impersonation Example

When impersonation is disabled and user Bob issues a query through the SQLLine client, SQLLine passes the query to the connecting Drillbit. The Drillbit executes the query as the system user that started the Drill process on the node. For the purpose of this example, we will assume that the system user has full access to the filesystem. Drill executes the query and returns the results back to the client.

When impersonation is enabled and user Bob issues a query through the SQLLine client, the Drillbit uses Bob's credentials to access data in the filesystem. The filesystem checks to see if Bob has permission to access the data. If Bob has permission, Drill returns the query results to the client. If Bob does not have permission, Drill returns an error.

Impersonation Support

Drill supports impersonation with the following clients, storage plugins, and types of queries:

- **Clients**
  - ODBC
  - JDBC
  - REST API
  - Drill Web UI
- **Storage plugins**
  - MapR File System
  - MapR Database
  - Hive
- **Types of queries**

  Note: When you enable impersonation, the setting applies to queries on data and metadata. For example, if you issue the SHOW SCHEMAS command, Drill impersonates the user logged into the client to access the requested metadata. If you issue a SELECT query on a workspace, Drill impersonates the user logged in to the client to access the requested data.

  Drill applies impersonation to queries issued using the following commands:

  - SHOW SCHEMAS
  - SHOW DATABASES
  - SHOW TABLES
  - CTAS
  - SELECT
  - CREATE VIEW
  - DROP VIEW

last-updated: Apr 11, 2022

- SHOW FILES.

Note: To successfully run the CTAS and CREATE VIEW commands, a user must have write permissions on the directory where the table or view will exist. Running these commands creates artifacts on the filesystem.

Impersonation and Views
You can use views with impersonation to provide granular access to data and protect sensitive information.

When you create a view, Drill stores the view definition in a file and suffixes the file with `view.drill`. For example, if you create a view named myview, Drill creates a view file named `myview.view.drill` and saves it in the current workspace or the workspace specified, such as `dfs.views.myview`. See CREATE VIEW.

You can create a view and grant read permissions on the view to give other users access to the data that the view references. When a user queries a view on which s/he has read access, Drill impersonates the view owner to access the underlying data. If the user tries to query the data directly (instead of using the view), Drill returns a permission denied error. A user with read access to a view can create new views from the originating view to further restrict access on data.

View Permissions

A user must have write permission on a directory or workspace to create a view, as well as read access on the table(s) and/or view(s) that the view references. When a user creates a view, permission on the view is set to owner by default. Users can query an existing view or create new views from the view if they have read permissions on the view file and the directory or workspace where the view file is stored.

When users query a view, Drill accesses the underlying data as the user that created the view. If a user does not have permission to access a view, the query fails and Drill returns an error. Only the view owner or a superuser can modify view permissions to change them from owner to group or world.

The view owner or a superuser can modify permissions on the view file directly or they can set view permissions at the system or session level prior to creating any views. Any user that alters view permissions must have write access on the directory or workspace in which they are working.

Modifying Permissions on a View File

Only a view owner or a super user can modify permissions on a view file to change them from owner to group or world readable. Before you grant permission to users to access a view, verify that they have access to the directory or workspace in which the view file is stored.

Use the `chmod` and `chown` commands with the appropriate octal code to change permissions on a view file:

```
hadoop fs -chmod <octal code> <file_name>
hadoop fs -chown <user>:<group> <file_name>
//hadoop fs -chmod 750 employees.view.drill
```

Modifying SYSTEM|SESSION Level View Permissions

Use the `ALTER SESSION|SYSTEM` command with the `new_view_default_permissions` parameter and the appropriate octal code to set view permissions at the system or session level prior to creating a view.

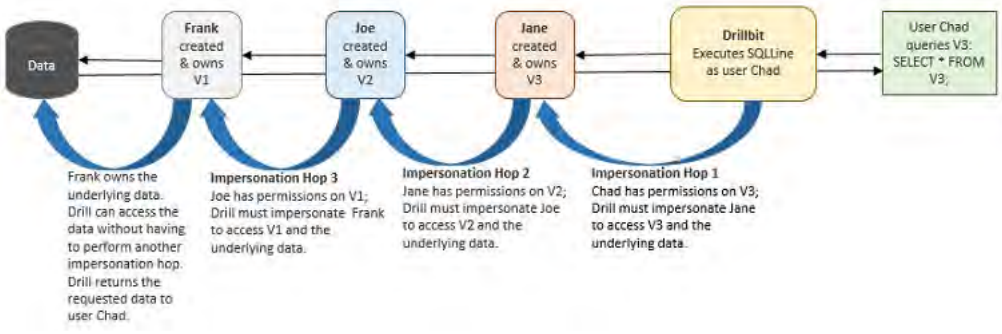
```
ALTER SESSION SET `new_view_default_permissions` = '<octal_code>';
ALTER SYSTEM SET `new_view_default_permissions` = '<octal_code>';
//ALTER SESSION SET `new_view_default_permissions` = '777';
```

After you set this parameter, Drill applies the same permissions on each view created during the session or across all sessions if set at the system level.

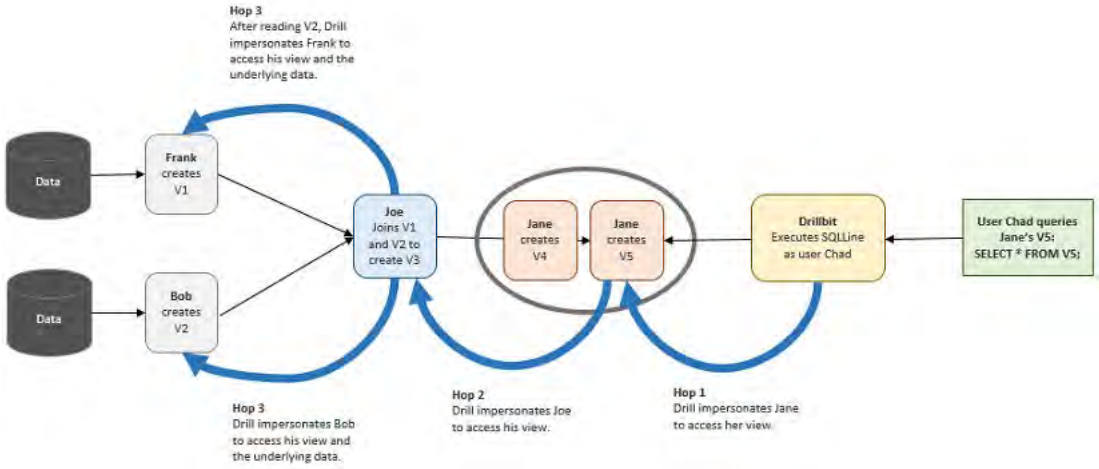
Chained Impersonation
You can configure Drill to allow chained impersonation on views when you enable impersonation in the `drill-override.conf` file. Chained impersonation controls the number of identity transitions that Drill can make when a user queries a view. Each identity transition is equal to one hop.

An administrator can set the maximum number of hops for impersonation to limit the number of times that Drill can impersonate a different user when other users query a view. The default maximum number of hops is set at 3. When the maximum number of hops is set to 0, Drill does not allow impersonation chaining, and a user can only read data for which they have direct permission to access. An administrator may set the chain length to 0 to protect highly sensitive data.

The following diagram depicts a scenario where the maximum hop number is set to 3, and Drill must impersonate three users to access data when Chad queries a view that Jane created:



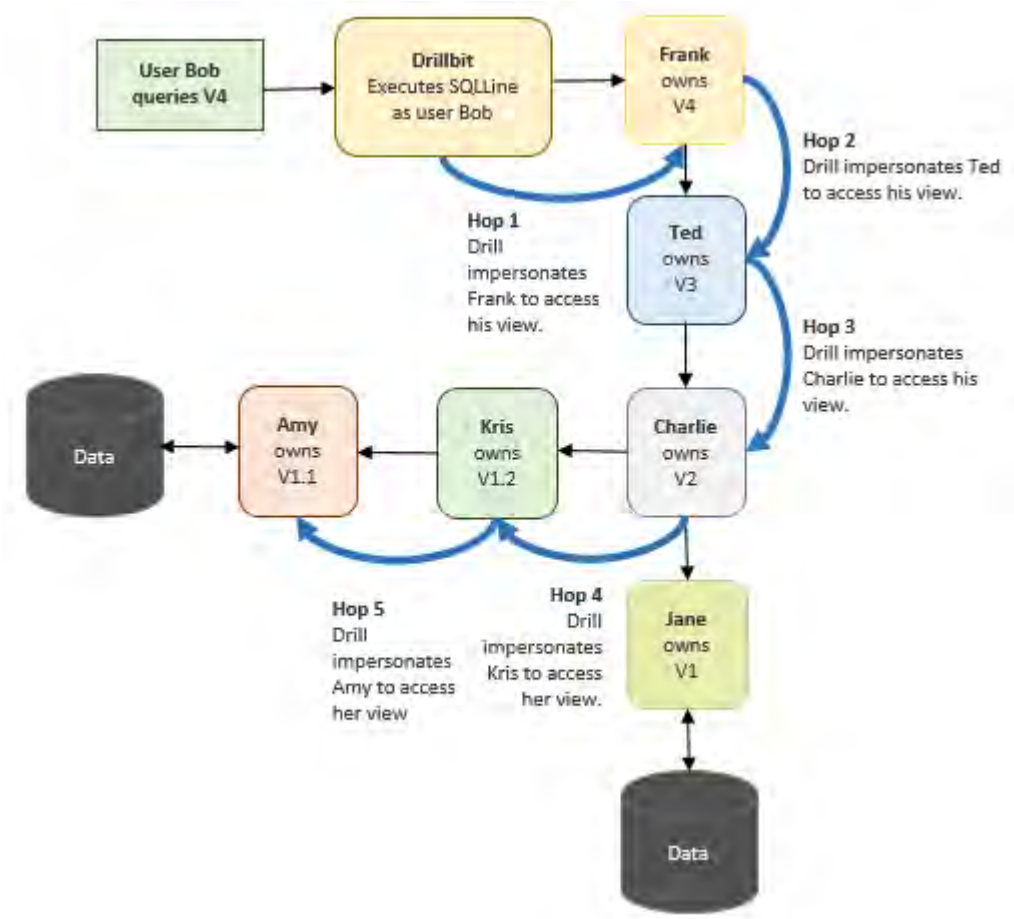
In the previous example, Joe created V2 from the view that user Frank created. In the following example, Joe created V3 by joining a view that Frank created with a view that Bob created.



Although V3 was created by joining two different views, the number of hops remains at 3 because Drill does not read the views at the same time. Drill reads V2 first and then reads V1.

In the next example, Bob queries V4 which was created by Frank. Frank's view was created from several underlying views. Charlie created V2 by joining Jane's V1 with Kris's V1.2. Kris's V1.2 was created from Amy's V1.1, increasing the complexity of the chaining. Assuming that the hop limit is set at 4, this scenario exceeds the limit.

last-updated: Apr 11, 2022



When Bob queries Franks's view, Drill returns an error stating that the query cannot complete because the number of hops required to access the data exceeds the maximum hop setting of 4.

If users encounter this error, the administrator can increase the maximum hop setting to accommodate users running queries on views.

Configuring Impersonation and Chaining

Impersonation allows a service to act on behalf of a client while performing the action requested by the client. Chaining is a system-wide setting that applies to all views. Currently, Drill does not provide an option to allow different chain lengths for different views.

Complete the following steps on each Drillbit node to enable user impersonation, and set the maximum number of chained user hops that Drill allows:

1. Navigate to `<drill_installation_directory>/conf/` and edit `drill-override.conf`.

last-updated: Apr 11, 2022

2. Under `drill.exec`, add the following:

```
drill.exec.impersonation: {
                  enabled: true,
                  max_chained_user_hops: 3
  }
```

   Alternatively, you can nest impersonation within the `drill.exec` block, as shown in the following example:

```
drill.exec: {
           cluster-id: "cluster_name",
           zk.connect:
"<hostname>:<port>,<hostname>:<port>,<hostname>:<port>",
           sys.store.provider.zk.blobroot: "hdfs://",
           impersonation: {
             enabled: true,
             max_chained_user_hops: 3
           }
         }
```

3. Set the maximum number of chained user hops.

4. In `<drill_installation_directory>/conf/drill-env.sh`, add one of the following lines:

   - If the underlying filesystem has MapR security enabled, add the following line: `export MAPR_TICKETFILE_LOCATION=/opt/mapr/conf/maprusertickет`
   - If the underlying filesystem is not secure, add the following line: `export MAPR_IMPERSONATION_ENABLED=true`

5. Restart the Drillbit process on each Drill node.

   ```
   maprcli node services -name drill-bits -action restart -nodes
   <node-hostnames-separated-by-a-space> -f
   ```

Example: Impersonation and Chaining
This example demonstrates how to use impersonation and chaining to limit access to data. Impersonation allows a service to act on behalf of a client while performing the action requested by the client. Chaining controls the number of identity transitions that Drill can make when a user queries a view.

Note: The number of identity transitions in controled by the `max_chained_user_hops` option in the `drill-override.conf` file. See Chained Impersonation and Configuring Impersonation and Chaining for more information.

Frank is a senior HR manager at a company. Frank has access to all of the employee data because he is a member of the hr group. Frank created a table named “employees” in his home directory to store the employee data he uses. Only Frank has access to this table.

```
drwx------ frank:hr /user/frank/employees
```

Each record in the employees table consists of the following information: emp_id, emp_name, emp_ssn, emp_salary, emp_addr, emp_phone, emp_mgr

Frank needs to share a subset of this information with Joe who is an HR manager reporting to Frank. To share the employee data, Frank creates a view called emp_mgr_view that accesses a subset of the data. The emp_mgr_view filters out sensitive employee information, such as the employee social security

last-updated: Apr 11, 2022

numbers, and only shows data for the employees that report directly to Joe. Frank and Joe both belong to the mgr group. Managers have read permission on Frank's directory.

```
rwxr----- frank:mgr /user/frank/emp_mgr_view.view.drill
```

The emp_mgr_view.view.drill file contains the following view definition:

```
(view definition: SELECT emp_id, emp_name, emp_salary, emp_addr, emp_phone
FROM `/user/frank/employee` WHERE emp_mgr = 'Joe')
```

When Joe issues SELECT * FROM emp_mgr_view, Drill impersonates Frank when accessing the employee data, and the query returns the data that Joe has permission to see based on the view definition. The query results do not include any sensitive data because the view protects that information. If Joe tries to query the employees table directly, Drill returns an error or null values.

Because Joe has read permissions on the emp_mgr_view, he can create new views from it to give other users access to the employee data even though he does not own the employees table and cannot access the employees table directly.

Joe needs to share employee contact data with his direct reports, so he creates a special view called emp_team_view to share the employee contact information with his team. Joe creates the view and writes it to his home directory. Joe and his reports belong to a group named joeteam. The joeteam group has read permissions on Joe's home directory so they can query the view and create new views from it.

```
rwxr----- joe:joeteam /user/joe/emp_team_view.view.drill
```

The emp_team_view.view.drill file contains the following view definition:

```
(view definition: SELECT emp_id, emp_name, emp_phone FROM `/user/frank/
emp_mgr_view.drill`);
```

When anyone on Joe's team issues SELECT * FROM emp_team_view, Drill impersonates Joe to access the emp_team_view and then impersonates Frank to access the emp_mgr_view and the employee data. Drill returns the data that Joe's team has can see based on the view definition. If anyone on Joe's team tries to query the emp_mgr_view or employees table directly, Drill returns an error or null values.

Because Joe's team has read permissions on the emp_team_view, they can create new views from it and write the views to any directory for which they have write access. Creating views can continue until Drill reaches the maximum number of impersonation hops (chained impersonation).

User Impersonation with Hive

You can configure Drill impersonation with Hive impersonation to authorize access to metadata in the Hive metastore repository and data in the Hive warehouse. Drill impersonation works with Hive when Hive has impersonation enabled and optionally, storage based or SQL standard based authorization enabled. Drill impersonation can also work with Hive when the Hive metastore has Kerberos enabled on a secure cluster. Currently, Drill does not support Hive configured with Sentry authorization.

Storage Based Authorization

Hive storage based authorization is a remote metastore server security feature that uses the underlying filesystem permissions to determine permissions on databases, tables, and partitions. The permissions a user or group has on directories in the filesystem determines access to data. Because the filesystem controls access at the directory and file level, storage based authorization cannot control access to data at the column or view level.

You manage user and group privileges through permissions and access controls in the distributed filesystem. DDL statements that manage permissions, such as GRANT and REVOKE, do not have any effect on permissions in the storage based authorization model.

For more information, see Storage Based Authorization in the Metastore Server.

SQL Standard Based Authorization

The SQL standard based authorization model can control which users have access to columns, rows, and views. SQL standard based authorization is configured in HiverServer2 and enforced during query processing. Users with the appropriate permissions can issue the GRANT and REVOKE statements to manage privileges from Hive.

For more information, see SQL Standard Based Hive Authorization.

Prerequisites

To configure user impersonation with Hive, the system must meet the following requirements:

- MapR version 4.1 or later
- Drill installed with Drillbits running as the `mapr` user
- Supported version of Hive installed with the following:
  - User impersonation enabled
  - Configured Hive remote metastore repository
  - (Optional) SQL standard based authorization or storage based authorization configured

Note: See EEP Components and OS Support on page 5536 for supported versions of Hive.

Configuration

Complete the steps listed in Configuring User Impersonation with Hive.

Configuring User Impersonation with Hive

Complete the following steps on a secure or insecure MapR cluster to configure user impersonation with Hive:

Step 1: Modify drill-env.sh

Modify `<DRILL_HOME>/conf/drill-env.sh` to include the required environment variables on each Drill node.

Insecure Cluster	On an insecure cluster, include the following environment variable: `export MAPR_IMPERSONATION_ENABLED=true`

Secure Cluster	On a secure cluster, include the following environment variables:
	`export DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Djava.security.auth.login.config=/opt/mapr/conf/mapr.login.conf -Dzookeeper.sasl.client=true"`
	`export DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dmapr_sec_enabled=true -Dhadoop.login=maprsasl_keytab -Dzookeeper.saslprovider=com.mapr.security.maprsasl.MaprSaslProvider -Dmapr.library.flatclass"`

last-updated: Apr 11, 2022

```
export MAPR_TICKETFILE_LOCATION=/opt/
mapr/conf/maprusertickет
```

Step 2: Modify drill-override.conf
For secure and inecure clusters, modify `<DRILL_HOME>/conf/drill-override.conf` on each Drill node to enable impersonation in Drill, and set the maximum number of chained user hops that Drill allows.

Add the following configuration properties to the `drill.exec` block in `drill-override.conf`:

```
drill.exec: {
 cluster-id: "<drill_cluster_name>",
 zk.connect: "<hostname>:5181,<hostname>:5181,<hostname>:5181"
 impersonation: {
       enabled: true,
       max_chained_user_hops: 3
 }
}
```

Step 3: Modify the Hive Storage Plugin in Drill
Modify the Hive storage plugin configuration in the Drill Web UI based on the authorization and security scenario for the cluster. You can only access the Drill Web UI for a running Drillbit.

Complete the following steps to modify the Hive storage plugin configuration:

1. Navigate to `http://<drillbit_hostname>:8047`, and select the **Storage** tab.
2. Click **Update** next to the hive option.
3. In the configuration window, add the required properties based on the authorization type and security scenario:

Storage Based Authorization or No Authorization Enabled

For a *insecure cluster*, add the following properties to the configuration:

```
{
 type:"hive",
 enabled: true,
 configProps : {

"hive.metastore.uris" : "thrift://
<metastore_hostname>:9083",
   "fs.default.name" : "maprfs:///",
   "hive.metastore.sasl.enabled" :
"false",
   "hive.server2.enable.doAs" :
"true",

"hive.metastore.execute.setugi" :
"true"
 }
}
```

For a *secure cluster*, add the following properties to the configuration:

```
{
"type": "hive",
"enabled": true,
```

```
"configProps": {
  "hive.metastore.uris": "thrift://
<metastore_hostname>:9083",
  "fs.default.name": "maprfs:///",
  "hive.server2.enable.doAs": "true"
   }
}
```

Add the following additional properties if the Hive metastore is configured with Kerberos in a secure cluster; include a comma after each line except for the last:

```
"hive.metastore.kerberos.principal":
 "hive/<metastore_thrift_server>"
"hive.metastore.sasl.enabled":
"true"
```

SQL Standard Based Authorization

For an *insecure cluster*, add the following properties to the configuration:

```
{
 type:"hive",
 enabled: true,
 configProps : {
   "hive.metastore.uris" :
"thrift://
<metastore_hostname>:9083",
   "fs.default.name" : "maprfs:///",

"hive.security.authorization.enabled
" : "true",

"hive.security.authenticator.manager
" :
"org.apache.hadoop.hive.ql.security.
SessionStateUserAuthenticator",

"hive.security.authorization.manager
" :
"org.apache.hadoop.hive.ql.security.
authorization.plugin.sqlstd.SQLStdHi
veAuthorizerFactory",
   "hive.metastore.sasl.enabled" :
"false",
   "hive.server2.enable.doAs" :
"false",

"hive.metastore.execute.setugi" :
"false"
 }
}
```

For a *secure cluster*, add the following properties to the configuration:

```
{
"type": "hive",
"enabled": true,
"configProps": {
```

```
  "hive.metastore.uris": " thrift://
<metastore_hostname>:9083",
  "fs.default.name": "maprfs:///",

"hive.security.authorization.enabled
": "true",

"hive.security.authenticator.manager
":
"org.apache.hadoop.hive.ql.security.
SessionStateUserAuthenticator",

"hive.security.authorization.manager
":
"org.apache.hadoop.hive.ql.security.
authorization.plugin.sqlstd.SQLStdHi
veAuthorizerFactory",
  "hive.server2.enable.doAs":
"false",
  "hive.metastore.execute.setugi":
"true"
 }
}
```

Add the following additional properties if the Hive metastore is configured with Kerberos in a secure cluster; include a comma after each line except for the last:

```
"hive.metastore.kerberos.principal":
 "hive/<metastore_thrift_server>"
"hive.metastore.sasl.enabled":
"true"
```

Step 4: Restart Warden
Run the following command on all nodes to restart the Warden service:

```
service mapr-warden restart
```

If you have `clush` installed, you can run the following command to restart Warden on all nodes at once:

```
clush -a "service mapr-warden restart"
```

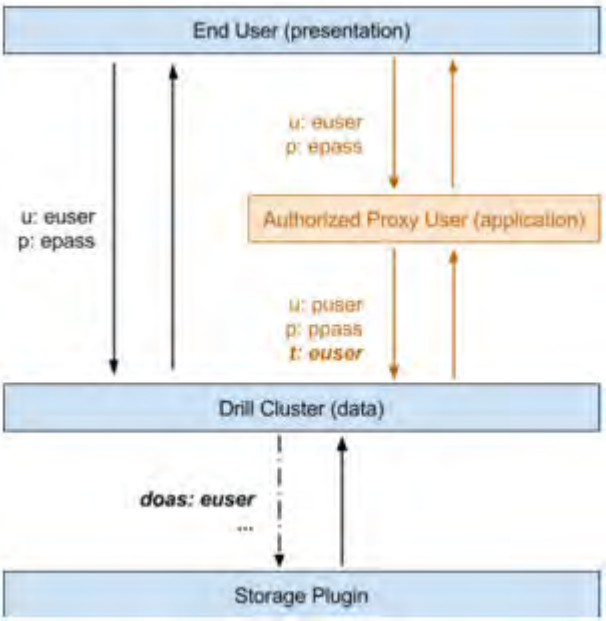
Inbound Impersonation
An administrator can define inbound impersonation policies to impersonate the end user.

Drill supports user impersonation where queries run as the user that created a connection. However, this user is not necessarily the end user who submits the queries. For example, in a classic three-tier architecture, the end user interacts with Tableau Desktop, which communicates with a Tableau Server, which in turn communicates with a Drill cluster. In this scenario, a proxy user creates a connection, and the queries are submitted to Drill by the proxy user on behalf of the end user, and not by the end user directly. In this particular case, the query needs run run as the end user.

The proxy user must be authorized to submit queries on behalf of the specified end user. Otherwise, any user can impersonate another user. The query runs as the end user, and data authorization is based on this user's access permissions. Note that without authentication enabled in both communication channels, a user can impersonate any other user.

Drill trusts proxy users to provide the correct end user identity information. Drill does not authenticate the end user. The proxy user (application) is responsible for end user authentication, which is usually enabled.

The following diagram shows how identity is propagated through various layers (with authentication enabled). The flow on the left is Drill with user impersonation enabled. The flow on the right is Drill with user impersonation and inbound impersonation enabled. `t:euser` is a property on the connection (u is `username`, pis `password`, `t` is `impersonation_target`).



The following topic provides instructions for configuring inbound impersonation:

Configuring Inbound Impersonation

Administrators can configure inbound impersonation in the `drill-override.conf` file.

Complete the following steps to enable inbound impersonation:

1. If user impersonation is not enabled, you must enable it before configuring inbound impersonation. To enable user impersonation, edit `/opt/mapr/drill/drill-<version>/drill-override.conf` and set the option to true, as shown:

```
{
      drill.exec.impersonation.enabled: true,
      ...
      }
```

2. Define inbound impersonation policies. For example, the following ALTER SYSTEM statement authorizes:

   - `puser1` to impersonate any user (use * as a wildcard character)
   - `puser2` to impersonate `euser1` and all users in `egroup2`
   - all users in `pgroup3` to impersonate all users in `egroup3`

```
ALTER SYSTEM SET `exec.impersonation.inbound_policies`='[
  { proxy_principals : { users: ["puser1"] },
    target_principals: { users: ["*"] } },
  { proxy_principals : { users: ["puser2"] },
    target_principals: { users: ["euser1"], groups :  ["egroup2"] } },
  { proxy_principals : { groups: ["pgroup3"] },
    target_principals: { groups: ["egroup3"] } } ]';
```

last-updated: Apr 11, 2022

Policy format:

```
{ proxy_principals : { users : ["...", "..."], groups : ["...", "..."] },
  target_principals: { users : ["...", "..."], groups : ["...",
"..."] } }
```

3. Ensure that the proxy user (application) passes the username of the impersonation target user to Drill when creating a connection through the `impersonation_target` connection property. For example, through sqlline:

```
bin/sqlline -u
"jdbc:drill:schema=dfs;zk=myclusterzk;impersonation_target=euser1" -n
puser1 -p ppass1
```

Note: In this example, `puser1` is the user submitting the queries. This user is authenticated. Since this user is authorized to impersonate any user, queries through the established connection are run as `euser1`.

https://drill.apache.org/docs/configuration-options-introduction/#system-options

MapR Security (Tickets)

Drill supports authentication and encryption through the MapR Security (tickets) security mechanism. Authentication is the process of establishing confidence of authenticity. Encryption is the process of converting information or data from plain text into ciphertext to prevent unauthorized access. An administrator can manually configure Drill to use MapR Security. When MapR Security is enabled, all Drill clients, such as JDBC and ODBC, must connect to Drillbits through MapR Security.

The MapR Security mechanism secures the communication path between the Drill client, such as JDBC/ODBC and Drillbit, Drillbit and ZooKeeper, and also between Drillbits.

Note: The Drill web communication path (web client to web server) does not support MapR Security-based authentication and encryption.

Note: The Apache JDBC driver packaged with Drill does not support MapR Security.

Configuration parameters in the Drill startup configuration file, `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`, enable or disable authentication and encryption.

Prerequisites

- Ensure that your MapR cluster is secure. To manually configure secure clusters with MapR Security, see Enable Wire-Level Security.
- When you configure Drill to use encryption, authentication must also be configured and enabled with the encryption-specific configurations.
- For encryption and authentication to work together, the Drill client and Drillbits must all run Drill 1.11 or later. Drill clients running earlier versions of Drill cannot connect to Drillbits when encryption is enabled.
- The client-side should have created a user mapr ticket for the authenticating user. See maprlogin for more information.

Post-requisite

You must restart the Drillbit process on each node after you enable security and/or modify the configuration options, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

Download and configure the MapR-specific JDBC or ODBC Drill drivers. See Drill Drivers for more information.

The following topics provide configuration information to enable authentication and encryption in Drill:

Configuring Authentication
An administrator can enable MapR Security as the only authentication mechanism, or in addition to other mechanisms, such as Kerberos and Plain authentication in `drill-override.conf`.

Note: When Drill is installed on the MapR Data Platform, Drill distribution defaults are stored in the `drill-distrib.conf` file. To override the defaults, you must explicitly disable them in the `drill-override.conf` file.

The following sections provide configuration examples for several configuration scenarios:

Note: For client-side configuration, see Drill Drivers.

Example 1: Drill Client to Drillbit Authentication using MapR Security Only

```
drill.exec:{
              security: {
                 user.auth.enabled: true,
                 auth.mechanisms : ["MAPRSASL"]
          }
}
```

Note: Drill executes all queries as a service or process user when impersonation is disabled.

Example 2: Drill Client to Drillbit Authentication with User Impersonation using MapR

```
drill.exec:{
                security: {
                   user.auth.enabled: true,
                   auth.mechanisms : ["MAPRSASL"],
                    }
                impersonation: {
                   enabled: true,
                   max_chained_user_hops: 3
              }
        }
```

Note: Drill executes all queries as the authenticated (ticket) user when impersonation is enabled. The client to Drillbit communication path will not be encrypted.

Example 3: Drill Client to Drillbit using Multiple Authentication Mechanisms

```
drill.exec:{
                 security: {
                     user.auth.enabled: true,
                     user.auth.impl: "pam4j",
                     security.user.auth.packages +=
"org.apache.drill.exec.rpc.user.security",
                     user.auth.pam_profiles: ["sudo", "login",
```

```
"mapr-admin"],
                     auth.mechanisms : ["MAPRSASL", "KERBEROS", "PLAIN"],
                     auth.principal : "mapr/_host@REALM.COM",
                     auth.keytab : "/opt/mapr/conf/mapr.keytab"
                   },
                  impersonation: {
                    enabled: true,
                    max_chained_user_hops: 3
              }

          }
```

Example 4: Drillbit to Drillbit Authentication using MapR Security

```
drill.exec:{
              security: {
                  auth.mechanisms : ["MAPRSASL"],
                  bit.auth.enabled : true
                  bit.auth.mechanism : "MAPRSASL"
       }
}
```

Example 5: Drill Client to Drillbit and Drillbit to Drillbit Authentication using MapR Security

```
drill.exec {
              security: {
                  user.auth.enabled: true,
                  auth.mechanisms : ["MAPRSASL"],
                  bit.auth.enabled : true,
                  bit.auth.mechanism : "MAPRSASL"
                     },
              impersonation: {
                   enabled: true,
                   max_chained_user_hops: 3
              }
            }
```

Configuring Encryption
An administrator can enable encryption with MapR Security (tickets).

Note: When the `sasl_encrypt` (for JDBC) or `EnforceSaslEncrypt` (for ODBC) connection parameter is set to `"true"` or `1`, the Drill client only accepts encrypted connections. If the client tries connecting to a Drillbit with encryption disabled, the connection fails.

Note: For client-side configuration, see Drill Drivers.

Set the encryption options to `"true"` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`.

The following table lists the encryption configuration options with their descriptions and default values:

Note: If you installed Drill on a MapR cluster that was installed with the default MapR security configuration, the following options are set to "true" by default.

Option	Description	Default
drill.exec.security.user.encryption.sasl.enabled	Determines if encryption on the server is enabled for negotiating privacy with the Drill client.	false

drill.exec.security.bit.encryption.sasl.enabled	Determines if the server is enabled for negotiating privacy with another Drillbit.	false

The following sections provide configuration examples for Drill client to Drillbit encryption and Drillbit to Drillbit encryption.

Example 1: Drill Client to Drillbit Connection with MapR Security Authentication and Encryption
In the following server configuration, the Drill client connection to the Drillbit is encrypted using the MapR Security mechanism when the client is running with encryption support.

Note: Drill clients running Drill 1.10 and earlier cannot connect to the Drillbit through MapR Security with encryption enabled.

```
drill.exec {
            security: {
                user.auth.enabled: true,
                auth.mechanisms : ["MAPRSASL"]
                user.encryption.sasl.enabled : true
                    }
                }
```

Note: Drill executes all queries as a service or process user when impersonation is disabled.

Example 2: Drillbit to Drillbit Connection with MapR Security Authentication and Encryption
The following configuration authenticates and encrypts the path between Drillbits using the MapR Security mechanism.

```
drill.exec {
              security: {
                  auth.mechanisms : ["MAPRSASL"],
                  bit.auth.enabled : true
                  bit.auth.mechanisms : "MAPRSASL"
                  bit.encryption.sasl.enabled : true
        }
}
```

Example 3: Drill Client to Drillbit and Drillbit to Drillbit Connection with MapR Security Authentication and Encryption
The following configuration authenticates and encrypts the path between the Drill client and Drillbit, and between Drillbits using the MapR Security mechanism.

```
drill.exec {
              security: {
                 user.auth.enabled: true,
                 auth.mechanisms : ["MAPRSASL"],
                 user.encryption.sasl.enabled : true

                 bit.auth.enabled : true
                 bit.auth.mechanism : "MAPRSASL"
                 bit.encryption.sasl.enabled : true
                    }
                }
```

Note: Drill executes all queries as a service or process user when impersonation is disabled.

last-updated: Apr 11, 2022

Example 4: Drill Client to Drillbit and Drillbit to Drillbit Connection with MapR Security Authentication and Encryption and Impersonation Enabled
The following configuration authenticates and encrypts the path between the Drill client and Drillbit, and between Drillbits using the MapR Security mechanism.

```
drill.exec {
              security: {
                 user.auth.enabled: true,
                 auth.mechanisms : ["MAPRSASL"],
                 user.encryption.sasl.enabled : true

                 bit.auth.enabled : true
                 bit.auth.mechanism : "MAPRSASL"
                 bit.encryption.sasl.enabled : true
                    },
            impersonation: {
                   enabled: true,
                   max_chained_user_hops: 3
              }
          }
```

Note: Drill executes all queries as the authenticated (ticket) user when impersonation is enabled.

Example 5: Drill Client to Drillbit Authentication and Encryption Enabled using Multiple Mechanisms and Drillbit to Drillbit Authentication using MapR Security
The following configuration authenticates and encrypts the connection between the Drill client and Drillbit using multiple authentication mechanisms, and also authenticates and encrypts the connection between Drillbits using the MapR security mechanism.

Note: Plain authentication not supported in this configuration.

```
drill.exec {
              security: {
                  user.auth.enabled: true,
                  auth.mechanisms : ["MAPRSASL", "KERBEROS"],
                  auth.principal : "mapr/_host@REALM.COM",
                  auth.keytab : "/opt/mapr/conf/mapr.keytab",
                  user.encryption.sasl.enabled : true,
                  bit.auth.enabled : true,
                  bit.auth.mechanism : "MAPRSASL",
                  bit.encryption.sasl.enabled : true
                      }
              impersonation: {
                  enabled: true,
                  max_chained_user_hops: 3
              }
           }
```

Note: Drill executes all queries as a service or process user when impersonation is disabled.

Kerberos
Drill supports Kerberos v5 network security authentication and encryption. Kerberos is a network authentication protocol built on symmetric-key cryptography. Kerberos eliminates the need to store passwords locally or send them over the network and reduces the risk of impersonation.

Kerberos provides a security infrastructure called a Kerberos Realm. A Kerberos Realm is comprised of clients, services or hosts, and a KDC (key-distribution center). The KDC is a trusted third-party service that

generates tickets to coordinate authentication between a client and server or host. Tickets are cached on the client machine, which allows for single sign-on.

Clients use a password or a special file called a “keytab” to get tickets from the KDC. Clients exchange the tickets and secret keys with the KDC and service or host to prove their identity for access to the requested service. This authentication process of exchanging tickets and secret keys runs in the background, unseen by the user trying to access the service. When a client request to access a service is granted, a unique session key is established between the client and service. The unique session key proves the authenticity of the user. The session key is used for all communication between the client and service. Kerberos also supports encryption between the client and server to prevent data theft from a man-in-the-middle attack during communication.

A KDC administrator must create the password or keytab for the clients and servers, as well as a principal (a name for the user or server identity) to securely authenticate using the Kerberos infrastructure.

Note: Proper setup, configuration, administration, and usage of a Kerberos environment is beyond the scope of this documentation. See the MIT Kerberos documentation for more detailed information about Kerberos.

The following sections list the prerequisites for using Kerberos with Drill and describe the authentication process.

Prerequisites

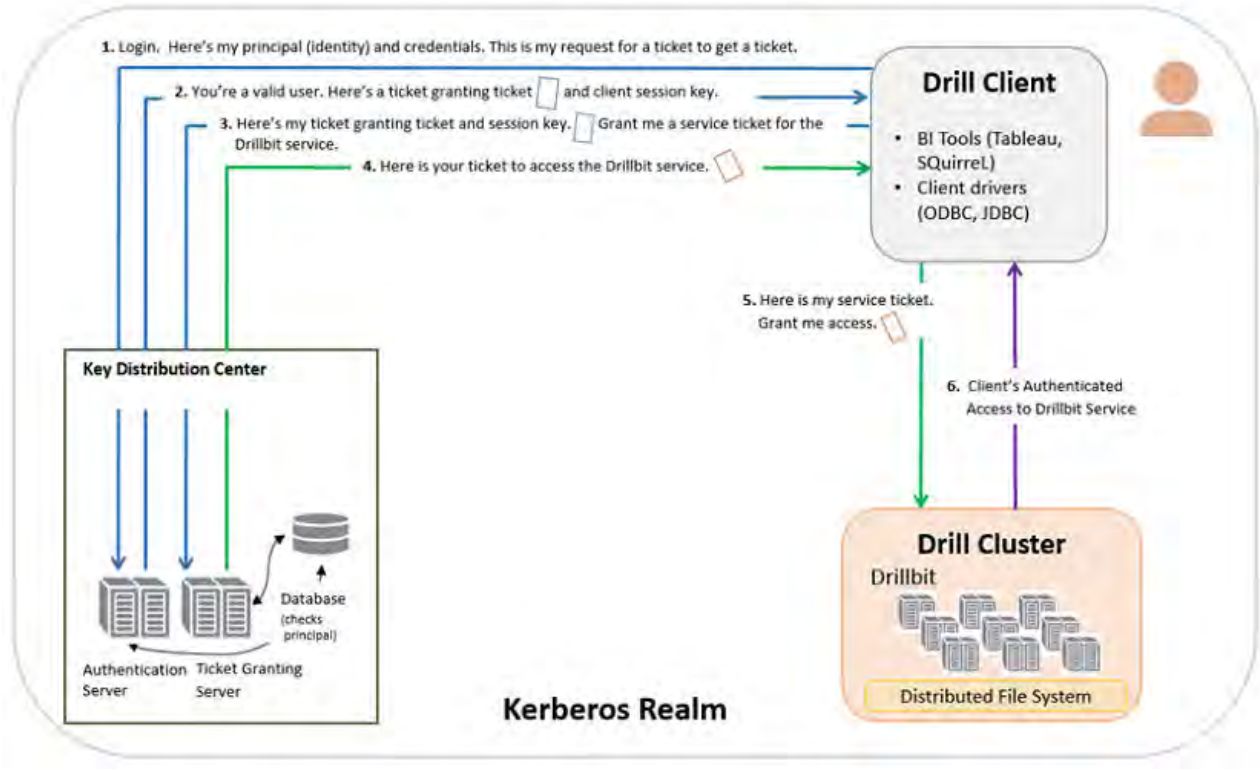
- The MapR Drill driver includes the required Kerberos plugin to authenticate to secure Kerberos Drill clusters. To use Kerberos with Drill, you must have a working Kerberos infrastructure, which Drill does not provide.
- Either a ticket granting ticket (TGT) is pre-generated on the client node, or a keytab file and the client principal is available to provide in the connection URL for Kerberos authentication between the Drill client and Drill server. Drill does not generate the TGT.
- You must be working in a Linux-based or Windows Active Directory (AD) Kerberos environment with secure clusters and have a Drill server configured for Kerberos.

Client Authentication Process

This section provides a high-level overview of the Kerberos client authentication process. For this overview, assume that Kerberos credentials are present in the client.

The following diagram shows the process of authenticating a client:

last-updated: Apr 11, 2022



1. The client sends a request for a ticket granting ticket that contains the user principal to the Kerberos KDC, a network service that supplies tickets and temporary session keys.
2. The authentication server validates the principal's identity and sends the client a ticket granting ticket and session key encrypted with a secret key. A session key is a temporary encryption key used for one login session.
3. Using the ticket granting ticket, the principal requests access to a Drillbit service from the ticket granting server.
4. The ticket granting server checks for a valid ticket granting ticket and the principal identity. If the request is valid, the ticket granting server returns a ticket granting service ticket.
5. The client uses the service ticket to request access to the Drillbit.
6. The Drillbit service has access to the keytab, a file that contains a list of keys for principals. The key allows the service to decrypt the client's ticket granting service ticket, identify the principal, and grant access.

Server Authentication Process

For Kerberos server authentication information, see the MIT Kerberos administration documentation.

Configuring Drill with Kerberos

The topics listed below provide configuration and connection information.

Configuring Authentication and Encryption
To enable authentication and encryption, you must create a Kerberos principal identity and a keytab file. You add the principal and keytab file to `<DRILLINSTALL_HOME>/conf/drill-override.conf` with the specified configuration parameters. In addition, you can configure a mapping from a Kerberos principal to a Drill user account. This mapping is used by a Drillbit to convert an authenticated client principal to

last-updated: Apr 11, 2022

a corresponding Kerberos short name, which is used to determine administrator privileges for the client principal. After you complete the configuration steps, restart the Drillbit.

To enable authentication and encyption using the Kerberos mechanism, configure the following Kerberos-specific parameters in `drill-override.conf`:

Note: Only Drill 1.11 and later supports encryption.

Note: For client-side configuration, see Drill Drivers.

Parameters	Communication Path	Description	Default
drill.exec.security.auth.principal	Drill client (ODBC/ JDBC) to Drillbit	String representation of the Kerberos principal used by the Drillbit service.	N/A
drill.exec.security.auth.keytab	Drill client (ODBC/ JDBC) to Drillbit	Location of the keytab file for the configured Drillbit service principal. **Note:** The Kerberos keytab file that contains the encrypted key for the Drillbit service principal. The file should be readable by the Drillbit process user.	N/A
drill.exec.security.auth.auth_to_local	Drill client (ODBC/ JDBC) to Drillbit	Custom rules to convert the Kerberos principal to the Kerberos short name. **Note:** Drill uses a Hadoop Kerberos name and rules to transform the Kerberos principal provided by client to the one it will use internally as the client's identity. This client identity is used to determine administrator privileges. See Mapping from Kerberos Principal to OS user account in the Hadoop in Secure Mode documentation for details about how the rule works.	The primary name of the Kerberos principal. By default, this mapping rule extracts the first part from the provided principal. For example, if the principal format is `<Name1>/ <Name2>@realm`, the default rule extracts only `Name1` from the principal and `Name1` as the client's identity on server side.
drill.exec.security.user.encryption.sasl.enabled	Drill client (ODBC/ JDBC) to Drillbit	Enables/disables encryption for the communication path between the Drill client and Drillbit.	false
drill.exec.security.bit.auth.use_login_principal	Drilbit to Drillbit	When set to true, the Drillbit uses the same logged in service principal configured with drill.exec.security.auth.principal for the Drillbit to Drillbit communication paths. When this parameter is set to false, a principal is constructed using the hostname from ZooKeeper for the remote Drillbit and keeping the primary and realm information the same as the logged in principal set by drill.exec.security.auth.principal .	false

last-updated: Apr 11, 2022

Parameters	Communication Path	Description	Default
drill.exec.security.bit.encryption.sasl.enabled	Drillbit to Drillbit	Enables/disables encryption for the communication path between the Drillbits.	false

Steps to Enable Kerberos Authentication and Encryption

Complete the following steps to enable Drill to use Kerberos for authentication and encryption:

1. Create a Kerberos principal identity and a keytab file. You can create one principal for each Drillbit or one principal for all Drillbits in a cluster.

   Note: The adminstrator must own the `drill.keytab` file and have the ability to read the file.

   - For a single principal per node in cluster:

     ```
     # kadmin
     : addprinc -randkey <username>/<FQDN>@<REALM>.COM
     : ktadd -k /opt/mapr/conf/drill.keytab <username>/
     <FQDN>@<REALM>.COM
     ```

   - For a single principal per cluster, use `<clustername>` instead of `<FQDN>`:

     ```
     # kadmin
     : addprinc -randkey <username>/<clustername>@<REALM>.COM
     : ktadd -k /opt/mapr/conf/drill.keytab <username>/
     <clustername>@<REALM>.COM
     ```

   Note: The instance name must be lowercase. If _HOST is set as the instance name in the principal, it is replaced with the fully qualified domain name of that host for the instance name. For example, if a Drillbit running on `host01.aws.lab` uses `drill/_HOST@<EXAMPLE>.COM` as the principal, the canonicalized principal is `drill/host01.aws.lab@<EXAMPLE>.COM`.

2. Add the Kerberos principal identity, keytab file, and parameters specific to Kerberos to the `drill-override.conf` file. You can use the following configuration examples for enabling authentication, encryption, or both between the Drill client and Drillbit and between Drillbits.

Example 1: Enabling Kerberos Authentication Between the Drill Client and Drillbit

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab"
```

last-updated: Apr 11, 2022

```
            }
        }
```

Example 2: Enabling Kerberos Authentication and Encryption Between the Drill Client and Drillbit

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
              }
            }
        }
```

Example 3: Enabling Kerberos Authentication Between Drill Client and Drillbits and Between Drillbits

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab"
              }
        security.bit: {
                auth.enabled: true,
                auth.mechanism:
"Kerberos",

auth.use_login_principal: true
               }
        }
```

Example 4: Enabling Kerberos Authentication and Encryption Between Drill Client and Drillbits and Between Drillbits

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
              }
        security.bit: {
                auth.enabled: true,
                auth.mechanism:
"Kerberos",

auth.use_login_principal: true,

encryption.sasl.enabled: true
              }
        }
```

Note: In examples 3 and 4 above, the Drillbit will use the same logged in service principal as configured in `drill.exec.security.auth.principal`.

Example 5: Enabling Kerberos Authentication and Encryption Between Drill Client and Drillbits and Between Drillbits. For Drillbit to Drillbit authentication, where the service principal is created using the hostname from ZooKeeper for a remote Drillbit as an instance name. The primary and the realm component of the service principal is used from the drill.exec.security.auth.principal parameter.

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
```

last-updated: Apr 11, 2022

```
                }
        security.bit: {
                auth.enabled: true,
                auth.mechanism:
"Kerberos",

encryption.sasl.enabled: true
                }
        }
```

Note: For the configuration in example 5, if the hostname of the remote Drillbit known to ZooKeeper is **host01.aws.lab**, then the service principal used by a Drillbit to authenticate with the remote Drillbit will be **drill/host01.aws.lab@<REALM>.COM**.

3. Restart the Drillbit process on each Drill node.

```
$ maprcli node services -name drill-bits -action restart -nodes <node
host names separated by a space>
```

Related concepts

Plain Authentication on page 3309
An administrator can configure Drill to use the Linux pluggable authentication module (PAM) for Plain (username and password) authentication. PAM provides an authentication module that interfaces with any installed PAM authentication entity, such as the local operating system password file (/etc/passwd) or LDAP.

Configuring Drill to Use Kerberos with Hive Metastore

To configure Drill to use Kerberos with the Hive metastore, modify the hive storage plugin in the Drill Web UI and then restart the Warden service.

Note: When you configure Drill to use Kerberos with the Hive metastore, Drill submits requests to the Hive metastore as the `mapr` superuser. If you want Drill to submit requests to the Hive metastore as any other user, configure Drill impersonation with Hive instead of performing this task. Drill impersonation works with or without Kerberos configured for the Hive metastore.

Prerequisites

The configurations described in this document have the following dependencies:

- MapR cluster.
- Drill installed with Drillbits running as the `mapr` user.
- Supported version of Hive installed with the following:
  - Hive Metastore configured to use Kerberos authentication
  - Configured Hive remote metastore repository

Note: See the Drill Support Matrix on page 5629 for supported versions of Hive.

Modify the Hive Storage Plugin in Drill

Modify the Hive storage plugin configuration in the Drill Web UI based on the authorization and security scenario for the cluster. You can only access the Drill Web UI for a running Drillbit.

last-updated: Apr 11, 2022

Complete the following steps to configure Drill to use Kerberos with Hive Metastore:

1. Navigate to `http://<drillbit_hostname>:8047`, and select the **Storage** tab.

   Note: You can only access the Drill Web UI for a running Drillbit.

2. Click **Update** next to the hive option.

3. In the configuration window, add the `hive.metastore.sasl.enabled`, `hive.metastore.kerberos.principal`, and `hive.security.authorization.enabled` properties, as shown below, if configuration does not contain them already. Note that other properties shown may or may not be required in your environment:

```
{
  "type": "hive",
  "enabled": true,
  "configProps": {
    "hive.metastore.uris": "thrift://<metastore_hostname>:9083",
    "fs.default.name": "maprfs:///",
    "hive.server2.enable.doAs": "false",
    "hive.metastore.sasl.enabled": "true",
    "hive.metastore.kerberos.principal":
"<metastore_server_principal_name>",
    "hive.security.authorization.enabled": "true"
  }
}
```

Restart Warden

Issue the following command on all nodes to restart the Warden service:

```
service mapr-warden restart
```

If you have `clush` installed, you can run the following command to restart Warden on all nodes at once:

```
clush -a "service mapr-warden restart"
```

Connection URLs for Kerberos using JDBC Drivers to connect via SQLLine
You can use client-side connection URL parameters for Kerberos authentication in multiple combinations to authenticate a client with Drill.

Client Credentials

A client can provide its credentials in two ways:

- With a ticket granting ticket (TGT) generated on client side. The TGT must be present on client node; Drill does not generate the TGT.
- With a keytab file and the client principal provided in the user property of the connection URL.

Configuration Options

The following table lists configuration options for connection URLs. See the Connection URL Examples section for sample URLs.

last-updated: Apr 11, 2022

Connection Parameter (Apache Drill JDBC Driver)	Description	Connection Parameter (Drill JDBC Driver)	Mandatory/Optional	Default Value
auth	Authentication deduced if not provided. A Drill client can also explicitly specify a particular authentication mechanism to use using this parameter. For example, for Kerberos along with service_name, service_host or principal and for the Plain authentication with username and password.	Auth	Optional	The preference order is Kerberos and Plain.
principal	Drillbit service principal. Required if the principal is not provided using this configuration. For Kerberos, the Drill service principal is derived if the value is not provided. The service_name (primary) and service_host (instance) are used to generate a valid principal. Since the ticket or keytab contains the realm information, the realm is optional.	Principal	Optional	

keytab	For Kerberos, if you authenticate using a keytab, set the keytab parameter to the location of the keytab file. This is passed through the user parameter. A Kerberos ticket is used as the default credential (It is assumed to be present on the client-side. The Drill client does not generate the required credentials.)	If the client chooses to use a keytab rather than a ticket, the client principal must be provided	Optional	
sasl_encrypt	When set to true, ensures that a client connects to a server with encryption capabilities. For example, Drill 1.11 Drillbits, which support client-to-drillbit encryption.		Optional	FALSE
service_name	Primary name of the Drillbit service principal.		Optional	drill
service_host	Instance name of the Drillbit service principal.		Optional	Since this value is usually the hostname of the node where a Drillbit is running, the default value is the Drillbit hostname is provided either through ZooKeeper or through a direct connection string.
realm	Kerberos realm of the principal. The realm name for the Drillbit service ticket or keytab contains the realm information.		Optional	

Client Encryption

A client can specify that it requires a server with encryption capabilities only by setting the

`sasl_encrypt` connection parameter to "true." If the cluster to which client is connecting has encryption disabled, the client will fail to connect to that server.

```
drill.exec {
 security:  {
      user.auth.enabled: true,
      auth.mechanisms: ["KERBEROS"],
      auth.principal: "drill/serverhostname@REALM.COM",
      auth.keytab: "/etc/drill/conf/drill.keytab",
      user.encryption.sasl.enabled: true
          }
}
```

Connection URL Examples

The following five examples show the JDBC connection URL that the embedded JDBC client uses for Kerberos authentication. The first section, Example of a Simple Connection URL, includes a simple connection string and the second section, Examples of Connection URLs Used with Previously Generated TGTs, includes examples to use with previously generated TGTs.

Example of a Simple Connection URL

Example 1: TGT for Client Credentials

The simplest way to connect using Kerberos is to generate a TGT on the client side. Only specify the service principal in the JDBC connection string for the Drillbit the user wants to connect to.

```
jdbc:drill:drillbit=10.10.10.10;principal=<principal for host 10.10.10.10>
```

In this example, the Drill client uses the:

- Default `service_name`, which is **`drill`**.
- `service_host` from the Drillbit name provided in the connection URL, which is **`10.10.10.10`**.

The service principal format is `<primary>/<instance>@<realm from TGT>`. The service principal is **`principal for host 10.10.10.10`**.

Examples of Connection URLs Used with Previously Generated TGTs

If you do not provide a service principal in the connection string when using Kerberos authentication, then use the `service_name` or `service_host` parameters. Since these parameters are optional, their default values will be used internally (if not provided) to create a valid principal.

Examples 2 through 4 show a valid connection string for Kerberos authentication if a client has previously generated a TGT. Realm information will be extracted from the TGT if it is not provided.

Note: For end-to-end authentication to function, it is assumed that the proper principal for the Drillbit service is configured in the KDC.

Example 2: Drillbit Provided by Direct Connection String and Configured with a Unique Service Principal

This type of connection string is used when:

- Each Drillbit in the cluster is configured with its own service principal.
- The instance component is the host address of the Drillbit.

  ```
  jdbc:drill:drillbit=host1;auth=kerberos
  ```

In this example, the Drill client uses the:

- Default `service_name`, which is **`drill`**.

- `service_host`, which is the Drillbit name provided in the connection URL (**`host1`**).

The internally created service principal will be **`drill/host1@<realm from TGT>`**.

Example 3: Drillbit Selected by ZooKeeper and Configured with Unique Service Principal

This type of connection string is used when the Drillbit is chosen by ZooKeeper instead of directly from the connection string.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill
```

In this example, the Drill client uses the:

- Provided `service_name`, which is **`myDrill`** as the primary name of the principal.
- `service_host` as the address of the Drillbit, which is chosen from the list of active drillbits that ZooKeeper provides (**`host01.aws.lab:5181`**).

The internally created service principal will be **`myDrill/<host address from zk>@<realm from TGT>`**.

Example 4: Drillbit Selected by Zookeeper and Configured with a Common Service Principal

This type of connection string is used when all Dillbits in a cluster use the same principal.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill;service
_host=myDrillCluster
```

In this example, the Drill client uses the:

- Provided `service_name`, which is **`myDrill`**.
- `service_host`, which is **`myDrillCluster`**.

The internally created service principal, which will be **`myDrill/myDrillCluster@<realm from TGT>`**.

Example 5: Keytab for Client Credentials

If a client chooses to provide its credentials in a keytab instead of a TGT, it must also provide a principal in the user parameter. In this case, realm information will be extracted from the `/etc/krb5.conf` file on the node if it is not provided in the connection URL. All other parameters can be used as shown in the preceding examples (1-4). This connection string is for the case when all Drillbits in a cluster use the same principal.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill;service
_host=myDrillCluster;keytab=<path to keytab file>;user=<client principal>
```

In this example, the Drill client:

- Will authenticate itself with the:
  - Keytab (**`path to keytab file`**) and
  - Principal provided in the user parameter (**`client principal`**)
- Uses the:
  - Provided `service_name`, which is **`myDrill`**.
  - `service_host`, which is **`myDrillCluster`**.

The internally created service principal will be **`myDrill/myDrillCluster@<realm from krb5.conf>`**.

Plain Authentication

An administrator can configure Drill to use the Linux pluggable authentication module (PAM) for Plain (username and password) authentication. PAM provides an authentication module that interfaces with any installed PAM authentication entity, such as the local operating system password file (/etc/passwd) or LDAP.

Note: Starting in EEP 5.0, Drill supports form-based authentication between the web client and Drillbit. Form-based authentication is like Plain authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. Configuring Drill to Use libpam4j includes configuration details. When using form-based authentication, you can also configure Drill to use SPNEGO. See SPNEGO for HTTP Authentication.

When using PAM for authentication, each user with permission to run Drill queries must exist in the list of users that resides on each Drill node in the cluster. The username (including uid) and password for each user must be identical across all Drill nodes.

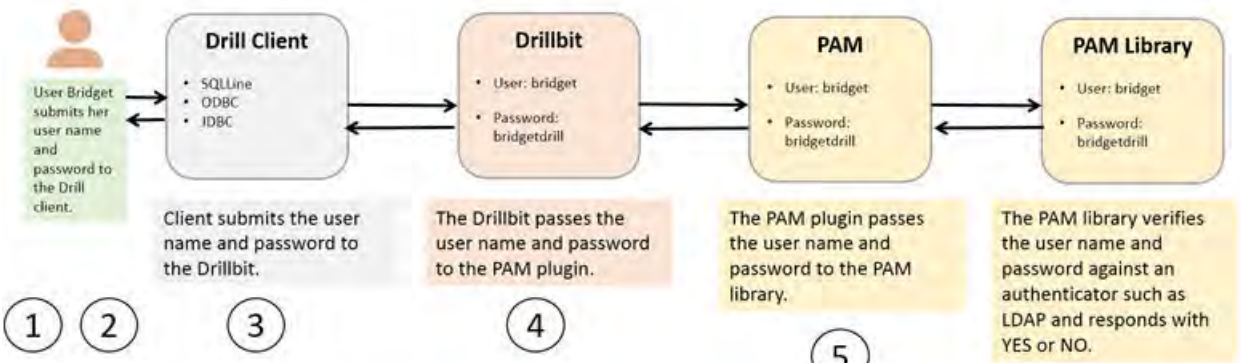
If you use PAM with /etc/passwd for authentication, verify that the users permitted to start the Drill process are part of the shadow user group on all nodes in the cluster. This enables Drill to read the /etc/shadow file for authentication.

Note: Plain authentication does not support SASL encryption. You can use SSL/TLS for encryption when Plain authentication is enabled. You can also enable user impersonation and create views to limit user access to data.

Authentication Process Overview

During the authentication process, the client passes a username and password to the Drillbit as part of the connection request, which then passes the credentials to PAM. If PAM authenticates the user, the connection request passes the authentication phase, and the connection is established. The user will be authorized to access Drill and issue queries against the filesystem or other storage plugins, such as Hive.

The following image illustrates the PAM user authentication process in Drill:



Plain (Username and Password) Authentication Process

If PAM cannot authenticate the user, the connection request does not pass the authentication phase and the user will not be authorized to access Drill. The connection is terminated as AUTH_FAILED.

For more PAM information (including a JPAM User Guide), see JPAM.

Configuring Plain Authentication in Drill

Drill supports the libjpam and libpam4j libraries. In Drill 1.12 and later, the libpam4j library is packaged with Drill. There is no download or external dependency required to use libpam4j. Using libpam4j is recommended for Drill 1.12 and later.

last-updated: Apr 11, 2022

Note: You can configure Drill to use multiple types of authenication mechanisms. For example, you can configure Drill to use Plain, Kerberos, and MapR-SASL; however, only SSL/TLS is supported for encryption when Plain authentication is configured with other authentication mechanisms.

The following sections provide information for configuring Drill to use libpam4j or libjpam, as well as instructions for connecting to Drill from SQLLine and BI tools when Plain authentication is enabled:

Configuring Drill to Use libpam4j
You can configure Drill to use libpam4j for Plain authentication between a client, such as ODBC, and the Drillbit.

Starting in EEP 5.0, you can configure Drill to use libpam4j for form-based authentication between a web client and Drillbit (web server). Form-based authentication is like Plain authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. When using form-based authentication, you can also configure Drill to use SPNEGO. See SPNEGO for HTTP Authentication.

Complete the following steps to configure Plain authentication (for JDBC/ODBC clients) and form-based authentication (for the web client) in Drill:

1. Add the following configurations to the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file:

```
drill.exec:{
   cluster-id:"drillbits1",

zk.connect:"<zk-node-hostname>:5181,<zk-node-hostname>:5181,<zk-node-host
name>:5181",
   security:{
      auth.mechanisms:[ "PLAIN"],
   },
   security.user.auth:{
      enabled:true,
      packages += "org.apache.drill.exec.rpc.user.security",
      impl:"pam4j",
      pam_profiles:[ "sudo", "login" ]
   },
   http.auth.mechanisms:[ "FORM" ]
}
```

2. (Optional) To add or remove different PAM profiles, add or delete the profile names in the `pam_profiles` array portion of the configuration:

```
pam_profiles: [ "sudo", "login" ]
```

3. Restart the Drillbit process on each Drill node, as shown:

```
/opt/mapr/drill/drill-<version>/bin/drillbit.sh restart
```

Configuring Drill to Use libjpam
You can configure Drill to use libjpam for Plain authentication between a client, such as ODBC, and the Drillbit.

To configure Drill to use libjpam, complete the following steps:

1. Copy the libjpam.so file from /opt/mapr/lib to a directory that does not contain other Hadoop components, for example /opt/pam/.

last-updated: Apr 11, 2022

2. Add the following line to /opt/mapr/drill/drill-<version>/conf/drill-env.sh, including the directory where the libjpam.so file is located, as shown:

```
export
DRILLBIT_JAVA_OPTS="$DRILLBIT_JAVA_OPTS -Djava.library.path=<directory>"
Example: export
DRILLBIT_JAVA_OPTS="$DRILLBIT_JAVA_OPTS -Djava.library.path=/opt/pam/"
```

3. Add the following configuration to the drill.exec block in /opt/mapr/drill/drill-<version>/conf/drill-override.conf:

```
drill.exec: {
             cluster-id: "drillbits1",
             zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.lab:5181,qa102-83.qa.lab:5181",
             impersonation: {
               enabled: true,
               max_chained_user_hops: 3
          },
             security: {
                auth.mechanisms : ["PLAIN"],
                 },
              security.user.auth: {
                enabled: true,
                packages += "org.apache.drill.exec.rpc.user.security",
                impl: "pam",
                pam_profiles: [ "sudo", "login", "mapr-admin" ]
        }
       }
```

4. (Optional) To add or remove different PAM profiles, add or delete the profile names in the pam_profiles array portion of the configuration:

```
pam_profiles: [ "sudo", "login" ]
```

5. Restart the Drillbit process on each Drill node, as shown:

```
/opt/mapr/drill/drill-<version>/bin/drillbit.sh restart
```

Connection URL for Plain Authentication using the Apache JDBC Driver to connect via SQLLine
When Plain authentication is enabled, each user that accesses the Drillbit process through a client, must provide username and password credentials for access.

Connecting to Drill from SQLLine

Include the `-n` and `-p` parameters with your username and password when launching SQLLine, as shown in the following example:

```
sqlline -u jdbc:drill:zk=10.10.11.112:5181 -n <username> -p <password>
```

Alternatively, you can launch SQLLine and then issue the `!connect` command to hide the password.

Complete the following steps to hide the password:

1. Run the sqlline script, as shown:

```
$ /etc/drill/bin/sqlline
```

2. At the prompt, enter the `!connect` command followed by

```
jdbc:drill:zk=zk=<zk name>[:<port>][,<zk name2>[:<port>]...]
```

, as shown:

```
`sqlline> !connect jdbc:drill:zk=localhost:5181 scan complete in 1385m`s
```

3. When prompted, enter a username and password; the password is hidden as it is typed, as shown:

```
Enter username for jdbc:drill:zk=localhost:5181: yourusername
Enter password for jdbc:drill:zk=localhost:5181: *************
```

Connecting to Drill from BI Tools

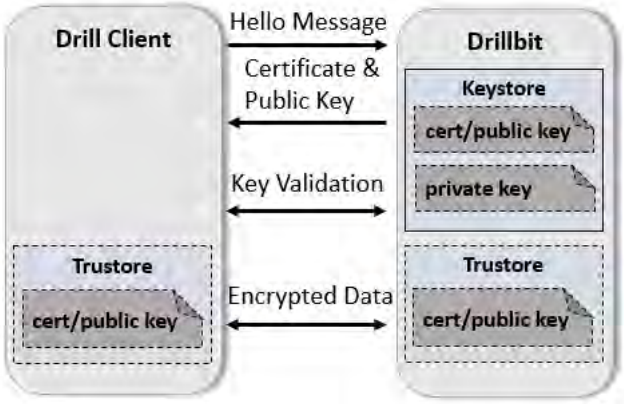
When you connect to Drill from a BI tool, such as Tableau, the ODBC driver prompts you for the authentication type, username, and password. For PAM, select **Basic Authentication** in the Authentication Type drop-down menu.

SSL/TLS for Encryption

You can enable SSL for Drill in a secure or unsecure cluster. SSL (Secure Sockets Layer), more recently called TLS, is a security mechanism that encrypts data passed between the Drill client and Drillbit (server). SSL also provides one-way authentication through which the Drill client verifies the identity of the Drillbit.

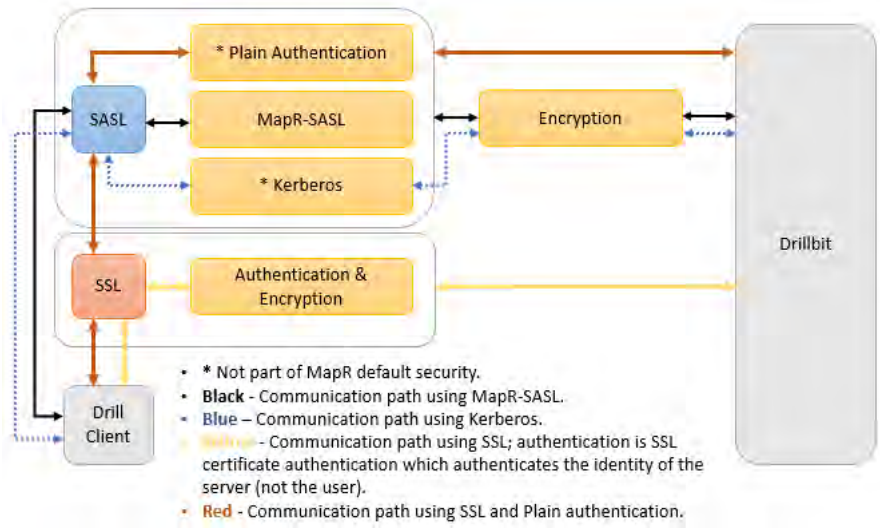
Authentication occurs during the SSL handshake when the Drillbit (server) presents its certificate to the client, and the client checks if the certificate exists in its truststore or if the certificate is signed by a trusted CA (Certificate Authority) that exists in its truststore.

The following diagram depicts the communication between the Drill client and the Drillbit (server):



The SASL feature in Drill provides authentication and an option to encrypt data, however the encryption feature is not available when using Plain authentication. If you need to use Plain authentication (certain BI tools only use Plain authentication), you can enable SSL to encrypt data. Using SSL and SASL encryption together is strongly discouraged.

The following diagram depicts the SSL communication paths between the Drill client and Drillbit (server), including the scenario where Plain authentication is used:



Note: The REST API supports HTTPS. SSL is not supported for communication between Drillbits.

The following sections provide information about how to use certificates in secure and unsecure clusters, enabling and configuring SSL, connection parameters, and common SSL issues.

Related concepts

SSL Certificates on page 689
Describes how certificates are used to perform authentication and encryption for websites that use the HTTPS protocol.

SSL Certificates in Secure and Insecure Clusters

The Drill server requires an SSL certificate. The certificate can be self-signed or signed by a CA (Certificate Authority).

The sections below describe how to use SSL certificates in secure and insecure MapR Data Platform clusters.

SSL in a Secure Cluster

By default, SSL is configured in a secure MapR cluster, but not enabled. In a secure cluster the keystore is configured for you. The security in a MapR cluster uses a self-signed certificate. If you have a certificate signed by a certificate authority, follow the instructions for Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster and then enable and configure SSL.

To use SSL, enable the SSL option and then modify any of the available configuration options as needed.

- To enable SSL for the ODBC/JDBC client to Drillbit communication path, you must enable SSL on the client side and Drillbit. See Drill Drivers for client instructions. See Configuring SSL/TLS for the Drillbit.
- To enable SSL for the Drill Web UI, see Configuring the Drill Web UI and Web API Security.

After you modify the configuration options, restart Drill, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

SSL in an Insecure Cluster

Before you can enable SSL in an insecure cluster, you must either get or generate a certificate and then import the certificate into the Java keystore. You can do this using the Java keytool utility. See To Use keytool to Create a Server Certificate for instructions.

last-updated: Apr 11, 2022

If you have a custom certificate, you can import it using the method described in Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster. You may also want to reference this document.

After you generate or import a server certificate, add the path (and password) to the keystore in the SSL configuration for Drill. See Configuring SSL for information on how to update the SSL configuration.

Restart Drill after you modify the configuration options, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

Configuring SSL/TLS
Enable SSL in `<DRILL_INSTALL_HOME>/conf/drill-override.conf`. You can use several configuration options to customize SSL/TLS.

You must restart the Drillbit process on each node after you modify the configuration options, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

The following sections provide information and instructions for enabling and configuring SSL:

Enabling SSL

When SSL is enabled, all Drill clients, such as JDBC and ODBC, must connect to Drill servers using SSL. Enable SSL in the Drill startup configuration file, `drill-override.conf`, located in `/opt/mapr/drill/drill-<version>/conf`.

To enable SSL for Drill, set the `drill.exec.security.user.encryption.ssl.enabled` option in `drill-override.conf` to `"true."`

Configuring SSL

You can customize SSL on a Drillbit through the SSL configuration options. You can set the options from the command-line (using Java system properties), in the `drill-override.conf` file, or in the property file to which the Hadoop parameter `hadoop.ssl.server.conf` points (recommended).

Note: Specifying values in `drill-override.conf` can expose the security parameters to end users. Administrators should set these values in the Hadoop security file and restrict permissions on that file.

If a parameter is specified in multiple places, the value in the Hadoop configuration takes precedence over the Drill configuration, which takes precedence over the system property.

The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the Hadoop `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml`, which contains the property names to configure SSL. Both the `core-site.xml` file and the `ssl-server.xml` file must exist in Drill's classpath. Drill's SSL configuration picks up the Hadoop SSL configuration.

Note: Since the Drillbit implementation is based on JSSE, several standard parameters that apply to JSSE will also apply to the Drillbit. However, you typically do not need to configure JSSE parameters.

The following are the SSL configuration options with their descriptions and default values:

drill.exec.security.user.encryption.ssl.enabled	*Hadoop Property Name:* N/A *System Property Name:* N/A

last-updated: Apr 11, 2022

	Description: Enable or disable TLS for Drill client - Drill Server communication. You must set this option in `drill-override.conf`. *Allowed Values:* `true` or `false` *Drill Default:* `false`
drill.exec.ssl.protocol	*Hadoop Property Name:* N/A *System Property Name:* N/A *Description:* The version of the TLS protocol to use. *Allowed Values:* TLS, TLSV1, TLSv1.1, TLSv1.2 *Drill Default:* TLSv1.2 (recommended)
drill.exec.ssl.keyStoreType	*Hadoop Property Name:* ssl.server.keystore.type *System Property Name:* javax.net.ssl.keyStoreType *Description:* Format of the keystore file *Allowed Values:* jks, jceks, pkcs12 *Drill Default:* jks
drill.exec.ssl.keyStorePath	*Hadoop Property Name:* ssl.server.keystore.location *System Property Name:* javax.net.ssl.keyStore *Description:* Location of the Java keystore file containing the Drillbit's own certificate and private key. On Windows, the specified pathname must use forward slashes,`/`, in place of backslashes. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.keyStorePassword	*Hadoop Property Name:* ssl.server.keystore.password *System Property Name:* javax.net.ssl.keyStorePassword *Description:* Password to access the private key from the keystore file. This password is used twice: To unlock the keystore file (store password), and to decrypt the private key stored in the keystore (key password) unless a key password is specified separately. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.keyPassword	*Hadoop Property Name:* ssl.server.keystore.keypassword *System Property Name:* Not Applicable *Description:* Password to access the private key from the keystore file. May be different from the keystore password. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.trustStoreType	*Hadoop Property Name:* ssl.server.truststore.type *System Property Name:* javax.net.ssl.trustStoreType *Description:* Format of the truststore file *Allowed Values:* jks, jceks, pkcs12 *Drill Default:* jks
drill.exec.ssl.trustStorePath	*Hadoop Property Name:* ssl.server.truststore.location

	System Property Name: javax.net.ssl.trustStore *Description:* Location of the Java keystore file containing the collection of CA certificates trusted by the Drill client. On Windows, the specified pathname must use forward slashes, `/`, in place of backslashes. **Note:** If the `trustStorePath` is not provided, Drill ignores the `trustStorePassword` parameter and gets the default Java truststore instead, which causes issues if the Java truststore has a non-default password. The Java APIs to load the default keystore assume the default password. The only way to use the default keystore with a non-default password is to specify both the path and the password to the keystore. To work around this issue, pass the default Java truststore to the `trustStorePath` parameter. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.trustStorePassword	*Hadoop Property Name:* ssl.server.truststore.password *System Property Name:* javax.net.ssl.trustStorePassword *Description:* Password to access the private key from the keystore file specified as the truststore. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.provider	*Hadoop Property Name:* Not Applicable *System Property Name:* Not Applicable *Description:* Changes the underlying implementation to the chosen value. *Allowed Values:* OpenSSL or JDK *Drill Default:* JDK
drill.exec.ssl.useHadoopConfig	*Hadoop Property Name:* Not Applicable *System Property Name:* Not Applicable *Description:* Use the setting in the Hadoop configuration file. The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml`, which contains the property names to configure TLS. *Allowed Values:* `true` or `false` *Drill Default:* `true`

JDBC Connection Parameters

Use the SSL JDBC connection parameters and fully qualified host name to configure the jdbc connection string in SQLLine and connect to Drill.

The following table lists the parameters that you can include in the `jdbc` connection string using SQLLine:

Note: Examples are provided after the table. For additional instructions, see the Drill JDBC Driver documentation.

last-updated: Apr 11, 2022

Parameter	Value	Required
enableTLS	true/false	[Optional] If true, TLS is enabled. If not set or set to false, TLS is not enabled.
trustStoreType	string	[Optional] Default: JKS The trustStore type. Allowed values are : JKS PKCS12 If the useSystemTrustStore option is set to true (on Windows only), the allowed values are: Windows-MY Windows-ROOT Import the certificate into the "Trusted Root Certificate Authorities" and set trustStoreType=Windows-ROOT. Also import the certificate into "Trusted Root Certificate Authorities" or "Personal" and set trustStoreType=Windows-MY.
trustStorePath	string	[Optional] Path to the truststore. If not provided the default Java truststore will be used. If this is not provided the trustStorePassword parameter will be ignored. Note that the order for looking for the default trustStore java-home/lib/security/jssecacerts then java-home/lib/security/cacerts
trustStorePassword	string	[Optional] Password to the truststore.
disableHostVerification	true/false	[Optional] If true, we will not verify that the host in the certificate is the host we are connecting to. False by default (Hostname verification follows the specification in RFC2818).
disableCertificateVerification	true/false	[Optional] If true we will not validate the certificate against the truststore. False by default.
TLSProtocol	TLS, TLSV1, TLSv1.1, TLSv1.2	[Optional] Default: TLSv1.2 (recommended)

last-updated: Apr 11, 2022

TLSHandshakeTimeout	Time in milliseconds	[Optional] Default: 10 seconds In some cases, the TLS handshake may fail and leave the client hanging. This option sets the time for the client to timeout.
TLSProvider	JDK/OPENSSL	[Optional] Default: JDK Changes the underlying implementation to the chosen value.
useSystemTrustStore	true/false	[Optional, Windows only] Default: false If provided, the client will read certificates from the Windows truststore. In this case, trustStorePath and trustStorePassword, if specified, will be ignored. The user should set the default provider in $JRE_HOME/lib/security/java.security to SunMSCAPI. The trustStoreType should be set to either Windows-MY or Windows-ROOT.

Examples

The following examples show you how to connect to Drill through SQLLine with the `jdbc` connection string when SSL is not enabled and when SSL is enabled with and without a truststore.

No SSL/TLS

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=l
ocalhost:31010;enableTLS=false"
```

SSL/TLS Enabled - No truststore

The default JSSE truststore will be tried with default password; the provided password will be ignored. If the default truststore password has been changed, this gives an error. To use the default truststore with a different password, pass the path to the default truststore with the password.

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=l
ocalhost:31010;enableTLS=true;trustSto
rePassword=drill123"
```

SSL/TLS enabled - With truststore

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=l
ocalhost:31010;enableTLS=true;trustSto
rePath=~/ssl/
truststore.ks;trustStorePassword=drill
123"
```

ODBC Connection Parameters

Use the SSL ODBC connection parameters to configure a connection to Drill through an ODBC tool.

The following table lists the ODBC connection parameters:

Note: The Drill ODBC driver does not support password protected PEM/CRT files or multiple CRT certificates in a single PEM/CRT file. For additional instructions, see the Drill ODBC Driver documentation.

Name	Value	Required	Description
SSL	Clear (0)	No.	This option specifies whether the cliet uses an SSL encrypted connection to communicate with Drill. • Enabled(1):The client communicates with Drill using SSL. • Disabled(0):SS Lis disabled. SSL is configured independently of authentication. When authentication and SSL are both enabled, the driver performs the specified authentication method over an SSL connection.
TLSProtocol	Empty, which defaults to tlsv12.	No	This property specifies the TLS protocol version used. Accepted values are: • tlsv1 • tlsv11 • tlsv12
TrustedCerts	The cacerts.pem file in the \lib subfolder within the Driver's installation directory. The exact file path varies depending on the version of the driver that is installed. For example, the path for the Windows driver is different from the path for the Mac OS driver.	No	The full path of the PEM file containing Trusted CA certificates, for verifying the server. If this option is not set, then the driver defaults to using the trusted CA certificates PEM file installed by the driver.

last-updated: Apr 11, 2022

UseSystemTrustStore	Clear (0)	No	This option specifies whether to use a CA certificate from the system truststore, or from a specified PEM file. • Enabled (1): The driver verifies the connection using a certificate in the system truststore • Disabled (0): The driver verifies the connection using a specified PEM file. **Note:** This option is only available on Windows. If using this option, import the certificate into the "Trusted Root Certificate Authorities" certificate store.
DisableCertificateVerification	0	No	This property specifies that the driver verifies the host certificate against the truststore. Accepted values are: • 0: The driver verifies the certificate against the truststore. • 1: The driver does not verify the certificate against the truststore.
DisableHostVerification	0	No	This property specifies if the driver verifies that the host in the certificate is the host being connected to. Accepted values are: • 0: The driver verifies the certificate against the host being connected to. • 1: The driver does not verify the certificate against the host.

Avoiding Common SSL Issues
The following sections provide insight to some common error messages that you may encounter with SSL.

ERROR: No Cipher suites in common.

This is a general purpose error message that may have many reasons. The most common reason is that in order to use certain cipher suites, JSSE needs to use the private key stored in the Keystore. If this key is not accessible, JSSE filters out all cipher suites that need a private key. This effectively prunes out all available cipher suites so that no cipher suites match between the client and the server.

The private key from the keystore may be inaccessible for the following reasons:

- Missing Keystore file

- Invalid Keystore password
- Empty key password or a key password that is different from the keystore password

JSSE does not allow a key password that is null or an empty string even though it is possible to create a keystore with such a key password. Also, JSSE does not provide a system property to specify the key password. Drill provides a way to set the key password, but if you are using only system properties to configure JSSE, Drill will use the *keystore* password. If the keystore password is not the same as the key password, the key will again be inaccessible.

- Corrupt keystore

You can validate the keystore using keytool.

ERROR: SSL is enabled, but cannot be initialized due to the 'Cannot recover key' exception.

The key is protected with a password and the provided password is not correct.

ERROR: Client connection timeout.

A client connection can timeout because of networking issues or if there is a mismatch between the TLS/SSL configuration on the client and server.

Before trying to debug the TLS/SSL configuration, check if the server is reachable from the client.

If there is a mismatch between the TLS/SSL configuration, the TLS/SSL handshake between the client and server will fail. The server will silently drop the connection and the client will eventually time out. The handshake may fail due to many reasons, including:

1. The server is configured to enableTLS and the client is not (and vice versa).
   a. If the client is not configured to use TLS and the server is, the error message will be similar to the following:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.RpcException: HANDSHAKE_COMMUNICATION :
Channel closed /10.10.10.11:49907 <--> hostname/10.10.10.11:31010.
(state=,code=0)
java.sql.SQLNonTransientConnectionException: Failure in
connecting to Drill: org.apache.drill.exec.rpc.RpcException:
HANDSHAKE_COMMUNICATION : Channel closed /10.10.10.11:49907
<-->hostname/10.10.10.11:31010.
```

   b. If the server is not configured to use TLS and the client tries to connect using TLS, the error message will be similar to the following:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.NonTransientRpcException: Connecting to the
server timed out. This is sometimes due to a mismatch in the SSL
configuration between client and server. [ Exception: Timeout waiting
for task.] (state=,code=0)
```

2. The server presents a certificate to the client containing a hostname that is not valid. When the client connects to a server, the hostname the client used to connect to the server must match the name of the host the certificate was assigned to. Certificates can contain wildcards for the hostname, so if you're connecting to a Drill cluster via ZooKeeper, it would be best to have a certificate that contains wildcards that cover all the hosts on which Drill might be running. It is also important to ensure that the DNS and the hostnames of the machines in the cluster are set up consistently so that the Drillbits are registered with ZooKeeper using the same name as the name assigned in the certificate. The error message in this case is the same as the previous case:

   ```
   Error: Failure in connecting to Drill:
   org.apache.drill.exec.rpc.NonTransientRpcException: Connecting to the
   server timed out. This is sometimes due to a mismatch in the SSL
   configuration between client and server. [ Exception: Timeout waiting
   for task.] (state=,code=0)
   ```

   Hostname verification can be turned off if there is no way to change the host configuration or the certificate. This is generally not recommended.

Security Between ZooKeeper and Drillbits

When Drill is installed on clusters with the default security enabled, authentication is enabled between the Drillbits and ZooKeeper. The ZooKeeper znode information is secured automatically through authentication and znode ACLs. Communication between the Drillbits and Zookeeper is not encrypted.

Note: If you installed Drill on a cluster that does not have the default security configuration, and you are configuring custom security, you must enable authentication and manually set ACLs on the znodes.

Drill uses ZooKeeper to store certain cluster-level configuration and query profile information in znodes. A znode is an internal data tree in ZooKeeper that stores coordination and execution related information. If information in the znodes is not properly secured, cluster privacy and/or security is compromised.

ZooKeeper uses ACLs to control access to znodes and secure the information they store. Starting in Drill 1.15, you can create a custom ACL (Access Control List) on the znodes to secure data. ACLs specify sets of ids and permissions that are associated with the ids.

Prior to Drill 1.15, ZooKeeper ACLs in secure and insecure clusters were set to `[world:all]`, meaning that all users had create, delete, read, write, and administrator access to the zknodes. Starting in Drill 1.15, ACLs in insecure clusters are set to `[world:all]`. ACLs in secure clusters are set to `[authid: all]`, which provides full access to the authenticated user that created the znode only. Discovery znodes (znodes with the list of Drillbits) have an additional ACL set to `[world:read]` making the list of Drillbits readable by any user.

Note: View the drill-override-example.conf file to see example ACL configurations.

Securing znodes

Complete the following steps to create a custom ACL and secure znodes:

1. Write a class that implements the `ZKACLProvider` interface. This class will contain the ACLs that need to be set on the znodes. You can use the ZKSecureACLProvider class as a sample reference.

2. Add the following dependency to the `pom` file of the project module created:

   ```
   <groupId>org.apache.drill.exec</groupId>
   <artifactId>drill-java-exec</artifactId>
   ```

3. Refer to the steps listed at https://drill.apache.org/docs/manually-adding-custom-functions-to-drill/ to create a JAR and then add the JAR to Drill's classpath.

4. In `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`, set `zk.acl_provider` to the `ZKACLProviderTemplate` type.

5. Restart Drill. When you restart Drill, the ACL, as mentioned in your custom class, is applied to the znode created when Drill starts.

Note: Existing ACLs for persistent znodes will not be affected if a Drillbit is restarted with a different ACL setting. ACLs are applied only at znode creation time. Drill does not recreate any znode that is already present. If you want to change an ACL for existing znodes, connect to the ZooKeeper server using zkCli and then use option a or b, as described:

- a) Shutdown Drillbits, delete the persistent znodes, change the ACL settings, and restart the Drillbit.
- b) Manually change the ACLs on the existing znodes to reflect the new ACL settings, using the `setAcl` command in the zkCli.

For either option to work, an authenticated connection between the zkCli and ZooKeeper Server must be established.

For additional information, refer to:

- ZooKeeper access control using ACLs
- ZooKeeper and SASL

Configuring Drill Web UI and Web API Security

The Drill web client and web API communicate with web browsers or web tools, like curl, through the HTTP or HTTPS. Drill uses HTTP by default.

Drill supports form-based (similar to Plain authentication) and SPNEGO authentication mechanisms to authenticate the communication between the web client and web browser or web tools. Drill supports SSL/TLS for encryption with form-based and SPNEGO authentication.

An administrator can configure security mechanisms and set up Drill Web UI administrators and administrator-user groups to control access to the Drill Web UI and Web API client applications. For example, limiting user access to Drill Web UI functionality, such as viewing or canceling queries submitted by other users.

Note:

- The Drill web server does not support MAPR-SASL (tickets).
- With Drill Web UI security in place, users without administrator privileges must execute the SHOW SCHEMAS command in the Drill Web UI Query page to see storage plugin configuration information.

Form-Based Authentication

In EEP 5.0 and later, Drill supports form-based authentication between the web client and Drillbit. Form-based authentication is like Plain Authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. Form-based authentication also uses the Linux PAM (Pluggable Authentication Module).

Configuring Drill to Use libpam4j provides configuration details. When using form-based authentication, you can also configure Drill to use SPNEGO for HTTP Authentication and SSL/TLS for encryption.

last-updated: Apr 11, 2022

HTTPS Support

The Drill Web UI supports the HTTPS protocol for encryption. With the default security configuration, HTTPS is enabled for Drill and it uses SSL trust- and keystore, which comes with cluster installation.

To use custom certificates, see SSL Certificates in Secure and Unsecure MapR Clusters.

The following example shows the default HTTPS configuration in `<DRILL_INSTALL_HOME>/conf/drill-distrib.conf` for a secure cluster installation:

```
drill.exec: {
             http.ssl_enabled: true,
             ssl.useHadoopConfig: true
}
```

You can configure additional parameters:

Drill Property Name	Hadoop Property Name	System Property Name	Description
drill.exec.http.ssl_enabled:			Enable or disable communication. Y
drill.exec.ssl.keyStorePath	ssl.server.keystore.location	javax.net.ssl.keyStore	Location of the Ja own certificate ar pathname must u
drill.exec.ssl.keyStorePassword	ssl.server.keystore.password	javax.net.ssl.keyStorePassword	Password to acce This password is password), and to (key password) u
drill.exec.ssl.keyPassword	ssl.server.keystore.keypassword		Password to acce be different from
drill.exec.ssl.trustStorePath	ssl.server.truststore.location	javax.net.ssl.trustStore	Location of the Ja certificates truste pathname must u
drill.exec.ssl.trustStorePassword	ssl.server.truststore.password	javax.net.ssl.trustStorePassword	Password to acce specified as the t
drill.exec.ssl.useHadoopConfig			Use the setting in hadoop configura the hadoop.ssl.se file. Typically, this ssl-server.xml wh TLS.  **Note:** Verify is located in symbolic lin for example `<DRILL_` .

Setting up Web UI Administrators and Administrator-User Groups
The `security.admin.user_groups` and `security.admin.users` options set the administrative users when authentication is enabled.

last-updated: Apr 11, 2022

Users listed in `security.admin.users` and the users belonging to the groups listed in `security.admin.user_groups` get administrative privileges. By default, these options are set to the username and groups of the user who started the Drill process. You can modify these options from the Drill Web UI or using the ALTER SYSTEM command.

An administrative user that authenticates to a Drillbit through MapR-SASL, Kerberos, Plain mechanism or through the HTTPS web interface can modify the `security.admin.user_groups` and `security.admin.users` options. The administrator can add or remove user names or user groups.

The `security.admin.user_groups` and `security.admin.users` options allow a single user/group name or a comma separated list of user/group names. When you view these options in the Drill Web UI, dummy default strings appear until the user explicitly changes the values.

Authenticated administrative users can view the current administrative user and administrative user groups on the Drill Web UI landing page (https://<node-ip-address>:8047) in the *Encryption Info* section.

Drill REST API and Web UI

This topic provides information about the Drill REST API and Web UI, including permission requirements.

If Drill has authentication enabled, you must supply credentials when using the Drill REST API.

Although Drill (in HPE Ezmeral Data Fabric) does not support HTTP basic authentication, you can work around this if your HTTP client saves cookies between requests. As a workaround, save the authenticated cookie to a file and then use the cookie in subsequent requests, as shown in the following example:

```
//Log in and save the authenticated cookie to a file:

curl -X POST \
    -H "Content-Type: application/x-www-form-urlencoded" \
    -k -c cookies.txt -s \
    -d "j_username=DRILL_USER" \
    -d "j_password=DRILL_PASSWORD" \
    https://HOSTNAME:8047/j_security_check

//In subsequent requests, use the cookie from that request:

curl -kv \
       -b cookies.txt  \
       -X POST \
       -H "Content-Type: application/json" \
       -d @/tmp/hive-storage-plugin.json
       https://HOSTNAME:8047/storage/hive.json
```

Note: The session remains active for one hour. You can increase the session time through the `drill.exec.http.session_max_idle_secs` option in `drill-override.conf`:

```
drill.exec: {
  http: {
    session_max_idle_secs: 86400, # 24hr
  }
}
```

REST API Methods and Web UI Functions

The following table and subsections describe requests and privilege levels for accessing the REST API methods and corresponding Drill Web UI functions. Privileges in the table are listed as AMDIN, USER, and ALL. ALL indicates privileges given to both the user and administrator.

Path	Request Type	Output Type	Functionality	Privileges

last-updated: Apr 11, 2022

/	GET	text/html	Returns Drillbit stats in a table in HTML format.	ALL
/stats.json	GET	application/json	Returns Drillbit stats such as ports and max direct memory in json format.	ALL
/status	GET	text/html	Returns Running!	ALL
/options.json	GET	application/json	Returns a list of options. Each option consists of name-value-type-kind (for example: (boot system datatype).	ALL
/options	GET	text/html	Returns an HTML table where each row is a form containing the option details and ability to modify the option values.	ALL
/option/{optionName}	POST	text/html	Updates the options and calls getSystemOptions to display list of options.	ADMIN
/storage.json	GET	application/json	Returns a list of storage plugin wrappers each containing name-config (instance of StoragePluginConfig) and enables the storage plugin configuration.	ADMIN
/storage	GET	text/html	Returns an HTML page with sections that contain: • a table where each row is a form containing the plugin button for update page link and a button to disable the plugin. • a table where each row is a form containing the plugin button for update page and a button to enable the plugin.	ADMIN
/storage/{name}.json	GET	application/json	Returns a plugin config wrapper for the requested web page.	ADMIN
/storage/{name}	GET	text/html	Returns an HTML page that has an editable text box for configuration editing, followed by buttons for creating,updating, and deleting. Each of the buttons make calls that generate the new page again.	ADMIN
/storage/{name}/enable/{val}	GET	application/json	Updates the storage plugin status. Returns success or failure.	ADMIN
/storage/{name}.json	DELETE	application/json	Deletes the storage plugin. Returns success or failure.	ADMIN
/storage/{name}/delete	GET	application/json	Same as deletePluginJSON but a GET instead of a DELETE request.	ADMIN
/storage/{name}.json	POST	application/json	Creates or updates the storage plugin. Returns success or failure. Expects JSON input.	ADMIN

/storage/{name}	POST	application/json	Same as createOrUpdatePluginJSON expects JSON or FORM input.	ADMIN
/profiles.json	GET	application/json	Returns currently running and completed profiles from PStore. For each profile a queryId, startTime, foremanAddress, query, user, and state is returned. Each list (running and completed) is organized in reverse chronological order.	ADMIN, USER
/profiles	GET	text/html	Generates an HTML page from the data returned by getProfilesJSON with a hyperlink to a detailed query page.	ADMIN, USER
/profiles/{queryid}.json	GET	application/json	Returns the entire profile in JSON.	ADMIN, USER
/profiles/{queryid}	GET	text/html	Returns a complex profile page.	ADMIN, USER
/profiles/cancel/{queryid}	GET	text/html	Cancels the given query and sends a message.	ADMIN, USER
/query	GET	text/html	Gets the query input page.	ALL
/query.json	POST	application/json	Submits a query and waits until it is completed and then returns the results as one big JSON object.	ALL
/query	POST	text/html	Returns the results of submitQueryJSON in an HTML table.	ALL
/status/metrics	GET	application/json	Returns a page that fetches metric info from resource, status, and metrics.	ALL
/status/threads	GET	text/html	Returns a page that fetches metric information from resource, status, and threads.	ALL
/login	GET	text/html	Returns an HTML log in page. If the user is already logged in, returns the home page. If the URL contains a redirect, sets the redirect URI for the session and forwards the user to the redirect page after the user is successfully logged in.	ALL
/login	POST	text/html	Returns a validation error for incorrect credentials.	ALL
/logout	GET	text/html	Ends a session.	ALL

GET /profiles.json

- ADMIN - gets all profiles on the system.
- USER - only the profiles of the queries the user has launched.

GET /profiles

- ADMIN - gets all profiles on the system.

last-updated: Apr 11, 2022

- USER - only the profiles of the queries the user has launched.

GET /profiles/{queryid}.json

- ADMIN - return the profile.
- USER - if the query is launched the by the requesting user return it. Otherwise, return an error saying no such profile exists.

GET /profiles/{queryid}

- ADMIN - return the profile.
- USER - if the query is launched the by the requesting user return it. Otherwise, return an error saying no such profile exists

GET /profiles/cancel/{queryid}

- ADMIN - can cancel the query.
- USER - cancel the query only if the query is launched by the user requesting the cancellation.

https://drill.apache.org/docs/rest-api/

SPNEGO for HTTP Authentication

Drill 1.13 and later supports the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) to extend the Kerberos-based single sign-on authentication mechanism to HTTP. An administrator configures the web server (Drillbit) to use SPNEGO for authentication. Depending on the system, either the administrator or the user configures the client (web browser or web client tool) to use SPNEGO for authentication.

An administrator can configure both FORM (username and password) and SPNEGO authentication together, which provides the ability for clients with different security preferences to connect to the same Drill cluster. When a client (a web browser or a web client tool, such as curl) requests access to a secured page from the web server (Drillbit), the SPNEGO mechanism uses tokens to perform a handshake that authenticates the client browser and the web server.

The Drill Web UI provides two possible log in options for a user depending on the configuration. If a user selects FORM, s/he must enter their username and password to access restricted pages in the Drill Web UI. The user is authenticated through PAM. If the user selects SPNEGO, the user is automatically logged in if they are an authenticated Kerberos user. If accessing a protected page directly, the user is redirected to the authentication log in page. If the client fails to authenticate using SPNEGO, an error page displays with an option to use FORM authentication, assuming FORM authentication is configured on the server side.

Browser Support

The following browsers were tested with Drill configured to use SPNEGO authentication:

- Firefox
- Chrome
- Safari
- Internet Explorer

- Web client tool, such as curl

Prerequisites

SPNEGO authentication for Drill requires the following:

- Drill 1.13 or later installed on each node.
- A working Kerberos infrastructure, which Drill does not provide.
- A Linux-based or Windows Active Directory (AD) Kerberos environment with secure clusters and a Drill server configured for Kerberos.
- Kerberos principal and keytab on each web server (Drillbit) that will use SPNEGO for authentication.
- Kerberos Ticket Granting Ticket on the client machine for the user accessing the Drillbit (web server).
- Drill web server configured for SPNEGO.

Configuring SPNEGO on the Web Server and Web Client

The following sections provide the steps that an administrator can follow to configure SPNEGO on the web server (Drillbit). An administrator or a user can follow the steps for configuring the web browser or client tool.

Configuring SPNEGO on the Drillbit (Web Server)
To configure SPNEGO on the web server, complete the following steps:

1. Generate a Kerberos principal on each web server that will receive inbound SPNEGO traffic. Each principal must have a corresponding keytab. The principal must have the following form:

```
"HTTP/<client-known-server-hostname@realm>"

   Example: "HTTP/example.QA.LAB@QA.LAB"
   //In this example, the client known server hostname is example.QA.LAB.
```

   Note: If HTTPS is enabled on the Drillbit (web server), the SPNEGO principal should also start with "HTTP/", not "HTTPS/" even though the URL includes HTTPS.

2. Update the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file on each Drillbit with the following server-side SPNEGO configurations:
   - To enable SPNEGO, add the following configuration to `drill-override.conf`:

```
impersonation: {
                    enabled: true,
                    max_chained_user_hops: 3
             },
             drill.exec.http: {
                    spnego.auth.principal:"HTTP/hostname@realm",
                    spnego.auth.keytab:"path/to/keytab",
                    auth.mechanisms: ["SPNEGO"]
             }
      }
      //The default authentication mechanism is "FORM".
```

last-updated: Apr 11, 2022

- To enable SPNEGO and FORM authentication, add the following configuration to `drill-override.conf`:

```
impersonation: {
                enabled: true,
                max_chained_user_hops: 3
              },
              security.user.auth: {
                      enabled: true,
                      packages +=
"org.apache.drill.exec.rpc.user.security",
                      impl: "pam4j",
                      pam_profiles: [ "sudo", "login" ]
                },
             drill.exec.http: {
                      spnego.auth.principal:"HTTP/hostname@realm",
                      spnego.auth.keytab:"path/to/keytab",
                      auth.mechanisms: ["SPNEGO", "FORM"]
             }
      }
```

3. (Optional) To configure the mapping from a Kerberos principal to a user account used by Drill, update the `drill.exec.security.auth.auth_to_local` property in the `drill-override.conf` file with custom rules, as described in Mapping from Kerberos Principal to OS user account.

   Note: Drill uses a Hadoop Kerberos name and rules to transform the client Kerberos principal to the principal Drill uses internally as the client's identity. By default, this mapping rule extracts the first portion from the provided principal. For example, if the principal format is Name1/Name2@realm, the default rule extracts only Name1 from the principal and stores Name1 as the client's identity on server side. Drill uses the short name, for example Name1, as the user account known to Drill. This user account name is used to determine if the authenticated user has administrative privileges.

Configuring SPNEGO on the Client

An administrator or user can configure SPNEGO on the client (web browser or client tools, such as curl). To configure SPNEGO on the client, a Kerberos Ticket Granting Ticket must exist for the user accessing the web server. The Kerberos Ticket Granting Ticket generated on the client side is used by the web client to get a service ticket from the KDC. This service ticket is used to generate a SPNEGO token, which is presented to the web server for authentication.

The client should use the same web server hostname (as configured in the server-side principal) to access the Drill Web Console. If the server hostname differs, SPNEGO authentication will fail. For example, if the server principal is `"HTTP/example.QA.LAB@QA.LAB"`, the client should use `http://example.QA.LAB:8047` as the Drill Web Console URL.

The following sections provide instructions for configuring the supported client-side browsers:

Firefox

To configure Firefox to use a negotiation dialog, such as SPNEGO to authenticate, complete the following steps:

1. Go to **About > Config**, and accept the warnings.
2. Navigate to the network settings.
3. Set `network.negotiate-auth.delegation-uris to "http://,https://"`.
4. Set `network.negotiate-auth.trusted-uris` to “http://,https://”.

Chrome

For MacOS or Linux, add the `--auth-server-whitelist` parameter to the `google-chrome` command. For example, to run Chrome from a Linux prompt, run the `google-chrome` command, as shown:

```
google-chrome --auth-server-whitelist = "hostname/domain"
  Example: google-chrome --auth-server-whitelist = "example.QA.LAB"
```

Safari

No configuration is required for Safari. Safari automatically authenticates using SPNEGO when requested by the server.

Internet Explorer

To configure Internet Explorer to use a negotiation dialog, such as SPNEGO to authenticate, complete the following steps:

1. Go to **Tools > Options > Security > Local Intranet > Sites**, and select all options.
2. Select **Advanced**, and add one or both of the following URLs to server:
   - http://
   - https://

   Note: Make sure you use the hostname of the Drillbit in the URL.
3. Close the **Advanced** tab, and click **OK**.
4. Go to **Tools > Options > Advanced > Security** (in the checkbox list), and enable the **Integrated Windows Authentication** option.
5. Click **OK**.
6. Close and reopen IE. You can browse to your Spengo protected resource.

REST API

You can use CURL commands to authenticate using SPNEGO and access secure web resources over REST.

Issue the following `curl` command to log in using SPNEGO, and save the authenticated session cookie to a file, such as `cookie.txt`, as shown:

```
curl -v --negotiate -c cookie.txt -u : http://<hostname>:8047/spnegoLogin
```

Use the authenticated session cookie stored in the file, for example `cookie.txt`, to access the Drill Web Console pages, as shown in the following example:

```
curl -v --negotiate -b cookie.txt -u : http://<hostname>:8047/query
   Example: curl -v --negotiate -b cookie.txt -u : http://
example.QA.LAB:8047/query
```

Using ACEs on Views to Limit Data Access

Describes how to use access control expressions to limit data access for Views.

Apache Drill on page 3185 is a distributed SQL query layer that runs on the data platform. You can enable user impersonation and create views in Drill to control user access to data stored in the data platform at the

last-updated: Apr 11, 2022

row and column levels. Access to data is based on file permissions set on the data (source files) and on the view definition files.

In addition to standard POSIX permissions, ACEs (access control expressions) are supported to secure data in the distributed filesystem. ACEs are a flexible access control mechanism that applies to files, tables, and streams. Setting an ACE (access control expression) on a file modifies the file permission to honor the *ACE* setting. Drill honors *ACE* set on Drill view files and on the source files that views access.

Each Drill view created has an associated view definition file, with a `.view.drill` extension, on which you can set ACEs to secure the view.

Example

Frank creates a workspace in the dfs storage plugin configuration in Drill that points to his home directory in the distributed filesystem. He then uses Drill to create a table named “employees” that he and the HR group can access:

```
-rwxr----- frank:hr /user/frank/employees
```

Joe, a member of the HR and MGR groups, creates a view named `emp_mgr_view` in his home directory to share a subset of the employees data with managers that belong to the MGR group:

```
-rwxr----- joe:mgr /user/joe/emp_mgr_view.drill.view
```

Managers in the MGR group have read permission on the `emp_mgr_view.drill.view` file so they can query the `emp_mgr_view` that Joe created and they can create new views from his view.

Setting *ACE* on the underlying data source (the “employees” table) or on the view file (`emp_mgr_view.drill.view`) that accesses the underlying data source resets the POSIX mode bits to match the permissions granted through *ACE* settings.

For example, if Frank issues the following command to apply an *ACE* to the “employees” table, a user must be a member of the EXEC group to read data in the “employees” table:

```
hadoop mfs -setace -R -readfile 'g:exec' employees
```

Anyone in the HR group that previously had access to the table can no longer access the table data unless they also belong to the EXEC group.

Running the `-getace` command on the table lists the *ACE* settings on the table:

```
hadoop mfs -getace /user/frank/employees
```

```
Path: /user/frank/employees
 readfile: g:exec
 writefile:
 executefile:
 readdir:
 addchild:
 deletechild:
 lookupdir:
 inherit: true
 mode: ---------
```

Similarly, if Joe issues the following command on the on the `emp_mgr_view.drill.view` file, only members of the HR group can read the file. Users that belong to the MGR group can no longer access the data through the view, unless they also belong to the HR group.

```
hadoop mfs -setace -R -readfile 'g:hr' emp_mgr_view.drill.view
```

Running the `-getace` command on view file shows the *ACE* settings on the file:

```
hadoop mfs -getace /user/joe/emp_mgr_view.drill.view
```

```
Path: /user/joe/emp_mgr_view.drill.view
 readfile: g:hr
 writefile:
  executefile:
  readdir:
  addchild:
  deletechild:
  lookupdir:
  inherit: true
  mode: ---------
```

You may also want to view another File ACE Example on page 1455.

Drill Drivers
HPE Ezmeral Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

The following table provides links to driver download sites and documentation:

Driver	Driver Download Site	Driver Documentation
Drill ODBC Driver	All versions of the Drill ODBC driver are located at https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Drill/.	• Information about the driver, including Drill driver version compatibility and important messages, is located at Drill ODBC Driver on page 3345. • Driver documentation, including installation and configuration instructions, is located in the Drill ODBC Driver PDF file.
Drill JDBC Driver	All versions of the Drill JDBC driver are located at https://package.mapr.hpe.com/tools/MapR-JDBC/MapR_Drill/.	• Information about the driver, including Drill driver version compatibility and important messages, is located at Drill JDBC Drivers on page 3333. • Driver documentation, including installation and configuration instructions, is located in the Drill JDBC Driver PDF file.

Drill JDBC Drivers
Download the Drill JDBC driver and use it on all platforms to connect BI tools, such as SQuirreL and Spotfire, to Drill. Drill also includes an embedded, open-source JDBC driver.

The downloadable Drill JDBC driver provides read-only access to Drill data sources and supports the security features described in Securing Drill.

Alternatively, you can use the open-source JDBC driver embedded in Drill; however, *the open-source JDBC driver is not tested on the MapR Data Platform*. The open-source driver supports Kerberos and Plain authentication mechanisms, but does not support the -SASL authentication mechanism. After you install Drill from the `mapr-drill` package, you can find the open-source JDBC driver files in the following directories:

- `$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-<drill-version>.jar`
- `$DRILL_HOME/jars/drill-jdbc-<drill-version>.jar`

Drill JDBC Driver Download

Use the version of the driver that correlates with the version of the installed Drill server. Although older versions of the driver may connect to an upgraded version of Drill, the older drivers do not include all the server features available in the newer drivers.

The following table provides links to the download locations for the Drill JDBC drivers that correlate with each of the Drill versions listed:

Drill Version	JDBC Version
1.16.0.x	1.6.7.1010 **Attention:** This driver supports JRE 8 only and includes updated driver classes. See Driver Class on page 3334.
1.16.0.x	1.6.6.1009
1.16.1.x	1.6.6.1008
1.16.0	1.6.0.1001
1.15.0	1.6.0.1001
1.14.0	1.6.0.1001
1.13.0	1.5.9.1018
1.12.0	1.5.8.1017
1.11.0	1.5.6.1012
1.10.0	1.5.3.1006

Driver Class

Important: The Drill JDBC Driver installation and configuration PDF document does not include the information provided in the following sections:

Driver Class

The *Registering the Driver Class* section of the Drill JDBC Driver documentation incorrectly lists the driver classes as `com.simba.drill.jdbc41.Driver` and `com.simba.drill.jdbc41.DataSource`.

- For driver version **1.6.6.1009 and earlier**, the correct driver classes are:
  - `com.mapr.drill.jdbc41.Driver`
  - `com.mapr.drill.jdbc41.DataSource`
- For driver version **1.6.7.1010**, the correct driver classes are:
  - `com.mapr.drill.jdbc.Driver`
  - `com.simba.drill.jdbc.DataSource`

JDBC Connection String

You can indicate the `schema` parameter in the connection string, as shown in the following example:

```
jdbc:drill:zk=10.10.100.30:5181,10.10.100.31:5181,10.10.100.32:5181/drill/
drillbits1;schema=hive
```

You can also include the authentication mechanism in the connection string using the `AuthMech` or `auth` parameter. For MapR-SASL, use `auth=MAPRSASL`.

- If using the MapR-SASL or Plain authentication mechanism, you must add the Drill JDBC JAR files and `/opt/mapr/lib/*` to the classpath of the third-party client tool, as shown in the following example for SQuirreL when the path to the driver is `C:\driver\MapRDrillJDBC41-1.5.6.1012:`

  ```
  -cp
  "%SQUIRREL_CP%;C:\driver\MapRDrillJDBC41-1.5.6.1012\*;C:\opt\mapr\lib\*"
  ```

  The driver JAR files should appear before `/opt/mapr/lib/*` in the classpath.

Using MapR-SASL for Authentication on Windows

Drill is automatically configured with MapR security when you install Drill on a MapR cluster configured with default security. To successfully connect to Drill from a Windows JDBC client, a user ticket must exist on the Windows client in the %TEMP% directory or in the location specified by the $MAPR_TICKETFILE_LOCATION environment variable.

The JDBC driver locates user tickets for the current Windows user in the default ticket location, %TEMP%, or in the location specified by the environment variable, $MAPR_TICKETFILE_LOCATION. See Tickets and Generating a MapR User Ticket for more information.

You can either copy a user ticket that was generated on the MapR cluster into the default location (%TEMP%), or you can install the MapR client on the Windows client and then run the maprlogin command to generate the ticket on the Windows client.

Note: The JDBC user must be the same as the Windows user that created the ticket.

Example

If you want to connect to Drill as the mapr user, you must create a ticket for the mapr user, as shown:

```
$ maprlogin password -user mapr
[Password for user 'mapr' at cluster 'Cluster1':]
```

The credentials for the mapr user in Cluster1 are written to /tmp/maprticket_1000.

Next, place the ticket in the %TEMP% directory on the Windows client. For example, the default location for a Windows 10 user named Tabetha Stephens is shown:

```
'C:\Users\TABETH~1\AppData\Local\Temp/maprticket_Tabetha Stephens'
```

To override this location, set the "MAPR_TICKETFILE_LOCATION" global variable for the Windows user.

Note: Using the MAPR_TICKETFILE_LOCATION is recommended because the %TEMP% directory differs between Windows versions. You may also want to set the MAPR_TICKETFILE_LOCATION per user on the operating system to prevent all users from using the same user ticket on the client.

Avoiding Driver Conflicts

If you download and use the Drill JDBC driver, rename the embedded JDBC driver files to avoid any conflict between the downloaded driver and the open-source driver. The embedded JDBC driver files are in the following directories after you install Drill:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-1.10.0.jar
$DRILL_HOME/jars/drill-jdbc-1.10.0.jar
```

last-updated: Apr 11, 2022

Changing the file extension to rename these files, as shown in the following example, prevents Drill or any other application, such as SQLLine, from picking up the embedded driver:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-1.10.0.jar.original
$DRILL_HOME/jars/drill-jdbc-1.10.0.jar.original
```

Connecting to Drill via the Drill Shell (SQLLine)

See Connecting to Drill via the Drill Shell (SQLLine) on page 3336.

Driver Limitations

When using MapR-SASL with JDBC or ODBC drivers, there is no way to specify the target cluster name as part of the connection parameters. MapR-SASL reads the first entry in the `/opt/mapr/conf/mapr-clusters.conf` file and assumes it is the target cluster name.

For example, if the `mapr-clusters.conf` file has an entry for '`cluster1`' followed by an entry for '`cluster2`' and you want to connect to a node in '`cluster2`', authentication fails. As a workaround, manually switch the order of entries in the `mapr-clusters.conf` file.

Connecting to Drill via the Drill Shell (SQLLine)
SQLLine is a JDBC application that is packaged with Drill and serves as the Drill shell. When you issue queries from the SQLLine client, SQLLine passes the queries to the connected Drillbit (Drill node).

You can connect to Drill through Sqlline directly or through a connection-property file. To avoid exposing credentials, connect through the connection-property file.

A JDBC connection string supplies the connection information to a Drill node or ZooKeeper cluster. When you connect to a ZooKeeper cluster, ZooKeeper selects the Drillbit for SQLLine to connect to.

JDBC Connection String Example

Here is an example of a JDBC connection string that connects SQLLine to drillnode1:

```
jdbc:drill:drillbit=drillnode1:31010
```

The default port on a Drill node is 31010.

Connection Parameters

You can include SQLLine connection parameters in the connection string and run various shell commands, as described in Configuring the Drill Shell.

In the following example, `-u` is the connection parameter for the JDBC connection string, `-n` is the parameter for the username, and `-p` is the parameter for the password:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=drillnode1:31010" -n mapr -p mapr
```

Starting SQLLine

Start SQLLine from the Drill installation directory, as shown:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
jdbc:drill:drillbit=drillnode1:31010
```

Configuration Options

You can also include configuration options, such as `schema`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs" -n <username> -p <password>
```

Schema	The `schema` is the name of a storage plugin configuration to use as the default for queries. If you indicate the schema in the connection URL, you do not have to run the `USE <schema>;` query to switch to the schema you want to use. All queries run against the schema indicated in the JDBC connection string.
Authentication	If authentication (Plain, MAPRSASL, or Kerberos) is enabled, include the `auth` option in the connection string. If Drill is installed on a cluster secured by default security, set `auth=MAPRSASL`. For additional configuration options, refer to the *Driver Configuration Options* section in the JDBC Installation and Configuration Guide.

Connecting to a Specific Drill Node

Indicate which Drill node you want SQLLine to connect to in the JDBC connection string by using the following JDBC connection string format:

```
jdbc:drill:drillbit=<host>:<port>
```

Note that properties are case-sensitive. The `host` is the DNS or IP address of the server (Drill node). By default, the driver connects to port 31010.

Example	The following example shows how to run SQLLine with the JDBC connection string and includes the username, password, and auth parameters to authenticate to the server with Plain authentication:
	
	`/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit=<ip-address>:<port>;auth=PLAIN" -n <username> -p <password>`
	
	If you installed Drill on a cluster with default security enabled, set the `auth` type to `maprsasl`:
	
	`/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit=<ip-address>:<port>;auth=MAPRSASL" -n <username> -p <password>`

Connecting to ZooKeeper

When you include the ZooKeeper nodes in the JDBC connection string, ZooKeeper selects an available Drill node for SQLLine to use.

last-updated: Apr 11, 2022

Indicate the ZooKeeper cluster you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:zk=<zk-server-list>/drill/<clustername>
```

The `zk-server-list` is a comma-separated list of the ZooKeeper nodes in the cluster. The `clustername` is the unique name of the Drillbit cluster that you want to connect to.

Important: You can locate the name of the Drillbit cluster in `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf`. The default name of the Drillbit cluster is `drillbits1`. The name is set by the `cluster-id` property. If you have multiple Drill clusters, you might want to override the Drillbit cluster name in `drill-override.conf`. However, first back-up your storage plugin configurations, as they might reset to the defaults when you change the cluster name. Restart Drill after you edit `drill-override.conf`.

Note that properties are case-sensitive. The `host` is the DNS or IP address of the server (ZooKeeper node).

Example

The following example shows you how to configure the JDBC connection string to connect SQLLine to the ZooKeeper cluster:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-i
p>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=PLAIN
```

Note: The default port for ZooKeeper nodes in a data-fabric cluster is 5181.

If you installed Drill on a secure cluster, set the `auth` type to `maprsasl`:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-i
p>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=MAPRSASL
```

Using a Connection-Property File with SQLLine

If you use a connection-property file, make sure you restrict user permission on the file to only those users you want to have access.

Complete the following steps to create a connection-property file and connect to Drill:

1. Create a connection-property file named `login.properties` with the following information:

```
url:<jdbc-connection-url>
user:<username>
password:<password>

//Example
cat login.properties
url:jdbc:drill:schema=dfs;drillbit=drill-lab-node01
user:drilluser
password:letsdrill
```

2. To connect to Drill, run SQLLine, as shown:

```
sqlline <sqlline args> <path/to/login.properties file>
```

The following examples show you how to connect to Drill through the connection-property file and how to verify that log in details are safe:

Example 1: Connecting to Drill via the connection-property file

```
sqlline login.properties

Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"drill baby drill"
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01
0: jdbc:drill:schema=dfs>!q
```

Example 2 : Submitting a query when connecting to Drill via the connection-property file

```
sqlline -q "SELECT version FROM
sys.version" login.properties
Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"the only truly happy people are
children, the creative minority and
drill users"
0: jdbc:drill:schema=dfs> select
version from sys.version
. . . . . . . . . . . . . > +----------+
| version  |
+----------+
| 1.16.0   |
+----------+
1 row selected (0.295 seconds)
0: jdbc:drill:schema=dfs> Closing:
org.apache.drill.jdbc.impl.DrillConnec
tionImpl
$
```

Example 3: Use the properties command to connect to Drill via the connection-property file

```
Run sqlline from /opt/mapr/drill/
drill-<version>/bin sqlline

Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"a little sql for your nosql"

sqlline> !properties /home/drilluser/
login.properties
0: jdbc:drill:schema=dfs>
```

```
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01
0: jdbc:drill:schema=dfs>
```

Example 4: Verify that Login Details are Safe

You can verify sqlline process information to confirm login details are not exposed to other users.

```
ps -ef | grep sqlline
drilluser     18938 21924 99 14:14
pts/0    00:00:03 /opt/
jdk1.8.0_141/bin/
java -XX:MaxPermSize=512M -Djava.secur
ity.auth.login.config=/opt/mapr/conf/
mapr.login.conf \
-Dzookeeper.sasl.client=false -Dhadoop
.login=simple -Dlog.path=/opt/mapr/
drill/drill-1.10.0/logs/
sqlline.log -Dlog.query.path=/opt/
mapr/drill/drill-1.16.0/logs/
sqlline_queries.json \
-cp /opt/mapr/drill/drill-1.10.0/
conf:/opt/mapr/drill/drill-1.16.0/
jars/*:/opt/mapr/drill/drill-1.16.0/
jars/ext/*:/opt/mapr/drill/
drill-1.16.0/jars/3rdparty/*:/opt/
mapr/drill/drill-1.16.0/jars/classb/*
sqlline.SqlLine -d
org.apache.drill.jdbc.Driver --maxWidt
h=10000 --color=true login.properties
drilluser     20119  1691  0 14:14
pts/1    00:00:00 grep sqlline
```

How to Protect the Password

Use the `!connect` command to mask and protect the password, as shown in the following example:

```
sqlline> !connect
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010

Enter username for
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010: alice
Enter password for
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010: ********
```

Start|Stop the Drill Service

You can start|stop|restart the Drillbit service on one or more nodes by using the Control System or the following command:

```
maprcli node services -name drill-bits -action start|restart|stop -nodes
<node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

Drill Log Files

You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

Using the Drill JDBC Driver with SQuirreL
You can use the Drill JDBC driver with SQuirreL to connect to Drill and query the data sources configured in Drill.

To use the Drill JDBC Driver with SQuirreL, verify that your system meets the prerequisites and then download and configure the driver.

Prerequisites

Verify that the system meets the following prerequisites:

- Java Runtime Environment (JRE), version 7.0 or later, installed on each machine where you plan to use the JDBC driver.
- Drill installed in distributed mode on one or multiple nodes in a cluster with data sources configured. See Connecting Drill to Data Sources.
- Verify that the system can resolve the hostnames of the ZooKeeper nodes of the Drill cluster. You can do this by configuring DNS for all of the systems. Alternatively, you can edit the hosts file to include the hostnames and IP addresses of all the ZooKeeper nodes used with the Drill cluster.
  - For Windows, create the entry in the `%WINDIR%\system32\drivers\etc\hosts`.
  - For Linux and Mac, create the entry in `/etc/hosts`.

    Example: `127.0.1.1 maprdemo`

Downloading and Configuring the Driver

This topic provides instructions for downloading and configuring the Drill JDBC driver for SQuirreL.

When you configure the driver, you define the driver and create an alias. The alias is a specific instance of the driver configuration. SQuirreL uses the driver definition and alias to connect to Drill so you can access data sources that you have registered with Drill. When you create the alias, you provide a connection URL that includes the name of the Drill directory stored in ZooKeeper and the cluster ID. The URL has the following format:

```
jdbc:drill:zk=<zookeeper_quorum>/<drill_directory_in_zookeeper>/<cluster_ID>
```

The following example shows a URL for Drill installed on a single node:

```
jdbc:drill:zk=10.10.100.56:5181/drill/demo_mapr_com-drillbits
jdbc:drill:zk=10.10.100.24:2181/drill/drillbits1
```

The following example shows a URL for Drill installed in distributed mode with a connection to a ZooKeeper quorum:

```
jdbc:drill:zk=10.10.100.30:5181,10.10.100.31:5181,10.10.100.32:5181/drill/
drillbits1
```

last-updated: Apr 11, 2022

Note:

- The ZooKeeper port is 2181. In a MapR cluster, the ZooKeeper port is 5181.
- The Drill directory stored in ZooKeeper is `/drill`.
- The Drill default cluster ID is `drillbits1`. To determine the cluster ID, check the following file:

  ```
  <drill-installation>/conf/drill-override.conf
  ```

  For example:

  ```
  ... drill.exec: { cluster-id: "docs41cluster-drillbits", zk.connect:
  "centos23.lab:5181,centos28.lab:5181,centos29.lab:5181" } ...
  ```

To use the Drill JDBC driver with SQuirreL, complete the following steps:

1. Download the latest Drill JDBC Driver and then unzip the file. The Drill JDBC Driver JAR files must exist in a directory on your machine before you can configure the driver in the SQuirreL client.
2. *If using the MapR-SASL or Plain authentication mechanism*, add the Drill JDBC JAR files and /opt/mapr/lib/* to Squirrel's classpath, as shown in the following example when the path to the driver is C:\driver\MapRDrillJDBC41-1.5.6.1012:

   ```
   -cp
   "%SQUIRREL_CP%;C:\driver\MapRDrillJDBC41-1.5.6.1012\*;C:\opt\mapr\lib\*"
   ```

   Note: The driver JAR files should appear before /opt/mapr/lib/* in the classpath.
3. Define the driver.
   a) Open the SQuirreL client.
   b) In the SQuirreL toolbar, select **Drivers > New Driver**. The Add Driver dialog appears.
   c) Enter the following information:
      - **Name** - Name for the Drill JDBC Driver
      - **Example URL** - `jdbc:drill:zk=<zookeeper_quorum>`

        Example: `jdbc:drill:zk=maprdemo:5181`
      - **Website URL** - `jdbc:drill:zk=<zookeeper_quorum>`

        Example: `jdbc:drill:zk=maprdemo:5181`

        Example: `jdbc:drill:zk=10.10.100.113:5181,10.10.100.115:5181`
   d) Select **Extra Class Path**, and click **Add**.
   e) Navigate to the directory that contains the JDBC JAR files.
   f) Select all of the files in the directory, and click **Choose**.
   g) In the Class Name drop-down field, select the driver class. For driver version 1.6.6.1009 and earlier, select **com.mapr.drill.jdbc41.Driver** or type **com.mapr.drill.jdbc41.Driver** in the field if the option does not appear. For driver version 1.6.7.1010, select **com.mapr.drill.jdbc.Driver** or type **com.mapr.drill.jdbc.Driver** in the field if the option does not appear.

h) Click **Ok**. The SQuirreL client displays a message stating that the driver registration is successful, and you can see the driver in the Drivers panel.

4. Create a database alias.
   a) Select the **Aliases** tab.
   b) In the SQuirreL toolbar, select **Aliases > New Alias**. The Add Alias dialog box appears.
   c) Enter the following information and click **Ok**.
      - **Alias Name** - A unique name for the Drill JDBC Driver alias
      - **Driver** - Select the Drill JDBC Driver
      - **URL** - Enter the connection URL with the name of the Drill directory stored in ZooKeeper and the cluster ID.
      - **User Name** - admin
      - **Password** - admin

      The *Connect to:* dialog appears.
   d) Click **Connect**. SQuirreL displays a message stating that the connection is successful.
   e) Click **Ok**. SQuirrel is connected to Drill through the Drill JDBC driver. You can run your queries.

Running a Drill Query from SQuirreL

Query sample data in Drill to verify that the SQuirreL client is successfully connected to the cluster through the Drill JDBC driver.

Run a test query on sample data to test the Drill connection.

To query sample data with Squirrel, complete the following steps:

1. Click the **SQL** tab.
2. Enter the following query in the query box: `SELECT * FROM cp.`employee.json`;`
3. Press **Ctrl+Enter** to run the query. The query results display.

You have successfully run a Drill query from the SQuirreL client!

Java Sample Code

To use the Drill JDBC driver in an application, you must include all of the JAR files from the ZIP archive in the classpath for the Java project.

The following Java code demonstrates how to use the JDBC API to:

- Register the driver for Drill
- Establish a connection to a Drill server
- Query the database
- Parse a result set
- Handle exceptions
- Clean up to avoid memory leakage

```
// java.sql packages are required
import java.sql.*;
```

last-updated: Apr 11, 2022

```
class DrillJDBCExample {
     // Define a string as the fully qualified class name
     // (FQCN) of the desired JDBC driver
       private static final String JDBC_DRIVER =
       "com.mapr.drill.jdbc.Driver";
     // Define a string as the connection URL
        private static final String CONNECTION_URL =
        "jdbc:drill:drillbit=192.168.1.1:31010";

            public static void main(String[] args) {
                Connection con = null;
                Statement stmt = null;
                ResultSet rs = null;
    // Define a plain query
       String query = "SELECT first_name, last_name, emp_id
       FROM `hive`.`default`.`emp`";

                try {

                    // Register the driver using the class name
                    Class.forName(JDBC_DRIVER);
                    // Establish a connection using the connection
                    // URL
                    con = DriverManager.getConnection(CONNECTION_
                    URL);
                    // Create a Statement object for sending SQL
                    // statements to the database
                    stmt = con.createStatement();

                    // Execute the SQL statement
                    rs = stmt.executeQuery(query);
                    // Display a header line for output appearing in
                    // the Console View
                    System.out.printf("%20s%20s%20s\r\n", "FIRST
                    NAME", "LAST NAME" , "EMPLOYEE ID");

                    // Step through each row in the result set
                    // returned from the database
                    while(rs.next()) {
                        // Retrieve values from the row where the

                        // cursor is currently positioned using
                        // column names
                        String FirstName = rs.getString("first_
                        name");
                        String LastName = rs.getString("last_name");
                        String EmployeeID = rs.getString("emp_id");

                    // Display values in columns 20 characters
                    // wide in the Console View using the
                    // Formatter
                    System.out.printf("%20s%20s%20s\r\n",
                    FirstName, LastName, EmployeeID);
                    }
                } catch (SQLException se) {
                    // Handle errors encountered during interaction
                    // with the data source
                } catch (Exception e) {
                    // Handle other errors
                } finally {
                    // Perform clean up
                try {
                    if (rs != null) {
                        rs.close();
```

```
                    }
                } catch (SQLException se1) {
                    // Log this
                }
                try {
                    if (stmt != null) {
                        stmt.close();
                }
                } catch (SQLException se2) {
                    // Log this
                }
                try {
                    if (con != null) {
                        con.close();
                    }
                } catch (SQLException se3) {
                    // Log this
                } // End try
            } // End try
        } // End main
    } // End DrillJDBCExample
```

Drill ODBC Driver

HPE Ezmeral Data Fabric provides a Drill ODBC driver that you can download and use on all platforms to connect BI tools, such as Tableau, to Drill.

Use the version of the driver that correlates with the version of the installed Drill server. Although older versions of the driver may be able to connect to an upgraded version of Drill, the older drivers do not include all the server features available in the newer drivers.

The following table provides links to the download locations for the Drill ODBC drivers that correlate with each of the Drill versions listed:

Drill Version	ODBC Version
1.16.0.100, 1.16.1.100	1.5.1.1002
1.16.0, 1.16.1.0	1.3.22.1055
1.15.0	1.3.22.1055
1.14.0	1.3.22.1055
1.13.0	1.3.16.1049
1.12.0	1.3.15.1048
1.11.0	1.3.15.1046
1.10.0	1.3.8.1030

Important:

- Detailed documentation for the Drill ODBC driver is available at Drill ODBC Driver.
- The 32-bit version of the Drill ODBC driver does not support MapR-SASL. MapR-SASL is only supported in the 64-bit Drill ODBC driver.
- If you plan to use MapR-SASL for authentication on Windows, review the following section for additional information and instructions.

last-updated: Apr 11, 2022

Using MapR-SASL for Authentication on Windows

Drill is automatically configured with default security when you install Drill 1.11 and later on a secure (version 6.x or later) cluster configured with the default security. To successfully connect to Drill from a Windows ODBC client, the MapR client must be installed and a `mapr` user ticket must exist on the Windows client in the %TEMP% directory or in the location specified by the $MAPR_TICKETFILE_LOCATION environment variable.

The ODBC driver locates user tickets for the current Windows user in the default ticket location, %TEMP%, or in the location specified by the environment variable, $MAPR_TICKETFILE_LOCATION. See Tickets and Generating a MapR User Ticket for more information.

You can either copy a user ticket that was generated on the cluster into the default location (%TEMP%), or you can run the `maprlogin` command to generate the ticket on the Windows client.

If you copy a user ticket that was generated on the cluster, you must copy the `mapr-clusters.conf` file to the client machine. Copy the file from `/opt/mapr/conf/mapr-clusters.conf` to `C:/opt/mapr/conf/mapr-clusters.conf` on the client machine. Verify that the cluster to which the client is connecting is listed as the first entry in the `mapr-clusters.conf` file. Also, if the cluster is secure, verify that `secure=true` for the cluster entry in the file.

Note: The ODBC user must be the same as the Windows user that created the ticket.

Example

If you want to connect to Drill as the `mapr` user, you must create a ticket for the `mapr` user, as shown:

```
$ maprlogin password -user mapr
[Password for user 'mapr' at cluster 'Cluster1':]
```

The credentials for the `mapr` user in Cluster1 are written to `/tmp/maprticket_1000`.

Next, place the ticket in the %TEMP% directory on the Windows client. For example, the default location for a Windows 10 user named Tabetha Stephens is shown:

```
'C:\Users\TABETH~1\AppData\Local\Temp/maprticket_Tabetha Stephens'
```

To override this location, set the "MAPR_TICKETFILE_LOCATION" global variable for the Windows user.

Note: Using the MAPR_TICKETFILE_LOCATION is recommended because the %TEMP% directory differs between Windows versions. You may also want to set the MAPR_TICKETFILE_LOCATION per user on the operating system to prevent all users from using the same user ticket on the client.

Driver Limitations

When using MapR-SASL with JDBC or ODBC drivers, there is no way to specify the target cluster name as part of the connection parameters. MapR-SASL reads the first entry in the `/opt/mapr/conf/mapr-clusters.conf` file and assumes it is the target cluster name.

For example, if the `mapr-clusters.conf` file has an entry for '`cluster1`' followed by an entry for '`cluster2`' and you want to connect to a node in '`cluster2`', authentication fails. As a workaround, manually switch the order of entries in the `mapr-clusters.conf` file.

Drill Configuration Files

The Drill installation includes configuration files with start-up options that you can modify prior to starting Drill.

The configuration files reside in a HOCON configuration file format, which is a hybrid between a properties file and a JSON file. The files have a nested relationship and a hierarchical structure, where one file overrides another. You can locate the files in the /opt/mapr/drill/drill-<version>/conf directory.

last-updated: Apr 11, 2022

The configuration files are listed below in their hierarchical order. The drill-distrib.conf file overrides the drill-module.conf file, and the drill-override.conf file overrides the drill-distrib.conf file.

- drill-override.conf
- drill-distrib.conf
- drill-module.conf

Environment variables are also overridden in the same way, in the order listed below:

- drill-env.sh (or explicitly defined in environment)
- distrib-env.sh
- drill-config.sh

The following table lists the configuration files with their descriptions:

File Name	Description	Default Configuration with Secure Installation
drill-distrib.conf	Contains distribution-specific configurations for Drill. Automatically updated by configure.sh when you configure the cluster.	• Enables authentication, impersonation, and encryption with MapR -SASL as the default mechanism. • Enables TLS for the HTTPS channel.  **Note:** By default, HTTPS uses the SSL certificate provided by the cluster installation; however, an administrator can specify a certificate in a keystore. • Enables the inbound impersonation policy for administrators to impersonate any other user.
distrib-env.sh	Contains distribution-specific defaults for various environment variables.	• Enables authentication between the Drillbits and ZooKeeper. • Configures the location of the default security configuration file, mapr.login.conf, used by Drill.
drill-env.sh	The drill-env.sh file contains the cluster admininstrator-specific environment variables that can differ from the defaults. You can modify this file to override the default values of system properties defined in the distrib-env.sh file or to define a new system property. For example, you can configure the amount of heap and direct memory allocated to Drill. See Configuring Drill Memory on page 3239.	Empty upon installation.

last-updated: Apr 11, 2022

drill-override.conf	Use the drill-override.conf file to override the default values obtained from drill-module.conf and drill-distrib.conf. A cluster administrator can update this file to configure a Drillbit as required (different from default installation)	When you first install Drill, drill-override.conf contains ZooKeeper and Drillbit configuration information; however, after you run configure.sh -R, the entries are removed and the file does not contain any configurations.

Monitoring Drill Metrics

You can monitor Drill metrics and logs using the Kibana and Grafana interfaces that are available through MapR Monitoring. The Kibana interface is a log monitoring tool. The Grafana interface is a metrics monitoring tool where you can view system-level metrics for Drill.

Drill uses JMX (Java Management Extensions) to monitor queries at runtime. JMX provides the architecture to dynamically manage and monitor applications. JMX collects Drill system-level metrics that you can access through Grafana or through the Metrics page in the Drill Web Console.

You must install a specific set of services on cluster nodes to use the Kibana and Grafana monitoring tools. You can install the services using the MapR installer, or you can install these services manually. If you install the monitoring services in a cluster running Drill, you must restart Drill in order for Drill to communicate with JMX. However, if you install Drill after the monitoring services are installed, you must run the `configure.sh` command and restart the Drillbit service in order for the monitoring services to recognize that a new application is running in the cluster.

The following table lists the predefined Drill system-level metrics that you can view in Grafana:

Metric	Description
mapr.drill.allocator_root_used	The amount of memory used by the internal memory allocator. Measured in bytes.
mapr.drill.queries_running	The number of queries running for which the Drillbit is the foreman.
mapr.drill.queries_completed	The number of completed, cancelled, or failed queries for which the Drillbit was the foreman.
mapr.drill.fragments_running	The number of query fragments currently running in the Drillbit.
mapr.drill.allocator_root_peak	The peak amount of memory used by the internal memory allocator. Measured in bytes.
mapr.drill.heap_used	The amount of heap memory used by the JVM. Measured in bytes.
mapr.drill.non_heap_used	The amount of non-heap memory used by the JVM. Measured in bytes.
mapr.drill.count	The number of live daemon and non-daemon threads.
mapr.drill.fd_usage	The ratio of used file descriptors to total file descriptors.
mapr.drill.runnable_count	The number of threads executing in the JVM. This metric is useful for debugging Drill issues.
mapr.drill.waiting_count	The number of threads waiting to be executed. This may occur when a thread waits on another thread to perform an action before proceeding. This metric is useful for debugging Drill issues.
mapr.drill.blocked_count	The number of blocked threads waiting for a monitor lock. This metric is useful for debugging Drill issues.

Optimizing Queries with Indexes

MapR Database provides a highly scalable key-value database platform on which you can run SQL queries using Drill. As of the 6.0 release of the MapR Data Platform, MapR Database natively supports indexes on secondary fields in JSON tables.

Note: MapR Database does not support indexes on binary tables.

An index is a special table that stores a subset of document fields from a JSON table. The primary field in a JSON table is the `_id` field (unique key field). By default, MapR Database sorts the JSON table by the `_id` field. All other fields in the JSON table are secondary fields. You can create indexes on the secondary fields in a JSON table to eliminate full tables scans and significanlty improve query performance. See MapR Database as a Document Database and Secondary Index Concepts for more information.

Benefits of Indexes

Well-designed indexes can optimize access to data stored in MapR Database JSON tables and improve performance for high read operations, fast integrated analytics, and complex operational analytics. See Secondary Indexes for more information about the benefits of indexes.

Types of Queries that Benefit from Indexes

Indexes primarily benefit queries with filters in the WHERE clause and queries with an ORDER BY clause for sorting, as described in the following table:

Query Type	Description
Equality	Equality queries contain equality conditions, such as a=1 and can also include IN. See Equality Queries.
Range	Range queries contain range conditions, such as <=, >=, and the LIKE pattern matching condition. See Range Queries. **Note:** The LIKE operator only works on fields that have varchar data types. To use the LIKE operator in queries, use the CAST function to explicitly cast fields to varchar. To use indexes for such queries, create indexes on the cast expressions, as explained in Using Casts in Secondary Indexes.
ORDER BY	ORDER BY queries specify a sort order. If the ordering and sorting of the index key list match the ordering specified in a query, the optimizer in Drill does not have to sort the data after the index scan. See ORDER BY Queries.
Multi-index	Multi-index queries contain conditions on multiple fields. Drill can scan multiple indexes and use the intersection of the matching documents to optimize these queries. Multi-index queries are an alternative to using composite key indexes. See Multi-Index Queries.

Drill can create index plans for queries with and without filters in the WHERE clause. For example, Drill can create an index plan for an ORDER BY query that does not have filters.

Drill 1.12 and later also supports the following types of queries without filters :

- GROUP BY
- JOIN
- DISTINCT

last-updated: Apr 11, 2022

See Index Planning in Drill for more information.

Types of Indexes Supported by MapR Database

MapR Database supports several types of indexes on JSON tables including simple, composite, hashed, covering, and indexes with the CAST function.

Note: MapR Database enforces certain restrictions on indexes, such as a limit of 32 KB on the collective size of all indexed keys for each index. See Restrictions on Secondary Indexes for a full list of restrictions and Data Types Supported for Secondary Indexes.

The following table lists the supported index types with brief descriptions and links to topics that provide more information:

Index Type	Description
Simple	Simple indexes are indexes with a single indexed field (or key). See Simple Indexes.
Composite	Composite indexes are indexes that have more than one indexed field (or key). See Composite Indexes.
Hashed	Hashed indexes are indexes that distribute keys across logical partitions to avoid the creation of hot spots when MapR Database updates the index with new keys from the JSON table. See Hashed Indexes.
Covering	A covering index is an index that allows MapR Database to process a query using only the secondary indexes. MapR Database does not have to read data in the JSON table. See Covering Indexes on page 560.
Indexes with the CAST function	Indexes with the CAST function convert the indexed field to the data type specified by the CAST function and store the results. See Using Casts in Secondary Indexes.

Steps Required to Use Indexes

To use the index functionality with Drill, complete the following steps:

1. Install the latest version of the required MapR software on the cluster. See Preparing Clusters for Querying using Secondary Indexes on JSON Tables and Installing Drill.
2. Evaluate your queries and design indexes that support the queries. See Understanding the Secondary Index Workflow and Designing Secondary Indexes.
3. Create indexes on JSON tables in MapR Database. See Adding Secondary Indexes on JSON Tables and Managing Secondary Indexes.

   Note: The user that creates indexes on a JSON table must have created the table or have the `indexperm` permission in addition to `readAce` on the volume and `lookupdir` on directories in the table path. If you do not have these permissions, consult with your system administrator.
4. Issue queries.
5. Verify that Drill uses the available indexes. See Determining Index Use and Troubleshooting Indexes.

Additional Information

- To see how Drill selects a query plan, see Selection and Execution of Secondary Indexes.
- To learn about the index planning and execution configuration options available in Drill, see Index Planning and Execution Configuration Options.

last-updated: Apr 11, 2022

- For information about index architecture, see Implementation of Secondary Indexes.

Index Planning in Drill
Index planning reduces the I/O operation costs associated with full table scans. If an index is available, Drill can use the index to improve query performance.

Drill can use indexes to create query plans for queries that filter on indexed fields or fields included in an index. Fields in COUNT, COUNT DISTINCT, JOIN, GROUP BY, and ORDER BY also determine index use. Drill can create index-based query plans for queries with and without filters (WHERE clause).

Note: In Drill 1.11 and earlier, if a query does not have a filter, the query must have an ORDER BY clause.

Drill can create index plans for queries with an ORDER BY clause whether or not the query contains a filter, as shown in the following example:

```
SELECT L_LINENUMBER FROM lineitem ORDER BY L_LINENUMBER;
```

Note: In this example, L_LINENUMBER is an indexed field in the index selected for the query plan.

In Drill 1.12 and later, Drill can also create index-based query plans for the following types of queries when they do not have filters (WHERE clause):

- **GROUP BY** queries, as shown in the following example where L_COMMITDate is an indexed field in the index selected for the query plan:

  ```
  SELECT L_COMMITDate FROM lineitem GROUP BY L_COMMITDate;
  ```

- **JOIN** queries, as shown in the following example where L_ORDERKEY and O_ORDERKEY are indexed fields and L_LINESTATUS is an included field in the index selected for the query plan:

  ```
  SELECT L.L_LINESTATUS FROM lineitem L, orders O WHERE
  L.L_ORDERKEY=O.O_ORDERKEY;
  ```

  Note: If the planner picks two indexes, one for lineitem and one for orders, a sort merge join is used instead of a hash join.

- Queries with **DISTINCT** projections, as shown in the following examples where L_LINENUMBER is an indexed field in the index selected for the query plan:

  ```
  SELECT DISTINCT L_LINENUMBER FROM lineitem;
  SELECT COUNT(DISTINCT L_LINENUMBER) FROM lineitem;
  ```

Drill can use indexes for queries that GROUP BY or ORDER BY the leading fields in an index. Drill does not use indexes for queries that GROUP BY or ORDER BY the trailing or included fields in an index.

When a query contains GROUP BY and ORDER BY operations on the leading indexed column, Drill can use the sort order of the index to create index-based query plans that use streaming aggregates and merge joins to improve query performance.

You can run the EXPLAIN PLAN FOR command with a query to see the query plan that Drill creates. See Covering and Non-Covering Queries for more information about index planning in Drill.

last-updated: Apr 11, 2022

Index Planning and Execution Configuration Options

The 1.11 release of Drill introduces options that affect how Drill uses indexes when planning and executing queries. You can set the query planning and execution options, at the system or session level, using the ALTER SYSTEM|SESSION SET commands, as shown:

```
ALTER SYSTEM SET `planner.enable_index_planning` = true
ALTER SESSION SET `planner.enable_index_planning` = false
```

Options set at the session level only apply to queries that you run during the current Drill connection. Options set at the system level affect the entire system and persist between restarts. Session level settings override system level settings. Typically, you set the options at the session level unless you want the setting to persist across all sessions.

The following table lists the index planning and execution options that you can enable, disable, or modify:

Note: The planning option names are prefaced by planner, for example `planner.enable_index_planning`. The execution options are prefaced by exec, for example `exec.query.rowkeyjoin_batchsize`.

Option	Description	Default Value	Possible Values
planner.enable_index_planning	Enables or disables index planning	true	true|false
planner.index.force_sort_noncovering	Forces Drill to sort for non-covering indexes. If the query has an ORDER-BY on index columns and a non-covering index is chosen, by default Drill leverages the sortedness of the index columns and does not sort. Fast changing primary table data may produce a partial sort. This option forces a sort within Drill. **Note:** (Drill 1.11 only) You must enable this option for Drill to return the results of a non-covering query in sorted order.	false	true|false
planner.enable_rowkeyjoin_conversion	Introduced in Drill 1.13. Drill can push down the rowkey filter to MapR Database during runtime. For a query to qualify for runtime filter pushdown, the join condition must filter on a rowkey. A rowkey is the value of the _id field in a JSON document, for example: `SELECT t.mscIdentities FROM dfs.root.`/user/mapr/MixTable` t WHERE t.row_key IN (SELECT max(convert_fromutf8(i.KeyA.ENTRY_KEY)) FROM dfs.root.`/user/mapr/TableIMSI` i WHERE i.row_key='460021050005636')` Drill evaluates the results of the subquery at runtime. The subquery yields a list of rowkeys from the TableIMSI table. Drill pushes down the list of rowkeys to MapR Database. MapR Database uses the rowkeys to locate the corresponding documents in the MixTable table and sends the results to Drill. **Note:** Currently, Drill does not support runtime filters for queries with equality conditions. The query planner in Drill converts an equality condition to a left join. As a workaround, use the IN operator instead of the equality (=) operator for queries in which you want Drill to push down the rowkey filter to MapR Database. Drill does not perform runtime filter pushdown for queries that filter on rowkeys in small fact tables when the rowcount is generated from the right side of the join.	true	true|false

last-updated: Apr 11, 2022

planner.rowkeyjoin_conversion_selectivity_threshold	Introduced in Drill 1.13. Sets the selectivity (as a percentage) under which Drill uses a rowkey join for eligible queries.	0.01	Range: 0.0-1.0
planner.rowkeyjoin_conversion_using_hashjoin	Introduced in Drill 1.13. When enabled, Drill uses the hash join operator instead of a rowkey join.	false	true|false
planner.index.covering_selectivity_threshold	For covering indexes, this option specifies the filter selectivity that corresponds to the leading prefix of the index below which the index is considered for planning. For example, for the filter ‘a > 10 AND b < 20’ if an index has indexed fields (a, b, c) and the combined selectivity of the above condition is less than the threshold, the index is considered for the query plan.	0.75	0 - 1.0
planner.index.noncovering_selectivity_threshold	For non-covering indexes, this option specifies the filter selectivity that corresponds to the leading prefix of the index below which the index is considered for planning.	0.025	0 - 1.0
planner.index.max_chosen_indexes_per_table	The maximum number of “chosen” indexes for a table after index costing and ranking.	5	0 - 100
planner.index.rowkeyjoin_cost_factor	The cost factor that provides some control over the I/O cost for non-covering indexes when the rowkey join back to the primary table causes random I/O from the primary table.	0.1	0 - max_double
planner.enable_statistics	Enable or disable statistics for the filter conditions on indexed columns.	true	true|false
exec.query.rowkeyjoin_batchsize	For batch GET operations, this option specifies the batch size in terms of the number of rowkeys. Used for non-covering index plans when doing joins back to primary table.	128	0 - Long.MAX_VALUE
exec.query.progress.update	Enable or disable updating transient query state in ZooKeeper. Disable this option for short running operational queries. When disabled, you do not see the query state , such as STARTING and RUNNING in the Drill Web Console.	true	true|false
exec.udf.use_dynamic	Enable or disable using dynamic UDFs for the queries. Disable this option for operational queries. When disabled, you cannot use dynamic UDFs for queries.	true	true|false
exec.query_profile.save	Enable or disable saving query profiles for the queries. Disable this option for operational queries. When disabled, Drill does not save query profiles and they are not available for analysis or debugging.	true	true|false
planner.use_simple_optimizer	Enable or disable using simple optimizer for queries. Simple optimizer applies fewer rules to reduce planning time and is meant to be used only for simple operational queries that use limit, sort, and filter. This optimizer applies rules for leveraging secondary indexes when index planning is enabled. Enable this option for operational queries.	false	true|false

Index Planning and Execution Options for Operational Queries

The following table lists the index planning and execution options for operational queries that you can enable, disable, or modify:

Option	Description	Default Value	Possible Values

last-updated: Apr 11, 2022

exec.query.progress.update	Enable or disable updating transient query state in ZooKeeper. Disable this option for short running operational queries. When disabled, you do not see the query state , such as STARTING and RUNNING in the Drill Web Console.	true	true|false
exec.udf.use_dynamic	Enable or disable using dynamic UDFs for the queries. Disable this option for operational queries. When disabled, you cannot use dynamic UDFs for queries.	true	true|false
exec.query_profile.save	Enable or disable saving query profiles for the queries. Disable this option for operational queries. When disabled, Drill does not save query profiles and they are not available for analysis or debugging.	true	true|false
planner.use_simple_optimizer	Enable or disable using simple optimizer for queries. Simple optimizer applies fewer rules to reduce planning time and is meant to be used only for simple operational queries that use limit, sort, and filter. This optimizer applies rules for leveraging secondary indexes when index planning is enabled. Enable this option for operational queries.	false	true|false

Covering and Non-Covering Queries

Drill uses a cost-based approach to determine an optimal query plan. When queries are eligible for index planning, the queries are either covering or non-covering.

For covering queries, only the index is needed to process the query. Drill creates an index-based query plan that includes an index scan. Covering queries avoid the overhead of fetching data from the primary table.

For non-covering queries, the index only contains a subset of the data required to process the query. Drill creates a query plan that includes an index scan and a join back to the primary table. In some scenarios, a full table scan is more cost efficient than an index scan and Drill will not create an index plan.

Note: (Drill 1.11 only) You must enable the `planner.index.force_sort_noncovering` option for Drill to return the results of a non-covering query in sorted order. See Index Planning and Execution Configuration Options

.

Indexes for covering and non-covering queries can contain indexed fields, or a combination of indexed and included fields. MapR Database stores included fields in the index. Each field added to the index increases the storage requirement for the index. As the storage size increases, the cost of reading the index also increases. Likewise, for the cost of adding and updating documents. Consider the impact on storage and updates when adding included fields to an index.

last-updated: Apr 11, 2022

- For information about how Drill selects a query plan, see Selection and Execution of Secondary Indexes.
- For information about the types of queries that qualify for index-based plans, see Queries that Benefit from Secondary Indexes.
- For index concepts, see Secondary Index Concepts.

Covering and Non-Covering Query Examples

A query can be covering or non-covering based on the fields referenced in the query and the fields on which an index is created and/or includes.

The following query examples use an index, *l_comp_1*, created on a table, *lineitem*.

The *l_comp_1* index was created using the `maprcli table index add` command, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/range/lineitem -index l_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY
```

Covering Query Example

The following query references the L_LINESTATUS, L_QUANTITY, L_LINENUMBER, and L_ORDERKEY fields in the *lineitem* table:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE L_LINENUMBER = 1 AND
L_ORDERKEY BETWEEN 40 AND 75;
```

Because the *l_comp_1* index includes all fields referenced in the query, Drill creates a query plan that uses the index only.

Running the EXPLAIN PLAN FOR command with the query shows that Drill created a query plan that only uses the index to process the query:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;

00-00    Screen
00-01      Project(L_LINESTATUS=[$0], L_QUANTITY=[$1])
00-02        Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_comp_1], columns=[`L_LINESTATUS`, `L_QUANTITY`]]])
```

Reading the query plan, you can see that the plan includes an index scan, as indicated by *groupscan=[JsonTableGroupScan* and *indexName*. Drill and MapR Database can process this query using only the index.

Non-Covering Query Example

The following query references the L_RETURNFLAG, L_LINESTATUS, L_QUANTITY L_LINENUMBER, and L_ORDERKEY fields in the *lineitem* table:

```
SELECT L_RETURNFLAG, L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;
```

Because the *l_comp_1* index does not include the L_RETURNFLAG field, Drill creates a query plan that uses the index, but also includes a join on the primary table.

Running the EXPLAIN PLAN FOR command with the query shows that Drill includes an index scan and a table scan:

```
EXPLAIN PLAN FOR SELECT L_RETURNFLAG, L_LINESTATUS, L_QUANTITY FROM
lineitem WHERE L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;

00-00    Screen
00-01      Project(L_RETURNFLAG=[$0], L_LINESTATUS=[$1], L_QUANTITY=[$2])
00-02        Project(L_RETURNFLAG=[$2], L_LINESTATUS=[$3], L_QUANTITY=[$4])
00-03          Project(L_LINENUMBER=[$0], L_ORDERKEY=[$1],
L_RETURNFLAG=[$2], L_LINESTATUS=[$3], L_QUANTITY=[$4])
00-04            RowKeyJoin(condition=[=($5, $6)], joinType=[inner])
00-06              Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[RestrictedJsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75}))],
columns=[`L_LINENUMBER`, `L_ORDERKEY`, `L_RETURNFLAG`, `L_LINESTATUS`,
`L_QUANTITY`, `_id`], rowcount=60012.15000000001]])
00-05              Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_comp_1], columns=[`_id`]]])
```

Reading the query plan, you can see that the plan includes an index scan, as indicated by the *groupscan=[JsonTableGroupScan* and *indexName*, and also a scan on the primary table, as indicated by the *groupscan=[RestrictedJsonTableGroupScan* and the *RowKeyJoin*. To process this query, Drill and MapR Database can use the index, but MapR Database must also use the rowkey to perform a join on the primary table to fetch data in the L_RETURNFLAG field.

If this query ran on a regular basis, you could remove the *l_comp_1* index and create a new index that includes all fields referenced in the query, including the L_RETURNFLAG field, to improve query performance. However, running a query only once or a few times may not justify the overhead of removing the old index and creating a new index.

Non-Hashed and Hashed Indexes
You can create non-hashed and hashed indexes for queries on JSON tables in MapR Database.

Non-hashed indexes support conditional queries with an ORDER BY clause because MapR Database sorts the data in non-hashed indexes. When processing ORDER BY queries, Drill does not have to perform sort operations on the data.

Hashed indexes support the same conditional queries as non-hashed indexes, but they do not have a guaranteed sort order. Hashed indexes enable MapR Database to evenly distribute new writes on an index across logical partitions to avoid hot spotting. Drill must perform a sort for ORDER BY queries that use hashed indexes. Sorting the data can increase the CPU costs and negatively impact performance. See Hashed Indexes for additional information.

If you notice performance issues with ORDER BY queries that use hashed indexes, review the query plans to see if the plans include sort and merge operations. If this is the case, create non-hashed indexes to support the queries and achieve the best performance.

Examples of Hashed and Non-Hashed Index Plans for an ORDER BY Query

The examples here show the difference between a hashed and non-hashed index plan for the following query on the lineitem table that contains the ORDER BY clause:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE L_LINENUMBER = 1 AND
L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;
```

Hashed Index Plan Example

A hashed index, *l_hash_comp_1*, was created using the *maprcli table index add* command on a table, *lineitem*, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/hash/lineitem -index l_hash_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY -hashed true
```

Running the example query with the EXPLAIN PLAN FOR command shows that Drill produces an index plan with sort and merge operations to process the query when using the hashed index, as follows:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;

00-00    Screen
00-01      Project(L_LINESTATUS=[$0], L_QUANTITY=[$1])
00-02        SingleMergeExchange(sort0=[2])
01-01          SelectionVectorRemover
01-02            Sort(sort0=[$2], dir0=[ASC])
01-03              Project(L_LINESTATUS=[$2], L_QUANTITY=[$3],
L_LINENUMBER=[$0])
01-04                Scan(table=[[si, tpch_sf1_maprdb_hash,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/hash/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_hash_comp_1], columns=[`L_LINENUMBER`, `L_ORDERKEY`,
`L_LINESTATUS`, `L_QUANTITY`]]])
```

Reading the query plan, you can see that Drill uses the hashed index in the plan, as indicated by *indexName=l_hash_comp_1*. To process the query, MapR Database can use the index, but Drill must sort and merge the data, as indicated by the *Sort* and *SingleMergeExchange* operations in the query plan.

Using the hashed index plan for this ORDER BY query requires additional processing and negatively impacts performance.

Non-Hashed Index Plan Example

A non-hashed index, *l_comp_1*, was created using the `maprcli table index add` command on a table, *lineitem*, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/range/lineitem -index l_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY
```

Running the example query with the EXPLAIN PLAN FOR command shows that Drill produces an index plan without the additional sort and merge operations when using the non-hashed index to process the query, as follows:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;

00-00    Screen
00-01      Project(L_LINESTATUS=[$0], L_QUANTITY=[$1])
00-02        Project(L_LINESTATUS=[$2], L_QUANTITY=[$3], L_LINENUMBER=[$0])
00-03          Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
```

last-updated: Apr 11, 2022

```
indexName=l_comp_1], columns=[`L_LINENUMBER`, `L_ORDERKEY`, `L_LINESTATUS`,
`L_QUANTITY`]]])
```

Reading the query plan, you can see that Drill uses the non-hashed index plan, as indicated by *indexName=l_comp_1*. To process the query, MapR Database uses the index and Drill does not have to perform sort and merge operations on the data, as indicated by the absence of the Sort and SingleMergeExchange operations in the query plan. MapR Database sorted the data in the index when the index was created.

Writing Drill Queries that Leverage Indexes on Array Fields

Starting in EEP 6.0, the query planner in Drill can leverage indexes created on MapR Database JSON document fields with array data types, such as `"NUMBERS": [1, 2, 3, 4, 5]` and `"ADDRESSES": [{"CITY" : "SAN JOSE"}, {"CITY" : "PALO ALTO"}]`.

See JSON Document Data Types and Data Types and Secondary Index Fields for definitions and detailed examples.

If you want the query planner in Drill to leverage an index created on a field with an array data type, you must write the Drill query such that it includes specific SQL syntax, as shown in bold in the following example:

```
SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
               FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
          FROM CUSTOMERS) as t
               WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA')
;
```

The specific SQL syntax indicates (to the query planner in Drill) that the query is eligible for an index-based query plan.

The FLATTEN function separates elements in an array into individual records in a table. For example, if an array consists of five elements, FLATTEN separates each element into a single row, creating a table with five rows.

The IN operator prevents Drill from returning duplicate rows. For example, when an array is flattened into a table, duplicate values may exist for a particular _id (rowkey). Using IN prevents Drill from returning rows with duplicate values.

Example

Suppose a JSON primary table named CUSTOMERS exists in MapR Database with the following data:

```
{ "_id": "001",
 "NAME": "ALICE",
 "PHONE": "408-555-1212",
 "ADDRESSES": [{"CITY" : "SAN JOSE" , "ZIPCODE" : 95124, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR":
7}]}, {"CITY" : "PALO ALTO", "ZIPCODE" : 94020, "STATE" : "CA",
"UNITS" : [{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]},
{"CITY" : "SANTA CLARA", "ZIPCODE" : 95050, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]}],
  "QTY": [11, 25, 16, 2, 10, 39, 5, 8, 7, 11]
}
{ "_id": "002",
 "NAME": "BOB",
 "PHONE": "408-555-1313",
 "ADDRESSES": [{"CITY" : "SAN JOSE" , "ZIPCODE" : 95132, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":838, "FLOOR": 8}, {"UNIT_NO":888, "FLOOR":
8}]}, {"CITY" : "SAN JOSE", "ZIPCODE" : 95127, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]}, {"CITY" :
```

```
"SAN RAMON", "ZIPCODE" : 94582, "STATE" : "CA", "UNITS" : [{"UNIT_NO":123,
"FLOOR": 1}, {"UNIT_NO":124, "FLOOR": 1}]}],
 "QTY": [2, 8, 1, 4, 3, 10, 2, 23]
}
{ "_id": "003",
 "NAME": "CHRIS",
 "PHONE": "408-555-1414",
 "ADDRESSES": [{"CITY" : "MOUNTAIN VIEW", "ZIPCODE" : 94043, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":922, "FLOOR": 9}, {"UNIT_NO":958, "FLOOR":
9}]}, {"CITY" : "PALO ALTO", "ZIPCODE" : 94020, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":666, "FLOOR": 6}, {"UNIT_NO":728, "FLOOR": 7}]}, {"CITY" :
"SUNNYVALE", "ZIPCODE" : 94086, "STATE" : "CA", "UNITS" : [{"UNIT_NO":226,
"FLOOR": 2}, {"UNIT_NO":333, "FLOOR": 3}]}],
 "QTY": [56, 19, 45, 25, 4, 77, 110, 3, 2, 1]
}
```

Note: The QTY field is an array. The ADDRESSES field is an array of maps.

The following query on the CUSTOMERS table returns the result of flattening the “ADDRESSES" array field into a column aliased as “f" where each element in the array is flattened into individual rows:

Note: In the results, notice that Bob has two addresses where the “CITY" is “SAN JOSE". Later in this example, you will see that using the IN operator prevents the query from returning duplicate rows.

```
SELECT NAME, PHONE, f FROM (SELECT NAME, PHONE, FLATTEN(ADDRESSES) AS f
FROM CUSTOMERS);

| BOB   | 408-555-1313 | {"CITY":"SAN JOSE","STATE":"CA","UNITS":
[{"FLOOR":5,"UNIT_NO":555},
{"FLOOR":7,"UNIT_NO":777}],"ZIPCODE":95127}
         |
+-------+--------------+-----------------------------------------------------------------
```

Suppose a composite index exists on `ADDRESSES[].CITY` and `ADDRESSES[].STATE`with "NAME" as an included field. For the query planner to use the index, you must write the query using the specific SQL syntax that indicates that the query is eligible for an index-based query plan, as shown:

```
SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
               FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
          FROM CUSTOMERS) as t
               WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA');

//Issuing this query against the data in the CUSTOMERS table returns the
following results:
+--------+--------------+
|  NAME  |     PHONE    |
+--------+--------------+
| ALICE  | 408-555-1212 |
| BOB    | 408-555-1313 |
+--------+--------------+
```

Note: Although Bob has two addresses where the "CITY" is "SAN JOSE", the query returns only one result. The IN operator prevents the query from returning duplicate rows.

The following list summarizes key points about this query:

- The innermost subquery projects on the _id field (rowkey) and includes the FLATTEN function to separate the array elements in the “ADDRESSES” field. The field “ADDRESSES” is flattened into a table aliased as “t”, in a column aliased as “f”.
- The query uses the IN operator to ensure that the results returned contain unique values only; no duplicates. DISTINCT on the subquery to the right of IN is implicit. The SQL query pattern indicates to the query planner that the query is eligible for an index-based query plan.
- The query projects on column “NAME” and “PHONE”. “PHONE” requires a join back to the primary table on the _id field (rowkey) because it is not included in the composite index.
- The query planner recognizes that t.f.CITY references t.ADDRESSES[].CITY and t.f.STATE references t.ADDRESSES[].STATE and creates an index-based query plan.
- The index table in MapR Database is already flattened for the array field, “ADDRESSES”. Flatten is not evaluated in Drill. Drill pushes the filter conditions on the array field into MapR Database.

Filter Conditions on Various Types of Array Fields

The following table shows examples of filter conditions on various types of array fields and includes the MapR Database notation for the array field with the filter condition, as well as the SQL syntax for writing queries against the array fields.

Note: The queries in the table are written against the CUSTOMERS data used in the previous example.

Filter condition on …	Example using MapR Database notation (not SQL notation)	SQL

Array of scalar values	QTY[] < 10	`SELECT NAME, PHONE`
		`FROM CUSTOMERS`
		`WHERE _id IN ( SELECT _id`
		`FROM ( SELECT _id, FLATTEN(Q`
		`FROM CUSTOMERS) as t`
		`WHERE t.f<10);`
		
		This query returns the following results:
		
		`+--------+---------------+`
		`|  NAME  |     PHONE     |`
		`+--------+---------------+`
		`| ALICE  | 408-555-1212  |`
		`| BOB    | 408-555-1313  |`
		`| CHRIS  | 408-555-1414  |`
		`+--------+---------------+`

last-updated: Apr 11, 2022

Map field within an array of maps	ADDRESSES[].ZIPCODE > 94000 and ADDRESSES[].ZIPCODE < 95000	<pre>SELECT NAME, PHONE
		FROM CUSTOMERS
		**WHERE _id IN (SELECT _id
		FROM (SELECT _id, FLATTEN(ADDR
		FROM CUSTOMERS) as t
		WHERE t.f.ZIPCODE BETWEEN 94000**</pre>This query returns the following results:<pre>+--------+---------------+
		| NAME | PHONE |
		+--------+---------------+
		| ALICE | 408-555-1212 |
		| BOB | 408-555-1313 |

| ALICE  | 408-555-1212 |
| BOB    | 408-555-1313 |
+--------+--------------+
```
</td>
</tr>
</table>

Performance Considerations

When writing queries that leverage indexes on array fields, consider the following points about performance:

- Query patterns that match those described previously in this document are pushed down to MapR Database. Drill does not evaluate the filter conditions, which adds considerable performance benefits even when the query planner does not select an index-based query plan.

last-updated: Apr 11, 2022

- Deduplication on the _id is an extra operation (compared to regular, non-complex, indexes) that requires the overhead of hash aggregation.
- Try to avoid array columns in included fields within an index table, as they add a significant amount of storage overhead. However, this may result in the query planner selecting non-covering plans.
- Indexes with deeply nested array elements, such as `a[].b[].c[]...x.y`, can add to the MapR Database storage overhead and can potentially make Drill queries longer and more complex.

Limitations

Drill queries that leverage indexes on array fields have the following limitations:

- Only queries with patterns similar to those described previously in this document are eligible for index planning, assuming that the index is defined on an array field.
- The following conditions do not produce a covering index plan:
  - Pushdown conditions on indexed fields and included fields on same array element. For example, if an index has indexed fields a[].b and included fields a[].c, elementAND(a[], b > 10, c > 20) does not produce a covering index plan.
  - Pushdown conditions on scalar indexed fields and included fields containing an array element. For example, an index with indexed field m and included fields a[].b, m = 10 AND a[].b > 20 does not produce a covering index plan.
- For included array fields, the element must be provided without the [] for the query planner to pick covering plans. For example, a and not `a[]`. Note that MapR Database considers both a and a[] syntaxes as equivalent for included fields.
- Index planning is disabled for queries with multi-level flattens and intermediate filters that reference multi-level flattens. A filter can reference the root level flatten, but not the intermediate flattens.

Determining Index Use

Evaluate the query plan to analyze query performance and determine if Drill uses indexes. You can view query plans in the Drill Web Console or through the command line using the EXPLAIN command. You can also disable the indexing option in Drill and compare an index-based plan to a full table scan plan.

Drill leverages indexes during the physical planning phase of the query. Drill estimates the cost of an index-based plan and a plan that includes a full table scan. See Selection and Execution of Secondary Indexes for information about how Drill selects a query plan. In cases where Drill does not select the index-based plan and instead selects a full table scan plan, you may want to remove the indexes to free up storage space and eliminate the overhead of the indexes.

The following example shows you how to determine if Drill selected an index-based plan for a query through the query profile in the Drill Web Console and the EXPLAIN PLAN FOR output.

Example

The subsequent sections assume that an index exists on a table named "lineitem." The index, l_single_c_5, is a single field index created on the L_QUANTITY field. The index also covers the L_SUPPKEY, L_DISCOUNT, L_SHIPDate, and L_SHIPMODE fields. If a query contains fields covered by the index, the query is a covering query. If a query contains fields not covered by the index, the query is non-covering and requires a lookup back into the primary table to retrieve data.

The following list summarizes the assumptions:

- **Table name:** lineitem
- **Index name:** l_single_c_5

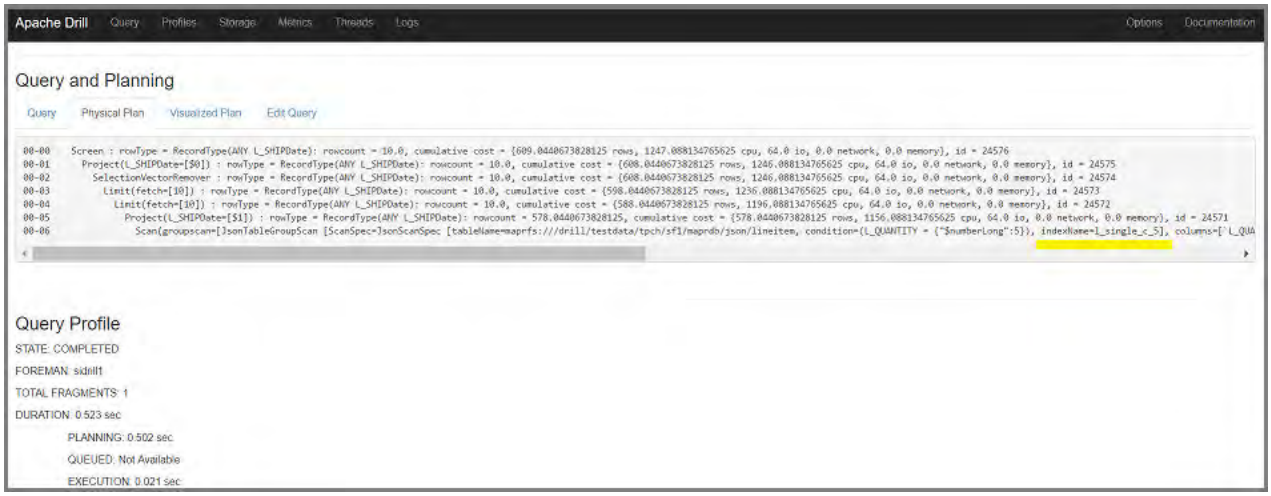
- **Indexed field:** L_QUANTITY
- **Included fields:** L_SUPPKEY, L_DISCOUNT, L_SHIPDate, L_SHIPMODE

Query Profile

View the query plan on the **Profiles** tab in the Drill Web Console. See Starting the Web Console. Select the query you want to evaluate and then select the **Physical Plan** tab. You can see the physical plan that Drill used to execute the query.

The following image shows the physical plan that Drill used to execute this simple equality query:

```
SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5;
```



In the plan, you can see that Drill scanned the index, l_single_c_5, instead of the primary table. The query was completely covered by the index because the index contains all fields referenced in the query and the query filtered on the indexed field.

EXPLAIN PLAN

Alternatively, you can issue the EXPLAIN command to see how Drill executes a query. To see the chosen physical execution plan for a query without running the query, issue the EXPLAIN PLAN FOR command. This command shows you if Drill plans to use the index when executing the query.

The following image shows the physical plan that Drill plans to use to execute this simple equality query:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+------+------+
| text | json |
+------+------+
| 00-00    Screen
00-01      Project(L_SHIPDate=[$0])
00-02        SelectionVectorRemover
00-03          Limit(fetch=[10])
00-04            Limit(fetch=[10])
00-05              Project(L_SHIPDate=[$1])
00-06                Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5], columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

last-updated: Apr 11, 2022

In the plan, you can see that Drill plans to use the index, l_single_c_5, instead of performing a full table scan. The query is completely covered by the index because the index contains all fields referenced in the query and the query filters on the indexed field.

Compare Plans

If you want to compare an index-based plan against a plan with a full table scan, disable the planner.enable_index_planning option in Drill, and run the EXPLAIN PLAN FOR command for the query. Running this command with the planner.enable_index_planning option disabled forces Drill to generate a plan that includes a full table scan. You can compare the full table scan plan against the index-based plan to compare the costs and resource consumption of each plan.

You can see in the following query, with the indexing feature turned on, Drill generated a plan using the index:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+------+------+
| text | json |
+------+------+
| 00-00    Screen
00-01      Project(L_SHIPDate=[$0])
00-02        SelectionVectorRemover
00-03          Limit(fetch=[10])
00-04            Limit(fetch=[10])
00-05              Project(L_SHIPDate=[$1])
00-06                Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5], columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

If you turn the option off, as shown:

```
ALTER SESSION SET planner.enable_index_planning = false
```

You can run the EXPLAIN PLAN FOR command again to see the plan with a full table scan included:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+------+------+
| text | json |
+------+------+
| 00-00    Screen
00-01      Project(L_SHIPDate=[$0])
00-02        SelectionVectorRemover
00-03          Limit(fetch=[10])
00-04            UnionExchange
01-01              SelectionVectorRemover
01-02                Limit(fetch=[10])
01-03                  Project(L_SHIPDate=[$1])
01-04                    Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5})],
columns=[`L_QUANTITY`, `L_SHIPDate`]]])
 |
```

Note: To see the cost of each plan, go to the Drill Web Console and view the query profile for each EXPLAIN PLAN FOR command that you issue through the command line.

Drill Limitations
Provides information about Drill limitations.

last-updated: Apr 11, 2022

Working with subqueries

- The SELECT list in a scalar subquery can only contain one item/column.
- Correlated subqueries should return exactly one row.
- A WHERE clause of a subquery should not refer to more than one column of the table in the outer query.

Flume

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Apache Flume™ is a distributed, reliable, and available service for efficiently collecting, aggregating, and moving large amounts of log data. It has a simple and flexible architecture based on streaming data

last-updated: Apr 11, 2022

flows. It is robust and fault tolerant with tunable reliability mechanisms and many failover and recovery mechanisms. It uses a simple extensible data model that allows for online analytic application.

This section provides information about installing, configuring, and using Flume with MapR, but does not duplicate Apache documentation. You can refer also to documentation available from the Apache Flume Project and the Flume Release Notes for MapR.

Configuring Flume

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This section contains information about configuring Flume with MapR. Additional documentation is available on the Apache Flume website.

Configure a Secure HBase Sink

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Configure Flume agents to use Kerberos when you want to write sinks to secure HBase.

1. Create a keytab file called `flume.keytab` that contains a principal that matches the Kerberos identity of the user that will be running `flume-ng`. For example:

   ```
   # kadmin
   : addprinc -randkey username/<FQDN@REALM>
   : ktadd -k /opt/mapr/conf/flume.keytab username/<FQDN@REALM>
   ```

   The `flume.keytab` file must be owned and readable only by the `mapr` user.

2. In the `flume.conf` file, configure the following properties:

Property	Value	Description
`<agent>.sinks.<hbaseSink>.kerberosPrincipal`	username/FQDN@REALM.COM	The Kerberos identity of the user running `flume-ng`.
`<agent>.sinks.<hbaseSink>.kerberosKeytab`	path_to_keytab	The path to a valid keytab file (flume.keytab) for the user running `flume-ng`

For additional properties that you may want to configure, see the Apache Flume documentation.

Note: Once Kerberos is enabled, the maprlogin ticket generation is performed implicitly.

Configure a Secure File System Sink

When writing to the file system on a secure MapR cluster, you must configure Flume agents to use either a user ticket or a Kerberos ticket.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

A secure MapR cluster may use either SASL or Kerberos to provide authentication. Therefore, the user that launches the flume-ng JVM agent on a secure cluster can authenticate with the MapR file system using a MapR user ticket or a Kerberos ticket. When you authenticate with Kerberos, the user does not need to run the `maprlogin` utility to authenticate with the cluster as long a a valid kerberos ticket is present. When you authenticate with a mapr user ticket, you must run the maprlogin utility to generate a ticket before you launch the flume-ng JVM agent.

last-updated: Apr 11, 2022

Configure Flume agents to use MapR user tickets when writing to MapR file system

If you use MapR SASL (MapR user ticket) to authenticate, configure a dummy value for the Kerberos principal and keytab file in the `flume.conf`. Example:

```
agent1.sinks.sink1.hdfs.kerberosPrincipal = mapr
agent1.sinks.sink1.hdfs.kerberosKeytab = /opt/mapr/conf/cldb.conf
```

These dummy Kerberos principal and keytab files are not used with the HDFSSink operations. However, when the dummy Kerberos properties are not configured, Flume agent error logs display the following error messages:

```
Dec 2013 13:01:42,448 ERROR [conf-file-poller-0]
        (org.apache.flume.sink.hdfs.HDFSEventSink.authenticate:510)  -
Hadoop running in secure
        mode, but Flume config doesn't specify a principal to use for
Kerberos auth.
10 Dec 2013 13:01:42,448 ERROR [conf-file-poller-0]
        (org.apache.flume.sink.hdfs.HDFSEventSink.configure:241)  - Failed
to authenticate!
```

These errors relate to Kerberos authentication prerequisite failures and can be ignored when you are not using Kerberos. Secure Flume operations with `maprlogin`-mediated tickets continue to be available.

Configure Flume agents to use a Kerberos ticket when writing to MapR file system

1. Create a keytab file called `flume.keytab` which contains a principal that matches the Kerberos identity of the user that will be running `flume-ng`. Example:

   ```
   # kadmin
   : addprinc -randkey username/<FQDN@REALM>
   : ktadd -k /opt/mapr/conf/flume.keytab username/<FQDN@REALM>
   ```

   The `flume.keytab` file must be owned and readable only by the mapr user.

2. In the `flume.conf` file, configure the following properties:

Property	Value	Comment
`<agent>.sinks.<sink>.type`	HDFS	
`<agent>.sinks.<sink>.hdfs.proxyUser`	weblogs	
`<agent>.sinks.<sink>.hdfs.kerberosPrincipal`	username/FQDN@REALM.COM	The user component of the principal must be the username of the user running `flume-ng`.
`<agent>.sinks.<sink>.hdfs.kerberosKeytab`	*path to file*	Provide the path to your `flume.keytab` file.

Note: Flume does not support any authentication mechanism for an Avro client.

For additional properties that you may want to configure, see the Apache Flume documentation.

Flume Thrift Security Parameters
On a secure cluster, SSL for Flume Thrift Source and Sink is automatically configured.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

In your MapR secure cluster, if the `flume-agent` configuration file does not specify SSL parameters, they are automatically supplied as follows:

- In EEP 6.0.0, SSL for Flume Thrift Source and Sink is automatically configured.
- In EEP 6.0.1, SSL for Flume Thrift and Avro Source and Sink is automatically configured.

Flume Thrift clients have the following configuration parameters for wire-level security:

Parameter for SSL

`ssl`	Enables SSL. If set to `true`, the `keystore` and `keystore-password` parameters must also be specified. Default: `false`. If the `ssl` parameter is not specified, it is defaulted to `true` for Thrift clients if cluster security is enabled.

Parameters for Thrift Source

`keystore`	Specifies the path to the Java keystore. The `ssl_keystore` uses the same `ssl_keystore` specified in the `ssl.server.keystore.location` section of `/opt/mapr/conf/ssl-client.xml`, `/opt/mapr/conf/ssl_keystore`.
`keystone-password`	Specifies the password for the Java keystore. The `keystore-password` uses the same password specified in the `ssl.client.keystore.password` of `/opt/mapr/conf/ssl-client.xml`, `<ssl-keystore-password>`.
`keystore-type`	Specifies the type of the Java keystore: `JKS` or `PKCS12`. The `keystore-type` uses the same `ssl_keystore` specified in the `ssl.client.keystore.type` section of `/opt/mapr/conf/ssl-client.xml`.

Parameters for Thrift Sink

`truststore`	Specifies the path to the Java truststore. The `truststore` uses the same `ssl_keystore` specified in the `ssl.client.truststore.location` section of `/opt/mapr/conf/ssl-client.xml`.
`truststore-password`	Specifies the password for the Java truststore. The `truststore-password` uses the same `ssl_keystore` specified in the `ssl.client.truststore.password` section of `/opt/mapr/conf/ssl-client.xml`.
`truststore-type`	Specifies the type of the Java keystore. This can be `JKS` or `PKCS12`. The `truststore-type` uses the same `ssl_keystore` specified in the `ssl.client.truststore.type` section of `/opt/mapr/conf/ssl-client.xml`.

Configure User Impersonation for Flume

Configure impersonation for Flume agents to allow one user (the mapr super user) to access data and submit jobs on behalf of another user.

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Complete the steps to enable Impersonation for the mapr Superuser.
2. Configure the `flume.conf` file with the following properties:

Property	Value	Comment
`<agent>.sinks.<sink>.type`	HDFS	
`<agent>.sinks.<sink>.hdfs.proxyUser`	*user ID of target user*	Can be any valid MapR user identity.
`<agent>.sinks.<sink>.hdfs.kerberosPrincipal`	mapr/FQDN@REALM.COM	The user component of the principal must be the username of the user running `flume-ng`. Flume agents that use impersonation must run as the user mapr on the cluster.
`<agent>.sinks.<sink>.hdfs.kerberosKeytab`	*path to file*	If you are not using Kerberos to authenticate, this can the path to any valid file. If you are using Kerberos to authenticate, provide the path to your `flume.keytab` file.

3. In the `flume-ng` file (`/opt/mapr/flume/flume-<version>/bin/flume-ng`), add export `MAPR_IMPERSONATION_ENABLED=1` after the `HADOOP_HOME` setting:

Example for Flume 1.6 and Later

```
if [ $HADOOP_VERSION == 1.0.3 ];
then
   export HADOOP_HOME=${BASEMAPR}/
hadoop/hadoop-<current_version>/
else
   export HADOOP_HOME=${BASEMAPR}/
hadoop/${HADOOP_VERSION}/
fi
export MAPR_IMPERSONATION_ENABLED=1
```

Example for Flume 1.5 and Earlier

```
HADOOP_VERSION=`readlink \`which
hadoop\` | awk -F "/" '{print$5}'`
export HADOOP_HOME=${BASEMAPR}/
hadoop/${HADOOP_VERSION}/
export MAPR_IMPERSONATION_ENABLED=1
```

Integrate Flume with MapR Event Store For Apache Kafka

Integrate Flume 1.6 with MapR Event Store For Apache Kafka when you want to write Flume source data to a MapR Event Store For Apache Kafka topic or when you want to write MapR Event Store For Apache Kafka topics to a Flume sink.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can use Flume and MapR Event Store For Apache Kafka for many different use cases; however, here are a few examples:

Write MapR Event Store For Apache Kafka topics to file on the MapR filesystem	To write MapR Event Store For Apache Kafka topics to the MapR filesystem, create an agent with a Kafka source and a HDFS sinks.

last-updated: Apr 11, 2022

Write MapR Event Store For Apache Kafka topics to MapR Database	To write MapR Event Store For Apache Kafka topics to MapR Database, create an agent with a Kafka source and a MapR Database sink.
Write data from any supported Flume source to MapR Event Store For Apache Kafka topics	To write data from any supported Flume source to MapR Event Store For Apache Kafka topics, create an agent with the appropriate Flume source type and a Kafka sink or Kafka channel. For example, you can use a syslogs source to turn logs into a MapR stream topic.

Note: Before you integrate Flume with MapR Event Store For Apache Kafka, verify that the Streams Client is installed on all Flume nodes. For more information, see Installing Flume on page 182.

Read and Write MapR Event Store For Apache Kafka Messages With Flume

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Flume uses agent files to define the data flow. To read or write MapR Event Store For Apache Kafka data, you configure Flume agent files with Flume sources, channels, and sinks.

When you read MapR Event Store For Apache Kafka topics, you use a Kafka source or a Kafka channel. When you write to a MapR Event Store For Apache Kafka topic, you can use a Kafka channel or a Kafka sink.

See the following topics for information on how to configure the agent file:

- Read MapR Event Store For Apache Kafka Using a Kafka Source on page 3372
- Read or Write to MapR Event Store For Apache Kafka using a Kafka Channel on page 3373
- Write to MapR Event Store For Apache Kafka using a Kafka Sink on page 3374

See Example Agents Files: Flume 1.6 or Lower and MapR Event Store For Apache Kafka Integration on page 3376 and Example Agents Files: Flume 1.7 or Above and MapR Event Store For Apache Kafka Integration on page 3375 for example agent files.

Read MapR Event Store For Apache Kafka Using a Kafka Source

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following parameters are required when configuring Kafka source to read data from MapR Streams topics:

Property Name	Description
channels	If the source writes events to a channel, this is the name of the channel that the source writes events to.
type	This property must be set to `org.apache.flume.source.kafka.KafkaSource`
kafka.consumer.group.id	A unique identifier of the consumer group. This defaults to `flume`. Setting the same id in multiple sources or agents indicates that they are part of the same consumer group; when these sources or agents are running at the same time, they will each read a unique set of partitions for the topics in the group.

last-updated: Apr 11, 2022

Property Name	Description
kafka.topics	A comma separated list of MapR Event Store For Apache Kafka topics where each topic is specified with the volume path and stream name. For example: `/volume_path/stream_name:topic_name1, /volume_path/stream_name:topic_name2` **Note:** It is critical that the path to the topic starts with a slash(/), as the slash is what distinguishes the topic as a MapR Event Store For Apache Kafka topic.
batchDurationMillis	Maximum number of milliseconds to wait before closing a batch. The default value is 1000.

For additional properties that you may want to configure, see the Flume documentation. However, note that `kafka.bootstrap.servers` is not required for reading MapR Event Store For Apache Kafka.

Tip: To increase throughput, set the `batchSize` to a higher value. The `batchSize` is the maximum number of messages written to Channel in one batch. By default, it is set to 1000.

Read or Write to MapR Event Store For Apache Kafka using a Kafka Channel

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Using a Kafka channel without a Flume sink or Flume source is more reliable; it also involves less code. A Kafka channel is also useful when you want to use one agent to store messages in a topic and then copy the messages to another type of sink.

Note: Do not use a Kafka Channel when you have the following requirements:

- Maintain of the order of each event.
- Read or write data from more than one topic.
- Good performance. Writing messages to a topic with a Kafka sink can be twice as fast as a Kafka channel.

The following parameters are required when configuring Kafka channel to read or write data in MapR Event Store For Apache Kafka:

Property Name	Description
type	This property must be set to `org.apache.flume.channel.kafka.KafkaChannel`
kafka.topic	A topic is specified with the volume path and stream name. For example: `/volume_path/stream_name:topic_name1`

last-updated: Apr 11, 2022

Property Name	Description
	Note: It is critical that the path to the topic starts with a slash (/), as the slash is what distinguishes the topic as a MapR Event Store For Apache Kafka topic as opposed to a Kafka topic.
kafka.pollTimeout	The maximum amount of time in milliseconds the channel will wait for events if they are not available. The default is 500.
parseAsFlumeEvent	This must be set to `false` if other channels or sinks write to the same topic.
producer.linger.ms	These properties are used to configure the Kafka Producer. Any producer property supported by Kafka can be used. The only requirement is to prepend the property name with the prefix `kafka.producer`. For example: `kafka.producer.linger.ms=0`
capacity	The maximum number of events stored in the channel. The default value is 100.
transactionCapacity	The maximum number of events the channel will take from a source or give to a sink per transaction. The default value is 100.

For additional properties that you may want to configure for the Kafka channel, see the Flume documentation. Note that `brokerList` is not required when writing to MapR Event Store For Apache Kafka.

Write to MapR Event Store For Apache Kafka using a Kafka Sink

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following parameters are required when configuring Kafka sink to write to a MapR Stream:

Property Name	Description
type	This property must be set to `org.apache.flume.sink.kafka.KafkaSink`
kafka.topic	A topic specified with the volume path and stream name. For example: `/streaming_data/flume_stream:topic1` **Note:** It is critical that the path to the topic starts with a slash(/), as the slash is what distinguishes the topic as a MapR Event Store For Apache Kafka topic. The default is "default-flume-topic". **Note:** If the header for a given message contains a "topic" field, the message will be published to that topic instead of the topic that you configure here.

last-updated: Apr 11, 2022

For additional properties that you may want to configure for the Kafka sink, see the Flume documentation.

Note: `kafka.flumeBatchSize` sets the number of messages to process in a batch and the default is 100. To ensure that the events are written in the original order, set `kafka.flumeBatchSize=1` and specify a topic with a single partition. If maintaining the order is not required, you can increase the value. However, note that larger batches improve throughput while also adding latency.

Example Agents Files: Flume 1.7 or Above and MapR Event Store For Apache Kafka Integration

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following examples can be used to understand how you might want to configure Flume agent files in Flume version 1.7 and above.

Example: Read MapR Event Store For Apache Kafka topics and Write to MapR Filesystem

In this example, the agent reads two topics (`log_topic1 and log_topic2`), stores the event data in memory channel, and then writes the event data to a file on the filesystem (`maprfs:///flume/log_data`).

```
agent1.sources = source1
agent1.channels = channel1
agent1.sinks = sink1
agent1.sources.source1.channels = channel1
agent1.sinks.sink1.channel = channel1
agent1.sources.source1.type = org.apache.flume.source.kafka.KafkaSource
agent1.sources.source1.kafka.topics = /streaming_data/
flume_stream:log_topic1,
/streaming_data/flume_stream:log_topic2
agent1.sources.source1.kafka.consumer.group.id = flume
agent1.sources.source1.batchSize = 20
agent1.sources.source1.batchDurationMillis = 1000
agent1.sinks.sink1.type = hdfs
agent1.sinks.sink1.hdfs.path = maprfs:///flume/log_data
agent1.sinks.sink1.hdfs.filePrefix = source
agent1.sinks.sink1.hdfs.rollCount = 0
agent1.sinks.sink1.hdfs.rollInterval = 0
agent1.sinks.sink1.hdfs.rollSize = 10485760
agent1.sinks.sink1.hdfs.fileType = DataStream
agent1.channels.channel1.type = memory
agent1.channels.channel1.capacity = 10000
agent1.channels.channel1.transactionCapacity = 1000
```

Example: Read Log File and Write Log File to a Streams Topic

In this example, the agent uses an exec source to read messages from a local error log file, stores data in a channel, and then publishes the data as messages in a MapR Event Store For Apache Kafka topic (`/streaming_data/error_stream:error_log_topic`).

```
agent1.sources = source1
agent1.channels = channel1
agent1.sinks = sink1
agent1.sources.source1.channels = channel1
agent1.sinks.sink1.channel = channel1
agent1.sources.source1.type = exec
agent1.sources.source1.command = tail -f /opt/app/logs/error_log_file
agent1.channels.channel1.type = memory
agent1.channels.channel1.capacity = 10000
agent1.channels.channel1.transactionCapacity = 1000
agent1.sinks.sink1.type = org.apache.flume.sink.kafka.KafkaSink
```

last-updated: Apr 11, 2022

```
agent1.sinks.sink1.kafka.topic = /streaming_data/
error_stream:error_log_topic
agent1.sinks.sink1.flumeBatchSize = 5
```

Example: Read Log Events and Write to a MapR Filesystem File

In this example, the agent reads events from syslogtcp server, uses a Kafka channel to store events in a streams topic (`/streaming_data/flume_stream:syslogtcp_topic`), and then writes the data to a file on the filesystem (`maprfs:///flume/analytics`).

```
agent1.sources = source1
agent1.channels = channel1
agent1.sinks = sink1
agent1.sources.source1.channels = channel1
agent1.sinks.sink1.channel = channel1
agent1.sources.source1.type = syslogtcp
agent1.sources.source1.host=syslog_host
agent1.sources.source1.port=5140
agent1.channels.channel1.type = org.apache.flume.channel.kafka.KafkaChannel
agent1.channels.channel1.kafka.pollTimeout = 500
agent1.channels.channel1.kafka.topic = /streaming_data/
flume_stream:syslogtcp_topic
agent1.channels.channel1.transactionCapacity = 1000
agent1.channels.channel1.capacity = 1000
agent1.channels.channel1.producer.linger.ms=0
agent1.sinks.sink1.type = hdfs
agent1.sinks.sink1.hdfs.path = maprfs:///flume/analytics
agent1.sinks.sink1.hdfs.rollInterval = 5
agent1.sinks.sink1.hdfs.rollSize = 0
agent1.sinks.sink1.hdfs.rollCount = 0
agent1.sinks.sink1.hdfs.fileType = DataStream
```

Example Agents Files: Flume 1.6 or Lower and MapR Event Store For Apache Kafka Integration

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following examples can be used to understand how you might want to configure Flume agent files in Flume version 1.6 or lower.

Example: Read MapR Event Store For Apache Kafka topics and Write to MapR Filesystem

In this example, the agent reads two topics (`log_topic1 and log_topic2`), stores the event data in memory channel, and then writes the event data to a file on the filesystem (`maprfs:///flume/log_data`).

```
agent1.sources = source1
agent1.channels = channel1
agent1.sinks = sink1
agent1.sources.source1.channels = channel1
agent1.sinks.sink1.channel = channel1
agent1.sources.source1.type = org.apache.flume.source.kafka.v09.KafkaSource
agent1.sources.source1.kafka.topics = /streaming_data/
flume_stream:log_topic1,
/streaming_data/flume_stream:log_topic2
agent1.sources.source1.kafka.consumer.group.id = flume
agent1.sources.source1.batchSize = 20
agent1.sources.source1.batchDurationMillis = 1000
agent1.sinks.sink1.type = hdfs
agent1.sinks.sink1.hdfs.path = maprfs:///flume/log_data
agent1.sinks.sink1.hdfs.filePrefix = source
```

last-updated: Apr 11, 2022

```
agent1.sinks.sink1.hdfs.rollCount = 0
agent1.sinks.sink1.hdfs.rollInterval = 0
agent1.sinks.sink1.hdfs.rollSize = 10485760
agent1.sinks.sink1.hdfs.fileType = DataStream
agent1.channels.channel1.type = memory
agent1.channels.channel1.capacity = 10000
agent1.channels.channel1.transactionCapacity = 1000
```

Example: Read Log File and Write Log File to a Streams Topic

In this example, the agent uses an exec source to read messages from a local error log file, stores data in a channel, and then publishes the data as messages in a MapR Event Store For Apache Kafka topic (`/streaming_data/error_stream:error_log_topic`).

```
agent1.sources = source1
agent1.channels = channel1
agent1.sinks = sink1
agent1.sources.source1.channels = channel1
agent1.sinks.sink1.channel = channel1
agent1.sources.source1.type = exec
agent1.sources.source1.command = tail -f /opt/app/logs/error_log_file
agent1.channels.channel1.type = memory
agent1.channels.channel1.capacity = 10000
agent1.channels.channel1.transactionCapacity = 1000
agent1.sinks.sink1.type = org.apache.flume.sink.kafka.v09.KafkaSink
agent1.sinks.sink1.kafka.topic = /streaming_data/
error_stream:error_log_topic
agent1.sinks.sink1.flumeBatchSize = 5
```

Example: Read Log Events and Write to a MapR Filesystem File

In this example, the agent reads events from syslogtcp server, uses a Kafka channel to store events in a MapR Event Store For Apache Kafka topic (`/streaming_data/flume_stream:syslogtcp_topic`), and then writes the data to a file on the filesystem (`maprfs:///flume/analytics`).

```
agent1.sources = source1
agent1.channels = channel1
agent1.sinks = sink1
agent1.sources.source1.channels = channel1
agent1.sinks.sink1.channel = channel1
agent1.sources.source1.type = syslogtcp
agent1.sources.source1.host=syslog_host
agent1.sources.source1.port=5140
agent1.channels.channel1.type =
org.apache.flume.channel.kafka.v09.KafkaChannel
agent1.channels.channel1.kafka.pollTimeout = 500
agent1.channels.channel1.kafka.topic = /streaming_data/
flume_stream:syslogtcp_topic
agent1.channels.channel1.transactionCapacity = 1000
agent1.channels.channel1.capacity = 1000
agent1.channels.channel1.producer.linger.ms=0
agent1.sinks.sink1.type = hdfs
agent1.sinks.sink1.hdfs.path = maprfs:///flume/analytics
agent1.sinks.sink1.hdfs.rollInterval = 5
agent1.sinks.sink1.hdfs.rollSize = 0
agent1.sinks.sink1.hdfs.rollCount = 0
agent1.sinks.sink1.hdfs.fileType = DataStream
```

last-updated: Apr 11, 2022

Using Flume

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Start a Flume Agent

You can start a Flume agent with the following command:

```
 /opt/mapr/flume/flume-<version>/bin/flume-ng agent --conf-file <path to
conf file> -name <agent name>
```

Note: To send debugging output to the console, add the flag `-Dflume.root.logger=DEBUG,console`. To send debugging output to a log file, add the flag `-Dflume.root.logger=DEBUG,LOGFILE`. You can configure the location of this logfile in the `flume-<version>/conf/log4j.properties` file.

Additional Documentation

You can also refer to the following documents available on the Apache Flume website:

- Flume User Guide
- Flume Developer Guide

- Search the MapR Blog for Flume topics

Flume 1.7.0 API

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This section contains the following:

New API in Flume 1.7.0

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Flume 1.7.0 includes the following new classes and interfaces.

New Classes

Class	Description
org.apache.flume.source.taildir.ReliableTaildirEventReader	Creates a ReliableTaildirEventReader to watch the directory.
org.apache.flume.source.taildir.TaildirMatcher	Identifies and caches the files matched by single file pattern for TAILDIR source.
org.apache.flume.source.taildir.TaildirSource	Class is responsible for starting, stoping and configurating taildir source
org.apache.flume.source.taildir.TaildirSourceConfigurationConstants	Constants used for configuration TaildirSource

last-updated: Apr 11, 2022

org.apache.flume.source.taildir.TailFile	Class is responsible for reading and writing positions of event
org.apache.flume.auth.KerberosUser	Simple Pair class used to define a unique (principal, keyTab) combination.
org.apache.flume.conf.LogPrivacyUtil	Utility class to help any Flume component determine whether logging potentially sensitive information is allowed or not.
org.apache.flume.formatter.output.DefaultPathManager	Creates the files used by the RollingFileSink.
org.apache.flume.formatter.output.DefaultPathManager.Builder	Constructs path manager
org.apache.flume.formatter.output.PathManagerFactory	Creates PathManager instances.
org.apache.flume.formatter.output.PathManagerType	Enum that specify Builder class
org.apache.flume.formatter.output.RollTimePathManager	Appends time to end of file
org.apache.flume.formatter.output.RollTimePathManager.RollTimePathManager.Builder	Constructs path manager from given context
org.apache.flume.source.http.BLOBHandler	BLOBHandler for HTTPSource that accepts any binary stream of data as event.
org.apache.flume.source.kafka.KafkaSource.Subscriber	This class is a helper to subscribe for topics by using different strategies

New Interfaces

Interface	Description
org.apache.flume.formatter.output.PathManager.Builder	Knows how to construct this path manager. Note: Implementations MUST provide a public a no-arg constructor.

Removed API in Flume 1.7.0

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following API classes have been removed in Flume 1.7.0

Class
org.apache.flume.sink.kafka.KafkaSinkUtil
org.apache.flume.source.kafka.KafkaSourceUtil

Changed API in Flume 1.7.0

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Flume 1.7.0 includes the following changed classes.

Changed Classes

Class	Description and notes
org.apache.flume.channel.kafka.KafkaChannel	Class responsible for starting, stoping and configurating kafka channel

last-updated: Apr 11, 2022

org.apache.flume.channel.kafka.KafkaChannelConfiguration	Configuration for Kafka Channel
org.apache.flume.client.avro.ReliableSpoolingFileEventReader.Builder	Special builder class for ReliableSpoolingFileEventReader
org.apache.flume.formatter.output.BucketPath	These are useful to other classes which might want to search for tags in strings.
org.apache.flume.formatter.output.PathManager	Creates the files used by the RollingFileSink
org.apache.flume.serialization.AvroEventSerializerConfigurationConstants	Configuration constants
org.apache.flume.serialization.ResettableFileInputStream	This class makes the following assumption: The underlying file is not changing while it is being read
org.apache.flume.sink.hbase.HBaseSinkConfigurationConstants	Constants used for configuration of HBaseSink and AsyncHBaseSink
org.apache.flume.sink.kafka.KafkaSink	A Flume Sink that can publish messages to Kafka
org.apache.flume.sink.kafka.KafkaSinkConstants	Kafka sink constants
org.apache.flume.source.NetcatSourceConfigurationConstants	Configuration constants
org.apache.flume.source.SpoolDirectorySource	Track of which files have been converted into Flume events and which still need to be processed
org.apache.flume.source.SpoolDirectorySourceConfigurationConstants	Configuration constants
org.apache.flume.source.SyslogUDPSource	Process Suyslog from given source
org.apache.flume.source.kafka.KafkaSourceConstants	Configuration constants
org.apache.flume.tools.TimestampRoundDownUtil	Utility class for timestamps

Deprecated API in Flume 1.7.0

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following interfaces, classes, fields, constructors, and methods have been deprecated in Flume 1.7.0.

Deprecated Interfaces

Interface
org.apache.flume.formatter.output.EventFormatter

Deprecated Classes

Class	Use this instead
org.apache.flume.source.SyslogTcpSource	MultiportSyslogTCPSource

Deprecated Fields

Deprecated Field	Use this instead
org.apache.flume.source.SpoolDirectorySourceConfigurationConstants.BUFFER_MAX_LINE_LENGTH	

org.apache.flume.source.SpoolDirectorySourceConfigurationConstants.BUFFER_MAX_LINES	
org.apache.flume.source.SpoolDirectorySourceConfigurationConstants.DEFAULT_BUFFER_MAX_LINE_LENGTH	
org.apache.flume.source.SpoolDirectorySourceConfigurationConstants.DEFAULT_BUFFER_MAX_LINES	
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_CREATE_FK	ConfigurationConstants.CONFIG_CREATE_FK
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_CREATE_INDEX	ConfigurationConstants.CONFIG_CREATE_INDEX
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_CREATE_SCHEMA	ConfigurationConstants.CONFIG_CREATE_SCHEMA
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_DATABASE_TYPE	ConfigurationConstants.CONFIG_DATABASE_TYPE
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_JDBC_DRIVER_CLASS	ConfigurationConstants.CONFIG_JDBC_DRIVER_CLASS
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_JDBC_PROPS_FILE	ConfigurationConstants.CONFIG_JDBC_PROPS_FILE
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_JDBC_SYSPROP_PREFIX	ConfigurationConstants.CONFIG_JDBC_SYSPROP_PREFIX
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_MAX_CAPACITY	ConfigurationConstants.CONFIG_MAX_CAPACITY
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_MAX_CONNECTIONS	ConfigurationConstants.CONFIG_MAX_CONNECTIONS
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_PASSWORD	ConfigurationConstants.CONFIG_PASSWORD
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_TX_ISOLATION_LEVEL	ConfigurationConstants.CONFIG_TX_ISOLATION_LEVEL
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_URL	ConfigurationConstants.CONFIG_URL
org.apache.flume.channel.jdbc.ConfigurationConstants.OLD_CONFIG_USERNAME	ConfigurationConstants.CONFIG_USERNAME

Deprecated Constructors

Constructor
org.apache.flume.conf.FlumeConfiguration(Properties)

last-updated: Apr 11, 2022

Deprecated Methods

Deprecated Method
org.apache.flume.formatter.output.BucketPath.containsTag(string)
org.apache.flume.formatter.output.BucketPath.expandShorthand(char)
org.apache.flume.formatter.output.BucketPath.getEscapeMapping(string, Map)
org.apache.flume.formatter.output.BucketPath.getEscapeMapping(String, Map, Boolean, int, int)
org.apache.flume.api.RpcClientFactory.getInstance(string, integer)
org.apache.flume.api.RpcClientFactory.getInstance (string, integer, integer)
org.apache.flume.formatter.output.BucketPath.replaceShorthand(char, Map)
org.apache.flume.formatter.output.BucketPath.replaceShorthand(char, Map, Boolean, int, int)
org.apache.flume.formatter.output.BucketPath.replaceShorthand(char, Map, TimeZone, Boolean, int, int, Boolean)

HBase

Apache HBase™ is the Hadoop database, a distributed, scalable, big data store. You can use Apache HBase when you need random, realtime read-write access to your Big Data. This section describes how to use HBase with the MapR Platform, but does not duplicate Apache documentation.

The goal of Apache HBase is to host very large tables – billions of rows with millions of columns – atop clusters of commodity hardware. Apache HBase is an open-source, distributed, versioned, column-oriented store modeled after Google's Bigtable: A Distributed Storage System for Structured Data by Chang et al. Just as Bigtable leverages the distributed data storage provided by the Google File System, Apache HBase provides Bigtable-like capabilities on top of Hadoop and Hadoop-compatible filesystems, such as the MapR File System.

Installing Apache HBase on a MapR cluster involves storing all HBase components in a single volume mapped to directory `/hbase` in the cluster. Tables are stored in a flat namespace, not grouped logically with related files. Because all Apache HBase data resides in one volume, only one set of storage policies can be applied to the entire Apache HBase datastore. Mirrors and snapshots of the HBase volume do not provide functional replication of the datastore. Despite this limitation, mirrors can be used to back up HLogs and HFiles in order to provide a recovery point for Apache HBase data.

This section documents how to work with HBase on the MapR Converged Data Platform. You can refer also to documentation available from the Apache HBase project.

Note: The MapR Database provides native storage for table data, compatible with the HBase API. For new applications, consider using MapR Database binary tables for increased performance, more versatile table operations, and easier cluster administration.

Configuring HBase
Configure MapR-SASL Security (Authentication and Encryption) for HBase
This section describes the manual method for configuring security in HBase.

Starting with EEP 6.3.0, HBase services are secured by default with MapR-SASL. After installing HBase, you configure it by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option. There are two methods to configure HBase to be secure by default:

- Automatic Method
- Manual Method

Automatic Method

If you installed HBase by using the MapR Installer, the MapR Installer configures HBase daemons during installation. Additional configuration is not required.

Manual Method

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Four HBase services require configuration:

- HBase Master
- HBase RegionServer
- HBase Thrift
- HBase REST

Each service can be configured for authentication and encryption, as shown later on this page:

HBase Master and RegionServer

The Master and RegionServer services require the same configuration for security.

Authentication

To enable MapR-SASL authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Encryption

To enable MapR-SASL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rpc.protection</name>
  <value>privacy</value>
</property>
```

Possible values for the `hbase.rpc.protection` property are:

- `authentication (auth)`
- `integrity (auth-int)`
- `privacy (auth-conf)`

The best practice is to spell out the values (authentication/integrity/privacy). The abbreviated values (in parentheses) can work, but using them is not recommended. Encryption is enabled only for the highest level of security (`privacy`).

HBase Thrift

It is possible to configure the HBase Thrift service to work over sockets or over the HTTP protocol. For authentication purposes, configuration is the same for both cases. For encryption, configuration is different for each case. Note that starting with the EEP6.3.0 property,

last-updated: Apr 11, 2022

`hbase.thrift.security.authentication` is no longer used to configure HBase Thrift for authentication.

Authentication

HBase Thrift relies on the same property used for Master and RegionServer. To enable authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Encryption for Thrift over Sockets

To enable encryption with MapR-SASL for Thrift over sockets, make sure that the `hbase.regionserver.thrift.http` property is set to `false` and the following property is present in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
```

Possible values for `hbase.thrift.security.qop` are:

- `auth`
- `auth-int`
- `auth-conf`

Encryption is enabled only for the highest level of security (`auth-conf`).

Encryption for Thrift over HTTP

To enable Thrift to work over the HTTP protocol, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

To enable Thrift over HTTP encryption through SSL, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
  <value>true</value>
</property>
```

HBase REST

Authentication

To enable HBase REST authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.authentication.type</name>
```

```
<value>org.apache.hadoop.security.authentication.server.MultiMechsAuthentica
tionHandler</value>
</property>
```

With the MultiMechsAuthenticationHandler, MapR-SASL, Kerberos, and PAM authentication headers are supported. A custom AuthenticationHandler could be implemented and specified with the full class name in this property.

Encryption

To enable HBase REST SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

HBase Services Web UIs

Web UIs are available for each HBase service. The Web UIs run simultaneously with the service and within the same process. Security for these UIs must be configured too.

Authentication

To enable HBase Web UI authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Authentication is implemented through the MultiMechsAuthenticationHandler and therefore supports MapR-SASL, Kerberos, and PAM authentication headers.

Encryption

To enable HBase Web UI SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.ssl.enabled</name>
  <value>true</value>
</property>
```

Configure HBase to use Kerberos

HBase supports MapR-SASL and Kerberos security, and can run securely independently of the security status of your MapR cluster.

To configure HBase to use Kerberos, perform the following steps:

1. Install the `mapr-hbase-master` and `mapr-hbase-regionserver` packages on the cluster.
2. On all HBase nodes, perform the following steps:
   a) Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
   b) Set up the HBase Kerberos principal `mapr/<fqdn>@<realm>`. Each node requires a unique keytab file and Kerberos identity.
   c) Create an `hbase.keytab` file with the HBase Kerberos principal with the same process used to generate the CLDB keytab.
   d) Copy the `hbase.keytab` file to the `/opt/mapr/conf` directory.

last-updated: Apr 11, 2022

e) Use the `chown` command to change the keytab file's ownership to `mapr:mapr`.

f) Use the `chmod` command to set the file's permissions to `600`.

g) Update the `hbase-site.xml` file by adding the following section:

```
<property>
   <name>hbase.security.authentication</name>
   <value>kerberos</value>
 </property>
 <property>
  <name>hbase.security.authorization</name>
   <value>true</value>
 </property>
 <property>
   <name>hbase.regionserver.kerberos.principal</name>
   <value>mapr/_HOST@<KERBEROS_REALM></value>
 </property>
 <property>
   <name>hbase.master.kerberos.principal</name>
  <value>mapr/_HOST@<KERBEROS_REALM></value>
 </property>
```

h) On a MapR cluster with security features enabled, replace the `${SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` property with `${KERBEROS_LOGIN_OPTS}` and the value of the `MAPR_HBASE_CLIENT_OPTS` property with `${HYBRID_LOGIN_OPTS}`. Also remove the `-Dzookeeper.sasl.client=false` option from the definition of `MAPR_HBASE_CLIENT_OPTS`.

These properties are located in the `/opt/mapr/conf/env.sh` file.

i) On a MapR cluster with security features disabled, replace the `${SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` and `MAPR_HBASE_CLIENT_OPTS` properties in the `/opt/mapr/conf/env.sh` file with `${KERBEROS_LOGIN_OPTS}`.

3. On all HBase regionserver nodes, update the `hbase-site.xml` file by adding the following section:

```
<property>
   <name>hbase.regionserver.keytab.file</name>
   <value>/opt/mapr/conf/hbase.keytab</value>
 </property>
 <property>
   <name>hbase.coprocessor.region.classes</name>
   <value>
org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.hadoop.hb
ase.security.access.AccessController</value>
 </property>
```

4. On the HBase master node, update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.master.keytab.file</name>
  <value>/opt/mapr/conf/hbase.keytab</value>
</property>
<property>
  <name>hbase.coprocessor.master.classes</name>
  <value>org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

5. Restart the HBase master and regionserver nodes.

Enable Impersonation for HBase

HBase can be configured to offer impersonation, with or without Kerberos. This means that users can send commands to HBase through Hue without losing the fact that they will be run under their own credentials, instead of the `hue` user.

For instructions, see Enable Impersonation for HBase Thrift1 Gateway.

Configure HBase ACLs

HBase supports Access Control Lists (ACLs) to limit the privileges of users on the system. Before you can use ACLs, you need to perform the steps to enable ACLs.

HBase ACLs support the following privileges:

- `Read`
- `Write`
- `Execute`
- `Create tables`
- `Administrator`

The possible scopes are:

- `Superuser`
- `Global`
- `Namespace`
- `Table`
- `ColumnFamily`
- `Cell`

For information about each scope, see Understanding Access Levels.

Once you enable the use of ACLs, you can grant and remove privileges from users by using the `grant` and `revoke` commands from the HBase shell. The following example grants user `jfoo` read privileges from column family `cf1` of table `mytable`:

```
hbase(main):001:0> grant 'jfoo' 'R' 'mytable','cf1'
```

This example removes user `kbar`'s administrative privileges on the cluster:

```
hbase(main):001:0> revoke 'kbar' 'A'
```

last-updated: Apr 11, 2022

Enable HBase Access Control
The following steps explain how to enable HBase ACLs.

1. On the HBase Region Server, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
    <name>hbase.coprocessor.region.classes</name>

<value>org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
<property>
    <name>hbase.superuser</name>
    <value><admin1>,<admin2>,@<group1>,...</value> <!-- group names are prefixed with '@' -->
  </property>
```

2. On the HBase Master, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
    <name>hbase.coprocessor.master.classes</name>
    <value>org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
<property>
    <name>hbase.superuser</name>
    <value><admin1>,<admin2>,@<group1>,...</value> <!-- group names are prefixed with '@' -->
  </property>
```

3. Restart HBase on every node.

Set Up Compression with HBase
Using compression with HBase reduces the number of bytes transmitted over the network and stored on disk. These benefits often outweigh the performance cost of compressing the data on every write and uncompressing it on every read.

GZip Compression

GZip compression is included with most Linux distributions and works natively with HBase. To use GZip compression, specify it in the per-column family compression flag while creating tables in HBase shell. For example:

```
create 'mytable', {NAME=>'colfam', COMPRESSION=>'gz'}
```

LZ4 Compression

The LZ4 algorithm gives a slightly worse compression ratio than the LZO algorithm – which in turn is worse than algorithms like DEFLATE. However, compression speeds are similar to LZO and several times faster than DEFLATE, while decompression speeds can be significantly higher than LZO. Here is an example of configuring LZ4 compression:

```
create 'mytable1', {NAME=>'colfam', COMPRESSION=>'lz4'}
```

Snappy Compression

The Snappy compression algorithm is optimized for speed over compression. Snappy compression is included in the core MapR installation, and no additional configuration is required.

Configure the Default Database for HBase Clients

For HBase version 1.1 and later, a default database configuration determines whether clients connect to HBase tables or MapR Database tables. You can change the default setting for all HBase clients, or you can set the database for a particular job. This setting is ignored for HBase 0.98.12 client connections.

Set the Default Database using configure.sh

`configure.sh` automatically sets the default database for a node based on the presence of the following `mapr` packages:

- `mapr-hbase-master`
- `mapr-hbase-regionserver`

`configure.sh` also provides a parameter that you can use to set the default database. To explicitly set the default database to either `maprdb` or `hbase`, run `configure.sh` with the `-defaultdb` parameter. For example:

```
configure.sh -R -defaultdb maprdb
```

The following table describes the effect of various `configure.sh` commands on the default database setting:

Table

If ...	And you run `configure.sh` with the following `-defaultdb` parameter ...		
	No `-defaultdb` parameter specified	`-defaultdb hbase`	`-defaultdb maprdb`
`hbasemaster` or `hbaseregionserver` is installed on a node	The default database is set to `hbase`.	The default database is set to `hbase`	The default database is set to `hbase`, and the `maprdb` setting is ignored.
`hbasemaster` and `hbaseregionserver` are NOT installed on a node	The default database is set to `maprdb`.	The default database is set to `hbase`. However, this configuration does not work because HBase is not running.	The default database is set to `maprdb`.

For more information about `configure.sh`, see configure.sh on page 2053.

Set the Default Database using hbase-site.xml

You can configure the `mapr.hbase.default.db` property in the `hbase-site.xml` to override the default database that is set for the cluster:

1. In the `hbase-site.xml`, edit the default value of `mapr.hbase.default.db`, and set it to either `hbase` or `maprdb`.

   For example:

   ```
   <property>
       <name>mapr.hbase.default.db</name>
       <value>hbase</value>
   </property>
   ```

2. Copy the property to the `hbase-site.xml` on each node that runs HBase, including any HBase client nodes.

last-updated: Apr 11, 2022

Set the Database Type in the Job Configuration

To set the database type in the job configuration you can add the following code:

- To connect to MapR Database tables:

```
Configuration conf = HBaseConfiguration.create();
conf.set("mapr.hbase.default.db", "maprdb");
Connection connection = ConnectionFactory.createConnection(conf);
Table table = connection.getTable(<TABLE_NAME>);
```

- To connect to HBase tables:

```
Configuration conf = HBaseConfiguration.create();
conf.set("mapr.hbase.default.db","hbase");
Connection connection = ConnectionFactory.createConnection(conf);
Table table = connection.getTable(<TABLE_NAME>);
```

HBase Configuration Properties
This section describes and shows examples of the configuration properties used in the `hbase-site.xml` file.

Table

Category	Property	Description
Basic Properties	`Hbase.rootdir`	Specifies where the HBase data is stored. If not specified, by default HBase uses the `/tmp/` local folder. It is possible to use the local filesystem and MapR File System or a remote MapR File System instance.
	<property> <name>hbase.rootdir</name> <value>maprfs:///hbase</value> </property>	
	`HBase.cluster.distributed`	The mode the cluster will be in. Possible values are `false` for standalone mode and `true` for distributed mode. If `false`, startup runs all HBase and ZooKeeper daemons together in the one JVM. **Default:** `false`.
	<property> <name>hbase.cluster.distributed</name> <value>true</value> </property>	
	`Hbase.zookeeper.quorum`	Comma-separated list of servers in the ZooKeeper ensemble. For example, "host1.mydomain.com,host2.mydomain.com,host3.mydomain.com". By default this property is set to localhost for local and pseudo-distributed modes of operation. For a fully-distributed setup, this property should be set to a full list of ZooKeeper ensemble servers. If HBASE_MANAGES_ZK is set in `hbase-env.sh`, this is the list of servers that HBase will start or stop ZooKeeper on as part of cluster start or stop. Client-side, we will take this list of ensemble members and put it together with the `hbase.zookeeper.property.clientPort config.` and pass it into the Zookeeper constructor as the `connectString` parameter. Port could be specified together with hosts. In this case, the `hbase.zookeeper.property.clientPort` configuration is useless.
	<property> <name>hbase.zookeeper.quorum</name> <value>node11.cluster.com:5181</value> </property>	
	`Dfs.support.append`	Specifies whether DFS allows appends to files.
	<property> <name>dfs.support.append</name> <value>true</value> </property>	
	`Hbase.fsutil.maprfs.impl`	Specifies the FSUtil class (the utility methods for interacting with the underlying filesystem) used in HBase.
	<property> <name>hbase.fsutil.maprfs.impl</name> <value>org.apache.hadoop.hbase.util.FSMapRUtils</value> </property>	
	`Hbase.regionserver.handler.count`	Sets the count of RPC Listener instances spun up on RegionServers. The Same property is used by the Master for a count of master handlers. Too many handlers can be counter-productive. Make it a multiple of the CPU count. If mostly read-only, handlers count close to CPU count does well. Start with

last-updated: Apr 11, 2022

Table (Continued)

Category	Property	Description
Security Properties*	`Hbase.security.authorization`	Specifies whether authorization is enabled or not.
	<property> <name>hbase.security.authorization</name> <value>true</value> </property>	
	`Hbase.security.exec.permission.checks`	Without this option, all users continue to have access to execute endpoint coprocessors. This option is not enabled when you enable HBase Secure Authorization for backward compatibility.
	<property> <name>hbase.security.exec.permission.checks</name> <value>true</value> </property>	
	`hbase.coprocessor.master.classes`	A comma-separated list of coprocessors that are loaded by the master (MasterObserver coprocessors). The AccessController has to be active to support authorization.
	<property> <name>hbase.coprocessor.master.classes</name> <value>org.apache.hadoop.hbase.security.access. AccessController</value> </property>	
	`Hbase.coprocessor.region.classes`	A comma-separated list of RegionObserver and Endpoint coprocessors. TokenProvider and AccessController must be active to support authorization.
	<property> <name>hbase.coprocessor.region.classes</name> <value>org.apache.hadoop.hbase.security.token.TokenProvider. org.apache.hadoop.hbase.security.access.AccessController</value> </property>	

Table (Continued)

Category	Property	Description
Authentication and Encryption Properties	`hbase.security.authentication`	Defines whether to use SASL mechanisms in HBase to authenticate RPC connections from clients to HBase Master and RegionServer. Also defines whether to support authentication for HBaseThrift. Specifying `maprsasl` enables authentication for HBaseThrift over http.
	<property> <name>hbase.security.authentication</name> <value>maprsasl</value> </property>	
	`hbase.rpc.protection`	Enables or disables transport security encryption. To support encryption, the `auth-conf` (privacy) value must be specified. Possible values are: • `auth` or `authentication` • `auth-int` or `integrity` • `auth-conf` or `privacy`
	<property> <name>hbase.rpc.protection</name> <value>auth-conf</value> </property>	
	`hbase.ssl.enabled`	Enables or disables SSL encryption for HBase WebUIs.
	<property> <name>hbase.ssl.enabled</name> <value>true</value> </property>	
	`hbase.thrift.ssl.enabled`	Enables or disables SSL encryption for HBaseThrift. Works only for HBaseThrift over http (the `hbase.regionserver.thrift.http` property must be set to `true`).
	<property> <name>hbase.thrift.ssl.enabled</name> <value>true</value> </property>	
	`Hbase.thrift.security.qop`	Enables or disables transport security encryption for HBaseThrift. Use the `Auth-conf` value to support encryption. This property works only for HBaseThrift over sockets (the `hbase.regionserver.thrift.http` property must be set to `false`). Possible values are: • `auth` • `auth-int` • `auth-conf`
	<property> <name>hbase.thrift.security.qop</name> <value>auth-conf</value> </property>	

last-updated: Apr 11, 2022

Table (Continued)

Category	Property	Description
Impersonation Properties	`hbase.thrift.support.proxyuser`	Enables or disables impersonation for HBaseThrift. Works only for thrift over http (the `hbase.regionserver.thrift.http` property must be set to `true`).
	<property> <name>hbase.thrift.support.proxyuser</name> <value>true</value> </property>	
	`hbase.rest.support.proxyuser`	Enables or disables impersonation for HBaseRest.
	<property> <name>hbase.rest.support.proxyuser</name> <value>true</value> </property>	
	`hbase.regionserver.thrift.http`	Defines whether to use HBaseThrift over http (if `true` is specified) or over sockets. Used to support impersonation for thrift over http.
	<property> <name>hbase.regionserver.thrift.http</name> <value>true</value> </property>	

*To support authorization, four properties must be enabled:

- `hbase.security.authorization`
- `hbase.security.exec.permission.checks`
- `hbase.coprocessor.master.classes`
- `hbase.coprocessor.region.classes`

If any of them is missing, authorization will not be fully supported.

Using HBase

This section includes the following topics about working with HBase:

Getting Started in HBase

In this section, we'll create an HBase table on the cluster, enter some data, query the table, then clean up the data and exit.

HBase tables are organized by column, rather than by row. Furthermore, the columns are organized in groups called *column families*. When creating an HBase table, you must define the column families before inserting any data. Column families should not be changed often, nor should there be too many of them, so it is important to think carefully about what column families will be useful for your particular data. Each column family, however, can contain a very large number of columns. Columns are named using the format `family:qualifier`.

Unlike columns in a relational database, which reserve empty space for columns with no values, HBase columns simply don't exist for rows where they have no values. This not only saves space, but means that different rows need not have the same columns; you can use whatever columns you need for your data on a per-row basis.

1. Start the HBase shell by typing the following command:

```
hbase shell
```

2. Create a table called `weblog` with one column family named `stats`:

```
create 'weblog', 'stats'
```

3. Verify the table creation by listing everything:

```
list
```

4. Add a test value to the `daily` column in the `stats` column family for row 1:

```
put 'weblog', 'row1', 'stats:daily', 'test-daily-value'
```

5. Add a test value to the `weekly` column in the `stats` column family for row 1:

```
put 'weblog', 'row1', 'stats:weekly', 'test-weekly-value'
```

6. Add a test value to the `weekly` column in the `stats` column family for row 2:

```
put 'weblog', 'row2', 'stats:weekly', 'test-weekly-value'
```

7. Type `scan 'weblog'` to display the contents of the table. Sample output:

```
ROW                  COLUMN+CELL
 row1                column=stats:daily, timestamp=1321296699190,
value=test-daily-value
 row1                column=stats:weekly, timestamp=1321296715892,
value=test-weekly-value
 row2                column=stats:weekly, timestamp=1321296787444,
value=test-weekly-value
2 row(s) in 0.0440 seconds
```

8. Type `get 'weblog', 'row1'` to display the contents of row 1. Sample output:

```
COLUMN               CELL
 stats:daily         timestamp=1321296699190, value=test-daily-value
 stats:weekly        timestamp=1321296715892, value=test-weekly-value
2 row(s) in 0.0330 seconds
```

last-updated: Apr 11, 2022

9. Type `disable 'weblog'` to disable the table.

10. Type `drop 'weblog'` to drop the table and delete all data.

11. Type `exit` to exit the HBase shell.

Running MapReduce Jobs with HBase

To run MapReduce applications with data stored in HBase, use a command such as the following to export table data to the MapR filesystem:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1
```

or

```
$  hbase org.apache.hadoop.hbase.mapreduce.Export t1 /user/mapr/t4
```

The result is the same because of the tools included in the hbase-server.jar file:

```
$ hadoop fs -ls /user/mapr/t1/
Found 2 items
-rwxr-xr-x   3 mapr mapr          0 2019-11-11 15:00 /user/mapr/t1/_SUCCESS
-rw-r--r--   3 mapr mapr        249 2019-11-11 15:00 /user/mapr/t1/
part-m-00000
$ hadoop fs -ls /user/mapr/t4/
Found 2 items
-rwxr-xr-x   3 mapr mapr          0 2019-11-11 15:09 /user/mapr/t4/_SUCCESS
-rw-r--r--   3 mapr mapr        249 2019-11-11 15:09 /user/mapr/t4/
part-m-00000
$
```

Following is an example of the full output:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1

The following table shows the tools included in the hbase-server.jar:

Name[1]	Class[2]	Description
rowcounter	RowCounter	Count rows in HBase table
CellCounter	CellCounter	Count cells in HBase table
export	Export	Write table data to MapR filesystem
import	Import	Import data written by Export
importtsv	ImportTsv	Import data in TSV format
completebulkload	LoadIncrementalHFiles	Complete a bulk data load
copytable	CopyTable	Export a table from local cluster to peer cluster
verifyrep	VerifyReplication	Compare the data from tables in two different clusters  **Note:** This function does not work for incrementColumnValues cells since the timestamp is changed after being appended to the log.
WALPlayer	WALPlayer	Replay WAL files
exportsnapshot	ExportSnapshot	Export the specific snapshot to a given FileSystem

[1] Class is used for `hbase.org.apache.hadoop.hbase.mapreduce.<class>....`

[2] Name is used for `hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/hbase-server-1.1.13.0-mapr-1912.jar <name>...`

Using the libhbase Library

libhbase is a JNI-based, thread-safe C library that implements a native HBase client. You can use libhbase to build applications that access HBase.

This page contains the following topics:

- Installing libhbase
- Upgrading libhbase
- Building applications with libhbase
- Configuring the application environment
- Running a libhbase performance test

For examples that show how to use the APIs, see the sample source file.

Installing libhbase

Install libhbase on the nodes from which you will build and run the application.

last-updated: Apr 11, 2022

Complete the following steps to install libhbase from a repository:

1. Configure the repository to point to http://package.mapr.hpe.com/releases/MEP/MEP-6.3.0/.
2. Based on your operating system, run one of the following commands to install the package:
   - On Red Hat /Centos: `yum install mapr-libhbase`
   - On SLES: `zypper install mapr-libhbase`
   - On Ubuntu: `apt-get install mapr-libhbase`

Once the installation completes, the libhbase installation includes the following directories under `/opt/mapr/libhbase/libhbase-<version>`:

```
/
+---bin/
+---conf/
+---include/
|   +--hbase/
+---lib/
|   +---native/
+---src
    +---examples/
    |   +---async/
    +---test/
        +---native/
            +---common/
```

Note: The `include` folder contains the headers required to build applications. The `lib/native` directory contains shared libraries.

Upgrading libhbase

To upgrade to a more recent version of libhbase:

1. Install the new version.
2. Re-configure the application environment to refer to the new libraries.

Building Applications with libhbase

libhbase should be installed on each node that builds the application.

Note the following items when you build applications with libhbase:

- The headers required to build applications are located under `/opt/mapr/libhbase/libhbase-<version>/include`.
- libhbase shared library is located in the following directory: `/opt/mapr/libhbase/libhbase-<version>/lib/native`.
- Since libhbase uses JNI, you must also link your application against libjvm. In general, the libjvm library is located within the JDK/JRE installation directory.

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/
libhbase/libhbase-0.98.7/include -L/opt/mapr/libhbase/libhbase-0.98.7/lib/
native -lhbase -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

last-updated: Apr 11, 2022

Configuring the Application Environment

Complete the following steps to configure the node from which you run the application:

- Verify that libhbase is installed on the node.
- Verify that both the libhbase and libjvm shared libraries are in the application's library search path. The libhbase shared library is located under `/opt/mapr/libhbase/libhbase-<version>/lib/native`. In general, the libjvm library is located within the JDK/JRE installation directory.
- Specify any JARs required by the application with one of the following environment variables: `CLASSPATH` or `HBASE_LIB_DIR`.
- Specify custom JVM options, such as `-Xmx`, using the environment variable `LIBHBASE_OPTS`.

Running a libhbase Performance Test

libhbase 0.98.7 includes a performance test that supports sequential/random gets and puts. In libhbase 0.98.9, the performance test utility also includes support for Zipfian, support for uniform random key generation, and it test for scans. You can run the test using this shell script.

HBase Client and MapR Database Binary Tables

MapR 6.0.x and 6.1 provide Apache HBase-compatible APIs and client interfaces but do not support HBase as an ecosystem component. MapR Database binary tables provide native storage for table data and include high performance and availability, versatile table operations, and streamlined cluster administration. The following APIs and tools are available for MapR Database binary tables:

HBase Client	• After installing the HBase Client, you can use HBase Shell commands to manipulate MapR Database binary tables on a remote machine. See Installing HBase on a Client Node on page 185 and MapR Database HBase Shell (Binary Tables) on page 5325. • MapR Database supports binary tables through the libMapRClient (a library of C APIs) and Apache HBase Java APIs. See Developing Applications for Binary Tables on page 2452.
HBase REST Gateway	• The HBase REST Gateway allows users to manipulate MapR Database binary tables through the HBase REST API. See Installing the HBase REST Gateway on page 187.
HBase Thrift Gateway	• The HBase Thrift Gateway allows users to manipulate MapR Database binary tables through the HBase Thrift API. See Installing the HBase Thrift Gateway on page 186.

Using the HBase Thrift Gateway

HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to MapR Database and HBase tables. The HBase Thrift Gateway is installed as a service that is managed by Warden. When `mapr-hbasethrift` is installed, the `warden.hbasethrift.conf` file is added to the `/opt/mapr/conf/conf.d` directory.

Note: MapR SASL authentication, encryption, and impersonation for HBase Thrift Gateway are enabled by default on secure clusters.

last-updated: Apr 11, 2022

Starting the HBase Thrift Service

To start the HBase thrift service, enter the following command with the name of the host where hbasethrift is running:

```
maprcli node services -name hbasethrift -action start -nodes <node_hostname>
```

Configure Kerberos for HBase Thrift Gateway

1. Add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
    <name>hbase.thrift.keytab.file</name>
    <value>$KEYTAB</value>
</property>
<property>
    <name>hbase.thrift.kerberos.principal</name>
    <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
    <!-- This may need to be HTTP/_HOST@<REALM> and _HOST may not work.
You may have to put the concrete full hostname. -->
</property>
<property>
   <name>hbase.thrift.security.qop</name>
   <value>auth-conf</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
    <name>hbase.thrift.dns.interface</name>
    <value>default</value>
</property>
<property>
    <name>hbase.thrift.dns.nameserver</name>
    <value>default</value>
</property>
```

   Substitute the appropriate credential and keytab for $USER and $KEYTAB respectively.

2. If you are running HBase Thrift in HTTP mode, you must add additional properties to the `hbase-site.xml` to enable HTTP connections through Kerberos. This is required if you enabled the following property in the `hbase-site.xml`:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

   Add the following properties to enable HTTP connections through Kerberos:

```
<property>
    <name>hbase.thrift.spnego.principal</name>
    <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
    <name>hbase.thrift.spnego.keytab.file</name>
    <value>$KEYTAB</value>
</property>
```

last-updated: Apr 11, 2022

3. To use MapR Database tables without the full path, add the following property to the `core-site.xml` file:

```
<property>
    <name>hbase.table.namespace.mappings</name>
    <value>*:/</value>
</property>
```

   Add this property ONLY if you are working with MapR Database tables. Working with HBase tables is not possible when this property is present. For more information, see Considerations for Upgrading to HBase 1.1.13 on page 337. For more information about mapping tables, see Mapping to HBase Table Namespaces on page 430.

The Thrift gateway authenticates with HBase using the supplied credential. No authentication is performed by the Thrift gateway itself. All client access via the Thrift gateway uses the Thrift gateway's credential and has its privilege.

Enable Impersonation for HBase Thrift Gateway

To configure the Thrift gateway to authenticate to HBase on the client's behalf, and to access HBase using a proxy user:

1. To allow proxy users, add the following to the `hbase-site.xml` file for every HBase node:

```
<property>
    <name>hadoop.proxyuser.$USER.groups</name>
    <value>$GROUPS</value>
</property>
<property>
    <name>hadoop.proxyuser.$USER.hosts</name>
    <value>$GROUPS</value>
</property>
```

2. To enable the `doAs` feature, add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
    <name>hbase.regionserver.thrift.http</name>
    <value>true</value>
</property>
<property>
    <name>hbase.thrift.support.proxyuser</name>
    <value>true/value>
</property>
```

3. Restart the Thrift gateway processes for the changes to take effect. If a node is running Thrift, the output of the `jps` command will list a `ThriftServer` process.
   - To restart Thrift on a node, use the following `maprcli` command:

```
maprcli node services -name hbasethrift -action restart -nodes
<node_hostname>
```

Using the HBase REST Gateway

HBase REST Gateway includes an API and a service that accepts REST requests to connect to MapR Database and HBase tables. Starting in version 0.98.9, the HBase REST Gateway is installed as a service that is managed by Warden. When mapr-hbase-rest is installed, the `warden.hbase-rest.conf` file is added to the `/opt/mapr/conf/conf.d` directory.

last-updated: Apr 11, 2022

Note: PAM authentication, encryption, and impersonation for HBase REST are enabled by default on secure clusters.

Starting the HBase REST Service

To start the HBase REST service, enter the following command with the name of the host where hbaserest is running:

```
maprcli node services -name hbaserest -action start -nodes <node_hostname>
```

Configure Kerberos for HBase REST Gateway

1. Add the following to the `hbase-site.xml` file for every REST Gateway:

   ```
   <property>
       <name>hbase.rest.keytab.file</name>
       <value>$KEYTAB</value>
   </property>
   <property>
       <name>hbase.rest.kerberos.principal</name>
       <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
   </property>
   ```

   Substitute the appropriate credential and keytab for $USER and $KEYTAB respectively.

   The REST Gateway will authenticate with HBase using the supplied credential.

2. To enable REST Gateway Kerberos authentication for client access, add the following to the `hbase-site.xml` file for every REST Gateway:

   ```
   <property>
       <name>hbase.rest.authentication.type</name>
       <value>kerberos</value>
   </property>
   <property>
       <name>hbase.rest.authentication.kerberos.principal</name>
       <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
   </property>
   <property>
       <name>hbase.rest.authentication.kerberos.keytab</name>
       <value>$KEYTAB</value>
   </property>
   <!-- Add these if you need to configure a different DNS interface from
   the default -->
   <property>
       <name>hbase.rest.dns.interface</name>
       <value>default</value>
   </property>
   <property>
       <name>hbase.rest.dns.nameserver</name>
       <value>default</value>
   </property>
   ```

   Substitute the keytab for HTTP for $KEYTAB.

Enable Impersonation for HBase REST Gateway

To enable HBase REST Gateway impersonation, configure all HBase servers to allow proxy users, then configure every REST Gateway to enable impersonation.

last-updated: Apr 11, 2022

- To enable REST Gateway impersonation, add the following to the `hbase-site.xml` file for every REST gateway:

```
<property>
    <name>hbase.rest.support.proxyuser</name>
    <value>true</value>
</property>
```

HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL
Starting in EEP 6.0.0, HBase REST and HBase Thrift use SSL by default on secured clusters.

1. On a secure cluster, by default, HBase REST and HBase Thrift read the `ssl-client.xml` file and configure SSL using this file.
2. To enable HBase REST and Thrift encryption, use the following properties. Note that SSL for Thrift is enabled only when the `hbase.regionserver.thrift.http` property is `true`:

   Enabling HBase REST encryption

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

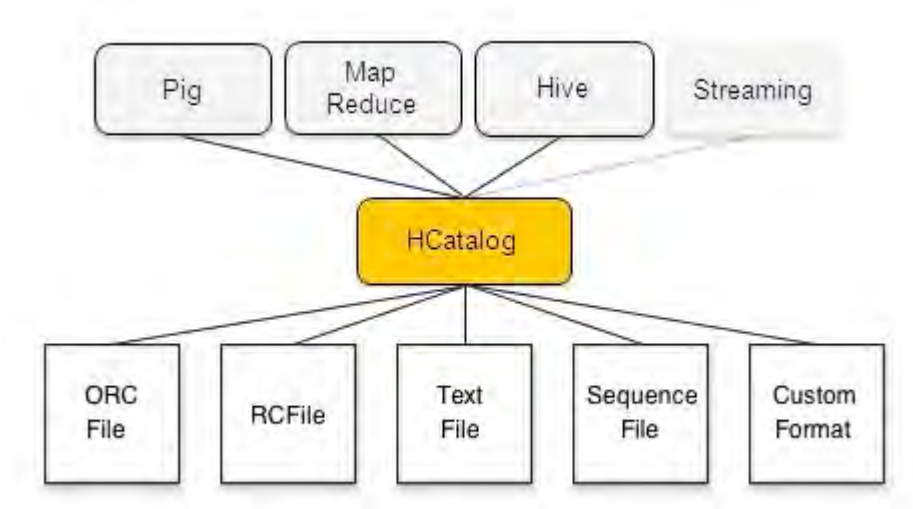
   Enabling HBase Thrift encryption

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
  <value>true</value>
</property>
```

HCatalog

HCatalog is a table and storage management layer for Hadoop that enables users with different data processing tools — Pig, MapReduce — to more easily read and write data on the grid. HCatalog's table abstraction presents users with a relational view of data in the Hadoop distributed filesystem (HDFS) and ensures that users need not worry about where or in what format their data is stored — RCFile format, text files, SequenceFiles, or ORC files.

HCatalog supports reading and writing files in any format for which a SerDe (serializer-deserializer) can be written. By default, HCatalog supports RCFile, CSV, JSON, and SequenceFile, and ORC file formats. To use a custom format, you must provide the InputFormat, OutputFormat, and SerDe.



HCatalog is also automatically installed and upgraded along with Hive. For information about using HCatalog with Hive, see Hive and WebHCat Integration and Hive and HCatalog Integration.

Hive

Apache Hive™ is a data warehouse system for Hadoop that facilitates easy data summarization, ad-hoc queries, and the analysis of large datasets stored in Hadoop-compatible file systems, such as the MapR Converged Data Platform. Hive provides a mechanism to project structure onto this data and query the data using a SQL-like language called HiveQL. At the same time this language also allows traditional map/reduce programmers to plug in their custom mappers and reducers when it is inconvenient or inefficient to express this logic in HiveQL.

last-updated: Apr 11, 2022

You can refer also to documentation available from the Apache Hive project.

Hive components include the following:

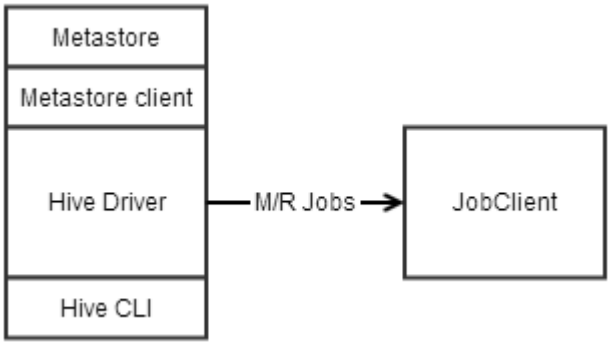
- Hive Metastore
- HiveServer2
- HCatalog
- WebHCat
- Hive CLI
- Beeline

Note: If you installed Hive using the installer with the "Enable Security" check box selected, Hive is secured and no further configuration is required. However, if you installed Hive manually and wish to enable security for Hive, see Hive Security Configuration Options on page 3427 for information.

The following examples show how these components communicate with each other and when you might want to configure security features such as authentication and encryption:

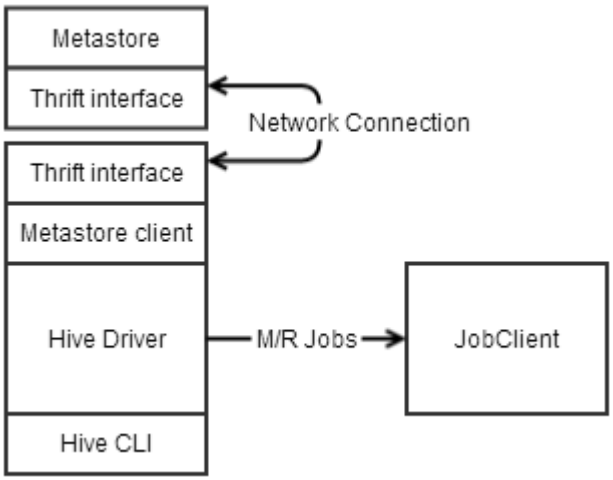
Case 1: Jobs Submitted by the Hive CLI, Embedded Metastore

In this case, all the information needed by Hive is contained within a single process, and no security is needed beyond that already provided by the JobClient's communications.



Case 2: Jobs Submitted by the Hive CLI, Remote Metastore

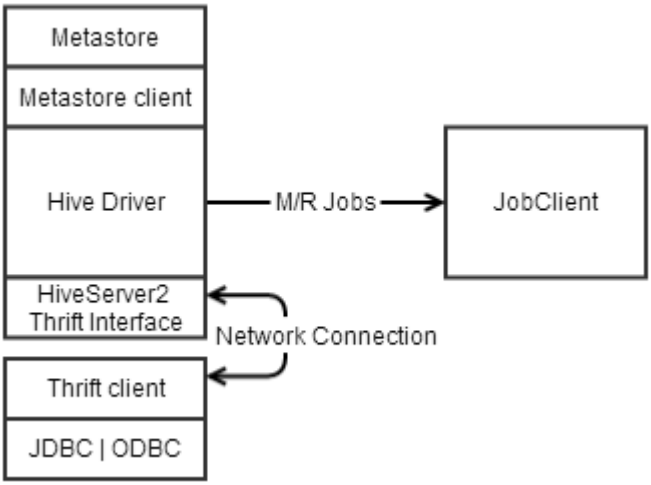
In this case, Hive needs to access a metastore remote to Hive's process using a Thrift interface. This communication can be left non-secured, secured with Kerberos, or secured with MapR-SASL.



Case 3: Jobs Submitted by HiveServer2, Embedded Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver for parsing. The communication between JDBC and HiveServer2 can be secured with username and password with SSL, MapR-SASL, or with Kerberos. Either approach offers authentication and encryption. JDBC/ODBC can also be configured to use username and password without SSL, which offers authentication *only*.

To use SSL from a client machine the `ssl_truststore` file must be copied from the cluster to the client.



Case 4: Jobs Submitted by HiveServer2, Remote Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver, which runs the query and returns the results. The metastore is remote. In this case, there are two communications links to secure: the Thrift interface between the metastore client and server, and the Thrift interface between the client JDBC/ODBC and HiveServer2. The security arrangements for these links are identical to Cases 2 and 3.

Getting Started with Hive

In this tutorial, you'll create a Hive table, load data from a tab-delimited text file, and run a couple of basic queries against the table. For details on setting up HiveServer2 and starting BeeLine, see Using JDBC or Beeline to Connect to HiveServer2 on page 3516.

last-updated: Apr 11, 2022

Note: If you are using HiveServer2, you will use the BeeLine CLI instead of the Hive shell, as shown below.

Take a look at the source data

First, take a look at the contents of the file using the terminal:

1. Save the following data to a text file named `sample-table.txt`:

   The `sample-table.txt` table columns are delimited by tabs:

   ```
   1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
   192.168.10.1
   1320352533    1002    http://www.mapr.com    http://www.example.com
   192.168.10.10
   1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
   192.168.10.1
   ```

   If you are working on the MapR Virtual Machine, we'll be loading the file from the MapR Virtual Machine's local filesystem (not the cluster storage layer), so save the file in the MapR Home directory (for example, `/home/mapr`).

2. Make sure you are in the Home directory where you saved `sample-table.txt` (type `cd ~` if you are not sure).

3. Type `cat sample-table.txt` to display the following output.

```
mapr@mapr-desktop:~$ cat sample-table.txt
1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
192.168.10.1
1320352533    1002    http://www.mapr.com    http://www.example.com
192.168.10.10
1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
192.168.10.1
```

Notice that the file consists of only three lines, each of which contains a row of data fields separated by the TAB character. The data in the file represents a web log.

Create a table in Hive and load the source data:

1. Type the following command to start the Hive shell, using tab-completion to expand the `<version>`:

   ```
   /opt/mapr/hive/hive-<version>/bin/hive
   ```

2. At the `hive>` prompt, type the following command to create the table:

   ```
   CREATE TABLE web_log(viewTime INT, userid BIGINT, url STRING, referrer
   STRING, ip STRING) ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t';
   ```

3. Type the following command to load the data from `sample-table.txt` into the table:

   ```
   LOAD DATA LOCAL INPATH '/home/mapr/sample-table.txt' INTO TABLE web_log;
   ```

Run basic queries against the table

- Try the simplest query, one that displays all the data in the table:

  ```
  SELECT web_log.* FROM web_log;
  ```

  This query would be inadvisable with a large table, but with the small sample table it returns very quickly.

- Try a simple SELECT to extract only data that matches a desired string:

  ```
  SELECT web_log.* FROM web_log WHERE web_log.url LIKE '%doc';
  ```

  This query launches a MapReduce application to filter the data.

Configuring Hive

This section contains the following topics:

Configure Hive Directories

You can configure the following Hive directories:

- Hive Scratch Directory
- Hive Warehouse Directory
- Hive Error Logs Directory

Hive Scratch Directory

In Hive 1.0, MapR configures the Hive scratch directory to be `/user/<user.name>/tmp/hive/<user.name>`. In Hive 0.13, the default scratch directory is /user/<user.name>/tmp/hive. The hive user must have write access to the /user folder.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the hive.exec.scratchdir property elements from the $HIVE_HOME/conf/hive-default.xml.template file and paste them into an XML configuration element in the $HIVE_HOME/conf/hive-site.xml file. Then, modify the value elements for these directories in the hive-site.xml file.
- Set this parameter from the Hive shell. Example:

  ```
  hive> set hive.exec.scratchdir=/myvolume/tmp
  ```

Note: You will see better performance when queries import data from a table that is in the same MapR volume as Hive scratch directory.

How Hive Handles Scratch Directories on MapR

When a query requires Hive to query existing tables and create data for new tables, Hive uses the following workflow:

1. Create the query scratch directory `hive_<timestamp>_<randomnumber>` under the Hive scratch directory.
2. Create the following directories as subdirectories of the scratch directory:
   a. Final query output directory. This directory's name takes the form `-ext-<number>`.

last-updated: Apr 11, 2022

   b. An output directory for each MapReduce application. These directories' names take the form `-mr-<number>`.

3. Hive executes the tasks, including MapReduce applications and loading data to the query output directory.
4. Hive loads the data from output directory into a table. By default, the table's directory is in the `/user/hive/warehouse` directory. You can configure this location with the `hive.metastore.warehouse.dir` parameter in `hive-site.xml`, unless the table DDL specifies a custom location. Hive renames the output directory to the table directory in order to load the output data to the table.
5. The scratch directories are automatically deleted after the query completes successfully.

MapR uses Administering Volumes on page 856, which are logical units that enable you to apply policies to a set of files, directories, and sub-volumes. When the output directory and the table directory are in different volumes, this workflow involves moving data across volumes. Moving data across volumes is slower than moving data within a volume. Therefore, MapR sets `hive.optimize.insert.dest.volume` to `true` to automatically create a scratch directory in the same volume as the target table.

Hive Warehouse Directory

Hive tables are stored in the Hive warehouse directory. By default, MapR configures the Hive warehouse directory to be `/user/hive/warehouse` under the root volume. This default is defined in the `$HIVE_HOME/conf/hive-default.xml.template` file.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the hive.metastore.warehouse.dir property elements from the $HIVE_HOME/conf/hive-default.xml.template file and paste them into an XML configuration element in the $HIVE_HOME/conf/hive-site.xml file. Then, modify the value elements for these directories in the hive-site.xml file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.metastore.warehouse.dir=/myvolume/mydirectory
```

Note: You will see better performance when queries move data between tables in the same volume.

Hive Error Logs Directory

The log files are stored in `/opt/mapr/hive/hive-<version>/logs/<user>` by default.

To modify the log location:

1. Configure `hive.log.dir` in `$HIVE_HOME/conf/hive-log4j.properties` file. Example:

```
hive.log.dir=<other_location>
```

2. Set the sticky bit on the new directory. Example:

```
chmod 1777 <other_location>
```

Configuring Hive Client on MapR Client Node

This topic describes how to configure the Hive client on a MapR client node.

last-updated: Apr 11, 2022

Configuring Hive Client for Previous EEP 8.1.0

To use the Hive client with secure and non-secure clusters for previous EEP 8.1.0, perform the following steps:

1. Install MapR client. See Installing the MapR Client on CentOS, RedHat, Oracle Linux on page 390.
2. Copy the `daemon.conf` file from the `MAPR_HOME/conf` directory on the cluster to the `MAPR_HOME/conf` directory on the MapR client.

Configuring Hive Client for EEP 8.1.0 and Later

To use the Hive client with secure and non-secure clusters for EEP 8.1.0 and later, perform the following steps:

1. Install MapR client. See Installing the MapR Client on CentOS, RedHat, Oracle Linux on page 390.
2. Copy the `daemon.conf` file from the `MAPR_HOME/conf` directory on the cluster to the `MAPR_HOME/conf` directory on the MapR client.
3. Copy `maprtrustcreds.jceks` from the `MAPR_HOME/conf` directory on the cluster to the `MAPR_HOME/conf` directory on the MapR client.

Configuring `MSCK REPAIR TABLE`

This section guides you through configuring `MSCK REPAIR TABLE` command to compare and update the partitions in Hive Metastore and file systems.

Use the `MSCK REPAIR TABLE` command to manually update (ADD, DROP, SYNC) the partitions on Hive metastore with respect to file systems like HDFS, Amazon S3, filesystem, and others.

For example: You specify the location of filesystem when you create a Hive table. When you add or delete the partitions to or from the filesystem, the partitions in filesystem and Hive metastore becomes inconsistent.

Run `MSCK REPAIR TABLE` command to compare the partitions in filesystem and the partitions in Hive metastore and update the partitions in Hive metastore.

```
MSCK [REPAIR] TABLE <table name> [ADD/DROP/SYNC PARTITIONS];
```

Configure the Hive Metastore with the following Hive property:

Property	Default	Description
hive.msck.repair.batch.max.retries	0	Maximum number of retries for the msck repair command when adding unknown partitions. If the value is greater than zero it will retry adding unknown partitions until the maximum number of attempts is reached or batch size is reduced to 0, whichever is earlier. In each retry attempt, it will reduce the batch size by a factor of 2 until it reaches zero. If the value is set to zero it will retry until the batch size becomes zero as described above.

Configuring Database for Hive Metastore

The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the MapR filesystem. The following sections describe how to configure other DBs for Hive Metastore.

last-updated: Apr 11, 2022

CAUTION: Do not use `datanucleus.schema.autoCreateAll` for populating underlying databases. For more details, see prohibited usage of `datanucleus.schema.autoCreateAll` property .

Use MySQL for the Hive Metastore
The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the MapR filesystem. Derby only allows one connection at a time; if you want multiple concurrent Hive sessions, you can use MySQL for the Hive Metastore.

Review the following prerequisites before you begin:

- Verify that MySQL (version 5.6.17 or later) is installed on the machine that will host the Hive metastore, and also verify that you can connect to the MySQL server from the Hive machine. You can run the Hive metastore on any machine that is accessible from Hive. You can test this with the following command:

  ```
  mysql -h <hostname> -u <user>
  ```

- The database administrator must create a database for the Hive metastore data, and the username specified in `javax.jdo.option.ConnectionUserName` must have permissions to access it. The database can be specified using the `ConnectionURL` parameter. The tables and schemas are created automatically when the metastore is first started.

  Tip: In MapR 6.1.0 and earlier releases, the following steps can be used interchangeably for MariaDB.

Complete the following steps to configure Hive to use MySQL for the Hive Metastore:

Important: For MySQL 8, set the `javax.jdo.option.ConnectionDriverName` property to `com.mysql.cj.jdbc.Driver`. The `com.mysql.jdbc.Driver` is deprecated. The new driver class is `com.mysql.cj.jdbc.Driver`. However, the driver is automatically registered via the Service Provider Interface, so manual loading of the driver class is generally unnecessary.

1. Update the `hive-site.xml` in the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`) with the following contents:

```
<configuration>

 <property>
    <name>javax.jdo.option.ConnectionURL</name>
    <value>jdbc:mysql://localhost:3306/hive?
createDatabaseIfNotExist=true</value>
    <description>JDBC connect string for a JDBC metastore</description>
</property>

 <property>
    <name>javax.jdo.option.ConnectionDriverName</name>
    <value>com.mysql.jdbc.Driver</value>
    <description>Driver class name for a JDBC metastore</description>
 </property>

 <property>
    <name>javax.jdo.option.ConnectionUserName</name>
    <value>root</value>
    <description>username to use against metastore database</description>
 </property>

 <property>
    <name>javax.jdo.option.ConnectionPassword</name>
    <value><fill in with password></value>
    <description>password to use against metastore database</description>
 </property>

 <property>
    <name>hive.metastore.uris</name>
    <value>thrift://localhost:9083</value>
 </property>

</configuration>
```

2. Run the `schematool` command as an initialization step.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

3. To connect to an existing MySQL metastore, make sure the `ConnectionURL` parameter and the `Thrift URIs` parameters in `hive-site.xml` point to the metastore's host and port.

4. To set a specific port for Thrift URIs, add the command `export METASTORE_PORT=<port>` into the file `hive-env.sh` (if `hive-env.sh` does not exist, create it in the Hive configuration directory). Example:

```
export METASTORE_PORT=9083
```

5. Start the Hive Metastore service using one of the following commands:

   If you want the Hive Metastore to be managed by Warden, the maprcli, and the Control System:

   ```
   maprcli node services -name hivemeta -action start -nodes <space
   delimited list of nodes>
   ```

   If you want the Hive Metastore to be managed with standard hive commands:

   ```
   /opt/mapr/hive/hive-<version>/bin/hive --service metastore --start
   ```

   You can use also use `nohup hive --service metastore` to run the Metastore in the background.

   Warning: If you have not configured a MySQL Metastore, do not run the Hive shell from an NFS mount location. If you try to do this, Hive will fail. The same problem will occur if you use the `hive-site.xml` file to configure the Metastore on an NFS mount location. Avoid both of these configurations.

Configuring a Remote MySQL Database for the Hive Metastore

After installing MySQL, perform the following steps to configure Hive Metastore on MySQL

1. Install the MySQL connector. To install:

   - **MySQL connector on a RHEL 6+ system**

     On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

     ```
     $ sudo yum install
     mysql-connector-java
     $ ln -s /usr/share/
     java/mysql-connector-java.jar /opt/
     mapr/hive/hive-<version>/lib/
     mysql-connector-java.jar
     ```

   - **MySQL connector on a SLES system**

     On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

     ```
     $ sudo zypper install
     mysql-connector-java
     $ ln -s /usr/share/
     java/mysql-connector-java.jar /opt/
     mapr/hive/hive-<version>/lib/
     mysql-connector-java.jar
     ```

   - **MySQL connector on a Debian/Ubuntu system**

     On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file into the `/opt/mapr/hive/hive-<version>/lib/` directory.

     ```
     $ sudo apt-get install
     libmysql-java
     $ ln -s /usr/
     share/java/libmysql-java.jar /opt/
     ```

last-updated: Apr 11, 2022

```
mapr/hive/hive-<version>/lib/
mysql-connector-java.jar
```

2. Create the database and an associated user. The following commands are for a Hive Metastore with hostname `metastorehost` to create a MySQL user with name `hive` and password `mypassword`:

```
$ mysql -u root -p

mysql> CREATE DATABASE metastore;
mysql> CREATE USER 'hive'@'metastorehost' IDENTIFIED BY 'mypassword';
...
mysql> REVOKE ALL PRIVILEGES, GRANT OPTION FROM 'hive'@'metastorehost';
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'hive'@'metastorehost';
mysql> FLUSH PRIVILEGES;
mysql> quit;
```

3. Configure the Metastore service to communicate with the MySQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file.

   Suppose a MySQL database running on `myhost` and the user account `hive` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://myhost/metastore</value>
  <description>the URL of the MySQL database</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hive</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

   Note: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

4. Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

Configuring a Remote PostgreSQL Database for the Hive Metastore
Before you can run the Hive metastore with a remote PostgreSQL database, you must configure a JDBC driver to the remote PostgreSQL database, set up the initial database schema, and configure the PostgreSQL user account for the Hive user.

After installing PostgreSQL, perform the following steps to configure Hive Metastore on PostgreSQL.

Installing and Configuring PostgreSQL for the Hive Metastore

1. Download the PostgreSQL JDBC driver.

   Refer to the official PostgreSQL JDBC Driver website to download the JDBC driver and get information about the latest updates. Determine the appropriate database version and get the released drivers and JAR file.

2. Run the following commands using `sudo`:

   a. Move the JAR into the Java `share` directory:

   ```
   sudo mv <postgresql-jdbc.jar> /usr/share/java/postgresql-jdbc.jar
   ```

   b. Change the access mode of the JAR file to 644:

   ```
   sudo chmod 644 /usr/share/java/postgresql-jdbc.jar
   ```

   c. Create symbolic link to the `/usr/lib/hive/lib/ directory`, for example:

   ```
   sudo ln -s /usr/share/java/postgresql-jdbc.jar /opt/mapr/hive/
   hive-<version>/lib/postgresql-jdbc.jar
   ```

3. Create the Metastore database and user accounts:

   ```
   $ sudo -u postgres psql

   postgres=# CREATE USER hiveuser WITH PASSWORD 'mypassword';
   postgres=# CREATE DATABASE metastore;
   ```

   To verify the connection from the Metastore service host, run the following command:

   ```
   psql -h myhost -U hiveuser -d metastore
   metastore=#
   ```

4. Configure the Metastore service to communicate with the PostgreSQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file. Suppose a PostgreSQL database running on host `myhost` under the user account `hive` with the password `mypassword`, set the following configuration properties in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:postgresql://myhost/metastore</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.postgresql.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
  </property>
```

Note: Though you can use the same `hive-site.xml` properties on all the hosts (client, metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all of the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType postgres -initSchema
```

Configuring a Remote Oracle Database for the Hive Metastore

After installing Oracle, perform the following steps to configure Hive Metastore on Oracle.

1. Install the Oracle JDBC Driver.
   a) Download the Oracle JDBC Driver (`ojdbc6.jar`) from the Oracle website.
   b) Move the `ojdbc6.jar` file to `/opt/mapr/hive/hive-<version>/lib/` directory

last-updated: Apr 11, 2022

2. Create the Metastore database and user account.

   Connect to your Oracle database as administrator, create the user that will use the Hive Metastore, and create the Metastore schema. For example:

   ```
   $ sqlplus "sys as sysdba"
   SQL> create user hiveuser identified by mypassword;
   SQL> grant connect to hiveuser;
   SQL> grant all privileges to hiveuser;
   SQL>CREATE DATABASE metastore
   ```

3. Configure the Metastore service to communicate with the Oracle database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file.

   Suppose an Oracle database running on `myhost` and the user account `hiveuser` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

   ```
   <property>
     <name>javax.jdo.option.ConnectionURL</name>
     <value>jdbc:oracle:thin:@//myhost/metastore</value>
   </property>

   <property>
     <name>javax.jdo.option.ConnectionDriverName</name>
     <value>oracle.jdbc.OracleDriver</value>
   </property>

   <property>
     <name>javax.jdo.option.ConnectionUserName</name>
     <value>hiveuser</value>
   </property>

   <property>
     <name>javax.jdo.option.ConnectionPassword</name>
     <value>mypassword</value>
   </property>

   <property>
     <name>hive.metastore.uris</name>
     <value>thrift://<n.n.n.n>:9083</value>
     <description>IP address (or fully-qualified domain name) and port of
   the metastore host</description>
   </property>
   ```

   Note: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

4. Run `schemaTool` to create the initial DB structure.

   ```
   /opt/mapr/hive/hive-<version>/bin/schematool -dbType oracle -initSchema
   ```

Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

Use `schematool` to view and create relational database management system (RDBMS) schemas.

See Apache Hive documentation for the detailed steps.

Configuring a Remote MS SQL SERVER Database for the Hive Metastore

last-updated: Apr 11, 2022

After installing MS SQL, perform the following steps to configure Hive Metastore on MS SQL.

1. Create `hiveuser` and Metastore schema.

```
1>CREATE DATABASE metastore;
2>GO
1>CREATE LOGIN <hiveuser> with password='<mypassword>;
2>CREATE USER <hiveuser> for login <hiveuser>;
3>GRANT <PRIVILEGES> to <hiveuser>;
4>GO
```

2. Download JDBC Driver from here, untar the file, and follow instructions in the `install.txt` file to install the driver.

3. Copy the JAR file to `/opt/mapr/hive/hive-version>/lib/` directory.

   - For Java 7

```
cp ~/sqljdbc_6.0/enu/jre7/sqljdbc41.jar /opt/mapr/hive/
hive-<version>/lib/
```

   - For Java 8

```
cp ~/sqljdbc_6.0/enu/jre8/sqljdbc42.jar /opt/mapr/hive/
hive-<version>/lib/
```

last-updated: Apr 11, 2022

4. Configure the Metastore service to communicate with the MS SQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file.

   Suppose an MS SQL database running on `myhost` and the user account `hiveuser` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:sqlserver://<SERVER_NAME>:1433;DatabaseName=metastore;</
value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.microsoft.sqlserver.jdbc.SQLServerDriver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
  </property>
```

   Note: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mssql -initSchema
```

Configuring MariaDB for the Hive Metastore

Installing MariaDB

To install MariaDB, use the MariaDB Repository Configuration Tool. See MariaDB Downloads.

Configuring Repositories

The following steps describe how to configure a repository and install the latest available stable version of MariaDB for different operating systems.

1. Configure a repository for MariaDB:

- **Red Hat / CentOS and SLES**

  Copy and paste the following custom MariaDB repository entry into a file under `/etc/yum.repos.d/`. You can name the file `MariaDB.repo` or something similar:

  ```
  # MariaDB 10.4 RedHat repository list
  # http://downloads.mariadb.org/mariadb/repositories/
  [mariadb]
  name = MariaDB
  baseurl = http://yum.mariadb.org/10.4/rhel7-amd64
  gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
  gpgcheck=1
  ```

- **Ubuntu**

  You can also create a custom MariaDB `sources.list` file. To do so, after importing the signing key as outlined above, copy and paste the following into a file under `/etc/apt/sources.list.d/`. You can name the file `MariaDB.list` or something similar. Or you can add it to the bottom of your `/etc/apt/sources.list` file:

  ```
  # MariaDB 10.4 repository list - created 2020-04-17 08:34 UTC
  # http://downloads.mariadb.org/mariadb/repositories/
  deb [arch=amd64,arm64,ppc64el] http://mirror.mephi.ru/mariadb/repo/
  10.4/ubuntu bionic main
  deb-src http://mirror.mephi.ru/mariadb/repo/10.4/ubuntu bionic main
  ```

2. After the `sources.list` file is in place, install MariaDB:

   - **Red Hat / CentOS**

     ```
     sudo yum clean all && sudo yum install MariaDB-server MariaDB-client
     ```

   - **SLES**

     ```
     sudo zypper update && sudo zypper install mariadb
     ```

   - **Ubuntu**

     ```
     sudo apt update && sudo apt install mariadb-server
     ```

3. Start the MariaDB server:

   - **Red Hat / CentOS and Ubuntu**

     ```
     sudo service mariadb start
     ```

   - **SLES**

     ```
     sudo systemctl start mariadb
     ```

4. In the command line, run the `mysql_secure_installation` shell script:

```
sudo mysql_secure_installation
Enter current password for root (enter for none): press Enter
Set root password? Y
New password: Type new root password
Re-enter new password: Confirm the password
Remove anonymous users? Y
Disallow root login remotely? Y
Remove test database and access to it? Y
Reload privilege tables now? Y
```

Configuring a JDBC Driver for MariaDB

Before you can run the Hive Metastore with a MariaDB database, you must:

- Configure a JDBC driver for the MariaDB database.
- Set up the initial database schema.
- Configure the MariaDB user account for the Hive user.

Use the following steps:

1. Install the MariaDB Connector/J manually with a `.jar` file. The MariaDB Connector/J can also be installed by manually installing a `.jar` file to a directory in your CLASSPATH. Download the MariaDB Connector/J `.jar` files from the following URL: https://downloads.mariadb.com/Connectors/java/connector-java-2.5.4/.

2. Copy the `.jar` files to the `/opt/mapr/hive/hive-<version>/lib/` directory:

```
cp mariadb-java-client-2.5.4-sources.jar /opt/mapr/hive-<version>/lib/
cp mariadb-java-client-2.5.4.jar /opt/mapr/hive/hive-<version>/lib/
cp mariadb-java-client-2.5.4-javadoc.jar /opt/mapr/hive/
hive-<version>/lib/
```

3. Restart Hive services:

```
maprcli node services -name hivemeta -action restart -nodes 'hostname -f'
maprcli node services -name hs2 -action restart -nodes 'hostname -f'
```

4. Create the Hive Metastore database and user accounts:

```
$ mysql -u root -p <password>

MariaDB [(none)]> CREATE USER hiveuser IDENTIFIED BY PASSWORD 'password';
MariaDB [(none)]> CREATE DATABASE metastore;
MariaDB [(none)]> REVOKE ALL PRIVILEGES, GRANT OPTION FROM
'hiveuser'@'metastorehost';
MariaDB [(none)]> GRANT ALL PRIVILEGES ON metastore.* TO
'hiveuser'@'metastorehost';
MariaDB [(none)]> FLUSH PRIVILEGES;
MariaDB [(none)]> quit;
```

Configuring the Hive Metastore on MariaDB

Use these steps:

1. In the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`), update the `hive-site.xml` file with the following properties.

```
<property>
    <description>the URL of the MariaDB database</description>
    <name>javax.jdo.option.ConnectionURL</name>
    <value>jdbc:mysql://<hostname>:3306/metastore</value>
</property>
<property>
    <name>javax.jdo.option.ConnectionDriverName</name>
    <value>org.mariadb.jdbc.Driver</value>
</property>
<property>
    <name>javax.jdo.option.ConnectionUserName</name>
    <value><hiveuser></value>
</property>
<property>
    <name>javax.jdo.option.ConnectionPassword</name>
    <value><fill in with password></value>
</property>
<property>
    <description>IP address (or FQDN) and port of the metastore host</
description>
    <name>hive.metastore.uris</name>
    <value>thrift://<hostname>:9083</value>
</property>
```

2. Run the `schematool` command as an initialization step:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

User Impersonation for Hive

User impersonation enables Hive to submit jobs as a particular user. Without impersonation, Hive submits queries and hadoop commands as the user that started HiveServer2 and Hive Metastore. On a MapR cluster, this user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable.

Note: Impersonation is enabled by default.

last-updated: Apr 11, 2022

Enable User Impersonation

On non-secure clusters

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

On secure (MAPR-SASL and Kerberos) clusters

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>false</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>false</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

Note: The `hive.metastore.execute.setugi` property is set to false automatically after `/opt/mapr/server/configure.sh -R` is running.

On both secure and non-secure clusters

On nodes where the **Resource Manager** and the **Node Manager** are installed, set the following properties in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
  <description>Allow the superuser mapr to impersonate any member of any
group</description>
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
  <description>The superuser can connect from any host to impersonate a
user</description>
</property>
```

last-updated: Apr 11, 2022

Warning: The impersonated user must have write permissions to `/user/hive/warehouse` and `/user/mapr-user/tmp/hive` directories.

Verify that User Impersonation is Enabled

To verify that Hive queries do not run as the `mapr` user, connect to HiveServer2 as a user other than `mapr`. Then run queries and verify that queries were run as the user that connected to HiveServer2.

To verify that hadoop commands submitted by Hive do not run as the `mapr` user, start the shell or connect to HiveServer2 as a user other than `mapr`. Then create some tables, and verify that the tables in `/user/hive/warehouse` are created under the user that started the shell or the user connected to HiveServer2.

Example: Hive Impersonation

The following examples illustrate Hive impersonation:

Example 1

1. Log in as a non-`mapr` user and generate a MapR ticket:

```
$ su mapruser1
$ maprlogin password
```

2. Connect to HiveServer2:

```
$ hive --service beeline
Beeline version 2.3.3-mapr-SNAPSHOT by Apache Hive
beeline> !connect jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connecting to jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table, and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/defau> create table
impersonation_example_first (id int, username string);
0: jdbc:hive2://node4.cluster.com:10000/defau> insert into
impersonation_example_first values (1, 'mapruser1');
```

4. To check that impersonation works, use the following commands to check the `/warehouse` directory of the MapR file system:

```
$ hadoop fs -ls /user/hive/warehouse
Found 1 items
drwxr-xr-x   - mapruser1 mapruser1          1 2019-05-22 14:40
/user/hive/warehouse/impersonation_example_first

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_first
Found 1 items
-rwxrwxrwx   3 mapruser1 mapruser1         12 2019-10-15 07:21
/user/hive/warehouse/impersonation_example_first/000000_0
```

Example 2

1. Generate a MapR ticket for a non-`mapr` user.
2. Connect through JDBC using the `hive.server2.proxy.user` option with a non-`mapr` user name as an argument:

```
$ hive --service beeline
beeline> !connect
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Connecting to
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Client: auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/default> create table
impersonation_example_second (id int);
0: jdbc:hive2://node4.cluster.com:10000/default> insert into table
impersonation_example_second values (1), (2), (3), (5);
```

4. Check the owner of the table and data:

```
$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
drwxrwxrwx   - mapruser1 mapruser1          1 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
-rwxrwxrwx   3 mapruser1 mapruser1          8 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second/000000_0
```

Hive Security

You can configure the following features for Hive security:

Hive Security Configuration Options
This section describes changes made in Hive default configuration. It shows how to configure Hive after manual installation.

Unlike the previous releases, starting in EEP 4.0, Hive should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option after installing Hive. Hive demons will not start automatically if Hive is not configured correctly. The security configuration are described in the following sections:

1. Automatic
2. Manual
3. Custom

Note: Do not use ecosystem `$HIVE_HOME/bin/configure.sh` script for Hive configuration. Every configuration of Hive should be done via the `$MAPR_HOME/server/configure.sh` utility by running it with the `-R` option. The core `$MAPR_HOME/server/configure.sh` utility invokes the ecosystem `configure.sh` script automatically with appropriate security option.

Automatic

If you installed Hive using the MapR Installer, the MapR Installer configures Hive daemons during installation. Additional configuration is not required.

Manual

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Table

Node, Package	Hive	HiveServer2	Hive Metastore	WebHCat
Node 1	X	X		
Node 2	X		X	
Node 3	X			X

- After a manual installation, run the following command on Node 1, Node 2, and Node 3:

  ```
  $MAPR_HOME/server/configure.sh -R
  ```

As a result:

- All Hive daemons are configured to support MapR-SASL. If the `hive.metastore.sasl.enabled` property is enabled in the `hive-site.xml` file, its value is set to `true`. If the property is not present, it is added in the `configuration` section as follows:

  ```
  <property>
     <name>hive.metastore.sasl.enabled</name>
     <value>true</value>
  </property>
  ```

- HiveServer2 is configured to support encryption between Hiveserver2 and Hive clients. If the `hive.server2.thrift.sasl.qop` property is available in the `hive-site.xml` file, its value is set to `auth-conf`. If the property is not present, it is added in the configuration section as follows:

  ```
  <property>
     <name>hive.server2.thrift.sasl.qop</name>
     <value>auth-conf</value>
  </property>
  ```

- The `configure.sh` script creates a backup folder for the current Hive configuration before it changes the configuration. All configuration properties including `*.conf`, `*.properties`, and `*.xml` are saved in the backup folder.

  ```
  $HIVE_HOME/conf.YYYYMMDD_HHMMS
  ```

last-updated: Apr 11, 2022

- 644 Unix permissions are applied to all configuration files. Each run of `configure.sh` with the `-R` option overwrites permissions of the configuration files to 644.
- The Hive default ports listed below are verified as available. If a port is not available, the `configure.sh` script generates an error message during configuration.

Hive default ports are as follows:

Role	Default Port
Hive Metastore	9083
HiveServer2	10000
HiveWebHCat	50111

Custom

For PAM, LDAP, and Kerberos custom configurations, run `configure.sh` with the `-R` option:

```
$MAPR_HOME/server/configure.sh -R
```

The `hive-site.xml` file is not changed. However, Warden files are copied and a `HIVE_HOME/conf` backup folder is created.

Preventing a Non-Administrative User from Installing Hooks

For a fresh install of EEP 6.1, a non-administrative user is prevented from installing hooks by default. For a minor version update (for example, EEP 6.0.0 to EEP 6.1.0 or EEP 5.0.1 to EEP 5.0.2), you need to modify the Hive configuration to prevent a malicious user from using Hive hooks to install malware on your MapR cluster.

In general, a hook is a mechanism for intercepting events, messages, or function calls during processing. Hive hooks are a mechanism to tie into the internal workings of Hive without the need of re-compiling Hive. Hive hooks, in this sense, provide the ability to extend and integrate external functionality with Hive.

Any user using beeline can install Java code as a Hive hook. On the MapR platform, these hooks run as the `mapr` user, which could represent a security vulnerability. To prevent a malicious user from using Hive hooks to install malware on a MapR cluster, the cluster admin should add the following properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file, and then restart HiveServer 2 (HS2):

- `hive.exec.pre.hooks`
- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`

Adding the properties prevents a non-admin user from installing hooks into Hive.

1. Add all hook-related properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file:

   Hive 2.3

   - `hive.exec.pre.hooks`
   - `hive.exec.post.hooks`
   - `hive.exec.failure.hooks`

- `hive.exec.query.redactor.hooks`
- `hive.semantic.analyzer.hook`
- `hive.query.lifetime.hooks`
- `hive.exec.driver.run.hooks`
- `hive.server2.session.hook`

Hive 2.1

- `hive.exec.pre.hooks`
- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`
- `hive.semantic.analyzer.hook`
- `hive.exec.driver.run.hooks`
- `hive.server2.session.hook`

2. Make sure `hive.conf.restricted.list` configuration parameter already has a default value which contains:

Hive 2.3

```
hive.security.authenticator.manager
hive.security.authorization.manager
Hive.security.metastore.authorizatio
n.manager
hive.security.metastore.authenticato
r.manager
Hive.users.in.admin.role,hive.server
2.xsrf.filter.enabled
hive.security.authorization.enabled
hive.server2.authentication.ldap.bas
eDN
hive.server2.authentication.ldap.url
hive.server2.authentication.ldap.Dom
ain
hive.server2.authentication.ldap.gro
upDNPattern
hive.server2.authentication.ldap.gro
upFilter
hive.server2.authentication.ldap.use
rDNPattern
hive.server2.authentication.ldap.use
rFilter
hive.server2.authentication.ldap.gro
upMembershipKey
hive.server2.authentication.ldap.use
rMembershipKey
hive.server2.authentication.ldap.gro
upClassKey
hive.server2.authentication.ldap.cus
tomLDAPQuery
```

Hive 2.1

```
hive.security.authenticator.manager
hive.security.authorization.manager
hive.users.in.admin.role
hive.server2.xsrf.filter.enabled
```

3. Add the default values already present in `hive.conf.restricted.list` to the `hive-site.xml` file:

Hive 2.3

```
<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,

hive.security.authorization.manager,

hive.security.metastore.authorizatio
n.manager,

hive.security.metastore.authenticato
r.manager,

hive.users.in.admin.role,hive.server
2.xsrf.filter.enabled,

hive.security.authorization.enabled,

hive.server2.authentication.ldap.bas
eDN,

hive.server2.authentication.ldap.url
,

hive.server2.authentication.ldap.Dom
ain,

hive.server2.authentication.ldap.gro
upDNPattern,

hive.server2.authentication.ldap.gro
upFilter,

hive.server2.authentication.ldap.use
rDNPattern,

hive.server2.authentication.ldap.use
rFilter,

hive.server2.authentication.ldap.gro
upMembershipKey,

hive.server2.authentication.ldap.use
rMembershipKey,

hive.server2.authentication.ldap.gro
upClassKey,

hive.server2.authentication.ldap.cus
```

```
tomLDAPQuery,
     hive.exec.pre.hooks,
     hive.exec.post.hooks,
     hive.exec.failure.hooks,
     hive.exec.query.redactor.hooks,
     hive.semantic.analyzer.hook,
     hive.query.lifetime.hooks,
     hive.exec.driver.run.hooks,
     hive.server2.session.hook,
  </value>
</property>
```

Hive 2.1

```
<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,

hive.security.authorization.manager,
     hive.users.in.admin.role,

hive.server2.xsrf.filter.enabled,
     hive.exec.pre.hooks,
     hive.exec.post.hooks,
     hive.exec.failure.hooks,
     hive.exec.query.redactor.hooks,
     hive.semantic.analyzer.hook,
     hive.exec.driver.run.hooks,
     hive.server2.session.hook,
  </value>
</property>
```

Note: Values of the `hive.conf.restricted.list` are split into separate lines for better readability. In the actual `hive-site.xml` file, no spaces or newlines exist between the commas.

Configuring Security Headers for Web Servers

This section describes how to configure response headers for REST API servers used in Hive WebHCat and the HiveServer2 web UI.

About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/hive/hive-<version>/conf/headres.xml
```

The `headres.xml` file contains the following headers:

```
<?xml version="1.0" encoding="utf-8" ?>
<!DOCTYPE properties SYSTEM "http://java.sun.com/dtd/properties.dtd">
<properties>
  <entry key="X-Content-Type-Options">nosniff</entry>
  <entry key="X-XSS-Protection">1; mode=block</entry>
  <entry key="Strict-Transport-Security">max-age=31536000;
includeSubDomains</entry>
  <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

Header	Description	Default Value
X-XSS-Protection	Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.	`1: mode=block`
X-Content-Type-Options	Indicates that the MIME types advertised in the `Content-Type` headers should not be changed and should be followed.	`nosniff`
Strict-Transport-Security	Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.	`max-age=31536000;includeSubDomains`
Content-Security-Policy	Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS).	`default-src https:`

Configuring Security Headers for WebHCat

To enable security headers for WebHCat, add the following to the `webhcat-site.xml` file, and replace `<version>` with your Hive version:

```
<property>
<name>templeton.jetty.response.headers.file</name>
<value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

After configuring and restarting WebHCat, you should see security headers in the server response. For example:

```
< HTTP/1.1 200 OK
< Date: Thu, 03 Oct 2019 11:35:39 GMT
< Set-Cookie:
hadoop.auth="u=mapr&p=mapr&t=multiauth&e=1570138539451&s=CpX+tI7sScnnSUZpA1K
df+7hamM="; Path=/; Domain=.cluster.com; Expires=Thu, 03-Oct-2019 21:35:39
GMT; Secure; HttpOnly
< Content-Security-Policy: default-src https:
< X-XSS-Protection: 1; mode=block
< X-Content-Type-Options: nosniff
< Strict-Transport-Security: max-age=31536000
< Content-Type: application/json
< Transfer-Encoding: chunked
< Server: Jetty(9.4.19.v20190610)
```

Configuring Security Headers for HiveServer2 Web UI

To enable security headers for the Hiveserver2 Web UI, add the following to the `hive-site.xml` file, replacing `<version>` with your Hive version:

```
<property>
    <name>hive.server2.webui.jetty.response.headers.file</name>
    <value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

Then restart HiveServer2.

last-updated: Apr 11, 2022

Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add `Custom-header` as follows:

```
<entry key="Custom-header">custom-value</entry>
```

Security Headers Auto-Configuration

If you install Hive on a secure cluster (MapR SASL or Kerberos) and run the following command after Hive installation, Hive automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

Hive Authentication
The authentication method that you configure for the Hive Metastore, HiveServer2, and WebHcat determines how these Hive components access and connect to each other.

Clients of these components may require additional configuration and specific connection strings based on the selected authentication method.

To enable and use authentication for Hive, complete the following steps:

1. Determine which authentication methods are supported for each component and its clients.
2. Configure authentication for Hive components and their clients. See the following topics:
   - Authentication for Hive Metastore
   - Authentication for HiveServer2
   - Authentication for WebHCat
3. Determine how clients connect to each component. See Connecting to Hive.

Hive Metastore Authentication Support

The following table describes the different supported authentication methods for Hive Metastore and how it impacts the authentication options for its clients:

MapR Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options	WebHCat Authentication Options
Secure	NONE	• NONE • KERBEROS • LDAP • PAM • CUSTOM • MAPRSASL • NOSASL	PAM
Secure	KERBEROS	KERBEROS	KERBEROS with SPNEGO
Secure	MAPRSASL (default)*	MAPRSASL (default)*	PAM

last-updated: Apr 11, 2022

MapR Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options	WebHCat Authentication Options
Not Secure	NONE	NONE	Simple authentication with <user.name> only
*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the MapR cluster is secure.			

HiveServer2 Authentication Support

The following table describes the different supported authentication option for HiveServer2 based on the authentication method configured for Hive Metastore:

MapR Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options
Secure	NONE	NONE
Secure	NONE	KERBEROS
Secure	NONE	LDAP
Secure	NONE	PAM (default)*
Secure	NONE	CUSTOM
Secure	NONE	MAPRSASL*
Secure	KERBEROS	KERBEROS
Secure	MAPRSASL (default)*	MAPRSASL*
Not Secure	NONE	NONE
*As of Hive 0.13-1510, Hive 1.0-1510, and Hive 1.2.1-1510, PAM and MapR-SASL are enabled by default when the cluster is secure. In Hive 0.13-1508 and Hive 1.0-1508, PAM is enabled by default when the cluster is secure. In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is supported and enabled by default when the MapR cluster is secure.		

Clients of HiveServer2 authenticate with the same authentication method that is configured for HiveServer2. Clients of HiveServer 2 include ODBC, JDBC, and Beeline.

Note: Connections to HiveServer2 using ODBC do not support MapR-SASL.

WebHCat Authentication Support

The following table describes the different authentication options for WebHCat based on the authentication method configured for Hive Metastore :

MapR Cluster	Hive Metastore (Remote) Authentication	WebHCat Authentication
Secure	KERBEROS	KERBEROS with SPNEGO
Secure	KERBEROS	PAM
Secure	MAPRSASL (default)*	PAM
Not Secure	NONE	Simple authentication with user.name only

last-updated: Apr 11, 2022

MapR Cluster	Hive Metastore (Remote) Authentication	WebHCat Authentication
*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the MapR cluster is secure.		

Clients of WebHCat authenticate with the same authentication method that is configured for WebHCat. Web browsers are clients of WebHCat.

Description of Security Values

The following table describes the different security values:

Authentication Options	Description
NONE	No authentication check
LDAP	LDAP/AD based authentication
KERBEROS	Kerberos/GSSAPI authentication
CUSTOM	Custom authentication provider (use with property `hive.server2.custom.authentication.class`)
PAM	Pluggable authentication module
NOSASL	Raw transport
MAPRSASL	MapR SASL security

Authentication for Hive Metastore

You can configure authentication for in-bound client connections to the Hive Metastore when the metastore is remote, not embedded. Clients of Hive Metastore include the HiveCLI, HCatalog, HiveServer2, and WebHCat.

Hive Metastore supports the following authentication methods:

- MapR-SASL authentication
- Kerberos Authentication

MapR-SASL Authentication

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0 and it is the default authentication method when the cluster is secure.

Kerberos Authentication

When the cluster is secure, you can configure Hive Metastore to use Kerberos authentication. You must also configure Hive Metastore clients to use Kerberos when authenticating with Hive Metastore.

Configuring Hive Metastore Authentication

This section describes how to configure the `hive.metastore.authentication` property for secured and unsecured clusters. It describes cases when the property must be configured explicitly and when it can be omitted from `hive-site.xml`.

Hive Metastore supports two types of authentication: `MAPRSASL` and `KERBEROS`. At startup, Hive Metastore reads the system property `metastore.auth`. If `metastore.auth` is equal to null, then the authentication type is `NONE`. Otherwise, Hive Metastore takes the value of the

system property `metastore.auth` and assigns it to the Hive Metastore configuration property `hive.metastore.authentication`.

You do not need to set up the `metastore.auth` system property manually. If a cluster is secured, Hive assigns the `MAPRSASL` value to the `metastore.auth` property. If a cluster is not secured, Hive assigns the `NONE` value to the `metastore.auth` property.

To enable Kerberos authentication, set the value of `hive.metastore.authentication` directly in `hive-site.xml`, as shown in the following table:

Table

Security	Value of `hive.metastore.authentication`	Notes
No security	`NONE`	The value is set automatically. You do not need to make an entry in `hive-site.xml`.
MapR SASL security	`MAPRSASL`	The value is set automatically. You do not need to make an entry in `hive-site.xml`.

Kerberos security	`KERBEROS`	You must make the following entry in `hive-site.xml`:
		`<property>`
		`<name>hive.metastore.authentication</name>`
		`<value>KERBEROS</value>`
		`</property>`

Configure Hive Metastore to use MapR-SASL

Edit the `/opt/mapr/conf/env.sh` file and set the following properties:

```
MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"
```

Configuring Hive Metastore Clients to use MapR-SASL

The Hive metastore clients are configured to use MapR-SASL when authenticating with Hive Metastore.

Note: Hive Metastore clients must provide a valid MapR ticket to connect to the Hive Metastore. See Connecting to Hive on page 3515 for details.

1. Ensure that the cluster is secure.
2. Edit the `/opt/mapr/conf/env.sh` file and set the following property:

```
MAPR_HIVE_LOGIN _OPTS="-Dhadoop.login=maprsasl"
```

Configure Hive Metastore to use Kerberos

Enabling Hive Metastore to use Kerberos authentication requires a kerberos principal, kerberos keytab, and the following configurations.

last-updated: Apr 11, 2022

Complete the following steps on each node where a Hive Metastore is installed:

1. Create a Kerberos server identity and add it to a keytab file. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file:

   Note: MapR clusters do not provide Kerberos infrastructure. The tips in this step assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

   ```
   # kadmin
       : addprinc -randkey username/<FQDN@REALM>
       : ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>
   ```

   The `hive.keytab` file must be owned and readable only by the `mapr` user.

2. Configure the following properties in the following file:

   ```
   /opt/mapr/hive/hive-<version>/conf/hive-site.xml
   ```

Property	Value
`hive.metastore.kerberos.keytab.file`	The Keytab file that contains the HiveMetastore principal.
`hive.metastore.kerberos.principal`	<The HiveMetastore principal. For example, mapr/<FQDN@REALM>.>

```
<property>
  <name>hive.metastore.kerberos.keytab.file</name>
  <value>/opt/mapr/conf/metastore.keytab</value>
  <description>The path to the Kerberos Keytab file
containing the metastore thrift server's service principal.</
description>
</property>
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
  <description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

3. Configure the following properties in `/opt/mapr/conf/env.sh` on each node where the Hive Metastore is installed:

   - Set MAPR_HIVE_LOGIN _OPTS to

     ```
     "-Dhadoop.login=hybrid"
     ```

   - Set MAPR_HIVE_SERVER_LOGIN_OPTS to

     ```
     "-Dhadoop.login=hybrid"
     ```

Configure Hive Metastore Clients to use Kerberos

When the Hive Metastore is configured to use Kerberos authentication, you must also configure Hive Metastore Clients to use Kerberos when authenticating with Hive Metastore.

last-updated: Apr 11, 2022

Complete the following steps on each node where a Hive Metastore client is installed:

1. Configure MAPR_HIVE_LOGIN _OPTS to `" -Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.
2. Configure the following property in `hive-site.xml`:

Property	Value
`hive.metastore.kerberos.principal`	The HiveMetastore principal. For example, mapr/<FQDN@REALM>.

```
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
  <description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

See Connecting to Hive on page 3515 for details on how to connect to HiveMetastore once the server and client node are configured to use Kerberos.

Note: The MAPR_HIVE_LOGIN_OPTS and MAPR_HIVE_SERVER_LOGIN_OPTS were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set MAPR_ECOSYSTEM_LOGIN_OPTS and MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.

Authentication for HiveServer2

You can configure authentication for in-bound client connection to HiveServer2. Clients of HiveServer 2 include beeline and odbc/jdbc client applications.

Credentials are submitted from the HiveServer2 clients to HiveServer2 as plain text. To secure the credential transmission, MapR supports SSL encryption for HiveServer2. For information about how to configure encryption, see Hive Encryption.

HiveServer2 supports the following authentication methods:

Configure MapR-SASL Authentication for HiveServer 2

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0. However, the configuration requirements for MapR-SASL differ based on the version of Hive that you have installed:

- As of Hive 0.13-1501, Hive 1.0-1510, and Hive 1.2-1510, MapR-SASL and PAM are enabled by default on a secure cluster; no configuration is required. Complete the steps below if you want HiveServer2 to only accept MapR-SASL authentication.
- In Hive 0.13-1508 and Hive 1.0-1508, MapR-SASL is not the default and must be configured.

last-updated: Apr 11, 2022

- In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is the default authentication method when the cluster is secure. No configuration is required.

1. Configure the following property in hive-site.xml on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	MAPRSASL

```
<property> <name>hive.server2.authentication</name> <value>MAPRSASL</
value></property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of
    nodes>
```

Configure HiveServer2 to use LDAP Authentication

1. Configure the following properties in the `hive-site.xml` file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	LDAP
hive.server2.authentication.ldap.url	The access URL for your LDAP server
hive.server2.authentication.ldap.baseDN	The base LDAP DN for your LDAP server. For example, `ou=People,dc=mycompany,dc=com`.
hive.server2.authentication.ldap.userDNPattern	User DN Pattern - A DN pattern that can be used to directly login users to the LDAP database. This pattern is used for creating a DN string for "direct" user authentication, where the pattern is relative to the base DN in `ldapUrl`.

```
<property>
  <name>hive.server2.authentication</name>
  <value>LDAP</value>
</property>
<property>
  <name>hive.server2.authentication.ldap.url</name>
  <value><LDAP URL></value>
</property>
<property>
  <name>hive.server2.authentication.ldap.baseDN</name>
  <value><LDAP Base DN></value>
</property>
```

For generic LDAP servers, you must use:

a. `hive.server2.authentication.ldap.baseDN`

b. `hive.server2.authentication.ldap.userDNPattern`

However, Active Directory (AD) does not require the above two options, they can be replaced by the following property:

- hive.server2.authentication.ldap.Domain

last-updated: Apr 11, 2022

Property	Value
hive.server2.authentication.ldap.Domain	The active directory domain for your environment.

```
<property>
  <name>hive.server2.authentication.ldap.Domain</name>
  <value><AD Domain Name></value>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 to use PAM Authentication

You can configure HiveServer2 to use Pluggable Access Modules (PAM). The configuration requirements for PAM differ based on the version of Hive that you have installed.

Hive Version		Default Configuration	Configuration Requirement
Hive 2.3	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
Hive 2.1	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1803	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.

Configure HiveServer2 to explicitly use PAM Authentication

1. In the `hive-site.xml` on each HiveServer2 node, set the `hive.server2.authentication` property to PAM:

```
<property>
  <name>hive.server2.authentication</name>
  <value>PAM</value>
</property>
```

2. Restart HiveServer2 to apply these changes:

```
maprcli node services -name hs2 -action restart -nodes <comma-separated
list of nodes>
```

Configure HiveServer 2 to use Custom Authentication

1. Create a custom Authenticator class derived from the following interface:

```
public interface PasswdAuthenticationProvider {
  /**
   * The Authenticate method is called by the HiveServer2 authentication
layer
   * to authenticate users for their requests.
   * If a user is to be granted, return nothing/throw nothing.
   * When a user is to be disallowed, throw an appropriate {@link
AuthenticationException}.
   *
   * For an example implementation, see {@link
LdapAuthenticationProviderImpl}.
   *
   * @param user - The username received over the connection request
   * @param password - The password received over the connection request
   * @throws AuthenticationException - When a user is found to be
   * invalid by the implementation
   */
  void Authenticate(String user, String password) throws
AuthenticationException;
}
```

   The SampleAuthenticator.java on page 3442 code has an example implementation that has stored usernames and passwords.

2. Configure the following properties in the `hive-site.xml` file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	CUSTOM
hive.server2.custom.authentication.class	The authentication class name. For example, hive.server2.custom.authentication.class

```
<property>
<name>hive.server2.authentication</name>
<value>CUSTOM</value>
</property>

<property>
<name>hive.server2.custom.authentication.class</name>
<value>hive.test.SampleAuthenticator</value>
</property>
```

3. Restart Hiveserver2 to apply the changes:

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

SampleAuthenticator.java

```
package hive.test;

import java.util.Hashtable;
import javax.security.sasl.AuthenticationException;
import org.apache.hive.service.auth.PasswdAuthenticationProvider;
```

```
/*
 javac -cp $HIVE_HOME/lib/hive-service-0.11-mapr.jar
SampleAuthenticator.java -d .
 jar cf sampleauth.jar hive
 cp sampleauth.jar $HIVE_HOME/lib/.
*/

public class SampleAuthenticator implements PasswdAuthenticationProvider {

  Hashtable<String, String> store = null;

  public SampleAuthenticator () {
    store = new Hashtable<String, String>();
    store.put("user1", "passwd1");
    store.put("user2", "passwd2");
  }

  @Override
  public void Authenticate(String user, String  password)
      throws AuthenticationException {

    String storedPasswd = store.get(user);

    if (storedPasswd != null && storedPasswd.equals(password))
      return;

    throw new AuthenticationException("SampleAuthenticator: Error
validating user");
  }

}
```

Configure HiveServer 2 to use Kerberos

Note: You can configure HiveServer2 to use Kerberos authentication. MapR clusters do not provide Kerberos infrastructure. The tips in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

Enabling HiveServer to use Kerberos authentication requires following steps on each node where HiveServer 2 is installed:

1. Create a Kerberos Identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file: The `hive.keytab` file must be owned and readable only by the `mapr` user.

   ```
   # kadmin
       : addprinc -randkey username/<FQDN@REALM>
       : ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>
   ```

2. Configure the following properties in hive-site.xml on each node where hiveserver2 is installed:

Property	Value
hive.server2.authentication	KERBEROS
hive.server2.authentication.kerberos.principal	<HiveServer2 Principle. For example, mapr/FQDN@REALM>

last-updated: Apr 11, 2022

Property	Value
hive.server2.authentication.kerberos.keytab	<The keytab file for the HiverServer2 principle. For example, /opt/mapr/conf/hive.keytab>

```
<property>
  <name>hive.server2.authentication</name>
  <value>KERBEROS</value>
  <description>authenticationtype</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.principal</name>
  <value>mapr/FQDN@REALM</value>
  <description>HiveServer2 principal. If _HOST is used as the FQDN
portion, it will be replaced with the actual hostname of the running
instance.</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.keytab</name>
  <value>/opt/mapr/conf/hive.keytab</value>
  <description>Keytab file for HiveServer2 principal</description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where hiveserver2 is installed:

   Note: These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see About env_override.sh on page 2290.

Existing Configuration	Required Configuration
`MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"` `MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"`	`MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"` `MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"`

4. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer 2 Clients to use Kerberos

When HiveServer 2 is configured to use Kerberos authentication, you must also configure HiveServer2 clients to use Kerberos.

On each node where HiveServer2 clients (not including Beeline) are installed, reconfigure the following option in `env.sh` (`/opt/mapr/conf/env.sh`) file:

Existing Configuration	Required Configuration
`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"`	`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"`

last-updated: Apr 11, 2022

Note: This configuration is listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the change in the `/opt/mapr/conf/env_override.sh` file. For more information, see About env_override.sh on page 2290.

On each node where Beeline is installed, reconfigure the following option in `beeline.sh` (`$hive_home/bin/ext/beeline.sh`) file:

Existing Configuration	Required Configuration
`HADOOP_OPTS="$HADOOP_OPTS${MAPR_HIVE_LOGIN_OPTS}"`	`HADOOP_OPTS="$HADOOP_OPTS${KERBEROS_LOGIN_OPTS}"`

For more information, see Connecting to Hive on page 3515.

Note: The MAPR_HIVE_LOGIN_OPTS and MAPR_HIVE_SERVER_LOGIN_OPTS were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set MAPR_ECOSYSTEM_LOGIN_OPTS and MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS to `"-Dhadoop.login=hybrid"` in /opt/mapr/conf/env.sh.

Configure HiveServer2 Web UI to use PAM Authentication

You can configure HiveServer2 web UI to use Pluggable Access Modules (PAM) authentication. The following Hive properties are added to enable PAM authentication for the HiveServer2 web UI:

```
hive.server2.webui.use.pam
Default value: false
Description: If true, the HiveServer2 WebUI will be secured with PAM
```

```
hive.server2.webui.pam.authenticator
Default value: org.apache.hive.http.security.PamAuthenticator
Description: Class for PAM authentication
```

Modifying the hive-site.xml file:

Configure the following properties in the hive-site.xml file to enable authentication on each node where HiveServer2 is installed:

```
<!-- HS2 web UI PAM -->
<property>
  <name>hive.server2.webui.use.pam</name>
  <value>true</value>
</property>

<!-- HS2 web UI SSL -->
<property>
  <name>hive.server2.webui.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>hive.server2.webui.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>hive.server2.webui.keystore.password</name>
```

last-updated: Apr 11, 2022

```
  <value><ssl-keystore-password></value>
</property>
```

Note: After running `/opt/mapr/server/configure.sh -R`, all properties needed for HiveServer2 Web UI to use PAM authentication is added automatically to hive-site.xml on the Mapr-SASL secure cluster. Connections to HiveServer2 using ODBC do not support MapR-SASL.

Authentication for WebHCat

You can configure authentication for in-bound client connections to WebHCat. Clients of WebHCat include web browsers. WebHCat is a client of Hive Metastore.

WebHCat supports the following authentication methods:

Configure Kerberos Authentication for WebHCat

When security features are enabled on your MapR cluster and Kerberos is in use, communications between WebHCat and its clients can use Kerberos with SPNEGO.

To enable WebHCat to use Kerberos, complete the following steps on the node where WebHCat is installed.

1. Create the principal `HTTP/<FQDN@REALM>` for WebHCat and add the principal to the keytab file. For example:

   ```
   kadmin: addprinc -randkey HTTP/<FQDN@REALM>
   kadmin: xst -k /opt/mapr/HTTP.keytab HTTP/<FQDN>
   ```

2. Verify the following:
   - The principal was added to the `/opt/mapr/conf/HTTP.keytab` file and that the file is only readable by the `mapr` user. For example: chown mapr /opt/mapr/conf/HTTP.keytab
   - The node where the WebHCat server is running has an HTTP user with a valid `maprlogin` password.

3. Add the following section to the `/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml` file:

   ```
   <property>
       <name>templeton.kerberos.secret</name>
       <value>secret value</value>
   </property>
   <property>
       <name>templeton.kerberos.principal</name>
       <value>HTTP/<FQDN@REALM></value>
   </property>
   <property>
       <name>templeton.kerberos.keytab</name>
       <value>/opt/mapr/conf/HTTP.keytab</value>
   </property>
   ```

last-updated: Apr 11, 2022

4. Add the following section to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
      <name>hadoop.proxyuser.HTTP.groups</name>
      <value>*</value>
      <description>Allow the superuser mapr to impersonate any member of
any group</description>
</property>
<property>
      <name>hadoop.proxyuser.HTTP.hosts</name>
      <value>*</value>
      <description>The superuser can connect from any host to
impersonate a user</description>
</property>
```

5. Start WebHCat. See Managing the WebHCat Server.

6. To test if the connection is working, generate a Kerberos ticket with the `kinit` utility and then run the following command:

```
curl --negotiate -i -u : 'http://<FQDN>:50111/templeton/v1/ddl/
database/'
```

Configure Simple Authentication for WebHCat

When the MapR cluster is not secure, simple authentication is enabled for WebHCat. No configuration is required.

Configure PAM Authentication for WebHCat

When the MapR cluster is secure, username and password authentication is enabled for WebHCat. No configuration is required.

Hive Encryption

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

Encryption is supported when HiveServer2 has no authentication or when it is configured to use MapR-SASL or Kerberos authentication.

This section contains the following topics:

Configure Encryption with MapR-SASL or Kerberos Authentication

Complete the following steps on each node where HiveServer2 is installed:

1. In `hive-site.xml` file, set the following property:

Property	Value
`hive.server2.thrift.sasl.qop`	`auth-conf`

Note: As of Hive 0.13-1504 and Hive 1.0-1504, `hive.server2.thrift.sasl.qop` is set to `auth-conf` by default on secure clusters.

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
  <description>Sasl QOP value; one of 'auth', 'auth-int' and
```

last-updated: Apr 11, 2022

```
'auth-conf'</description>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure Encryption without Authentication

Complete the following steps on each node where HiveServer2 is installed:

1. In `hive-site.xml` file, set the following properties:

Property	Value
`hive.server2.use.SSL`	`true`
`hive.server2.ssl.keystore`	<path to keystore file>
`hive.server2.ssl.keystore.password`	<password>

Warning: If you specify the password in the `hive-site.xml` file, protect the file with the appropriate file permissions. HiveServer2 automatically prompts for the keystore password during startup when no password is stored in the `hive-site.xml` file.

```
<property>
  <name>hive.server2.use.ssl</name>
  <value>true</value>
  <description>enable/disable SSL communication</description>
</property>
<property>
  <name>hive.server2.ssl.keystore</name>
  <value><path-to-keystore-file></value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.ssl.keystore.password</name>
  <value><password></value>
  <description>keystore password</description>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 Clients to use Encryption

Based on the encryption method, the requirements for clients to connect to HiveServer2 differ.

- When HiveServer2 uses encryption with MapR-SASL or Kerberos authentication, the client must specify the same sasl qop value that is set for HiveServer2 (auth-conf is the default, recommended option).
- When HiveServer2 uses SSL encryption without authentication, the client must specify a truststore. The `ssl_truststore` file must be copied from the cluster to the client. Specifying a truststore password is optional.

last-updated: Apr 11, 2022

For details, see Connecting to Hive on page 3515.

Configure the TLS (SSL) Protocol Version in Hive

Beginning with EEPs 6.3.1 and 7.0.0, the default protocol version for TLS (SSL) is `TLSv1.2`, but you can use the `hive.ssl.protocol.version` property to set a custom value for TLS (SSL).

Setting the TLS (SSL) Protocol Version

To enable the direct configuration of the TLS (SSL) version, Hive provides the following property:

Property	Type	Default Value	Description
`hive.ssl.protocol.version`	`String`	`TLSv1.2`	SSL protocol versions for all Hive servers.

To set a custom value for the TLS (SSL) protocol version in Hive:

1. Add the following to the `hive-site.xml` file:

```
<property>
<name>hive.ssl.protocol.version</name>
<value><custom_value></value>
</property>
```

In this example, `<custom_value>` can be one of the following:

- `SSLv2`
- `SSLv3`
- `SSLv2Hello`
- `TLSv1`
- `TLSv1.1`
- `TLSv1.2`

For more information, see the following table:

#	Algorithm Name (TLS/SSL Version)	Description
1	`Default`	Use the default algorithm.
2	`SSL`	Supports some versions of SSL; may support other versions.
3	`SSLv2`	Supports SSL version 2 or later; may support other versions.
4	`SSLv3`	Supports SSL version 3; may support other versions.
5	`TLS`	Supports some versions of TLS; may support other versions.
6	`TLSv1`	Supports RFC 2246: TLS version 1.0; may support other versions.
7	`TLSv1.1`	Supports RFC 4346: TLS version 1.1; may support other versions.
8	`TLSv1.2`	Supports RFC 5246: TLS version 1.2; may support other versions.

2. Restart all Hive services.

last-updated: Apr 11, 2022

Special Considerations for Protocol Versions

Note these special considerations for the protocol versions:

- When `hive.ssl.protocol.version` is set to `TLSv1.2`, the protocol supports TLS 1.2. When `hive.ssl.protocol.version` is set to `TLSv1`, the protocol supports TLS versions up to TLS 1.0 (but not TLS 1.1 and 1.2). When `hive.ssl.protocol.version` is set to `TLSv1.1`, the protocol supports versions up to TLS 1.1 (but not TLS 1.2).
- `SSLv2Hello` is not a real encryption protocol. It merely enables clients to find out which encryption protocols are supported by the server to which they connect. As long as `SSLv2Hello` is used only by clients and servers to negotiate a safe protocol, such as `TLSv1.1` or `TLSv1.2`, it does not pose a security risk.
- Hive has a property called `hive.ssl.protocol.blacklist` with a default value of `SSLv2,SSLv3,SSLv2Hello,TLSv1,TLSv1.1`. If you want to enable `TLSv1.1`, for example, you must remove it from the blacklist above. For example:

```
<property>
<name>hive.ssl.protocol.blacklist</name>
<value>SSLv2,SSLv3,SSLv2Hello,TLSv1</value>
</property>

<property>
<name>hive.ssl.protocol.version</name>
<value>TLSv1.1</value>
</property>
```

- If you use the TLS (SSL) protocol version from the blacklist, you will get the following exception when connecting to Hiveserver2 via JDBC:

```
Unknown HS2 problem when communicating with Thrift server.
Error: Could not open client transport with JDBC
Uri: jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true:
javax.net.ssl.SSLHandshakeException: Received fatal alert:
handshake_failure (state=08S01,code=0)
```

- Empty values are allowed for `hive.ssl.protocol.version`. Hive uses the default value in that case. The same is true for `hive.ssl.protocol.blacklist`.
- The `hive.ssl.protocol.version` property is out of scope for a secure-by-default configuration. This means that it will not appear in the `hive-site.xml` after you use the Hive `configure.sh` script. Nevertheless, the default value of `hive.ssl.protocol.version` is still `TLSv1.2`, and you do not need to set it explicitly.

Hive Password Encryption
EEP 4.0 introduces default configuration for Hive Metastore password encryption using the MapR Installer. The password is stored in the `hive-site.xml` file.

EEP 4.0 introduces default configuration for Hive Metastore password encryption using the MapR Installer. The password is stored in the `hive-site.xml` file.

Note: For Hive-2.1 (EEP-5.0.0 and later) and Hive-2.3 (EEP-6.0.0 and later) installed using the MapR Installer, `javax.jdo.option.ConnectionPassword` is automatically encrypted.

```
<property>
  <name>javax.jdo.option.ConnectionPassword<name>
```

```
  <value>{password}<value>
<property>
```

The `hadoop.security.credential.provider.path` configuration property replaces the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file that contains the path to the keystore file created by the Hadoop Crediential Provider. Credential providers store and protect passwords out of clear text for the underlying database. By default, the MapR Installer creates the keystore file in MapR filesystem. `/user/${MAPR_USER}/hivemetastore.jceks`.

Note: Starting from Hive-2.3 EEP 6.0.0, SSL keystore passwords, `hive.server2.webui.keystore.password`, `hive.server2.keystore.password`, and `templeton.keystore.password`, are automatically read from the `/opt/mapr/conf/ssl-client.xml` file without any additional steps from your side. But you can still encrypt them manually and store them in the `*jceks` files.

Reset MapR Installer Default Configuration

To remove changes made by the MapR Installer and reset Hive to its default setting:

1. Open the `hive-site.xml` file.
2. Delete the `hadoop.security.credential.provider.path` property.
3. Add the `javax.jdo.option.ConnectionPassword` property.
4. Save and close the `hive-site.xml` file.

Manual Password Encryption

Note: For any user to use Hive, the keystore file requires read permission (644). To limit keystore file access to a smaller number of Hive users, modify permissions as necessary.

To encrypt a password manually:

1. Create the keystore file using the Hadoop Credential Provider as follows:

   ```
   hadoop credential create javax.jdo.option.ConnectionPassword -provider
   <path-to-keystore>
   ```

   Where `<path-to-keystore>` is `jceks://<file-system-name>/<path-to-keystore>`.

   For example, `jceks://maprfs/user/mapr/hivemetastore.jceks`.

2. Delete the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file:

   ```
   <property>
     <name>javax.jdo.option.ConnectionPassword</name>
     <value>{yourpassword}</value>
   </property>
   ```

last-updated: Apr 11, 2022

3. Add the `hadoop.security.credential.provider.path` property to the `/opt/mapr/hive/hive-2.3/conf/hive-site.xml` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://maprfs/user/mapr/hivemetastore.jceks</value>
  <description>password to use against metastore database</description>
</property>
```

4. Restart the Hive services to update the configuration:

```
maprcli node services -name hivemeta -action restart -nodes `hostname -f`
maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hcat -action restart -nodes `hostname -f`
```

Hive Authorization

MapR Data Platform has built-in platform authorization that protects all data regardless of the execution engine. This topic describes alternative authorization modes you can choose to implement.

For more information, refer to Authorization in MapR on page 687.

In addition to the centralized authorization provided by the MapR Data Platform, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

Understanding Hive Authorization Use Cases

Table Storage Layer and SQL Query Engine are the two primary use cases for client-based authorization protection, delivered as part of the open source project.

Use Case 1: Table Storage Layer

This is the use case for Hive HCatalog API users.

In this case, Hive provides a table abstraction and metadata for files on storage (typically MapR filesystem). You have direct access to MapR filesystem and the metastore server (which provides an API for metadata access).

MapR filesystem access is authorized through the use of MapR filesystem permissions. You need to authorize metadata access using Hive configuration.

Use Case 2: SQL Query Engine

This is one of the most common use cases of Hive. This is the "Hive view" of SQL users and BI tools. This use case has the following two subcategories:

- Hive command line users - You have direct access to MapR filesystem and the Hive metastore, which makes this use case similar to use case 1.
- ODBC/JDBC and other HiveServer2 API users (Beeline CLI is an example) - You have all data or metadata access through HiveServer2. You do not have direct access to MapR filesystem or the metastore.

Understanding Hive Authorization Modes

Different modes of Hive authorization are available to satisfy different use cases.

Secure by Default Configuration (Storage Based Authorization in the Metastore Server)

Hive default security configuration is the storage based authorization in the Metastore server. Managed by mapr-tickets and impersonation level, Hive configurations control the data access and MapR filesystem permissions act as one source of truth for the table storage access. By enabling storage based

authorization in the metastore server, you can use this single source for truth and have a consistent data and metadata authorization policy.

For use cases where the users have direct access to the data, Hive configurations do not control the data access. The MapR filesystem permissions act as the one source of truth for table storage access. To control metadata access on the metadata objects such as databases, tables, and partitions, MapR filesystem checks if you have permission to access the corresponding directories on the filesystem.

You can also protect access through HiveServer2 (use case 2.2) by ensuring that the queries run as the end user. The `hive.server2.enable.doAs` option should be `true` in the HiveServer2 configuration, this is a default value.

For more information, see Hive Security Configuration Options on page 3427.

SQL Standards Based Authorization in HiveServer2

Although storage based authorization provides access control at the level of databases, tables, and partitions, it can only control authorization at finer levels such as columns and views for MapR Database tables and not for files because the access control provided by the filesystem is at the level of directory and files. SQL standards authorization makes authorization possible for files BUT at the expense of not being able to enforce that access from any other tool.

For enabling SQL standards based authorization, refer to SQL Standards-Based Hive Authorization on page 3453.

Legacy Hive Authorization

Old default authorization is the authorization mode that has been available in earlier versions of Hive. However, this mode does not have a complete access control model, leaving many security gaps unaddressed.

For example, the permissions needed to grant privileges for a user are not defined, and any user can grant themselves access to a table or database.

This model is similar to the SQL standards based authorization mode, in that it provides grant or revoke statement-based access control. However, the access control policy is different from SQL standards based authorization, and they are not compatible. Use of this mode is also supported for Hive command line users. However, for reasons mentioned under the discussion of SQL standards based authorization, it is not a secure mode of authorization for the Hive command line.

Related Links

For information related to Hive authorization modes, see:

- Storage Based Authorization in the Metastore Server
- HCatalog Authorization
- SQL Standard Based Hive Authorization
- Hive deprecated authorization mode / Legacy Mode
- Hive security design document
- Hive security document

SQL Standards-Based Hive Authorization

Using EEP 6.0.0 and later, you can configure SQL standards-based authorization to enable fine grained access control with SQL commands.

The SQL standards-based authorization mode can be used in conjunction with storage-based authorization on the Metastore server. Similar to the current default authorization in Hive, SQL

standards-based authorization is also enforced at query compilation time. To provide security through this option, the client will have to be secured. You can do this by allowing users access only through HiveServer2, and by restricting the user code and non-SQL commands that can be run. The checks will happen against the user who submits the request, but the query will run as the Hive server user. The directories and files for input data would have read access for this Hive server user. For users who do not have the need to protect against malicious users, this could potentially be supported through the Hive command line as well.

1. Add the following properties to `hive-site.xml`:

```
<!-- SQL standard based authorization -->
<property>
  <name>hive.server2.enable.doAs</name>
  <value>false</value>
</property>
<property>
  <name>hive.users.in.admin.role</name>
  <value>mapr</value>
</property>
<property>
  <name>hive.security.metastore.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.MetaStoreAuthzAPI
AuthorizerEmbedOnly</value>
</property>
<property>
  <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
StdConfOnlyAuthorizerFactory</value>
</property>
```

2. Create a `hiveserver2-site.xml` configuration file:

```
touch /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml
```

   Add the following properties to the `hiveserver2-site.xml` file:

```
<configuration>
<property>
  <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
StdHiveAuthorizerFactory</value>
</property>
<property>
  <name>hive.security.authorization.enabled</name>
  <value>true</value>
</property>
<property>
  <name>hive.security.authenticator.manager</name>

<value>org.apache.hadoop.hive.ql.security.SessionStateUserAuthenticator</
value>
</property>
<property>
  <name>hive.metastore.uris</name>
  <value></value>
</property>
</configuration>
```

3. Change owner of the `hiveserver2-site.xml` file to `mapr`, and restart Hive services:

```
chown mapr:mapr /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml

maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hivemeta -action restart -nodes `hostname -f`
```

If you are a database administrator and want to run commands such as `create role` and `drop role` or to access objects without being given explicit access, you must run the `set role` command.

1. Create a test role:

```
hive> set role admin;
OK
Time taken: 0.02 seconds

hive> create role example_role;
OK
Time taken: 0.099 seconds

hive> show roles;
OK
admin
public
role1
example_role
Time taken: 0.02 seconds, Fetched: 3 row(s)
```

2. Grant access:

```
hive> GRANT example_role to USER testuser;
OK
Time taken: 0.058 seconds

hive> GRANT SELECT  on table eg_test to role example_role;
OK
Time taken: 0.146 seconds
```

3. Using the test role, check access:

```
sudo -u mapruser1 hive
```

If there is an access violation, correct it. The following is an example of an access violation error:

```
hive> insert into table eg_test values (4), (5), (6);
FAILED: RuntimeException Cannot create staging directory
'maprfs:///user/hive/warehouse/
eg_test/.hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1'
:
User mapruser1(user id 5001) has been denied access to
create .hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1
```

You can apply access restrictions to all actions except for READ access.

The following are examples of permitted access operations:

last-updated: Apr 11, 2022

- Select:

```
hive> select count (*) from eg_test;
OK
3
Time taken: 2.491 seconds, Fetched: 1 row(s)
```

- Describe:

```
hive> describe extended eg_test;
OK
id                      int

Detailed Table Information
Table(tableName:eg_test, dbName:default, owner:mapr,
createTime:1528453013, lastAccessTime:0, retention:0,
sd:StorageDescriptor(cols:[FieldSchema(name:id, type:int,
comment:null)],
location:maprfs:/user/hive/warehouse/eg_test,

viewExpandedText:null, tableType:MANAGED_TABLE, rewriteEnabled:false)
Time taken: 0.12 seconds, Fetched: 3 row(s)
```

- Show columns:

```
hive> SHOW COLUMNS from eg_test;
OK
id
Time taken: 0.049 seconds, Fetched: 1 row(s)
```

Note: For more information about privileges required for Hive operations, see the open source documentation.

Configure Hive Metastore to use Storage-Based Authorization

You can enable storage-based authorization (SBA) for the Hive Metastore server.

Storage-based authorization controls access to the data using HDFS permissions (HDFS ACL). To control metadata access on the metadata objects, such as Databases, Tables, and Partitions, it checks if you have permission on the corresponding directories on the filesystem.

To enable storage-based authorization for the Hive Metastore server, set these properties in `hive-site.xml`:

Property	Value	Description
`hive.metastore.pre.event.listeners`	`org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener*`	Turns on Metastore security. A MetaStorePreEventListener that performs authorization or authentication checks on the metastore side. Note that this can only perform authorizaiton checks on defined metastore PreEventContexts, such as the adding, dropping, and altering of databases, tables, and partitions.
`hive.security.metastore.authorization.manager`	`org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider*` **Note:** The `StorageBasedAuthorizationProvider` setting first appeared, on the Metastore side only, in Hive 0.10.0. With Hive 0.12.0 and later, it can also run on the client side. **Note:** Starting from EEP 6.1.0, `hive.security.metastore.authorization.manager` is set to the `StorageBasedAuthorizationProvider` value by default.	`StorageBasedAuthorizationProvider` - Specifies use of an HDFS permission-based model (recommended) for the Metastore-side authorization provider. `DefaultHiveMetastoreAuthorizationProvider` - This default implements the standard Hive grant/revoke model.
`hive.security.metastore.authenticator.manager`	`org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator` (default)	Authentication manager class name to be used in the metastore for authentication. The user-defined authenticator should implement the `org.apache.hadoop.hive.ql.security.HiveAuthenticationProvider` interface.
`hive.security.metastore.authorization.auth.reads`	true (default)	Default value (does not appear in `hive-site.xml` file). Set to `true`, Metastore authorization also performs a read authorization check (first supported in Hive 0.14.0).
`hive.server2.enable.doAs`	`true` (default)	Use for protected access through HiveServer2.

* In secure clusters, the MapR "Secure-by-Default" configuration implicitly configures these properties in the `hive-site.xml` file.

SBA configuration example in hive-site.xml File

```
<property>
    <name>hive.security.metastore.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider</value>
 </property>

<property>
    <name>hive.security.metastore.authenticator.manager</name>
```

last-updated: Apr 11, 2022

```
<value>org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticato
r
    </value>
</property>

<property>
    <name>hive.security.metastore.authorization.auth.reads</name>
    <value>true</value>
</property>

<property>
    <name>hive.server2.enable.doAs</name>
    <value>true</value>
</property>

<property>
    <name>hive.metastore.pre.event.listeners</name>

<value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEven
tListener</value>
</property>
```

If you use storage-based authorization, you still need to use one of the following authorization models to protect actions within the HiveServer2:

- Configuring Fallback Hive Authorizer on page 3458
- Configure Hive to use Sentry Authorization on page 3830 (supported only for Impala users)
- SQL Standards-Based Hive Authorization on page 3453

Fallback Hive Authorizer
Fallback Hive Authorizer is used by Hive DDL (Data Definition Language) tasks for access control and for checking authorization from `Driver.doAuthorization()`.

It is designed to prevent CVE-2018-11777.

In addition to the centralized authorization provided by the MapR Data Platform, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

Configuring Fallback Hive Authorizer

You can enable protection of actions within the HiveServer2 instance by using the Fallback Authorizer.

Use the Fallback Authorizer when you want to protect access for Hive clients (JDBC/ODBC, Beeline CLI, and other HiveServer2 API users).

To enable Fallback Authorization for Hive clients, set these properties in the `hive-site.xml` file:

Property	Value	Description
`hive.security.authorization.enabled`	`true*`	Enable or disable the Hive client authorization.
`hive.security.authorization.manager`	`org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory*`	Class name for the Hive client authorization manager.

Property	Value	Description
`hive.users.in.admin.role`	`mapr*`	Comma-separated list of users who need to be added to the `admin` role. Note that a user who belongs to the `admin` role needs to run the `set role` command before getting the privileges of the `admin` role, as the `admin` role is not in `current roles` by default.

* In secure clusters, the MapR "Secure-by-Default" configuration implicitly configures the Fallback Authorizer in the `hive-site.xml` file.

Fall Back Authorizer applies the following restrictions:

- Allows `set` only for selected whitelist parameters.
- Disallows dfs commands except for `admin`.
- Disallows local file location in SQL statements except for `admin`.
- Disallows `ADD JAR`, `COMPILE`, and `TRANSFORM` statements.

Fallback Authorization Configuration Example in hive-site.xml File

```
<property>
    <name>hive.security.authorization.enabled</name>
    <value>true</value>
</property>

<property>
    <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.Fall
backHiveAuthorizerFactory</value>
</property>

<property>
    <name>hive.users.in.admin.role</name>
    <value>mapr</value>
 </property>
```

Action Restrictions with Fallback Hive Authorizer

After enabling Fallback Hive Authorizer, you can perform action restriction operations.

- Disallow local file location in SQL statements for all except the administrator.
- Allow `set` for selected white list parameters.
- Disallow `dfs` commands for all except the administrator.
- Disallow `ADD JAR` statements for all except the administrator.
- Disallow `COMPILE` statements for all except the administrator.
- Disallow `TRANSFORM` statements.

Using a White List with Fallback Hive Authorizer

You can add an exception to Fallback Hive Authorizer restrictions using the `hive.security.authorization.sqlstd.confwhitelist.append` property.

last-updated: Apr 11, 2022

The `hive.security.authorization.sqlstd.confwhitelist` property is list of comma-separated Java regexes that you can append to. Appending to this list instead of updating the original list means that you can append to the default set by SQL-standard authorization instead of replacing it entirely.

You can modify the configurations parameters that match these regexes when SQL-standard authorization is enabled.

To get the default value, use the `set <param>` command. The `hive.conf.restricted.list` checks are still enforced after the white-list check.

An example of a white-list configuration is as follows:

```
<property>
  <name>hive.security.authorization.sqlstd.confwhitelist.append</name>
  <value>hive.reloadable.aux.jars.path</value>
</property>
```

- After adding this configuration to the `hive-site.xml` file, execute the following command:

  ```
  set hive.reloadable.aux.jars.path=/path/to/jar
  ```

Integrating Hive

Hive and MapR Database Integration

You can create MapR Database binary tables from Hive that can be accessed by both Hive and MapR Database. You can run Hive queries on MapR Database binary tables, convert existing MapR Database binary tables into Hive-MapR Database tables, and run Hive queries on those tables as well.

Install and Configure Hive

1. Install and configure Hive if it is not already installed. See Installing Hive on page 187 for details.
2. Execute the `jps` command and ensure that all relevant Hadoop, MapR, and Zookeeper processes are running. Example:

   ```
   $ jps
   1549 jenkins.war
   15051 QuorumPeerMain
   30935 Jps
   15551 CommandServer
   15293 ResourceManager
   15328 NodeManager
   15131 WardenMain
   ```

3. Open the `hive-site.xml` file with your favorite editor, or create a `hive-site.xml` file if it doesn't already exist:

   ```
   $ cd $HIVE_HOME
   $ vi conf/hive-site.xml
   ```

4. Copy the following XML code and paste it into the `hive-site.xml` file.

   Note: If you already have an existing `hive-site.xml` file with a `configuration` element block, just copy the `property` element block code below and paste it inside the `configuration` element block in the `hive-site.xml` file. Be sure to use the correct values for the paths to your auxiliary JARs and ZooKeeper IP numbers.

   Example configuration:

```
configuration>

<property>
  <name>hive.aux.jars.path</name>
  <value>file:///opt/mapr/hive/hive-<version>/lib/
hive-hbase-handler-<version>-mapr.jar,
file:///opt/mapr/hbase/hbase-<version>/lib/
hbase-client-<version>-mapr.jar, file:///opt/mapr/hbase/
hbase-<version>/lib/hbase-server-<version>-mapr.jar,file:///opt/mapr/
hbase/hbase-<version>/lib/hbase-protocol-<version>-mapr.jar,file:///opt/
mapr/zookeeper/zookeeper-<version>/zookeeper-<version>.jar</value>
  <description>A comma separated list (with no spaces)
of the jar files required for Hive-HBase integration</description>
</property>

<property>
  <name>hbase.zookeeper.quorum</name>
  <value>xx.xx.x.xxx,xx.xx.x.xxx,xx.xx.x.xxx</value>
  <description>A comma separated list (with no spaces) of
the IP addresses of all ZooKeeper servers in the cluster.</description>
</property>

<property>
  <name>hbase.zookeeper.property.clientPort</name>
  <value>5181</value>
  <description>The Zookeeper
client port. The MapR default clientPort is 5181.</description>
</property>

</configuration>
```

5. Save and close the `hive-site.xml` file.

If you have successfully completed all of the steps in this section, you're ready to begin the tutorial in the next section.

Getting Started with Hive and MapR Database Binary Integration

In this tutorial we will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-MapR Database table
- Introspect the Hive-MapR Database table from the HBase shell
- Populate the Hive-MapR Database table with data from the Hive table
- Query the Hive-MapR Database table from Hive

last-updated: Apr 11, 2022

- Convert an existing MapR Database table into a Hive-MapR table

Be sure that you have successfully completed all of the steps in Installing Hive on page 187 and review the MapR Database topics before beginning this Getting Started tutorial.

This Getting Started tutorial is based on the Hive-HBase Integration section of the Apache Hive Wiki. However, please note that there are some significant differences.

Create a Hive table with two columns

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

Execute the CREATE TABLE command to create the Hive pokes table

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

To see if the pokes table has been created successfully, execute the `SHOW TABLES` command

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The `pokes` table appears in the list of tables. **Populate the Hive pokes table with data:**

The `kv1.txt` file is provided in the `$HIVE_HOME/examples/files` directory. Execute the LOAD DATA LOCAL INPATH command to populate the Hive `pokes` table with data from the `kv1.txt` file.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
Time taken: 0.278 seconds
hive>
```

Execute a SELECT query on the Hive pokes table

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the application output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive `pokes` table with a key of 98.

Warning:

Hive tables can have multiple identical keys. As we will see shortly, MapR Database tables cannot have multiple identical keys, only unique keys.

Create a Hive-MapR Database table

Enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE mapr_table_1(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cf1:val")
    > TBLPROPERTIES ("hbase.table.name" = "/user/mapr/xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-MapR Database integration may find it easier to understand what's going on if Hive and MapR Database use different names for the same table.

In this example, Hive will recognize this table as "mapr_table_1" and MapR Database will recognize this table as "xyz".

Start the HBase shell

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

Execute the `list` command to see a list of HBase tables

```
hbase(main):001:0> list
TABLE
/user/mapr/xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-MapR Database table named `xyz` in directory `/user/mapr`. This is the same table known to Hive as `mapr_table_1`.

Display the description of the `/user/mapr/xyz` table in the HBase shell

```
hbase(main):004:0> describe "/user/mapr/xyz"
DESCRIPTION                                          ENABLED
 {NAME => '/user/mapr/xyz', FAMILIES => [{NAME => 'cf1', DATA_B true
 LOCK_ENCODING => 'NONE', BLOOMFILTER => 'NONE', REP
 LICATION_SCOPE => '0', VERSIONS => '3', MIN_VERSION
 S => '0', TTL => '2147483647', KEEP_DELETED_CELLS =
 > 'false', BLOCKSIZE => '65536', IN_MEMORY => 'fals
 e', ENCODE_ON_DISK => 'true', BLOCKCACHE => 'true'}
 ]}
1 row(s) in 0.0240 seconds
```

From the Hive prompt, insert data from the Hive table pokes into the Hive-MapR Database table `mapr_table_1`

```
hive> INSERT OVERWRITE TABLE mapr_table_1 SELECT * FROM pokes WHERE foo=98;
...
```

last-updated: Apr 11, 2022

```
2 Rows loaded to mapr_table_1
OK
Time taken: 13.384 seconds
```

Query `mapr_table_1` to see the data we have inserted into the Hive-MapR Database table

```
hive> SELECT * FROM mapr_table_1;
OK
98      val_98
Time taken: 0.56 seconds
```

Even though we loaded two rows from the Hive `pokes` table that had the same key of 98, only one row was actually inserted into `mapr_table_1`. This is because `mapr_table_1` is a MapR Database table, and although Hive tables support duplicate keys, MapR Database tables only support unique keys. MapR Database tables arbitrarily retain only one key, and silently discard all of the data associated with duplicate keys.

Convert a pre-existing MapR Database table to a Hive-MapR Database table

To convert a pre-existing MapR Database table to a Hive-MapR Database table, enter the following four commands at the Hive prompt.

Note that in this example the existing MapR Database table is `my_mapr_table` in directory `/user/mapr`.

```
hive> CREATE EXTERNAL TABLE mapr_table_2(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
    > TBLPROPERTIES("hbase.table.name" = "/user/mapr/my_mapr_table");
```

Now we can run a Hive query against the pre-existing MapR Database table `/user/mapr/my_mapr_table` that Hive sees as `mapr_table_2`:

```
hive> SELECT * FROM mapr_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401     val_401
402     val_402
403     val_403
404     val_404
406     val_406
407     val_407
409     val_409
Time taken: 9.452 seconds
```

Optimizing MapR Database Tables Search by ID

Starting from the 1904 release (EEP 6.0.2, EEP 6.1.1, and EEP 6.2.0), search by ID is supported with Hive MapR Database JSON tables.

Property of Optimization

The property name is `hive.mapr.db.json.fetch.by.id.task.conversion` and the value has a boolean type and by default is set to `true`, which means it is enabled.

- To disable optimization, set `hive.mapr.db.json.fetch.by.id.task.conversion` to `false`.

Conditions for Optimization

- This optimizer is designed for queries such as:

```
SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value>;
```

or:

```
SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value> AND (<condition_1>) AND
(<condition_2>) ... AND (<condition_N>);
```

or:

```
SELECT *
FROM <mapr_db_json_table>
WHERE <Constant false operator>
```

where `_id` is a key column of MapR Database JSON table. It provides usage of the `findById()` method of the MapR Database JSON table. The following functionality is not supported:

- joins
- group by
- distinct
- lateral view
- subquery
- create table as select (CTAS) or insert
- analyze
- single source

The predicate is not actually a part of the filter, so it is ignored by push down:

```
SELECT * FROM t WHERE (CASE WHEN _id = 'value_a' THEN 2 ELSE 4 END) > 3;
```

Using Optimization

1. Consider the following MapR Database JSON table:

```
CREATE TABLE t(doc_id string, col1 string, col2 string)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/user/mapr/
db_json_table","maprdb.column.id" = "doc_id");
```

2. Run the `EXPLAIN` command:

```
EXPLAIN SELECT col1 FROM t WHERE doc_id='id_004';
```

3. The following output is produced:

```
STAGE DEPENDENCIES:
 Stage-0 is a root stage

STAGE PLANS:
 Stage: Stage-0
  MapR DB JSON Fetch By Id Operator
  limit: -1
  Processor Tree:
  TableScan
  alias: t_small
  filterExpr: (doc_id = 'id_004') (type: boolean)
  Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
stats: NONE
  Filter Operator
   predicate: (doc_id = 'id_004') (type: boolean)
   Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
stats: NONE
   Select Operator
   expressions: col1 (type: string)
   outputColumnNames: _col0
   Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
stats: NONE
   ListSink
```

An important part of a query plan is that it shows if optimization is available for the query:

```
STAGE PLANS:
Stage: Stage-0
MapR DB JSON Fetch By Id Operator
```

Connecting Using Hive MapR Database JSON Connector

This section describes the Hive connector for MapR Database JSON table.

The Hive connector supports the creation of MapR Database based Hive tables. You can create a JSON table on MapR Database and load CSV data and/or JSON files to MapR Database using the connector. MapR Database based Hive tables can be:

- Queried just like MapR File System based Hive tables.
- Combined with MapR File System based Hive tables in joins and sub-queries.

Note: If you use Drill to query Hive tables based on MapR Database tables, you can enable the native Drill reader, which can improve query performance.

The following table lists the Hive data type and the corresponding (supported) MapR Database OJAI type:

Hive Type	MapR Database OJAI Type
BOOLEAN	BOOLEAN
BINARY	BINARY
TINYINT	BYTE
DATE	DATE
DOUBLE	DOUBLE
FLOAT	FLOAT
INT	INT

last-updated: Apr 11, 2022

Hive Type	MapR Database OJAI Type
BIGINT	LONG
SMALLINT	SHORT
STRING	STRING
TIMESTAMP	TIMESTAMP

The Hive connector for MapR Database JSON table also supports the use of the following complex data types:

- map
- array
- struct

Note: The MapR Database JSON tables do not support ACID transactions, bucketing, and alteration.

Creating a MapR Database JSON Table and Hive Table Using Hive

- To create a table, run the command similar to the following:

  Note: The required properties are shown in bold.

```
CREATE TABLE primitive_types (
 id string,
 bo boolean,
 d double,
 da date,
 f double,
 i int,
 s string,
 ts timestamp)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/tbl","maprdb.column.id" = "id");
```

  Here:

  - The `maprdb.table.name`, `maprdb.column.id` and `STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'` are mandatory properties.
  - The value for `maprdb.column.id` column should be of type string or binary.

  To create a Hive table that exists on MapR Database, specify `EXTERNAL` in the table DDL. If the table created is EXTERNAL, when the table is dropped, only its metadata is deleted; the underlying MapR Database data remains intact. On the other hand, if the table is not EXTERNAL, dropping the table deletes both the metadata associated with the table and the underlying MapR Database data.

  For example, suppose a JSON table named `/apps/my_users` with the following values:

```
{"_id":"001","first_name":"John","last_name":"Doe","age":34}
{"_id":"002","first_name":"Jack","last_name":"Smith","age":26}
```

  To create a Hive table over existing MapR Database JSON table:

```
CREATE EXTERNAL TABLE primitive_types (
 user_id string,
```

last-updated: Apr 11, 2022

```
 first_name string,
 last_name string,
 age int)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/apps/my_users","maprdb.column.id" =
"user_id");
```

Now, because table `primitive_types` points to MapR Database table, you can perform ETL query similar to MapR File System based Hive tables:

```
SELECT COUNT(*) FROM test_external;
SELECT MAX(age) AS label FROM test_external;
...
```

Loading CSV Data to MapR Database JSON Table

1. Create intermediate table.
   For example:

   ```
   CREATE TABLE stage(id STRING, name STRING, age INT) ROW FORMAT DELIMITED
   FIELDS TERMINATED BY ',';
   ```

2. Load data to table.
   For example:

   ```
   LOAD DATA INPATH '/data' into table stage;
   ```

3. Create MapR Database table in Hive.
   For example:

   ```
   CREATE TABLE users(id STRING, name STRING, age INT)
   STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
   TBLPROPERTIES("maprdb.table.name" = "/users","maprdb.column.id" = "id");
   ```

4. Insert data through stage table.
   For example:

   ```
   INSERT INTO TABLE users select id, name, age from stage;
   ```

Loading JSON Files to MapR Database JSON Table

1. Add SerDe JAR for JSON.
   For example:

   ```
   add jar /opt/mapr/hive/hive-<version>/hcatalog/share/hcatalog/
   hive-hcatalog-core-<version>-mapr.jar
   ```

2. Create intermediate table.
   For example:

   ```
   CREATE EXTERNAL TABLE stage(id string, name string, age int)
   ROW FORMAT SERDE 'org.apache.hive.hcatalog.data.JsonSerDe'
   STORED AS TEXTFILE;
   ```

3. Load data in stage table.
   For example:

```
LOAD DATA INPATH '/data' into table stage;
```

   Note: If there is a key in the JSON file that starts with "_" (for example, "_id"), then treat the names as literals upon creating the schema and query using the same literal syntax. For example, specify `` `_id` string `` without any special serde properties. Then in the query, use `` select `_id` from sometable; ``. Alternatively, you can use 'org.openx.data.jsonserde.JsonSerDe' and add WITH SERDEPROPERTIES ("mapping.id" = "_id") to your table definition.

4. Create MapR Database table in Hive.
   For example:

```
CREATE TABLE users(id STRING, name STRING, age INT)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/users","maprdb.column.id" = "id");
```

5. Insert data through stage table.
   For example:

```
INSERT INTO TABLE users select id, name, age from stage;
```

   If there is a key in your JSON file that starts with "_" (for example, "`_id`"), treat the names as literals upon creating the schema and also query using the same literal syntax. In the above example, it would look like `` `_id` string `` without any special serde properties for it. Then, use again in query as shown below:

```
select `_id`  from sometable;
```

   Alternatively, use `org.openx.data.jsonserde.JsonSerDe` and add `WITH SERDEPROPERTIES ("mapping.id" = "_id" )` to your table definition.

Refer to Hive MapR Database JSON Connector Tutorial for a connector example.

Understanding the UPDATE Statement

Starting with EEP 6.0.0 (Hive 2.3), EEP 5.0.1 (Hive 2.1), EEP 4.1.2, and EEP 3.0.4, the UPDATE statement is supported with Hive MapR Database JSON tables.

You can use the `UPDATE` statement to update primitive, complex, and complex nested data types in MapR Database JSON tables, using the Hive connector.

Updating Primitive Data Types

last-updated: Apr 11, 2022

This section describes how to use the UPDATE statement to update primitive data types in MapR Database JSON tables, using the Hive connector.

1. Create a MapR Database JSON table and a Hive table:

```
CREATE TABLE simple_types_update (
>>>>>>> Incorporated edit comments
  doc_id string,
  bo boolean,
  d double,
  da date,
  f float,
  i int,
  s string,
  ts timestamp,
  ti tinyint,
  bi bigint,
  si smallint,
  bin binary)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/
simple_types_update","maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE simple_types_update VALUES ('1', true, 124.14,
'2017-11-29', 9192.12,
214566190, 'text', '2017-03-17 00:14:13', 125, 9223372036854775806,
23434, "binary string");
```

3. Run the UPDATE command on the table:

```
UPDATE simple_types_update
SET da = '2018-12-11',
bo = FALSE,
f = 91.777
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and MapR Database JSON tables.
   - Verifying Hive table data:

```
hive> SELECT * FROM simple_types_update;

1    false    124.14    2018-12-11    91.777    214566190    text
2017-03-17 00:14:13    125    9223372036854775806    23434    binary
string
```

   - Verifying MapR Database JSON table data:

```
find '/simple_types_update'

{"_id":"1","bi":{"$numberLong":9223372036854775806},"bin":
{"$binary":"YmluYXJ5IHN0cmluZwAAAAAAAA=="},
 "bo":false,"d":124.14,"da":{"$dateDay":"2018-12-11"},
 "f":{"$numberFloat":91.777},"i":{"$numberInt":214566190},
 "s":"text","si":{"$numberShort":23434},"ti":{"$numberByte":125},"ts":
{"$date":"2017-03-17T00:14:13.000Z"}}
```

last-updated: Apr 11, 2022

Updating Complex Data Types

This section describes how to use the UPDATE statement to update complex data types in MapR Database JSON tables, using the Hive connector.

1. Create a MapR Database JSON table and a Hive table:

```
CREATE TABLE complex_types_update (
  doc_id string,
  info MAP<STRING, INT>,
  pets ARRAY<STRING>,
  user_info STRUCT<name:STRING, surname:STRING, age:INT, gender:STRING>)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/
complex_types_update","maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_types_update SELECT '1', map('age', 28),
array('Cat', 'Cat', 'Cat'),
named_struct('name', 'Santa', 'surname', 'Claus','age', 1000,'gender',
'MALE');
```

3. Run the UPDATE command on the table:

```
UPDATE complex_types_update SET
info = map('year', 32),
pets = array('Dog', 'Cat', 'Pig'),
user_info = named_struct('name', 'Vasco', 'surname', 'da Gama','age',
558,'gender', 'MALE')
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and MapR Database JSON tables.
   - Verifying Hive table data:

```
hive> SELECT * FROM complex_types_update;

1    {"year":32}    ["Dog","Cat","Pig"]
{"name":"Vasco","surname":"da Gama","age":558,"gender":"MALE"}
```

   - Verifying MapR Database JSON table data:

```
find '/complex_types_update'

{"_id":"1","info":{"year":{"$numberInt":32}},"pets":
["Dog","Cat","Pig"],"user_info":{"age":{"$numberInt":558},
 "gender":"MALE","name":"Vasco","surname":"da Gama"}}
```

Updating Complex Nested Data Types

This section describes how to use the UPDATE statement to update complex nested data types in MapR Database JSON tables, using the Hive connector.

1. Create a MapR Database JSON table and a Hive table using Hive:

```
CREATE TABLE complex_nested_data_type_update
(
          entry STRING,
          num INT,
          postal_addresses MAP <STRING,
          struct
<USER_ID:STRING,ADDRESS:STRING,ZIP:STRING,COUNTRY:STRING>>
)
stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
(
           "maprdb.table.name" = "/complex_nested_data_type_update",
           "maprdb.column.id" = "entry"
);
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_nested_data_type_update
SELECT '001', '1',
MAP ( 'Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'USA'));
```

3. Run the UPDATE command on the table by updating the COUNTRY value in `map(struct)`:

```
UPDATE complex_nested_data_type_update
SET postal_addresses = MAP ('Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'Hun'))
WHERE entry = '001';
```

4. Verify that the data is inserted in both Hive and MapR Database JSON tables.
   - Verifying Hive table data:

```
hive> SELECT * FROM complex_nested_data_type_update;

001    1    {"Bill":{"user_id":"1","address":"3205 Woodlake
ct","zip":"45040","country":"Hun"}}
```

   - Verifying MapR Database JSON table data:

```
find '/complex_nested_data_type_update'
{"_id":"001","num":{"$numberInt":1},"postal_addresses":{"Bill":
{"address":"3205 Woodlake
ct","country":"Hun","user_id":"1","zip":"45040"}}}
```

UPDATE Statement Limitations

This section describes the features that the UPDATE statement does not support.

The UPDATE statement has the following known limitations:

- The UPDATE statement is fully supported only for primitive data types (see Connecting to MapR Database).
- The UPDATE statement is partly supported for complex data types; you can replace only the whole value of a complex type with new a value.
- You cannot update the `maprdb.column.id` value.

Understanding the INSERT INTO Statement

This section describes how to use the `INSERT INTO` statement to insert or overwrite rows in nested MapR Database JSON tables, using the Hive connector.

- Single-row insert on page 3473
- Multiple-row insert on page 3475
- Overwriting data on page 3478

Note: The output shown in these examples is for illustration only; actual Hive CLI output varies, depending on your specific situation.

Single-row insert

You can use the `INSERT INTO` statement to insert a single table row into a nested MapR Database table using one of two methods.

For example, imagine that you have the following Hive MapR Database JSON table, `nested_data_insert`:

```
 CREATE TABLE nested_data_insert
 (
    entry STRING,
    num INT,
    postal_addresses MAP <STRING,
    struct <USER_ID:STRING,ADDRESS:STRING,ZIP:STRING,COUNTRY:STRING>>
 )
 stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
 (
    "maprdb.table.name" = "/nested_data_insert",
    "maprdb.column.id" = "entry"
 );
```

- You can insert the new row into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '001' AS KEY,
          '1' AS num,
          MAP ('Adam',
               Named_struct ('user_id', '1', 'address', '3205 Woodlake
ct', 'zip', '45040', 'country', 'Usa'),
               'Wilfred',
               Named_struct ('user_id', '2', 'address', '777 Brockton
Avenue', 'zip', '34000', 'country', 'Ita')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

last-updated: Apr 11, 2022

- Alternatively, you can insert the new row into your table by using a `SELECT` statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '002',
       '2',
       MAP ('Bill',
            Named_struct ('user_id', '1', 'address', '328 Virginia Ave',
'zip', '54956', 'country', 'Bol'),
            'Stiv',
            Named_struct ('user_id', '2', 'address', 'Schererville',
'zip', '46375', 'country', 'Efi'));
```

After you insert data, you should verify that the data is inserted in both Hive and MapR Database JSON tables:

- Verify the insertion into the Hive table by using the `SELECT * FROM` syntax.

```
SELECT * FROM nested_data_insert;
```

Sample output:

Table

		postal_address				
entry	**num**		**USER_ID**	**ADDRESS**	**ZIP**	**COUNTRY**
001	1	Adam	1	3205 Woodlake ct	45040	Usa
		Wilfred	2	777 Brockton Avenue	34000	Ita
002	2	Bill	1	328 Virginia Ave	54956	Bol
		Stiv	2	Schererville	46375	Efi

- Verify the insertion into the MapR Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
  "Adam": {
      "user_id": "1",
      "address": "3205 Woodlake ct",
      "zip": "45040",
      "country": "Usa"
          },
  "Wilfred": {
      "user_id": "2",
      "address": "777 Brockton Avenue",
      "zip": "34000",
      "country": "Ita"
          }
       }
{
   "Bill": {
      "user_id": "1",
      "address": "328 Virginia Ave",
      "zip": "54956",
      "country": "Bol"
       },
   "Stiv": {
      "user_id": "2",
      "address": "Schererville",
      "zip": "46375",
      "country": "Efi"
       }
}
```

Multiple-row insert

Now imagine that you want to insert three rows of data into `nested_data_insert`.

- You can insert the new rows into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '003' AS KEY,
          '3' AS num,
          MAP ('Rony',
               Named_struct ('user_id', '1', 'address', '4333 Backer
str', 'zip', '12311', 'country', 'Hun')) AS postal_addresses
   UNION ALL SELECT '004' AS KEY,
                    '4' AS num,
                    MAP ('Ivan',
                         Named_struct ('user_id', '1', 'address', '833
Bridle Avenue', 'zip', '95111', 'country', 'CA')) AS postal_addresses
   UNION ALL SELECT '005' AS KEY,
                    '5' AS num,
                    MAP ('Ivan',
                         Named_struct ('user_id', '1', 'address', '664
Devon Ave', 'zip', '92021', 'country', 'Tog')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

last-updated: Apr 11, 2022

- Alternatively, you can insert the new rows into your table by using a `SELECT` statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '006',
       '6',
       MAP ('Rony',
            Named_struct ('user_id', '1', 'address', '150 National City',
'zip', '91950', 'country', 'Hun'))
UNION ALL
SELECT '007',
       '7',
       MAP ('Tomason',
            Named_struct ('user_id', '1', 'address', '272 Ocean Circle' ,
'zip', '92801', 'country', 'CA'))
UNION ALL
SELECT '008',
       '8',
       MAP ('Davin',
            Named_struct ('user_id', '1', 'address', '81 Augusta Ave',
'zip', '93905', 'country', 'CA'));
```

After you insert data, you should verify that the data is inserted in both Hive and MapR Database JSON tables:

- Verify the insertion into the Hive table by using the `SELECT * FROM` syntax.

```
SELECT * FROM nested_data_insert WHERE entry > '002' ;
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
003	3	Rony	1	4333 Backer str	12311	Hun
004	4	Ivan	1	833 Bridle Avenue	95111	CA
005	5	Ivan	1	664 Devon Ave.	92021	Tog
006	6	Rony	1	150 National City	91950	Hun
007	7	Tomason	1	272 Ocean Circle	92801	CA
008	8	Davin	1	81 Augusta Ave	93905	CA

- Verify the insertion into the MapR Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
   "_id": "003",
   "num": {
     "$numberInt": 3
          },
   "postal_addresses": {
        "Rony": {
             "address": "4333 Backer str",
             "country": "Hun",
             "user_id": "1",
             "zip": "12311"
             }
         }
      }
{
   "_id": "004",
   "num": {
       "$numberInt": 4
          },
   "postal_addresses": {
          "Ivan": {
              "address": "833 Bridle Avenue",
              "country": "CA",
              "user_id": "1",
              "zip": "95111"
            }
       }
 }
 {
   "_id": "005",
   "num": {
           "$numberInt": 5
          },
   "postal_addresses": {
           "Ivan": {
               "address": "664 Devon Ave",
               "country": "Tog",
               "user_id": "1",
                "zip": "92021"
          }
       }
    }
{
     "_id": "006",
     "num": {
           "$numberInt": 6
            },
     "postal_addresses": {
          "Rony": {
             "address": "150 National City",
             "country": "Hun",
             "user_id": "1",
             "zip": "91950"
           }
        }
    }
{
    "_id": "007",
    "num": {
```

```
          "$numberInt": 7
            },
    "postal_addresses": {
          "Tomason": {
              "address": "272 Ocean Circle",
              "country": "CA",
              "user_id": "1",
              "zip": "92801"
           }
       }
    }
{
    "_id": "008",
    "num": {
          "$numberInt": 8
            },
    "postal_addresses": {
           "Davin": {
                "address": "81 Augusta Ave",
                "country": "CA",
                "user_id": "1",
                "zip": "93905"
            }
          }
}
```

Overwriting data

Still using sample table `nested_data_insert`, you can use the INSERT statement on a dummy table to overwrite one or more complete rows.

For example, to overwrite the first row in `nested_data_insert (001)` with new values, use the following syntax:

```
WITH dummy_table AS
(SELECT '001' AS KEY,
'1' AS num,
MAP ('newAdam',
Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

After you overwrite data, you should verify that the data is changed in both Hive and MapR Database JSON tables:

- Verify the data into the Hive table by using the `SELECT * FROM` syntax.

  ```
  hive> SELECT * FROM nested_data_insert WHERE entry = '001';
  ```

  Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	1	newAdam	1	newAddress	newZip	newCountry

- Verify the data in the MapR Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 001

{
   "_id": "001",
   "num": {
   "$numberInt": 1
           },
   "postal_addresses": {
        "newAdam": {
              "address": "newAdress",
              "country": "newCountry",
              "user_id": "1",
              "zip": "newZip"
           }
       }
}
```

For another example, imagine that you want to overwrite `003` and `004` rows in `nested_data_insert` with new values:

```
WITH dummy_table AS (
SELECT '003' AS KEY,
'3' AS num,
MAP ('newName1',
Named_struct ('user_id', '1', 'address', 'newAdress1', 'zip', 'newZip1',
'country', 'newCountry1')) AS postal_addresses
UNION ALL
SELECT '004' AS KEY,
'4' AS num,
MAP ('newName2',
Named_struct ('user_id', '1', 'address', 'newAdress2', 'zip', 'newZip2',
'country', 'newCountry2')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT * FROM dummy_table;
```

After you overwrite the data, you should verify that the data is changed in both Hive and MapR Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry IN ('003', '004');
```

Sample output:

Table

		postal_address				
entry	**num**		**USER_ID**	**ADDRESS**	**ZIP**	**COUNTRY**
003	3	newName1	1	newAddress1	newZip1	newCountry1
004	4	newName2	1	newAddress2	newZip2	newCountry2

Verify the data in the MapR Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 003
{
  "_id": "003",
  "num": {
```

```
       "$numberInt": 3
          },
  "postal_addresses": {
  "newName1": {
       "address": "newAdress1",
       "country": "newCountry1",
       "user_id": "1",
       "zip": "newZip1"
          }
        }
    }
findbyid '/nested_data_insert' --id 004
     {
       "_id": "004",
       "num": {
          "$numberInt": 4
          },
       "postal_addresses": {
           "newName2": {
              "address": "newAdress2",
              "country": "newCountry2",
              "user_id": "1",
              "zip": "newZip2"
           }
        }
    }
```

Warning: If you exclude columns both from the SELECT statement in your INSERT statement and from the table schema, the value of this column changes to NULL.

Finally, imagine that you want to overwrite the first row in `nested_data_insert (001)` with new values and overwrite the `num` column to `NULL`:

```
WITH dummy_table AS
(SELECT '001' AS KEY,
MAP ('newAdam',
Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert (entry, postal_addresses)
SELECT * FROM dummy_table;
```

After you overwrite data, you should verify that the data is changed in both Hive and MapR Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

  ```
  hive> SELECT * FROM nested_data_insert WHERE entry = '001';
  ```

  Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	NULL	newAdam	1	newAddress	newZip	newCountry

last-updated: Apr 11, 2022

- Verify the data in the MapR Database JSON table (num row is not present):

```
findbyid '/nested_data_insert' --id 001

{
   "_id": "001",
   "postal_addresses": {
   "newAdam": {
         "address": "newAdress",
         "country": "newCountry",
         "user_id": "1",
         "zip": "newZip"
        }
     }
}
```

Understanding the MERGE Statement

You can use the MERGE statement to perform record-level INSERT and UPDATE operations efficiently within Hive tables.

The MERGE statement can be a key tool of MapR-cluster data management. It is based on ANSI-standard SQL.

The following scenarios can help you understand how to use the MERGE statement:

Simple merge.maprdb.column.id is the join key

Consider merging the following example source and target tables:

Table

id	first_name	last_name	age
001	Dorothi	Hogward	7777
002	Alex	Bowee	7777
088	Robert	Dowson	25

Table

id	first_name	last_name	age
001	John	Smith	45

Table (Continued)

id	first_name	last_name	age
002	Michael	Watson	27
003	Den	Brown	33

You can use the following SQL-standard MERGE statement:

```
MERGE into customer_db_json_target trg
USING customer_source src
ON src.id = trg.id
WHEN MATCHED THEN UPDATE SET age = src.age
WHEN NOT MATCHED THEN
INSERT VALUES (src.id, src.first_name, src.last_name, src.age);
```

The result is:

id	first_name	last_name	age
001	John	Smith	7777
002	Michael	Watson	7777
003	Den	Brown	33
088	Robert	Dowson	25

Note: The age column is updated and a new `id` column is inserted.

Simple `merge.maprdb.column.id` is not the join key

Merging when `merge.maprdb.column` is not the join key is not recommended.

Deleting while merging (EEP 6.3.0 and previous)

Deletions are not supported in a `MERGE` statement. This example:

```
MERGE INTO  customer_db_json old
USING customer_new new ON new.id = old.id
WHEN MATCHED AND old.age > 10 THEN DELETE;
```

Raises the following exception:

```
Error: Error while compiling statement: FAILED: SemanticException Deletes
are not supported for MapR DB JSON tables (state=42000,code=40000)
```

DELETE syntax in the MERGE statement (EEP 6.3.1 and later)

This section describes how to use the `DELETE` syntax in the `MERGE` statement for MapR Database JSON tables. Included are examples of usage and limitations.

Consider two tables: `tgt` which is the target table of the `MERGE` statement, and `src`, which is the source table from which data will be taken. Both tables use `MapRDBJsonStorageHandler` to store data. The following table shows the initial contents of the `tgt` table:

Table

id	Value
1	AAA

Table (Continued)

2	BBB
3	CCC
4	DDD
5	EEE

The following table shows the initial contents of the `src` table:

Table

id	Value
1	AAA
222	BBB---
3	CCC
444	DDD---
5	EEE

The following merge statement contains a `WHEN MATCHED THEN DELETE` clause. It means that if the `id` from the `tgt` table equals the `id` from the `src` table, the row is removed from the `tgt` table. When the value of `id` does not match, a new row is inserted into the `tgt` table:

```
MERGE INTO tgt
USING src ON tgt.id=src.id
WHEN MATCHED THEN DELETE
WHEN NOT MATCHED THEN INSERT VALUES (src.id, src.value);
```

The following table shows the result of the merge:

Table

id	Value
2	BBB
222	BBB---
4	DDD
444	DDD---

Here we removed rows with `id` 1, 3, and 5 from the `tgt` table because they existed in the `src` table, and they matched values from the `tgt` table. We did not touch rows with `id` 2 and 4, because there were no such values in the `src` table. We inserted new rows with `id` values 222 and 444 because they existed in the `src` table and did not exist in the `tgt` table.

Limitations

The preceding solution has three limitations:

1. Subqueries are not supported as a source when `DELETE` is used.
2. The source table should be a MapR Database JSON table when deletion is used in a `MERGE` operator.
3. The `DELETE` operator is not supported with additional conditions after `WHEN MATCHED`. Use either a single `UPDATE` or `DELETE`.

last-updated: Apr 11, 2022

Limitation #3 means that queries like the following are not supported:

```
MERGE INTO tgt
USING src
ON tgt._id = src._id
WHEN MATCHED AND [boolean expression1] THEN DELETE
WHEN MATCHED AND [boolean expression2] THEN UPDATE
WHEN NOT MATCHED THEN INSERT
```

Multiple source rows match a given target row (cardinality violation)

Consider merging the two tables `customer_db_json` and `customer_new`:

Table

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

And:

Table

id	first_name	last_name	age
001	Dorothi	Hogward	77
001	Dorothi	Hogward	77
088	Robert	Dowson	25

To `MERGE customer_new` and `customer_db_json`:

```
MERGE INTO customer_db_json trg
USING customer_new src ON src.id = trg.id
WHEN MATCHED THEN UPDATE
SET first_name = src.first_name,
last_name = src.last_name
WHEN NOT MATCHED THEN INSERT VALUES
(src.id, src.first_name, src.last_name, src.age);
```

This example causes an exception because of duplicate values in the `id` column in the `customer_new` table:

```
Caused by: org.apache.hadoop.hive.ql.metadata.HiveException: Error
evaluating cardinality_violation(_col0)
```

To avoid cardinality violation, set `hive.merge.cardinality.check=false`, but in this case the result is unpredictable because there is no rule that defines the order of duplicated data that will be inserted by using the `MERGE` statement.

Merge on mixed data types

The merge operation also supports mixed data types, such as arrays, maps, and structures.

Consider two tables `mixed_types_source` and `mixed_types_target`:

last-updated: Apr 11, 2022

Table

doc_id	user_info
1	{"name":"Brandon","surname":"Lee","age":31,"gender":"MALE"}
2	{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}
3	{"name":"Mary","surname":"Dowson","age":11,"gender":"FEMALE"}
4	{"name":"Paul","surname":"Rodgers","age":41,"gender":"MALE"}

And:

Table

id	user_info
1	{"name":"Lexx","surname":"Comfuzer","age":31,"gender":"MALE"}

To merge `mixed_types_source` and `mixed_types_target`:

```
MERGE INTO mixed_types_target trg
USING mixed_types_source src
ON src.doc_id = old.doc_id
WHEN MATCHED THEN UPDATE
SET user_info = src.user_info
WHEN NOT MATCHED THEN INSERT VALUES
(src.doc_id, src.user_info);
```

The result is:

Table

id	first_name
1	`{"name":"Brandon","surname":"Lee","age":31,"gender":"MALE"}`
2	`{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}`
3	`{"name":"Mary","surname":"Dowson","age":11,"gender":"FEMALE"}`
4	`{"name":"Paul","surname":"Rodgers","age":41,"gender":"MALE"}`

Note that you cannot update only a part of a complex structure field. For example, suppose you have a structure stored as one field in a Hive table:

```
{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}
```

You cannot update only the `age` field in the structure. You can only replace all values of the structure with new ones. For details, see Understanding the UPDATE Statement on page 3469.

Merge into external MapR Database JSON tables

The `MERGE` operator is also available for external MapR Database JSON tables. You can use the MERGE statement to insert and update values in external MapR database JSON table targets.

Merge into partitioned MapR Database JSON tables

Partitioned MapR Database JSON tables are not supported.

Merge into temporary MapR Database JSON tables

The `MERGE` operator is also available for temporary MapR Database JSON tables. Use temporary tables as target tables for merge. No additional syntax is needed.

Understanding the DELETE FROM Operation

In EEP 6.3.1 and later, you can use the `DELETE FROM` operation with MapR Database JSON tables.

Delete All Data from a Table

To delete all data from a MapR DatabaseJSON table use the following operator:

```
DELETE FROM <table_name>;
```

Example. In this example we create a table, insert data, and delete all rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query gives an empty set. Deletions are supported only for MapR Database JSON tables and transactional tables.

```
DELETE FROM customer;
SELECT doc_id, first_name, last_name FROM customer;
```

Example. In this example, we try to delete data from a non-transactional and non-MapR Database JSON table:

```
DROP TABLE IF EXISTS simple_data;
CREATE TABLE simple_data (id INT);
INSERT INTO TABLE simple_data VALUES (1), (2), (3);
DELETE FROM simple_data;
```

The result is:

```
FAILED: SemanticException Operation is not supported. Table is nor ACID
neither MapRDbJSON
```

Delete a Single Row from a Table

To delete a single row from a MapR Database JSON table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> = <value>;
```

Where:

`<table_name>` is the MapR Database JSON table.

last-updated: Apr 11, 2022

<id> is a key column of the MapR Database JSON table. It corresponds to the maprdb.column.id property.

<value> is the value to be deleted.

Example. In this example, we create a table, insert data, and delete a single row:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes a single row using the WHERE clause:

```
DELETE FROM customer WHERE doc_id = "002";
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
003	Robby	Smart

Note. Deletions are supported only for key columns of MapR Database JSON tables.

Example. In this example, we try to use a column other than a key column of the MapR Database JSON table in deletion.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Column first_name is not the key column of the table.

```
DELETE FROM customer WHERE first_name = "Max";
```

The result is:

```
FAILED: SemanticException Deletion over column first_name is forbidden. Use
only key column of MapR Db Json table: doc_id
```

Delete Several Rows from a Table

To delete several rows from a table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> IN (<value1>, <value2>, ...);
```

Where:

`<table_name>` is the MapR Database JSON table.

`<id>` is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

`<value1>, <value2>,` are values to be deleted.

Example. In this example, we create a table, insert data, and delete several rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes several rows using the `WHERE ... IN` clause:

```
DELETE FROM customer WHERE doc_id IN ("001", "002");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

Delete All Rows in a Table Except Listed Rows

To delete all rows from a table except a listed row, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> NOT IN (<value1>, <value2>, ...);
```

Where:

`<table_name>` is the MapR Database JSON table.

`<id>` is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

`<value1>, <value2>,` are values to be preserved.

Example. In this example, we create a table, insert data, and delete all rows except the listed rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
```

```
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes all rows except the listed rows:

```
DELETE FROM customer WHERE doc_id NOT IN ("003");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

Limitations of the DELETE FROM Operation

The following are three limitations of the current implementation:

- The current implementation does not support arbitrary conditions in the `WHERE` clause of the `DELETE` statement even if a key column is used.

  Example. In this example, `DELETE FROM` is used with an arbitrary condition:

  ```
  DELETE FROM customer WHERE doc_id == "003" OR doc_id <> "005";
  ```

  The result is:

  ```
  FAILED:
          SemanticException This condition is not supported for MapR Db
  Json deletions. Supported
          WHERE clauses are: <id> = value, <id> IN (value1, value2, ...),
  <id> NOT IN (value1, value2,
          ...)
  ```

- The current implementation does not support subqueries in the `WHERE` clause.
- The current implementation does not support deletions in the `MERGE` statement.

Hive and HBase Integration

You can create HBase tables from Hive that can be accessed by both Hive and HBase. This allows you to run Hive queries on HBase tables. You can also convert existing HBase tables into Hive-HBase tables and run Hive queries on those tables as well.

Install and Configure Hive and HBase

1. Install and configure Hive if it is not already installed. See Installing Hive on page 187.

last-updated: Apr 11, 2022

2. Install and configure HBase if it is not already installed. See Installing HBase on page 183.
3. Run the `jps` command, and ensure that all relevant Hadoop, HBase and Zookeeper processes are running:

```
$ jps
21985 HRegionServer
1549 jenkins.war
15051 QuorumPeerMain
30935 Jps
15551 CommandServer
15698 HMaster
15293 ResourceManager
15328 NodeManager
15131 WardenMain
```

Getting Started with Hive-HBase Integration

In this tutorial you will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HBase table
- Introspect the Hive-HBase table from HBase
- Populate the Hive-Hbase table with data from the Hive table
- Query the Hive-HBase table from Hive
- Convert an existing HBase table into a Hive-HBase table

Be sure that you have successfully completed all the steps in the Install and Configure Hive and HBase section before beginning this Getting Started tutorial. This Getting Started tutorial closely parallels the Hive-HBase Integration section of the Apache Hive Wiki, and thanks to Samuel Guo and other contributors to that effort.

Create a Hive table with two columns:

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

Execute the CREATE TABLE command to create the Hive pokes table:

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

To see if the pokes table has been created successfully, execute the SHOW TABLES command:

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The `pokes` table appears in the list of tables.

Populate the Hive pokes table with data

Execute the LOAD DATA LOCAL INPATH command to populate the Hive `pokes` table with data from the `kv1.txt` file.

The `kv1.txt` file is provided in the `$HIVE_HOME/examples` directory.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
Time taken: 0.278 seconds
hive>
```

Execute a SELECT query on the Hive pokes table:

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the job output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive `pokes` table with a key of 98. Note: This is a good illustration of the concept that Hive tables can have multiple identical keys. As we will see shortly, HBase tables cannot have multiple identical keys, only unique keys.

To create a Hive-HBase table, enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE hbase_table_1(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cf1:val")
    > TBLPROPERTIES ("hbase.table.name" = "xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HBase integration may find it easier to understand what's going on if Hive and HBase use different names for the same table.

In this example, Hive will recognize this table as "hbase_table_1" and HBase will recognize this table as "xyz".

Start the HBase shell:

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
```

```
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

Execute the list command to see a list of HBase tables:

```
hbase(main):001:0> list
TABLE
xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HBase table named `xyz`. This is the same table known to Hive as `hbase_table_1`.

Display the description of the xyz table in the HBase shell:

```
hbase(main):004:0> describe "xyz"
DESCRIPTION
      ENABLED
 {NAME => 'xyz', FAMILIES => [{NAME => 'cf1', BLOOMFILTER => 'NONE',
REPLICATI true
 ON_SCOPE => '0', COMPRESSION => 'NONE', VERSIONS => '3', TTL =>
'2147483647', BL
 OCKSIZE => '65536', IN_MEMORY => 'false', BLOCKCACHE => 'true'}]}
1 row(s) in 0.0190 seconds
```

From the Hive prompt, insert data from the Hive table pokes into the Hive-HBase table hbase_table_1

```
hive> INSERT OVERWRITE TABLE hbase_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to hbase_table_1
OK
Time taken: 13.384 seconds
```

Query hbase_table_1 to see the data we have inserted into the Hive-HBase table:

```
hive> SELECT * FROM hbase_table_1;
OK
98      val_98
Time taken: 0.56 seconds
```

Even though we loaded two rows from the Hive `pokes` table that had the same key of 98, only one row was actually inserted into `hbase_table_1`. This is because `hbase_table_1` is an HBASE table, and although Hive tables support duplicate keys, HBase tables only support unique keys. HBase tables arbitrarily retain only one key, and will silently discard all the data associated with duplicate keys.

Convert a pre-existing HBase table to a Hive-HBase table

To convert a pre-existing HBase table to a Hive-HBase table, enter the following four commands at the Hive prompt.

Note that in this example the existing HBase table is `my_hbase_table`.

```
hive> CREATE EXTERNAL TABLE hbase_table_2(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
    > TBLPROPERTIES("hbase.table.name" = "my_hbase_table");
```

Now we can run a Hive query against the pre-existing HBase table `my_hbase_table` that Hive sees as `hbase_table_2`:

```
hive> SELECT * FROM hbase_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401     val_401
402     val_402
403     val_403
404     val_404
406     val_406
407     val_407
409     val_409
Time taken: 9.452 seconds
```

Hive and HPL/SQL Integration

Note: This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

HPL/SQL includes a Hive UDF function that allows you to execute HPL/SQL scripts (user-defined functions written in HPL/SQL language) in Hive queries.

HPL/SQL uses the `hplsql_locals.sql` file to parse a prepared procedure that can be used in the Hive query. If you want to add and use multiple functions, you should add each function to the `hplsql_locals.sql` file.

For example, to call the `hello` function from a Hive query, you can add a `hello` function to the `hplsql_locals.sql` file:

```
CREATE FUNCTION hello(text STRING)
 RETURNS STRING
BEGIN
 RETURN 'Hello, ' || text || '!';
END;
```

There are two possible ways to run the HPL/SQL `hello` function:

Running HPL/SQL from Hive CLI/Hive Beeline

The `hplsql_locals.sql` file must be located in the directory where the Hive CLI is started or in the `/opt/mapr/hive/hive-<version>/bin` directory if you are using Beeline. After adding the `hello` function to the `hplsql_locals.sql` file, register the HPL/SQL UDF in Hive as follows:

```
CREATE TEMPORARY FUNCTION hplsql AS 'org.apache.hive.hplsql.Udf';
```

To use the `hello` function written in HPL/SQL language in Hive, use a query such as the following:

```
SELECT hplsql('hello(:1)', name) FROM users;
```

Running HPL/SQL from the HPL/SQL CLI

When you run HPL/SQL scripts using the HPL/SQL CLI, you can use user-defined functions the same way you use built-in functions:

```
hplsql -e "SELECT hello(name) FROM users;"
```

last-updated: Apr 11, 2022

The HPL/SQL CLI automatically connects to HiveServer2 using the configuration from the `hplsql-site.xml` file, registers the Hive UDF, and modifies the function call in the SQL statements. But you must ensure that the `hplsql_locals.sql` file containing the user-defined functions is located in the `/opt/mapr/hive/hive-<version>/bin` directory, where HiveServer2 can parse it.

For more information, see User-Defined Functions and Stored Procedures.

Hive and HCatalog Integration

The HCatalog on page 3404 library provides applications with a table view of the MapR File System layer in your cluster, expanding your application's options from read/write data streams to add table operations such as get row and store row. The HCatalog library stores the metadata required for its operations in the Hive Metastore.

The `hcat` utility can execute any of the data definition language (DDL) commands available in Hive that do not involve launching a MapReduce application. Internally, the `hcat` utility passes DDL commands to the `hive` program. Data stored in the MapR filesystem is serialized and deserialized through `InputStorageFormats` and `OutputStorageFormats` objects for records. Fields within a record are parsed with `SerDes`.

Warning:

The `hive-json-serde-0.2.jar` JSON serializer/deserializer has not implemented a `serialize()` method and as a result does not function.

The WebHCat server provides a REST-like web API for HCatalog. For more information about using WebHCat, see Hive and WebHCat Integration on page 3496.

This section contains the following topics:

Accessing HCatalog Tables from Hive

To access tables created in HCatalog in Hive, use the following command to append paths to your `HADOOP_CLASSPATH` environment variable:

```
export HADOOP_CLASSPATH=${HADOOP_CLASSPATH}:$HCAT_HOME/share/hcatalog/
storage-handlers/hbase/lib/hbase-storage-handler-<version>.jar:$HCAT_HOME/
share/hcatalog/hcatalog-core-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-pig-adapter-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-server-extensions-<version>-mapr.jar
```

Loading and Retrieving Data from Pig

To use the HCatalog library `HCatLoader` and `HCatStorer` to load and retrieve data from Pig:

1. Create a table with the `hcat` utility.

   ```
   hcat -e "create table hcatpig(key int, value string)"
   ```

2. Verify that the table and table definition both exist.

   ```
   hcat -e "describe formatted hcatpig"
   ```

3. Load data into the table from Pig: Copy the `$HIVE_HOME/examples/files/kv1.txt` file into the MapRFS file system, then start Pig and load the file with the following commands:

```
pig -useHCatalog -Dfs.default.name=maprfs://CLDB_Host:7222/
grunt> A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
grunt> STORE A INTO 'hcatpig' USING
org.apache.hive.hcatalog.pig.HCatStorer();
```

4. Retrieve data from the `hcatpig` table with the following Pig commands: Another way to verify that the data is loaded into the `hcatpig` table is by looking at the contents of `maprfs://user/hive/warehouse/hcatpig/`. HCatalog tables are also accessible from the Hive CLI. All Hive queries work on HCatalog tables.

```
B = LOAD 'default.hcatpig' USING
org.apache.hive.hcatalog.pig.HCatLoader();
dump B; // this should display the records in kv1.txt
```

Running MapReduce Applications

This example uses a sample MapReduce program named `HCatalogMRTest.java`.

1. From the command line, issue the following commands to define the environment:

```
export LIB_JARS=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar,
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar,
$HIVE_HOME/lib/libthrift-<version>.jar,
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar,
$HIVE_HOME/lib/libfb303-<version>.jar,
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar,
$HIVE_HOME/lib/slf4j-api-<version>.jar

export HADOOP_CLASSPATH=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar:
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar:
$HIVE_HOME/lib/libthrift-<version>.jar:
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar:
$HIVE_HOME/lib/libfb303-<version>.jar:
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar:
$HIVE_HOME/conf:
$HADOOP_HOME/conf:
$HIVE_HOME/lib/slf4j-api-<version>.jar
```

2. Compile `HCatalogMRTest.java`:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar HCatalogMRTest.java -d .
```

3. Create a JAR file:

```
jar -cf hcatmrtest.jar org
```

4. Create an output table:

```
hcat -e "create table hcatpigoutput(key int, value int)"
```

5. Run the job: At the end of the job, the file `hcatpigoutput` should have entries in the form `key, count`.

```
hadoop --config $HADOOP_HOME/conf jar ./hcatmrtest.jar
org.myorg.HCatalogMRTest -libjars $LIB_JARS hcatpig hcatpigoutput
```

Running Non-MapReduce Applications

This example uses a sample MapReduce program named `TestReaderWriter.java`.

1. Add the following JAR files to your `$HADOOP_CLASSPATH` environment variable with the following command:

```
export HADOOP_CLASSPATH=$HADOOP_CLASSPATH:/opt/
mapr/hive/hive-<version>/lib/antlr-runtime-3.4.jar:/opt/mapr/hive/
hive-<version>/lib/hive-cli-<veresion>-mapr.jar
```

2. Compile the test program with the following command:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar TestReaderWriter.java -d <directory>
```

3. Create a JAR file with the following command:

```
jar -cf hcatrwtest.jar org
```

4. Run the job with the following command:

```
hadoop jar /root/<username>/hcatalog/hcatrwtest.jar
org.apache.hive.catalog.data.TestReaderWriter -libjars $LIB_JARS
```

The last command should result in a table named `mytbl` that is populated with data.

Hive and WebHCat Integration

The WebHCat server provides a REST-like web API for HCatalog. Applications make HTTP requests to run Pig, Hive, and HCatalog DDL from within applications.

This topic contains the following sections:

Configuring the WebHCat Server

The properties to configure WebHCat are in the following file:

```
/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml
```

When you set up WebHCat, you can configure MapR File System and Zookeeper as storage.

1. To configure storage for WebHCat, add the MapRFS location property.

```
<property> <name>templeton.storage.class</name>
<value>org.apache.hive.hcatalog.templeton.tool.HDFSStorage</value> </
property> <property> <name>templeton.storage.root</name> <value>/user/
mapr/webhcat</value> <description>The path to the directory to use for
storage</description> </property>
```

2. To configure WebHCat for Pig:

a) Compress the Pig installation, then move the compressed file to the MapRFS layer.

```
# cd /opt/mapr/pig
# tar -czvf /tmp/pig-<version>.tar.gz pig-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/pig-<version>.tar.gz /user/mapr/webhcat/
```

b) Set the value of the `templeton.pig.archive` property to the location of the compressed file.

```
<property> <name>templeton.pig.archive</name> <value>maprfs:///user/
mapr/webhcat/pig-<version>.tar.gz</value> </property>
```

c) Set the value of the `templeton.pig.path` property to the path inside the compressed Pig file where the Pig binary is located.

```
<property>
    <name>templeton.pig.path</name>
    <value>pig-<version>.tar.gz/pig-<version>/bin/pig</value>
</property>
```

3. To configure WebHCat for Hive:

a) Compress the Hive installation, then move the compressed file to the MapR File System layer.

```
# cd /opt/mapr/hive
# tar -czvf /tmp/hive-<version>.tar.gz hive-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/hive-<version>.tar.gz /user/mapr/webhcat
```

b) Set the value of the `templeton.hive.archive` property to the location of the compressed file.

```
<property> <name>templeton.hive.archive</name> <value>maprfs:///user/
mapr/webhcat/hive-<version>.tar.gz</value> </property>
```

c) Set the value of the `templeton.hive.path` property to the path inside the compressed Hive file where the Hive binary is located.

```
<property>
     <name>templeton.hive.path</name>
     <value>hive-<version>.tar.gz/hive-<version>/bin/hive</value>
</property>
```

4. To Configure WebHCat for streaming:

a) Copy the Streaming JAR to the MapR File System layer.

```
# hadoop fs -put
/opt/mapr/hadoop/hadoop-<version>/contrib/streaming/
hadoop-<version>-dev-streaming.jar /user/mapr/webhcat
```

b) Set the `templeton.streaming.jar` property to the location of the streaming JAR.

```
<property> <name>templeton.streaming.jar</name> <value>maprfs:///user/
mapr/webhcat/hadoop-<version>-dev-streaming.jar</value> </property>
```

last-updated: Apr 11, 2022

Configure WebHCat Server to use SSL Encryption

You can configure WebHCat REST-API to use SSL (Secure Sockets Layer) encryption. The following WebHCat properties are added to enable SSL:

```
templeton.use.ssl
Default value: false
Description: Set this to true for using SSL encryption for  WebHCat server

templeton.keystore.path
Default value: <empty string>
Description: SSL certificate keystore location for WebHCat server

templeton.keystore.password
Default value: <empty string>
Description: SSL certificate keystore password for WebHCat server

templeton.ssl.protocol.blacklist
Default value: SSLv2,SSLv3
Description: SSL Versions to disable for WebHCat server

templeton.host
Default value: 0.0.0.0
Description: The host address the WebHCat server will listen on
```

Modifying the `webhcat-site.xml` file:

Configure the following properties in the `webhcat-site.xml` file to enable SSL encryption on each node where HWebHCat is installed:

```
<!-- WebHCat SSL -->
<property>
  <name>templeton.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>templeton.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>htempleton.keystore.password</name>
  <value><ssl-keystore-password></value>
</property>
```

Note: After running `/opt/mapr/server/configure.sh -R`, all properties needed to enable SSL encryption for WebHCat are added automatically to `webhcat-site.xml` on the Mapr-SASL secure cluster.

To check status of WebHCat server configured for SSL encryption, use following command:

```
curl -k 'https://<user>:<password>@<host>:50111/templeton/v1/status'
```

Requirements for Using Automatically Generated PEM Files
To use automatically generated PEM files for the WebHCat REST API on a MapR-SASL cluster, you need to have a cluster with a host name that consists at least of three parts: administrator user name and password, and WebHCat REST API host.

Check the status of the WebHCat REST API to make sure you have a cluster with a host name that consists of the administrator user name and password, and WebHCat REST API host service:

```
curl  --cacert /opt/mapr/conf/ssl_truststore.pem  -u
<cluster_admin_user>:<cluster_admin_password>
"https://<myhost.mapr.com>:50111/templeton/v1/status" -v
```

The sample output for this example is as follows:

```
* TCP_NODELAY set
* Connected to c74v610.mapr.com (192.168.122.254) port 50111 (#0)
* Cipher selection: ALL:!EXPORT:!EXPORT40:!EXPORT56:!aNULL:!LOW:!
RC4:@STRENGTH
* successfully set certificate verify locations:
CAfile: /opt/mapr/conf/ssl_truststore.pem
CApath: none
* (303) (OUT), TLS Unknown, Certificate Status (22):
* (303) (OUT), TLS handshake, Client hello (1):
* (303) (IN), TLS handshake, Server hello (2):
* (303) (IN), TLS handshake, Certificate (11):
* (303) (IN), TLS handshake, Server key exchange (12):
* (303) (IN), TLS handshake, Server finished (14):
* (303) (OUT), TLS handshake, Client key exchange (16):
* (303) (OUT), TLS change cipher, Client hello (1):
* (303) (OUT), TLS handshake, Finished (20):
* (303) (IN), TLS change cipher, Client hello (1):
* (303) (IN), TLS handshake, Finished (20):
* SSL connection using unknown / ECDHE-RSA-AES256-GCM-SHA384
* Server certificate:
*  subject: CN=*.mapr.com
*  start date: May 10 15:18:03 2018 GMT
*  expire date: Apr 16 15:18:03 2118 GMT
*  common name: *.mapr.com (matched)
*  issuer: CN=*.mapr.com
*  SSL certificate verify ok.
* Server auth using Basic with user 'mapr'
> GET /templeton/v1/status HTTP/1.1
> Host: c74v610.mapr.com:50111
> Authorization: Basic bWFwcjptYXBy
> User-Agent: curl/7.59.0
> Accept: */*
>
< HTTP/1.1 200 OK
< Set-Cookie:
hadoop.auth="u=mapr&p=mapr&t=multiauth&e=1526001586135&s=dgOtxP2Hs95DBl0Jyxy

GMT; Secure; HttpOnly
< Content-Type: application/json
< Transfer-Encoding: chunked
< Server: Jetty(7.6.0.v20120127)
<
* Connection #0 to host c74v610.mapr.com left intact
{"version":"v1","status":"ok"}
```

Managing the WebHCat Server

As of Hive 0.13-1504 and Hive 1.0-1504, WebHCat is managed by Warden. Therefore, you can start and stop WebHCat using maprcli and the Control System.

Starting the WebHCat Server

Applies to versions prior to Hive 0.13-1504 and Hive 1.0-1504:

```
# ./webhcat_server.sh start
```

Starting WebHCat Using the maprcli

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hcat -action start -nodes <space delimited
list of nodes>
```

Stopping WebHCat Using the maprcli

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hcat -action stop -nodes <space delimited
list of nodes>
```

Starting or Stopping WebHCat Using the Control System

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **WebHcat** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the WebHcat row under Manage Node Services to start WebHcat.

Checking the Error Logs

Go to the following folder:

```
/opt/mapr/hive/hive-<version>/logs/<user.name>/webhcat
```

Note: If you are running a Hive 0.13 version prior Hive 0.13-1504, go to the /tmp/<user.name>/webhcat folder to view the error logs.

Verifying the Server's Status

In a web browser, navigate to:

```
http://hostname:50111/templeton/v1/status?user.name=root
```

A healthy server will return the string `{"status":"ok","version":"v1"}`. You can change the port number from the default value of 50111 by editing the `webhcat-site.xml` file.

Running Jobs on the WebHCat Server

REST Calls in WebHCat

The base URI for REST calls in WebHCat is `http://<host>:<port>/templeton/v1/`. The following table lists elements appended to the base URI and DDL commands.

last-updated: Apr 11, 2022

URI	Description
Server Information	
/status	Shows WebHCat server status.
/version	Shows WebHCat server version.
DDL Commands	
/ddl/database	List existing databases.
/ddl/database/<mydatabase>	Shows properties for the database named *mydatabase*.
/ddl/database/<mydatabase>/table	Shows tables in the database named *mydatabase*.
/ddl/database/<mydatabase>/table/<mytable>	Shows the table definition for the table named *mytable* in the database named *mydatabase*.
/ddl/database/<mydatabase>/table/<mytable>/property	Shows the table properties for the table named *mytable* in the database named *mydatabase*.

Launching a MapReduce Job with WebHCat

WebHCat launches two jobs for each MapReduce job. The first job, `TempletonControllerJob`, has one map task. The map task launches the actual job from the REST API call. Check the status of both jobs and the output directory contents.

1. Copy the MapReduce example job to the MapRFS layer:

```
hadoop fs -put /opt/mapr/hadoop/hadoop-<version>/
hadoop-<version>-dev-examples.jar /user/mapr/webhcat/examples.jar
```

2. Use the `curl` utility to launch the job:

```
curl -s -d jar=examples.jar -d class="terasort" -d
arg=teragen.test -d arg=whop3 'http://localhost:50111/templeton/v1/
mapreduce/jar?user.name=<username>'
```

Launching a Streaming MapReduce Job with WebHCat

1. Use the `curl` utility to launch the job:

```
curl -s -d arg=teragen.test -d output=mycounts -d mapper=/bin/cat -d
reducer="/usr/bin/wc -w" 'http://localhost:50111/templeton/v1/mapreduce/
streaming?user.name=<username>'
```

2. Check the job status for both WebHCat jobs at the jobtracker page in the Control System.

Launching a Pig Job with WebHCat

1. Copy a data file into MapRFS:

```
hadoop fs -put $HIVE_HOME/examples/files/kv1.txt /user/<user name>/
```

2. Create a `test.pig` file with the following contents:

```
A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
STORE A INTO 'pig.output';
```

3. Copy the `test.pig` file into MapR filesystem:

```
hadoop fs -put test.pig /user/<user name>/
```

4. Run the Pig REST API command:

```
curl -s -d file=test1.pig -d arg=-v 'http://localhost:50111/templeton/v1/
pig?user.name=<username>'
```

5. Monitor the contents of the `pig.output` directory.

6. Check the JobTracker page for two jobs: `TempletonControllerJob` and `PigLatin`.

Launching a Hive Job with WebHCat

1. Create a table:

```
curl -s -d execute="create+external+table+ext3(t+TIMESTAMP)+location /
user/<user name>/ext3'" 'http://localhost:50111/templeton/v1/hive?
user.name=<username>'
```

2. Load data into the table:

```
curl -s -d execute="insert+overwrite+table+ext3+select+*+from+datetable"
'http://localhost:50111/templeton/v1/hive?user.name=<username>'
```

3. List the tables:

```
curl -s -d execute="show+tables" -d statusdir='hive.output' 'http://
localhost:50111/templeton/v1/hive?user.name=<username>'
```

   The list of tables is in `hive.output/stdout`.

The Job Queue

To show HCatalog jobs for a particular user, navigate to the following address:

```
http://<hostname>:<port>/templeton/v1/queue/?user.name=<username>
```

The default port for HCatalog is 50111.

Hive and Tez Integration
You can use Tez, instead of MapReduce, for generic data processing tasks. Tez significantly increases the processing speed. Tez, working with Hive, provides lower latency for interactive queries and higher throughput for batch queries.
Configuring Hive and Tez

To configure Hive on Tez, repeat the following steps on each node where you want to configure Hive on Tez. Tez mode for MR jobs is not compatible with all MR jobs, so do not set up the whole cluster to work on Tez.

There is a known issue related to the incomplete removal of previously installed Tez packages. The issue affects platforms on which Tez was installed but later removed using `sudo apt-get remove mapr-tez`. Because of Ubuntu-specific behavior and Tez source-code issues, the `remove` command removes Tez only partially in some installations. If this happens, an error is generated when you try to re-install Tez on Ubuntu, as described following in step 1. If you believe your installation might have this issue, you can prevent the error. Before performing the following steps, use the `purge` command to completely remove all previously installed Tez packages.

1. Install Tez if it is already not installed. To install Tez, run the following command:

On CentOS / RedHat	`yum install mapr-tez`
On SLES	`zypper install mapr-tez`
On Ubuntu	`apt-get install mapr-tez`

   Note: Repeat this step on each node where you want Hive on Tez to be configured.

2. Create the `/apps/tez` directory on MapR filesystem.

   To create, run the following commands:

```
hadoop fs -mkdir /apps
hadoop fs -mkdir /apps/tez
```

3. Upload the Tez libraries to the `/tez` directory on the MapR file system.

   To upload, run the following commands:

```
hadoop fs -put /opt/mapr/tez/tez-<version> /apps/tez
hadoop fs -chmod -R 755 /apps/tez
```

4. Verify the upload.

   To verify, run the following command:

```
hadoop fs -ls /apps/tez/tez-<version>
```

5. Set the Tez environment variables. To set, open the `/opt/mapr/hive/hive-<version>/conf/hive-env.sh` file, add the following lines, and save the file:

```
export TEZ_CONF_DIR=/opt/mapr/tez/tez-<version>/conf
export TEZ_JARS=/opt/mapr/tez/tez-<version>/*:/opt/mapr/tez/
tez-<version>/lib/*
export HADOOP_CLASSPATH=$TEZ_CONF_DIR:$TEZ_JARS:$HADOOP_CLASSPATH
```

   Note: Repeat this step on each node where you want Hive on Tez to be configured.

last-updated: Apr 11, 2022

6. Configure Hive for Tez engine. To configure, open the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file, add the following lines, and save the file.

```
<property>
  <name>hive.execution.engine</name>
  <value>tez</value>
</property>
```

Add the `hive.exec.pre.hooks`, `hive.exec.post.hooks`, and `hive.exec.failure.hooks` properties with value `org.apache.hadoop.hive.ql.hooks.ATSHook` to use the Hive queries page in the Tez UI.

Note: Starting from EEP 6.3.4, the following execution-hooks properties are managed by running `configure.sh` command with `-R` option.

```
<property>
  <name>hive.exec.pre.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>

<property>
  <name>hive.exec.post.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>

<property>
    <name>hive.exec.failure.hooks</name>
    <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>
```

Note: Repeat this step on each node where you want Hive on Tez to be configured.

7. Run `configure.sh` with the `-R` option.

```
/opt/mapr/server/configure.sh -R
```

Note: Starting in EEP 6.0.1 and later, Tez should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option.

8. Configure Tez shuffle on a secured cluster:

   Refer to Tez Shuffle on page 3511 to configure SSL encryption on shuffle.

Known Issues and Restrictions

Sqoop importing data into Hive fails when the entire cluster is configured to use Tez.	This is because of Sqoop's incompatibility with Tez. **Workaround:** Do not configure the entire cluster to use Tez.
Percentage sampling is not supported in `org.apache.hadoop.hive.ql.io.HiveInputFormat`.	Hive uses `org.apache.hadoop.hive.ql.io.HiveInputFormat` by default and so queries like `'SELECT * FROM tablename TABLESAMPLE(20 percent);'` will not work for Hive on Tez. **Workaround:** Instead of `org.apache.hadoop.hive.ql.io.HiveInputFormat`, use

last-updated: Apr 11, 2022

	`org.apache.hadoop.hive.ql.io.CombineHiveInputFormat`.
	To change input format, do one of the following:
	• Set `hive.tez.input.format` in hive shell. For example:
	`hive> set hive.tez.input.format=org.apache.hadoop.hive.ql.io.CombineHiveInputFormat;`
	• Add `org.apache.hadoop.hive.ql.io.CombineHiveInputFormat` to `hive-site.xml` file. For example:
	`<property> <name>hive.tez.input.format</name> <value>org.apache.hadoop.hive.ql.io.CombineHiveInputFormat</value> </property>`

Hive on Tez does not work well with Sequence Files Schema changes	TEZ-2741
Limitations with common joins	HIVE-11693: The CommonMergeJoinOperator only sets big table position when it has inputs for big table. If the input is empty, the method is not called.
HiveServer2 on Tez doesn't support concurrent queries within one session	HIVE-9223: When multiple queries are submitted in the same HS2 session concurrently, some queries fail with an error.

Tez upgrade issues	• No support for preserving configuration from EEP-5.0.0 and EEP-4.1.1 (ECO-1803) to EEP-6.0.0(1808) or EEP-5.0.1(1808) on Ubuntu.
	• No support for preserving Tomcat configuration from previous EEPs to EEP-6.0.0 (1808).
	• You should manually stop the Tomcat service and delete the tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:
	`EEP-4.0.0`
	`EEP-4.1.0`

Tez shuffle SSL encryption issue	During a shuffle phase, the `javax.net.ssl.SSLException` error could occur on a multi-node cluster due to insufficient Tez shuffle SSL encryption configuration, see Tez Shuffle on page 3511 for a solution.

SQL Limitations

The following is a list of SQL limitations on Hive on Tez:

Issue	Summary
HIVE-11693	CommonMergeJoinOperator throws exception with Tez.

last-updated: Apr 11, 2022

Issue	Summary
HIVE-9989	Hive on Tez group by with cast(NULL AS BIGINT) throws NPE.
HIVE-11270	Tez gives different responses when run on Physical tables and logical views.
HIVE-9223	HiveServer2 on Tez doesn't support concurrent queries within one session.
HIVE-13623	Hive on Tez produces wrong results when withClause and (outer) joins.
TEZ-2741	Hive on Tez does not work well with Sequence Files Schema changes.
HIVE-13926	Cannot limit reduce (not both Map and Reduce) memory in Tez engine.

Hive-on-Tez User Interface

This section describes how to install, configure, manage, and start the Hive-on-Tez user interface.

Warning: The Hive-on-Tez user interface supports RM HA only starting from the 1803 release (EEP 4.1.1 and EEP-5.0.0).

Installing the Hive-on-Tez User Interface

This topic describes installation of the Hive-on-Tez user interface by using the MapR Installer or manual steps.

Installation Using the MapR Installer

When you use the MapR Installer to install Tez, the timeline server for the Hive-on-Tez user interface is installed automatically. If the **Enable MapR Secure Cluster** option is enabled in the MapR Installer, the timeline server is installed to be secure.

The Tomcat server is installed into this folder:

```
/opt/mapr/tez/tez-<version>/tomcat/apache-tomcat-<version>
```

To start using the Hive-on-Tez user interface if the **Enable MapR Secure Cluster** option is enabled or if the cluster is Kerberized, you must log in to the timeline server user interface:

```
https://<hostname>:8190
```

Manual Installation

To install the Hive-on-Tez user interface manually:

1. Install and configure `mapr-tez` as described in Configuring Hive and Tez on page 3502.
2. Install the timeline server:

On CentOS / Red Hat	`yum install mapr-timelineserver`
On SLES	`zypper install mapr-timelineserver`
On Ubuntu	`apt-get install mapr-timelineserver`

Note: Install the timeline server on a single node. The Hive-on-Tez user interface does not support High Availability (HA).

last-updated: Apr 11, 2022

Configuring the Timeline Server to Use the Hive-on-Tez User Interface

This topic describes how to configure the timeline server to use the Hive-on-Tez user interface. This topic includes security configuration information.

When the timeline server is installed using the MapR Installer, the installer secures the timeline server automatically. When you install the timeline server manually, use these steps.

Note: This procedure assumes that you have previously configured the cluster using the `configure.sh` script.

1. Run `configure.sh -R` (on all Hive nodes), replacing `<hostname>` with the name of your timeline server node:

```
sudo /opt/mapr/server/configure.sh -R -TL <hostname>
```

   Note: Make sure the hostname matches the CN in ssl_keystore for secure clusters. If not, all hive and yarn jobs fail. The hostname can be obtained using the `$hostname -f` command.

   Running `configure.sh -R` configures the timeline server properties in `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` for enhanced security.

2. To use the timeline server with Kerberos, you need to make additional entries to the `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` file. Replace the following variables with real values:
   - MAPR_PRINCIPAL
   - PATH_TO_KEYTAB
   - HTTP_PRINCIPAL

```
<property>
  <name>yarn.timeline-service.principal</name>
  <value>MAPR_PRINCIPAL</value>
</property>
<property>
<name>yarn.timeline-service.keytab</name>
  <value>PATH_TO_KEYTAB</value>
</property>
<property>
  <name>yarn.timeline-service.http-authentication.kerberos.principal</
name>
  <value>HTTP_PRINCIPAL</value>
</property>
<property>
 <name>yarn.timeline-service.http-authentication.kerberos.keytab</name>
 <value>PATH_TO_KEYTAB</value>
</property>
```

3. Restart the resource manager:

```
maprcli node services -name resourcemanager -action restart -nodes
<hostname>
```

Configuring the Tomcat Server

This topic describes how to configure and manage the Tomcat server for the Hive-on-Tez user interface.

last-updated: Apr 11, 2022

Extracting the Tomcat Server

You can only extract the Tomcat server after you manually install Tez. Tez has a built-in Tomcat Server archive with the latest version. You can find the archive at:

```
$TEZ_HOME/tomcat/tomcat.tar.gz
```

To extract the Tomcat server, use these commands in the command line:

```
cd $TEZ_HOME/tomcat/
sudo tar -zxvf tomcat.tar.gz -C $TEZ_HOME/tomcat
```

Change the permissions for the tomcat directory to the user who will be running the Tomcat server:

```
sudo chown -R <$USER>:<$USER_GROUP> $TEZ_HOME/tomcat
```

Configuring the Timeline Server Base URL and Resource Manager WEB URL

To set the `timelineBaseUrl` and `RMWebUrl`, update the Tez configuration file.

For EEP 6.2.0 and earlier, the file location is:

```
nano $TEZ_HOME/tomcat/apache-tomcat-<version>/webapps/tez-ui/config/
configs.env
```

For EEP 6.3.0 and later, the file location is:

```
nano $TEZ_HOME/tomcat/apache-tomcat-<version>/webapps/tez-ui/config/
configs.js
```

To configure the Timeline Server Base URL and Resource Manager WEB URL:

1. Replace TIME_LINE_BASE_URL with the real URL, for example:
   - For a non-secure configuration:

     ```
     'http://localhost:8188'
     ```

   - For a secure configuration:

     ```
     'https://localhost:8190'
     ```

2. Replace RM_WEB_URL with the real URL, for example:
   - For a non-secure configuration:

     ```
     'http://localhost:8088'
     ```

   - For a secure configuration:

     ```
     'https://localhost:8090'
     ```

- For a proxy server, specify the user-defined URL in the `yarn-site.xml` file, as shown:

```
<property>
   <name>yarn.web-proxy.address</name>
   <value><hostname>:<port></value>
</property>
```

  Replace RM_WEB_URL with the value specified as the `yarn.web-proxy.address` property.

Configuring SSL for the Tomcat Server on a Secure Cluster

To start the Tomcat server with the exposed SSL port, edit the following properties in the `$TEZ_HOME/tomcat/apache-tomcat-9.0.1/conf/server.xml` file, replacing `<ssl-keystore-password>` with the real SSL keystore password.

1. Find default configuration of the exposed port:

```
<Connector port="9383"
  protocol="HTTP/1.1"
  connectionTimeout="20000"
  redirectPort="8443" />
```

2. Change configuration for SSL:

```
<Connector port="9393"
SSLEnabled="true"
maxThreads="150"
scheme="https"
secure="true"
clientAuth="false"
sslProtocol="TLS"
keystoreFile="/opt/mapr/conf/ssl_keystore"
keystorePass="<ssl-keystore-password>"/>
```

Starting and Stopping the Tomcat Server

To start the Tomcat server, run this script:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/bin/startup.sh
```

To stop the Tomcat server, run this script:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/bin/shutdown.sh
```

Note: The `timelineBaseUrl` maps to the YARN Timeline Server, and the `RMWebUrl` maps to the YARN Resource Manager. For default port information, see Ports Used by MapR Software on page 2290.

Integrating the Hive-on-Tez User Interface with Tez

This topic describes how to integrate the Hive-on-Tez user interface with Tez.

last-updated: Apr 11, 2022

1. Add the following entry to the `/opt/mapr/tez/tez-<version>/conf/tez-site.xml` file, replacing `<hostname>:<port>` with the real host name. You can use 9383 or 9393 for the port. 9383 is HTTP and 9393 is HTTPS Tomcat port for the Hive-on-Tez user interface.

```
<property>
  <description>Enable Tez to use the Timeline Server for History
Logging</description>
  <name>tez.history.logging.service.class</name>

<value>org.apache.tez.dag.history.logging.ats.ATSHistoryLoggingService</
value>
</property>

<property>
  <description>URL for where the Tez UI is hosted</description>
  <name>tez.tez-ui.history-url.base</name>
   <value>http(s)://<hostname>:<port>/tez-ui/</value>
</property>
```

Repeat this step on each node where you want the Hive-on-Tez user interface to be configured.

Connecting to the Hive-on-Tez User Interface

This topic describes how to connect to the Hive-on-Tez user interface.

To start using the Hive-on-Tez user interface on a MapR secure or Kerberized cluster or non-secure cluster, you must log in to the timeline server user interface and RM UI:

```
https://<hostname>:8190
```

```
https://<hostname>:8090
```

To connect to the Hive-on-Tez user interface on secure clusters, use a browser to navigate to:

```
https://<hostname>:9393/tez-ui/
```

where `<hostname>` is the host where the Tomcat server is running.

Hive-on-Tez User Interface Known Issues

This topic describes known issues that you should be aware of while troubleshooting.

Timeline Server Known Issues

(**Issue 29538**) After an incremental install or rolling upgrade to MapR 6.1, the timeline server does not start. To resolve this issue, add the following entry to `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-env.sh`:

```
export YARN_TIMELINESERVER_OPTS="${YARN_TIMELINESERVER_OPTS} $
{MAPR_LOGIN_OPTS}"
```

To grant administrative privileges to any user(s), modify `yarn-site.xml`, as shown:

```
<property>
  <name>yarn.admin.acl</name>
  <value><user_name></value>
</property>
```

After the `yarn.admin.acl` property takes effect, the user specified by `<user_name>` has administrative privileges and access to all jobs.

For example, User-A can access all the jobs owned by User-A, by default. If User-A needs access to jobs owned by other users, administrative privileges can be granted to User-A through the `yarn.admin.acl` property.

Tez Shuffle

Tez uses `org.apache.hadoop.mapred.ShuffleHandler` provided by MapReduce version 2.0 (MRv2) as an auxiliary service, which you can choose to configure via the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/mapred-site.xml` file.

On a secured cluster, Tez shuffle, SSL encryption configuration is enabled in `/opt/mapr/tez/tez-<version>/conf/tez-site.xml` by default:

`tez.runtime.shuffle.ssl.enable`	`true`
`tez.runtime.shuffle.keep-alive.enabled`	`true`

Also, you must configure Tez shuffle for YARN by adding the following property to the `mapred-site.xml` file. Edit the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/mapred-site.xml` file:

`mapreduce.shuffle.ssl.enabled`	`true`

Queue Management with Hive-on-Tez

HiveServer2 provides built-in functionality to set-up and handle a pool of Tez sessions in default queues. Tez initiates a session and keeps it alive to run sequential queries. Quereies can be submitted through HiveServer2 clients, such as Beeline and the Hive CLI. You can manage queues through properties in `hive-site.xml`.

Queue management is strongly connected to the type of YARN Scheduler used. By default, a MapR cluster uses Fair Scheduler and Hive-on-Tez to run queries in queues with a user name. If a query is submitted from the Hive CLI, the real user name is used. If a query is submitted from a HiveServer2 client, such as Beeline, the queue name depends on the HiveServer2 impersonation configuration property, `hive.server2.enable.doAs`, where the queue name could be the real user name or the user name of the Hiveserver2 process.

With Capacity Scheduler, Hive queries submitted from the CLI and Beeline are configured through the `capacity-scheduler.xml` file. Default queue names are chosen from the scheduler settings, but you can also use the `tez.queue.name=<queue_name>` property to run queries in a specific queue.

Application Masters (AM) are strongly bound to YARN. You cannot change the queue for an AM that is already started. If impersonation is enabled for HiveServer2, a new AM starts next to an existing AM for a default queue. Do not use or close a default queue at the end of a lifetime.

Note: HiveServer2 works with or without impersonation. Impersonation is set through the `hive.server2.enable.doAs` property.

Run Queries in a Specific Queue

If you want all queries to run in a specific queue, you can configure a queue name through the `tez.queue.name` property. When you configure a queue name through the `tez.queue.name` property, Tez sets the queue name for all jobs submitted from the client to the configured `tez.queue.name`. You can set this property before each query through the Hive SET command, as shown:

```
set tez.queue.name=<queue_name>;
```

last-updated: Apr 11, 2022

Or, you can set the property in the `hive-site.xml` file, as shown:

```
<property>
   <name>tez.queue.name</name>
   <value>my_queue</value>
</property>
```

Important: If you set `tez.queue.name` in hive-site.xml, and you want the queue name to persist across all queries in the session, you must also set the `hive.server2.tez.unset.tez.queue.name` property in hive-site.xml to `false`, as shown:

```
<property>
   <name>tez.queue.name</name>
   <value>my_queue</value>
</property>
<property>
    <name>hive.server2.tez.unset.tez.queue.name</name>
    <value>false</value>
</property>
```

If `hive.server2.tez.unset.tez.queue.name` is set to `true`, Hive will not persist the `tez.queue.name` across queries and instead uses the default cluster queue names.

Configuration Properties

HiveServer2 has several settings related to queue management. Specify the following properties in the `hive-site.xml` file:

Property	Description	Default Value
tez.queue.name	The queue name for all jobs submitted from a given client. Set through the Hive CLI via the SET command before running a query or through hive-site.xml. If you set the property through hive-site.xml, and you want the setting to persist across all queries that run, set `hive.server2.tez.unset.tez.queue.name` to `false`.	No default. Must be explicitly set.
hive.server2.tez.initialize.default.sessions	When set to true, enables you to use HiveServer2 without turning on Tez for HiveServer2. Useful when you want to run queries over Tez without the pool of sessions.	false
hive.server2.tez.default.queues	A list of comma-separated values that correspond to YARN queues of the same name. When HiveServer2 is launched in Tez mode, this configuration must be set to enable multiple Tez sessions to run in parallel on the cluster.	empty string
hive.server2.tez.sessions.per.default.queue	A positive integer that determines the number of Tez sessions that should launch in each of the queues specified by `hive.server2.tez.default.queues`. Determines the parallelism on each queue. For example, if you specify two default queues and two sessions per default queue, four application masters start.	1
hive.server2.tez.session.lifetime	Defines the lifetime of the Tez sessions launched by HiveServer2 when default sessions are enabled. Set to `0` to disable session expiration.	162h

last-updated: Apr 11, 2022

Property	Description	Default Value
hive.server2.tez.unset.tez.queue.name	Controls whether the `tez.queue.name` persists across all queries in a session. Must be set to `false` for the `tez.queue.name` to persist. When set to `true`, the `tez.queue.name` only applies to the first query that runs; thereafter, the default cluster queue names are used.  **Note:** This functionality was introduced in EEP 7.01 and EEP 6.3.2. A patch for previous EEP versions is available. See Applying a Patch.	true

Managing Hive Services

This section includes the following topics:

Starting Hive

You can start the Hive shell from `HIVE_HOME/bin/` with the `hive` command. Example:

```
/opt/mapr/hive/hive-<version>/bin/hive
```

When the Hive shell starts, it reads an initialization file called `.hiverc` which is located in the `HIVE_HOME/bin/` or `$HOME/` directories. You can edit this file to set custom parameters or commands that initialize the Hive command-line environment, one command per line.

When you run the Hive shell, you can specify a MySQL initialization script file using the `-i` option. Example:

```
/opt/mapr/hive/hive-<version>/bin/hive -i <filename>
```

Setting the Execution Engine

Consider the following definitions:

- Runtime: execution time of job.
- Session time: time from the start of Hive shell or Beeline until you exit.

You can change the execution engine during a session (session time), but not while executing job in the session (runtime). If you specify the execution engine before starting the job, it will override the `hive.execution.engine` property in `hive-site.xml` file. For example, to specify the execution engine:

```
hive> set hive.execution.engine=tez;
hive> *perform some query here*
```

If you open another session of hive shell or beeline, you will not see the setting in the session from before and you can set needed properties for every session.

MapR Technologies highly recommends configuring Tez as an execution engine instead of MR execution engine. MR execution engine is deprecated in Hive.

If you are currently using the MR execution engine for accessing Hive CLI and HS2, Hive will throw the following warning message:

```
Hive-on-MR is deprecated in Hive 2 and may not be available in the future
versions. Consider using a different execution engine (i.e. spark, tez) or
using Hive 1.X releases.
```

To install and configure Tez as an execution engine for Hive, see Configuring Hive and Tez.

last-updated: Apr 11, 2022

Managing Hive Metastore

The Hive Metastore is started automatically by the warden at installation time if the `mapr-hivemetastore` package is installed. It is sometimes necessary to start or stop the service (for example, after changing the configuration). You can start and stop Hive Metastore in two ways:

- Using the `maprcli node services` command - Using this command, you can start Hive Metastore on multiple nodes at one time.
- Using the MapR Control System

To start Hive Metastore using the maprcli:

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprcli node services command:

```
/opt/mapr/bin/maprcli node services -name hivemeta -action start -nodes
<space delimited list of nodes>
```

To stop Hive Metastore using the maprcli:

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hivemeta -action stop -nodes <space
delimited list of nodes>
```

To start or stop Hive Metastore using the Control System:

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **Hive Metastore** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the Hive Metastore row under Manage Node Services to start Hive Metastore.

Managing Hiveserver2

Hiveserver2 is started automatically at installation time by the warden if the `mapr-hiveserver2` package is installed. It is sometimes necessary to start or stop the service (for example, after changing the configuration). You can start and stop Hiveserver2 in two ways:

- Using the `maprcli node services` command - Using this command, you can start Hiveserver2 on multiple nodes at one time.
- Using the MapR Control System

To start Hiveserver2 using the maprcli:

1. Make a list of nodes on which Hiveserver2 is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hs2 -action start -nodes <space delimited
list of nodes>
```

To stop Hiveserver2 using the maprcli:

1. Make a list of nodes on which Hiveserver2 is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hs2 -action stop -nodes <space delimited
list of nodes>
```

To start or stop Hiveserver2 using the Control System:

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **Hiveserver2** to open the Nodes screen displaying all the nodes on which Hiveserver2 is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the Hiveserver2 row under Manage Node Services to start Hiveserver2.

Connecting to Hive

This section contains the following topics:

Connecting to Hive Metastore

The connection requirements Hive Metastore clients use to connect to Hive Metastore is based on the Hive Metastore authenication method:

Authentication Method	Connection Requirements
MapR-SASL	Client nodes require the following: • They are configured to use MapR-SASL when authenticating with Hive Metastore. • A valid MapR ticket.
Kerberos	Client nodes require the following: • They are configured to use Kerberos when authenticating with Hive Metastore. • A valid Kerberos ticket.
No Authentication	If the cluster is not secure, client nodes do not require any MapR tickets.

Connecting to HMS is provided by the thrift service. You can configure it in hive-site.xml with hive.metastore.uris property:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n<:9083</value>
  <description>IP address (or fully-qualified domain name) and port of the
metastore host</description>
</property>
```

Connecting to HiveServer2

The method that HiveServer2 clients use to connect to HiveServer2 is based on the HiveServer2 Authentication method and the type of client.

last-updated: Apr 11, 2022

Using JDBC or Beeline to Connect to HiveServer2
The HiveServer2 authentication method and client type determine how the HiveServer2 clients connect to HiveServer2.

> **Tip:** For details on how to install and use ODBC to connect to Hive, see Using ODBC to Connect to HiveServer2 on page 3522. When connecting to Hive via ODBC, the client must have a valid MapR or Kerberos ticket.

Using JDBC or Beeline to Connect to HiveServer2

The default port for HiveServer2 is 10000.

The following table lists HiveServer2 authentication mechanisms with the connection parameters required in the JDBC connection string. For a complete list of the JDBC connection string parameters, refer to the next section, Hive JDBC Connection String Parameters.

HiveServer2 Authentication	Connection Requirements
No Authentication	**Connection String:** `jdbc:hive2://<hs2_hostname>:10000<database>;` You must enter a valid user name. **For encryption, JDBC requires a truststore and an optional truststore password.** • **Connection String with Encryption**: `jdbc:hive2://<hs2_hostname>:10000/<database>;` You must enter a valid user name.`ssl=true;sslTrustStore=<path-to-truststore>;sslTrustStorePassword=<password>` • **Connection String with Encryption (truststore passed in JVM arguments)**: `jdbc:hive2://<hs2_hostname>:<port>/<database>;ssl=true` **Note:** Prior to connecting to an application that uses JDBC, such as Beeline, you can run the following command to pass the truststore parameters as Java arguments: `export HADOOP_OPTS="-Djavax.net.ssl.trustStore=<path-to-trust-store-file> -Djavax.net.ssl.trustStorePassword=<password>"`
MapR-SASL (included as part of the secure by default configuration)	**Connection String**: `jdbc:hive2://<hs2_hostname>:10000/<database>;auth=maprsasl;ssl=true;` MapR-SASL encryption is enabled by default. For more information, see Configuring JDBC Connection String with SSL Encryption Enabled or Disabled. **Note:** MapR-SASL is not supported for Hive in HTTP mode. **Connection for Java Application**: Use the `-D` flag to append the JVM argument: `-Dhadoop.login=maprsasl`.

last-updated: Apr 11, 2022

HiveServer2 Authentication	Connection Requirements
PAM	**Connection String**: `jdbc:hive2://<hs2_hostname>:10000/<database>;user=<user>;password=<password>`
PAM + SSL (included as part of the secure by default configuration)	**Connection String**: `jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;user=<user>;password=<password>`. For more information, see Configuring JDBC Connection String with SSL Encryption Enabled or Disabled.
Kerberos	**Connection String**: `jdbc:hive2://<hostname>:10000/default;principal=mapr/<FQDN@REALM>` **Connection for Java Application**: Use the `-D` flag to append the JVM argument: `-Dhadoop.login=hybrid` **Note:** The client nodes must also have a Kerberos ticket and be configured to connect to HiveServer2 to use Kerberos.
LDAP	**Connection String:** `jdbc:hive2://<hs2_hostname>:10000/<database>;user=<ldap_user>;password=<ldap_password>`
ZooKeeper	**Connection String**: `jdbc:hive2://<hostname>:<port>,<hostname>:<port>/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2` **Example**: `hive --service beeline -u 'jdbc:hive2://zookeeper1.com:5181,zookeeper2.com:5181,zookeeper3.com:5181/;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2' -n mapr -p`

Hive JDBC Connection String Parameters

The following example shows a common Hive JDBC connection string:

```
jdbc:hive2://zookeeper_quorum|hs2_host:port/[db]
[;principal=<hs2_principal>/<hs2_host>|_HOST@<KDC_REALM>]
[;transportMode=binary|http][;httpPath=<http_path>]
[;serviceDiscoveryMode=zookeeper;zooKeeperNamespace=<zk_namespace>]
[;auth=maprsasl][;ssl=true|false][;sslKeyStore=<key_store_path>]
[;keyStorePassword=<key_store_password][;sslTrustStore=<trust_store_path>]
[;trustStorePassword=<trust_store_password>][;twoWay=true|false]
```

The following table lists all the Hive JDBC connection string parameters with default values where applicable:

JDBC Parameter	Default	Comment
zookeeper_quorum		Zookeeper quorum. Used only if HA mode for HiveServer2 is enabled.

last-updated: Apr 11, 2022

hs2_host		The hostname of the node with an active HS2 server running.
port	10000/10001	HiveServer2 port. Defaults to 10000 in binary mode. Defaults to 10001 in HTTP transport mode.
[db]	default	The database name to which you want to connect.
[;principal=<hs2_principal>/<hs2_host>|_HOST@<KDC_REALM>]		Kerberos principal. Used with Kerberos security only.
[;transportMode=binary|http]	binary	HS2 uses a TThreadPoolServer (from Thrift) for TCP (binary) mode, or a Jetty server for the HTTP mode. HTTP mode is required when a proxy is needed between the client and server, for example, for load balancing or security reasons.
[;httpPath=<http_path>]	cliservice or /	The corresponding HTTP endpoint. The default value is cliservice or /. See conf hive.server2.thrift.http.path
[;serviceDiscoveryMode=zookeeper;zooKeeperNamespace=<zk_namespace>]		<zk_namespace> is the parent node in ZooKeeper used by HiveServer2 when supporting dynamic service discovery.
[;auth=maprsasl]		Used with MapR SASL security.
[;ssl=true|false]	false	Used to enable SSL encryption.
[;sslKeyStore=<key_store_path>]	Default value is read from $MAPR_HOME/conf/ssl-client.xml	This parameter only takes effect when ssl=true. Path is the path to the keystore.
[;keyStorePassword=<key_store_password]	Default value is read from $MAPR_HOME/conf/ssl-client.xml	This param will take effect only when ssl=true. Keystore password.
[;sslTrustStore=<trust_store_path>]	Default value is read from $MAPR_HOME/conf/ssl-client.xml	This param will take effect only when ssl=true. Path is the path to the truststore.
[;trustStorePassword=<trust_store_password>]	Default value is read from $MAPR_HOME/conf/ssl-client.xml	This parameter only takes effect when ssl=true. Password is the truststore password.

[;twoWay=true|false]		HIVE-10447 enabled the JDBC driver to support 2-way SSL in HTTP mode. Currently, HiveServer2 does not support 2-way SSL. This features is useful when there is an intermediate server, such as Knox, which requires the client to support 2-way SSL.

Beeline Examples

This page shows examples for connecting to HiveServer2 using Beeline.

The following table is a guide for interpreting the examples on this page. In the examples, replace the variables (information in brackets) with your site-specific values. Be sure to remove the brackets when you insert your information:

Variable	Description
<hs2_hostname>	The name of the host where HiveServer2 is installed.
<database>	The database name to connect to.
<username>	The JDBC username.
<password>	The password for the JDBC user.
<FQDN@realm>	Fully qualified domain name & Kerberos realm.

Using Beeline with no Encryption and no Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;: <username>
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Using Beeline with Encryption and no Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp
Connecting to jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp
Enter username for jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp:
<username>
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Connecting to HiveServer2 with MapR-SASL Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;auth=maprsasl;ssl=true
Connecting to jdbc:hive2://<hs2_hostname>:10000/
<database>;auth=maprsasl;ssl=true
19/01/31 12:15:33 [main]: WARN maprsasl.MaprSaslClient: SASL
```

last-updated: Apr 11, 2022

```
Server qopProperty: auth-confis different from Client:
auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-1901)
Driver: Hive JDBC (version 2.3.3-mapr-1901)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Starting from EEP 6.0.0, with secure by default configuration, it is a default connection string for a secure cluster. For more information, see Configuring JDBC Connection String with SSL Encryption Enabled or Disabled.

Using Beeline with PAM Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;: <username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>;:
<password>
Connected to: Apache Hive (version 2.3.3-mapr-1901)
Driver: Hive JDBC (version 2.3.3-mapr-1901)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Connecting to HiveServer2 with ZooKeeper

```
hive --service beeline -u
'jdbc:hive2://
zookeeper1.com:5181,zookeeper2.com:5181,zookeeper3.com:5181/;serviceDiscover
yMode=zooKeeper;zooKeeperNamespace=hiveserver2' -n mapr -p
```

Connecting to HiveServer2 with PAM Authentication and SSL Encryption

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>: <username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>: <password>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Starting from EEP 6.0.0, with secure-by-default configurations, the default connection string is for a secure cluster. For more information, see Configuring JDBC Connection String with SSL Encryption Enabled or Disabled.

Using Beeline with Kerberos

Beeline must pass the Kerberos principal for HiveServer2 in the JDBC connection string. The connection strings you pass to Beeline must use the principal name that you configured for HiveServer2.

The following example shows a sample Beeline authentication with Kerberos:

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
```

```
<database>;principal=mapr<FQDN@REALM>
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;principal=mapr/
<FQDN@REALM>
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/def>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Using Beeline with Encryption but no Authentication (truststore parameters passed as JVM arguments)

```
Hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:1000/<database>;ssl=true
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true:
<username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true:
<password>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Generating a Kerberos Ticket

Use the `kinit` utility to generate the ticket and then use `klist` to verify that a ticket exists.

```
# kinit <username>/<FQDN@REALM>
# klist

Credentials cache: API:501:9
        Principal: username/<FQDN@REALM>
    Cache version: 0

Server: krbtgt/<FQDN@REALM>
Client: username/<FQDN@REALM>
Ticket etype: aes128-cts-hmac-sha1-96
Ticket length: 256
Auth time:  Jun 11 10:01:48 2014
End time:   Jun 12 18:01:34 2014
Renew till: Jun 18 10:01:48 2014
Ticket flags: pre-authent, initial, renewable, forwardable
Addresses: addressless
```

Configuring JDBC Connection String with SSL Encryption Enabled or Disabled

You can configure a JDBC connection string with SSL encryption enabled or disabled.

SSL encryption to HiveServer2 is enabled (`hive.server2.use.SSL=true`)

The following table describes the JDBC connection string when SSL encryption is enabled between the Hive client and HiveServer2.

last-updated: Apr 11, 2022

Table

Authentication Type	JDBC Parameter	Example
PAM	`ssl=true`	`jdbc:hive2://<hostname>:10000/default;ssl=true <login> <password>`
MapR-SASL	`ssl=true`	`jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true`
Kerberos	`ssl=true`	`jdbc:hive2://<hostname>:10000/default;principal=<user/fqdn@EXAMPLE.COM>;ssl=true`

SSL encryption to HiveServer2 is disabled (`hive.server2.use.SSL=false`)

The following table describes the JDBC connection string when SSL encryption is disabled between the Hive client and HiveServer2.

Table

Authentication Type	JDBC Parameter	Example
PAM	--	`jdbc:hive2://<hostname>:10000/default; <login> <password>`
MapR-SASL	--	`jdbc:hive2://<hostname>:10000/default;auth=maprsasl`
Kerberos	--	`jdbc:hive2://<hostname>:10000/default;principal=<user/fqdn@EXAMPLE.COM`

Using ODBC to Connect to HiveServer2

This section contains details about setting up and using the ODBC Connector for Hive.

Before You Begin

The MapR Hive ODBC Connector is an ODBC driver for Apache Hive 0.7.0 and later that complies with the ODBC 3.52 specification. You can download the Hive ODBC connector from https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Hive/. After downloading the driver, refer to documentation for Hive ODBC Driver to install and configure the driver.

The Hive ODBC Driver supports the following Advanced Options:

- Enable Auto Reconnect
- Driver Config Take Precedence
- Fast SQL Prepare
- Get Tables With Query
- Invalid Session Auto Recover
- Show System Table

- Socket Timeout
- Default String Column Length
- Rows Fetched Per Block
- Use Native Query

To use the ODBC driver, configure a *Data Source Name* (DSN), a definition that specifies how to connect to Hive. DSNs are typically managed by the operating system and may be used by multiple applications. Some applications do not use DSNs. You will need to refer to your particular application's documentation to understand how it connects using ODBC.

The standard query language for ODBC is SQL. HiveQL, the standard query language for Hive, includes a subset of ANSI SQL-92. Applications that connect to Hive using ODBC may need queries altered if the queries use SQL features that are not present in Hive. Applications that use SQL will recognize HiveQL, but might not provide access to HiveQL-specific features such as multi-table insert.

Please refer to the Hive Language Manual for up-to-date information on HiveQL.

The SQL Connector

The SQL Connector feature translates standard SQL-92 queries into equivalent HiveQL queries. The SQL Connector performs syntactical translations and structural transformations. For example:

- Quoted Identifiers: When quoting identifiers, HiveQL uses back quotes (`), while SQL uses double quotes ("). Even when a driver reports the back quote as the quote character, some applications still generate double-quoted identifiers.
- Table Aliases: HiveQL does not support the AS keyword between a table reference and its alias.
- The `JOIN`, `INNER JOIN`, and `CROSS JOIN` SQL syntaxes are translated to the HiveQL `JOIN` syntax.
- SQL `TOP N` queries are transformed to HiveQL `LIMIT` queries.

Hive ODBC Connector on Linux

System Requirements

- The 32-bit and 64-bit version of the following operating systems:
  - Red Hat® Enterprise Linux® (RHEL) 6 or 7
  - CentOS 6 or 7
  - SUSE Linux Enterprise Server (SLES) 11 or 12
  - Debian 8 or 9
  - Ubuntu 14.04, 16.04, or 18.04
- 45 MB of available disk space.
- An installed ODBC driver manager:
  - iODBC 3.52.7 or above (OR)
  - unixODBC 2.2.12 or above

The MapR ODBC Driver with SQL Connector for Apache Hive requires a Hadoop cluster with the Hive service installed and running. The MapR ODBC Driver with SQL Connector for Apache Hive is suitable for use with all versions of Hive. Download the ODBC connector from the following location: MapR_Hive.

The RPM files are applicable for:

- Red Hat® Enterprise Linux® (RHEL) 6 or 7
- CentOS 6 or 7
- SUSE Linux Enterprise Server (SLES) 11 or 12

The DEB files are applicable for:

- Debian 8 or 9
- Ubuntu 14.04, 16.04, or 18.04

The latest version of the Hive ODBC connector is at version 2.6.1.1001.

Install the Hive ODBC Connector on Linux

The MapR ODBC Driver with SQL Connector for Apache Hive driver files are installed in the following directories:

- `/opt/mapr/hiveodbc/ErrorMessages` – Error messages files directory
- `/opt/mapr/hiveodbc/Setup` – Sample configuration files directory
- `/opt/mapr/hiveodbc/lib/32` – 32-bit shared libraries directory
- `/opt/mapr/hiveodbc/lib/64` – 64-bit shared libraries directory

To install the MapR ODBC Driver with SQL Connector for Apache Hive:

1. Log in as the `root` user.
2. Use RPM to install the rpm package corresponding to your Linux distribution:
   - 32-bit
   - 64-bit

   The MapR ODBC Driver with SQL Connector for Apache Hive depends on the following resources:
   - cyrus-sasl-2.1.22-7 or later
   - cyrus-sasl-gssapi-2.1.22-7 or later
   - cyrus-sasl-plain-2.1.22-7 or later

   If the package manager in your Linux distribution cannot resolve the dependencies automatically when installing the driver, download and manually install the packages required by the version of the driver that you want to install.

Configure the Hive ODBC Connector Driver on Linux

The LD_LIBRARY_PATH environment variable must include the paths to the:

- Libraries for the installed ODBC driver manager
- Shared libraries for the MapR ODBC Driver with SQL Connector for Apache Hive

Important: The Linux version of the driver bundles together functionality for both 32-bit and 64-bit environments. Do not include the paths to both 32- and 64-bit shared libraries in LD_LIBRARY PATH at the same time. Include only the path to the shared libraries corresponding to the driver matching the bitness of the client application used. For example, if you are using a 64-bit client application and ODBC driver manager libraries are installed in `/usr/local/lib`, then set LD_LIBRARY_PATH as follows:

```
export LD_LIBRARY_PATH=/usr/local/lib:/opt/mapr/hiveodbc/lib/64
```

For more information about how to set environment variables permanently, refer to your Linux shell documentation.

Configuring ODBC Connections for Linux

Files

ODBC driver managers use configuration files to define and configure ODBC data sources and drivers. By default, the following configuration files residing in the user's home directory are used:

- `.odbc.ini` – The file used to define ODBC data sources (required)
- `.odbcinst.ini` – The file used to define ODBC drivers (optional)
- `.mapr.hiveodbc.ini` – The file used to configure the MapR ODBC Driver with SQL Connector for Apache Hive (required)

Sample Files

The driver installation contains the following sample configuration files in the Setup directory:

- `odbc.ini`
- `odbcinst.ini`
- `mapr.hiveodbc.ini`

The names of the sample configuration files do not begin with a period (.) so that they will appear in directory listings by default. A filename beginning with a period (.) is hidden. For odbc.ini and odbcinst.ini, if the default location is used, then the filenames must begin with a period (.). For mapr.hiveodbc.ini, the filename must begin with a period (.) and must reside in the user's home directory. If the configuration files do not already exist in the user's home directory, then the sample configuration files can be copied to that directory and renamed. If the configuration files already exist in the user's home directory, then the sample configuration files should be used as a guide for modifying the existing configuration files.

Configuring the Environment

By default, the configuration files reside in the user's home directory. However, two environment variables, ODBCINI and ODBCSYSINI, can be used to specify different locations for the `odbc.ini` and `odbcinst.ini` configuration files. Set ODBCINI to point to your `odbc.ini` file. Set ODBCSYSINI to point to the directory containing the odbcinst.ini file. For example, if your `odbc.ini` file is located in `/etc` and your `odbcinst.ini` file is located in `/usr/local/odbc`, then set the environment variables as follows:

```
export ODBCINI=/etc/odbc.ini export ODBCSYSINI=/usr/local/odbc
```

```
export ODBCINI=/etc/odbc.ini export ODBCSYSINI=/usr/local/odbc
```

For version 2.1.8 and above, you must also set MAPRHIVEINI to point to the mapr.hiveodbc.ini file in the user's home directory:

```
export MAPRHIVEINI=/etc/.mapr.hiveodbc.ini
```

last-updated: Apr 11, 2022

For version 2.1.5 and below, you set MAPRINI to point to the mapr.hiveodbc.ini file in the user's home directory:

```
export MAPRINI=/<user_home>/.mapr.hiveodbc.ini
```

Configuring the `odbc.ini` File

ODBC Data Sources are defined in the odbc.ini configuration file. The file is divided into several sections:

- [ODBC] is optional and used to control global ODBC configuration, such as ODBC tracing.
- [ODBC Data Sources] is required, listing DSNs and associating DSNs with a driver.
- A section having the same name as the data source specified in the [ODBC Data Sources] section is required to configure the data source.

Here is an example `odbc.ini` configuration file for Linux:

```
[ODBC Data Sources]
Sample MapR Hive DSN 32=MapR Hive ODBC Driver 32-bit
[Sample Mapr Hive DSN 32]
Driver=/opt/mapr/hiveodbc/lib/32/libmaprhiveodbc32.so
HOST=MyHiveServer
PORT=10000
```

To create a data source:

1. Open the `.odbc.ini` configuration file in a text editor.
2. Add a new entry to the [ODBC Data Sources] section. Type the data source name (DSN) and the driver name.
3. To set configuration options, add a new section having a name matching the data source name (DSN) you specified in step 2. Specify configuration options as keyvalue pairs.
4. Save the `.odbc.ini` configuration file.

Note: You can set configuration options in your `odbc.ini` and `.mapr.hiveodbc.ini` files. Configuration options set in a `.mapr.hiveodbc.ini` file apply to all connections, whereas configuration options set in an `odbc.ini` file are specific to a connection. Configuration options set in `odbc.ini` take precedence over configuration options set in `.mapr.hiveodbc.ini`.

Configuring the `odbcinst.ini` File

ODBC Drivers are defined in the odbcinst.ini configuration file. The configuration file is optional because drivers can be specified directly in the odbc.ini configuration file. The odbcinst.ini file is divided into the following sections:

- [ODBC Drivers] lists the names of all the installed ODBC drivers.
- section having the same name as the driver name specified in the [ODBC Drivers] section lists driver attributes and values.

Here is an example odbcinst.ini file for Linux:

```
[ODBC Drivers]
Mapr Hive ODBC Driver 32-bit=Installed
Mapr Hive ODBC Driver 64-bit=Installed
[Mapr Hive ODBC Driver 32-bit]
Description=Mapr Hive ODBC Driver (32-bit)
```

```
Driver=/opt/mapr/hiveodbc/lib/32/libmaprhiveodbc32.so
[Mapr Hive ODBC Driver 64-bit]
Description=Mapr Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

To define a driver:

1. Open the `.odbcinst.ini` configuration file in a text editor.
2. Add a new entry to the [ODBC Drivers] section. Type the driver name, and then type **=Installed**

   Note: Assign the driver name as the value of the Driver attribute in the data source definition instead of the driver shared library name.
3. In `.odbcinst.ini`, add a new section having a name matching the driver name you typed in step 2, and then add configuration options to the section based on the sample `odbcinst.ini` file provided with the MapR ODBC Driver with SQL Connector for Apache Hive in the Setup directory. Specify configuration options as keyvalue pairs.
4. Save the `.odbcinst.ini` configuration file.

Configuring the `mapr.hiveodbc.ini` File

To configure the MapR ODBC Driver with SQL Connector for Apache Hive to work with your ODBC driver manager:

1. Open the `.mapr.hiveodbc.ini` configuration file in a text editor.
2. Edit the DriverManagerEncoding setting. The value usually must be UTF-16 or UTF-32, depending on the ODBC driver manager you use. iODBC uses UTF-32 and unixODBC uses UTF-16. Consult your ODBC Driver Manager documentation for the correct setting to use.
3. Edit the ODBCInstLib setting. The value is the name of the ODBCInst shared library for the ODBC driver manager you use. The configuration file defaults to the shared library for iODBC. In Linux, the shared library name for iODBC is `libiodbcinst.so`.

   Note: Consult your ODBC driver manager documentation for the correct library to specify. You can specify an absolute or relative filename for the library. If you intend to use the relative filename, then the path to the library must be included in the library path environment variable. In Linux, the library path environment variable is named `LD_LIBRARY_PATH`.
4. Save the `.mapr.hiveodbc.ini` configuration file.

Configuring Authentication

You can configure the following types of authentication:

- No authentication
- User name
- User name and password
- Kerberos

When `hive.server2. authentication` is set to KERBEROS, then you must configure your connection to use Kerberos.

To find out the authentication setting your Hive Server 2 is set to use, review the following properties in the `hive-site.xml` file:

last-updated: Apr 11, 2022

- `hive.server2.authentication`
- `hive.server2.enable.doAs`

Using No Authentication

To use no authentication, set the AuthMech configuration key for the DSN to 0.

Using User Name

To configure User Name authentication:

1. Set the AuthMech configuration key for the DSN to 2.
2. Set the UID key to the appropriate user name recognized by the Hive server.

Using User Name and Password

To configure User Name and Password authentication:

1. Set the AuthMech configuration key for the DSN to 3.
2. Set the UID key to the appropriate user name recognized by the Hive server.
3. Set the PWD key to the password corresponding to the user name you provided in step 2.

Using Kerberos

To configure Kerberos authentication:

1. Set the H2SAuthMech configuration key for the DSN to 1.
2. If your Kerberos setup does not define a default realm or if the realm of your Hive server is not the default, then set the appropriate realm using the HS2KrbRealm key.
3. Set the HS2HostFQDN key to the fully qualified domain name of the Hive Server 2 host.
4. Set the HS2KrbServiceName key to the service name of the Hive Server 2 host.

Hive ODBC Connector on Windows

There are versions of the connector for 32-bit and 64-bit applications. The 64-bit version of the connector works only with 64-bit DSNs; the 32-bit connector works only with 32-bit DSNs. Because 64-bit Windows machines can run both 64-bit and 32-bit applications, install both versions of the connector in order to set up DSNs to work with both types of applications. If both the 32-bit connector and the 64-bit connector are installed, you must configure DSNs for each independently, in their separate Data Source Administrators.

Install the Hive ODBC Connector on Windows

To use MapR Hive ODBC Connector on Windows requires:

- Windows® 7 Professional or Windows® 2008 R2. Both 32 and 64-bit editions are supported.
- The Microsoft Visual C++ 2010 Redistributable Package (runtimes required to run applications developed with Visual C++ on a computer that does not have Visual C++ 2010 installed.)
- A Hadoop cluster with the Hive service installed and running. You should find out from the cluster administrator the hostname or IP address for the Hive service and the port that the service is running on. (The default port for Hive is 10000.)

1. Run the installer to get started:

- To install the 64-bit connector, download and run the following package:

```
https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Hive/
MapRHive_odbc_2.6.1.1001/MapRHiveODBC64.msi
```

- To install the 32-bit connector, download and run the following package:

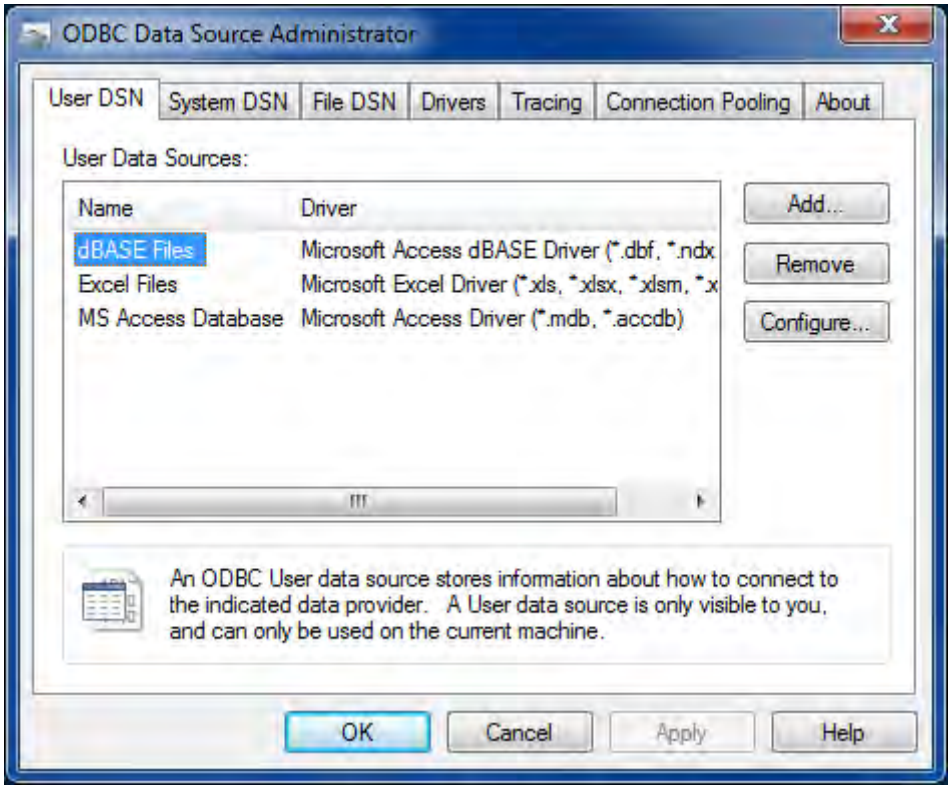
```
https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Hive/
MapRHive_odbc_2.6.1.1001/MapRHiveODBC32.msi
```

2. Accept the license agreement.
3. Select an installation folder.
4. On the Information window, click **Next**.
5. On the Completing... window, click **Finish.**
6. Install a DSN corresponding to your Hive server.

Configure Hive ODBC Connections on Windows

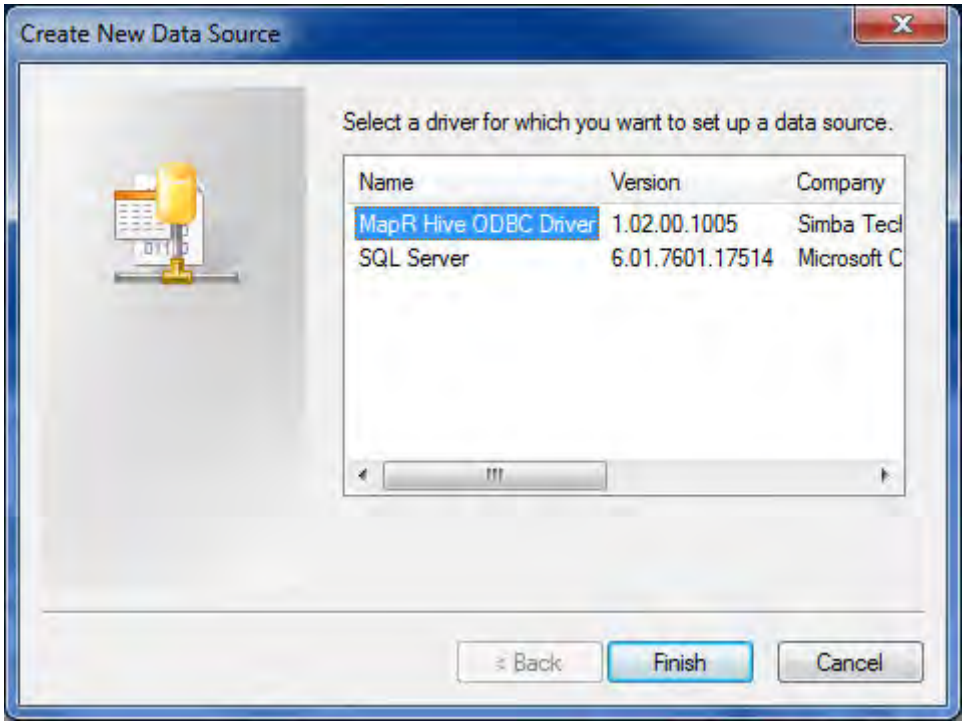
To create a Data Source Name (DSN)

1. Open the Data Source Administrator from the Start menu. Example: **Start > MapR Hive ODBC Driver 2.0 > 64-Bit ODBC Driver Manager**
2. On the **User DSN** tab click **Add** to open the Create New Data Source dialog.



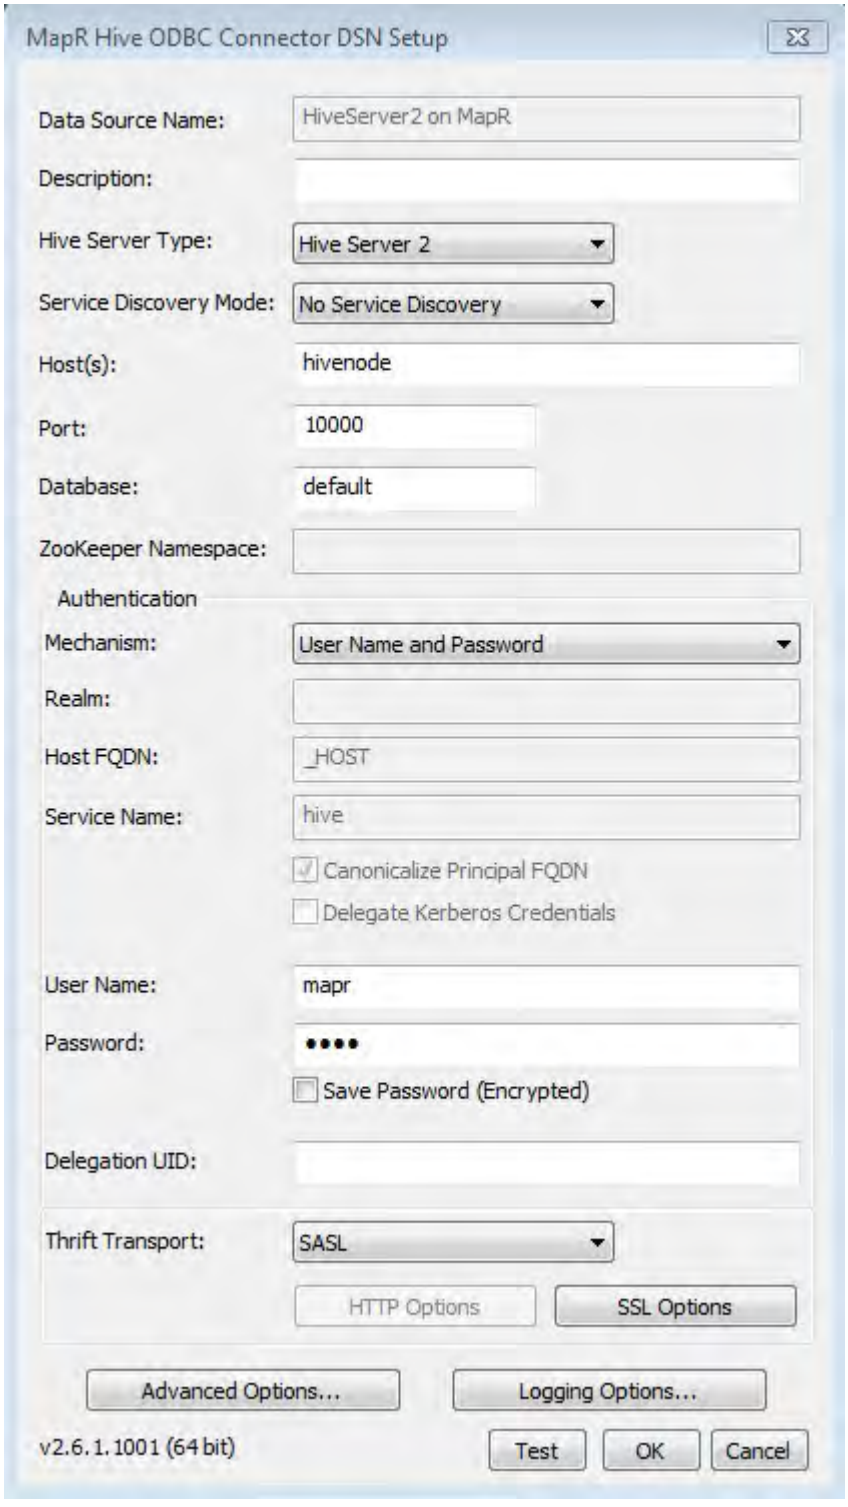
3. Select **MapR Hive ODBC Connector** and click **Finish** to open the Hive ODBC Driver DSN Setup window.

last-updated: Apr 11, 2022



4. Enter the connection information for the Hive instance:

last-updated: Apr 11, 2022

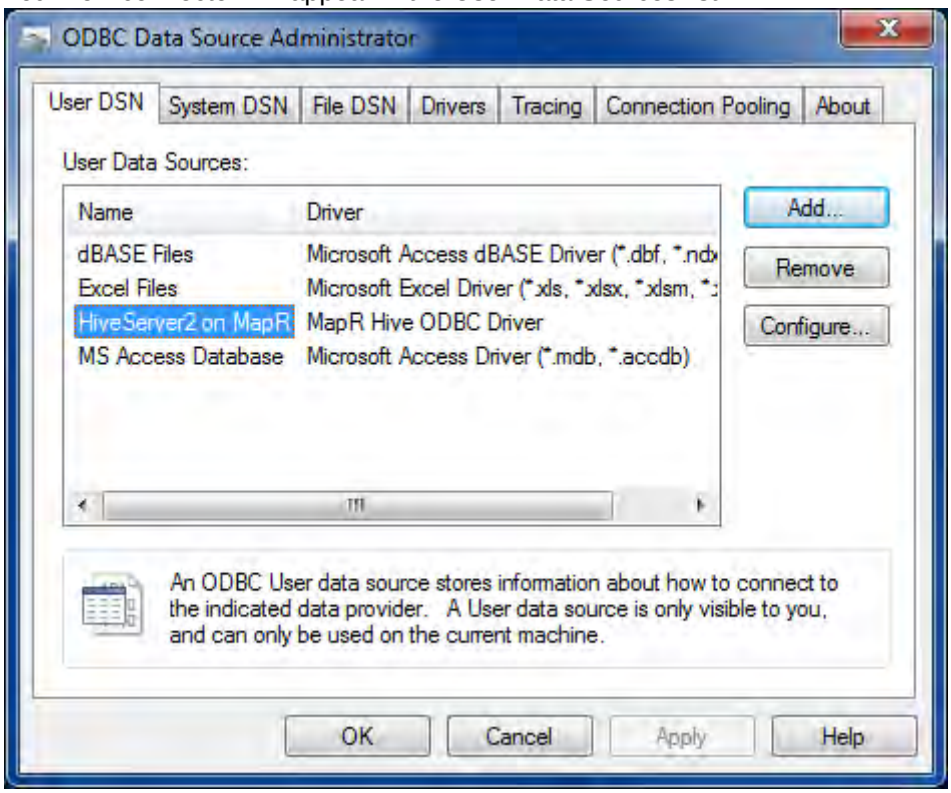


- **Data Source Name** — Specify a name for the DSN.
- **Description** — Enter an optional description for the DSN.
- **Host** — Enter the hostname or IP of the server running HiveServer1 or HiveServer2.
- **Port** — Enter the listening port for the Hive service.

last-updated: Apr 11, 2022

- **Database** — Leave as `default` to connect to the default Hive database, or enter a specific database name.
- **Hive Server Type:** — Set to HiveServer1 or HiveServer2.
- **Authentication** — If you are using HiveServer2, set the following.
  - **Mechanism:** — Set to the authentication mechanism you're using. The MapR ODBC driver supports user name, user name and password, username and password over SSL authentication, and Kerberos.
  - **User Name:** — Set the user to run queries as.
  - **Password:** — The user's password, if your selected authentication mechanism requires one.

5. Optionally, click **Test** to test the connection.
6. Click OK.
   Your new connector will appear in the User Data Sources list.



For steps to apply custom configurations, see Hive ODBC Driver.

Hive ODBC Connector on Mac OS X

System Requirements

- Mac OS X version 10.6.8 or later
- 100 MB of available disk space
- iODBC 3.52.7 or above
- unixODBC 2.2.12 or above

last-updated: Apr 11, 2022

The MapR ODBC Driver with SQL Connector for Apache Hive requires a Hadoop cluster with the Hive service installed and running. The MapR ODBC Driver with SQL Connector for Apache Hive is suitable for use with all versions of Hive. The driver supports both 32- and 64-bit client applications.

Download the MacOS Hive ODBC connector from https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Hive/MapRHive_odbc_2.6.1.1001/MapRHiveODBC.dmg.

Installation

The MapR ODBC Driver with SQL Connector for Apache Hive driver files are installed in the following directories:

- `/opt/mapr/hiveodbc/ErrorMessages` – Error messages files directory
- `/opt/mapr/hiveodbc/Setup` – Sample configuration files directory
- `/opt/mapr/hiveodbc/lib/universal` – Binaries directory

To install the MapR ODBC Driver with SQL Connector for Apache Hive:

1. Double-click to mount the `MapRHiveODBC.dmg` disk image.
2. Double-click `MapRHiveODBC.pkg` to run the Installer.
3. Follow the instructions in the Installer to complete the installation process.
4. When the installation completes, click **Close**.

Configuration

Setting the DYLD_LIBRARY_PATH Environment Variable

The `DYLD_LIBRARY_PATH` environment variable must include the paths to:

- Installed ODBC driver manager libraries
- Installed MapR ODBC Driver with SQL Connector for Apache Hive shared libraries

For example, if ODBC driver manager libraries are installed in `/usr/local/lib`, then set `DYLD_LIBRARY_PATH` as follows:

```
export DYLD_LIBRARY_PATH=/usr/local/lib/opt/mapr/hiveodbc/lib/universal
```

Refer to your Mac OS X shell documentation for details on how to set environment variables permanently.

Configure Hive ODBC Connections on Mac OS X

See Configuring ODBC Connections for Linux for details on creating ODBC connections.

Configuring Encryption for ODBC Connection

Explains how to configure SSL encryption between ODBC connection to Hiveserver2 on non-secure cluster.

Hive uses cyrus-sasl-plain package for ODBC connection.

1. Generate `ssl_keystore/ssl_truststore` by running the following command:

   ```
   sudo bash /opt/mapr/server/manageSSLKeys.sh create -ug mapr:mapr
   ```

   Important: Make a note of the `CN=HOST_NAME` parameter in the output.

2. Configure SSL for Hive as described in Configure Encryption without Authentication on page 3448.

3. Generate the `.pem` file. To generate:

   a) Verify that `ssl_keystore` and `ssl_truststore` are present on the system.

   ```
   cd /opt/mapr/conf
   ll *ssl*store*
   ```

   If `ssl_keystore` and `ssl_truststore` are not present, then generate them.

   b) Generate `.pem` file using `<ssl-keystore-password>` password.

   ```
   keytool -importkeystore -srckeystore ssl_keystore -destkeystore
   ssl_keystore.p12 -srcstoretype jks -deststoretype pkcs12
   ```

   c) Verify that the `ssl_keystore.p12` and `ssl_keystore.pem` files are created.

   For example:

   ```
   openssl pkcs12 -in ssl_keystore.p12 -out ssl_keystore.pem
   openssl x509 -text -in ssl_keystore.pem
   ```

4. Configure SSL for ODBC driver by making the following changes in the `/etc/odbc.ini`, `/etc/odbcinst.ini`, and `/etc/mapr.hiveodbc.init` files. That is, in the:

   - `/etc/odbc.ini` file:

a. Replace <HOST_NAME> with the host name.

b. Set the value for `TrustedCerts` to path to `ssl_keystore.pem` file.

c. Add the following to the file:

```
[ODBC Data Sources]
Sample MapR Hive DSN=Hive Hive ODBC Driver 64-bit
[Hive]
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
HOST=<HOST_NAME>
PORT=10000
SSL=1
CAIssuedCertNamesMismatch=1
TrustedCerts=/opt/mapr/conf/ssl_keystore.pem
AuthMech=4
```

- `/etc/odbcinst.ini` file, add the following:

```
[ODBC Drivers]
Mapr Hive ODBC Driver=Installed
[Mapr Hive ODBC Driver 64-bit]
Description=Mapr Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

- `etc/mapr.hiveodbc.ini` file, add the following:

```
[Driver]
ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessages/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

Sample /etc/odbc.ini file

```
[ODBC Data Sources]
Sample MapR Hive DSN=Hive Hive ODBC Driver 64-bit
[Hive]
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
HOST=<HOST_NAME>
PORT=10000
SSL=1
CAIssuedCertNamesMismatch=1
TrustedCerts=/opt/mapr/conf/ssl_keystore.pem
AuthMech=4
```

Sample /etc/odbcinst.ini file

```
[ODBC Drivers]
Mapr Hive ODBC Driver=Installed
[Mapr Hive ODBC Driver 64-bit]
Description=Mapr Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

Sample /etc/mapr.hiveodbc.ini file

```
[Driver]
ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessages/
LogLevel=0
```

last-updated: Apr 11, 2022

```
LogPath=
SwapFilePath=/tmp
```

Connecting to WebHCat

The method that WebHCat clients use to connect to WebHCat is based on the WebHCat Authentication method:

WebHCat Authentication	Connection Requirements
Simple	Clients pass the username as the `user.name` parameter in the REST call. No password is required. Example: `http://<hostname>:50111/templeton/v1/ddl/database/default/table/table01?user.name=juser`
PAM	Clients enter username and password authentication through a pop-up dialog box in the web browser session.
Kerberos with SPNEGO	Clients can use one of the following methods: • curl example: `curl --negotiate -i -u : 'http://<FQDN>:50111/templeton/v1/ddl/database/'` • Web browser with user name and password. For more information, see Configuring SPNEGO on MapR on page 1436 **Note:** With either method you must also have a Kerberos ticket in the cache. See Example: Generating a Kerberos Ticket

Enabling High Availability for Hive

This section describes how to enable High Availability for HiveServer2 and HiveMetastore.

Note: You can achieve High Availability(HA) through HA tools like HAProxy or F5. Based on the tools used, you need to configure reverse DNS lookups and implement other security features. However, the MapR Data Platform does not support any HA tool.

Related concepts

Enabling High Availability for Spark Thrift Server on page 4046

Enabling High Availability for HiveServer2

Perform the following steps to enable High Availability for HiveServer2.

Configuring Hive

1. Modify the `warden.hs2.conf` file as shown below on all the nodes where Hive is installed.

   ```
   services=hs2:all
   ```

2. Add the following properties to the `hive-site.xml` file on all the nodes where HiveServer2 is installed.

last-updated: Apr 11, 2022

Property	Value	Description
`hive.server2.support.dynamic.service.discovery`	`true` (default is `false`)	Set to `true` to enable HiveServer2 dynamic service discovery for its clients.
`hive.server2.zookeeper.namespace`	hiveserver2 (default value)	The parent node in ZooKeeper, which is used by HiveServer2 when supporting dynamic service discovery.
`hive.zookeeper.quorum`	**<hostname>**:5181,**<hostname>**:5181,**<hostname>**:5181	List of ZooKeeper servers to talk to. Used in connection string by JDBC/ODBC clients instead of URI of specific HiveServer2 instance.
`hive.zookeeper.client.port`	5181 (default value)	The port of the ZooKeeper servers to talk to. If the list of Zookeeper servers specified in `hive.zookeeper.quorum` does not contain port numbers and so, this value is used.
`hive.zookeeper.session.timeout`	600000 (default value)	Zookeeper client's session timeout value. The client is disconnected, and as a result, all locks are released if a heartbeat is not sent within the timeout period.

3. Restart all the nodes where Hive service is installed after updating the configuration.

Connecting with JDBC/ODBC Clients

- Connect to HiveServer2 with JDBC/ODBC clients using the following connection string:

```
jdbc:hive2://<zookeeper_ensemble>/;serviceDiscoveryMode=zooKeeper;
zooKeeperNamespace=<hiveserver2_zookeeper_namespace>
```

Here:

<zookeeper_ensemble>	Specifies a comma-separated list of ZooKeeper servers that form the ensemble. For example: `<zk_host1>:<zk_port1>,<zk_host2>:<zk_port2>,<zk_host3>:<zk_p`
<hiveserver2_zookeeper_namespace>	Specifies the namespace on Zookeeper under which HiveServer2 znodes are add The namespace value is configured in `hive.server2.zookeeper.name` space

Deregistering HiveServer2 Instances from Zookeeper

Remove a HiveServer2 instance from Zookeeper by running the following commands (in the ZooKeeper command line interface) to deregister the server.

1. Launch the ZooKeeper command line interface and get the HiveServer2 znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

2. Run the command to deregister HiveServer2. To deregister:

last-updated: Apr 11, 2022

- A particular HiveServer2, run the following command:

```
delete /hiveserver2 serverUri=<hostname:port>;version=<hive
version>;sequence=<sequence number>
```

  After you deregister the HiveServer2 from Zookeeper, it will not return the deregistered HiveServer2 for new client connections. However, active client sessions are not affected by deregistering the HiveServer2 from Zookeeper.

- All HiveServer2 instances of a particular version, run the following command:

```
hive --service hiveserver2 --deregister <version_number>
```

Example HiveServer2 High Availability Setup

This section describes a High Availability set up for HiveServer2 on a sample MapR Data Platform cluster. Suppose a three node cluster with the following (optional) IP addresses and host names:

IP Address	Host Name
192.168.33.11	node1
192.168.33.12	node2
192.168.33.13	node3

Connection to HiveServer2 can be accomplished using the following string:

```
jdbc:hive2://
node1:5181,node2:5181,node3:5181/;serviceDiscoveryMode=zooKeeper;zooKeeperNa
mespace=hiveserver2
```

To deregister HiveServer2:

1. Launch the ZooKeeper command line interface using the following command:

```
/opt/mapr/zookeeper/zookeeper-3.4.5/bin/zkCli.sh -server
192.168.33.13:5181
```

2. Look at the ZooKeeper namespace using the following command:

```
ls /hiveserver2
```

   Output:

```
[serverUri=node3:10000;version=2.1.1-mapr-1703;sequence=0000000004,
serverUri=node1:10000;version=2.1.1-mapr-1703;sequence=0000000006]
```

3. Deregister:

   - HiveServer2 on node3:

```
delete
serverUri=node3:10000;version=2.1.1-mapr-1703;sequence=0000000004
```

- All HiveServer2 instances:

```
hive --service hiveserver2 --deregister 2.1.1-mapr-1703
```

Enabling High Availability for Hive Metastore

To enable High Availability for Hive Metastore, perform the following steps:

1. Enable remote access to the underlying database from different nodes.
2. Add all Metastore instances to `hive.metastore.uris` on all the nodes:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<hostname>:9083,thrift://<hostname>:9083</value>
</property>
```

3. Restart Hive.

Note that enabling high availability for the Hive Metastore does not require changes to the `warden.hivemetastore.conf` file. Active-active mode is not supported for Hive Metastore.

Example

Suppose HiveMetastore is on the following two nodes:

IP Address	Host Name
192.168.33.11	node1
192.168.33.12	node2

1. Change the MySQL configuration:

```
nano /etc/my.cnf
```

2. Comment out the following properties:

```
#bind-address
#skip-networking
```

If these properties are not in `my.cnf`, you can skip editing `my.cnf`. Restart the MySQL server.

3. Enable remote access for the underlying database by granting permissions in the underlying database:

```
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'root'@'192.168.33.11'
IDENTIFIED BY 'secret' WITH GRANT OPTION;
```

```
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'root'@'192.168.33.12'
IDENTIFIED BY 'secret' WITH GRANT OPTION;
```

4. Verify the connection to the MySQL server from `node1` and `node2`. For example, run the following commands:
   - On `node1`:

```
mysql -h node1 -uroot -psecret
```

- On node2:

```
mysql -h node2 -uroot -psecret
```

5. Add all Metastore instances to `hive.metastore.uris` on all nodes with the Hive instance:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://192.168.33.11:9083,thrift://192.168.33.12:9083</value>
</property>
```

6. Restart Hive.

Hive Features in MapR Data Platform
Describes MapR Data Platform-specific features in Hive.

Removing Temporary Hive Files

Starting from EEP 8.1.0 and EEP 6.3.6, to remove the temporary Hive files created during the Hive session, set the value of `hive.scratchdir.lock` property to `true` on `hive-site.xml` file.

```
<property>
   <name>hive.scratchdir.lock</name>
   <value>true</value>
</property>
```

For the previous EEP versions, manually remove the temporary Hive files that are not used by the active Hive sessions.

You have two different situations:

- If you have configured the HiveServer2 in a node, set `hive.scratchdir.lock` property on the `hive-site.xml` file to automatically remove the temporary Hive files.
- If you have not configured the HiveServer2 in a node, set the `hive.scratchdir.lock` property and run the following command to remove the temporary Hive files.

```
hive --service cleardanglingscratchdir
```

Hive 2.3 API Changes
This topic describes the public API changes that occurred between Hive 2.1 EEP 5.0.0 and Hive 2.3 EEP 6.0.0.

For more information, see the Hive 2.1.1-1803 (EEP 4.1.1 and EEP 5.0.0) Release Notes on page 5978 and Hive 2.3.3-1808 (EEP 6.0.0) Release Notes on page 5953.

JDBC classes API changes

This section contains changes made to classes related to the JDBC API in Hive.

Table

Method	Description
`List<String> parseInitFile(String initFile)`	Parses initial SQL file skipping comments that starts with # or `--`.

last-updated: Apr 11, 2022

Table

Method	Description
`void setInPlaceUpdateStream(InPlaceUpdate stream)`	Only used by the beeline client to set the stream on which in place progress updates are to be shown.

Table

Method	Description

`JdbcConnectionParams parseURL(String uri)`	Parse JDBC connection URL The new format of the URL is:
	`jdbc:hive2://:,:/dbName;sess_var_list?hive_conf_list#hive_var_list`
	where the optional `sess`, `conf`, and `var` lists are semicolon separated = pairs. For utilizing dynamic service discovery with HiveServer2, multiple comma-separated host:port pairs can be specified as shown above. The JDBC driver resolves the list of URIs and picks a specific server instance to connect to. Currently, dynamic service discovery using ZooKeeper is supported, in which case the host:port pairs represent a ZooKeeper ensemble. As before, if the host/port is not specified, it the driver runs an embedded Hive:
	• `jdbc:hive2://ubuntu:11000/db2?hive.cli.conf.printheader=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID`
	• `jdbc:hive2://?hive.cli.conf.printheader=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID`
	• `jdbc:hive2://ubuntu:11000/db2;user=foo;password=bar`
	Connect to `http://server:10001/hs2`, with specified `basicAuth` credentials and initial database:
	`jdbc:hive2://server:10001/db;user=foo;password=bar?hive.server2.transport.mode=http;hive.server2.thrift.http.path=hs2`

Security-related API changes

The following properties are removed from the default `hive-site.xml` configuration on a secured cluster:

Table

Property	Value
`hive.server2.webui.keystore.path`	`/opt/mapr/conf/ssl_keystore`.
`hive.server2.webui.keystore.password`	`Default keystore password`.

The following property is added to the default `hive-site.xml` configuration on a secured cluster:

Table

Method	Description
`hive.server2.use.SSL true`	`true`

Since the HiveServer2 server is configured to use SSL encryption by default starting from Hive-2.3 EEP-6.0.0, add `ssl=true;` to a JDBC connection string when PAM or MAPR-SASL authentication is used.

For example:

Old JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;
```

New JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;ssl=true;
```

Note: All API functionality changes are compatible with previous versions.

Hive 2.1 API

This section contains the following:

New Classes in Hive 2.1

Hive 2.1 includes the following new classes:

Class	Description
org.apache.hadoop.hive.common.DiskRangeInfo	Contains disk range information including disk ranges and total length.
org.apache.hadoop.hive.common.JvmPauseMonitor	This is based on the JvmPauseMonitor from Hadoop.
org.apache.hadoop.hive.common.StringableMap	A utility class that can convert a HashMap of Properties into a colon separated string, and can take the same format of string and convert it to a HashMap of Properties.
org.apache.hadoop.hive.common.ValidCompactorTxnList	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.common.io .DiskRange	The sections of a file.
org.apache.hadoop.hive.common.io.DiskRangeList	Alternative for Java linked list iterator interface to support concurrent modifications of the same list by multiple iterators.
org.apache.hadoop.hive.common.jsonexplain.tez.Printer	Creation of output string to show JSON plan.
org.apache.hadoop.hive.common.jsonexplain.tez.TezJsonParserUtils	JsonParser for Tez that prints a JSONObject nto outputStream.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.common.metrics.LegacyMetrics	The Metrics Subsystem allows exposure of a number of named parameters/counters via JMX, is intended to be used as a static subsystem, and has a couple of primary ways in which it can be used: • Using the set and get methods to set and get named parameters. • Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set. • Using the startScope and endScope methods to start and end named "scopes" that record the number of times they have been instantiated and amount of time (in milliseconds) spent inside the scopes.
org.apache.hadoop.hive.common.type.RandomTypeUtil	Creates random data of different object types.
org.apache.hadoop.hive.conf.VariableSubstitution	Substitution of environment variables.
org.apache.hadoop.hive.contrib.genericudf.example.GenericUDFAdd10	Intializes the GenericUDF (once per instance), evaluates the GenericUDF with the arguments, and gets the string to display.
org.apache.hadoop.hive.io.HdfsUtils	Utils to resolve file properties in MAPR filesystem.
org.apache.hadoop.hive.metastore.AcidEventListener	It handles cleanup of dropped partition/table/database in ACID related metastore tables.
org.apache.hadoop.hive.metastore.FileMetadataHandler	The base implementation of a file metadata handler for a specific file type.
org.apache.hadoop.hive.metastore.FileMetadataManager	Handle storage functions of metadata.
org.apache.hadoop.hive.metastore.HMSMetricsListener	Report metrics of metadata added and deleted by this Hive Metastore.
org.apache.hadoop.hive.metastore.Metastore	Class to arrange work with Metastore.
org.apache.hadoop.hive.metastore.PartFilterExprUtil	Utility functions for working with partition filter expressions.
org.apache.hadoop.hive.metastore.api.AbortTxnsRequest	Class for handling transactions request.
org.apache.hadoop.hive.metastore.api.AddForeignKeyRequest	Class for handling foreign key request.
org.apache.hadoop.hive.metastore.api.AddPrimaryKeyRequest	Class for handling primary key request.
org.apache.hadoop.hive.metastore.api.CacheFileMetadataRequest	Class for caching metadata requests.
org.apache.hadoop.hive.metastore.api.CacheFileMetadataResult	Class for caching metadata results.
org.apache.hadoop.hive.metastore.api.ClearFileMetadataResult	Class for clearing metadata results.
org.apache.hadoop.hive.metastore.api.DropConstraintRequest	Class for dropping constraint requests.
org.apache.hadoop.hive.metastore.api.ForeignKeysRequest	Class for handling foreign key requests.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.metastore.api.ForeignKeysResponse	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api.GetAllFunctionsResponse	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api.GetFileMetadataByExprRequest	Class for getting metadata from expression response.
org.apache.hadoop.hive.metastore.api.GetFileMetadataByExprResult	Class for getting metadata from expression result.
org.apache.hadoop.hive.metastore.api.MetadataPpdResult	Class for describing metadata rpd result.
org.apache.hadoop.hive.metastore.api.PrimaryKeysRequest	Class for describing primary key result.
org.apache.hadoop.hive.metastore.api.PrimaryKeysResponse	Class for describing primary key response.
org.apache.hadoop.hive.metastore.api.PutFileMetadataRequest	Class for output metadata request to file.
org.apache.hadoop.hive.metastore.api.PutFileMetadataResult	Class for output metadata result to file.
org.apache.hadoop.hive.metastore.api.SQLForeignKey	Class for describing SQL foreign key.
org.apache.hadoop.hive.metastore.api.SQLPrimaryKey	Class for describing SQL primary key.
org.apache.hadoop.hive.metastore.api.TableMeta	Class for describing table metadata.
org.apache.hadoop.hive.metastore.model.MConstraint	Model of constraints stored in metastore.
org.apache.hadoop.hive.metastore.txn.TxnUtils	Class for handling transactions.
org.apache.hadoop.hive.ql.CompilationOpContext	Contains the operator sequence ID and a subset of compilation context that is passed to operators to get rid of some globals.
org.apache.hadoop.hive.ql.QueryDisplay	Contains limited query information to save for WebUI. The class is synchronized, as WebUI may access information about a running query.
org.apache.hadoop.hive.ql.QueryState	The class to store query level info such as queryId.
org.apache.hadoop.hive.ql.exec.AbstractMapOperator	Abstract Map operator.
org.apache.hadoop.hive.ql.exec.GlobalWorkMapFactory	Get job that has been executed on cluster as a map value.
org.apache.hadoop.hive.ql.exec.ObjectCacheWrapper	Wapping class for ObjectCache class.
org.apache.hadoop.hive.ql.exec.SerializationUtilities	Utilities related to serialization and deserialization.
org.apache.hadoop.hive.ql.exec.UDFClassLoader	UDFClassLoader is used to dynamically register udf (and related) jars. This was introducted to fix HIVE-11878. Each session will have its own instance of UDFClassLoader to support HiveServer2, which can contain multiple active sessions.
org.apache.hadoop.hive.ql.exec.spark.CacheTran	Class for making cache persistent.
org.apache.hadoop.hive.ql.exec.spark.SmallTableCache	Class for cache cleaning if new query is present.
org.apache.hadoop.hive.ql.exec.spark.SparkDynamicPartitionPruner	The spark version of DynamicPartitionPruner.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.spark.status.impl.SparkJobUtils	Utilities for spark job.
org.apache.hadoop.hive.ql.exec.tez.ColumnarSplitSizeEstimator	Split size estimator for columnar file formats.
org.apache.hadoop.hive.ql.exec.tez.HostAffinitySplitLocationProvider	This maps a split (path + offset) to an index based on the number of locations provided.
org.apache.hadoop.hive.ql.exec.tez.InPlaceUpdates	Class responsible for inplace updates.
org.apache.hadoop.hive.ql.exec.tez.KeyValuesFromKeyValue	Provides a key/values (note the plural values) interface out of a KeyValueReader, needed by ReduceRecordSource when reading input from a key/value source.
org.apache.hadoop.hive.ql.exec.tez.KeyValuesFromKeyValues	Provides a key/values interface out of a KeyValuesReader for use by ReduceRecordSource.
org.apache.hadoop.hive.ql.exec.tez.LlapObjectCache	Llap implementation for the shared object cache.
org.apache.hadoop.hive.ql.exec.tez.Utils	Utilities for running tez jobs.
org.apache.hadoop.hive.ql.exec.vector.IntervalDayTimeColumnVector	This class represents a nullable interval day time column vector capable of handing a wide range of interval day time values.
org.apache.hadoop.hive.ql.exec.vector.ListColumnVector	The representation of a vectorized column of list objects.
org.apache.hadoop.hive.ql.exec.vector.MapColumnVector	The representation of a vectorized column of map objects.
org.apache.hadoop.hive.ql.exec.vecto.MultiValuedColumnVector	The representation of a vectorized column of multi-valued objects, such as lists and maps.
org.apache.hadoop.hive.ql.exec.vector.StructColumnVector	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive.ql.exec.vector.TimestampColumnVector	This class represents a nullable timestamp column vector capable of handing a wide range of timestamp values.
org.apache.hadoop.hive.ql.exec.vector.UnionColumnVector	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive.ql.exec.vector.VectorSparkHashTableSinkOperator	Vectorized version of SparkHashTableSinkOperator. It delegates all the work to super class Copied from VectorFileSinkOperator.
org.apache.hadoop.hive.ql.exec.vector.VectorSparkPartitionPruningSinkOperator	Vectorized version for SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.exec.vector.expressions.BRoundWithNumDigitsDoubleToDouble	Banking rounding implementation.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastDoubleToTimestamp	Cast double type to timestamp type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastLongToTimestamp	Cast long type to timestamp type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastMillisecondsLongToTimestamp	Cast milliseconds long type to timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastStringGroupToString	Cast string group type to string type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToBoolean	Cast timestamp type to boolean.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToDate	Cast timestamp type to decimal type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToDouble	Cast timestamp type to double type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToLong	Cast timestamp type to long type.
org.apache.hadoop.hive.ql.exec.vector.expressions.DateColSubtractDateColumn	Substract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions.DateColSubtractDateScalar	Substract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions.DateScalarSubtractDateColumn	Substract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions.FilterStructColumnInList	Evaluates an IN filter on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions.FilterTimestampColumnInList	Evaluates IN filter on a batch for a vector of timestamps.
org.apache.hadoop.hive.ql.exec.vector.expressions.FuncBRoundWithNumDigitsDecimalToDecimal	Banking rounding for decimal digits.
org.apache.hadoop.hive.ql.exec.vector.expressions.FuncDecimalToTimestamp	This is a superclass for unary decimal functions and expressions returning timestamps that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.FuncTimestampToDecimal	This is a superclass for unary timestamp functions and expressions returning decimals that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.FuncTimestampToLong	This is a superclass for unary timestamp functions and expressions returning long that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprDoubleColumnDoubleColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprLongColumnLongColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColEqualLongColumn	If equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColEqualLongScalar	If equal long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterEqualLongColumn	If greater or equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterEqualLongScalar	If greater or equal long column and long scalar.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterLongColumn	If greater two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterLongScalar	If greater long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessEqualLongColumn	If less equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessEqualLongScalar	If less equal long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessLongColumn	If less two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessLongScalar	If less long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColNotEqualLongColumn	If not equal two columns as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongColNotEqualLongScalar	If not equal long column and long scalar as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarEqualLongColumn	If equal long scalar and long column.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarGreaterEqualLongColumn	If greater equal long scalar and long column as vector.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarGreaterLongColumn	If greater long scalar and long column as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarLessEqualLongColumn	If less equal long scalar and long column as vector.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarLessLongColumn	If less long scalar and long column as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarNotEqualLongColumn	If not equal long scalar and long column as vectors.
org.apache.hadoop.hive.ql.exec.vector.expressions.SelectStringColLikeStringScalar	Select like statement for string column and string scalar.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.StructColumnInList	Evaluates an IN boolean expression (not a filter) on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions.TimestampColumnInList	Returns a boolean value indicating if a column is IN a list of constants.
org.apache.hadoop.hive.ql.exec.vector.expressions.TimestampToStringUnaryUDF	This is a superclass for unary long functions returning strings that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDateTimestamp	Vectorized version of TO_DATE(timestamp).
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDayOfMonthDate	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDayOfMonthTimestamp	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFHourDate	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFHourTimestamp	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMinuteDate	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMinuteTimestamp	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMonthDate	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMonthTimestamp	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFSecondDate	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFSecondTimestamp	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFTimestampFieldDate	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFTimestampFieldTimestamp	Abstract class to return various fields from a Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFUnixTimeStampDate	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFUnixTimeStampTimestamp	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFWeekOfYearDate	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFWeekOfYearTimestamp	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFYearDate	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFYearTimestamp	Expression to get year as a long.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates.VectorUDAFAvgTimestamp	Generated from template VectorUDAFAvg.txt.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates.VectorUDAFStdPopTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates.VectorUDAFStdSampTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates.VectorUDAFVarPopTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates.VectorUDAFVarSampTimestamp	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.hooks.LineageLogger	Implementation of a post execute hook that logs lineage info to a log file.
org.apache.hadoop.hive.ql.hooks.PostExecOrcFileDump	Post execution hook to print orc file dump for files that will be read by fetch task.
org.apache.hadoop.hive.ql.hooks.PostExecTezSummaryPrinter	Post execution hook to print hive tez counters to console error stream.
org.apache.hadoop.hive.ql.io.HdfsUtils	Utilities for hadoop fs.
org.apache.hadoop.hive.ql.io.IOContextMap	Uses the global static map of IOContext-s inside IOContext, uses threadlocal for Spark, and creates inheritable threadlocal with attemptId (only set in LLAP), which will propagate to all the Tez threads.
org.apache.hadoop.hive.ql.io.NullScanFileSystem	Filesystem that does not allow Hive to read files for nullscans.
org.apache.hadoop.hive.ql.io.ProxyLocalFileSystem	This class is to workaround existing issues on LocalFileSystem.
org.apache.hadoop.hive.ql.io.SyntheticFileId	Create synthetic ID for file.
org.apache.hadoop.hive.ql.io.orc.ExternalCache	Metastore-based footer cache storing serialized footers.
org.apache.hadoop.hive.ql.io.orc.MetastoreExternalCachesByConf	An implementation of external cache and factory based on metastore.
org.apache.hadoop.hive.ql.io.orc.OrcFileFormatProxy	File format proxy for ORC.
org.apache.hadoop.hive.ql.io.orc.RecordReaderImpl	Implementation of record reader.
org.apache.hadoop.hive.ql.io.parquet.read.ParquetFilterPredicateConverter	Translate the search argument to the filter predicate parquet uses.
org.apache.hadoop.hive.ql.io.sarg.ConvertAstToSearchArg	Converting asterisk and use it as a search argument.
org.apache.hadoop.hive.ql.io.sarg.SearchArgumentImpl	The implementation of SearchArguments.
org.apache.hadoop.hive.ql.lib.PreOrderOnceWalker	This class takes list of starting nodes and walks them in pre-order.
org.apache.hadoop.hive.ql.log.HiveEventCounter	A log4J2 appender that simply counts logging events in four levels: fatal, error, warn, and info.
org.apache.hadoop.hive.ql.log.NoDeleteRollingFileAppender	Instantiate a RollingFileAppender and open the file designated by `filename`. The opened filename will become the output destination for this appender.
org.apache.hadoop.hive.ql.log.NullAppender	A NullAppender that never outputs a message to any device.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.log.PidFilePatternConverter	FilePattern converter that converts %pid pattern to @ information obtained at runtime.
org.apache.hadoop.hive.ql.metadata.ForeignKeyInfo	ForeignKeyInfo is a metadata structure containing the foreign keys associated with a table.
org.apache.hadoop.hive.ql.metadata.PrimaryKeyInfo	PrimaryKeyInfo is a metadata structure containing the primary key associated with a table.
org.apache.hadoop.hive.ql.metadata.TableIterable	Gets Table objects for a table list.
org.apache.hadoop.hive.ql.optimizer.OperatorComparatorFactory	Comparator for table operators.
org.apache.hadoop.hive.ql.optimizer.PartitionColumnsSeparator	Takes a Filter expression, and if its predicate contains an IN operator whose children are constant structs or structs containing constant fields, it will try to generate predicate with IN clauses containing only partition columns.
org.apache.hadoop.hive.ql.optimizer.PointLookupOptimizer	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, it will try to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.RedundantDynamicPruningConditionsRemoval	Takes a Filter operator on top of a TableScan and removes dynamic pruning conditions if static partition pruning has been triggered already.
org.apache.hadoop.hive.ql.optimizer.SparkRemoveDynamicPruningBySize	Disables pruning if the number of keys for dynamic pruning is too large.
org.apache.hadoop.hive.ql.optimizer.calcite.HivePlannerContext	Creating context for Hive Planner.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelBuilder	Builder for relational expressions in Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelFactories	Factory class for creating relational operators for queries.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRexExecutorImpl	Hive registry executor implementation.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRexUtil	Utilities for hive registry executor.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveBetween	Operand type-inference strategy where an unknown operand type is derived from the first operand with a known type, but the first operand is a boolean.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveIn	Create in clause instance for hive queries.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveMultiJoin	A HiveMultiJoin represents a succession of binary joins.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit	Sorting limit in hive queries.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateJoinTransposeRule	Planner rule that pushes an org.apache.calcite.rel.core.Aggregate past a org.apache.calcite.rel.core.Join.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateProjectMergeRule	Planner rule that recognizes a HiveAggregate on top of a HiveProject and if possible, aggregates through the project or removes the project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregatePullUpConstantsRule	Rule for pull up constants aggregation.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterAggregateTransposeRule	Transpose rule for filter aggregation.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterProjectTSTransposeRule	Transpose rule for filtering project TST.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterSortTransposeRule	Transpose rule for filtering sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinProjectTransposeRule	Transpose rule for join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HivePointLookupOptimizerRule	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, tries to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectFilterPullUpConstantsRule	Planner rule that infers constant expressions from Filter into a Project operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectSortTransposeRule	Transpose rule for project sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveReduceExpressionsRule	Collection of planner rules that apply various simplifying transformations on RexNode trees.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveReduceExpressionsWithStatsRule	This rule simplifies the condition in Filter operators using the column statistics (if available).
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveRelColumnsAlignment	Infers the order in Aggregate columns and the order of conjuncts in a Join condition that might be more beneficial to avoid additional sort stages.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortJoinReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveJoin.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortLimitPullUpConstantsRule	Planner rule that pulls up constant keys through a SortLimit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortMergeRule	This rule will merge two HiveSortLimit operators.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortProjectTransposeRule	Transpose rule for sort project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortRemoveRule	Planner rule that removes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortUnionReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past aorg.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveUnion.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveUnionPullUpConstantsRule	Planner rule that pulls up constants through a Union operator.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdPredicates	Infers predicates for a project.
org.apache.hadoop.hive.ql.optimizer.physical.LlapDecider	LlapDecider takes care of tagging certain vertices in the execution graph as "llap", which in turn causes them to be submitted to an llap daemon instead of a regular yarn container.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.optimizer.physical.MemoryDecider	MemoryDecider is a simple physical optimizer that adjusts the memory layout of tez tasks.
org.apache.hadoop.hive.ql.optimizer.physical.SerializeFilter	SerializeFilter is a simple physical optimizer that serializes all filter expressions in Tablescan Operators.
org.apache.hadoop.hive.ql.optimizer.spark.CombineEquivalentWorkResolver	CombineEquivalentWorkResolver searches inside SparkWork, finds and combines equivalent works.
org.apache.hadoop.hive.ql.optimizer.spark.SparkPartitionPruningSinkDesc	Description of spark partition pruning sink.
org.apache.hadoop.hive.ql.parse.AnalyzeCommandUtils	Utilities for command analysis.
org.apache.hadoop.hive.ql.parse.ColumnStatsAutoGatherContext	ColumnStatsAutoGatherContext is passed to the compiler when set hive.stats.autogather is true during the INSERT OVERWRITE command.
org.apache.hadoop.hive.ql.parse.MaskAndFilterInfo	Information for masking and filtering.
org.apache.hadoop.hive.ql.parse.TableMask	The main purpose for this class is for authorization.
org.apache.hadoop.hive.ql.parse.spark.SparkPartitionPruningSinkOperator	This operator gets partition info from the upstream operators and writes them to HDFS.
org.apache.hadoop.hive.ql.parse.spark.SplitOpTreeForDPP	This processor triggers on SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.plan.AbortTxnsDesc	Descriptor for aborting transactions.
org.apache.hadoop.hive.ql.plan.CacheMetadataDesc	Description for metadata cache.
org.apache.hadoop.hive.ql.plan.ShowCreateDatabaseDesc	Shows the name of the database.
org.apache.hadoop.hive.ql.plan.VectorPartitionConversion	PartitionConversion.
org.apache.hadoop.hive.ql.plan.VectorPartitionDesc	VectorMapDesc.
org.apache.hadoop.hive.ql.plan.VectorReduceSinkDesc	VectorReduceSinkDesc.
org.apache.hadoop.hive.ql.plan.VectorReduceSinkInfo	VectorGroupByAggregrationInfo.
org.apache.hadoop.hive.ql.ppd.SimplePredicatePushDown	Implementation of predicate push down.
org.apache.hadoop.hive.ql.security.authorization.DefaultHiveAuthorizationTranslator	Default implementation of HiveAuthorizationTranslator.
org.apache.hadoop.hive.ql.security.authorization.plugin.AbstractHiveAuthorizer	Abstract class that extends HiveAuthorizer.
org.apache.hadoop.hive.ql.session.ClearDanglingScratchDir	A tool to remove dangling scratch directory.
org.apache.hadoop.hive.ql.stats.StatsCollectionContext	Creating context for stats collection.
org.apache.hadoop.hive.ql.txn.compactor.HouseKeeperServiceBase	Housekeeper for running services.
org.apache.hadoop.hive.ql.udf.UDFChr	UDFChr converts an integer into its ASCII equivalent.
org.apache.hadoop.hive.ql.udf.UDFCrc32	UDFCrc32.
org.apache.hadoop.hive.ql.udf.UDFMd5	UDFMd5.
org.apache.hadoop.hive.ql.udf.UDFReplace	UDFReplace replaces all substrings that are matched with a replacement substring.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.udf.UDFSha1	UDFSha.
org.apache.hadoop.hive.ql.udf.UDFVersion	UDFVersion
org.apache.hadoop.hive.ql.udf.generic.BaseMaskUDF	User defined function for masking.
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFSumEmptyIsZero	User defined aggregation function for summing empy as zeros.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesBase	Base for user defined functions.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesDecrypt	User defined function for decryption.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesEncrypt	User defined function for encryption.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBRound	User defined function for banking rounding.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBaseNwayCompare	Base class for comparison UDF's (Greatest and Least).
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMask	User defined function for masking.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskFirstN	User defined function for masking first n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskHash	User defined function that returns a hashed value based on str.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskLastN	User defined function for masking last n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskShowFirstN	User defined function for showing masked first n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskShowLastN	User defined function for showing masked last n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFParamUtils	Generic UDF params utility class.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFQuarter	GenericUDFQuarter.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFRegExp	UDF to extract a specific group identified by a java regex.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFSha2	GenericUDFSha2.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFSubstringIndex	GenericUDFSubstringIndex.
org.apache.hadoop.hive.ql.udf.generic.GenericUDTFGetSplits	GenericUDTFGetSplits.
org.apache.hadoop.hive.ql.util.DependencyResolver	Query dependency resolver.
org.apache.hadoop.hive.ql.util.ResourceDownloader	Resource downloader.
org.apache.hadoop.hive.ql.util.TimestampUtils	Utitilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.serde2.DefaultFetchFormatter	Serializes row by user specified serde and calls toString() to make string type result.
org.apache.hadoop.hive.serde2.NoOpFetchFormatter	A No-op fetch formatter.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.serde2.binarysortable.BinarySortableSerDeWithEndPrefix	Serializer desrializer for binary sortable.
org.apache.hadoop.hive.serde2.thrift.ColumnBuffer	Column buffer.
org.apache.hadoop.hive.serde2.thrift.ThriftFormatter	Thrift formatter.
org.apache.hadoop.hive.serde2.thrift.ThriftJDBCBinarySerDe	Serializes the final output to thrift-able objects directly in the SerDe.
org.apache.hadoop.hive.thrift.HiveDelegationTokenManager	Delegation token manager.
org.apache.hive.beeline.ClientCommandHookFactory	Updates some client side information after executing some Hive commands.
org.apache.hive.beeline.ClientHook	This is the client's hook and used for new Hive CLI.
org.apache.hive.common.util.DateParser	Date parser class for Hive.
org.apache.hive.common.util.FixedSizedObjectPool	Simple object pool of limited size.
org.apache.hive.common.util.HashCodeUtil	Utilities for hash code.
org.apache.hive.common.util.IntervalDayTimeUtils	DateUtils.
org.apache.hive.hcatalog.streaming.AbstractRecordWriter	Class for defining record writer.
org.apache.hive.jdbc.HttpTokenAuthInterceptor	The class is instantiated with the username and password, it is then used to add header with these credentials to HTTP requests
org.apache.hive.jdbc.XsrfHttpRequestInterceptor	Http request interceptor for xsrf token.
org.apache.hive.service.cli.operation.GetCrossReferenceOperation	GetCrossReferenceOperation.
org.apache.hive.service.cli.operation.GetPrimaryKeysOperation	GetPrimaryKeysOperation.
org.apache.hive.service.cli.operation.SQLOperationDisplay	Used to display some info in the HS2 WebUI.
org.apache.hive.service.cli.operation.SQLOperationDisplayCache	Cache some SQLOperation information for WebUI
org.apache.hive.service.cli.thrift.RetryingThriftCLIServiceClient	RetryingThriftCLIServiceClient.

New Interfaces in Hive 2.1

Hive 2.1 includes the following new interfaces:

Interface	Description
org.apache.hadoop.hive.common.*Pool*	Simple object pool to prevent GC on small objects passed between threads.
org.apache.hadoop.hive.common.io.*Allocator*	An allocator provided externally to storage classes to allocate MemoryBuffer-s.
org.apache.hadoop.hive.common.io.*DataCache*	An abstract data cache that IO formats can use to retrieve and cache data.
org.apache.hadoop.hive.conf.*HiveVariableSource*	Getting hive variables.
org.apache.hadoop.hive.metastore.*FileFormatProxy*	Same as PartitionExpressionProxy, but for file format specific methods for metadata cache.

last-updated: Apr 11, 2022

org.apache.hadoop.hive.metastore.*HouseKeeperService*	Runs arbitrary background logic inside the metastore service.
org.apache.hadoop.hive.metastore.txn.*TxnStore*	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.ql.exec.tez.*KeyValuesAdapter*	Key-values interface for the Reader used by ReduceRecordSource
org.apache.hadoop.hive.ql.exec.vector.expressions.*IStructInExpr*	Interface used for both filter and non-filter versions of IN to simplify VectorizationContext code.
org.apache.hadoop.hive.ql.exec.vector.expressions.*ITimestampInExpr*	Interface used to proccess timestamp in expression.
org.apache.hadoop.hive.ql.io.*ColumnarSplit*	Interface when implemented should return the estimated size of columnar projections that will be read from the split.
org.apache.hadoop.hive.ql.io.*LlapAwareSplit*	Split that is aware that it could be executed in LLAP.
org.apache.hadoop.hive.ql.io.*LlapWrappableInputFormatInterface*	Marker interface for LLAP; serves no other purpose.
org.apache.hadoop.hive.ql.io.*SelfDescribingInputFormatInterface*	Marker interface to indicate a given input format is self-describing and can perform schema evolution itself.
org.apache.hadoop.hive.ql.io.*StreamingOutputFormat*	Marker interface for streaming output formats.
org.apache.hadoop.hive.ql.security.authorization.plugin.*HiveAuthorizationTranslator*	This interface has functions that provide the ability to customize the translation from Hive internal representations of Authorization objects to the public API objects This is an interface that is not meant for general use, it is targeted to some specific use cases of Apache Sentry (incubating).
org.apache.hadoop.hive.serde2.*FetchFormatter*	(**For internal-use only**) Used in ListSinkOperator for formatting final output.

Changed Classes in Hive 2.1

The following classes have changes in Hive 2.1:

Class	Description
org.apache.hadoop.hive.accumulo.mr.HiveAccumuloTableOutputFormat	Output format for accumulo tables.
org.apache.hadoop.hive.cli.CliDriver	CliDriver.
org.apache.hadoop.hive.cli.OptionsProcessor	OptionsProcessor.
org.apache.hadoop.hive.common.CompressionUtils	Contains methods used for the purposes of compression. This class should not be accessed from code run in Hadoop.
org.apache.hadoop.hive.common.FileUtils	Collection of file manipulation utilities common across Hive.
org.apache.hadoop.hive.common.HiveStatsUtils	HiveStatsUtils.
org.apache.hadoop.hive.common.JavaUtils	Collection of Java class loading/reflection related utilities common across Hive.
org.apache.hadoop.hive.common.LogUtils	Utilities common to logging operations.
org.apache.hadoop.hive.common.ObjectPair	Creating pair out of templates.
org.apache.hadoop.hive.common.ServerUtils	ServerUtils (specific to HiveServer version 1)

Class	Description
org.apache.hadoop.hive.common.StatsSetupConst	Defines the constant strings used by the statistics implementation.
org.apache.hadoop.hive.common.ValidReadTxnList	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by readers.
org.apache.hadoop.hive.common.cli.CommonCliOptions	Reusable code for Hive Cli's.
org.apache.hadoop.hive.common.io.NonSyncByteArrayInputStream	A thread-not-safe version of ByteArrayOutputStream, which removes all synchronized modifiers.
org.apache.hadoop.hive.common.type.HiveDecimal	HiveDecimal.
org.apache.hadoop.hive.common.type.HiveIntervalDayTime	Day-time interval type representing an offset in days/hours/minutes/seconds, with nanosecond precision.
org.apache.hadoop.hive.common.type.HiveVarchar	HiveVarChar.
org.apache.hadoop.hive.conf.HiveConf	Hive Configuration.
org.apache.hadoop.hive.conf.HiveConfUtil	Hive Configuration utils
org.apache.hadoop.hive.contrib.serde2.MultiDelimitSerDe	This SerDe allows user to use multiple characters as the field delimiter for a table.
org.apache.hadoop.hive.contrib.serde2.RegexSerDe	RegexSerDe uses regular expression (regex) to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2.TypedBytesSerDe	TypedBytesSerDe uses typed bytes to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2.s3.S3LogDeserializer	S3LogDeserializer.
org.apache.hadoop.hive.hbase.AbstractHBaseKeyPredicateDecomposer	Simple abstract class to help with creation of a DecomposedPredicate.
org.apache.hadoop.hive.hbase.CompositeHBaseKeyFactory	Factory that creates composite keys.
org.apache.hadoop.hive.hbase.HBaseLazyObjectFactory	Replaces original keyOI with OI which is create by HBaseKeyFactory provided by serde property for hbase.
org.apache.hadoop.hive.hbase.HBaseSerDe	HBaseSerDe can be used to serialize object into an HBase table and deserialize objects from an HBase table.
org.apache.hadoop.hive.hbase.HBaseSerDeHelper	Helper class for HBaseSerDe
org.apache.hadoop.hive.hbase.HiveHBaseTableInputFormat	HiveHBaseTableInputFormat implements InputFormat for HBase storage handler tables, decorating an underlying HBase TableInputFormat with extra Hive logic such as column pruning and filter pushdown.
org.apache.hadoop.hive.hbase.HiveHBaseTableOutputFormat	HiveHBaseTableOutputFormat implements HiveOutputFormat for HBase tables.
org.apache.hadoop.hive.hbase.LazyHBaseCellMap	LazyHBaseCellMap refines LazyMap with HBase column mapping.
org.apache.hadoop.hive.hwi.HWIContextListener	After getting a contextInitialized event, this component starts an instance of the HiveSessionManager.
org.apache.hadoop.hive.hwi.HWIServer	This is the entry point for HWI.
org.apache.hadoop.hive.hwi.HWISessionItem	HWISessionItem can be viewed as a wrapper for a Hive shell.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.hwi.HWISessionManager	HiveSessionManager is a Runnable started inside a web application context.
org.apache.hadoop.hive.metastore.Deadline	Monitors long running methods in a thread.
org.apache.hadoop.hive.metastore.HiveAlterHandler	Hive specific implementation of alter.
org.apache.hadoop.hive.metastore.HiveMetaStore	Removes application logic to a separate interface.
org.apache.hadoop.hive.metastore.HiveMetaStoreClient	Hive Metastore Client.
org.apache.hadoop.hive.metastore.HiveMetaStoreFsImpl	Class to handle methods for filesystem and data related to metastore.
org.apache.hadoop.hive.metastore.LockComponentBuilder	A builder for LockComponents.
org.apache.hadoop.hive.metastore.LockRequestBuilder	Builder class to make constructing LockRequest easier.
org.apache.hadoop.hive.metastore.MetaStoreSchemaInfo	Information about metastore schemas stored in database.
org.apache.hadoop.hive.metastore.MetaStoreUtils	Utilities to handle metastore data.
org.apache.hadoop.hive.metastore.ObjectStore	Interface between the application logic and the database store that contains the objects.
org.apache.hadoop.hive.metastore.PartitionDropOptions	Generalizes the switches for dropPartitions().
org.apache.hadoop.hive.metastore.RetryingHMSHandler	Handler for hive metastore.
org.apache.hadoop.hive.metastore.RetryingMetaStoreClient	RetryingMetaStoreClient.
org.apache.hadoop.hive.metastore.StatObjectConverter	Contains conversion logic that creates Thrift stat objects from JDO stat objects and plain arrays from DirectSQL.
org.apache.hadoop.hive.metastore.Warehouse	Represents a warehouse where data of Hive tables is stored.
org.apache.hadoop.hive.metastore.api.AbortTxnRequest	Aborting transaction request.
org.apache.hadoop.hive.metastore.api.AddDynamicPartitions	Adding dynamic partitions.
org.apache.hadoop.hive.metastore.api.AddPartitionsRequest	Adding partition request.
org.apache.hadoop.hive.metastore.api.AddPartitionsResult	Adding partition result.
org.apache.hadoop.hive.metastore.api.AggrStats	Aggregation statistics.
org.apache.hadoop.hive.metastore.api.BinaryColumnStatsData	Binary column statistics data.
org.apache.hadoop.hive.metastore.api.BooleanColumnStatsData	Boolean column statistics data.
org.apache.hadoop.hive.metastore.api.CheckLockRequest	Checking request on acquiring lock.
org.apache.hadoop.hive.metastore.api.ColumnStatistics	Column statistics class.
org.apache.hadoop.hive.metastore.api.ColumnStatisticsDesc	Column statistics description.
org.apache.hadoop.hive.metastore.api.ColumnStatisticsObj	Column statistics object.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.metastore.api.CommitTxnRequest	Commit transaction request.
org.apache.hadoop.hive.metastore.api.CompactionRequest	Compaction request.
org.apache.hadoop.hive.metastore.api.CurrentNotificationEventId	Current notification event ID.
org.apache.hadoop.hive.metastore.api.Database	Class that describes database.
org.apache.hadoop.hive.metastore.api.Date	Date class.
org.apache.hadoop.hive.metastore.api.DateColumnStatsData	Date column statistics data.
org.apache.hadoop.hive.metastore.api.Decimal	Handling decimal type.
org.apache.hadoop.hive.metastore.api.DecimalColumnStatsData	Decimal column statistics data.
org.apache.hadoop.hive.metastore.api.DoubleColumnStatsData	Double column statistics data.
org.apache.hadoop.hive.metastore.api.DropPartitionsExpr	Drop partitions expression.
org.apache.hadoop.hive.metastore.api.DropPartitionsRequest	Drop partitions request.
org.apache.hadoop.hive.metastore.api.DropPartitionsResult	Drop partitions result.
org.apache.hadoop.hive.metastore.api.EnvironmentContext	Environment context structure.
org.apache.hadoop.hive.metastore.api.FieldSchema	Field schema structure.
org.apache.hadoop.hive.metastore.api.FireEventRequest	Fire event request.
org.apache.hadoop.hive.metastore.api.FireEventResponse	Fire event response.
org.apache.hadoop.hive.metastore.api.Function	Function structure.
org.apache.hadoop.hive.metastore.api.GetOpenTxnsInfoResponse	Getter for open transactions information about response.
org.apache.hadoop.hive.metastore.api.GetOpenTxnsResponse	Getter for open transactions response.
org.apache.hadoop.hive.metastore.api.GetPrincipalsInRoleRequest	Getting request for principals in role.
org.apache.hadoop.hive.metastore.api.GetPrincipalsInRoleResponse	Getting response for principals in role.
org.apache.hadoop.hive.metastore.api.GetRoleGrantsForPrincipalRequest	Getting request for granting role for principal.
org.apache.hadoop.hive.metastore.api.GetRoleGrantsForPrincipalResponse	Getting response for granting role for principal.
org.apache.hadoop.hive.metastore.api.GrantRevokePrivilegeRequest	Request for revoking granted privilege.
org.apache.hadoop.hive.metastore.api.GrantRevokePrivilegeResponse	Response for revoking granted privilege.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.metastore.api.GrantRevokeRoleRequest	Request for revoking granted role.
org.apache.hadoop.hive.metastore.api.GrantRevokeRoleResponse	Response for revoking granted role.
org.apache.hadoop.hive.metastore.api.HeartbeatRequest	Request for heartbeat.
org.apache.hadoop.hive.metastore.api.HeartbeatTxnRangeRequest	Request for transaction range request.
org.apache.hadoop.hive.metastore.api.HeartbeatTxnRangeResponse	Response for transaction range response.
org.apache.hadoop.hive.metastore.api.HiveObjectPrivilege	Description of privileges for hive object.
org.apache.hadoop.hive.metastore.api.HiveObjectRef	Hive object reference.
org.apache.hadoop.hive.metastore.api.Index	Description of index.
org.apache.hadoop.hive.metastore.api.InsertEventRequestData	Class to handle data about insert event on request.
org.apache.hadoop.hive.metastore.api.LockComponent	Description of lock component.
org.apache.hadoop.hive.metastore.api.LockRequest	Description of lock request.
org.apache.hadoop.hive.metastore.api.LockResponse	Description of lock response.
org.apache.hadoop.hive.metastore.api.LongColumnStatsData	Description of long column statistics data.
org.apache.hadoop.hive.metastore.api.NotificationEvent	Description of notification event.
org.apache.hadoop.hive.metastore.api.NotificationEventRequest	Description of notification event on request.
org.apache.hadoop.hive.metastore.api.NotificationEventResponse	Description of notification event on response.
org.apache.hadoop.hive.metastore.api.OpenTxnRequest	Description of open transactions on request.
org.apache.hadoop.hive.metastore.api.OpenTxnsResponse	Description of open transactions on response.
org.apache.hadoop.hive.metastore.api.Order	Description of order.
org.apache.hadoop.hive.metastore.api.Partition	Description of partition.
org.apache.hadoop.hive.metastore.api.PartitionListComposingSpec	Description of partition list composing specification.
org.apache.hadoop.hive.metastore.api.PartitionSpec	Description of partition specification.
org.apache.hadoop.hive.metastore.api.PartitionSpecWithSharedSD	Description of partition specification with shared sd.
org.apache.hadoop.hive.metastore.api.PartitionWithoutSD	Description of partition without sd.
org.apache.hadoop.hive.metastore.api.PartitionsByExprRequest	Description of partitions by expression request.
org.apache.hadoop.hive.metastore.api.PartitionsByExprResult	Description of partitions by expression result.
org.apache.hadoop.hive.metastore.api.PartitionsStatsRequest	Description of partition statistics request.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.metastore.api.PartitionsStatsResult	Description of partitions statistics result.
org.apache.hadoop.hive.metastore.api.PrincipalPrivilegeSet	Description of setting principal privilege.
org.apache.hadoop.hive.metastore.api.PrivilegeBag	Description of privilege bag.
org.apache.hadoop.hive.metastore.api.PrivilegeGrantInfo	Description of granted privilege info.
org.apache.hadoop.hive.metastore.api.ResourceUri	Description of resource URI.
org.apache.hadoop.hive.metastore.api.Role	Description of role.
org.apache.hadoop.hive.metastore.api.RolePrincipalGrant	Description of granted principal role.
org.apache.hadoop.hive.metastore.api.Schema	Description of schema.
org.apache.hadoop.hive.metastore.api.SerDeInfo	Description of serializer deserializer information.
org.apache.hadoop.hive.metastore.api.SetPartitionsStatsRequest	Description of setting partition statistics on request.
org.apache.hadoop.hive.metastore.api.ShowCompactRequest	Show compaction on request.
org.apache.hadoop.hive.metastore.api.ShowCompactResponse	Show compaction on response.
org.apache.hadoop.hive.metastore.api.ShowCompactResponseElement	Show compaction response element.
org.apache.hadoop.hive.metastore.api.ShowLocksRequest	Show locks on request.
org.apache.hadoop.hive.metastore.api.ShowLocksResponse	Show locks on response.
org.apache.hadoop.hive.metastore.api.ShowLocksResponseElement	Show locks response element.
org.apache.hadoop.hive.metastore.api.SkewedInfo	Description for skewed information.
org.apache.hadoop.hive.metastore.api.StorageDescriptor	Description for storage descriptor.
org.apache.hadoop.hive.metastore.api.StringColumnStatsData	Description for string column statistics data.
org.apache.hadoop.hive.metastore.api.Table	Description for data.
org.apache.hadoop.hive.metastore.api.TableStatsRequest	Description for table statistics request.
org.apache.hadoop.hive.metastore.api.TableStatsResult	Description for table statistics result.
org.apache.hadoop.hive.metastore.api.AlreadyExistsException	Custom exception to handle already exists error.
org.apache.hadoop.hive.metastore.api.ConfigValSecurityException	Custom exception to handle configuration value security error.
org.apache.hadoop.hive.metastore.api.IndexAlreadyExistsException	Custom exception to handle index already exists error.
org.apache.hadoop.hive.metastore.api.InvalidInputException	Custom exception for invalid input error.
org.apache.hadoop.hive.metastore.api.InvalidObjectException	Custom exception for invalid object error.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.metastore.api.InvalidOperationException	Custom exception for invalid operation error.
org.apache.hadoop.hive.metastore.api.InvalidPartitionException	Custom exception for invalid partition error.
org.apache.hadoop.hive.metastore.api.MetaException	Custom exception for metastore related error.
org.apache.hadoop.hive.metastore.api.NoSuchLockException	Custom exception in case of invalid lock.
org.apache.hadoop.hive.metastore.api.NoSuchObjectException	Custom exception in case of invalid object.
org.apache.hadoop.hive.metastore.api.NoSuchTxnException	Custom exception in case of invalid transaction.
org.apache.hadoop.hive.metastore.api.TxnAbortedException	Custom exception in case of aborted transaction.
org.apache.hadoop.hive.metastore.api.TxnOpenException	Custom exception in case of not close transaction.
org.apache.hadoop.hive.metastore.api.UnknownDBException	Custom exception in case of unknown database.
org.apache.hadoop.hive.metastore.api.UnknownPartitionException	Custom exception in case of unknown partition.
org.apache.hadoop.hive.metastore.api.UnknownTableException	Custom partition in case of unknown table.
org.apache.hadoop.hive.metastore.events.EventCleanerTask	Cleaning tasks from event table.
org.apache.hadoop.hive.metastore.parser.ExpressionTree	Represents the filter as a binary tree.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Information on a possible or running compaction.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Utility methods for creating and destroying txn database/ schema, plus methods for querying against metastore tables.
org.apache.hadoop.hive.ql.Context	Context for Semantic Analyzers.
org.apache.hadoop.hive.ql.Driver	Driver to process commands on cluster.
org.apache.hadoop.hive.ql.QueryPlan	QueryPlan can be serialized to disk to restart/resume the progress of it in the future, either within or outside of the current JVM.
org.apache.hadoop.hive.ql.QueryProperties	QueryProperties.
org.apache.hadoop.hive.ql.exec.AbstractFileMergeOperator	Fast file merge operator for ORC and RCfile.
org.apache.hadoop.hive.ql.exec.AbstractMapJoinOperator	Class to handle join input's join keys.
org.apache.hadoop.hive.ql.exec.AppMasterEventOperator	AppMasterEventOperator sends any rows it receives to the Tez AM.
org.apache.hadoop.hive.ql.exec.AutoProgressor	AutoProgressor periodically sends updates to the job tracker so that it doesn't consider this task attempt dead if there is a long period of inactivity.
org.apache.hadoop.hive.ql.exec.CollectOperator	Buffers rows emitted by other operators.
org.apache.hadoop.hive.ql.exec.ColumnStatsTask	ColumnStatsTask implementation.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.ColumnStatsUpdateTask	ColumnStatsUpdateTask implementation.
org.apache.hadoop.hive.ql.exec.CommonJoinOperator	Join operator implementation.
org.apache.hadoop.hive.ql.exec.CommonMergeJoinOperator	Consolidate the join algorithms to either hash based joins (MapJoinOperator) or sort-merge based joins, this operator is being introduced.
org.apache.hadoop.hive.ql.exec.ConditionalTask	Conditional Task implementation.
org.apache.hadoop.hive.ql.exec.DDLTask	DDLTask implementation.
org.apache.hadoop.hive.ql.exec.DefaultBucketMatcher	Finding right bucket.
org.apache.hadoop.hive.ql.exec.DemuxOperator	DemuxOperator is an operator used by MapReduce Jobs optimized by CorrelationOptimizer.
org.apache.hadoop.hive.ql.exec.DummyStoreOperator	For SortMerge joins, this is a dummy operator, which stores the row for the small table before it reaches the sort merge join operator.
org.apache.hadoop.hive.ql.exec.ExplainTask	ExplainTask implementation.
org.apache.hadoop.hive.ql.exec.FetchOperator	FetchTask implementation.
org.apache.hadoop.hive.ql.exec.FetchTask	FetchTask implementation.
org.apache.hadoop.hive.ql.exec.FileSinkOperator	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec.FilterOperator	Filter operator implementation.
org.apache.hadoop.hive.ql.exec.ForwardOperator	Forward Operator Just forwards.
org.apache.hadoop.hive.ql.exec.FunctionRegistry	FunctionRegistry.
org.apache.hadoop.hive.ql.exec.FunctionTask	FunctionTask.
org.apache.hadoop.hive.ql.exec.GroupByOperator	GroupBy operator implementation.
org.apache.hadoop.hive.ql.exec.HashTableDummyOperator	Hash table operator implementation.
org.apache.hadoop.hive.ql.exec.HashTableSinkOperator	Hash table sink operator implementation.
org.apache.hadoop.hive.ql.exec.JoinOperator	Join operator implementation.
org.apache.hadoop.hive.ql.exec.LateralViewForwardOperator	LateralViewForwardOperator.
org.apache.hadoop.hive.ql.exec.LateralViewJoinOperator	The lateral view join operator is used for FROM src LATERAL VIEW udtf()...
org.apache.hadoop.hive.ql.exec.LimitOperator	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec.ListSinkOperator	For fetch task with operator tree, row read from FetchOperator is processed via operator tree and finally arrives to this operator.
org.apache.hadoop.hive.ql.exec.MapJoinOperator	Map side Join operator implementation.
org.apache.hadoop.hive.ql.exec.MapOperator	Map operator.
org.apache.hadoop.hive.ql.exec.MapredContext	Runtime context of MapredTask providing additional information to GenericUDF
org.apache.hadoop.hive.ql.exec.MoveTask	MoveTask implementation.
org.apache.hadoop.hive.ql.exec.MuxOperator	MuxOperator is used in the Reduce side of MapReduce jobs optimized by Correlation Optimizer.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.ObjectCacheFactory	ObjectCacheFactory returns the appropriate cache depending on settings in the hive conf.
org.apache.hadoop.hive.ql.exec.Operator	Base operator implementation.
org.apache.hadoop.hive.ql.exec.OperatorFactory	OperatorFactory.
org.apache.hadoop.hive.ql.exec.OperatorUtils	Utilities to handle operators.
org.apache.hadoop.hive.ql.exec.OrcFileMergeOperator	Fast file merge operator for ORC files.
org.apache.hadoop.hive.ql.exec.PTFOperator	Class to handle partitioned table functions operators.
org.apache.hadoop.hive.ql.exec.PTFPartition	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive.ql.exec.PTFRollingPartition	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive.ql.exec.PTFUtils	Utilities to handle partitioned table functions.
org.apache.hadoop.hive.ql.exec.PartitionKeySampler	Class to handle partition key sampler.
org.apache.hadoop.hive.ql.exec.RCFileMergeOperator	Fast file merge operator for RC files.
org.apache.hadoop.hive.ql.exec.ReduceSinkOperator	Reduce Sink Operator sends output to the reduce stage.
org.apache.hadoop.hive.ql.exec.Registry	Function registry.
org.apache.hadoop.hive.ql.exec.SMBMapJoinOperator	Sorted Merge Map Join Operator.
org.apache.hadoop.hive.ql.exec.ScriptOperator	ScriptOperator.
org.apache.hadoop.hive.ql.exec.SelectOperator	Select operator implementation.
org.apache.hadoop.hive.ql.exec.SkewJoinHandler	At runtime in Join, output big keys in one table into one corresponding directories, and all same keys in other tables into different dirs (one for each table).
org.apache.hadoop.hive.ql.exec.SparkHashTableSinkOperator	Operator for spark hashtable sink.
org.apache.hadoop.hive.ql.exec.StatsNoJobTask	StatsNoJobTask is used in cases where stats collection is the only task for the given query (no parent MR or Tez job).
org.apache.hadoop.hive.ql.exec.TableScanOperator	Table Scan Operator If the data is coming from the map-reduce framework, just forward it.
org.apache.hadoop.hive.ql.exec.Task	Task implementation.
org.apache.hadoop.hive.ql.exec.TaskResult	TaskResult implementation.
org.apache.hadoop.hive.ql.exec.TemporaryHashSinkOperator	Operator temporary hash sink.
org.apache.hadoop.hive.ql.exec.TerminalOperator	Terminal Operator Base Class.
org.apache.hadoop.hive.ql.exec.TezDummyStoreOperator	A dummy store operator same as the dummy store operator but for tez.
org.apache.hadoop.hive.ql.exec.TopNHash	Stores binary key/value in sorted manner to get top-n key/value TODO: rename to TopNHeap?
org.apache.hadoop.hive.ql.exec.UDTFOperator	UDTFOperator.
org.apache.hadoop.hive.ql.exec.UnionOperator	Union Operator Just forwards.
org.apache.hadoop.hive.ql.exec.Utilities	Utilities.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.mr.ExecDriver	ExecDriver is the central class in co-ordinating execution of any map-reduce task.
org.apache.hadoop.hive.ql.exec.mr.ExecMapper	ExecMapper is the generic Map class for Hive.
org.apache.hadoop.hive.ql.exec.mr.ExecMapperContext	ExecMapperContext is the generic Map context class for Hive.
org.apache.hadoop.hive.ql.exec.mr.HadoopJobExecHelper	Handle information about hadoop job.
org.apache.hadoop.hive.ql.exec.mr.JobDebugger	JobDebugger takes a RunningJob that has failed and grabs the top 4 failing tasks and outputs this information to the Hive CLI.
org.apache.hadoop.hive.ql.exec.mr.MapredLocalTask	MapredLocalTask represents any local work (i.e.: client side work) that hive needs to execute.
org.apache.hadoop.hive.ql.exec.mr.Throttle	Intelligence to make clients wait if the cluster is in a bad state.
org.apache.hadoop.hive.ql.exec.persistence.BytesBytesMultiHashMap	HashMap that maps byte arrays to byte arrays with limited functionality necessary for MapJoin hash tables, with small memory overhead.
org.apache.hadoop.hive.ql.exec.persistence.HashMapWrapper	Simple wrapper for persistent Hashmap implementing only the put/get/remove/clear interface.
org.apache.hadoop.hive.ql.exec.persistence.HybridHashTableContainer	Hash table container that can have many partitions -- each partition has its own hashmap, as well as row container for small table and big table.
org.apache.hadoop.hive.ql.exec.persistence.KeyValueContainer	An eager key/value container that puts every row directly to output stream.
org.apache.hadoop.hive.ql.exec.persistence.MapJoinBytesTableContainer	Table container that serializes keys and values using LazyBinarySerDe into BytesBytesMultiHashMap, with very low memory overhead.
org.apache.hadoop.hive.ql.exec.persistence.MapJoinKey	The base class for MapJoinKey.
org.apache.hadoop.hive.ql.exec.persistence.MapJoinTableContainerSerDe	Serialization/deserialization of table container for join.
org.apache.hadoop.hive.ql.exec.persistence.ObjectContainer	An eager object container that puts every row directly to output stream.
org.apache.hadoop.hive.ql.exec.persistence.RowContainer	Simple persistent container for rows.
org.apache.hadoop.hive.ql.exec.persistence.UnwrapRowContainer	Unwraps values from current key with valueIndex in mapjoin desc.
org.apache.hadoop.hive.ql.exec.spark.GroupByShuffler	Shuffle group by operator.
org.apache.hadoop.hive.ql.exec.spark.HiveSparkClientFactory	Factory class for spark client.
org.apache.hadoop.hive.ql.exec.spark.LocalHiveSparkClient	LocalSparkClient submit Spark job in local driver, it's responsible for build spark client environment and execute spark work.
org.apache.hadoop.hive.ql.exec.spark.MapInput	Input for mapper.
org.apache.hadoop.hive.ql.exec.spark.MapTran	Mapper tran.
org.apache.hadoop.hive.ql.exec.spark.ReduceTran	Reduce tran.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.spark.RemoteHiveSparkClient	RemoteSparkClient is a wrapper of org.apache.hive.spark.client.SparkClient, which wrap a spark job request and send to an remote SparkContext.
org.apache.hadoop.hive.ql.exec.spark.ShuffleTran	Shuffle tran.
org.apache.hadoop.hive.ql.exec.spark.SortByShuffler	Sorting class for shuffler.
org.apache.hadoop.hive.ql.exec.spark.SparkTask	Description of spark task.
org.apache.hadoop.hive.ql.exec.spark.SparkUtilities	Contains utilities methods used as part of Spark tasks.
org.apache.hadoop.hive.ql.exec.spark.session.SparkSessionImpl	Implementation of spark session.
org.apache.hadoop.hive.ql.exec.spark.status.impl.JobMetricsListener	Listener for job metrics.
org.apache.hadoop.hive.ql.exec.spark.status.impl.LocalSparkJobStatus	Spark job local status.
org.apache.hadoop.hive.ql.exec.spark.status.impl.RemoteSparkJobStatus	Used with remove spark client.
org.apache.hadoop.hive.ql.exec.tez.DagUtils	DagUtils.
org.apache.hadoop.hive.ql.exec.tez.DynamicPartitionPruner	DynamicPartitionPruner takes a list of assigned partitions at runtime (split generation) and prunes them using events generated during execution of the dag.
org.apache.hadoop.hive.ql.exec.tez.HiveSplitGenerator	Generates splits inside the AM on the cluster.
org.apache.hadoop.hive.ql.exec.tez.MapRecordProcessor	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez.MapRecordSource	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez.MergeFileRecordProcessor	Record processor for fast merging of files.
org.apache.hadoop.hive.ql.exec.tez.RecordProcessor	Process input from tez LogicalInput and write output It has different subclasses for map and reduce processing
org.apache.hadoop.hive.ql.exec.tez.ReduceRecordProcessor	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez.ReduceRecordSource	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez.SplitGrouper	SplitGrouper is used to combine splits based on head room and locality.
org.apache.hadoop.hive.ql.exec.tez.TezJobMonitor	TezJobMonitor keeps track of a tez job while it's being executed.
org.apache.hadoop.hive.ql.exec.tez.TezProcessor	Hive processor for Tez that forms the vertices in Tez and processes the data.
org.apache.hadoop.hive.ql.exec.tez.TezSessionPoolManager	This class is for managing multiple tez sessions particularly when HiveServer2 is being used to submit queries.
org.apache.hadoop.hive.ql.exec.tez.TezSessionState	Holds session state related to Tez

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.tez.TezTask	TezTask handles the execution of TezWork.
org.apache.hadoop.hive.ql.exec.tez.tools.KeyValueInputMerger	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive.ql.exec.tez.tools.KeyValuesInputMerger	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive.ql.exec.vector.BytesColumnVector	This class supports string and binary data by value reference.
org.apache.hadoop.hive.ql.exec.vecto.ColumnVector	ColumnVector contains the shared structure for the sub-types, including NULL information, and whether this vector repeats, i.e.
org.apache.hadoop.hive.ql.exec.vector.DecimalColumnVector	A vector of HiveDecimalWritable objects.
org.apache.hadoop.hive.ql.exec.vector.DoubleColumnVector	This class represents a nullable double precision floating point column vector.
org.apache.hadoop.hive.ql.exec.vector.LongColumnVector	This class represents a nullable int column vector.
org.apache.hadoop.hive.ql.exec.vector.TimestampUtils	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.ql.exec.vector.VectorAppMasterEventOperator	App Master Event operator implementation.
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRow	This class assigns specified columns of a row from a Writable row objects.
org.apache.hadoop.hive.ql.exec.vector.VectorColumnOrderedMap	This class collects column information for mapping vector columns, including the hive type name.
org.apache.hadoop.hive.ql.exec.vector.VectorColumnSetInfo	Class to keep information on a set of typed vector columns.
org.apache.hadoop.hive.ql.exec.vector.VectorCopyRow	This class copies specified columns of a row from one VectorizedRowBatch to another.
org.apache.hadoop.hive.ql.exec.vector.VectorDeserializeRow	This class deserializes a serialization format into a row of a VectorizedRowBatch.
org.apache.hadoop.hive.ql.exec.vector.VectorExtractRow	This class extracts specified VectorizedRowBatch row columns into writables.
org.apache.hadoop.hive.ql.exec.vector.VectorFileSinkOperator	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec.vector.VectorFilterOperator	Filter operator implementation.
org.apache.hadoop.hive.ql.exec.vector.VectorGroupByOperator	Vectorized GROUP BY operator implementation.
org.apache.hadoop.hive.ql.exec.vector.VectorHashKeyWrapper	A hash map key wrapper for vectorized processing.
org.apache.hadoop.hive.ql.exec.vector.VectorLimitOperator	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec.vector.VectorMapJoinBaseOperator	The *NON-NATIVE* base vector map join operator class used by VectorMapJoinOperator and VectorMapJoinOuterFilteredOperator.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.VectorMapJoinOperator	The vectorized version of the MapJoinOperator.
org.apache.hadoop.hive.ql.exec.vector.VectorMapJoinOuterFilteredOperator	This is the *NON-NATIVE* vector map join operator for just LEFT OUTER JOIN and filtered.
org.apache.hadoop.hive.ql.exec.vector.VectorMapOperator	The vectorized MapOperator.
org.apache.hadoop.hive.ql.exec.vector.VectorReduceSinkOperator	The vectorized reduce sink operator.
org.apache.hadoop.hive.ql.exec.vector.VectorSMBMapJoinOperator	VectorSMBJoinOperator.
org.apache.hadoop.hive.ql.exec.vector.VectorSelectOperator	Select operator implementation.
org.apache.hadoop.hive.ql.exec.vector.VectorSerializeRow	This class serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive.ql.exec.vector.VectorizationContext	Context class for vectorization execution.
org.apache.hadoop.hive.ql.exec.vector.VectorizedBatchUtil	The vectorized MapOperator.
org.apache.hadoop.hive.ql.exec.vector.VectorizedRowBatch	A VectorizedRowBatch is a set of rows, organized with each column as a vector.
org.apache.hadoop.hive.ql.exec.vector.VectorizedRowBatchCtx	Context for Vectorized row batch.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastDecimalToTimestamp	Type cast decimal to timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToDecimal	To be used to cast timestamp to decimal.
org.apache.hadoop.hive.ql.exec.vector.expressions.ColAndCol	Evaluate AND of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive.ql.exec.vector.expressions.ColOrCol	Evaluate OR of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive.ql.exec.vector.expressions.ConstantVectorExpression	Constant is represented as a vector with repeating values.
org.apache.hadoop.hive.ql.exec.vector.expressions.DecimalUtil	Utility functions for vector operations on decimal values.
org.apache.hadoop.hive.ql.exec.vector.expressions.FilterExprOrExpr	Represents an Or expression.
org.apache.hadoop.hive.ql.exec.vector.expressions.FilterStringColumnInList	Evaluate an IN filter on a batch for a vector of strings.
org.apache.hadoop.hive.ql.exec.vector.expressions.FuncRoundWithNumDigitsDecimalToDecimal	Function for rounding decimals.
org.apache.hadoop.hive.ql.exec.vector.expressions.MathExpr	Math expression evaluation helper functions.
org.apache.hadoop.hive.ql.exec.vector.expressions.NullUtil	Utility functions to handle null propagation.
org.apache.hadoop.hive.ql.exec.vector.expressions.StringColumnInList	Evaluate an IN boolean expression (not a filter) on a batch for a vector of strings.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.StringExpr	String expression evaluation helper functions.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDateAddColCol	Vectorized user defined function for adding columns.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDateAddColScalar	Vectorized user defined function for adding column and scalar.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDateDiffColCol	Vectorized user defined function forfinding difference between two columns.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDateLong	Vectorized version of TO_DATE(TIMESTAMP)/ TO_DATE(DATE).
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDateString	Vectorized version of TO_DATE(STRING) As TO_DATE() now returns DATE type, this should be the same behavior as the DATE cast operator.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinCommonOperator	Common operator class for native vectorized map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinGenerateResultOperator	Contains methods for generating vectorized join results and forwarding batchs.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerBigOnlyGenerateResultOperator	This class has methods for generating vectorized join results for the big table only variation of inner joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerBigOnlyLongOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerBigOnlyMultiKeyOperator	Specialized class for doing a vectorized map join that is an inner join on Multi-Key and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerBigOnlyStringOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerGenerateResultOperator	Contains methods for generating vectorized join results for inner joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerLongOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerMultiKeyOperator	Specialized class for doing a vectorized map join that is an inner join on a Multi-Key using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinInnerStringOperator	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinLeftSemiGenerateResultOperator	Contains methods for generating vectorized join results for left semi joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinLeftSemiLongOperator	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column Long using a hash set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinLeftSemiMultiKeyOperator	Specialized class for doing a vectorized map join that is an left semi join on Multi-Key using hash set.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinLeftSemiStringOperator	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column String using a hash set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterGenerateResultOperator	Contains methods for generating vectorized join results for outer joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterLongOperator	Specialized class for doing a vectorized map join that is an outer join on a Single-Column Long using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterMultiKeyOperator	Specialized class for doing a vectorized map join that is an outer join on Multi-Key using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterStringOperator	Specialized class for doing a vectorized map join that is an outer join on a Single-Column String using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinRowBytesContainer	An eager bytes container that puts row bytes to an output stream.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashMap	Bytes key hash map optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash map implementations.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashMultiSet	Bytes key hash multi-set optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash multi-set implementations.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashUtil	Utilities for bytes key hash multi-set optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastHashTable	Vector map join fast hash table.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastKeyStore	Vector map join fast key store.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashMap	Vector map join fact long hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashMultiSet	Vector mapr join fast long hash multi set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashSet	A single LONG key hash set optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashTable	A single long value map optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashUtil	Utilities for vector map join of single long value.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashMap	A multi-key value hash map optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashMultiSet	A multi-key hash multi-set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashSet	A multi-key hash set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastStringCommon	A single byte array value hash map optimized for vector map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastTableContainer	HashTableLoader for Tez constructs the hashtable from records read from a broadcast edge.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable.VectorMapJoinHashMapResult	Abstract class for a hash map result. For reading the values, one-by-one.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable.VectorMapJoinHashTableResult	Root abstract class for a hash table result.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.optimized.VectorMapJoinOptimizedCreateHashTable	Create hash table for vector map join.
org.apache.hadoop.hive.ql.hooks.HookContext	Hook Context keeps all the necessary information for all the hooks.
org.apache.hadoop.hive.ql.hooks.PostExecutePrinter	Implementation of a post execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.hooks.PreExecutePrinter	Implementation of a pre execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.index.HiveIndex	Holds index related constants.
org.apache.hadoop.hive.ql.index.HiveIndexQueryContext	Used to pass information between the IndexProcessor and the plugin IndexHandler during query processing
org.apache.hadoop.hive.ql.index.HiveIndexResult	HiveIndexResult parses the input stream from an index query to generate a list of file splits to query.
org.apache.hadoop.hive.ql.index.HiveIndexedInputFormat	Input format for doing queries that use indexes.
org.apache.hadoop.hive.ql.index.IndexPredicateAnalyzer	IndexPredicateAnalyzer decomposes predicates, separating the parts which can be satisfied by an index from the parts which cannot.
org.apache.hadoop.hive.ql.index.IndexSearchCondition	IndexSearchCondition represents an individual search condition found by IndexPredicateAnalyzer.
org.apache.hadoop.hive.ql.index.TableBasedIndexHandler	Index handler for indexes that use tables to store indexes.
org.apache.hadoop.hive.ql.index.compact.HiveCompactIndexInputFormat	Hive compact index input format.
org.apache.hadoop.hive.ql.io.AcidUtils	Utilities that are shared by all of the ACID input and output formats.
org.apache.hadoop.hive.ql.io.BucketizedHiveInputFormat	BucketizedHiveInputFormat serves the similar function as hiveInputFormat but its getSplits() always group splits from one input file into one wrapper split.
org.apache.hadoop.hive.ql.io.CombineHiveInputFormat	CombineHiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io.HiveFileFormatUtils	An util class for various Hive file format tasks.
org.apache.hadoop.hive.ql.io.HiveInputFormat	HiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io.IOConstants	Input output constants.
org.apache.hadoop.hive.ql.io.IOContext	IOContext basically contains the position information of the current key/value.
org.apache.hadoop.hive.ql.io.NullRowsInputFormat	NullRowsInputFormat outputs null rows, maximum 100.
org.apache.hadoop.hive.ql.io.OneNullRowInputFormat	OneNullRowInputFormat outputs one null row.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.io.RCFileInputFormat	RCFileInputFormat.
org.apache.hadoop.hive.ql.io.SequenceFileInputFormatChecker	SequenceFileInputFormatChecker.
org.apache.hadoop.hive.ql.io.avro.AvroContainerOutputFormat	Write to an Avro file from a Hive process.
org.apache.hadoop.hive.ql.io.merge.MergeFileMapper	Mapper for fast file merging of ORC and RC files.
org.apache.hadoop.hive.ql.io.merge.MergeFileTask	Task for fast merging of ORC and RC files.
org.apache.hadoop.hive.ql.io.orc.CompressionKind	An enumeration that lists the generic compression algorithms that can be applied to ORC files.
org.apache.hadoop.hive.ql.io.orc.OrcFile	Contains factory methods to read or write ORC files.
org.apache.hadoop.hive.ql.io.orc.OrcFileKeyWrapper	Key for OrcFileMergeMapper task.
org.apache.hadoop.hive.ql.io.orc.OrcFileStripeMergeRecordReader	Record reader for orc file stripe merge.
org.apache.hadoop.hive.ql.io.orc.OrcFileValueWrapper	Value for OrcFileMergeMapper.
org.apache.hadoop.hive.ql.io.orc.OrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive.ql.io.orc.OrcNewSplit	OrcFileSplit.
org.apache.hadoop.hive.ql.io.orc.OrcRecordUpdater	A RecordUpdater where the files are stored as ORC.
org.apache.hadoop.hive.ql.io.orc.OrcSerde	A serde class for ORC.
org.apache.hadoop.hive.ql.io.orc.OrcSplit	OrcFileSplit.
org.apache.hadoop.hive.ql.io.orc.ReaderImpl	Implementation of record reader.
org.apache.hadoop.hive.ql.io.orc.VectorizedOrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive.ql.io.orc.WriterImpl	An ORC file writer.
org.apache.hadoop.hive.ql.io.parquet.LeafFilterFactory	Factory class for leaf filter.
org.apache.hadoop.hive.ql.io.parquet.MapredParquetOutputFormat	A Parquet OutputFormat for Hive (with the deprecated package mapred)
org.apache.hadoop.hive.ql.io.parquet.convert.DataWritableRecordConverter	A MapWritableReadSupport, encapsulates the tuples
org.apache.hadoop.hive.ql.io.parquet.convert.ETypeConverter.BinaryConverter	ETypeConverter is an easy way to set the converter for the right type.
org.apache.hadoop.hive.ql.io.parquet.convert.HiveCollectionConverter	Converter for collections.
org.apache.hadoop.hive.ql.io.parquet.convert.HiveGroupConverter	Converter for groups.
org.apache.hadoop.hive.ql.io.parquet.convert.HiveStructConverter	A MapWritableGroupConverter, real converter between hive and parquet types recursively for complex types.
org.apache.hadoop.hive.ql.io.parquet.read.DataWritableReadSupport	A MapWritableReadSupport Manages the translation between Hive and Parquet
org.apache.hadoop.hive.ql.io.parquet.read.ParquetRecordReaderWrapper	Wrapper for parquet record reader.
org.apache.hadoop.hive.ql.io.parquet.serde.ParquetHiveSerDe	A ParquetHiveSerDe for Hive (with the deprecated package mapred)

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.io.parquet.write.DataWritableWriter	DataWritableWriter sends a record to the Parquet API with the expected schema in order to be written to a file.
org.apache.hadoop.hive.ql.io.parquet.write.ParquetRecordWriterWrapper	Wrapper for parquet record writer.
org.apache.hadoop.hive.ql.io.rcfile.stats.PartialScanMapper	PartialScanMapper.
org.apache.hadoop.hive.ql.io.rcfile.stats.PartialScanTask	PartialScanTask.
org.apache.hadoop.hive.ql.io.rcfile.stats.PartialScanWork	Partial Scan Work.
org.apache.hadoop.hive.ql.io.rcfile.truncate.ColumnTruncateMapper	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive.ql.io.rcfile.truncate.ColumnTruncateTask	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive.ql.io.sarg.SearchArgumentFactory	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive.ql.lib.DefaultGraphWalker	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive.ql.lib.RuleExactMatch	Implentation of the Rule interface for Nodes Used in Node dispatching to dispatch process/visitor functions for Nodes.
org.apache.hadoop.hive.ql.lockmgr.DbLockManager	An implementation of HiveLockManager for use with org.apache.hadoop.hive.ql.lockmgr.DbTxnManager.
org.apache.hadoop.hive.ql.lockmgr.DbTxnManager	An implementation of HiveTxnManager that stores the transactions in the metastore database.
org.apache.hadoop.hive.ql.lockmgr.HiveLockObject	The class is used to uniquely identify a HiveLockObject.
org.apache.hadoop.hive.ql.lockmgr.LockException	Exception from lock manager.
org.apache.hadoop.hive.ql.lockmgr.zookeeper.ZooKeeperHiveLock	The class is used to uniquely identify ZookeeperHiveLock.
org.apache.hadoop.hive.ql.lockmgr.zookeeper.ZooKeeperHiveLockManager	Zookeeper lock manager.
org.apache.hadoop.hive.ql.log.PerfLogger	PerfLogger.
org.apache.hadoop.hive.ql.metadata.Hive	Contains functions that implement meta data/DDL operations using calls to the metastore.
org.apache.hadoop.hive.ql.metadata.HiveException	Generic exception class for Hive.
org.apache.hadoop.hive.ql.metadata.HiveMetaStoreChecker	Verify that the information in the metastore matches what is on the filesystem.
org.apache.hadoop.hive.ql.metadata.HiveUtils	General collection of helper functions.
org.apache.hadoop.hive.ql.metadata.Partition	A Hive Table Partition: is a fundamental storage unit within a Table.
org.apache.hadoop.hive.ql.metadata.SessionHiveMetaStoreClient	Client for hivemetastore during session.
org.apache.hadoop.hive.ql.metadata.Table	A Hive Table: is a fundamental unit of data in Hive that shares a common schema/DDL.
org.apache.hadoop.hive.ql.metadata.VirtualColumn	Provides metadata that is not stored in table itself.
org.apache.hadoop.hive.ql.metadata.formatting.JsonMetaDataFormatter	Format table and index information for machine readability using json.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.metadata.formatting.MetaDataFormatUtils	This class provides methods to format table and index information.
org.apache.hadoop.hive.ql.optimizer.BucketMapJoinOptimizer	this transformation does bucket map join optimization.
org.apache.hadoop.hive.ql.optimizer.BucketingSortingReduceSinkOptimizer	This transformation does optimization for enforcing bucketing and sorting.
org.apache.hadoop.hive.ql.optimizer.ColumnPruner	Implementation of one of the rule-based optimization steps.
org.apache.hadoop.hive.ql.optimizer.ColumnPrunerProcCtx	This class implements the processor context for Column Pruner.
org.apache.hadoop.hive.ql.optimizer.ColumnPrunerProcFactory	Factory for generating the different node processors used by ColumnPruner.
org.apache.hadoop.hive.ql.optimizer.ConstantPropagate	Implementation of one of the rule-based optimization steps.
org.apache.hadoop.hive.ql.optimizer.ConstantPropagateProcCtx	Implements the processor context for Constant Propagate.
org.apache.hadoop.hive.ql.optimizer.ConstantPropagateProcFactory	Factory for generating the different node processors used by ConstantPropagate.
org.apache.hadoop.hive.ql.optimizer.ConvertJoinMapJoin	ConvertJoinMapJoin is an optimization that replaces a common join (aka shuffle join) with a map join (aka broadcast or fragment replicate join when possible.
org.apache.hadoop.hive.ql.optimizer.GenMRProcContext	Processor Context for creating map reduce task.
org.apache.hadoop.hive.ql.optimizer.GenMapRedUtils	General utility common functions for the Processor to convert operator into map-reduce tasks.
org.apache.hadoop.hive.ql.optimizer.GlobalLimitOptimizer	This optimizer is used to reduce the input size for the query for queries which are specifying a limit.
org.apache.hadoop.hive.ql.optimizer.GroupByOptimizer	This transformation does group by optimization.
org.apache.hadoop.hive.ql.optimizer.IdentityProjectRemover	This optimization tries to remove SelectOperator from tree which don't do any processing except forwarding columns from its parent to its children.
org.apache.hadoop.hive.ql.optimizer.JoinReorder	Implementation of rule-based join table reordering optimization.
org.apache.hadoop.hive.ql.optimizer.LimitPushdownOptimizer	Make RS calculate top-K selection for limit clause.
org.apache.hadoop.hive.ql.optimizer.MapJoinProcessor	Implementation of one of the rule-based map join optimization.
org.apache.hadoop.hive.ql.optimizer.NonBlockingOpDeDupProc	Merges SEL-SEL or FIL-FIL into single operator
org.apache.hadoop.hive.ql.optimizer.ReduceSinkMapJoinProc	This processor addresses the RS-MJ case that occurs in Tez on the small/hash table. The work that RS will be a part of must be connected to the MJ work via a broadcast edge.
org.apache.hadoop.hive.ql.optimizer.SamplePruner	The transformation step that does sample pruning.
org.apache.hadoop.hive.ql.optimizer.SimpleFetchAggregation	Execute final aggregation stage for simple fetch query on fetch task.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.optimizer.SimpleFetchOptimizer	Tries to convert simple fetch query to single fetch task, which fetches rows directly from location of table/ partition.
org.apache.hadoop.hive.ql.optimizer.SkewJoinOptimizer	SkewJoinOptimizer.
org.apache.hadoop.hive.ql.optimizer.SortedDynPartitionOptimizer	When dynamic partitioning (with or without bucketing and sorting) is enabled, this optimization sorts the records on partition, bucket and sort columns respectively before inserting records into the destination table.
org.apache.hadoop.hive.ql.optimizer.SortedMergeBucketMapJoinOptimizer	Replace a bucket map join with a sorted merge map join.
org.apache.hadoop.hive.ql.optimizer.StatsOptimizer	There is a set of queries which can be answered entirely from statistics stored in metastore.
org.apache.hadoop.hive.ql.optimizer.Transform	Optimizer interface.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveCalciteUtil	Generic utility functions needed for Calcite based Hive CBO.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelOptUtil	Splits different join conditions.
org.apache.hadoop.hive.ql.optimizer.calcite.RelOptHiveTable	Class for handling all table metadata.
org.apache.hadoop.hive.ql.optimizer.calcite.TraitsUtil	Traits utilities.
org.apache.hadoop.hive.ql.optimizer.calcite.cost.HiveRelMdCost	HiveRelMdCost supplies the implementation of cost model.
org.apache.hadoop.hive.ql.optimizer.calcite.cost.HiveVolcanoPlanner	Refinement of org.apache.calcite.plan.volcano.VolcanoPlanner for Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveAggregate	Describing aggregate function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveFilter	Describing filter function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveJoin	Describing join function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveProject	Creates a HiveProject.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSemiJoin	Describing semi join operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveTableScan	Relational expression representing a scan of a HiveDB collection.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveUnion	Describing union operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterJoinRule	Creates a PushFilterPastJoinRule with an explicit root operand.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinProjectTransposeRule	Transpose rule for hive join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterSetOpTransposeRule	Creates a HiveFilterSetOpTransposeRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveInsertExchange4JoinRule	Not an optimization rule.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinAddNotNullRule	Creates an HiveJoinAddNotNullRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinPushTransitivePredicatesRule	Planner rule that infers predicates from on a org.apache.calcite.rel.core.Join and creates org.apache.calcite.rel.core.Filters if those predicates can be pushed to its inputs.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinToMultiJoinRule	Rule that merges a join with multijoin/join children if the equi compared the same set of input columns.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HivePreFilteringRule	Pull out deterministic expressions from non-deterministic and push down deterministic expressions as a separate filter.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectMergeRule	ProjectMergeRule merges a org.apache.calcite.rel.core.Project into another org.apache.calcite.rel.core.Project, provided the projects aren't projecting identical sets of input references.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveRelFieldTrimmer	Hive relational expression field trimmer.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdCollation	Hive relational expression metadata collation.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdDistinctRowCount	Hive relational expression metadata.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdDistribution	Hive relational expression metadata distribuiton.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdMemory	Hive relational expression metadata memory
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdParallelism	Hive relational expression metadata parallelism.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdRowCount	Hive relational expression metadata row count.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdSelectivity	Hive relational expression metadata selectivity.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdSize	Hive relational expression metadata size.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdUniqueKeys	Hive relational expression metadata unique keys.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.ASTConverter	Abstract syntax tree converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.ExprNodeConverter	Expression node converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.HiveOpConverter	Hive operation converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.HiveOpConverterPostProc	Post processing hive operation converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.PlanModifierForASTConv	Modifying plan for converting abstract syntax tree.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.PlanModifierForReturnPath	Modifying plan for operation tree.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.translator.RexNodeConverter	Row expression node converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.SqlFunctionConverter	Converting SQL function.
org.apache.hadoop.hive.ql.optimizer.correlation.CorrelationOptimizer	Implementation of Correlation Optimizer.
org.apache.hadoop.hive.ql.optimizer.correlation.CorrelationUtilities	Utilities for both CorrelationOptimizer and ReduceSinkDeDuplication.
org.apache.hadoop.hive.ql.optimizer.correlation.ReduceSinkDeDuplication	If two reducer sink operators share the same partition/ sort columns and order, they can be merged.
org.apache.hadoop.hive.ql.optimizer.index.RewriteGBUsingIndex	RewriteGBUsingIndex is implemented as one of the Rule-based Optimizations.
org.apache.hadoop.hive.ql.optimizer.index.RewriteParseContextGenerator	RewriteParseContextGenerator is a class that offers methods to generate operator tree for input queries.
org.apache.hadoop.hive.ql.optimizer.lineage.ExprProcFactory	Expression processor factory for lineage.
org.apache.hadoop.hive.ql.optimizer.lineage.Generator	Generates the lineage information for the columns and tables from the plan before it goes through other optimization phases.
org.apache.hadoop.hive.ql.optimizer.lineage.LineageCtx	Contains the lineage context that is passed while walking the operator tree in Lineage.
org.apache.hadoop.hive.ql.optimizer.lineage.OpProcFactory	Operator factory for the rule processors for lineage.
org.apache.hadoop.hive.ql.optimizer.listbucketingpruner.ListBucketingPruner	The transformation step that does list bucketing pruning.
org.apache.hadoop.hive.ql.optimizer.metainfo.annotation.AnnotateWithOpTraits	This class annotates each operator with its traits. The OpTraits class specifies the traits that are populated for each operator.
org.apache.hadoop.hive.ql.optimizer.pcr.PartitionConditionRemover	The transformation step that does partition condition remover.
org.apache.hadoop.hive.ql.optimizer.pcr.PcrExprProcFactory	Expression processor factory for partition condition removing.
org.apache.hadoop.hive.ql.optimizer.physical.CrossProductCheck	Check each MapJoin and ShuffleJoin Operator to see they are performing a cross product.
org.apache.hadoop.hive.ql.optimizer.physical.Vectorizer	Class to define vectorization.
org.apache.hadoop.hive.ql.optimizer.ppr.PartitionExpressionForMetastore	The basic implementation of PartitionExpressionProxy that uses ql package classes.
org.apache.hadoop.hive.ql.optimizer.ppr.PartitionPruner	The transformation step that does partition pruning.
org.apache.hadoop.hive.ql.optimizer.spark.SparkReduceSinkMapJoinProc	This processor addresses the RS-MJ case that occurs in spark on the small/hash table side of things. The work that RS will be a part of must be connectedto the MJ work via be a broadcast edge.
org.apache.hadoop.hive.ql.optimizer.stats.annotation.AnnotateWithStatistics	Create a list of top op nodes
org.apache.hadoop.hive.ql.optimizer.unionproc.UnionProcessor	FileSinkProcessor is a simple rule to remember seen unions for later processing.
org.apache.hadoop.hive.ql.parse.ASTNode	Definition of abstract syntax tree node.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.parse.BaseSemanticAnalyzer	BaseSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.CalcitePlanner	Cost based optimizer planner.
org.apache.hadoop.hive.ql.parse.ColumnAccessAnalyzer	Analysis of column access.
org.apache.hadoop.hive.ql.parse.ColumnStatsSemanticAnalyzer	ColumnStatsSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.DDLSemanticAnalyzer	DDLSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExplainSQRewriteSemanticAnalyzer	ExplainSQRewriteSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExplainSemanticAnalyzer	ExplainSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExportSemanticAnalyzer	ExportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.FunctionSemanticAnalyzer	FunctionSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.GenTezProcContext	GenTezProcContext.
org.apache.hadoop.hive.ql.parse.GenTezUtils	GenTezUtils is a collection of shared helper methods to produce TezWork.
org.apache.hadoop.hive.ql.parse.GlobalLimitCtx	context for pruning inputs.
org.apache.hadoop.hive.ql.parse.ImportSemanticAnalyzer	ImportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.LoadSemanticAnalyzer	LoadSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.MacroSemanticAnalyzer	MacroSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.MapReduceCompiler	Compiling list of tasks.
org.apache.hadoop.hive.ql.parse.MetaDataExportListener	Listens for drop events and, if set, exports the table's metadata as JSON to the trash of the user performing the drop
org.apache.hadoop.hive.ql.parse.ParseContext	Parse Context: The current parse context.
org.apache.hadoop.hive.ql.parse.ParseDriver	ParseDriver.
org.apache.hadoop.hive.ql.parse.ParseUtils	Library of utility functions used in the parse code.
org.apache.hadoop.hive.ql.parse.QB	Implementation of the query block.
org.apache.hadoop.hive.ql.parse.QBParseInfo	Implementation of the parse information related to a query block.
org.apache.hadoop.hive.ql.parse.RowResolver	Implementation of the Row Resolver.
org.apache.hadoop.hive.ql.parse.SemanticAnalyzer	Implementation of the semantic analyzer.
org.apache.hadoop.hive.ql.parse.SemanticAnalyzerFactory	SemanticAnalyzerFactory.
org.apache.hadoop.hive.ql.parse.SplitSample	Stores all the information specified in the TABLESAMPLE(...) clause.
org.apache.hadoop.hive.ql.parse.TaskCompiler	TaskCompiler is a the base class for classes that compile operator pipelines into tasks.
org.apache.hadoop.hive.ql.parse.TezCompiler	TezCompiler translates the operator plan into TezTasks.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.parse.TypeCheckCtx	This class implements the context information that is used for typechecking phase in query compilation.
org.apache.hadoop.hive.ql.parse.TypeCheckProcFactory	The Factory for creating typecheck processors.
org.apache.hadoop.hive.ql.parse.UpdateDeleteSemanticAnalyzer	A subclass of the org.apache.hadoop.hive.ql.parse.SemanticAnalyzer that just handles update and delete statements.
org.apache.hadoop.hive.ql.parse.WindowingSpec	Windowing Specification.
org.apache.hadoop.hive.ql.parse.spark.GenSparkProcContext	GenSparkProcContext maintains information about the tasks and operators as we walk the operator tree to break them into SparkTasks.
org.apache.hadoop.hive.ql.parse.spark.GenSparkUtils	GenSparkUtils is a collection of shared helper methods to produce SparkWork Cloned from GenTezUtils.
org.apache.hadoop.hive.ql.parse.spark.GenSparkWorkWalker	Walks the operator tree in DFS fashion.
org.apache.hadoop.hive.ql.parse.spark.OptimizeSparkProcContext	OptimizeSparkProcContext.
org.apache.hadoop.hive.ql.plan.AbstractOperatorDesc	Operator description.
org.apache.hadoop.hive.ql.plan.AlterTableDesc	AlterTableDesc.
org.apache.hadoop.hive.ql.plan.AlterTableSimpleDesc	Contains information needed to modify a partition or a table
org.apache.hadoop.hive.ql.plan.BaseWork	BaseWork.
org.apache.hadoop.hive.ql.plan.ColumnStatsDesc	Contains the information needed to persist column level statistics
org.apache.hadoop.hive.ql.plan.ColumnStatsWork	ColumnStats Work.
org.apache.hadoop.hive.ql.plan.CommonMergeJoinDesc	Description of merge join operator.
org.apache.hadoop.hive.ql.plan.CreateTableDesc	CreateTableDesc.
org.apache.hadoop.hive.ql.plan.CreateViewDesc	CreateViewDesc.
org.apache.hadoop.hive.ql.plan.DDLWork	DDLWork.
org.apache.hadoop.hive.ql.plan.DropTableDesc	DropTableDesc.
org.apache.hadoop.hive.ql.plan.DynamicPartitionCtx	Dynamic partition context.
org.apache.hadoop.hive.ql.plan.DynamicPruningEventDesc	Dynamic pruning event description.
org.apache.hadoop.hive.ql.plan.ExplainWork	ExplainWork.
org.apache.hadoop.hive.ql.plan.ExprNodeDesc	ExprNodeDesc.
org.apache.hadoop.hive.ql.plan.ExprNodeDescUtils	Utilities for expression node description.
org.apache.hadoop.hive.ql.plan.FetchWork	FetchWork.
org.apache.hadoop.hive.ql.plan.FileSinkDesc	FileSinkDesc.
org.apache.hadoop.hive.ql.plan.FilterDesc	FilterDesc.
org.apache.hadoop.hive.ql.plan.GroupByDesc	GroupByDesc.
org.apache.hadoop.hive.ql.plan.HashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan.JoinCondDesc	Join conditions Descriptor implementation.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.plan.JoinDesc	Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan.LateralViewJoinDesc	LateralViewJoinDesc.
org.apache.hadoop.hive.ql.plan.LimitDesc	LimitDesc.
org.apache.hadoop.hive.ql.plan.LoadTableDesc	LoadTableDesc.
org.apache.hadoop.hive.ql.plan.MapJoinDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan.MapWork	MapWork represents all the information used to run a map task on the cluster.
org.apache.hadoop.hive.ql.plan.MapredWork	MapredWork.
org.apache.hadoop.hive.ql.plan.MergeJoinWork	Creating merge join work.
org.apache.hadoop.hive.ql.plan.PartitionDesc	PartitionDesc.
org.apache.hadoop.hive.ql.plan.PlanUtils	PlanUtils.
org.apache.hadoop.hive.ql.plan.ReduceSinkDesc	ReduceSinkDesc.
org.apache.hadoop.hive.ql.plan.ReduceWork	ReduceWork represents all the information used to run a reduce task on the cluster.
org.apache.hadoop.hive.ql.plan.SelectDesc	SelectDesc.
org.apache.hadoop.hive.ql.plan.SparkHashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan.Statistics	Statistics.
org.apache.hadoop.hive.ql.plan.StatsWork	ConditionalStats.
org.apache.hadoop.hive.ql.plan.TableScanDesc	Table Scan Descriptor Currently, data is only read from a base source as part of map-reduce framework.
org.apache.hadoop.hive.ql.plan.TezWork	TezWork.
org.apache.hadoop.hive.ql.plan.UnionWork	Simple wrapper for union all cases.
org.apache.hadoop.hive.ql.plan.VectorGroupByDesc	VectorGroupByDesc.
org.apache.hadoop.hive.ql.plan.ptf.BoundaryDef	Map-reduce boundaries definition.
org.apache.hadoop.hive.ql.plan.ptf.CurrentRowDef	Current row definition.
org.apache.hadoop.hive.ql.plan.ptf.OrderExpressionDef	Order expression definition.
org.apache.hadoop.hive.ql.plan.ptf.RangeBoundaryDef	Range boundary definition.
org.apache.hadoop.hive.ql.plan.ptf.ValueBoundaryDef	Value boundary definition.
org.apache.hadoop.hive.ql.plan.ptf.WindowFrameDef	Window frame definition.
org.apache.hadoop.hive.ql.ppd.ExprWalkerInfo	Context for Expression Walker for determining predicate pushdown candidates It contains a ExprInfo object for each expression that is processed.
org.apache.hadoop.hive.ql.ppd.OpProcFactory	Operator factory for predicate pushdown processing of operator graph Each operator determines the pushdown predicates by walking the expression tree.
org.apache.hadoop.hive.ql.ppd.PredicatePushDown	Implements predicate pushdown.
org.apache.hadoop.hive.ql.ppd.PredicateTransitivePropagate	Propagates filters to other aliases based on join condition
org.apache.hadoop.hive.ql.ppd.SyntheticJoinPredicate	Creates synthetic predicates that represent "IN (keylist other table)"

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.processors.AddResourceProcessor	AddResourceProcessor.
org.apache.hadoop.hive.ql.processors.CommandProcessorResponse	Encapsulates the basic response info returned by classes the implement the CommandProcessor interface.
org.apache.hadoop.hive.ql.processors.CompileProcessor	Processor allows users to build code inside a hive session, then use this code as a UDF, Serde, or even a more complex entity like an input format or hook.
org.apache.hadoop.hive.ql.processors.CryptoProcessor	Processes HADOOP commands used for HDFS encryption.
org.apache.hadoop.hive.ql.processors.DeleteResourceProcessor	DeleteResourceProcessor.
org.apache.hadoop.hive.ql.processors.DfsProcessor	DfsProcessor.
org.apache.hadoop.hive.ql.processors.SetProcessor	SetProcessor.
org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener	AuthorizationPreEventListener : A MetaStorePreEventListener that performs authorization/ authentication checks on the metastore-side.
org.apache.hadoop.hive.ql.security.authorization.AuthorizationUtils	Utility code shared by hive internal code and sql standard authorization plugin implementation
org.apache.hadoop.hive.ql.security.authorization.HiveAuthorizationProviderBase	Class for authorization that returns userNames and groupNames.
org.apache.hadoop.hive.ql.security.authorization.plugin.AuthorizationMetaStoreFilterHook	Metastore filter hook for filtering out the list of objects that the current authorization implementation does not allow user to see
org.apache.hadoop.hive.ql.security.authorization.plugin.HiveAuthorizerImpl	Convenience implementation of HiveAuthorizer.
org.apache.hadoop.hive.ql.security.authorization.plugin.HiveAuthzContext	Provides context information in authorization check call that can be used for auditing and/or authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin.HivePrivilegeObject	Represents the object on which privilege is being granted/revoked, and objects being used in queries.
org.apache.hadoop.hive.ql.security.authorization.plugin.HiveV1Authorizer	Hive v1 authorization class.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.DummyHiveAuthorizationValidator	A no-op HiveAuthorizationValidator for use from hive cli.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQLAuthorizationUtils	Utilities for SQL based authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQLStdHiveAccessController	Implements functionality of access control statements for sql standard based authorization
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQLStdHiveAuthorizationValidator	Class to check if user has privileges to perform certain action according to SQL standart hive authorization.
org.apache.hadoop.hive.ql.session.LineageState	LineageState.
org.apache.hadoop.hive.ql.session.OperationLog	OperationLog wraps the actual operation log file, and provides interface for accessing, reading, writing, and removing the file.
org.apache.hadoop.hive.ql.session.SessionState	SessionState encapsulates common data associated with a session.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.stats.StatsFactory	A factory of stats publisher and aggregator implementations of the StatsPublisher and StatsAggregator interfaces.
org.apache.hadoop.hive.ql.stats.StatsUtils	Utilities of stats publisher and aggregator.
org.apache.hadoop.hive.ql.stats.fs.FSStatsAggregator	File system stats aggregator.
org.apache.hadoop.hive.ql.stats.fs.FSStatsPublisher	File system stats publisher.
org.apache.hadoop.hive.ql.txn.compactor.CompactorMR	Performs compactions via an MR job.
org.apache.hadoop.hive.ql.txn.compactor.Worker	Performs compactions.
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFAverage	GenericUDAFAverage.
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFStreamingEvaluator	User defined aggregate function streaming evaluator.
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFSum	GenericUDAFSum.
org.apache.hadoop.hive.ql.udf.generic.GenericUDF	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBasePad	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBridge	GenericUDFBridge encapsulates UDF to provide the same interface as GenericUDF.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFDateAdd	UDFDateAdd.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFDateSub	UDFDateSub.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFFromUtcTimestamp	Generic user defined fuction to compute UTC timestamp.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFGreatest	GenericUDF Class for SQL construct "greatest(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic.GenericUDFLeast	GenericUDF Class for SQL construct "least(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic.GenericUDFLpad	UDFLpad.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPAnd	GenericUDF Class for computing and.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPEqual	GenericUDF Class for operation EQUAL.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPEqualOrGreaterThan	GenericUDF Class for operation EqualOrGreaterThan.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPEqualOrLessThan	GenericUDF Class for operation EqualOrLessThan.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPGreaterThan	GenericUDF Class for operation GreaterThan.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPLessThan	GenericUDF Class for operation LessThan.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPNotEqual	GenericUDF Class for operation Not EQUAL.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPNotNull	GenericUDFOPNotNull.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPNull	GenericUDFOPNull.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFOPOr	GenericUDF Class for computing or.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFRound	Rounding function permits rounding off integer digits in decimal numbers, which essentially downgrades the scale to negative territory.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFRpad	UDFRpad.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFToUnixTimeStamp	Deterministic version of UDFUnixTimeStamp.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFUtils	Util functions for GenericUDF classes.
org.apache.hadoop.hive.ql.udf.generic.NumDistinctValueEstimator	Take the average of the index for all the bit vectors and get the estimated NDV (estimateNumDistinctValues).
org.apache.hadoop.hive.ql.udf.generic.NumericHistogram	A generic, re-usable histogram class that supports partial aggregations.
org.apache.hadoop.hive.ql.udf.generic.RoundUtils	Utility class for generic round UDF.
org.apache.hadoop.hive.ql.udf.ptf.WindowingTableFunction	A window function performs a calculation across a set of table rows that are somehow related to the current row.
org.apache.hadoop.hive.ql.util.DateTimeMath	Operations involving/returning year-month intervals.
org.apache.hadoop.hive.ql.util.DosToUnix	Converting windows script to UNIX.
org.apache.hadoop.hive.ql.util.ZooKeeperHiveHelper	Get the ensemble server addresses from the configuration. The format is: host1:port,host2:port
org.apache.hadoop.hive.serde2.AbstractSerDe	Abstract class for implementing SerDe.
org.apache.hadoop.hive.serde2.ColumnProjectionUtils	ColumnProjectionUtils.
org.apache.hadoop.hive.serde2.DelimitedJSONSerDe	DelimitedJSONSerDe.
org.apache.hadoop.hive.serde2.MetadataTypedColumnsetSerDe	MetadataTypedColumnsetSerDe.
org.apache.hadoop.hive.serde2.OpenCSVSerde	OpenCSVSerde use opencsv to deserialize CSV format.
org.apache.hadoop.hive.serde2.RegexSerDe	RegexSerDe uses regular expression (regex) to deserialize data.
org.apache.hadoop.hive.serde2.SerDeUtils	SerDeUtils.
org.apache.hadoop.hive.serde2.WriteBuffers	The structure storing arbitrary amount of data as a set of fixed-size byte buffers.
org.apache.hadoop.hive.serde2.avro.AvroLazyObjectInspector	Lazy objectinspector for avro serialization
org.apache.hadoop.hive.serde2.avro.AvroSerDe	Read or write Avro data from Hive.
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils	Utilities useful only to the AvroSerde itself.
org.apache.hadoop.hive.serde2.binarysortable.BinarySortableSerDe	BinarySortableSerDe can be used to write data in a way that the data can be compared byte-by-byte with the same order.
org.apache.hadoop.hive.serde2.binarysortable.fast.BinarySortableDeserializeRead	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.binarysortable.fast.BinarySortableSerializeWrite	Directly serialize, field-by-field, the BinarySortable format.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.serde2.io.DateWritable	DateWritable Writable equivalent of java.sql.Date.
org.apache.hadoop.hive.serde2.io.HiveDecimalWritable	Get a HiveDecimal instance from the writable and constraint it with maximum precision/scale.
org.apache.hadoop.hive.serde2.io.TimestampWritable	TimestampWritable Writable equivalent of java.sq.Timestamp Timestamps are of the format YYYY-MM-DD HH:MM:SS.[fff...] We encode Unix timestamp in seconds in 4 bytes, using the MSB to signify whether the timestamp has a fractional portion.
org.apache.hadoop.hive.serde2.lazy.LazyBinary	LazyBinary stores a binary object in a LazyObject.
org.apache.hadoop.hive.serde2.lazy.LazyHiveDecimal	LazyHiveDecimal stores hive decimal object in LazyObject.
org.apache.hadoop.hive.serde2.lazy.LazyMap	LazyMap stores a map of Primitive LazyObjects to LazyObjects.
org.apache.hadoop.hive.serde2.lazy.LazySerDeParameters	SerDeParameters.
org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe	LazySimpleSerDe can be used to read the same data format as MetadataTypedColumnsetSerDe and TCTLSeparatedProtocol.
org.apache.hadoop.hive.serde2.lazy.LazyUtils	LazyUtils.
org.apache.hadoop.hive.serde2.lazy.fast.LazySimpleDeserializeRead	Directly deserialize with the caller reading field-by-field the LazySimple (text) serialization format.
org.apache.hadoop.hive.serde2.lazy.fast.LazySimpleSerializeWrite	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyListObjectInspector	LazyListObjectInspector works on array data that is stored in LazyArray.
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyMapObjectInspector	LazyMapObjectInspector works on struct data that is stored in LazyStruct.
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyUnionObjectInspector	LazyUnionObjectInspector works on union data that is stored in LazyUnion.
org.apache.hadoop.hive.serde2.lazybinary.LazyBinarySerDe	The LazyBinarySerDe class combines the lazy property of LazySimpleSerDe class and the binary property of BinarySortable class.
org.apache.hadoop.hive.serde2.lazybinary.fast.LazyBinaryDeserializeRead	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.lazybinary.fast.LazyBinarySerializeWrite	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.objectinspector.ObjectInspectorFactory	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector.ObjectInspectorUtils	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector.ReflectionStructObjectInspector	ReflectionStructObjectInspector works on struct data that is stored as a native Java object.
org.apache.hadoop.hive.serde2.objectinspector.SettableUnionObjectInspector	SettableUnionObjectInspector.
org.apache.hadoop.hive.serde2.objectinspector.StandardStructObjectInspector	ListStructObjectInspector works on struct data that is stored as a Java List or Java Array object.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.serde2.objectinspector.StandardUnionObjectInspector	StandardUnionObjectInspector works on union data that is stored as UnionObject.
org.apache.hadoop.hive.serde2.objectinspector.ThriftUnionObjectInspector	Always use the ObjectInspectorFactory to create new ObjectInspector objects, instead of directly creating an instance of this class.
org.apache.hadoop.hive.serde2.typeinfo.HiveDecimalUtils	Utilities for decimal precision and scale.
org.apache.hadoop.hive.serde2.typeinfo.TypeInfoUtils	TypeInfoUtils.
org.apache.hadoop.hive.shims.Hadoop23Shims	Implemention of shims against Hadoop 0.23.0.
org.apache.hadoop.hive.shims.HadoopShimsSecure	Base implemention for shims against secure Hadoop 0.20.3/0.23.
org.apache.hadoop.hive.shims.ShimLoader	ShimLoader.
org.apache.hadoop.hive.shims.Utils	Utilities for split location provider.
org.apache.hadoop.hive.thrift.DelegationTokenSecretManager	A Hive specific delegation token secret manager.
org.apache.hadoop.hive.thrift.HadoopThriftAuthBridge	Functions that bridge Thrift's SASL transports to Hadoop's SASL callback handlers and authentication classes.
org.apache.hadoop.hive.thrift.TokenStoreDelegationTokenSecretManager	Extension of DelegationTokenSecretManager to support alternative to default in-memory token management for fail-over and clustering through plug-able token store (ZooKeeper etc.).
org.apache.hive.beeline.BeeLine	A console SQL shell with command completion.
org.apache.hive.beeline.Commands	Implementation of beeline commands.
org.apache.hive.common.util.BloomFilter	BloomFilter is a probabilistic data structure for set membership check.
org.apache.hive.common.util.DateUtils	DateUtils.
org.apache.hive.common.util.HiveStringUtils	HiveStringUtils General string utils Originally copied from o.a.hadoop.util.StringUtils
org.apache.hive.common.util.HiveTestUtils	Utilities for testing hive.
org.apache.hive.common.util.Murmur3	Murmur3 is successor to Murmur2 fast non-crytographic hash algorithms.
org.apache.hive.common.util.ShutdownHookManager	The ShutdownHookManager enables running shutdownHook in a deterministic order, higher priority first.
org.apache.hive.common.util.StreamPrinter	StreamPrinter.
org.apache.hive.hcatalog.cli.HCatCli	HCatalog command line interface.
org.apache.hive.hcatalog.common.HCatConstants	List of constants used by HCatalog.
org.apache.hive.hcatalog.streaming.ConnectionError	Exception to catch connection errors.
org.apache.hive.hcatalog.streaming.DelimitedInputWriter	Streaming Writer handles delimited input (eg.
org.apache.hive.hcatalog.streaming.HiveEndPoint	Information about the hive end point (i.e.
org.apache.hive.hcatalog.streaming.InvalidTable	Exception to catch invalid table.
org.apache.hive.hcatalog.streaming.StrictJsonWriter	Streaming Writer handles utf8 encoded Json (Strict syntax).

last-updated: Apr 11, 2022

Class	Description
org.apache.hive.hcatalog.templeton.AppConfig	The configuration for Templeton.
org.apache.hive.hcatalog.templeton.Main	The main executable that starts up and runs the Server.
org.apache.hive.jdbc .HiveConnection	HiveConnection.
org.apache.hive.jdbc .HiveDatabaseMetaData	HiveDatabaseMetaData.
org.apache.hive.jdbc .HivePreparedStatement	HivePreparedStatement.
org.apache.hive.jdbc .HiveQueryResultSet	HiveQueryResultSet.
org.apache.hive.jdbc .HiveStatement	HiveStatement.
org.apache.hive.jdbc .JdbcColumn	Column metadata.
org.apache.hive.jdbc .Utils	Utilities for jdbc.
org.apache.hive.service.ServiceUtils	Utilities to correctly process domain names etc.
org.apache.hive.service.auth.AuthenticationProviderFactory	Helps select a PasswdAuthenticationProvider for a given {@code AuthMethod}.
org.apache.hive.service.auth.HiveAuthFactory	Helps in some aspects of authentication.
org.apache.hive.service.auth.LdapAuthenticationProviderImpl	Utilities to correctly process domain names etc.
org.apache.hive.service.auth.TSetIpAddressProcessor	Sets the ipAddress for operations executed via HiveServer2.
org.apache.hive.service.cli.CLIService	CLIService.
org.apache.hive.service.cli.CLIServiceUtils	CLIServiceUtils.
org.apache.hive.service.cli.ColumnBasedSet	ColumnBasedSet.
org.apache.hive.service.cli.ColumnDescriptor	ColumnDescriptor.
org.apache.hive.service.cli.ColumnValue	Protocols before HIVE_CLI_SERVICE_PROTOCOL_V6 (used by RowBasedSet)
org.apache.hive.service.cli.EmbeddedCLIServiceClient	Embedded CLI Service Client.
org.apache.hive.service.cli.FetchOrientation	Fetch Orientation.
org.apache.hive.service.cli.GetInfoType	Get Info type.
org.apache.hive.service.cli.GetInfoValue	Get Info value.
org.apache.hive.service.cli.Handle	Handle.
org.apache.hive.service.cli.HandleIdentifier	Handle identifier.
org.apache.hive.service.cli.HiveSQLException	Hive SQL exception.

last-updated: Apr 11, 2022

Class	Description
org.apache.hive.service.cli.OperationHandle	Handler for operation.
org.apache.hive.service.cli.OperationState	Operation State.
org.apache.hive.service.cli.OperationStatus	Operation Status.
org.apache.hive.service.cli.OperationType	OperationType.
org.apache.hive.service.cli.RowBasedSet	Row Based Set.
org.apache.hive.service.cli.RowSetFactory	Row set factory class.
org.apache.hive.service.cli.SessionHandle	Session Handle.
org.apache.hive.service.cli.TableSchema	Table Schema.
org.apache.hive.service.cli.TypeDescriptor	Type Descriptor.
org.apache.hive.service.cli.TypeQualifiers	Holds type qualifier information for a primitive type, such as char/varchar length or decimal precision/scale.
org.apache.hive.service.cli.operation.ClassicTableTypeMapping	Classic Table Type Mapping.
org.apache.hive.service.cli.operation.ExecuteStatementOperation	Implementation of statement execution.
org.apache.hive.service.cli.operation.HiveCommandOperation	Executes a HiveCommand.
org.apache.hive.service.cli.operation.HiveTableTypeMapping	Hive Table Type Mapping.
org.apache.hive.service.cli.operation.LogDivertAppender	Divert appender to redirect operation logs to separate files.
org.apache.hive.service.cli.operation.MetadataOperation	Metadata Operation.
org.apache.hive.service.cli.operation.Operation	Class to define operation.
org.apache.hive.service.cli.operation.OperationManager	Operation Manager.
org.apache.hive.service.cli.operation.SQLOperation	SQL Operation.
org.apache.hive.service.cli.session.HiveSessionImpl	Hive Session.
org.apache.hive.service.cli.session.HiveSessionImplwithUGI	Hive session implementation with UGI.
org.apache.hive.service.cli.session.SessionManager	Session Manager.
org.apache.hive.service.cli.thrift.ThriftBinaryCLIService	Initialize worker threads in hive CLI startup.
org.apache.hive.service.cli.thrift.ThriftCLIService	Thrift CLI Service.
org.apache.hive.service.cli.thrift.ThriftCLIServiceClient	Thrift CLI Service Client.
org.apache.hive.service.cli.thrift.ThriftHttpCLIService	Service to handle requests over HTTP.
org.apache.hive.service.cli.thrift.ThriftHttpServlet	Thrift Http servlet.
org.apache.hive.spark.client.MetricsCollection	Provides metrics collected for a submitted job.
org.apache.hive.spark.client.SparkClientUtilities	Utilities for spark client.
org.apache.hive.spark.client.rpc.Rpc	Encapsulates the RPC functionality.
org.apache.hive.spark.client.rpc.RpcConfiguration	Definitions of configuration keys and default values for the RPC layer.
org.apache.hive.spark.client.rpc.RpcServer	An RPC server.

last-updated: Apr 11, 2022

Changed Interfaces in Hive 2.1

The following interfaces have changed in Hive 2.1:

Interface	Description
org.apache.hadoop.hive.common.*ValidTxnList*	Models the list of transactions that should be included in a snapshot.
org.apache.hadoop.hive.metastore.*AlterHandler*	Interface for Alter Table and Alter Partition code
org.apache.hadoop.hive.metastore.*IMetaStoreClient*	Wrapper around hive metastore thrift api
org.apache.hadoop.hive.metastore.*RawStore*	
org.apache.hadoop.hive.metastore.*PartitionExpressionProxy*	The proxy interface that metastore uses for variety of QL operations (metastore can't depend on QL because QL depends on metastore; creating metastore-client module would be a proper way to solve this problem).
org.apache.hadoop.hive.ql.exec.persistence.*MapJoinTableContainer*	
org.apache.hadoop.hive.ql.exec.spark.*SparkShuffler*	
org.apache.hadoop.hive.ql.exec.spark.*SparkTran*	
org.apache.hadoop.hive.ql.exec.spark.session.*SparkSession*	
org.apache.hadoop.hive.ql.exec.spark.status.*SparkJobStatus*	SparkJobStatus identify what Hive want to know about the status of a Spark job.
org.apache.hadoop.hive.ql.exec.vector.expressions.*VectorExpressionWriter*	Interface used to create Writable objects from vector expression primitives.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable.*VectorMapJoinHashTable*	
org.apache.hadoop.hive.ql.io.*InputFormatChecker*	Check for validity of the input files.
org.apache.hadoop.hive.ql.io.orc.*Reader*	The interface for reading ORC files.
org.apache.hadoop.hive.ql.io.orc.*RecordReader*	A row-by-row iterator for ORC files.
org.apache.hadoop.hive.ql.io.orc.*Writer*	The HIVE interface for writing ORC files.
org.apache.hadoop.hive.ql.io.sarg.*SearchArgument*	Primary interface for SearchArgument, which are the subset of predicates that can be pushed down to the RecordReader.
org.apache.hadoop.hive.ql.lockmgr.*HiveTxnManager*	An interface that allows Hive to manage transactions.
org.apache.hadoop.hive.ql.metadata.formatting.*MetaDataFormatter*	Interface to format table and index information.
org.apache.hadoop.hive.ql.plan.*OperatorDesc*	
org.apache.hadoop.hive.ql.security.authorization.plugin.*HiveAuthorizationValidator*	Interface used to check if user has privileges to perform certain action.
org.apache.hadoop.hive.ql.security.authorization.plugin.*HiveAuthorizer*	Interface for hive authorization plugins.
org.apache.hadoop.hive.ql.stats.*StatsAggregator*	An interface for any possible implementation for gathering statistics.
org.apache.hadoop.hive.ql.stats.*StatsPublisher*	An interface for any possible implementation for publishing statics.

last-updated: Apr 11, 2022

Interface	Description
org.apache.hadoop.hive.shims.*HadoopShims*	In order to be compatible with multiple versions of Hadoop, all parts of the Hadoop interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hive.hcatalog.streaming.*StreamingConnection*	Represents a connection to a HiveEndPoint.
org.apache.hive.hcatalog.streaming.*TransactionBatch*	Represents a set of Transactions returned by Hive.
org.apache.hive.service.cli.*ICLIService*	
org.apache.hive.service.cli.*RowSet*	
org.apache.hive.service.cli.operation.*TableTypeMapping*	
org.apache.hive.service.cli.session.*HiveSession*	
org.apache.hive.service.cli.session.*HiveSessionBase*	Methods that don't need to be executed under a doAs context are here.
org.apache.hive.spark.client.*JobContext*	Holds runtime information about the job execution context.
org.apache.hive.spark.client.*SparkClient*	Defines the API for the Spark remote client.

Removed API in Hive 2.1

The following classes and interfaces are not available with Hive 2.1:

Removed Classes

Class	Description
org.apache.hadoop.hive.common.metrics.Metrics	Metrics Subsystem - allows exposure of a number of named parameters/counters via jmx, intended to be used as a static subsystem Has a couple of primary ways it can be used: (i) Using the set and get methods to set and get named parameters (ii) Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set.
org.apache.hadoop.hive.hbase.HBaseStatsAggregator	A class that implements the StatsAggregator interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsPublisher	A class that implements the StatsPublisher interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsSetupConstants	HBase constants statistics setup.
org.apache.hadoop.hive.hbase.HBaseStatsUtils	Utilities for hbase statistics.
org.apache.hadoop.hive.metastore.ProtectMode	Protection Mode.
org.apache.hadoop.hive.metastore.txn.CompactionTxnHandler	Extends the transaction handler with methods needed only by the compactor threads.
org.apache.hadoop.hive.metastore.txn.TxnHandler	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.metastore.txn.ValidCompactorTxnList	And implmentation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.ql.exec.DefaultFetchFormatter	Serializes row by user specified serde and call toString() to make string type result

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.exec.Heartbeater	Class to handle heartbeats for MR and Tez tasks.
org.apache.hadoop.hive.ql.exec.vector.RandomRowObjectSource	Generates object inspector and random row object[].
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRowDynBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRowSameBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive.ql.exec.vector.VectorSerializeRowNoNulls	Serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive.ql.exec.vector.VectorizedColumnarSerDe	VectorizedColumnarSerDe is used by Vectorized query execution engine for columnar based storage supported by RCFile.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDayOfMonthLong	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFHourLong	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMinuteLong	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMonthLong	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFSecondLong	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFTimestampFieldLong	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFUnixTimeStampLong	Return Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFWeekOfYearLong	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFYearLong	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastIntHashUtil	Utilities for mapr join in vectorization mode.
org.apache.hadoop.hive.ql.io.VectorizedRCFileInputFormat	A MapReduce/Hive Vectorized input format for RC files.
org.apache.hadoop.hive.ql.io.VectorizedRCFileRecordReader	RCFileRecordReader.
org.apache.hadoop.hive.ql.io.orc.FileDump	A tool for printing out the file structure of ORC files.
org.apache.hadoop.hive.ql.io.orc.InStream	Class to define input stream.
org.apache.hadoop.hive.ql.io.orc.Metadata	Metadata stored in underlying db.
org.apache.hadoop.hive.ql.io.orc.MetadataReader	Class to read and process metadata.
org.apache.hadoop.hive.ql.io.orc.OrcProto	Class to serialize data stored in orc.
org.apache.hadoop.hive.ql.io.orc.OrcUtils	Utilities to process orc files.
org.apache.hadoop.hive.ql.io.orc.RecordReaderFactory	Factory to create ORC tree readers.
org.apache.hadoop.hive.ql.io.orc.RecordReaderUtils	Stateless methods shared between RecordReaderImpl and EncodedReaderImpl.

last-updated: Apr 11, 2022

Class	Description
org.apache.hadoop.hive.ql.io.orc.StripeStatistics	Information about index data stored in stripe.
org.apache.hadoop.hive.ql.io.orc.TreeReaderFactory	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.log.PidDailyRollingFileAppender	Logging pids in file.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveConfigContext	Hive configuration context.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveLimit	Define limit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSort	Define sort operator.
org.apache.hadoop.hive.ql.parse.VariableSubstitution	The Hive variable substitution mechanism was designed to avoid some of the code that was getting baked into the scripting language on top of Hive.
org.apache.hadoop.hive.ql.session.DependencyResolver	Creating list of dependency jars.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregator	Counter statistics aggregator.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorSpark	Counter statistics aggregator for Spark.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorTez	This class aggregates stats via counters and does so for Tez Tasks.
org.apache.hadoop.hive.ql.stats.CounterStatsPublisher	Counter statistics publisher.
org.apache.hadoop.hive.ql.udf.UDFRegExp	UDFRegExp.
org.apache.hadoop.hive.shims.Hadoop20SShims	Implemention of shims against Hadoop 0.20 with Security.
org.apache.hadoop.hive.shims.HiveEventCounter	Hive event counter.
org.apache.hadoop.hive.shims.Jetty20SShims	In order to be compatible with multiple versions of Jetty, all parts of the Jetty interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hadoop.mapred.WebHCatJTShim20S	This is in org.apache.hadoop.mapred package because it relies on JobSubmissionProtocol which is package private
org.apache.hive.benchmark.vectorization.VectorizationBench	Measures the performance for vectorization.
org.apache.hive.jdbc.ZooKeeperHiveClientHelper	Resolve to a host:port by connecting to ZooKeeper and picking a host randomly.
org.apache.hive.service.cli.Column	Column.
org.apache.hive.service.cli.Type	Type.
org.apache.hive.service.cli.thrift.TArrayTypeEntry	Array type entry.
org.apache.hive.service.cli.thrift.TBinaryColumn	Binary column.
org.apache.hive.service.cli.thrift.TBoolColumn	Boolean column.
org.apache.hive.service.cli.thrift.TBoolValue	Boolean value.
org.apache.hive.service.cli.thrift.TByteColumn	Byte column.
org.apache.hive.service.cli.thrift.TByteValue	Byte value.

last-updated: Apr 11, 2022

Class	Description
org.apache.hive.service.cli.thrift.TCLIService	Command line interface service.
org.apache.hive.service.cli.thrift.TCLIServiceConstants	Command line interface constatnts.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenReq	Cancel delegation token request.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenResp	Cancel delegation token response.
org.apache.hive.service.cli.thrift.TCancelOperationReq	Cancel operation request.
org.apache.hive.service.cli.thrift.TCancelOperationResp	Cancel operation response.
org.apache.hive.service.cli.thrift.TCloseOperationReq	Close operation request.
org.apache.hive.service.cli.thrift.TCloseOperationResp	Close operation response.
org.apache.hive.service.cli.thrift.TCloseSessionReq	Close session request.
org.apache.hive.service.cli.thrift.TCloseSessionResp	Close session response.
org.apache.hive.service.cli.thrift.TColumn	Column.
org.apache.hive.service.cli.thrift.TColumnDesc	Column description.
org.apache.hive.service.cli.thrift.TColumnValue	Column value.
org.apache.hive.service.cli.thrift.TDoubleColumn	Double column.
org.apache.hive.service.cli.thrift.TDoubleValue	Double value.
org.apache.hive.service.cli.thrift.TExecuteStatementReq	Execute statement request.
org.apache.hive.service.cli.thrift.TExecuteStatementResp	Execute statement response.
org.apache.hive.service.cli.thrift.TFetchOrientation	Fetch orientation.
org.apache.hive.service.cli.thrift.TFetchResultsReq	Fetch results request.
org.apache.hive.service.cli.thrift.TFetchResultsResp	Fetch results response.
org.apache.hive.service.cli.thrift.TGetCatalogsReq	Get catalogs request.

Removed Interfaces

Interface	Description
org.apache.hadoop.hive.ql.exec.*FetchFormatter*	(For internal-use only) Used in ListSinkOperator for formatting final output
org.apache.hadoop.hive.ql.io.orc.*BinaryColumnStatistics*	Statistics for binary columns.
org.apache.hadoop.hive.ql.io.orc.*BooleanColumnStatistics*	Statistics for boolean columns.
org.apache.hadoop.hive.ql.io.orc.*ColumnStatistics*	Statistics that are available for all types of columns.
org.apache.hadoop.hive.ql.io.orc.*CompressionCodec*	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc.*CompressionCodec.Modifier*	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc.*ConversionTreeReaderFactory*	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.io.orc.*DateColumnStatistics*	Statistics for DATE columns.

Interface	Description
org.apache.hadoop.hive.ql.io.orc.*DecimalColumnStatistics*	Statistics for decimal columns.
org.apache.hadoop.hive.ql.io.orc.*DirectDecompressionCodec*	Decompression codec.
org.apache.hadoop.hive.ql.io.orc.*DoubleColumnStatistics*	Statistics for float and double columns.
org.apache.hadoop.hive.ql.io.orc.*IntegerColumnStatistics*	Statistics for all of the integer columns, such as byte, short, int, and long.
org.apache.hadoop.hive.ql.io.orc.*PositionProvider*	An interface used for seeking to a row index.
org.apache.hadoop.hive.ql.io.orc.*StringColumnStatistics*	Statistics for string columns.
org.apache.hadoop.hive.ql.io.orc.*StripeInformation*	Information about the stripes in an ORC file that is provided by the Reader.
org.apache.hadoop.hive.ql.io.orc.*TimestampColumnStatistics*	Statistics for Timestamp columns.
org.apache.hadoop.hive.ql.stats.*StatsCollectionTaskIndependent*	Marker interface to differentiate between stats publisher / aggregator which don't track stats per task, as oppose to others which do.

Deprecated API in Hive 2.1

The following classes, interfaces, and fields have been deprecated in Hive 2.1.

Deprecated Classes

org.apache.hadoop.hive.ql.exec.ByteWritable
org.apache.hadoop.hive.serde.Constants
org.apache.hadoop.hive.ql.io.FlatFileInputFormat
org.apache.hadoop.hive.ql.io.FlatFileInputFormat.FlatFileRecordReader
org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat *use HiveIgnoreKeyTextOutputFormat instead}*
org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe.SerDeParameters
org.apache.hadoop.hive.ql.exec.UDAF *Either implement* GenericUDAFResolver2 *or extend AbstractGenericUDAFResolver instead.*

Deprecated Interfaces

org.apache.hadoop.hive.serde2.Deserializer
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFEvaluator.AggregationBuffer *use GenericUDAFEvaluator.AbstractAggregationBuffer instead*
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFResolver *Use GenericUDAFResolver2 instead.*
org.apache.hadoop.hive.serde2.SerDe
org.apache.hadoop.hive.serde2.Serializer

Deprecated Fields

org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.AVRO_SERDE_SCHEMA
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_DOC
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_LITERAL
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_NAME
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_NAMESPACE
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_RETRIEVER
org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_URL
org.apache.hive.hplsql.HplsqlParser.tokenNames *Use HplsqlParser.VOCABULARY instead.*
org.apache.hive.hplsql.HplsqlLexer.tokenNames *Use HplsqlLexer.VOCABULARY instead.*

Deprecated Methods

org.apache.hadoop.hive.metastore.IMetaStoreClient.addDynamicPartitions(long, String, String, List<String>) *in Hive 1.3.0/2.1.0 - will be removed in 2 releases*
org.apache.hadoop.hive.metastore.HiveMetaStoreClient.addDynamicPartitions(long, String, String, List<String>)
org.apache.hadoop.hive.serde2.ColumnProjectionUtils.appendReadColumnIDs(Configuration, List<Integer>) *for backwards compatibility with <= 0.12, use appendReadColumns*
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.bucketCols(List<String>, int)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.collectionItemsTerminatedBy(char)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.comments(String)
org.apache.hadoop.hive.metastore.IMetaStoreClient.compact(String, String, String, CompactionType)
org.apache.hadoop.hive.metastore.HiveMetaStoreClient.compact(String, String, String, CompactionType)
org.apache.hadoop.hive.ql.metadata.HiveStorageHandler.configureTableJobProperties(TableDesc, Map<String, String>)
org.apache.orc.impl.InStream.create(String, ByteBuffer[], long[], long, CompressionCodec, int)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.create(String, String, List<HCatFieldSchema>)
org.apache.hive.hcatalog.api.HCatAddPartitionDesc.create(String, String, String, Map<String, String>)
org.apache.hadoop.hive.serde2.lazy.LazyFactory.createColumnarStructInspector(List<String>, List<TypeInfo>, byte[], Text, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte, boolean)
org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte, boolean, ObjectInspectorFactory.ObjectInspectorOptions)
org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte, ObjectInspectorFactory.ObjectInspectorOptions)

last-updated: Apr 11, 2022

org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyStructInspector(List<String>, List<TypeInfo>, byte[], Text, boolean, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyStructInspector(List<String>, List<TypeInfo>, byte[], Text, boolean, boolean, byte, boolean)
org.apache.hadoop.hive.metastore.IMetaStoreClient.dropTable(String, boolean) *As of release 0.6.0 replaced by IMetaStoreClient.dropTable(String, String, boolean, boolean). This method will be removed in release 0.7.0.*
org.apache.hadoop.hive.metastore.HiveMetaStoreClient.dropTable(String, boolean)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.escapeChar(char)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.fieldsTerminatedBy(char)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.fileFormat(String)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getBucketCols()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getCols()
org.apache.hadoop.hive.serde2.dynamic_type.SimpleCharStream.getColumn()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getComments()
org.apache.hadoop.hive.ql.io.RCFile.Writer.getCompressionCodec()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getDatabaseName()
org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getDatabaseName()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getExternal()
org.apache.hadoop.hive.ql.exec.Utilities.getFileExtension(JobConf, boolean) *Use Utilities.getFileExtension(JobConf, boolean, HiveOutputFormat)*
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getFileFormat()
org.apache.hive.hcatalog.common.HCatUtil.getHiveClient(HiveConf)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleListObjectInspector(ObjectInspector, byte, Text, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleMapObjectInspector(ObjectInspector, ObjectInspector, byte, byte, Text, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List<String>, List<ObjectInspector>, byte, Text, boolean, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List<String>, List<ObjectInspector>, byte, Text, boolean, boolean, byte, ObjectInspectorFactory.ObjectInspectorOptions)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List<String>, List<ObjectInspector>, List<String>, byte, Text, boolean, boolean, byte)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List<String>, List<ObjectInspector>, List<String>, byte, Text, boolean, boolean, byte, ObjectInspectorFactory.ObjectInspectorOptions)
org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazyUnionObjectInspector(List<ObjectInspector>, byte, Text, boolean, byte)
org.apache.hadoop.hive.serde2.dynamic_type.SimpleCharStream.getLine()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getLocation()
org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getLocation()

org.apache.hive.hcatalog.data.schema.HCatFieldSchema.getMapKeyType() *as of 0.13, slated for removal with 0.15 use HCatFieldSchema.getMapKeyTypeInfo() instead*
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getNumBuckets()
org.apache.hadoop.hive.ql.udf.generic.SimpleGenericUDAFParameterInfo.getParameters()
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFParameterInfo.getParameters()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getPartitionCols()
org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getPartitionSpec()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getSerdeParams()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getSortCols()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getStorageHandler()
org.apache.hadoop.hive.metastore.IMetaStoreClient.getTable(String) *As of release 0.6.0 replaced by IMetaStoreClient.getTable(String, String). This method will be removed in release 0.7.0.*
org.apache.hadoop.hive.metastore.HiveMetaStoreClient.getTable(String)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getTableName()
org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getTableName()
org.apache.hive.hcatalog.api.HCatCreateTableDesc.getTblProps()
org.apache.hive.hplsql.HplsqlParser.getTokenNames()
org.apache.hive.hplsql.HplsqlLexer.getTokenNames()
org.apache.hive.hcatalog.data.schema.HCatFieldSchema.getType() *as of 0.13, slated for removal with 0.15 use HCatFieldSchema.getTypeInfo() instead*
org.apache.orc.Reader.getTypes() *use getSchema instead*
org.apache.hadoop.hive.serde2.AbstractSerDe.initialize(Configuration, Properties)
org.apache.hadoop.hive.serde2.AbstractEncodingAwareSerDe.initialize(Configuration, Properties)
org.apache.hadoop.hive.ql.udf.generic.GenericUDTF.initialize(ObjectInspector[])
org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe.initSerdeParams(Configuration, Properties, String)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.isTableExternal(boolean)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.linesTerminatedBy(char)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.location(String)
org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.mapKeysTerminatedBy(char)
org.apache.hive.hcatalog.streaming.HiveEndPoint.newConnection(boolean) *As of release 1.3/2.1. Replaced by HiveEndPoint.newConnection(boolean, String)*
org.apache.hive.hcatalog.streaming.HiveEndPoint.newConnection(boolean, HiveConf) *As of release 1.3/2.1. Replaced by HiveEndPoint.newConnection(boolean, HiveConf, String)*

org.apache.hive.hcatalog.streaming.HiveEndPoint.newConnection(boolean, HiveConf, UserGroupInformation) *As of release 1.3/2.1. Replaced by HiveEndPoint.newConnection(boolean, HiveConf, UserGroupInformation, String)*

Troubleshooting Hive and Tez

This section includes Hive and Tez troubleshooting tips.

HDFS Literal Deprecated

Starting in Hive-2.3, the `hdfs` literal is deprecated. Specifying a table location using the `hdfs` URI scheme will cause queries to fail because the Hive parser recognizes the `hdfs` literal in the LOCATION key word and triggers HDFS encryption, which is not supported.

If you use the `hdfs` literal with the LOCATION keyword in Hive queries:

```
CREATE TABLE IF NOT EXISTS i (id INT) LOCATION 'hdfs:///i';
```

The system logs the following warning:

```
LOG.warn("hdfs:// is deprecated filesystem and will be removed in future
releases. Use maprfs://
        instead");
```

To avoid `hdfs` literal issues, update all instances of `hdfs` with `maprfs` in tables, partitions, and databases. Also update the `hive-site.xml` file to remove `hdfs` from the URI scheme list.

Update hive-site.xml

Remove `hdfs` from the `hive.exim.uri.scheme.whitelist` Hive configuration property in `hive-site.xml`, as shown:

```
<property>

<name>hive.exim.uri.scheme.whitelist</
name>
    <value>maprfs,…,…,s3</value>
</property>
```

Update Tables and Partitions

To replace the table and partition location with `maprfs`, run:

```
MariaDB [hive]>  update SDS set
LOCATION = REPLACE(LOCATION, 'hdfs',
'maprfs') where LOCATION like
'%hdfs%';
```

Update Databases

To replace the database location with `maprfs`, run:

```
MariaDB [hive]> update
DBS set DB_LOCATION_URI =
REPLACE(DB_LOCATION_URI, 'hdfs',
'maprfs') where DB_LOCATION_URI like
'%hdfs%';
```

Prohibited usage of `datanucleus.schema.autoCreateAll` property

The usage of the `datanucleus.schema.autoCreateAll` property is prohibited in all cases. Instead of using this property, you must run the `schematool` command. Refer to HIVE-21302 for more information.

WebHCat

Secure WebHCat operations depend on the Hive metastore having Kerberos enabled. If Kerberos is not enabled for the Hive metastore, null pointer exceptions similar to the following will appear:

```
2013-10-06 20:38:55,198 ERROR metastore.RetryingHMSHandler
(RetryingHMSHandler.java:invoke(134)) -
MetaException(message:java.lang.NullPointerException)

18)
```

If you are updating to the `mapr-hive-2.3.6-mapr-1912` (EEP-6.3.0) package, you should manually replace the old `webhcat-default.xml` configuration file with the new one and restart the WebHCat service:

```
cp /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat.new/
webhcat-default.xml /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat/
```

Hive in an Azure Cluster

When Hive services are installed on an Azure cluster, it is possible that the services will not start because Azure assigns too long (over 64 symbols) host names. Perform following steps to fix this issue:

Note: This issue is fixed on MapR core 6.0.1 starting from build `20180320175756.GA-1.x86_64`.

last-updated: Apr 11, 2022

1. Edit the `/etc/hosts` file:

```
nano /etc/hosts
```

   This is an example of a `/etc/hosts` file for an Azure cluster:

```
127.0.0.1   localhost localhost.localdomain localhost4
localhost4.localdomain4
::1         localhost localhost.localdomain localhost6
localhost6.localdomain6
172.24.8.4
anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0
172.24.8.5
anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1
172.24.8.6
anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2
172.24.8.7
anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3
172.24.8.8
anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4
```

2. Add a short alias for each node:

   Note: You can use any short alias. In this example, `vm0`, `vm1`, `vm2`, `vm3`, and `vm4` are used:

```
127.0.0.1   localhost localhost.localdomain localhost4
localhost4.localdomain4
::1         localhost localhost.localdomain localhost6
localhost6.localdomain6
172.24.8.4
anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0 vm0
172.24.8.5
anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1 vm1
172.24.8.6
anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2 vm2
172.24.8.7
anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3 vm3
172.24.8.8
anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4led1p3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4 vm4
```

3. Perform step 1 and 2 for each node in the cluster.

Tez Upgrade Issues

- Preserving configuration on Ubuntu is not supported from EEP 4.1.1 and EEP 5.0.0 (1803) to EEP 6.0.0 (1808) or EEP 5.0.1 (1808).
- Preserving Tomcat configuration is not supported from any previous EEP to EEP 6.0.0 (1808).

last-updated: Apr 11, 2022

- You must manually stop the Tomcat service and delete the Tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:
  - EEP 4.0.0
  - EEP 4.1.0

User Names, Group Names, and LDAP

LDAP configuration allows you to use group names and usernames with spaces, so it is possible to name groups with spaces in them, for example, `domain users`. The following structure is possible in the MapR FileSystem:

```
drwxr-xr-x   - afischer      domain users          0 2018-10-03 16:10 /
user/abc
drwxr-xr-x   - mapr          mapr                  0 2018-10-05 16:51 /
user/def
drwxr-xr-x   - dschexnayder  domain users          8 2018-10-10 13:30 /
user/xyz
drwxr-xr-x   - mapr          mapr                  1 2018-10-09 14:23 /user/
hive
drwxr-xr-x   - mapr          mapr                 11 2018-10-10 01:56 /user/
mapr
drwxr-xr-x   - mlitovsky     domain users          0 2018-10-06 11:08 /user/
hjbs
drwxr-xr-x   - pcurtis       domain users          5 2018-10-04 19:33 /user/
jknd
drwxr-xr-x   - mapr          mapr                  3 2018-10-08 16:29 /user/
ewkd
drwxr-xr-x   - talvarez      domain users          0 2018-10-04 17:02 /
user/lkd
```

According to HADOOP-12505, the Hadoop community does not allow spaces in group names, and because of that so does Hive. Each time you perform a query in Hive on a group name that has a space, you will see the following exception:

```
-chgrp: 'domain users' does not match expected pattern for group
```

The workaround is to not use spaces in group names or user names.

HiveServer 2 takes time to start because of `get_all_databases`

Materialized view registry and cache is introduced in HIVE-14496 for Hive 2.3.0.

The goal of the cache is to avoid parsing and creating logical plans for the materialized views at query runtime. When a query arrives, you need to consult this cache and extract the logical plans for the views (which are already parsed) from it. Materialized view registry class scans all databases and tables in each database during initialization and that may cause long time to start HiveServer2.

Property `hive.materializedview.enable.views.registry` is added to control the usage of materialized view registry:

Property: `hive.materializedview.enable.views.registry`

Default value: true

Description: In case of a large amount of databases and tables in Hive, usage of materialized view registry and cache force HiveServer2 to scan all of them in order to cache the query plan for a view. This leads to an extremely long time for HiveServer2 to start.

This property is used to disable view registry and cache for this case. To disable materialized view registry and cache, add the following to `hive-site.xml` and restart Hive services.

```
<property>
  <name>hive.materializedview.enable.views.registry</name>
  <value>false</value>
</property>
```

Database and Table Names Containing a Dot (.)

HIVE-16907 rejects queries with database and table names that contain a dot (`.`), and this behavior is backported to Hive 2.3.

Databases and tables that contain a dot (`.`) in the name are not supported now. For example:

```
{code}
insert into `tdb.t1` select * from t2;
{code}
Throws error:
{code}
FAILED: SemanticException
org.apache.hadoop.hive.ql.parse.SemanticException: Line 1:12 Table or
database name may not contain dot(.) character 'tdb.t1'
{code}
```

Avoid using unsupported characters in database and table names.

Hive Logging

This section describes Hive logging for Hive 2.1 and later releases and includes information about log splitting.

Hive Logging (Hive 2.3 and Later)

For Hive 2.3 and later starting with EEP 6.3.0, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

Hive Log Folder Structure

Table 1 shows the Hive log folder structure:

Table

Folder or File			Description
`${HIVE_HOME}/log`			Root folder for all Hive logs

	`hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out`
	`hive-${ADMIN_USER}-metastore-${HOSTNAME}.out`
	`init_derby_db_${TIMESTAMP}.log`
			Each service has a separate file for logging

`${HIVE_HOME}/log/${ADMIN_USER}`			Root folder for admin cluster logs

		`${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`
		`${ADMIN_USER}-metastore-${HOSTNAME}.log`
		`${ADMIN_USER}-cli-${HOSTNAME}.log`
			Cluster admin log files

last-updated: Apr 11, 2022

Table (Continued)

Folder or File	Description
`${HIVE_HOME}/log/${ADMIN_USER}/webhcat/`	Root folder for webHcat logs

`webhcat.log`
`webhcat-console.log`
`webhcat-console-error.log`
	WebHcat log files

`${HIVE_HOME}/log/${OTHER_USER}`	Root folder for a user other than the admin user
`${OTHER_USER}-cli-${HOSTNAME}.log`	CLI log for a user other than the admin user

In Table 1:

This element	Represents
`${HIVE_HOME}`	The Hive home folder, which is usually `/opt/mapr/hive/hive`.
`${ADMIN_USER}`	The admin user of a cluster that runs HiveServer2 and HiveMetastore daemons. Usually, this is the `mapr` user.
`${HOSTNAME}`	The name of the host where the daemon runs.
`${TIMESTAMP}`	The date and time of log creation.
`${OTHER_USER}`	A user other than the admin user.
`${OTHER_USER}-cli-${HOSTNAME}.log`	The log file that is created when `${OTHER_USER}` launches the Hive CLI.

Content of Log Files

Table 2 shows the content of the log files:

Table

File Name	Description
`hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out`	Contains information about when the HiveServer2 daemon was started and the PID of the file.
`hive-${ADMIN_USER}-metastore-${HOSTNAME}.out`	Contains information about when the HiveMetastore daemon was started and the PID of the file.
`${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`	Contains information from the HiveServer2 daemons. This file also contains the job progress.
`${ADMIN_USER}-metastore-${HOSTNAME}.log`	Contains information from the HiveMetastore daemons.
`${ADMIN_USER}-cli-${HOSTNAME}.log`	Created when a user runs the Hive CLI over the ${ADMIN_USER}. This file contains the job progress.
`${OTHER_USER}-cli-${HOSTNAME}.log`	Created when a user runs the Hive CLI over the ${OTHER_USER}. This file also contains the job progress.
`init_derby_db_${TIMESTAMP}.log`	Created if and only if Hive was configured for Apache Derby through cluster installation.

last-updated: Apr 11, 2022

Log Files in a Multinode Hive Installation

Table 3 shows a Hive multinode installation (that is, Hive packages installed on different nodes):

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1	⅓		
node2		⅓	
node3			⅓

See Table 4 for the log configurations:

Table

File or Folder Name	node1	node2	node3
`hive-${ADMIN_USER}-metastore- ${HOSTNAME}.out`	⅓		
`${ADMIN_USER}-metastore- ${HOSTNAME}.log`	⅓		
`hive-${ADMIN_USER}-hiveserver2- ${HOSTNAME}.out`		⅓	
`${ADMIN_USER}-hiveserver2- ${HOSTNAME}.log`		⅓	
`/webhcat/`			⅓
`webhcat.log`			⅓
`webhcat-console.log`			⅓
`webhcat-console-error.log`			⅓
`/${ADMIN_USER}/`	⅓	⅓	⅓

Related concepts

Disabling Log Splitting of Hive Log Files on page 3606
By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID on page 3606
Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metestore log files by process ID.

Hive Logging (Hive 2.1 and Later)

For certain Hive 2.1 and later releases, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

The Hive log information in this topic applies to Hive 2.1 and later releases beginning with the 1803 release-date identifier. Included are the Hive releases in MapR Ecosystem Packs (EEPs) 3.0.3, 3.0.4, 3.0.5, 4.1.1, 4.1.2, 4.1.3, 4.1.4, 5.0.x, 6.0.x, 6.1.1, and 6.2.0. For more information about release-date identifiers, see Release History for EEPs on page 5623.

Default log folder structure

Hive logs have the following folder structure:

```
${HIVE_HOME}/log
${HIVE_HOME}/log/hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out
${HIVE_HOME}/log/hive-${ADMIN_USER}-metastore-${HOSTNAME}.out
${HIVE_HOME}/log/init_derby_db_${TIMESTAMP}.log
${HIVE_HOME}/log/${ADMIN_USER}
```

last-updated: Apr 11, 2022

```
${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-metastore-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console-error.log
${HIVE_HOME}/log/${OTHER_USER}
${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log
```

Here:

```
${HIVE_HOME} - Hive home folder. Usually this is /opt/mapr/hive/hive.
${ADMIN_USER} - Admin user of cluster that runs HiveServer2 and
HiveMetastore daemons. Usually this is mapr.
${HOSTNAME} - Name of the host where a daemon runs.
${TIMESTAMP} - Date and time of log creation.
${OTHER_USER} - Not an admin user.
```

Content of log files

Files `$HIVE_HOME/log/hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out` and `$HIVE_HOME/log/hive-${ADMIN_USER}-metastore-${HOSTNAME}.out` contain information about when HiveServer2 and HiveMetastore daemons are stated, and what are their PIDs.

Files `$HIVE_HOME/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log` and `$HIVE_HOME/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log` contain information from HiveServer2 and HiveMetastore daemons. File `${ADMIN_USER}-hiveserver2-${HOSTNAME}.log` also contains job progress.

The `${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log` file is created when somebody runs Hive CLI over the `${OTHER_USER}`. The `${OTHER_USER}-hiveserver2-${HOSTNAME}.log` file contains job progress.

The `${HIVE_HOME}/log/init_derby_db_${TIMESTAMP}.log` file is created if and only if Hive was configured for Derby Db through cluster installation.

Log files on multi node Hive installation

Consider Hive multi node installation (that is Hive packages are installed on different nodes). See Table 1:

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1	⅓		
node2		⅓	
node3			⅓

See Table 2 for log configurations.

Table

	node1	node2	node3
`${HIVE_HOME}/logs/hive-${ADMIN_USER}-metastore- ${HOSTNAME}.out`	⅓		
`${HIVE_HOME}/logs/${ADMIN_USER}/${ADMIN_USER}-metastore- ${HOSTNAME}.log`	⅓		
`${HIVE_HOME}/logs/hive-${ADMIN_USER}-hiveserver2- ${HOSTNAME}.out`		⅓	

Table (Continued)

	node1	node2	node3
`${HIVE_HOME}/logs/${ADMIN_USER}/${ADMIN_USER}-hiveserver2- ${HOSTNAME}.log`		⅓	
`${HIVE_HOME}/logs/${ADMIN_USER}/webhcat/`			⅓
`${HIVE_HOME}/logs/${ADMIN_USER}/webhcat/webhcat.log`			⅓
`${HIVE_HOME}/logs/${ADMIN_USER}/webhcat/webhcat-console.log`			⅓
`${HIVE_HOME}/logs/${ADMIN_USER}/webhcat/webhcat-console-error.log`			⅓
`${HIVE_HOME}/logs/${ADMIN_USER}`	⅓	⅓	⅓

Related concepts

Disabling Log Splitting of Hive Log Files on page 3606
By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID on page 3606
Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metestore log files by process ID.

Disabling Log Splitting of Hive Log Files

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

This information is valid for Hive-2.1+ starting from the EEP-1803 release.

Disabling Log Splitting of Hive Log Files

You can disable splitting the Hive log files into HiveServer2 and Metastore log files. To write all logs to the `hive.log` file, use these steps:

1. Edit the `hive-env.sh` file to set `SPLIT_HIVE_LOGS_INTO_FILES` property to `false`.

   ```
   export SPLIT_HIVE_LOGS_INTO_FILES="false"
   ```

   Note: To restore the default behavior from your previous Hive log configuration, set the `SPLIT_HIVE_LOGS_INTO_FILES` property to `true`, or comment out this property and restart Hive services.

2. Restart Hive services.

Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metestore log files by process ID.

To enable this feature, you must create a `hive-log4j2.properties` file, if one does not already exist, and then edit it:

1. If the `hive-log4j2.properties` file does not exist, create it from the template:

```
cp /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties.template  /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties
```

2. Edit the `hive-log4j2.properties` file to replace Daily Rolling File Appender (DRFA) with the PID appender:

```
#property.hive.root.logger = DRFA
property.hive.root.logger = PID
#appenders = console, DRFA
appenders = console, PID
```

3. Restart Hive services.

The resultant Hive log structure is as follows:

The HiveServer2 log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where HiveServer2 log file is placed.
- `<PID>` is the process ID of HiveServer2.

The Metastore log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-metastore-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where Hive Metastore log file is placed.
- `<PID>` is the process ID of Hive Metastore.

Logging CLI session

After splitting logs for HiveServer2 and Hive Metastore, CLI log appears separately for each CLI session at `${HIVE_HOME}/logs/<USERNAME>`.

A log file is created for every launched CLI session:

```
${HIVE_HOME}/log/<USERNAME>/
<USERNAME>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where `<PID>` is process identifier of the CLI session.

last-updated: Apr 11, 2022

Viewing Hive Audit Logs

Starting in EEP 6.3.4, you can view Hive audit logs for connected, disconnected, and total connected users.

To view audit logs, add the following property in the `hive-site.xml` file:

```
<property>
    <name>hive.enable.full.list.of.connected.users</name>
    <value>true</value>
</property>
```

By default, logs are updated every five seconds.

The following table describes the Hive Parameters used to manage the user audit logs:

Parameter	Default value	Description
hive.enable.full.list.of.connected.users	false	Enables the logging of the users currently connected to Hive when set to true. Use for debugging purposes only.
hive.full.list.of.connected.users.update.interval	5	Enables the log updates for currently connected Hive users in seconds. Must be used with the `hive.enable.full.list.of.connected.users` parameter. Use for debugging purposes only.

How to View Audit Logs

Enable the `hive.enable.full.list.of.connected.users` property in `hive-site.xml` file. You can view audit logs for connected, disconnected, and total connected users in HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

The following examples show you how the audit logs look in different scenarios:

Logs display for new user connection

Log entries for connected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Connected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

Logs display for disconnected user

Log entries for disconnected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Disconnected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

Logs display for total connected users

Log entries for total connected users start with a message -Start of connected users list, and provides the current session ID, username, IP address of the user, operation count, active time, idle time,

last-updated: Apr 11, 2022

authentication type, and end with a message- End of the connected user's list.

```
INFO [pool-4-thread-1]
SessionManager.audit: Start of the
connected users list

How to Audit a Hive Query

The audit log in HiveServer2 allows you to trace the activities of a Hive query. The log entries for a Hive query includes username, user's IP address, query ID, query type, and query string.

To audit a Hive query, run any Hive query and then see the HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

```
INFO [HiveServer2-Background-Pool: Thread-54]
Driver.audit: user=mapr ip=192.168.33.11
queryId=mapr_20210426155754_ace67f82-9a0c-4d0e-9ac5-c529b9798ec7 query
type=SHOWTABLES queryStr=show tables
```

HttpFS

HttpFS provides a service that enables you to submit HTTP REST calls to distributed file systems. You can use HttpFS to perform read and write operations on the filesystem.

This section includes the following topics:

Authentication on Secure Clusters for HttpFS

In secure clusters, HttpFS can use any of the following authentication methods:

- HttpFS authentication, such as native security (data-fabric SASL)
- Kerberos (for which additional configuration is required)

- Plain security using PAM, which is determined automatically

In a secure cluster, HttpFS runs a script to set the following properties by default. In a non-secure cluster, you must add the following properties manually to the `httpfs-site.xml` file:

```
httpfs.hadoop.authentication.type=multiauth
httpfs.authentication.type=multiauth
```

Configuring HttpFS

You can configure the following features to perform distributed filesystem operations securely through HttpFS.

The following topics describe how to configure various security mechanisms for HttpFS.

Kerberos Authentication for HttpFS

Complete the following steps to enable Kerberos security on nodes that run the HttpFS service:

Step 1: Set up a Kerberos Principal and keytab File

Each node running the HttpFS service must have a keytab file (`/opt/mapr/conf/mapr.keytab`) and these two principals:

- HTTP/<fully.qualified.domain.name>
- mapr/<fully.qualified.domain.name>

Note: For complete instructions on generating a Kerberos principal and keytab file, see Configuring Kerberos.

To check whether the keytab already exists, and if it contains the two necessary principals, run the `klist` command with the `-k` (keytab keys), `-e` (encryption type) and `-t` (timestamp) options:

```
$ klist -ket /opt/mapr/conf/mapr.keytab
```

The output from this command displays the following information:

- KVNO (key version number)
- Timestamp (the time the key was generated)
- Principal names
- Encryption types

If the keytab file does not exist, or does not contain both principals, generate them by following these steps:

1. Generate a Kerberos principal for the `mapr` user. The principal is of the form `mapr/<fully.qualified.domain.name>@<your-realm>.com`, where `<fully.qualified.domain.name>` is unique for each HttpFS node. In the following example, `perfnode153.perf.lab@dev-maprtech.com` is used for the `<fully.qualified.domain.name>@<your-realm>.com`.

   ```
   $ kadmin
   kadmin: addprinc -randkey mapr/perfnode153.perf.lab@dev-maprtech.com
   ```

2. Generate a Kerberos principal for `HTTP/<fully.qualified.domain.name>`. This is required for Kerberos authentication of the HttpFS server using HTTP SPNEGO.

```
$ kadmin
kadmin: addprinc -randkey HTTP/perfnode153.perf.lab@dev-maprtech.com
```

3. If the current node does not already have a keytab file created for another service, create one and name it `mapr.keytab`. Note that each node references the same keytab file (usually located at `/opt/mapr/conf/mapr.keytab`), and each keytab file can have multiple principals.

```
kadmin: ktadd -k /opt/mapr/conf/mapr.keytab mapr/perfnode153.perf.lab
```

4. Change the owner of the keytab file from the `root` user (the default) to the `mapr` user.

```
$ chown mapr:mapr /opt/mapr/conf/mapr.keytab
```

5. Set read-only permissions on the `mapr.keytab` file.

```
$ chmod 600 mapr:mapr /opt/mapr/conf/mapr.keytab
```

Step 2: Verify Credentials in the keytab File

To test that the credentials in the `mapr.keytab` file work, run the `klist` command with the three options:

- **`-k`** for keytab keys
- **`-e`** for encryption type
- **`-t`** for timestamp

Example

```
$ klist -ket /opt/mapr/conf/mapr.keytab
```

Verify that the output lists only one key version number (KVNO) for each principal name. If you see the same principal listed more than once with a different KVNO, this could indicate a problem. The latest version number is used, which means you might not be able to log in to the node and authenticate with your user credentials.

Here is sample output for a node that has the HttpFS and CLDB services installed.

```
Keytab name: FILE:/opt/mapr/conf/mapr.keytab
KVNO Timestamp Principal
---- -----------------
  -------------------------------------------------------
 2 07/18/14 18:50:07 mapr/perfnode153.perf.lab@dev-maprtech
  (aes256-cts-hmac-sha1-96)
 2 07/18/14 18:50:07 mapr/perfnode153.perf.lab@dev-maprtech (arcfour-hmac)
 2 07/18/14 18:50:08 mapr/perfnode153.perf.lab@dev-maprtech (des3-cbc-sha1)
 2 07/18/14 18:50:08 mapr/perfnode153.perf.lab@dev-maprtech (des-cbc-crc)
 2 07/18/14 18:50:26 HTTP/perfnode153.perf.lab@dev-maprtech
  (aes256-cts-hmac-sha1-96)
 2 07/18/14 18:50:26 HTTP/perfnode153.perf.lab@dev-maprtech (arcfour-hmac)
 2 07/18/14 18:50:26 HTTP/perfnode153.perf.lab@dev-maprtech (des3-cbc-sha1)
 2 07/18/14 18:50:26 HTTP/perfnode153.perf.lab@dev-maprtech (des-cbc-crc)
 6 07/18/14 18:50:56 mapr/my.cluster.com@dev-maprtech
  (aes256-cts-hmac-sha1-96)
```

```
 6 07/18/14 18:50:56 mapr/my.cluster.com@dev-maprtech (arcfour-hmac)
 6 07/18/14 18:50:56 mapr/my.cluster.com@dev-maprtech (des3-cbc-sha1)
 6 07/18/14 18:50:57 mapr/my.cluster.com@dev-maprtech (des-cbc-crc)
```

In the example, the following principals are listed for the `perfnode153.perf.lab` node:

- **`mapr/perfnode153.perf.lab@dev-maprtech`** for authenticating to the HttpFS service
- **`HTTP/perfnode153.perf.lab@dev-maprtech`** for communicating securely over HTTP
- **`mapr/my.cluster.com`** for authenticating to the CLDB service

Step 3: Modify the httpfs-site.xml File

A Kerberos-ready version of the `httpfs-site.xml` file called `httpfs-site.xml.kerberos` is provided in `/opt/mapr/httpfs/httpfs-<version>/etc/hadoop`. Edit this file and specify the Kerberos principal name for the nodes running HttpFS, restart the HttpFS server, and then test the set-up. Each step is explained here.

Note that the directory differs based on the httpfs version:

- In EEP 7.0.1 and earlier, the directory is `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`.
- In EEP 7.1.0 and later, the directory is `/opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop/httpfs-site.xml`.

To set up the `httpfs-site.xml` file for each node running the HttpFS service, follow these steps:

1. Assign a new name to the existing `httpfs-site.xml` file (to preserve the original version when the file gets overwritten in step 2).
   - In 7.0.1 and earlier, run:

     ```
     cp /opt/mapr/httpfs/httpfs-1.0/etc/hadoop httpfs-site.xml
     httpfs-site.xml.original
     ```

   - In 7.1.0 and later, run:

     ```
     cp /opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop httpfs-site.xml
     httpfs-site.xml.original
     ```

2. Copy the kerberos version (`httpfs-site.xml.kerberos`) to the existing `httpfs-site.xml` file.
   - In 7.0.1 and earlier, run:

     ```
     cp /opt/mapr/httpfs/httpfs-1.0/etc/hadoop httpfs-site.xml.kerberos
     httpfs-site.xml
     ```

   - In 7.1.0 and later, run:

     ```
     cp /opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop httpfs-site.xml.kerberos
     httpfs-site.xml
     ```

3. Edit the `httpfs-site.xml` file and insert the principal name as shown, substituting your fully qualified domain name and realm for `perfnode153.perf.lab@mapr.com`.

```
<property>
  <name>
    httpfs.authentication.kerberos.principal
  </name>
  <value>
    HTTP/perfnode153.perf.lab@mapr.com
  </value>
</property>
```

4. Restart the HttpFS server so the changes will take effect.

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

5. Test that security is in place by entering the following command to create a file in the MapR filesystem. The command will fail if security is not set up correctly.

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt -i -X PUT
"http://perfnode153.perf.lab:14000/webhdfs/v1/user/mapr/some_file?
op=MKDIRS"
```

(Optional) Configure the HTTP Header Size

For EEP 7.0.1 and earlier, the `maxHttpHeaderSize` parameter defines the maximum size of the request and response HTTP header, specified in bytes. If it is not specified, this parameter defaults to 8192 (8KB).

When Kerberos security is enabled, you may need to increase this value in the `server.xml` file:

```
/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml
```

Example

```
<Connector port="${httpfs.http.port}" maxHttpHeaderSize="32000"
protocol="HTTP/1.1" connectionTimeout="20000" redirectPort="8443"/>
```

If you do not increase this value, you may encounter errors of the following form:

```
HTTP/1.1 400 Bad Request
```

Note: After making this configuration change, restart the HttpFS server.

PAM Authentication for HttpFS

Complete the following steps to enable PAM authentication for HttpFS.

1. Add the `httpfs.hadoop.authentication.type` and `httpfs.authentication.type` properties to the `/opt/mapr/httpfs/httpfs-version/etc/hadoop/`**`httpfs-site.xml`** file, as shown. Note that the directory differs based on the httpfs version:
   - In EEP 7.0.1 and earlier, the directory is `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`.

- In EEP 7.1.0 and later, the directory is `/opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop/httpfs-site.xml`.

```
<property>
        <name>httpfs.hadoop.authentication.type</name>
        <value>multiauth</value>
</property>

<property>
        <name>httpfs.authentication.type</name>
        <value>multiauth</value>
</property>
```

Note: On secure clusters, the **`multiauth`** authentication is enabled by default.

2. Restart the HttpFS service.

```
sudo -u mapr /opt/mapr/httpfs/httpfs-1.0/sbin/httpfs.sh stop
sudo -u mapr /opt/mapr/httpfs/httpfs-1.0/sbin/httpfs.sh start
```

3. After restarting the service, run cURL with the PUT operation, as shown in this example:

Note: If HttpFS is configured with plain authentication through PAM, the cURL request must contain a username and password.

```
curl -X PUT "https://mapr:mapr@node1:14000/webhdfs/v1/tmp/example?
op=mkdirs"
```

SSL Security for HttpFS

Use this procedure with MapR 6.0 and earlier to explicitly enable security on HttpFS. Although SSL for HttpFS is enabled by default on secure clusters in MapR 6.0.1, you must manually configure it in MapR 6.0 and earlier, including whether you want it to use certificate-based authentication or not.

You also need to enable SSL if custom security is enabled.

Enabling SSL Security for HttpFS
Enable SSL security for HttpFS using a `ssl_keystore` and `ssl_truststore`. These are generated automatically for a secure cluster in `/opt/mapr/conf/`. When using SSL on insecure clusters, you must manually generate a `keystore` and `truststore`.
Configuring Certificate-Based Authentication for HttpFS
To configure certificate-based authentication for HttpFS you need to make changes to the `server.xml` and `web.xml` file and restart the HttpFS server. To use this method, each client requires a client certificate issued by trusted CA.

1. To enable certificate-based authentication, perform the following steps:

a) Verify that the `clientAuth` attribute is set to "**true**" and set properties related to `keystore` and `truststore` in **`server.xml`** (`/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml`).

   For example:

```
<Connector port="${httpfs.http.port}" SSLEnabled="true"
maxThreads="150" scheme="https" secure="true" clientAuth="true"
sslProtocol="TLS"
keystoreFile="/opt/mapr/conf/ssl_keystore"
keystorePass="<ssl-keystore-password>"
truststoreFile="/opt/mapr/conf/ssl_truststore"
truststorePass="<ssl-keystore-password>"/>
```

b) In **`web.xml`** (`/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/webapps/webhdfs/WEB-INF/`**`web.xml`**), un-comment the following section:

```
<security-constraint>
  <web-resource-collection>
    <web-resource-name>Protected Context</web-resource-name>
    <url-pattern>/*</url-pattern>
  </web-resource-collection>
  <auth-constraint>
    <role-name>sample</role-name>
  </auth-constraint>
  <user-data-constraint>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
  </user-data-constraint>
</security-constraint>

<security-role>
  <role-name>sample</role-name>
</security-role>

<login-config>
  <auth-method>CLIENT-CERT</auth-method>
</login-config>
```

c) Verify that **tomcat-users.xml** (/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/**tomcat-users.xml**) contains the roles and users in the certificates.

```
<tomcat-users>
  <role rolename="sample"/>
  <user name="CN=<hostname>" password="null" roles="sample" />
</tomcat-users>
```

Note: The name value should include information from your certificate. For example, <tomcat-users> <role rolename="**sample**"/> <user name="**CN=www.mapr.com, OU=mapr, O=mapr, L=San Jose, ST=San Jose, C=CA**" password="**null**" roles="**sample**" /> </tomcat-users> You can run the following command to view the contents of the certificate file: openssl x509 -text -in /opt/mapr/hue/hue-<version>/**cert.pem**

```
<tomcat-users>
  <role rolename="sample"/>
  <user name="CN=www.mapr.com, OU=mapr, O=mapr, L=San Jose,
       ST=San Jose, C=CA" password="null" roles="sample" />
</tomcat-users>
```

2. Restart the HttpFS server using the following command:

```
maprcli node services -name httpfs -action restart -nodes <space
delimited list of nodes>
```

Verifying SSL Security for HttpFS
You need to run curl commands to verify that HTTPS is enabled for HttpFS.

Run one of the following curl commands to check that HTTPS is enabled. These commands fetch the file **some_file.txt** from the file system under /user/**mapr** and attempt to open it securely over HTTPS.

- To check if HTTPS is enabled, run the following command (which differs for non-secure and secure clusters):
  - For non-secure clusters:

```
curl "http://localhost:14000/webhdfs/v1/user/mapr/some_file.txt?
op=open&user.name=mapr"
```

  - For secure clusters:

```
curl -u <user_name> -k
 "https://localhost:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

- If you configured Hue to use SSL encryption with certificate-based authentication for communication with HttpFS, run the following command (which differs for non-secure and secure clusters):
  - For non-secure clusters:

```
curl
  --cert /opt/mapr/hue/hue-<version>/cert.pem
  --key /opt/mapr/hue/hue-<version>/hue_private_keystore.pem
  "http://localhost:14000/webhdfs/v1/user/mapr/some_file.txt?
op=open&user.name=mapr"
```

- For secure clusters:

```
curl -u <user_name> -k
 --cert /opt/mapr/hue/hue-<version>/cert.pem
 --key /opt/mapr/hue/hue-<version>/hue_private_keystore.pem
 "https://localhost:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

User Impersonation for HttpFS

You can set up proxy user functionality if you want HttpFS to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups. When you configure proxy user functionality, the proxy user can perform “doAs” operations. Add configuration properties to the `httpfs-site.xml` and `core-site.xml` files to configure proxy user functionality.

Complete the following steps to configure user impersonation for HttpFS:

1. Add the following configuration properties to the `httpfs-site-site.xml` file:
   - `httpfs.proxyuser.#USER#.hosts`
   - `httpfs.proxyuser.#USER#.groups`
2. Replace #USER# with the username of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (*) as the value for host and group properties. To add multiple users, copy the property and replace #USER# with the proxy user name.

   Host Example

```
<property>
        <name>httpfs.proxyuser.mapr.hosts</name>
        <value>*</value>
</property>
```

   Group Example

```
<property>
        <name>httpfs.proxyuser.mapr.groups</name>
        <value>*</value>
</property>
```

To use impersonation, issue a cURL command with the `doas=<impersonated_user's name>` parameter.

Example 1

Where `user.name` is `mapr` and `doas` (or the impersonated user's name) is **sampleusername**.

```
curl -i -X PUT -T one
"http://<node_name>:14000/webhdfs/v1/user/mapr/TEST/one
?op=CREATE&user.name=mapr&doas=sampleusername&data=true"
-H "Content-Type:application/octet-stream"
```

Example 2

For any user (and password) other than the `mapr` user (for example, **test_user1**), set the `hadoop.proxyuser.<user_name>.hosts</name>` property in the `/opt/mapr/httpfs/httpfs-<version>/etc/hadoop/httpfs-site.xml` file, as shown. Note that the directory differs based on the version of httpfs, for example:

last-updated: Apr 11, 2022

- In EEP 7.0.1 and earlier, the directory is `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`.
- In EEP 7.1.0 and later, the directory is `/opt/mapr/httpfs/httpfs-1.1.0/etc/hadoop/httpfs-site.xml`.

```
<property>
          <name>hadoop.proxyuser.<test_user1>.hosts</name>
          <value>*</value>
</property>
```

Run cURL.

Where `trueuser.name` is **test_user1** and `doas` (or the impersonated user's name) is **test_user2**.

```
curl -u fred -i -X PUT -T /etc/hosts --header "Content-Type:application/
octet-stream"
"http://<node_name>:14000/webhdfs/v1/<path_to_test_file>
?op=CREATE&doas=<test_user2>&data=true&user.name=<test_user1>"
```

Finishing HTTPFS Configuration Changes

After making configuration changes for the `mapr-httpfs` package provided by EEP 4.0.0 or later, run the `configure.sh` script on all nodes where the `mapr-httpfs` package was installed:

```
sudo bash /opt/mapr/server/configure.sh -R
```

Troubleshooting HttpFS

To debug authentication issues, follow these steps:

1. Edit the `log4j` properties file located at `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-log4j.properties` and insert the following lines to activate debug capabilities:

   ```
   log4j.logger.org.apache.hadoop.fs.http.server=DEBUG, httpfs
   log4j.logger.org.apache.hadoop.lib=DEBUG, httpfs
   log4j.logger.org.apache.hadoop.security.authentication.server=DEBUG,
   httpfs
   ```

2. Search the logs located at `/opt/mapr/httpfs/httpfs-1.0/logs` for the words *ERROR* or *Exception*.

Hue

Hue is the open source UI that interacts with Apache Hadoop and its ecosystem components, such as Hive, Pig, and Oozie. It is also a framework for creating interactive Web applications.

For information about Hue versions, see the Ecosystem Support Matrix.

Hue is supported on the following browsers:

Windows	Linux	Mac
Chrome	Chrome	Chrome

Windows	Linux	Mac
Firefox 3.6+	Firefox 3.6+	Firefox 3.6+
Safari 5+		Safari 5+
Internet Explorer 8+		

Hue Feature Support

The following table lists supported and unsupported Hue functionality:

Supported	Not Supported
Query editors • Hive (for performing queries on Apache Hive) • Impala (for submitting interactive SQL and HiveQL queries) • DB Query (for viewing data in MySQL, PostgreSQL, Oracle and Sqlite) • Pig (for submitting Pig scripts) • Job Designer (for creating and submitting MapReduce/Streaming/Java jobs) • Spark (beta feature for submitting Spark jobs for hue-3.9.0/3.10.0) • Drill (for performing queries on Apache Drill through JDBC) in hue-3.12 Data browsers • Metastore Tables (for managing databases, tables, and partitions of the Hive metastore) • HBase browser (for creating, editing, and searching tables) • Sqoop Transfer (for transferring bulk data between Hadoop and various types of structured datastores) Workflows • Oozie (for creating and running workflow and coordinator jobs) Hue 4.X supports ADLS browser for accessing files and directories in Azure Data Lake Store. S3 Browser (for accessing files and directories in Amazon S3) File Browser (for accessing files and directories in MapR File System) • Job Browser (for accessing MapReduce applications) • User Admin (for adding, deleting, and managing Hue users and groups)	Hue integration with the following components is not supported: • Sentry 1.6, 1.7 on a secure cluster that uses MapR-SASL authentication. **Note:** Sentry 1.6, 1.7 on a secure cluster that uses Kerberos authentication is supported. • Solr Search • Zookeeper

Configure Hue

After you install Hue, perform the following configuration steps:

last-updated: Apr 11, 2022

1. Complete the general configuration steps. This includes integrating Hue with ResourceManager and HttpFS.
2. Perform the steps to integrate each additional component that you want to use with Hue.
   - Hive
   - MapR Database
   - Impala
   - Oozie
   - Spark
   - Sqoop2

You may also want to:

- Configure Security
- Configure DB Query
- Configure Hue Interface Authentication

Note: The `hue.ini` file is the main configuration file for running Hue on a cluster. This file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`. When you update the value of a property in the `hue.ini`, remove any hashes (##) that appear directly before the property name. You must also restart Hue for these changes to take effect.

Configure General Hue Settings

The following topics provide instructions for configuring general Hue settings:

Enable User Impersonation for Hue

To enable Hue to submit requests on behalf of any other user, complete the following steps:

1. Verify or configure the following lines to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file for all nodes running ResourceManager:

```
<property>
  <name>hadoop.proxyuser.<default_user>.hosts</name>
  <value>*</value>
</property>

<property>
  <name>hadoop.proxyuser.<default_user>.groups</name>
  <value>*</value>
</property>
```

2. To enable the Hue file browser to view files in the MapR filesystem, add the following proxy user settings in the configuration block of the `httpfs-site.xml`:

```
<!-- Hue HttpFS proxy user setting -->
<configuration>
  <property>
    <name>httpfs.proxyuser.<default_user>.hosts</name>
    <value>*</value>
  </property>

  <property>
    <name>httpfs.proxyuser.<default_user>.groups</name>
    <value>*</value>
  </property>
</configuration>
```

3. Perform any additional Hue configurations and then restart Hue so that the changes will take effect. See Starting the Hue Webserver.

   In most cases, mapr is the <default_user>. The <default_user> you specify must also be the default_user that is configured in the [desktop] section of the `hue.ini`.

   Note: Based on the ecosystem components that you want to use, addition configuration may be required.

Disable an Application in the Hue Interface (optional)

If you want to disable an application (such as Impala), follow these steps:

1. In the `[desktop]` section of the `hue.ini` file, uncomment the `# app_blacklist=` statement and insert the name of the app you want to disable (impala in this example).

   Note: Do not remove `search` from the app_blacklist. The Hue UI will not work if the search application is enabled.

```
# Comma-separated list of apps not to load at server startup.
# Note that rdbms is the name used for dbquery.
app_blacklist=spark,zookeeper,search,impala,sqoop,rdbms
```

   Note: After removing an application from `app_blacklist`, you must update the Hue internal database to create the tables required for the application that was enabled:

```
sudo /opt/mapr/server/configure.sh -R
```

2. Once all changes are made, restart Hue so the changes will take effect.

   Note: You can re-enable a blacklisted application at any time, and then restart Hue.

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

Change the File Size Restriction for the File Browser (optional)

The Hue File Browser will not open files that are 1.0 GB or greater. Starting with Hue 4.2, file size limitation equals 1.0 GB with no way to modify it.
Prevent Hue from Creating User Home Directories
Describes how to disable the automatic creation of user home directories.

By default, Hue creates a directory in the filesystem for a user when the user logs in to the Hue service.

last-updated: Apr 11, 2022

For example, if a /user volume is configured in the filesystem, Hue creates a /user/<username> directory in the volume each time a user logs in to the Hue service. If a quota is not placed on that /user volume, a user could potentially place an unlimited amount of data in the volume.

If you do not want Hue to create a home directory for each user that logs in to the Hue service, disable the `ensure_home_directory` option in the `[desktop] [[auth]]` section of the `hue.ini` file, as shown:

```
[desktop]
  [[auth]]
    ensure_home_directory=false
```

Restart the Hue service for the setting to take effect.

Note: This functionality is available by default starting in EEP 7.1.0. Previous versions of EEP can obtain this functionality through a patch. See Applying a Patch on page 437.

Configure Hue Interface Authentication

You can configure the following user authentication methods for the Hue interface:

Authentication Method	Description
Hue User Administration	Use the Hue interface to create and manage user accounts for each Hue user.
LDAP	Import LDAP users into Hue and then use LDAP to authenticate users with their LDAP credentials. For more information, see Configure Hue with LDAP.
PAM	Use multiple PAM modules to authenticate users. PAM authentication is configured by default. When you use this method, you cannot edit users in the Hue interface.

Using a Non-Default Authentication Method

The default authentication method is PAM.

To edit the authentication method used for the Hue interface, complete the following steps:

1. Set the `backend` property equal to your selected authentication method. For example, to use Hue's user authentication, select `desktop.auth.backend.AllowFirstUserDjangoBackend.`
2. If you choose not to use PAM, comment the `pam_service property.`

Example hue.ini configued to use PAM Authentication

```
[[auth]]
# Authentication backend. Common settings are:
# - django.contrib.auth.backends.ModelBackend (entirely Django backend)
# - desktop.auth.backend.AllowAllBackend (allows everyone)
# - desktop.auth.backend.AllowFirstUserDjangoBackend
# (Default. Relies on Django and user manager, after the first login)
# - desktop.auth.backend.LdapBackend
# - desktop.auth.backend.PamBackend - WARNING: existing users in Hue may be
unaccessible if they not exist in OS
# - desktop.auth.backend.SpnegoDjangoBackend
# - desktop.auth.backend.RemoteUserDjangoBackend
# - libsaml.backend.SAML2Backend
# - libopenid.backend.OpenIDBackend
# - liboauth.backend.OAuthBackend
# (Support Twitter, Facebook, Google+ and Linkedin
backend=desktop.auth.backend.PamBackend
```

last-updated: Apr 11, 2022

```
# The service to use when querying PAM.
pam_service=sudo sshd login
```

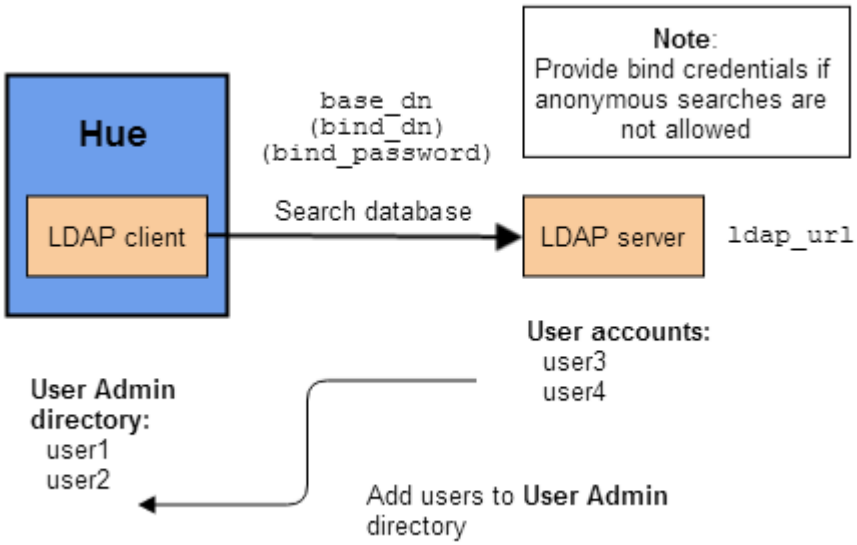
Configure Hue with LDAP

If you use LDAP to authenticate users, you can retrieve user account information from your LDAP database and import it directly into Hue's `User Admin` directory. This way, you do not have to use the Hue interface to create user accounts for each Hue user individually.

Once you import users, you can also use LDAP with Hue to authenticate users with their LDAP credentials. Each of these tasks is explained in the following sections:

Setting up Users from an LDAP Database

This diagram shows how the LDAP client embedded in Hue searches the LDAP server's database for user names, and then adds them to the `User Admin` directory for Hue.



The following table shows the parameters you need to set in the `ldap` section of the `hue.ini` file so you can import users.

Warning: The `hue.ini` file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/.`

Parameter	Description	Comments
`ldap_url`	The URL of your LDAP server.	
`base_dn`	Top of the search tree, which defines the search scope.	
`bind_dn`	Distinguished name (DN) of the user to bind as.	Can be omitted for anonymous searches.
`bind_password`	Password of the bind user.	Can be omitted for anonymous searches.
`user_filter`	Limits the scope of the search by applying a filter.	This parameter is optional.
`user_name_attr`	The attribute used for username in the LDAP schema.	Examples: `cn` (for common name) or `uid` (for user ID).

last-updated: Apr 11, 2022

To set up Hue users by importing information from an LDAP database:

1. Establish communication with the LDAP server by setting the `ldap_url` parameter in the `ldap` section of the `hue.ini` file. Uncomment the line and change the value from the default (`ldap://localhost`) to the URL for your LDAP server.

```
# URL of the LDAP server
    ##ldap_url=ldap://localhost
```

2. Provide the `base_dn` information to define the search scope. Uncomment the line where `base_dn` is defined and replace with your `base_dn`.

```
# The search base for finding users and groups
    ## base_dn="DC=mycompany,DC=com"
```

3. If your LDAP server does not support anonymous searches, you need to provide the `bind_dn` and `bind_password`. Uncomment the lines with these parameters and change the values to your `bind_dn` and your `bind_password`.

```
# Distinguished name of the user to bind as -- not necessary if the LDAP
server
    # supports anonymous searches
    ## bind_dn="CN=ServiceAccount,DC=mycompany,DC=com"

    # Password of the bind user -- not necessary if the LDAP server
supports
    # anonymous searches
    ## bind_password=
```

4. If you want to narrow the scope of the directory search, specify a `user_filter` in the `users` section under the `ldap` section of the `hue.ini` file. This is optional.

```
[[[users]]]

      # Base filter for searching for users
      ## user_filter="objectclass=*"
```

5. Set the `user_name_attr` parameter in the `users` section under the `ldap` section of the `hue.ini` file. If your LDAP directory schema does *not* use the attribute `sAMAccountName` for the username, uncomment the line and change the value of the `user_name_attr` to the attribute you use. For example, if the directory schema uses the `uid` attribute, change the value of the parameter as shown:

```
[[[users]]]

      # The username attribute in the LDAP schema
      ## user_name_attr=sAMAccountName
```

```
user_name_attr=uid
```

6. Restart httpfs so ldap settings will take effect.
7. Restart Hue once all configuration changes have been made so the changes will take effect.

Authenticating Hue Users with LDAP Credentials

last-updated: Apr 11, 2022

This section explains how to edit the `ldap` section of the `hue.ini` file to enable Hue user authentication with LDAP credentials. These instructions assume you have completed the steps in Setting up Users from an LDAP Database.

Warning:

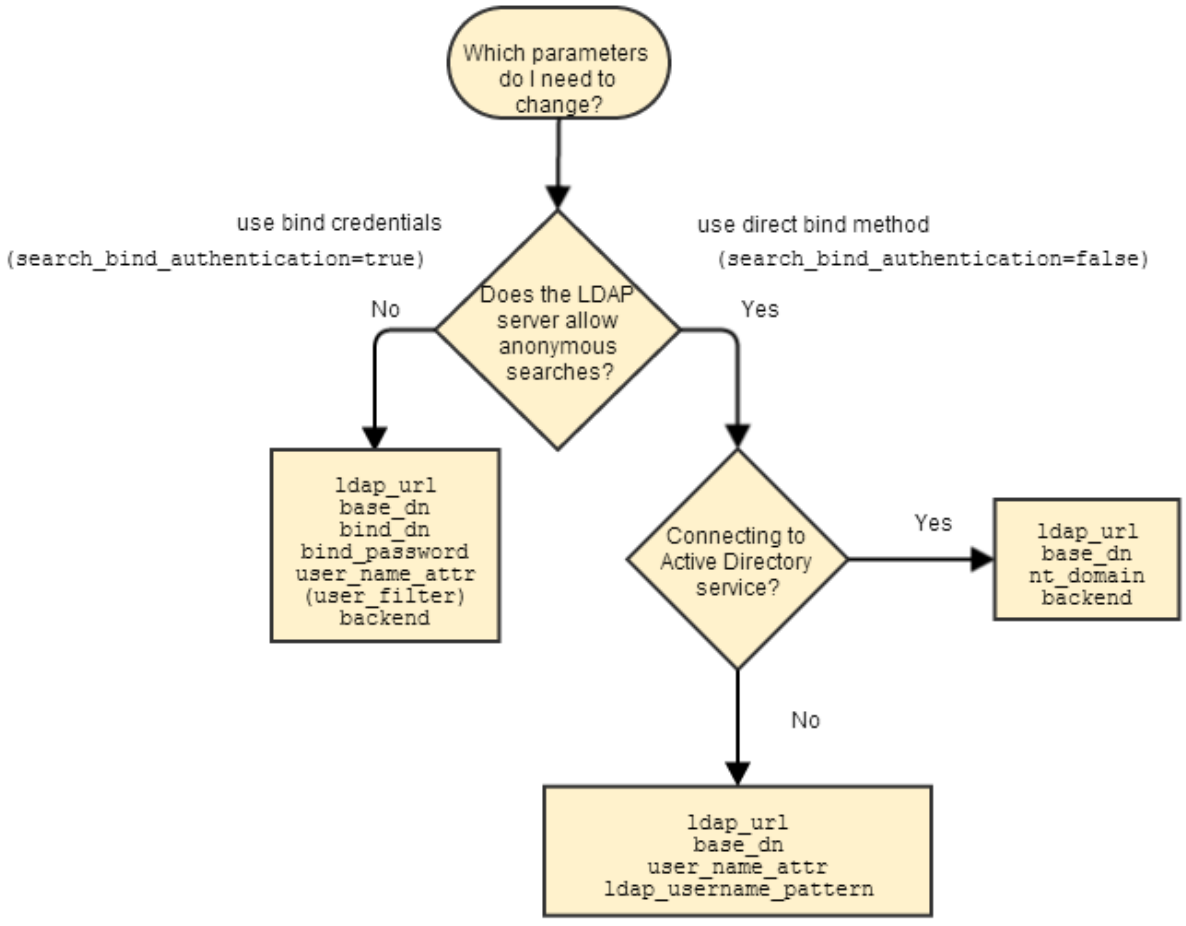
If you switch to authentication through LDAP credentials, the Hue User Admin users will lose superuser privileges unless you take one of the following actions:

- Import one or more superuser accounts from LDAP and assign them superuser permission.
- If you have already enabled the LDAP authentication back end, log into Hue using the LDAP back end, which will create an LDAP user. Next, disable the LDAP authentication back end and use User Admin to give the superuser permission to the new LDAP user.

Before you edit the parameters in the `hue.ini` file, determine whether your LDAP server allows anonymous searches.

- If anonymous searches *are* allowed, use the **direct bind** method.
- If anonymous searches *are not* allowed, use bind credentials (also known as **search and bind**).

The following flow chart shows which parameters you must specify for each of these authentication methods:



These are the parameters you need to set in the `ldap` section of the `hue.ini` file so you can authenticate Hue users with LDAP credentials:

last-updated: Apr 11, 2022

Parameter	Description	Comments
`search_bind_authentication`	Determines which authentication method to use: search and bind, or direct bind.	When set to *true*, Hue performs an LDAP search using `bind_dn` and `bind_password` as provided in `hue.ini`. The search can be further limited by the search filter `user_filter`. When set to *false*, Hue performs a direct bind to LDAP using the credentials provided from one of these sources: • the UPN, formed by concatenating `<shortname>` (the user name provided on the Hue login page) and `nt_domain` (if `nt_domain` is specified) • the `ldap_username_pattern` (if `nt_domain` is not specified)
`nt_domain`	The NT domain to connect to. This parameter is *only* used with Active Directory.	Used with the *direct bind* method of authentication. If `nt_domain` is specified, then `ldap_username_pattern` is ignored.
`ldap_username_pattern`	Used to connect to directory services other than Active Directory.	Used with the *direct bind* method of authentication. Usually takes the form `"cn=<username>,dc=example,dc=com"`
`backend`	The backend to use for authenticating users.	Needs to be set to `desktop.auth.backend.LdapBackend` for Hue authentication.

Using Bind Credentials (Search and Bind)

To use the search and bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

1. Set `search_bind_authentication=true`.
2. In the `Authentication backend` section, add the following line after the `##backend=` statement: Hue searches `base_dn` for an entry with `user_name_attr` that contains the user name provided on the Hue login page.

   ```
   backend=desktop.auth.backend.LdapBackend
   ```

3. Restart Hue once all configuration changes have been made so the changes will take effect.

Using Direct Bind

To use the direct bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

1. Set `search_bind_authentication=false`.

2. If you are using the Active Directory directory service, uncomment the line with the `nt_domain` parameter. Change the value from `nt_domain=mycompany.com` to the NT domain you want to connect to.
3. If you are using any other directory service, uncomment the line with `ldap_username_pattern` and specify the format, such as the one shown here: Note that `<username>` will be replaced by the information provided on the Hue login page.

   ```
   ldap_username_pattern="cn=<username>,dc=example,dc=com"
   ```

4. Restart Hue once all configuration changes have been made so the changes will take effect.

Configure Hue with DB Query

Hue's DB Query application provides a way to view data in these four database formats:

- SQLite
- MySQL
- PostgreSQL
- Oracle

To configure Hue to work with DB Query, edit the `[librdbms]` section of the `hue.ini` file and change the parameters related to the particular database you are using.

Warning: To disable the DB Query application, add `rdbms` to the blacklist as shown in Disabling an Application.

Default librdbms Settings in hue.ini

Database settings are contained in the `[librdbms]` section of the `hue.ini` file. Two databases (SQLite and MySQL) are already configured in their own sections under the `[[databases]]` heading. Note that PostgreSQL and Oracle work similarly to MySQL, so the `[[[mysql]]]` section can be treated as a template that can be edited for these two databases.

The DB Query application supports four types of databases, which are configured in the `[[databases]]` section.

The default version of the `librdbms` section of the `hue.ini` file looks like this:

```
###########################################################################
# Settings for the RDBMS application
###########################################################################
[librdbms]
 # The RDBMS app can have any number of databases configured in the
databases
 # section. A database is known by its section name
 # (i.e. sqlite, mysql, psql, and oracle in the list below).
 [[databases]]
   # sqlite configuration.
   ## [[[sqlite]]]
     # Name to show in the UI.
     ## nice_name=SQLite
     # For SQLite, name defines the path to the database.
     ## name=/opt/mapr/hue/hue-<version>/desktop/desktop.db
     # Database backend to use.
     ## engine=sqlite
   # mysql, oracle, or postgresql configuration.
```

last-updated: Apr 11, 2022

```
   ## [[[mysql]]]
     # Name to show in the UI.
     ## nice_name="My SQL DB"
     # For MySQL and PostgreSQL, name is the name of the database.
     # For Oracle, Name is instance of the Oracle server. For express
edition
     # this is 'xe' by default.
     ## name=mysqldb
     # Database backend to use. This can be:
     # 1. mysql
     # 2. postgresql
     # 3. oracle
     ## engine=mysql

     # IP or hostname of the database to connect to.
     ## host=localhost

     # Port the database server is listening to. Defaults are:
     # 1. MySQL: 3306
     # 2. PostgreSQL: 5432
     # 3. Oracle Express Edition: 1521
     ## port=3306

     # Username to authenticate with when connecting to the database.
     ## user=example

     # Password matching the username to authenticate with when
     # connecting to the database.
     ## password=example
```

Using DB Query with SQLite

To configure Hue to work with SQLite, edit the `sqlite` section of the `hue.ini` file and replace default values as necessary.

Default sqlite Section

The default version of the `sqlite` section is shown here.

```
# sqlite configuration
## [[[sqlite]]]
  # Name to show in the UI.
  ## nice_name=SQLite

  # For SQLite, name defines the path to the database.
  ## name=/tmp/sqlite.db

  # Database backend to use.
  ## engine=sqlite
```

Modifying the sqlite Section

To configure Hue's DB Query application to work with SQLite, edit the `sqlite` section of the `hue.ini` file as follows:

1. Remove the comment characters (##) in front of the [[[sqlite]]] statement.
2. Replace the default values for the following parameters as necessary.

last-updated: Apr 11, 2022

Parameter	Default Value	New Value
`nice_name`	`SQLite`	The name that you want to appear in the UI
`name`	`/tmp/sqlite.db`	The path to the SQLite database

3. Remove the comment characters (##) for the parameter values you changed. Otherwise, the default values are used.

Using DB Query with MySQL, PostgreSQL, or Oracle

Instructions for MySQL, PostgreSQL, and Oracle are similar. These instructions show how to configure Hue to work with MySQL. You can adapt the instructions to configure Hue to work with PostgreSQL or Oracle.

The next section shows the default `mysql` section of the `hue.ini` file for illustration. For instructions on configuring Hue so the DB Query application can display data from a MySQL database, see Modifying the mysql Section.

Default mysql Section

The default version of the `mysql` section is shown here.

```
# mysql, oracle, or postgresql configuration.
## [[[mysql]]]
  # Name to show in the UI.
  ## nice_name="My SQL DB"
  # For MySQL and PostgreSQL, name is the name of the database.
  # For Oracle, Name is the instance of the Oracle server. For    express
edition
  # this is 'xe' by default.
  ## name=mysqldb
  # Database backend to use. This can be:
  # 1. mysql
  # 2. postgresql
  # 3. oracle
  ## engine=mysql

  # IP or hostname of the database to connect to.
  ## host=localhost

  # Port the database server is listening to. Defaults are:
  # 1. MySQL: 3306
  # 2. PostgreSQL: 5432
  # 3. Oracle Express Edition: 1521
  ## port=3306

  # Username to authenticate with when connecting to the database.
  ## user=example

  # Password matching the username to authenticate with when
  # connecting to the database.
  ## password=example
```

Modifying the mysql Section

To configure Hue so the DB Query application can work with MySQL, edit the `mysql` section of the `hue.ini` file as follows:

1. Replace the default values for the following parameters.

last-updated: Apr 11, 2022

Parameter	Default Value	New Value
`nice_name`	`"My SQL DB"`	The name that you want to appear in the UI
`name`	`mysqldb`	The name of the database
`host`	`localhost`	IP address or hostname of the database to connect to
`user`	`example`	The username to use for authentication when connecting to the database
`password`	`example`	The password to use with the username (above) for authentication when connecting to the database

2. Remove the comment characters (##) for the parameter values you changed. Otherwise, the default values are used.

Activating DB Query with mySQL

To activate DBQuery with MySQL, follow these steps:

1. Move the mysql python library to a back-up location and regenerate it to match the version on the deployment machine. mv /opt/mapr/hue/hue-<VERSION>/python2.6/site-packages/MySQL_python-1.2.3c1-py2.6-linux-x86_64.egg MySQL_python-1.2.3c1-py2.6-linux-x86_64.egg.bk
2. Regenerate the mysql python library by running the following command: /opt/mapr/hue/hue-<VERSION>/build/env/bin/pip install mysql-python

Modifying the mysql Section for PostgreSQL

If you are working with a PostgreSQL database, edit the `mysql` section of the `hue.ini` file and rename it `postgresql`. Next, replace the MySQL default values as shown:

1. Replace the following MySQL default values with PostgreSQL values.

Parameter	Default Value	New Value
`nice_name`	`"My SQL DB"`	The name that you want to appear in the UI
`name`	`mysqldb`	The name of the database
`engine`	`mysql`	postgresql (the database backend)
`port`	`3306`	5432

2. Replace the following default values with your host machine, username, and password.

Parameter	Default Value	New Value
`host`	`localhost`	IP address or hostname of the database to connect to
`user`	`example`	The username to use for authentication when connecting to the database

last-updated: Apr 11, 2022

Parameter	Default Value	New Value
password	example	The password to use with the username (above) for authentication when connecting to the database

3. Remove the comment characters (##) at the beginning of each line where you changed parameter values. Otherwise, the MySQL default values are used.

Modifying the mysql Section for Oracle

If you are working with an Oracle database, edit the `mysql` section of the `hue.ini` file and rename it `oracle`. Next, replace the MySQL default values as shown:

1. Replace the following MySQL default values with Oracle values.

Parameter	Default Value	New Value
nice_name	"My SQL DB"	The name that you want to appear in the UI
name	mysqldb	The instance of the Oracle server (for express edition, this is xe by default)
engine	mysql	oracle (the database backend)
port	3306	1521 (for Oracle Express Edition)

2. Replace the following default values with your host machine, username, and password.

Parameter	Default Value	New Value
host	localhost	IP address or hostname of the database to connect to
user	example	The username to use for authentication when connecting to the database
password	example	The password to use with the username (above) for authentication when connecting to the database

3. Remove the comment characters (##) at the beginning of each line where you changed parameter values. Otherwise, the mysql default values are used.

Configure the Hue Database

The Hue server stores user-account information, the job submission history, and Hive queries in one of the following supported databases:

- SQLite, the embedded Hue database (the default database)
- MySQL
- PostgreSQL
- Oracle
- MariaDB

last-updated: Apr 11, 2022

Note: Using SQLite is not recommend.

Configure Hue to Store Data in MySQL or MariaDB

Hue supports MySQL 5.5.x - 5.7.x. Hue does not support MySQL 8 and later.

1. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties with your database connection parameters:

```
[desktop]
  ...
  [[database]]
    engine=mysql
    host=<host>
    port=3306
    user=<user>
    password='<password>'
    name=<database>
```

   Example of configuration:

```
[desktop]
  ...
  [[database]]
    engine=mysql
    host=node1
    port=3306
    user=hue
    password=hue_password
    name=hue
```

   If the connection is secured through SSL/TLS, specify the CA, Cert, and Key paths, as shown in the following example:

```
[desktop]
[[database]]
...
options='{"ssl": {"key": "/path/to/client-key.pem", "cert": "/path/to/
client-cert.pem", "ca": "/path/to/ca.pem"}}'
```

   You can find detailed documentation for other options in the Django Connecting to the Database documentation.

2. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

Related information

https://docs.djangoproject.com/en/1.11/ref/databases/#version-support

Configure Hue to Store Data in PostgreSQL

1. Install the following packages:

CentOS	`yum install gcc python-devel postgresql-devel`
SLES	`zypper install gcc python-devel postgresql-devel`
Ubuntu	`apt-get install gcc python-dev postgresql-server-dev-all`

2. Ensure that the `pg_config` command is in your `PATH`. For example, on CentOS with PostgreSQL 9.4 development package from the postgresql.org official repository, you need to add the directory with `pg_config` manually:

```
export PATH="/usr/pgsql-9.4/bin:$PATH"
```

3. Install the Python `psycopg2` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install psycopg2
deactivate
```

4. Configure database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties for your database connection parameters:

```
[desktop]
  ...
  [[database]]
    engine=postgresql_psycopg2
    host=<host>
    port=5432
    user=<user>
    password=<password>
    name=<database>
    schema=<schema>
```

Example of Configuration

```
[desktop]
  ...
  [[database]]
    engine=postgresql_psycopg2
    host=node1
    port=5432
    user=hue
    password=hue_password
    name=hue
    schema=public
```

5. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

last-updated: Apr 11, 2022

6. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

Configure Hue to Store Data in Oracle Database

Note: To configure Hue with Oracle 12, you need the Oracle 11 Instant Client Base and SDK.

1. Install the following packages:

CentOS	`yum install gcc python-devel`
SLES	`zypper install gcc python-devel`
Ubuntu	`apt-get install gcc python-dev`

2. Ensure that the library required to install the Oracle module in Hue is available through the `LD_LIBRARY_PATH` environment variable. The module that provides support for Oracle in Hue requires the `libclntsh.so` library to be available through the `LD_LIBRARY_PATH` environment variable. Typically, the library is located under the `$ORACLE_HOME` or `$ORACLE_HOME/lib` directories. Also, the library might include a version in the filename (for example, `libclntsh.so.11.1`), but the Oracle module for Hue requires it to be named `libclntsh.so`.
   a) Ensure that the `ORACLE_HOME` environment variable is set:

```
export ORACLE_HOME=<path_to_oracle_installation>
```

   b) Use the `find` command to locate the library:

```
find "$ORACLE_HOME" -name "libclntsh.so*"
```

   c) Go to the directory and ensure that the library is available and has the proper filename. If not, you can create a symbolic link:

```
ln -s libclntsh.so.11.* libclntsh.so
```

   d) Add the following variables to the Hue environment configuration by creating a file in `/opt/mapr/hue/hue-<version>/bin/env.d/`. For example, create `/opt/mapr/hue/hue-<version>/bin/env.d/99custom` with the following content:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME:$LD_LIBRARY_PATH"
```

   or the following, depending on your Oracle configuration:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME/lib:$LD_LIBRARY_PATH"
```

3. Depending on the Oracle instant client version installed:
   a) Run the shell script:

```
$ sudo sh -c "echo /usr/lib/oracle/<version-number>/client64/lib
> /etc/ld.so.conf.d/oracle-instantclient.conf"
```

last-updated: Apr 11, 2022

b) Use the `ldconfig` command to create the linking:

```
$ sudo ldconfig
```

c) Verify the dynamic linking:

```
 $ sudo ldconfig -p | grep -i oracle
```

For example:

```
ldconfig -p | grep -i oracle
libocijdbc11.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libocijdbc11.so
libociei.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libociei.so
libocci.so.11.1 (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libocci.so.11.1
libnnz11.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libnnz11.so
libclntsh.so.11.1 (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libclntsh.so.11.1
```

4. Install the Python `cx_Oracle` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install cx_Oracle==5.3
deactivate
```

Note: Python cx_Oracle version 5.3 is supported.

5. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Note these considerations:

   - Make sure that you have the appropriate permissions to use LOBs; for example, `SQL GRANT on SYS.DBMS_LOB`.
   - SID refers to the Oracle system ID, which is used to uniquely identify the database.

```
[desktop]
  ...
  [[database]]
    engine=oracle
    host=<host>
    port=1521
    user=<user>
    password=<password>
    name=<SID of the database>
```

- To achieve a multithreading environment, you can specify the `options={'threaded':true}` parameter in this section. For example:

```
[desktop]
  ...
  [[database]]
    engine=oracle
    host=node1
    port=1521
    user=hue
    password=hue_password
    name=XE
    options={'threaded':true}
```

By setting the `port=0` parameter, you can use the Oracle Service Name instead of specifying the SSID. For example:

```
[desktop]
  ...
  [[database]]
    engine=oracle
    port=0
    user=hue
    password=hue_password
    name=node1:1521/hue
```

6. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

7. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

Edit the `hue.ini` file to use an Oracle database:

For detailed steps, see `inspectdb` and `dumpdb` Hue commands, http://gethue.com/hue-api-execute-some-builtin-commands/.

Configure Hue with Security

Based on the Hue version and the version of the other components that Hue communicates with, you can configure the following security features:

Note: You cannot enable both Kerberos and MapR-SASL on the same cluster.

Configure Hue to use Kerberos

After you set up a Kerberos principal and keytab file, you can configure Hue to use the Kerberos authentication protocol.

After you set up a Kerberos principal and keytab file, enable the Kerberos Ticket Renewal service, update `hue.ini` and `core-site.xml` with the required parameters, and restart the Warden and Hue services.

last-updated: Apr 11, 2022

Enabling the Kerberos Ticket Renewer Service

Important: This functionality requires a patch. The patch works with EEP-6.3.0 (Core-6.1.0 and Hue 4.3.0). To install patches, see Applying a Patch.

The Kerberos Ticket Renewer service (kt_renewer) renews tickets for the Hue service. Hue automatically starts the kt_renewer process on clusters that use Kerberos for authentication. Kerberos tickets have a default expiration time of 7 days. The kt_renewer service extracts the Kerberos ticket from the keytab file and renews the ticket before it expires.

You can access the kt_renewer process log files in the following locations:

- `${HUE_HOME}/logs/kt_renewer.out`
- `${HUE_HOME}/logs/kt_renewer.log`

To use the Kerberos Ticket Renewer service:

1. Enable the Kerberos Ticket Renewer Service:
   - In the `kdc.conf` file, add the `max_renewable_life` parameter.
   - In the `krb5.conf` file, add the `renew_lifetime` parameter.
2. Update the `hue.ini` file to include the Kerberos credentials cache path (`ccache_path`) and ticket renewal frequency (`keytab_reinit_frequency`), as shown in the following example:

```
[desktop]
               [[kerberos]]
                 …
                 # Path to keep Kerberos credentials cached
                 # ccache_path=/tmp/custom_hue_krb5_ccache
                 # Frequency in seconds with which Hue will renew its
keytab
                 # keytab_reinit_frequency=86400
                 …
```

Modifying the hue.ini File

In the `kerberos` section of the `hue.ini` file, make the following changes:

1. Supply the path to Hue's Kerberos keytab file.
2. Supply the Kerberos principal name for Hue.
3. Supply the path to kinit.
4. In the `[[yarn_clusters]] [[[default]]]` section:
   - If you are using a certificate signed by the CA (Certificate Authority), set the `ssl_cert_ca_verify` value to `True`.
   - If you are using a self-signed certificate or no certificate, leave the value set to `False`.
5. **For Hue with secure Hive**: In the `beeswax` section, make sure that the `hive_conf_dir` property points to a directory containing a valid `hive-site.xml` file (either the original or a synced copy).
6. **Optional**: To enable SSL encryption, see Enable SSL Encryption Between Hue and Hive.

last-updated: Apr 11, 2022

7. Make sure that you specified a fully-qualified domain name (FQDN) for all services integrated with Hue that uses Kerberos:

   HttpFS: Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[[default]]]` section.

   HiveServer2: Set the `hive_server_host` property in the `[beeswax]` section.

   Impala: Set the `server_host` property in the `[impala]` section.

   Spark: Set the `livy_server_url` property in the `[impala]` section.

   Note: Support for Kerberos integration with Livy was introduced in Hue 4.X.

   Sqoop2: Set the `server_url` property in the `[sqoop]` section.

   Oozie: Set the `oozie_url` property in the `[liboozie]` section.

   HBase: Set the `hbase_clusters` property in the `[hbase]` section.

   Drill: Refer to section.

The changes are summarized in the following `hue.ini` files, which you can use as a template:

```
[desktop]
   [[kerberos]]
     # Path to Hue's Kerberos keytab file
     hue_keytab=/opt/mapr/conf/mapr.keytab

     # Kerberos principal name for Hue
     # hue_principal=mapr/<hostname>@<realm>
     # Substitute your hostname and realm in the example below
     hue_principal=mapr/perfnode181.perf.lab@dev-maprtech

     # Path to keep Kerberos credentials cached
     # ccache_path=/tmp/custom_hue_krb5_ccache
     # Frequency in seconds with which Hue will renew its keytab
     # keytab_reinit_frequency=86400

     # Path to kinit
     # Note that the actual path depends on which Linux OS you are using
     kinit_path=/usr/bin/kinit

[beeswax]
  # If Kerberos security is enabled, use fully-qualified domain name
  # (FQDN)
  hive_server_host=<FQDN of Hive Server>
  # Hive configuration directory, where hive-site.xml is located.
  hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
  # Change this if your Hive is secured
  security_enabled=true
  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=GSSAPI

[impala]
  # Host of the Impala Server (one of the Impalad)
  server_host=<FQDN of Impalad>
  # Kerberos principal
  impala_principal=mapr/perfnode181.perf.lab@dev-maprtech

[hadoop]
  ...
  [[hdfs_clusters]]
     [[[default]]]
```

```
  # Enter the filesystem uri
  fs_defaultfs=maprfs:///

  # Use WebHdfs/HttpFs as the communication mechanism.
  # Domain should be the NameNode or HttpFs host.
  # Default port is 14000 for HttpFs.
  webhdfs_url=https://<FQDN of HttpFS>:14000/webhdfs/v1

  # Change this if your HDFS cluster is secured
  security_enabled=True

  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=GSSAPI
  ...
[[yarn_clusters]]
  [[[default]]]
  # Enter the host on which you are running the ResourceManager
  ## resourcemanager_host=localhost

  # The port where the ResourceManager IPC listens on
  ## resourcemanager_port=8032

  # Whether to submit jobs to this cluster
  submit_to=true

  # Change this if your YARN cluster is secured
  security_enabled=true

  # URL of the ResourceManager API
  ## resourcemanager_api_url=https://localhost:8090

  # URL of the ProxyServer API
  ## proxy_api_url=https://localhost:8090

  # URL of the HistoryServer API
  history_server_api_url=https://localhost:19890

  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=GSSAPI

  # In secure mode (HTTPS), if SSL certificates from Resource Manager's
  # Rest Server have to be verified against certificate authority
  ssl_cert_ca_verify=False

[spark]
  # The Livy Server URL.
  livy_server_url=https://<FQDN of Livy Server>:8998

  # Whether Livy requires client to perform Kerberos authentication.
  security_enabled=True

  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
  mechanism=GSSAPI

[liboozie]
  # The URL where the Oozie service runs on. This is required in order for
  # users to submit jobs.
  oozie_url=https://<FQDN of Oozie>:<oozie_port_number>/oozie

  # Requires FQDN in oozie_url if enabled
  security_enabled=true
  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
 mechanism=GSSAPI
```

last-updated: Apr 11, 2022

```
[hbase]
  # Comma-separated list of HBase Thrift servers for clusters in the format
of '(name|host:port)'.
  # Use full hostname with security.
  # If using Kerberos we assume GSSAPI SASL, not PLAIN.
  hbase_clusters=(Cluster|<FQDN of Hbase Thrift Server>:9090)
  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=GSSAPI
```

Note: You need to manually set `security_enabled` property to `true` and `mechanism` property to `GSSAPI` for a Kerberised environment. These options are automatically configured only on a MapR-SASL cluster.

Modifying the core-site.xml File

In the `core-site.xml` file, provide the shortname for the Kerberos principal as shown. In addition, verify that you configured the proxyuser during configuration. See Configure Hue for details.

```
<!-- Hue security configuration -->
<property>
  <name>hue.kerberos.principal.shortname</name>
  <value>mapr</value>
</property>
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value> <!-- A group that all users of Hue belong to, or the
wildcard value "*" -->
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value><hue_server_FQDN></value>
</property>
```

Restarting Warden and Hue

After you make all the changes to the files listed above, restart Warden and Hue so the changes will take effect.

Configure Hue to use MapR-SASL

You can configure Hue to use MapR-SASL for its communications with various components on a secure MapR cluster. Hue automatically detects and sets the security configuration of the cluster and its components. Therefore, in some cases, minimal configuration is required.

The following components are supported by Hue with MapR-SASL:

- HttpFS
- YARN and Spark History Server
- Hive
- Livy
- Sqoop2
- HBase Thrift
- Oozie
- Drill

last-updated: Apr 11, 2022

Note: For secure by default clusters or for clusters where the `customSecurity` flag is not added, Hue automatically sets `security_enabled` to `true` and `mechanism` to `MAPR-SECURITY` for these components. In all other cases, `${security_enabled}` and `${mechanisms}` variables are set to `false` and `none` respectively, but these options can be configured manually for custom setups.

An example of a default configuration with automatically defined `security_enabled` and `mechanism` properties for HttpFS is as follows:

```
[hadoop]
 [[hdfs_clusters]]
   # HA support by using HttpFs
   [[[default]]]
        ...
   # Change this if your HDFS cluster is secured
   security_enabled=${security_enabled}

   # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
   mechanism=${mechanism}
        ...
```

An example of a manual configuration of `security_enabled` and `mechanism` properties for HttpFS is as follows:

```
[hadoop]
 [[hdfs_clusters]]
   # HA support by using HttpFs
   [[[default]]]
        ...
   # Change this if your HDFS cluster is secured
   security_enabled=true

   # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
   mechanism=MAPR-SECURITY
        ...
```

Note: After you configure the `hue.ini`, you must restart Hue. However, if you configure multiple sections of the same file, you can restart Hue one time after your updates are complete.

Configure LDAP Authentication Between Hue and Hive

You can configure Hue to use LDAP Authentication when it communicates with HiveServer2. Before you configure Hue to use LDAP authentication with HiveServer2, verify that HiveServer2 is configured to use LDAP authentication. For more information, see Configure HiveServer2 to use LDAP Authentication on page 3440.

Complete the following steps to configure LDAP authentication between Hue and Hive:

1. Configure Hue to connect to Hive with LDAP authentication:
   a) Configure the `[beeswax]` section of the `hue.ini:` set `mechanism` option.

```
[beeswax]
  ...
  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=LDAP
```

b) Configure the `[beeswax]` section of the `hue.ini` (for Hive integration only):

```
[beeswax]
  ...
 # Override the default desktop username and password of the hue user
used for authentications with other services.
  # e.g. Used for LDAP/PAM pass-through authentication.
  auth_username=sampleuser
  auth_password=123456
  ...
```

Or configure the `[desktop]` section of the `hue.ini` to set the username and password for all services that require username/password authentication:

```
[desktop]
  ...
  # Default LDAP/PAM/.. username and password of the hue user used
for authentications with other services.
  # Inactive if password is empty.
  # e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
  auth_username=sampleuser
  auth_password=123456
  ...
```

2. **Optional:** Configure Hue to authenticate users through LDAP. See Configure Hue with LDAP.

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <space delimited
list of nodes>
```

Configure PAM Authentication Between Hue and Hive

In Hue 3.10, you can configure Hue to use PAM authentication when it communicates with HiveServer2. Before you configure Hue to use PAM authentication with HiveServer2, verify that HiveServer2 is configured to use PAM authentication. See Configure HiveServer2 to Use PAM Authentication for more information.

Complete the following steps to configure PAM authentication between Hue and Hive:

1. Configure the `[beeswax]` section of the `hue.ini` file. Set the `mechanism` option to `none`. Set the `auth_username` and `auth_password` options in the `[desktop]` or `[beeswax]` sections of `hue.ini` (where `auth_username` and `auth_password` are the user credentials for the user who authenticates the Hue service with HiveServer2).
   The following example summarizes these changes:

```
[desktop]
     ...
     # Default LDAP/PAM/.. username and password of the Hue user used
for authentication with other services.
     # Inactive if password is empty.
     # e.g. LDAP pass-through authentication for HiveServer2 or Impala.
 Apps can override them individually.
       auth_username=mapr
       auth_password=<user_password>
     ...
 [beeswax]
     ...
     # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
       mechanism=none
```

2. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <Hue node>
```

Configure Kerberos Between Hue and Sqoop2

You can configure Kerberos authentication between Hue and Sqoop2.

- The MapR cluster must be configured to use Kerberos. For more information, see Configuring Kerberos User Authentication.
- Sqoop2 must be configured to use Kerberos. For more information, see Configure Kerberos Authentication for Sqoop2.

To configure Kerberos authentication between Sqoop2 and Hue, complete the following steps:

1. Configure Hue to use Kerberos for YARN. For more information, see Configure Hue to use Kerberos.
2. In the `[sqoop]` section of the `hue ini`, set `mechanism` to `GSSAPI`. For example:

```
[sqoop]
  # For autocompletion, fill out the librdbms section.
  # Sqoop server URL
  server_url=http://localhost:12000/sqoop
  # Change this if your cluster is secured
  security_enabled=${security_enabled}
  # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
  mechanism=GSSAPI
```

3. Restart Hue.

```
maprcli node services -name hue -action start -nodes <space delimited
list of nodes>
```

Enable SSL Encryption Between Hue and Hive

Hue automatically determines when SSL encryption is enabled in Hive by reading the `hive-site.xml` file.

Note: Starting from EEP 6.0.0, SSL encryption is enabled by default for Hive in a secured cluster. To configure SSL for Hive on a non-secure cluster, refer to Hive Encryption on page 3447.

1. The following example shows how to correctly configure the directory path where the `hive-site.xml` file is located in the `hive_conf_dir` property in `[beeswax]` section of the `hue.ini` file:

```
[beeswax]
   ...
   # Hive configuration directory, where hive-site.xml is located
   hive_conf_dir=/opt/mapr/hive/hive-2.3/conf
```

2. The following examples show how to enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in `[desktop]` section of the `hue.ini` file:

   Example for enabling certificate verification:

```
[desktop]
   ...

  # Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
  ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

  # Choose whether Hue should validate certificates received from the
server.
  ssl_validate=true
```

   Example for disabling certificate verification:

```
[desktop]
   ...

   # Path to default Certificate Authority certificates. As an example: /
path/to/cacert.pem
   # ssl_cacerts=

   # Choose whether Hue should validate certificates received from the
server.
   ssl_validate=false
```

3. After you change these properties, restart Hue to apply your changes:

```
maprcli node services -name hue -action start -nodes <hostname>
```

Enable SSL Encryption Between Hue and HttpFS

As of HttpFS 1.0-1504 and Hue 3.7-1505, you can enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure MapR cluster that is version 4.0.2 or greater.

Complete the following steps to enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster:

1. Configure HttpFS to use SSL or verify that HttpFS is configured to use SSL. For details, see SSL Security for HttpFS.

2. Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[[default]]]` section of the `hue.ini` file to contain the correct URL for HttpFS with the HTTPS schema and domain of the HttpFS server:

```
[hadoop]
  [[hdfs_clusters]]
    [[[default]]]
      # Use WebHdfs/HttpFs as the communication mechanism.
      # Domain should be the NameNode or HttpFs host.
      # Default port is 14000 for HttpFs.
      webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
```

3. You can enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in the `[desktop]` section of the `hue.ini` file.

   Example for enabling certificate verification:

```
[desktop]
   ...

  # Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
  ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

  # Choose whether Hue should validate certificates received from the
server.
  ssl_validate=true
```

   Example for disabling certificate verification:

```
[desktop]
   ...

  # Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
  # ssl_cacerts=

  # Choose whether Hue should validate certificates received from the
server.
  ssl_validate=false
```

4. [OPTIONAL] Configure mutual authentication between Hue and HttpFS. Add the following configuration in the `hue.ini` file under the `[hadoop] [[hdfs_clusters]] [[[default]]]` section.

   - `mutual_ssl_auth=True`
   - `ssl_cert=/path/to/certificate.pem`
   - `ssl_key=/path/to/private_key.pem`

   Use absolute paths for `ssl_cert` and `ssl_key`. Hue does not support private keys with a passphrase in this step.

last-updated: Apr 11, 2022

The changes are summarized in the following example in the `hue.ini` file, which you can use as a template:

```
[hadoop]
 [[hdfs_clusters]]
  # HA support by using HttpFs
 [[[default]]]
  # Use WebHdfs/HttpFs as the communication mechanism.
  # Domain should be the NameNode or HttpFs host.
  # Default port is 14000 for HttpFs.
  webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
      ....
  # SSL certificate based authentication
  ssl_cert=/path/to/certificate.pem
  ssl_key=/path/to/private_key.pem
```

5. Restart Hue.

```
maprcli node services -name hue -action start -nodes <ip_address>
```

6. To test that SSL encryption is enabled for HttpFS, run the following command:

```
curl -k --cert /path/to/certificate.pem --key /path/to/private_key.pem
"https://node1.cluster.com:14000/webhdfs/v1?
op=GETFILESTATUS&user.name=mapr"
```

Enable SSL Encryption Between Hue and Sqoop2

The following procedure explains how to enable SSL encryption between Hue and Sqoop2.

1. Configure Sqoop2 to use SSL, or verify that Sqoop2 is configured to use SSL. For details, see "Enabling SSL Encryption in Sqoop2."
2. In the `hue.ini` file:
   a) Add the following entry under the [desktop] section:

   ```
   ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem
   ```

   b) Add the following entry under the [sqoop] section:

   ```
   server_url=https://<host>:12000/sqoop
   ```

   The following example `hue.ini` file summarizes the changes. You can use this example as a template:

   ```
   ….
   [desktop]
   ….
   # Path to default Certificate Authority certificates.
   ssl_cacerts=/opt/mapr/hue/hue-4.2.0/cert.pem
   ….
   [sqoop]
   # For autocompletion, fill out the librdbms section.

   # Sqoop server URL
   server_url=https://ubuntu500:12000/sqoop
   ```

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

Troubleshoot Hue Security Issues

To troubleshoot Kerberos security issues, enable the debugger by changing the following setting in the `/opt/mapr/conf/env.sh` file:

```
# uncomment the following line to debug client kerberos issues
#MAPR_KERBEROS_DEBUG="-Dsun.security.krb5.debug=true -Dsun.security.spnego.d
ebug=true -Djavax.net.debug=all"
```

Under the Hue installation directory, check `logs/runcpserver.log` for errors. Some sample error messages are shown below.

Could not start SASL
If you see this message, try using renewable tickets:

```
TypeError: TTransportException('Could not start SASL: Error in
sasl_client_start (-1) SASL(-1): generic failure: GSSAPI Error: Unspecified
GSS failure.  Minor code may provide more information (Ticket expired)',)
is not JSON serializable
```

Run the `kinit` command to generate a new ticket with a long running lifetime, then restart the Hue webserver.

Configuration Error

If you see this message, it means that the ticket generated by the `kinit` command from `maprlogin kerberos` was not copied to `/tmp/hue_krb5_ccache`:

```
Caused by: javax.security.auth.login.LoginException: Configuration Error -
useTicketCache should be set to true to use the ticket cache /tmp/
hue_krb5_ccache
```

This can happen when you generate a new ticket after the original ticket expires and forget to copy it into the ticket cache. Run the following command to copy the ticket into the ticket cache:

```
kinit -k -t /opt/mapr/conf/mapr.keytab -c /tmp/hue_krb5_ccache mapr/
perfnode181.perf.lab@dev-maprtech
```

Password incorrect while getting initial credentials

This message (`Password incorrect while getting initial credentials`) appears when you create a keytab file, but try to authenticate with a password. The act of creating a keytab causes a new random key to be placed in the Kerberos database and into the keytab file (`/opt/mapr/conf/mapr.keytab`). That key does not have a password associated with it, so you can only authenticate using the keytab.

If you want to authenticate with a password, run the `cpw` command in `kadmin` instead of the `ktadd` command.

Integrate Hue

This section contains the following topics with information for integrating Hue with other ecosystem components:

last-updated: Apr 11, 2022

Integrate Hue with MapR Database Binary Tables

You can use the Hue HBase application to access MapR Database binary tables.

Note: In order to use the Hue HBase application, you need to install the HBase Client and the HBase Thrift Gateway. For more information, see the Installing MapR and MapR Ecosystem Components on page 128.

Step 1: Setting up MapR Database Binary Table Mapping

To use the Hue HBase application to access MapR Database binary tables, you need to set the `hbase.table.namespace.mappings` property.

Table Mapping Naming Conventions

A table mapping takes the form *`name`*`:`*`map`*, where *`name`* is the table name to redirect and *`map`* is the modification made to the name. The value in *`name`* can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Example: Map Table Names to MapR Database

In the following example, the `hbase.table.namespace.mappings` property is set so that any flat table name, such as `mytable`, is treated as a MapR Database table in the directory `/tables_dir/mytable`.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*:/tables_dir</value>
</property>
```

Once you finish enabling table mapping in the `core-site.xml` file, start (or restart) the HBase thrift server so the changes will take effect.

```
maprcli node services -name hbasethrift -action start -nodes node001
```

Step 2: Configure Hue for MapR Database

To configure Hue for MapR Database, edit the `hbase` section of the `hue.ini` file, which looks like this:

```
[hbase]
  # Comma-separated list of HBase Thrift servers for
  # clusters in the format of '(name|host:port)'.
  ## hbase_clusters=(Cluster|localhost:9090)

  # Hard limit of rows or columns per row fetched before truncating.
  ## truncate_limit = 500
```

last-updated: Apr 11, 2022

In this file, make the following changes:

1. Uncomment the `## hbase_clusters=(Cluster|localhost:9090)` statement and provide the list of HBase Thrift servers.

```
hbase_clusters=(<clustername1>|<hostname1>:9090),(<clustername2>|
<hostname2>:9090)[,...]
```

2. Uncomment the `truncate_limit` statement and change the value if necessary.

Integrate Hue with Hive
Describes how to integrate Hue with Hive through settings in the `hue.ini` file.

By default, Hue connects to a single instance of HiveServer2 through the `hive_server_host` parameter in `hue.ini`; however, if high availability (HA) is enabled for HiveServer2, Hue can leverage that. If one instance of HiveServer2 goes down, the client automatically connects to another instance of HiveServer2.

Verify the Hive Version

Before you integrate Hue with HiveServer2 (HA or single instance), verify that the path specified in the `hive_conf_dir` property applies to the Hive version that you have installed. If needed, update the path to reflect the Hive version that you have installed.

```
# Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
```

If Hue and Hive are installed on separate nodes, you must also copy the Hive `conf` directory to the Hue node.

Integrating Hue with HiveServer2 High Availability

If you want Hue to leverage HiveServer2 HA, enable high availability for HiveServer2, and update the `hue.ini` file to include the following properties and settings:

```
[beeswax]
  #Whether to use service discovery for llap.
  hive_discovery_llap = true
  #Is llap (hive server interactive) running in HA.
  hive_discovery_llap_ha = true
  #Whether to use service discovery for HiveServer2.
  hive_discovery_hs2 = true
[libzookeeper]
  #ZooKeeper ensemble; comma-separated list of host/port.
  ensemble=<host:port>:5181
```

Note that the `hive_server_host` and `hive_server_port` properties in `hue.ini` are not required if using HiveServer2 HA. Service discovery overrides the server and thrift port.

Perform any additional Hue configurations and then restart Hue for changes to take effect. See Starting the Hue Webserver.

Integrating Hue with a Single Instance of HiveServer2

Update the beeswax section of the `hue.ini` file to include the following properties and settings:

Note: This is not required on a single node cluster.

```
[beeswax]

# Host where HiveServer2 is running.
```

```
# If Kerberos security is enabled, use fully-qualified domain name (FQDN).
  hive_server_host=<FQDN of Hive Server>

# Port that HiveServer2 Thrift server runs on.
  hive_server_port=10000
```

Perform any additional Hue configurations and then restart Hue for changes to take effect. See Starting the Hue Webserver.

Configuring Data and Metadata Directories

When Hue and Hive are used together, they are usually configured to share metadata and data directories. However, you can create separate directories for Hue and Hive.

The locations of the shared directories are specified by the following properties in the `hive-site.xml` file:

- `hive.metastore.uris` (the hostname and port of the Hive Metastore node)
- `hive.metastore.warehouse.dir` (the directory where the default database for the warehouse is located)

See Configure Shared Hive Data and Metadata Directories for Hue and Configure Separate Hive Data and Metadata Directories for Hue for more information.

Configure Shared Hive Data and Metadata Directories for Hue

To configure shared Hive data and metadata directories for Hue:

1. Change the `hive.metastore.uris` property as shown:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://localhost:9083</value>
  <description> URI where clients contact Hive metastore server </
description>
</property>
```

   Note: The `hive.metastore.warehouse.dir` property can keep its default value and does not need to be changed.

2. Enable Hue impersonation by setting the following property to `true`.

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description> Set this property to enable Hive Metastore service
impersonation in unsecure mode.
   In unsecure mode, setting this property to true causes the metastore
to execute DFS operations
   using the client's reported user and group permissions. Note that
this property must be set on
   BOTH the client and server sides. </description>
</property>
```

3. Set the location of the `sharelib`.

```
<property>
  <name>oozie.service.WorkflowAppService.system.libpath</name>
  <value>/oozie/share/lib</value>
</property>
```

4. To enable the Hive Metastore service to share the embedded Derby database, add the following property blocks to the `hive-site.xml` file on the node running hiveserver2 to point to the location of the Derby metastore:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:derby:;databaseName=/<local dir>/metastore_db;create=true</
value>
  <description>JDBC connect string for a JDBC metastore</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.apache.derby.jdbc.EmbeddedDriver</value>
  <description>Driver class name for a JDBC metastore</description>
</property>
```

5. To enable the Hive Metastore service to share a MySQL database, add the following property blocks to the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://<ip_address>:3306/hive_11?
createDatabaseIfNotExist=true</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value><UserName></value>
  <description>Substitute the actual username</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value><Password></value>
  <description>Substitute the actual password</description>
</property>
```

Configure Separate Hive Data and Metadata Directories for Hue

If you want to store Hue data and metadata in separate directories from Hive data and metadata, follow these steps:

1. Copy `hive-site.xml` to a new location. (The original `hive-site.xml` file remains in the previous location for use by Hive.)

last-updated: Apr 11, 2022

2. Edit `hue.ini` and change the `hive_conf_dir` property so it points to the new location for `hive-site.xml`.
3. Change the `hive.metastore.warehouse.dir` property in the new `hive-site.xml` file so it points to the directory where Hue data will be located.
4. Change the `hive.metastore.uris` property so it points to the directory for Hue's `metastore_db`.
5. Set the `hive.metastore.execute.setugi` property to `true`.

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description> Set this property to enable Hive Metastore service
impersonation in non-secure mode.
   In non-secure mode, setting this property to true causes the
metastore to execute DFS operations
   using the client's reported user and group permissions. Note that
this property must be set on
   BOTH the client and server sides. </description>
</property>
```

Integrate Hue with Impala

Hue's Impala application supports interactive SQL and HiveQL queries from within your browser. Hue provides additional functionality with Impala that is not available from the command line such as parameterized queries, syntax highlighting, and saving queries.

For information about installing Impala, see Installing Impala.

Warning: To disable the Impala application, see Disabling an Application.

To configure Hue to work with Impala, edit the `impala` section of the `hue.ini` file and change parameter values as necessary. The next section shows the default version of the Impala settings in `hue.ini`. For instructions on how to change Impala settings, see Modifying the hue.ini File.

Default Impala Settings in hue.ini

The default version of the `impala` section of the `hue.ini` file is shown below.

```
###########################################################################
# Settings to configure Impala
###########################################################################

[impala]
 # Host of the Impala Server (one of the Impalad)
 ## server_host=localhost

 # Port of the Impala Server
 ## server_port=21050

 # Turn on/off impersonation mechanism when talking to Impala
 ## impersonation_enabled=False
```

Modifying the hue.ini File

To configure Hue to work with Impala, change the values of the following parameters in the `impala` section of the `hue.ini` file:

Parameter	Default Value	Description
`server_host`	localhost	The hostname or IP address of the Impala server
`server_port`	21050	The port of the Impala server
`impersonation_enabled`	False	Turns the impersonation mechanism on or off when talking to Impala

1. If `server_host` is not localhost, change the hostname (and remove the ## characters to uncomment the line).

   ```
   ## server_host=<hostname>
   ```

2. If you are *not* using the default server port (21050), change the `server_port` setting to the port you are using (and remove the ## characters to uncomment the line).

   ```
   ## server_port=<port_number>
   ```

3. Enable impersonation in Impala so the user `mapr` can impersonate any Linux PAM user on the cluster:
   a) Edit the `/opt/mapr/impala/impala-<version>/conf/env.sh` file, and add the following property to the section `IMPALA_SERVER_ARGS=*/`:

      ```
      authorized_proxy_user_config=mapr=*"
      ```

   b) Restart Impala.

      ```
      sudo maprcli node services -name impalaserver -action restart -nodes
      <ip_address>
      ```

4. Enable impersonation for Impala in the `hue.ini` file by setting `impersonation_enabled` to `true` (and remove the ## characters to uncomment the line).

   ```
   ## impersonation_enabled=true
   ```

5. Restart Hue so the changes will take effect.

Integrate Hue with Oozie

Complete the following steps to integrate Hue with Oozie:

1. Edit the `hue.ini` file to configure the location where the Oozie service is running. The path to the `hue.ini` file is: `/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`.

   ```
   [liboozie]
   # The URL (host IP address) where the Oozie service is running. This is
   required in order for # users to submit jobs.
   oozie_url=http://<ip_address>:<oozie_port_number>/oozie
   ```

   The `<oozie_port_number>` depends on whether your cluster is secure.

2. Enable user impersonation for Oozie through Hue:

last-updated: Apr 11, 2022

a) Add the following lines to the `oozie-site.xml` file (the path to the file is: `/opt/mapr/oozie/oozie-4.2.0/conf/oozie-site.xml`):

```
<property>

<name>oozie.service.ProxyUserService.proxyuser.<default_user>.hosts</
name>
  <value>*</value>
</property>
<property>

<name>oozie.service.ProxyUserService.proxyuser.<default_user>.groups</
name>
  <value>*</value>
</property>
```

In most cases, mapr is the <default_user>. This should be the same default user that is specified in the `hue.ini` and the `core-site.xml`.

b) Restart Oozie. To restart Oozie, first stop Oozie then start it:

```
maprcli node services -name oozie -action restart -nodes <ip_address>
```

To verify that the Oozie server started, enter:

```
lsof -i:<oozie_port_number>
```

The output from this command should look similar to this:

```
COMMAND PID USER FD TYPE DEVICE SIZE/OFF NODE NAME java 16644 mapr
35u IPv6 69926776 0t0 TCP *:irisa (LISTEN)
```

You can also check Oozie logs to verify that Oozie started. The log is found here: `/opt/mapr/oozie/oozie-<version>/logs/oozie.log`

3. Perform any additional Hue configurations and then restart Hue so that the changes will take effect. See Starting the Hue Webserver.

Integrate Hue with Spark (Experimental Only)

You can configure Hue to use the Spark Notebook UI. This allows users to submit Spark jobs from Hue.

Note: Spark Notebook is a feature that utilizes the Spark REST Job Server (Livy). The `mapr-livy` package must be installed on a node were the mapr-spark package is installed or the Livy service will not start.

1. In the `[spark]` section of the `hue.ini`, set the `livy_server_host` parameter to the host where the Livy server is running.

```
[spark]
# IP or hostname of livy server.
livy_server_url=https://<host>:8998
```

Note: If the Livy server runs on the same node as the Hue UI, you are not required to set this property as the value defaults to the local host.

2. Restart Hue.

```
maprcli node services -name hue -action restart -nodes <hue node>
```

Additional Information

- If needed, you can use the Control System or `maprcli` to start, stop, or restart the Livy Server. For more information, see Managing Services on page 827.

Note: Troubleshooting Tip

If you have more that one version of Python installed, you may see the following error when executing Python samples:

```
Py4JJavaError: An error occurred while calling
z:org.apache.spark.api.python.PythonRDD.collectAndServe...
```

Workaround:

Set the following environment variables in /opt/mapr/spark/spark-<version>/conf/spark-env.sh:

```
export PYSPARK_PYTHON=/usr/bin/python2.7
export PYSPARK_DRIVER_PYTHON=/usr/bin/python2.7
```

Integrate Hue with Drill

Starting in EEP 6.0, Drill is officially supported with Hue. When you integrate Drill with Hue, users can run Drill queries from the Hue interface and visualize data.

Drill integrates with Hue through configuration options in the `/opt/mapr/hue/hue-<version>/conf/hue.ini` file. A user can authenticate to Hue through Plain, Kerberos, or MapR-SASL authentication. The user that authenticates to Hue is the user that runs the Drill queries from Hue.

When connecting to Drill, Hue performs outbound impersonation to Drill as the user that authenticated to Hue. Drill accepts the outbound impersonation from Hue as an inbound impersonation. Drill then performs outbound impersonation to the MapR filesystem or MapR Database.

Note: In a secure cluster, you can only access the Hue interface through HTTPS.

Note: SSL encryption is currently not supported.

Prerequisites

Note the following prerequisites before you integrate Hue with Drill:

- The cluster must have the latest versions of Hue, Drill, and HTTPFS installed. Hue uses HTTPFS to communicate with the MapR file system. You can see the latest component versions in the Component Versions for Released EEPs. If you install Hue and Drill on a secure MapR cluster, Hue and Drill are installed with the default MapR security configurations and outbound impersonation is enabled.
  - **MapR Installer**

    When you install Hue and Drill using the MapR Installer, HTTPFS is installed automatically, and Hue is automatically configured to integrate Drill without having to perform any manual configuration. The installer configures a Zookeeper connection to Drill in `hue.ini`, by default.

  - **Manual Installation**
    - Install HTTPFS and then configure Hue, as described in the following section, *Configuring Hue*
- In a secure cluster, Drill must have user impersonation enabled.

- Drill has an inbound impersonation policy option, `exec.impersonation.inbound_policies`, that allows the Hue process user (proxy user) to impersonate the Hue authenticated user as an outbound impersonation from Hue to Drill. This option is automatically configured when Drill and Hue are installed using the MapR Installer with MapR default security enabled, or when you run configure.sh on a secure cluster. If you do not run configure.sh, you must manually add this option to the impersonation configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```
impersonation.enabled: true,
  impersonation.max_chained_user_hops: 3,
  exec.impersonation.inbound_policies: "[{proxy_principals:{users:
[\"mapr\"]},target_principals:{users:[\"*\"]}}]",
```

- If you plan to use Kerberos for authentication, you will need to include the Hue keytab file and Kerberos principal name for Hue in the hue.ini file. If needed, complete the steps listed in the Creating a Kerberos Principal and Extracting the Kerberos Ticket from the keytab File sections on the Configure Hue to use Kerberos on page 3636 page.

Configuring Hue

If you manually installed Hue, Drill, and HTTPFS, you must modify the `hue.ini` file to include the configuration information needed for Hue to connect with Drill and HTTPFS. The `hue.ini` file contains sections where you configure Hue to integrate with various components, like Drill and HTTPFS. You can access the `hue.ini` file in the `/opt/mapr/hue/hue-<version>/desktop/conf` directory. Start/Restart the services after you update the `hue.ini` file.

Note: If you installed Hue and Drill using the MapR Installer, these options are populated automatically in the `hue.ini` file; no configuration is required. In a secure MapR cluster, the authentication mechanism defaults to MAPR-SECURITY.

Complete the following steps to integrate Hue with Drill:

1. **Edit the Drill configuration in `hue.ini`.**

   The `hue.ini` file contains a `[[[drill]]]` section under which you can see configuration options needed for Hue to connect with Drill. You must uncomment an option (remove the # character) in the `hue.ini` file for the option to take effect.

   The following tables list and describe the Drill options with possible values and also provide examples:

Options	Descriptions	Examples
connection_type=	Tells Hue how to connect to Drill. Enter one of the following values: • direct • zookeeper A direct connection is a connection in which Hue connects directly to a Drillbit. A ZooKeeper connection is a connection in which Hue communicates with ZooKeeper and ZooKeeper provides Hue with a Drillbit to connect with.	connection_type=zookeeper

drillbits=	Enter the node IP address of the Drillbit that Hue connects with. Only enter a node address if using the “direct” connection_type.	drillbits=10.10.100.2:31010 To list multiple Drillbits, separate each IP address by a comma, as shown: drillbits=10.10.100.2:31010, 10.10.100.3:31010 **Note:** Port 31010 is the user port between nodes in a Drill cluster. This port is needed for an external client to connect into the cluster nodes and for the Drill Web Console.
zk_quorum=	Enter the list of ZooKeeper node IP addresses in the ZooKeeper quorum. Only enter the IP addresses for the ZooKeeper quorum if using the “zookeeper” connection_type.	zk_quorum=10.10.100.3:5181, 10.10.100.4:5181, 10.10.100.5:5181
zk_cluster_id=	Enter the name of the Drill cluster that you want Hue to connect to.	zk_cluster_id=dev-drillbits
mechanism=	The type of authentication enabled. Enter one of the following values: • None • GSSAPI • MapR-SECURITY Use None for Plain authentication. Use GSSAPI for Kerberos authentication. Use MAPR-SECURITY for maprsasl. If you set the mechanism to “none” and impersonation is enabled, you must set the username and password to the admin or proxy user that will impersonate Hue end users. You can set these with the user= and password= options. If you set the mechanism to GSSAPI, you must also include the ccache_path= option. For this option, enter the caching location for Kerberos credentials, for example: `ccache_path=/tmp/hue_krb5_ccache` **Note:** See Configure Hue to use Kerberos on page 3636 You can set the Drill Kerberos principal and/or Hue impersonation using the option named “`options=`.” See “options=” below.	mechanism=none

user=	If using Plain authentication, enter the username. If using another authentication mechanism, do not enter a value. Set the username to the admin or proxy user that will impersonate Hue end users. If impersonation is disabled, the you can set the user to any user. Hue will connect to Drill as the user specified.	user=mapr
password=	If using Plain authentication, enter the password. If using another authentication mechanism, do not enter a value. Set the password for the admin or proxy user that will impersonate Hue end users. If impersonation is disabled, set the password for the use specified.	password=mapr8

password_script=	Indicates which script to run for the database password when a password is required and the password= option is not set. Enter the location of the script.
	The following shell script is an example of a password script:
	`#!/bin/bash`
	`case $1 in`
	`drill) echo "password_1";;`
	`some-output) echo "password_2";;`
	`*) echo "wrong argument" >&2 exit 1;;`
	`esac`
		password_script='/root/hue_password_script/password_script.sh drill'

options=	Additional options related to impersonation and Kerberos authentication. This option takes the following values: • impersonation • principal Impersonation enables or disables outbound impersonation in Hue. Principal is the Drill service principal when Kerberos authentication is enabled.	options='{"impersonation": true, "principal": "mapr/localhost@REALM"}' options='{"impersonation": true}' options='{"impersonation": false}'

2. **Add the HTTPFS URL in `hue.ini`.**

   The `hui.ini` file contains a `[[[default]]]` section in the `[hadoop]` block under which you can see HDFS configuration options. You must uncomment an option (remove the # character) in the `hue.ini` file for the option to take effect.

   In the `[[[default]]]` section of the `[hadoop]` block, enter the IP address of the HTTPFS node as the value for the `webhdfs_url=` option, as shown:

   ```
   # Use WebHdfs/HttpFs as the communication mechanism.
   # Domain should be the NameNode or HttpFs host.
   # Default port is 14000 for HttpFs.
   webhdfs_url=https://<httpfs-node-ip-address>:14000/webhdfs/v1
   ```

3. **Start the services.**

   Start/Restart Hue, Drill, and HTTPS to apply the updated configurations, as shown in the following examples:

   ```
   maprcli node services -name hue -action start -nodes
   <hue-node-ip-address>

   maprcli node services -name drill-bits -action start -nodes
   <list-of-drill-node-ip-addresses>

   maprcli node services -name httpfs -action start -nodes
   <httpfs-node-ip-address>
   ```

Run Drill Queries in Hue

Once you have configured Hue and started the services, you can run Drill queries from Hue and visualize your data.

Complete the following steps to run Drill queries in Hue:

1. In your web browser, enter the Hue URL to navigate to the Hue web interface, as shown:

   ```
   http://hue-node-ip-address:8888
   ```

2. If prompted, enter your user credentials. The Hue interface opens.
3. In the **Query** drop-down, select **Editor > Drill**. The left navigation panel displays the list of schemas available in Drill.
4. Select a schema, for example `dfs.default`, and then enter a query in the text field.
5. Click the blue play button to execute the query. Query results display.
6. Optionally, you can use the buttons to the left of the query results to visualize the data.

Configure Hue to use Drill on a MapR-SASL-Secured Cluster
You can configure Hue to use Drill on a MapR-SASL cluster.

1. Configure Hue to use Drill:

a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=MAPR-SECURITY

    # Available options:
    # "impersonation" to enable or disable outbound impersonation.
    # "principal" of Drill service. Used when Kerberos authentication
is enabled.
    options='{"impersonation": true, "principal": "mapr/
<node>@REALM"}'
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to use Drill on Kerberos-Secured Cluster
You can configure Hue to use Drill on a Kerberos-secured cluster.

1. Configure Hue to use Drill:

a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name=”Drill”

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=GSSAPI

    # Available options:
    # "impersonation" to enable or disable outbound impersonation.
    # "principal" of Drill service. Used when Kerberos authentication
is enabled.
    options='{"impersonation": true, "principal": "mapr/
<node>@REALM"}'
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to use Drill on PAM-Secured Cluster
You can configure Hue to use Drill on a Pluggable Authentication Modules (PAM) secured cluster.

1. Configure Hue to use Drill:

a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name=”Drill”

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=none

    # Username to authenticate with when connecting to the database.
    # Used with plain authentication (mechanism set to "none").
    user=<user>

    # Password matching the username to authenticate with when
    # connecting to the database.
    # Used with plain authentication (mechanism set to "none").
    password=<password>
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Configure Hue to use Drill on an Unsecured Cluster
You can configure Hue to use Drill on an unsecure cluster.

1. Configure Hue to use Drill:

a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name=”Drill”

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=none
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

Integrate Hue 3.10+ With Spark 2

Important: Hue integration with Spark is an experimental feature. This topic describes how to integrate Hue 3.10 or later (expressed as "3.10+") with Spark 2 or later.

1. In the [spark] section of the `hue.ini` file, set the `livy_server_host` and `livy_server_port` parameters to the host and port where the Livy server is running:

```
[spark]
  # Host address of the Livy Server.
  livy_server_host=ubuntu500
  # Port of the Livy Server.
  livy_server_port=8998
```

2. To configure Hue to use Spark modes, modify `livy.conf` (`/opt/mapr/hue-livy/hue-livy-<version>/conf/livy.conf`):
   a) If Spark jobs run on local mode, set the `livy.spark.master` property:

```
…
# What spark master Livy sessions should use.
livy.spark.master = local[*]
….
```

b) If Spark jobs run on YARN mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
….
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
….
```

c) If Spark jobs run on Standalone mode, set the `livy.spark.master` property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = spark://ubuntu500:7077
```

d) If Spark jobs run on Mesos mode, set the `livy.spark.master` property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

Note: Integration of Spark on Mesos with Hue is not supported in cluster deployment mode.

3. If you want to be able to access Hive through Spark in Hue, you should configure Spark with Hive, and set `livy.repl.enableHiveContext` to `true` in `livy.conf`. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

4. If you are planning to use PySpark, you will need to set the PYTHONPATH environment variable in `livy-env.sh` (`/opt/mapr/livy/livy-<version>/conf/livy-env.sh`):

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-<version>-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

For example:

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-0.10.7-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

5. Make sure that R is installed on the node if you are planning to run SparkR. To install R to run SparkR jobs:

On Ubuntu	`sudo apt-get install r-base`
On Red Hat / CentOS	`sudo yum install R`

6. Restart the Spark REST Job Server (Livy).

```
maprcli node services -name livy -action restart -nodes <livy node>
```

7. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <hue node>
```

Configure Hue with Sqoop2

Hue's Sqoop Transfer application is used to import data from MySQL to MapR File System and to export data from MapR File System to MySQL. Before you can run the Sqoop Transfer application, you need to:

- Install the Sqoop2 server and Sqoop2 client packages. For more information, see the Installing MapR and MapR Ecosystem Components on page 128.
- Edit the `hue.ini` file to configure Hue with Sqoop2.
- You can configure Hue to use Kerberos with Sqoop2. For more information, see Configure Kerberos Between Hue and Sqoop2.

Warning:

To disable the Sqoop2 application, see Disabling an Application.

Modifying the hue.ini File

1. Locate the `sqoop` section of the `hue.ini` file.

```
[sqoop]
  # For autocompletion, fill out the librdbms section.

  # Sqoop server URL
  ## server_url=https://localhost:12000/sqoop
```

2. Uncomment the `## server_url=https://localhost:12000/sqoop` statement and change `localhost` to the IP address or host name of the node where the Sqoop2 server is running.

```
server_url=https://<ip_address>:12000/sqoop
```

Warning: In Hue 3.x releases, Sqoop2 only supports files in comma-separated value (`.csv`) format.

Use Hue

This section provides information about using Hue, but it does not duplicate the Hue documentation.

You can also refer to the Hue documentation.

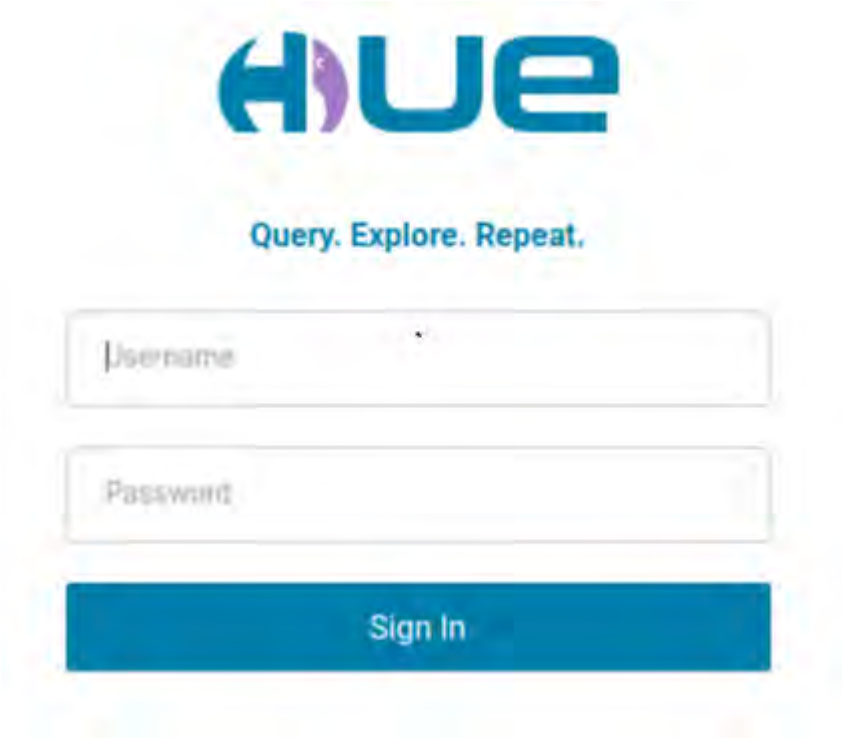
This section includes the following topics:

Logging in to Hue 4.X

Once Hue is installed and the configuration files have been edited, direct your browser to the IP address where you installed Hue.

- Open the Hue homepage: `ip_address>:8888`
  The following screen appears:

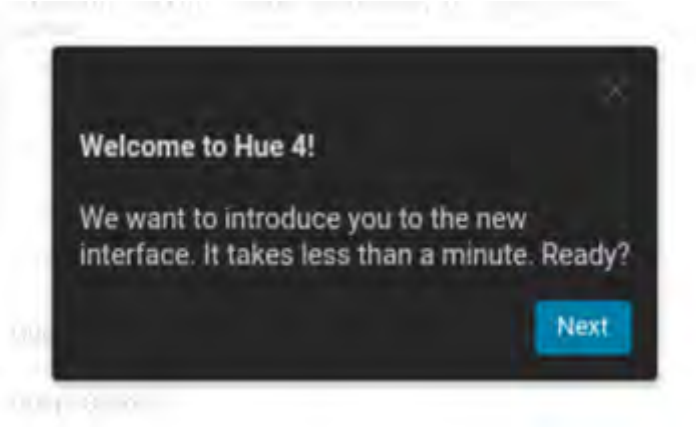
last-updated: Apr 11, 2022



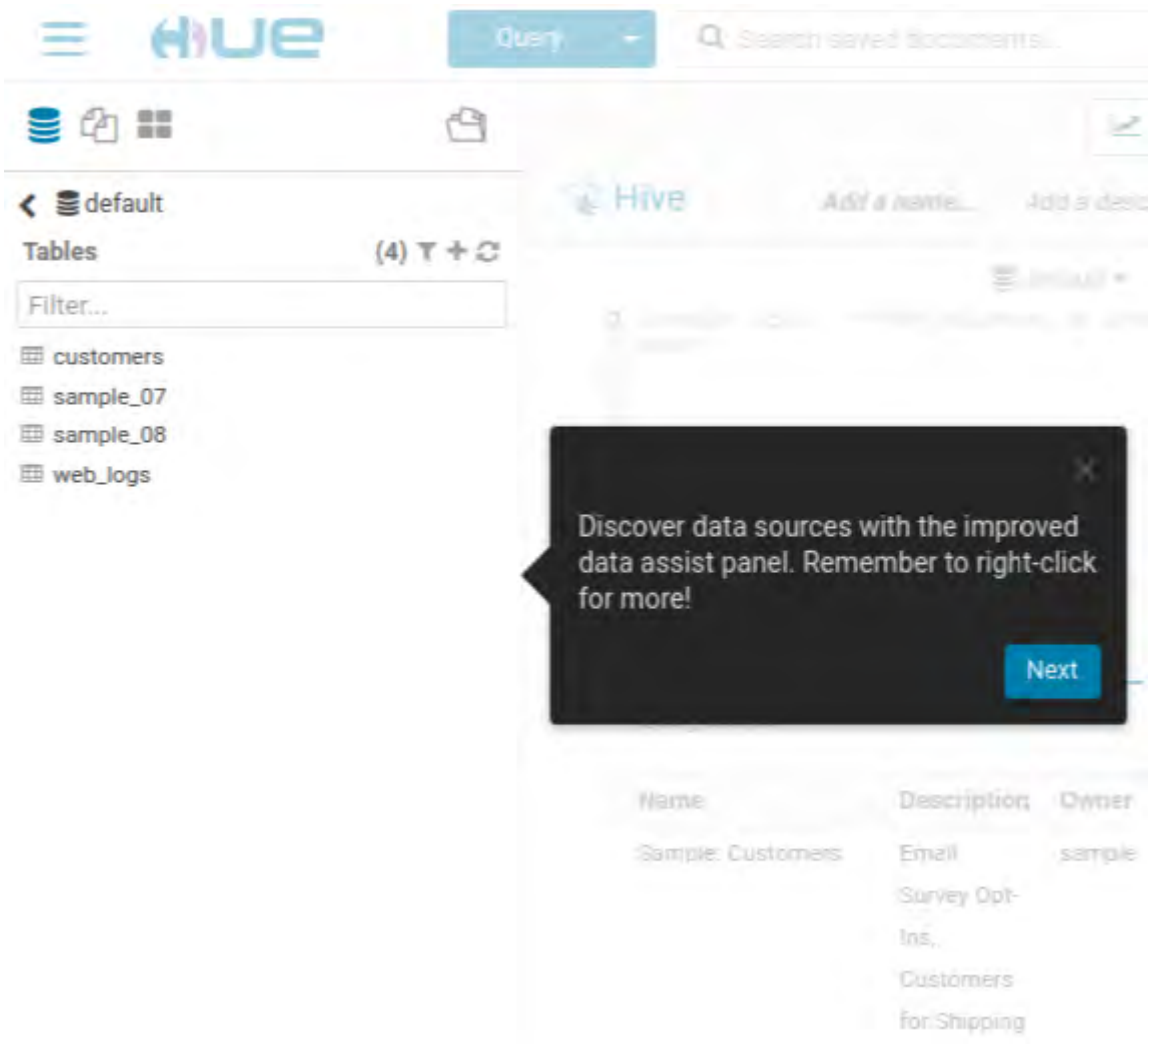
- Sign in with your username, enter the password `mapr` and click **Sign in**. You can find your username in the `/opt/mapr/conf/daemon.conf` file.

Using Hue Welcome Tour
After your first login, you will be introduced to the new features in Hue 4 by the "Welcome Hue 4!" tour.

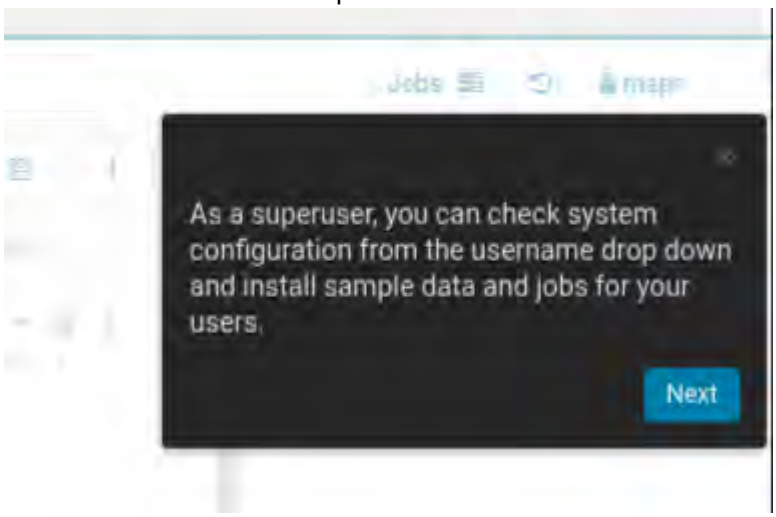
1. Start the welcome tour.
   The following screen appears:



2. You are first introduced to the navigation bar:



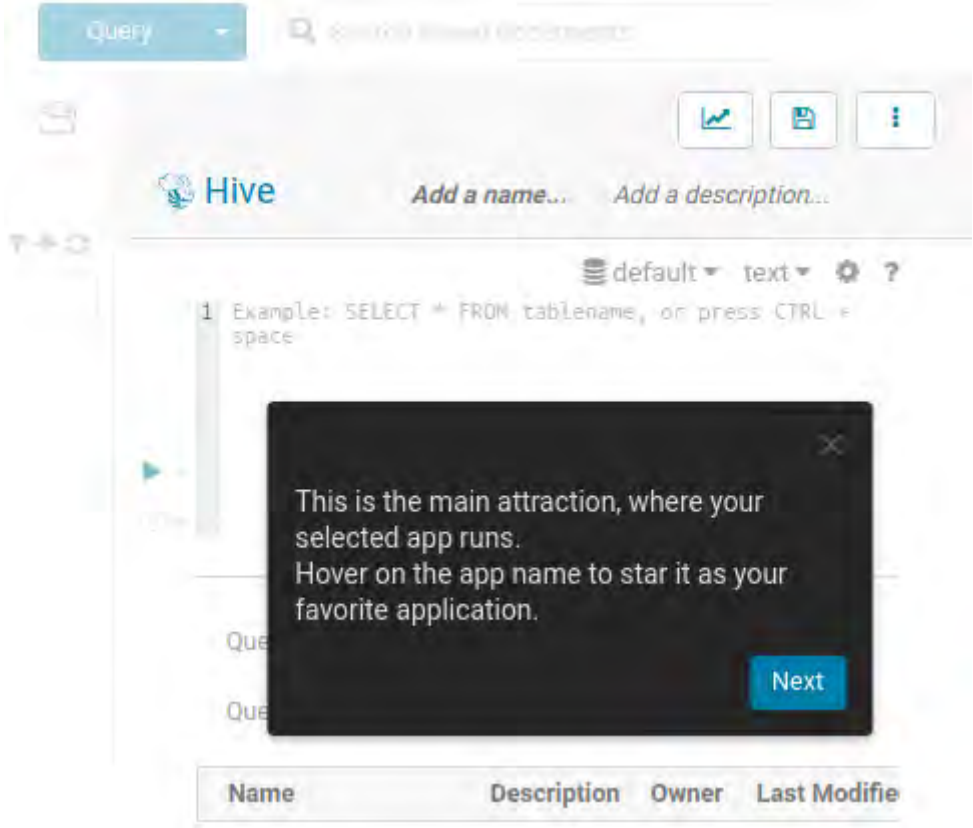
3. You are introduced to the superuser menu:



4. You are introduced to the left assist panel:

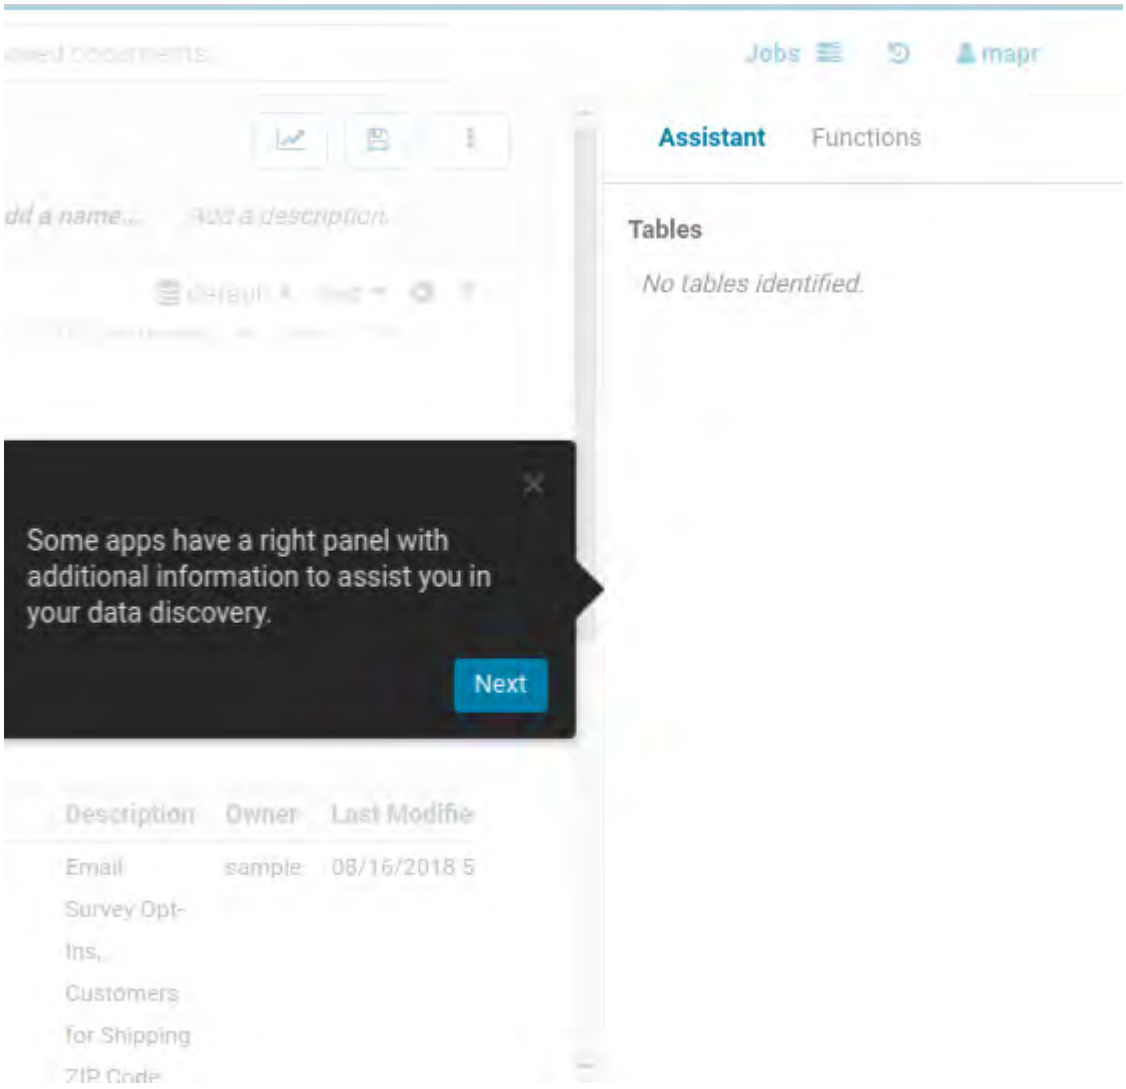
last-updated: Apr 11, 2022

5. You are introduced to the main working zone:

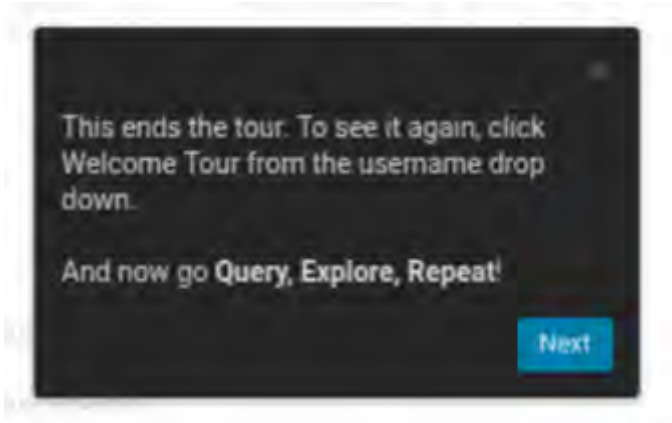


6. You are introduced to the right assist panel:

last-updated: Apr 11, 2022



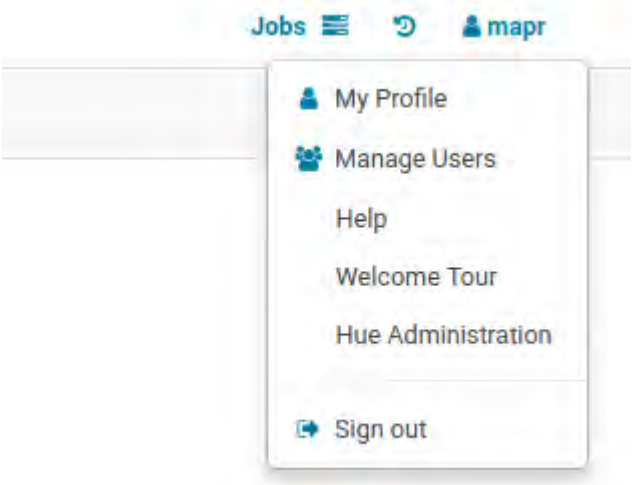
7. You then come to the end of the tour:



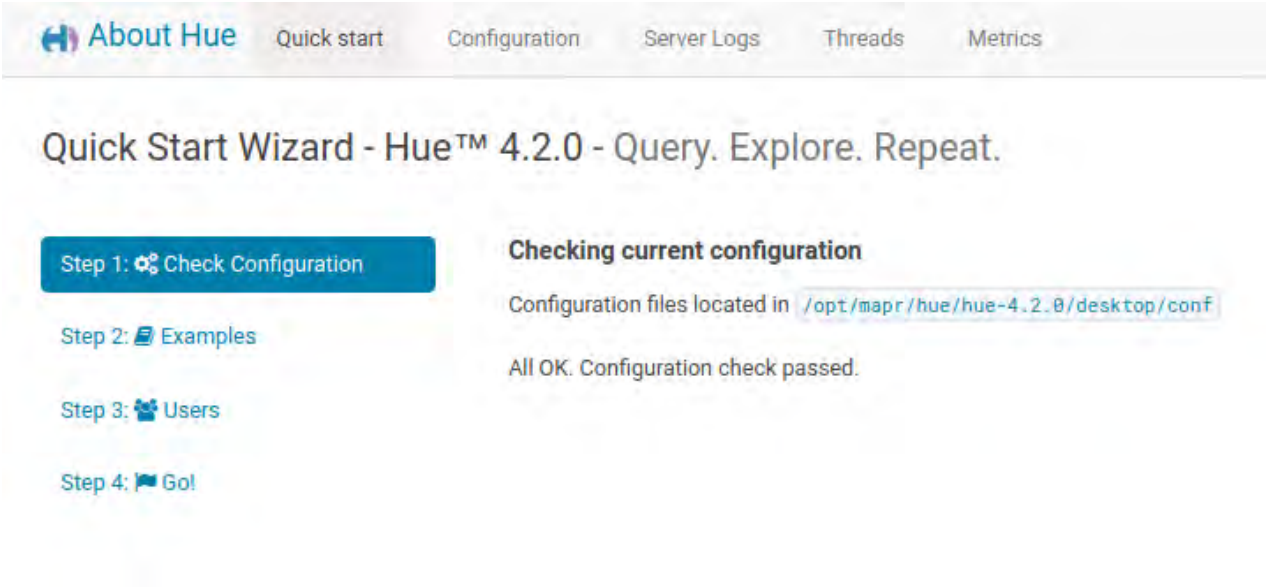
Getting Started with the Quick Start Wizard (Hue 4.X)
With the Quick Start Wizard you can check configuration, install examples, and create users.

Click on ***Hue Administration*** in the user menu:

last-updated: Apr 11, 2022

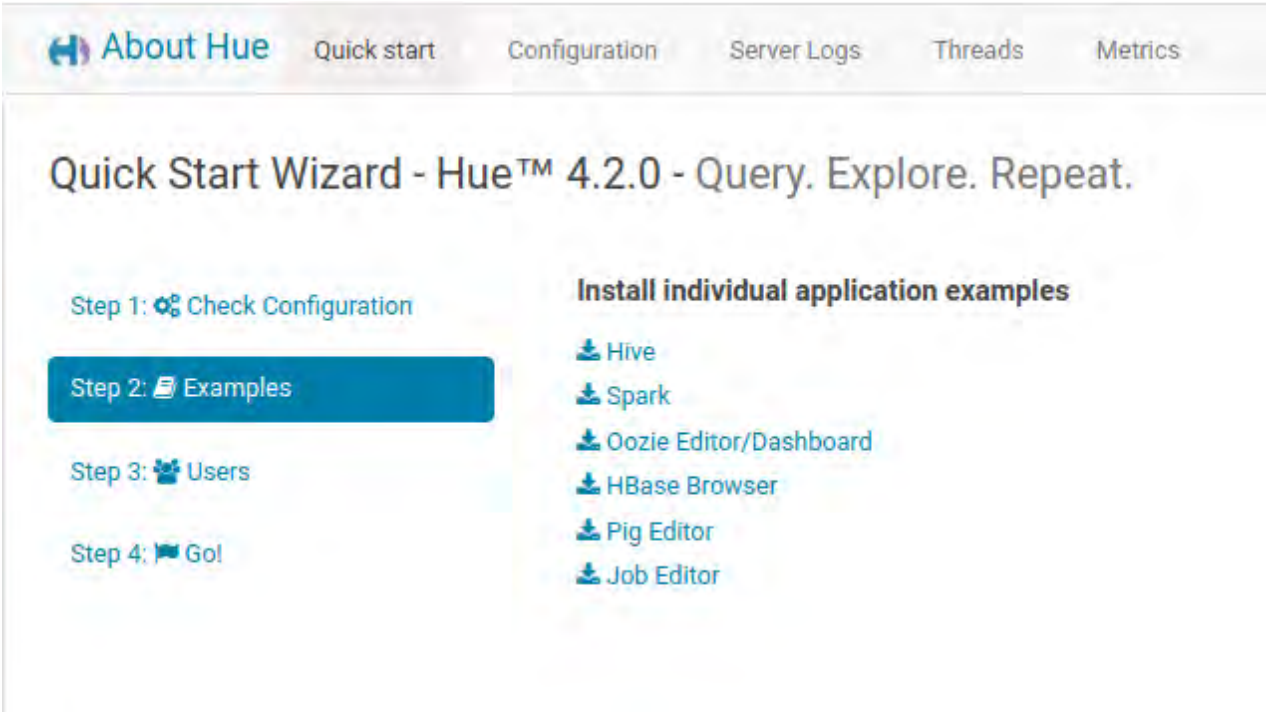


Step 1: Check Configuration

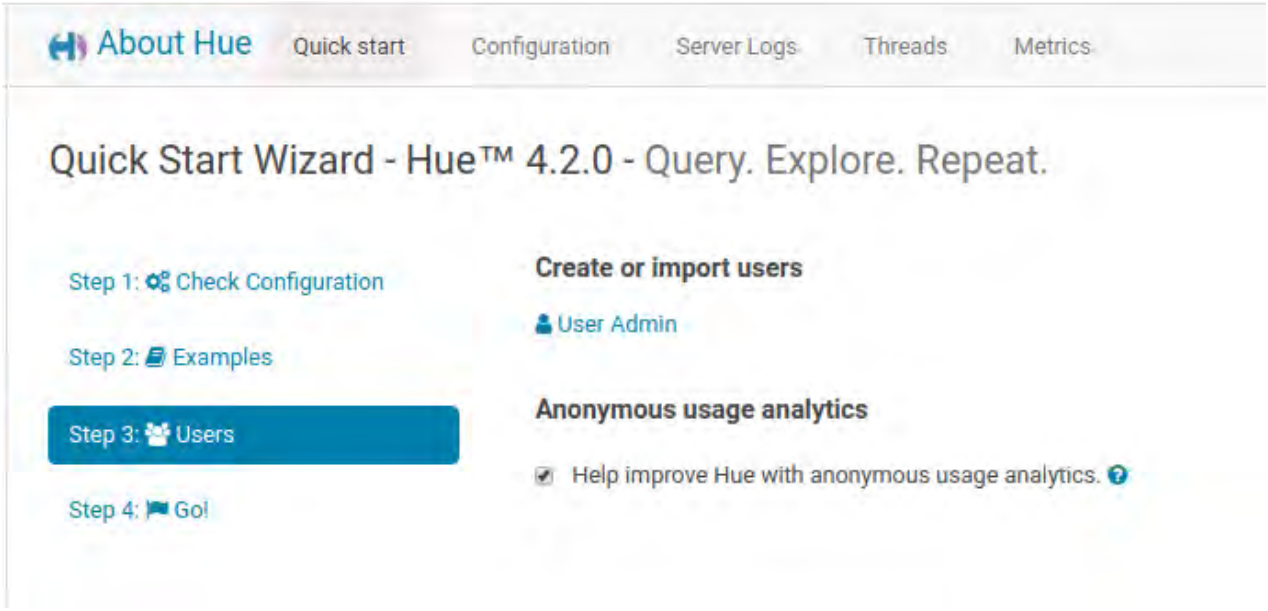


last-updated: Apr 11, 2022

Step 2: Examples



Step 3: Users



Note: By default, the Hue interface is configured to use PAM for authentication; so you cannot create or import users. For more information, see Configure Hue Interface Authentication.

User Administration in Hue 4.X

By default, the Hue interface is configured to use PAM for authentication; so you cannot use the Hue interface to create users or edit their passwords.

Note: For more information, see Configure Hue Interface Authentication.

This section contains the following topics:

last-updated: Apr 11, 2022

Changing Your Password
Once you log in, you can change your Hue password.

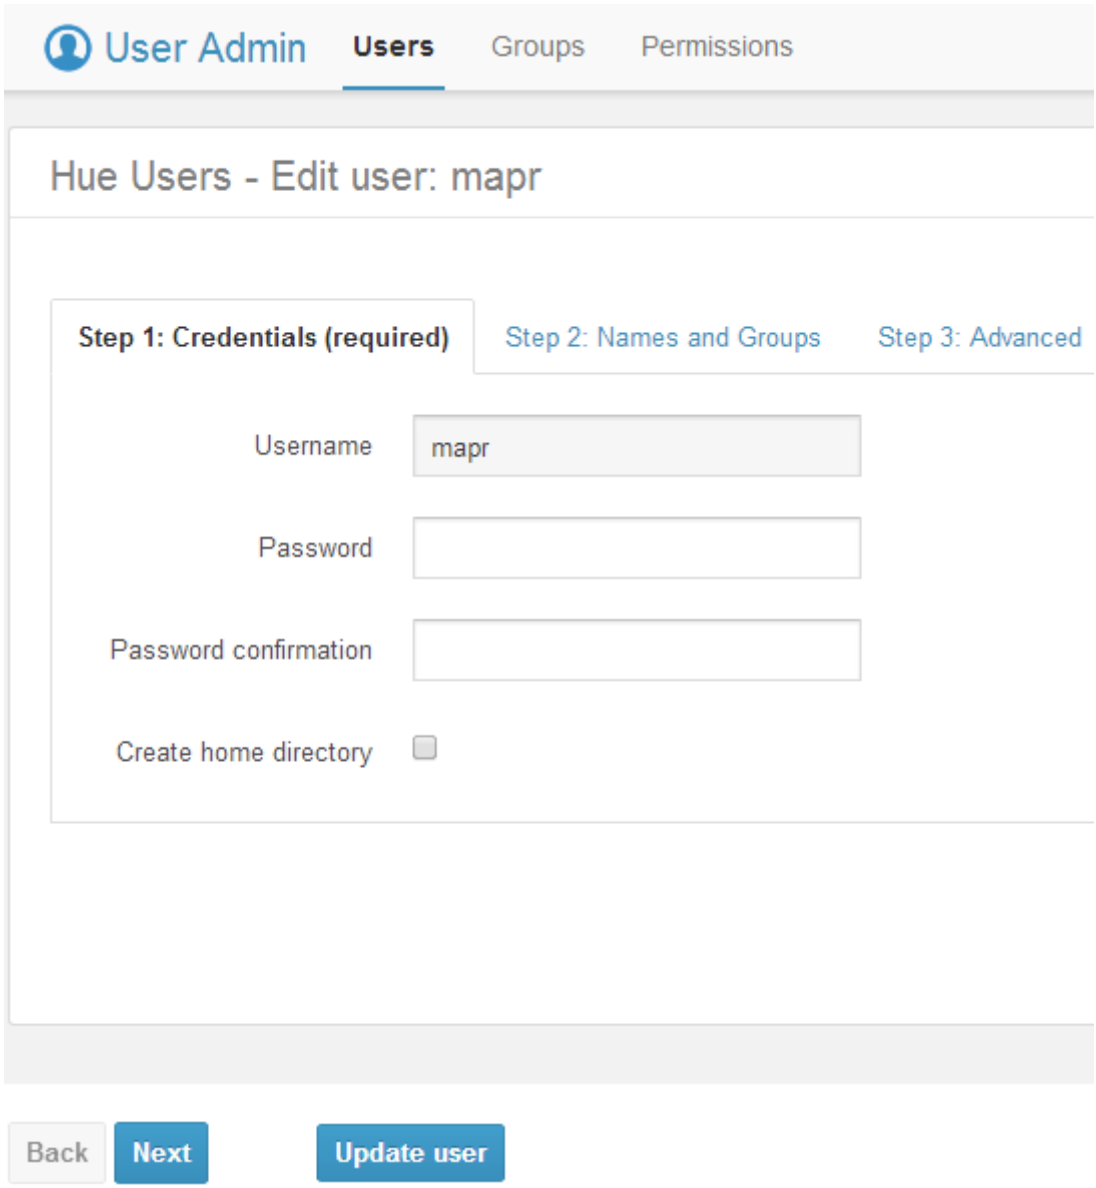
To change your Hue password, perform the following steps:

1. Click on your ***Username*** at the top right of the navigation menu bar and select **Edit Profile** from the drop-down menu. In this example, the username is **mapr**.

   The *Hue Users* dialog box opens.

2. Enter your current password in the *Current password* field and enter your new password in the *New Password* field. Retype the password in the *Password confirmation* field.

last-updated: Apr 11, 2022



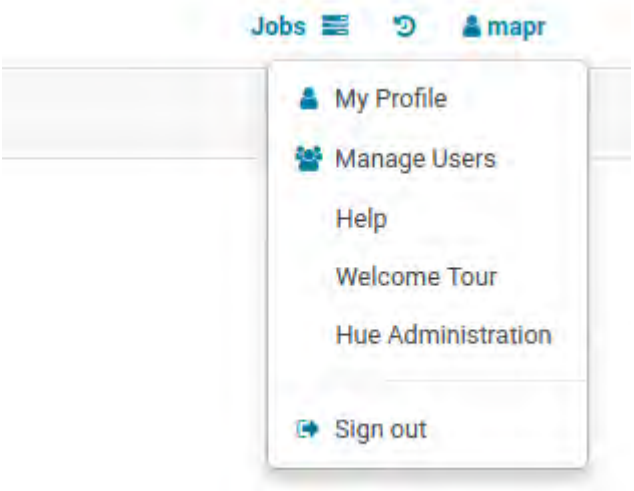
3. Click **Update user**.

Adding Users
When you click on your username, all users are displayed.

To create more users, follow these steps:

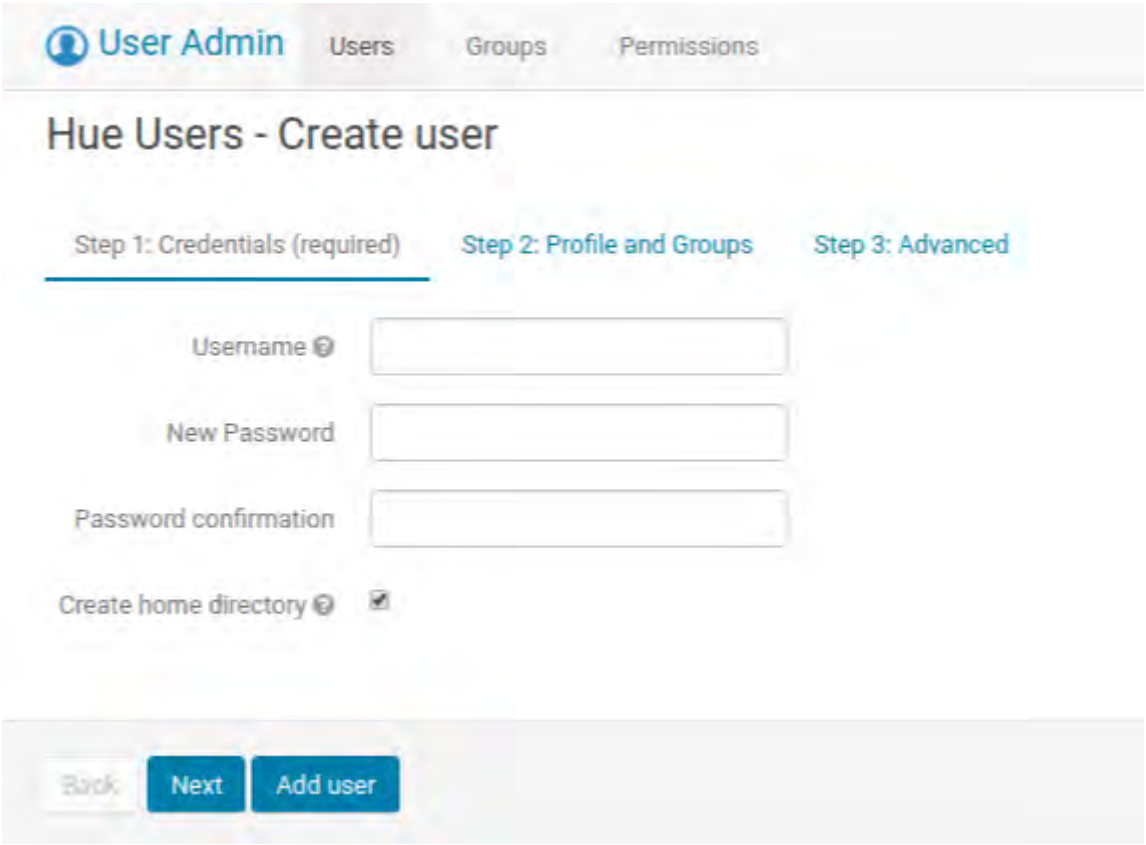
1. Click on your ***Username*** at the top right of the navigation menu bar and select **Manage Users** from the drop-down menu.

last-updated: Apr 11, 2022



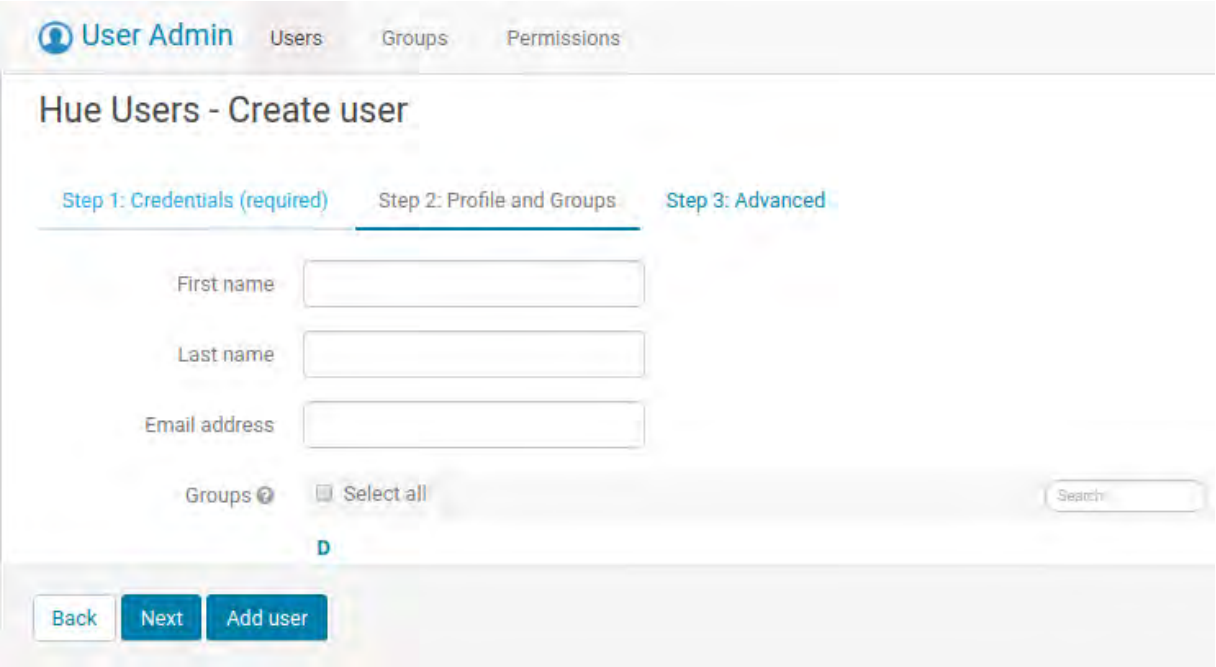
In this example, the username is **mapr**.

2. The *Hue Users - Create user* dialog box opens.

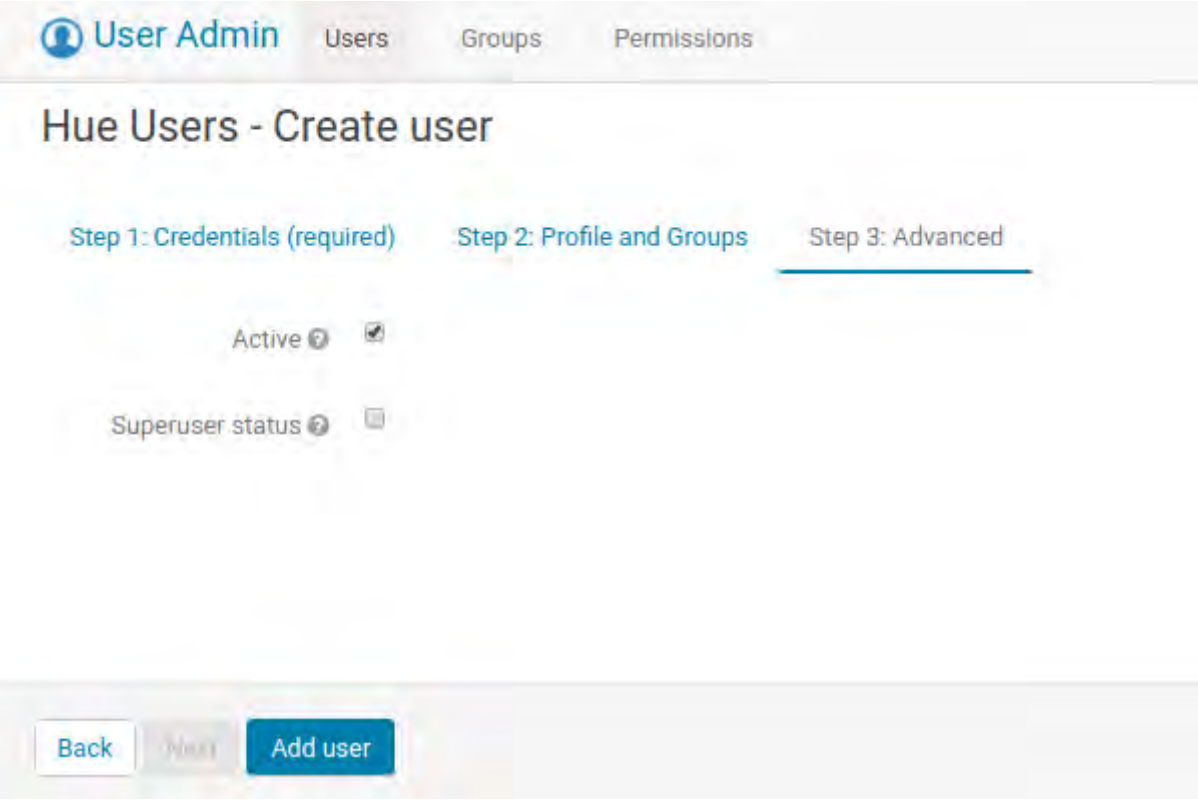


Click **Add user** to finish the process. If you want to assign superuser privileges to the user, click **Next** to proceed to the next screen.

3. Fill in the *Username*, *New Password*, and *Password confirmation* fields.
4. (Optional) Fill in the user's name and email address, and assign a group.



5. (Optional) Assign superuser privileges to the user that you just added by checking the *Superuser status* box.



6. Click **Add User**.

Managing MapR Database Binary Tables in Hue 4.X
You can create and manage MapR Database binary tables in the HBase Browser of the Hue interface.

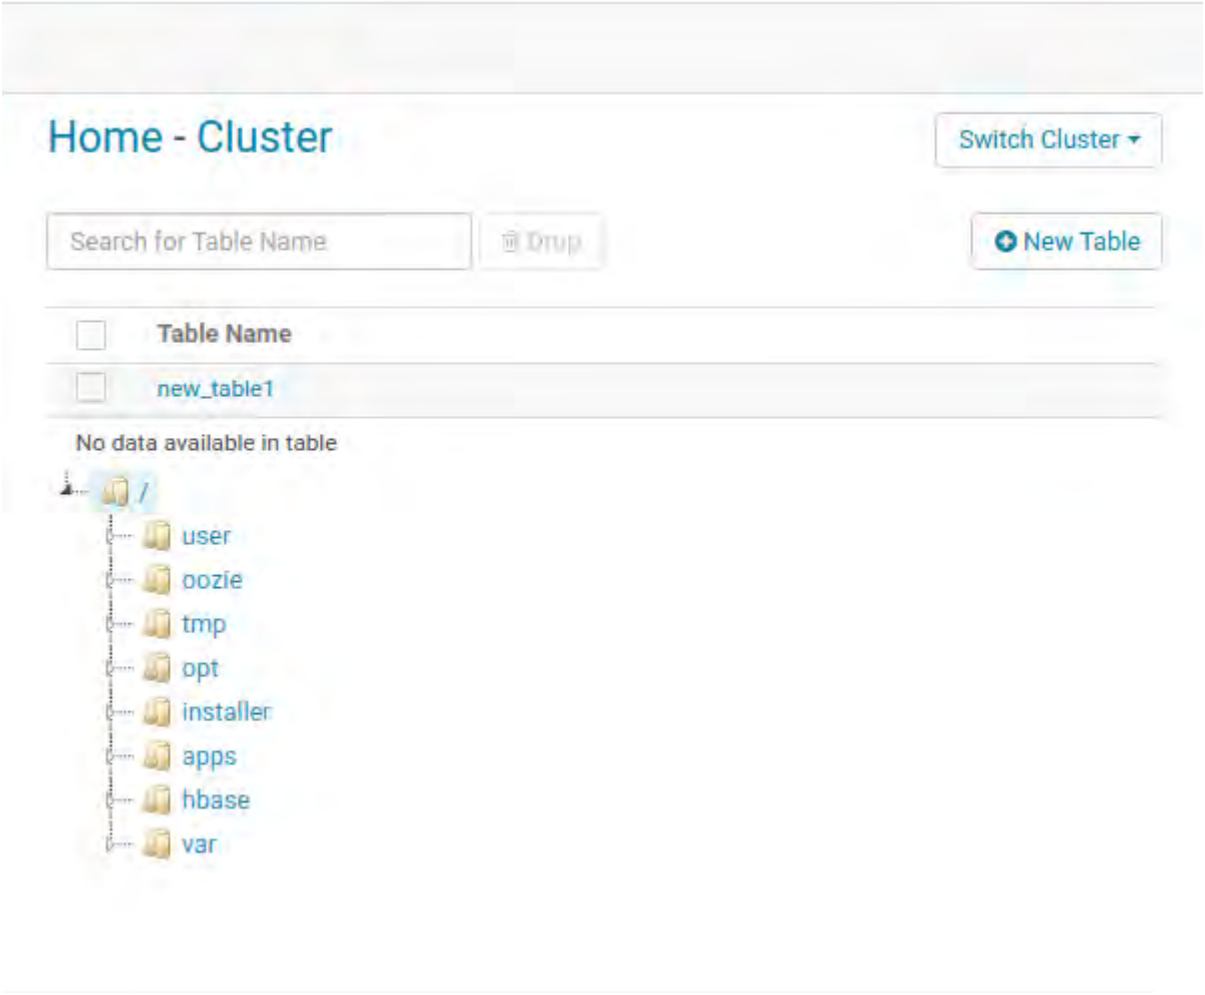
This section includes the following sections:

last-updated: Apr 11, 2022

Using the Hbase Browser
When you open the Hbase Browser, you can view the all the directories and MapR Database binary tables available in MapR Filesystem.

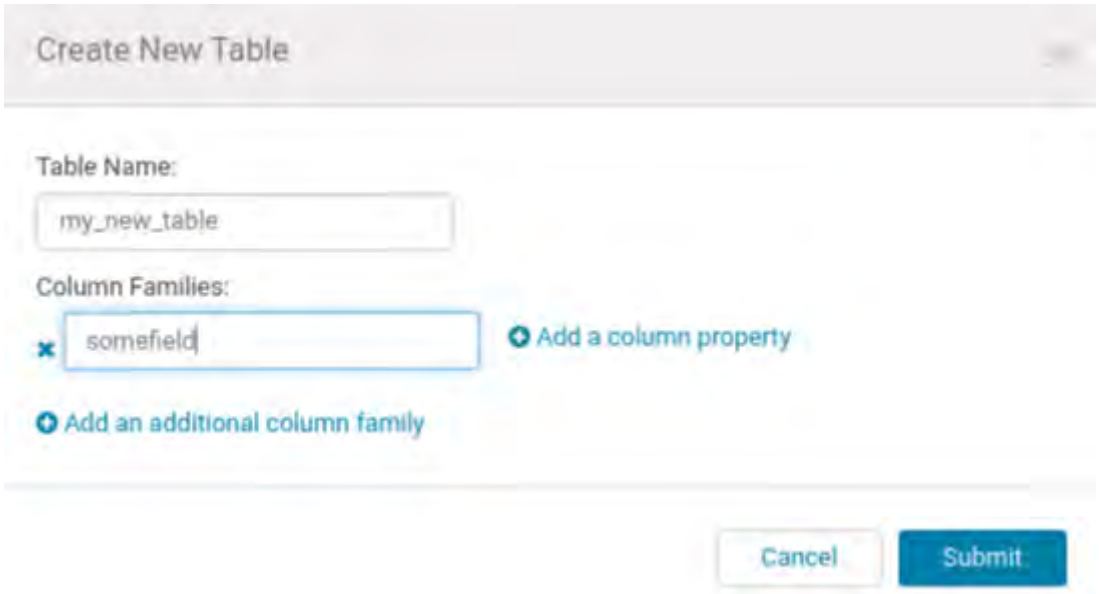
You can use the HBase Browser to create, edit, and search for MapR Database binary tables. However, you cannot enable, disable, or drop MapR Database binary tables.

Note: The browser also lists MapR Database JSON tables. However, their appearance is not different from that of MapR Database binary tables. You cannot edit JSON tables.

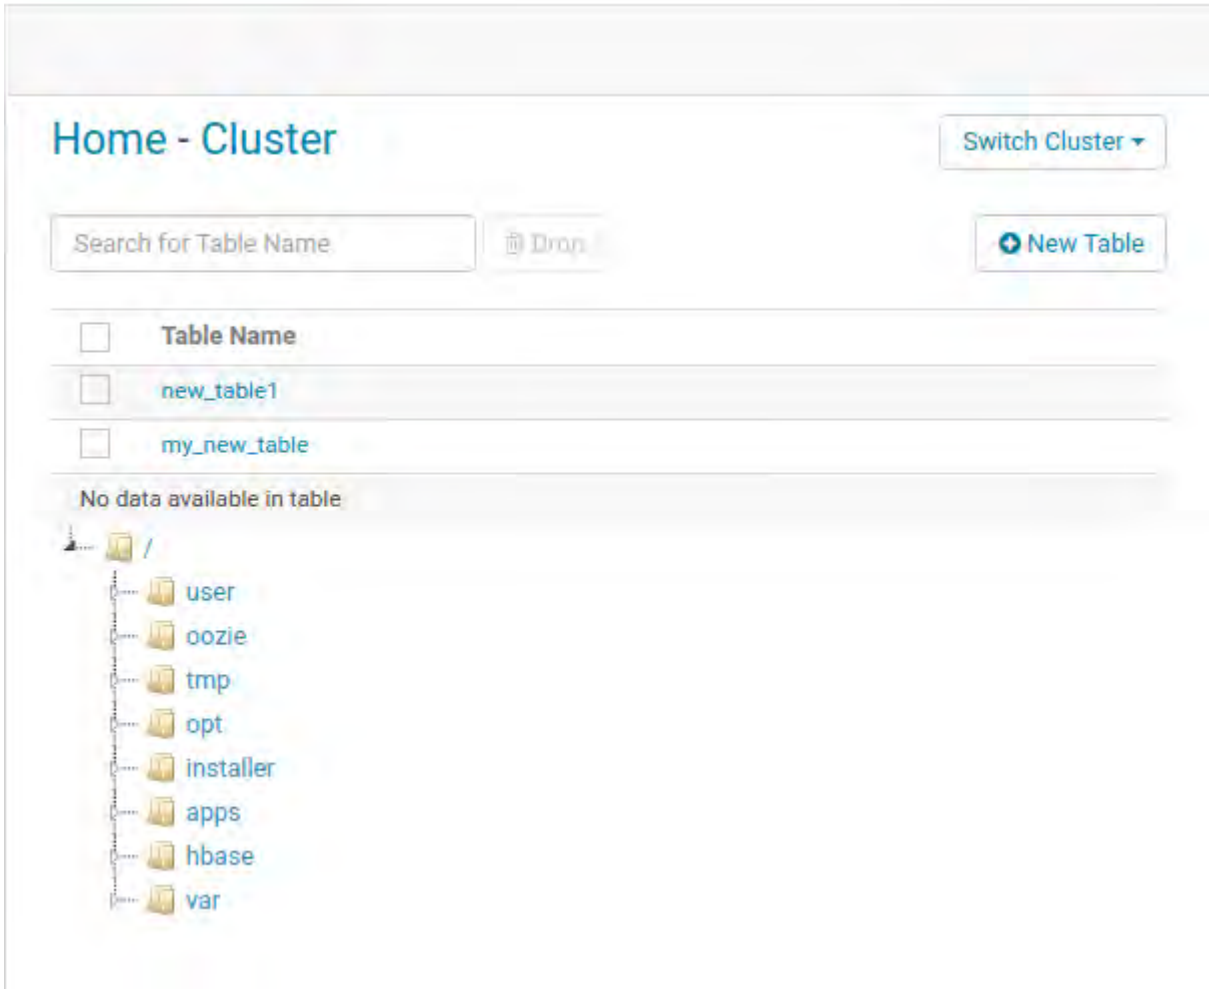


Creating a MapR Database Binary Table
You can create a new MapR Database Binary Table.

1. In the Hbase Browser, click **New Table**.
2. In the **Table Name** field, provide the full name of the table that you want to create. For example, `my_new_table`.



3. In the *Column Families* field, you can add column families and column properties.
4. Click **Submit.** The table that you created appears in the Hbase Browser:



last-updated: Apr 11, 2022

Starting the Hue Webserver
After you configure the `hue.ini`, you need to start the Hue Webserver and verify that it has started.

1. To start/restart the Hue Webserver, run the following command:
   - If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to start the Hue webserver:

     ```
     maprcli node services -name hue -action start -nodes <ip_address>
     ```

   - If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to restart the Hue webserver:

     ```
     maprcli node services -name hue -action restart -nodes <ip_address>
     ```

   - If Hue is installed on an edge node (not recommended), run the following command to start the Hue webserver:

     ```
     /opt/mapr/hue/hue-<version>/bin/hue-server start
     ```

2. To verify that the Hue webserver started, enter: `lsof -i:8888`

   The output from this command should look similar to this:

   ```
   COMMAND     PID USER   FD   TYPE   DEVICE SIZE/OFF NODE NAME
   python2.6 27688 mapr    3u  IPv4 69955314      0t0  TCP *:ddi-tcp-1
   (LISTEN)
   python2.6 27691 mapr    3u  IPv4 69955314      0t0  TCP *:ddi-tcp-1
   (LISTEN)
   ```

   You can also check Hue webserver logs to verify that Hue webserver started. If the Hue webserver was installed on a *cluster* node or an *edge* node, the log is found here:

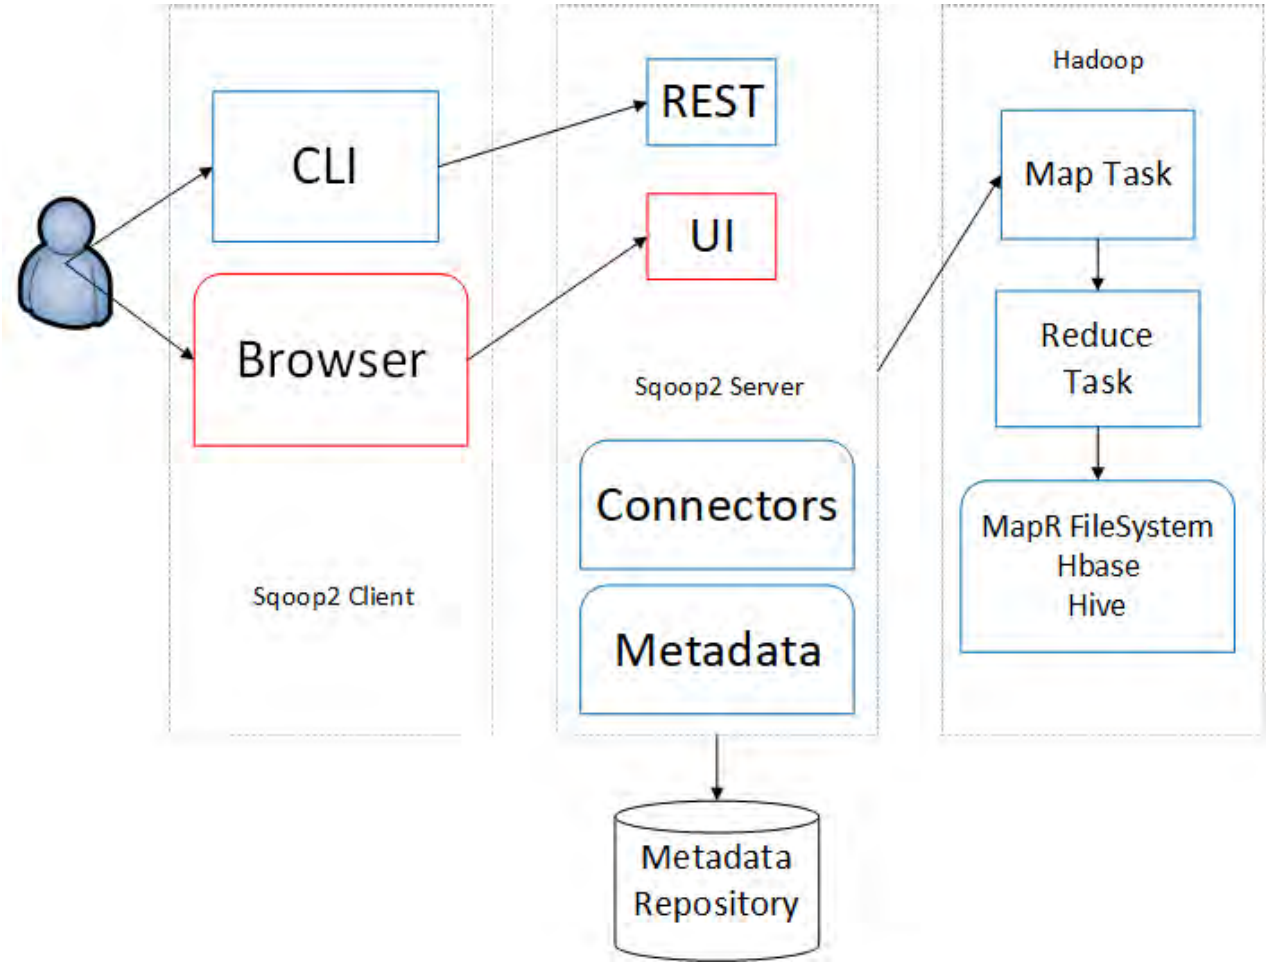
   `/opt/mapr/hue/hue-<version>/logs/runcpserver.log`

Sqoop2

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Sqoop2 transfers bulk data between Hadoop and various types of structured datastores, such as relational databases, enterprise data warehouses, and NoSQL systems. Sqoop2 is installed and configured server-side. When you install the Sqoop2 server package, the Sqoop2 client package is installed as well.

Sqoop2 can be used in conjunction with Hue, which is a web-based GUI that facilitates the importing and exporting of data from these structured datastores. This illustration shows how a user can access Sqoop2 from a browser, such as Hue.



This documentation does not duplicate Apache documentation. You can also refer to documentation available from the Apache Sqoop website.

Note: Sqoop2 does not officially support HA.

Sqoop2 Connector Support
Connector support differs for each version of Sqoop2.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Connector Name	Details
ftp-connector	Connects to FTP servers. **Supported Version:** 1.99.7 **Supported Direction:** To
generic-jdbc-connector	Connects to any data source that adheres to the JDBC 4 specification. **Supported Version:** 1.99.6 and 1.99.7 **Supported Direction:** To and From
hdfs-connector	Connects to MapR File System. **Supported Version:** 1.99.6 and 1.99.7

last-updated: Apr 11, 2022

Connector Name	Details
	Supported Direction: To and From **Additional Information:** • As of 1.99.7, the Parquet data format is supported. The sequence and text file formats continue to be supported.
kafka-connector	Not Supported
kite-connector	Connects to MapR File System and Hive Metastore. **Supported Versions** 1.99.7 **Supported Direction:** To and From **Additional Information:** • The kite connector cannot be used to connect to Hive on secure clusters. • Csv and avro formats are not supported. The parquet data format is supported.
oracle-jdbc-connector	Connects to Oracle databases. **Supported Versions** 1.99.6 **Supported Direction:** To and From
sftp-connector	Connects to Secure File Transfer Protocol (SFTP) servers. **Supported Version:** 1.99.7 **Supported Direction:** To

Configuring Sqoop2

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This section provides information about configuring Sqoop2, but it does not duplicate Apache documentation.

Starting with the EEP 4.0 release, for secure clusters, Sqoop2 is configured to enable MapR-SASL and SSL. Prior to the EEP 4.0 release, by default, Sqoop2 is not configured with any type of security or encryption.

For additional configuration details, see the Apache Sqoop website.

Configure Kerberos Authentication for Sqoop2
You can configure Sqoop2 to use Kerberos authentication. When Sqoop2 uses Kerberos authentication, the cluster and other components that work with Sqoop2, such as Hue, must also use Kerberos authentication.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Note the following items when you complete the configuration steps:

- Replace `<FQDN>` with the FQDN of the server. To determine this value, run `hostname -f` in the command line.

last-updated: Apr 11, 2022

- Replace <REALM> with the realm name in the `krb5.conf` file, which is generated when you install the KDC server on the cluster.

Configuring Kerberos Authentication for Sqoop2:

1. Using the `kadmin` program, run the following commands to create principals for Sqoop 2:

   ```
   addprinc -randkey HTTP/<FQDN>@<REALM>
   addprinc -randkey mapr/<FQDN>@<REALM>
   ```

   Kerberos uses the principal `HTTP/<FQDN>@<REALM>` for communication between Sqoop2 client and Sqoop2 server. The principal `mapr/<FQDN>@<REALM>` is the Sqoop2 user that communicates between Sqoop2 server and MapR File System.

2. Using the `kadmin` program, run the following commands to create keytabs for the principals:

   ```
   xst -k /opt/mapr/conf/mapr.keytab HTTP/<FQDN>@<REALM>
   xst -k /opt/mapr/conf/mapr.keytab mapr/<FQDN>@<REALM>
   ```

3. Modify the following properties in Sqoop2 configuration file (sqoop.properties).

   In Sqoop 1.99.6, the sqoop.properties file is in the following directory: `/opt/mapr/sqoop/sqoop-<version>/server/conf/`. In Sqoop 1.99.7, the sqoop.properties file is in the following directory: `/opt/mapr/sqoop/sqoop-<version>/conf/`.

   ```
   org.apache.sqoop.security.authentication.type=KERBEROS
   org.apache.sqoop.security.authentication.handler=org.apache.sqoop.securit
   y.authentication.KerberosAuthenticationHandler
   org.apache.sqoop.security.authentication.kerberos.principal=mapr/
   <FQDN>@<REALM>
   org.apache.sqoop.security.authentication.kerberos.keytab=/opt/mapr/conf/
   mapr.keytab
   org.apache.sqoop.security.authentication.kerberos.http.principal=HTTP/
   <FQDN>@<REALM>
   org.apache.sqoop.security.authentication.kerberos.http.keytab=/opt/mapr/
   conf/mapr.keytab
   org.apache.sqoop.security.authentication.enable.doAs=true
   org.apache.sqoop.security.authentication.proxyuser.mapr.users=*
   ```

4. Start Sqoop2 server.

   ```
   maprcli node services -name sqoop2 -action start -nodes <space delimited
   list of nodes>
   ```

5. Using the `kinit` program, run the following command to generate a ticket:

   ```
   kinit HTTP/<FQDN>@<REALM> -kt /opt/mapr/conf/mapr.keytab
   ```

6. Start the Sqoop2 client.

   ```
   sudo -u mapr /opt/mapr/sqoop/sqoop-<version>/bin/sqoop.sh client
   ```

Configure MapR-SASL for Sqoop2

This section describes how to configure Sqoop2 to use MapR-SASL. Starting with the EEP 4.0 release, for secure clusters, MapR-SASL is automatically configured for Sqoop2 and you can skip the steps outlined in this section.

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

When you configure MapR-SASL for Sqoop2, other components that communicate with Sqoop, such as Hue, must also be configured to use MapR-SASL. Complete the following steps on each node that runs the Sqoop2 server:

1. Remove the # before the following properties in the Authentication configuration section of the `sqoop.properties` file.

   In Sqoop 1.99.6, the sqoop.properties file is in the following directory: `/opt/mapr/sqoop/sqoop-<version>/server/conf/`. In Sqoop 1.99.7, the sqoop.properties file is in the following directory: `/opt/mapr/sqoop/sqoop-<version>/conf/`.

   ```
   #org.apache.sqoop.security.authentication.type=CUSTOM
   #org.apache.sqoop.security.authentication.custom_handler=org.apache.hadoop.security.authentication.server.MultiMechsAuthenticationHandler
   ```

2. Restart Sqoop2 server.

   ```
   maprcli node services -name sqoop2 -action restart -nodes <space delimited list of nodes>
   ```

Note: To start Sqoop2 client with MapR-SASL, run the following command:

```
sudo -u mapr /opt/mapr/sqoop/sqoop-<version>/bin/sqoop.sh client --custom
```

Configure SSL for Sqoop2

As of Sqoop 1.99.7, you can configure SSL to enable encrypted communications between the Sqoop2 server and its clients. Starting with the EEP 4.0 release, for secure clusters, SSL is automatically configured for Sqoop2 and you can skip the steps outlined in this section.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Stop the Sqoop2 server:

   ```
   maprcli node services -name sqoop2 -action stop -nodes <space delimited list of nodes>
   ```

2. In the sqoop.properties file (/opt/mapr/sqoop/sqoop-<version>/conf/sqoop.properties), uncomment the SSL related properties. For example:

   ```
   #Enable Sqoop SSL
   org.apache.sqoop.security.tls.enabled=true
   #Change SSL protocol
   org.apache.sqoop.security.tls.protocol=TLSv1.2
   #Path to MapR ssk keystore
   org.apache.sqoop.security.tls.keystore=/opt/mapr/conf/ssl_keystore
   #Keystore password
   org.apache.sqoop.security.tls.keystore_password=<passwd>
   ```

   Note: You can use the default ssl_keystore and password. The password for the default ssl_keystore is `<ssl-keystore-password>`.

last-updated: Apr 11, 2022

3. Remove the Sqoop2 repository.

```
rm -rf /opt/mapr/sqoop/repository
```

4. Start the Sqoop2 server.

```
maprcli node services -name sqoop2 -action start -nodes <space delimited
list of nodes>
```

5. Start the Sqoop2 client:

```
sudo -u mapr /opt/mapr/sqoop/sqoop-<version>/bin/sqoop.sh client
```

Note: If you are using MapR-SASL, run the following command instead: `sudo -u mapr /opt/mapr/sqoop/sqoop-<version>/bin/sqoop.sh client --custom`.

6. Configure the Sqoop2 client to communicate the Sqoop2 server using SSL.

```
set server --host <sqoop_server_hosname> --port <sqoop_port> --webapp
<sqoop_webapp> --tls
```

For example:

```
sqoop:000> set server --host localhost --port 12000 --webapp sqoop --tls
```

7. Configure the Sqoop2 client truststore and truststore password.

```
set truststore --truststore /opt/mapr/conf/
ssl_truststore --truststore-password <passwd>
```

Each time you start the Sqoop2 client, you must reset the server and truststore configuration.

Configure Repository Encryption for Sqoop2

As of Sqoop 1.99.7, you can configure the Sqoop2 repository to encrypt password data.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Stop the Sqoop2 server.

```
maprcli node services -name sqoop2 -action stop -nodes <space delimited
list of nodes>
```

last-updated: Apr 11, 2022

2. In the sqoop.properties file (`/opt/mapr/sqoop/sqoop-<version>/conf/sqoop.properties`), configure the repository encryption related properties. For example:

```
org.apache.sqoop.security.repo_encryption.enabled=true
org.apache.sqoop.security.repo_encryption.password=<ssl-keystore-password
>
org.apache.sqoop.security.repo_encryption.hmac_algorithm=HmacSHA256
org.apache.sqoop.security.repo_encryption.cipher_algorithm=AES
org.apache.sqoop.security.repo_encryption.cipher_key_size=16
org.apache.sqoop.security.repo_encryption.cipher_spec=AES/CBC/
PKCS5Padding
org.apache.sqoop.security.repo_encryption.initialization_vector_size=16
org.apache.sqoop.security.repo_encryption.pbkdf2_algorithm=PBKDF2WithHmac
SHA1
org.apache.sqoop.security.repo_encryption.pbkdf2_rounds=4000
```

3. Remove the Sqoop2 repository.

```
rm -rf /opt/mapr/sqoop/repository
```

4. Start the Sqoop2 server.

```
maprcli node services -name sqoop2 -action start -nodes <space delimited
list of nodes>
```

Using Sqoop2

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This documentation provides all relevant details about using Sqoop2, but does not duplicate Apache documentation.

For more information, see the Apache Sqoop website.

Manage Sqoop2 Server and Client

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Starting the Sqoop2 Command Line Client

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Sqoop install directory (`<SQOOP_INSTALL_DIR>`) is of the form `/opt/mapr/sqoop/sqoop-<version_number>`.

- To start the sqoop2 command line client without MapR-SASL authentication, enter:

```
$ cd <SQOOP_INSTALL_DIR>
$ ./bin/sqoop.sh client
```

When Sqoop2 does not use MapR-SASL, any user that has access to run jobs on the cluster can start the Sqoop2 client.

- To start the Sqoop2 command line client with MapR-SASL authentication, enter:

```
$ cd <SQOOP_INSTALL_DIR>
$ ./bin/sqoop.sh client --custom
```

When Sqoop2 uses MapR-SASL, any user with a MapR ticket can start the Sqoop2 client.

Starting and Stopping the Sqoop2 Server

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To start the Sqoop2 server on a node called `node001`, enter the following command at the command line:

```
maprcli node services -name sqoop2 -action start -nodes node001
```

To stop the Sqoop2 server, enter the following command at the command line:

```
maprcli node services -name sqoop2 -action stop -nodes node001
```

Verifying Server Status

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Sqoop2 server uses port 12000. To verify server status, enter:

```
lsof -i:12000
```

The output of this command should look similar to this:

```
COMMAND   PID USER   FD   TYPE  DEVICE SIZE/OFF NODE NAME
java    14444 mapr  103u  IPv6 2795065      0t0  TCP *:12000 (LISTEN)

Logs:
/opt/mapr/sqoop/sqoop-2.0.0/logs/sqoop.log
/opt/mapr/sqoop/sqoop-2.0.0/logs/server/logs/catalina.out
```

Create Links and Jobs

Use connectors to create links to data sources and then create jobs to execute the data transfer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Create a link to each data source using the connector name.

```
sqoop:000>  create link --connector <connector-name>
```

For example, to create a link with the `kite-connector`:

```
sqoop:000>  create link --connector kite-connector
```

2. Use link names to create a job.

```
sqoop:000>  create job --from <link_name> --to <link_name>
```

last-updated: Apr 11, 2022

For more information about using connectors, see the Sqoop2 connector documentation for Sqoop 1.99.6 and Sqoop 1.99.7.

Note: Prior to using an FTP or an SFTP connector, verify that the associated FTP or SFTP server is configured.

Example Kite Connector Link and Job Configuration Data

The following example shows the types of prompts that you can expect when setting up links and jobs. It also provides tips that may be helpful when you configure links and jobs with the Kite Connector.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Kite Connector Link Configuration for MapR File System

```
sqoop:000> create link --connector
kite-connector
Name: kite_maprfs

Global configuration
MAPRFS or Hive Metastore URI:
maprfs:///
Hadoop conf directory: /opt/mapr/
hadoop/hadoop-2.7.0/etc/hadoop/
```

Note: Set the Hadoop conf directory to /opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/.

Kite Connector Job Configuration for MapR File System

```
Dataset URI: dataset:maprfs:///
<somefolder>
File format:
  0 : CSV
  1 : AVRO
  2 : PARQUET
Choose: 2
```

Kite Connector Link Configuration for Hive

```
sqoop:000> create link --connector
kite-connector
Name: kite_hive

Global configuration
MAPRFS or Hive Metastore URI:
<hostname>:9083
Hadoop conf directory: /opt/mapr/hive/
hive-1.2/conf/
```

Note: Set the Hadoop conf directory to the Hive conf directory.

Kite Connector Job Configuration for Hive

```
Dataset URI:
dataset:hive:databasename/tablename
File format:
  0 : CSV
  1 : AVRO
  2 : PARQUET
Choose: 2
```

last-updated: Apr 11, 2022

Submit Sqoop2 Jobs

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Use one of the following methods to submit Sqoop2 jobs:

- Submit jobs with the Sqoop2 client. See the Sqoop2 documentation.
- Submit jobs from Hue. See the Hue documentation. See the Hue documentation.

Sqoop 1.99.7 API Changes
The following APIs have been deprecated in Sqoop 1.99.7.

Instead of this deprecated API...	Use...
/v1/connectors - [GET]	/v1/connector/all - [GET]
/v1/connector/[cid] - [GET]	/v1/connector/[cname] - [GET]

Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Note:

SQL-on-Hadoop is an emerging space with several promising open-source technologies at various stages of maturity including Apache Drill, Apache Hive-on-Tez, Impala, Presto, Shark-on-Spark, Phoenix. MapR provides the broadest availability of these options to ensure that customers can pick the right tool for their use case.

MapR announces availability of Impala packages for MapR Converged Data Platform. Customers can easily install and run Impala on MapR clusters and evaluate its fit for their use cases. MapR will also provide build and installation support to help customers get started.

last-updated: Apr 11, 2022

Overview

Impala is an open source, interactive SQL engine for Hadoop that you can use to access data on MapR clusters. With Impala, you can use business intelligence (BI) tools to run ad-hoc queries directly on Hadoop. Impala provides the following benefits:

- Broad availability of Hadoop data to the business community
- Leverages familiar SQL tools and skill sets on Hadoop
- Full fidelity data analysis
- Cost savings by offloading from traditional DWH/Analytics platforms
- Time savings because you do not have to move around data

Impala uses the Apache Hive query language (HiveQL) and Hive metadata. You can use the most common SQL-92 features of HiveQL, including SELECT, joins, and aggregate functions to query data in your cluster. You can issue queries from the impala-shell command-line tool, or through an ODBC or JDBC client. When you submit a query, Impala works with other components in the cluster to process the query.

Impala uses the Hive metastore to store metadata. The Hive metastore is typically the same database that Hive uses to store metadata. Impala can access tables you create in Hive when they contain datatypes, file formats, and compression codecs that Impala supports.

If you have MapR Database configured to store table data, you can define the tables in Hive and then map them to equivalent tables in MapR Database. After you map the tables, you can use Impala to query the MapR Database tables and perform table joins between MapR Database and Hive tables.

The following table contains a list of components that work together to process a query issued to Impala:

Component	Description
Clients	The impala-shell, JDBC client, or ODBC client that you connect to Impala from. You issue a query to Impala from the client.
Hive Metastore	Stores information about the tables that Impala can access.
Impala (impalad, statestored, catalogd)	Impalad is a process that runs on designated nodes in the cluster. It coordinates and runs queries. Each node running the Impala process can receive, plan, and coordinate queries sent from a client. Statestored tracks the state of the Impalad processes in the cluster. Catalogd communicates new or updated metadata to all the other Impala nodes when Impala changes table data or metadata on a node.
MapR File System/MapR Database	MapR File System is the MapR filesystem that stores data files and tables. MapR Database stores MapR tables natively.

Impala Daemon

The Impala daemon (impalad) is the core Impala process. Install the impala server package on all nodes that you want to run the Impala service on. You can submit queries to any node configured with the Impala daemon. When you submit a query to a node running the Impala daemon process, the node becomes the central coordinator for the query. The coordinator distributes work to the other nodes running the Impala daemon process to complete the query request.

The coordinator node running the Impala daemon process completes the following tasks:

last-updated: Apr 11, 2022

- Accepts the query from the client
- Parallelizes queries and distributes pieces of the query to other impalad nodes
- Receives query results from other impalad nodes
- Builds the final result set for the query and passes it to the client
- Communicates with the statestore service

All nodes running the Impala daemon process perform the following tasks:

- Read and write data to files
- Transmit partial query results back to the coordinator
- Communicate with the statestore service

Impala Statestore

The Impala statestore service (statestored) verifies the health of nodes running the Impala daemon process. The node running the statestore service communicates node health to all nodes running the Impala daemon process. The statestore service ensures that impalad nodes only pass query work to active nodes running the Impala daemon process.

If the node running the statestore service goes offline, other Impala nodes continue the query work. If any of the other Impala nodes go offline while the statestore service is unavailable, query time may increase. The statestore service can automatically communicate with the Impala nodes and resume work when the node is back online.

Catalog Service

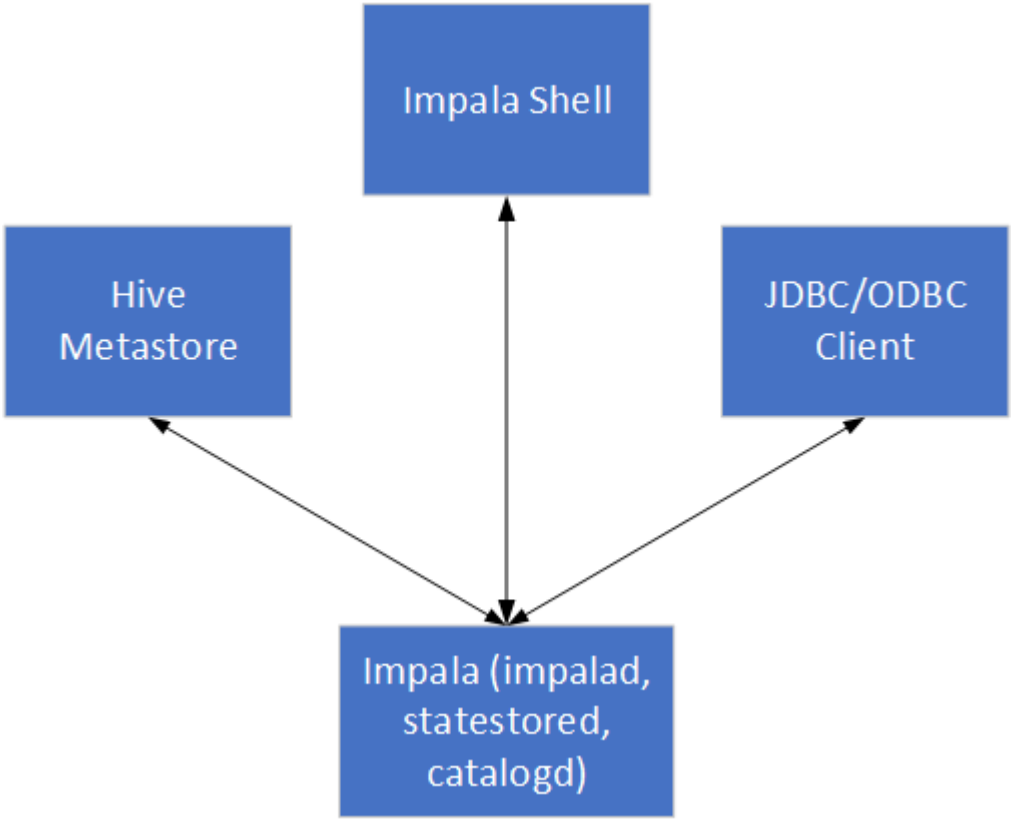
The catalog service (catalogd) resides on the same node as statestored. The catalog service communicates new or updated metadata to all of the other Impala nodes when Impala changes table data or metadata on one node. You no longer need to use the `REFRESH` or `INVALIDATE METADATA` statements after issuing the following statements to Impala:

- `CREATE TABLE`
- `ALTER TABLE`
- `DROP TABLE`
- `INSERT`
- `LOAD DATA`

The catalog service only works on operations performed through Impala. If you perform operations through the Hive shell or through MapR File System, you must issue the `REFRESH` and `INVALIDATE METADATA` statements. The catalog service broadcasts the results of the `REFRESH` and `INVALIDATE METADATA` operations to other Impala nodes so that you only have to issue the statements once.

The following image represents how the various components communicate:

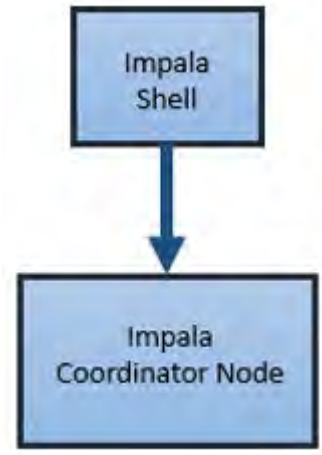
last-updated: Apr 11, 2022



Query Execution

Each node running the Impala service can receive, plan, and coordinate queries. The Impala daemon process on each node listens for requests from ports on each client. Requests from the impala-shell are routed to the impala daemons through one particular port. JDBC and ODBC requests are routed through other ports.

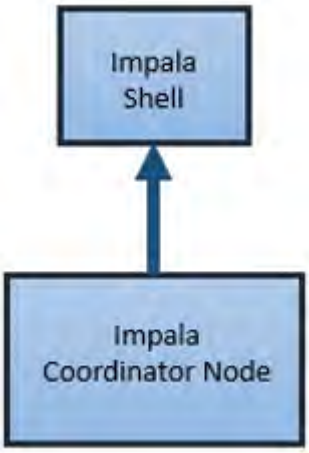
When you send a query to Impala, the client connects to a node running the Impala process. The node that the client connects to becomes the coordinator for the query.



The coordinator node parses the query into fragments and analyzes the query to determine what tasks the nodes running Impala must perform. The coordinator distributes the fragments across other nodes running the Impala daemon process. The nodes process the query fragments and return the data to the coordinator node.

last-updated: Apr 11, 2022

The coordinator node sends the result set back to the client.



New Features in Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Each release of Impala for MapR has new features for improved performance and functionality. Refer to the following sections for a list of new features in each MapR release of Impala:

New Features in Impala 2.10 for MapR

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Impala 2.10.0 for MapR introduces some new features that enhance the behavior and performance of Impala.

Functions

The following sections provide information about new and improved Impala functions:

String function, replace()

Faster than `regexp_replace()` for simple string substitutions.

Description: `replace(string initial, string target, string replacement)`

Purpose: Returns the initial argument with all occurrences of the target string replaced by the replacement string.

Return type: string

Usage notes: Because this function does not use any regular expression patterns, it is typically faster than `regexp_replace()` for simple string substitutions. If any argument is NULL, the return value is NULL. The matching is case-sensitive. If the replacement string contains another instance of the target string, the expansion is only performed once, instead of applying it again to the newly constructed string.

Example:

```
[localhost:21000] > select replace('hello world','world','earth');
Query: select replace('hello world','world','earth')
Query submitted at: 2018-02-08 05:10:11 (Coordinator: http://
localhost.lab:25000)
Query progress can be monitored at: http://localhost:25000/query_plan?
query_id=5e4686bd9b870724:f281e86f00000000
+-----------------------------------------+
| replace('hello world', 'world', 'earth') |
+-----------------------------------------+
| hello earth |
+-----------------------------------------+
Fetched 1 row(s) in 0.02s
```

Date/time function, last_day()

For finding the date corresponding to the last day of a particular month.

Description: `last_day(timestamp t)`

Purpose: timestamp

Usage notes: If the input argument does not represent a valid Impala TIMESTAMP including both date and time portions, the function returns NULL. For example, if the input argument is a string that cannot be implicitly cast to TIMESTAMP, does not include a date portion, or is out of the allowed range for Impala TIMESTAMP values, the function returns NULL.

Example:

```
[localhost:21000] > select
> now() as right_now
> , dayofmonth(now()) as day
> , extract(day from now()) as also_day
> , dayofmonth(last_day(now())) as last_day
> , extract(day from last_day(now())) as also_last_day;
Query: select now() as right_now
, dayofmonth(now()) as day
, extract(day from now()) as also_day
, dayofmonth(last_day(now())) as last_day
, extract(day from last_day(now())) as also_last_day
Query submitted at: 2018-02-08 05:07:59 (Coordinator: http://
localhost:25000)
Query progress can be monitored at: http://localhost:25000/query_plan?
query_id=5147af5bc88d7632:1e42f5c100000000
+-------------------------------+-----+----------+----------+---------------+

| right_now | day | also_day | last_day | also_last_day |
+-------------------------------+-----+----------+----------+---------------+

| 2018-02-08 05:07:59.999909000 | 8 | 8 | 28 | 28 |
+-------------------------------+-----+----------+----------+---------------+
```

Date/time function, last_day()
Provides a simple way to get a stable, interoperable representation of a TIMESTAMP value without using a chain of functions to convert between representations and apply a specific timezone.

Other Features

Impala Query History

You can re-execute previously queries via `@query_number(from start)` or `@-query_number(from end)`:

```
[localhost:21000] >@1;
Rerunning invalidate metadata;
Query: invalidate metadata
[localhost:21000] > @-1;
Rerunning show tables in default;
Query: show tables in default
```

Drop partitions via special symbols (<, >, <>, !=, <=, >=)

ALTER TABLE query for DROP partition can use special symbols for drop range of the partitions:

```
ALTER TABLE db.table DROP PARTITION (partition<=partition_value);
```

CREATE TABLE with SORT BY

Introduced SORT BY clause in the CREATE TABLE statement:

```
CREATE TABLE sorted_tbl (id int, name char(22), age int) SORT BY (age);
```

TRUNK() can now apply to numeric types (FLOAT, DOUBLE, and DECIMAL) in addition to TIMESTAMP

Although this functionality was already available through the truncate() function, the new signatures for trunc() make it easier to port code from other popular database systems to Impala.

Support ENUM type for parquet tables

The CREATE TABLE LIKE PARQUET statement can now handle Parquet files produced outside of Impala and containing ENUM types. The ENUM columns become STRING columns in the target table, and the ENUM values are turned into corresponding STRING values.

New Features in Impala 2.7.0 for MapR

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Impala 2.7.0 for MapR introduces some new features that enhance the behavior and performance of Impala.

Performance Improvements

Impala 2.7.0 for MapR introduces the following performance improvements:

- Overall performance improvements for secure clusters.
- Overall performance improvements for join queries. A pre-fetching mechanism is used while building the in-memory hash table to evaluate join predicates.
- Improved query time for queries run against DECIMAL columns in Avro tables. The code that parses DECIMAL values from Avro now uses native code generation.
- Improved efficiency in LLVM code generation that can reduce codegen time, especially for short queries.
- Improved performance reading Parquet files.
- Improved performance for top-N queries, or queries that include both ORDER BY and LIMIT clauses.

last-updated: Apr 11, 2022

Support for the Amazon S3 File System

You can use Impala to query data in the Amazon S3 filesystem. Impala can query any file type supported by the S3 filesystem.

To run Impala on the Amazon S3 filesystem, add the properties below to the core-site.xml file, copy the core-site.xml file to the IMPALA_CONF_DIR (located in /opt/mapr/impala/impala-2.7.0/conf), and restart the MapR Warden service.

```
<property>
<name>fs.s3a.access.key</name>
<value><ACCESS_KEY></value>
</property>

<property>
<name>fs.s3a.secret.key</name>
<value><SECRET_KEY></value>
</property>
```

Note:

If you plan to run Impala on a secure cluster, create and add the root Certificate Authority (CA) certificate that signed the Amazon S3 certificate to the truststore. Alternatively, you can add the following property to core-site.xml:

```
<property>
  <name>fs.s3a.connection.ssl.enabled</name>
  <value>false</value>
</property>
```

Impala Web User Interface Improvements

In version 2.7.0, Impala provides the following Web User Interface improvements:

- Forced session expiry from the **/sessions** tab. You can force a session to end by clicking on the link provided in the tab.
- Additional Impala memory information on the **/memz** tab.
- A **Memory** tab on the **Details** page for a query.

Set Column Stats Clause

In version 2.7.0, you can use the SET COLUMN STATS clause with the ATLER TABLE statement to set a specific statistical value for a column. You can set a column to the number of distinct values, number of nulls, maximum size, or average size using the respective case-insensitive symbolic names:

`numDVs, numNulls, avgSize, maxSize`

Note: This operation applies to an entire table, not a specific partition. You must use single quotation marks around the symbolic name and value.

Run the ALTER TABLE command with the SET COLUMN STATS clause from the impala-shell, as shown in the following example:

```
$ impala-shell -i localhost
...
[localhost:21000] > create table example (id int);
[localhost:21000] > insert into example values (1), (2), (3);
[localhost:21000] > show column stats example;
+--------+--------+------------------+--------+----------+----------+
```

```
| Column | Type   | #Distinct Values | #Nulls | Max Size | Avg Size |
+--------+--------+------------------+--------+----------+----------+
| id     | INT    | -1               | -1     | 4        | 4        |
+--------+--------+------------------+--------+----------+----------+
[localhost:21000] > alter table example set column stats id
('numDvs'='3','numNulls'='0');
[localhost:21000] > show column stats example;
+--------+--------+------------------+--------+----------+----------+
| Column | Type   | #Distinct Values | #Nulls | Max Size | Avg Size |
+--------+--------+------------------+--------+----------+----------+
| id     | INT    | 3                | 0      | 4        | 4        |
+--------+--------+------------------+--------+----------+----------+
```

SOURCE Command

The SOURCE command runs SQL statements from an SQL source file. You issue the SOURCE command from the impala-shell. The source file can contain SQL statements and impala-shell commands, as well as additional SOURCE commands. Each statement or command must end with a semicolon (;), except for the last statement or command in the file.

Including additional SOURCE commands inside the source file allows you to set up flexible statement sequences for use cases, such as schema setup, ETL, or reporting.

Run the SOURCE command from the impala-shell, as shown in the following example:

```
$ cat example.sql
show databases;
show tables in customers;
$ impala-shell -i localhost
...
[localhost:21000] > source example.sql;
Query: show databases
+------------------+-------------------------------------------------+
| name             | comment                                         |
+------------------+-------------------------------------------------+
| customers        | Stores customer records                         |
| default          | Default Hive database                           |
+------------------+-------------------------------------------------+
Fetched 2 row(s) in 0.06s
Query: show tables in customers
+--------------+
| name         |
+--------------+
| customer_001 |
| customer_002 |
| customer_003 |
| customer_004 |
| customer_005 |
+--------------+
Fetched 5 row(s) in 0.03s
```

Additionally, you can run the SOURCE command on an SQL file that contains statements and calls a SOURCE command from another SLQ file, as shown in the following example:

```
$ cat example1.sql
show databases;
source example2.sql
$ cat example2.sql
show tables in customers;

$ impala-shell -i localhost
...
```

```
[localhost:21000] > source example1.sql;
Query: show databases
+------------------+-----------------------------------------------+
| name             | comment                                       |
+------------------+-----------------------------------------------+
| customers        | Stores customer records                       |
| default          | Default Hive database                         |
+------------------+-----------------------------------------------+
Fetched 2 row(s) in 0.06s
Query: show tables in customers
+--------------+
| name         |
+--------------+
| customer_001 |
| customer_002 |
| customer_003 |
| customer_004 |
| customer_005 |
+--------------+
Fetched 5 row(s) in 0.03s
```

New Runtime Filter Options

The Runtime Filtering feature was introduced in Impala 2.5.0 to optimize queries against partitioned tables or to evaluate join conditions when partial table data is needed. Impala 2.7.0 introduces two new filtering options that fine-tune the sizes of the Bloom filter structures used in runtime filtering:

The following table lists the new query options and their descriptions. Only modify these options when tuning long-running queries with a combination of large partitioned tables and joins on large tables.

Option	Description	Type	Default
RUNTIME_FILTER_MIN_SIZE	Adjusts runtime filtering settings. Defines the minimum size for a filter, regardless of the estimates produced by the planner. This setting overrides any smaller value set for the RUNTIME_BLOOM_FILTER_SIZE option. Impala rounds filter sizes up to the nearest power of two.	integer	0 (indicates that the value from the corresponding impalad startup option is used)
RUNTIME_FILTER_MAX_SIZE	Adjusts runtime filtering settings. Defines the maximum size for a filter, regardless of the estimates produced by the planner. This setting overrides any smaller value set for the RUNTIME_BLOOM_FILTER_SIZE option. Impala rounds filter sizes up to the nearest power of two.	integer	0 (indicates that the value from the corresponding impalad startup option is used)

New Features in Impala 2.5.0 for MapR

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Impala 2.5.0 for MapR introduces some new features that enhance the behavior and performance of Impala.

Performance Improvements

The following updates improve the performance of Impala:

- Impala caches file handles to avoid the overhead of repeatedly opening the same file which improves I/O performance.
- Basic query types, such as counting the elements of a complex column, use an optimized code path that improves the performance of queries involving nested complex types.
- Impala uses code generation in certain parts of queries, such as evaluating functions in the WHERE clause, even when code generation is not used in some phases of query execution.
- Using DECIMAL values in a GROUP BY clause triggers code generation optimization, which speeds up queries that group by values, such as prices, and improves performance and reliability of the DECIMAL data type.
- Improved coordination and parallelization between Impala nodes results in faster query startup time for queries that involve tables with many partitions or complex queries with many fragments.
- The coordinator node requires less memory, making it faster and less resource-intensive when performing joins that involve several tables with thousands of partitions.
- Impala only re-evaluates metadata for partitions that are affected by a DDL operation, not all partitions in the table. While a DDL or insert statement is in progress, other Impala statements that attempt to modify metadata for the same table wait until the first one finishes, improving performance and reliability of DDL and insert operations on partitioned tables with a large number of partitions.
- A new query option, OPTIMIZE_PARTITION_KEY_SCANS, speeds up aggregation operations that involve only the partition key columns of partitioned tables. This optimization can produce different results when files in a partition are manually deleted or are empty.

Security

This release of Impala provides the following new security features:

Column-Level Authorization

You can use column-level authorization to define access to particular columns within a table instead of the entire table. Creating views to set up authorization schemes for subsets of information is not required. This functionality requires Sentry 1.6

Column-level authorization has the following syntax:

```
GRANT SELECT(column_name) ON TABLE
table_name TO ROLE role_name;
REVOKE SELECT(column_name) ON TABLE
table_name FROM ROLE role_name;
```

LDAP Password Retrieval

You can use a new impala-shell command line option, `--ldap_password_cmd`, to retrieve the LDAP password. The resulting password is used to authenticate the impala-shell command with the LDAP server.

Scripting Capability Improvements

Scripting capability improvements for the impala-shell enable you to define substitution variables and use them in SQL statements that you execute through command-line options. The `--var` command-line option

last-updated: Apr 11, 2022

passes key-value pairs to the impala-shell. The shell substitutes the values into an SQL statement where it contains the notation `${var:varname}` before Impala executes the query.

You can use the SET and UNSET commands in a session to define or clear substitution variables with the `SET|UNSET VAR:variable_name=value` notation or a script file processed by the `-f` option. You cannot define your own substitution variables through the SET statement in a JDBC or ODBC application.

Dynamic Partition Pruning

Dynamic partition pruning is a technique that prevents Impala from reading data files from partitions that are not included in the result set. This occurs when a query references a partition key column in the WHERE clause and the column values are unknown until the query runs. Impala evaluates the predicate and skips the I/O for unnecessary partitions. This technique is useful for join queries that involve large partitioned tables.

You can control the level of dynamic partition pruning through the `RUNTIME_FILTER_MODE` query option. By default, this option is enabled and set at medium level: `RUNTIME_FILTER_MODE=LOCAL)`. The maximum setting uses more memory for queries than in previous releases. You can set `RUNTIME_FILTER_MODE=GLOBAL` to fully enable dynamic partition pruning. Before you run a query, check the EXPLAIN output to verify that partition pruning is applied.

Nested Loop Join Queries

Nested loop joins make additional non-equijoin queries possible and optimize queries that retrieve values from complex type columns. Some join queries that previously needed equality comparisons can use operators.

Live Progress Reporting

The live progress reporting feature enables you to monitor the status of queries through two command-line options, --live_progress and --live_summary. The live progress option provides an interactive progress bar that represents the percent completion for queries submitted through the impala-shell command. The live summary option summarizes the work performed in various stages of a query with the measurements updated in real time as the query progresses. These query options are disabled by default. To enable these options, start the impala-shell with the --live_progress and --live_summary command-line options, or use the SET command with LIVE_SUMMARY and LIVE_PROGRESS during a session:

```
set live_progress=true|false;
set live_summary=true|false;
```

Runtime Filtering

Runtime filtering is technique where Impala determines the filter conditions as a query runs and broadcasts the information to the Impala nodes reading a table. This technique is useful for optimizing queries against partitioned tables or to evaluate join conditions when only partial table data is needed. The technique eliminates the I/O required to read all of the partitioned data, as well as unnecessary network traffic.

The following table lists the new query options related to runtime filtering:

Option	Description	Type	Default
RUNTIME_FILTER_MODE	Adjusts the settings, turns the feature on and off, and controls how extensively the filters are transmitted between hosts.	numeric (0, 1, 2) or corresponding mnemonic strings (OFF, LOCAL, GLOBAL)	1 (same as LOCAL)
MAX_NUM_RUNTIME_FILTERS	Sets an upper limit on the number of runtime filters produced for each query.	integer	10

last-updated: Apr 11, 2022

RUNTIME_BLOOM_FILTER_SIZE	Size (in bytes) of Bloom filter data structure used by the runtime filtering feature.	integer	1048576 (1 MB) Max: 16 MB
RUNTIME_FILTER_WAIT_TIME_MS	Maximum filter wait time in milliseconds. By default, each scan node waits for up to 1 second (1000 milliseconds) for filters to arrive. If all filters have not arrived within the specified interval, the scan node proceeds, using whatever filters did arrive to help avoid reading unnecessary data. If a filter arrives after the scan node begins reading data, the scan node applies that filter to the data that is read after the filter arrives, but not to the data that was already read.	integer	1000 milliseconds
DISABLE_ROW_RUNTIME_FILTERING	Reduces the scope of the runtime filtering feature. Queries still dynamically prune partitions, but do not apply the filtering logic to individual rows within partitions. Only applies to queries against Parquet tables. For other file formats, Impala only prunes at the level of partitions, not individual rows.	Boolean; recognized values are 1 and 0, or true and false; any other value interpreted as false	false

Data Types

Impala now supports new complex data types that can encode multiple named fields, positional items, or key-value pairs within a single column. You can combine these types to produce nested types with arbitrarily deep nesting. Currently, complex data types are only supported for the Parquet file format.

The following table lists the complex data types and the syntax for each:

Data Type	**Syntax**
STRUCT	*column_name* STRUCT < *name* : *type* [COMMENT '*comment_string*'], ... > type ::= *primitive_type* | *complex_type*
ARRAY	*column_name* ARRAY < *type* > type ::= *primitive_type* | *complex_type*
MAP	*column_name* MAP < *primitive_type*, *type* > type ::= *primitive_type* | *complex_type*

Operators

The following table provides the new and improved operators with descriptions and syntax:

last-updated: Apr 11, 2022

Operator	Description	Syntax
ILIKE	Improvements enable the ILIKE operator to perform case-insensitive wildcard matches or regular expression matches, rather than explicitly converting column values with UPPER or LOWER.	*string_expression* ILIKE *wildcard_expression* *string_expression* NOT ILIKE *wildcard_expression*
IREGEXPR	Improvements enable the IREGEXPR operator to perform case-insensitive wildcard matches or regular expression matches, rather than explicitly converting column values with UPPER or LOWER.	*string_expression* IREGEXP *regular_expression*
IS [NOT] DISTINCT FROM	Compares values for a true or false result, even if one or both values are NULL. The IS NOT DISTINCT FROM operator, or its equivalent <=> notation, improves the efficiency of join queries that treat key values that are NULL in both tables as equal.	*expression1* IS DISTINCT FROM *expression2* *expression1* IS NOT DISTINCT FROM *expression2* *expression1* <=> *expression2*

Statements

The following table lists new or improved statements with their descriptions and syntax:

Statement	Description	Syntax
TRUNCATE TABLE	Removes all data from a table without removing the table itself. The statement accepts the IF EXISTS clause, making TRUNCATE TABLE easier to use in setup or ETL scripts where the table might or might not exist.	TRUNCATE TABLE [IF EXISTS] [*db_name*.]*table_name*
CREATE TABLE AS SELECT	The CREATE TABLE AS SELECT statement accepts a PARTITIONED BY clause. You can create a partitioned table and insert data into the table with a single statement.	CREATE [EXTERNAL] TABLE [IF NOT EXISTS] *db_name*.]*table_name* [PARTITIONED BY (*col_name*[, ...])] [COMMENT '*table_comment*'] [WITH SERDEPROPERTIES ('*key1*'='*value1*', '*key2*'='*value2*', ...)] [[ROW FORMAT *row_format*] [STORED AS *file_format*]] [LOCATION '*hdfs_path*'] [TBLPROPERTIES ('*key1*'='*value1*', '*key2*'='*value2*', ...)] [CACHED IN '*pool_name*' [WITH REPLICATION = *integer*] | UNCACHED] AS *select_statement*

last-updated: Apr 11, 2022

SHOW DATABASES	The SHOW DATABASES statement returns two columns rather than one. The second column includes the associated comment string, if it exists, for each database.	SHOW DATABASES;
DESCRIBE	The DESCRIBE statement displays metadata about a database.	DESCRIBE DATABASE db_name;
DROP DATABASE	The DROP DATABASE statement works for a nonempty database. When you specify the optional CASCADE clause, any tables in the database are dropped before the database itself is removed.	DROP (DATABASE|SCHEMA) [IF EXISTS] *database_name* [RESTRICT | CASCADE];
DROP TABLE/ALTER TABLE DROP PARTITION	The DROP TABLE, ALTER TABLE, and DROP PARTITION statements have an optional keyword, PURGE. PURGE causes Impala to immediately remove the relevant data files rather than sending them to the trashcan. This feature can help to avoid out-of-space errors on storage devices, and to avoid files being left behind in case of a problem with the trashcan. PURGE works when the trashcan is enabled.	DROP TABLE [IF EXISTS] [db_name.]table_name [PURGE] ALTER TABLE name { ADD [IF NOT EXISTS] | DROP [IF EXISTS] } PARTITION (partition_spec) [PURGE]

Functions

The following sections provide information about new and improved Impala functions.

User-Defined Functions

User-defined functions written in C++ persist when the catalog service is restarted. You no longer have to run the CREATE FUNCTION statements again after a restart. You must still reissue the CREATE FUNCTION statement for any Java-based user-defined functions. User-defined aggregate functions have more flexibility for intermediate data types.

Analytic (Window) Functions

The following table lists the new analytic functions:

Function	Description	Syntax

PERCENT_RANK	Calculates the rank, expressed as a percentage, of each row within a group of rows. If rank is the value for that same row from the RANK() function (from 1 to the total number of rows in the partition group), then the PERCENT_RANK() value is calculated as (*rank* - 1) / (*rows_in_group* - 1). If there is only a single item in the partition group, its PERCENT_RANK() value is 0. The ORDER BY clause is required. The PARTITION BY clause is optional. The window clause is not allowed.	PERCENT_RANK (*expr*) OVER ([*partition_by_clause*] *order_by_clause*)
NTILE	Returns the "bucket number" associated with each row, between 1 and the value of an expression. For example, creating 100 buckets puts the lowest 1% of values in the first bucket, while creating 10 buckets puts the lowest 10% of values in the first bucket. Each partition can have a different number of buckets. The ORDER BY clause is required. The PARTITION BY clause is optional. The window clause is not allowed.	NTILE (*expr* [, *offset* ...] OVER ([*partition_by_clause*] *order_by_clause*)

CUME_DIST	Returns the cumulative distribution of a value. The value for each row in the result set is greater than 0 and less than or equal to 1. The ORDER BY clause is required. The PARTITION BY clause is optional. The window clause is not allowed.	CUME_DIST (*expr*) OVER ([*partition_by_clause*] *order_by_clause*)

Math Functions

The following table lists the new math functions:

Function	Description	Return Type
cot(double a)	Returns the cotangent of the argument.	double
factorial(integer_type a)	Computes the factorial of an integer value and works with any integer type. You can use either the factorial() function or the ! operator. The factorial of 0 is 1. The factorial() function returns 1 for any negative value. The maximum positive value for the input argument is 20; a value of 21 or greater overflows the range for a BIGINT and causes an error.	bigint
radians(double a)	Converts the argument value from degrees to radians.	double

String Functions

The following table lists the new string functions:

Function	Description	Return Type

btrim(string a), btrim(string a, string chars_to_trim)	Removes all instances of one or more characters from the start and end of a STRING value. By default, removes only spaces. If a non-NULL optional second argument is specified, the function removes all occurrences of characters in that second argument from the beginning and end of the string.	string
chr(int character_code)	Returns a character specified by a decimal code point value. The interpretation and display of the resulting character depends on your system locale. Because consistent processing of Impala string values is only guaranteed for values within the ASCII range, only use this function for values corresponding to ASCII characters. In particular, parameter values greater than 255 return an empty string.	string

last-updated: Apr 11, 2022

regexp_like(string source, string pattern[, string options])	Returns true or false to indicate whether the source string contains anywhere inside it the regular expression given by the pattern. The optional third argument consists of letter flags that change how the match is performed, such as i for case-insensitive matching.	boolean
split_part(string source, string delimiter, bigint n)	Returns the nth field within a delimited string. The fields are numbered starting from 1. The delimiter can consist of multiple characters, not just a single character. All matching of the delimiter is done exactly, not using any regular expression patterns.	string

Date/Time Functions

The following table lists the new date and time functions:

Function	Description	Return Type
int_months_between(timestamp newer, timestamp older)	Returns the number of months between the date portions of two TIMESTAMP values, as an INT representing only the full months that passed.	int

months_between(timestamp newer, timestamp older)	Returns the number of months between the date portions of two TIMESTAMP values. Can include a fractional part representing extra days in addition to the full months between the dates. The fractional component is computed by dividing the difference in days by 31 (regardless of the month).	double
timeofday()	Returns a string representation of the current date and time, according to the time of the local system, including any time zone designation.	string
timestamp_cmp(timestamp t1, timestamp t2)	Tests if one TIMESTAMP value is newer than, older than, or identical to another TIMESTAMP.	int (either -1, 0, 1, or NULL)

Bit Manipulation Functions

The following table lists the new bit manipulation functions:

Function	Description	Return Type
bitand(integer_type a, same_type b)	Returns an integer value representing the bits that are set to 1 in both of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. Equivalent to the & binary operator.	Same as the input value

bitnot(integer_type a)	Inverts all the bits of the input argument. Equivalent to the ~ unary operator.	Same as the input value
bitor(integer_type a, same_type b)	Returns an integer value representing the bits that are set to 1 in either of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. Equivalent to the | binary operator.	Same as the input value
bitxor(integer_type a, same_type b)	Returns an integer value representing the bits that are set to 1 in one but not both of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. Equivalent to the ^ binary operator.	Same as the input value
countset(integer_type a [, int zero_or_one])	By default, returns the number of 1 bits in the specified integer value. If the optional second argument is set to zero, it returns the number of 0 bits instead.	Same as the input value

last-updated: Apr 11, 2022

getbit(integer_type a, int position)	Returns a 0 or 1 representing the bit at a specified position. The positions are numbered right to left, starting at zero. The position argument cannot be negative. When you use a literal input value, it is treated as an 8-bit, 16-bit, and so on value, the smallest type that is appropriate. The type of the input value limits the range of the positions. Cast the input value to the appropriate type if you need to ensure it is treated as a 64-bit, 32-bit, and so on value.	Same as the input value

rotateleft(integer_type a, int positions)	Rotates an integer value left by a specified number of bits. As the most significant bit is taken out of the original value, if it is a 1 bit, it is "rotated" back to the least significant bit. Therefore, the final value has the same number of 1 bits as the original value, just in different positions. Specifying a second argument of zero leaves the original value unchanged. Rotating a -1 value by any number of positions still returns -1, because the original value has all 1 bits and all the 1 bits are preserved during rotation. Similarly, rotating a 0 value by any number of positions still returns 0. Rotating a value by the same number of bits as in the value returns the same value. Because this is a circular operation, the number of positions is not limited to the number of bits in the input value. For example, rotating an 8-bit value by 1, 9, 17, and so on positions returns an identical result in each case.	Same as the input value

last-updated: Apr 11, 2022

rotateright(integer_type a, int positions)	Rotates an integer value right by a specified number of bits. As the least significant bit is taken out of the original value, if it is a 1 bit, it is "rotated" back to the most significant bit. Therefore, the final value has the same number of 1 bits as the original value, just in different positions. Specifying a second argument of zero leaves the original value unchanged. Rotating a -1 value by any number of positions still returns -1, because the original value has all 1 bits and all the 1 bits are preserved during rotation. Similarly, rotating a 0 value by any number of positions still returns 0. Rotating a value by the same number of bits as in the value returns the same value. Because this is a circular operation, the number of positions is not limited to the number of bits in the input value. For example, rotating an 8-bit value by 1, 9, 17, and so on positions returns an identical result in each case.	Same as the input value

last-updated: Apr 11, 2022

setbit(integer_type a, int position [, int zero_or_one])	By default, changes a bit at a specified position to a 1, if it is not already. If the optional third argument is set to zero, the specified bit is set to 0 instead. If the bit at the specified position was already 1 (by default) or 0 (with a third argument of zero), the return value is the same as the first argument. The positions are numbered right to left, starting at zero. (Therefore, the return value could be different from the first argument even if the position argument is zero.) The position argument cannot be negative. When you use a literal input value, it is treated as an 8-bit, 16-bit, and so on value, the smallest type that is appropriate. The type of the input value limits the range of the positions. Cast the input value to the appropriate type if you need to ensure it is treated as a 64-bit, 32-bit, and so on value.	Same as the input value

last-updated: Apr 11, 2022

shiftleft(integer_type a, int positions)	Shifts an integer value left by a specified number of bits. As the most significant bit is taken out of the original value, it is discarded and the least significant bit becomes 0. The final value has either the same number of 1 bits as the original value, or fewer. Shifting an 8-bit value by 8 positions, a 16-bit value by 16 positions, and so on produces a result of zero. Specifying a second argument of zero leaves the original value unchanged. Shifting any value by 0 returns the original value. Shifting any value by 1 is the same as multiplying it by 2, as long as the value is small enough; larger values eventually become negative when shifted, as the sign bit is set. Starting with the value 1 and shifting it left by N positions gives the same result as 2 to the Nth power, or pow(2,N).	Same as the input value

shiftright(integer_type a, int positions)	Shifts an integer value right by a specified number of bits. As the least significant bit is taken out of the original value, it is discarded and the most significant bit becomes 0. Therefore, the final value has either the same number of 1 bits as the original value, or fewer. Shifting an 8-bit value by 8 positions, a 16-bit value by 16 positions, and so on produces a result of zero. Specifying a second argument of zero leaves the original value unchanged. Shifting any value by 0 returns the original value. Shifting any positive value right by 1 is the same as dividing it by 2. Negative values become positive when shifted right.	Same as the input value

Miscellaneous Functions

The following table lists a new miscellaneous function:

Function	Description	Syntax

last-updated: Apr 11, 2022

uuid()	The uuid() function generates an alphanumeric value that you can use as a guaranteed unique identifier. The uniqueness applies across tables in cases where an ascending numeric sequence is not suitable.	select uuid();
typeof(type value)	A type conversion function that returns the name of the data type corresponding to an expression. For types with extra attributes, such as length for CHAR and VARCHAR, or precision and scale for DECIMAL, includes the full specification of the type.	select typeof(type value); Returns the type For example, select typeof('xyz'); returns STRING For example, select typeof(5.30001 / 2342.1); returns DECIMAL(13,11)

New Features in Impala 2.2.0 for MapR

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Spill to Disk

Impala 2.2.0 for MapR introduces the "spill to disk" feature which prevents queries that use memory-intensive operations, such as large sort, join, aggregation, or analytic function operations, from failing with out-of-memory errors. Impala automatically writes data to disk when queries with memory-intensive operations exceed the set memory limit on an Impala node. You can enable or disable the spill to disk feature in `/opt/mapr/impala/impala-<version>/conf/env.sh`. You can also change the DISABLE_UNSAFE_SPILLS setting at the session level to allow or prevent data spills.

See Spill to Disk for more information about this feature.

Security

You can use SQL statements to create roles and grant/revoke privileges on objects.

Note: This security functionality requires Sentry 1.6 .

The following statements create roles and grant privileges:

- CREATE ROLE - creates roles for users and groups

last-updated: Apr 11, 2022

- GRANT - grants privileges on objects

The following statements revoke roles and privileges:

- DROP ROLE - removes roles from the metastore database
- REVOKE - revokes roles or privileges on a specified object from groups

The following statements display role related information:

- SHOW GRANT ROLE - list all the grants for the given role name
- SHOW ROLES - displays roles
- SHOW ROLE GRANT GROUP - lists all the roles assigned to a specified group

Smaller Parquet and MapR File System Block Size

The default setting for the `PARQUET_FILE_SIZE` query option has changed from 1 GB to 256 MB. This makes the file more accurate and reduces the amount of memory reserved during an INSERT into Parquet tables, potentially avoiding out-of-memory errors and improving scalability when inserting data into Parquet tables

.impalarc Configuration File

You can specify impala-shell options from the command line or in the `$HOME/.impalarc` configuration file. You can define a set of default options for your impala-shell environment in the`$HOME/.impalarc` configuration file. For every command line option, there is an equivalent setting in the `$HOME/.impalarc` configuration file. Options specified from the impala-shell command line override corresponding options in the configuration file. See Impala-Shell Command Line Options for more information. The configuration file must contain a header label `[impala]`, followed by the options specific to impala-shell. This is a standard convention for configuration files that enables a single file to hold configuration options for multiple applications. To specify a different filename or path for the configuration file, specify the argument

```
--config_file=path_to_config_file
```

on the impala-shell command line.

Files

Impala can read GZIP, BZIP, or Snappy compressed text files.The files do not require special table settings to work in an Impala text table. Impala ignores temporary files typically produced by ETL tools, such as those with the suffixes .copying and .tmp.

Log Rotation

Log rotation is the automatic removal of unneeded or old log files. By default, Impala switches out old log files every 5 seconds, based on the default interval specified in the `logbufsecs` setting. The `-max_log_files` configuration option specifies how many log files to keep at each severity level (INFO, WARNING, ERROR, and FATAL). You can configure the

`-max_log_files` option for each Impala daemon (impalad, statestored, and catalogd) in the `env.sh`configuration file. By default, Impala preserves the latest 10 log files for each severity level and removes old logs based on the logbufsecs setting. Setting `-max_log_files` to 0 preserves all of the log files. This setting requires manual log rotation. Setting`-max_log_files` to 1 preserves only the latest log file.

Impala Debug Web Interface

The Impala debug web interface displays a visual representation of the query plan. You can access the Impala debug web interface at

`http://<impala-node-hostname>:25000/`. To see visual representation of the query plan, select the **/queries** tab and click **Details** for a particular query. The Details page includes a Plan tab with a plan diagram for which you can zoom in or out using your mouse or trackpad.

Date and Time Improvements

Flexibility to interpret `TIMESTAMP` values using the UTC time zone or using the local time zone, for compatibility with `TIMESTAMP` values produced by Hive.

Startup flags for the impalad daemon enable a higher level of compatibility with `TIMESTAMP` values written by Hive and more flexibility for working with date and time data using the local time zone instead of UTC. To enable these features, set the impalad startup flags `-use_local_tz_for_unix_timestamp_conversions=true` and `-convert_legacy_hive_parquet_utc_timestamps=true`.

The `-use_local_tz_for_unix_timestamp_conversions` setting controls how the `unix_timestamp()`, `from_unixtime()`, and `now()` functions handle time zones. By default, this setting disabled, and Impala considers all `TIMESTAMP` values to be in the UTC time zone when converting to or from Unix time values. When this setting is enabled, Impala treats `TIMESTAMP` values passed to or returned from these functions to be in the local time zone. When this setting is enabled, verify that all hosts in the cluster have the same timezone settings to avoid inconsistent results depending on which host reads or writes `TIMESTAMP` data.

The `-convert_legacy_hive_parquet_utc_timestamps` setting causes Impala to convert `TIMESTAMP` values to the local time zone when it reads them from Parquet files written by Hive. This setting only applies to data using the Parquet file format where Impala can use metadata in the files to reliably determine that the files were written by Hive. If in the future Hive changes the way it writes `TIMESTAMP` data in Parquet, Impala will automatically handle that new `TIMESTAMP` encoding.

Built-in functions that accept or return integers representing TIMESTAMP values use the BIGINT type for parameters and return values rather than INT. This change prevents the date and time functions from having overflow errors that would otherwise occur on January 19th, 2038 (known as the "Year 2038 problem" or "Y2K38 problem"). This change affects the from_unixtime() and unix_timestamp() functions. You might need to change application code that interacts with these functions, change the types of columns that store the return values, or add CAST() calls to SQL statements that call these functions.

Analytic Functions

Analytic (window) functions operate on a set of rows and return a single value for each row from the underlying query. The term "window" describes the set of rows on which the function operates. A window function uses values from the rows in a window to calculate the returned values. When you use a window function in a query, you define the window using the OVER() clause. The OVER() clause (window clause) differentiates window functions from other analytical and reporting functions.

As of Impala 2.2.0, you can use the following analytic functions in queries:

- MAX()
- MIN()
- SUM()
- COUNT()
- AVG()

- RANK()
- LAG()
- LEAD()
- FIRST_VALUE()

The analytic functions support the following syntax:

```
function(args) OVER([partition_by_clause] [order_by_clause [window_clause]])
partition_by_clause ::= PARTITION BY expr [, expr ...]order_by_clause ::=
ORDER BY expr  [ASC | DESC] [NULLS FIRST | NULLS LAST] [, expr [ASC |DESC]
[NULLS FIRST | NULLS LAST] ...]
```

The window clause supports the following syntax:

```
ROWS BETWEEN [ { m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT
ROW | { UNBOUNDED | n } FOLLOWING] ]
```

```
RANGE BETWEEN [ {m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT
ROW | { UNBOUNDED | n } FOLLOWING] ]
```

Query Options

You issue query options to Impala using the SET command. SET has been promoted to an SQL statement and can be used in client applications through the JDBC and ODBC APIs.

The following table lists new query options that you can use with the SET statement:

APPX_COUNT_DISTINCT()	Allows multiple COUNT(DISTINCT) operations within a single query. When used in a query, Impala rewrites each COUNT(DISTINCT) to use the NDV() function, resulting in an approximate count rather than precise. Default is`false` (shown as 0 in output of `SET` statement). Syntax: `set APPX_COUNT_DISTINCT=true|false;`
SET EXEC_SINGLE_NODE_ROWS_THRESHOLD	This query option controls how many rows constitute a small query providing a guideline for when to turn optimizations on or off which prevents the unnecessary overhead of parallelizing and generating native code. Impala can complete small queries quickly and free-up YARN resources and admission control slots for data-intensive queries. Default is 100. Syntax: `SET EXEC_SINGLE_NODE_ROWS_THRESHOLD=number_of_rows;`
PARQUET_FILE_SIZE	Specifies the maximum size of each Parquet data file produced by Impala `INSERT` statements. Specify the size in bytes or with a trailing `m` or gcharacter to indicate megabytes or gigabytes. For example: `-- 128 megabytes.set PARQUET_FILE_SIZE=134217728 \ INSERT OVERWRITE parquet_table SELECT`

```
* FROM text_table;
-- 512 megabytes.set
PARQUET_FILE_SIZE=512m; \
INSERT OVERWRITE parquet_table SELECT
* FROM text_table;
-- 1 gigabyte.set
PARQUET_FILE_SIZE=1g; \
INSERT OVERWRITE parquet_table SELECT
* FROM text_table;
```

Syntax: `set PARQUET_FILE_SIZE=size INSERT OVERWRITE parquet_table SELECT * FROM text_table;`

QUERY_TIMEOUT_S

Sets the idle query timeout value, in seconds, for the session. Impala automatically cancels queries that sit idle for longer than the timeout value specified. QUERY_TIMEOUT_S must be smaller than or equal to the `--idle_query_timeout` value if the `--idle_query_timeoutstartup` option is set.

Syntax: `SET QUERY_TIMEOUT_S=seconds;`

Functions

The following table lists new functions with their descriptions and syntax:

APPX_MEDIAN()

An aggregate function that uses sampling to produce an estimate for the median value of a column. This function returns a value that is approximately the median (midpoint) of values in the set of input values. The input type must support less-than and greater-than comparison operators.

Return type: Same as the input value, except for CHAR and VARCHAR arguments which produce a STRING result

The return value is always the same as one of the input values, not an "in-between" value produced by averaging.

Syntax: `APPX_MEDIAN([DISTINCT | ALL] expression)`

CURRENT_DATABASE()

Utility function that returns the database that the session is currently using. Returns`default` if no database was selected or the database that the session switched to with the USE statement or the

```
impalad-d
```

option. Return type: string

Syntax: `CURRENT_DATABASE()`

DATE_PART()

A new date and time function, similar to EXTRACT(), but with the order of the arguments reversed. You can also call the EXTRACT() function using the SQL-99 syntax, EXTRACT(*unit* FROM *timestamp*). These enhancements simplify the porting process for date-related code from other systems. Return type: int

Syntax: `DATE_PART(string,timestamp)`

last-updated: Apr 11, 2022

DECODE()	A function that compares an expression to one or more possible values and returns a corresponding result when a match is found. This function works as a shorthand for a CASE() expression and improves compatibility with SQL code containing vendor extensions. Return type: Same as the initial argument value, except that integer values are promoted to BIGINT and floating-point values are promoted to DOUBLE; use CAST() when inserting into a smaller numeric column. Syntax: `decode(type expression, type search1, type result1 [, type search2, type result2...] [, type default] )`
isfalse(), isnotfalse(), isnottrue(), istrue(), nonnullvalue(), nullvalue()	These conditional functions provide enhanced compatibility when porting code that uses industry extensions.
mod()	This function returns the modulus of a number. MOD is equivalent to using the % arithmetic operator. It works with any size integer type, any size floating-point type, and DECIMAL with any precision and scale. Return type: Same as the input value. Syntax: `mod(numeric_type a, same_type b)`
NDV()	This aggregate function now returns DOUBLE results rather than STRING. Prior to 2.2.0, you had to CAST() the result to a numeric type before using the function in arithmetic operations. Syntax: `NDV([DISTINCT | ALL] expression)`
STDDEV(), STDDEV_POP(), STDDEV_SAMP()	These aggregate functions now return DOUBLE results rather than STRING. Prior to 2.2.0, you had to CAST() the result to a numeric type before using the function in arithmetic operations. Syntax: `{ STDDEV | STDDEV_SAMP | STDDEV_POP }([DISTINCT | ALL] expression)`
VARIANCE(), VARIANCE_POP(), VARIANCE_SAMP()	These aggregate functions now return DOUBLE results rather than STRING. Prior to 2.2.0, you had to CAST() the result to a numeric type before using the function in arithmetic operations.`VAR_SAMP()` and `VAR_POP()` are aliases for the existing `VARIANCE_SAMP()` and `VARIANCE_POP()` functions. Syntax: `{ VARIANCE | VAR[IANCE]_SAMP | VAR[IANCE]_POP } ([DISTINCT | ALL] expression)`

Statements

The following table lists new or improved statements with their descriptions and syntax:

COMPUTE|DROP INCREMENTAL STATS	This statement collects or drops statistics for individual partitions in a partitioned table instead of processing the entire table for each COMPUTE STATS statement. Use the COMPUTE STATS statement for non-partitioned tables or partitioned tables that are unchanging or have content that is entirely replaced. Syntax: `COMPUTE|DROP INCREMENTAL STATS [db_name.]table_name [PARTITION`

	`(partition_spec)] partition_spec ::= partition_col=constant_value`
CREATE ROLE	This statement creates a role. You can grant privileges to roles and then assign roles to users. A user can only exercise the privileges associated with a particular role. Only users that have administrative privileges can create/drop roles. By default, the `hive`, `impala` and `hue` users have administrative privileges in Sentry. Syntax: `CREATEROLErole_name`
DROP ROLE	Removes a role from the metastore database. When you drop a role, the role is revoked from all users to whom it was previously assigned, and all privileges granted to that role are revoked. In progress queries are not affected. Impala verifies the role information approximately every 60 seconds. Syntax: `DROPROLE role_name`

GRANT	This statement grants roles or privileges on specified objects to groups. The object name is typically an identifier. For URIs, it is a string literal.
	Only administrative users (initially, a predefined set of users specified in the Sentry service configuration file) can use this statement.
	The `WITH GRANT OPTION` clause allows members of the specified role to issue `GRANT` and `REVOKE` statements for those same privileges. If a role has the `ALL` privilege on a database and the `WITH GRANTOPTION` set, users granted that role can execute `GRANT`/`REVOKE` statements only for that database or child tables of the database. This means a user could revoke the privileges of the user that provided them the `GRANT OPTION`.
	You cannot revoke the `WITH GRANT OPTION` from a privilege that was previously granted to a role. To remove the `WITH GRANT OPTION`, revoke the privilege and grant it again without the `WITHGRANT OPTION` flag.
	Syntax:
	`GRANT ROLE role_name TO GROUP group_name`
	
	`GRANT privilege ON object_type object_name TO [ROLE] roleName [WITH GRANT OPTION]`
	
	`privilege ::= SELECT | INSERT | ALL object_type ::= TABLE | DATABASE | SERVER | URI`

REVOKE	This statement revokes roles or privileges on a specified object from groups. The object name is typically an identifier. For URIs, it is a string literal. Only administrative users (those with `ALL` privileges on the server, defined in the Sentry policy file) can use this statement. The revocation has a cascading effect.

last-updated: Apr 11, 2022

For example, revoking the `ALL` privilege on a database also revokes the same privilege for all the tables in that database.

Syntax:

```
REVOKE ROLE role_name FROM GROUP
group_name

REVOKE privilege ON object_type
object_name
FROM [ROLE] role_name
privilege ::= SELECT | INSERT | ALL
object_type ::= TABLE | DATABASE |
SERVER | URI
```

SHOW FILES

This statement displays the files that constitute a specified table or a partition within a partitioned table. Results include the names of the files, file sizes, and the applicable partition for a partitioned table. The size includes a suffix of B for bytes, MB for megabytes, and GB for gigabytes. SHOW FILES applies to tables and partitions stored on the MapR filesystem or S3. It does not apply to views or tables mapped to HBase. HBase does not use the same file-based storage layout.

Syntax: `SHOW FILES IN table`

SHOW GRANT ROLE

This statement lists all the grants for the given role name. This statement is only allowed for Sentry administrative users and other users that have been granted the specified role. This syntax is available when you are using the Sentry authorization framework along with the Sentry service. It does not apply when you use the Sentry framework with privileges defined in a policy file. When authorization is enabled, the output of the `SHOW` statement is limited to those objects for which you have some privilege, though there might be other concealed database and tables.

Syntax: `SHOWGRANTROLErole_name`

SHOW ROLES

This statement displays roles. This syntax is available when you are using Sentry authorization with the Sentry service. It does not apply when you use the Sentry framework with privileges defined in a policy file. When authorization is enabled, the output of the `SHOW` statement is limited to those objects for which you have some privilege, though there might be other concealed database and tables.

Syntax: `SHOW ROLES`

SHOW ROLEGRANT GROUP

This statement lists all the grants for the given group. This statement is only allowed for Sentry administrative users and other users that have been granted the specified role. This syntax is available when you are using the Sentry authorization framework along with the Sentry service. It does not apply when you use the Sentry framework with privileges defined in a policy file. When authorization is enabled, the output of the `SHOW` statement is limited to those objects for which you have some privilege, though there might be other concealed database and tables.

Syntax: `SHOWROLEGRANT GROUP group_name`

Data Types

The following table lists new or improved data types with their descriptions:

Data Type	Description
Complex	Impala can run queries against Parquet data containing columns with composite or nested data types.
CHAR	A fixed-length character type, padded with trailing spaces if necessary to achieve the specified length. If values are longer than the specified length, Impala truncates any trailing characters. The maximum length you can specify is 255. Provides enhanced support for `CHAR`in the COMPUTE STATS statement.
VARCHAR	A variable-length character type, truncated during processing if necessary to fit within the specified length. Short values are padded with spaces on the right. The maximum length you can specify is 65,535. Provides enhanced support for `VARCHAR` types in the COMPUTE STATS statement.

Clauses and Operators

The following table lists new or improved clauses and operators with descriptions and syntax:

[NOT] EXISTS

The EXISTS operator checks if a subquery returns any results. The NOT EXISTS operator finds values in a table that do not correspond to values in another table. You can use either of these operators in the WHERE clause of a subquery. Correlated subqueries used in the EXISTS operator cannot include a LIMIT clause.

Syntax: `[NOT]EXISTS (subquery)`

[NOT] IN

The IN operator compares an argument value to a set of values. If an argument value matches any value in a set, the result is TRUE. The NOT IN operator checks if the argument value is not part of a set of values. Correlated subqueries used in the IN operator cannot include a LIMIT clause.

Syntax: `expression [NOT] IN (expression [,expression])`

LEFT|RIGHT ANTI JOIN

These clauses return results from one table that has no match in another table. The LEFT ANTI JOIN clause returns those values from the left-hand table that have no matching value in the right-hand table. RIGHT ANTI JOIN reverses the comparison and returns values from the right-hand table.

Syntax:

```
SELECT select_list FROM
table_or_subquery1 {LEFT | RIGHT}
ANTI JOIN table_or_subquery2 |
[ ON col1 = col2 [AND col3 =
col4 ...] |
USING (col1 [, col2 ...]) ]
[other_join_clause ...]
[ WHERE where_clauses ]
```

Hint

The Impala SQL dialect supports query hints to fine-tune the inner workings of queries. You can specify hints as a temporary workaround for expensive queries where missing statistics or other factors cause inefficient performance.

Insert + immediately before a hint name to include hints inside comments that use `/* */` or `--` notation.

Example:

```
INSERT insert_clauses
/* +SHUFFLE|NOSHUFFLE */
SELECT remainder_of_query;
INSERT insert_clauses
-- +SHUFFLE|NOSHUFFLE
SELECT remainder_of_query;
```

New Features in Impala 1.4.1 for MapR

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Admission Control

A new feature that enforces limits on concurrent SQL queries and statements that run in an Impala cluster with heavy workloads. When admission control is enabled, Impala queues SQL queries and statements that it would otherwise cancel or re-run due to insufficient resources or performance bottlenecks.

You can configure admission control options that Impala uses to enforce limits on the following behaviors:

- Number of concurrent queries that run in the cluster
- Query queue size
- Number of delayed queries that the queue can hold
- Amount of memory that queries use
- Time that queries can exist in queue before Impala cancels them

Refer to Admission Control for more information.

Partition Pruning

Partition pruning now includes performance improvements that reduce the time spent on query planning for partitioned tables with thousands of partitions. Previously, Impala could query tables with up to approximately 3000 partitions. Now, Impala can comfortably query tables with tens of thousands of partitions.

Impala Daemon Options

The following table lists new Impala daemon start up options that you can add to the `env.sh` configuration file:

Option	Default	Description
load_catalog_in_background	true	New start up option to control the parallelism of metadata loading during start up for the catalogd daemon. Makes Impala use background threads after start up to load and cache metadata.

last-updated: Apr 11, 2022

num_metadata_loading_threads	16	New start up option for controlling the parallelism of metadata loading during start up for the catalogd daemon. Determines how much parallelism Impala devotes to loading metadata in the background. You can increase this value for systems with a huge number of databases, tables, or partitions. You can lower this value for busy systems that have CPU-constraints due to jobs from other components running in the cluster.
insert_inherit_permissions	Same permissions as parent directory	New start up option that causes Impala INSERT statements to create each new partition with the same MapR filesystem permissions as its parent directory. By default, INSERT statements create directories for new partitions using default MapR filesystem permissions.

Impala-Shell Command Line Options

The following table lists the new option with its description:

Option	Description
strict_unicode	The impala-shell interpreter now supports UTF-8 characters for input and output. You can control whetherimpala-shell ignores invalid Unicode code points through this option.

Security

The following table contains new security features and their descriptions:

Feature	Description
LDAP	LDAP connections can be secured through either SSL or TLS.
Sentry-based authorization	Impala can now use Sentry-based authorization based onthe original policy file.

Functions

The following table lists new functions and their descriptions:

Statement	Description
NULLIF() NULLIFZERO() ZEROIFNULL()	New conditional functions that simplify porting SQL containing vendor extensions to Impala.
CURRENT DATABASE()	New utility function that returns the database that the session is currently using.

Built-In Functions

The following table lists new built-in functions and their descriptions:

last-updated: Apr 11, 2022

Function	Description
ADD_MONTHS()	A built-in function that is an alias for the existing MONTHS_ADD() function.
EXTRACT()	A new built-in function that returns one date or time field from a TIMESTAMP value.
ROUND()	A new built-in function that rounds DECIMAL values to a specified number of fractional digits.
TRUNC()	A new built-in function that truncates date/time values to a particular granularity, such as year, month, day, hour, and so on.
STDDEV(), STDDEV_SAMP(), STDDEV_POP(), VARIANCE(), VARIANCE_SAMP(), VARIANCE_POP()	Built-in aggregate functions for computing properties for statistical distributions.
MAX_INT(), MIN_SMALLINT()	New built-in functions that you can use to check whether data values are in an expected range. You might be able to switch a column to a smaller type to save memory during processing.
IS_INF(), IS_NAN()	New built-in functions that check for special values infinity and “not a number”. These values could be specified as inf or nan in text data files. They may also be produced by certain arithmetic expressions.

Statements

The following table lists new or improved statements and their descriptions:

Statement	Description

last-updated: Apr 11, 2022

COMPUTE STATS	Use this statement to collect table and column statistics with a single statement. Useful for query planning, join queries, queries on partitioned tables, and any other data intensive operations. This release includes the following performance improvements for the statement: • The `NDV` function is sped up through native code generation. • Because the NULL count is not currently used by the Impala query planner, in Impala 1.4.0 and higher, `COMPUTE STATS` does not count the NULL values for each column. The #Nulls field of the stats table is left as -1, signifying that the value is unknown.
CREATE TABLE	SQL syntax for creating a table. This release includes the following improvements for the statement: • You can now specify the clause FIELDS TERMINATED BY '\0' to use text data files that use ASCII 0 (nul) characters as a delimiter. • For interoperability with Parquet files created through other Hadoop components, such as Pig or MapReduce applications, you can create an Impala table that automatically sets up the column definitions based on the layout of an existing Parquet data file. • Has a STORED AS AVRO clause, enabling you to create Avro tables through Impala.
EXPLAIN PLAN	When you run EXPLAIN PLAN followed by a SELECT query, it returns the query execution plan. EXPLAIN PLAN now provides more detail in a simpler format with the following verbosity levels: • 0 – Most concise • 1 • 2 • 3 – Most verbose
INVALIDATE METADATA table_name	Impala loads metadata for a Hive table when you issue the INVALIDATE METADATA table_name statement if a Hive table exists with the same name.

SHOW FUNCTIONS	Shows user-defined functions associated with a particular database. This release includes the following improvements for the statement: • Now displays the return type and argument type of each function. • You can now specify the clause FIELDS TERMINATED BY '\0' with a CREATE TABLE statement to use text data files that use ASCII 0 (nul) characters as a delimiter.
SHOW PARTITIONS	Displays information about each partition in a partitioned table. Run the COMPUTE STATS statement after creating all table partitions and then run SHOW PARTITIONS for more informative output.

Data Types

The following table lists new or improved data types with their descriptions:

Data Type	Description
DECIMAL	A numeric data type that you can use in CREATE TABLE and ALTER TABLE statements to store fixed-precision values when working with currency or other fractional values where it is important to represent values exactly and avoid rounding errors. Useful for calculations where the imprecise representation and rounding behavior of FLOAT and DOUBLE make them impractical to use. Includes enhancements to built-in functions, numeric literals, and arithmetic expressions.
TIMESTAMP	Accepts more input string formats through the UNIX TIMESTAMP function, and produces more string formats through the FROM UNIXTIME function.

Clauses and Operators

The following table lists new or improved clauses and operators with descriptions:

Feature	Description
ORDER BY	No longer requires a LIMIT clause. If the size of the result set to be sorted exceeds the memory available to Impala,Impala uses a temporary work space on disk to perform the sort operation.
REGEXP RLIKE	Improved compatibility with the regular expression support for popular database systems. There is no change to the behavior of the regexp_extract() and regexp_replace() built-in functions. These operators now match a regular expression string that occurs anywhere inside the target string; the same as if the regular expression was enclosed on each side by .*.

New Features in Impala 1.2.3 for MapR

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Join Order Optimizations

A primary new feature of Impala 1.2.3 is join order optimizations that automatically distribute and parallelize the work for a join query to minimize disk I/O and network traffic. Automatic optimization reduces the need to use query hints or to rewrite join queries with the tables in a specific order based on size or importance.

Use the COMPUTE STATS statement when you want to gather critical, statistical information about each table when you enable join optimizations. If a join query is inefficient due to outdated statistics or unexpected data distribution, you can use the STRAIGHT_JOIN keyword immediately after the SELECT statement to prevent Impala from reordering the joined tables.

The STRAIGHT_JOIN keyword turns off the reordering of join clauses that Impala does internally, and produces a plan that relies on optimal ordering of the join clauses in the query text. For example, you rewrite the query so that the largest table is on the left, followed by the next largest, and so on until the smallest table is on the right.

Impala Catalog Service

When Impala changes table data or metadata on one node, the catalog service communicates the new or updated metadata to all the other Impala nodes. You no longer need to use the REFRESH or INVALIDATE METADATA statements after issuing the following statements to Impala:

- CREATE TABLE
- ALTER TABLE
- DROP TABLE
- INSERT
- LOAD DATA

Note:

The catalog service only works on operations performed through Impala. If you perform operations through the Hive shell or through the MapR filesystem, you must issue the REFRESH and INVALIDATE METADATA statements. The catalog service broadcasts the results of the REFRESH and INVALIDATE METADATA results to other Impala nodes so that you only have to issue the statements once.

Impala Daemon Options

The following table lists new Impala daemon startup options that you can add to the env.sh file:

Option	Description
--idle_query_timeout	Impala daemon option that controls how long a query can be idle before Impala cancels the query.
--idle_session_timeout	Impala daemon option that controls how long a session can be idle before the session expires.
--enable_ldap_auth	Enables LDAP authentication between Impala and the client. Example: -enable_ldap_auth=true \

last-updated: Apr 11, 2022

--ldap_uri	Sets the URI of the LDAP server to use. Typically, the URI is prefixed with ldap://<hostname>. Optionally, the URI can specify the port. For example, ldap://<hostname>:<port>. Example: -ldap_uri=ldap://10.250.1.5/ \
--ldap_manual_configextendingcolumn	Bypasses all the automatic configuration if you need to provide a custom SASL.
--ldap_tls	Tells Impala to start a TLS connection to the LDAP server and to fail authentication if Impala cannot start the TLS connection.

Security

The following table contains new security features and their descriptions:

Feature	Description
Impersonation support	Allows you to give users the permission to submit requests using the credentials of another user. Only available through the Hue interface.
LDAP authentication	You can configure LDAP authentication for client connections with Impala.

Functions

The following table lists new functions and their descriptions:

Function	Description
User-Defined Functions (UDFs)	Reusable SQL functions that you can create to encapsulate code that processes column values during an Impala query. You can run scalar UDFs and UDAs (user-defined aggregate functions). Impala accepts UDFs and UDAFs written in C++ or you can use Hive functions written in Java. For more information about user-defined functions, refer to Impala User-Defined Functions on page 3794.
NDV ()	An aggregate function that you can use to quickly return an approximate result instead of using COUNT (DISTINCT col).
GROUP_CONCAT()	An aggregate function that you can use to concatenate column values across all rows of a result set.

Built-In Functions

Several built-in functions and operators are now overloaded for more numeric data types to reduce CAST() function use with INSERT statements. Addition, subtraction, and multiplication functions now produce a result that is only one step bigger than their arguments. Numeric and conditional functions can return SMALLINT, FLOAT, and other smaller types instead of BIGINT or DOUBLE.

The following table lists new built-in functions and their descriptions:

Function	Description

last-updated: Apr 11, 2022

least ()	A mathematical function that returns the smallest value from a list of expressions. The return type is the same as the initial argument value, except that integer values are promoted to BIGINT and floating-point values are promoted to DOUBLE. Use CAST() when inserting into a smaller numeric column.
greatest ()	A mathematical function that returns the largest value from a list of expressions. The return type is the same as the initial argument value, except that integer values are promoted to BIGINT and floating-point values are promoted to DOUBLE. Use CAST() when inserting into a smaller numeric column.
initcap ()	Returns the input string with the first letter capitalized.
fnv_hash ()extending col	A mathematical function for constructing hashed values that returns a consistent 64-bit value derived from the input argument, for convenience of implementing hashing logic in an application. The return type is BIGINT.

Statements, Options, and Hints

The following table lists new statements, options, hints and their descriptions:

Statement	Description
COMPUTE STATS	You can use this statement to collect table and column statistics with a single statement. This is useful for query planning, join queries, queries on partitioned tables, and any other data intensive operations. Collect stats for each table involved in a join query.
CREATE TABLE AS SELECT	SQL syntax that you can use to create a table and copy data into the table in a single operation.
SHOW TABLE STATS	SQL syntax that you can use to verify that statistics are available and to see the values used during query planning.
SHOW COLUMN STATS	SQL syntax that you can use to verify that statistics are available and to see the values used during query planning.
SHOW CREATE TABLE	Summarizes the effects of the original CREATE TABLE statement and subsequent ALTER TABLE statements to provide a CREATE TABLE statement that recreates the current structure and layout for the table. You can use this statement to create a simplified setup script for a schema.
EXPLAIN_LEVEL	A query option that you can enable and use with the EXPLAIN and PROFILES statements to provide more verbose results. The verbose results provide estimated resource requirements and the available table and column statistics.
SYNC_DDL	A query option that you can enable before you issue a DDL, INSERT, or LOAD statement which causes the statement to wait and return only after the Catalog service broadcasts changes to all Impala nodes in the cluster.

last-updated: Apr 11, 2022

[SHUFFLE] [NOSHUFFLE]	You can use these hints in INSERT statements when inserting into Parquet tables to avoid problems due to memory consumption and open files in the filesystem, by collecting new data for each partition on a specific node.

Clauses and Operators

The following table lists new clauses, operators, and their descriptions:

Feature	Description
CROSS JOIN	A clause that you can use in the SELECT statement to allow joins without an equality comparison between columns in both tables.
NULLS FIRST	A clause that you can use to ensure consistent placement of NULL values in ORDER BY queries.
NULLS LAST	A clause that you can use to ensure consistent placement of NULL values in ORDER BY queries.
OFFSET	A clause that you can use with the ORDER BY and LIMIT clauses to produce paged result sets, like items 1-10, 11-20...
STORED AS PARQUET	You can use this clause instead of STORED AS PARQUETFILE for conciseness in new code.
TBLPROPERTIES	A clause that you can use with the CREATE TABLE and ALTER TABLE statements to associate random pieces of metadata with a table as key-value pairs.
WITH SERDEPROPERTIES	A clause that you can use with the CREATE TABLE and ALTER TABLE statements to specify the serializer and deserializer (SerDes) classes that read and write data for a table, which may be needed for Hive compatibility with Impala.
LIMIT	This clause accepts an arithmetic expression and numeric literals.
STRAIGHT_JOIN	You can use this operator to override the reordering of tables in a join query. Uses the original technique of ordering join tables in descending order of size enabling you to fine-tune the join query plan.

Additional Impala Configuration Options

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can modify the `env.sh` file located in `/opt/mapr/impala/impala-<version>/conf/` to set certain Impala start up options.

Modifying Startup Options

The `env.sh` file contains values that the Impala server, statestore, and catalog services use during start up. The file also has information about resources allocated for Impala. Most of the default values in the `env.sh` file should work effectively, however there are some values that you can modify. You can check the current value of all the settings through the Impala web interface, available by default at `http://<impala-node-hostname>:25000/varz`.

You may want to modify the following content in the `env.sh` file:

- Statestore address

last-updated: Apr 11, 2022

- Amount of memory available to Impala
- Core dump enablement
- Session and query idle time

To modify the values, edit the `env.sh` file and then restart the Impala server, Impala statestore, and Impala catalog to implement the changes.

Example of some file content that you may want to modify:

```
HIVE_METASTORE_URI=thrift://localhost:9083
  # not needed if /opt/mapr/hive is configured
IMPALA_STATE_STORE_HOST=127.0.0.1
IMPALA_STATE_STORE_PORT=24000
IMPALA_BACKEND_PORT=22000
IMPALA_LOG_DIR=/opt/mapr/impala/impala-1.1.1/log
export IMPALA_STATE_STORE_ARGS=${IMPALA_STATE_STORE_ARGS:- \
-log_dir=${IMPALA_LOG_DIR}} \
-state_store_port=${IMPALA_STATE_STORE_PORT}
export IMPALA_SERVER_ARGS=${IMPALA_SERVER_ARGS:- -log_dir=${IMPALA_LOG_DIR}
\
-state_store_port=${IMPALA_STATE_STORE_PORT} \
-use_statestore
-state_store_host=${IMPALA_STATE_STORE_HOST} \
-be_port=${IMPALA_BACKEND_PORT}}
export ENABLE_CORE_DUMPS=false
```

The following table contains a list of settings that you can edit in `/opt/mapr/impala/impala-<version>/conf/env.sh` with descriptions for how to change them:

Setting	Description

Statestore address	You can modify this setting to change the statestore IP address or hostname.
	Example:
	If a machine with an IP address of 192.168.0.28 is hosting statestore, you can change
	`IMPALA_STATE_STORE_HOST=127.0.0.1`
	to
	`IMPALA_STATE_STORE_HOST=192.168.0.28.`

last-updated: Apr 11, 2022

Memory limits	If you run Impala on nodes that also run MapReduce, both frameworks may compete for memory. Configure memory based on your job requirements and SLAs to ensure that each framework has enough memory to avoid conflicts.
	
	You can include the `mem_limit` parameter in IMPALA_SERVER_ARGS to limit the amount of memory available to Impala. Use absolute notation, such as 500M or 2G, or a percentage of physical memory, such as 50% to specify the memory limit. Impala aborts queries that exceeds the specified memory limit. Percentage limits are based on the physical memory of the machine.
	
	You can also include the `num_threads_per_disk` parameter in IMPALA_SERVER_ARGS to limit the number of threads that each disk processes per impala server daemon. Limiting the number of threads per disk can reduce the overall amount of memory consumed.
	
	Example:
	
	To limit Impala to 50% of system memory, modify:
	
	`export IMPALA_SERVER_ARGS=${IMPALA_SERVER_ARGS:- \ -log_dir=${IMPALA_LOG_DIR} \ -state_store_port=${IMPALA_STATE_STORE_PORT} \ -use_statestore -state_store_host=${IMPALA_STATE_STORE_HOST} \ -be_port=${IMPALA_BACKEND_PORT}}`
	
	to
	
	`export IMPALA_SERVER_ARGS=${IMPALA_SERVER_ARGS:- \ -log_dir=${IMPALA_LOG_DIR} \ -state_store_port=${IMPALA_STATE_STORE_PORT} \ -use_statestore -state_store_host=${IMPALA_STATE_STORE_HOST} \ -be_port=${IMPALA_BACKEND_PORT} \ -mem_limit=50% \ -num_threads_per_disk=2}`

Core dump enablement	Core dump file locations can vary depending on your operating system configuration. Other security settings may prevent Impala from writing core dumps when you enable this option. To enable core dumps, change export `ENABLE_CORE_DUMPS=false` to `export ENABLE_CORE_DUMPS=true`.

last-updated: Apr 11, 2022

Session and query idle time	You can modify the time for which sessions and queries can remain idle by adding the following options to `env.sh`:
	`--idle_session_timeout`
	`--idle_query_timeout`
	Example:
	`IMPALA_SERVER_ARGS=" \ -log_dir=${IMPALA_LOG_DIR} \ -state_store_port=${IMPALA_STATE_STORE_PORT} \ -idle_query_timeout=<value in seconds> \ -idle_session_timeout=<value in seconds> \ -use_statestore \ -state_store_host=${IMPALA_STATE_STORE_HOST} \ -catalog_service_host=${CATALOG_SERVICE_HOST} \ -be_port=${IMPALA_BACKEND_PORT}"`

Use background threads to loadand cache metadata	The following option controls the parallelism of metadata loading during start up for the catalogd daemon and makes Impala use background threads after start up to load and cache metadata. `--load_catalog_in_background` The default setting is `true`.
Determine how much parallelism Impala devotes to loading metadata in background	The following option controls the parallelism of metadata loading during start up for the catalogd daemon and determines how much parallelism Impala devotes to loading metadata in the background: `--num_metadata_loading_threads` The default is 16, but you can increase this value for systems with a huge number of databases, tables, or partitions. You can lower this value for busy systems that have CPU-constraints due to jobs from other components running in the cluster.
INSERT to create new partition and inherit permissions	The following option causes Impala INSERT statements to create each new partition with the same MapR filesystem permissions as its parent directory: `--insert_inherit_permissions` By default, INSERT statements create directories for new partitions using default MapR filesystem permissions.

After you edit `/opt/mapr/impala/impala-<version>/conf/env.sh`, use the following commands to restart the Impala server and services:

last-updated: Apr 11, 2022

- Issue the following command to restart the Impala server:

```
$ sudo maprcli node services -name impalaserver -action restart -nodes
<IP address where impala server is installed>
```

- Issue the following command to restart the Impala statestore:

```
$ sudo maprcli node services -name impalastore -action restart -nodes <IP
address where impala statestore is installed>
```

- Issue the following command to restart the Impala catalog:

```
$ sudo maprcli node services -name impalacatalog -action restart -nodes
<IP address where impala catalog is installed>
```

Admission Control

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Admission control enforces limits on concurrent SQL queries and statements that run in an Impala cluster with heavy workloads. When admission control is enabled, Impala queues SQL queries and statements that it would otherwise cancel or re-run due to insufficient resources or performance bottlenecks.

You can configure admission control options that Impala uses to enforce limits on the following behaviors:

- Number of concurrent queries that run in the cluster
- Query queue size
- Number of delayed queries that the queue can hold
- Amount of memory that queries use
- Time that queries can exist in queue before Impala cancels them

Query Queuing

Admission control is embedded within each impalad daemon and communicates through the statestore service. The impalad daemon determines if a query runs immediately or if the query is queued. The queue can include queries submitted through multiple Impala nodes.

Impala executes queries in the order that they are submitted to allow for dependent statements, such as a CREATE TABLE statement followed by an INSERT INTO statement. Impala may not execute queries submitted through different nodes in the order that the queries were received. When Impala must execute a sequence of statements in order, you should submit the statements on the same Impala node within a single session. When statement order is not important, you can set up your table structures and submit statements through different Impala nodes.

If a sudden flow of requests causes more queries to run concurrently than expected, the overall Impala memory limit and the Linux cgroups mechanism serve as hard limits to prevent over allocation of memory. When queries hit these limits, Impala cancels the queries.

Configuring Admission Control

You can use a combination of Impala start-up options, and optionally edit configuration settings in `fair-scheduler.xml`, to configure admission control. Admission control uses the Fair Scheduler configuration settings to determine how to map users and groups to different resource pools.

Fair Scheduler Settings

You can configure settings in fair-scheduler.xml that admission control can use to determine how to map users and groups to different resource pools. The `<aclSubmitApps>` tag in fair-scheduler.xml contains users and groups that can submit Impala statements to a corresponding Impala resource pool. The user and group lists are separated by a space, as shown in the following example:

```
<aclSubmitApps>user1,user2,user3 dev,tech,admin</aclSubmitApps>
```

If the `<aclSubmitApps>` tag is empty for a pool, no one can submit directly to that pool, however child pools can have their own `<aclSubmitApps>` values to allow users and groups to submit to the child pools.

Impala does not use the `vcores` and `disks` values, however you must specify them to satisfy YARN requirements for the file content. For more information about Fair Scheduler configuration settings, refer to the Apache wiki.

The following fair-scheduler.xml shows examples of the `<aclSubmitApps>` tag and also shows the `vcores` and `disks` values:

```
<allocations>
    <queue name="root">
        <aclSubmitApps> </aclSubmitApps>
        <queue name="default">
            <maxResources>40000 mb, 0 vcores, 0 disks</maxResources>
            <aclSubmitApps>*</aclSubmitApps>
        </queue>
        <queue name="dev">
            <maxResources>100000 mb, 0 vcores, 0 disks</maxResources>
            <aclSubmitApps>user1,user2 dev,tech,admin</aclSubmitApps>
        </queue>
        <queue name="prod">
            <maxResources>2000000 mb, 0 vcores, 0 disks</maxResources>
            <aclSubmitApps> tech,admin</aclSubmitApps>
        </queue>
    </queue>
    <queuePlacementPolicy>
        <rule name="specified" create="false"/>
        <rule name="default" />
    </queuePlacementPolicy>
</allocations>
```

Impala Start-up Options

To configure admission control, modify Impala's start-up options. You can modify the start-up options in

```
/opt/mapr/impala/impala-<version>/conf/env.sh.
```

For more information about how to modify Impala start-up options, refer to Additional Impala Configuration Options.

The following table lists the admission control start-up options that you can configure:

last-updated: Apr 11, 2022

Option	Type	Default	Description
-default_pool_max_queued	int64	0	The maximum number of requests allowed in the queue. Impala rejects additional requests when the queue reaches this limit. This a “soft” limit that applies cluster-wide. Each Impala node decides independently whether to run queries immediately or to queue them. Impala allows for the overall number of queued queries to be slightly higher that the limit during times of heavy load. A negative value or 0 indicates that requests are always rejected once the maximum concurrent requests are executing. Ignored if fair_scheduler_config_path is set.
-default_pool_max_requests	int64	-1	The maximum number of concurrent requests allowed to run before incoming requests are queued. This a “soft” limit that applies cluster-wide. Each Impala node decides independently whether to run queries immediately or to queue them. The overall number of concurrent queries might be slightly higher during times of heavy load. A negative value indicates no limit. Ignored if fair_scheduler_config_path is set.

last-updated: Apr 11, 2022

Option	Type	Default	Description
-default_pool_mem_limit	string	"" (empty string)	The maximum amount of memory that all outstanding requests in this pool can use before new requests to this pool are queued. Specified in bytes, megabytes, or gigabytes by a number followed by the suffix b (optional), m, or g, either upper- or lowercase. You can specify floating-point values for megabytes and gigabytes, to represent fractional numbers such as 1.5. You can also specify it as a percentage of the physical memory by specifying the suffix %. 0 or no setting indicates no limit. Defaults to bytes if no unit is given. This is a soft limit applied cluster-wide. Each Impala node makes independent decisions to run queries immediately or queue them, so the overall memory used by concurrent queries might be slightly higher during times of heavy load. Ignored if fair_scheduler_config_path is set. **Note:** Impala relies on the statistics produced by the COMPUTE STATS statement to estimate memory usage for each query.
-disable_admission_control	Boolean	false	Turns off the admission control feature entirely, regardless of other configuration option settings.
-disable_pool_max_requests	Boolean	false	Disables all per-pool limits on the maximum number of running requests.
-disable_pool_mem_limits	Boolean	false	Disables all per-pool memory limits.
-fair_scheduler_allocation_path	String	"" (empty string)	Path to the Fair Scheduler allocation file, `fair-scheduler.xml`. Admission control can only use a small subset of the settings that can go in this file.

last-updated: Apr 11, 2022

Option	Type	Default	Description
-queue_wait_timeout_ms	int64	60000	The maximum amount of time (in milliseconds) that a request waits in queue to be executed before timing out.

Admission Control with Clients

Admission control works with JDBC and ODBC client interfaces, however you may experience the following scenarios due to limits enforced by this feature:

- The API call blocks SQL statements in the query queue instead of running them immediately. Query execution begins when the statement moves out of the query queue, at which time the client program can request the results, which may also block until they become available.
- If a SQL statement is canceled due to prolonged queue time or because it exceeded the memory limit during execution, an error occurs and the client program receives an error message.

You cannot set the following options from JDBC or ODBC applications:

- You must set the REQUEST_POOL option for a session through the impala-shell interpreter, or through the Impala start-up options if you want the setting to apply cluster-wide.
- You must set the MEM_LIMIT query option through the impala-shell interpreter. It cannot be used directly through JDBC or ODBC applications.

Admission Control Guidelines

The admission control system is not aware of other Hadoop workloads, such as MapReduce applications.

The following table lists some admission control guidelines to follow:

Guideline	Description
Examine query profile output	Examine the profile output for a query to see how admission control works for the query. The profile output provides details about the admission decision, such as whether the query was queued or not and which resource pool it was assigned to. It also includes the estimated and actual memory usage for the query, so you can fine-tune the configuration for the memory limits of the resource pools. In impala-shell, you can also specify which resource pool to direct queries to by setting the REQUEST_POOL query option. You can run the PROFILE statement in the impala-shell right after you run the query to see the query output, or you can review the Impala log file.
You cannot use admission control with Hue deployed	Unclosed Hue queries accumulate and exceed the queue size limit. To use admission control, you must explicitly enable it by specifying --disable_admission_control=false in the impalad command-line options safety valve field.
Set the MEM_LIMIT query option to override the query estimated memory usage	When a query cannot run due to high estimated memory usage, set the MEM_LIMIT query option in the impala-shell and issue the query through the shell in the same session to override the estimate. Impala treats the MEM_LIMIT value as the estimated amount of memory and overrides the estimate that Impala would generate based on table and column statistics. This value is used only for making admission control decisions, and is not pre-allocated by the query.

last-updated: Apr 11, 2022

Guideline	Description
Increase memory if needed when inserting into Parquet tables	Admission control affects query statements, as well as INSERT and CTAS. Inserting into a Parquet tables is memory intensive because 1GB of data is buffered before writing out each Parquet data block. When inserting into a partitioned Parquet table, Impala redistributes the data among the nodes to reduce memory consumption. You may need to temporarily increase the memory dedicated to Impala during the insert operation, or break up the load operation into several INSERT statements, or both.
Limits on queued queries affect subsequent statements in the same session	If Impala queues a query due to a limit on concurrent queries or memory usage, subsequent statements in the same session are also queued to ensure that the statements are processed in the correct order.
Reuse classifications and hierarchy developed for use with Sentry security	If you set up different resource pools for different users and groups, consider reusing any classifications and hierarchy you developed for use with Sentry security. See Enabling Sentry Authorization for Impala for details. For details about all the Fair Scheduler configuration settings, see the Apache wiki, in particular the tags such as <queue> and <aclSubmitApps> to map users and groups to particular resource pools (queues).
Use the COMPUTE STATS statement for large tables involved in join queries	Although COMPUTE STATS is an important statement to help optimize query performance, it is especially important when admission control is enabled. Admission control relies on COMPUTE STATS to generate accurate memory usage estimates for complex queries.

Spill to Disk

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Impala 2.2.0 for MapR introduces the "spill to disk" feature which prevents queries that use memory-intensive operations, such as large sort, join, aggregation, or analytic function operations, from failing with out-of-memory errors. Impala automatically writes data to disk when queries with memory-intensive operations exceed the set memory limit on an Impala node. You can enable or disable the spill to disk feature in `/opt/mapr/impala/impala-<version>/conf/env.sh`. You can also change the DISABLE_UNSAFE_SPILLS setting at the session level to allow or prevent data spills.

Impala reserves a certain amount of memory for memory-intensive operations that reach the set memory threshold. This memory reserve serves as a buffer that slows an operation's use of memory and in some instances prevents operations from exceeding the memory limit on a node. If the amount of memory used exceeds the set memory limit, Impala starts writing data to disk (spilling to disk).

Impala writes data to a temporary work area on disk. The default location of this work area is `/tmp/impala-scratch`. You can start the impalad daemon with the `--scratch_dirs="path_to_directory"` configuration option to change the directory location, however the scratch directory must reside on the local filesystem. You can specify a single directory, or a comma-separated list of directories. If there is less than 1 GB of available space on the filesystem where the scratch directory resides, Impala writes a warning message to its log when it runs. When an operation completes, the data is removed from the disk.

Prevent Data from Spilling to Disk

Spilling to disk can have significant performance implications due to the additional I/O required. Ideally, you want to optimize queries, system parameters, and the hardware configurations to prevent data from spilling to disk. The following points describe some techniques that can prevent data from spilling to disk:

last-updated: Apr 11, 2022

- View the query profile after you run queries to determine how often they spill to disk and how much temporary data is written to disk. You can run the PROFILE command from the impala-shell or you can view the Impala debug web user interface to see the profile for the query.
- Increase the number of Impala nodes in the cluster to increase the aggregate memory available.
- Increase the overall memory capacity of each node at the hardware level.
- On a multi-tenant cluster, use resource management features to allocate more memory for Impala.
- If you are running concurrent queries rather than a few memory-intensive ones, use the admission control feature to lower the limit on the number of concurrent queries. You can schedule the most resource-intensive queries to avoid spikes in memory usage and improve overall response times. See Admission Control.
- Use the following techniques to tune the queries with the highest memory requirements:
  - Run the COMPUTE STATS statement for all tables involved in large-scale joins and aggregation queries.
  - Minimize the use of STRING columns in join columns. Use numeric values instead.
  - Evaluate the EXPLAIN plan to see the execution plan used for the most resource-intensive queries.
  - Add hints to the most resource-intensive queries to select the right execution strategy.
  - If your queries experience substantial performance overhead due to spilling, enable the DISABLE_UNSAFE_SPILLS query option to prevent queries from spilling to disk.

DISABLE_UNSAFE_SPILLS

You can categorize queries that spill to disk as safe or unsafe. A spill that results from optimized queries may represent a safe spill, whereas a spill that results from running large ad-hoc queries with unknown performance implications may represent an unsafe spill. For example, if a query does not include a hint to set the most efficient mechanism for a join or an INSERT ... SELECT into a partitioned table, these tables will most likely result in suboptimal execution plans that could cause unnecessary spilling.

When DISABLE_UNSAFE_SPILLS is enabled (set to "`true`"), you can run the COMPUTE STATS statement on large tables involved in join queries and resource-intensive operations. The COMPUTE STATS statement collects table and column statistics to help estimate memory usage for each query before you allow data to spill to disk.

If you have determined that your queries will spill safely to disk, run the following command to turn the DISABLE_UNSAFE_SPILLS option off:

```
set DISABLE_UNSAFE_SPILLS=false
```

Disable the Spill to Disk Feature

You can disable the spill to disk feature if spilling to disk negatively affects performance or you do not know the performance implications or memory usage of queries in advance.

To disable the spill to disk feature, complete the following steps:

1. On each node running the Impala server, edit `/opt/mapr/impala/impala-<version>/conf/env.sh` , and set the following options to “`false`”:

   ```
   -enable_partitioned_aggregation=false
   -enable_partitioned_hash_join=false
   ```

last-updated: Apr 11, 2022

2. Save the `env.sh` file and then run the following commands to restart the Impala service and instances:
   a. Run the following command to restart the Impala server:

```
$ sudo maprcli node services -name impalaserver -action
restart -nodes <IP address where impala server is installed>
```

   b. Run the following command to restart the Impala statestore:

```
$ sudo maprcli node services -name impalastore -action restart -nodes
<IP address where impala statestore is installed>
```

   c. Run the following command to restart the Impala catalog:

```
$ sudo maprcli node services -name impalacatalog -action
restart -nodes <IP address where impala catalog is installed>
```

Working with Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

After you start Impala, use the impala-shell or a JDBC or ODBC client to query data. You can query data stored in files, as well as data stored in MapR Database tables. Impala depends on the Hive metastore to track table metadata. The MapR filesystem tracks the metadata of other files. Impala supports Text and Parquet file formats. If you want to query data using SequenceFile, RCFile, and Avro file formats, use Hive to load the data. Impala supports Snappy, GZIP, Deflate, and BZIP compression codecs.

Impala File Formats

The following table summarizes the supported Impala text formats:

File Type	Format	Compression Codecs	Can Impala Create?	Can Impala INSERT?
Text	Unstructured	Snappy, GZIP, BZIP	Yes, for CREATE TABLE with no STORED AS clause;default file format is uncompressed text with values separated by ASCII 0x01 characters, typically represented a Ctrl-A	Yes. CREATE TABLE, INSERT, and query.
SequenceFile	Structured	Snappy, GZIP, deflate, BZIP2	Yes	No. Query only. Load data using Hive.
RCFile	Structured	Snappy, GZIP, deflate, BZIP2	Yes	No. Query only. Load data using Hive.
Parquet	Structured	Snappy (default), GZIP	Yes	Yes. CREATE TABLE, INSERT, and query.
Avro	Structured	Snappy, GZIP, deflate, BZIP2	No, create using Hive.	No. Query only. Load data using Hive.

Impala SQL Dialect

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

Impala uses the SQL query language and is compatible with the Hive query language, HiveQL. You can use other languages, such as Java, to interact with Impala through ODBC and JDBC interfaces. The Impala SQL dialect supports a subset of SQL and HiveQL functions, statements, datatypes, operators, and built-in functions.

The Impala SQL dialect supports DML statements similar to the DML component of HiveQL. The Impala SQL dialect does not support UPDATE and DELETE statements, and does not support the INSERT… VALUES syntax to insert a single row.

Refer to Supported and Unsupported SQL/HiveQL Language Features for a list of supported and unsupported functions, statements, datatypes, operators, and features.

Example: Running an Impala SQL Query

In this example scenario, download a customer CSV file and use the Hive shell to create a table and import customer data into the table and then run an Impala query on the table.

1. Download the following CSV file to `/root/customers_sample_data.csv`:

   customers_sample_data.csv

2. Issue the following command from the hive-shell to import the CSV file and create a table:

```
hive> create table customers(FirstName string,
LastName string,Company string,Address string,
City string,County string,State string,Zip string,
Phone string,Fax string,Email string,Web string)
row format delimited fields terminated by ',' stored as textfile;
```

3. Issue the following command in the hive-shell to load the customer data into the customers table:

```
Hive> load data local inpath '/root/customers_sample_data.csv' overwrite
into table customers;
```

4. Issue the following command to start the Impala shell:

```
$ impala-shell
```

5. To connect to an instance of Impala, issue the following CONNECT command, replacing `impalad-host` with the host name you have configured on a node running Impala:

```
[Not connected] > connect impalad-host
[impalad-host:21000] >
```

6. Issue the following command to query the data to find the total number of customers:

```
select count(*) from customers
```

The query returns the following result:

```
+--------+
| count(*) |
+--------+
| 6 |
+--------+
```

last-updated: Apr 11, 2022

Query MapR Database Binary Tables with Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can use Impala to query data in MapR Database binary tables. Create an external table in the Hive shell and then map the Hive table to the corresponding MapR Database binary table. You can map a MapR Database binary table to a Hive table with or without string row keys. When you create an external table in Hive, use the HBaseStorageHandler clause in the Hive CREATE TABLE statement to allow Hive to access data stored in the MapR Database binary table. The HBaseStorageHandler has two important properties:

`hbase.columns.mapping`	Specifies the Hive column to column family mapping.
`hbase.table.name`	Absolute path of the table or just the table name, depending on whether the table path is mapped.

Example:

```
CREATE EXTERNAL TABLE students
(id string,
name string,
street string,
zipcode int,
state string)
STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler' WITH
SERDEPROPERTIES
('hbase.columns.mapping'=':key,account:name,address:street,address:zipcode,a
ddress:state')
TBLPROPERTIES ('hbase.table.name'='/user/userA/students');
```

Once you have mapped the MapR Database binary table to Hive, you can query or insert into the table from Impala because Hive and Impala share the metastore database. Impala nodes cache table metadata if a table contains a large amount of data or has many partitions. Caching the metadata reduces runtime for future queries on the table.

If you insert new data into a Hive or MapR Database binary table, use the Impala shell to issue the REFRESH statement to refresh the data location cache. The REFRESH command only applies to the node that the Impala shell is connected to. If you route all SQL statements to the same node, you do not have to issue regular REFRESH statements when table data is updated on other nodes.

If you create, drop, or alter any external tables or databases, use the Impala shell to issue the INVALIDATE METADATA statement to refresh table structure metadata.

To ensure Impala is quering MapR Database binary tables and not HBase, add the next property to `$HBASE_HOME/conf/hbase-site.xml`:

```
<property>
  <name>mapr.hbase.default.db</name>
  <value>maprdb</value>
</property>
```

Example: Running an Impala Query on MapR Database Binary Tables

In this example scenario, a professor wants to know how many times a student clicks on Google from his webpage. He wants to use Impala to query the data in MapR Database. One of his students offered to load the data into MapR Database so he can access it. In order to complete the professor's request, the student must use the HBase shell to create two MapR Database binary tables that contain the following schema and then put data in the tables:

- student
  - account – id, name

last-updated: Apr 11, 2022

  - address – street, zipcode, state
- clicks
  - clickinfo – clickid, studentid, url, time
  - iteminfo – itemid, quantity

Each bullet corresponds to a column family with a list of columns. In order to access the tables using Impala, the student must create external tables in Hive with mapped columns that match the MapR Database columns.

If you would like to be the student, you can perform the following steps to help the professor:

1. Use the HBase shell to create two tables in MapR Database: “student” and “clicks”. To create the tables, issue the following commands:

```
echo "create '/user/userA/students','account','address'" | hbase shell
echo "create '/user/userA/clicks','clickinfo','iteminfo'" | hbase shell
```

2. Issue the `hadoop fs -ls` command on the table location to verify that the tables exist.

```
hadoop fs -ls /user/userA
echo "describe '/user/usera/student'" | hbase shell
echo "describe '/user/usera/clicks'" | hbase shell
```

3. Create external tables in Hive with the appropriate column mapping for the “student” and “clicks” tables using a string row key. Remember the two important properties for HBaseStorageHandler:
   - `hbase.columns.mapping`, which specifies Hive column to column family mapping.
   - `hbase.table.name`, which can be the absolute path of the table or just the table name, depending on whether the table path is mapped.

   To create the external tables in Hive, run the following commands:

```
CREATE EXTERNAL TABLE students
(id string,
name string,
street string,
zipcode int,
state string)
STORED BY
'org.apache.hadoop.hive.hbase.HBaseStorageHandler' WITH SERDEPROPERTIES
('hbase.columns.mapping'=':key,account:name,address:street,address:zipcod
e,address:state')
TBLPROPERTIES
('hbase.table.name'='/user/userA/students');

CREATE EXTERNAL TABLE clicks
(clickid string,
studentid string,
url string,
time timestamp,
itemtype string,
quantity int)
STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
WITH SERDEPROPERTIES ('hbase.columns.mapping'=':key, clickinfo:studentid,
clickinfo:url, clickinfo:time, iteminfo:itemtype, iteminfo:quantity')
TBLPROPERTIES
('hbase.table.name'='/user/userA/clicks');
```

last-updated: Apr 11, 2022

4. Create a `testdata.txt` file with the following content to add data into the “students” and “clicks” MapR Database binary tables.

```
cat > testdata.txt
put '/user/userA/students','student1','account:name','Alice'
put '/user/userA/students','student1','address:street','123 Ballmer Av'
put '/user/userA/students','student1','address:zipcode','12345'
put '/user/userA/students','student1','address:state','CA'
put '/user/userA/students','student2','account:name','Bob'
put '/user/userA/students','student2','address:street','1 Infinite Loop'
put '/user/userA/students','student2','address:zipcode','12345'
put '/user/userA/students','student2','address:state','CA'
put '/user/userA/students','student3','account:name','Frank'
put '/user/userA/students','student3','address:street','435 Walker Ct'
put '/user/userA/students','student3','address:zipcode','12345'
put '/user/userA/students','student3','address:state','CA'
put '/user/userA/students','student4','account:name','Mary'
put '/user/userA/students','student4','address:street','56 Southern Pkwy'
put '/user/userA/students','student4','address:zipcode','12345'
put '/user/userA/students','student4','address:state','CA'
put '/user/userA/clicks','click1','clickinfo:studentid','student1'
put '/user/userA/clicks','click1','clickinfo:url','http://www.google.com'
put '/user/userA/clicks','click1','clickinfo:time','2014-01-01
12:01:01.0001'
put '/user/userA/clicks','click1','iteminfo:itemtype','image'
put '/user/userA/clicks','click1','iteminfo:quantity','1'
put '/user/userA/clicks','click2','clickinfo:studentid','student1'
put '/user/userA/clicks','click2','clickinfo:url','http://www.amazon.com'
put '/user/userA/clicks','click2','clickinfo:time','2014-01-01
01:01:01.0001'
put '/user/userA/clicks','click2','iteminfo:itemtype','image'
put '/user/userA/clicks','click2','iteminfo:quantity','1'
put '/user/userA/clicks','click3','clickinfo:studentid','student2'
put '/user/userA/clicks','click3','clickinfo:url','http://www.google.com'
put '/user/userA/clicks','click3','clickinfo:time','2014-01-01
01:02:01.0001'
put '/user/userA/clicks','click3','iteminfo:itemtype','text'
put '/user/userA/clicks','click3','iteminfo:quantity','2'
put '/user/userA/clicks','click4','clickinfo:studentid','student2'
put '/user/userA/clicks','click4','clickinfo:url','http://www.ask.com'
put '/user/userA/clicks','click4','clickinfo:time','2013-02-01
12:01:01.0001'
put '/user/userA/clicks','click4','iteminfo:itemtype','text'
put '/user/userA/clicks','click4','iteminfo:quantity','5'
put '/user/userA/clicks','click5','clickinfo:studentid','student2'
put '/user/userA/clicks','click5','clickinfo:url','http://
www.reuters.com'
put '/user/userA/clicks','click5','clickinfo:time','2013-02-01
12:01:01.0001'
put '/user/userA/clicks','click5','iteminfo:itemtype','text'
put '/user/userA/clicks','click5','iteminfo:quantity','100'
put '/user/userA/clicks','click6','clickinfo:studentid','student3'
put '/user/userA/clicks','click6','clickinfo:url','http://www.google.com'
put '/user/userA/clicks','click6','clickinfo:time','2013-02-01
12:01:01.0001'
put '/user/userA/clicks','click6','iteminfo:itemtype','image'
put '/user/userA/clicks','click6','iteminfo:quantity','1'
put '/user/userA/clicks','click7','clickinfo:studentid','student3'
put '/user/userA/clicks','click7','clickinfo:url','http://www.ask.com'
put '/user/userA/clicks','click7','clickinfo:time','2013-02-01
12:45:01.0001'
put '/user/userA/clicks','click7','iteminfo:itemtype','image'
put '/user/userA/clicks','click7','iteminfo:quantity','10'
```

last-updated: Apr 11, 2022

```
put '/user/userA/clicks','click8','clickinfo:studentid','student4'
put '/user/userA/clicks','click8','clickinfo:url','http://www.amazon.com'
put '/user/userA/clicks','click8','clickinfo:time','2013-02-01
22:01:01.0001'
put '/user/userA/clicks','click8','iteminfo:itemtype','image'
put '/user/userA/clicks','click8','iteminfo:quantity','1'
put '/user/userA/clicks','click9','clickinfo:studentid','student4'
put '/user/userA/clicks','click9','clickinfo:url','http://www.amazon.com'
put '/user/userA/clicks','click9','clickinfo:time','2013-02-01
22:01:01.0001'
put '/user/userA/clicks','click9','iteminfo:itemtype','image'
put '/user/userA/clicks','click9','iteminfo:quantity','10'
```

5. Press Control + Z to finish editing the file and pipe these commands to the HBase shell to insert the test data:

```
cat testdata.txt | hbase shell
```

6. Scan the tables to verify that the data was inserted correctly. Run the following commands to perform the scan:

```
echo "scan '/user/userA/students'" | hbase shell
echo "scan '/user/userA/clicks'" | hbase shell
```

7. Use Hive to verify that the data was inserted into the tables. Issue the SELECT statement against students and clicks to verify the count in each table.

```
hive
hive> select * from students;
OK
student1        Alice   123 Ballmer Av  12345   CA
student2        Bob     1 Infinite Loop 12345   CA
student3        Frank   435 Walker Ct   12345   CA
student4        Mary    56 Southern Pkwy        12345   CA
hive> select * from clicks;
OK
click1  student1        http://www.google.com   2014-01-01
12:01:01.0001        image   1
click2  student1        http://www.amazon.com   2014-01-01
01:01:01.0001        image   1
click3  student2        http://www.google.com   2014-01-01
01:02:01.0001        text    2
click4  student2        http://www.ask.com      2013-02-01
12:01:01.0001        text    5
click5  student2        http://www.reuters.com  2013-02-01
12:01:01.0001        text    100
click6  student3        http://www.google.com   2013-02-01
12:01:01.0001        image   1
click7  student3        http://www.ask.com      2013-02-01
12:45:01.0001        image   10
click8  student4        http://www.amazon.com   2013-02-01
22:01:01.0001        image   1
click9  student4        http://www.amazon.com   2013-02-01
22:01:01.0001        image   10
```

Since the Impala shell was running when you inserted the data, verify that the metadata is refreshed to make sure that Impala is aware of the new tables created.

last-updated: Apr 11, 2022

8. From the Impala shell , issue the INVALIDATE METADATA statement to refresh the metadata.

```
> invalidate metadata;
> select * from students ;
Query: select * from students
Query finished, fetching results ...
+----------+-------+-------+------------------+---------+
| id       | name  | state | street           | zipcode |

Managing Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To manage Impala, you can start and stop the Impala services, modify resource allocation, and use log files to identify and resolve issues.

Starting/Stopping Impala
From the Control System

You must start the statestore service before you start the catalog or the Impala service.

To start the Impala statestore and catalog services from the Control System, complete the following steps:

1. In the Navigation pane, expand the Cluster Views pane and click Dashboard.
2. In the Services pane, click Impala statestore. The Nodes screen appears and displays the node configured with the statestore service.
3. Click the hostname of the node with the statestore and catalog services configured to display the Node Properties screen.
4. Use the Stop/Start button in the Impala statestore row under Manage Services to start Impala statestore.
5. Use the Stop/Start button in the Impala catalog row under Manage Services to start Impala catalog.

To start Impala server from the Control System, complete the following steps:

1. In the Navigation pane, expand the Cluster Views pane and click Dashboard.
2. In the Services pane, click Impala server. The Nodes screen appears and displays the nodes configured with the Impala server.
3. Click the hostname of the a node with the Impala server configured to display its Node Properties screen.
4. Use the Stop/Start button in the Impala server row under Manage Services to start the Impala server.
5. Repeat steps 3 and 4 for the remaining nodes configured with the Impala server.

last-updated: Apr 11, 2022

From the CLI

You must start the statestore service before you start the catalog or the Impala service.

To start Impala from the command line, complete the following steps:

1. Issue the following command to start the statestore service on the node with statestored:

```
$ sudo maprcli node services -name impalastore -action start|stop -nodes
<node IP addresses separated by a space>
Example:
$ sudo maprcli node services -name impalastore -action start -nodes
10.10.30.166
```

2. Issue the following command to start the catalog service on the node with catalogd:

```
$ sudo maprcli node services -name impalacatalog -action start|
stop -nodes <node IP addresses separated by a space>
Example:
$ sudo maprcli node services -name impalacatalog -action start -nodes
10.10.30.166
```

3. Issue the following command to start the Impala service on the node(s) with impalad:

```
$ sudo maprcli node services -name impalaserver -action start|
stop -nodes < node IP addresses separated by a space >
Example:
$ sudo maprcli node services -name impalaserver -action start -nodes
10.10.30.166
```

4. Optionally, you can run the following command to launch the impala-shell if you want to issue queries from the command line:

```
${IMPALA_HOME}/bin/impala-shell.sh
```

Modify Resource Allocation

If you run Impala on nodes that also run MapReduce, both frameworks may suffer poor performance if they have to compete for resources. You can configure memory based on your job requirements and SLAs to ensure that each framework has enough resources to avoid conflicts. For information about modifying memory, refer to Additional Impala Configuration Options.

Impala Logs

Impala logs provide information errors, configuration, and completed jobs. You can review log files on each node. An Impala administrator should review the log files and set log levels.

Impala uses the glog_v logging system to store information. Some messages refer to C++ file names. The GLOG_v environment variable specifies which types of messages Impala logs.

Reviewing Logs

You can locate log files in the Impala installation directory (/opt/mapr/impala/impala-<version>/logs) on each node with Impala. Impala creates a new set of log files on each statestored or impalad restart.

The following table provides a list of the important log files for the impalad and statestored processes with descriptions:

Log Type	Impalad Filename	Statestored Filename	File Content

INFO	impalad.INFO	statestored.INFO	Shows configuration settings for the processes.
WARNING	impalad.WARNING	statestored.WARNING	Shows problem information, including such things as suboptimal settings and also serious runtime errors.
ERROR	impalad.ERROR	statestored.ERROR	Shows the most serious errors, such as process crashes, failed queries. The .WARNING file also shows these messages.

Setting Log Levels

The GLOG system has three logging levels that you can adjust by exporting variable settings. The logging levels are cumulative. Increasing logging levels may decrease performance and increases log size. Change logging settings before you start impalad.

The following table provides the logging levels and their descriptions:

Level	Description
GLOG_v=1	Default. Logs information about each connection and query that is initiated to an impalad instance, including runtime profiles
GLOG_v=2	Logs everything from GLOG_v=1 plus information for each RPC initiated. This level also records query execution progress information, including details on each file read.
GLOG_v=3	Logs everything from GLOG_v=2 plus it logs row read. This level is only applicable for the most serious troubleshooting and tuning scenarios, because it can produce exceptionally large and detailed large log files.

Use the following command to change logging settings:

```
export GLOG_v=1
```

For more information on how to configure GLOG, including how to set variable logging levels for different system components, see Fixed in 5.2 r1.0.

Log Rotation

Log rotation is the automatic removal of unneeded or old log files. By default, Impala switches out old log files every 5 seconds, based on the default interval specified in the `logbufsecs` setting. The `-max_log_files` configuration option specifies how many log files to keep at each severity level (INFO, WARNING, ERROR, and FATAL). You can configure the `-max_log_files` option for each Impala daemon (impalad, statestored, and catalogd) in the `env.sh` configuration file. By default, Impala preserves the latest 10 log files for each severity level and removes old logs based on the `logbufsecs` setting. Setting `-max_log_files` to 0 preserves all of the log files. This setting requires manual log rotation. Setting `max_log_files` to 1 preserves only the latest log file.

Impala Ports

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Before you deploy Impala, verify that the TCP ports are open on each system.

Impala uses the following ports:

last-updated: Apr 11, 2022

Component	Service	Port	Type	Description
Impala Daemon	Impala Daemon Frontend Port	21000	External	Impala uses this port to communicate commands and receive results through the impala-shell and the ODBC driver.
Impala Daemon	Impala Daemon Frontend Port	21050	External	Impala uses this port to communicate commands and receive results through applications.
Impala Daemon	Impala Daemon Backend Port	22000	Internal	The Impala daemons use this port to communicate with each other.
Impala Daemon	StateStoreSubscriber Service Port	23000	Internal	The Impala daemons listen for updates from the statestore on this port.
Impala Daemon	Impala Daemon HTTP Server Port	25000	External	The Impala web interface that administrators use for troubleshooting.
Impala Statestore Daemon	StateStore Service Port	24000	Internal	The statestore listens on this port for registration requests.
Impala Statestore Daemon	StateStore HTTP Server Port	25010	External	The statestore web interface that administrators use for troubleshooting.
Impala Catalog Daemon	Catalog HTTP Server Port	25020	External	The catalog service web interface that administrators use for troubleshooting.
Impala Catalog Daemon	Catalog Service Port	26000	Internal	The catalog service uses this port to communicate with the Impala daemons.

Programming Interfaces

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can connect to Impala daemons through the impala-shell or through a JDBC or ODBC client. You can use the impala-shell to query data from a Linux environment. In a non-Linux environment, you can query data using JDBC and ODBC applications.

last-updated: Apr 11, 2022

Impala Shell

The Impala-shell is a command line tool that you can use for setting up databases and tables, inserting data, and issuing queries using SQL statements and some shell commands. The impala-shell can reside on any client machine.

You can connect to the same node and issue all SQL statements through that particular node to avoid issuing the REFRESH statement frequently. For load balancing, you can connect to different nodes for each impala-shell session. When you connect to different Impala nodes, you may need to issue the REFRESH and INVALIDATE METADATA statements to update table data and metadata.

When you run commands from within the impala-shell, use a semi-colon to terminate commands. Each command can span multiple lines. Refer to Impala-Shell Commands and Command Line Options for a list of commands and options that you can issue from within the impala-shell.

Connecting to impalad from impala-shell

You can connect to any node running the Impala daemon process from the impala-shell using the CONNECT command. Once connected, you can send queries to the Impala node from the command line.

To connect to impalad, complete the following steps:

1. Issue the following command to start the impala-shell without a connection:

   ```
   $ impala-shell
   ```

2. Issue the CONNECT command to connect to an instance of Impala, replacing impalad-host with the hostname of the node that you want to connect to.

   Example:

   ```
   [Not connected] > connect impalad-host
   [impalad-host:21000] >
   ```

JDBC and ODBC Clients

You can use a JDBC or ODBC client to connect to Impala and run queries against data stored in MapR File System and MapR Database. The client or application issues a query to an Impala daemon through an ODBC or JDBC connection. The ODBC and JDBC driver submits the query to Impala in the form of a SQL statement.

Install a JDBC or ODBC driver on the client machine and then configure the driver to enable communication between the client and Impala. For driver download, installation, and connection information, refer to the following documentation:

JDBC/ODBC

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

JDBC

The MapR Impala JDBC Driver is available in a JAR file. You can download the driver to access Impala from a Java application or any tool that uses a JDBC connection. You can download the Impala JDBC driver from `https://package.mapr.hpe.com/tools/MapR-JDBC/MapR_Impala/`. The documentation for the Impala JDBC 1.0.46 driver is available at Impala JDBC Driver.

last-updated: Apr 11, 2022

ODBC

The MapR Impala ODBC Driver is available for Microsoft Windows, Linux, and Mac OS X. The driver complies with the ODBC 3.52 data standard and adds Unicode and 32- and 64-bit support on all platforms. The ODBC driver connects to an Impala server regardless of the server's host operating system. You can download the Impala ODBC driver from https://package.mapr.com/tools/MapR-ODBC/MapR_Impala/. The documentation for the Impala ODBC 1.2.16 driver is available at Impala ODBC Driver.

The following sections provide JDBC and ODBC connection information:

JDBC Connections

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can connect to Impala through a JDBC client tool, such as the SQuirreL client. You can also use the driver in a Maven application.

Using the JDBC Driver with a Client Application

You can download the Impala JDBC driver from https://package.mapr.hpe.com/tools/MapR-JDBC/MapR_Impala/MapR_Impala_jdbc_v1.0.46.1057/. After downloading the driver, refer to the documentation at Impala JDBC Driver to install and configure the JDBC driver.

Before you connect to Impala from a JDBC client tool, complete the following tasks:

1. Configuring the JDBC Port. The default JDBC port that Impala accepts connections through is port 21050. Verify that this port can communicate with other hosts on your network. If your JDBC application connects through a different port, use the - - hs2_port option when you start `impalad` to specify the port number.

2. Enable the JDBC driver on client machines. The JDBC driver is packaged in JAR files. From a system that has Hive installed, download the following JAR files to each client machine:

   - The JDBC driver is in /opt/mapr/hive/hive-2.1/lib/hive-jdbc-2.1.1-mapr-1710.jar.
   - The hadoop-common-2.7.0 jar file for MRv2 (YARN) is in /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common.
   - The other required JAR files are in /opt/mapr/hive/hive-2.1/lib/.

   Download the following JARs:

   ```
   commons-logging-1.1.3.jar
   guava-14.0.1.jar
   hive-exec-2.1.1-mapr-1710.jar
   hive-jdbc-2.1.1-mapr-1710.jar
   hive-metastore-2.1.1-mapr-1710.jar
   hive-service-2.1.1-mapr-1710.jar
   hive-shims-2.1.1-mapr-1710.jar
   httpclient-4.4.jar
   httpcore-4.4.jar
   libfb303-0.9.2.jar
   libthrift-0.9.2.jar
   ```

   Note: You may have a different Hive 2.1 version installed. This list pertains to the 1710 version of Hive 2.1.You also need the `slf4j-api-1.7.5.jar` and `slf4j-log4j12-1.7.5.jar` files, which are available in /opt/mapr/lib.

last-updated: Apr 11, 2022

3. Update the CLASSPATH. The client application needs to locate the JAR files. Set the CLASSPATH for the client process to include the JARs. Consult the documentation for your JDBC client application for more details on how to install new JDBC drivers.

   If the existing CLASSPATH on your client machine refers to an older version of the Hive JARs, verify that the new JARs are listed first. You can put the new JAR files ahead of the older JAR files, or delete the other references to Hive JAR files.

4. Specify a connection string to establish a connection between Impala and JDBC. The JDBC driver classpath is `org.apache.hive.jdbc.HiveDriver`.Use the following connection string to establish the connection:

   ```
   jdbc:hive2://host:port/;auth=noSasl
   ```

   Example:

   `jdbc:hive2://myhost.example.com:21050/;auth=noSasl`

Using the JDBC Driver in a Maven Application

To use the JDBC driver in a Maven application, complete the following steps:

1. Configure a MapR Maven repository. Refer to Maven Artifacts for MapR to configure the Maven repository in your Java application.

2. Add the following dependency in the `pom.xml`:

   ```
   <dependency>
       <groupId>org.apache.hive</groupId>
       <artifactId>hive-jdbc</artifactId>
       <version>0.12-mapr[[mapr-version-number]]</version>
   </dependency>
   ```

last-updated: Apr 11, 2022

3. Specify the connection string in the Java application. The following code shows a working example:

```
import java.sql.*;
public class ImpalaJdbcExample
{
       private static String connectionString =
"jdbc:hive2://10.10.80.231:21050/;auth=noSasl";
       private static String driverName =
"org.apache.hive.jdbc.HiveDriver";
       private static String queryString = "select count(*) from
customers";
       private static Connection con;
       private static ResultSet resultSet;
       private static Statement sqlStatement;
       public static void main(String[] args)
       {
               System.out.println("Loaded the driver successfully.
Trying to establish connection");
               try
               {
                       Class.forName(driverName);
                       con =
DriverManager.getConnection(connectionString);
                       System.out.println("Created connection. Preparing
statement");
                       sqlStatement = con.createStatement();
                       System.out.println("Executing "+queryString);
                       resultSet =
sqlStatement.executeQuery(queryString);
                       while(resultSet.next())
                       {
                               System.out.println("Result set
"+resultSet.getString(1));
                       }
                       con.close();
               }
               catch(SQLException sqle)
               {
                       System.out.println("Got sql exception");
                       sqle.printStackTrace();
               }
               catch(Exception e)
               {
                       System.out.println("Got exception");
                       e.printStackTrace();
               }
       }
}
```

ODBC Client Connections on Mac OS X

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can use an ODBC client tool to connect to Impala from Mac OS X. Install the driver and configure it to pass a SQL query to Impala. After you install the driver, see Configure the MapR Impala ODBC Driver for Linux and Mac OS X.

Before you install the driver, verify that your system meets the following prerequisites:

- Mac OS X version 10.8 or later

- 100 MB of available disk space
- iODBC 3.52.7 or above

To install and configure the MapR Impala ODBC Driver, complete the following steps:

1. Download the MapR Impala ODBC Driver.
2. Install the MapR Impala ODBC Driver on the machine from which you connect to the Impala service. The driver supports 32- and 64-bit applications. To install the driver:
   a. Double-click to mount the `MapRImpalaODBC.dmg` disk image.
   b. Double-click `MapRImpalaODBC.pkg` to run the Installer.
   c. Follow the instructions in the installer to complete the installation process.
   d. When the installation completes, click **Close.**

   MapR Impala ODBC Driver files install in the following locations:
   - /opt/mapr/impalaodbc/ErrorMessages – Error messages files directory
   - /opt/mapr/impalaodbc/Setup – Sample configuration files directory
   - /opt/mapr/impalaodbc/lib/universal – Binaries directory
3. Update the DYLD_LIBRARY_PATH environment variable. The DYLD_LIBRARY_PATH environment variable must include the paths to the:
   - Installed ODBC driver manager libraries
   - Installed MapR Impala ODBC Driver for Impala shared libraries

   For example, if the ODBC driver manager libraries are installed in /usr/local/lib, then set DYLD_LIBRARY_PATH to the following:

```
export DYLD_LIBRARY_PATH=/usr/local/lib:/opt/mapr/impalaodbc/lib/
universal
```

Next Step: See Configure the MapR Impala ODBC Driver for Linux and Mac OS X.

ODBC Client Connections on Linux

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can use an ODBC client tool to connect to Impala from Linux. Install the driver and configure it to pass a SQL query to Impala. After you install the driver, Configure the MapR Impala ODBC Driver for Linux and Mac OS X.

Before you install the driver, verify that your system meets the following system prerequisites:

- RedHat 6.x or CentOS 6.x
- 50 MB of available disk space
- An installed ODBC driver manager, such as unixODBC 2.3.0/2.3.1 or iODBC 3.52.7

To install and configure the MapR Impala ODBC Driver, complete the following steps:

1. Download the MapR Impala ODBC Driver. You can install the 32- or 64-bit driver on Linux. Download and install the version of the driver that matches the architecture of the client application that you use to access Impala. The 64-bit editions of Linux support 32- and 64-bit applications.

   Click on the link to download the driver appropriate for your system:

Operating System	Version	Drivers
RedHat	6.x	MapRImpalaODBC-1.2.1.1001-1.el6.x86_64.rpm
		MapRImpalaODBC-32bit-1.2.1.1001-1.el6.i686.rpm

2. Install the MapR Impala ODBC Driver on the machine that you connect to the Impala service from.

   a. Login as **root**.

   b. Navigate to the folder that contains the driver RPM packages to install.

   c. Enter the following command where *RPMFileName* is the file name of the RPM package containing the version of the driver that you want to install:

   ```
   yum localinstall --nogpgcheck RPMFileName
   ```

   MapR Impala ODBC Driver files install in the following locations:

   - /opt/mapr/impalaodbc/ErrorMessages – Error messages files directory
   - /opt/mapr/impalaodbc/Setup – Sample configuration files directory
   - /opt/mapr/impalaodbc/lib/32 – 32-bit shared libraries directory
   - /opt/mapr/impalaodbc/lib/64 – 64-bit shared libraries directory

   The MapR Impala ODBC Driver depends on the following resources:

   - cyrus-sasl-2.1.22-7 or above
   - cyrus-sasl-gssapi-2.1.22-7 or above
   - cyrus-sasl-plain-2.1.22-7 or above

   If the package manager in your Linux or Mac OS X distribution cannot resolve the dependencies automatically when installing the driver, download and manually install the packages.

3. Set the shared LD_LIBRARY_PATH environment variable. Update the shared library environment variable to include the paths to the following directories:

   - Installed ODBC driver manager libraries
   - Installed MapR Impala ODBC Driver for Impala shared libraries

   Note: You can have both 32- and 64-bit versions of the driver installed at the same time on the same computer, but do not include the paths to both 32- and 64-bit shared libraries in LD_LIBRARY PATH at the same time. Only include the path to the shared libraries that correspond to the driver matching the architecture of the client application used. For example, if you are using a 64-bit client application and ODBC driver manager libraries are installed in /usr/local/lib, then set LD_LIBRARY_PATH as follows:

   ```
   export LD_LIBRARY_PATH=/usr/local/lib:/opt/mapr/impalaodbc/lib/64
   ```

last-updated: Apr 11, 2022

Next Step: Configure the MapR Impala ODBC Driver for Linux and Mac OS X.

ODBC Client Connections on Windows

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can connect to Impala through an ODBC client tool, such as Tableau, from a Windows operating system. Use the MapR Impala ODBC Driver for SQL access to files and tables. Install the driver and configure it to pass a SQL query to Impala. You can run 32- and 64-bit applications on 64-bit Windows operating systems. You can install both versions of the driver on the same computer, however you should use the version of the driver that matches the architecture of the client application running the query.

Before you install the driver, verify that your system meets the following system prerequisites:

- Administrator privileges on the machine.
- One of the following operating systems (32- and 64-bit editions are supported):
  - Windows 7
  - Windows Server 2008 R2
  - Windows Server 2012
- 25 MB of available disk space

To install and the configure the MapR Impala ODBC Driver, complete the following steps:

1. Download the MapR Impala ODBC Driver:
   - MapRImpalaODBC32.msi (32-bit)
   - MapRImpalaODBC64.msi (64-bit)
2. Install the MapR Impala ODBC Driver on the machine that you connect to the Impala service from. When you install the driver, the driver program updates the system path to include the JVM directory. To install the driver:
   a. Double-click the file.
   b. Click **Next**.
   c. Accept the terms of the License Agreement, and click **Next**.
   d. Select an installation location and then click **OK**. To accept the installation location, click **Next**.
   e. Click **Install**.
   f. When the installation completes, click **Finish**.
3. Configure the MapR Impala ODBC Driver. To configure the driver:
   a. Click the Windows **Start** button.
   b. Click **All Programs**.
   c. Select the MapR Impala ODBC Driver. If you installed both versions of the driver, two options appear. Select the version that matches the architecture of your application. For example, a DSN that is defined for the 32-bit driver will only be accessible from 32-bit applications.
   d. Click 64-bit ODBC Administrator or 32-bit ODBC Administrator. The ODBC Data Source Administrator window opens.

last-updated: Apr 11, 2022

e. Click the **Drivers** tab, and verify that the MapR Impala ODBC Driver appears in the list of ODBC drivers that are installed on your system.

f. Click the **System DSN**tab to create a system DSN or click the User DSN tab to create a user DSN. All users that login to a workstation can see a system DSN. A user DSN is specific to a user on the workstation. Only the user who creates a user DSN can see it.

g. Click **Add**. The Create New Data Source window opens.

h. Select **MapR Impala ODBC Driver** and then click **Finish**. The MapR Impala ODBC Driver DSN Setup dialog opens.

i. Enter the DSN information. Optionally, you can select **Advanced Options**, and enter the following information in the Advanced Options window:

Option	Description
Use Native Query	Select this option to disable translating ODBC SQL to Impala SQL. By default, the driver applies transformations to the queries produced by an application to convert the queries to an equivalent form in Impala SQL. If the application produces Impala SQL, you can turn off the translation to avoid additional overhead of query transformation.
Rows Fetched Per Block	Enter the number of rows to fetch per block. You can enter any positive 32-bit integer as a value.
Socket Timeout	Enter the number of seconds Impala waits to close an idle connection with the client application. If you want to disable this option, set the value to 0.
Allow Common Name Hostname Mismatch	Select this option to allow the common name of a CA-issued SSL certificate to mismatch the hostname of the Impala server. **Note:** This setting only applies to the User Name and Password (SSL) and No Authentication (SSL) authentication mechanisms. Other authentication mechanisms ignore this setting.
Trusted Certificates field	Enter the path to the file that contains the trusted certificates in this field to configure the driver to load trusted certificates (such as the certificate from the Impala server) from a specific file when authenticating the Impala server using SSL. **Note:** This setting only apples to the User Name and Password (SSL) and No Authentication (SSL) authentication mechanisms. Other authentication mechanisms ignore this setting. SSL certificates in the trusted certificates file must be in PEM format. If this setting is not set, then the driver defaults to using the trusted CA certificates PEM file installed by the driver.

j. Click **OK**.

k. Optionally, if the operations against Impala are to be done on behalf of a user that is different than the authenticated user for the connection, enter the user name of the user to be delegated in the **Delegation UID** text box.

l. Click **Test** to test the connection.

m. Review the connection test results, and click **OK** in the Test Results dialog.

n. In the MapR Impala ODBC Driver DSN Setup dialog, click **OK**.

last-updated: Apr 11, 2022

4. Configure authentication. The Impala server supports multiple authentication mechanisms. You must determine the authentication type your server is using and configure your DSN accordingly. The following table provides the authentication methods available with configuration instructions:

Method	Configuration
Kerberos	Kerberos must be configured before you can use this authentication mechanism. For details, see Configuring Kerberos Authentication for Windows on page 3763. After Kerberos is installed and configured, configure your DSN to use Kerberos authentication. To configure your DSN to use Kerberos authentication, complete the following steps: **a.** In the MapR Impala ODBC Driver DSN Setup dialog, click the drop-down arrow next to the Mechanism field, and then select **Kerberos** **b.** If your Kerberos setup does not define a default realm or if the realm of your Impala server is not the default, then type the Kerberos realm of the Impala server host in the Realm field. Otherwise, leave the field blank. **c.** In the Host FQDN field, type the fully qualified domain name of the Impala host. **d.** In the Service Name field, type the service name of the Impala server. For example, if the principle for the Impala server is `impala/fully.qualified.domain.name@your-realm.com` , then the value in the service name field is impala. If you are unsure of the correct service name to use for your particular Hadoop deployment, contact your Hadoop administrator. **e.** In the Transport Buffer Size field, type the number of bytes to reserve in memory for buffering unencrypted data from the network. **Note:** In most circumstances, the default value of 1000 bytes is optimal.
No Authentication	For this authentication mechanism, you do not need to configure any additional settings. To configure your DSN for connections that do not require authentication, click the drop-down arrow next to the Mechanism field, and then select **No Authentication** in the driver DSN Setup dialog.

last-updated: Apr 11, 2022

Method	Configuration
No Authentication (SSL)	This authentication mechanism uses SSL but does not require a user name or a password. The driver accepts self-signed SSL certificates. To configure your DSN to use No Authentication (SSL) authentication, complete the following steps: **a.** In the MapR Impala ODBC Driver DSN Setup dialog, click the drop-down arrow next to the Mechanism field, and then select **No Authentication (SSL)** **b.** Optionally, configure the driver to allow a mismatch between the common name of a CA-issued certificate and the host name of the Impala server by clicking **Advanced Options** and selecting the Allow Common Name Host Name Mismatch check box. **Note:** For self-signed certificates, the driver always allows the common name of the certificate to not match the host name. Optionally, configure the driver to load SSL certificates from a specific file by clicking **Advanced Options** and typing the path to the file in the Trusted Certificates field. **Note:** By default, the driver uses the trusted CA certificates PEM file that is installed with the driver.
User Name	This authentication mechanism requires a user name but does not require a password. The user name labels the session, facilitating database tracking. To configure your DSN to use User Name authentication, complete the following steps: **a.** In the MapR Impala ODBC Driver DSN Setup dialog, click the drop-down arrow next to the Mechanism field, and then select **User Name** **b.** In the User Name field, type a user name that is recognized by the Impala server. **c.** In the Transport Buffer Size field, type the number of bytes to reserve in memory for buffering unencrypted data from the network. **Note:** In most circumstances, the default value of 1000 bytes is optimal.

Method	Configuration
User Name and Password	This authentication mechanism requires a user name and a password. **Note:** This authentication mechanism should not be used with an Impala configuration that does not have LDAP enabled. To configure your DSN for User Name and Password authentication, complete the following steps: **a.** In the MapR Impala ODBC Driver DSN Setup dialog, click the drop-down arrow next to the Mechanism field, and then select **User Name and Password** **b.** In the User Name field, type a user name that is recognized by the Impala server. **c.** In the Password field, type the password corresponding to the user name you typed in step 2.
User Name and Password (SSL)	This authentication mechanism uses SSL and requires a user name and a password. The driver accepts self-signed SSL certificates. **Note:** This authentication mechanism should not be used with an Impala configuration that does not have LDAP enabled. To configure your DSN to use User Name and Password (SSL) authentication, complete the following steps: **a.** In the MapR Impala ODBC Driver DSN Setup dialog, click the drop-down arrow next to the Mechanism field, and then select **User Name and Password (SSL)** **b.** In the User Name field, type a user name that is recognized by the Impala server. **c.** In the Password field, type the password corresponding to the user name you typed in step 2. **d.** Optionally, configure the driver to allow a mismatch between the common name of a CA-issued certificate and the host name of the Impala server by clicking **Advanced Options** and selecting the Allow Common Name Host Name Mismatch check box. **Note:** For self-signed certificates, the driver always allows the common name of the certificate to not match the host name Optionally, configure the driver to load SSL certificates from a specific file by clicking **Advanced Options** and typing the path to the file in the Trusted Certificates field. **Note:** By default, the driver uses the trusted CA certificates PEM file that is installed with the driver.

Configuring Kerberos Authentication for Windows

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

You can configure Kerberos Authentication for Windows through Active Directory or MIT Kerberos.

Active Directory

The MapR ODBC Driver for Impala supports Active Directory Kerberos on Windows. Before you can use Active Directory Kerberos on Windows, the following prerequisites must be met:

- MIT Kerberos is not installed on the client Windows machine.
- The MIT Kerberos Hadoop realm has been configured to trust the Active Directory realm, so that users in the Active Directory realm can access services in the MIT Kerberos Hadoop realm.

MIT Kerberos

To use Kerberos, you must download and install MIT Kerberos for Windows 4.0.1.

Complete the following steps to use MIT Kerberos:

1. Download MIT Kerberos for Windows 4.0.1.
   - **Download for 64-bit Computers**

     To download the Kerberos installer for 64-bit computers, use the following download link from the MIT Kerberos website:

     http://web.mit.edu/kerberos/dist/kfw/4.0/kfw-4.0.1-amd64.msi

     This installer includes both 32-bit and 64-bit libraries.

   - **Download for 32-bit Computers**

     To download the Kerberos installer for 32-bit computers, use the following download link from the MIT Kerberos website:

     http://web.mit.edu/kerberos/dist/kfw/4.0/kfw-4.0.1-i386.msi

     This installer includes 32-bit libraries only.
2. Run the MIT Kerberos for Windows 4.0.1 installer.
   a. To run the installer, double-click the .msi file that you downloaded.
   b. Follow the instructions in the installer to complete the installation process.
   c. When the installation completes, click **Finish**.
3. Setup the Kerberos configuration file.

   Settings for Kerberos are specified through a configuration file. You can set up the configuration file as a .ini file in the default location (the C:\ProgramData\MIT\Kerberos5directory) or as a .conf file in a custom location.

   Normally, the C:\ProgramData\MIT\Kerberos5 directory is hidden. Consult your Windows documentation if you want to view and use this hidden directory.

   Setup in the Default Location

   To set up the Kerberos configuration file in the default location, obtain the krb5.conf configuration file from your Kerberos administrator. Alternatively, you can obtain the /etc/krb5.conf configuration file on the machine that is hosting the Impala server and then complete the following steps:

   a. Rename the configuration file from krb5.conf to krb5.ini.
   b. Copy the krb5.ini file to the C:\ProgramData\MIT\Kerberos5 directory, and overwrite the empty sample file.

last-updated: Apr 11, 2022

Note: For more information on configuring Kerberos, consult the MIT Kerberos documentation.

Setup in a Custom Location

To set up the Kerberos configuration file in a custom location, obtain the krb5.conf configuration file from your Kerberos administrator. Alternatively, you can obtain the /etc/krb5.conf configuration file on the machine that is hosting the Impala server and then complete the following steps:

a. Place the krb5.conf file in an accessible directory and make note of the full path name.

b. Click Start, then right-click Computer, and then click Properties.

c. Click Advanced system settings. In the System Properties dialog, click the Advanced tab, and then click Environment Variables.

d. In the Environment Variables dialog, under the System variables list, click New.

e. In the New System Variable dialog, in the Variable Name field, type KRB5_CONFIG.

f. In the Variable Value field, type the absolute path to the krb5.conf file from step 2.

g. Click OK to save the new variable.

h. Ensure the variable is listed in the System variables list.

i. Click OK to close the Environment Variables dialog, and then click OK to close the System Properties dialog.

4. Setup the Kerberos Credential Cache File. Kerberos uses a credential cache to store and manage credentials. To set up the Kerberos credential cache file, complete the following steps:

a. Create a directory where you want to save the Kerberos credential cache file. For example, create the following directory: **C:\temp**

b. Click **Start**, then right-click **Computer**,and then click **Properties**.

c. Click **Advanced system settings**.

d. In the System Properties dialog, click the **Advanced** tab, and then click **Environment Variables.**

e. In the Environment Variables dialog, under the **System variables** list, click **New**.

f. In the New System Variable dialog, in the Variable Name field, type **KRB5CCNAME**.

g. In the Variable Value field, type the path to the folder you created in step 0, and then append the file name krb5cache For example, if you created the folder C:\temp in step 0, then type C:\temp\krb5cache.

Note: krb5cache is a file (not a directory) that is managed by the Kerberos software, and it should not be created by the user. If you receive a permission error when you first use Kerberos, ensure that krb5cache does not already exist as a file or a directory.

a. Click **OK** to save the new variable.

b. Ensure the variable appears in the **System variables** list.

c. Click **OK** to close the Environment Variables dialog, and then click **OK** to close the System Properties dialog.

d. To ensure that Kerberos uses the new settings, restart your computer.

5. Obtain a Ticket for a Kerberos Principal. A principal is a user or service that can authenticate to Kerberos. To authenticate to Kerberos, a principal must obtain a ticket by using a password or a keytab file. You can specify a keytab file to use, or use the default keytab file of your Kerberos configuration.

   Obtain a Ticket Using a Password

   a. Click the **Start** button, then click **All Programs**, and then click the **Kerberos for Windows (64-bit)** or the **Kerberos for Windows (32-bit)** program group.

   b. Click **MIT Kerberos Ticket Manager.**

   c. In the MIT Kerberos Ticket Manager, click **Get Ticket.**

   d. In the Get Ticket dialog, type your principal name and password, and then click **OK.**

   If the authentication succeeds, then your ticket information appears in the MIT Kerberos Ticket Manager.

   Obtain a Ticket Using a keytab File

   a. Click the **Start** button **> All Programs > Accessories > Command Prompt.**

   b. In the Command Prompt, type a command using the following syntax:

   ```
   kinit -k -t keytab_file principal
   ```

   keytab_file is the full path to the keytab file.

   For example:

   ```
   C:\mykeytabs\impalaserver.keytab
   ```

   principal is the Kerberos principal to use for authentication.

   For example:

   ```
    impala/impalaserver.example.com@EXAMPLE.COM
   ```

   If the cache location KRB5CCNAME is not set or not used, then use the -c option of the kinit command to specify the credential cache. In the command, the -c argument must appear last. For example:

   ```
   kinit -k -t C:\mykeytabs\impalaserver.keytab
          impala/fully.qualified.domain.name@your-realm.com -c
        C:\ProgramData\MIT\krbcache
   ```

   Note: krbcache is the Kerberos cache file, not a directory.

   Obtain a Ticket Using the Default keytab File

   Note: For instructions on configuring a default keytab file for your Kerberos configuration, consult the MIT Kerberos documentation.

   a. Click the **Start** button **> All Programs > Accessories > Command Prompt**

   b. In the Command Prompt, type a command using the following syntax:

   ```
   kinit -k principal
   ```

   principal is the principal to use for authentication.

For example:

```
impala/impalaserver.example.com@EXAMPLE.COM
```

If the cache location KRB5CCNAME is not set or not used, then use the -c option of the kinit command to specify the credential cache. In the command, the

-c argument must appear last.

For example:

```
kinit -k impala/fully.qualified.domain.name@your-realm.com -c
C:\ProgramData\MIT\krbcache
```

Note: krbcache is the Kerberos cache file, not a directory.

Configure the MapR Impala ODBC Driver for Linux and Mac OS X

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The configuration files reside in the the home directory. You can use the two environment variables, ODBCINI and ODBCSYSINI, to specify different locations for the odbc.ini and odbcinst.ini configuration files. Set ODBCINI to point to your odbc.ini file. Set ODBCSYSINI to point to the directory containing the odbcinst.ini file. For example, if your odbc.ini file is located in /etc and your odbcinst.ini file is located in /usr/local/odbc, set the environment variables as follows:

- `export ODBCINI=/etc/odbc.ini`
- `export ODBCSYSINI=/usr/local/odbc`

Sample Files

The driver installation contains the following sample configuration files in the Setup directory:

- `odbc.ini`
- `odbcinst.ini`
- `mapr.impalaodbc.ini`

The sample files appear in the directory listings by default because the filenames do not begin with a (.) Filenames that begin with a (.) are hidden. If the default location is used for odbc.ini and odbcinst.ini, filenames must begin with a period (.). For mapr.impalaodbc.ini, the filename must begin with a (.) and must reside in the user's home directory.

If the configuration files do not already exist in the home directory, you can copy the sample configuration files to that directory and rename them. If the configuration files already exist in the home directory, use the sample configuration files as a guide for modifying the existing configuration files.

Step 1: Configure the Environment

By default, the configuration files reside in the user's home directory. However, the ODBCINI, ODBCSYSINI, and SIMBAINI environment variables can be used to specify different locations for the odbc.ini, odbcinst.ini, and mapr.impalaodbc.ini configuration files. Set ODBCINI to point to your odbc.ini file.

last-updated: Apr 11, 2022

Set ODBCSYSINI to point to the directory containing the odbcinst.ini file. Set SIMBAINI to point to your mapr.impalaodbc.ini file. For example, if your odbc.ini and mapr.impalaodbc.ini files are located in /etc and your odbcinst.ini file is located in /usr/local/odbc, then set the environment variables as follows:

- `export ODBCINI=/etc/odbc.ini`
- `export ODBCSYSINI=/usr/local/odbc`
- `export SIMBAINI=/etc/mapr.impalaodbc.ini`

The following search order is used to locate the mapr.impalaodbc.ini file:

1. If the SIMBAINI environment variable is defined, then the driver searches for the file specified by the environment variable.

   Important: SIMBAINI must contain the full path, including the filename.

2. The current working directory of the application is searched for a file named mapr.impalaodbc.ini **not** beginning with a period.
3. The directory ~/ (that is, $HOME) is searched for a hidden file named .mapr.impalaodbc.ini.
4. The directory /etc is searched for a file named mapr.impalaodbc.ini **not** beginning with a period.

Step 2: Configure the odbc.ini File

Define the ODBC data sources in the odbc.ini configuration file. This file is divided into the following optional and required sections:

- (Optional) [ODBC]. Controls global ODBC configuration.
- (Required) [ODBC Data Sources]. Lists DSNs and associates them with a driver.
- (Required) A section with the same name as the data source specified in the [ODBC Data Sources] section. This is required to configure the data source.

Example odbc.ini sample file for Linux

```
[ODBC Data Sources]
Sample MapR Impala DSN 32=MapR Impala ODBC Driver 32-bit

[Sample MapR Impala DSN 32]
Driver=/opt/mapr/impalaodbc/lib/32/libmaprimpalaodbc32.so
HOST=MyImpalaServer
PORT=21050
```

Example odbc.ini file for Mac OS X

```
[ODBC Data Sources]
Sample MapR Impala DSN=MapR Impala ODBC Driver

[Sample MapR Impala DSN]
Driver=/opt/mapr/impalaodbc/lib/universal/libmaprimpalaodbc.dylib
HOST=MyImpalaServer
PORT=21050
```

Create a Data Source

To create a data source, complete the following steps:

1. Open the .odbc.ini configuration file in a text editor.
2. Add a new entry to the [ODBC Data Sources] section. Type the data source name (DSN) and the driver name.
3. To set configuration options, add a new section having a name matching the data source name (DSN) you specified in step 2. Specify configuration options as key-value pairs.
4. Save the .odbc.ini configuration file.

Refer to Driver Configuration Options for Linux and Mac OS X for available configuration options that control DSN behavior.

Step 3: Configure the odbcinst.ini File

The odbcinst.ini is an optional configuration file that defines the ODBC Drivers. This configuration file is optional because you can specify drivers directly in the odbc.ini configuration file. The odbcinst.ini file is divided into the following sections:

- [ODBC Drivers] lists the names of all the installed ODBC drivers.
- A section having the same name as the driver name specified in the [ODBC Drivers] section lists driver attributes and values.

Example odbcinst.ini sample file for Linux

```
[ODBC Drivers]
MapR Impala ODBC Driver 32-bit=Installed
MapR Impala ODBC Driver 64-bit=Installed

[MapR Impala ODBC Driver 32-bit]
Description= MapR Impala ODBC Driver (32-bit)
Driver=/opt/mapr/impalaodbc/lib/32/libmaprimpalaodbc32.so

[MapR Impala ODBC Driver 64-bit]
Description=MapR Impala ODBC Driver (64-bit)
Driver=/opt/mapr/impalaodbc/lib/64/libmaprimpalaodbc64.so
```

Example odbcinst.ini file for Mac OS X

```
[ODBC Drivers]
MapR Impala ODBC Driver=Installed

[MapR Impala ODBC Driver]
Description=MapR Impala ODBC Driver
Driver=/opt/mapr/impalaodbc/lib/universal/libmaprimpalaodbc.dylib
```

Define a Driver

To define a driver, complete the following steps:

1. Open the .odbcinst.ini configuration file in a text editor.
2. Add a new entry to the [ODBC Drivers] section. Type the driver name, and then type `=Installed`. Assign the driver name as the value of the Driver attribute in the data source definition instead of the driver shared library name.
3. In .odbcinst.ini, add a new section having a name matching the driver name you typed in step 2, and add configuration options to the section based on the sample odbcinst.ini file provided with MapR Impala ODBC Driver for Impala in the Setup directory. Specify configuration options as key-value pairs.
4. Save the .odbcinst.ini configuration file.

last-updated: Apr 11, 2022

Step 4: Configure the mapr.impalaodbc.ini File

Configure the MapR Impala ODBC Driverto work with your ODBC driver manager.

To configure mapr.impalaodbc.ini, complete the following steps:

1. Open the .mapr.impalaodbc.ini configuration file in a text editor.
2. Edit the DriverManagerEncoding setting. The value is typically UTF-16 or UTF-32, but depends on the driver manger used. iODBC uses UTF-32 and unixODBC uses UTF-16. Review your ODBC Driver Manager documentation for the correct setting.
3. Edit the ODBCInstLib setting. The value is the name of the ODBCInst shared library for the ODBC driver manager you use. The configuration file defaults to the shared library for iODBC. In Linux, the shared library name for iODBC is libiodbcinst.so. In Mac OS X, the shared library name for iODBC is libiodbcinst.dylib.

   Note: Review your ODBC Driver Manager documentation for the correct setting. Specify an absolute or relative filename for the library. If you use the relative filename, include the path to the library in the library path environment variable. In Linux, the library path environment variable is LD_LIBRARY_PATH. In Mac OS X, the library path environment variable is DYLD_LIBRARY_PATH.
4. Save the .mapr.impalaodbc.ini configuration file.

Step 5: Configure Authentication

The Impala server supports multiple authentication mechanisms. You must determine the authentication type your server is using and configure your DSN accordingly. The following table provides the authentication methods available with configuration instructions:

Note: For details on the keys involved in configuring authentication, see Driver Configuration Options for Linux and Mac OS X.

Method	Configuration
No Authentication	For this authentication mechanism, you do not need to configure any additional settings. To configure your DSN for connections that do not require authentication, set the AuthMech configuration key for the DSN to 0.

last-updated: Apr 11, 2022

Kerberos	For information on operating Kerberos, refer to the documentation for your operating system. To configure your DSN to use Kerberos authentication, complete the following steps: **1.** Set the AuthMech configuration key for the DSN to 1 **2.** If your Kerberos setup does not define a default realm or if the realm of your Impala server is not the default, then set the appropriate realm using the KrbRealm key. **3.** Set the KrbFQDN key to the fully qualified domain name of the Impala host. **4.** Set the KrbServiceName key to the service name of the Impala server. For example, if the principle for the Impala server is impala/fully.qualified.domain.name@your-realm.com, then the value in the service name field is impala. If you are unsure of the correct service name to use for your particular Hadoop deployment, contact your Hadoop administrator.
User Name	This authentication mechanism requires a user name but does not require a password. The user name labels the session, facilitating database tracking. To configure your DSN to use User Name authentication, complete the following steps: **1.** Set the AuthMech configuration key for the DSN to 2. **2.** Set the UID key to a user name that is recognized by the Impala server.
User Name and Password	This authentication mechanism requires a user name and a password. **Note:** This authentication mechanism should not be used with an Impala configuration that does not have LDAP enabled. To configure your DSN to use User Name and Password authentication, complete the following steps: **1.** Set the AuthMech configuration key for the DSN to 3. **2.** Set the UID key to a user name that is recognized by the Impala server. **3.** Set the PWD key to the password corresponding to the user name you provided in step 2.

last-updated: Apr 11, 2022

User Name and Password (SSL)	This authentication mechanism uses SSL and requires a user name and a password. The driver accepts self-signed SSL certificates. **Note:** This authentication mechanism should not be used with an Impala configuration that does not have LDAP enabled. To configure your DSN to use User Name and Password (SSL) authentication, complete the following steps: **1.** Set the AuthMech configuration key for the DSN to 4. **2.** Set the UID key to a user name that is recognized by the Impala server. **3.** Set the PWD key to the password corresponding to the user name you provided in step 2. **4.** Optionally, configure the driver to allow a mismatch between the common name of a CA-issued certificate and the host name of the Impala server by setting the CAIssuedCertNamesMismatch key to 1. **Note:** For self-signed certificates, the driver always allows the common name of the certificate to mismatch the host name. For more details, see Driver Configuration Options for Linux and Mac OS X. Optionally, configure the driver to load SSL certificates from a specific file by setting the TrustedCerts configuration key to the path of the file. **Note:** By default, the driver uses the trusted CA certificates PEM file that is installed with the driver. For more details, see Driver Configuration Options for Linux and Mac OS X.
No Authentication (SSL)	This authentication mechanism uses SSL but does not require a user name or a password. The driver accepts self-signed SSL certificates. **T**o configure your DSN to use No Authentication (SSL) authentication, complete the following steps: **1.** Set the AuthMech configuration key for the DSN to 5. **2.** Optionally, configure the driver to allow a mismatch between the common name of a CA-issued certificate and the host name of the Impala server by setting the CAIssuedCertNamesMismatch key to 1. **Note:** For self-signed certificates, the driver always allows the common name of the certificate to mismatch the host name. For more details, see Driver Configuration Options for Linux and Mac OS X. Optionally, configure the driver to load SSL certificates from a specific file by setting the TrustedCerts configuration key to the path of the file. **Note:** By default, the driver uses the trusted CA certificate PEM file that is installed with the driver. For more details, see Driver Configuration Options for Linux and Mac OS X.

Driver Configuration Options for Linux and Mac OS X

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The configuration options that you can use to control the behavior of the MapR ODBC Driver for Impala are listed and described in the table below.

Note: You can set configuration options in your odbc.ini and mapr.impalaodbc.ini files. Configuration options set in the mapr.impalaodbc.ini file apply to all connections, whereas configuration options set in an odbc.ini file are specific to a connection. Configuration options set in odbc.ini take precedence over configuration options set in mapr.impalaodbc.ini.

Key	Default Value	Default
AuthMech	0	You can use the following authentication mechanism values: • **0** – No Authentication • **1** – Kerberos • **2** – User Name • **3** – User Name and Password • **4** – User Name and Password (SSL) • **5** – No Authentication (SSL)
CAIssuedCertNamesMismatch	0	Whether to allow the common name of a CA-issued SSL certificate to mismatch the host name of the Impala server. The following values are possible: • **0** – Do not allow the names to mismatch. • **1** – Allow the names to mismatch. **Note:** This setting is only applicable to the User Name and Password (SSL) and No Authentication (SSL) authentication mechanisms. It is ignored by other authentication mechanisms.
Driver		The location of the MapR ODBC Driver for Impala shared object file.
HOST		The IP address or hostname of the Impala server.
KrbFQDN		The fully qualified domain name of the Impala host used.
KrbRealm		If there is no default realm configured or if the realm of the Impala host is different from the default realm for your Kerberos setup, use this option to define the realm of the Impala host.
KrbServiceName		The Kerberos service principal name of the Impala server.
PORT	10000	The listening port for the service.

last-updated: Apr 11, 2022

PWD		The password of a user account on the host that is running Impala. PWD is required if AuthMech is set to User Name and Password or User Name and Password (SSL).
RowsFetchedPerBlock	10000	The maximum number of rows that a query returns at a time. Any positive 32-bit integer is a valid value, but testing has shown that performance gains are marginal beyond the default value of 10000 rows.
SocketTimeout	0	The number of seconds after which Impala closes the connection with the client application if the connection is idle.

TrustedCerts	For 32 bit driver:
	`/opt/mapr/impalaodbc/lib/32/cacerts.pem`
	For 64 bit driver:
	`/opt/mapr/impalaodbc/lib/64/cacerts.pem`
		Used to specify the location of the file containing trusted CA certificates for authenticating the Impala server when using SSL.
		If this setting is not set, then the driver defaults to using the trusted CA certificates file installed by the driver.
		Note: This setting is only applicable to User Name and Password (SSL) and No Authentication (SSL) authentication mechanisms, and it is ignored by other authentication mechanisms.

TSaslTransportBufSize	1000	The number of bytes to reserve in memory for buffering unencrypted data from the network. **Note:** In most circumstances, the default value of 1000 bytes is optimal.
UID	anonymous	The user name of an existing account on the host that is running Impala. UID is required if AuthMech is set to User Name and Password or User Name and Password (SSL). UID is optional if AuthMech is set to User Name.

UseNativeQuery	0	By default, the driver transforms the queries emitted by an application to convert the queries into an equivalent form in Impala SQL. Use this option to specify whether or not the driver transforms queries. The following values are possible: • **0** – Transform the queries into Impala SQL. • **1** – Do not transform the queries (use the native query instead). **Note:** If the application is Impala-aware and already emits Impala SQL, then set this option to 1 to avoid the extra overhead of query transformation.

Impala-Shell Commands

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can specify `impala-shell` options from the command line or in the `$HOME/.impalarc` configuration file. You can define a set of default options for your `impala-shell` environment in the `$HOME/.impalarc` configuration file. For every command line option, there is an equivalent setting in the `$HOME/.impalarc` configuration file. Options specified from the `impala-shell` command line override corresponding options in the configuration file.

The configuration file must contain the header label `[impala]`, followed by the options specific to the `impala-shell`. This is a standard convention for configuration files that enables a single file to hold configuration options for multiple applications. To specify a different file name or path for the configuration file, specify the argument `--config_file=`*`path_to_config_file`* from the command line.

Impala-Shell Commands

After you connect to an instance of `impalad` from the `impala-shell`, you can issue certain commands from within the shell. Enter a command at the prompt or use the `-q` option to pass it as an argument. The `impala-shell` passes most of the commands to `impalad` as SQL statements.

Command	Description
alter	Changes table schema in an Impala table, or a table shared between Impala and Hive.
compute stats	Gathers critical, statistical information about each table when you enable join optimizations.
connect	Connects impala-shell to a specific instance of impalad. The default port is 21000 unless modified. You can connect to any host in your cluster running impalad. If you connect to an instance of impalad that was started with an alternate port specified by the --fe_port flag, provide the alternate port.
describe	Shows the columns, column data types, and column comments for the table specified. DESCRIBE FORMATTED shows additional information, such as the MapR filesystem data directory, partitions, and internal table properties. You can use desc as an abbreviated alternative for describe.

last-updated: Apr 11, 2022

drop	Removes a schema object and its associated data files.
explain	Provides the query execution plan and represents a query as a series of steps.
help	Provides a list of available commands and options.
history	Maintains an enumerated cross-session command history. The history is stored in ~/.impalahistory.
insert	Writes query results to the table specified. Overwrites table data or appends data to the existing table content.
invalidate metadata	Updates impalad metadata. Use this command after creating, dropping, or altering databases, tables, or partitions in Hive.
profile	Displays low-level information about the most recent query. Used for performance diagnosis and tuning.
quit	Exits the shell. Include the final semicolon to ensure that the shell recognizes the end of the command.
refresh	Refreshes impalad metadata. Issue the REFRESH command to refresh metadata after you make database changes, such as adding or removing a table.
select	Specifies the data set to complete an action upon. You can send the information returned from select to an output, such as the console or a file. You can also use it to complete another query element.
set	Manages query options for an impala-shell session. Issue query options to Impala using the SET command. Issue SET without arguments to see display a current list query options. Use these options for query tuning and troubleshooting. SET has been promoted to an SQL statement and can be used in client applications through the JDBC and ODBC APIs. To modify option values, issue commands with the syntax `SET option=value`. To restore an option to its default, use the UNSET command. Some options take Boolean values of true and false. Others take numeric arguments, or quoted string values.
shell	Executes commands specified in the operating system shell without exiting impala-shell. Use ! as an abbreviation for the shell command.
show	Displays metastore data for schema objects created and accessed through Impala and Hive. Use show to gather information about databases or tables.
summary	Summarizes the work performed in various stages of a query. It provides a high-level view of the information displayed by the `EXPLAIN` command.
unset	Removes user-specified values for a query option and returns the option to its default value.
use	Indicates the database against which to run subsequent commands. Avoid using fully qualified names when referring to tables in databases other than default. Do not use with the -q option.
version	Returns Impala version information.

last-updated: Apr 11, 2022

Impala-Shell Command Line Options

Specify the command-line options to change how shell commands run when you start the `impala-shell`. These options do not apply to `impalad` configuration.

Option	Configuration File Setting	Description
-B or --delimited	write_delimited=true	Prints query results in plain text format. Specify the delimiter character with the --output_delimiter option. Store query results in a file instead of printing to the screen with the -B option.
--print_header	print_header=true	Prints a header.
-o filename or --output_file filename	output_file=filename	Stores all query results in the file specified.
--output_delimiter=delimiter_character	output_delimiter=character	Defaults to tab ('\t'), and specifies the character to use as a delimiter between fields when query results are printed in plain text format by the -B option.
-p or --show_profiles	show_profiles=true	Displays the query execution plan. Provides the same output as the EXPLAIN statement with a detailed itemization of execution steps, for every query executed by the shell.
-h or --help	N/A	Displays help information.
-i hostname or --impalad=hostname	impalad=hostname[:portnum]	Connects to impalad on the host specified. The default port of 21000 is assumed unless you provide another value. If you connect to an instance of impalad that was started with an alternate port specified by the --fe_port flag, provide that port.
-q query or --query=query	query=query	Passes a query or shell command from the command line. The shell immediately exits after processing the statement. You can use the following statements with the command: • SELECT • CREATE TABLE • SHOW TABLES • Any other statement recognized in impala-shell Fully qualify the names for tables outside the default database. You can also issue the -f option to pass a file with a USE statement followed by other queries.
-f query_file or --query_file=query_file	query_file=path_to_query_file	Passes a SQL query from a file. The file must be semicolon (;) delimited.

last-updated: Apr 11, 2022

-k or --kerberos	use_kerberos=true	Uses Kerberos authentication when the shell connects to `impalad`. If Kerberos is not enabled on the `impalad` instance, an error displays.
-s kerberos_service_name or --kerberos_service_name=name	kerberos_service_name=name	Instructs the`impala-shell` to authenticate to a particular `impalad` service principal. If a kerberos_service_name is not specified, `impala` is used by default. Using this option in conjunction with a connection in which Kerberos is not supported returns erros.
-V or --verbose	verbose=true	Enables verbose output.
--quiet	verbose=false	Disables verbose output.
-v or --version	version=true	Displays version information.
-c	ignore_query_failure=true	Continues on query failure.
-r or --refresh_after_connect	refresh_after_connect=true	Refreshes Impala metadata upon connection. Equivalent to running the REFRESH statement after connecting.
-d default_db or --database=default_db	default_db=default_db	Specifies the database to use on startup. Equivalent to running the USE statement after connecting. If you do not specify a name, a database named default is used.
-ssl	ssl=true	Enables SSL for impala-shell.Default: ssl=true
--ca_cert=path_to_certificate	ca_cert=path_to_certificate	The local pathname that points to the third-party CA certificate or a copy of the server certificate for self-signed server certificates. If `--ca_cert` is not set, impala-shell enables SSL, but does not validate the server certificate. This is useful for connecting to a known-good Impala that is only running over SSL, when a copy of the certificate is not available (such as when debugging customer installations).
-l	use_ldap=true	Enables LDAP authentication.
-u	user=user_name	Sets the user. The impala-shell prompts you for the password. Per Active Directory, the user is the short username, not the full LDAP distinguished name.
--config_file=path_to_config_file	N/A	Specifies the path to the file that contains the impala-shell configuration settings. The default path is$HOME/.impalarc. You can only specify this setting on the command line.

last-updated: Apr 11, 2022

Note:

The `--strict_unicode` option no longer exists. To avoid problems with Unicode values in impala-shell, define the following setting before running impala-shell:

```
export LC_CTYPE=en_US.UTF-8
```

Impala Built-In Functions

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can use built-in functions to transform data directly in SELECT statements to avoid post processing in another application. Built-in functions allow an SQL query to return result sets with formatting, calculating, and type conversions already applied.

Impala supports the following categories of functions:

- Aggregation Functions
- Type Conversion Functions
- Mathematical Functions
- Date and Time Functions
- String Functions
- Conditional Functions
- Bit Manipulation Functions
- Analytic Window Functions
- Miscellaneous Functions

The following table provides a few rules that apply to built-in functions:

Rule	Example

Call functions through the SELECT statement.
You can omit the FROM clause in most functions.
Supply literal values for any required arguments.
	`select abs(-1);`
	
	`select concat('The sly ', 'brown fox');`
	
	`select power(2,5);`

When you include a FROM clause and specify a column name as a function argument, the function is applied to each item in the result set.	`select concat('State = ',state_code) from all_states where population > 20000000;`
	
	`select round(price) as dollar_value from product_directory where price between 400.0 and 500.0;`

last-updated: Apr 11, 2022

If an argument to a built-in function is NULL, the result value NULL.	`select cos(null);`
	`select power(2,null);`
	`select concat('a',null,'b');`

Aggregate functions require a FROM clause in the query. They calculate a return value across all items in a result set. Aggregate functions ignore NULL values rather than returning a NULL result.	`select count(customer_id) from customer_directory;` `select max(weight), avg(weight) from census_data where age > 40;`

The following sections list the available functions:

Aggregation Functions

You can use the following aggregation functions:

- APPX_MEDIAN()
- AVG()
- COUNT()
- MAX()
- MIN()
- NDV()
- STDDEV()
- STDDEV_SAMP()
- STDDEV_POP()
- SUM()
- VARIANCE()
- VARIANCE_SAMP()
- VARIANCE_POP()

Type Conversion Functions

Use conversion functions in combination with other functions to explicitly pass the expected data types.

CAST	Use CAST when passing a column value or literal to a function that expects a parameter with a different type. Syntax `cast(expr as type)`

last-updated: Apr 11, 2022

Example

```
select concat('Here are the first
',10,' results.'); -- Fails
select concat('Here are the first
',cast(10 as string),' results.'); --
Succeeds
```

TYPEOF

Available as of Impala 2.5.0. Use `typeof` to reutrn the name of the data type corresponding to an expression. For types with extra attributes, such as length for CHAR and VARCHAR, or precision and scale for DECIMAL, includes the full specification of the type.

Syntax

```
typeof(type value)
```

Examples

```
select typeof(2);
select typeof('xyz');
select typeof(5.30001 / 2342.1);
```

The examples above return tinyint, string, and DECIMAL(13,11) respectively.

Mathematical Functions

The following functions were added in Impala 2.5.0:

- dceil(double a), dceil(decimal(p,s) a)
- dexp(double a)
- dfloor(double a), dfloor(decimal(p,s) a)
- dlog10(double a)
- dpow(double a, double p), fpow(double a, double p)
- dround(double a), dround(double a, int d), dround(decimal(p,s) a, int_type d)
- dsqrt(double a)
- dtrunc(double_or_decimal a[, digits_to_leave])
- factorial(integer_type a)
- radians(double a)
- random(), random(int seed)

The following table lists the mathematical functions with their descriptions and return types:

Function	Description	Return type
abs(double a)	Ensures all return values are positive. Returns the absolute value of the argument.	double

last-updated: Apr 11, 2022

acos(double a)	Returns the arccosine of the argument.	double
asin(double a)	Returns the arcsine of the argument.	double
bin(bigint a)	Returns the binary representation of an integer value.	string
ceil(double a), ceiling(double a),dceil(double a), dceil(decimal(p,s) a)	Returns the smallest integer > or = to the argument.	int or decimal(p,s) depending on the type of the input argument
conv(bigint num, int from_base, int to_base), conv(string num, int from_base, int to_base)	Returns a string representation of an integer value in a particular base. The input value can be a string. To use the return value as a number, use CAST() to convert to the appropriate type.	string
cos(double a)	Returns the cosine of the argument.	double
cot(double a)	Returns the cotangent of the argument.	double
degrees(double a)	Converts the argument value from radians to degrees.	double
e()	Returns the mathematical constant e.	double
exp(double a), dexp(double a)	Returns the mathematical constant e raised to the power of the argument.	double
factorial(integer_type a)	Computes the factorial of an integer value. It works with any integer type. You can use either the factorial() function or the ! operator. The factorial of 0 is 1. Likewise, the factorial() function returns 1 for any negative value. The maximum positive value for the input argument is 20; a value of 21 or greater overflows the range for a BIGINT and causes an error.	bigint
floor(double a), dfloor(double a), dfloor(decimal(p,s) a)	Returns the largest integer that is less than or equal to the argument.	int, bigint, or decimal(p,s) depending on the type of the input argument
fnv_hash(type v)	Returns a consistent 64-bit value, derived from the input argument. Use for implementing hashing logic in an application.	bigint
greatest()	Returns the largest value from a list of expressions.	The return type is the same as the initial argument value. Integer values are promoted to BIGINT. Floating-point values are promoted to DOUBLE. Use CAST() when inserting into a smaller numeric column.
hex(bigint a), hex(string a)	Returns the hexadecimal representation of an integer value, or of the characters in a string.	string
is_inf(double a)	Tests whether a value is equal to the special value "inf", signifying infinity.	boolean

last-updated: Apr 11, 2022

is_nan(double a)	Tests whether a value is equal to the special value "NaN", signifying "not a number".	boolean
least()	Returns the smallest value from a list of expressions.	The return type is the same as the initial argument value. Integer values are promoted to BIGINT. Floating-point values are promoted to DOUBLE. Use CAST() when inserting into a smaller numeric column.
ln(double a)	Returns the natural logarithm of the argument.	double
log(double base, double a)	Returns the logarithm of the second argument to the specified base.	double
log10(double a), dlog10(double a)	Returns the logarithm of the argument to the base 10.	double
log2(double a)	Returns the logarithm of the argument to the base 2.	double
mod()	This function returns the modulus of a number. MOD is equivalent to using the % arithmetic operator. It works with any size integer type, any size floating-point type, and DECIMAL with any precision and scale.	Same as the input value
negative(int a), negative(double a)	Returns the argument with the sign reversed; returns a positive value if the argument was already negative. If return values must be negative, use -abs(a) instead.	int or double
max_int(),min_smallint()	Checks whether data values are in an expected range. You might be able to switch a column to a smaller type to save memory during processing.	The same as the integral type being checked.
pi()	Returns the constant pi.	double
pmod(int a, int b), pmod(double a, double b)	Purpose: Returns the positive modulus of a number.	int or double
positive(int a), positive(double a)	Returns the original argument; applies to negative arguments also. If return values must be positive, use abs().	int or double
pow(double a, double p), power(double a, double p), dpow(double a, double p), fpow(double a, double p)	Returns the first argument raised to the power of the second argument.	double
quotient(int numerator, int denominator)	Returns the first argument divided by the second argument and discards any fractional part. Avoids promoting arguments to DOUBLE as happens with the / SQL operator.	int
radians(double a)	Converts argument value from degrees to radians.	double

last-updated: Apr 11, 2022

rand(), rand(int seed), random(), random(int seed)	Returns a random value between 0 and 1. After rand() is called with a seed argument, produces a consistent random sequence based on the seed value. Currently, the random sequence is reset after each query, and multiple calls to rand() within the same query return the same value each time. For different number sequences that are different for each query, pass a unique seed value to each call to rand(). For example, select rand(unix_timestamp()) from ...	double
round(double a), round(double a, int d), dround(double a), dround(double a, int d), dround(decimal(p,s) a, int_type d)	Rounds a floating-point value. By default (with a single argument), rounds to the nearest integer. Values ending in .5 are rounded up for positive numbers, down for negative numbers. The second argument is optional and specifies how many digits to leave after the decimal point. Values greater than zero produce a floating-point return value rounded to the requested number of digits to the right of the decimal point.	bigint for single and double argument; double for two-argument signature when second argument is greater than zero; for DECIMAL values, the smallest DECIMAL(p,s) type with appropriate precision and scale
sign(double a)	Returns -1, 0, or 1 to indicate the sign of the argument value.	int
sin(double a)	Returns the sine of the argument.	double
sqrt(double a), dsqrt(double a)	Returns the square root of the argument.	double
tan(double a)	Returns the tangent of the argument.	double
truncate(double_or_decimal a[, digits_to_leave]), dtrunc(double_or_decimal a[, digits_to_leave])	Removes some or all fractional digits from a numeric value. With no argument, removes all fractional digits, leaving an integer value. The optional argument specifies the number of fractional digits to include in the return value, and only applies with the argument type is DECIMAL. truncate() and dtrunc() are aliases for the same function.	decimal for DECIMAL arguments; bigint for DOUBLE arguments
unhex(string a)	Returns a string of characters with ASCII values corresponding to pairs of hexadecimal digits in the argument.	string

Date and Time Functions

TIMESTAMP is the underlying datatype for data and time data. Functions that extract a single field, such as hour() or minute(), typically return an integer value. Functions that format the date portion, such as date_add() or to_date(), typically return a string value.

The following table lists the date and time functions with their descriptions and return types:

Function	Description	Return Type
add_months()	Alias for the existing MONTHS_ADD() function.	timestamp

last-updated: Apr 11, 2022

date_add(string startdate, int days)	Adds a specified number of days to a date represented as a string.	string
date_part()	A new date and time function, similar to EXTRACT(), but with the order of the arguments reversed. You can also call the EXTRACT() function using the SQL-99 syntax, EXTRACT(*unit* FROM *timestamp*). These enhancements simplify the porting process for date-related code from other systems.	int
date_sub(string startdate, int days)	Subtracts a specified number of days from a date represented as a string.	string
datediff(string enddate, string startdate)	Returns the number of days between two dates represented as strings.	int
day(string date), dayofmonth(string date)	Returns the day field from a date represented as a string.	int
dayname(string date)	Returns the day field from a date represented as a string, converted to the string corresponding to that day name. The range of return values is 'Sunday' to 'Saturday'. Use in report-generating queries, instead of calling dayofweek() and turning that numeric return value into a string using a CASE expression.	string
dayofweek(string date)	Returns the day field from a date represented as a string, corresponding to the day of the week. The range of return values is 1 (Sunday) to 7 (Saturday).	int
extract()	Returns one date or time field from a TIMESTAMP value.	timestamp
from_unixtime(bigint unixtime[, string format])	Converts the number of seconds from the Unix epoch to the specified time into a string.	string
from_utc_timestamp(timestamp, string timezone)	Converts a specified UTC timestamp value into the appropriate value for a specified time zone.	timestamp
hour(string date)	Returns the hour field from a date represented as a string.	int
int_months_between(timestamp newer, timestamp older)	Available as of Impala 2.5.0. Returns the number of months between the date portions of two TIMESTAMP values, as an INT representing only the full months that passed.	int
minute(string date)	Returns the minute field from a date represented as a string.	int
month(string date)	Returns the month field from a date represented as a string.	int

last-updated: Apr 11, 2022

months_between(timestamp newer, timestamp older)	Available as of Impala 2.5.0. Returns the number of months between the date portions of two TIMESTAMP values. Can include a fractional part representing extra days in addition to the full months between the dates. The fractional component is computed by dividing the difference in days by 31 (regardless of the month).	double
now()	Returns the current date and time (in the UTC time zone) as a timestamp value.	timestamp
second(string date)	Returns the second field from a date represented as a string.	int
timeofday()	Available as of Impala 2.5.0. Returns a string representation of the current date and time, according to the time of the local system, including any time zone designation.	string
timestamp_cmp(timestamp t1, timestamp t2)	Available as of Impala 2.5.0. Tests if one TIMESTAMP value is newer than, older than, or identical to another TIMESTAMP	int (either -1, 0, 1, or NULL)
to_date(string timestamp)	Returns the date field from a timestamp represented as a string.	string
to_utc_timestamp(timestamp, string timezone)	Converts a specified timestamp value in a specified time zone into the corresponding value for the UTC time zone.	timestamp
trunc()	Truncates date/time values to a particular granularity, such as year, month, day, hour, and so on.	
unix_timestamp(), unix_timestamp(string date), unix_timestamp(string date, string pattern)	Returns a timestamp representing the current date and time, or converts from a specified date and time value represented as a string.	bigint
weekofyear(string date)	Returns the corresponding week (1-53) from a date represented as a string.	int
year(string date)	Returns the year field from a date represented as a string.	int

String Functions

The following table lists the string functions with their descriptions and return types:

Function	**Description**	**Return Type**
ascii(string str)	Returns the numeric ASCII code of the first character of the argument.	int

last-updated: Apr 11, 2022

btrim(string a), btrim(string a, string chars_to_trim)	Available as of Impala 2.5.0. Removes all instances of one or more characters from the start and end of a STRING value. By default, removes only spaces. If a non-NULL optional second argument is specified, the function removes all occurrences of characters in that second argument from the beginning and end of the string.	string
chr(int character_code)	Available as of Impala 2.5.0. Returns a character specified by a decimal code point value. The interpretation and display of the resulting character depends on your system locale. Because consistent processing of Impala string values is only guaranteed for values within the ASCII range, only use this function for values corresponding to ASCII characters. In particular, parameter values greater than 255 return an empty string.	string
concat(string a, string b...)	Returns a single string representing all the argument values joined together.	string
concat_ws(string sep, string a, string b...)	Returns a single string representing the second and following argument values joined together, delimited by a specified separator.	string
find_in_set(string str, string strList)	Returns the position (starting from 1) of the first occurrence of a specified string within a comma-separated string. Returns NULL if either argument is NULL, 0 if the search string is not found, or 0 if the search string contains a comma.	int
initcap(string str)	Returns the input string with the first letter capitalized.	string
instr(string str, string substr)	Returns the position (starting from 1) of the first occurrence of a substring within a longer string.	int
length(string a)	Returns the length in characters of the argument string.	int
locate(string substr, string str[, int pos])	Returns the position (starting from 1) of the first occurrence of a substring within a longer string, optionally after a particular position.	int
lower(string a), lcase(string a)	Returns the argument string converted to all-lowercase.	string
lpad(string str, int len, string pad)	Returns a string of a specified length, based on the first argument string. If the specified string is too short, it is padded on the left with a repeating sequence of the characters from the pad string. If the specified string is too long, it is truncated on the right.	string

last-updated: Apr 11, 2022

ltrim(string a)	Returns the argument string with any leading spaces removed from the left side.	string
parse_url(string urlString, string partToExtract [, string keyToExtract])	Returns the portion of a URL corresponding to a specified part. The part argument can be 'PROTOCOL', 'HOST', 'PATH', 'REF', 'AUTHORITY', 'FILE', 'USERINFO', or 'QUERY'. Literal values must be uppercase. You can specify a key to retrieve only the associated value from the key-value pairs in the query string when you request the query portion of the URL. Useful for importing web logs.	string
regexp_extract(string subject, string pattern, int index)	Returns the specified () group from a string based on a regular expression pattern.	string
regexp_like(string source, string pattern[, string options])	Available as of Impala 2.5.0. Returns true or false to indicate whether the source string contains anywhere inside it the regular expression given by the pattern. The optional third argument consists of letter flags that change how the match is performed, such as i for case-insensitive matching.	boolean
regexp_replace(string initial, string pattern, string replacement)	Returns the initial argument with the regular expression pattern replaced by the final argument string.	string
repeat(string str, int n)	Returns the argument string repeated a specified number of times.	string
reverse(string a)	Purpose: Returns the argument string with characters in reversed order.	string
rpad(string str, int len, string pad)	Returns a string of a specified length, based on the first argument string. If the specified string is too short, it is padded on the right with a repeating sequence of the characters from the pad string. If the specified string is too long, it is truncated on the right.	string
rtrim(string a)	Returns the argument string with any trailing spaces removed from the right side.	string
space(int n)	Returns a concatenated string of the specified number of spaces. Shorthand for repeat(' ',n).	string
split_part(string source, string delimiter, bigint n)	Available as of Impala 2.5.0. Returns the nth field within a delimited string. The fields are numbered starting from 1. The delimiter can consist of multiple characters, not just a single character. All matching of the delimiter is done exactly, not using any regular expression patterns.	string

last-updated: Apr 11, 2022

substr(string a, int start [, int len]), substring(string a, int start [, int len])	Returns the portion of the string starting at a specified point, optionally with a specified maximum length. The characters in the string are indexed starting at 1.	string
translate(string input, string from, string to)	Returns the input string with a set of characters replaced by another set of characters.	string
trim(string a)	Returns the input string with leading and trailing spaces removed. The same as passing the string through both ltrim() and rtrim().	string
upper(string a), ucase(string a)	Returns the argument string converted to all-uppercase.	string

Conditional Functions

Use the conditional functions to test equality, comparison operators, and nullity.

The following table lists the conditional functions with their descriptions and return types:

Function	Description	Return Type
CASE a WHEN b THEN c [WHEN d THEN e]... [ELSE f] END	Compares an expression to one or more possible values, and returns a corresponding result when a match is found.	Same as the initial argument value
CASE WHEN a THEN b [WHEN c THEN d]... [ELSE e] END	Tests whether any of a sequence of expressions is true, and returns a corresponding result for the first true expression.	Same as the initial argument value
coalesce(type v1, type v2, ...)	Returns the first specified argument that is not NULL, or NULL if all arguments are NULL.	Same as the initial argument value
decode()	Compares an expression to one or more possible values and returns a corresponding result when a match is found. This function works as a shorthand for a CASE() expression and improves compatibility with SQL code containing vendor extensions.	Same as the initial argument value, except that integer values are promoted to `BIGINT` and floating-point values are promoted to `DOUBLE`; use `CAST( )` when inserting into a smaller numeric column
if(boolean condition, type ifTrue, type ifFalseOrNull)	Tests an expression and returns a corresponding result depending on whether the result is true, false, or NULL.	Same as ifTrue argument value
isfalse(), isnotfalse(), isnottrue(), istrue(), notnullvalue(), nullvalue()	These conditional functions provide enhanced compatibility when porting code that uses industry extensions.	
isnull(type a, type ifNotNull)	Tests if an expression is NULL, and returns the expression result value if not. If the first argument is NULL, returns the second argument. Equivalent to the nvl() function from Oracle Database orifnull() from MySQL.	Same as the first argument value

last-updated: Apr 11, 2022

nullif(expr1,expr2)	Returns `NULL` if the two specified arguments are equal. If the specified arguments are not equal, returns the value of expr1. The data types of the expressions must be compatible. You cannot use an expression that evaluates to `NULL` for expr1, so you can distinguish a return value of `NULL` from an argument value of `NULL`, which would never match expr2.	Same as the initial argument value, except that integer values are promoted to `BIGINT` and floating-point values are promoted to `DOUBLE`; use `CAST( )` when inserting into a smaller numeric column
nullifzero(numeric_expr)	Returns `NULL` if the numeric expression evaluates to 0, otherwise returns the result of the expression.	Same as the initial argument value, except that integer values are promoted to `BIGINT` and floating-point values are promoted to `DOUBLE`; use `CAST( )` when inserting into a smaller numeric column
nvl(type a, type ifNotNull)	Alias for the isnull() function; added in Impala 1.1. Tests if an expression is NULL, and returns the expression result value if not. If the first argument is NULL, returns the second argument. Equivalent to the nvl() function from Oracle Database or ifnull() from MySQL.	Same as the first argument value
zeroifnull(numeric_expr)	Returns 0 if the numeric expression evaluates to `NULL`, otherwise returns the result of the expression.	Same as the initial argument value, except that integer values are promoted to `BIGINT` and floating-point values are promoted to `DOUBLE`; use `CAST( )` when inserting into a smaller numeric column

Bit Manipulation Functions

Impala 2.5.0 introduces bit manipulation functions.

The following table lists the bit manipulation functions with their descriptions and return types:

Function	Description	Return Type
bitand(integer_type a, same_type b)	Returns an integer value representing the bits that are set to 1 in both of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. The bitand() function is equivalent to the & binary operator.	Same as the input value
bitnot(integer_type a)	Inverts all the bits of the input argument. The bitnot() function is equivalent to the ~ unary operator.	Same as the input value
bitor(integer_type a, same_type b)	Returns an integer value representing the bits that are set to 1 in either of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. The bitor() function is equivalent to the | binary operator.	Same as the input value

bitxor(integer_type a, same_type b)	Returns an integer value representing the bits that are set to 1 in one but not both of the arguments. If the arguments are of different sizes, the smaller is promoted to the type of the larger. The bitxor() function is equivalent to the ^ binary operator.	Same as the input value
countset(integer_type a [, int zero_or_one])	By default, returns the number of 1 bits in the specified integer value. If the optional second argument is set to zero, it returns the number of 0 bits instead.	Same as the input value
getbit(integer_type a, int position)	Returns a 0 or 1 representing the bit at a specified position. The positions are numbered right to left, starting at zero. The position argument cannot be negative. When you use a literal input value, it is treated as an 8-bit, 16-bit, and so on value, the smallest type that is appropriate. The type of the input value limits the range of the positions. Cast the input value to the appropriate type if you need to ensure it is treated as a 64-bit, 32-bit, and so on value.	Same as the input value
rotateleft(integer_type a, int positions)	Rotates an integer value left by a specified number of bits. As the most significant bit is taken out of the original value, if it is a 1 bit, it is "rotated" back to the least significant bit. Therefore, the final value has the same number of 1 bits as the original value, just in different positions. Specifying a second argument of zero leaves the original value unchanged. Rotating a -1 value by any number of positions still returns -1, because the original value has all 1 bits and all the 1 bits are preserved during rotation. Similarly, rotating a 0 value by any number of positions still returns 0. Rotating a value by the same number of bits as in the value returns the same value. Because this is a circular operation, the number of positions is not limited to the number of bits in the input value. For example, rotating an 8-bit value by 1, 9, 17, and so on positions returns an identical result in each case.	Same as the input value

last-updated: Apr 11, 2022

rotateright(integer_type a, int positions)	Rotates an integer value right by a specified number of bits. As the least significant bit is taken out of the original value, if it is a 1 bit, it is "rotated" back to the most significant bit. Therefore, the final value has the same number of 1 bits as the original value, just in different positions. Specifying a second argument of zero leaves the original value unchanged. Rotating a -1 value by any number of positions still returns -1, because the original value has all 1 bits and all the 1 bits are preserved during rotation. Similarly, rotating a 0 value by any number of positions still returns 0. Rotating a value by the same number of bits as in the value returns the same value. Because this is a circular operation, the number of positions is not limited to the number of bits in the input value. For example, rotating an 8-bit value by 1, 9, 17, and so on positions returns an identical result in each case.	Same as the input value
setbit(integer_type a, int position [, int zero_or_one])	By default, changes a bit at a specified position to a 1, if it is not already. If the optional third argument is set to zero, the specified bit is set to 0 instead. If the bit at the specified position was already 1 (by default) or 0 (with a third argument of zero), the return value is the same as the first argument. The positions are numbered right to left, starting at zero. (Therefore, the return value could be different from the first argument even if the position argument is zero.) The position argument cannot be negative. When you use a literal input value, it is treated as an 8-bit, 16-bit, and so on value, the smallest type that is appropriate. The type of the input value limits the range of the positions. Cast the input value to the appropriate type if you need to ensure it is treated as a 64-bit, 32-bit, and so on value.	Same as the input value

shiftleft(integer_type a, int positions)	Shifts an integer value left by a specified number of bits. As the most significant bit is taken out of the original value, it is discarded and the least significant bit becomes 0. The final value has either the same number of 1 bits as the original value, or fewer. Shifting an 8-bit value by 8 positions, a 16-bit value by 16 positions, and so on produces a result of zero. Specifying a second argument of zero leaves the original value unchanged. Shifting any value by 0 returns the original value. Shifting any value by 1 is the same as multiplying it by 2, as long as the value is small enough; larger values eventually become negative when shifted, as the sign bit is set. Starting with the value 1 and shifting it left by N positions gives the same result as 2 to the Nth power, or pow(2,N).	Same as the input value
shiftright(integer_type a, int positions)	Shifts an integer value right by a specified number of bits. As the least significant bit is taken out of the original value, it is discarded and the most significant bit becomes 0. In computer science terms, this operation is a "logical shift". Usage notes: Therefore, the final value has either the same number of 1 bits as the original value, or fewer. Shifting an 8-bit value by 8 positions, a 16-bit value by 16 positions, and so on produces a result of zero. Specifying a second argument of zero leaves the original value unchanged. Shifting any value by 0 returns the original value. Shifting any positive value right by 1 is the same as dividing it by 2. Negative values become positive when shifted right.	Same as the input value

Analytic Functions

Analytic (window) functions operate on a set of rows and return a single value for each row from the underlying query. The term "window" describes the set of rows on which the function operates. A window function uses values from the rows in a window to calculate the returned values. When you use a window function in a query, you define the window using the OVER() clause. The OVER() clause (window clause) differentiates window functions from other analytical and reporting functions.

As of Impala 2.2.0, you can use the following analytic functions in queries:

- MAX()
- MIN()
- SUM()
- COUNT()

last-updated: Apr 11, 2022

- AVG()
- RANK()
- LAG()
- LEAD()
- FIRST_VALUE()

As of Impala 2.5.0, you can use the following analytic functions in queries:

- PERCENT_RANK
- NTILE
- CUME_DIST

The analytic functions support the following syntax:

```
function(args) OVER([partition_by_clause] [order_by_clause [window_clause]])
partition_by_clause ::= PARTITION BY expr [, expr ...]order_by_clause ::=
ORDER BY expr  [ASC | DESC] [NULLS FIRST | NULLS LAST] [, expr [ASC |DESC]
[NULLS FIRST | NULLS LAST] ...]
```

The window clause supports the following syntax:

```
ROWS BETWEEN [ { m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT
ROW | { UNBOUNDED | n } FOLLOWING] ]
```

```
RANGE BETWEEN [ {m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT
ROW | { UNBOUNDED | n } FOLLOWING] ]
```

Miscellaneous Functions

The following table lists miscellaneous functions with their descriptions and syntax:

Function	Description	Syntax
uuid()	The uuid() function generates an alphanumeric value that you can use as a guaranteed unique identifier. The uniqueness applies across tables in cases where an ascending numeric sequence is not suitable.	select uuid();

Impala User-Defined Functions

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

A user-defined function (UDF) is a SQL function that you create to encapsulate code that processes column values during an Impala query. UDFs are called from within a SQL statement, like a regular function, and return a single value. Starting in Impala 1.2.3 for MapR, you can create UDFs to perform custom calculations and transformations that built-in SQL operators and functions do not provide.

After you download and install the UDF development package, you can write your own UDFs and invoke them in the queries that you run on Impala. Impala can run scalar UDFs and UDAFs (user-defined aggregate functions).

last-updated: Apr 11, 2022

Note: User-defined functions written in C++ persist when the catalog service is restarted. You no longer have to run the CREATE FUNCTION statements again after a restart. You must still reissue the CREATE FUNCTION statement for any Java-based user-defined functions.

UDFs and UDAFs

UDFs and UDAFs differ in the number of rows that they accept as input. A UDF operates on a single row and produces a single row as the output. When you use a UDF in a query, the UDF is called once for each row in the result set. Mathematical and string functions are examples of UDFs. When you create a UDF, you issue the CREATE FUNCTION statement. After you create a UDF, you can use it in the expression of a SQL statement.

A UDAF operates on multiple input rows and produces a single row as output. The COUNT(), MAX(), SUM(), and AVG() aggregate functions are examples of UDAFs. You might use a UDAF in a query with a GROUP BY clause to produce a result set with a separate aggregate value for each combination of values from the GROUP BY clause. When you create UDAFs, use the CREATE AGGREGATE FUNCTION statement. After you create a UDAF, you can use it the expression of a SQL statement.

When you create UDFs and UDAFs, they cannot have the same name as any of the built-in functions.

UDFs in C++ and Java

Impala accepts UDFs and UDAFs written in C++, as well as Hive UDFs written in Java. A Java UDF may cause a query in Impala to run much slower than the equivalent native UDF written in C++. If you use Hive UDFs when you query Impala, the Hive UDFs must meet the following conditions:

- Parameters and return values must all use data types that Impala accepts. Impala does not accept nested and composite types.
- UDFs cannot accept or return the TIMESTAMP data type.
- The return type must be a writable type, like Text or IntWritable. UDFs return a NULL value for Java primitive types, like string or int.
- Impala does not accept Hive UDAFs or UDTFs.

For more information about Hive UDFs, refer to the Hive Language Manual UDF.

Get Started with UDFs

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Before you can write UDFs for your Impala queries, you must install the Impala development package that contains header and build configuration files and download the sample source code.

The development package provides a header file that is required to develop UDFs and UDAFs. The header contains the types that must be used and the FunctionContext object. This object is the interface object between the UDF or UDAF and the Impala process. You can access the header in /usr/include/impala_udf/udf.h

The sample source code provides sample files that you can view to see the declarations required to write UDFs and UDAFs, and sample source code used to create a simple UDF and UDAF example.

After you have installed the development package and sample source code, you can build the samples to create an environment that you can use to write your UDFs and UDAFs. Once you have completed your UDF or UDAF, you can deploy it.

Complete the following steps to create UDFs and UDAFs for use with Impala:

Install the Development Package

Use the appropriate commands for your operating system to install the development package.

last-updated: Apr 11, 2022

To install the development package, complete the following steps:

1. Install the gcc-c++ compiler and boost-devel using the command appropriate for your environment:

```
$ sudo yum install gcc-c++ cmake boost-devel
```

```
$ sudo apt-get install g++ libboost-devel cmake
```

2. Install the development package, using the command appropriate for your environment:

```
$ sudo yum install mapr-impala-udf
```

```
$ sudo apt-get install mapr-impala-udf
```

Warning: Impala is not required for UDF development. You can create UDFs on a minimal development system and then deploy the UDFs to a machine with Impala.

Download Sample Source Code

- To download the sample source code and build scripts, issue the following command:

```
git clone https://github.com/mapr/impala-udf-samples
```

The following table provides the source code file names and their descriptions:

File Name	Description
udf-sample.h	Header file that declares the signature for a scalar UDF.
udf-sample.cc	Sample source for a simple UDF that adds two integers.
udf-sample-test.cc	Basic unit tests for the sample UDF.
uda-sample.h	Header file that declares signature for sample aggregate functions.
uda-sample.cc	Sample source for simple UDAFs that show how to manage state transitions as underlying are called during various phases of query processing.
uda-sample-test.cc	Basic unit tests for the sample UDAFs.

Build the Samples

To build the samples, complete the following steps:

1. Issue the `cmake` configuration command. This command reads the file `CMakeLists.txt`, and generates a `Makefile` customized for your directory paths.

2. Issue the `make` command. The `make` command runs the build steps based on rules in the `Makefile`. Impala loads the shared library from a MapR filesystem location.

The samples get built to `build/`. This contains test executables that you can run locally, without the Impala service installed. It also contains shared object artifacts that you can run on Impala.

At this point, you can write your UDFs or UDAFs. When you write your functions, build a shared library to contain them. Use the `mapr` or `hadoop` commands to copy the binary files to a MapR filesystem location that Impala can read from.

Writing UDFs

When you write UDFs, use function-oriented programming best practices, and note data type differences when transferring values from high-level SQL to low-level UDF code.

The UDF code samples that you downloaded include the udf-sample.h and udf-sample.cc files that you can reference when you write your UDFs. The udf-sample.h file provides the basic declarations required to write a scalar UDF. This file defines a simple function named AddUdf() that you can reference. The udf-sample.cc file provides sample C++ code for a simple function named AddUdf().

Function Argument/Return Value Data Types

Every value that a UDF accepts as an argument or returns as a result, must map to a SQL data type that you can specify for a table column.

Every data type has a corresponding structure defined in the C++ and Java header files with two member fields and some predefined comparison operators and constructors:

- is_null indicates if a value is/is not NULL. When non-NULL, val holds the argument or return value.
- null () is a member function that constructs an instance of the struct with the is_null flag set.
- <,>=,BETWEEN,ORDER BY are built-in SQL comparison operators and clauses that work automatically based on the SQL return type of each UDF.
- Every struct within your UDF code defines == and != operators for comparisons with structs of the same type for typical C++ comparisons within your own code. Each kind of struct one or more constructors that define a filled-in instance of the struct.
- Every type of struct has a null() member function that returns an instance of the struct with is_null flag set.
- Impala cannot process UDFS that accept or return composite or nested types. This applies to UDFs written in C++ and Jave-based Hive UDFs.
- You can create multiple functions with the same SQL name and different argument types to overload functions, however you must use different C++ or Java entry point names in the underlying functions.

The following table lists the data types defined for C++ in `/usr/include/impala_udf/udf.h`:

Data Type	**Description**
IntVal	Represents an INT column.
BigIntVal	Represents a BIGINT column.
SmallIntVal	Represents a SMALLINT column.
TinyIntVal	Represents a TINYINT column.
StingVal	Represents a STRING column. It has a len field that represents the length of the string and a ptr field that points to the string data. It also has a constructor that creates a new StingVal struct based on a null-terminated C-style string or a pointer plus a length. It also has a constructor that takes a pointer to a FunctionContext struct and length, which does not allocate space for a new copy of the string data that you can use in UDFs that return string values.
BooleanVal	Represents a BOOLEAN column.
FloatVal	Represents a FLOAT column.

last-updated: Apr 11, 2022

DoubleVal	Represents a DOUBLE column.
TimestampVal	Represents a TIMESTAMP column. It has a 32-bit integer date field that represents the Gregorian date and a 64-bit integer time_of_day field that represents the current time of day in nanoseconds.

Variable-Length Argument List

Each argument is named explicitly in the signature of your C++ function. A UDF can take a fixed number of these named arguments, however a function can accept additional arguments if they are all of the same type.

You must code the signature of your function using the following format if you want your UDF to accept a variable-length argument list:

StringVal Concat(FunctionContext* context, const StringVal& separator, int num_var_args, const StringVal* args);

The SQL query call must pass at least one argument to the variable-length portion of the argument list. Impala calls the function and fills in the initial set of required arguments and then passes the extra arguments and a pointer to the first of the optional arguments.

NULL Values

Each UDF that you write must have the ability to handle NULL values. If a UDF receives a NULL value, it typically also returns a NULL value.

UDF Memory Allocation

Any memory allocated to a UDF is taken back by the system after the UDF exits. Input arguments remain allocated for the lifetime of a function. You can refer to the input arguments in expressions for return values. When using temporary variables to construct all new string values, use the StringValue() constructor, and copy the data into the newly allocated memory buffer. The StringValue() constructor takes an initial FunctionContext* argument followed by a length.

UDF Error Handling

Call functions that are members of the initial FunctionContext* argument passed to your function to handle UDF errors.

Use the following signature in the function to record warnings for conditions that indicate minor, recoverable problems that do not cause the query to stop:

```
bool AddWarning(const char* warning_msg);
```

Use the following signature if you want the UDF to set an error flag that prevents the query from returning any results in serious cases where the query cancellation must occur.

```
void SetError(const char* error_msg);
```

Writing UDAFs

A UDAF must maintain a state value across subsequent calls in order to accumulate a result across a set of calls, instead of deriving it purely from one set of arguments.

The underlying functions represent a UDAF:

Initialization function	Sets counters to zero, creates empty buffers, and performs any other initial setup for a query.
Update function	Processes the arguments for each row in the result set and accumulates an intermediate result for each node.

last-updated: Apr 11, 2022

Merge function	Combines the intermediate results from different nodes.
Finalize function	Passes through the combined result unchanged, or does one final transformation.

Deploying UDFs and UDAFs

To deploy your UDFs or UDAFs, complete the following steps from the impala-shell:

1. Issue a USE statement to the database that you want to associate your new function with.
2. Issue a CREATE FUNCTION statement in the impala-shell to make Impala aware of the new function.
   - To deploy a UDF, issue the CREATE FUNCTION statement.
   - To deploy a UDAF, issue the CREATE AGGREGATE FUNCTION statement. Specify the entry points of the underlying C++ functions using the clauses INIT_FN, UPDATE_FN, and FINALIZE_FN.

Warning: You can also issue the CREATE FUNCTION with a fully qualified database name to skip the USE statement step. Example: `CREATE FUNCTION <db_name.function_name>`

Hive UDFs

To use Hive UDFs in Impala, get the applicable JAR files from the Hive UDFs, and use the Impala UDF deployment process to create new UDFs with new names.

Data types of arguments must match the function signature exactly when reusing Hive Java code for built-in functions.

To use a Hive UDF with Impala, complete the following steps:

1. Get a copy of the Hive JAR file with the UDFs that you want to use with Impala.
2. Issue the following command to see a list of classes inside the JAR file: `jar -tf <jar_filename>`
3. Copy the JAR file to a MapR filesystem location that Impala can read.
4. From the impala-shell, create a database to use with the UDF.
5. To identify the data base that you want to query using the UDF, issue the USE statement to through the impala-shell for that particular database, or specify the SQL function name as `db_name.function_name`.
6. Issue a CREATE FUNCTION statement for each UDF that you want to use with Impala. The CREATE FUNCTION statement should contain a LOCATION clause with the full MapR filesystem path to the JAR file and a SYMBOL clause with a fully qualified name of the class. Use dots as separators. Do not use the `.classpath` extension.
7. Issue a query and call the function. Pass the correct type of arguments to the function.

UDF Limitations

Impala UDFs have the following limitations:

- Impala cannot work with UDFs that accept or return composite, nested, or types not available in Impala tables.
- UDFs must produce the same output each time the same argument value is passed.
- UDFs cannot spawn other threads or processes.

last-updated: Apr 11, 2022

- UDFs become undefined when you restart the catalogd process. In this scenario, you must reload the UDFs.
- You currently cannot include user-defined table functions in Impala queries.

UDF Security

If you enable the Impala authorization feature, consider the following:

- You must have the required read privilege for database and tables used in the query to call a UDF in the query.
- Only an administrative user can create UDFs because improperly coded UDFs can cause performance and capacity issues. Issuing the CREATE FUNCTION statement requires the ALL privilege on the server.

Supported SQL Language Features

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Impala SQL dialect supports many standard SQL language features and some extensions for Hadoop related to data loading and data warehousing. The impala-shell interpreter supports multi-line commands. A semicolon at the end of each statement is required.

SQL Features

Impala supports the following SQL features:

- Comments
- External/Internal tables
- Hints
- Joins
- Views

Statements

Impala supports the following SQL statements:

- ALTER TABLE
- CASCADE
- CREATE DATABASE
- CREATE TABLE
- CREATE TABLE AS SELECT
- CREATE VIEW
- DESCRIBE
- DROP DATABASE
- DROP TABLE/ALTER TABLE DROP PARTITION
- EXPLAIN

- INSERT
- INVALIDATE METADATA
- LOAD DATA
- PURGE
- REFRESH
- SELECT
- SHOW
- SHOW DATABASES
- TRUNCATE TABLE
- USE

Clauses

Impala supports the following SQL clauses:

- IF EXISTS
- WHRRE
- VALUES
- WITH
- GROUP BY
- HAVING
- LIMIT
- ORDER BY

Operators

Impala supports the following SQL operators:

- BETWEEN
- DISTINCT
- ILIKE
- IREGEXPR
- IS [NOT] DISTINCT FROM
- LIKE
- REGEXP
- RLIKE

Functions

Impala supports the following SQL functions:

- AVG
- BITAND
- BITNOT
- BITOR
- BITXOR
- BTRIM
- CHR
- COT
- COUNT
- COUNTSET
- CUME_DIST
- DCEIL
- DEXP
- DFLOOR
- DLOG10
- DPOW
- DROUND
- DSQRT
- DTRUNC
- FACTORIAL
- FPOW
- GETBIT
- GROUP_CONCAT
- INT_MONTHS_BETWEEN
- MAX
- MIN
- MONTHS_BETWEEN
- NDV
- NTILE

last-updated: Apr 11, 2022

- PERCENT_RANK
- REGEXP_LIKE
- ROTATELEFT
- ROTATERIGHT
- SETBIT
- SHIFTLEFT
- SHIFTRIGHT
- SPLIT_PART
- SUM
- TIMEOFDAY
- TIMESTAMP_CMP
- TYPEOF

Data Types

Impala supports the following SQL data types:

- BIGINT
- BOOLEAN
- DECIMAL
- DOUBLE
- FLOAT
- INT
- SMALLINT
- NULL
- STRING
- TIMESTAMP
- TINYINT

Impala supports the following complex data types:

- STRUCT
- ARRAY
- MAP

Supported and Unsupported SQL/HiveQL Language Features

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

Supported HiveQL Statements and Clauses

- JOIN
- AGGREGATE
- DISTINCT
- UNION ALL
- ORDER BY (Must use a LIMIT clause with ORDER BY.)
- LIMIT (Accepts arithmetic expressions and numeric literals. You can include the OFFSET clause with the LIMIT clause to produce paged result sets, like 11-20.)
- FROM (You can include FROM in an uncorrelated subquery.)
- INSERT INTO
- INSERT OVERWRITE
- LEFT|RIGHT ANTI JOIN

Supported SQL Statements

When you issue an SQL statement, use a semicolon at the end of each statement.

- COMPUTE INCREMENTAL STATS
- COMPUTE STATS
- CREATE ROLE
- CREATE TABLE
  - Use the STORED AS PARQUET or STORED AS TEXTFILE clause with CREATE TABLE to identify the format of the underlying data files.
  - Use the TBLPROPERTIES clause with CREATE TABLE to associate random metadata with a table as key-value pairs.
  - Use SERDEPROPERTIES with CREATE TABLE to set up metadata that defines how tables are read and written. This may be required for Hive compatibility.
  - USE WITH SERDEPROPERTIES with CREATE TABLE to specify the SerDe classes that read and write data for a table. This may be required for Hive compatibility.
- CREATE TABLE AS SELECT
- CREATE VIEW
- CURRENT DATABASE(Returns the database that the session is currently using.)
- DESCRIBE
- DROP INCREMENTAL STATS
- DROP ROLE
- EXPLAIN (You can issue the command SET EXPLAIN_LEVEL=verbose for more detailed EXPLAIN output. To revert, issue the command SET EXPLAIN_LEVEL=normal.)

- EXPLAIN PLAN
- GRANT
- INVALIDATE METADATA
- LOAD DATA
- REFRESH
- REVOKE
- SELECT
  - You can use the STRAIGHT_JOIN keyword immediately after SELECT to override the reordering of join clauses that Impala does internally.
- SHOW CREATE TABLE
- SHOW DATABASES
- SHOW FILES
- SHOW FUNCTIONS
- SHOW GRANT ROLE
- SHOW ROLE GRANT GROUP
- SHOW ROLES
- SHOW SCHEMAS
- SHOW TABLES
- SHOW COLUMN STATS
- SHOW TABLE STATS
- USE

Supported DDL Statements

DDL statements typically change the table schema. Issue an INVALIDATE METADATA statement manually on the other nodes to update metadata. You can use the SET command to enable the SYNC_DDL option with any DDL statements to return after the Impala catalog service has propagated changes on all Impala nodes.

- ALTER TABLE
  - Use the TBLPROPERTIES clause with ALTER TABLE to associate random metadata with a table as key-value pairs.
  - Use SERDEPROPERTIES with ALTER TABLE to set up metadata that defines how tables are read and written. This may be required for Hive compatibility.
- ALTER VIEW
- COMPUTE STATS
- CREATE DATABASE

- CREATE FUNCTION
- CREATE ROLE
- CREATE TABLE
- CREATE VIEW
- DROP DATABASE
- DROP FUNCTION
- DROP ROLE
- DROP TABLE
- DROP VIEW
- GRANT
- REVOKE

Supported DML Statements

Impala only supports the INSERT and LOAD DATA statements which modify data stored in tables.

- Issue the REFRESH statement on other nodes to refresh the data location cache.
- If the SYNC_DDL statement is enabled, INSERT statements complete after the catalog service propagates data and metadata changes to all Impala nodes.
- You can use the [SHUFFLE] and [NOSHUFFLE] hints with INSERT to redistribute work during INSERT...SELECT operations. You may want to use these hints when inserting into partitioned Parquet tables to avoid memory consumption problems and simultaneous open files, by collecting new data for each partition on a specific node.

Supported Datatypes

Impala supports datatypes with the same names and semantics equivalent to those in Hive.

- char
- varchar
- complex
- string
- tinyint
- smallint
- int
- bigint
- float
- double
- boolean

- string
- timestamp
- asSTRING

Supported Operators

SQL operators are a class of comparison functions used within the WHERE clauses of a SELECT statement.

- BETWEEN
- COMPARISON
- CROSS JOIN (Use as the join operator for Cartesian joins; does not use any ON clause.)
- IN
- IS NULL
- LIKE
- [NOT] EXISTS
- [NOT] IN
- REGEXP
- RLIKE

Supported Literals

Each of the Impala data types has corresponding notation for literal values of that type. Specify literal values in SQL statements, such as in the SELECT list or WHERE clause of a query, or as an argument to a function call.

- Numeric
- String
- Boolean
- Timestamp
- NULL (You can add the NULLS FIRST or NULLS LAST clause at the end of the ORDER BY clause to override or specify the sorting behavior for NULL.)

Supported Schema Objects and Object Names

- Aliases
- Identifiers
- Databases
- Tables
- Views
- Functions

Analytic Functions

Analytic (window) functions operate on a set of rows and return a single value for each row from the underlying query. The term "window" describes the set of rows on which the function operates. A window function uses values from the rows in a window to calculate the returned values. When you use a window function in a query, you define the window using the OVER() clause. The OVER() clause (window clause) differentiates window functions from other analytical and reporting functions.

As of Impala 2.2.0, you can use the following analytic functions in queries:

- MAX()
- MIN()
- COUNT()
- AVG()
- RANK()
- LAG()
- LEAD()
- FIRST_VALUE()
- MAX(), SUM()
- COUNT()

The analytic functions support the following syntax:

```
function(args) OVER([partition_by_clause] [order_by_clause [window_clause]])
partition_by_clause ::= PARTITION BY expr [, expr ...]
order_by_clause ::= ORDER BY expr  [ASC | DESC] [NULLS FIRST | NULLS LAST] [, expr
[ASC | DESC] [NULLS FIRST | NULLS LAST] ...]
```

The window clause supports the following syntax:

```
ROWS BETWEEN [ { m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT ROW |
{ UNBOUNDED | n } FOLLOWING] ]
RANGE BETWEEN [ {m | UNBOUNDED } PRECEDING | CURRENT ROW] [ AND [CURRENT ROW |
{ UNBOUNDED | n } FOLLOWING] ]
```

Supported Aggregate Functions

Aggregate functions calculate a return value across all the items in a result set. When you issues a function, you must include a FROM clause in the query. Aggregate functions ignore NULL values rather than returning a NULL result.

- APPX_MEDIAN()
- AVG()
- COUNT()
- GROUP_CONCAT()
- MAX()
- MIN()
- NDV()

- SUM()

Built-in Functions

Impala supports lots of built-in functions that you can use directly with a SELECT statement to perform data transformation operations, such as mathematical calculations, string manipulations, and data calculations.

Unsupported SQL Features

- Non-scalar data types, such as maps, arrays, structs
- LOAD DATA to load raw files
- Restricted set of literal formats for the TIMESTAMP data type and the from_unixtime() format string
- Extensibility mechanisms such as TRANSFORM, custom file formats, or custom SerDes
- XML and JSON functions
- The following HiveQL aggregate functions: variance, var_pop, var_samp, stddev_pop, stddev_samp, covar_pop, covar_samp, corr, percentile, percentile_approx,histogram_numeric, collect_set
- User Defined Table Generating Functions (UDTFs)
- User Defined Aggregate Functions (UDAFs)
- User Defined Funtions
- Sampling
- Lateral views
- Authorization features such as roles
- Multiple DISTINCT clauses per query

Unsupported HiveQL Statements

- ANALYZE TABLE (the Impala equivalent is COMPUTE STATS)
- DESCRIBE COLUMN
- DESCRIBE DATABASE
- EXPORT TABLE
- IMPORT TABLE
- SHOW PARTITIONS
- SHOW TABLE EXTENDED
- SHOW TBLPROPERTIES
- SHOW FUNCTIONS
- SHOW COLUMNS
- SHOW CREATE TABLE
- SHOW INDEXES

last-updated: Apr 11, 2022

Semantic Differences in Impala Statements vs HiveQL

- Different syntax and names for query hints.
- MapReduce specific features of SORT BY, DISTRIBUTE BY, or CLUSTER BY are not exposed.
- Queries do not need a FROM clause.
- Impala does not allow:
  - Implicit cast between string and numeric or Boolean types
  - Implicit casts among the numeric types or from string to timestamp
  - Storing timestamps using the local timezone; Timestamps are stored relative to GMT
  - Return column overflows as NULL; Impala returns the largest or smallest value in the range for the type
  - Virtual columns
- Impala does not:
  - Expose locking
  - Expose some configuration properties

Impala Limitations

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

What Impala Does Not Provide

Impala does not replace Hive or other frameworks built on MapReduce for long-running batch-oriented queries.

Impala is not fit as a query layer to support operational/OLTP applications (No update/deletes, not optimized for point look-ups).

Known Limitations in Impala

Impala has the following known limitations:

- The LOAD DATA statement does not work when the source directory and destination table are in different encryption zones.
- The Impala configuration option, `--disk_spill_encryption`, is not supported to secure sensitive data from being observed or tampered with when temporarily stored on disk.
- Redaction of sensitive data from Impala log files is not supported.
- You cannot use the lineage information feature to track who has accessed data through Impala SQL statements.

Impala UDFs (user-defined functions) have the following known limitations:

- Impala does not work with UDFs that accept or return composite, nested, or types not available in Impala tables.
- UDFs must produce the same output each time the same argument value is passed.

- UDFs cannot spawn other threads or processes.
- Prior to Impala 2.5.0, UDFs become undefined when you restart the catalog service. You must reload the UDFs.
- You currently cannot include user-defined table functions in Impala queries.

Impala Security

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Features

Warning: While Impala is compatible with the platform, using Impala security is not encouraged for several reasons:

- By design, Impala security secures data outside the underlying filesystem, which creates the potential of backdoor access. When you enable Impala authorization using Sentry, the MapR platform security is bypassed and the MapR converged data platform can no longer fully secure your data.
- If you enable this Impala security, impersonation will be disabled and data ownership will be shifted to the Impala user, which makes the "Impala" data inaccessible by regular users through means other than Hive or Impala (because the users no longer own the data).

You can configure Impala to use the security features listed in the next table on either a secure or a non-secure MapR cluster. If you use the MapR Installer and select **Enable Secure Cluster**, Impala will not be automatically secured.

Feature	Description
LDAP	You can configure LDAP authentication for client connections with Impala. You can use LDAP authentication with Sentry to authenticate users and provide precise levels of access to users. See LDAP Authentication for Impala.
Kerberos	You can configure Impala to use Kerberos for authentication. You can also use Sentry authorization in conjunction with Kerberos if you want to configure user-level access to databases, tables, columns, and partitions. See Enable Kerberos Authentication for Impala.
MapR Security	You can configure MapR security between Impala and Hive. See Configure Hive Metastore to use MapR-SASL on page 3437. **Note:** MapR security is not present between the Impala client and the Impala server. To avoid security holes, you must configure the Impala client on Kerberos or LDAP.
SSL	You can enable SSL network encryption for communication between Impala and client programs and between Impala nodes in a cluster. See Enable SSL for Impala.

last-updated: Apr 11, 2022

Important: The Impala client does not support MapR ticket security, but you can authentication connections as follows:

- Between the Impala server and client (JDBC, Impala-shell) - Kerberos or LDAP. However, you might encounter issues with Impala on Kerberos using the JDBC connector.
- Between Impala (the Impala catalog) and Hive metastore - MapR ticket security or Kerberos.

To avoid security holes, configure Impala on Kerberos or LDAP. If Impala is not secure or only has LDAP authentication enabled, only the client connection to Impala is authenticated and there is no wire level encryption or server-to-server authentication.

You can enable MapR SASL for the Hive metastore. When the Hive metastore is SASL enabled, Impala can run in any security mode (none, LDAP, or Kerberos).

Component Compatibility

You can configure Impala to use the components and/or features listed below on a secure MapR cluster. The following table assumes that each component is configured with Kerberos on Impala. Hive and Hue can be configured with MapR security for authentication.

Note: MapR security is not present between the Impala client and the Impala server. To avoid security holes, you must configure the Impala client on Kerberos or LDAP. Hive and Hue use security.

Component	Version	Impala 1.4.1	Impala 2.2.0	Impala 2.5.0	Impala 2.7.0	Impala 2.10
MapR	6.0.x and later	Yes	Yes	Yes	Yes	Yes
	5.1.x and later	Yes	Yes	Yes	Yes	Yes
	5.0.x	Yes	Yes	No	No	No
	4.0.1	Yes	No	No	No	No
LDAP	N/A	Yes	Yes	Yes	Yes	Yes
Kerberos	N/A	Yes	Yes	Yes	Yes	Yes
Sentry	1.7	No	No	No	Yes	Yes
	1.6	No	Yes	Yes	No	No
Hue	4.2	No	No	No	No	Yes
	3.12	No	No	No	Yes	Yes
	3.9	Yes	Yes	Yes	No	No
	3.6	Yes	No	No	No	No
	1.4	Yes	No	No	No	No
Hive	2.3	No	No	No	No	Yes
	2.1.x	No	No	No	Yes	Yes
	1.2.1	No	Yes	Yes	No	No
	0.13	Yes	No	No	No	No

The following table lists the supported and unsupported component and security combinations necessary to access the Hive metastore:

last-updated: Apr 11, 2022

Impala Client Security Mode	Hive + MapR SASL	Hive + Kerberos
	Note: The Impala Catalog will access Hive Metastore using MapR security.	
None	Supported	Not supported
LDAP	Supported	Not supported
Kerberos	Supported **Note:** Issues with JDBC might exist.	Supported

Related concepts

Using the Enable MapR Secure Cluster Option on page 5427
You use the Enable MapR Secure Cluster option to control whether or not the cluster is configured as a secure cluster.

Enable Kerberos Authentication

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can enable Kerberos authentication for Impala on a secure and non-secure MapR cluster.

Once you have configured Impala to use Kerberos for authentication, restart Impala and then start the `impala-shell` with the `-s mapr -k` flags to enable Kerberos.

To enable Kerberos authentication for Impala, complete the following steps:

1. Enable encryption between RPC services on Kerberos in core-site.xml (change "hadoop.rpc.protection" value to "privacy") and copy core-site.xml to Impala-conf directory:

   ```
   <property>
     <name>hadoop.rpc.protection</name>
     <value>privacy</value>
   </property>
   ```

   And restart the Warden service to apply changes in core-site.xml.

2. Copy the following files to the `$IMPALA_HOME/conf/` directory:

   - `$HIVE_HOME/conf/hive-site.xml`
   - `$HADOOP_HOME/etc/hadoop/core-site.xml`

   Note: Any time the `hive-site.xml` file is modified, copy the file to the `$IMPALA_HOME/conf/` directory.

3. Create service principals for each host that runs impalad, catalogd, or statestored and for the HTTP service. Principal names take the following form:

   ```
   mapr/<fully.qualified.domain.name>@<KERBEROS.REALM>
   ```

   a. Create an Impala service principal and specify the following information:

      - Name “mapr”

last-updated: Apr 11, 2022

- Fully qualified domain name of each node running impalad
- Realm name

```
kadmin: addprinc -requires_preauth -randkey -allow_renewable mapr/
impala_host.example.com@TEST.EXAMPLE.COM
```

b. Create an HTTP service principal.

```
kadmin: addprinc -randkey HTTP/
impala_host.example.com@TEST.EXAMPLE.COM
```

4. Create, merge, and distribute keytab files for the principals.

a. Create keytab files with both principals.

```
kadmin: xst -k /opt/mapr/conf/mapr.keytab mapr/impala_host.example.com
```

b. Use the keytab utility to read the content of the keytab files and then write the content to a new file.

```
ktutil
ktutil: rkt /opt/mapr/conf/mapr.keytab
ktutil: rkt /opt/mapr/conf/http.keytab
ktutil: wkt /opt/mapr/conf/mapr-http.keytab
ktutil: quit
```

c. Optionally, test the credentials in the merged keytab file to verify their validity and to verify that “renew until” data is set to a future time.

```
klist -e -k -t /opt/mapr/conf/mapr-http.keytab
```

d. Change the file owner to the `mapr` user to make `mapr` the only user authorized to read the file content.

```
chmod 400 /opt/mapr/conf/mapr-http.keytab
```

5. Edit `/opt/mapr/impala/impala-<version>/conf/env.sh` to include the fully qualified domain name for the IMPALA_STATE_STORE_HOST, IMPALA_STATE_STORE_HOST variables, and Kerberos options.

a. Set the IMPALA_STATE_STORE_HOST and CATALOG_SERVICE_HOST variables to point to the fully qualified domain name.

```
IMPALA_STATE_STORE_HOST=impala_host.example.com
IMPALA_STATE_STORE_PORT=24000
CATALOG_SERVICE_HOST=impala_host.example.com
```

b. Add the following Kerberos options for impalad, catalogd, and statestored daemons using the IMPALA_SERVER_ARGS, IMPALA_CATALOG_ARGS, and IMPALA_STATE_STORE_ARGS variables:

```
-kerberos_reinit_interval=60
-principal=mapr/impala_host.example.com@TEST.EXAMPLE.COM
-keytab_file=/opt/mapr/conf/mapr-http.keytab
```

```
IMPALA_SERVER_ARGS=" \
     -log_dir=${IMPALA_LOG_DIR} \
     -state_store_port=${IMPALA_STATE_STORE_PORT} \
     -use_statestore \
     -authorized_proxy_user_config=mapr=* \
     -state_store_host=${IMPALA_STATE_STORE_HOST} \
     -catalog_service_host=${CATALOG_SERVICE_HOST} \
     -be_port=${IMPALA_BACKEND_PORT} \
     -disable_admission_control=true \
     -kerberos_reinit_interval=60 \
     -principal=mapr/impala_host.example.com@TEST.EXAMPLE.COM \
     -keytab_file=/opt/mapr/conf/mapr-http.keytab "
```

c. Restart Impala and the catalog and statestore services. See Managing Impala.

d. To enable Kerberos from the impala-shell, start the impala-shell with the `-s mapr -k` flags.

```
impala-shell -s mapr -k
```

For more information on changing the Impala defaults specified in `env.sh`, see Impala-Shell Commands.

Enable SSL for Impala

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Impala 2.5.0 supports SSL encryption for internal Impala connections.

Complete the following steps to configure SSL for Impala:

1. Configure encryption in Hive. See Hive Encryption.
2. Configure client-server encryption only or configure client-server and Impala internal encryption.
   - To configure client-server encryption only, add the following start-up options for the Impala Server to `/opt/mapr/impala/impala-<version>/conf/env.sh`:

`-ssl_server_certificate`	Full path to the server certificate on the local filesystem.
`-ssl_private_key`	Full path to the server private key on the local filesystem.

   - To configure client-server and Impala internal encryption, add the following start-up options for the Impala server, catalog, and statestore to `/opt/mapr/impala/impala-<version>/conf/env.sh`:

`-ssl_server_certificate`	Full path to the server certificate on the local filesystem.
`-ssl_private_key`	Full path to the server private key on the local filesystem.

last-updated: Apr 11, 2022

`-ssl_client_ca_certificate`	Full path to the certificate on the local filesystem required for client/server encryption.

Note: When you add the SSL flags to Impala start-up options, Impala listens for HiveServer2 on the SSL-secured ports. A client program usually has equivalent options to verify a connection to the correct server.

After you enable SSL, you can issue the following options when you start the impala-shell:

Option	Description
`--ssl`	Enables SSL for the impala-shell.
`--ca_cert`	Local path name that points to the third-party CA certificate, or to a copy of the server certificate for self-signed server certificates. If --ca_cert is not set, impala-shell enables SSL, but does not validate the server certificate. This is useful for connecting to an Impala node that you know is only running over SSL when a copy of the certificate is not available.

For more information about the impala-shell, refer to Impala-Shell Commands.

For more information about configuring Impala start-up options, see Additional Impala Configuration Options.

LDAP Authentication

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

As of Impala 1.2.3, client connections with Impala can be authenticated against LDAP servers. You can configure LDAP authentication for client connections with Impala on a non-secure MapR cluster. When you configure LDAP authentication, you must configure SSL between the client and Impala, and between Impala and the LDAP server to avoid sending credentials over the wire in clear text. Configuration requirements apply to the server side when configuring and starting Impala.

If the Hive metastore has MapR-SASL enabled, copy `$HIVE_HOME/conf/hive-site.xml` to `$IMPALA_HOME/conf/`. Repeat this step any time the `hive-site.xml` file is modified.

Modify `/opt/mapr/impala/impala-<version>/conf/env.sh` and include the following options to configure Impala server LDAP authentication:

Options	Description
--enable_ldap_auth	Set this option to "`true`" in all environments to enable LDAP authentication between Impala and the client.
--ldap_uri	Sets the URI of the LDAP server to use. Typically, the URI is prefixed with `ldap://<hostname>`. Optionally, the URI can specify the port. For example, `ldap://<hostname>:<port>`.
--ldap_manual_config extend col	Bypasses all of the automatic configuration if you need to provide a custom SASL.
--ldap_tls	Tells Impala to start a TLS connection to the LDAP server and to fail authentication if Impala cannot start the TLS connection.

last-updated: Apr 11, 2022

Example:

```
IMPALA_SERVER_ARGS=" \
    -log_dir=${IMPALA_LOG_DIR} \
    -state_store_port=${IMPALA_STATE_STORE_PORT} \
    -enable_ldap_auth=true \
    -ldap_uri=ldap://10.250.1.5/ \
    -ldap_tls=true \
    -use_statestore \
    -state_store_host=${IMPALA_STATE_STORE_HOST} \
    -catalog_service_host=${CATALOG_SERVICE_HOST} \
    -be_port=${IMPALA_BACKEND_PORT}"
```

After you restart the Impala server, statestore, and catalog, you can connect to Impala using LDAP authentication. To connect to Impala, launch the impala-shell from a client node and issue the following commands:

Command	Description
`-l`	Enables LDAP authentication.
`-u`	Sets the user. The impala-shell prompts you for the password. Per Active Directory, the user is the short username, not the full LDAP distinguished name.
`--ldap_password_cmd`	(Impala 2.5.0 only) Sets the bash command to retrieve the LDAP user password.

Example:

```
impala-shell -l -u
uid=qa-user1,ou=People,dc=maprtech,dc=com --ldap_password_cmd="echo -n
      secret"
```

Sentry

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Important: MapR officially supports Sentry with Impala, Hive, Sqoop2, and Hue if you purchase Impala support and configure Impala to use Sentry.

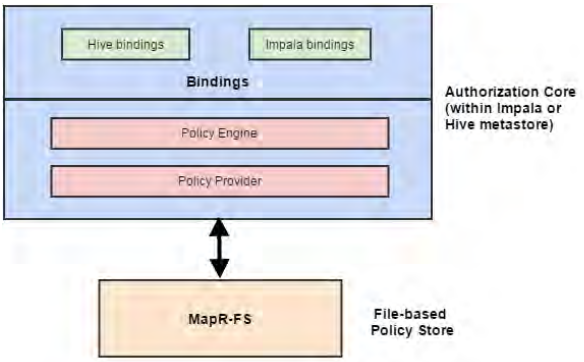
Apache Sentry is an authorization module for Hadoop that provides the granular, role-based authorization required to provide precise levels of access to authenticated users and applications. Sentry allows users to see only those objects for which they have privileges.

Storage Models

Sentry supports two models for storing policy rules:

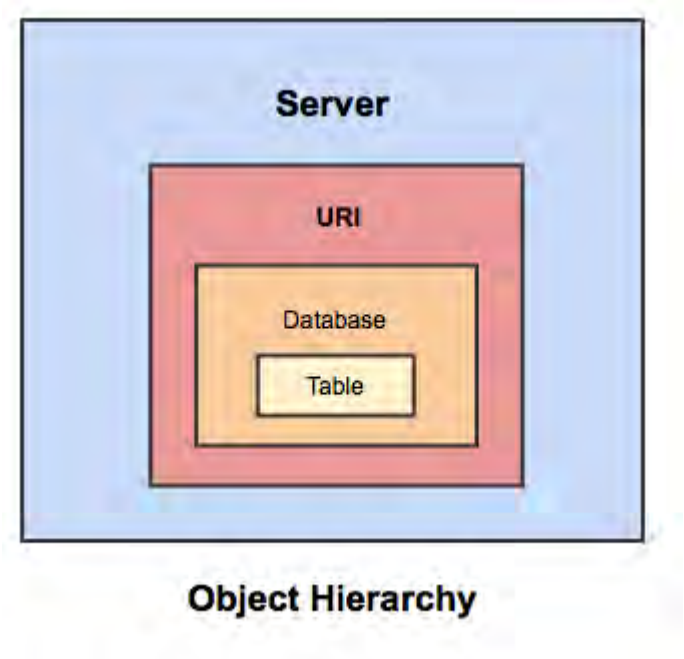
Database storage (preferred)	As of Sentry 1.6-1602, you can configure Sentry to use the database storage mode. With this mode, the Sentry service provides access to read and maintain privileges and roles from a database.
File-based storage	Privileges and roles are accessed from and maintained in a policy file (`global-policy.ini`) which you can store on the MapR filesystem. The following diagram illustrates the architecture of the file-based storage model:

last-updated: Apr 11, 2022



Privileges

Privileges are granted on different objects in the schema, including tables, databases, URIs and servers. The object hierarchy is set up like this, where objects inherit privileges from objects above them in the hierarchy:



Privileges and roles are specified in either a relational database (for database rule storage) or a `global-policy.ini` file (for file-based rule storage). The following examples show a `global-policy.ini` file along with the equivalent set of privileges and roles expressed in HiveSQL syntax.

Sample global-policy.ini File

```
[groups]
        # Assigns each Hadoop group to its set of roles
        manager = analyst_role, junior_analyst_role
        analyst = analyst_role
        jranalyst = junior_analyst_role
        customers_admin = customers_admin_role
        admin = admin_role

        [roles]
```

```
# The uris below define a landing pad which
# the user can use to import or export data from the system.
# Since the server runs as the user "hive," files in that directory
# must either have read/write permissions set for the group hive
# or have read/write permissions set for world.
analyst_role = server=HS2->db=analyst1, \
server=HS2->db=jranalyst1->table=*->action=select
server=HS2->uri=maprfs:/landing/analyst1
junior_analyst_role = server=HS2->db=jranalyst1, \
server=HS2->uri=maprfs:/landing/jranalyst1

# Implies everything on HS2.
admin_role = server=HS2
```

Known Issues

Upgrading Sentry

If you are upgrading from Sentry in EEP 6.3.1 or EEP 7.0.0 to Sentry in the latest EEP version, manually back up the `/conf` and `/logs` directories located in SENTRY_HOME. After the upgrade completes, add those directories back into the SENTRY_HOME directory.

You can see the `/conf` and `/logs` directories listed in the Sentry installation directory, as shown:

```
ll /opt/mapr/sentry/sentry-1.7.0
total 76
drwxr-xr-x 2 mapr mapr  4096 Jan  5
13:34 bin
-rw-r--r-- 1 mapr mapr 15211 Jan  5
10:26 CHANGELOG.txt
drwxr-xr-x 2 mapr mapr  4096 Jan  5
13:34 conf
drwxr-xr-x 2 mapr mapr  4096 Jan  5
13:34 conf.d
drwxr-xr-x 2 mapr mapr  4096 Jan  5
13:34 conf.new
drwxr-xr-x 4 mapr mapr 12288 Jan  5

10:26 README.md
drwxr-xr-x 3 mapr mapr  4096 Jan  5
13:34 scripts
```

See Pre-Upgrade Steps for Sentry on page 346 and Upgrading Sentry on page 368.

Removing Sentry

This issue applies to Sentry in EEP 6.3.1 and EEP 7.0.0.

If you try to remove Sentry on an Ubuntu OS before the Sentry process has started (the Sentry process

does not exist), the system may return the following error message:

```
...
dpkg: error processing package
mapr-sentry (--purge):
 subprocess installed pre-removal
script returned error exit status 1
Errors were encountered while
processing:
 mapr-sentry
E: Sub-process /usr/bin/dpkg returned
an error code (1)
...
```

As a workaround, to completely remove Sentry on an Ubuntu OS, run:

```
sudo mv /var/lib/dpkg/info/
mapr-sentry.* /tmp/
sudo
dpkg --remove --force-remove-reinstreq
 mapr-sentry
sudo rm -rf /opt/mapr/sentry/
```

Sentry Feature Support

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Important: MapR support for Sentry is limited to Impala users.

- HDFS ACLs are not supported.
- As of MapR Sentry 1.6-1602, the database storage mode is supported. It was not supported in the Sentry 1.4.0-1412 release.
- Sentry 1.7.0-1703 supports Sentry Simple Shell and Hive Authorization V2.

The global-policy.ini File

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The default `global-policy.ini` file defines the `admin_role`, which gives full access to the Hiveserver2 server for the `mapr` user. The file is located in `/opt/mapr/sentry/sentry-<version>/conf` in your local file system. You can relocate the file to the MapR filesystem if you prefer. By default, the file contains these sections:

```
[groups]
      mapr = admin_role

      [roles]
      admin_role = server=HS2
```

Sample sentry-provider.ini File

```
[databases]
        # Defines the location of the per-DB policy file for the customer's
```

```
DB or schema
        customers = /etc/sentry/customers.ini

        [groups]
        customers_admin = customers_admin_role

        [roles]
        customers_admin_role = server=HS2->db=customers
```

Sample customers.ini File

```
[groups]
        manager = customers_insert_role, customers_select_role
        analyst = customers_select_role

        [roles]
        customers_insert_role =
server=HS2->db=customers->table=*->action=insert
        customers_select_role =
server=HS2->db=customers->table=*->action=select
```

Configuring Sentry
The steps to configure Sentry are determined by the storage model, the type of security used by the cluster, and the components that will use Sentry authorization.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Configure Sentry to use one of the following storage models: file-based storage or database storage.
2. If the cluster is secure, you can configure Sentry to use kerberos authentication.
3. Based on your requirements, complete the steps to integrate Sentry with one or more ecosystem components.

Configure Sentry to use Database Storage

As of Sentry 1.6, the database storage model is the preferred method for storing privileges and roles. When you configure Sentry to use the database storage model, it also includes a service that is managed by Warden.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following databases can be used to store privileges and roles: MySQL, Oracle, Postgres, DB2 and Derby. Examples in the following procedure use MySQL as the database type.

Note: When you install Sentry with the MapR Installer and you specify MySQL as the database for Sentry, the MapR Installer performs the following configurations.

1. Create a database for Sentry.

   For example, run the following commands to create a MySQL database:

   ```
   mysql> create database sentry_store;
   mysql> use sentry_store;
   mysql> create user 'sentry'@'<hostname>' identified by 'sentry';
   mysql> grant all on *.* to 'sentry'@'<hostname>' identified by 'sentry';
   mysql> flush privileges;
   ```

last-updated: Apr 11, 2022

2. In `/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`, update the value of the following property:

Property	Configuration
sentry.hive.provider.backend	Set the value to `org.apache.sentry.provider.db.SimpleDBProviderBackend`

For example:

```
<property>
  <name>sentry.hive.provider.backend</name>
  <value>org.apache.sentry.provider.db.SimpleDBProviderBackend</value>
  <description> Options:
{org.apache.sentry.provider.db.SimpleDBProviderBackend,
org.apache.sentry.provider.file.SimpleFileProviderBackend}Privilege
provider to be used, we support file based or db based</description>
</property>
```

3. In the `sentry-site.xml` file (`/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`), add the following properties:

Property	Configuration
sentry.store.jdbc.url	Set the value to the JDBC connection URL.
sentry.store.jdbc.driver	Set the value to the Backend JDBC driver.
sentry.store.jdbc.user	Set the value to the JDBC user name.
sentry.store.jdbc.password	Set the value to the JDBC password.

For example:

```
<property>
  <name>sentry.store.jdbc.url</name>
  <value>jdbc:mysql://localhost/sentry_store</value>
</property>

<property>
  <name>sentry.store.jdbc.driver</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>sentry.store.jdbc.user</name>
  <value>sentry</value>
</property>

<property>
  <name>sentry.store.jdbc.password</name>
  <value>sentry</value>
</property>
```

4. Initialize the database schema.

```
/opt/mapr/sentry/sentry-<version>/bin/sentry --command
schema-tool --conffile /opt/mapr/sentry/sentry-<version>/conf/
sentry-site.xml --dbType mysql --initSchema
```

5. To add Sentry to the list of services that Warden monitors, copy `/opt/mapr/sentry/sentry-<version>/conf.d/warden.sentry.conf` to `/opt/mapr/conf/conf.d`.

Configure Sentry to use File-Based Storage

You can configure Sentry to use the file-based storage model where permissions are stored in the global-policy.ini.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

As of Sentry 1.6.0-1602, the properties in step 1 are configured by default.

1. In the sentry-xml file (/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml), edit or verify the configuration of the following verify properties:

Property	Configuration
sentry.hive.provider.backend	Set the value to `org.apache.sentry.provider.file.SimpleFileProviderBackend`
sentry.hive.provider.resource	Set the value to the location of the global-policy.ini.

For example:

```
<property>
                        <name> sentry.hive.provider.backend </name>
                        <value>
org.apache.sentry.provider.file.SimpleFileProviderBackend </value>
                        <description> The privilege provider to be used
(either file-based or db-based). </description>
                        </property>

                        <property>
                        <name> sentry.hive.provider.resource </name>
                        <value> file:///opt/mapr/sentry/sentry-<version>/
conf/global-policy.ini </value>
                        <description> Provides location of the policy
file. If the policy file is in the filesystem, then the URL should start
from next schema: 'maprfs:///'. </description>
                        </property>
```

2. Complete the steps to integrate Hive with Sentry. This includes the step to configure the global-policy.ini file. See The global-policy.ini File on page 3820

Configure Sentry to use Kerberos Authentication

You can configure Sentry to run in a secure cluster that uses Kerberos authentication.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

The same settings are valid for both the file-based and database storage modes.

1. Configure the following properties in the `/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml` file:

```
<property>
    <name>sentry.service.security.mode</name>
    <value>kerberos</value>
    <description>Options: kerberos, other, none. Authentication mode for
Sentry service.</description>
</property>
<property>
    <name>sentry.hive.testing.mode</name>
    <value>false</value>
</property>
```

2. Add the following properties to `/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`:

```
<property>
    <name>sentry.service.server.principal</name>
    <value>mapr/<FQDN@REALM></value>
</property>
<property>
    <name>sentry.service.server.keytab</name>
    <value>/opt/mapr/conf/mapr.keytab</value>
</property>
<property>
    <name>sentry.service.allow.connect</name>
    <value>mapr,hive,impala</value>
</property>
```

3. Before starting Sentry, use the kinit tool:

```
kinit -kt /opt/mapr/conf/mapr.keytab -p mapr/<CLUSTER_NAME@REALM>
```

Example

```
kinit -kt /opt/mapr/conf/mapr.keytab -p mapr/my.cluster.com@NODE1
```

Integrating Sentry
Integrate Sentry with other ecosystem components to enable those components to use Sentry authorization. You can also integrate Sentry with Hue in order to use the Hue Security application to manage Sentry privileges and roles.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Important: MapR officially supports Sentry with Impala, Hive, Sqoop2, and Hue only if you buy Impala support and configure Impala to use Sentry.

You can configure Sentry to provide authorization in the following scenarios:

Sentry Version	Sentry Storage Mode	Component Integration
1.6.0	Database	Impala 2.2.0 and Hive 1.2.1
1.6.0	Database	Sqoop2

last-updated: Apr 11, 2022

Sentry Version	Sentry Storage Mode	Component Integration
1.6.0	File-Based	Impala 2.2.0 and Hive 1.2.1
1.4.0	File-Based	Impala 1.4.1 and Hive 0.13

Note:

- When you configure Impala to use Sentry authorization, both Impala and Hive must use Sentry for authorization management. Also, impersonation cannot be enabled for Hive.
- For clusters with Hive but not Impala, authorization can be implemented using Hive's native authorization mechanisms;Sentry is not needed.

Configure Impala to Use Sentry Authorization

You can configure Impala to work with Sentry for authorization. When you configure Sentry authorization for Impala, Impala uses operating system IDs to associate privileges with each user that runs the impala-shell or client program.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Before you can configure Impala for Sentry authorization, you must have Hive and Sentry installed and configured to work together.

The following table provides the MapR and component versions required when you want to configure Impala to use Sentry authorization:

Component	Versions
MapR	6.1.0
Impala	Impala 2.12.0.x
Sentry	Sentry 1.7.0
Hive	Hive 2.3.6

Configure Impala to Use Sentry Authorization With the Database Storage Model

As of Sentry 1.6, Sentry can be configured to use the Database storage model. Complete the following steps to configure Impala to use Sentry authentication when Sentry uses the DB storage model:

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Set the following properties in env.sh (/opt/mapr/impala/impala-<version>/conf/env.sh):

```
IMPALA_SERVER_ARGS=" -server_name=HS2 -sentry_config=<SENTRY-HOME>/conf/
sentry-site.xml
IMPALA_CATALOG_ARGS=" -sentry_config=<SENTRY-HOME>/conf/sentry-site.xml
IMPALA_STATE_STORE_ARGS=" -sentry_config=<SENTRY-HOME>/conf/
sentry-site.xml
```

Note: SENTRY-HOME is a variable used in place of the ecosystem component home directory. Typically, the default ecosystem component home directory for a component is `/opt/mapr/<component>/<component>-<version>/`.

last-updated: Apr 11, 2022

2. Run the following commands to restart Impala:

```
sudo -u mapr maprcli node services -name impalaserver -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalastore -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalacatalog -action
restart -nodes <nodename>
```

3. When Impala is running, you can issue the following command to start the impala-shell as a particular user:

```
impala-shell -u <user_name>
```

Configure Impala to Use Sentry Authorization in File-Based Storage Model

Impala reads the file and controls which objects users can access and what operations they can perform on the objects. Impala caches the security information in the policy file every five minutes. If you make significant changes to security policies, restart Impala. Changes immediately take effect.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Edit `env.sh` located in `/opt/mapr/impala/impala-<version>/conf/`.
2. In the IMPALA_SERVER_ARGS declaration, add the following options:

Option	Description
-server_name	This option turns on Sentry authorization for Impala. Specify the symbolic server name to use as the argument for this option. You must also specify this server name as the value for the sentry.hive.server property in the sentry-site.xml configuration file for Hive. For example: `-server_name=<hive_server_2>`
-authorization_policy_file	You can store privileges in an authorization policy file. When you specify this option, in addition to the server_name option, Impala reads privilege information from the policy file instead of a database. Specify the MapR filesystem path to the policy file that contains the privilege information. For example: `- authorization_policy_file=file:///opt/mapr/sentry/sentry-/conf/.ini \` **Note:** If the policy file is stored in MapR filesystem, indicate the MapR filesystem location using the following format: `-authorization_policy_file=maprfs:///<path_to_policy_file>`

last-updated: Apr 11, 2022

3. Restart the Impala server, statestore service, and catalog service.

```
sudo -u mapr maprcli node services -name impalaserver -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalastore -action
restart -nodes <nodename>
```

```
sudo -u mapr maprcli node services -name impalacatalog -action
restart -nodes <nodename>
```

Note: Impala does not start if it detects any issues in the authorization settings or the policy file.

4. When Impala is running, you can issue the following command to start the impala-shell as a particular user:

```
impala-shell -u <user_name>
```

Configure Sqoop2 to use Sentry Authorization

As of Sentry 1.6.0, you can configure Sqoop2 to use Sentry authentication when Sentry uses the database storage model, the cluster is secure, and the cluster uses Kerberos authentication. Use these steps:

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Add the following properties to the `sentry-site.xml` file (`/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml`):

```
<property>
                        <name>sentry.sqoop.provider.backend</name>

<value>org.apache.sentry.provider.db.generic.SentryGenericProviderBackend
</value>
                        </property>

                        <property>
                        <name>sentry.service.allow.connect</name>
                        <value>mapr,sqoop</value>
                        <description>comma separated list of users -
List of users that are allowed to connect to the service (eg Hive,
Impala)</description>
                        </property>
```

last-updated: Apr 11, 2022

2. Configure the following properties in the `sqoop.properties` file (`/opt/mapr/sqoop/sqoop-2.0.0/server/conf/sqoop.properties`):

```
# Authentication configuration

org.apache.sqoop.security.authentication.type=KERBEROS

org.apache.sqoop.security.authentication.handler=org.apache.sqoop.security.authentication.KerberosAuthenticationHandler

org.apache.sqoop.security.authentication.kerberos.principal=mapr/<FQDN>@<REALM>

org.apache.sqoop.security.authentication.kerberos.keytab=/opt/mapr/conf/mapr.keytab

org.apache.sqoop.security.authentication.kerberos.http.principal=HTTP/<FQDN>@<REALM>

org.apache.sqoop.security.authentication.kerberos.http.keytab=/opt/mapr/conf/mapr.keytab

org.apache.sqoop.security.authentication.enable.doAs=true

org.apache.sqoop.security.authentication.proxyuser.mapr.users=*

org.apache.sqoop.security.authentication.proxyuser.mapr.groups=*

org.apache.sqoop.security.authentication.proxyuser.mapr.hosts=*

                        # Authorization configuration

org.apache.sqoop.security.authorization.handler=org.apache.sentry.sqoop.authz.SentryAuthorizationHander

org.apache.sqoop.security.authorization.access_controller=org.apache.sentry.sqoop.authz.SentryAccessController

org.apache.sqoop.security.authorization.validator=org.apache.sentry.sqoop.authz.SentryAuthorizationValidator

org.apache.sqoop.security.authorization.server_name=SqoopServer1
                        sentry.sqoop.site.url=file:///opt/mapr/sqoop/sqoop-2.0.0/server/conf/sqoop-sentry-site.xml
```

3. Copy the following JAR files from `/opt/mapr/sentry/sentry-<version>/lib` to `/opt/mapr/sqoop/sqoop-2.0.0/server/webapps/sqoop/WEB-INF/lib/`. (For Sqoop 1.99.7, use `/opt/mapr/sqoop/sqoop-2.0.0/server/lib/`):

   For Sentry Version 1.6.0

   - `sentry-provider-db-1.6.0-incubating-mapr-1606.jar`
   - `shiro-core-1.2.1.jar`
   - `sentry-core-common-1.6.0-incubating-mapr-1606.jar`
   - `sentry-core-model-db-1.6.0-incubating-mapr-1606.jar`
   - `sentry-core-model-search-1.6.0-incubating-mapr-1606.jar`

- `sentry-core-model-sqoop-1.6.0-incubating-mapr-1606.jar`
- `sentry-provider-common-1.6.0-incubating-mapr-1606.jar`
- `sentry-policy-common-1.6.0-incubating-mapr-1606.jar`
- `libthrift-0.9.2.jar`
- `sentry-provider-file-1.6.0-incubating-mapr-1606.jar`
- `sentry-binding-sqoop-1.6.0-incubating-mapr-1606.jar`
- `sentry-policy-sqoop-1.6.0-incubating-mapr-1606.jar`

For Sentry Version 1.7.0

- `sentry-provider-db-1.7.0-mapr-1703.jar`
- `shiro-core-1.2.3.jar`
- `sentry-core-common-1.7.0-mapr-1703.jar`
- `sentry-core-model-db-1.7.0-mapr-1703.jar`
- `sentry-core-model-search-1.7.0-mapr-1703.jar`
- `sentry-core-model-sqoop-1.7.0-mapr-1703.jar`
- `sentry-provider-common-1.7.0-mapr-1703.jar`
- `sentry-policy-common-1.7.0-mapr-1703.jar`
- `libthrift-0.9.2.jar`
- `sentry-provider-file-1.7.0-mapr-1703.jar`
- `sentry-binding-sqoop-1.7.0-mapr-1703.jar`
- `sentry-policy-sqoop-1.7.0-mapr-1703.jar`

4. Create `sqoop-sentry-site.xml` in the `/opt/mapr/sqoop/sqoop-2.0.0/server/conf/` directory. (If you use Sqoop 1.99.7, create `sqoop-sentry-site.xml` in the `/opt/mapr/sqoop/sqoop-2.0.0/conf` directory.)

last-updated: Apr 11, 2022

5. Add the following properties to the `sqoop-sentry-site.xml`:

```
<property>
                        <name>sentry.service.security.mode</name>
                        <value>kerberos</value>
                        </property>

                        <property>
                        <name>sentry.service.server.principal</name>
                        <value>mapr/<FQDN>@<REALM></value>
                        </property>

                        <property>
                        <name>sentry.service.server.keytab</name>
                        <value>/opt/mapr/conf/mapr.keytab</value>
                        </property>

                        <property>
                        <name>sentry.service.client.server.rpc-address</
name>
                        <value>localhost</value>
                        </property>

                        <property>
                        <name>sentry.service.client.server.rpc-port</
name>
                        <value>8038</value>
                        </property>

                        <property>
                        <name>sentry.sqoop.provider.backend</name>

<value>org.apache.sentry.provider.db.generic.SentryGenericProviderBackend
</value>
                        </property>

                        <property>
                        <name>sentry.service.admin.group</name>
                        <value>sqoop2,sqoop,hive,impala,solr,mapr</value>
                        </property>
```

6. Start the Sqoop2 server:

```
maprcli node services -name sqoop2 -action start -nodes <space delimited
list of nodes>
```

Configure Hive to use Sentry Authorization

Configure Hive to use Sentry when you want to use Sentry authorization with Impala.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

Complete the following steps to configure Hive to use Sentry authorization, and create an `admin` role for the `mapr` user:

1. For Sentry 1.6.0 and Hive 1.2, add the following properties to `hive-site.xml`:

```
<property>
    <name>hive.server2.session.hook</name>
    <value>org.apache.sentry.binding.hive.HiveAuthzBindingSessionHook</
value>
</property>
<property>
    <name>hive.sentry.conf.url</name>
    <value>file:///opt/mapr/sentry/sentry-<version>/conf/
sentry-site.xml</value>
    <description>sentry-site.xml file location</description>
</property>
<property>
    <name>hive.metastore.rawstore.impl</name>
    <value>org.apache.sentry.binding.metastore.AuthorizingObjectStore</
value>
</property>
<property>
    <name>hive.metastore.filter.hook</name>

<value>org.apache.sentry.binding.metastore.SentryMetaStoreFilterHook</
value>
</property>
<property>
    <name>hive.server2.enable.doAs</name>
    <value>false</value>
    <description>Set this property to enable impersonation in
Hive Server 2</description>
</property>
<property>
    <name>hive.metastore.execute.setugi</name>
    <value>true</value>
</property>
<property>
    <name>hive.sentry.subject.name</name>
    <value>mapr</value>
</property>
<property>
    <name>hive.stats.collect.scancols</name>
    <value>true</value>
    <description>Property for use column level privileges in
Hive and Sentry Integration</description>
</property>
```

Note: The `hive.metastore.rawstore.impl` property is optional, but is recommended for metadata read protection.

last-updated: Apr 11, 2022

2. If Sentry uses the database storage model for rules, add the following properties to `hive-site.xml`:

```
<property>
    <name>hive.support.concurrency</name>
    <description>Enable Hive's Table Lock Manager Service</description>
    <value>true</value>
</property>
<property>
    <name>hive.zookeeper.quorum</name>
    <description>ZooKeeper quorum used by Hive's Table Lock Manager</
description>
    <value>hostname</value>
</property>
<property>
    <name>hive.zookeeper.client.port</name>
    <description>The port where the clients connect</description>
    <value>5181</value>
</property>
<property>
    <name>hive.security.authorization.task.factory</name>

<value>org.apache.sentry.binding.hive.SentryHiveAuthorizationTaskFactoryI
mpl</value>
</property>
<property>
    <name>hive.metastore.rawstore.impl</name>
    <value>org.apache.sentry.binding.metastore.AuthorizingObjectStore</
value>
</property>
<property>
    <name>hive.metastore.pre.event.listeners</name>
    <value>org.apache.sentry.binding.metastore.MetastoreAuthzBinding</
value>
    <description>list of comma separated listeners for metastore
events.</description>
</property>
```

3. To configure Sentry with Hive 2.1 or later, add the following properties to `HIVE_HOME/conf/hive-site.xml`:

```
<property>
    <name>hive.server2.session.hook</name>

<value>org.apache.sentry.binding.hive.v2.HiveAuthzBindingSessionHookV2</
value>
</property>
<property>
    <name>hive.sentry.subject.name</name>
    <value>mapr</value>
    <description>sentry-site.xml file location</description>
</property>
<property>
    <name>hive.sentry.conf.url</name>
    <value>file:///opt/mapr/sentry/sentry-1.7.0/conf/sentry-site.xml</
value>
    <description>sentry-site.xml file location</description>
</property>
<property>
    <name>hive.security.authorization.task.factory</name>

<value>org.apache.sentry.binding.hive.v2.SentryHiveAuthorizationTaskFacto
ryImplV2</value>
</property>
<property>
    <name>hive.metastore.rawstore.impl</name>

<value>org.apache.sentry.binding.hive.v2.metastore.AuthorizingObjectStore
V2</value>
</property>
<property>
    <name>hive.metastore.filter.hook</name>

<value>org.apache.sentry.binding.metastore.SentryMetaStoreFilterHook</
value>
</property>
<property>
    <name>hive.server2.enable.doAs</name>
    <value>false</value>
    <description>Set this property to enable impersonation in Hive
Server 2</description>
</property>
<property>
    <name>hive.metastore.execute.setugi</name>
    <value>true</value>
</property>
<property>
    <name>hive.internal.ss.authz.settings.applied.marker</name>
    <value>true</value>
</property>
<property>
    <name>hive.security.authorization.manager</name>
    <value>org.apache.sentry.binding.hive.v2.SentryAuthorizerFactory</
value>
</property>
<property>
    <name>hive.security.authenticator.manager</name>

<value>org.apache.hadoop.hive.ql.security.SessionStateUserAuthenticator</
value>
</property>
```

last-updated: Apr 11, 2022

```
<property>
    <name>hive.security.authorization.enabled</name>
    <value>true</value>
</property>
<property>
    <name>hive.metastore.pre.event.listeners</name>

<value>org.apache.sentry.binding.hive.v2.metastore.MetastoreAuthzBindingV
2</value>
    <description>list of comma separated listeners for metastore
events.</description>
</property>
<property>
<name>hive.metastore.event.listeners</name>

<value>org.apache.sentry.binding.hive.v2.metastore.SentryMetastorePostEve
ntListenerV2</value>
    <description>list of comma separated listeners for metastore, post
events.</description>
</property>
<property>
    <name>hive.zookeeper.client.port</name>
    <value>5181</value>
    <description>The Zookeeper client port. The MapR default clientPort
is 5181.</description>
</property>
<property>
    <name>hive.zookeeper.quorum</name>
    <description>Zookeeper quorum used by Hive's Table Lock Manager</
description>
    <value><!--host with Zookeper--></value>
</property>
```

4. Restart HiveServer2 and the Hive Metastore:

```
sudo -u mapr maprcli node services -name hs2 -action restart -nodes
<nodename>
sudo -u mapr maprcli node services -name hivemeta -action restart -nodes
<nodename>
```

5. If Sentry was configured to use the database storage model, issue the following command to restart Sentry:

```
sudo -u mapr maprcli node services -name sentry -action restart -nodes
<nodename>
```

6. Create the `admin` role.
   - For the database storage model, run the following commands from the Hive beeline to create the admin role for the mapr user:

```
>create role admin_role;
>grant all on server HS2 to role admin_role;
>grant role admin_role to group mapr;
```

last-updated: Apr 11, 2022

- For the file-based model, update the The global-policy.ini File on page 3820 in `/opt/mapr/sentry/sentry-<version>/conf`. For example:

```
[groups]
mapr = admin_role
testuser = test_role
[roles]
admin_role = server=HS2
test_role = server=HS2->db=test_db1->table=test_table->action=all
```

Note: If you include a non-existent mapping or path to a JAR file that represents a UDF (user-defined function) in any section of the `global-policy.ini` file, Sentry silently fails and cannot control access to Hive. For example, if you include a mapping to a role that does not exist in the `[groups]` section, Sentry fails. For more information, see Getting Started with Sentry in Hive.

Integrate Hue with Sentry

You can integrate Hue with Sentry 1.6 on a secure cluster that uses Kerberos authentication; however, the integration is not supported on a secure cluster using MapR-SASL authentication. Integrate Hue with Sentry when you want to use the Hue Security application to manage Sentry roles and privileges. When you integrate Hue with Sentry, Sentry must use the database storage model.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Note: The Hue user that manages Sentry roles and privileges in Hue must belong to a Hue group that is also part of the Sentry admin group.

1. In the [libsentry] section of the hue.ini (/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini), configure the following properties:

```
[libsentry]
                        # Hostname or IP of server.
                        hostname=localhost

                        # Port the sentry service is running on.
                        port=8038

                        # Sentry configuration directory, where
sentry-site.xml is located.
                        sentry_conf_dir=/opt/mapr/sentry/
sentry-<version>/conf/sentry-site.xml
```

2. If Sentry uses Kerberos authentication, edit the following property in sentry-site.xml (/opt/mapr/sentry/sentry-<version>/conf/sentry-site.xml) to enable the Hue admin user (mapr) to connect to Sentry:

```
<property>
                        <name>sentry.service.allow.connect</name>
                        <value>impala,hive,mapr</value>
                        </property>
```

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

Sentry 1.7.0 API Changes

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This page lists the API changes that occurred between Sentry 1.6.0 and Sentry 1.7.0:

Added Classes

```

Livy

Apache Livy is primarily used to provide integration between Hue and Spark.

Beginning with EEP 4.0.0, Livy is included as its own package in EEP repositories. Before EEP 4.0.0, Livy was included as `mapr-hue-livy` and released only as a part of Hue. For more information about Livy, see Apache Livy.

This documentation set covers the following topics for Livy:

- Installing Livy on page 204
- Configure Livy on page 3839
- Pre-Upgrade Steps for Livy on page 341
- Upgrading Livy on page 361
- Post-Upgrade Steps for Livy on page 378

Livy Limitations

This page describes some limitations of the MapR Data Platform implementation of Apache Livy.

Current limitations are as follows:

- The Livy programmatic Java/Scala/Python API is not supported.
- Livy artifacts are not published in the public Maven repository with other MapR Data Platform artifacts.

Configure Livy

This topic describes how to configure Livy.

For information about the required package names to configure the Livy server, see Livy on page 3839.

Configure Livy with Security

Starting from EEP 6.0.0, MapR SASL authentication, encryption, and impersonation for Livy are enabled by default on secure clusters.

The Livy user interface is available on port 8998. To start the user interface, open a browser, and navigate to the following address:

```
https://<hostname>:8998
```

Configure Livy on Kerberos

This topic describes how to configure Livy on Kerberos.

last-updated: Apr 11, 2022

To configure Livy on Kerberos, add the following properties to the `livy.conf` file:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/_HOST@HADOOP.LOCALDOMAIN
livy.server.auth.kerberos.keytab = $KEYTAB
livy.server.launch.kerberos.principal = $USER/_HOST@HADOOP.LOCALDOMAIN
livy.server.launch.kerberos.keytab = $KEYTAB
```

For example:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/node2.cluster@NODE1
livy.server.auth.kerberos.keytab = /opt/mapr/conf/mapr.keytab
livy.server.launch.kerberos.principal = mapr/node2.cluster@NODE1
livy.server.launch.kerberos.keytab = /opt/mapr/conf/mapr.keytab
```

Livy UI on Kerberos

Note: You can login to the Livy UI on a Kerberos setup only using a web browser configured with SPNEGO.

The other option is to configure multiauth authentication on Kerberized configurations to allow you to login to Livy UI not only with `SPNEGO/Mapr-Negotiation` mechanisms but also with PAM credentials.

Configure Livy with Custom SSL Encryption
This topic describes how to configure Livy with custom SSL encryption.

1. By default, on a secure cluster, Livy reads the `ssl-server.xml` file and configures SSL from this file.
2. If you want to use custom SSL configuration, add the following properties to the `livy.conf` file:

```
## Use this keystore for the SSL certificate and key.
 livy.keystore = <path-to-ssl_keystore>

# Specify the keystore password.
livy.keystore.password = <password>

# Specify the key password.
livy.key-password = <password>
```

Configure Livy with Spark Modes
This topic describes how to configure Livy with different Spark modes.

Use these steps to configure Livy:

1. Modify the `livy.conf` file (`/opt/mapr/livy/livy-<version>/conf/livy.conf`):
   a. If Spark jobs run in local mode, set the `livy.spark.master` property:

```
...
# What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

b. If Spark jobs run in YARN mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

c. If Spark jobs run in Standalone mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
…
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
…
```

or

```
…
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
…
```

d. If Spark jobs run in Mesos mode, set the `livy.spark.master` property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

2. To you want to use impersonation with Livy, set `livy.impersonation.enabled` to `true` in `livy.conf`. For example:

```
# If livy should impersonate the requesting users when creating a new
session.
livy.impersonation.enabled = true
```

3. If you want to be able to access Hive through Spark for Livy, you should configure Spark with Hive, and set `livy.repl.enableHiveContext` to `true` in `livy.conf`. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

Note: If Hive is installed on a cluster and if Spark is configured on Hive, this property is set to true by default: `livy.repl.enableHiveContext = true`.

4. To apply the needed changes, restart the Livy service:

```
maprcli node services -name livy -action restart -nodes <livy node>
```

MapR Event Store For Apache Kafka Clients and Tools

Describes the supported MapR Event Store For Apache Kafka tools and clients.

MapR Event Store For Apache Kafka Tools

The following Kafka tools are supported:

Table

MapR Event Store For Apache Kafka Tool	EEP Release	MapR version	Kafka version
Kafka Streams	6.0 EEP release	6.1	1.1
KSQL	6.0 EEP release	6.1	1.1
Kafka REST 4.1	6.0 EEP release	6.1	1.1
Kafka Connect 4.1	6.0 EEP release	6.1	1.1
Kafka Schema Registry 4.1.1	6.1 EEP release	6.1	1.1
Spark Streaming	6.0 EEP release	6.1	1.1

Starting in EEP 8.0.0 and Core 6.2, Kafka 2.6.1.0 supports the following tools and components:

- Kafka Streams API 1.1
- KSQL 6.0.0.0
- Kafka REST 6.0.0.0
- Kafka Connect 10.0.0.0
- Kafka Schema Registry 6.0.0.0
- Spark Streaming

For a complete list of supported versions in each EEP, see Component Versions for Released EEPs on page 5586.

The following points describe the Kafka tools and provide links to additional information:

- Kafka Streams on page 3854: This tool is a programming library used for creating Java or Scala streaming applications.

- KSQL on page 3843: This tool is an open source streaming SQL engine that implements continuous, interactive queries.
- Kafka Schema Registry: This tool provides a RESTful interface for storing and retrieving Avro schemas.
- Kafka REST Proxy on page 3865: This tool is used as a RESTful interface to MapR Event Store For Apache Kafka.
- Kafka Connect on page 3903: This tool is used to stream data between MapR Event Store For Apache Kafka and other storage systems.

MapR Event Store For Apache Kafka Clients

MapR Event Store For Apache Kafka client applications can be developed for MapR Event Store For Apache Kafka (as of MapR 5.2.1 with EEP 3.0). The MapR Event Store For Apache Kafka clients are based on distributions of librdkafka that works with MapR Event Store For Apache Kafka.

- MapR Event Store For Apache Kafka C Client - Used to develop MapR Event Store For Apache Kafka applications in C. See MapR Event Store For Apache Kafka C Applications on page 2795
- MapR Event Store For Apache Kafka Java Client - Used to develop MapR Event Store For Apache Kafka applications in Java. See MapR Event Store For Apache Kafka Java Applications on page 2754
- MapR Event Store For Apache Kafka Python Client - Used to develop MapR Event Store For Apache Kafka applications in Python. This client is available as of MapR 5.2.1 with EEP 3.0. See MapR Event Store For Apache Kafka Python Applications on page 2998

Table

MapR release	EEP Release	Kafka librdkafka version
As of MapR 6.0.1	As of 5.0	0.11.3

KSQL

KSQL is an open-source streaming SQL engine that implements continuous, interactive queries.

Use KSQL to query, read, write, and process data in real-time, at scale, through SQL commands. KSQL interacts directly with the Kafka Streams API, eliminating the need for a Java application.

The KSQL data flow architecture is designed such that the user interacts with the KSQL server and the KSQL server interacts with the MapR Event Store For Apache Kafka server.

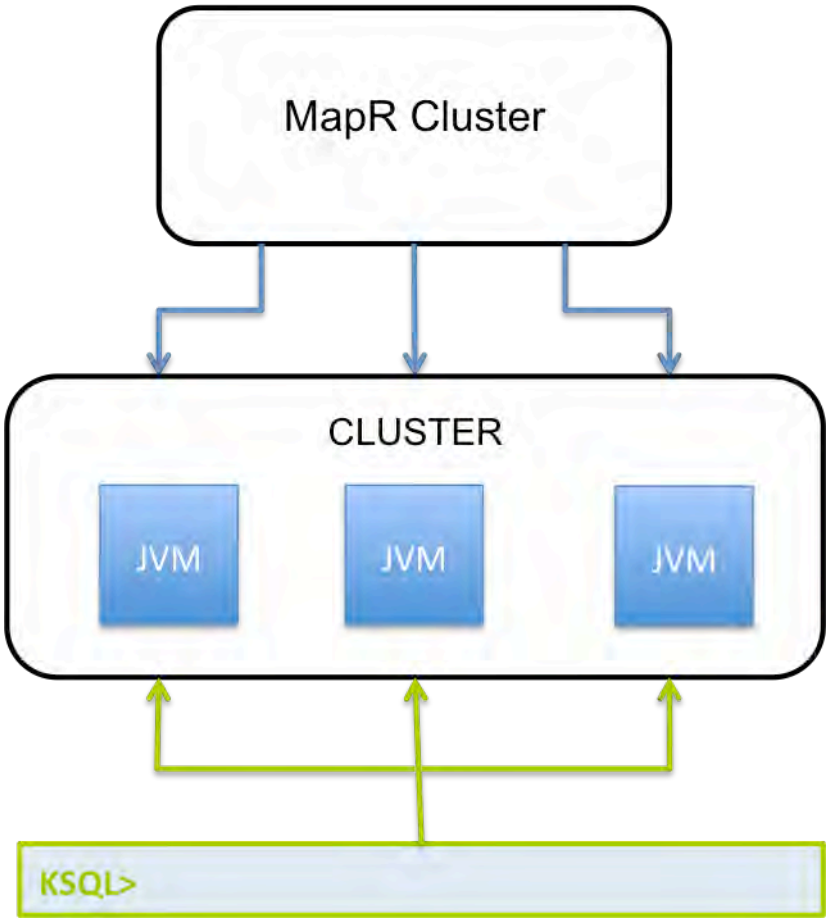
Use Cases

Common use cases include fraud detection, personalization, notifications, real-time analytics, and sensor data and IoT.

Architecture

A set of KSQL processes run as a cluster, and the KSQL server process completes queries. You can dynamically add more processing capacity by starting more instances of the KSQL server. These instances are fault-tolerant: if one fails, the others continue the work. Queries are launched using the interactive KSQL command line client, which sends commands to the cluster over a REST API. The command line allows you to inspect the available streams and tables, issue new queries, check the status of and terminate running queries.

last-updated: Apr 11, 2022



KSQL Server	The KSQL server runs the engine that completes KSQL queries. This includes processing, reading, and writing data to and from the target Kafka cluster. KSQL servers form KSQL clusters and can run in containers, virtual machines, and bare-metal machines. You can add and remove servers in a KSQL cluster during live operations to elastically scale processing capacity. You can deploy different KSQL clusters to achieve workload isolation.
KSQL CLI	You can interactively write KSQL queries through the KSQL command line interface (CLI). The KSQL CLI acts as a client to the KSQL server.

KSQL Deployment Modes

You can deploy KSQL queries through Interactive or Non-Interactive mode.

Interactive Mode	In Interactive mode, users interact with the KSQL server through a REST API, such as the KSQL CLI. Interactive mode is useful when users need to write and verify their queries interactively on a shared KSQL cluster. In interactive KSQL clusters, the authenticated KSQL user must have open access to create, read, write, delete topics, and use of any consumer group. Interactive KSQL clusters are not supported in a production environment. When you deploy queries to the production environment, lock-down access to KSQL servers by deploying a non-interactive (headless) environment.

last-updated: Apr 11, 2022

Non-Interactive Mode (Headless Mode)	Non-interactive mode supports locked-down or “headless” deployment scenarios where interactive use of the KSQL cluster is disabled, thereby preventing KSQL CLI access. In this mode, you can write queries to an SQL file, which allows for version control, and lock down access to KSQL servers to prevent users from interacting directly with the KSQL cluster. Non-interactive KSQL clusters (headless mode) is the main deployment model for KSQL queries on MapR (similar to the Apache Kafka model). Use non-interactive mode for production scenarios.

For More Information

- Apache Kafka KSQL
- Configuring Apache Kafka KSQL Server
- Apache Kafka Streams

KSQL Security
Discusses KSQL security topics.

KSQL COMMANDS

The KSQL COMMANDS internal topic is used to backup information about KSQL streams, KSQL tables, KSQL persistent queries, and so on. KSQL uses KSQL COMMANDS to restore the KSQL server state in case there is a fault or server restart.

Each KSQL Server cluster has a unique service ID which is provided through the `ksql.service.id` property. By default, the `kslq.service.id` is `_default`. To provide additional security, `ksql.service.id`-specific folders are created in the `ksql-internal-stream` stream.

Note: The `/apps` directory has only write access to `mapr` user. Therefore, the `/apps/ksql` directory cannot be modified or deleted by any user other than `mapr` user.

KSQL `ksql.service.id`-specific folders are created in the `/apps/ksql/` directory for every KSQL server cluster (represented by `ksql.service.id`).

Default Stream

KSQL Server provides a default stream for topics when they are being processed. When KSQL Server is not impersonated (non-interactive or interactive+no-impersonation), the KSQL Server default stream is used.

KSQL Cleanup

The KSQL cleanup feature is integrated to ensure that the underlying KSQL state (such as internal topics) are cleaned up correctly. See Application Reset Tool on page 3860 for more information.

Deployment

Note: A service ID (`ksql.service.id`) is uniquely created for the KSQL implementation; this means that the user associated with the `service ID` cannot grant permissions to other users to use the same service ID.

MapR KSQL deployment model is the same as Apache Kafka's deployment model. The KSQL Servers are not managed as part of the MapR cluster (for example, mapr-warden); you are required to run (or manage) your own KSQL Servers.

For More Information

- Apache Kafka KSQL
- Configuring Apache Kafka KSQL Server

KSQL Configuration
Set KSQL configuration and security parameters in the `ksql-server.properties` file. The default port for KSQL is 8084.

Configuring KSQL to Run in Non-Interactive (Headless) Mode

To run KSQL in non-interactive mode, set the parameters shown and then start KSQL.

Note: Note that the `ksql.default.stream` parameter is optional, but recommended. This parameter sets the default stream to consume from and send the messages to. The default stream is used if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message is sent to `/exampleStream:exampleTopic`.

Set the following properties in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://localhost:8084
ksql.default.stream=/sample-stream
```

Start KSQL:

```
$KSQL_INSTALL_DIR/bin/ksql-server-start
$KSQL_INSTALL_DIR/etc/ksql/ksql-server.properties --queries-file
some-queries-file.sql
```

Configuring KSQL to Run in Interactive Mode

The following example shows the configuration parameters that you must set in the `ksql-server.properties` file to run KSQL in interactive (distributed) mode:

```
ksql.command.topic.suffix=commands
            ksql.service.id=app2
            listeners=http://192.168.121.73:8084
            ksql.default.stream=/sample-stream
```

Note: You must set the `listeners` parameter to an actual IP address.

For more information

- For installation information, see Installing KSQL on page 195.
- For Apache Kafka information, see the Apache Kafka Streams API, Apache Kafka Producer Clients, and the Apache Kafka Consumer Clients.

KSQL Configuration Parameters

Set the KSQL configuration parameters in the `/opt/mapr/ksql/ksql-<version>/config/ksql-server.properties` file. For more information about configuration parameters, see KSQL Configuration Parameter Reference.

Note: The default KSQL configuration parameters are stored in `$KSQL_INSTALL_DIR/etc/ksql`. The default value for KSQL_INSTALL_DIR is `/opt/mapr/ksql/ksql-<version>/`.

The following table describes some KSQL configuration parameters:

Parameters	Description
`listeners`	Set this parameter to your localhost when using KSQL in non-interactive (headless) mode. Set this parameter to an actual IP address when using KSQL in interactive (distributed) mode. Default: 8084
`ksql.default.stream`	(Optional, but Recommended) The default stream to consume from and send the messages to. The default stream is used if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message will be sent to `/exampleStream:exampleTopic`.

KSQL Reference
KSQL-specific commands are commands for setting your KSQL configuration, exiting the CLI, and so on.

Run the KSQL with --help to see the available options.

```
./bin/ksql --help
```

CLI commands include:

- help
- clear
- output
- output <format>
- history
- version
- exit

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

KSQL Statements

General Syntax

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

KSQL statements must be terminated with a semicolon (;).

For multi-line statements:

last-updated: Apr 11, 2022

- In the CLI, you use a back-slash (\) to indicate continuation of a statement on the next line.
- Do not use backslashes (\) for multi-line statements in .sql files.

CREATE STREAM

CREATE STREAM WITH clause

Creates a new stream with the specified columns and properties.

```
CREATE STREAM stream_name ( { column_name data_type } [, ...] )
  WITH ( property_name = expression [, ...] );
```

CREATE STREAM WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding MapR Event Store For Apache Kafka topic.

```
CREATE STREAM stream_name
        [WITH ( property_name = expression [, ...] )]
        AS SELECT  select_expr [, ...]
        FROM from_item [, ...]
        [ WHERE condition ]
        [PARTITION BY column_name]
```

CREATE TABLE

CREATE TABLE WITH clause

Creates a new KSQL table with the specified columns and properties.

```
CREATE TABLE table_name ( { column_name data_type } [, ...] )
        WITH ( property_name = expression [, ...] );
```

CREATE TABLE WITH clause and AS SELECT

Creates a new stream with the specified columns and properties along with the corresponding MapR Event Store For Apache Kafka topic and stream.

```
CREATE TABLE table_name
        [WITH ( property_name = expression [, ...] )]
        AS SELECT  select_expr [, ...]
        FROM from_item [, ...]
        [ WINDOW window_expression ]
  [ WHERE condition ]
  [ GROUP BY grouping_expression ]
  [ HAVING having_expression ];
```

DESCRIBE

DESCRIBE

Lists the columns in a stream or table along with their data type and other attributes.

```
DESCRIBE (stream_name|table_name);
```

DESCRIBE EXTENDED

Displays DESCRIBE information with additional runtime statistics, MapR Event Store For Apache Kafka topic details, and the set of queries that populate the table or stream.

```
DESCRIBE [EXTENDED] (stream_name|table_name);
```

EXPLAIN

EXPLAIN

Shows the execution plan for a SQL expression or, given the ID of a running query, shows the execution plan plus additional runtime information and metrics.

```
EXPLAIN (sql_expression|query_id);
```

DROP STREAM

DROP STREAM

Drops an existing stream

```
DROP STREAM stream_name;
```

DROP TABLE

DROP TABLE

Drops an existing table.

```
DROP TABLE table_name;
```

PRINT

PRINT

Prints topic contents to the KSQL CLI.

Note: SQL grammar defaults to uppercase formatting. To print topics containing lower-case characters, use quotations.

```
PRINT qualified_name (FROM BEGINNING)? ((INTERVAL | SAMPLE) number)?
```

Print Example

```
ksql> print '/sample-stream:streams-pipe-input' FROM BEGINNING;
Format:STRING
3/16/18 1:04:39 AM EET , 1 , record1
3/16/18 1:04:39 AM EET , 5 , record5
3/16/18 1:04:39 AM EET , 6 , record6
3/19/18 4:22:51 PM EET , null , Hello
3/19/18 4:23:05 PM EET , null , Hello2
```

SELECT

last-updated: Apr 11, 2022

SELECT

Selects rows from a KSQL stream or table. The result of this statement is not persisted in a topic and is only printed out in the console. To stop the continuous query in the CLI press Ctrl-C.

```
SELECT select_expr [, ...]
        FROM from_item [, ...]
        [ WINDOW window_expression ]
        [ WHERE condition ]
        [ GROUP BY grouping_expression ]
        [ HAVING having_expression ];
```

SELECT CAST expression type

Casts an expression's type to a new type.

```
CAST (expression AS data_type);
```

For example, to convert BIGINT to VARCHAR type:

```
SELECT page_id, CONCAT(CAST(COUNT(*) AS VARCHAR), '_HELLO')
  FROM pageviews_enriched
  WINDOW TUMBLING (SIZE 20 SECONDS)
  GROUP BY page_id;
```

SELECT LIKE operator

The LIKE operator is used for prefix or suffix matching. Currently KSQL supports %, which represents zero or more characters.

```
column_name LIKE pattern;
```

For example:

```
SELECT user_id
  FROM users
  WHERE user_id LIKE 'santa%';
```

SHOW TOPICS

Note: Information about active consumers and consumer groups is not available.

SHOW TOPICS

Prints topic information for all topics for the default stream (specified by ksql.default.stream). If the default stream is not specified, then an exception is thrown.

```
SHOW TOPICS;
```

SHOW TOPICS <stream_name>

Prints topic information for all topics from the specified stream. For example: /sample-stream

```
SHOW TOPICS '/sample-stream';
```

SHOW STREAMS

SHOW STREAMS

List the defined streams.

```
SHOW | LIST STREAMS;
```

SHOW TABLES

SHOW TABLES

List the defined TABLES.

```
SHOW | LIST TABLES;
```

SHOW QUERIES

SHOW QUERIES

List the running persistent queries.

```
SHOW | LIST QUERIES;
```

SHOW PROPERTIES

SHOW PROPERTIES

Lists the configuration setting that are currently in effect.

```
SHOW PROPERTIES;
```

TERMINATE

TERMINATE

Terminate a persistent query. Persistent queries run continuously until they are explicitly terminated

```
TERMINATE query_id;
```

Scalar Functions

The following are scalar functions for KSQL.

Table

Function	Example	Description
ABS	ABS(col1)	Absolute value of a value.
CEIL	CEIL(col1)	Ceiling of a value.
CONCAT	CONCAT(col1, '_hello')	Concatenate two strings.
EXTRACTJSONFILELD	EXTRACTJSONFIELD(message, '$.log.cloud')	Given a sring column in JSON format, extract the field that matches.
ARRAYCONTAINS	ARRAYCONTAINS('[1, 2, 3]', 3	Given a JSON or AVRO array, checks if a search value is contained in it.
FLOOR	FLOOR(col1)	Floor of a value.
LCASE	LCASE(col1)	Convert a string to lowercase.
LEN	LEN(col1)	Length of a string.

last-updated: Apr 11, 2022

Table (Continued)

Function	Example	Description
RANDOM	RANDOM()	Returns a random DOUBLE value between 0 and 1.0
ROUND	ROUND(col1	Round a value to the nearest BIGINT value.
STRINGTOTIMESTAMP	STRINGTOTIMESTAMP(col1, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a string value in the given format into the BIGINT value representing the timestamp.
SUBSTRING	SUBSTRING(col1, 2, 5)	Returns the substring with the start and end indices.
TIMESTAMPTOSTRING	TIMESTAMPTOSTRING(ROWTIME, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a BIGINT timestamp value into the string representation of the timestamp in the given format.
TRIM	TRIM(col1)	Trim the spaces from the beginning and the end of the string.
CASE	CASE(col1)	Convert a string to uppercase.

Aggregate Functions

The following are aggregate functions for KSQL.

Table

Function	Example	Description
COUNT	COUNT(col1)	Counts the number of rows.
MAX	MAX(col1)	Returns the maximum value for a given column and window.
MIN	MIN(col1)	Returns the minimum value for a given column and window.
SUM	SUM(col1)	Sums the column values.
TOPK	TOPK(col1, K)	Returns the TopK values for the given column and window.
TOPKDISTINCT	TOPKDISTINCT(col1, K)	Returns the distinct TopK values for the given column and window.

Pipe Code Sample
Provides sample code for a Pipe example.

The following is a Pipe code sample that moves an inputTopic to an outputTopic:

```
ksql> CREATE STREAM stream3 (message varchar) WITH (kafka_topic='/
sample-stream:inputTopic', value_format='DELIMITED');

ksql> CREATE STREAM stream4  WITH (kafka_topic='/
sample-stream:streams-pipe-output1', value_format='DELIMITED') AS SELECT *
FROM stream3;
```

KSQL Demo
The following demo example creates a stream, performs a non-persistent query, and a persistent query.

Setup

Complete the following steps to prepare your environment for querying:

1. Create a default stream using `/sample-stream`:

```
maprcli stream create -path /sample-stream
    -produceperm p -consumeperm p -topicperm p
```

2. Run the following script to generate test data that writes to an MapR Event Store For Apache Kafka topic:

```
./bin/ksql-datagen quickstart=pageviews format=delimited
topic=/sample-stream:pageviews maxInterval=10000
```

3. Run KSQL CLI and create a KSQL table:

```
> ./bin/ksql
ksql> CREATE TABLE pageviews_original_table
    (viewtime bigint, userid varchar, pageid varchar)
    WITH (kafka_topic='/sample-stream:pageviews',
value_format='DELIMITED', key='viewtime');
```

4. Run the SHOW TABLES command to list your KSQL tables:

```
ksql> SHOW TABLES;
```

Run a Non-persistent Query

For a non-persistent query, run:

```
ksql> SELECT * FROM pageviews_original_table;
```

For a non-persistent query in KSQL 6.0, run:

Run a Persistent Query

For a persistent query, do the following:

1. Create the topic, `/sample-stream:input-topic`:

```
maprcli stream topic create -path /sample-stream -topic input-topic
```

2. Create a KSQL input stream:

```
ksql> CREATE STREAM stream1 (message varchar) WITH
    (kafka_topic='/sample-stream:input-topic' ,
value_format='DELIMITED');
```

3. Create persistent query with filtering:

```
ksql> CREATE STREAM stream2
    WITH (kafka_topic='/sample-stream:output-topic' ,
value_format='DELIMITED')
    AS SELECT * FROM stream1 WHERE LEN(message) > 2;
```

last-updated: Apr 11, 2022

4. List your queries:

```
ksql> SHOW QUERIES;
```

5. Run the provided sample code for the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
    --broker-list fake.server.id:9092 --topic /sample-stream:input-topic
```

6. Run the provided sample code for the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
    --bootstrap-server fake.server.id:9092
    --topic /sample-stream:output-topic
```

7. Produce some data:

```
>Hi
>Hello
>No
>Yes
```

8. Get the next results:

```
Hello
Yes
```

Auxiliary Scripts Location

The sample code for `kafka-console-producer.sh` and `kafka-console-consumer.sh` is packaged with MapR Kafka. Once MapR Kafka is installed, you can find them at:

```
/opt/mapr/kafka/kafka-<version>/bin/
```

Kafka Streams

Kafka Streams is a programming library used for creating Java or Scala streaming applications and, specifically, building streaming applications that transform input topics into output topics.

Kafka Streams allows you to build moderately complex operational streaming applications faster by offloading common functions such as failure recovery, joins and enrichment, and aggregations and windowing.

Kafka Streams application is a distributed Java application that is launched with one or more Kafka Streams application instances. Kafka Streams applications can be built using the KStream library. A KStream application instance is required to be provided with an `application.id` property. The `application.id` property uniquely identifies the Kafka Streams distributed application.

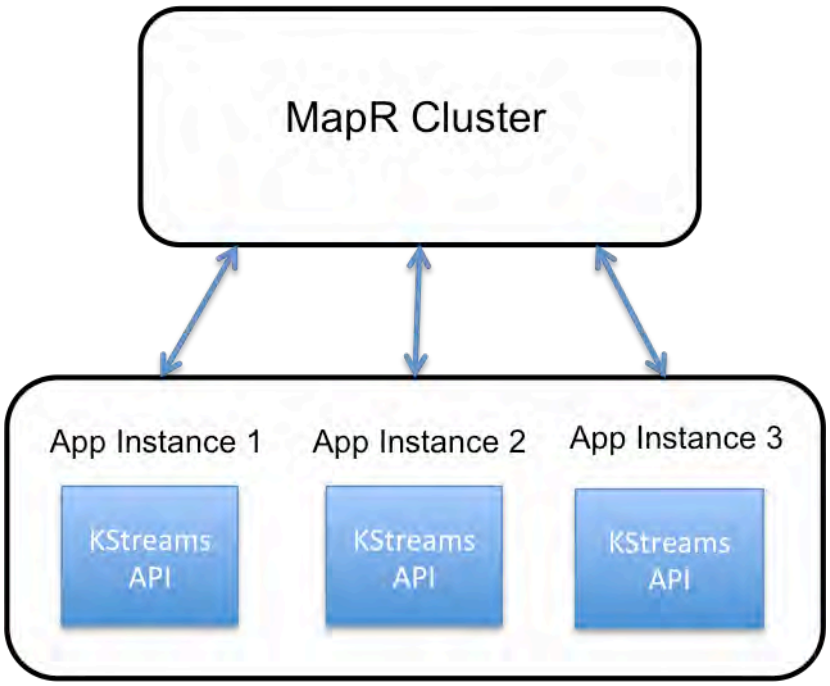
Attention: The Kafka Streams application must always be launched as the same user.

Architecture

An application that uses the Kafka Streams API is a normal Java application. Package, deploy, and monitor it like you would do for any other Java application. There is no need to install separate processing clusters or similar special-purpose and expensive infrastructure.

Note: You can run one or more instances of your application. They run independently but will automatically discover each other and collaborate. In addition, you can elastically add and remove application instances during live operations. If one instance dies, another instance continues where that instance left off.

The following diagram shows an application that is running three (3) application instances.



For More Information

Apache Kafka Streams

Kafka Streams Configuration
Describes how to configure Kafka Streams.

Kafka Streams Configuration

To configure Kafka Streams, set the following parameters in the Java API StreamsConfig instance:

- (Optional) Set the MapR Event Store For Apache Kafka `streams.default.stream` configuration parameter. See Apache Kafka Streams: Configuring a Streams Application for more information about all of the configuration parameters, required and optional.

  The default stream is used to consume from and send the messages to, if the topic name does not include the stream name. For example, if a message is sent to exampleTopic and this parameter is set to /exampleStream, then the message will be sent to /exampleStream:exampleTopic.

  Note: If the default stream option is not set and the topic name is specified without a stream name, an exception is thrown.

- Set the Apache Kafka Streams `application.id` configuration parameter. See Apache Kafka Streams: Configuring a Streams Application for more information about all of the configuration parameters, required and optional.

For more information

- For installation information, see Installing Kafka Streams on page 196.

last-updated: Apr 11, 2022

- For Apache Kafka Streams information, see Apache Kafka Streams: Configuring a Streams Application.

Supported Apache Kafka Streams APIs
Specifies the supported and not supported Apache Kafka Streams APIs.

Supported APIs

MapR Kafka Streams uses the same APIs as Apache Kafka Streams. Behavior for MapR Event Store For Apache Kafka is the same as for Apache Kafka Streams. See Apache Kafka Streams documentation .

Not Supported APIs

The following `stream` methods in the `StreamsBuilder` class are not supported:

- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern)`

- ```
  <K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern,
  Consumed<K,V> consumed)
  ```

Use the following `stream` method instead:

- `<K,V> KStream<K,V>stream(java.util.Collection<java.lang.String> topics)`

Running a Kafka Streams Java App
Describes how to set up and run a Kafka Streams Java application.

Setup

To set up your project, add the required dependencies to the `pom.xml` file, as shown in the example. Note that the versions you use may differ from the versions shown in the example. Version numbers typically change with new releases.

Maven artifacts are published to https://repository.mapr.com/maven/. You can also refer to Maven Artifacts for MapR on page 4155 for dependency versions.

Example pom.xml
The following example shows the dependencies you must add to `pom.xml`.

```
<repository>
    <id>mapr-releases</id>
<url>https://repository.mapr.com/maven/</url>
</repository>
<dependency>
    <groupId>org.apache.kafka</groupId>
    <artifactId>kafka-clients</artifactId>
    <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
    <groupId>org.apache.kafka</groupId>
    <artifactId>kafka-streams</artifactId>
    <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
    <groupId>com.mapr.streams</groupId>
    <artifactId>mapr-streams</artifactId>
    <version>6.2.0.0-mapr</version>
</dependency>
```
```

```
<dependency>
     <groupId>org.rocksdb</groupId>
     <artifactId>rocksdbjni</artifactId>
     <version>5.7.3</version>
</dependency>
<dependency>
     <groupId>commons-logging</groupId>
     <artifactId>commons-logging</artifactId>
     <version>1.1.1</version>
</dependency>
```

Running a Kafka Streams App on a Cluster

To run a Kafka Streams Java application on a cluster:

1. Copy the <Kafka Streams Java application>.jar file to an arbitrary folder on your cluster.
2. Run the following shell command on your cluster:
   - For Kafka 2.1.1, run:

     ```
     java -cp "$(mapr clientclasspath):<Kafka Streams Java
     application>.jar" <Kafka Streams Application Main Class Name>
     ```

   - For Kafka 2.6.1, run:

     ```
     java cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka<version>/libs/
     kafka-eventstreams<version>.jar:<Kafka Streams Java application>.jar"
     <Kafka Streams Application Main Class Name>
     ```

Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves records from an inputTopic to an outputTopic:

```
...
final StreamsBuilder builder = new StreamsBuilder();
KStream<String.String> source = builder stream(inputTopic);
source.to(outputTopic);
final Topology topology= builder.build();
final KafkaStreams streams=new KafkaStreams(topology, props);
...
streams.start();
...
```

Kafka Streams Demo

Provides a Kafka Streams demo example that creates a stream and topics and runs the WordCountDemo class code. The sample code produces and consumes messages.

1. Create the a stream named /sample-stream:

   ```
   maprcli stream create -path /sample-stream -produceperm p -consumeperm
   p -topicperm p
   ```

2. Create word-count-input and word-count-output topics:

```
maprcli stream topic create -path /sample-stream -topic word-count-input
maprcli stream topic create -path /sample-stream -topic word-count-output
```

3. Build the word count application and copy its JAR file to your cluster.

4. Run the WordCountDemo class.
   - For Kafka 2.1.1 and earlier, run:

```
java -cp "$(mapr clientclasspath):<Word Count Application Name>.jar"
WordCountDemo
```

5. Run the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092
--topic /sample-stream:word-count-input
```

6. Run the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:word-count-output
--property print.key=true
```

7. Produce some input with the console producer:

```
>word27 word28 word27 word29
```

8. Get the following output:

```
word28 1
word27 2
Word29 1
```

WordCountDemo Class Code

```
import org.apache.kafka.common.serialization.Serdes.StringSerde;
import org.apache.kafka.common.serialization.Serdes;
import org.apache.kafka.common.utils.Bytes;
import org.apache.kafka.streams.KafkaStreams;
import org.apache.kafka.streams.StreamsBuilder;
import org.apache.kafka.streams.StreamsConfig;

import org.apache.kafka.streams.state.KeyValueStore;

import java.util.Arrays;
import java.util.Locale;
import java.util.Properties;
import java.util.concurrent.CountDownLatch;

public class WordCountDemo {
```

```
    public static final String INPUT_TOPIC = "/
sample-stream:word-count-input";
    public static final String OUTPUT_TOPIC = "word-count-output"; //
Default stream will be used

    public static final String DEFAULT_STREAM = "/sample-stream";

    public static final String APP_ID = "app-id";

    public static void main(String[] args) {
        Properties props = new Properties();
        props.put(StreamsConfig.APPLICATION_ID_CONFIG, APP_ID);
        props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
StringSerde.class);
        props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
StringSerde.class);

        props.put(StreamsConfig.COMMIT_INTERVAL_MS_CONFIG, 500); // Put
attention to this property
        props.put(StreamsConfig.STREAMS_DEFAULT_STREAM_CONFIG,
DEFAULT_STREAM);

        final StreamsBuilder builder = new StreamsBuilder();

        KStream<String, String> wordCountStream = builder.<String,
String>stream(INPUT_TOPIC)
                .flatMapValues(value ->
Arrays.asList(value.toLowerCase(Locale.getDefault()).split("\\W+")))
                .groupBy((key, value) -> value)
                .count(Materialized.<String, Long, KeyValueStore<Bytes,
byte[]>>as("counts-store"))
                .mapValues(x -> x.toString())

                .toStream();

        wordCountStream.to(OUTPUT_TOPIC, Produced.with(Serdes.String(),
Serdes.String()));

        final Topology topology = builder.build();
        final KafkaStreams streams = new KafkaStreams(topology, props);
        final CountDownLatch latch = new CountDownLatch(1);

        // attach shutdown handler to catch control-c
        Runtime.getRuntime().addShutdownHook(new
Thread("streams-shutdown-hook") {
            @Override
            public void run() {
                streams.close();
                latch.countDown();
            }
        });

        try {
            streams.start();
            latch.await();
        } catch (Throwable e) {
            e.printStackTrace();
            System.exit(1);
        }
        System.exit(0);
```

last-updated: Apr 11, 2022

```
    }
}
```

Note: The `kafka-console-producer.sh` and `kafka-console-consumer.sh` scripts are part of the **mapr-kafka** package.

Application Reset Tool
This tool allows your to reset an application and force it to reprocess its data from scratch by using the application reset tool. This tool can be useful for development and testing, or when fixing bugs.

Description

The application reset tool (ART) handles the Kafka Streams user topics (input, output, and intermediate topics) and internal topics differently when resetting the application.

The application reset tool does the following for each topic type:

- Input topics: Reset to the beginning of the topic. This means that it sets the application's committed consumer offsets for all partitions to each partition's `earliest` offset (for consumer group `application.id`).
- Intermediate topics: Skip to the end of the topic, i.e., set the application's committed consumer offsets for all partitions to each partition's `logSize` (for consumer group `application.id`).
- Internal topics: Delete the internal topic (this automatically deletes any committed offsets).

The application reset tool does not do the following:

- Reset output topics of an application. If any output (or intermediate) topics are consumed by downstream applications, it is your responsibility to adjust those downstream applications as appropriate when you reset the upstream application.
- Reset the local environment of your application instances. It is your responsibility to delete the local state on any machine on which an application instance was run.

See Confluent Application Reset Tool for additional reference information.

Running the Application Reset Tool

Invoke the application reset tool from the command line:

```
/opt/mapr/bin/kafka-streams-application-reset.sh
```

The tool accepts the following parameters:

Note: Parameters can be combined as needed. For example, if you want to restart an application from an empty internal state, but not reprocess previous data, simply omit the `--input-topics` and `--intermediate-topics` parameters.

Option	Description
--application-id <String: id>	(Required) The Kafka Streams application ID (application.id).
--default-stream	The default stream that is used when the topic name is specified but the stream name is not.
--config-file <String: file name>	Property file containing configs to be passed to admin clients and embedded consumer.
--dry-run	Display the actions that would be performed without executing the reset commands.

last-updated: Apr 11, 2022

Option	Description
--input-topics <String: list>	Comma-separated list of user input topics. For these topics, the tool will reset the offset to the earliest available offset.
--intermediate-topics <String: list>	Comma-separated list of intermediate user topics (topics used in the through() method). For these topics, the tool will skip to the end.

Resetting your Local Environments

To reset the local environments of your application instances, you must delete your application's local state directory on any machines where the application instance was run. You must do this before restarting an application instance on the same machine. You can use either of these methods:

Note: This a a complete application reset

The API method KafkaStreams#cleanUp() in your application code. Manually delete the corresponding local state directory (default location: /tmp/kafka-streams/<application.id>). For more information, see state.dir StreamsConfig class.

Example

In this example you are developing and testing an application locally and you want to iteratively improve your application via run-reset-modify cycles.

```
package mapr.examples.streams;

import ...;

public class ResetDemo {

  public static void main(String[] args) throws Exception {
  // Kafka Streams configuration
    Properties streamsConfiguration = new Properties();
    streamsConfiguration.put(StreamsConfig.APPLICATION_ID_CONFIG,
"my-streams-app");
    // ...and so on...

    // Define the processing topology
    StreamsBuilder builder = new StreamsBuilder();
    builder.stream("my-input-topic")
        .selectKey(...)
        .through("rekeyed-topic")
        .countByKey("global-count")
        .to("my-output-topic");

    KStreams app = new KafkaStreams(builder.build(), streamsConfiguration);

    // Delete the application's local state.
    // Note: In real application you'd call `cleanUp()` only under
    // certain conditions.  See tip on `cleanUp()` below.
    app.cleanUp();

    app.start();

    // Note: In real applications you would register a shutdown hook
    // that would trigger the call to `app.close()` rather than
    // using the sleep-then-close example we show here.
    Thread.sleep(30 * 1000L);
    app.close();
```

last-updated: Apr 11, 2022

```
  }

}
```

You can then perform run-reset-modify cycles as follows:

```
# Run your application
$ bin/kafka-run-class mapr.examples.streams.ResetDemo

# After stopping all application instances, reset the application
$ bin/kafka-streams-application-reset.sh --application-id my-streams-app \
                                         --input-topics my-input-topic \
                                         --intermediate-topics rekeyed-topic

# Now you can modify/recompile as needed and then re-run the application
again.
# You can also experiment, for example, with different input data without
# modifying the application.
```

Kafka Streams Security
Discusses Kafka Streams security topics.

Internal Topics

All Kafka Streams application's internal topics are grouped in the Kafka Streams application directory: **/apps/kafka-streams**.

- The **/apps** directory has only write access to **mapr user**. The **/apps/kafka-streams** directory is not modifiable/deletable by any user other than **mapr user**.
- All users can create sub-directories inside the **/apps/kafka-streams** directory. Only the following users have read/write/delete permission for sub-directories or files created in this directory.
  - **mapr user**
  - Current user of the sub-directory:
    - If security is enabled, the current user is the MapR ticket identity. See Managing Tickets on page 1424 for more information.
    - If security is ***not*** enabled, the current MapR identity.

Kafka Streams Application Specific Folders

Some Kafka Streams applications need to create internal topics. These topics are created in the **/apps/kafka-streams/<application.id>** directory.

Important: This directory is created at runtime by the Kafka Streams application and can only be modified by the current user or super users. This directory can only be deleted by the Application Reset Tool on page 3860 (ART) and, again, by only the current user or super users.

Application Reset Tool and Cleanup APIs

The application reset tool allows to reset a Kafka Streams application's internal state, such that it can re-process its input data from scratch. Kafka Streams internal topics can be cleaned using application reset tool.

Only the current user of the Kafka Streams application or **mapr user** has permissions to clean up a Kafka Streams application using Application Reset Tool. The Application Reset Tool is integrated with the cleanup APIs so that the application's internal topics are prefixed with the same directory.

The application reset tool takes `application.id` as the input for cleaning up Kafka Streams application. As part of this process, all internal-topics are deleted for the application user under the **/apps/kafka-streams/<application.id>** directory, including the **/apps/kafka-streams/<application.id>** directory. See Application Reset Tool on page 3860 for more information.

Changes in Kafka 2.6.1

Describes several differences to note when upgrading from Kafka 2.1.1 to 2.6.1.

Classpath change	• Kafka 2.6.1 uses classes from `kafka-eventstreams.jar` instead of `mapr-streams.jar` to access the cluster. • If an application fails with a `ClassNotFoundException` or `NoClassDefFoundError` for classes in packages under `com.mapr.kafka.eventstreams.*`, verify that `kafka-eventstreams.jar` is in the Java classpath. You can find `kafka-eventstreams.jar` in the `/opt/mapr/lib/` directory, or you can download it from the Maven repository.
Scala changes	• Scala version 2.11 is no longer supported. Scala versions 2.12 and 2.13 are supported. • Scala code leveraging the `NewTopic(String, int, short)` constructor with literal values must explicitly call `toShort` on the second literal.
RocksDBs change	• Kafka Streams version 2.6.1 requires RocksDB version 5.18.4.
Default consumer group id	• The default consumer group id has been changed from the empty string ("") to `null`. Consumers that use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of the consumer configuration. For more information, see KIP-289.
client.dns.lookup	The default value for the `client.dns.lookup` configuration has been changed from default to `use_all_dns_ips`. If a hostname resolves to multiple IP addresses, clients and brokers will now attempt to connect to each IP in sequence until the connection is successfully established. For more information, see KIP-602.
DSL	• Use the DSL operator, `cogroup()`, to aggregate multiple streams together at once. • Kafka Streams DSL switches its used store types. While this change is mainly transparent to users, there are some corner cases that may require code changes.
KStream.toTable() API	Use the KStream.toTable() API to translate an input event stream into a KTable.

last-updated: Apr 11, 2022

Serde type Void	Use the Serde type, Void, to represent null keys or null values from an input topic.
Sticky partitioning	The DefaultPartitioner now uses a sticky partitioning strategy. This means that records for a specific topic with null keys and no assigned partition will be sent to the same partition until the batch is ready to be sent. When a new batch is created, a new partition is chosen. This decreases latency to produce, but it may result in uneven distribution of records across partitions in edge cases. Generally, users will not be impacted, but this difference may be noticeable in tests and other situations producing records for a very short amount of time.
Rebalancing	• We are introducing incremental cooperative rebalancing to the clients' group protocol, which allows consumers to keep all of their assigned partitions during a rebalance and in the end revoke only those which must be migrated to another consumer for the overall cluster balance. The ConsumerCoordinator will choose the latest RebalanceProtocol that is commonly supported by all of the consumer's supported assignors. • We are introducing a new rebalancing protocol for Kafka Connect based on incremental cooperative rebalancing. The new protocol does not require stopping all the tasks during a rebalancing phase between Connect workers. Instead, only the tasks that need to be exchanged between workers are stopped and they are started in a follow-up rebalance. The new Connect protocol is enabled by default. For more details on how it works and how to enable the old behavior of eager rebalancing, checkout incremental cooperative rebalancing design.
Deprecated APIs	• Deprecated UsePreviousTimeOnInvalidTimestamp and replaced with UsePartitionTimeOnInvalidTimeStamp. • Provided support to query stale stores (for high availability) and the stores belonging to a specific partition by deprecating KafkaStreams.store(String, QueryableStoreType) and replacing it with KafkaStreams.store(StoreQueryParameters). • The internal PartitionAssignor interface has been deprecated and replaced with a new ConsumerPartitionAssignor in the public API. Some methods/signatures are slightly different between the two interfaces. Users implementing a custom PartitionAssignor should migrate to the new interface as soon as possible. • The blocking KafkaConsumer#committed methods have been extended to allow a list of partitions as input parameters rather than a single partition. It enables fewer request/response iterations between clients and brokers fetching for the committed offsets for the consumer group. The old overloaded functions are deprecated and we would recommend users making their code changes to leverage the new methods

last-updated: Apr 11, 2022

- The default consumer group id has been changed from the empty string ("") to `null`. Consumers who use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of their consumer configuration.

Kafka REST Proxy
The Kafka REST Proxy provides a RESTful interface to MapR Event Store For Apache Kafka clusters to consume and produce messages and to perform administrative operations.

It allows you to:

- Consume messages from topics or concrete topic partitions.
- Produce messages to topics or partitions.
- View the state of the cluster.

Use cases include ingesting messages into a stream-processing framework and scripting administrative operations.

Configuration
This section describes how to configure the Kafka REST Proxy for MapR Event Store For Apache Kafka.

You can set these configuration parameters in the `kafka-rest.properties` file. The Control System displays information about the Kafka REST Proxy for the MapR Event Store For Apache Kafka service. By default, the service runs on port **8082**.

To install the Kafka REST Proxy, see Installing MapR Event Store For Apache Kafka Tools on page 202.

To configure the Kafka REST Proxy for MapR Event Store For Apache Kafka, edit the following file:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

To view the Kafka REST Proxy for MapR Event Store For Apache Kafka log files, see the following location:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/logs/kafka-rest.log
```

Note: After installation, Warden automatically detects the configuration and starts the service. To configure the Kafka REST Proxy for MapR Event Store For Apache Kafka, stop the service, configure the parameters, and restart the service. To stop and restart services, see maprcli node services. For example:

```
maprcli node services -name kafka-rest -action stop
```

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

Configuration Parameters
This section provides the Kafka REST Proxy for MapR Event Store For Apache Kafka parameters.

last-updated: Apr 11, 2022

These parameters are configurable in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

Table

Parameter	Description
streams.default.stream	The default stream the consumer should poll messages from and the producer should send messages to. If the topic name does not specify the stream path, and the property has a valid value, then this topic name is found in the default stream.
id	Unique ID for this REST server instance. This is used in generating unique IDs for consumers that do not specify their ID. The ID is empty by default, which makes a single server setup easier to get up and running, but is not safe for multi-server deployments where automatic consumer IDs are used. Type: string. Default: empty
consumer.threads	The number of threads to run consumer requests on. Type: int. Default: 1
simpleconsumer.cache.max.records	Maximum number of records that can be stored in a single cache. Records with higher offsets replace records with lower ones. The value must be greater than 0. Type: int. Default: 1000.
simpleconsumer.max.caches.num	Maximum number topic-partition combinations for which records are cached. If this parameter is set to 0, then caching is disabled and extra records are thrown away. Cache improves performance if records are fetched sequentially thus increasing offsets. A pool of caches are available to store extra fetch records by a KafkaConsumer for a particular TopicPartition. The cache increases performance when records are fetched from a particular topic partition in a sequential manner. For example, every next request will start with the following offset after the offset of the latest fetched record in the previous request. Type: int. Default: 0
simpleconsumer.max.poll.time	Specifies the maximum number of milliseconds that are spent for polling records by a simpleconsumer. The greater the value means greater latency but higher throughput. Type: int. Default: 1000
simpleconsumer.pool.size.max	Maximum number of SimpleConsumers that can be instantiated. If 0, then the pool size is not limited. Type: int. Default: 25
simpleconsumer.pool.timeout.ms	Amount of time to wait for an available SimpleConsumer from the pool before failing. Use 0 for no timeout. Type: int. Default: 1000
consumer.instance.timeout.ms	Amount of idle time (in milliseconds) before a consumer instance is automatically destroyed. Type: int. Default: 300000 (5 minutes)
consumer.iterator.backoff.ms	Amount of time (in milliseconds) to backoff when an iterator runs out of data. If a consumer has a dedicated worker thread, this is effectively the maximum error for the entire request timeout. This parameter should be small enough to closely target the timeout, but large enough to avoid busy waiting. Type: int. Default: 50
consumer.request.max.bytes	Maximum number of bytes in unencoded message keys and values returned by a single request. This can be used by administrators to limit the memory used by a single consumer and to control the memory usage required to decode responses on clients that cannot perform a streaming decode. Note that the actual payload will be larger due to overhead from base64 encoding the response data and from JSON encoding the entire response. Type: long. Default: 6710884

Table (Continued)

Parameter	Description
consumer.request.timeout.ms	The maximum total time (in milliseconds) to wait for messages for a request if the maximum number of messages has not yet been reached. Type: int. Default: 1
producer.threads	Number of threads to run producer requests on. Type: int. Default: 5
request.logger.name	Name of the SLF4J logger to write the NCSA Common Log Format request log. Type: string. Default: io.confluent.rest-utils.requests.
response.mediatype.default	The default response media type that should be used if no specify types are requested in an Accept header. Type: string. Default: application/vnd.kafka.v1+json
response.mediatype.preferred	An ordered list of the server's preferred media types used for responses, from most preferred to least. Type: list. Default: application/vnd.kafka.v1+json, application/vnd.kafka+json, application/json
access.control.allow.methods	Sets the value to the Jetty Access-Control-Allow-Origin header for specified methods. Type: string. Default: empty
access.control.allow.origin	Sets the value for the Jetty Access-Control-Allow-Origin header. Type: string. Default: empty
host.name	The host name used to generate absolute URLs in responses. If empty, the default canonical hostname is used. Type: string. Default: empty
debug	Boolean indicating whether extra debugging information is generated in some error response entities. Type: Boolean. Default: false
shutdown.graceful.ms	Amount of time to wait after a shutdown request for outstanding requests to complete. Type: int. Default: 1000
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporterinterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics. Type: list. Default: empty
metrics.jmx.prefix	Prefix to apply to metric names for the default JMX reporter. Type: string. Default: kafka.rest
metrics.num.samples	The number of samples maintained to compute metrics. Type: int. Default: 2
metrics.sample.window.ms	The metrics system maintains a configurable number of samples over a fixed window size. This configuration controls the size of the window. For example, used to maintain two samples each measured over a 30 second period. When a window expires, the oldest window is erased and overwritten. Type: long. Default: 30000

Security Parameters
Describes Kafka REST security parameters.

Configure security for Kafka REST through the security parameters in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

Note: Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

last-updated: Apr 11, 2022

Table

Parameter	Description	Type	Default
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: http://localhost:8082	list	none
`rest.proxy.enable.doAs`	Specifies whether or not to enable impersonation for MapR Event Store For Apache Kafka topics. For this to take effect, PAM authentication must be enabled.	boolean	true
`authentication.method`	Specifies whether or not to enable PAM authentication. Set to NONE to disable.	string	BASIC
`authentication.realm`	Specifies realm for PAM authentication. Set to an empty string ("") to disable PAM. Set to jpamLogin to enable authentication	string	jpam
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	• TLS_DHE.* • TLS_EDH.* • .DES. • .MD5. • .RC4.
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	• SSLv3 • TLSv1.0
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=https. Leave blank to use Jetty's default.	string	none

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description	Type	Default
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. **Note:** If the ssl-client.xml file is changed, Kafka REST must be restarted.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty
ssl.keystore.location	Location of the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. **Note:** If the ssl-client.xml file is changed, Kafka REST must be restarted.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. **Note:** If the ssl-client.xml file is changed, Kafka REST must be restarted.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLS-v1.2-
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description	Type	Default
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false

SSL Security Configuration
Describes how to configure Kafka REST security.

Secure by Default

As of MapR 6.0, the MapR Installer performs the Kafka REST configuration for new installations. This means that:

- If MapR core is installed as *secure*, then Kafka REST is also installed as *secure*.
- If MapR core is installed as *insecure*, then Kafka REST is also installed as *insecure*.

Manually Securing Kafka REST Only

CAUTION: This configuration is ***not*** a typical configuration.

If you have an *insecure* MapR cluster, and you want to *secure* Kafka REST, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `kafka-rest.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8082,https://0.0.0.0:8085
            ssl.keystore.location=<ssl-keystore-path>
            ssl.keystore.password=<ssl-keystore-password>
            ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8085/streams/%2Ftesting/topics --cacert
<certificate-path>
```

Manually Unsecuring Kafka REST

Warning: This scenario is ***NOT*** recommended or supported.

If you have an *secure* MapR cluster, and you want to *insecure* Kafka REST, do the following:

1. In the `kafka-rest.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.*** properties. For example:

```
listeners=http://0.0.0.0:8082
```

last-updated: Apr 11, 2022

2. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

User Impersonation
Describes how to disable, enable, and use impersonation with Kafka REST.

User impersonation enables Kafka REST jobs to be submitted as a particular user. Without impersonation, Kafka REST submits jobs as the user that started Kafka REST server.

On an MapR Data Platform cluster, the impersonated user is typically the `mapr` user or the user specified in the MAPR_USER environment variable. By default, impersonation and PAM authentication in Kafka REST are enabled on all types of security.

Disabling User Impersonation

To disable user impersonation, you need to first disable the PAM authentication properties in the kafka-rest.properties file and then disable the rest.proxy.enable.doAs property.

1. Disable PAM authentication. Set the following properties in `opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties:`
   - authentication.method=NONE
   - authentication.realm=""
2. Once authentication is disabled, set the following property in `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties:`
   - rest.proxy.enable.doAs=false

Example: Verify that a list of topics is owned by an impersonated user

This example demonstrates how to get a list of topics from a particular stream and then verifies that the list of topics is owned by a particular user. Depending on whether or not impersonation is enabled (the default), you may need to use a different `curl` command.

```
$  sudo maprcli stream info -json  -path /stream1
{
 "timestamp":1505471089855,
  "timeofday":"2017-09-15 10:24:49.855 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
       {
       "path":"/stream1",
       "physicalsize":245760,
       "logicalsize":114688,
       "numtopics":2,
       "defaultpartitions":1,
       "ttl":604800,
       "compression":"lz4",
       "autocreate":true,
       "produceperm":"u:root",
       "consumeperm":"u:root",
       "topicperm":"u:root",
       "copyperm":"u:root",
       "adminperm":"u:root",
       "ischangelog":false
       }
```

last-updated: Apr 11, 2022

```
    ]
 }
```

If impersonation is enabled (the default), use the following query, where the query is submitted as the root user.

```
$ curl -u root  -X GET http://localhost:8082/topics/%2Fstream%3Atopic1
Enter host password for user 'root':
{"name":"/stream:topic1","configs":null,"partitions":
  [{"partition":0,"leader":0,"replicas":
[{"broker":0,"leader":true,"in_sync":true},
   {"broker":0,"leader":false,"in_sync":true}]}]}
```

If impersonation is disabled, use the following query, where the query is submitted as the `mapr` user.

```
$ curl  -X GET http://localhost:8082/topics/%2Fstream%3Atopic1
{"error_code":40401,"message":"Topic not found."}
```

Saving Kafka REST Configurations
Describes how Kafka REST configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka REST is stored in a folder with a timestamp.

- The configuration files are saved *and* overwritten by new configuration files when upgrading from:
  - 4.1.0 to 5.1.2
  - 5.1.2 to 6.0.0.0
- The configuration files are saved only (not overwritten) when upgrading from:
  - 5.1.2 to 5.1.2

Example

The following example shows the list of configuration files that are saved after upgrading from EEP 6.3.1 to EEP 6.3.2:

```
ls /opt/mapr/kafka-rest/
kafka-rest-4.1.0  kafka-rest-4.1.0.202009150334  kafka-restversion

ls /opt/mapr/kafka-rest/kafka-rest-4.1.0.202009150334/config/
kafka-rest.properties  log4j.properties  warden.kafka-rest.conf
```

Services Management
The Kafka REST Proxy for MapR Event Store For Apache Kafka service can be started, restarted, and stopped via the maprcli nodes services command or using the REST API equivalent.

The following `maprcli nodes services` commands summarize the commands. For more information, see node services on page 1730.

CLI commands

```
maprcli node services -name kafka-rest -action start -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action restart -nodes <node_list>
```

REST

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

HTTP Methods and URI Summary
This section provides HTTP method and URI summaries for multiple Kafka REST Proxy API versions for MapR Event Store For Apache Kafka.

API v2: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	/topics	Retrieves a list of topic names.
GET	/topics/{string: topic_name}	Retrieves metadata about a specific topic.
POST	/topics/{string: topic_name}	Produces messages to a topic.
GET	/topics/{string: topic_name}/partitions	Retrieves a list of partitions for the topic.
GET	/topics/{string: topic_name}/partitions/{string: partition_id}	Retrieves metadata about a specific partition within a topic.
POST	/topics/{string: topic_name}/partitions/{string: partition_id}	Produces messages into a partition of a topic.
POST	/consumers/{string: group_name}	Creates a new consumer instance in the consumer group.
DELETE	/consumers/{string: group_name}/instances/{string: instance_id}	Destroys the consumer instance.
POST	/consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets	Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.
GET	/consumers/{string: group_name)/instances/{string: instance_id}/offsets	Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).
POST	/consumers/{string: group_name}/instances/{string: instance_id}/subscription	Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.
GET	/consumers/{string: group_name}/instances/{string: instance_id}/subscription	Gets the current subscribed list of topics.
DELETE	/consumers/{string: group_name}/instances/{string: instance_id}/subscription	Unsubscribes from topics currently subscribed to.
POST	/consumers/{string: group_name}/instances/{string: instance_id}/assignments	Manually assigns a list of partitions to a consumer.
GET	/consumers/{string: group_name}/instances/{string: instance_id}/assignments	Retrieves the list of partitions manually assigned to this consumer.

last-updated: Apr 11, 2022

HTTP Method	URI	Description
POST	/consumers/{string: group_name}/instances/{string: instance_id}/positions	Overrides the fetch offsets that the consumer will use for the next set of records to fetch.
POST	/consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning	Seek to the first offset for each of the given partitions.
POST	/consumers/{string: group_name}/instances/{string: instance_id}/positions/end	Seek to the last offset for each of the given partitions.
GET	GET /consumers/{string: group_name}/instances/{string: instance_id}/records	Fetches data for the topics or partitions specified using one of the subscribe/ assign APIs.
GET	/streams/{string: stream_name}/topics	Retrieves a list of topics in a given stream.

API v1: Kafka REST Proxy Summary

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	/topics	Retrieves a list of topic names.
GET	/topics/{topic: string}	Retrieves metadata about a specific topic.
POST	/topics/{topic: string}	Produces a message into a topic.
GET	/topics/{topic: string}/partitions	Retrieves a list of partitions for the topic.
GET	/topics/{topic: string}/partitions/{partition_id: string}	Retrieves metadata about specific partition in a topic.
POST	/topics/{topic: string}/partitions/{partition_id: string}	Produces messages to one partition of the topic.
GET	/topics/{topic: string}/partition/{partition_id: string}/ messages?offset={int}[&count={int}]	Consumes messages from one partition of the topic.
GET	/stream/{stream: string}/topics	Retrieves a list of topics in a given stream.
POST	/consumers/{group: string}	Creates a new consumer instance in the consumer group.
POST	/consumers/{group: string}/instances/{instance: string}/ offsets	Commits offsets for the consumer. Returns a list of the partitions with the committed offsets.
DELETE	/consumers/{group: string}/instances/{instance: string}	Destroys the consumer instance.
GET	/consumers/{group: string}/instances/{instance: string}/ topics/{topic: string}	Consumes messages from a topic.

API v2 HTTP Methods and URIs

GET /topics

Retrieves a list of topic names.

last-updated: Apr 11, 2022

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in Configuration Parameters on page 3865

Table

Parameters Defined	Response
streams.default.stream is defined	Returns a list of topic names in the default stream. Returns topic names that contain a stream path.
streams.default.stream is not defined	Returns {"error_code":80001,"message":"MapR Event Store For Apache Kafka does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}

Syntax

```
http://<host>:8082/topics
```

Request Example

```
$ curl "Content-Type: application/vnd.kafka.v2+json" "http://localhost:8082/
topics"
```

Response Example

```
[
        "streaming_data/stream:testtopic1",
        "streaming_data/stream:testtopic2"
        ]
```

GET /topics/{string: topic_name}
Retrieves metadata about a specific topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in Configuration Parameters on page 3865

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about a specific MapR Event Store For Apache Kafka topic. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to default_stream:topic1
streams.default.stream is not defined	Gets metadata about a specific MapR Event Store For Apache Kafka topic. A fully qualified topic name is passed that contains the stream path.

Note: The full name for the MapR Event Store For Apache Kafka topic contains characters such as a forward slash (/) and a colon (:), therefore, it should be encoded. For example, `/streaming_data/stream:topic-1` is equivalent to `%2Fstreaming_data%2Fstream%3Atopic-1`.

last-updated: Apr 11, 2022

Table

Parameters	Description
topic_name (string)	Name of the topic to get metadata about.

Syntax

Syntax for a topic in a default stream where the default stream is configured:

```
http://<host>:8082/topics/<topic_string>
```

Syntax for a topic where the fully qualified topic name is specified:

```
http://<host>:8082/topics/%2F<streaming_data>%2F<stream>%3A<topic1>
```

Request Example

```
curl "http://localhost:8082/topics/test"
```

Response Example

```
{
  "name":"test",
  "configs":null,
  "partitions":
    [
      {
        "partition":0,
        "leader":0,
        "replicas":
          [
            {"broker":0,"leader":true, "in_sync":true},
            {"broker":0,"leader":false, "in_sync":true}
          ]
      }
    ]
}
```

POST /topics/{string: topic_name}

Produces messages to a topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in Configuration Parameters on page 3865

Table

Parameters Defined	Response
streams.default.stream is defined	Produces messages into specific MapR Event Store For Apache Kafka topics. If the topic name does not contain a stream path, then the default stream path is used.
streams.default.stream is not defined	Produces messages into a MapR Event Store For Apache Kafka topic. The topic name should contain a stream path and be encoded.

last-updated: Apr 11, 2022

Note: If the topic does not exist, the following error results: [“error_code”:40401, “message”: ”Topic not found.”}. New topics are not created by the POST operation.

Table

Parameters	Description
topic_name (*string*)	Name of the topic to produce the messages to.

Syntax

```
http://<host>:8082/topics/<topic_string>
```

Request Example

This example produces a message using binary embedded data with the value, Kafka, to the topic, test.

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2" --data
'{"records":[{"value":"S2Fma2E="}]}' "http://localhost:8082/topics/test"
```

Response Example

```
{
   "offsets":
    [{
        "partition":0,
        "offset": 1,
        "error_code":null,
        "error":null
      }],
  "key_schema_id":null,
  "value_schema_id":null
}
```

GET /topics/{string: topic_name}/partitions
Retrieves a list of partitions for the topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about specific MapR Event Store For Apache Kafka partitions within a topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific MapR Event Store For Apache Kafka partitions within topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
topic_name (*string*)	Name of the topic.

last-updated: Apr 11, 2022

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
"http://localhost:8082/topics/testtopic1/partitions"
```

Response Example

```
[
  {
    "partition":0,
    "leader":0,
    "replicas":
      [{
          "broker":0,
          "leader":true,
          "in_sync":true
        }]
  },
  {
    "partition":1,
    "leader":0,
    "replicas":
      [{
          "broker":0,
          "leader":true,
          "in_sync":true
         }]
  }
]
```

GET /topics/{string: topic_name}/partitions/{string: partition_id}
Retrieves metadata about a specific partition within a topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about a specific partition within a MapR Event Store For Apache Kafka topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific MapR Event Store For Apache Kafka partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
topic_name (*string*)	Name of the topic.
partition_id (*int*)	ID of the partition to inspect.

last-updated: Apr 11, 2022

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/
partitions/0
```

Response Example

```
{
  "partition":0,
  "leader":0,
  "replicas":
    [{
      "broker":0,
      "leader":true,
      "in_sync":true
      }]
}
```

GET /topics/{string: topic_name}/partitions/{string: partition_id}/offsets
Returns a summary with beginning and end offsets for the given topic and specific partition.

Description

Information retrieved varies depending on the configuration. See the `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets summary with beginning and end offsets for the specific partition of the MapR Event Store topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets summary with beginning and end offsets for the specific MapR Event Store partition within a topic. You can only pass the fully qualified topic names that contain the stream path.

Table

Parameter	Description
topic_name (*string*)	Name of the topic.
partition_id (*int*)	ID of the partition to inspect.

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>/offsets
```

Request Example

```
curl -X GET -H "Content-Type:
application/vnd.kafka.v2" http://localhost:8082/topics/
%2Fstreaming_data%2Fstream%3Atesttopic1/partitions/0/offsets
```

Response Example

```
{
  "beginning_offset":0,
  "end_offset":0
}
```

POST /topics/{string: topic_name}/partitions/{string: partition_id}
Produces messages into a partition of a topic.

Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Produces messages into a partition of MapR Event Store For Apache Kafka topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, messages are produced into topics in the default stream path.
streams.default.stream is not defined	Produces messages into a partition within MapR Event Store For Apache Kafka topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
topic_name (*string*)	Topic to produce the messages to.
partition_id (*int*)	Partition to produce the messages to.

Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2+json" --data
'{"records":[{"key":"a2v5","value":"Y29uZmx1ZW50"}]}'
"http://localhost:8082/topics/testtopic1/partitions/0"
```

Response Example

```
{
  "offsets":
    [{
       "partition":0,
       "offset":1,
       "error_code":null,"error":null}
```

```
    ],
  "key_schema_id":null,
  "value_schema_id":null
}
```

POST /consumers/{string: group_name}

Creates a new consumer instance in the consumer group.

Description

Table

Parameters	Description
group_name (*string*)	The name of the consumer group to join.
name (*string*)	Name for the consumer instance, which will be used in URLs for the consumer. This must be unique, at least within the proxy process handling the request. If omitted, falls back on the automatically generated ID. Using automatically generated names is recommended for most use cases.
format (*string*)	The format of consumed messages, which is used to convert messages into a JSON-compatible form. Valid values: “binary”, “avro”, “json”. If unspecified, defaults to “binary”.
auto.offset.reset (*string*)	Sets the **auto.offset.reset** setting for the consumer. Values: latest, earliest, none
auto.commit.enable (*string*)	Sets the **auto.commit.enable** setting for the consumer.

Note: You cannot set the time-to-live (TTL) for consumer instances or consumer groups. However, consumers can be configured to be deleted after some idle time. The amount of idle time before a consumer instance is automatically destroyed is set by the `consumer.instance.timeout.ms` property in the **kafka-rest.properties** file. See Configuration Parameters on page 3865.

Syntax

```
http://<host>:8082/consumers/<group_name>
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json"
 --data '{"name":"user","format": "binary", "auto.offset.reset":
"earliest"}'
 http://localhost:8082/consumers/grouptest
```

Response Example

The response JSON object is in the following form:

- **instance_id** (*string*) – Unique ID for the consumer instance in this group. The `instance_id` is automatically generated if the `name` parameter is not specified.
- **base_uri** (*string*) – Base URI used to construct URIs for subsequent requests against this consumer instance. This will be of the form `http://hostname:port/consumers/consumer_group/instances/instance_id`.

```
{
        "instance_id":"user",
```

last-updated: Apr 11, 2022

```
        "base_uri":"http://localhost:8082/consumers/grouptest/instances/
user"
}
```

DELETE /consumers/{string: group_name}/instances/{string: instance_id}
Destroys the consumer instance.

Description

The request must be made to the specific REST proxy instance holding the consumer instance.

Table

Parameters	Description
group_name (*string*)	The name of the consumer group.
instance (*string*)	The ID of the consumer instance

Syntax

```
http://<host>:8082/topics/<group_name>/instances/<instance_string>
```

Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/consumers/my_binary_consumer/instances/
rest-consumer-11561681-
8ba5-4b46-bed0-905ae1769bc6
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets
Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.

Parameters

Table

Parameters	Description
group_name (*string*)	The name of the consumer group.
instance_id (*string*)	The ID of the consumer instance.
offsets	A list of offsets to commit for partitions.
offsets[i].topic (*string*)	Name of the topic
offsets[i].partition (*int*)	Partition ID
offset	The offset to commit.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_instance_id>/
offsets
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic":
"/mystream:first","partition": 0,"offset":5}]}'
https://node2:8082/consumers/grouptest/instances/user/offsets
```

Response Example

```
HTTP/1.1 200 OK
```

GET /consumers/{string: group_name)/instances/{string: instance_id}/offsets
Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.
partitions	A list of partitions to find the last committed offsets.
partitions[i].topic (*string*)	Name of the topic.
partitions[i].partition (*int*)	Partition ID

Syntax

```
http://localhost:8082/consumers/<group_name>/instances/<consumer_name>/
offsets
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.binary.v2+json" --data
'{"partitions":[{"topic":"/stream:topic","partition":0}]}'
https://node2:8082/consumers/grouptest/instances/user/offsets
```

Response Example

The response JSON object is in the following form:

- offsets - A list of committed offsets.
- offsets[i].topic (string) – Name of the topic for which an offset was committed
- offsets[i].partition (int) – Partition ID for which an offset was committed
- offsets[i].offset (int) – Committed offset
- offsets[i].metadata (string) – Metadata for the committed offset

```
{"offsets":
  [
    {
```

```
        "topic": "/stream:topic",
        "partition": 0,
        "offset": 21,
        "metadata":""
    }
  ]
}
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/subscription
Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"topics":["/stream:first","/stream:second"]}'
https://localhost:8082/consumers/grouptest/instances/user/subscription
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group_name}/instances/{string: instance_id}/subscription
Gets the current subscribed list of topics.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/subscription
```

Response Example

The response JSON object is in the following form:

- topics – A list of subscribed topics
- topics[i] (string) – Name of the topic

```
{
  "topics":[
            "/stream:first",
            "/stream:second"
           ]
}
```

DELETE /consumers/{string: group_name}/instances/{string: instance_id}/subscription
Unsubscribes from topics currently subscribed to.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
https:/localhost:8082/consumers/grouptest/instances/user/subscription
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/assignments
Manually assigns a list of partitions to a consumer.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.

last-updated: Apr 11, 2022

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions":[{"topic":"first","partition":0}]}'
https://localhost:8082/consumers/grouptest/instances/user/assignments
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group_name}/instances/{string: instance_id}/assignments
Retrieves the list of partitions currently assigned to this consumer.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/assignments
```

Response Example

The response JSON object is in the following form:

- partitions – A list of partitions assigned to this consumer.
- partitions[i].topic (*string*) – Name of the topic.
- partitions[i].partition (*int*) – Partition ID

```
{
  "partitions": [
    {
      "topic": "test",
      "partition": 0
    },
    {
      "topic": "test",
      "partition": 1
    }
```

```
  ]
}
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/positions
Overrides the fetch offsets that the consumer will use for the next set of records to fetch.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.
offsets	A list of offsets
offsets[i].topic (*string*)	Name of the topic
offsets[i].partition (*int*)	Partition ID
offsets[i].offset (*int*)	Seek to offset for the next set of records to fetch.

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions
```

Request Example

```
curl  -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic": "/stream:first","partition": 0,"offset":3}]}'
https://localhost:8082/consumers/grouptest/instances/user/positions
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning
Seek to the first offset for each of the given partitions.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.
partitions	A list of partitions.
partitions[i].topic (*string*)	Name of the topic
partitions[i].partition (*int*)	Partition ID

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/beginning
```

Request Example

```
curl  -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first","partition": 0}]}'
https://localhost:8082/consumers/grouptest/instances/user/positions/
beginning
```

Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group_name}/instances/{string: instance_id}/positions/end
Seek to the last offset for each of the given partitions.

Parameters

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.
partitions	A list of partitions.
partitions[i].topic (*string*)	Name of the topic
partitions[i].partition (*int*)	Partition ID

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/end
```

Request Example

```
curl  -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first","partition": 0}]}'
https://localhost:8082/consumers/grouptest/instances/user/positions/end
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group_name}/instances/{string: instance_id}/records
Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.

Parameters

The format of the embedded data returned by this request is determined by the format specified in the initial consumer instance creation request and must match the format of the Accept header.

Note: This request *must* be made to the specific REST proxy instance holding the consumer instance.

Table

Parameter	Description
group_name (*string*)	Name of the consumer group.
instance (*string*)	ID of the consumer instance.
timeout	The number of milliseconds for the underlying client library poll(timeout) request to fetch the records. Default: 5000ms.
max_bytes	The maximum number of bytes of unencoded keys and values that should be included in the response. This provides approximate control over the size of responses and the amount of memory required to store the decoded response. The actual limit is the minimum of this setting and the server-side configuration consumer.request.max.bytes. Default: unlimited

Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/records
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/records
```

Response Example

```
[
  {
    "topic": "test",
    "key": "a2V5",
    "value": "Y29uZmx1ZW50",
    "partition": 1,
    "offset": 100,
  },
  {
    "topic": "test",
    "key": "a2V5",
    "value": "a2Fma2E=",
    "partition": 2,
    "offset": 101,
  }
]
```

GET /streams/{string: stream_name}/topics

Retrieves a list of topics in a given stream.

Description

Stream names contain characters such as backslashs (/) and colons (:) and, therefore, should be encoded.

Table

Parameters	Description
stream_name *(string)*	The name of the stream.

last-updated: Apr 11, 2022

Syntax

```
http://<host>:8082/streams/<stream_name>/topics
```

Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/streams/%2Fstreaming_data%2Fstream/topics
```

Response Example

```
[
  "/streaming_data/stream:testtopic1",
  "/streaming_data/stream:testtopic2"
]
```

API v3 HTTP Methods and URIs

GET /v3/clusters
Retrieves a list of metadata about the cluster.

Description

Retrieves one cluster only. Always retrieves the current MapR Data Platform cluster.

Syntax

```
http://<host>:8082/v3/clusters
```

Request Example

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/
clusters
```

Response Example

```
{
  "kind":"KafkaClusterList",
  "metadata":
    {
      "self":"http://node1.cluster.com:8082/v3/clusters",
      "next":null
    },
  "data":
    [
      {
        "kind":"KafkaCluster",
        "metadata":
          {
            "self":"http://node1.cluster.com:8082/v3/clusters/
682798077049224619",
            "resource_name":"crn:///kafka=682798077049224619"
          },
        "cluster_id":"682798077049224619",
        "controller":
          {
            "related":"http://node1.cluster.com:8082/v3/clusters/
```

```
682798077049224619/brokers/0"
          },
        "acls":
          {

```

GET /v3/clusters/{string: cluster_id}

Retrieves metadata about a specific cluster.

Parameters

Parameters	Description
cluster_id (*string*)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>
```

Request Example

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/
clusters/682798077049224619
```

Response Example

```
{
  "kind":"KafkaCluster",
  "metadata":
```

last-updated: Apr 11, 2022

```
    {
      "self":"http://node1.cluster.com:8082/v3/clusters/682798077049224619",
      "resource_name":"crn:///kafka=682798077049224619"

}
```

GET /v3/clusters/{string: cluster_Id}/topics

Retrieves a list of topic names on the specific cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Returns a list of topic names and metadata in the default stream. Returns topic names and metadata that contains a stream path.
streams.default.stream is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics"
```

Response Example

```

            }
        }
    ]
}
```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}
Retrieves metadata about a specific topic within a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about a specific MapR Event Store topic on this cluster. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to default_stream:topic1.
streams.default.stream is not defined	Gets metadata about a specific MapR Event Store topic on this cluster. A fully qualified topic name is passed that contains the stream path.

Note: The full name for the MapR Event Store topic contains characters such as a forward slash (/) and a colon (:). Therefore, the topic should be encoded. For example, `/streaming_data/stream:topic-1` is equivalent to `%2Fstreaming_data%2Fstream%3Atopic-1`.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.
topic_name (*string*)	Name of the topic.

Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2"
```

Response Example

```
{
  "kind":"KafkaTopic",
  "metadata":
    {
      "self":"http://node1.cluster.com:8082/v3/clusters/682798077049224619/

    }
}
```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions

Retrieves a list of partitions for the topic within a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about specific MapR Event Store partitions within a topic on this cluster. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.

Table (Continued)

Parameters Defined	Response
streams.default.stream is not defined	Gets metadata about specific MapR Event Store partitions within topic on this cluster. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.
topic_name (*string*)	Name of the topic.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions"
```

Response Example

```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}

Retrieves metadata about a specific partition within a topic and a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about a specific partition within a MapR Event Store topic on this cluster. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific MapR Event Store partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.
topic_name (*string*)	Name of the topic.
partition_id (*int*)	ID of the partition to inspect.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1"
```

Response Example

```
{
  "kind":"KafkaPartition",
  "metadata":
    {
      "self":"http://node1.cluster.com:8082/v3/clusters/682798077049224619/

}
```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas
Retrieves a list of replicas within a partition, a topic, and a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about specific replicas of the MapR Event Store partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific replicas of the MapR Event Store partition within a topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.
topic_name (*string*)	Name of the topic.
partition_id (*int*)	ID of the partition to inspect.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas"
```

Response Example

}
```

GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas/{string: broker_id}

Retrieves metadata about a specific replica within a partition, a topic, and a cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Gets metadata about specific broker of the MapR Event Store partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
streams.default.stream is not defined	Gets metadata about specific broker of the MapR Event Store partition within a topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.
topic_name (*string*)	Name of the topic.
partition_id (*int*)	ID of the partition to inspect.
broker_id (*int*)	ID of the broker to inspect.

last-updated: Apr 11, 2022

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas/<broker_id>
```

Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas/0"
```

Response Example

```
{
  "kind":"KafkaReplica",
  "metadata":
    {
      "self":"http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/str:tp-2/partitions/1/replicas/0",
      "resource_name":"crn:///kafka=682798077049224619/topic=str:tp-2/
partition=1/replica=0"
    },
  "cluster_id":"682798077049224619",
  "topic_name":"/str:tp-2",
  "partition_id":1,
  "broker_id":0,
  "is_leader":true,
  "is_in_sync":true,
  "broker":
    {
      "related":"http://node1.cluster.com:8082/v3/clusters/
682798077049224619/brokers/0"
    }
}
```

POST /v3/clusters/{string: cluster_Id}/topics

Creates a new topic on the specific cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865

Table

Parameters Defined	Response
streams.default.stream is defined	Creates a topic in the default stream and returns its metadata.
streams.default.stream is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

Request Example

```
$ curl -X POST -H "Content-Type: application/json" --data '{"topic_name":
"new-topic","partitions_count": 4}' "http://localhost:8082/v3/clusters/
682798077049224619/topics"
```

Request Response

```
{
  "kind":"KafkaTopic",
  "metadata":
    {
      "self":"http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/new-topic",
      "resource_name":"crn:///kafka=682798077049224619/topic=new-topic"
    },
  "cluster_id":"682798077049224619",
  "topic_name":"new-topic",
  "is_internal":false,
  "replication_factor":0,
  "partitions":
    {
      "related":"http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/partitions"
    },
  "configs":
    {
      "related":"http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/configs"
    },
  "partition_reassignments":
    {
      "related":"http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/partitions/-/reassignment"
    }
}
```

DELETE /v3/clusters/{string: cluster_id}/topics/{string: topic_name}

Deletes a topic from the specific cluster.

Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in Configuration Parameters on page 3865.

Table

Parameters Defined	Response
streams.default.stream is defined	Deletes topic from the default stream.
streams.default.stream is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
cluster_id (*string*)	Cluster's id.
topic_name (*string*)	Name of the topic.

Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

Request Example

```
$ curl -X DELETE -H "Content-Type: application/json" "http://
localhost:8082/v3/clusters/68279807704922 4619/topics/new-topic"
```

Response Example

```
HTTP/1.1 204 No Content
```

Kafka Connect
Kafka Connect is a utility for streaming data between MapR Event Store For Apache Kafka and other storage systems.

Examples of other systems include:

- Relational databases
- Logs and metrics
- Hadoop and data warehouses
- NoSQL data stores

Kafka Connect makes it easy to integrate all your data via Kafka, making it available as realtime streams. For example, you can use Kafka Connect to:

- Stream changes from a relational database to make events available with low latency for stream processing applications.
- Import realtime logs and metrics into MapR Event Store For Apache Kafka and process them to detect anomalies.
- Implement a process of loading data into MapR Event Store For Apache Kafka from your primary data storage systems, performing filtering, transformations, and enrichment with a stream processing framework, and publish the data to the HPE Ezmeral Data Fabric File Store.

Note: Built-in security is not available.

Architecture of Kafka Connect
Kafka Connect for MapR Event Store For Apache Kafka has the following major models in its design: connector, worker, and data.

Connector Model

A connector is defined by specifying a Connector class and configuration options to control what data is copied and how to format it.

last-updated: Apr 11, 2022

- Each Connector instance is responsible for defining and updating a set of Tasks that actually copy the data.
- Kafka Connect manages the Tasks; the Connector is only responsible for generating the set of Tasks and indicating to the framework when they need to be updated.
- Source and Sink Connectors/Tasks are distinguished in the API to ensure the simplest possible API for both.

There are two types of tasks:

- **Source** - Source tasks ingest data from data storage systems and stream the data to MapR Event Store For Apache Kafka.
- **Sink** - Sink tasks stream data from MapR Event Store For Apache Kafka to other storage systems.

MapR Data Platform supports the following connectors:

- JDBC Source Connector

  The Kafka JDBC source connector is a type connector used to stream data from relational databases into MapR Event Store For Apache Kafka topics. JDBC Source Connector for MapR Event Store For Apache Kafka supports integration with Hive 2.1.

- JDBC Sink Connector

  The Kafka JDBC sink connector is a type connector used to stream data from MapR Event Store For Apache Kafka topics to relational databases that have a JDBC driver.

- HDFS Sink Connector

  The Kafka HDFS sink connector is a type connector used to stream data from MapR Event Store For Apache Kafka to MapR File System. By default, the resulting data is produced to MapR File System in Avro format. In addition, Parquet files can be written to MapR File System.

Worker Model

A Kafka Connect for MapR Event Store For Apache Kafka cluster consists of a set of Worker processes that are containers that execute Connectors and Tasks. A worker is a JVM process with a REST API that is able to execute streaming tasks.

- Workers automatically coordinate with each other to distribute work and provide scalability and fault tolerance.
- The Workers distribute work among any available processes, but are not responsible for management of the processes;
- Any process management strategy can be used for Workers. For example, cluster management tools like YARN or Mesos, configuration management tools like Chef or Puppet, or direct management of process lifecycles.

Data Model

Connectors copy streams of messages from a partitioned input stream to a partitioned output stream, where at least one of the input or output is *always* Kafka.

- Each of these streams is an ordered set messages where each message has an associated offset.
- The format and semantics of these offsets are defined by the Connector to support integration with a wide variety of systems; however, to achieve certain delivery semantics in the face of faults requires that offsets are unique within a stream and streams can seek to arbitrary offsets.

- Message contents are represented by Connectors in a serialization-agnostic format.
- Pluggable Converters are available for storing this data in a variety of serialization formats.
- Schemas are built-in, allowing important metadata about the format of messages to be propagated through complex data pipelines. However, schema-free data can also be use when a schema is simply unavailable.

Connectors, Tasks, and Workers
Describes how Kafka Connect for MapR Event Store For Apache Kafka works and how connectors, tasks, offsets, and workers are associated.

Connectors

Connectors (or a **connector instance**) are logical jobs that are responsible for managing the copying of data between MapR Event Store For Apache Kafka and another systems. Each connector instantiates a set of **tasks** that copies the data. By allowing the connector to break a single job into many tasks, support is built-in for parallelism and scalable data copying with very little configuration. **Connector plugins** are jars that add the classes that implement a connector.

Offsets

As connectors run, Kafka Connect tracks **offsets** for each one so that connectors can resume from their previous position in the event of failures or graceful restarts for maintenance. They track the current position in the stream of data being copied and because each connector may need to track many offsets for different **partitions** of the stream. For example, when loading data from a database, the offset might be a transaction ID that identifies a position in the database change log.

Users generally do not need to worry about the format of offsets, especially since they differ from connector to connector. However, Kafka Connect does require persistent storage for offset data to ensure it can recover from faults. This storage for offset data is configurable. See Standalone Worker Configuration Options on page 3910 and Distributed Worker Configuration Options on page 3910.

Workers

Connectors and tasks are logical units of work and must be scheduled to execute in a process. Kafka Connect calls these processes **workers.** With Kafka Connect for MapR streams, the worker processors run as a service. This service can be run in either standalone mode or distributed mode.

- In standalone mode, the cluster consists of a single worker that is supplied with tasks that are useful for testing and debugging purposes.
- In distributed mode, the cluster consisting from multiple workers with the same group.id, offset.storage.topic, and config.storage.topic. Connector tasks are submitted via the Kafka Connect REST API.

The following list the location of the standalone and distributed worker configuration files:

```
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

Note: Distributed mode is supported on MapR 5.2.1 and above

Note: Port 8083 is the default port.

Note: If you running multiple workers on the same node, the rest.port parameter must be different for each worker.

last-updated: Apr 11, 2022

Configuring in Standalone Mode
The section describes how to configure and execute workers in Kafka connect standalone mode.

Standalone mode is the simplest mode, where a single process is responsible for executing all connectors and tasks. Since it is a single process, it requires minimal configuration.

Configuring and running in standalone mode, involves configuring the standalone properties and connector parameters before executing the standalone shell command along with the properties files on the command line.

The following parameters must be provided in the **connect-standalone.properties** file.

- offset.storage.file.filename - Storage for connector offsets which are stored on the local filesystem in standalone mode. Using the same file leads to offset data being deleted or overwritten with different values.
- rest.port - Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this parameter must have different values for each instance.

Note: If you are running multiple standalone instances on the same host, these parameters must be different for each instances. Therefore, an additional properties file is created for the instance with different parameter values.

To run a worker in standalone mode:

1. Edit the **./config/connect-standalone.properties** file and add the name of the local file that will store the connector offsets.
2. Edit the **quickstart-sqlite.properties** file (JDBC connector configuration file).
3. Run the **./bin/connect-standalone.sh** command along with the properties files on the command line.

For example:

```
cd /opt/mapr/kafka/kafka-<version>
./bin/connect-standalone.sh
./config/connect-standalone.properties
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
```

The first parameter is always a configuration file for the worker. This configuration gives you control over settings such as which cluster to use and the serialization format. See JDBC Connector on page 3915 for more information. All additional parameters should be connector configuration files. Each file contains a single connector configuration.

Configuring in Distributed Mode
This section describes how to configure and run workers in Kafka Connect distributed mode.

Distributed mode provides scalability and automatic fault tolerance for Kafka Connect. In distributed mode, multiple worker processes are started using the same group.id. These processes automatically coordinate to schedule execution of connectors and tasks across all available workers. If a worker is added, shuts down, or fails unexpectedly, the rest of the workers detect this and automatically coordinate to redistribute connectors and tasks across the updated set of available workers.

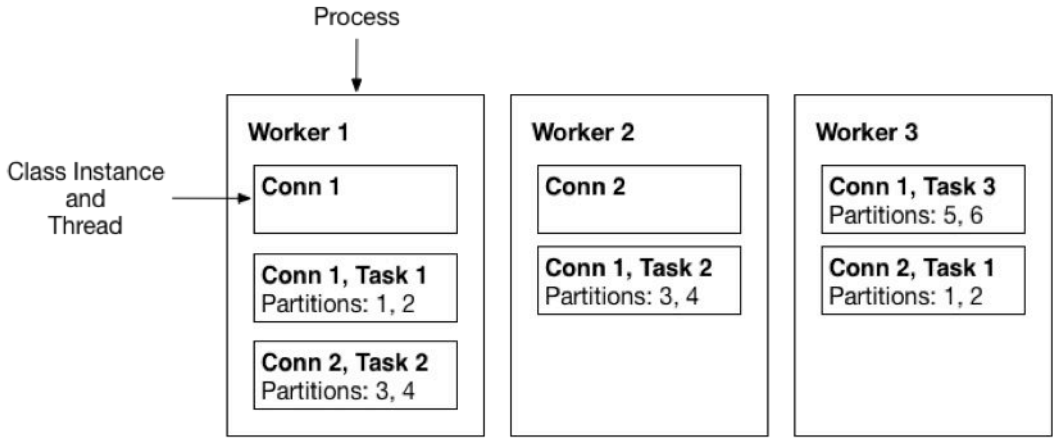
Note: Distributed mode is available as of EEP 2.0.1.

The following diagrams illustrates a three-node Kafka Connect distributed mode cluster where:

- Connectors are monitoring the source or sink system for changes that require reconfiguring tasks.
- Tasks are automatically balanced across the active workers by copying a subset of a connector's data.

last-updated: Apr 11, 2022

- The division of work between tasks is shown by the partitions that each task is assigned.



Interaction with a distributed-mode cluster is via the REST API (rather than on the command line). To create a connector, the workers are started and then REST request is made to create a connector. See REST API on page 3931.

Note: Kafka Connect workers do not have a special “leader” process that you have to interact with to use the REST API. All nodes can respond to REST requests, including creating, listing, modifying, and destroying connectors.

To run the worker in distributed mode:

1. In the `connect-distributed.properties` file, define the topics that will store the connector state, task configuration state, and connector offset state.

   In distributed mode, the workers need to be able to discover each other and have shared storage for connector configuration and offset data. In addition to the usual worker settings, ensure you have configured the following for the cluster:

   - **group.id** - ID that uniquely identifies the cluster these workers belong to. Ensure this is unique for all groups that work with a cluster.
   - **config.storage.topic** - Topic to store the connector and task configuration state in. Although this topic can be auto-created if your cluster has auto topic creation enabled, it is highly recommended that you create it before starting the cluster. This topic should **always** have a single partition and be highly replicated (3x or more).
   - **offset.storage.topic** - Topic to store the connector offset state in. To support large MapR Event Store For Apache Kafka clusters, this topic should have a large number of partitions (for example, 25 or 50 partitions and highly replicated (3x or more).
   - **rest.port** - Port where the REST interface listens for HTTP requests. If you run more than one worker per host (for example, if you are testing distributed mode locally during development), this setting must have different values for each instance.

2. Set the group.id value for all of the workers in the cluster.

   Note: All workers that belong to the same cluster must have the same group.id value.

last-updated: Apr 11, 2022

3. Start the Kafka Connect service in distributed mode:

```
maprcli node services -name kafka-connect -action start -nodes
<node_list>
```

For more information, see Managing Kafka Connect Services on page 3925.

Note: >Distributed mode does not have any additional command line parameters. If other instances are already running, new workers either start a new group or join an existing one, and then wait for work to do. For information on managing the connectors running in the cluster, see REST API on page 3931.

Connector Configuration
This section describes how and where connectors are configured.

Connector configurations are key-value mappings. For standalone mode, these parameters are defined in a properties file and passed to the Connect process on the command line. In distributed mode, they will be included in the JSON payload for the request that creates (or modifies) the connector. Most configurations are connector dependent, but there are a few settings common to all connectors:

- name - Unique name for the connector. Attempting to register again with the same name will fail.
- connector.class - The Java class for the connector
- tasks.max - The maximum number of tasks that should be created for this connector. The connector may create fewer tasks if it cannot achieve this level of parallelism.

Sink connectors also have one additional option to control their input:

- topics - A list of topics to use as input for this connector

For other options, consult the documentation for the JDBC and HDFS connectors. See JDBC Connector on page 3915 and HDFS Connector on page 3925.

Worker Configuration
This section describes how and where to configure workers.

Whether you're running standalone or distributed mode, Kafka Connect workers are configured by passing a properties file containing any required or overridden options as the first parameter to the worker process.

Common Worker Configuration Options
You can set common worker configuration options for standalone or distributed mode in the `connect-<standalone/distributed>.properties` file. The options control basic functionality, including which cluster to communicate with and data format.

Setting the Schema Registry URL for the Avro Converter

Set the Schema Registry URL for the converter through the following properties:

- `key.converter.schema.registry.url=<URL:PORT>`
- `value.converter.schema.registry.url=<URL:PORT>`
- For Avro, use `io.confluent.connect.avro.AvroConverter`.
-
-

If you do not set these properties, the Schema Registry URL is taken from ZooKeeper.

The following table describes the common worker configuration parameters:

last-updated: Apr 11, 2022

Parameter	Description
plugin.path	The comma-separated list of paths to directories that contain Kafka Connect plugins. • Type: string • Default: empty
key.converter	Converter class for key Connect data. This controls the format of the data that will be written to MapR Event Store For Apache Kafka for source connectors or read from MapR Streams for sink connectors. • Type: class • Default: empty
value.converter	Converter class for value Connect data. This controls the format of the data that will be written to MapR Event Store For Apache Kafka for source connectors or read from MapR Streams for sink connectors. • Type: class • Default: empty
internal.key.converter	Converter class for internal key Connect data that implements the Converter interface. Used for converting data like offsets and configs. • Type: class • Default:
internal.value.converter	Converter class for offset value Connect data that implements the Converter interface. Used for converting data like offsets and configs. • Type: class • Default:
offset.flush.interval.ms	Interval (milliseconds) at which to try committing offsets for tasks. • Type: long • Default: 60000
offset.flush.timeout.ms	Maximum number of milliseconds to wait for records to flush and partition offset data to be committed to offset storage before cancelling the process and restoring the offset data to be committed in a future attempt. • Type: long • Default: 5000
rest.advertised.host.name	If set, this is the hostname that will be given out to other workers to connect to. • Type: string
rest.advertised.port	If set, this is the port that will be given out to other workers to connect to. • Type: int

last-updated: Apr 11, 2022

Parameter	Description
rest.host.name	Hostname for the REST API. If this is set, it will only bind to this interface. • Type: string
rest.port	Port for the REST API to listen on. • Type: int • Default: 8083
task.shutdown.graceful.timeout.ms	Amount of time to wait (milliseconds) for tasks to shutdown gracefully. This is the total amount of time, not per task. All task have shutdown triggered, then they are waited on sequentially. • Type: long • Default: 5000
streams.consumer.streams.default.stream	If set, topic names can be used in the Sink task configuration without the stream name. The defined default stream is used.
streams.producer.producer.default.stream	If set, topic names can be used in the Source task configuration without the stream name. The defined default stream is used.

Standalone Worker Configuration Options
This section describes worker parameters that are specific to standalone configurations.

The offset.storage.file.filename and rest.port parameter are specific to the standalone worker configuration. These parameters are sent in the `connect-standalone.properties` file.

Table

Parameter	Description
rest.port	Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this setting must have different values for each instance. Type: int. Default: 8083
offset.storage.file.filename	The file to store connector offsets in. By storing offsets on disk, a standalone process can be stopped and started on a single node and resume where it previously left off. Type: string. Default: empty

Distributed Worker Configuration Options
This topic describes the worker parameters that are specific to distributed configurations.

In addition to the common worker configuration options, the following are available in distributed mode. These parameters are set in the `connect-distributed.properties` file.

Table

Parameter	Description	Type	Default
group.id	A unique string that identifies the Connect cluster group that the worker belongs to.	string	“”
config.storage.topic	The name of the MapR Event Store For Apache Kafka topic to store connector and task configuration data in. This *must* be the same for all workers with the same group.id. For example: `/path/to/stream:topic-prefix-`	string	“”

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description	Type	Default
status.storage.topic	The name of the MapR Event Store For Apache Kafka topic where connector and task configuration updates are stored. This *must* be the same for all workers with the same group.id.	string	“”
offset.storage.topic	The MapR Event Store For Apache Kafka topic to store offset data for connectors in. This *must* be the same for all workers with the same group.id. For example: `/path/to/stream:topic-prefix-`	string	“”
heartbeat.interval.ms	The expected time between heartbeats to the group coordinator when using Kafka’s group management facilities. Heartbeats are used to ensure that the worker’s session stays active and to facilitate rebalancing when new members join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	int	3000
session.timeout.ms	The timeout used to detect failures when using Kafka’s group management facilities.	int	30000
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	long	540000
receive.buffer.bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	int	32768
request.timeout.ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	int	40000
send.buffer.bytes	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	int	131072
worker.sync.timeout.ms	When the worker is out of sync with other workers and needs to resynchronize configurations, wait up to this amount of time before giving up, leaving the group, and waiting a backoff period before rejoining.	int	3000
worker.unsync.backoff.ms	When the worker is out of sync with other workers and fails to catch up within worker.sync.timeout.ms, leave the Connect cluster for this long before rejoining.	int	300000
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just IP/port by allowing a logical application name to be included in server-side request logging.	string	“”
metadata.max.age.ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven’t seen any partition leadership changes to proactively discover any new brokers or partitions.	long	300000

Table (Continued)

Parameter	Description	Type	Default
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporterinterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	list	[]
metrics.num.samples	The number of samples maintained to compute metrics.	int	2
metrics.sample.window.ms	The number of samples maintained to compute metrics.	long	30000
reconnect.backoff.ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	long	50
retry.backoff.ms	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	long	100

Security Configuration Options
Describes Kafka Connect security parameters.

The following security parameters provide an authentication, encryption, and impersonation layer between the Kafka Connect REST API clients and the Kafka Connect REST Gateway.

These parameters are configurable in the `connect-distributed.properties` file.

```
/opt/mapr/kafka/kafka-&lt;version>/config/connect-distributed.properties
```

Note: Ensure that both an ssl_keystore and ssl_truststore file have been created.

Table

Parameter	Description	Type	Default
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. If a listener uses HTTPS, the appropriate SSL configuration parameters need to be set as well. Each listener must include the protocol, hostname, and port. For example: http://localhost:8082	list	none
connect.enable.doAs	Specifies whether or not to enable impersonation for MapR Event Store For Apache Kafka topics. For this to take effect, PAM authentication must be enabled.	boolean	true
authentication.method	Specifies whether or not to enable PAM authentication. Set to NONE to disable.	string	BASIC
authentication.realm	Specifies realm for PAM authentication. Set to an empty string ("") to disable PAM. Set to jpamLogin to enable authentication	string	jpam
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description	Type	Default
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list.	list	• TLS_DHE.* • TLS_EDH.* • .*DES.* • .*MD5.* • .*RC4.*
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	• SSLv3 • TLSv1.0
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=https. Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.keystore.location	Location of the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.password	The store password for the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLSv1.2
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS

last-updated: Apr 11, 2022

SSL Security Configuration
Describes how to configure Kafka Connect security on a MapR Data Platform cluster.

Secure by Default

As of Core 6.0, the Installer performs the Kafka Connect configuration for new installations. This means that:

- If core is installed as *secure*, then Kafka Connect is also installed as *secure*.
- If core is installed as *unsecure*, then Kafka Connect is also installed as *unsecure*.

Important: In addition, every time the MapR configuration script is run with the `-R` option (`configure.sh -R`), the default settings for MapR core are re-established.

This means that if you manually configure Kafka Connect for *unsecure* on a *secure* MapR core, Kafka Connect will revert back to *secure* when `configure.sh -R` is run.

Manually Securing Kafka Connect Only

CAUTION: This configuration is ***not*** a typical configuration.

If you have an *unsecure* MapR Data Platform cluster, and you want to *secure* Kafka Connect, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `connect-distributed.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8083
            ssl.keystore.location=<ssl-keystore-path>
            ssl.keystore.password=<ssl-keystore-password>
            ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8083/connectors --cacert <certificate-path>
```

Manually Unsecuring Kafka Connect

Warning: This scenario is ***NOT*** recommended or supported.

If you have a *secure* MapR Data Platform cluster, and you want to *unsecure* Kafka Connect, do the following:

1. In the `connect-distributed.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.*** properties. For example:

```
listeners=http://0.0.0.0:8083
```

last-updated: Apr 11, 2022

2. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

User Impersonation
Describes how to disable, enable, and use impersonation with Kafka Connect.

User impersonation enables Kafka Connect jobs to be submitted as a particular user. Without impersonation, Kafka Connect submits jobs as the user that started the worker

On a MapR Data Platform cluster, the impersonated user is typically the `mapr` user or the user specified in the MAPR_USER environment variable. By default, impersonation and PAM authentication in Kafka Connect are enabled on all types of security.

Disabling User Impersonation

To disable user impersonation, you need to first disable the PAM authentication properties in the connect-distributed.properties file and then disable the connect.proxy.enable.doAs property.

1. Disable PAM authentication. Set the following properties in `opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties:`
   - authentication.method=NONE
2. Once authentication is disabled, set the following property in `/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties:`
   - connect.proxy.enable.doAs=false

JDBC Connector
The topics describes the JDBC connector, drivers, and configuration parameters.

The JDBC connector allows you to import data from any relational database into MapR Event Store For Apache Kafka and export data from MapR Event Store For Apache Kafka to any relational database with a JDBC driver. By using JDBC, this connector can support a wide variety of databases without requiring custom code for each one.

The JDBC connector provides flexibility regarding which databases you can import data from and how that data is imported. JDBC connector implements the data copying functionality on the generic JDBC APIs, and relies on JDBC drivers to handle the database-specific implementation of those APIs.

The supported relational databases include:

- MySQL
- Oracle
- PostgreSQL
- SQLite
- SQL Server
- Hive is supported for the JDBC Source Connector

JDBC Driver
Kafka Connect for MapR Event Store For Apache Kafka provides a JDBC driver jar along with the connector configuration.

The JDBC driver (kafka-connect-jdbc) is set up by specifying the CLASSPATH variable. See Installing MapR Event Store For Apache Kafka Tools on page 202.

last-updated: Apr 11, 2022

The packaged connector is installed in the **share/java/kafka-connect-jdbc** directory, relative to the installation directory.

Alternatively, to add a new driver to the CLASSPATH,

1. Put the classpath of the connectors in the **kafka-connect-jdbc** directory:

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<connector version>/
share/java/kafka-connect-jdbc/
```

2. Create a symlink into the **share/java/kafka-connect-jdbc/** directory.

JDBC Configuration Options
Use the following parameters to configure the Kafka Connect for MapR Event Store For Apache Kafka JDBC connector; they are modified in the `quickstart-sqlite.properties` file.

Configuration Modes

In *standalone* mode, JDBC connector configuration is specified in the **quickstart-sqlite.properties** file. Additional configurations such as the offset storage location and the port for the REST interface are specified in the **connect-standalone.properties** file. See Configuring in Standalone Mode on page 3906.

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See POST /connectors on page 3933 and PUT /connectors/(string:name)/config on page 3935 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See Configuring in Distributed Mode on page 3906 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

JDBC Source Configuration Options

Table

Parameters	Description
connection.url	JDBC connection URL for the database to load. • Type: string • Default: “”
connection.user	JDBC connection user. • Type: string • Default: NULL
connection.password	JDBC connection password. • Type: password • Default: NULL

Table (Continued)

Parameters	Description
connection.attempts	Maximum number of attempts to retrieve a valid JDBC connection. • Type: int • Default: 3
connection.backoff.ms	Backoff time in milliseconds between connection attempts. • Type: long • Default: 10000
table.whitelist	List of tables to include in copying. If specified, table.blacklist may not be set. • Type: list • Default: []
table.blacklist	List of tables to exclude from copying. If specified, table.whitelist may not be set. • Type: list • Default: []
numeric.precision.mapping	Whether or not to attempt mapping *numeric* values by precision to integral types. • Type: boolean • Default: false
schema.pattern	Schema pattern to fetch table metadata from the database. "" - Retrieves those without a schema. * - NULL (default) means that the schema name should not be used to narrow the search, all tables metadata would be fetched, regardless their schema.

last-updated: Apr 11, 2022

Table (Continued)

Parameters	Description
mode	The mode for updating a table each time it is polled. Options include: • bulk - perform a bulk load of the entire table each time it is polled. • incrementing - use a strictly incrementing column on each table to detect only new rows. Note that this will not detect modifications or deletions of existing rows. • timestamp - use a timestamp (or timestamp-like) column to detect new and modified rows. This assumes the column is updated with each write, and that values are monotonically incrementing, but not necessarily unique. • timestamp+incrementing - use two columns, a timestamp column that detects new and modified rows and a strictly incrementing column which provides a globally unique ID for updates so each row can be assigned a unique stream offset. • Type: string • Default: “” Valid Values: [, bulk, timestamp, incrementing, timestamp+incrementing] The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an autoincrementing column. This column may not be nullable. • Type: string • Default: “” **Note:** If you are using Hive JDBC with incrementing or timestamp mode, you should set the `validate.non.null` property to false because there are no "not null" columns in Hive.
timestamp.column.name	The name of the timestamp column to use to detect new or modified rows. This column may not be nullable. • Type: string • Default: “”
validate.non.null	By default, the JDBC connector will validate that all incrementing and timestamp tables have NOT NULL set for the columns being used as their ID/timestamp. If the tables don’t, JDBC connector will fail to start. Setting this to false will disable these checks. • Type: boolean • Default: true **Note:** If this parameter is false, specify exactly all columns that need to be imported to MapR Event Store For Apache Kafka in the query parameter. For example instead of `"query" : "select * from table"`, use `"query" : "select col1, col2 from table"`

Table (Continued)

Parameters	Description
incrementing.column.name	The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an auto-incrementing column. This column may not be nullable. • Type: string • Default: “”
query	If specified, the query to perform to select new or updated rows. Use this setting to join tables, select subsets of columns in a table, or filter data. If used, this connector will only copy data using this query – whole-table copying will be disabled. Different query modes may still be used for incremental updates, but in order to properly construct the incremental query, it must be possible to append a WHERE clause to this query (i.e. no WHERE clauses may be used). If you use a WHERE clause, it must handle incremental queries itself. • Type: string • Default: “”
poll.interval.ms	Frequency (milliseconds) to poll for new data in each table. • Type: int • Default: 5000
batch.max.rows	Maximum number of rows to include in a single batch when polling for new data. This setting can be used to limit the amount of data buffered internally in the connector. • Type: int • Default: 100
table.poll.interval.ms	Frequency (milliseconds) to poll for new or removed tables, which may result in updated task configurations to start polling for data in added tables or stop polling for data in removed tables. • Type: long • Default: 60000
topic.prefix	Prefix to prepend to table names to generate the name of the Kafka topic to publish data to, or in the case of a custom query, the full name of the topic to publish to. For example: `/path/to/stream:topic-prefix-`. • Type: string • Default: “”

last-updated: Apr 11, 2022

Table (Continued)

Parameters	Description
table.types	By default, the JDBC connector will only detect tables with type TABLE from the source Database. This config allows a command separated list of table types to extract. Options include: • TABLE • VIEW • SYSTEM TABLE • GLOBAL TEMPORARY • LOCAL TEMPORY • ALIAS • SYNONYM Typically, TABLE or VIEW are used. • Type: list • Default: TABLE
timestamp.delay.interval.ms	How long to wait after a row with certain timestamp appears before it is included in the result. You may choose to add some delay to allow transactions with earlier timestamp to complete. The first execution fetches all available records (for example, starting at timestamp 0) until the current time minus the delay. Every following execution retrieves data from the last time data was fetched until the current time minus the delay. • Type: long • Default: 0

JDBC Sink Configuration Options

Table

Parameters	Description
connection.url	JDBC connection URL. • Type: string • Default: “”
connection.user	JDBC connection user. • Type: string • Default: NULL
connection.password	JDBC connection password. • Type: password • Default: NULL

last-updated: Apr 11, 2022

Table (Continued)

Parameters	Description
insert.mode	The insertion mode to use. • INSERT - Use standard SQL INSERT statements. • UPSERT - Use the appropriate upsert semantics for the target database if it is supported by the connector. For example: INSERT or IGNORE • UPDATE - Use the appropriate update semantics for the target database if it is supported by the connector. For example: UPDATE • Type: string • Default: INSERT • Valid Values: insert, upsert, update
batch.size	Specifies how many records to attempt to batch together for insertion into the destination table, when possible. • Type: int • Default: 3000 • Valid Values: 0,...
table.name.format	A format string for the destination table name, which may contain `${topic}` as a placeholder for the originating topic name. For example, table_${topic} for the topic `orders` maps to the table name `table_orders`. • Type: string • Default: ${topic}
pk.mode	The primary key mode, also refer to pk.fields documentation for interplay. Supported modes are: • none - No keys utilized. • kafka - Kafka coordinates are used as the PK. • record_key - Field(s) from the record key are used, which may be a primitive or a struct. • record_value - Field(s) from the record value are used, which must be a struct. • Type: string • Default: none • Valid Values: none, kafka, record_key, record_value

last-updated: Apr 11, 2022

Table (Continued)

Parameters	Description
pk.fields	List of comma-separated primary key field names. The runtime interpretation of this config depends on the pk.mode: • none - Ignored as no fields are used as primary key in thes mode. • kafka - Must be a trio representing the Kafka coordinates. Defaults to __connect_topic,__connect_partition,__connect_offset if empty. • record_key - If empty, all fields from the key struct will be used, otherwise used to extract the desired fields - for primitive key only a single field name must be configured. • record_value - If empty, all fields from the value struct will be used, otherwise used to extract the desired fields. • Type: list • Default: ""
fields.whitelist	List of comma-separated record value field names. If empty, all fields from the record value are utilized, otherwise used to filter to the desired fields. Note: pk.fields is applied independently in the context of which field(s) form the primary key columns in the destination database, while this configuration is applicable for the other columns. • Type: list • Default: ""
auto.create	Whether to automatically create the destination table based on record schema if it is found to be missing by issuing CREATE. • Type: boolean • Default: false
auto.evolve	Whether to automatically add columns in the table schema when found to be missing relative to the record schema by issuing ALTER. • Type: boolean • Default: false
max.retries	The maximum number of times to retry on errors before failing the task. • Type: int • Default: 10 • Valid Values: 0,..
retry.backoff.ms	The time in milliseconds to wait following an error before a retry attempt is made. • Type: int • Default: 3000 • Valid Values: 0,..

Whitelists and Custom Query JDBC Examples
This section provides common usage scenarios using whitelists and custom queries.

Using Whitelists

Use a whitelist to limit changes to a subset of tables in a MySQL database, using id and modifiedcolumns that are standard on all whitelisted tables to detect rows that have been modified. This mode is the most robust because it can combine the unique, immutable row IDs with modification timestamps to guarantee modifications are not missed even if the process dies in the middle of an incremental update query.

The following is an example of a whitelist.

Note: Before running this example, you need to create the stream `/kafka-connect`

```
name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector tasks.max=10
connection.url=jdbc:mysql://mysql.example.com:3306/my_database?
user=alice&password=secret
table.whitelist=users,products,transactions
mode=timestamp+incrementing
timestamp.column.name=modified
incrementing.column.name=id
topic.prefix=/kafka-connect:mysql-
```

Using Custom Queries

Use a custom query instead of loading tables to join data from multiple tables. As long as the query does not include its own filtering, you can still use the built-in modes for incremental queries (in this case, using a timestamp column).

Note: This limits you to a single output per connector and because there is no table name, the topic “prefix” is actually the full topic name in this case.

The following is an example of a custom query.

Note: Before running this example, you need to create the stream `/kafka-connect`

```
name=mysql-whitelist-timestamp-source
        connector.class=io.confluent.connect.jdbc.JdbcSourceConnector
        tasks.max=10
        connection.url=jdbc:postgresql://postgres.example.com/test_db?
user=bob&password=secret&ssl=true
        query=SELECT users.id,
        users.name,
        transactions.timestamp,
        transactions.user_id,
        transactions.payment FROM users JOIN transactions ON (users.id =
transactions.user_id)
        mode=timestamp
        timestamp.column.name=timestamp
        topic.prefix=/kafka-connect:mysql-joined-data
```

Streaming Data JDBC Examples
This section provides common usage scenarios of streaming data between different databases to or from MapR Event Store For Apache Kafka.

Streaming Data from MapR Event Store For Apache Kafka to a MySQL Database

The following is example code for streaming data from MapR Event Store For Apache Kafka stream topics to a MySQL database.

```
POST /connectors HTTP/1.1
 Host: connect.example.com
 Content-Type: application/json
 Accept: application/json
{"name": "mysql-sink-connector",
"config": {
"connector.class":"io.confluent.connect.jdbc.JdbcSinkConnector",
"connection.url":"jdbc:mysql://hostname:3306/mysql_db?
user=<user>&password=<password>",
"auto.create":"true",
"topics":"/kafka-connect:topic1",
"tasks.max":"2",
"insert.mode":"insert"
}}
```

Streaming Data from a MySQL Database to MapR Event Store For Apache Kafka

The following is example code for streaming data from a MySQL database to MapR Event Store For Apache Kafka stream topics.

```
POST /connectors HTTP/1.1
 Host: connect.example.com
 Content-Type: application/json
 Accept: application/json
{"name": "mysql-source-connector",
"config":
{ "connector.class":"io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url":"jdbc:mysql://hostname:3306/newdb?
user=<user>&password=<password>"
"mode":"incrementing",
"incrementing.column.name":"id",
"topic.prefix":"/kafka-connect:mysql-",
"tasks.max":"1"
}}
```

Streaming Data from a Hive Database to MapR Event Store For Apache Kafka

The following is example code for streaming data from a Hive database to MapR Event Store For Apache Kafka stream topics.

```
POST /connectors HTTP/1.1
 Host: connect.example.com
 Content-Type: application/json
 Accept: application/json
{"name": "hive-source-connector",
"config": {
"connector.class":"io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url":"jdbc:hive2://hostname:10000/
database_name;user=<user>;password=<pa
ssword>",
"mode":"bulk",
"topic.prefix":"/kafka-connect:hive-",
"tasks.max":"1"
}}
```

Note: For a secure MapR Data Platform cluster, use next connection.url jdbc:hive2://hostname:10000/database_name;auth=maprsasl

.

Managing Kafka Connect Services
Lists the commands you use to start, stop, or restart Kafka Connect Services

Use the `maprcli node services` command with the `-action` parameter as follows:

```
maprcli node services -name kafka-connect -action start -nodes <node_list>
```

```
maprcli node services -name kafka-connect -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-connect -action restart -nodes
<node_list>
```

For more information see node services on page 1730

HDFS Connector
These topics describe the Kafka Connect for MapR Event Store For Apache Kafka HDFS connector, driver, and configuration parameters.

The HDFS connector allows you to export data from MapR Event Store For Apache Kafka topics to MapR File System or HDFS files in a variety of formats. In addition, Hive integration is available, which can be use to make data immediately available for querying with HiveQL.

HDFS Configuration Options
Use the following parameters to configure the Kafka Connect for MapR Event Store For Apache Kafka HDFS connector.

Note: For the HDFS connector, both Avro and Parquet files can be written.

In *standalone* mode, specify the HDFS connector configuration in the **quickstart-hdfs.properties** file. You can also configure the offset storage location and the port for the REST interface, which are specified in the **connect-standalone.properties** file. See Configuring in Standalone Mode on page 3906.

```
/opt/mapr/kafka-connect-hdfs/kafka-connect-hdfs-<version>/etc/
kafka-connect-hdfs/quickstart-hdfs.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See POST /connectors on page 3933 and PUT /connectors/(string:name)/config on page 3935 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See Configuring in Distributed Mode on page 3906 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

Table

Parameter	Description
flush.size	Number of records written to the filesystem before invoking file commits. • Type: int • Default: ""

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description
hdfs.url	The filesystem connection URL. This configuration has the format of maprfs:// hostname:port and specifies the MapR filesystem to export data to. • Type: string • Default: ""
connect.hdfs.keytab	The path to the keytab file for the HDFS connector principal. This keytab file should only be readable by the connector user. • Type: string • Default: ""
connect.hdfs.principal	The principal used when the filesystem is using Kerberos for authentication. • Type: string • Default: ""
format.class	The format class used when writing data to the filesystem. • Type: string • Default: "io.confluent.connect.hdfs.avro.AvroFormat" **Note:** If you want to write to a Parquet set, use "io.confluent.connect.hdfs.parquet.ParquetFormat"
hadoop.conf.dir	The Hadoop configuration directory. • Type: string • Default: ""
hadoop.home	The Hadoop home directory. • Type: string • Default: ""
hdfs.authentication.kerberos	Specifies whether the filesystem uses Kerberos for authentication. • Type: boolean • Default: false
hdfs.namenode.principal	The Kerberos principal for CLDB. • Type: string • Default: ""
hive.conf.dir	The Hive configuration directory. • Type: string • Default: ""

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description
hive.database	The database used when the connector creates tables in Hive. • Type: string • Default: "default"
hive.home	The Hive home directory. • Type: string • Default: ""
hive.integration	Specifies whether Hive is integrated when running the connector. • Type: boolean • Default: false
hive.metastore.uris	The Hive metastore URIs. Can be an IP address or fully-qualified domain name and port of the metastore host. • Type: string • Default: ""
logs.dir	Top-level filesystem directory to store the write ahead logs. • Type: string • Default: "logs"
partitioner.class	The partitioner used when writing data to the filesystem. You can use DefaultPartitioner, which preserves the Kafka partitions; FieldPartitioner, which partitions the data to different directories according to the value of the partitioning field specified in partition.field.name; TimeBasedPartitioner, which partitions data according to the time ingested to the filesystem. • Type: string • Default: "io.confluent.connect.hdfs.partitioner.DefaultPartitioner"
rotate.interval.ms	The time interval (milliseconds) before invoking file commits. This configuration ensures that file commits are invoked every configured interval. This configuration is useful when data ingestion rate is low and the connector didn't write enough messages to commit files. The default value -1 means that this feature is disabled. • Type: long • Default: -1
schema.compatibility	The schema compatibility rule used when the connector is observing schema changes. The supported configurations are NONE, BACKWARD, FORWARD and FULL. • Type: string • Default: "NONE"

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description
topics	A list of topics to use as input for the HDFS connector. • Type: string • Default: ""
topics.dir	Top-level filesystem directory to store the data ingested from Kafka. • Type: string • Default: "topics"
locale	The locale used when partitioning with TimeBasedPartitioner. • Type: string • Default: ""
partition.duration.ms	The duration of a partition (milliseconds) used by TimeBasedPartitioner. The default value -1 means that TimeBasedPartitioner is not being used. • Type: long • Default: -1
partition.field.name	The name of the partitioning field when FieldPartitioner is used. • Type: string • Default: ""
path.format	This configuration is used to set the format of the data directories when partitioning with TimeBasedPartitioner. The format set in this configuration converts the Unix timestamp to proper directories strings. For example, if you setpath.format='year'=YYYY/'month'=MM/'day'=dd/'hour'=HH/, the data directories will have the format /year=2015/month=12/day=07/hour=15 • Type: string • Default: ""
shutdown.timeout.ms	Clean shutdown timeout. This makes sure that asynchronous Hive metastore updates are completed during connector shutdown. • Type: long • Default: 3000
timezone	The timezone to use when partitioning with TimeBasedPartitioner. • Type: string • Default: ""

Table (Continued)

Parameter	Description
filename.offset.zero.pad.width	Sets the width to the zero-pad offsets in the filesystem filenames. If the offsets are too short it provides fixed width filenames that can be ordered by simple lexicographic sorting. • Type: int • Default: 10
kerberos.ticket.renew.period.ms	The period in milliseconds to renew the Kerberos ticket. • Type: long • Default: 3600000 (milliseconds)
retry.backoff.ms	Used to notify Kafka Connect to retry delivering a message batch or performing recovery in case of transient exceptions. The retry backoff is in milliseconds. • Type: long • Default: 5000 (milliseconds)
schema.cache.size	The sized of the schema cache used in the Avro converter. • Type: int • Default: 1000
storage.class	The underlying storage layer. The default is MapR-FS. • Type: string • Default: "io.confluent.connect.hdfs.storage.HdfsStorage"

HDFS Examples
These examples provides sample code for streaming data to and from MapR File System.

Streaming Data from MapR Event Store For Apache Kafka to MapR File System

This example provides sample code for streaming data from MapR Event Store For Apache Kafka to MapR File System.

```
POST /connectors HTTP/1.1
        Host: connect.example.com
        Content-Type: application/json
        Accept: application/json

        {
        "name": "maprfs-sink-connector",
        "config": {
        "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
        "tasks.max": "1",
        "topics": "/kafka-connect:topic1",
        "hdfs.url": "maprfs:///",
        "flush.size": "5",
        "rotate.interval.ms": "1000"
        }
        }
```

Streaming Data from MapR Event Store For Apache Kafka to MapR File System in Parquet

This example provides sample code for streaming data from MapR Event Store For Apache Kafka to MapR File System in Parquet.

```
POST /connectors HTTP/1.1
        Host: connect.example.com
        Content-Type: application/json
        Accept: application/json

        {
        "name":"hdfs-connector-parquet",
        "config":{
        "connector.class":"io.confluent.connect.hdfs.HdfsSinkConnector",
        "tasks.max":"10",
        "topics":"/kafka-connect:topic2",
        "hdfs.url":"maprfs:///",
        "format.class":"io.confluent.connect.hdfs.parquet.ParquetFormat",
        "flush.size":"3"
        }
        }
```

Hive Integration

This topic describes how to integrate a Hive database with Kafka Connect for MapR Event Store For Apache Kafka.

Kafka Connect for MapR Event Store For Apache Kafka supports Hive integration. If a Hive database is enabled, an external Hive table is created and that can be queried via Hive shell.

Note: As of Kafka Connect 4.0.0 for MapR Event Store For Apache Kafka Hive 2.1 is supported.

The Hive table name is constructed using a topic name in the following manner:

- In the MapR Event Store For Apache Kafka topic, /stream_path:topic-name, the first forward slash (/) is removed, all other slashes are translated to underscores (_), and the colon (:) is translated to an underscore (_).
- All non-alphanumeric and non-underscore characters are removed from the string representing the Hive table name.

Renaming Topics for Hive usage

The following example shows a topic named /test-12:test1 is renamed for Hive usage.

```
$ hadoop fs -ls -R /topics
        drwxr-xr-x   - mapr mapr          1 2016-10-05 19:46 /topics/+tmp
        drwxr-xr-x   - mapr mapr          1 2016-10-05 19:46 /topics/+tmp/
test12_test1
        drwxr-xr-x   - mapr mapr          0 2016-10-05 19:50 /topics/+tmp/
test12_test1/partition=1
        drwxr-xr-x   - mapr mapr          1 2016-10-05 19:46 /topics/
test12_test1
        drwxr-xr-x   - mapr mapr          2 2016-10-05 19:50 /topics/
test12_test1/partition=1
        -rwxr-xr-x   3 mapr mapr        241 2016-10-05 19:47 /topics/
test12_test1/partition=1/test12_test1+1+0000000078+0000000080.avro
        -rwxr-xr-x   3 mapr mapr        241 2016-10-05 19:50 /topics/
test12_test1/partition=1/test12_test1+1+0000000081+0000000083.avro
```

last-updated: Apr 11, 2022

The following query and results shows the topic data in the Hive table.

```
> select * from test12_test1;
        OK
        16/10/05 20:06:59 INFO mapred.FileInputFormat: Total input paths to

Streaming Data from MapR Event Store For Apache Kafka to the Hive database

This example provides sample code for streaming data from MapR Event Store For Apache Kafka to the Hive database.

```
POST /connectors HTTP/1.1
        Host: connect.example.com
        Content-Type: application/json
        Accept: application/json

        {
        "name":"hdfs-connector-hive",
          "config":{
          "hive.integration":"true",
          "hive.database":"db3",
            "hive.conf.dir":"/opt/mapr/hive/hive-1.2/conf",
          "hive.metastore.uris":"thrift://localhost:9083",
          "schema.compatibility":"BACKWARD",
          "connector.class":"io.confluent.connect.hdfs.HdfsSinkConnector",
          "tasks.max":"1",
          "topics":"/kafka-connect:topic3",
          "hdfs.url":"maprfs:///",
          "flush.size":"1"
          }
        }
```

REST API

The Kafka Connect REST API for MapR Event Store For Apache Kafka manages connectors.

In standalone mode, a connector request is submitted on the command line. This mode is useful for getting status information, adding and removing connectors without stopping the process, and testing and debugging.

In distributed mode, the REST API is the primary interface to the cluster. Requests can be made to any cluster member where the REST API automatically forwards requests.

Content Types

The REST API supports application/json as both the request and response entity content type. For example:

```
Accept: application/json
Content-Type: application/json
```

Status & Errors

The REST API returns standards-compliant HTTP statuses.

Note: By default, the Kafka Connect REST API for MapR Event Store For Apache Kafka service in run on port 8083.

Table

HTTP	URI	Description
GET	/connectors	Gets a list of active connectors.
POST	/connectors	Creates a new connector, returning the current connector information is successful.
GET	/connectors/(string:name)	Gets information about the connector.
GET	/connectors/(string:name)/config	Gets the configuration for the connector.
PUT	/connectors/(string:name)/config	Creates a new connector using the given configuration or updates the configuration for an existing connector.
GET	/connectors/(string:name)/tasks	Gets a list of tasks current running for the connector.
DELETE	/connectors/(string:name)/	Deletes a connector, halting all tasks and deleting its configuration.
GET	/connector-plugins	Lists the connector plugins available on this worker,
POST	/connectors/(string:name)/restart	Restarts a connector and its tasks.
GET	/connectors/(string:name)/tasks/(int:taskId)/status	Gets the status for a task.
POST	/connectors/(string:name)/tasks/(int:number of tasks)/restart	Restarts an individual task.
PUT	/connectors/(string:name)/pause	Pauses the connector and its tasks, which stops message processing until the connector is resumed.
PUT	/connectors/(string:name)/resume	Resumes a paused connector or do nothing if the connector is not paused.
GET	/connectors/(string:name)/status	Get current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

GET /connectors
Gets a list of active connectors.

Syntax

```
http://<host>:8083/connectors
```

Request Example

```
GET /connectors HTTP/1.1 Host: connect.example.com Accept: application/json
```

Response Example

The response JSON object is in the following form:

- **connectors** (*array*) – List of connector names.

```
HTTP/1.1 200 OK Content-Type: application/json  ["my-jdbc-source",
"my-hdfs-sink"]
```

last-updated: Apr 11, 2022

POST /connectors
Creates a new connector, returning the current connector information if successful.

Description

The POST request along with the parameters is used to create connectors in distributed mode.

The following table provides the parameters needed to create a new connector.

Table

Parameters	Description
name (*string*)	Name of the created connector
config (*map*)	Configuration parameters for the connector. See HDFS Connector on page 3925 and JDBC Connector on page 3915 for configuration options.
tasks (*array*)	List of active tasks generated by the connector.
tasks[i].connector (*string*)	Name of the connector that the task belongs to.
tasks[i].task (*int*)	Task ID within the connector.

Syntax

```
http://<host>:8083/connectors/?
name=<connector_name>&config=<config_parameters>
```

Request Example

```
POST /connectors HTTP/1.1 Host: connect.example.com Content-Type:
application/json Accept: application/json
{     "name": "hdfs-sink-connector",
        "config": {
          "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
          "tasks.max": "1",
          "topics": "test-topic",
          "hdfs.url": "hdfs://fakehost:9000",
          "hadoop.conf.dir": "/opt/hadoop/conf",
          "hadoop.home": "/opt/hadoop",
          "flush.size": "100",
          "rotate.interval.ms": "1000"     }
 }
```

Response Example

The response JSON object is in the following form:

- **name** (*string*) – Name of the connector to create.
- **config** (*map*) – Configuration parameters for the connector. All values should be strings.
- **tasks** (*array*) – List of active tasks generated by the connector.

```
HTTP/1.1 201 Created Content-Type: application/json
{
      "name": "hdfs-sink-connector",
      "config":
```

last-updated: Apr 11, 2022

```
        {
          "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
          "tasks.max": "10",
          "topics": "test-topic",
          "hdfs.url": "hdfs://fakehost:9000",
          "hadoop.conf.dir": "/opt/hadoop/conf",
          "hadoop.home": "/opt/hadoop",
          "flush.size": "100",
          "rotate.interval.ms": "1000"
        },
      "tasks": [
          { "connector": "hdfs-sink-connector", "task": 1 },
          { "connector": "hdfs-sink-connector", "task": 2 },
          { "connector": "hdfs-sink-connector", "task": 3 }
       ]
}
```

GET /connector/(string:name)
Gets information about a specific connector.

Description

Table

Parameters	Description
name (*string*)	Name of the created connector.
config (*map*)	Configuration parameters for the connector.
tasks (*array*)	List of active tasks generated by the connector.
tasks[i].connector (*string*)	Name of the connector the task belongs to.
tasks[i].task (*int*)	Task ID within the connector.

Syntax

```
http://<host>:8083/connectors/<name>
```

Request Example

```
GET /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
Accept: application/json
```

Response Example

```
HTTP/1.1 200 OK Content-Type: application/json
{     "name": "hdfs-sink-connector",
  "config": {
    "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"     },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
```

```
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }     ]
 }
```

GET /connectors/(string:name)/config
Gets the configuration for the connector.

Description

Table

Parameters	Description
config (*map*)	Configuration parameters for the connector.

Syntax

```
http://<host>:8083/connectors/<string_name/config
```

Request Example

```
GET /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
```

Response Example

```
HTTP/1.1 200 OK Content-Type: application/json
{     "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
      "tasks.max": "10",
      "topics": "test-topic",
      "hdfs.url": "hdfs://fakehost:9000",
      "hadoop.conf.dir": "/opt/hadoop/conf",
      "hadoop.home": "/opt/hadoop",
      "flush.size": "100",
      "rotate.interval.ms": "1000"
}
```

PUT /connectors/(string:name)/config
Creates a new connector using the given configuration or updates the configuration for an existing connector. Returns information about the connector after the change has been made.

Description

The PUT request along with the parameters is used to create connectors in distributed mode.

Table

Parameters	Description
name (*string*)	Name of the created connector.
config (*map*)	Configuration parameters for the connector. See HDFS Connector on page 3925 and JDBC Connector on page 3915 for configuration options.
tasks (*array*)	List of active tasks generated by the connector.
tasks[i].connector (*string*)	Name of the connector that the task belongs to.
tasks[i].task (*int*)	Task ID within the connector.

last-updated: Apr 11, 2022

Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

Request Example

```
PUT /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
{
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
}
```

Response Example

The response JSON object is in the following form:

- config (map) – Configuration parameters for the connector. All values should be strings.

Note: In this example, the return status indicates that the connector was created. In the case of a configuration update, the status would be 200 OK.

```
HTTP/1.1 201 Created Content-Type: application/json
{
    "name": "hdfs-sink-connector",
    "config":
        {
            "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
            "tasks.max": "10",
            "topics": "test-topic",
            "hdfs.url": "hdfs://fakehost:9000",
            "hadoop.conf.dir": "/opt/hadoop/conf",
            "hadoop.home": "/opt/hadoop",
            "flush.size": "100",
            "rotate.interval.ms": "1000"
            },
     "tasks": [
        { "connector": "hdfs-sink-connector", "task": 1 },
        { "connector": "hdfs-sink-connector", "task": 2 },
        { "connector": "hdfs-sink-connector", "task": 3 }     ]
}
```

GET /connectors/(string:name)/tasks
Gets a list of tasks currently running for the connector.

Description

Table

Parameters	Description
tasks (*array*)	List of active task configurations created by the connector.
tasks[i].id (*string*)	ID of the task.

Table (Continued)

Parameters	Description
tasks[i].id.connector (*string*)	Name of the connector that the task belongs to.
tasks[i].id.task (*int*)	Task ID within the connector.
tasks[i].config (*map*)	Configuration parameters for the task.

Syntax

```
http://<host>:8083/connectors/<connector_name>/tasks
```

Request Example

```
GET /connectors/hdfs-sink-connector/tasks HTTP/1.1 Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK
[     {
          "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
          "topics": "test-topic",
          "hdfs.url": "hdfs://fakehost:9000",
          "hadoop.conf.dir": "/opt/hadoop/conf",
          "hadoop.home": "/opt/hadoop",
          "flush.size": "100",
          "rotate.interval.ms": "1000"     },
       {
          "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
          "topics": "test-topic",
          "hdfs.url": "hdfs://fakehost:9000",
          "hadoop.conf.dir": "/opt/hadoop/conf",
          "hadoop.home": "/opt/hadoop",
          "flush.size": "100",
          "rotate.interval.ms": "1000"     }
]
```

DELETE /connectors/(string:name)/
Deletes a connector by halting all tasks and deleting its configuration.

Syntax

```
http://<host>:8083/connectors/<connector_name>/
```

Request Example

```
DELETE /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
```

Response Example

```
HTTP/1.1 204 No Content
```

GET /connector-plugins
Lists the connector plugins available on this worker.

Syntax

```
http://<host>:8083/connector-plugins>
```

Request Example

```
GET /connector-plugins/ HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK

[
    {
        "class": "io.confluent.connect.hdfs.HdfsSinkConnector"
    },
    {
        "class": "io.confluent.connect.jdbc.JdbcSourceConnector"
    }
]
```

POST /connectors/(string:name)/restart
Restarts a connector and its tasks.

Syntax

```
http://<host>:8083/connectors/<string_name>/restart
```

Request Example

```
POST /connectors/hdfs-sink-connector/restart HTTP/1.1
Host: connect.example.com
```

Response Example

Return 409 (Conflict) if rebalance is in process.

```
HTTP/1.1 200 OK
```

GET /connectors/(string:name)/tasks/(int:taskId)/status
Gets the status for a task.

Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<task ID>/status
```

Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/status HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK

{"state":"RUNNING","id":1,"worker_id":"192.168.86.101:8083"}
```

POST /connectors/(string:name)/tasks/(int:number of tasks)/restart
Restarts an individual task.

Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<number of tasks>/restart
```

Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/restart HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 200 OK
```

PUT /connectors/(string:name)/pause
Pauses the connector and its tasks, which stops message processing until the connector is resumed.

Syntax

```
http://<host>:8083/connectors/<string_name>/pause
```

Note: This call is asynchronous and the tasks will not transition to PAUSED state at the same time.

Request Example

```
PUT /connectors/hdfs-sink-connector/pause HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 202 Accepted
```

PUT /connectors/(string:name)/resume
Resumes a paused connector or do nothing if the connector is not paused.

Syntax

```
http://<host>:8083/connectors/<string_name>/resume
```

Note: This call is asynchronous and the tasks will not transition to RUNNING state at the same time.

last-updated: Apr 11, 2022

Request Example

```
PUT /connectors/hdfs-sink-connector/resume HTTP/1.1
Host: connect.example.com
```

Response Example

```
HTTP/1.1 202 Accepted
```

GET /connectors/(string:name)/status
Gets current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

Syntax

```
http://<host>:8083/connectors/<string_name>/status
```

Request Example

```
GET /connectors/hdfs-sink-connector/status HTTP/1.1
Host: connect.example.com
```

Response Example

The response JSON object includes the following:

- name (string) – Name of the connector
- connector (map) – Map containing connector status
- tasks[i] (map) – Map containing the task status

```
HTTP/1.1 200 OK

{
    "name": "hdfs-sink-connector",
    "connector": {
        "state": "RUNNING",
        "worker_id": "localhost:8083"
    },
    "tasks":
    [
        {
            "id": 0,
            "state": "RUNNING",
            "worker_id": "localhost:8083"
        },
        {
            "id": 1,
            "state": "FAILED",
            "worker_id": "localhost:8083",
            "trace":
"org.apache.kafka.common.errors.RecordTooLargeException\n"
        }
    ]
}
```

Saving Kafka Connect Configurations

Describes how Kafka Connect configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka Connect is stored in a folder with a timestamp.

- Files are saved *and* overwritten by new configuration files:
  - when upgrading from 4.1.0 to 5.1.2.
  - when upgrading from 5.1.2 to 10.0.0.
- Files are saved only (*not* overwritten):
  - when upgrading from 5.1.2 to 5.1.2.

Example

The following example shows the list of configuration files that are saved after upgrading from EEP 6.3.1 to EEP 6.3.2:

```
ls /opt/mapr/kafka
kafka-1.1.1  kafka-1.1.1.202009040123  kafkaversion

ls /opt/mapr/kafka/kafka-1.1.1.202009040123/config/
connect-console-sink.properties    connect-distributed.properties
connect-file-source.properties  connect-standalone.properties
connect-console-source.properties  connect-file-sink.properties
connect-log4j.properties
```

Kafka Schema Registry

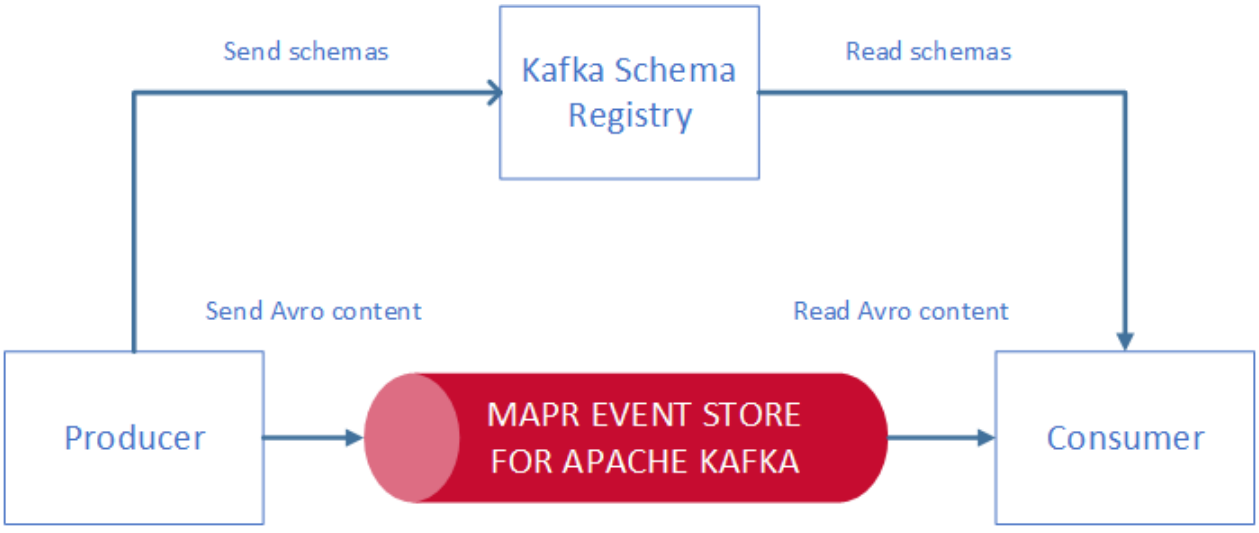
Kafka Schema Registry provides a RESTful interface for storing and retrieving schemas.

Note: This feature is presented as a *developer preview*. Developer previews are not tested for production environments, and should be used with caution.

Schema Registry can store and retrieve Avro schemas.

When you implement Kafka Schema Registry for your data schemas, they can self-evolve for compatibility with downstream consumers.

Kafka Schema Registry acts as a standalone serving layer for metadata, interacting with both the producer and consumer. It stores schemas for keys and values of records.



last-updated: Apr 11, 2022

Kafka Schema Registry enables you to perform the following tasks:

- Store a versioned history of all schemas.
- Provide multiple compatibility settings.
- Support schema evolution according to the configured compatibility settings and the expanded support for the schema format.
- Provide serializers that interface with Kafka clients and manage schema storage and retrieval for Kafka messages that are sent in one of the supported schema formats.
- Develop your own custom formats to use with this interface.

You can also perform these tasks:

- List schemas by subject and also list all versions of a subject (schema).
- Retrieve a schema by version or ID.
- Retrieve the latest version of a schema.
- Verify that a schema is compatible with a certain version.

Architecture

Kafka Schema Registry is designed to be distributed with a single master architecture. ZooKeeper coordinates the master election, based on the configuration. Kafka-coordinated master election is not currently supported.

MapR Event Store For Apache Kafka is designed to be the durable backend for schema registry, providing a write-ahead change log for the state of schema registry and the schemas it contains.

Interoperability

Kafka Schema Registry can interface with the following components:

- Kafka Client (producer, consumer APIs)
- KStreams
- KSQL
- Kafka Connect
- Kafka REST

Performance and Scalability Impact

You can improve performance by decreasing the size of the message payload. Without Kafka Schema Registry, the message payload contains the user data and the schema metadata. With the Kafka Schema Registry, the message payload contains the user data and only the schema ID that is unique for each schema.

For scalability, you can launch Kafka Schema Registry on several nodes.

For More Information

- Installing Kafka Schema Registry
- Confluent Schema Registry documentation

Building and Deploying Kafka Schema Registry
To build and deploy Kafka Schema Registry with Maven, you must first install development versions of Kafka `common` and `rest-utils` utilities.

You can run Kafka Schema Registry instances on several cluster nodes. One node is the primary node and the other ones are secondary nodes.

Kafka Schema Registry requires ZooKeeper and MapR Event Store For Apache Kafka.

The REST interface to schema registry includes a built-in Jetty server. The wrapper scripts `bin/schema-registry-start` and `bin/schema-registry-stop` are the recommended methods for starting and stopping the service.

In Apache Kafka, a schema is produced when:

- A message is produced and there is no equivalent schema in the schema registry
- A schema is created for key or value portion of the message

The associated schema subject is a “topic-key”:

- Each schema is associated with a version
- Every schema gets a globally unique ID

The consumer gets the messages’ schema using the schema ID:

```
$ curl -X GET http://localhost:8087/schemas/ids/1
       {"schema":"\"string\""}
```

You can also query a schema for a given topic using the associated schema subject. For example, for `topic1` (for either key or value), `schema`, `all`, `latest`, or `specific` schema versions can be queried using the following REST commands:

```
$ curl -X GET http://localhost:8087/subjects/topic1-value/versions
    [1]
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
    {"subject":"Kafka-value","version":1,"id":1,"schema":"\"string\""}
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
    {"subject":"Kafka-value","version":1,"id":1,"schema":"\"string\""}
```

For a complete list of supported APIs, see Confluent Schema Registry API Reference.

Kafka Schema Registry Limitations
Describes the limitations related to the Kafka Schema Registry.

- Kafka REST support limitation

  Avro schema is not supported for Kafka REST.

- Security limitation

  MapR ticket based authentication, SSL, and other security mechanisms are not supported.

- MapR Installer

  You cannot use the MapR Installer to install the Kafka Schema Registry.

- Avro-console-producer and Avro-console-consumer

  You cannot use avro-console-producer and avro-console-consumer in the current release.

- SchemaParseException

  Loading data via JDBC Source connector from Hive throws an exception.

last-updated: Apr 11, 2022

- Replication Limitation

  Replication for Kafka Schema Registry is not supported.

- KSQL and Kafka Connect Limitation

  To work with Avro schemas, you need to manually modify the KSQL and Kafka Connect configuration files.

Kafka Schema Registry Use Cases
Describes typical use cases to register and query a schema and serialize and deserialize data.

Use Case 1: Registering and Querying a Schema for a Kafka Topic

While Kafka topics do not have a schema, having an external store that tracks this metadata for a given Kafka topic helps answer the following questions:

- What are the different events in any given Kafka topic?
- What can I put into a given Kafka topic?
- Do all Kafka events have a similar type of schema?
- How do I parse and use the data in a given Kafka topic?

Sample workflow code:

The following sample commands register and query a schema in a Kafka topic:

```
# Register a new version of a schema under the subject "Kafka-key"

$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
    --data '{"schema": "{\"type\": \"string\"}"}' \
    http://localhost:8087/subjects/Kafka-key/versions
    {"id":1}

# Register a new version of a schema under the subject "Kafka-value"

$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
    --data '{"schema": "{\"type\": \"string\"}"}' \
    http://localhost:8087/subjects/Kafka-value/versions
    {"id":1}

# List all subjects

$ curl -X GET http://localhost:8087/subjects
    ["Kafka-value","Kafka-key"]

# List all schema versions registered under the subject "Kafka-value"

$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions
    [1]

# Fetch a schema by globally unique id 1

$ curl -X GET http://localhost:8087/schemas/ids/1
    {"schema":"\"string\""}

# Fetch version 1 of the schema registered under subject "Kafka-value"

$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
    {"subject":"Kafka-value","version":1,"id":1,"schema":"\"string\""}
```

```
# Fetch the most recently registered schema under subject "Kafka-value"

$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
    {"subject":"Kafka-value","version":1,"id":1,"schema":"\"string\""}
```

Use Case 2: Serializing and Deserializing Data in a Kafka Topic

In addition to storing the schema metadata for a topic, Kafka Schema Registry also provides mechanisms for reading and writing data to a Kafka topic in supported formats.

You can plug the appropriate Serializer into the KafkaProducer to send messages to Kafka. A Serializer is available for each of the supported formats.

For Avro, use the `KafkaAvroSerializer`.

Currently, primitive types of `null`, `Boolean`, `Integer`, `Long`, `Float`, `Double`, `String`, `byte[]`, and the complex `IndexedRecord` type are supported.

Sending data of other types to KafkaAvroSerializer causes a SerializationException to occur. Typically, `IndexedRecord` is used for the value of the Kafka message. If used, the key of the Kafka message is often of one of the primitive types.

For example, when sending a message to a topic `t`, the schema for the key and the value is automatically registered in the Kafka Schema Registry under the subject `t-key` and `t-value`, respectively, if the compatibility test passes. The only exception is when the null type is never registered in the Kafka Schema Registry.

For consuming messages from a Kafka topic, the deserializer can be plugged analogically to the serializer.

Use Case 3: Supporting KSQL Streams or Tables in Supported formats

KSQL requires that you use the Kafka Schema Registry to create KSQL Streams or Tables in supported formats.

Schema Registry supports Avro format. Specify `VALUE_FORMAT='AVRO'` to work with topics that contain messages in Avro format.

Sample workflow code:

The following commands create and register a schema using an Avro console producer:

```
# Create a stream

$ maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p

# Use Avro console producer to create and register a schema

/sample-stream:pageviews-avro-topic

CREATE STREAM pageviews WITH (KAFKA_TOPIC='pageviews-avro-topic',
VALUE_FORMAT='AVRO');

CREATE TABLE users WITH (KAFKA_TOPIC='users-avro-topic',
VALUE_FORMAT='AVRO',
        KEY='userid');
```

Managing Kafka Schema Registry
Describes how to manage the internal stream for Kafka Schema Registry.

Schema Registry Internal Stream

By default, the `schema-registry-internal-stream` topic stores the schemas.
The `schema-registry-internal-stream` topic is located `in /apps/schema-registry/schema-registry-internal-stream`. The `kafkastore.stream` property in the `SR_CONF_DIR/schema-registry.properties` file sets the internal stream topic.
By default, the `kafkastore.stream` property is set to `/apps/schema-registry/schema-registry-internal-stream`.

The internal stream is automatically created if it does not already exist. If the internal stream already exists and has the same permissions as the default, the system returns a warning. If `kafkastore.stream` is set to a value other than the default, the system returns an error if the stream does not exist. You must explicitly set permissions on the stream you designate as the Schema Registry internal stream.

You can use Warden and `/opt/mapr/server/configure.sh` to manage and configure Kafka Schema Registry. Any time you change Schema Registry configurations, run `configure.sh` for changes to take effect.

Secure Cluster Default Permissions on the Internal Stream

By default, the internal stream is readable by all the users and writable only by the cluster administrator. For secure clusters, the default permissions are:

- `-produceperm u:$CLUSTER_ADMIN`
- `-consumeperm p`
- `-topicperm u:$CLUSTER_ADMIN`

The cluster admin is typically `mapr` or the value set for MAPR_USER.

Insecure Cluster Default Permissions on the Internal Stream

The stream has both read and write permissions for all users. The default permissions can be modified by means of the `maprcli stream` API. For insecure clusters, the default permissions are:

- `-produceperm p`
- `-consumeperm p`
- `-topicperm p`

Log Compaction for the Schema Registry Internal Stream

Log compaction is the process of purging messages previously published to a topic partition while retaining the latest version. Log compaction for the Schema Registry internal stream is enabled by default.

Important: Log compaction requires a gateway on the same cluster as the Schema Registry internal stream. Also, TTL should be disabled because it can interfere with log compaction.

Installing a Gateway

Run the command appropriate for your system:

- RedHat/CentOS

```
yum install mapr-gateway
```

- Ubuntu

```
apt-get install mapr-gateway
```

- SLES

```
zypper install mapr-gateway
```

Related concepts

Log Compaction on page 641
Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

Related information

Preparing Clusters for Log Compaction on page 1141
Describes how to prepare your environment so you can use log compaction.

Enabling High Availability for Kafka Schema Registry

You can enable high availability by installing multiple instances of schema registry on the same cluster.

One node in the cluster acts as the primary instance. Only the primary instance can publish writes to the underlying Kafka log. The primary node can also manage read requests.

All other secondary nodes manage only read requests. These nodes serve registration requests indirectly by forwarding them to the current primary node and returning any response supplied by the primary node.

1. Install schema registry on several nodes. For installation instructions, see Installing Kafka Schema Registry.
2. Configure high availability for the ensemble of ZooKeeper nodes. You can find the steps for this in the open source documentation, section Clustered (Multi-Server) Setup.
3. Modify the schema registry configuration file on each node to specify the `kafkastore.connection.url` property with the ZooKeeper nodes that form the HA ensemble.
4. Run the `configure.sh -R` command on each schema registry node.

Schema Registry Demos

Provides demonstrations for using Kafka Schema Registry to store and retrieve schemas.

The following topics demonstrate how to use Kafka Schema Registry to store and retrieve schemas in the supported formats:

Kafka Schema Registry Demo for Avro
Implements a Kafka Schema Registry demo example that stores and retrieves Avro schemas.

Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
   <repository>
       <id>confluent</id>
       <url>http://packages.confluent.io/maven/</url>
   </repository>
   <repository>
       <id>mapr-maven</id>
       <url>https://repository.mapr.com/maven/</url>
       <releases><enabled>true</enabled></releases>
       <snapshots><enabled>true</enabled></snapshots>
   </repository>
</repositories>
```

The following dependencies are needed for Avro and Kafka:

```
<dependency>
   <groupId>org.apache.avro</groupId>
   <artifactId>avro</artifactId>
   <version>1.9.2</version>
</dependency>
<dependency>
   <groupId>io.confluent</groupId>
   <artifactId>kafka-avro-serializer</artifactId>
   <version>5.1.2.0-mapr-700</version>
</dependency>
```

Creating a Java class that corresponds to the Avro schema

Add the following plugins to the `pom.xml` file:

- Plugin to build code:

```
<plugin>
  <groupId>org.apache.avro</groupId>
  <artifactId>avro-maven-plugin</artifactId>
  <version>1.8.2</version>
  <executions>
    <execution>
       <phase>generate-sources</phase>
       <goals>
           <goal>schema</goal>
           <goal>protocol</goal>
           <goal>idl-protocol</goal>
       </goals>
       <configuration>
          <sourceDirectory>${project.basedir}/src/main/resources/avro/</
sourceDirectory>
          <stringType>String</stringType>
          <createSetters>false</createSetters>
          <enableDecimalLogicalType>true</enableDecimalLogicalType>
          <fieldVisibility>private</fieldVisibility>
       </configuration>
     </execution>
   </executions>
</plugin>
```

- Plugin to force the discovery of the generated classes:

```
<plugin>
    <groupId>org.codehaus.mojo</groupId>
    <artifactId>build-helper-maven-plugin</artifactId>
    <version>3.0.0</version>
    <executions>
       <execution>
         <id>add-source</id>
         <phase>generate-sources</phase>
         <goals>
            <goal>add-source</goal>
         </goals>
         <configuration>
           <sources>
            <source>target/generated-sources/avro</source>
           </sources>
         </configuration>
       </execution>
     </executions>
</plugin>
```

- Create a file with filename extension `.avsc` in the `scr/main/resources` directory.

An example of an Avro schema is as follows:

```
{
  "namespace": "com.example",
  "type": "record",
  "name": "Employee",
  "doc" : "Represents an Employee at a company",
  "fields": [
      {"name": "firstName", "type": "string", "doc": "The persons given
name"},
```

last-updated: Apr 11, 2022

```
      {"name": "lastName", "type": "string"},
      {"name": "age",  "type": "int", "default": -1},
      {"name": "emails", "default":[], "type":{"type": "array", "items":
"string"}},
      {"name": "phoneNumber",  "type": "string"}
   ]
}
```

The `Employee.class` Java class is auto-generated in the `target/classes/com/example` directory after executing the following commands:

```
$ mvn clean
$ mvn package
```

You can use this class in your program after performing these steps.

Creating an Avro Producer

1. Import the following properties for the Kafka Producer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroSerializer;
import io.confluent.kafka.serializers.KafkaAvroSerializerConfig;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.ArrayList;
import java.util.List;
import java.util.Properties;
```

2. Configure the following properties for Event Data Streams:

```
Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
        IntegerSerializer.class.getName());

// Configure the KafkaAvroSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
        KafkaAvroSerializer.class.getName());

//Schema registry location.
properties.setProperty(KafkaAvroSerializerConfig.SCHEMA_REGISTRY_URL_CONF
IG,
        "http://localhost:8087");

KafkaProducer<Integer, Employee> producer =
        new KafkaProducer<>(properties);
```

3. The following code sends n different objects of class `Employee.java` to the topic `avro_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
Employee employee;

for (int i = 0; i < n; i++) {

    List<String> emails = new ArrayList<>();
    for (int j = 0; j < i; j++) {
        emails.add("john" + j + ".doe" + i + "@mail.com");
    }

    employee = Employee.newBuilder()
            .setFirstName("John" + i)
            .setLastName("Doe")
            .setAge(i + 5)
            .setEmails(emails)
            .setPhoneNumber("+1-202-555-" + i + i + i + i)
            .build();

    ProducerRecord<Integer, Employee> record =
        new ProducerRecord(topic, i, employee);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success!" );
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

Creating an Avro Consumer

1. Import the following properties for the Kafka Consumer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroDeserializer;
import io.confluent.kafka.serializers.KafkaAvroDeserializerConfig;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.util.Collections;
import java.util.Properties;
```

last-updated: Apr 11, 2022

2. The properties to configure are similar to the Kafka producer, only Deserializers must be used instead of Serializers. Add one more property called `KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG`:

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
        IntegerDeserializer.class.getName());

//Use Kafka Avro Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
        KafkaAvroDeserializer.class.getName());

//Use Specific Record or else you get Avro GenericRecord.
properties.put(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
"true");

//Schema registry location.
properties.put(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
        "http://localhost:8087");

KafkaConsumer<Integer, Employee> consumer =
        new KafkaConsumer<>(properties);
```

3. The following code reads objects of the `Employee.java` class from the `avro_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, Employee> records =
                consumer.poll(Duration.ofMillis(100));
        records.forEach(record -> {

            Employee employeeRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                    record.partition(), record.offset(), employeeRecord);
        });
    }
} finally {
    consumer.close();
}
```

Structured Streaming in Spark
Starting in EEP 5.0.0, structured streaming is supported in Spark.

Related Links

Spark streaming is integrated with MapR Event Store For Apache Kafka for Apache Kafka.

- MapR Event Store For Apache Kafka Clients and Tools

Prerequisites for Using Structured Streaming in Spark
To deploy a structured streaming application in Spark, you must create a MapR Streams topic and install a Kafka client on all nodes in your cluster.

Creating a MapR Streams Topic

- Create a MapR Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

Installing a Kafka Client

- Install a kafka-client on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

Using Apache Kafka

Scala

```
val spark = SparkSession
       .builder
       .appName("StructuredKafkaWordCo
unt")
       .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
       .readStream
       .format("kafka")
       .option("kafka.bootstrap.server
s", bootstrapServers)
       .option(subscribeType, topics)
       .load()
       .selectExpr("CAST(value AS
STRING)")
       .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
       .outputMode("complete")
       .format("console")
       .option("checkpointLocation",
checkpointLocation)
       .start()

query.awaitTermination()
```

Java

```
SparkSession spark = SparkSession
             .builder()
             .appName("JavaStructured
KafkaWordCount")
             .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
             .readStream()
             .format("kafka")
```

last-updated: Apr 11, 2022

```
              .option("kafka.bootstrap
.servers", bootstrapServers)
              .option(subscribeType,
topics)
              .load()
              .selectExpr("CAST(value
AS STRING)")
              .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
              .outputMode("complete")
              .format("console")
              .start();

query.awaitTermination();
```

Python

```
spark = SparkSession\
          .builder\
          .appName("StructuredKafkaWor
dCount")\
          .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
          .readStream\
          .format("kafka")\
          .option("kafka.bootstrap.ser
vers", bootstrapServers)\
          .option(subscribeType,
topics)\
          .load()\
          .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
        split(lines.value, ' ')
       ).alias('word')
     )

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
```

```
query = wordCounts\
           .writeStream\
           .outputMode('complete')\
           .format('console')\
           .start()

query.awaitTermination()
```

Using MapR Event Store for Apache Kafka

For MapR Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val df1 = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
   "maprdemo:9092").option("subscribe", topic).option("group.id",
   "testgroup").option("startingOffsets",
"earliest").option("failOnDataLoss",
          false).option("maxOffsetsPerTrigger", 1000).load()
```

Writing a Structured Spark Stream to MapR Database JSON Table

The example in this section writes a structured stream in Spark to MapR Database JSON table.

To write a structured Spark stream to MapR Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

Scala

```
import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
  .writeStream
  .format(MapRDBSourceConfig.Format)
  .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
  .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
  .option(MapRDBSourceConfig.CreateTab
leOption, true)
  .option(MapRDBSourceConfig.BulkModeO
ption, true)
  .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
  .outputMode("append")
}
```

Java

```
import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig;
```

```
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStr
eamReader;
import
org.apache.spark.sql.streaming.DataStr
eamWriter;
import
org.apache.spark.sql.streaming.Streami
ngQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
   return df.selectExpr("CAST(value
AS STRING) as _id")
            .writeStream()
            .format(MapRDBSourceConfig
.Format())
            .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
            .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
            .option(MapRDBSourceConfig
.CreateTableOption(), true)
            .option(MapRDBSourceConfig
.BulkModeOption(), true)
            .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
            .outputMode("append");
 }
```

Python

```
from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
  return df.selectExpr("CAST(value AS
STRING) as _id") \
           .writeStream \
           .format("com.mapr.db.spark.
streaming") \
           .option("checkpointLocation
", checkpoint_dir) \
           .option("tablePath",
table_path) \
           .option("idFieldPath",
"value") \
           .option("createTable",
True) \
           .option("bulkMode", True) \
           .option("sampleSize", 1000)
```

Writing a Spark Stream Word Count Application to MapR Database

The example in this section writes a Spark stream word count application to MapR Database.

Scala

```
val spark = SparkSession
      .builder
```

```
      .appName("StructuredKafkaWordCou
nt")
      .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
      .readStream
      .format("kafka")
      .option("kafka.bootstrap.servers
", bootstrapServers)
      .option(subscribeType, topics)
      .load()
      .selectExpr("CAST(value AS
STRING)")
      .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
      .format(MapRDBSourceConfig.Forma
t)
      .option(MapRDBSourceConfig.Table
PathOption, resultTable)
      .option(MapRDBSourceConfig.Creat
eTableOption, true)
      .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
      .outputMode("complete")
      .start()

query.awaitTermination()
```

Java

```
SparkSession spark = SparkSession
           .builder()
           .appName("JavaStructuredKaf
kaWordCount")
           .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
            .readStream()
            .format("kafka")
            .option("kafka.bootstrap.s
ervers", bootstrapServers)
            .option(subscribeType,
topics)
            .load()
            .selectExpr("CAST(value
AS STRING)")
            .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
```

last-updated: Apr 11, 2022

```
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
            .format(MapRDBSourceConfig
.Format())
            .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
            .option(MapRDBSourceConfig
.CreateTableOption(), true)
            .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
            .outputMode("complete");
            .start();

query.awaitTermination();
```

Python

```
spark = SparkSession\
           .builder\
           .appName("StructuredKafkaWo
rdCount")\
           .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
          .readStream\
          .format("kafka")\
          .option("kafka.bootstrap.ser
vers", bootstrapServers)\
          .option(subscribeType,
topics)\
          .load()\
          .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
       split(lines.value, ' ')
       ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
              .writeStream\
              .format("com.mapr.db.spa
```

```
rk.streaming") \
                .option("tablePath",
table_path) \
                .option("createTable",
True) \
                .option("idFieldPath",
"value") \
                .outputMode('complete')\
                .start()

query.awaitTermination()
```

S3 Gateway

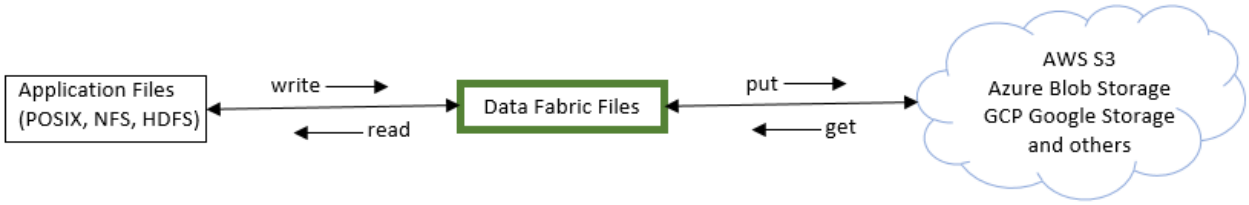
The S3 gateway is a service that provides an S3-compatible interface to expose data in MapR Data Platform as objects. The S3 gateway manages all inbound S3 API requests to put data into and get data out of cloud storage.

Notice: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

The S3 gateway can expose data generated through multiple data protocols, such as NFS, POSIX, S3, and HDFS as objects.

The MapR Data Platform filesystem stores an object as a file. The file can be of any data type, but must have a unique name as part of the S3 API call. Files can be accessed by the S3 API requests and by MapR Data Platform file interfaces. Data objects are grouped into a logical container called a bucket. A bucket correlates with a folder in MapR Data Platform.

The following image shows the flow of data to and from MapR Data Platform:



You can use the S3 API to `create`, `list`, or `delete` a bucket. You can also use it to `get`, `put`, `list`, or `delete` a data object within a bucket. The first time the S3 API accesses a file, it generates metadata. Metadata is required to fulfill the API requests.

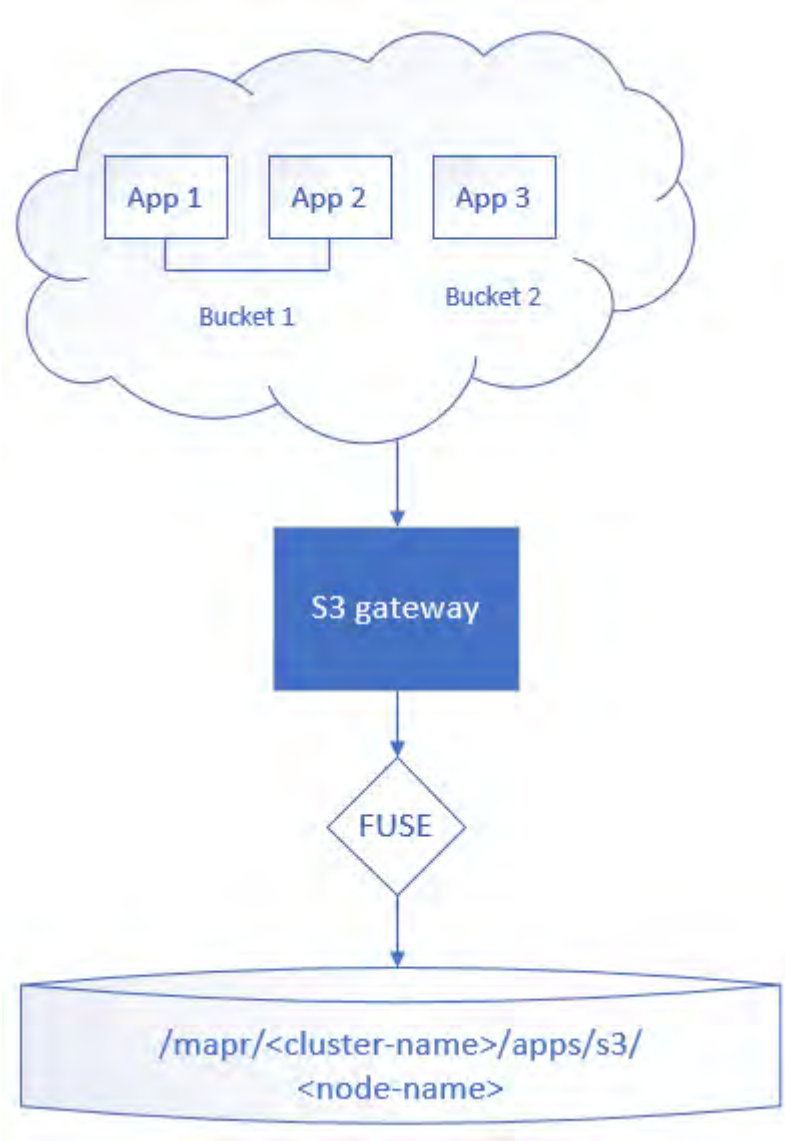
The S3 gateway also supports object notification through MapR Event Store For Apache Kafka. See Using the MapR Event Store For Apache Kafka for S3 Bucket Event Notifications on page 3965.

S3 Deployment Mode

The S3 gateway only supports the *Amazon S3 standalone deployment mode* because each instance of the S3 gateway can only interact with one bucket or set of buckets at a time.

When you use the S3 API in standalone mode, each S3 gateway instance must have its own back-end directory in the MapR Data Platform filesystem. You can either map a volume mount point to the directory or use the directory path itself. An S3 instance exclusively uses the allocated directory or volume in the filesystem to serve an exclusive set of buckets.

The following deployment scenario shows one S3 gateway per cluster that supports multiple applications and multiple buckets with bucket sharing:



This scenario is useful if you want an application to access multiple buckets without knowing about bucket locations beforehand. The single S3 gateway instance serves all requests without having to partition any buckets.

If you need to migrate buckets to another S3 instance, you can move or copy the buckets to another directory or volume. See AWS CLI. If a bucket does not exist, an application can create a bucket through any S3 gateway; however, the bucket created will only be served through the one gateway.

Authorization to Access Data

By default, the S3 gateway provides a two-tier authorization model that starts with an S3 bucket policies check at the S3 REST API level, followed by a file permissions check on the MapR Data Platform.

When an S3 gateway instance receives a request from a tenant to access a bucket or object, it first checks for bucket policies that reference that particular tenant. If the tenant does not have access via the bucket policy, the request fails and no other checks are performed.

If the tenant has access via the bucket policy, the filesystem performs the next check using the mapped UID and GID credentials for the tenant.

last-updated: Apr 11, 2022

Configuring S3 Gateway on page 3961 describes how to modify the type of authorization, configure tenants and credentials, and secure data. To see a configuration example, see Multi-Tiered Authorization Example.

Related Links

- For information about installation and configuration, see Installing S3 Gateway on page 204
- For a complete list of supported APIs, see Amazon S3 documentation
- For release-specific information, see S3 Gateway Release Notes on page 6260
- For information about object tiering (archiving files in the cloud), see Data Tiering on page 469.

Configuring S3 Gateway
Describes how to configure the S3 gateway.

Notice: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

To configure the S3 Gateway, add S3 gateway tenants (users) and credentials to the `tenants.json` file and change the deployment mode in the `minio.json` file. After you update and save the files, restart the `objectstore service.`

Important: If a bucket does not have custom policies applied and `mixed` deployment mode is set, you must remove the policy file for the bucket and restart the `objectstore service` to avoid permissions issues any time you:

- change the owner of the bucket
- add new tenants that are also bucket owners

The bucket policy file is located in `FS_PATH/.minio.sys/buckets/BUCKET_NAME/policy.json.` To restart the objectstore service, see Restarting the S3 Gateway Service on page 3964.

Distributed Mode

S3 gateway 2.1.0 and later supports distributed mode. S3 gateway 2.0.x does not support distributed mode.

Note the following points related to S3 gateway 2.1.0 and later in distributed mode:

- In distributed mode, instances of S3 gateway share user and policy information only, as well as locks between nodes.
- Distributed mode does not include proxy or load balancing in front of instances. You must configure and install proxy and load balancing manually.
- Distributed mode only works for S3 mode.
- Three or more nodes is recommended for S3 gateway in distributed mode. If only one node is active, the node will be in read-only mode.

To enable distributed mode for S3 gateway 2.1.0 and later:

1. Configure S3 gateway 2.1.0 or later on three or more nodes.
2. Disable caching in Fuse clients.

last-updated: Apr 11, 2022

3. On each S3 gateway node, update the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file with the `accessKey`, `secretKey`, and `ldap`. The value for each of these properties must be identical across all the `minio.json` files.

4. On all S3 gateway 2.1.0 or later nodes, verify that the `distributedHosts` property contains the list of nodes with mount paths, for example:

   ```
   "distributedHosts": "http(s)://HOST1:PORT1/MOUNT_PATH1 http(s)://
   HOST2:PORT2/MOUNT_PATH2"
   ```

   Note that the mount path on all nodes should target the same folder in the filesystem.

5. If the cluster is secure with self-signed certificates, copy the public certificates for each host to the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/certs/CAs` directory. To ignore validation of the certificates, set `"insecureSkipVerify": true`.

About Credentials

In the S3 world, credentials represent the application and not the identity of the end user. The application layer is responsible for end-user verification. The S3 administrator must assign S3 credentials for the application or set of applications and optionally, map those S3 credentials to a data-fabric identity.

As defined in the Amazon S3 documentation, the S3 REST API uses a “key” and “secret” (in a REST-like manner) as credentials to authenticate to the underlying object storage and authorize access to data.

S3 gateway supports a multi-tenant scenario in which the S3 administrator can configure one or more credentials with the appropriate data-fabric credential mapping. The S3 administrator can assign credentials to a user and, optionally, map them to a data-fabric identity.

For an overview of tenants and multi-tenancy, see Multitenancy on File System on page 488.

Add Tenants and Credentials in the tenants.json File

The `tenants.json` file describes the tenants configuration. This file consists of a JSON object with two keys: `credentials` and `tenants`. The `credentials` key relates more to S3 gateway authorization, whereas the `tenants` key relates to the users in the system.

The `credentials` key contains an array of objects with the following fields:

- `accessKey` - S3 format access key
- `secretKey` - S3 format secret key
- `Tenant` - Internal tenant name, used to link an access key to an operating system user

The `tenants` key contains an array of objects with the following fields:

- `uid` - Operating system user ID for file impersonation
- `gid` - Operating system group ID for file impersonation
- `name` - Internal tenant name, used to link an access key to an operating systems user

You add or update tenants (object storage users) and credentials in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/tenants.json` file. The `/opt/mapr/objectstore-client/objectstore-client-<version>/conf` directory also contains a `tenants-sample.json` file that you can use for reference.

Example of a `tenants.json` configuration:

```
{
    "tenants": [
        {
            "name": "tenant1",
            "uid": 5001,
            "gid": 5001
        }
    ],

    "credentials": [
        {
            "accessKey": "accessKey1",
            "secretKey": "secretKey1",
            "tenant": "tenant1"
        }
    ]
}
```

Set the Deployment Mode (Authorization Type) in the minio.json File

The deployment mode sets the type of authorization being used. The default deployment mode is `mixed`. You can edit the `deploymentMode` parameter in the `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` file to change the deployment mode setting.

The S3 gateway supports the following deployment modes:

Option	Deployment Mode	Description
1	fs_only	Enforced by MapR File System file permissions only. The S3 bucket policy is disabled. Access is granted based on the bucket owner UID and GID, not read/write/execute permissions. • Configuration maps the application key or secret to a MapR ID. • S3 policy is not used and the policy check is skipped. • MapR file security validates inbound mapped UID and GID to authorize read or write file permissions.
2	mixed	The default setting. Uses a mix of the MapR File System and S3 bucket policy security enforcement. • Configuration maps the application key or secret to a MapR ID. • S3 bucket policy and MapR file security are enforced. Specifically, the two authorization models. • The access key is ignored and the filesystem permissions determine access.

last-updated: Apr 11, 2022

Option	Deployment Mode	Description
3	s3_only	Enforced by s3 bucket policy only. • No configuration to map the application key or secret to a MapR ID. • All the files in the filesystem are owned by the user that runs the S3 gateway processes (typically the `mapr` user). • Access is controlled by the secret access key and the key ID.

Secure the Data

To prevent unauthorized access to data, secure the data based on the configured deployment mode:

- For `mixed` mode, set folder permissions and upload the S3 policies.
- For `fs_only` mode, set folder permissions to allow authorized users access to folders.
- For `s3_only` mode, upload the S3 policies.

Set the Path to Mount the Filesystem

If you are using `fs_only` or `mixed` mode, set the path to mount the filesystem.

- **Server node** - In the `minio.json` file, set the `fsPath` parameter to the filesystem mount path. By default, the path is set to `/mapr/<clustername>/apps/s3/<nodename>`. If you want to share existing folders with users, set the `fsPath` parameter to point to the directory with the folders that you want to share. All the folders in the directory (to which `fsPath` points) are accessible as buckets.
- **Edge node** - If you completed the Edge Node Installation steps, you may have already set the path to mount the filesystem when you ran the objectstore `configure.sh` script with the `--path` parameter. No action is required.

For more information about deployment modes, see S3 Gateway on page 3959.

Restarting the S3 Gateway Service

Start, restart, or stop the S3 gateway by using the command appropriate for the node:

Server Node

```
/opt/mapr/bin/maprcli node services -name objectstore -nodes
<node_name> -action [ start |
          restart | stop ]
```

Edge Node

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
objectstore.sh [ start |
        stop ]
```

Multiple-Tiered Authorization Example

The example shows a multi-tiered configuration where a bucket policy and MapR ACEs are both used for authorization.

last-updated: Apr 11, 2022

 **Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

Tenant A creates bucket B1. The system applies on the bucket, the default bucket policy of `read/write/execute` permission to only the owner and no access to other tenants. These permissions are UNIX permissions: `0700`.

Tenant A calls the REST API for bucket policy resulting in the following policy on bucket B1:

```
"Version": "2012-10-17",
"Id": "ExamplePolicy01",
"Statement": [
   {
     "Sid": "ExampleStatement01",
     "Effect": "Allow",
     "Principal": {
           "AWS": "B"
       },
      "Action": [
        "s3:GetObject",
      ],
      "Resource": [
        "arn:aws:s3:::B1/*",
      ]
    }
  ]
}
```

This policy is processed by the S3 gateway and allows access to tenant B. The policy indicates that the *ACE* is set up for the objects, as `-readdir u:B | u:A` and is applied to the bucket directory, while the *ACE* expression `-readfile u:B | u:A` is applied to all existing files. In mixed mode, tenant B has access.

Using the MapR Event Store For Apache Kafka for S3 Bucket Event Notifications
You can use the MapR Event Store For Apache Kafka to receive event notifications for buckets. For example, when an object is created in a bucket. Install the event store, create a stream and topic, and then enable notifications in `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/config.json`. You can then configure S3 event notifications through the S3 REST API, and use the AWS CLI to manage the notifications.

 **Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

To enable bucket-notification functionality, complete the following steps:

1. Install the `mapr-kafka*` package:

   ```
   zypper|yum|apt-get install mapr-kafka
   ```

2. Create a stream and topic:

   ```
   maprcli stream create -path /path/to/stream
   maprcli stream topic create -path /path/to/stream -topic nameOfTopic
   ```

3. Set up `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/config.json` in block notifications:

```
"notify": {
  "kafka": {
    "notifyBlockName": {
      "enable": true,
      "brokers": [""],
      "topic": "/path/to/stream:nameOfTopic"
      }
   }
}
```

4. Restart the S3 gateway.

Install and configure the AWS CLI to manage notifications from the command line. See Install and Configure the AWS CLI for installation and configuration details.

The following examples demonstrate some useful commands:

- To read a topic:

```
./kafka/kafka-<version>/bin/kafka-console-consumer.sh --topic /path/to/
stream:nameOfTopic --bootstrap-server some:9092 --from-beginning
```

- To add notifications to a bucket:

```
aws s3api --endpoint-url http://node1.cluster.com:9000
put-bucket-notification-configuration  --notification-configuration
file://fileWithNotificationRules.json --bucket bucketName
```

- To get notifications for a bucket:

```
aws s3api --endpoint-url https://node1.cluster.com:9000
get-bucket-notification-configuration  --bucket bucketName
```

Configure S3 Event Notifications

You can configure event notifications in the S3 REST API if you want to receive notifications about specific events that happen in a bucket. To enable notifications, add a notification configuration that identifies the events you want published to a topic. For additional details and instruction, see Configuring Amazon S3 Event Notifications.

The following examples demonstrate how to configure event notifications:

Create an object event for all names

```
{
  "QueueConfigurations": [
  {
   "Id": "1",
   "QueueArn":
"arn:minio:sqs::notifyBlockName:kafka"
,
   "Events": [
       "s3:ObjectCreated:*"
      ],
   "Filter": {
       "Key": {
       "FilterRules": [
```

```
      {
        "Name": "prefix",
        "Value": "*"
       }
     ]
    }
   }
  }
 ]
}
```

Remove object events that have names with the `mybuck` prefix

```
{
  "QueueConfigurations": [
    {
     "Id": "1",
     "QueueArn":
"arn:minio:sqs::notifyBlockName:kafka"
,
     "Events": [
          "s3:ObjectRemoved:*"
        ],
       "Filter": {
            "Key": {
            "FilterRules": [
              {
                "Name": "prefix",
                "Value": "mybuck"
              }
            ]
          }
        }
      }
    ]
 }
```

AWS CLI

You can install and use the AWS Command Line Interface (CLI) with the S3 gateway.

Installing the AWS CLI

Notice: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

To install the AWS CLI on Ubuntu, RedHat/CentOS, or SLES, run:

```
pip install awscli
```

To configure the AWS CLI, use the AWS `configure` command with the values shown in the following table:

Value	Description
AWS Access Key ID	Insert the `accessKey` from the `tenants.json` file
AWS Secret Access Key	Insert the `secretKey` from the `tenants.json` file
Default region name	Specify `'us-west-1'`
Default output format	Specify `json`

last-updated: Apr 11, 2022

Using the AWS CLI

The following table provides examples of commands that can help you manage buckets and files.

Note: The `public.crt` file is the public certificate for the node that is generated by MapR Data Platform.

```
# Create a bucket and upload a file
aws s3 mb s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

echo "HelloS3World" > /tmp/helloS3world.txt
aws s3 cp /tmp/helloS3world.txt s3://mybucket/
helloS3world.txt --endpoint-url https://<ip-address>:9000 --ca-bundle /
absolute/path/to/public.crt

# Move an object from one bucket to another
aws s3 mv s3://firstbucket/helloS3world.txt s3://mybucket/
helloS3world.txt --endpoint-url https://<ip-address>:9000 --ca-bundle /
absolute/path/to/public.crt

# Delete an object from a bucket
aws s3 rm s3://mybucket/helloS3world.txt --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

# Delete the bucket
aws s3 rb s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

# List all files in the bucket
aws s3 ls s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

# Show all files on the filesystem
ls -al /mapr/demo.mapr.com/apps/s3/$(hostname)/mybucket/
```

Note: The public SSL certificate is generated when installing the S3 gateway at `/opt/mapr/objectstore-client/objectstore-client-1.0.0/conf/certs/public.crt`.

For a non-secure cluster, use `http` instead of `https` and do not use `--ca-bundle /absolute/path/to/public.crt`. For example:

```
# List all files in the bucket for secure cluster
aws s3 ls s3://mybucket/ --endpoint-url https://
<ip-address>:9000 --ca-bundle /absolute/path/to/public.crt

# List all files in the bucket for non-secure cluster
aws s3 ls s3://mybucket/ --endpoint-url http://<ip-address>:9000
```

Related concepts

Provides a comprehensive listing of the key store and trust store files.

Related reference

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

Logs for the S3 Gateway

Logs for the S3 Gateway are available after the first run. You can access logs in `/opt/mapr/objectstore-client/objectstore-client-<version>/logs/`.

 **Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

The `minio.log` is rotated daily. Logs from previous days are archived to `minio.log-<date>.gz`.

To change the level of detail (verbosity) displayed in `minio.log`, you can edit the `logLevel` field in the `minio.json` file:

```
/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json
```

Specify a number (1 through 6) to set the log verbosity level:

```
1 - Panic (less detail)
2 - Fatal
3 - Error
4 - Warning
5 - Info
6 - Debug (more detail)
```

Troubleshooting S3 Gateway
This section shows some common error messages generated by the S3 gateway.

 **Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

ERROR: Bucket does not exist

Make sure you are performing an operation on a bucket that is not empty.

ERROR: s3a://bucketname: No such file or directory

Add a `/` at the end of your command, after the bucket name:

```
hadoop fs -ls s3a://bucketname/
```

S3 Gateway Limitations
The S3 Gateway has certain limitations and restrictions involving protocol support, object naming, and specific object and bucket APIs that are not supported.

 **Notice:** The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

Multiple protocol support limitation	You can write data via S3 API and read data via NFS/ POSIX. But, you CANNOT write to NFS and read via the S3 API as NFS has no ability to populate the necessary S3 metadata required by S3 gateway.
S3 gateway instance limitation	You can use only one instance of S3 gateway on any given bucket.
Object name character restrictions	You cannot use object names that contain characters `^*|" are NOT supported in Windows and other file systems which do not support them.
S3 object APIs not supported	• ObjectACL (Use bucket policies instead) • ObjectTorrent • ObjectVersions

S3 Bucket APIs not supported	• BucketACL (Use bucket policies instead) • BucketCORS (CORS enabled by default on all buckets for all HTTP verbs) • BucketLifecycle (Not required for Minio erasure coded backend) • BucketReplication (Use mc mirror instead) • BucketVersions, BucketVersioning (Use s3git) • BucketWebsite (Use caddy or nginx) • BucketAnalytics, BucketMetrics, BucketLogging (Use bucket notification APIs) • BucketRequestPayment • BucketTagging
File deletion limitation	If you delete a file using S3 gateway, it will delete the metadata file but not the metadata directory of the file.

Myriad

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Myriad enables the co-existence of Apache Hadoop and Apache Mesos on the same physical infrastructure. By running Hadoop YARN as a Mesos framework, YARN applications and Mesos frameworks can run side-by-side while dynamically sharing cluster resources. Resource allocation and management of Mesos services is supported by MapR Warden. The `configure.sh` script provides additional options for configuring Myriad.

With Apache Myriad, you can:

- Run your operational applications (including those running in Docker) side-by-side with your analytic applications.
- Achieve Hadoop multi-tenancy by provisioning logical Hadoop clusters for each user or group.

Key Features

- YARN running as a Mesos Framework, with resource manager and node managers running inside Mesos containers.
- YARN clusters running on Mesos that can allocate resources in one of the following ways:
- Static - Administrators can use an API or a GUI to add or remove node managers or auxiliary services like the JobHistoryServer.
- Fine-grained - Administrators can provision thin node managers that are dynamically resized based on application demand.
- High Availability (HA) and graceful restart of YARN daemons.
- Ability to launch multiple YARN clusters on the same set of nodes.

- Support for YARN FairScheduler and all functionality such as hierarchical queues with weights. Ability to deploy YARN Resource Manager using Marathon. This feature leverages Marathon's dynamic scheduling, process supervision, and integration with service discovery (Mesos-DNS).
- Ability to run MapReduce version 2 and associated libraries such as Hive and Pig.

Configure Myriad

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This section provides the steps for configuring Myriad.

1. Modify the **myriad-config-default.yml** file.

   As a minimum, the following Myriad configuration parameters must be set:

   - mesosMaster
   - zkServers
   - YARN_HOME

   Note: The value of mesosMaster parameters may be similar to `<mesosMasterHost>:5050` or `zk://<zkHost>:5181/<path_to_mesos_master>`

last-updated: Apr 11, 2022

2. Configure YARN to use Myriad.
   Edit the **$YARN_HOME/etc.hadoop/yarn-site.xml** file and add the following properties:

```
<property>
    <name>yarn.resourcemanager.hostname</name>
    <value>RESOURCEMANAGER_HOSTNAME</value>
</property>

<property>
  <name>yarn.resourcemanager.recovery.enabled</name>
  <value>true</value>
</property>

<property>
  <name>yarn.resourcemanager.scheduler.class</name>
<value>org.apache.myriad.scheduler.yarn.MyriadFairScheduler</value>
</property>

<property>
  <name>yarn.nodemanager.resource.cpu-vcores</name>
  <value>${nodemanager.resource.cpu-vcores}</value>
</property>

<property>
  <name>yarn.nodemanager.resource.memory-mb</name>
  <value>${nodemanager.resource.memory-mb}</value>
</property>

<property>
  <name>yarn.nodemanager.address</name>
  <value>${myriad.yarn.nodemanager.address}</value>
</property>

<property>
  <name>yarn.nodemanager.webapp.address</name>
  <value>${myriad.yarn.nodemanager.webapp.address}</value>
</property>

<property>
  <name>yarn.nodemanager.webapp.https.address</name>
  <value>${myriad.yarn.nodemanager.webapp.address}</value>
</property>

<property>
  <name>yarn.nodemanager.localizer.address</name>
  <value>${myriad.yarn.nodemanager.localizer.address}</value>
</property>

<property>
  <name>mapreduce.shuffle.port</name>
  <value>${myriad.mapreduce.shuffle.port}</value>
</property>

<property>
  <name>yarn.nodemanager.aux-services</name>
<value>mapreduce_shuffle,mapr_direct_shuffle,myriad_executor</value>
</property>

<property>
  <name>yarn.nodemanager.aux-services.myriad_executor.class</name>
  <value>org.apache.myriad.executor.MyriadExecutorAuxService</value>
</property>
```

last-updated: Apr 11, 2022

```
<property>
  <name>yarn.resourcemanager.store.class</name>
<value>org.apache.hadoop.yarn.server.resourcemanager.recovery.MyriadFileS
ystemRMStateStore</value>
</property>

<property>
  <name>yarn.scheduler.minimum-allocation-mb</name>
  <value>0</value>
 </property>

<property>

  <value>0</value>
</property>

<property>
  <name>yarn.scheduler.minimum-allocation-disks</name>
  <value>0</value>
</property>
```

See Configuring Services on page 3973 for information about configuring JobHistoryServer and other services. See Use Myriad for information about using Myriad.

Configuring Mesos-DNS

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

After installing Mesos-DNS on its master node, configure Mesos-DNS by updating values in the `config.json` file on the node where Mesos-DNS is installed and update the `/etc/resolv.conf` file on every node in the cluster.

Note: The Mesos-DNS package can be installed on any node that is designated as its master. For more information, see https://github.com/mesosphere/mesos-dns/tree/master/docs.

Important: The first nameserver specified in the `/etc/resolv.conf` file must be the IP address where Mesos-DNS is installed. This is to prevent issues associated with slow interconnectivity.

In the following example, 10.10.100.16 is the Mesos-DNS IP address:

```
vi /etc/resolv.conf

nameserver 10.10.100.16
nameserver 10.10.1.10
nameserver 12.250.1.3
```

Configuring Services

Services, such as JobHistoryServer, can be launched as a task from the Myriad Framework.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To configure services, define the service in the Myriad configuration file, `myriad-config-default.yml`. Once defined, the Myriad Service REST API can be used to launch an instance as a task for the service.

The services and service properties are as follows:

```
<!-- Define services as a task -->
services:
```

last-updated: Apr 11, 2022

```
    serviceName:        # Name of the service
    jvmMaxMemoryMB:     # Memory needed for service
    cpus:               # CPU needed for Service
    ports:              # Map of ports: port property and value
                        # (Default: 0 which indicates that port will be
assigned randomly)
                        # Uses the syntax, <name>: <value>
    envSettings:        # Any environment settings
    taskName:           # Again service name
    maxInstances:       # If defined maximum number of instances this
service can have per myriad framework
    command:            # Command to be executed
    serviceOptsName:    # Name of the env. variable that may need to be set
for the service that will include env. settings
```

To configure additional services:

1. Edit the `myriad-config-default.yml` file.
2. For the `services` property, specify a service and provide the appropriate parameters.

   For example, to define a TimeLineServer task:

   ```
   services:
       jobhistory:
           jvmMaxMemoryMB: 64
           cpus: 0.5
           ports:
              myriad.mapreduce.jobhistory.admin.address: 10033
              myriad.mapreduce.jobhistory.address: 10020
              myriad.mapreduce.jobhistory.webapp.address: 19888
           envSettings:
           taskName: jobhistory
           serviceOptsName: HADOOP_JOB_HISTORYSERVER_OPTS
           command: $YARN_HOME/bin/mapred historyserver
           maxInstances: 1
       timelineserver:
           jvmMaxMemoryMB: 1024
           cpus: 1
           ports:
               myriad.mapreduce.timeline.address: 10200
               myriad.mapreduce.timeline.webapp.address: 8188
           envSettings:
           taskName: timelineserver
           command: $YARN_HOME/bin/yarn timelineserver
           maxInstances: 1
   ```

3. Copy or update the `myriad-config-default.yml` file on every node in the cluster.
4. Restart the initial Resource Manager from Marathon.

Configuring Multiple YARN Clusters

This topic describes how to set up multiple Myriad frameworks and multiple YARN clusters in the Mesos environment.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Multiple YARN clusters are created in the Mesos environment when multiple Myriad frameworks are each running a Resource Manager. The Resource Manager spawns Node Managers and Job History Service processes which form a cluster. To create multiple YARN clusters, a Resource Manager is run under the Myriad framework with the cluster name specified. The cluster name differentiates between

staging, system, and local volume MapReduce directories. When configuring for multiple YARN clusters, run `configure.sh` on the nodes where you want the 1st Myriad framework and YARN cluster, then run `configure.sh` with different parameters on the nodes where you want the 2nd Myriad framework and YARN cluster, and so on.

1. Run `configure.sh` on the slave nodes for the YARN cluster. Specify a Resource Manager hostname, Job History name, Myriad framework, and cluster prefix name.

   Note: It is recommended that you use the same value for the `-RM, -HS, -MF, and -MCL` parameters.

   For example, if you set the parameter value to **framework1** for each of the parameters, the `configure.sh` parameters could be similar to the following:

   ```
   /opt/mapr/server/configure.sh \
   -C 10.10.100.16 \
   -Z 10.10.100.16 -u mapr -g mapr \
   -N myCluster \
   -F /root/disk.list \
   -RM framework1.marathon.mesos \
   -HS jobhistory.framework1.mesos \
   -MF framework1 \
   -MCL framework1
   ```

2. Run `configure.sh` on the slave nodes for each new YARN cluster. Specify new values for Resource Manager hostname, Job History name, Myriad framework, and cluster prefix name.

   For example, on the subsequent YARN cluster, if you set the parameter value to **framework2** for each of the parameters, the `configure.sh` parameters could be similar to the following:

   ```
   /opt/mapr/server/configure.sh \
   -C 10.10.100.16 \
   -Z 10.10.100.16 -u mapr -g mapr \
   -N myCluster \
   -F /root/disk.list \
   -RM framework2.marathon.mesos \
   -HS jobhistory.framework2.mesos \
   -MF framework2 \
   -MCL framework2
   ```

For example, the following creates three Myriad frameworks and the associated YARN cluster name prefix (framework1, framework2, and framework3). In the following examples, -N is set to **myCluster**, the primary IP address is 10.10.100.16, and the values for the -RM, -HS, -MF, and -MCL parameters change for each YARN cluster.

Create the 1st cluster for framework1:

```
// On slave nodes 1 - 3, run:
/opt/mapr/server/configure.sh \
-C 10.10.100.16 \
-Z 10.10.100.16 -u mapr -g mapr \
-N myCluster \
-F /root/disk.list \
-RM framework1.marathon.mesos \
-HS jobhistory.framework1.mesos \
-MF framework1 \
-MCL framework1
```

last-updated: Apr 11, 2022

Create the 2nd cluster for framework2:

```
// On slave nodes 4 - 6, run:
/opt/mapr/server/configure.sh \
-C 10.10.100.16 \
-Z 10.10.100.16 -u mapr -g mapr \
-N myCluster \
-F /root/disk.list \
-RM framework2.marathon.mesos \
-HS jobhistory.framework2.mesos \
-MF framework2 \
-MCL framework2
```

Create the 3rd cluster for framework3:

```
// On slave nodes 7 - 9, run:
/opt/mapr/server/configure.sh \
-C 10.10.100.16 \
-Z 10.10.100.16 -u mapr -g mapr \
-N myCluster \
-F /root/disk.list \
-RM framework3.marathon.mesos \
-HS jobhistory.framework3.mesos \
-MF framework3 \
-MCL framework3
```

Configuring Multiple YARN Clusters (Binary)

This topic describes how to set up multiple Myriad frameworks and multiple YARN clusters in the Mesos environment for binary distribution.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Set up a Myriad framework.

   Note: For each Myriad framework, setup different cluster name and resource manager hostname in yarn-site.xml file. See Using Multiple YARN Clusters on page 3984 for more information.

   a) Edit the `myriad-config-default.yml` file in the /opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/ and update the `nodeManagerUri` and `YARN_HOME` parameters:

   ```
   nodeManagerUri: maprfs://<full path to Hadoop tar file>
       // For example: maprfs:///dist/hadoop-2.7.0.framework1.tar.gz
   YARN_HOME: hadoop-2.7.0
       //  (or the relative path to the hadoop directory that will be
   created in the tar file)
   ```

2. Create a tar file for the Myriad framework.

   ```
   cd /opt/mapr/hadoop
   tar -czvf hadoop-2.7.0.framework1.tar.gz hadoop-2.7.0
   ```

3. Copy the Myriad framework tar file to the location specified by the `nodeManagerUri` parameter in the `myriad-config-default.yml` file.

4. Repeat steps 1 - 3 for each Myriad framework.

Using a Different Scheduler
Myriad uses MyriadFairScheduler by default. However, MyriadCapacityScheduler and MyriadFifoScheduler can also be used to run jobs.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Myriad Scheduler property is set in the `yarn-site.xml` file:

```
<property>
  <name>yarn.resourcemanager.scheduler.class</name>
  <value>org.apache.myriad.scheduler.yarn.MyriadFairScheduler</value>
  <description>You can configure other schedulers from following list:
     org.apache.myriad.scheduler.yarn.MyriadCapacityScheduler,
     org.apache.myriad.scheduler.yarn.MyriadFifoScheduler</description>
</property>
```

Important: Fine-grained scaling only works with a MyriadFairScheduler configuration.

To use either MyriadCapacityScheduler or MyriadFifoScheduler:

1. Edit the `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` file.
2. For the `yarn.resourcemanager.scheduler.class` property, specify either `org.apache.myriad.scheduler.yarn.MyriadCapacityScheduler` or `org.apache.myriad.scheduler.yarn.MyriadFifoScheduler`
3. Modify the YARN scheduler minimum allocation properties.
   The configure.sh sets these properties to zero (0) by default. When using a different scheduler, the properties must be set (as a minimum) to the following values:

   ```
   yarn.scheduler.minimum-allocation-mb = 1024
   yarn.scheduler.minimum-allocation-vcores = 1
   yarn.scheduler.minimum-allocation-disks = 0
   ```

4. Copy or update the `yarn-site.xml` file on every node in the cluster.
5. Restart the initial Resource Manager from Marathon.

Use Myriad

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Myriad environment is established by running an initial application for the Resource Manager. The initial application ID is established when you configure Myriad with `/opt/mapr/services/configure.sh` with the Resource Manager property (-RM) and the value: <RM app-name>>.marathon.mesos. For example, if the value of Resource Manager property is rm.marathon.mesos:

rm	The ID given to the Resource Manager when launched using Marathon. Mesos-DNS constructs the Resource Manager hostname using the ID.
marathon	The Mesos framework.

last-updated: Apr 11, 2022

If you are using Marathon, launch Marathon, and run an initial Resource Manager application. See Starting Resource Manager for more information.

Note: The Resource Manager can not be managed by the `maprcli nodes services` command.

Starting Resource Manager
A Resource Manager for Myriad must be launched before the Myriad UI becomes available.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The initial Resource Manager is started from Marathon. In addition, only one (1) Resource Manager can be launched on a cluster.

Note: Starting the Resource Manager from the command line results in an error, see Troubleshooting Myriad for a workaround.

To start the Resource Manager:

1. Launch Marathon with http://hostname:8080.
2. Click on **New App**.
3. Create a new application for the resource manager and specify:
   - ID - Default: rm
   - CPU - 0.2 minimum
   - Memory - 2048 minimum
   - Instances - 1 only
   - Command - `env && yarn resourcemanager`

   For example:

Table

Parameter	Example
ID	rm
CPU	0.2
Memory	2048
Instances	1
Command	`env && yarn resourcemanager`

Important: Only one instance of Myriad Resource Manager can be running. Scaling up instances (specifying more than one instance) may result in unpredictable behavior. Creating a new Myriad application from Marathon results in a new framework.

4. Access the Myriad UI with <hostname>:8192

   If you have multiple nodes in your cluster, Myriad may be started on any one of the nodes. To obtain the Myriad host, access the Mesos UI (`http://<hostname>:5050`) and check the **Active Tasks > Hosts** panel.

   If the Mesos-DNS entry is added on your local machine, the host can be accessed with the following address: `http://rm.marathon.mesos:8192`.

last-updated: Apr 11, 2022

Launching Myriad Services

The Myriad services are launched automatically and accessed from their designated ports.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Mesos primary, Mesos secondary, and Mesos Marathon services are launched automatically after configuration (running `configure.sh`). Myriad is launched once you run an initial Resource Manager, normally from the Marathon UI. In a browser, Mesos, Marathon, and Myriad are accessible (launched) from the following ports:

Table

Application	Port
Mesos Master UI	http://<hostname>:5050
Marathon UI	http://<hostname>:8080
Myriad UI	http://<hostname>:8192 **Note:** The Myriad UI is available once an initial Resource Manager is launched. **Note:** If you have multiple nodes in your cluster, Myriad may be started on any one of the nodes. To obtain the Myriad host, access the Mesos UI and check the **Active Tasks > Hosts** panel.
Control System	http://<hostname>:8443

Note: If your environment has both Mesos Marathon and Spark installed on the same node, a conflict occurs because the default port for both is 8080. To resolve this conflict, change the port for one of the applications.

Monitoring Myriad

Myriad is monitored using several application user interfaces.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following user interfaces are used to monitor application processes, tasks, configurations, and flexup or flexdown resources:

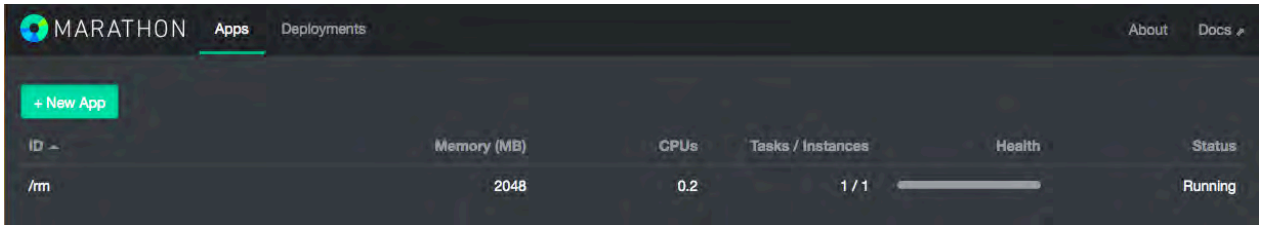
- Marathon UI
- Mesos UI
- Myriad UI
- Control System

Marathon UI

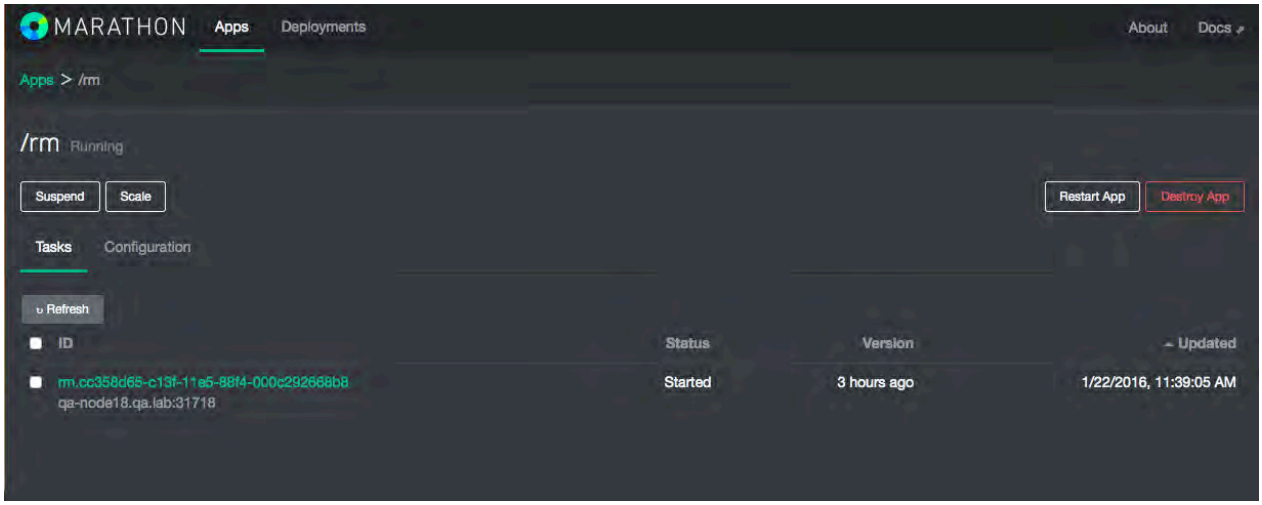
The Marathon UI is used to manage application processes. The **Apps** panel provides created, suspended, scaled, and refreshed as well as restarted and destroyed. To view task details, click on the application link.

The following screenshot shows the Marathon home page:

last-updated: Apr 11, 2022



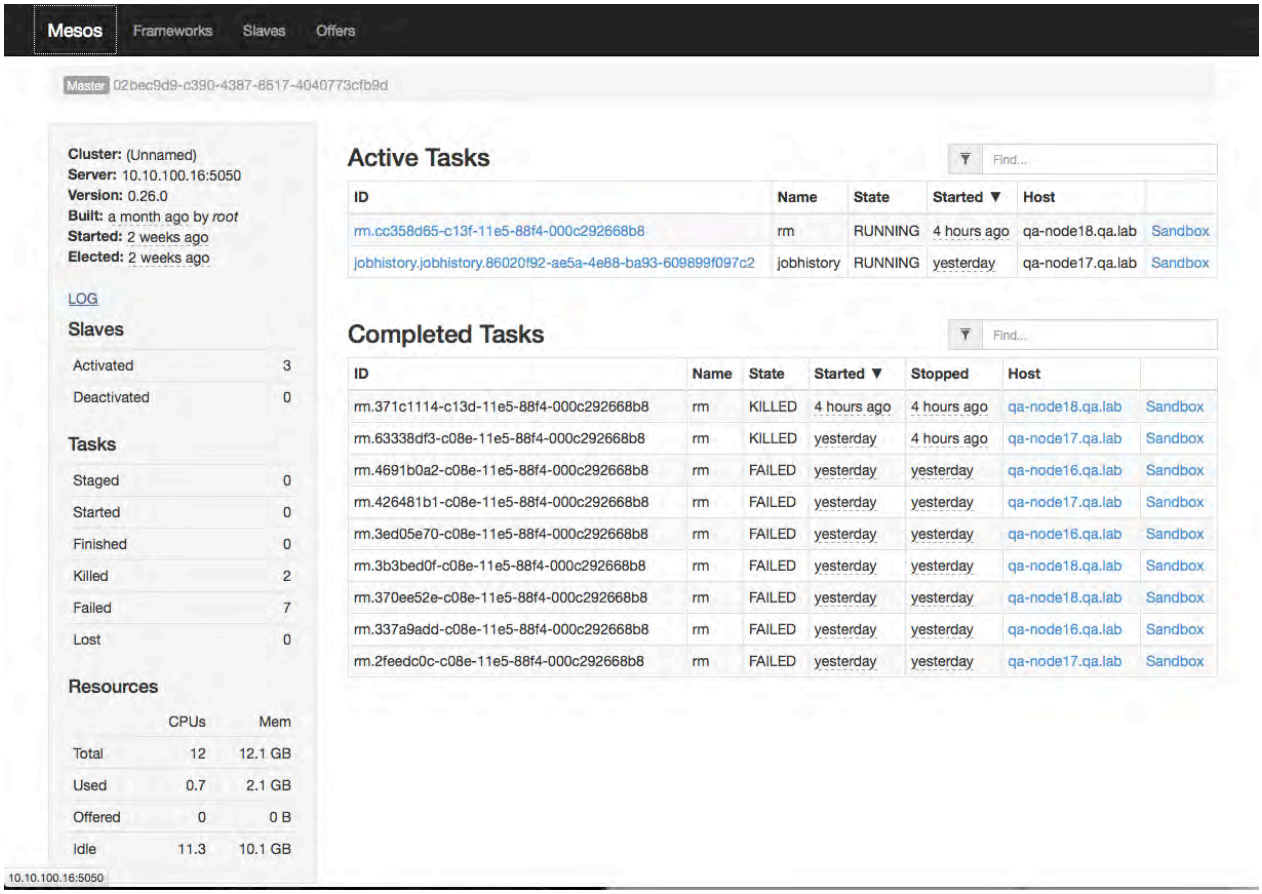
The following screenshot shows the Marathon application details page:



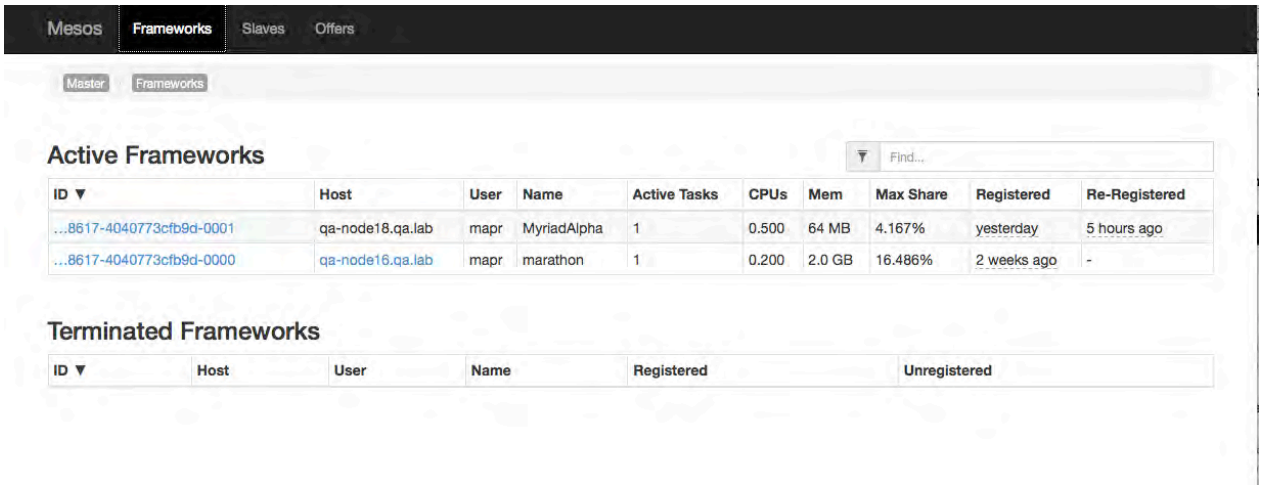
Mesos UI

The Mesos UI is used to monitor Mesos active and completed tasks, provide cluster information, provide active and terminated frameworks, Mesos secondary information, and Offers.

The following screenshot shows the Mesos home page:



The following screenshot shows the Mesos Frameworks page:



Myriad UI

The Myriad UI is used to flexup or flexdown Node Manager instances, that is, to allocate more or less resources using a predefined configuration as well as to monitor your tasks and display Myriad configuration.

- The main Myriad UI page shows the underlying REST API.

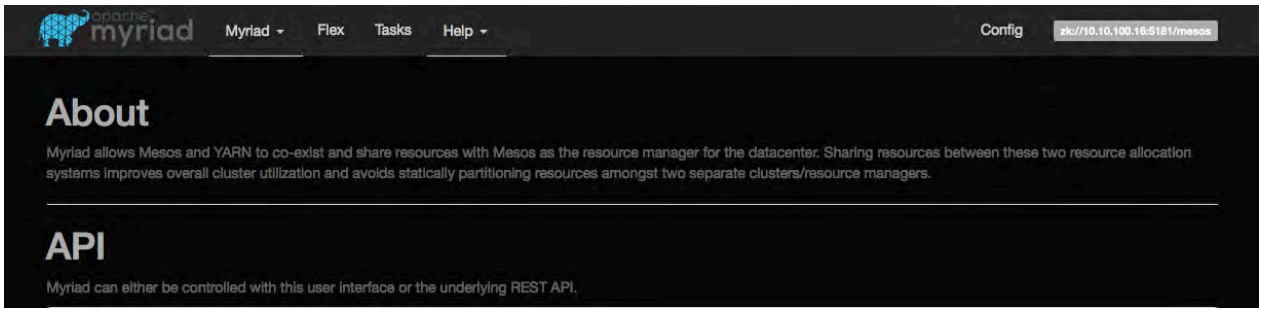
- The **Flex** button allows you to flex up or flex down instances by specifying the profile and number of instances to flex.

  Note: At this time, only one (1) instance is allowed.

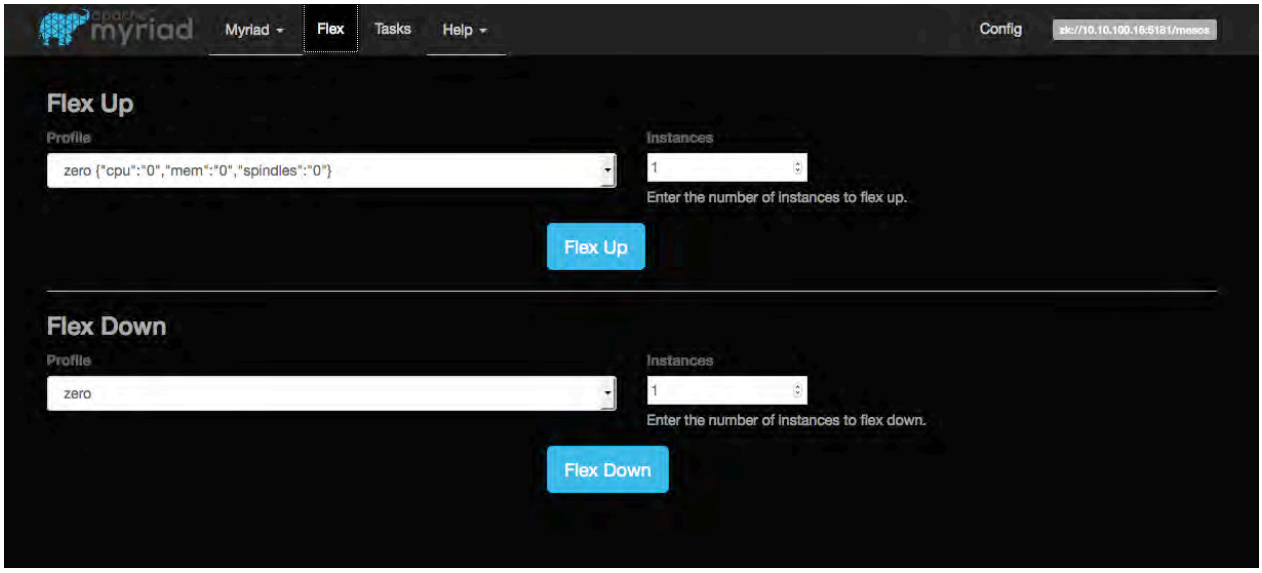
- The **Task** button shows the current active, killable, pending, and staging tasks.
- The **Config** button shows the defined profiles and the parameters in the Myriad configuration file (`myriad-config-default.yml`).

Flexing up and flexing down changes are reflected in the Mesos UI under the Myriad Framework name.

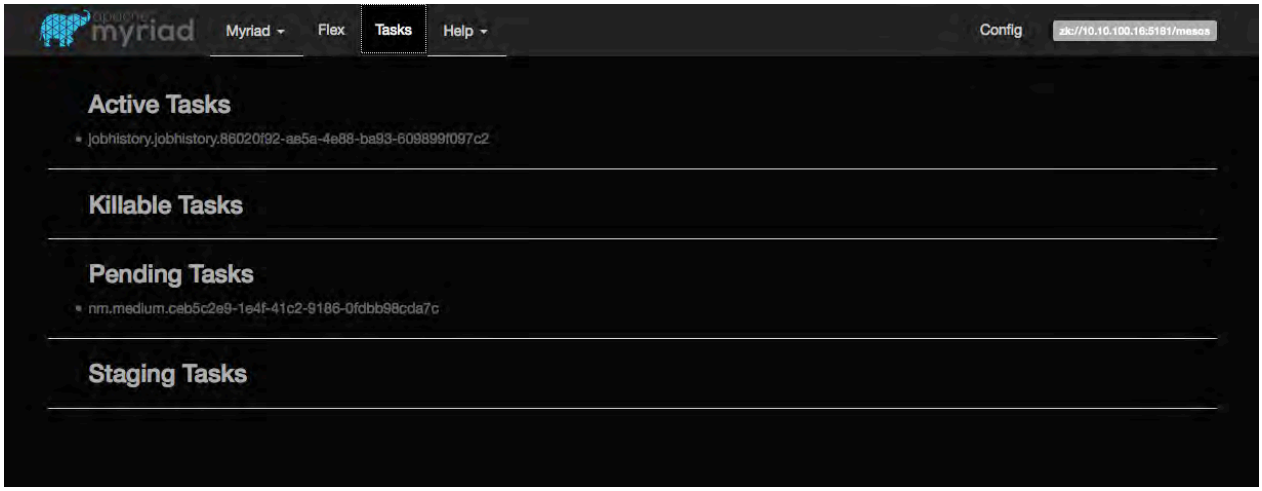
The following screenshot shows the Myriad home page:



The following screenshot shows the Myriad Flex page:



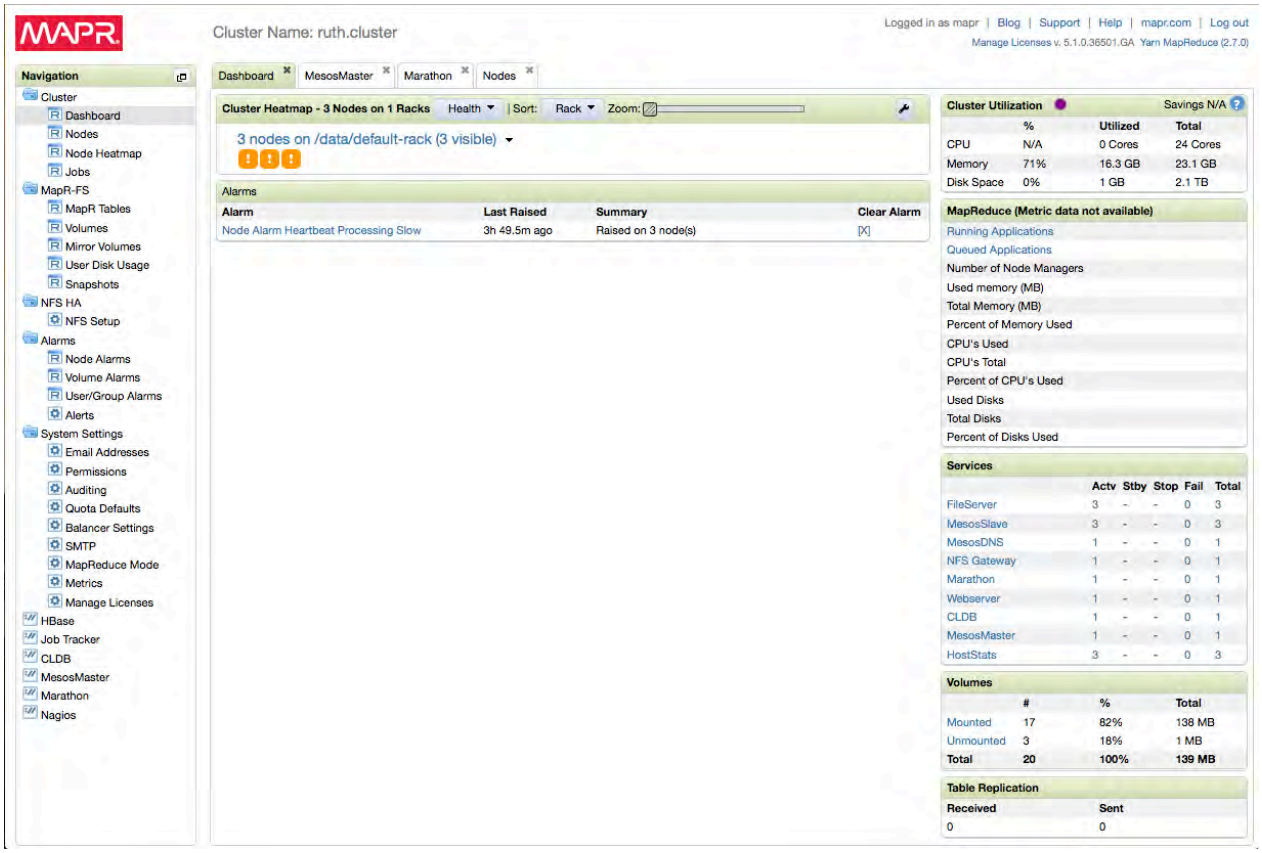
The following screenshot shows the Myriad Tasks page:



The Control System

The Control System is used as a central access point to navigate to Mesos Primary instance, Mesos Secondary instance, Mesos-DNS and Marathon information about the configured and running services in your cluster.

The following screenshot shows the Control System interface when Myriad is installed and configured:



The following Control System panel shows the Myriad services:

last-updated: Apr 11, 2022

Services					
	Actv	Stby	Stop	Fail	Total
FileServer	3	-	-	0	3
MesosSlave	3	-	-	0	3
MesosDNS	1	-	-	0	1
NFS Gateway	1	-	-	0	1
Marathon	1	-	-	0	1
Webserver	1	-	-	0	1
CLDB	1	-	-	0	1
MesosMaster	1	-	-	0	1
HostStats	3	-	-	0	3

Using Multiple YARN Clusters

This topic describes how to create multiple YARN clusters and to run Hadoop jobs in a multiple YARN cluster environment.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Multiple YARN clusters are created in the Mesos environment when multiple Myriad frameworks are each running a Resource Manager. Where there are multiple YARN clusters, clients must specify a cluster name prefix to identify which cluster the Hadoop job should be run on.

Creating Multiple YARN Clusters

The Resource Manager spawns Node Managers and Job History Service processes which form a cluster. To create multiple YARN clusters, a Resource Manager is run under the Myriad framework along with the cluster name prefix. The cluster name prefix differentiates between staging, system, and local volume MapReduce directories.

Note: The cluster name prefix setting is a value of the `cluster.name.prefix` property in the **yarn-site.xml** file. Also, you must set it an an `envSettings` variable for each service on a cluster. For example, the following show the `cluster.name.prefix` setting for jobHistoryServer:

```
services:
     jobhistory:
     jvmMaxMemoryMB: 64
     cpus: 0.5
     ports:
       myriad.mapreduce.jobhistory.admin.address: 10033
       myriad.mapreduce.jobhistory.address: 10020
       myriad.mapreduce.jobhistory.webapp.address: 19888
     envSettings: -Dcluster.name.prefix=/framework1
     taskName: jobhistory
     serviceOptsName: HADOOP_JOB_HISTORYSERVER_OPTS
     command: $YARN_HOME/bin/mapred historyserver
     maxInstances: 1
```

Cluster name prefix and Resource Manager parameters:

```
-Dyarn.resourcemanager.hostname=<RM appName>.marathon.mesos
-Dcluster.name.prefix=/<clusterNamePrefix>
```

last-updated: Apr 11, 2022

For example, the `cluster.name.prefix` and `yarn.resourcemanager.hostname` properties are both **framework1** in the **yarn-site.xml** file:

```
env && export
YARN_RESOURCEMANAGER_OPTS="-Dyarn.resourcemanager.hostname=framework1.marath
on.mesos
-Dcluster.name.prefix=/framework1"
&&/opt/mapr/hadoop/hadoop-2.7.0/bin/yarn resourcemanager
```

Running Jobs from the Client-side

When running Hadoop jobs from clients within a multiple YARN cluster environment, additional parameters are required. In this scenario, one client could submit jobs to a specific YARN cluster and a second client could submit jobs to a completely different YARN cluster. The following parameters are specified when multiple YARN clusters are implemented.

Table

Parameter	Parameter Values	Description
cluster.name.prefix	/<clusterNamePrefix>	Prefix for each Myriad cluster name. This is the top-level directory where all the staging and shuffle data is written for a specific Myriad framework. Specified by the `-MCL` parameter when running `configure.sh`. See Configure Myriad for more information.
yarn.resourcemanager.hostname	<RM appName>.marathon.mesos	Mesos hostname for Resource Manager. Specified by the `-RM` parameter when running `configure.sh`. See Configure Myriad for more information.
yarn.resourcemanager.dir	/var/mapr/cluster/yarn/<clusterNamePrefix>/rm	Directory for Resource Manager specific data. The directory is based on the cluster name prefix specified by the `-MCL` parameter when running `configure.sh`. See Configure Myriad for more information. .
mapr.mapred.localvolume.root.dir.name	/<clusterNamePrefix>/nodeManager	Directory for local volume MapReduce specific data. The directory is based on the cluster name prefix.

Command-line Parameters

```
-Dcluster.name.prefix=/<clusterNamePrefix>
-Dyarn.resourcemanager.hostname=<RM appName>.marathon.mesos
-Dyarn.resourcemanager.dir=/var/mapr/cluster/yarn/<clusterNamePrefix>/rm
-Dmapr.mapred.localvolume.root.dir.name=/<clusterNamePrefix>/nodeManager
```

For example, where the `cluster.name.prefix` and `yarn.resourcemanager.hostname` properties are both **framework1**:

```
hadoop jar
/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
```

last-updated: Apr 11, 2022

```
hadoop-mapreduce-examples-2.7.0-mapr-1506-SNAPSHOT.jar wordcount
-Dcluster.name.prefix=/framework1
-Dyarn.resourcemanager.hostname=framework1.marathon.mesos
-Dyarn.resourcemanager.dir=/var/mapr/cluster/yarn/framework1/rm
-Dmapr.mapred.localvolume.root.dir.name=/framework1/nodeManager
/test.log test.out
```

yarn-site.xml Properties

Alternatively, rather than specifying these parameters dynamically, add them to the client-side `yarn-site.xml` file.

For example, where the `cluster.name.prefix` and `yarn.resourcemanager.hostname` properties are both **framework1**:

```
// Property example for cluster.name.prefix
  <property>
    <name>cluster.name.prefix</name>
    <value>/framework1</value>
  </property>

// Property example for yarn.resourcemanager.hostname
  <property>
    <name>yarn.resourcemanager.hostname</name>
    <value>framework1.marathon.mesos</value>
  </property>

// Property example for yarn.resourcemanager.dir
  <property>
    <name>yarn.resourcemanager.dir</name>
    <value>/var/mapr/cluster/yarn/framework1/rm</value>
  </property>

// Property example for mapr.mapred.localvolume.root.dir.name
  <property>
    <name>mapr.mapred.localvolume.root.dir.name</name>
    <value>/framework1/nodeManager</value>
  </property>
```

Modifying Myriad Profiles

Myriad profiles can be changed and expanded depending on your requirements.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following are the default Myriad profiles:

```
profiles:
    zero:  # NMs launched with this profile dynamically obtain CPU/Memory
from Mesos
        cpu: 0
        mem: 0
        spindles: 0
    small:
        cpu: 2
        mem: 2048
        spindles: 1
    medium:
        cpu: 4
        mem: 4096
        spindles: 2
```

last-updated: Apr 11, 2022

```
    large:
        cpu: 10
        mem: 12288
        spindles: 4
```

To modify Myriad profiles:

1. Edit the `myriad-config-default.yml` file.
2. For the `profiles` property, you can modify existing profiles and create new profiles
   For example, to add a "super" profile:

   ```
      huge:
         cpu: 15
         mem: 12288
         spindles: 5
   ```

3. Copy or update the `myriad-configure-default.yml` file on every node in the cluster.
4. Restart the initial Resource Manager from Marathon.

Myriad REST API

Securing the Myriad REST API

To secure the Myriad REST API, set the `isSecure` property to **true** in the **myriad-config-default.yml** file. In this case, Myriad uses the same security type as the value of the `hadoop.http.authentication.type` parameter in the **core-site.xml** file

Note: On a secure cluster, the default value of this property is `org.apache.hadoop.security.authentication.server.MultiMechsAuthenticationHandler`. Authentication, such as Kerberos or plain (using PAM), is determined automatically.

Scaling the Cluster

To scale a cluster up or down, use the Cluster API. The Cluster API provide flexup and flex down capability the changes the size of one or more instances in a cluster. The instance size is a profile parameter that is a predefined value of zero, small, medium, and large. These predefined values are specified in the Myriad configuration file (myriad-config-default.yml).

Specify Service Instances

To specify the number of instances for a service, use the Service API. Services are configured in the Myriad configuration file (myriad-config-default.yml).

Retrieving Configuration and State

To retrieve the Myriad configuration and the Myriad Scheduler state, use the Configuration API and State API. See Myriad open source REST API for more information.

The Myriad REST API provides the following functionality:

Table

API	HTTP Method	URI	Description
Cluster	PUT	/api/cluster/flexup	Expands the cluster size. Parameters: profile, instances, constraints
Cluster	PUT	/api/cluster/flexdown	Shrinks the cluster size. Parameters: profile, instances, constraints
Service	PUT	/api/cluster/flexupservice	Increases the number of instances for a service. Parameters: instances, serviceName
Service	PUT	/api/cluster/flexdownservice	Shrinks the number of instances for a service. Parameters: instances, serviceName
Configuration	GET	/api/config	Retrieves the Myriad configuration.
State	GET	api/state	Retrieves a snapshot of the Myriad Scheduler state.
Framework	GET	/api/framework/shutdown/frameworkd	Destroys the Myriad framework. **Note:** With this release, GET is the method used to destroy the Myriad framework.

Troubleshoot Myriad
Explains how to troubleshoot Myriad.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Resource Manager not Starting

The Resource Manager cannot be started from the command line using the following command:

```
$ yarn resourcemanager
```

The following error occurs:

```
java.lang.UnsatisfiedLinkError: no mesos in java.library.path
```

Workaround:

Manually pass the MESOS_NATIVE_LIBRARY environment variable when starting the Resource Manager. For example:

```
env && export MESOS_NATIVE_LIBRARY=/usr/local/lib/libmesos.so && yarn
          resourcemanager
```

Note: This is not an issue when starting Resource Manager from the Marathon UI.

Marathon Fails

The Mesos-3602 fix in Mesos version 0.26 causes an issue when using the maprfs path for the URI. When starting Marathon, an extra forward slash (/) is appended to the URI path. The application fails with a message similar to the following:

```
hadoop fs -copyToLocal '/maprfs:///dist/hadoop-2.7.0.myriad1.tar.gz'
'/opt/mapr/slaves/67d1f64c-449b-4609-82f3-5da309f3c5c5-S9/
frameworks/67d1f64c-449b-4609-82f3-5da309f3c5c5-0000/

427fe309-82c5-4f8b-9fa3-6dd39a4a5ef4/hadoop-2.7.0.myriad1.tar.gz
-copyToLocal: java.net.URISyntaxException: Expected scheme-specific part at
index 7: maprfs:
```

Workaround:

Replace `maprfs:///` with `hdfs:///` when specifying the URI on Marathon application.

Note: This issue is fixed by MESOS-4304, which is available with in the Mesos 0.27 release.

Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Apache Oozie™ is a workflow scheduler system to manage Apache Hadoop jobs. Using Oozie, you can set up *workflows* that execute MapReduce applications and *coordinators* that manage workflows.

Oozie Workflow jobs are Directed Acyclical Graphs (DAGs) of actions. Oozie Coordinator jobs are recurrent Oozie Workflow jobs triggered by time (frequency) and data availability.

Oozie is integrated with the rest of the Hadoop stack and supports several types of Hadoop jobs out-of-the-box, such as Java map-reduce, Streaming map-reduce, Pig, Hive, Sqoop, and Distcp, as well as system-specific jobs, such as Java programs and shell scripts.

This section contains documentation for Oozie on the MapR Data Platform and provides all relevant details needed to use Oozie with MapR. The documentation in this section does not duplicate the documentation on the Apache Oziesite.

Configure Oozie

This topic describes how to configure Oozie.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To set up Oozie using a non-default administrative user (non-`mapr`), set the `yarn.resourcemanager.principal` property to the non-`mapr` user in the `yarn-site.xml` file. For more information, see yarn-site.xml.

In Oozie 4.3.0, when you modify the `yarn-site.xml` file on Oozie server nodes, you must rebuild the Oozie war file to include the latest changes using one of the following two methods:

last-updated: Apr 11, 2022

1. First method:
   a. Rebuild the Oozie war files:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh hadoop
<version> /opt/mapr/hadoop/hadoop<version> -secure
```

   b. Restart Oozie:

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

2. Second method:
   - Or, for EEP 4.x and Oozie 5.1 (EEP 6.x), you can run the following command:

```
/opt/mapr/server/configure.sh -R
```

Configuring Oozie on a Secure Cluster

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The default configuration for Oozie on a secure MapR cluster uses MapR tickets to authenticate between the Oozie client and server. The Oozie server uses MapR tickets to authenticate the connection between the YARN components and the JobClient embedded in the Oozie server. Starting in the EEP 4.0 release, for secure clusters, Oozie is also configured to use SSL encryption. This default configuration is in place once Oozie is installed and the security features for your cluster are enabled. See Enabling and Disabling Security. No further configuration is required. See User Impersonation for Oozie to enable user impersonation for Oozie.

The sections below provide instructions to manually configure Oozie features on a secure MapR cluster:

Oozie Server secured by default to use SSL

Starting in EEP 6.0.0, for Oozie 4.3.0 and above, Oozie server uses SSL by default for secured clusters.

1. By default, on a secure cluster, Oozie reads the `ssl-client.xml` file and configures SSL using this file.
2. If you want to use a custom SSL configuration, enable custom secure on your cluster.

Configuring the Oozie Server to use SSL (Oozie 5.1.0.0 and above)

Configure the settings necessary for enabling SSL or TLS support in the `oozie-site.xml` file.

1. Set the `oozie.https.enabled` property to `true`:

```
<property>
  <name>oozie.https.enabled</name>
  <value>true</value>
  <description>Controls whether SSL encryption is enabled.</description>
</property>

<property>
  <name>oozie.https.truststore.file</name>
  <value>/opt/mapr/conf/ssl_truststore</value>
  <description>Path to a TrustStore file.</description>
</property>

<property>
  <name>oozie.https.keystore.file</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
  <description>Path to a KeyStore file.</description>
</property>

<property>
  <name>oozie.https.keystore.pass</name>
  <value><password></value>
  <description>Password to the KeyStore.</description>
</property>
```

   Note: To configure the Oozie for `http`, set the `oozie.https.enabled` property to `false`.

2. Connect to the Oozie Web UI using SSL (HTTPS):

```
https://oozie.server.hostname:11443/oozie
```

You can also encrypt the Oozie keystore password. For more information, refer to the open source documentation.

Configuring Oozie Clients to Use SSL (Oozie 4.3.0)

To configure the Oozie clients, follow this step:

- Specify the path to the keystore and password at `/opt/mapr/oozie/oozie-<version>/conf/oozie-client-env.sh`:

```
export
OOZIE_CLIENT_OPTS="${OOZIE_CLIENT_OPTS} -Djavax.net.ssl.trustStore=/opt/
mapr/conf/ssl_truststore"
```

Using Kerberos to Securely Authenticate Between the Oozie Client and Server

Oozie can use Kerberos to secure authentication between the Oozie client and server. The Oozie server uses the Kerberos principal and keytab information specified in the Java Authentication and Authorization (JAAS) configuration file at `/opt/mapr/conf/mapr.login.conf`. Generate a Kerberos principal of the form `http/ <fqdn>@<realm>` and store the keytab in the cluster's keytab file. The default keytab file location is `/opt/mapr/conf/mapr.keytab`.

To use Kerberos authentication on a specific invocation of Oozie without modifying your client, use the `-auth KERBEROS` option when you start Oozie, as in the following example:

```
$ bin/oozie admin -status -auth KERBEROS
```

last-updated: Apr 11, 2022

Defining a Custom Principal and Keytab File

You can use custom Kerberos principals and keytab files if you wish. To specify the locations of these custom Kerberos principals and keytab files, make the following modifications to the `oozie-site.xml` file:

- Explicitly change the authentication type to Kerberos.

```
<property>
    <name>oozie.authentication.type</name>
    <value>kerberos</value>
    <description>
    Defines authentication used for Oozie HTTP endpoint.
    Supported values are: simple | kerberos |
#AUTHENTICATION_HANDLER_CLASSNAME#
    </description>
</property>
```

- Modify the following entries to use your custom principals and keytab. The principal takes the form `HTTP/<hostname>`, where *hostname* is the URL used by the client to connect to the server.

```
<property>
    <name>oozie.service.HadoopAccessorService.keytab.file</name>
    <value>/opt/mapr/conf/mapr.keytab</value>
    <description>
      Location of the Oozie user keytab file.
    </description>
</property>

<property>
    <name>local.realm</name>
    <value>{local.realm}</value>
    <description>
      Kerberos Realm used by Oozie and Hadoop. Using 'local.realm' aligns
with Hadoop configuration
    </description>
</property>

<property>
    <name>oozie.service.HadoopAccessorService.kerberos.principal</name>
    <value>mapr/<hostname>@${local.realm}</value>
    <description>
       Kerberos principal for Oozie service.
    </description>
</property>

<property>
    <name>oozie.authentication.kerberos.principal</name>
    <value>HTTP/<hostname>@${local.realm}</value>
    <description>
      Indicates the Kerberos principal to be used for the HTTP endpoint.
The principal MUST start with 'HTTP/' per the Kerberos HTTP SPNEGO
specification.
    </description>
</property>
```

- Optional: If you plan to run Oozie actions that require talking to external services, add the `oozie.credentials.credentialclasses` to `oozie-site.xml`. For more details, see the Oozie documentation.

```
<property>
    <name>oozie.credentials.credentialclasses</name>
    <value>
         hcat=org.apache.oozie.action.hadoop.HCatCredentials,
         hbase=org.apache.oozie.action.hadoop.HbaseCredentials,
         hive2=org.apache.oozie.action.hadoop.Hive2Credentials
    </value>
</property>
```

Note: No specific configuration is required for configuring Oozie to use MapR-SASL.

Disabling Cached Tokens

After a client authenticates to Oozie, the authentication token received by the client is cached in the user's home directory in the `.oozie-auth-token` file. As long as the cached token remains valid, future authentication requests from the same client use that token and succeed, even if the client's Kerberos or MapR credentials have expired or have been revoked. You can disable use of the cache file by using the `oozie` command-line interface with the `-Doozie.auth.token.cache false` option.

Configuring Security Headers for Web Servers for Oozie

This section describes how to configure response headers for REST API servers used in the Oozie web UI.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/oozie/oozie-<version>/conf/security-headers.xml
```

The `security-headers.xml` file contains the following headers:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<!DOCTYPE properties SYSTEM
"http://java.sun.com/dtd/properties.dtd">
<properties>
    <comment>Security headers that is used to minimize the possibility of
cross-site scripting and other attacks</comment>
    <entry key="X-XSS-Protection">1; mode=block</entry>
    <entry key="X-Content-Type-Options">nosniff</entry>
    <entry
key="Strict-Transport-Security">max-age=31536000;includeSubDomains</entry>
    <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

Header	Description	Default Value
X-XSS-Protection	Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.	`1: mode=block`

last-updated: Apr 11, 2022

Header	Description	Default Value
X-Content-Type-Options	Indicates that the MIME types advertised in the `Content-Type` headers should not be changed and should be followed.	`nosniff`
Strict-Transport-Security	Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.	`max-age=31536000;includeSubDomains`
Content-Security-Policy	Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS).	`default-src https:`

Configuring Security Headers for Oozie

To enable security headers for Oozie, add the following to the `oozie-site.xml` file, and replace `<version>` with your Oozie version:

```
<property>
<name>oozie.server.response.headers</name>
<value>/opt/mapr/oozie/oozie-<version>/conf/security-headers.xml</value>
</property>
```

Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add `Custom-header` as follows:

```
<entry key="Custom-header">custom-value</entry>
```

Security Headers Auto-Configuration

If you install Oozie on a secure cluster (MapR-SASL or Kerberos) and run the following command after Oozie installation, Oozie automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

Configure High Availability for Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To configure HA for Oozie on your cluster, the cluster must meet the following prerequisites:

- Your cluster must have access to a database with support for multiple concurrent connections. To prevent this database from becoming a single point of failure, the database must support HA. HA for the Oozie service works regardless of the database's HA status. See MySQL Data Store for Oozie.
- To prevent the ZooKeeper service from becoming a single point of failure, your cluster must have at least 3 ZooKeeper nodes. You can still configure HA for Oozie on clusters with a single ZK node.
- Multiple nodes on the cluster must have Oozie installed. For installation instructions, see the Installing MapR and MapR Ecosystem Components on page 128.

  Note: For greater consistency of behavior on your cluster, verify that all of the Oozie servers have the same configuration.

- A load balancer, virtual IP, or round-robin DNS set up, such as HAProxy. To prevent the load balancer from becoming a single point of failure, the load balancer must support HA.

1. Verify that the Oozie servers are all configured to connect to the same database. Do not start Oozie.
2. On each Oozie node, edit the `oozie-site.xml` file to add the following section, which changes the results in Oozie using the Zookeeper's version of the services, overriding the default implementations:

```
<property>
    <name>oozie.services.ext</name>
    <value>
        org.apache.oozie.service.ZKLocksService,
        org.apache.oozie.service.ZKXLogStreamingService,
        org.apache.oozie.service.ZKJobsConcurrencyService,
        org.apache.oozie.service.ZKUUIDService
    </value>
</property>
```

3. On each Oozie node, edit the `oozie-site.xml` file to include a comma-separated list of the host names and ports for the ZooKeeper servers. For example:

```
<property>
     <name>oozie.zookeeper.connection.string</name>
     <value>zk1:5181,zk2:5181,zk3:5181</value>
</property>
```

4. On each Oozie node, edit the `oozie-site.xml` file to include the Oozie server host name:

```
<property>
     <name>oozie.http.hostname</name>
     <value><FQDN></value>
</property>
```

5. On each Oozie node, edit the `oozie-site.xml` file to specify the namespace. Each Oozie server that communicates to other Oozie servers must use the same namespace:

```
<property>
     <name>oozie.zookeeper.namespace</name>
     <value>oozie</value>
</property>
```

6. On each Oozie node, change the value of the `OOZIE_BASE_URL` property in the `oozie-site.xml` file to point to the load balancer or virtual IP.

```
<property>
    <name>oozie.base.url</name>
    <value>http://my.loadbalancer.hostname:<oozie_port_number>/oozie</
value>
</property>
```

   The `<oozie_port_number>` depends on whether your cluster is secure.

last-updated: Apr 11, 2022

7. On all nodes, update the services line in the `warden.oozie.conf` file (stored at `/opt/mapr/conf/conf.d`; or for a fresh installation, at `/opt/mapr/oozie/oozie-<version>/conf/warden.oozie.conf`) from:

   ```
   services=oozie:1:cldb
   ```

   to

   ```
   services=oozie:all:cldb
   ```

8. Run the `configure.sh -R` command.

9. Run Oozie share lib update command to make sure that all Oozie services use the latest and the same version:

   ```
   {OOZIE_HOME}/bin/oozie admin -oozie="http(s)://
   my.loadbalancer.hostname:<oozie_port_number>" -sharelibupdate
   ```

Configure a MySQL Data Store for Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Follow these steps to configure Oozie to use a MySQL database as the Oozie data store (instead of the default Apache Derby database). The MySQL database can also be used to support high availability (HA).

1. Using the `mysql` command-line tool, create a MySQL database, user, and password for the Oozie user. For example:

   ```
   mysql> create database oozie;
   mysql> grant all privileges on oozie.* to '<oozie-user>'@'%' identified
   by '<oozie-passwd>';
   ```

2. Stop the Oozie server:

   ```
   maprcli node services -name oozie -action stop -nodes <node-list>
   ```

3. Set the following `JPAService` properties in the `oozie-site.xml` file: **Note**: In the JDBC URL property, use the correct hostname (where MySQL is running).

   ```
   <property>
       <name>oozie.service.JPAService.jdbc.driver</name>
       <value>com.mysql.jdbc.Driver</value>
   </property>
   <property>
       <name>oozie.service.JPAService.jdbc.url</name>
       <value>jdbc:mysql://localhost:3306/oozie</value>
       </property>
   <property>
       <name>oozie.service.JPAService.jdbc.username</name>
       <value>oozie</value>
   </property>
   <property>
       <name>oozie.service.JPAService.jdbc.password</name>
       <value>oozie</value>
   </property>
   ```

4. For earlier EEP 4.1.0 versions, copy the MySQL JDBC driver `mysql-connector-java-<version>-bin.jar` file to the following directory.

   ```
   /opt/mapr/oozie/oozie-<oozieversion>/libext
   ```

   For EEP 4.1.0 and later, the JDBC driver file `mysql-connector-java-<version>-bin.jar` is automatically copied from the `/opt/mapr/lib/` directory to the `/opt/mapr/oozie/oozie-<oozieversion>/libext` directory.

   See the repository to confirm default MySQL JDBC driver in `/opt/mapr/oozie/oozie-<oozieversion>/libext` directory is compatible with your MySQL or MariaDB version. Download and update the default JDBC driver file with the driver file that is compatible with your MySQL or Maria DB version.

5. Start the Oozie server:

   ```
   maprcli node services -name oozie -action start -nodes <node-list>
   ```

6. Check that MySQL is now in use by looking at the contents of the `oozie.log` file. For example:

   ```
   cat /opt/mapr/oozie/oozie-<version>/logs/oozie.log |grep mysql
   2015-07-24 06:10:07,023  INFO JPAService:541 - SERVER[local.novalocal]
   USER[-]
   GROUP[-] TOKEN[-] APP[-] JOB[-] ACTION[-] JPA configuration:
   DriverClassName=com.mysql.jdbc.Driver,Url=jdbc:mysql://localhost:3306/
   oozie,Username=oozie,...
   ```

7. To encrypt the Oozie database user password, see Encrypt the Oozie Database User Password on page 3997.

Configuring an Oracle Schema
You must create schemas for Oracle databases manually.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Create an Oozie SQL-with-schema file to reveal the schema:

```
bin/ooziedb.sh create -sqlfile oozie.sql -run
```

For more information, see the Apache Oozie documentation.

Encrypt the Oozie Database User Password

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Follow these steps to encrypt the password when Oozie uses a MySQL database as the Oozie data store (instead of the default Apache Derby database).

1. Configure Oozie to use a MySQL database as described in Configure a MySQL Data Store for Oozie on page 3996.

2. [OPTIONAL] Export the Hadoop credential store password as a system variable:

   ```
   $ export HADOOP_CREDSTORE_PASSWORD=password
   ```

3. Add `oozie.service.jpaservice.jdbc.password` to the `jceks` keystore:

```
$ hadoop credential create
oozie.service.jpaservice.jdbc.password -provider jceks://path/to/
oozie.jceks
Enter the password:
Enter the password again:
oozie.service.jpaservice.jdbc.password has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

4. Verify that the MySQL password was added:

```
Keystore type: JCEKS
Keystore provider: SunJCE

Your keystore contains 1 entry

Alias name: oozie.service.jpaservice.jdbc.password
Creation date: Apr 11, 2018
Entry type: SecretKeyEntry
```

5. Once the `jceks` file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file with the path to the `jceks` file. The `jceks` path location can be `maprfs` or a local file (`local-fs`).

```
<property>
   <name>hadoop.security.credential.provider.path</name>
   <value>jceks://path/to/oozie.jceks</value>
</property>
```

6. Update the `password` property to use `*****` instead of a word-readable password:

```
<property>
  <name>oozie.service.JPAService.jdbc.password</name>
  <value>*****</value>
</property>
```

Encrypt the Oozie Keystore Password

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Starting from Oozie 5.1.0.0, follow these steps to encrypt the keystore password when Oozie is configured to use SSL.

Note: Oozie 5.1.0.0 is configured to use SSL by default on secure clusters.

1. [OPTIONAL] Export the Hadoop credential store password as a system variable:

```
$ export HADOOP_CREDSTORE_PASSWORD=password
```

2. Add `oozie.https.keystore.pass` to the `jceks` keystore:

```
$ hadoop credential create oozie.https.keystore.pass -provider jceks://
path/to/oozie.jceks
Enter the password:
Enter the password again:
oozie.https.keystore.pass has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

3. Once the `jceks` file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file along with the path to the jceks file. The jceks path location can be `maprfs` or a local file (`local-fs`).

```
<property>
   <name>hadoop.security.credential.provider.path</name>
   <value>jceks://path/to/oozie.jceks</value>
</property>
```

4. Update the `password` property to use `*****` instead of a word-readable password:

```
<property>
  <name>oozie.https.keystore.pass</name>
  <value>*****</value>
</property>
```

Note: You can use the same `jceks` file for storing both database and keystore passwords.

User Impersonation for Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Oozie supports *impersonation*, which enables Oozie to run jobs as a user other than the user that started the Oozie server. You can set up proxy user functionality if you want Oozie to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups. When you configure proxy user functionality, the proxy user can perform “doAs” operations. Add configuration properties to the oozie-site.xml and core-site.xml files to configure proxy user functionality.

Add the following configuration properties to the oozie-site.xml file:

- `oozie.service.ProxyUserService.proxyuser.#USER#.hosts`
- `oozie.service.ProxyUserService.proxyuser.#USER#.groups`

Replace #USER# with the username of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (*) as the value for host and group properties. To add multiple users, copy the property and replace #USER# with the proxy user name.

Host Example

```
<property>
        <name>oozie.service.ProxyUserService.proxyuser.mapr.hosts</name>
        <value>*</value>
</property>
```

last-updated: Apr 11, 2022

Group Example

```
<property>
        <name>oozie.service.ProxyUserService.proxyuser.mapr.groups</name>
        <value>*</value>
</property>
```

Add the following configuration properties to the core-site.xml:

- `hadoop.proxyuser.#USER#.hosts`
- `hadoop.proxyuser.#USER#.groups`

Replace #USER# with the username of the proxy.

When you add the host property, the proxy user can only connect from a host to impersonate a user. When you add the group property, the proxy user can impersonate any member of any group.

Host Example

```
<property>
    <name>hadoop.proxyuser.mapr.hosts</name>
    <value>*</value>
</property>
```

Group Example

```
<property>
    <name>hadoop.proxyuser.mapr.groups</name>
    <value>*</value>
</property>
```

Updating the Oozie Shared Libraries

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You must update the Oozie shared libraries when:

- the `oozie.service.WorkflowAppService.system.libpath` property in the `oozie-site.xml` file is changed from the default value (`/oozie/share/lib`).
- a core patch is installed.

By default, the Oozie shared libraries are uploaded to the `maprfs:///oozie/share/lib` directory.

To update the Oozie shared libraries, complete the following steps:

1. Run the following command to copy the new Oozie shared libraries to the MapR filesystem:

   ```
   {OOZIE_HOME}/bin/oozie-setup.sh sharelib create -fs
   maprfs:/// -locallib /opt/mapr/oozie/oozie-<version>/share
   ```

2. Run the following command to update the Oozie classpath with the new shared libraries:

   ```
   {OOZIE_HOME}/bin/oozie admin -sharelibupdate -oozie https://<FQDN>:11443/
   oozie
   ```

last-updated: Apr 11, 2022

Use Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following sections provide information about using Oozie:

Manage Oozie Services and Interface

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can manage Oozie services and the Oozie interface through the command line or Oozie Web UI.

The following sections provide information about managing Oozie:

Starting, Stopping, and Restarting Oozie Services

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Warden daemon starts the Oozie server automatically at installation time. You can start and stop Oozie from the command line or from the Control System. Using the `maprcli node services` command enables you to start Oozie on multiple nodes at one time.

Starting, Stopping, and Restarting Oozie using maprcli

Complete the following steps to start | stop | restart Oozie from the command line:

1. Make a list of nodes on which Oozie is configured.
2. Issue the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Oozie is configured, separated by spaces.

   Example:

   ```
   maprcli node services -name oozie -action start|stop|restart -nodes
   <nodes list>
   ```

Enabling the Oozie Web UI

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Oozie web UI can display your job status, logs, and other related information. You must enable the Oozie Web UI after you install Oozie. However, depending on how you enable the Web UI, you may also need to perform manual steps to start the Web UI after you run `configure.sh` on the cluster.

1. Download the Ext JS 2.2 library as a zip archive (`ext-2.2.zip`). You can download this library from the Apache Oozie Quick Start guide. Search for "ExtJS 2.2" on the page to find the link.

   Note: The Ext JS 2.2 library is required only for the Oozie Web UI. A rewrite of the Oozie web UI has been proposed in the Oozie user community.

2. Copy the Ext JS 2.2 library into the `libext` directory:

   ```
   cp ext-2.2.zip /opt/mapr/oozie/oozie-<version>/libext/
   ```

3. **Applicable only for Oozie 4.X versions:** Perform one of the following options based on your preference:
   - If you want the Oozie Web UI to start whenever Oozie starts or restarts, perform the following steps:

last-updated: Apr 11, 2022

a. If Oozie is running, shut it down:

```
maprcli node services -name oozie -action stop -nodes <space
delimited list of nodes>
```

b. Run the oozie-setup.sh script, and specify the hadoop version.

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh -hadoop
<version> /opt/mapr/hadoop/hadoop-<version>
```

Note: If you are enabling the Oozie Web UI on a secure cluster and SSL must be configured, run the command with the `-secure` option:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh -hadoop
<version> /opt/mapr/hadoop/hadoop-<version> -secure
```

- If you want to manually start the Web UI when Oozie starts or restarts, perform the following steps:

a. If Oozie is running, shut it down:

```
maprcli node services -name oozie -action stop -nodes <space
delimited list of nodes>
```

b. Run the `oozie-setup.sh` script and specify the path to the `extjs` file.

```
cd /opt/mapr/oozie/oozie-<version>
bin/oozie-setup.sh prepare-war -extjs ~/ext-2.2.zip
```

4. Restart Oozie.

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

Checking the Status of Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Once Oozie is installed, you can check the status using the command line or the Oozie web console. The `<oozie_port_number>` noted in the URLs depend on whether your cluster is secure.

Check Status from Command Line

Use the `oozie admin` command:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie admin -oozie http(s)://
<oozie_node>:<oozie_port_number>/oozie -status
```

The following output indicates normal operation:

```
System mode: NORMAL
```

Check Status from the Oozie Web Console

Point your browser to `http://<oozie_node>:<oozie_port_number>/oozie`

Note:

- For non-secure clusters:

```
Oozie url: http://<oozie_node>:11000/oozie
```

- For secure clusters:

```
Oozie url: https://<oozie_node>:11443/oozie
```

Setup and Run Oozie Examples

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To get familiar with Oozie, set up and try the examples.

1. Complete the following steps to set up the examples and copy them to the cluster:
   a) Extract the oozie examples archive `oozie-examples.tar.gz`:

```
cd /opt/mapr/oozie/oozie-<version>
tar xvfz ./oozie-examples.tar.gz -C /opt/mapr/oozie/oozie-<version>/
```

   b) Copy the examples to MapR filesystem. Run the following command as a user that has permissions to write to the specified MapR filesystem directory:

```
hadoop fs -put examples maprfs:///user/<user_name>/examples
```

2. Complete the following steps to run the examples:
   a) Choose an example and run it with the `oozie job` command. You can use the following commands to run the following examples. The `<oozie_port_number>` depends on whether your cluster is secure.
      - MapReduce

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -oozie="http://
localhost:<oozie_port_number>/oozie" -config /opt/mapr/oozie/
oozie-<version>/examples/apps/map-reduce/job.properties -run
```

      - Spark

```
/opt/mapr/oozie/oozie-<version>/bin/oozie job -oozie="http://
localhost:<oozie_port_number>/oozie" -config /opt/mapr/oozie/
oozie-<version>/examples/apps/spark/job.properties -run
```

      Note: To run the packaged Hive examples, make `/tmp` on MapR filesystem world-writable. Set `/tmp` to 777. Example:

```
hadoop fs -chmod -R 777 /tmp
```

      If /tmp does not exist, create `/tmp` and then set it to 777.

last-updated: Apr 11, 2022

Check the Status of a Job

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can check the status of a job from the command line or the Oozie Web Console.

From the command line, issue the following (substituting the job ID for the `<job id>` placeholder):

```
# /opt/mapr/oozie/oozie-<version>/bin/oozie job -info <job id>
```

To check status from the Oozie Web Console, point your browser to `http://<Oozie_node>:<oozie_port_number>/oozie` and click **All Jobs**. The `<oozie_port_number>` depends on whether your cluster is secure.

Run Hive Jobs with Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You run Hive jobs with Oozie by configuring a Hive workflow.

1. **Configure a Hive workflow.** You can configure Oozie to perform a workflow by connecting to Hive Metastore or Hiveserver2.

   Configure a Hive Workflow with Connection to Hive Metastore

   a. To use a metastore server for the Hive job, add the following parameter to the hive-site.xml file:

   ```
   <property>
     <name>hive.metastore.uris</name>
     <value>thrift://<IP address>:<port></value>
     <description>IP address (or fully-qualified domain name) and port
   of the metastore host</description>
   </property>
   ```

   b. Copy the edited `hive-site.xml` file to the same location as your `workflow.xml` file.

   c. If you are using the Hive-on-Tez engine, and you have changed the default `tez-site.xml` configuration, perform one of the following steps:

   - Copy the tez-site.xml file to the same location as your workflow.xml file:

     1. Remove the forbidden (forbidden for Oozie) property from `tez-site.xml`:

     ```
     <property>
       <name>fs.defaultFS</name>
       <value>maprfs:///</value>
     </property>
     ```

     2. Make sure that you update the value for `tez.lib.uris` property after removing the `fs.defaultFS` property. For example:

     ```
     tez.lib.uris=maprfs:///apps/tez/tez-<version>,maprfs:///apps/tez/
     tez-<version>/lib
     ```

     3. Specify the `tez-site.xml` file in the `job-xml` parameter of your workflow.

   - Update `<OOZIE_HOME>/conf/action-conf/hive.xml` with the new `tez-site.xml` properties.

last-updated: Apr 11, 2022

d. Edit the `workflow.xml` file to include the following:

1. Specify the `hive-site.xml` in the `job-xml` parameter.
2. Specify the name of the script (for example, `script.q`) that contains the hive query in the script parameter.
3. Optionally, add properties used by the Oozie launcher job. Add the prefix `oozie.launcher` to the property names.

```
<workflow-app xmlns="uri:oozie:workflow:0.2" name="hive-wf">
    <start to="hive-node"/>
    <action name="hive-node">
        <hive xmlns="uri:oozie:hive-action:0.2">
            <job-tracker>${jobTracker}</job-tracker>
            <name-node>${nameNode}</name-node>
            <prepare>
                <delete path="${nameNode}/user/${wf:user()}/$
{examplesRoot}/output-data/hive"/>
                <mkdir path="${nameNode}/user/${wf:user()}/$
{examplesRoot}/output-data"/>
            </prepare>
            <job-xml>hive-site.xml</job-xml>
            <!- Add this property if you copied tez-site.xml to the
same location as your workflow.xml file -->
            <job-xml>tez-site.xml</job-xml>
            <configuration>
                <property>
                    <name>mapred.job.queue.name</name>
                    <value>${queueName}</value>
                </property>
            </configuration>
            <script>script.q</script>
            <param>INPUT=/user/${wf:user()}/${examplesRoot}/
input-data/table</param>
            <param>OUTPUT=/user/${wf:user()}/${examplesRoot}/
output-data/hive</param>
        </hive>
        <ok to="end"/>
        <error to="fail"/>
    </action>

    <kill name="fail">
        <message>Hive failed, error message[$
{wf:errorMessage(wf:lastErrorNode())}]</message>
    </kill>
    <end name="end"/>
</workflow-app>
```

Configure a Hive Workflow with Connection to HiveServer2

a. Copy the edited `hive-site.xml` file to the same location as your `workflow.xml` file.

b. On a Kerberos secure cluster for Oozie 4.3.0, perform the following steps:

1. Copy the `hive-site.xml` file to the `${OOZIE_HOME}/conf/action-conf/` directory.
2. Rebuild the Oozie war file:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie-setup.sh
-hadoop <version> /opt/mapr/hadoop/hadoop-<version>
```

last-updated: Apr 11, 2022

c. Edit the `workflow.xml` file to include the following:

1. Specify the JDBC URL used by Beeline for connections to Hiveserver2 in the `jdbc-url` element. See Connecting to HiveServer2 for details.

2. Specify the name of the script (for example, `script.q`) that contains the hive query in the script element.

```
<?xml version="1.0" encoding="UTF-8"?>
<workflow-app xmlns="uri:oozie:workflow:0.5" name="hive2-wf">
    <start to="hive2-node"/>
    <action name="hive2-node">
        <hive2 xmlns="uri:oozie:hive2-action:0.1">
            <job-tracker>${jobTracker}</job-tracker>
            <name-node>${nameNode}</name-node>
            <prepare>
                <delete path="${nameNode}/user/${wf:user()}/
output-data/hive2"/>
                <mkdir path="${nameNode}/user/${wf:user()}/
output-data"/>
            </prepare>
            <configuration>
                <property>
                    <name>mapred.job.queue.name</name>
                    <value>${queueName}</value>
                </property>
            </configuration>
            <jdbc-url>jdbc:hive2://localhost:10000/default</
jdbc-url>
            <script>script.q</script>
            <param>INPUT=/user/${wf:user()}/input-data/table</
param>
            <param>OUTPUT=/user/${wf:user()}/output-data/hive2</
param>
        </hive2>
        <ok to="end"/>
        <error to="fail"/>
    </action>
    <kill name="fail">
        <message>Hive2 (Beeline) action failed, error message[$
{wf:errorMessage(wf:lastErrorNode())}]</message>
    </kill>
    <end name="end"/>
</workflow-app>
```

Run Spark Jobs with Oozie

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Complete the following steps to configure Oozie to run Spark jobs:

Configure a Spark action:

1. For running a Spark action through Oozie, you should be able to connect to Hive on a secure cluster. Make sure the `hive-site.xml` file that is used by Oozie has the following property set:

```
<property>
  <name>hive.metastore.sasl.enabled</name>
  <value>true</value>
</property>
```

2. To add Spark configuration files (`spark-defaults.conf`, `hive-site.xml`, etc) to a Spark action, copy the files to the `{OOZIE_HOME}/share/lib/spark/` directory.

3. If needed, update the Oozie shared libraries as described in Updating the Oozie Shared Libraries on page 4000.

4. Run pySpark using Spark Action:

   a. Run pySpark using Spark Action by specifying pyspark and py4j zip files to the sharelib:

   ```
   cp /{SPARK_HOME}/python/lib/ pyspark*.zip {OOZIE_HOME}/share/lib/
   spark/
   cp /{SPARK_HOME}/python/lib/py4j*src.zip {OOZIE_HOME}/share/lib/spark/
   ```

   b. Update the Oozie shared libraries as described in Updating the Oozie Shared Libraries on page 4000.

5. When you configure a Spark action in the `workflow.xml`, specify the `master` and `mode` elements of the Spark job:

   - For Spark standalone mode, specify the Spark Master URL in the `master` element. For example, if your SparkMaster URL is `spark://ubuntu2:7077`, you would replace the `<master> [SPARK MASTER URL]</master>` in the example below with `<master> spark://ubuntu2:7077</master>`.

   - For Spark on YARN mode, specify `yarn-client` or `yarn-cluster` in the `master` element. For example, for `yarn-cluster` mode, you would replace `<master> [SPARK MASTER URL]</master>` with `<master>yarn</master>` and `<mode>[SPARK MODE]</mode>` with `<mode>cluster</mode>`.

     Here is an example of a Spark action within a `workflow.xml` file:

```
<workflow-app xmlns='uri:oozie:workflow:0.5' name='SparkFileCopy'>
  <start to='spark-node' />
  <action name='spark-node'>
     <spark xmlns="uri:oozie:spark-action:0.1">
        <job-tracker>${jobTracker}</job-tracker>
        <name-node>${nameNode}</name-node>
        <master>[SPARK MASTER URL]</master>
        <mode>[SPARK MODE]</mode>
        <name>Spark-FileCopy</name>
        <class>org.apache.oozie.example.SparkFileCopy</class>
        <jar>${nameNode}/user/${wf:user()}/${examplesRoot}/apps/
spark/lib/oozie-examples.jar</jar>
        <arg>${nameNode}/user/${wf:user()}/${examplesRoot}/input-data/
text/data.txt</arg>
        <arg>${nameNode}/user/${wf:user()}/${examplesRoot}/output</arg>
      </spark>
      <ok to="end" />
      <error to="fail" />
   </action>
   <kill name="fail">
      <message>Workflow failed, error
               message[${wf:errorMessage(wf:lastErrorNode())}]
      </message>
   </kill>
  <end name='end' />
</workflow-app>
```

last-updated: Apr 11, 2022

Oozie 5.1.0 API Changes

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Oozie 5.1.0 includes the following changes in the Web Services API. The complete documentation is available at http://oozie.apache.org/docs/5.1.0/WebServicesAPI.html

API	Description
Get missing dependencies	This endpoint is to show all missing dependencies of coordinator action(s).
Purge Command	Oozie admin purge command cleans up the Oozie Workflow, Coordinator, or Bundle records based on the specified parameters. The unit for parameters is `days`. The purge command deletes the workflow records (`wf=30`) older than 30 days, coordinator records (`coord=7`) older than 7 days, and bundle records (`bundle=7`) older than 7 days. The limit (`limit=10`) defines the number of records to be fetched at a given time. Turn on or off (`oldCoordAction true or false`) enables coordinator action record purging for long running coordinators. If any of these parameters are not specified, it is taken from the `oozie-default` or `oozie-site` configuration file.

Oozie 4.3.0 API Changes

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Oozie 4.3.0 includes the following changes in the Web Services API. Full documentation is available at http://oozie.apache.org/docs/4.3.0/WebServicesAPI.html

API	Description
Validate a local file	This endpoint is to validate a workflow, coordinator, bundle XML file.
Validate a file in MapR File System	You can validate a workflow, coordinator, bundle XML file in MapR File System. The XML file must already exist in MapR File System.

Oozie Known Issues

This topic describes known issues related to Oozie.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Spark Oozie Share Library Update Required if Core Patch Applied

If you installed a Core patch for EEP version 6.3.0, 6.3.1, or 7.0.0, the Spark Oozie Share Lib must be updated with the `maprbuildversion` JAR either manually or through an Oozie upgrade.

- When you upgrade to Oozie in EEP 6.3.2, 7.0.1, or later and run `/opt/mapr/server/configure.sh -R`, the `maprbuildversion` JAR is automatically copied from `$MAPR_HOME/lib` to `$OOZIE_HOME/share/lib/spark`.
- Alternatively, you can manually copy the `maprbuildversion` JAR from `$MAPR_HOME/lib` to `$OOZIE_HOME/share/lib/spark` and then run `/opt/mapr/server/configure.sh -R`.

last-updated: Apr 11, 2022

Oozie Share Library Update Required if Core Patch Applied

After a core patch installation, update the Oozie shared libraries under the maprfs directory, as described in Updating the Oozie Shared Libraries on page 4000.

Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Apache Pig™ is a platform for analyzing large data sets. Apache Pig™ is a high-level language for expressing data analysis programs coupled with an infrastructure to evaluate these programs. The infrastructure layer consists of a compiler that produces sequences of Map-Reduce programs. The language layer consists of a textual language called *Pig Latin*.

The following sections provide documentation about installing, upgrading, configuring and using Pig. You can also refer to the documentation available on the Apache Pig website.

Configure Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Pig runs in MapReduce mode by default. If you want to run Pig in local mode (`pig -x local`), add the following properties to the `/opt/mapr/pig/pig-<version>/conf/pig.properties file:`

```
fs.file.impl=org.apache.hadoop.fs.LocalFileSystem
io.file.buffer.size=4096
```

The `io.file.buffer.size` property defines how much data is buffered during read and write operations. This value defaults to `-1`, which causes Pig to fail if the local filesystem is used.

Use Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Once Pig is installed, the executable is located in `/opt/mapr/pig/pig-<version>/bin/pig`.

The following topics provide information about using Pig. You can also refer to the documentation available on the Apache Pig website.

Get Started with Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

In this tutorial, we will use Pig to run a MapReduce application that counts the words in the `/in/constitution.txt` file located in the `mapr` user's directory on the cluster, and store the results in the file `wordcount.txt`.

1. Download the ZIP file that contains constitution.txt and then extract the constitution.txt file.
2. Load the file onto the cluster and place it in the directory `/user/mapr/in`.
3. In the terminal, type the command `pig` to start the Pig shell.
4. At the `grunt>` prompt, type the following lines (press ENTER after each): After you type the last line, Pig starts a MapReduce application to count the words in the file `constitution.txt`.

```
A = LOAD '/user/mapr/in' USING TextLoader() AS (words:chararray);
```

```
B = FOREACH A GENERATE FLATTEN(TOKENIZE(*));
```

```
C = GROUP B BY $0;
```

```
D = FOREACH C GENERATE group, COUNT(B);
```

```
STORE D INTO '/user/mapr/wordcount';
```

5. When the MapReduce application is complete, type `quit` to exit the Pig shell and take a look at the contents of the directory `/myvolume/wordcount` to see the results.

Use ORC Storage with Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This section presents simple examples for using Hive ORC storage. Use the `grunt` shell in Pig to execute the commands. For more details, see the Pig documentation.

ORC is typically used to read (load) and write (store) data as follows:

```
<VAR_NAME> = load '/path/to/orc/formatted/file' using OrcStorage();
store <VAR_NAME> into '/path/to/output/orc/file' using OrcStorage('');
```

Example: Create an ORC file in the file system by storing the data in a Hive table and uploading it to Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You can create an ORC format file in the file system by using Hive to load a text file into a table with ORC storage. Then, you can upload the resulting ORC format file to Pig.

1. Create a sample test data file:

```
cd /home/mapr
nano test_pig.data
chown mapr:mapr test_pig.data
```

last-updated: Apr 11, 2022

2. Add data to the file.

```
John,Smith
Brian,May
Rodger,Taylor
John,Deacon
Max,Plank
Freddie,Mercury
Albert,Einstein
Fedor,Dostoevsky
Lev,Tolstoy
Niccolo,Paganini
```

Note: Do not include any extra lines at the end of the file.

3. Upload the test data to a Hive table:

```
sudo -u mapr hive
hive> create table test_pig(first_name string, last_name string) ROW
FORMAT DELIMITED FIELDS TERMINATED BY ',';
hive> load data local inpath '/home/mapr/test_pig.data' overwrite into
table test_pig;
```

4. Create a Hive table with ORC storage:

```
hive> create table test_pig_orc(first_name string, last_name string)
stored as orc tblproperties ("orc.compress"="NONE");
hive> insert overwrite table test_pig_orc select * from test_pig;
hive> select * from test_pig_orc;
```

5. Check that the ORC file was created:

```
hadoop fs -ls /user/hive/warehouse/test_pig_orc
```

6. Upload the ORC file to Pig:

```
sudo -u mapr pig
grunt> B = load '/user/hive/warehouse/test_pig_orc/000000_0'
using OrcStorage();
grunt> dump B;
```

Example: ***Upload a text file to the file system and use Pig to save it as an ORC file***

1. Upload the file to the file system:

```
cd /home/mapr
sudo -u mapr hadoop fs -put ./test_pig.data /test_pig.data
sudo -u mapr hadoop fs -mkdir /output
```

2. Start Pig and save the text file in ORC format:

```
sudo -u mapr pig
grunt> A = LOAD '/test_pig.data' using PigStorage(',') AS
(first_name:chararray, last_name:chararray);
grunt> store A into '/output/A' using OrcStorage('');
```

last-updated: Apr 11, 2022

3. Verify that the ORC file was created:

```
hadoop fs -ls /output/A/
```

Integrate Pig

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This following topics provide information about how to integrate Pig with other ecosystem components. You can also refer to the documentation available on the Apache Pig website.

Integrate Pig and HBase
This document shows an example of a Pig and HBase integration. The goal of integration is to upload data from the MapR File System to Pig and then move the data to an HBase table.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Configuring Pig and HBase

No additional configuration is needed to integrate HBase and Pig.

Pig and HBase Integration Example

1. Create sample data, and upload the data to the MapR File System:
   a. Create a sample data file:

```
vim input.csv
```

   b. Add data to the file:

```
1,aaa,bbb
2,ccc,ddd
3,rrr,fff
4,ttt,yyy
```

   c. Upload the data to the MapR File System:

```
hadoop fs -put input.csv /user/mapr/input.csv
```

2. Create a sample table in HBase:
   a. Start the HBase shell:

```
hbase shell
```

   b. Create a table:

```
hbase(main):012:0> create 'sample_names', 'info'
```

3. Load the data to Pig, and store the data in HBase:

a. Start the Pig shell:

```
pig
```

b. Load the data to Pig:

```
raw_data = LOAD '/user/mapr/input.csv' USING PigStorage(',') AS
(listing_id: chararray, fname: chararray, lname: chararray);
```

c. Store the data in HBase:

```
STORE raw_data INTO 'sample_names' USING
org.apache.pig.backend.hadoop.hbase.HBaseStorage ('info:fname
info:lname');
```

4. Verify the data in HBase:

a. Start the HBase shell:

```
hbase shell
```

b. Query the data:

```
hbase(main):017:0* scan 'sample_names'
```

The result is:

```
ROW
COLUMN+CELL

 1    column=info:fname, timestamp=1574946889082, value=aaa
 1    column=info:lname, timestamp=1574946889082, value=bbb
 2    column=info:fname, timestamp=1574946889091, value=ccc
 2    column=info:lname, timestamp=1574946889091, value=ddd
 3    column=info:fname, timestamp=1574946889091, value=rrr
 3    column=info:lname, timestamp=1574946889091, value=fff
 4    column=info:fname, timestamp=1574946889091, value=ttt
 4    column=info:lname, timestamp=1574946889091, value=yyy
```

Integrate Pig and MapR Database

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To configure Pig to work with MapR Database tables, perform the following steps:

1. On the client node where Pig is installed, add the following string to `/opt/mapr/conf/env.sh`:

```
export PIG_CLASSPATH=$PIG_CLASSPATH:/location-to-hbase-jar
```

2. If the client node where Pig is installed also has the `mapr-hbase` package installed, add the location of the `hbase-<version>.jar` file to the `PIG_CLASSPATH` variable from the previous step:

```
export PIG_CLASSPATH="$PIG_CLASSPATH:/opt/mapr/hbase/hbase-<version>/
hbase-<version>.jar"
```

3. If the client node where Pig is installed does not have the `mapr-hbase` package installed, copy the HBase JAR from a node that does have HBase installed to a location on the Pig client node. Add the HBase JAR's location to the definition from previous steps:

```
export PIG_CLASSPATH=$PIG_CLASSPATH:/opt/mapr/lib/hbase-<version>.jar
```

4. Add the HBase JAR to the Hadoop classpath:

```
export HADOOP_CLASSPATH="/opt/mapr/hbase/hbase-<version>/
hbase-<version>-mapr.jar:$HADOOP_CLASSPATH"
```

5. Launch a Pig job and verify that Pig can access HBase tables by using the HBase table name directly. Do not use the `hbase://` prefix.

Pig 0.16.0 API

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

This section contains the following topics:

New API in Pig 0.16.0

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Pig 0.16.0 includes the following new classes and interfaces.

New Classes

Class	Description

org.apache.pig.piggybank.evaluation.string.REPLACE_MULTI	REPLACE_MULTI implements eval function to replace all occurrences of search keys with replacement values. Replacement values are specified in Map. For example:
	`input_data = LOAD 'input_data' as (name);`
	`-- name = 'Hello World!' replaced_name = FOREACH input_data \`
	`GENERATE REPLACE_MULTI ( name, [ ''#'_', '!'#'', 'e'#'a', 'o'#'oo' ] );`
	`-- replaced_name = Halloo_Woorld`
	The first argument is the source string on which `REPLACE_MULTI` operation is performed. The second argument is a map having search key with replacement value pairs.

Class	Description
org.apache.pig.piggybank.storage.apachelog.LogFormatLoader	This is a pig loader that can load Apache HTTPD access logs written in (almost) any Apache HTTPD LogFormat. *Basic usage:* Feed the loader your (custom) logformat specification and it will show the fields that can be extracted from this logformat.
org.apache.pig.CounterBasedErrorHandler	Handles errors thrown by the `StoreFuncInterface.putNext()`.
org.apache.pig.backend.hadoop.HKerberos	Support for logging in using a Kerberos keytab file. Kerberos is an authentication system that uses tickets with limited validity time. Running a Pig script on a Kerberos secured Hadoop cluster limits the running time to at most the remaining validity time of the Kerberos tickets. When doing really complex analytics, this may become a problem as the job may need to run for a longer time than these ticket times allow. A Kerberos keytab file is a Kerberos specific form of the password of a user. It is possible to enable a Hadoop job to request new tickets when they expire by creating a keytab file and making it part of the job that is running in the cluster. This will extend the maximum job duration beyond the maximum renew time of the Kerberos tickets.
org.apache.pig.backend.hadoop.executionengine.mapReduceLayer.PigWritableComparators	Byte only raw comparators for faster comparison for non-orderby jobs. This does not reuse `JobControlCompiler.Pig<DataType>WritableComparator`, which extends `PigWritableComparator`. The `PigNullablePartitionWritable.compare` is not that efficient in cases where tuple is iterated for null checking instead of taking advantage of `TupleRawComparator.hasComparedTupleNull()`. This also skips multi-query index checking.
org.apache.pig.backend.hadoop.executionengine.physicalLayer.relationalOperators.StoreFuncDecorator	This class is used to decorate the `StoreFunc#putNext(Tuple)`. It handles errors by calling `OutputErrorHandler#handle(String, long, Throwable)` if the `StoreFunc` implements `ErrorHandling`.
org.apache.pig.backend.hadoop.executionengine.tez.runtime.PigInputFormatTez	Extends `org.apache.hadoop.mapreduce.InputFormat` and implements Pig and Tez specific functions.
org.apache.pig.backend.hadoop.executionengine.tez.util.TezUDFContextSeparator	Extends a visitor for the TezOperPlan class and serializes all (`LoadFunc`, `StoreFunc`, `UserFunc`).
org.apache.pig.impl.io.compress.BZip2CodecWithExtensionBZ	For historical reasons, Pig supports `.bz` and `.bz2` for `bzip2` extension. This class returns the additional `bzip2` file extension, `.bz`, as a string.
org.apache.pig.impl.util.UDFContextSeparator	`TezUDFContextSeparator` extends `PhyPlanVisitor`, which is the visitor class for the Physical Plan. To use this, create the visitor with the plan to be visited. Call the `visit()` method to traverse the plan in a depth first fashion. This class also visits the nested plans inside the operators. Extend this class to modify the nature of each visit and to maintain any relevant state information between the visits to two different operators.
org.apache.pig.parser.RegisterResolver	Resolves a JAR with a scripting language or namespace.

last-updated: Apr 11, 2022

Class	Description
org.apache.pig.tools.DownloadResolver	Makes a list of URIs of the downloaded JARs.

New Interfaces

Interface	Description
org.apache.pig.ErrorHandler	The interface that handles errors thrown by `StoreFuncInterface.putNext(Tuple)`.
org.apache.pig.ErrorHandling	The interface to enable handling of errors during `StoreFunc#putNext(Tuple)`.

Deprecated API in Pig 0.16.0

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following interfaces, classes, fields, and methods have been deprecated in Pig 0.16.0.

Deprecated Interfaces

Instead of this deprecated interface...	Use...
org.apache.pig.PigToStream	PigStreamingBase
org.apache.pig.StreamToPig	PigStreamingBase

Deprecated Classes

Instead of this deprecated class...	Use...
org.apache.pig.piggybank.evaluation.math.ABS	ABS
org.apache.pig.piggybank.evaluation.math.ACOS	ACOS
org.apache.pig.builtin.ARITY	SIZE
org.apache.pig.piggybank.evaluation.math.ASIN	ASIN
org.apache.pig.piggybank.evaluation.math.ATAN	ATAN
org.apache.pig.piggybank.evaluation.math.Base	Base
org.apache.pig.piggybank.evaluation.math.CBRT	CBRT
org.apache.pig.piggybank.evaluation.math.CEIL	CEIL
org.apache.pig.ComparisonFunc	N/A
org.apache.pig.piggybank.evaluation.stats.COR	COR
org.apache.pig.piggybank.evaluation.math.COS	COS
org.apache.pig.piggybank.evaluation.math.COSH	COSH
org.apache.pig.piggybank.evaluation.stats.COV	COV
org.apache.pig.data.DefaultTupleFactory	TupleFactory
org.apache.pig.piggybank.evaluation.math.DoubleAbs	DoubleAbs
org.apache.pig.piggybank.evaluation.math.DoubleBase	DoubleBase
org.apache.pig.piggybank.evaluation.math.DoubleRound	DoubleRound

last-updated: Apr 11, 2022

Instead of this deprecated class...	Use...
org.apache.pig.piggybank.evaluation.math.EXP	EXP
org.apache.pig.piggybank.evaluation.math.FloatAbs	FloatAbs
org.apache.pig.piggybank.evaluation.math.FloatRound	FloatRound
org.apache.pig.piggybank.evaluation.math.FLOOR	FLOOR
org.apache.pig.piggybank.evaluation.string.INDEXOF	INDEXOF
org.apache.pig.piggybank.evaluation.math.IntAbs	IntAbs
org.apache.pig.piggybank.storage.JsonMetadata	N/A
org.apache.pig.piggybank.evaluation.string.LASTINDEXOF	LAST_INDEX_OF
org.apache.pig.piggybank.evaluation.string.LcFirst	LCFIRST
org.apache.pig.piggybank.evaluation.math.LOG	LOG
org.apache.pig.piggybank.evaluation.math.LOG10	LOG10
org.apache.pig.piggybank.evaluation.math.LongAbs	LongAbs
org.apache.pig.piggybank.evaluation.string.LOWER	LOWER
org.apache.pig.piggybank.storage.PigStorageSchema	PigStorage with `-schema` option
org.apache.pig.piggybank.evaluation.string.RegexExtract	REGEX_EXTRACT
org.apache.pig.piggybank.evaluation.string.RegexExtractAll	REGEX_EXTRACT_ALL
org.apache.pig.piggybank.evaluation.string.REPLACE	REPLACE
org.apache.pig.piggybank.evaluation.math.ROUND	ROUND
org.apache.pig.piggybank.evaluation.math.SIN	SIN
org.apache.pig.piggybank.evaluation.math.SINH	SINH
org.apache.pig.piggybank.evaluation.string.Split	STRSPLIT
org.apache.pig.piggybank.evaluation.math.SQRT	SQRT
org.apache.pig.piggybank.evaluation.string.SUBSTRING	SUBSTRING
org.apache.pig.piggybank.evaluation.math.TAN	TAN
org.apache.pig.piggybank.evaluation.math.TANH	TANH
org.apache.pig.piggybank.evaluation.util.ToBag	TOBAG
org.apache.pig.piggybank.evaluation.util.Top	TOP
org.apache.pig.piggybank.evaluation.util.ToTuple	TOTUPLE
org.apache.pig.piggybank.evaluation.string.Trim	TRIM
org.apache.pig.piggybank.evaluation.string.UcFirst	UCFIRST
org.apache.pig.piggybank.evaluation.string.UPPER	UPPER

last-updated: Apr 11, 2022

Instead of this deprecated class...	Use...
org.apache.pig.impl.util.WrappedIOException	**Note:** This class was introduced to overcome the limitation that before Java 1.6, IOException did not have a constructor which took a Throwable argument. Since Pig code is now compiled with Java 1.6 and EvalFunc and LoadFunc user implementations should also use Java 1.6, they can use IOException instead. From Java 1.6, IOException has constructors which take a Throwable argument.

Deprecated Fields

Instead of this deprecated field...	Use...
org.apache.pig.tools.pigstats.PigStatsUtil.FS_COUNTER_GROUP	MRPigStatsUtil.FS_COUNTER_GROUP
org.apache.pig.PigConfiguration.INSERT_ENABLED **Note:** Will be removed in Pig 0.16	PigConfiguration.PIG_SCRIPT_INFO_ENABLED.
org.apache.pig.PigConfiguration.MAX_SCRIPT_SIZE **Note:** Will be removed in Pig 0.16.	PigConfiguration.PIG_SCRIPT_MAX_SIZE
org.apache.pig.PigConfiguration.OPT_FETCH **Note:** Will be removed in Pig 0.16.	PigConfiguration.PIG_OPT_FETCH
org.apache.pig.PigConfiguration.PARTAGG_MINREDUCTION **Note:** Will be removed in Pig 0.16.	PigConfiguration.PIG_EXEC_MAP_PARTAGG_MINREDUCTION
org.apache.pig.PigConfiguration.PROP_CACHEDBAG_MEMUSAGE **Note:** Will be removed in Pig 0.16.	PigConfiguration.PIG_CACHEDBAG_MEMUSAGE
org.apache.pig.PigConfiguration.PROP_EXEC_MAP_PARTAGG **Note:** Will be removed in Pig 0.16.	PigConfiguration.PIG_EXEC_MAP_PARTAGG
org.apache.pig.PigConfiguration.PROP_NO_COMBINER **Note:** Will be removed in Pig 0.16.	#PROP_NO_COMBINER1
org.apache.pig.PigConfiguration.SCHEMA_TUPLE_SHOULD_ALLOW_FORCE	N/A
org.apache.pig.PigConfiguration.SCHEMA_TUPLE_SHOULD_USE_IN_FOREACH	N/A
org.apache.pig.PigConfiguration.SCHEMA_TUPLE_SHOULD_USE_IN_FRJOIN	N/A
org.apache.pig.PigConfiguration.SCHEMA_TUPLE_SHOULD_USE_IN_MERGEJOIN	N/A

Instead of this deprecated field...	Use...
org.apache.pig.PigConfiguration.SCHEMA_TUPLE_SHOULD_USE_IN_UDF	N/A
org.apache.pig.impl.PigContext.scriptFiles	N/A
org.apache.pig.PigConfiguration.SHOULD_USE_SCHEMA_TUPLE	N/A
org.apache.pig.backend.hadoop.executionengine.mapReduceLayer.PigInputFormat.sJob	UDFContext in the following way to get the job's Configuration: `UdfContext.getUdfContext().getJobConf()`
org.apache.pig.backend.hadoop.executionengine.mapReduceLayer.PigGenericMapReduce.sJobConf	UDFContext in the following way to get the job's Configuration: `UdfContext.getUdfContext().getJobConf()`
org.apache.pig.tools.pigstats.PigStatsUtil.TASK_COUNTER_GROUP	MRPigStatsUtil.TASK_COUNTER_GROUP

Deprecated Methods

Instead of this deprecated method...	Use...
org.apache.pig.PigStreamingBase.deserialize(byte[])	N/A
org.apache.pig.impl.io.FileLocalizer.fileExists(String, DataStorage)	FileLocalizer.fileExists(String, PigContext)
org.apache.pig.impl.io.FileLocalizer.fullPath(String, DataStorage)	FileLocalizer.fullPath(String, PigContext)
org.apache.pig.tools.pigstats.JobStats.getAvgMapTime()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getAvgMapTime()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getAvgMapTime()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getAvgMapTime()	N/A
org.apache.pig.tools.pigstats.JobStats.getAvgREduceTime()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getAvgREduceTime()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getAvgREduceTime()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getAvgREduceTime()	N/A
org.apache.pig.impl.PigContext.getConf()	PigContext.getProperties()
org.apache.pig.tools.pigstats.PigStatusReporter.getCounter(Enum)	PigStatusReporter.incrCounter(java.lang.Enum<?>, long) This method returns MR counter which is not compatible with Tez mode. Use `incrCounter()` that is compatible with both MR and Tez mode.
org.apache.pig.tools.pigstats.PigStatusReporter.getCounter(String, String)	PigStatusReporter.incrCounter(java.lang.Enum<?>, long) This method returns MR counter which is not compatible with Tez mode. Use incrCounter() that is compatible with both MR and Tez mode.
org.apache.pig.tools.pigstats.PigStatsUtil.getEmptyPigStats()	N/A

last-updated: Apr 11, 2022

Instead of this deprecated method...	Use...
org.apache.pig.tools.pigstats.JobStats.getHadoopCounters()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getHadoopCounters()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getHadoopCounters()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getHadoopCounters()	N/A
org.apache.pig.tools.pigstats.PigStats.getJobClient()	N/A
org.apache.pig.tools.pigstats.mapreduce.SimplePigStats.getJobClient()	N/A
org.apache.pig.backend.hadoop.executionengine.HExecutionEngine.getJobConf()	N/A
org.apache.pig.tools.pigstats.JobStats.getMapInputRecords()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMapInputRecords()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMapInputRecords()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMapInputRecords()	N/A
org.apache.pig.tools.pigstats.JobStats.getMapOutputRecords()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMapOutputRecords()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMapOutputRecords()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMapOutputRecords()	N/A
org.apache.pig.tools.pigstats.JobStats.getMaxMapTime()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMaxMapTime()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMaxMapTime()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMaxMapTime()	N/A
org.apache.pig.tools.pigstats.JobStats.getMaxReduceTime()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMaxReduceTime()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMaxReduceTime()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMaxReduceTime()	N/A
org.apache.pig.tools.pigstats.JobStats.getMinMapTime()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMinMapTime()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMinMapTime()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMinMapTime()	N/A

last-updated: Apr 11, 2022

Instead of this deprecated method...	Use...
org.apache.pig.tools.pigstats.JobStats.getMinReduceTime()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMinReduceTime()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMinReduceTime()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMinReduceTime()	N/A
org.apache.pig.tools.pigstats.JobStats.getMultiInputCounters()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMultiInputCounters()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMultiInputCounters()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMultiInputCounters()	N/A
org.apache.pig.tools.pigstats.JobStats.getMultiStoreCounters()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getMultiStoreCounters()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getMultiStoreCounters()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getMultiStoreCounters()	N/A
org.apache.pig.tools.pigstats.JobStats.getNumberMaps()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getNumberMaps()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getNumberMaps()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getNumberMaps()	N/A
org.apache.pig.tools.pigstats.JobStats.getNumberReduces()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getNumberReduces()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getNumberReduces()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getNumberReduces()	N/A
org.apache.pig.tools.pigstats.JobStats.getProactiveSpillCountObjects()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getProactiveSpillCountObjects()
org.apache.pig.tools.pigstats.JobStats.getProactiveSpillCountRecs()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getProactiveSpillCountRecs()
org.apache.pig.tools.pigstats.JobStats.getReduceInputRecords()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getReduceInputRecords()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getReduceInputRecords()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getReduceInputRecords()	N/A

last-updated: Apr 11, 2022

Instead of this deprecated method...	Use...
org.apache.pig.tools.pigstats.JobStats.getReduceOutputRecords()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getReduceOutputRecords()
org.apache.pig.tools.pigstats.tez.TezVertexStats.getReduceOutputRecords()	N/A
org.apache.pig.tools.pigstats.tez.TezDAGStats.getReduceOutputRecords()	N/A
org.apache.pig.tools.pigstats.JobStats.getSMMSpillCount()	If you are using mapreduce, please cast JobStats to org.apache.pig.tools.pigstats.mapreduce.MRJobStats, then use MRJobStats.getSMMSpillCount()
org.apache.pig.EvalFunc.isAsynchronous()	N/A
org.apache.pig.impl.io.FileLocalizer.isDirectory(String, DataStorage)	FileLocalizer.isDirectory(String, PigContext)
org.apache.pig.impl.io.FileLocalizer.isFile(String, DataStorage)	FileLocalizer.isFile(String, PigContext)
org.apache.pig.impl.logicalLayer.schema.Schema.isTwoLevelAccessRequired() **Note:** twoLevelAccess is no longer needed.	N/A
org.apache.pig.impl.io.FileLocalizer.open(String, ExecType, DataStorage)	FileLocalizer.open(String, PigContext)
org.apache.pig.data.Tuple.reference(Tuple)	N/A
org.apache.pig.data.BagFactory.registerBag(DataBag)	As of Pig 0.11, bags register with the *SpillableMemoryManager* themselves. Register a bag with the *SpillableMemoryManager*. If the bags created by an implementation of BagFactory are managed by the *SpillableMemoryManager* then this method should be called each time a new bag is created.
org.apache.pig.PigStreamingBase.serialize(Tuple)	N/A
org.apache.pig.ResourceStatistics.setmBytes(Long)	ResourceStatistics.setSizeInBytes(Long)
org.apache.pig.impl.logicalLayer.schema.Schema.setTwoLevelAccessRequired(boolean) twoLevelAccess is no longer needed.	N/A
org.apache.pig.tools.pigstats.ScriptState.start(String, PigContext)	ScriptState.start(ScriptState)

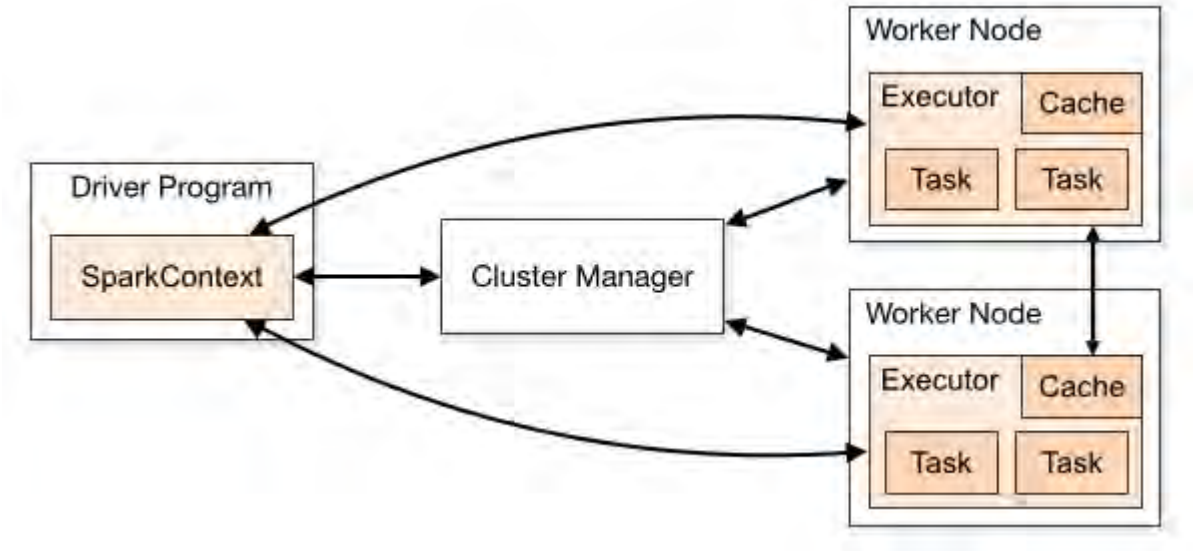
Sentry

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The Sentry documentation has moved. Sentry documentation can now be found at Sentry on page 3817.

Apache Spark

Apache Spark is an open-source processing engine that you can use to process Hadoop data. The following diagram shows the components involved in running Spark jobs. See Spark Cluster Mode Overview for additional component details.



MapR Data Platform supports the following types of cluster managers:

- Spark's standalone cluster manager
- YARN

The configuration and operational steps for Spark differ based on the Spark mode you choose to install. The steps to integrate Spark with other components are the same when using either Standalone of YARN cluster mode, except where otherwise noted.

This section provides documentation about configuring and using Spark with MapR Data Platform, but it does not duplicate the Apache Spark documentation.

You can also refer to additional documentation available on the Apache Spark Product Page.

Getting Started with Spark Interactive Shell
After you have a basic understanding of Apache Spark and have it installed and running on your cluster, you can use it to load datasets, apply schemas, and query data from the Spark interactive shell.

Reading Data from MapR File System

1. Copy sample data into MapR File System:

   - For this example, the dataset constitutes a CSV file of a list of auctions.

   - Download the file from GitHub: https://github.com/mapr-demos/getting-started-spark-on-mapr/tree/master/data.

   - Copy the file into your cluster, in the `/apps/` directory, using the `cp/scp` or `hadoop put` command:

   ```
   scp ./data/auctiondata.csv mapr@[mapr-cluster-node]:/mapr/[cluster-name]/
   apps/
   or
   $ hadoop fs -put ./data/auctiondata.csv /apps
   ```

   - This dataset is from eBay online auctions. The dataset contains the following fields:

   ```
   auctionid - Unique identifier of an auction.
   bid - Proxy bid placed by a bidder.
   bidtime - Time (in days) that the bid was placed from the start of the
   auction.
   bidder - eBay username of the bidder.
   ```

last-updated: Apr 11, 2022

```
bidderrate - eBay feedback rating of the bidder.
openbid - Opening bid set by the seller.
price - Closing price that the item sold for (equivalent to the second
highest bid + an increment).
item - Type of item.
```

The table below shows the fields with some sample data:

auctionid	bid	bidtime	bidder	bidderrate	openbid	price	item	daystolive
8213034705	95	2.927373	jake7870	0	95	117.5	xbox	3

2. Start the Spark interactive shell:

   - `$SPARK_HOME` represents the home of your Spark installation in MapR, for example: `/opt/mapr/spark/spark-2.2.1/`.

   ```
   $ $SPARK_HOME/bin/spark-shell --master local[2]
   ```

3. Once the Spark shell is ready, load the dataset:

   ```
   scala> val auctionData = spark.read.textFile("/apps/auctiondata.csv")
   ```

4. Display the first entry:

   ```
   scala> auctionData.first()
   ```

5. Count the number of entries:

   ```
   scala> auctionData.count()
   ```

6. Use other Spark actions:

   ```
   // Displays first 20 lines
   scala> auctionData.show()

   // Displays first 3 lines - change value to see more/less
   scala> auctionData.take(3)
   ```

7. Transform the dataset into a new one that contains only `xbox` lines, and count them:

   ```
   scala> val auctionWithXbox = auctionData.filter(line =>
   line.contains("xbox"))
   scala> auctionWithXbox.count()
   ```

   - This could also be done in a single line by chaining transformations and actions:

   ```
   scala> auctionData.filter(line => line.contains("xbox")).count()
   ```

8. Use Spark Dataframes:

```
scala> val auctionDataFrame =
spark.read.format("csv").option("inferSchema",
true).load("/apps/
auctiondata.csv").toDF("auctionid","bid","bidtime","bidder","bidderrate",
"openbid","price","item","daystolive")
```

9. Use a `filter` transformation on the Dataframe:

```
scala> auctionDataFrame.filter($"price" < 30).show()
```

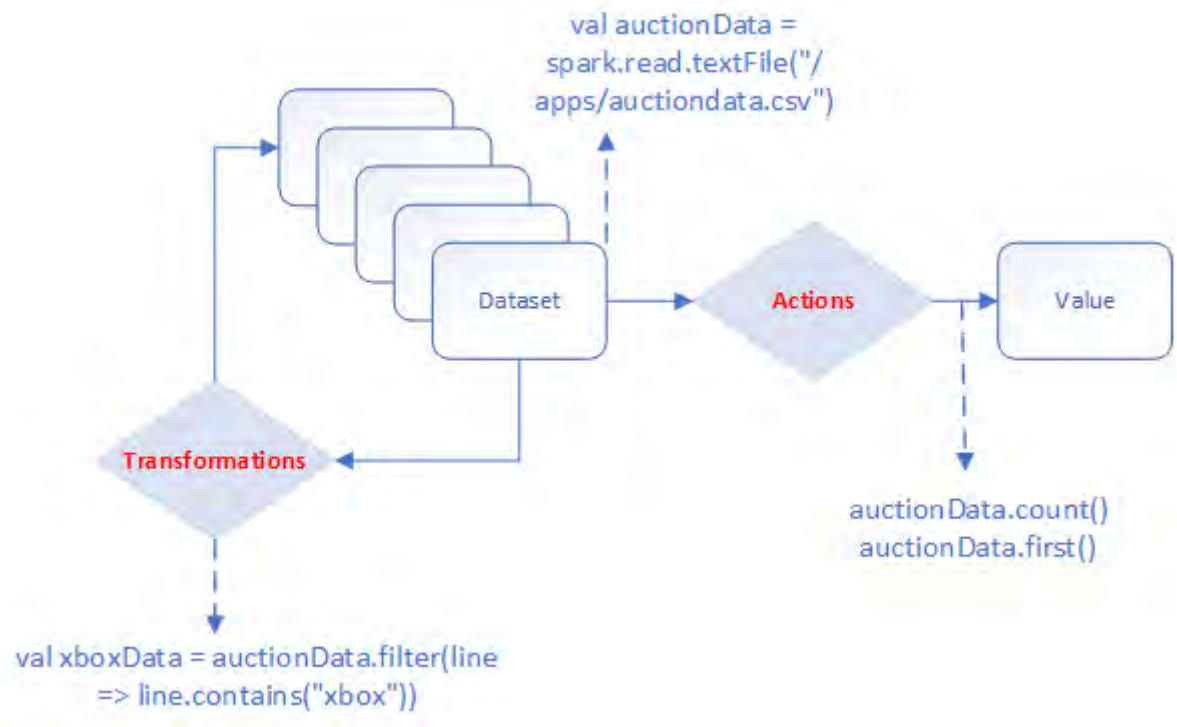


Figure 30: Schematic representation of performing transformations and actions on a dataset

Writing Data from MapR File System

Using the same dataset, save all `xbox` items as a file in MapR File System:

- You can use the `filter($"item" === "xbox")` filter and `write.json` or other options to save the result of the action to MapR File System.

```
scala> auctionDataFrame.filter($"item" === "xbox").write.json("/apps/
results/json/xbox")
```

This command creates the `/apps/results/json/xbox directory` in which you will see the JSON file(s) created. You can use the same command to create Parquet or any other file format:

```
scala> auctionDataFrame.filter($"item" === "xbox").write.parquet("/apps/
results/parquet/xbox")
```

last-updated: Apr 11, 2022

Writing Data to MapR Database JSON

The first step when you are working with MapR Database JSON is to define a document `_id` that uniquely identifies the document.

Add a new `_id` field in the csv file and generate UUIDs to add to this field.

To load the Dataframe into the MapR-DB JSON:

```
dataframe.saveToMapRDB("tableName", createTable = true, bulkInsert = false,
idFieldPath = "_id")
```

The following commands will create a table and insert the data into: `/apps/auction_json_table`.

```
scala> import spark.implicits._
scala> import java.util.UUID
scala> import org.apache.spark.sql.SparkSession
scala> import org.apache.spark.sql.types._
scala> import org.apache.spark.sql.SaveMode
scala> import com.mapr.db.spark.sql._  // import the MapR-DB OJAI Connector
scala> val generateUUID = udf(() => UUID.randomUUID().toString) // create
UDF to generate UUID
scala> // showing that you can create your own schema
  val customSchema =
  StructType(
   Array(
     StructField("actionid",StringType,true),
     StructField("bid",DoubleType,true),
     StructField("bidtime",DoubleType,true),
     StructField("bidder",StringType,true),
     StructField("bidderrate",IntegerType,true),
     StructField("openbid",DoubleType,true),
     StructField("price",DoubleType,true),
     StructField("item",StringType,true),
     StructField("daystolive",IntegerType,true)
     )
   )
```

You can now query the table using the MapR Database shell. Open a terminal on your cluster and run the following command:

```
$ mapr dbshell
maprdb mapr:> find /apps/auction_json_table --limit 10
```

Reading Data from MapR Database JSON

Now that you have the data in MapR Database JSON, you can create and query a Spark Dataframe using the following commands:

```
scala> import com.mapr.db.spark.sql._
scala> import org.apache.spark.sql.SparkSession
scala> val dataFromMapR = spark.loadFromMapRDB("/apps/auction_json_table")
scala> dataFromMapR.printSchema
scala> dataFromMapR.count

scala> dataFromMapR.filter($"price" < 30).show()   // use a filter
```

Apache Spark Feature Support

MapR Data Platform supports most Apache Spark features. However, there are some exceptions.

Spark SQL and Apache Derby Support on Spark	If you are using Spark SQL with Derby database without Hive or Hive Metastore installation, you will see the following exception: `java.lang.RuntimeException: Unable to instantiate org.apache.hadoop.hive.ql.metadata.SessionHiveMetaStoreClient` Add the `hive-service-2.3.*.jar` and `log4j2` jars to `/opt/mapr/spark/spark-3.x.x/jars` location to use Spark SQL with Derby Database without Hive or Hive Metastore installation. The `log4j2` jars are located at `/opt/mapr/lib/log4j2/log4j-*.jar` location. Spark 3.1.2 and Spark 3.2.0 does not support `log4j1.2` logging on HPE Ezmeral Data Fabric.
Symlink Support on Spark 2.4.4	For full Symlink support on Spark 2.4.4, request the patch. See Applying a Patch on page 437.
Spark Thrift JDBC/ODBC Server Support	Running the Spark Thrift JDBC/ODBC Server on a secure cluster is supported only on Spark 2.1.0 or later. You can run the Spark Thrift JDBC/ODBC Server to enable connections to Hive 1.2.1 using Beeline; however, you can connect only to Hive versions supported by your Spark version.
Spark SQL and Hive Support for Spark 2.1.0	Spark 2.1.0 is able to connect to Hive 2.1 Metastore; however, only features of Hive 1.2 are supported.
Spark SQL and Hive Support for Spark 2.0.1	Spark SQL is supported, but it is not fully compatible with Hive. For details, see the Apache Spark documentation. The following Hive functions are not supported in Spark SQL: • Tables with buckets • UNION type • Unique join • Column statistics collecting • Output formats: File format (for CLI), Hadoop Archive • Block-level bitmap indexes and virtual columns • Automatic determination of the number of reducers for JOIN and GROUP BY

last-updated: Apr 11, 2022

- Metadata-only query
- Skew data flag
- STREAMTABLE hint in JOIN
- Merging of multiple small files for query results

Spark SQL and Hive Support for Spark 1.6.1

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the Apache Spark documentation. The following Spark SQL operations support the following Hive table formats:

	Hive 1.2 Table Format				
Spark SQL Operations	AVRO	ORC	Parquet	RC	default
create	Yes	Yes	Yes	Yes	Yes
drop	Yes	Yes	Yes	Yes	Yes
insert into	Yes	Yes	Yes	Yes	Yes
insert overwrite	Yes	Yes	Yes	Yes	Yes
select	Yes	Yes	Yes	Yes	Yes
load data	Yes	Yes	Yes	Yes	Yes

Spark Standalone

This section includes topics about configuring and using Spark in Standalone mode.

To integrate Spark with other ecosystem components, see Integrating Spark.

For additional documentation, see the Apache Spark website.

Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

To set up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Spark is distributed as four separate packages:

Package	Description
`mapr-spark`	Install this package on any node where you want to install Spark. This package is dependent on the `mapr-client` package.
`mapr-spark-master`	Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the `mapr-spark` and the `mapr-core` packages.
`mapr-spark-historyserver`	Install this optional package on Spark History Server nodes. This package is dependent on the `mapr-spark` and `mapr-core` packages.
`mapr-spark-thriftserver`	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the `mapr-spark` and `mapr-core` packages.

last-updated: Apr 11, 2022

Run the following commands as `root` or using `sudo`.

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

   Note: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

On CentOS / Red Hat	`yum install mapr-spark mapr-spark-master mapr-spark-historyserver mapr-spark-thriftserver`
On Ubuntu	`apt-get install mapr-spark mapr-spark-master mapr-spark-historyserver mapr-spark-thriftserver`
On SLES	`zypper install mapr-spark mapr-spark-master mapr-spark-historyserver mapr-spark-thriftserver`

   Note: The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

   Spark is installed into the `/opt/mapr/spark` directory.

3. For Spark 2.x:

   Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

   For example:

```
localhost
worker-node-1
worker-node-2
```

4. Set up passwordless ssh for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x .

5. As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.

   For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

last-updated: Apr 11, 2022

6. If you want to integrate Spark with MapR Event Store For Apache Kafka, install the Streams Client on each Spark node:
   - On Ubuntu:
     ```
     apt-get install mapr-kafka
     ```
   - On RedHat/CentOS:
     ```
     yum install mapr-kafka
     ```
7. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.11.jar` from the MapR Data Platform Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).
8. After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at Configuring Spark Standalone on page 4030.

Configuring Spark Standalone

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run configure.sh -R as the final step in the configuration process.

Configure High Availability for SparkMaster
You configure high availability for the Spark Primary instance so that the instance does not become the single point of failure.

By using ZooKeeper to provide leader election and some state storage, you can launch multiple primary nodes in your cluster that are connected to the same ZooKeeper instance. Zookeeper elects one primary node to be the “leader,” and the others remain in standby mode. If the leader goes down, Zookeeper elects another primary node, recovers the old primary node's state, and resumes scheduling.

1. Set `SPARK_DAEMON_JAVA_OPTS` in `spark-env.sh` with the appropriate ZooKeeper information for the cluster.
   ```
   export SPARK_DAEMON_JAVA_OPTS="-Dspark.deploy.recoveryMode=ZOOKEEPER
   -Dspark.deploy.zookeeper.url=<zookeeper1:5181,zookeeper2:5181,...>
   -Djava.security.auth.login.config=/opt/mapr/conf/
   mapr.login.conf -Dzookeeper.sasl.client=false
   ```
2. Restart the Spark Primary instance and Spark History Server services:
   - For Spark 2.0.1 and later:
     ```
     maprcli node services -nodes <node-ip> -name spark-master -action
     restart
     ```
   - For Spark 1.6.1:
     ```
     maprcli node services -nodes <node-ip> -name spark-master -action
     restart
     maprcli node services -nodes <node-ip> -name
     spark-historyserver -action restart
     ```

3. On the primary node, restart the Spark Secondary instances as the `mapr` user.

   For Spark 2.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
   /opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
   ```

Configure Scratch Directory for Spark Standalone

By default, Spark uses the `/tmp` directory as scratch space. Map output files and RDDs are stored in the scratch directory. To use a different directory, or a comma-separated list of multiple directories, set `SPARK_LOCAL_DIRS` to the path to the new directory by adding the following line to the `$SPARK_HOME/conf/spark-env.sh` file:

```
export SPARK_LOCAL_DIRS=$SPARK_HOME/<path to scratch directory>
```

Make this change before starting the Spark services.

Community Edition (Without NFS Support)

Reserve space on your local disk to use as the scratch directory for Spark.

Enterprise Edition and Enterprise Database Edition (With NFS Support)

Create a local volume on each node with the `maprcli volume create` command, or from the Control System. Mount that local volume with NFS to a directory. Set that directory as the scratch directory for Spark.

Note: Due to https://issues.apache.org/jira/browse/SPARK-6313, make sure to set `spark.files.useFetchCache=false` in your `spark-defaults.conf` file.

Using Spark Standalone

For a simple test of your Spark installation, run the following command:

- On Spark 2.0.1 or later:

  ```
  /opt/mapr/spark/spark-<version>/bin/run-example --master spark://<Spark
  Master node hostname>:7077 SparkPi 10
  ```

- On Spark 1.6.1:

  ```
  MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/
  spark-<version>/bin/run-example org.apache.spark.examples.SparkPi 10
  ```

For more information about running Spark applications, see the Apache Spark Documentation.

Run the Spark Shell in Standalone Mode

- To run the Spark shell, use the following command:
  - On Spark 2.0.1 and later:

    ```
    /opt/mapr/spark/spark-<version>/bin/spark-shell --master spark://<Spark
    Master node hostname>:7077
    ```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/
spark-<version>/bin/spark-shell
```

Security with Spark Standalone

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the MapR installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See Spark configure.sh on page 4038 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

Spark on YARN

This section contains topics about installing, configuring and using Spark on YARN.

Important: Spark 2.0.1 (and later) YARN mode is supported only on clusters in MRv2 (YARN) mode. It is not supported on clusters in MRv1 (classic) mode.

To integrate Spark with other ecosystem components, see Integrating Spark on page 4113

For additional documentation, see the Apache Spark documentation.

Installing Spark on YARN

This topic describes how to use package managers to download and install Spark on YARN from the EEP repository.

To set up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Spark is distributed as three separate packages:

Package	Description
`mapr-spark`	Install this package on each node where you want to install Spark. This package is dependent on the `mapr-client` package.
`mapr-spark-historyserver`	Install this optional package on Spark History Server nodes. This package is dependent on the `mapr-spark` and `mapr-core` packages.
`mapr-spark-thriftserver`	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the `mapr-spark` and `mapr-core` packages.

To install Spark on YARN (Hadoop 2), execute the following commands as `root` or using `sudo`:

1. Verify that JDK 1.7 or later is installed on the node where you want to install Spark.
2. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory:

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

Note: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.

last-updated: Apr 11, 2022

3. Install the packages:

On Ubuntu	`apt-get install mapr-spark mapr-spark-historyserver mapr-spark-thriftserver`
On CentOS / Red Hat	`yum install mapr-spark mapr-spark-historyserver mapr-spark-thriftserver`
On SLES	`zypper install mapr-spark mapr-spark-historyserver mapr-spark-thriftserver`

   Note: The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.

4. If you want to integrate Spark with MapR Event Store For Apache Kafka, install the Streams Client on each Spark node:
   - **On Ubuntu:**

     ```
     apt-get install mapr-kafka
     ```

   - **On CentOS / Red Hat**:

     ```
     yum install mapr-kafka
     ```

5. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.11.jar` from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

   For repository-specific information, see Maven Artifacts for MapR on page 4155

6. After installing Spark on YARN but before running your Spark jobs, follow the steps outlined at Configuring Spark on YARN on page 4033.

Configuring Spark on YARN

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run configure.sh -R as the final step in the configuration process.

Configure data-fabric Client Node to Run Spark Applications

When Spark runs on YARN, data-fabric client nodes require the `hadoop-yarn-server-web-proxy` JAR file to run Spark applications. On Windows, the client node also requires an update to the SPARK_DIST_CLASSPATH. A data-fabric client node (a node with the mapr-client package, but without mapr-core packages) is also known as an edge node.

The mapr-client package does not include the JAR file required to run Spark applications. Therefore, you must copy the `/opt/mapr/hadoop/hadoop-2.x.x/share/hadoop/yarn/hadoop-yarn-server-web-proxy-<version>.jar` from a data-fabric cluster node to the same location on the data-fabric client node from which you want to run the Spark application.

Configure Spark JAR Location

last-updated: Apr 11, 2022

By default, Spark on YARN uses Spark JAR files that are installed locally. The Spark JAR files can also be added to a world-readable location on MapR File System. When you add the JAR files to a world-readable location, YARN can cache them on nodes to avoid distributing them each time an application runs. Complete the following steps to add the Spark JAR files to a world-readable locaton on MapR File System:

1. Create a zip archive containing all the JARs from the `SPARK_HOME/jars` directory. For example:

   ```
   cd /opt/mapr/spark/spark-<version>/jars/
   zip /opt/mapr/spark/spark-<version>/spark-jars.zip ./*
   ```

2. Copy the zip file from the local filesystem to a world-readable location on MapR File System. You can upload it to the home of the current user:

   ```
   hadoop fs -put /opt/mapr/spark/spark-<version>/spark-jars.zip
   ```

   For example:

   ```
   hadoop fs -put /opt/mapr/spark/spark-3.2.0/spark-jars.zip /user/mapr/
   ```

3. Set the `spark.yarn.archive` property in the `spark-defaults.conf` file located in `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` to point to the world-readable location where you added the zip file. Apply this setting on the node where you will be submitting your Spark jobs.

   ```
   spark.yarn.archive maprfs:///<path to zip>
   ```

   For example:

   ```
   spark.yarn.archive maprfs:///user/mapr/spark-jars.zip
   ```

Configure Spark with the NodeManager Local Directory Set to MapR File System

This procedure configures Spark to use the mounted NFS directory instead of the `/tmp` directory on the local filesystem. Note that spill to disk should be configured to spill to the MapR File System node local storage only if local disks are unavailable or space is limited on those disks.

1. Install the `mapr-loopbacknfs` and `nfs-utils` packages if they are not already installed. For reference, see Installing the mapr-loopbacknfs Package on page 400 and Setting Up MapR NFS.

2. Start the mapr-loopbacknfs service by following the steps at Managing the mapr-loopbacknfs Service on page 1236.

3. To configure Spark Shuffle on NFS, complete these steps **on all nodes**:
   a) Create a local volume for Spark Shuffle:

   ```
   sudo -u mapr maprcli volume
   create -name mapr.$(hostname -f).local.spark -path /var/mapr/local/$
   (hostname -f)/spark -replication 1 -localvolumehost $(hostname -f)
   ```

b) Point the NodeManager local directory to the Spark Shuffle volume mounted through NFS by setting the following property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml` file on the NodeManager nodes:

```
<property>
    <name>yarn.nodemanager.local-dirs</name>
    <value>/mapr/my.cluster.com/var/mapr/local/${mapr.host}/spark</
value>
</property>
```

c) (Optional) Configure how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the /tmp directory on the local filesystem. Increasing the value (default is 2) of this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch.

```
<property>
    <name>yarn.nodemanager.max-retry-file-delete</name>
    <value>2</value>
</property>
```

d) Restart the NodeManager service and the Resource Manager service on the main node to pick up the `yarn-site.xml` changes:

```
maprcli node services -name nodemanager -action restart -nodes <node
1> <node 2> <node 3>
maprcli node services -name resourcemanager -action restart -nodes
<node 1> <node 2> <node 3>
```

Using Spark on YARN

This section includes information about using Spark on YARN in a data-fabric cluster.

For a simple test of your Spark installation, run the following command as the mapr user:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master
yarn --deploy-mode client SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=yarn-client /opt/mapr/spark/spark-<version>/bin/run-example
org.apache.spark.examples.SparkPi 10
```

Note: These commands will fail if it is run as the root user.

For more information about running Spark applications, see the Apache Spark documentation.

Deployment Modes

Spark is preconfigured for YARN and does not require any additional configuration to run.

Two deployment modes can be used to launch Spark applications on YARN:

- In `cluster` mode, jobs are managed by the YARN cluster. The Spark driver runs inside an Application Master (AM) process that is managed by YARN. This means that the client can go away after initiating the application.

last-updated: Apr 11, 2022

- In `client` mode, the Spark driver runs in the client process, and the Application Master is used only to request resources from YARN.

MapR recommends using `cluster` deployment mode instead of `client` mode. If the Spark client that runs the job exits after submitting the job, there is no impact on job completion.

Note: In `cluster` deployment mode, the local directories used by the Spark executors and the Spark driver are the local directories that are configured for YARN (`yarn.nodemanager.local-dirs`).

Note: `SPARK_LOCAL_DIRS` is ignored when you run Spark on YARN.

Run Spark from the Spark Shell

In `yarn-client` mode, complete the following steps to run Spark from the Spark shell:

1. Navigate to the Spark-on-YARN installation directory, and insert your Spark version into the command.

```
cd /opt/mapr/spark/spark-<version>/
```

2. Issue the following command to run Spark from the Spark shell:
   - On Spark 2.0.1 and later:

```
./bin/spark-shell --master yarn --deploy-mode client
```

   - On Spark 1.6.1:

```
MASTER=yarn-client ./bin/spark-shell
```

Note: You must use `yarn-client` mode to run Spark from the Spark shell. The `yarn-cluster` mode is not supported.

Security with Spark on YARN

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the MapR installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See Spark configure.sh on page 4038 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

Configure Authentication for Spark on YARN
When authentication is enabled, authentication keys are randomly generated for each job.

Note: Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, running configure.sh -R, as the final step in the configuration process, enables these settings.

last-updated: Apr 11, 2022

Complete the following step to manually configure authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Configure the following property in the `spark-defaults.conf` file on each Spark node:

   ```
   spark.authenticate true
   ```

   The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`

2. If you have configured an external shuffle service, you must also add the following property to `yarn-site.xml` on page 2216 on each Spark node:

   ```
   <property>
         <name>spark.authenticate</name>
         <value>true</value>
   </property>
   ```

Configure SSL Encryption for Spark on YARN

Starting in EEP 6.0.0, you can remove `spark.ssl.keyStorePassword`, `spark.ssl.trustStorePassword`, and `spark.ssl.keyPassword` from the `spark-defaults.conf` file for additional security. These passwords are stored in the `/opt/mapr/conf/ssl-client.xml` file and Spark can access passwords from this file itself.

Note: If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-2.3.1/conf/spark-defaults.conf` files, then the password from the `spark-defaults.conf` file is used.

Complete the following step to manually configure encryption for the Spark HTTP file and broadcast servers:

In the `spark-defaults.conf` file on each spark node, configure the following properties. Starting in EEP 6.0.0, the configured algorithms mentioned in the following code are no longer available for your web service to pick up. You must remove the `spark.ssl.enabledAlgorithms TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA` line to let parties negotiate the matching ciphers.

- For Spark 2.0.1 and later:

  ```
  spark.ssl.fs.enabled true
  spark.ssl.keyPassword <ssl-keystore-password>
  spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
  spark.ssl.keyStorePassword <ssl-keystore-password>
  spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
  spark.ssl.trustStorePassword <ssl-keystore-password>
  spark.ssl.protocol TLSv1.2
  spark.ssl.enabledAlgorithms
  TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
  ```

Note: Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, running configure.sh -R, as the final step in the configuration process, enables these settings.

last-updated: Apr 11, 2022

- For Spark 1.6.1:

```
spark.ssl.akka.enabled true
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

Spark UI SSL is not needed when running Spark on YARN because encryption is provided by the YARN protocol. **For versions prior to EEP 4.1.0**, to enable users logged in with a normal user account (not mapr or root) to run spark jobs on the cluster, disable Spark SSL for Spark-on-YARN jobs. To disable Spark SSL, add `spark.ssl.ui.enabled false` to the `spark-defaults.conf` file on each spark node. The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`. Make sure SSL is enabled for the Spark history server.

When you manually configure encryption for Spark, set the same protocol and algorithms for each node. Otherwise, the connection between those components might fail.

Configure SASL Encryption for Spark on YARN

Note: Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, running configure.sh -R, as the final step in the configuration process, enables these settings.

Complete the following steps to manually enable SASL encryption on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that authentication is enabled, or configure authentication. SASL encryption uses the same authentication keys.

   For more information, see Configure Authentication for Spark on YARN on page 4036

2. Configure the following property in the `spark-defaults.conf` file on each spark node.

   ```
   spark.authenticate.enableSaslEncryption true
   ```

   The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`

Spark configure.sh
Starting in the EEP 4.0 release, run `configure.sh -R` to complete your Spark configuration when manually installing Spark or upgrading to a new version.

The command is the following:

```
/opt/mapr/server/configure.sh -R
```

Note: You do not need to run this script for new installs, if you are using the MapR installer in EEP 4.0 or later.

In the case of Spark Standalone on page 4028 and Spark on YARN on page 4032, this is the last step in the configuration process.

All security configuration properties are specified within the following comment block in the SPARK_HOME/conf/spark-defaults.conf file:

```
#SECURITY BLOCK
...
#END OF THE SECURITY CONFIGURATION BLOCK
```

Important: Do not remove these comments from the file, as well as any other comments within the block inserted by configure.sh. The script uses these comments to locate security properties.

Note: To set ports to special values, use the spark.driver.port and spark.blockManager.port properties.

Starting in EEP 6.0.0, Spark services such as the History Server, Thrift Server, or Master are restarted by configure.sh only for changes to the following Spark configuration files: spark-defaults.conf, spark-env.sh, hive-site.xml, or log4j.properties. If these files are unchanged, configure.sh does not restart any of the Spark services.

An update to Spark causes the conf directory from the previous the Spark version to be saved to the spark-<old-version>.<old-timestamp> directory. If your Spark version did not change during the update, then configurations from the spark-<old-version>.<old-timestamp> directory is automatically copied to the spark-<version> directory by the configure.sh script.

If you use .customSecure, at the first run, the configure.sh script copies the hive-site.xml file from Hive. For subsequent times, the hive-site.xml file is not copied from Hive and you would need to manually modify the $SPARK_HOME/conf/hive-site.xml file.

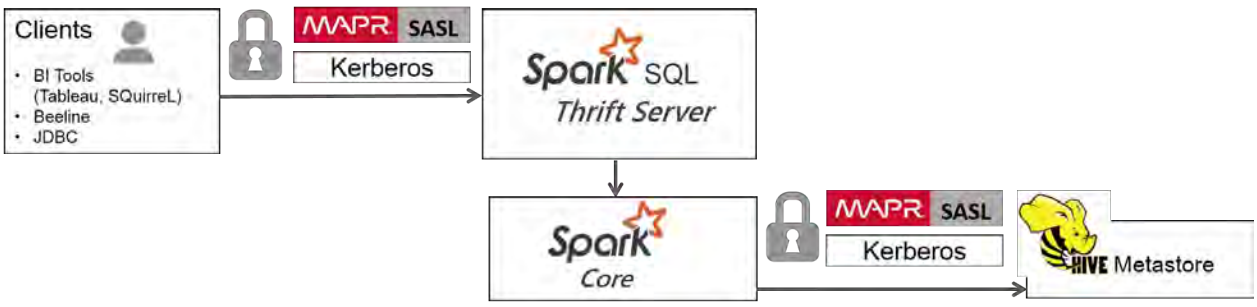
Spark SQL Thrift Server
Spark SQL Thrift (Spark Thrift) was developed from Apache Hive HiveServer2 and operates like HiveSever2 Thrift server.

Spark Thrift is supported on secure clusters. You can run the Spark Thrift server and connect to Hive versions supported by Spark 2.1.0 and later with Business Intelligence (BI) tools or the Beeline command-line tool.

Starting in the EEP 4.0 release, the Spark Thrift server is available as a separate package. To install this package, see Installing Spark Standalone on page 216 or Installing Spark on YARN on page 218, depending on the type of cluster manager you are installing.

In EEP 3.0, MapR introduces additional security mechanisms for Spark with the Spark Thrift server. MapR-SASL and Kerberos are supported:

- For JDBC connections into Spark Thrift server
- Between Spark and Hive metastore



To enable these security mechanisms for the Spark Thrift server, starting in the EEP 4.0 release, for secure clusters, running configure.sh -R configures MapR-SASL security. The script modifies or creates a SPARK_HOME/conf/hive-site.xml file as follows:

last-updated: Apr 11, 2022

- If Hive is installed in your cluster, the script copies `HIVE_HOME/conf/hive-site.xml` to `SPARK_HOME/conf` and modifies the file.
- If Hive is not installed and you are using MapR-SASL security, the script creates a new `SPARK_HOME/conf/hive-site.xml` file.
- Each time the script runs, if there is a pre-existing `SPARK_HOME/conf/hive-site.xml` file, the script saves a copy of the file in `SPARK_HOME/conf/hive-site.xml.old` before modifying it.

You can configure security manually by following the steps outlined in sub-topics listed on this page.

To launch the Spark Thrift server, perform the procedures required to configure Apache Spark on page 4022 to use Hive on page 3405.

Important:

- Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 10000.
- Starting in the EEP 5.0.4 and EEP 6.3.0 releases, if you start and stop the Spark Thrift server by running the `/opt/mapr/spark/<spark-version/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 2304.

Default Behavior

The default behavior of the Spark Thrift server is as follows:

1. After installation, the Spark Thrift server is started in the local master mode.
2. If the Spark master package is installed, then Spark Thrift server is started in the standalone master mode.
3. If the `spark.master` property is set in the `spark-defaults.conf` file, then Spark Thrift server uses the master set by this property.

Known Limitations

- MapR-SASL support is implemented for Spark 2.1.0 and later versions of Spark. For Spark version information, see Component Versions for Released EEPs on page 5586.
- The ODBC drivers do not support MAPR-SASL.
- Username and password authentication through PAM is not supported in EEP 3.0.
- Spark Thrift server supports only features and commands in Hive 1.2.
- Although Spark 2.1.0 can connect to Hive 2.1 Metastore, only Hive 1.2 features and commands are supported by Spark 2.1.0.

Spark Thrift Server Clients

With Spark Thrift server, you can use JDBC and ODBC connection interfaces that enable a variety of external tools to access Spark and run SQL queries.

- The ODBC interface is used by BI tools (often produced by MapR partners such as Tableau or Microstrategy).
- The JDBC interface is used by clients such as SQuirrel SQL or the Beeline simple SQL shell.

MapR Hive JDBC clients that connect to HiveServer2 can also connect to Spark Thrift server without additional configuration. For details about clients, see HiveServer2 Clients and Connecting to HiveServer2.

Important: Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version/sbin/{start,stop}-thriftserver.sh` scripts, the port number is 10000. Beginning with EEP 6.3.0, the connection port number is 2304 for both start/stop methods (using Warden and using `thriftserver.sh` scripts).

MapR-SASL JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for MapR-SASL environments is:

```
jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true
```

Otherwise, the port you use depends on the EEP version:

EEP 4.0 through 6.2.x	`jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true`
EEP 6.3.0 and later	`jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true`

Kerberos JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for clusters secured with Kerberos is:

```
jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true
```

Otherwise, the port you use depends on the EEP version:

last-updated: Apr 11, 2022

EEP 4.0 through 6.2.x	`jdbc:hive2://<hostname>:10000/default;principal=mapr/<FQDN@REALM>;ssl=true`
EEP 6.3.0 and later	`jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true`

Starting the Thrift Server on a Custom Port

To start the Spark Thrift Server on a custom port, use the `hive.server2.thrift.port` option. For example, you can specify the following in the `/opt/mapr/spark/spark-2.4.4/conf/hive-site.xml` file:

```
<property>
<name>hive.server2.thrift.port</name>
<value>34512</value>
</property>
```

For more information, see the Apache HiveServer2 documentation.

Using Authentication with Spark Thrift Server

Spark Thrift server supports both MapR-SASL and Kerberos authentication. The authentication method that you configure for the Spark Thrift server determines how the connection is secured. Clients might require additional configuration and specific connection strings based on the authentication type.

To enable authentication, see:

- Configuring Spark Thrift Server with MapR-SASL on page 4042
- Configuring Spark Thrift Server with Kerberos on page 4043

To configure PAM for Spark Thriftserver, run `configure.sh` on the secure cluster.

For information about Hive integration, see:

- Integrate Spark SQL with Hive
- Setting Up HiveServer2
- Hive
- Spark Feature Support

Configuring Spark Thrift Server with MapR-SASL
Describes how to enable and start the Spark Thrift server on all nodes.

You can configure Spark Thrift server to use MapR-SASL for its communications with various components on a secure MapR cluster. Minimal configuration is required.

Note: Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, running configure.sh -R enables these settings.

To manually enable MapR-SASL authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that the `hive.server2.authentication` property in `hive-site.xml` is set to the value, `MAPRSASL`.

```
<property>
     <name>hive.server2.authentication</name>
     <value>MAPRSASL</value>
</property>
```

2. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

   Important: The MapR administrative user (generally, the account named `mapr`) should start the Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

Bringing up the Spark Thrift server on every node

When you start and stop Warden after enabling Spark or after running configure.sh on page 2053 or after installing a patch, Spark starts only on one (1) node and not on all nodes. This happens because by default, the Warden configuration file for Spark has the value `1` instead of `all`. For example:

```
# grep services /opt/mapr/conf/conf.d/warden.spark-thriftserver.conf
services=spark-thriftserver:1:cldb
```

To fix this issue permanently:

1. Modify `/opt/mapr/spark/spark-2.4.0/warden/warden.spark-thriftserver.conf` and change `1` to `all`:

```
# grep services /opt/mapr/spark/spark-2.4.0/warden/
warden.spark-thriftserver.conf
            services=spark-thriftserver:all:cldb
```

2. Run `/opt/mapr/server/configure.sh -R`.

The change is then propogated to the `/opt/mapr/conf/conf.d/warden.spark-thriftserver.conf` file.

Configuring Spark Thrift Server with Kerberos

You can configure Spark Thrift server to use Kerberos for its communications with various components on a secure MapR cluster if necessary.

Note: MapR clusters do not provide Kerberos infrastructure. The information in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

To enable Kerberos authentication:

1. Create a Kerberos identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file.
   - The `hive.keytab` file must be owned and readable only by the `mapr` user.

last-updated: Apr 11, 2022

- FQDN@REALM is case-sensitive.

```
# kadmin
          : addprinc -randkey mapr/<FQDN@REALM>
          : ktadd -k /opt/mapr/conf/hive.keytab mapr/<FQDN@REALM>
```

2. Configure the following properties in `hive-site.xml` on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	KERBEROS
hive.server2.authentication.kerberos.principal	`mapr/FQDN@REALM` (where `mapr/FQDN@REALM` is the principal that you want to use for the Spark Thrift server)
hive.server2.authentication.kerberos.keytab	`/opt/mapr/conf/mapr.keytab` (where `/opt/mapr/conf/mapr.keytab` is path to the keytab that must be used)

```
<property>
     <name>hive.server2.authentication</name>
     <value>KERBEROS</value>
     <description>authenticationtype</description>
</property>
<property>
      <name>hive.server2.authentication.kerberos.principal</name>
      <value>mapr/FQDN@REALM</value>
      <description>Spark Thrift server principal. If _HOST is used as
the FQDN portion,
      it will be replaced with the actual hostname of the running
instance.
      </description>
</property>
<property>
     <name>hive.server2.authentication.kerberos.keytab</name>
     <value>/opt/mapr/conf/mapr.keytab</value>
     <description>Keytab file for Spark Thrift server principal</
description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where HiveServer2 is installed:

Note: These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see About env_override.sh on page 2290.

Existing Configuration	Required Configuration
`MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"`	`MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"`
`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"`	`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"`

last-updated: Apr 11, 2022

4. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

   Important: The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

- Setting Up HiveServer2
- Hive

Configuring Spark Thrift Server Encryption

Spark Thrift server encryption is supported when authentication is enabled. You can configure encryption with MapR SASL or with SSL/TLS.

Configuring Encryption with MapR SASL or Kerberos

Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done using MapR Installer, the Installer enables this configuration. For manual installs and upgrades, running configure.sh -R enables these settings.

To manually configure encryption with MapR-SASL or Kerberos authentication on a non-secure cluster or in versions earlier than EEP 4.0, complete the following steps:

1. Set the `hive.server2.thrift.sasl.qop` property in `hive-site.xml` to the value `auth-conf`. The SASL Quality of Protection (QOP), or *sasl.qop*, setting and the authentication with confidentiality (`auth-conf`) value support authentication:

```
<property>
    <name>hive.server2.thrift.sasl.qop</name>
    <value>auth-conf</value>
</property>
```

2. Restart Spark Thrift server to apply the change:

   Important: The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files are owned by this user, and impersonation support (where applicable) functions correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

Configuring Encryption with SSL/TLS

To enable encryption with SSL/TLS:

last-updated: Apr 11, 2022

1. Add the following properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

```
spark.ssl.enabled true
spark.ssl.fs.enabled true
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.protocol TLSv1.2
spark.ssl.keyStorePassword      mapr123
spark.ssl.trustStorePassword    mapr123
```

   After the properties are added, event logs will indicate that the job is encrypted.

2. To connect using Beeline with encryption, add the following properties to the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file:

```
<property>
  <name>hive.server2.use.SSL</name>
  <value>true</value>
  <description>enable/disable SSL </description>
</property>

<property>
  <name>hive.server2.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.keystore.password</name>
  <value>mapr123</value>
  <description>keystore password</description>
</property>
```

3. To start the Spark Thriftserver, use the following command:

```
/opt/mapr/spark/spark-<version>/sbin/start-thriftserver.sh --hiveconf
hive.server2.thrift.port=2304 --master yarn --deploy-mode client
```

   The following example shows a connection string using Beeline (PAM+SSL):

```
./bin/beeline
Beeline version 1.2.0-mapr-1808-spark by Apache Hive
beeline>  !connect jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connecting to jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connected to: Spark SQL (version 2.1.0-mapr-mep-3.x-1808)
Driver: Hive JDBC (version 1.2.0-mapr-1808-spark)
Transaction isolation: TRANSACTION_REPEATABLE_READ
1: jdbc:hive2://node1.cluster.com:2304/defaul>
```

Enabling High Availability for Spark Thrift Server

With MEPs 5.0.4 or 6.3.0 and later, you can enable high availability for the Spark Thrift Server. Unlike a HiveServer2 high-availability configuration, Spark has no concept of active-active instances. However, after configuration, you can can use Beeline to connect to the Spark Thrift Server on each node.

To enable high availability, use the following steps:

1. Install Spark Thrift Server on all the cluster nodes where it is needed:

On Ubuntu	`apt-get install mapr-spark-thriftserver`
On Red Hat / CentOS	`yum install mapr-spark-thriftserver`
On SLES	`zypper install mapr-spark-thriftserver`

last-updated: Apr 11, 2022

2. Add the following properties to the `/opt/mapr/spark/spark-<spark_version>/conf/hive-site.xml` file on all the nodes where the Spark Thrift Server is installed

```
<property>
<name>hive.zookeeper.quorum</name>
<value><zk_host1_>,<zk_host_2>,…,<zk_host_n></value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value><zk_port></value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value><zk_namespace></value>
</property>
```

For example:

```
<property>
<name>hive.zookeeper.quorum</name>
<value>node1.cluster.com,node2.cluster.com,node3.cluster.com</value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value>5181</value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value>ts2-ts2</value>
</property>
```

Note: The values that you provide for the `hive.server2.zookeeper.namespace` property should be different for the `hive-site.xml` in the Spark and Hive directories.

3. Restart the Spark Thrift Server to apply the changes following the script in the `.sbin` directory at `/opt/mapr/spark/spark-<spark_version>/` or by running a `maprcli` command on all configured nodes:

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

or

```
maprcli node services -nodes <host_1>,<host_2>,<host_n> -name
spark-thriftserver -action restart
```

4. Launch the Zookeeper command line interface, and check the Spark Thriftserver znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

For example:

```
/opt/mapr/zookeeper/zookeeper-3.4.11/bin/zkCli.sh -server
node1.cluster.com:5181
ls /ts2-ts2
[serverUri=node1.cluster.com:2304;version=;sequence=0000000000]
```

5. Using Beeline, you can connect to the Spark Thrift Server by using the following string:

```
beeline> !connect jdbc:hive2://<hostname -f>:5181/
default;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<hive.server2.z
ookeeper.namespace>;
```

For example:

```
./bin/beeline
Warning: Unable to determine $DRILL_HOME
Beeline version 1.2.0-mapr-spark-MEP-6.0.0-1912 by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
Connecting to jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
20/03/29 21:38:19 WARN MaprSaslClient: SASL Server qopProperty:

last-updated: Apr 11, 2022

Note: High availability for the Spark Thrift Server can be used in conjunction with HiveServer2 high availability. For more information about HiveServer2 high availability, see Enabling High Availability for Hive on page 3537.

Spark History Server SSL
Describes how to enable SSL for Spark History Server.

Note: For secure clusters, Spark History Server UI authentication is enabled by default.
If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-<spark_version>/conf/spark-defaults.conf` files, the password from the `spark-defaults.conf` file is used

Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, running configure.sh -R enables these settings.

To configure SSL manually in a non-secure cluster or in versions earlier than EEP 4.0, add the following properties to the `spark-default.conf` file:

```
#HistoryServer https configure
spark.yarn.historyServer.address <Spark History Server node
hostname>:18480
spark.ssl.protocol tls
spark.ssl.historyServer.enabled true
spark.ssl.trustStore $MAPR_HOME/conf/ssl_truststore
spark.ssl.keyStore $MAPR_HOME/conf/ssl_keystore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.keyStorePassword <ssl-keystore-password>
```

Note: If a cluster is secure and you use unsecured ports with HTTP, you will be automatically redirected to HTTPS with secure ports. For example, if on the secure cluster you go to `http://node1:18080`, you will be redirected to `https://node1:18480`.

MapR Database Connectors for Apache Spark
This section describes the MapR Database connectors that you can use with Apache Spark.

Apache Spark is a software framework that is used to process data in memory in a distributed manner. Spark is replacing MapReduce in many use cases. The MapR Database Connectors for Spark enable users to write applications that access MapR Database JSON and Binary tables.

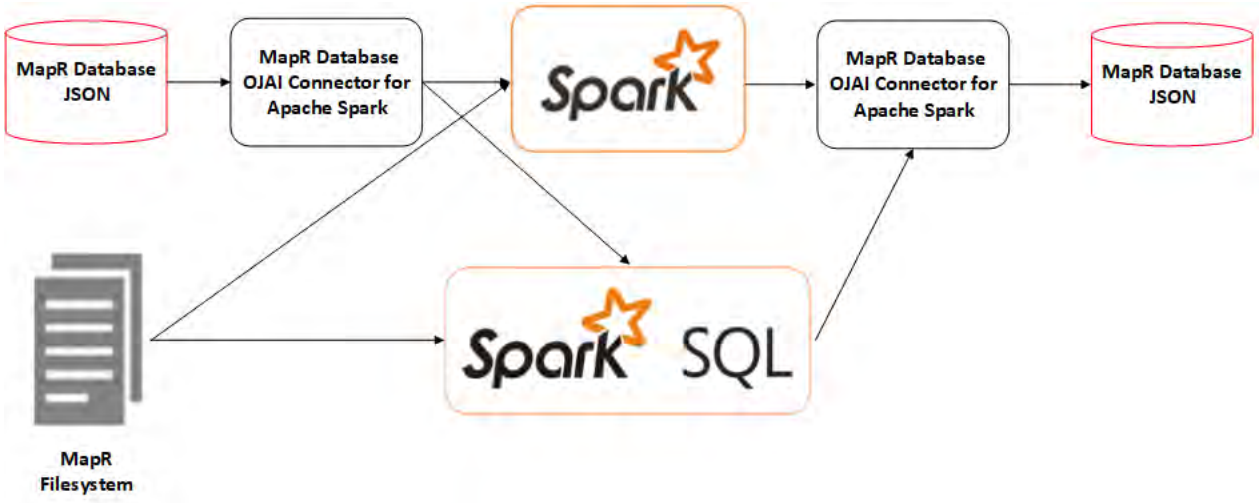
Understanding the MapR Database OJAI Connector for Spark
Using the MapR Database OJAI connector for Spark enables you build real-time and batch pipelines between your data and MapR Database JSON. Before getting started, it is important that you understand Spark terminology and workflow, system requirements and support, and OJAI connector and API features.

The MapR Database OJAI connector includes a set of APIs that enable you to write applications that consume MapR Database JSON tables and use them in Spark. The MapR Database OJAI Connector for Apache Spark is a companion to the MapR Database Binary Connector for Apache Spark on page 4101, which provides the equivalent functionality for MapR Database Binary tables.

MapR Database OJAI Connector with Spark Workflow

You can use the MapR Database OJAI Connector to extract data from MapR Database or MapR File System and transform that data using either Spark or Spark SQL, and then load it into MapR Database

JSON:



MapR Database OJAI Connector for Apache Spark Features

Principal features of the MapR Database OJAI Connector for Apache Spark include the following:

- Support for Scala and, beginning with EEP 4.1, Java and Python APIs

  This matrix shows the programming languages and features supported:

	Scala	Java	Python
RDD	Yes	Yes	No
DataFrame	Yes	Yes	Yes
Dataset	Yes	Yes	No
DStream	Yes	No	No

- APIs that enable you to load data from a MapR Database JSON table to an Apache Spark RDD, DataFrame, or Dataset
- Projection and filter pushdown for better performance
- Custom partitioner for RDDs that enables you to partition data for better performance
- APIs that save an Apache Spark RDD, DataFrame, or DStream to a MapR Database JSON table using either normal or bulk insert
- Support for Scala and Java bean classes
- Support for data locality
- Support for secondary indexes starting from EEP 7.0.0 and EEP 6.3.1.

The following features are not supported:

- MapR Database Binary tables

  Only MapR Database JSON tables are supported; access to MapR Database binary tables is provided through the MapR Database Binary Connector.

- Secondary indexes are not suported for previous EEP 7.0.0 and EEP 6.3.1 versions.

last-updated: Apr 11, 2022

Supported Product Versions and System Requirements

To use the MapR Database OJAI Connector for Apache Spark, you must have the following minimum software versions:

- MapR: 5.2.1 or later
- EEP 3.0 or later
- Spark 2.1.0 or later
- Scala 2.11 or later
- Java 8 or later

Support for DataFrames and Datasets is available starting in the EEP 4.0 release.

OJAI API

The MapR Database OJAI Connector for Apache Spark uses the OJAI API internally to access MapR Database JSON tables.

Configuring the MapR Database OJAI Connector for Apache Spark
Before using the MapR Database OJAI Connector for Apache Spark, you must edit the `pom.xml` file for your project.

Add the Spark core dependency into the `pom.xml` file:

Note: If all dependent JAR files are already present on the node, consider setting the `scope` parameter to `provided`. For example:

```
<scope>provided</scope>
```

Setting the scope this way reduces the size of the JAR file.

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_<scala_version></artifactId>
  <version><spark_artifact_version></version>
</dependency>
```

Add the Spark Maven dependency to the `pom.xml` file:

```
<dependency>
  <groupId>com.mapr.db</groupId>
  <artifactId>maprdb-spark</artifactId>
  <version><spark_artifact_version></version>
</dependency>
```

For example, see the dependencies for Spark 2.4.4.0 (EEP 6.3.0 release):

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_2.11</artifactId>
  <version>2.4.4.0-mapr-630</version>
```

```
</dependency>
<dependency>
  <groupId>com.mapr.db</groupId>
  <artifactId>maprdb-spark</artifactId>
  <version>2.4.4.0-mapr-630</version>
</dependency>
```

To enable Maven to download dependencies, add the following repository information to the `pom.xml` file:

```
<repository>
  <id>mapr-releases</id>
  <url>https://repository.mapr.com/maven/</url>
  <snapshots>
    <enabled>false</enabled>
  </snapshots>
  <releases>
    <enabled>true</enabled>
  </releases>
</repository>
```

Maven artifacts can be used for dependency management when developing applications based on the MapR platform.

Loading Data from MapR Database Using the MapR Database OJAI Connector for Apache Spark
The MapR Database OJAI Connector for Apache Spark supports loading data as an Apache Spark RDD. Starting in the EEP 4.0 release, the connector introduces support for Apache Spark DataFrames and Datasets. DataFrames and Datasets perform better than RDDs. Whether you load your MapR Database data as a DataFrame or Dataset depends on the APIs you prefer to use. It is also possible to convert an RDD to a DataFrame.

Loading Data from MapR Database as an Apache Spark RDD

You can use the following API to load JSON-format data from a MapR Database table into an Apache Spark RDD of a JSON document:

Scala

For loading as an RDD, apply the following method on a `SparkContext` object:

```
def loadFromMapRDB[T](table: String):
RDD[T]
```

Java

For loading as an RDD, apply the following method on a `MapRDBJavaSparkContext` object:

```
mapRDBSparkContext.loadFromMapRDB(tabl
eName: String, clazz: Class)
```

Note: The only required parameter to the methods is tableName. All the others are optional.

The following example creates a `userprofilesRDD` by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table (`"/tmp/user_profiles"`):

Scala

```
import com.mapr.db.spark._

val userprofilesRDD
```

last-updated: Apr 11, 2022

```
= sc.loadFromMapRDB("/tmp/
user_profiles")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
```

The following example creates a `usersInfo` RDD by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table (`"/tmp/UserInfo"`):

Scala

```
import com.mapr.db.spark._

val usersInfo =
sc.loadFromMapRDB("/tmp/UserInfo")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIDocument> usersInfo
=
mapRDBSparkContext.loadFromMapRDB("/tm
p/UserInfo")
```

In the previous example, the `usersInfo` data contains the following information:

- Address (map type)
- Date of birth (date type)
- First name (string type)
- Interests (string type)
- Last name (string type)

The following prints the fields and shows the output for a sample user:

Scala

```
usersInfo.foreach(println(_))
```

Java

```
usersInfo.foreach(System.out::println)
;
```

```
{
  "address":
     {"Pin":95035,"city":"milpitas","street":"350 holger way"},
  "dob":"1947-11-29",
  "first_name":"David",
  "interests":["football","books","movies"],
  "last_name":"Jones"
}
```

The following example shows a join operation performed on two different JSON documents using `address.city` as the join key:

Scala

```
import com.mapr.db.spark._

val maprd1 = sc.loadFromMapRDB("/tmp/
user_profiles")

val maprd2 = sc.loadFromMapRDB("/tmp/
user_income")

val collection = maprd1.map(a =>
(a.`address.city`[String],a))
.cogroup(maprd2.map(a=>(a.`address.cit
y`[String],a)))
.map(a =>
(a._1,a._2._1.size,a._2._2.size)).coll
ect
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import scala.Tuple3;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument> maprd1 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
MapRDBJavaRDD<OJAIDocument> maprd2 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_income");

List collection =
maprd1.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a))
.cogroup(maprd2.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a)))
.map(a -> new Tuple3<>(a._1,
((Collection<?>)a._2._1).size(),
((Collection<?>)a._2._2).size()))
.collect();
```

The resulting RDD, `collection`, contains the count of the users in the `user_profiles` and `user_income` MapR Database tables.

The following example adds a new field into all the JSON documents:

Scala

```
import com.mapr.db.spark._

val maprd = sc.loadFromMapRDB("/tmp/
user_profiles")
val documents = maprd.map(a =>
{ a.`address.country` = "USA";
a}).collect
documents.saveToMapRDB("/tmp/
cleaned_user_profiles")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIDocument> maprd =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<OJAIDocument> documents =
maprd.map(a ->
{a.set("address.country", "USA");
return a;})

    .collect();
mapRDBSparkContext.saveToMapRDB(docume
nts, "/tmp/cleaned_user_profiles");
```

Improving Performance by Using Projection Pushdown and Filter Pushdown

To improve performance, you can supply a WHERE clause and projection fields to the `loadFromMapRDB` API. In the following example, a condition is supplied to the `loadFromMapRDB` function and only certain fields are specified in the SELECT clause:

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
                        .where([condit
ion])
                        .select("addre
ss",

"first_name",
                                "_id",

"last_name")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;
```

last-updated: Apr 11, 2022

```
MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")

            .where([condition])

            .select("address",

                    "first_name",

                    "_id",

"last_name");
```

The data is loaded based on the condition. The condition is pushed down to the server, and the server returns data based on the filtering. Only the fields specified in the SELECT clause are projected.

In the following example, the WHERE clause is used as a filter condition:

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
                      .where(field("sa
lary") >= 100)
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
.where(MapRDB.newCondition().is("salar
y",
QueryCondition.Op.GREATER_OR_EQUAL,
100));
```

The `userprofilesRDD` includes only those documents with a salary field greater than 100.

By specifying an `_id` field, you can find and retrieve a row for a given key:

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
```

```
                                .where(field("_i
d") === "k2")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
                  .where(MapRDB.newCon
dition().is("_id",
QueryCondition.Op.EQUAL, "k2"));
```

WHERE Clause Semantics

The `loadFromMapRDB` API supports a WHERE clause to push down the filter to the JSON document API, ensuring that only relevant documents are propagated to the RDD.

You can use two options to provide the filter condition:

- Scala domain-specific language (DSL)
- `QueryCondition` (from OJAI API)

Following is an example of using `loadFromMapRDB` and supplying a condition by using Scala DSL:

Scala

```
Condition isDoe = field("last_name")
=== "Doe"
val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles").where(isDoe)
```

For more information about using Scala DSL, see Scala DSL for Specifying Filter Conditions on page 4060.

Following is an example of passing the condition using the `QueryCondition` API:

Scala

```
val maprd  =
sc.loadFromMapRDB(tableName)
            .where(MapRDB.newConditio
n()
            .is("_id",
QueryCondition.Op.EQUAL, "k2")
            .build())
```

Java

```
MapRDBJavaRDD rdd =
mapRDBJavaSparkContext.loadFromMapRDB(
tableName)
            .where(MapRDB.newConditio
n().is("_id",
```

```
QueryCondition.Op.EQUAL,
"k2").build());
```

For more information about `QueryCondition`, see Querying with Conditions on page 2642.

Note: For additional information, see Java Examples in the source code.

Creating an Apache Spark RDD of a Class

When loading data as an Apache Spark RDD, if you have a custom class in your application, you can present the data as objects of your class.

Scala

You must define the custom class using Jackson semantics for Scala modules. The following example defines a custom `User` class:

```
case class User (@JsonProperty("_id")
id:String,

@JsonProperty("first_name")
firstName:String,

@JsonProperty("last_name") lastName:
String,
            @JsonProperty("dob") dob:
ODate,

@JsonProperty("interests") interests:
List[String])
```

In the following example, by supplying `User` as a type parameter to the function while loading the MapR Database table, you can create an RDD of the `User` class:

```
val userprofilesRDD =
sc.loadFromMapRDB[User]("/tmp/
user_profiles")
                        .where("conditio
n")
```

When specifying a bean class, the SELECT clause is unnecessary and is ignored.

Java

You must define a custom bean class as follows:

```
public static class Person implements
Serializable {
            private String _id;
            private String firstName;
            private String lastName;
            private Date dob;
            private Seq<String>
interests;
            public String get_id()
{ return _id; }
            public void set_id(String
_id) { this._id = _id; }
            public String
getFirstName() { return firstName; }
            public void
setFirstName(String firstName)
```

last-updated: Apr 11, 2022

```
{ this.firstName = firstName; }
            public String
getLastName() { return lastName; }
            public void
setLastName(String lastName)
{ this.lastName = lastName; }
            public Date getDob()
{ return dob; }
            public void setDob(Date
dob) { this.dob = dob; }
            public Seq<String>
getInterests() { return interests; }
            public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
           }
```

In the following example, by supplying the `User` bean class as a type parameter while loading the MapR Database table, you can create a `MapRDBJavaRDD` of the `User` class:

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles",

User.class).where(<condition>);
```

Scala DSL for Specifying Filter Conditions

When loading data from MapR Database as an Apache Spark RDD, you can use Scala DSL to specify filter conditions. This section shows examples of these filter conditions.

In the following examples, a class named `field` is introduced to represent a field in a condition. The field condition takes an argument as a String. The following table shows conditions written using Scala DSL:

Condition	Example
equality	`val idOnlyPredicate = field("_id") === "k2"`
greatherThan	`val simplePredicateWithComparisonOperator = field("a.c.d") > 10`
notexists	`val simpleNotExistsPredicate = field("a.c.e") notexists`
IN	`val inPredicate = field("a.c.d") in Seq(ODate.parse("2011-05-21"), ODate.parse("2013-02-22"))`
typeof	`val simpleTypeOfPredicate = field("a.c.d") typeof "INT"`

Condition	Example
complex condition with and	`val inPredicateWithMapAndArray = (field("a.c.d") in Seq(5,10)) and (field("a.c.e") notin Seq("aaa","bbb"))`
another complex condition	`val compositePredicateWithAndOnly = ((field("a.b") notexists ) and (field("p.q") typeof "DATE")) and (field("a.c.d") > 20L)`
between	`val predicateWithBetweenOp = field("a.c.d") between (ODate.parse("2015-01-15"), ODate.parse("2015-05-15"))`
predicate with equality check on Sequence of elements (representing array)	`val eqPredicateWithList = field("a.b") === Seq(12345L, "xyz")`
predicate with equality check on a map	`val eqWithMapPredicate = field("a") === Map("k" -> "kite", "m" -> "map")`

The MapR Database OJAI Connector for Apache Spark supports these predicates:

- `>`
- `>=`
- `<`
- `<=`
- `===`
- `!=`
- `between`
- `exists`
- `notin`
- `in`
- `notexists`
- `typeof`
- `nottypeof`
- `like`
- `notlike`

last-updated: Apr 11, 2022

- `matches`
- `notmatches`
- `sizeOf`

Here are examples for these operators:

- `field("a") > 10`
- `field("a") >= 10`
- `field("a") < 10`
- `field("a") <= 10`
- `field("a") === 10`
- `field("a") === Seq("aa", 10)`
- `field("a") === Map("aa" -> 10)`
- `field("a") != 10`
- `field("a") != Seq("aa", 10)`
- `field("a") != Map("aa" -> 10)`
- `field("a) between (10,20)`
- `field("a") exists`
- `field("a") notin Seq(10,20)`
- `field("a") in Seq(10, 20)`
- `field("a") notexists`
- `field("a") typeof "INT"`
- `field("a") nottypeof "INT"`
- `field("a") like "%s"`
- `field("a") notlike "%s"`
- `field("a") matches "*s"`
- `field("a") notmatches "*s"`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`

- "STRING"
- "SHORT"
- "BYTE"
- "NULL"
- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The sizeOf operator can have the following operations:

- sizeOf(field("a")) === 10
- sizeOf(field("a")) < 10
- sizeOf(field("a")) > 10
- sizeOf(field("a")) >= 10
- sizeOf(field("a")) <= 10
- sizeOf(field("a")) != 10

Java DSL for Specifying Filter Conditions

When loading data from MapR Database as an Apache Spark RDD, you can use Java DSL to specify filter conditions. This section shows examples of these filter conditions.

Condition	Example
equality	`QueryCondition equality = MapRDB.newCondition().is("_id", QueryCondition.Op.EQUAL, "k2").build();`
greatherThan	`QueryCondition greatherThan = QueryCondition simpleWithComparisonOperator = MapRDB.newCondition().is("a.b.c", QueryCondition.Op.GREATER, 10).build();`

last-updated: Apr 11, 2022

Condition	Example
notexists	`QueryCondition notexists = MapRDB.newCondition().notExists("a.c.e").build();`

IN	`List<ODate> odateList = new ArrayList<>();`
	`odateList.add(ODate.parse("2011-05-21"));`
	`odateList.add(ODate.parse("2013-02-22"));`
	`QueryCondition in = MapRDB.newCondition().in("a", odateList).build();`

typeof	`QueryCondition typeOf = MapRDB.newCondition().typeOf("a.c.d", Value.Type.INT).build();`

complex condition with and	`QueryCondition complexConditionWithAnd = MapRDB.newCondition()`
	`.and()`
	`.condition(MapRDB.newCondition().in("a", Arrays.asList(5, 10)))`
	`.condition(MapRDB.newCondition().notIn("b", Arrays.asList("aaa", "bbb")))`
	`.close().build();`

another complex condition	`QueryCondition anotherComplexCondition = MapRDB.newCondition()`
	`.and()`
	`.condition(MapRDB.newCondition().notExists("a.b"))`
	`.condition(MapRDB.newCondition().typeOf("p.q", Value.Type.DATE))`
	`.condition(MapRDB.newCondition().is("a.c.d", QueryCondition.Op.GREATER, 20L))`
	`.close().build();`

The MapR Database OJAI Connector for Apache Spark supports these predicates:

- `is (LESS, LESS_OR_EQUAL, EQUAL, NOT_EQUAL, GREATER_OR_EQUAL, GREATER)`
- `equals`
- `and`
- `exists`
- `in`
- `like`
- `matches`
- `notEquals`
- `notExists`
- `notIn`
- `notLike`
- `notMatches`

- notTypeOf
- or
- sizeOf
- typeOf

Here are examples for these operators:

- MapRDB.newCondition().is("a", QueryCondition.Op.GREATER, 10);
- MapRDB.newCondition().is("a",QueryCondition.Op.GREATER_OR_EQUAL, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.LESS, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.LESS_OR_EQUAL, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.EQUAL, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.NOT_EQUAL, 10);
- MapRDB.newCondition().exists("a");
- MapRDB.newCondition().notIn("a", Arrays.asList(10, 20));
- MapRDB.newCondition().in("a", Arrays.asList(10, 20));
- MapRDB.newCondition().notExists("a");
- MapRDB.newCondition().typeOf("a", Value.Type.INT);
- MapRDB.newCondition().notTypeOf("a", Value.Type.INT);
- MapRDB.newCondition().like("a", "%s");
- MapRDB.newCondition().notLike("a", "%s");
- MapRDB.newCondition().matches("a", "*s");
- MapRDB.newCondition().notMatches("a", "*s");

For `typeof`, these are the right-hand side values:

- "INT"
- "INTEGER"
- "LONG"
- "BOOLEAN"
- "STRING"
- "SHORT"
- "BYTE"
- "NULL"

- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The `sizeOf` operator can have the following operations:

- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.EQUAL, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.NOT_EQUAL, 10);`

Using the Custom Partitioner with the MapR Database OJAI Connector for Apache Spark

In any distributed computing system, partitioning data is crucial to achieve the best performance. Apache Spark provides a mechanism to register a custom partitioner for partitioning the pipeline. The MapR Database OJAI Connector for Apache Spark includes a custom partitioner you can use to optimally partition data in an RDD.

The MapR Database OJAI Connector for Apache Spark's custom partitioner takes the following classes as keys:

- `String`
- `ByteBuffer` (as serializable `ByteBuffer`)

You can register this custom partitioner with either the `partitionBy` function or the `repartitionAndSortWithinPartitions` function.

The connector supports two versions of the custom partitioner. One version takes a MapR Database JSON table as an input. The partition information of the table is used to partition the data, so the `saveToMapRDB` call can use a `bulkInsert` to store the data. The `bulkInsert` option requires that you have the data already sorted on the `_id` key.

The other version of the custom partitioner takes an array of splits as an input.

Specifying tablename for the Partitioner

If you already have a table that has been created and partitioned based on a set of keys, you can can specify that the RDD be partitioned in the same way (using the same set of keys). In the following example, `/srctable` is provided as a reference partitioner for `/dsttable`:

Scala

```
sc.loadFromMapRDB("/srctable")
            .keyBy(doc =>
doc._id[String])
            .repartitionAndSortWithinP
artitions(MapRDBSpark.newPartitioner[S
tring]("/dsttable"))
            .saveToMapRDB("/
dsttable", createTable = false,
bulkInsert = true)
```

Specifying a String Seq as an Array of Splits

In the following example, the first line creates an array of splits as `id1`, `id2` ... `id9`. The rest of the example splits the RDD based on the array of splits:

Scala

```
val dstSplits: Array[String] = (1 to
9 by 3).map("id" + _).toArray
val partitionRDD =
sc.loadFromMapRDB("/srctable")
            .keyBy(doc =>
doc._id[String])
            .repartitionAndSortWithinP
artitions(MapRDBSpark.newPartitioner[S
tring](dstSplits))
            .saveToMapRDB("/
dsttable", createTable = true,
bulkInsert = true)
```

Specifying a ByteBuffer Seq as an Array of Splits

Suppose you have an array of byte buffers to use as the array of splits for the partitioner. You must convert the byte buffers to serializable byte buffers first:

Scala

```
// Converting bytebuffer to
serializable bytebuffer
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
sc.loadFromMapRDB("/srctable")
  //KeyBy serializable bytebuffer
  .keyBy(doc =>
doc.getBinarySerializable(binaryField)
)
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner(dstSplits))
  .saveToMapRDB("/dsttable",
createTable = true, bulkInsert = true)
```

Specifying tablename for the Partitioner with ByteBuffer as Id Fields

Suppose you have a table with keys that are binary or `ByteBuffer`, and you have an RDD with some rows and some values. You can repartition the RDD based on the partitions of the table. The following example reads the document from `/srctable`, but you could provide any table. In the second line, the example specifies a `keyBy` call on an ID that is binary serializable. In the last line, `/dsttable` is the RDD that has a key of serializable `ByteBuffers`:

Scala

```
sc.loadFromMapRDB("/srctable")
  .keyBy(doc =>
doc.getIdBinarySerializable())
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[ByteBuffer]
("/dsttable"))
```

Note: You must provide the key type of the `PairedRDD` on which the partitioning is specified. If the IDs are serializable bytebuffers, specify `ByteBuffer`. Otherwise, specify `String`.

After the data is partitioned with the custom partitioner, all the downstream transformations should be non-partition-changing transformations. Here is the code for passing on partitioner for an RDD:

Scala

```
user_profiles.repartitionAndSortWithin
Partitions
   (MapRDBSpark.newPartitioner[String]
(<table-name>))
```

Or you can use the `partitionBy` function on the RDD:

Scala

```
user_profiles.partitionBy(MapRDBSpark.
newPartitioner[String](<table-name>))
```

The key of the data for this partitioner should be of the same type as that of the key of the table name. This partitioner yields a single partition if the table supplied to it is not pre-split. The number of partitions is calculated based on the table's existing tablet information.

For a table created with the `bulkInsert` option set to `true`, one of the following applies:

- If the table is pre-split, then the resulting partitions can be > 1.
- If the table is no-split, then the resulting partitions will be 1 if no partition information is available from the RDD lineage.

Loading Data from MapR Database as an Apache Spark DataFrame

To load data from a MapR Database JSON table into an Apache Spark DataFrame, invoke the following API:

Scala

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](tableName:
String,
                schema: StructType):
DataFrame

import com.mapr.db.spark.sql._
```

```
val df
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles"): DataFrame
```

Java

For loading as a DataFrame (Datasets of Row), apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB(tableName: String,
schema: StructType, sampleSize:
Double):DataFrame

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

Note: Java supports only DataSets of Row (Dataset<Row>).

Python

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
loadFromMapRDB(table_name, schema,
sample_size)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")
```

Note: PySpark supports only DataFrames (Dataset<Row>).

Note: The only required parameter to the methods is tableName. All the others are optional.

This creates a DataFrame object corresponding to the MapR Database table specified by the `tableName` parameter.

Both DataFrames and MapR Database tables work with structured data. DataFrames need a fixed schema, whereas MapR Database allows for a flexible schema. When loading data into a DataFrame, you can map your data to a schema by specifying the schema parameter in the `loadFromMapRDB` call. You can also provide an application class as the type `[T]` parameter in the call. These two approaches are the preferred methods for loading data into DataFrames.

For data exploration use cases, you might not know the schema of your MapR Database table. For those situations, the MapR Database OJAI connector for Apache Spark can infer the schema by sampling data from the table.

Whenever possible, the MapR Database OJAI Connector for Apache Spark pushes projections and filters for better performance. This allows MapR Database to project and filter data before returning it to your client application.

The following subtopics describe these techniques.

last-updated: Apr 11, 2022

Optimizing MapR Database Lookups in Spark Jobs

The `lookupFromMapRDB()` API utilizes the primary and secondary indexes on a MapR Database table to optimize table lookups and outputs the results to an Apache Spark DataFrame.

Important: The `lookupFromMapRDB()` API functionality requires a patch. The patch works with EEP 6.2.0 (Core 6.1.0, Spark 2.4.0.0) and EEP 6.3.0 (Core 6.1.0, Spark 2.4.4.0). To install patches, see Applying a Patch

The `loadfromMapRDB()` API in MapR Database Connectors for Apache Spark is optimized to load massive amounts of data from MapR Database tables with high throughput. In cases where a Spark job needs to lookup a small number of documents based on the equality (or short range) condition on a primary or secondary key, the `lookupFromMapRDB()` API should be used.

Invoke the `lookupFromMapRDB()` API when the filter conditions in short range and equality queries reference primary and secondary keys. If the filter condition references any non-primary keys (fields other than the `_id` field), a secondary index must exist on the secondary keys. Indexes on the filtering keys is essential to achieving reasonable performance of lookup queries in MapR Database tables.

The `lookupFromMapRDB()` API uses the secondary keys in indexes to lookup values in the primary table. For example, if a query contains the filter conditions `mydate = '2012-03-26'` and `myid = '120026015'`, a secondary index (of type composite) created on the `mydate` and `myid` fields must exist for the query to quickly output results.

Examples on the following tabs demonstrate how to invoke the `lookupFromMapRDB()` API to perform a lookup in a MapR Database table and output the results to an Apache Spark DataFrame:

Scala

```
import com.mapr.db.spark.sql._
import spark.implicits._
val df = spark.lookupFromMapRDB("/
tbl")
df.filter("mydate" === "2012-03-26"
&& $"myid" === 120026015).show
```

Java

```
SparkSession sparkSession =
SparkSession.builder().getOrCreate();
MapRDBJavaSession mapRDBJavaSession =
new MapRDBJavaSession(sparkSession);
Dataset<Row> df2 =
mapRDBJavaSession.lookupFromMapRDB("/
tbl");
df2.filter("mydate = '2012-03-26' and
myid = '120026015'").show();
```

Python

```
from pyspark.sql import SparkSession
df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate = '2012-03-26' and
myid = '120026015'").show()
```

Loading Data into a DataFrame Using an Explicit Schema

If you know the schema of your data, you can specify an explicit schema when loading a DataFrame.

The following example loads data into a user profile table using an explicit schema:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._
```

last-updated: Apr 11, 2022

```
val addressSchema =
StructType(StructField("Pin",
IntegerType) ::

StructField("city", StringType) ::

StructField("street", StringType) ::
Nil)

val personSchema =
StructType(StructField("_id",
StringType) ::

StructField("first_name",
StringType) ::

StructField("last_name",
StringType) ::

StructField("address",
addressSchema) ::

StructField("interests",
ArrayType(StringType)) :: Nil)

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

StructField[] addressSchema = {
                                new
StructField("Pin", IntegerType, true,
Metadata.empty()),
                                new
StructField("city",StringType, true,
Metadata.empty()),
                                new
StructField("street", StringType,
true, Metadata.empty())
                               };
StructField[] schemaFields = {
   new StructField("_id", StringType,
true, Metadata.empty()),
   new StructField("first_name",
StringType, true, Metadata.empty()),
   new StructField("address", new
StructType(addressSchema), true,
Metadata.empty()),
   new StructField("interests", new
ArrayType(StringType, true), true,
Metadata.empty())
                              };
StructType personSchema = new
StructType(schemaFields);
MapRDBJavaSession maprSession = new
```

```
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles", personSchema);
```

Python

```
from pyspark.sql import SparkSession

addressSchema = [StructField("Pin",
IntegerType(), True),
                 StructField("city",
StringType(), True),

StructField("street", StringType(),
True)]
schemaFields = [StructField("_id",
StringType(), True),

StructField("first_name",
StringType(), True),

StructField("last_name",
StringType(), True),

StructField("address",
StructType(addressSchema), True),

StructField("interests",
ArrayType(StringType()), True)]
personSchema =
StructType(schemaFields)

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

To create the DataFrame object named `df`, pass the schema as a parameter to the load call. Invoke the `loadFromMapRDB` method on a `SparkSession` object.

The resulting schema of the object is the following:

```
df.printSchema()
 ---------------------------------
 root
 |-- _id: String (nullable = true)
 |-- first_name: String (nullable = true)
 |-- last_name: String (nullable = true)
 |-- address: Struct (nullable = true)
 |    |-- Pin: integer (nullable = true)
 |    |-- city: string (nullable = true)
 |    |-- street: string (nullable = true)
 |-- interests: array (nullable = true)
 |    |-- element: string (containsNull = true)
```

When specifying `StructField` in a schema, optionally specify whether the field is nullable. In the example above, all fields are nullable.

Depending on the nullability of the field in the schema and the existence of fields in the MapR Database table, the load returns an `InvalidSchema` exception in the following cases:

- The schema contains a non-nullable field and the load attempts to put a NULL value into the field.

- The schema contains a non-nullable field and the field does not exist in the MapR Database table.
- The MapR Database table has fields that do not exist in the specified schema.

Loading Data into a DataFrame Using a Type Parameter

If the structure of your data maps to a class in your application, you can specify a type parameter when loading into a DataFrame.

Specify the application class as the type parameter in the load call. The load infers the schema from the class.

The following example creates a DataFrame with a `Person` schema by passing the `Person` class as the type parameter in the load call:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

          case class Person(_id:
String,
          First_name: String,
          last_name: String,
          Address: Address,
          Interests: Seq[String])

val df
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

public static class Address
implements Serializable {
     private Integer pin;
     private String street;
     private String city;

     public Integer getPin() { return
pin; }
     public void setPin(Integer pin)
{ this.pin = pin; }
     public String getStreet()
{ return street; }
     public void setStreet(String
street) { this.street = street; }
     public String getCity() { return
city; }
     public void setCity(String city)
{ this.city = city; }
}
public static class Person implements
Serializable {
     private String _id;
     private String firstName;
```

last-updated: Apr 11, 2022

```
     private String lastName;
     private Date dob;
     private Seq<String> interests;

     public String get_id() { return
_id; }
     public void set_id(String _id)
{ this._id = _id; }
     public String getFirstName()
{ return firstName; }
     public void setFirstName(String
firstName) { this.firstName =
firstName; }
     public String getLastName()
{ return lastName; }
     public void setLastName(String
lastName) { this.lastName =
lastName; }
     public Date getDob() { return
dob; }
     public void setDob(Date dob)
{ this.dob = dob; }
     public Seq<String>
getInterests() { return interests; }
     public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}
MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
Person.class);
```

You must invoke the `loadFromMapRDB` method on a `SparkSession` or `MapRDBJavaSession` object.

All fields in an application bean class are nullable by default. The only circumstance in which the load returns an `InvalidSchema` exception is if the MapR Database table contains fields not included in the bean class.

The resulting schema of the object is as follows:

```
df.printSchema()
 ---------------------------------
 root
 |-- _id: String (nullable = true)
 |-- first_name: String (nullable = true)
 |-- last_name: String (nullable = true)
 |-- address: Struct (nullable = true)
 |    |-- Pin: integer (nullable = true)
 |    |-- street: string (nullable = true)
 |    |-- city: string (nullable = true)
 |-- interests: array (nullable = true)
 |    |-- element: string (containsNull = true)
```

Loading Data into a DataFrame Using Schema Inference

If you do not know the schema of the data, you can use schema inference to load data into a DataFrame. This section describes how to use schema inference and restrictions that apply

When you do not specify a schema or a type when loading data, schema inference triggers automatically. The MapR Database OJAI Connector for Apache Spark internally samples documents from the MapR Database JSON table and determines a schema based on that data sample. By default, the sample size is

1000 documents. Alternatively, you can specify a sample size parameter. The parameter is optional in the `loadFromMapRDB` call and is named `sampleSize`. The following example specifies using a sample size of 100 documents:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df =
sparkSession.loadFromMapRDB(tableName,
 sampleSize : 100)
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
100);
```

Python

```
from pyspark.sql import SparkSession

df = spark.loadFromMapRDB(table_name,
100)
```

Important: Because schema inference relies on data sampling, it is non-deterministic. It is not well suited for production use where you need predictable results. Inferring schema results in reading sample rows from the table, hence execution time varies with number of rows in the source table.

Sampling Using Reader Functions

An alternative to sampling data using the `loadFromMapRDB` call is to use reader functions.

To use the DataFrame reader function (for Scala only), call the following methods:

```
val df = sparkSession.read.maprdb(tableName)
```

To use the reader function with basic Spark, call the `read` function on a `SQLContext` object as follows:

Scala

```
import org.apache.spark.sql.SQLContext

val df =
sqlContext.read.format("com.mapr.db.sp
ark.sql")
         .option("tableName",
<table-name>)
         .option("sampleSize",
100).load()
```

Java

```
import
org.apache.spark.sql.SQLContext;
```

last-updated: Apr 11, 2022

```
Dataset<Row> df = sqlContext.read()
                    .format("com.mapr.db
.spark.sql")
                    .option("tableName",
 <table-name>).load();
```

Python

```
from pyspark.sql import SQLContext

df = sql_context.read\
     .format("com.mapr.db.spark.sql.De
faultSource")\
     .option("tableName",
<table-name>).load()
```

Type Conflict Resolution When Sampling

When sampling data during schema inference, you might encounter conflicting value types within a field. The connector uses the following rules to resolve type conflicts:

- If the two conflicting types are each one of the following, the resolved type is the wider of the two types:
  - `ByteType`
  - `ShortType`
  - `IntegerType`
  - `LongType`
  - `FloatType`
  - `DoubleType`

  The type list above is arranged in increasing order of width. For example, if one document contains a field of type `ByteType` and the other contains a field of type `FloatType`, the resultant type is `FloatType`.
- If one of the types is `DecimalType`, then the resultant type is `DecimalType`, if and only if `DecimalType` is the wider of the two types.
- If the two types are `StructType`, each with different fields, then the resultant type is a new `StructType` that contains all the fields in each `StructType`.
- If the two types are `ArrayType`, each with different element types, then the resultant type is a new `ArrayType` where the type of the elements in the array is resolved using the aforementioned rules.
- If none of the above rules can be used for resolving type conflicts, then during data conversion, the load reports a `ConflictType` exception.

Suppose `Name` contains String values in some rows and a map with `first_name` and `last_name` as nested fields in other rows. During schema inference, the conflict resolution logic encounters two different types for the same field, `StringType` and `MapType`. It will note the conflict and return a `ConflictType` exception later when converting the data during the load.

By default, conflict exceptions occur during data conversion. To change this so that the exception is returned during the conflict resolution stage, set the `FailOnConflict` option to true :

Scala

```
val df =
spark.read.maprdb(<tableName>,
Map("sampleSize" -> 100,
"FailOnConflict" -> true))
```

Invalid Schemas

When using schema inference, missing and extra fields are resolved in the following ways:

- If a field in the inferred schema is missing in the MapR Database JSON document, the field is set to null.
- If there are fields in a MapR Database JSON document that are not in the inferred schema, the load returns an `InvalidSchema` exception.

Type Mapping Between MapR Database JSON and DataFrames

This table maps data types between MapR Database JSON OJAI and Apache Spark DataFrame.

Note: Not all DataFrame data types are supported by MapR Database, for a list of supported data types, see JSON Documents on page 508.

OJAI Data Type	DataFrame Data Type
Boolean	BooleanType
String	StringType
Byte	ByteType
Short	ShortType
Int	IntegerType
Long	LongType
Float	FloatType
Double	DoubleType
Decimal	DecimalType
Date	DateType
Time	TimestampType
TimeStamp	TimeStampType
Interval	CalendarIntervalType
Binary	BinaryType
Map	StructType
Array	ArrayType

Note: The OJAI `Time` data type is converted to a Spark `TimestampType` with the date set to the epoch date. Spark SQL does not support a `TIME` type.

Loading Data from MapR Database as an Apache Spark Dataset

You can use one of three ways to load data from MapR Database into an Apache Spark Dataset:

- Load the data into a Dataset.
- Load the data into a DataFrame, and then convert it to a Dataset.

last-updated: Apr 11, 2022

- Load the data into a Dataset using a custom encoder.

Load into a Dataset

Scala

For loading as a Dataset, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](table: String,
schema : StructType).as [T]: Dataset

import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles").as [T]: Dataset
```

Java

For loading as a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB[T <:
java.lang.Object](tableName: String,
schema: StructType, sampleSize:
Double, clazz: Class[T]): Dataset[T]

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);

Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

Note: The only required parameter to the methods is tableName. All the others are optional.

Load into DataFrame and Convert to Dataset

To load the data as a DataFrame, see Loading Data from MapR Database as an Apache Spark DataFrame on page 4068. To convert the DataFrame to a Dataset, use the `as[<type>]` method. The `<type>` can be any of the basic types in Scala.

The following code example creates a `Dataset[Person]` using the `as[<type>]` method:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

case class Person (_id:String,
              first_name:String,
              last_name: String, dob:
java.sql.Date,
              Interests: Seq[String,
address: Address)
```

```
val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

public static class Address
implements Serializable {
     private Integer pin;
     private String street;
     private String city;

     public Integer getPin() { return
pin; }
     public void setPin(Integer pin)
{ this.pin = pin; }
     public String getStreet()
{ return street; }
     public void setStreet(String
street) { this.street = street; }
     public String getCity() { return
city; }
     public void setCity(String city)
{ this.city = city; }
}

public static class Person implements
Serializable {
     private String _id;
     private String firstName;
     private String lastName;
     private Date dob;
     private Seq<String> interests;
               public String get_id()
{ return _id; }
               public void
set_id(String _id) { this._id = _id; }
               public String
getFirstName() { return firstName; }
               public void
setFirstName(String firstName)
{ this.firstName = firstName; }
               public String
getLastName() { return lastName; }
               public void
setLastName(String lastName)
{ this.lastName = lastName; }
               public Date getDob()
{ return dob; }
               public void setDob(Date
dob) { this.dob = dob; }
               public Seq<String>
getInterests() { return interests; }
               public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
               }
Dataset<Person> ds =
```

last-updated: Apr 11, 2022

```
maprSession.loadFromMapRDB(tableName,
Person.class);
```

Load into Dataset Using Custom Encoder

You can create a custom encoder for Java bean classes by calling the `Encoders.bean` method. `Encoders.bean` only support Java classes. To create a Dataset of the Scala class, the previous code can be used. The following example shows how to load into a Dataset by creating a custom encoder for a Java class named `beanClass`:

Scala

```
import
org.apache.spark.sql.SparkSession

import com.mapr.db.spark.sql._

val ds =
sparkSession.loadFromMapRDB("/tmp/
user_profiles")
         .as(Encoders.bean(beanClass))
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(beanC
lass);
```

Filter Pushdown

After you have loaded data into a Dataset, you can apply filter pushdowns. The following example filters on `first_name`:

Scala

```
ds.filter($"first_name" === "David")
```

Java

```
ds.filter(col("first_name").equalTo("D
avid")).show();
```

See Projection and Filter Pushdown with Apache Spark DataFrames and Datasets on page 4080 for other examples.

Projection and Filter Pushdown with Apache Spark DataFrames and Datasets

Projection and filter pushdown improve query performance. When you apply the `select` and `filter` methods on DataFrames and Datasets, the MapR Database OJAI Connector for Apache Spark pushes these elements to MapR Database where possible.

Projection Pushdown

Projection pushdown minimizes data transfer between MapR Database and the Apache Spark engine by omitting unnecessary fields from table scans. It is especially beneficial when a table contains many columns.

When you invoke the following `select` method on a DataFrame, the connector pushes the projection:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.select("_id", "first_name",
"last_name");
```

Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

The equivalent example using Datasets is as follows:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.select("_id", "first_name",
"last_name")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles", Person.class);
ds.select("_id", "first_name",
"last_name");
```

last-updated: Apr 11, 2022

Filter Pushdown

Filter pushdown improves performance by reducing the amount of data passed between MapR Database and the Apache Spark engine when filtering data.

Consider the following example:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.filter("first_name = 'Bill'")
```

Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

The MapR Database OJAI Connector for Apache Spark pushes the filter `firstName = 'Bill'` down to MapR Database.

The equivalent example using Datasets is as follows:

Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.filter($"first_name" === "Bill")
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

Dataset ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(Perso
n.getClass()));
```

```
ds.filter(col("first_name").equalTo("B
ill"));
```

The following DataFrame filters those rows in which first_name is either `"David"` or `"Peter"`:

Scala

```
df.filter($"first_name" === "David"
|| $"first_name" === "Peter")
```

Java

```
df.filter(col("first_name").equalTo("D
avid").or(col("first_name").equalTo("P
eter")))
```

Python

```
df.filter((col("first_name") ==
"David") | (col("first_name") ==
"Peter"))
```

The following DataFrame retrieves only the rows in which the first_name is `"David"` and the last_name is `"Jones"`:

Scala

```
df.filter($"first_name" === "David"
&& $"last_name" === "Jones")
```

Java

```
df.filter(col("first_name").equalTo("D
avid").and(col("last_name").equalTo("J
ones")))
```

Python

```
df.filter((col("first_name") ==
"David") & (col("last_name") ==
"Jones"))
```

The following uses a `not` condition to return rows where the first_name is not `"David"` and the last_name is not `"Peter"`:

Scala

```
df.filter(not($"first_name" ===
"David || $"last_name" === "Peter"))
```

Java

```
df.filter(not(col("first_name").equalT
o("David").or(col("last_name").equalT
o("Peter"))))
```

Python

```
df.filter(~((col("first_name") ==
"David") | (col("last_name") ==
"Peter")))
```

The MapR Database OJAI Connector pushes down all of the filters shown in the earlier examples. It can push down the following types of filters, provided that the field is not an `Array` or `Map`:

- Equal To (=)

last-updated: Apr 11, 2022

- Not Equal To (`!=`)
- Less Than (<)
- Less Than or Equal To (<=)
- Greater Than (>)
- Greater Than or Equal To (>=)
- In Predicate (`IN`)
- Like predicate (`LIKE`)
- `AND`, `OR`
- `NOT`

Restrictions

Pushdowns with DataFrames and Datasets are not supported in the following scenarios:

- Filters on complex types, including arrays, maps, and structs

  For example, a filter on a field in a map, as shown in the following example, is not pushed down:

  Scala
  ```
  df.filter($"address.city" === "Milpitas")
  ```

  Java
  ```
  df.filter(col("address.city").equalTo("Milpitas"));
  ```

  Python
  ```
  df.filter(col("address.city") == "Milpitas")
  ```

- Filters with functions `sizeof`, `typeof`, and `matches`

  Spark SQL does not support these functions.

- Projections on complex types, including arrays, maps, and structs

  For example, if you select an element of an array, as shown in the following example, it is not pushed down:

  Scala
  ```
  ds.select($"hobbies" (0))
  ```

  Java
  ```
  df.select(col("hobbies").getItem(0));
  ```

  Python
  ```
  df.select(col("hobbies").getItem(0))
  ```

These limitations do not apply to pushdowns on RDDs. An alternative is to apply the pushdown using an RDD, and then convert the RDD to a DataFrame.

Note: MapR Database 6.0 introduces support for Secondary Indexes on page 544, but the MapR Database OJAI Connector for Spark does not currently leverage them.

Converting an Apache Spark RDD to an Apache Spark DataFrame

When APIs are only available on an Apache Spark RDD but not an Apache Spark DataFrame, you can operate on the RDD and then convert it to a DataFrame.

You can convert an RDD to a DataFrame in one of two ways:

- Use the helper function, `toDF`.
- Convert the RDD to a DataFrame using the `createDataFrame` call on a `SparkSession` object.

Using the toDF Helper Function

The `toDF` method is available through `MapRDBTableScanRDD`. The following example loads an RDD that filters on `first_name` equal to `"Peter"` and projects the `_id` and `first_name` fields, and then converts the RDD to a DataFrame:

Scala

```
import com.mapr.db.spark.sql._

val df =
sc.loadFromMapRDB(<table-name>)
           .where(field("first_name")
=== "Peter")
           .select("_id",
"first_name").toDF()
```

Using SparkSession.createDataFrame

With this approach, you can convert an `RDD[Row]` to a DataFrame by calling `createDataFrame` on a `SparkSession` object. The API for the call is as follows:

Scala

```
def createDataFrame(RDD, schema:
StructType)
```

You might need to first convert an `RDD[OJAIDocument]` to an `RDD[Row]`. The following example shows how to do this:

Scala

```
val df = sparkSession.createDataFrame(
         rdd.map(doc
=>MapRDBSpark.docToRow(doc, schema)),
schema)
```

`rdd` is of type `RDD[OJAIDocument]`. The `docToRow` call converts `rdd` to an `RDD[Row]` that is then passed to `createDataFrame`.

Working with Complex JSON Document Types

The MapR Database OJAI Connector for Apache Spark provides APIs to process JSON documents loaded from MapR Database.

Suppose you want to calculate the number of users located in each city:

Scala

```
import com.mapr.db.spark.sql._

val customerprofilesRDD =
```

last-updated: Apr 11, 2022

```
sc.loadFromMapRDB("/tmp/
user_profiles")
val numberOfCustaccCities =
customerprofilesRDD.map(a =>
(a.`address.city`[String],a))
                                .groupByKe
y()
                                .map(a =>
(a._1, a._2.size))
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
JavaRDD numberOfCustaccCities =
customerprofilesRDD.mapToPair
   (a -> new
Tuple2<>(a.getString("address.city"),
a)).groupByKey()
   .map(a -> new Tuple2<>(a._1,
((Collection<?>)a._2).size()));
```

If you have not provided an explicit cast, then the object is returned as `AnyRef`. To access methods specific to a class, such as `String` or `Integer`, you can cast it to a specific type later in the process.

Now suppose you want to collect all the addresses (`address` is of type `Map`) of all customers:

Scala

```
import com.mapr.db.spark.sql._

val customerprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
val customersAddress =
customerprofilesRDD.map(a =>
a.address).collect
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIDocument>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<String> customersAddress =
customerprofilesRDD.map(a ->
a.getString("address")).collect();
```

`customersAddress` contains all of the addresses, but is returned as an `AnyRef` object.

The MapR Database OJAI Connector for Apache Spark introduces three new classes to wrap complex JSON types:

Class	Type
`DBMapValue`	`Map[String, AnyRef]`
`DBArrayValue`	`Array[AnyRef]`
`DBBinaryValue`	`ByteBuffer`

These classes are not exposed; however, you can access the underlying elements of `DBArrayValue` and `DBMapValue` by using the same functions as in `Seq` and `Map`. `DBArrayValue` works like a sequence, while `DBMapValue` works like a map.

`DBBinaryValue` is a class wrapper around `ByteBuffer`. `ByteBuffer` is not serializable, so you will get serialization errors if you use the `ByteBuffer` in Spark code. You must ensure that byte buffers are converted to `DBBinaryValue` or serialized byte buffers. The MapR Database OJAI Connector for Apache Spark provides an API to convert `ByteBuffers` to serializable byte buffers.

Accessing Values in a Map

`DBMapValue` is a type of `Map[String, AnyRef]`. Any functions that you can use to access values in the `Map`, you can also use to access values in `DBMapValue`. In the following example, `customeraddress` contains the address of the customers who reside in San Jose. `customeraddress` is an `Array[DBMapValue]`:

Scala

```
val customerAddress = maprd.map(a =>
a.address[Map[String, AnyRef]])
            .filter(a => a!= null &&

a.get("city").contains("San Jose"))
            .collect
```

This example can also be written in Scala using a functional approach as follows:

Scala

```
val customerAddress = maprd.map(a
=> (a.address[Map[String, AnyRef]],
a).join(my_documents)
            .filter(a =>
Option(a).map(a =>

a.get("city").contains("San
Jose")).getOrElse(false)))
            .collect
```

Note: You can push the condition specified in the filter condition to the MapR Database table scan by using the `where` clause.

Accessing the Array JSON Object

This example uses a sequence to access the Array JSON object:

Scala

```
val custInterests = maprd.map(a =>
a.interests[Seq[AnyRef]])
                    .filter(a => a!=
null && a(0) == "sports")
                    .collect
```

last-updated: Apr 11, 2022

ByteBuffer Serialization

The MapR Database OJAI Connector for Apache Spark provides the following API to enable serialization of the `ByteBuffer`:

Scala

```
MapRDBSpark.serializableBinaryValue(byteBuffer)
```

The following example shows an array of byte buffers or binary values that are converted to serialized byte buffers by using `MapRDBSpark.serializableBinaryValue`:

Scala

```
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
```

Saving Data to a MapR Database JSON Table

The MapR Database OJAI Connector for Apache Spark provides an API to save an Apache Spark RDD to a MapR Database JSON table. Starting in the EEP 4.0 release, the connector introduces support for saving Apache Spark DataFrames and DStreams to MapR Database JSON tables.

Saving an Apache Spark RDD to a MapR Database JSON Table

Saving an RDD[OJAIDocument] to MapR Database

The MapR Database OJAI Connector for Apache Spark provides the following API to save an `RDD[OJAIDocument]` to a MapR Database table:

Scala

For saving an RDD, apply the following method on the RDD:

```
def saveToMapRDB(tablename: String,
createTable: Boolean =
false, bulkInsert: Boolean =
false, idFieldPath: String =
DocumentConstants.ID_KEY) : Unit
```

Java

For saving an RDD, apply one of the following methods on a `MapRDBJavaSparkContext` object:

```
def saveToMapRDB[D](javaRDD:
JavaRDD[D], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveRowRDDToMapRDB(javaRDD:
JavaRDD[Row], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveToMapRDB[K, V <: AnyRef]
(javaPairRDD: JavaPairRDD[K, V],
keyClazz: Class[K], valueClazz:
Class[V], tableName: String,
createTable: Boolean, bulkInsert:
Boolean): Unit
```

Note: The only required parameter to the methods is tableName. All the others are optional.

last-updated: Apr 11, 2022

In the following example, `address` and `first_name` data is loaded from the `"/tmp/user_profiles"` table, stored as an RDD (`userprofilesRDD`), and then saved to the `"/tmp/user_firstname_and_address"` table:

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
                      .where("condition
")
                      .select("address"
, "first_name")

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
              .where("condition")
              .select("address",
"first_name");
mapRDBSparkContext.saveToMapRDB(userpr
ofilesRDD, "/tmp/
user_firstname_and_address", true,
false, "_id");
```

The MapR Database OJAI Connector for Apache Spark also provides the following API to insert an `RDD[OJAIDocument]` to a MapR Database table:

Note: The `insertToMapRDB` API is available starting in the EEP 4.1.0 release.

Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
userprofilesRDD.insertToMapRDB(tablena
me, createTable = true, bulkInsert =
false, idFieldPath = "_id")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.sql.SparkSession;
```

last-updated: Apr 11, 2022

```
MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD<OJAIDocument>
userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
mapRDBSparkContext.insertRowRDDToMapRD
B(userprofilesRDD, tablename);
```

Note: The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

This API supports the following parameters:

Scala

Parameter	Default	Description
`tableName`	Not applicable	The name of the MapR Database table in which you are saving the document.
`createTable`	`false`	Creates the table before saving the documents. Note that if the table already exists and `createTable` is set to true, the API throws an exception.
`idFieldPath`	`_id`	Specifies the key to be used for the document.
`bulkInsert`	`false`	Loads a group of rows simultaneously. `bulkInsert` is similar to a bulk load in MapReduce.

Java

Parameter	Default	Description
`RDD (JavaRDD or JavaPairRDD)`	Not applicable	Specifies the RDD which you are saving to the MapR Database table.
`tableName`	`Not applicable`	Specifies the name of the MapR Database table in which you are saving the document.
`createTable`	`false`	Creates the table before saving the document. Note that if the table already exists and `createTable` is set to true, the API throws an exception.
`idFieldPath`	`_id`	Specifies the key to be used for the document.
`bulkInsert`	`false`	Loads a group of rows simultaneously. `bulkInsert` is similar to a bulk load in MapReduce.

Parameter	Default	Description
`keyClazz (Only for JavaPairRDD)`	Not applicable	Specifies the class type which is the key in the `JavaPairRDD` which you are saving into the MapR Database table.
`valueClazz(Only for JavaPairRDD)`	Not applicable	Specifies the class type which is the value in the `JavaPairRDD` which you are saving into the MapR Database table.

In Java, `saveToMapRDB` method works with `JavaRDD` and `JavaPairRDD`. For saving `JavaRDD[Row]`, use the `saveRowRDDToMapRDB` method.

The following example specifies a key by using the `idFieldPath` parameter and the `bulkInsert` value to save the RDD:

Scala

```
import com.mapr.db.spark._

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address",

idFieldPath = "user_id",

bulkInsert = false)
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
mapRDBSparkContext.saveToMapRDB(userpr
ofilesRDD, "/tmp/
user_firstname_and_address", false,
false, "user_id");
```

The following example saves an RDD of `Person` objects into the newly created `/tmp/Userinfo` table:

Scala

```
import com.mapr.db.spark._

val sparkConf =
new SparkConf().setAppName("json
app").setMaster("local[*]")
val sc = new SparkContext(sparkConf)
val people =
sc.parallelize(getUsers())
people.saveToMapRDB("/tmp/UserInfo",
createTable= true)
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

SparkConf sparkConf = new
```

```
SparkConf().setAppName("json
app").setMaster("local[*]");
SparkContext sc = new
SparkContext(sparkConf);
JavaRDD rdd =
sc.parallelize(getUsers());
mapRDBSparkContext.saveToMapRDB(rdd,
"/tmp/UserInfo", true);
```

The following example shows the `getUsers` function that allocates the `Person` objects:

Scala

```
def getUsers(): Array[Person] = {
    val users: Array[Person] =

    Array(
       Person("DavUSCalif", "David",
"Jones",
          ODate.parse("1947-11-29"),
          Seq("football", "books",
"movies"),
          Map("city" -> "milpitas",
"street" -> "350 holger way",
"Pin" -> 95035)),

       Person("PetUSUtah", "Peter",
"pan",
          ODate.parse("1974-1-29"),
          Seq("boxing", "music",
"movies"),
          Map("city" -> "salt lake",
"street" -> "351 lake way", "Pin" ->
89898)),

       Person("JamUSAriz", "James",
"junior",
          ODate.parse("1968-10-2"),
          Seq("tennis", "painting",
"music"),
          Map("city" -> "phoenix",
"street" -> "358 pond way", "Pin" ->
67765)),

       Person("JimUSCalif", "Jimmy",
"gill",
          ODate.parse("1976-1-9"),
          Seq("cricket",
"sketching"),
          Map("city" -> "san jose",
"street" -> "305 city way", "Pin" ->
95652)),

       Person("IndUSCalif",
"Indiana", "Jones",
          ODate.parse("1987-5-4"),
          Seq("squash", "comics",
"movies"),
          Map("city" -> "sunnyvale",
"street" -> "35 town way", "Pin" ->
95985)))
```

```
    users
  }
```

Saving a JSON Document to MapR Database

To save a JSON document using the MapR Database OJAI Connector for Apache Spark, you must first convert the JSON document into an OJAI document and then save the RDD, as shown in the following example:

Scala

```
import com.mapr.db.spark._

val documents = sc.parallelize((1 to
10)
            .map(i => s"""{"_id":
"$i", "test": "$i"}"""))
val maprd = documents.map(a =>
MapRDBSpark.newDocument(a))
maprd.saveToMapRDB("/tmp/testData")
```

Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.api.java.JavaSparkCon
text;

JavaRDD<String> documents =
JavaSparkContext.fromSparkContext(sc)
            .parallelize(Arrays.asLis
t(1, 2, 3, 4, 5, 6, 7, 8, 9, 10))
            .map(i -> { return
"{\"id\": \"" + i + "\", \"test\":
\"" + i + "\"}"; });
JavaRDD<OJAIDocument> maprd =
documents.map(MapRDBSpark::newDocument
);
mapRDBSparkContext.saveToMapRDB(maprd,
 "/tmp/testData");
```

An `_id` field is required to save JSON data into a table, so an `_id` field must be present. If you need only to convert the JSON data to an OJAI document (without saving to MapR Database), the `_id` field is not required. If the MapR Database table already contains a record with the same `_id` value, MapR Database replaces the record. Otherwise, it inserts a new record.

Just as you can load a JSON document into a Scala bean class (see Creating an RDD of a Class), you can save the RDD of Scala class objects in a MapR Database JSON table. `saveToMapRDB` can save any bean object as a JSON document by converting it to a JSON document.

Table Splits and saveToMapRDB

If the `createTable` parameter is set to true, `saveToMapRDB` can use the partition information from the RDD's lineage to create the splits for a new table:

Scala

```
sc.loadFromMapRDB("/tmp/
user_profiles").saveToMapRDB("/
userProfiles",
```

```
                createTable = true)
```

Suppose `/tmp/user_profiles` has a table with five splits. `saveToMapRDB` uses this information to create the `/userProfiles` table with the same number and range of splits. You can also supply this information by using `MapRDBSpark.newPartitioner`:

Scala

```
sc.loadFromMapRDB("/tmp/
user_profiles").keyBy(doc =>
doc.get("_id"))
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String]
      ("/profiles"))
  .saveToMapRDB("/userProfiles",
createTable = true)
```

For more information about partitioning, see Using the Custom Partitioner with the MapR Database OJAI Connector for Apache Spark on page 4066.

Saving an Apache Spark DataFrame to a MapR Database JSON Table

To save an Apache Spark DataFrame to a MapR Database, invoke the `saveToMapRDB` method on the `DataFrame` object (Scala). This returns a `DataFrameWriter` object, from which you can invoke the `saveToMapRDB` method. For Java and Python, invoke the `saveToMapRDB` method on the `MapRDBJavaSession` object or `SparkSession` object, respectively.

If a row with the same ID already exists, the `savetoMapRDB` method updates or overwrites that row. If you want an exception to be thrown in this case, you can use the `insertToMapRDB` method.

Scala

```
import com.mapr.db.spark.sql._

df.write.saveToMapRDB("/tmp/userInfo")
```

For EEP 4.1.0 and later, you can directly invoke the `saveToMapRDB` method on the `DataFrame` object:

```
def saveToMapRDB(tableName: String,
idFieldPath : String = "_id",
createTable: Boolean = false,
bulkInsert:Boolean = false): Unit

import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df = spark.loadFromMapRDB("/tmp/
user_profiles")
df.saveToMapRDB(tableName,
createTable = true)
```

Java

For saving a DataFrame (Dataset<Row>), apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](df: DataFrame[T],
tableName: String, idFieldPath:
String, createTable: Boolean,
bulkInsert: Boolean): Unit
```

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");

maprSession.saveToMapRDB(ds, "/tmp/
userInfo");
```

Python

For saving a DataFrame, apply the following method on a Dataframe:

```
def saveToMapRDB(dataframe,
table_name, id_field_path =
default_id_field, create_table =
False, bulk_insert = False)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")

sparkSession.saveToMapRDB(df,
table_name, create_table=True)
```

Inserting an Apache Spark DataFrame into a MapR Database JSON Table

Starting in the EEP 4.1.0 release, you can use the `insertToMapRDB` API to insert an Apache Spark DataFrame into a MapR Database JSON table in Python. The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

PySpark supports only DataFrame(Dataset<Row>):

Python

```
sparkSession.insertToMapRDB(df,
tableName, idFieldPath, bulkInsert)
```

Using Alternate Write Modes for MapR Database OJAI Connector

You can use alternate write modes supported by MapR Database OJAI Connector for Apache Spark to save an Apache Spark DataFrame to a MapR Database JSON table.

Normally, the Apache Spark `DataFrameWriter` class supports the following write modes:

- Append
- Overwrite
- ErrorIfExists
- Ignore

The MapR Database OJAI Connector for Apache Spark returns an `OperationNotSupported` exception if you attempt to use one of these modes. The following example returns the error:

Scala

```
import org.apache.spark.sql.SaveMode
import com.mapr.db.spark.sql._
```

```
df.write.mode(SaveMode.Append).saveToM
apRDB("/tmp/userInfo")
```

The MapR Database OJAI Connector for Apache Spark provides the following alternative modes:

Insert	Inserts the data into the MapR Database table. Throws a `DBException` if a row with same `_id` value already exists in the table.
Overwrite	Overwrites the data in the table with the current DataFrame data. This operation drops the table and creates a new table with the data.
ErrorIfExists	Returns an exception (`TableExistsException`) if the table already exists. Otherwise, creates the table and inserts the data.
Ignore	Ignores the data in the table if the table already exists. Otherwise, creates the table and inserts the data.
InsertOrReplace	Replaces the row with the row in the DataFrame, if a row with the same `_id` already exists in the table. Otherwise, inserts the new row.

You cannot specify these modes using the Apache Spark `SaveMode` method. Doing so results in the same `OperationNotSupported` exception noted earlier. To use these modes, you must call the `option` method on a `DataFrameWriter` object. The following example sets the `Insert` mode:

Scala

```
df.write.option("Operation",
"Insert").saveToMapRDB("/tmp/
usersInfo")
```

Note: The `UPDATE` mode for MapR Database OJAI Connector is not supported and it results in an `OperationNotSupported` exception.

Saving an Apache Spark DStream to a MapR Database JSON Table

The MapR Database OJAI Connector for Apache Spark enables you to use MapR Database as a sink for Apache Spark DStreams.

Note: Saving of Apache Spark DStream to MapR Database JSON table is currently only supported in Scala.

The following API saves a `DStream[OJAIDocument]` object to a MapR Database table:

Scala

```
def saveToMapRDB(tablename: String,
createTable: Boolean,
          bulkInsert: Boolean,
idFieldPath: String): Unit
```

The parameters are as follows:

Parameter	Default	Description
`tableName`	Not applicable	The name of the MapR Database table to which you are saving the DStream.
`createTable`	`false`	Creates the table before saving the DStream. Note that if the table already exists and `createTable` is set to true, the API throws an exception.
`idFieldPath`	`_id`	Specifies the key to be used for the DStream.
`bulkInsert`	`false`	Loads a group of streams simultaneously. `bulkInsert` is similar to a bulk load in MapReduce.

Note: The only required parameter for this function is tableName. All the others are optional.

The following example creates a DStream object, converts it to a `DStream[OJAIDocument]` object, and then stores it in MapR Database:

Scala

```
val clicksStream: DStream[String] =
createKafkaStream(…)
clicksStream.map(MapRDBSpark.newDocume
nt()).saveToMapRDB("/clicks",
createTable=true)
```

Note: You must use the `map(MapRDBSpark.newDocument())` API to convert the DStream object to a `DStream[OJAIDocument]` object.

If `clicksStream` is a DStream of Strings, it can be saved to MapR Database using the `saveToMapRDB` API:

Scala

```
clicksStream.map(MapRDBSpark.newDocume
nt(_)).saveToMapRDB("/clicks",
createTable = true);
```

Note: To use the `saveToMapRDB` API, you need to transform the DStream object to a `DStream[OJAIDocument]` by using the Apache Spark Map API.

Saving an Apache Spark Dataset to a MapR Database JSON Table

Starting in the EEP 4.1.0 release, the MapR Database OJAI Connector for Apache Spark provides the following API to save a Dataset to a MapR Database table:

Scala

For saving a Dataset, apply the following method on a `Spark` object:

```
def saveToMapRDB(tableName: String,
idFieldPath : String = "_id",
           createTable: Boolean =
false, bulkInsert:Boolean = false):
Unit
```

last-updated: Apr 11, 2022

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds = spark.loadFromMapRDB("/tmp/
user_profiles")
ds.saveToMapRDB(tableName,
createTable = true)
```

Java

For saving a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](ds: Dataset[T],
tableName: String, idFieldPath:
String,
            createTable:oolean,
bulkInsert: Boolean): Unit

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
maprSession.saveToMapRDB(ds, true);
```

The MapR Database OJAI Connector for Apache Spark also provides the following API to insert a Dataset into a MapR Database table:

Scala

```
import com.mapr.db.spark._

ds.insertToMapRDB(tableName,
idFieldPath, bulkInsert)
```

Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.insertToMapRDB(ds,
tableName, idFieldPath, bulkInsert)
```

Note: The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

Word Count Example Using MapR Database OJAI Connector

```

Using Serialization with the MapR Database OJAI Connector for Apache Spark
In the context of the MapR Database OJAI Connector for Apache Spark, serialization refers to the methods that read and write objects into bytes. This section describes how to configure your application to use a more efficient serializer.

The Apache Spark cluster framework requires serialization to exchange objects between driver and cluster executors. This type of serialization has nothing to do with the way MapR Database serializes the objects onto the disk.

Because classes used in Spark transformations or actions must be serializable, classes created for the MapR Database OJAI Connector for Apache Spark are serializable.

Spark uses Java serialization by default, but it can alternatively use Kyro Serialization. A new Kyro registrator is introduced so you can avoid using the default Java serialization. Kyro serialization provides better performance than Java serialization.

The following example shows how to set the new Kryo registrator in `sparkconf`:

Scala

```
new sparkconf()
   .set("spark.serializer",
"org.apache.spark.serializer.KryoSeria
lizer")
   .set("spark.kryo.registrator",
"com.mapr.db.spark.OJAIKryoRegistrator
")
```

A JSON document can use both complex and primitive value types. Java can serialize the primitive types, but for complex types (such as `Map`, `Array`, and `Binary`), you must use wrappers to achieve serialization. See Working with Complex JSON Document Types on page 4085 for details about these wrappers.

Time-related data types, such as `ODate`, `OInterval`, `OTime`, and `OTimeStamp`, use Java serialization by default. For efficiency, new serializers and comparators have been created for these data types.

Here are the new serializers and the type which each serializer applies:

Serializer	Type
`ODateSerializer`	`ODate` type
`OTimeSerializer`	`OTime`
`OTimeStampSerializer`	`OTimeStamp`
`OIntervalSerializer` -	`OInterval`
`DBBinaryValueSerializer`	`ByteBuffer`

MapR Database Binary Connector for Apache Spark
This section describes the three main interaction points between Spark and HBase APIs and provides examples for each interaction point.

The interaction points are:

Basic Spark	You can have an HBase Connection at any point in your Spark DAG.
Spark Streaming	You can have an HBase Connection at any point in your Spark Streaming application.

last-updated: Apr 11, 2022

Spark Structured Streaming	Using Spark structured streaming to write data to a MapR Database binary table is currently not supported.
Spark Bulk Load	This option is currently not supported for MapR Database.
SparkSQL/DataFrames	You can write SparkSQL that draws on tables that are represented in HBase.

The following pages provide examples of each of these interaction points.

Configuring the MapR Database Binary Connector for Apache Spark

Use these steps to configure the MapR Database Binary Connector for Apache Spark:

1. Verify that the `mapr-hbase` package is installed. For more information, refer to the HBase release notes.
2. Copy the `HBASE_HOME/conf/hbase-site.xml` file to `SPARK_HOME/conf/`.
3. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf`:

```
spark.yarn.dist.files   SPARK_HOME/conf/hbase-site.xml
```

MapR Database Binary Connector for Apache Spark Integration with Basic Spark
This page describes integration between Apache Spark and HBase APIs.

This section describes Spark integration with HBase APIs at the lowest and simplest levels. All other interaction points are built upon the concepts described here.

At the root of all integration with Spark and HBase APIs is the `HBaseContext`. The `HBaseContext` takes in HBase configurations and pushes them to the Spark executors. This allows you to have an `HBase Connection` per Spark executor in a static location.

HBaseContext Usage Example

This example shows how `HBaseContext` can be used to do a `foreachPartition` on an RDD in Scala:

```
val sc = new SparkContext("local", "test")
val config = new HbaseConfiguration()
...
val hbaseContext = new HBaseContext(sc, config)

rdd.hbaseForeachPartition(hbaseContext, (it, conn) => {
 val bufferedMutator = conn.getBufferedMutator(TableName.valueOf("/apps/
my_table"))
 it.foreach((putRecord) => {
    val put = new Put(putRecord._1)
    putRecord._2.foreach((putValue) =>
        put.addColumn(putValue._1,
        putValue._2, putValue._3))
    bufferedMutator.mutate(put)
 })
 bufferedMutator.flush()
 bufferedMutator.close()
})
Here is the same example implemented in Java:
JavaSparkContext jsc = new JavaSparkContext(sparkConf);

try {
  List<byte[]> list = new ArrayList<>();
  list.add(Bytes.toBytes("1"));
  ...
  list.add(Bytes.toBytes("5"));
```

```
  JavaRDD<byte[]> rdd = jsc.parallelize(list);
  Configuration conf = HBaseConfiguration.create();
  JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);

  hbaseContext.foreachPartition(
    rdd,
    new VoidFunction<Tuple2<Iterator<byte[]>, Connection>>() {
   public void call(Tuple2<Iterator<byte[]>, Connection> t) throws
Exception {
    Table table = t._2().getTable(TableName.valueOf(tableName));
    BufferedMutator mutator =
t._2().getBufferedMutator(TableName.valueOf(tableName));
    while (t._1().hasNext()) {
      byte[] b = t._1().next();
      Result r = table.get(new Get(b));
      if (r.getExists()) {
       mutator.mutate(new Put(b));
      }
    }

    mutator.flush();
    mutator.close();
    table.close();
   }
  });
} finally {
  jsc.stop();
}
```

All functionality between Spark and HBase Client is supported both in Scala and in Java, with the exception of SparkSQL, which supports any language that is supported by Spark. This section focuses on Scala examples.

The example here shows how to do a `foreachPartition` with a connection. A number of other Spark base functions are supported out of the box:

`bulkPut`	Enables massively parallel sending of puts to HBase.
`bulkDelete`	Enables massively parallel sending of deletes to HBase.
`bulkGet`	Enables massively parallel sending of gets to HBase to create a new RDD.
`mapPartition`	Enables the Spark Map function with a Connection object to allow full access to HBase.
`hBaseRDD`	Simplifies a distributed scan to create an RDD.

You can see examples of these commands in the source code of the HBase-Spark Module.

MapR Database Binary Connector for Apache Spark Integration with Spark Streaming

Spark Streaming is a micro-batching, stream-processing framework built on top of Spark. HBase APIs and Spark Streaming make great companions. When used alongside Spark Streaming, HBase APIs can serve as:

- A place to grab reference data or profile data on the fly.
- A place to store counts or aggregates in a way that supports the Spark Streaming promise of only once processing.

The MapR Database Binary Connector for Apache Spark integration points with Spark Streaming are similar to its normal Spark integration points. You can use the following commands straight off a Spark Streaming DStream:

`bulkPut`	Enables massively parallel sending of puts to HBase APIs.
`bulkDelete`	Enables massively parallel sending of deletes to HBase APIs.
`bulkGet`	Enables massively parallel sending of gets to HBase APIs to create a new RDD.
`mapPartition`	Enables the Spark Map function with a `Connection` object to allow full access to HBase APIs.
`hBaseRDD`	Simplifies a distributed scan to create an RDD.

`bulkPut` Example with DStreams

The following example shows a bulkPut with DStreams. It is similar to the RDD bulk put.

Note: To invoke the `hbaseBulkPut` method, make sure you import the `HBaseDStreamFunctions` class.

```
import org.apache.hadoop.hbase.spark.HBaseDStreamFunctions._

val sc = new SparkContext("local", "test")
val config = new HBaseConfiguration()

val hbaseContext = new HBaseContext(sc, config)
val ssc = new StreamingContext(sc, Milliseconds(200))

val rdd1 = ...
val rdd2 = ...
val queue = mutable.Queue[
    RDD[(Array[Byte],
    Array[(Array[Byte],
    Array[Byte],
    Array[Byte])])]]()

queue += rdd1
queue += rdd2

val dStream = ssc.queueStream(queue)

dStream.hbaseBulkPut(
  hbaseContext,
  TableName.valueOf(tableName),
  (putRecord) => {
   val put = new Put(putRecord._1)
   putRecord._2.foreach((putValue) =>
    put.addColumn(putValue._1, putValue._2, putValue._3))
   put
  })
```

The `hbaseBulkPut` function has three inputs:

- The `hbaseContext` that carries the configuration broadcast information link to the HBase Connections in the executors.
- The table name of the table you are putting data into.
- A function that will convert a record in the DStream into an HBase `Put` object.

The code snippet above has been extracted from https://github.com/mapr/hbase/blob/1.1.8-mapr-1703/hbase-spark/src/test/scala/org/apache/hadoop/hbase/spark/HBaseDStreamFunctionsSuite.scala.

Bulk Loading Data into HBase with Spark

There are two options for bulk loading data into HBase with Spark:

Note: The bulk load operation is currently not supported for MapR Database.

Basic bulk load functionality	The basic bulk load functionality works for cases where your rows have millions of columns and cases where your columns are not consolidated.
Thin-record bulk load option	The thin-record bulk load option with Spark is designed for tables that have fewer then 10,000 columns per row. The advantage of this option is higher throughput and less overall load on the Spark shuffle operation.

Both implementations work more or less like the MapReduce bulk load process. A partitioner partitions the RowKeys based on region splits, and the RowKeys are sent to the reducers in order, so that HFiles can be written directly from the reduce phase.

In Spark terms, the bulk load is implemented around a `SparkrepartitionAndSortWithinPartitions` followed by a Spark `foreachPartition`. Here is an example of using the basic bulk load functionality:

Bulk Loading Example

Note: Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark._
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.util.Bytes._
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
import org.apache.hadoop.hbase.client.{HBaseAdmin, HConnectionManager}
 val tableName = "table1"
    val stagingFolder = "/home/mapr"
    val columnFamily1 = "cf1"
    @transient val conf = HBaseConfiguration.create()
    val hbaseContext = new HBaseContext(sc, conf)
    conf.set(TableInputFormat.INPUT_TABLE, tableName)
    conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
    conf.setInt("hbase.zookeeper.property.clientPort", 5181)
    val rdd = sc.parallelize(Array(
      (toBytes("1"), (toBytes(columnFamily1), toBytes("a"),
toBytes("foo1"))),
      (toBytes("3"), (toBytes(columnFamily1), toBytes("b"),
toBytes("foo2.b")))
    ))
    rdd.hbaseBulkLoad(hbaseContext,
      TableName.valueOf(tableName),
      t => {
        val rowKey = t._1
        val family: Array[Byte] = t._2._1
        val qualifier = t._2._2
        val value: Array[Byte] = t._2._3
        val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
        Seq((keyFamilyQualifier, value)).iterator
      },
      stagingFolder)
    val connection = HConnectionManager.createConnection(conf)
    val table = connection.getTable(TableName.valueOf(tableName))
```

```
    val load = new LoadIncrementalHFiles(conf)
    load.doBulkLoad(
      new Path(stagingFolder),
      connection.getAdmin,
      table,
      connection.getRegionLocator(TableName.valueOf(tableName)))
```

Required Parameters for Bulk Loading with Spark

The `hbaseBulkLoad` function takes three required parameters:

- The name of the table you intend to bulk load to.
- A function that converts a record in the RDD to a tuple key-value pair, with the tuple key being a `KeyFamilyQualifer` object and the value being the cell value. The `KeyFamilyQualifer` object holds the RowKey, Column Family, and Column Qualifier. The shuffle partitions on the RowKey but sorts by all three values.
- The temporary path for the HFile to be written out to. Following the Spark bulk load command, use the HBase `LoadIncrementalHFiles` object to load the newly created HFiles into HBase.

Additional Parameters for Bulk Loading with Spark

You can set the following attributes with additional parameter options on `hbaseBulkLoad`:

- Max file size of the HFiles
- A flag to exclude HFiles from compactions
- Column Family settings for compression, bloomType, blockSize, and dataBlockEncoding

The following example shows the use of additional parameters:

Note: Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{FamilyHFileWriteOptions,
HBaseContext, KeyFamilyQualifier}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, HConstants, TableName}
import org.apache.spark.sql.SparkSession
  val tableName = "table2"
    val stagingFolder = "/home/mapr"
    val columnFamily1 = "cf1"
    val sc = spark.sparkContext
    @transient val conf = HBaseConfiguration.create()
    conf.set(TableInputFormat.INPUT_TABLE, tableName)
    conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
    conf.setInt("hbase.zookeeper.property.clientPort", 5181)
    val hbaseContext = new HBaseContext(sc, conf)
    val rdd = sc.parallelize(Array(
      (Bytes.toBytes("1"),
        (Bytes.toBytes(columnFamily1),
          Bytes.toBytes("a"), Bytes.toBytes("foo1"))),
      (Bytes.toBytes("3"),
        (Bytes.toBytes(columnFamily1),
```

```
          Bytes.toBytes("b"),
          Bytes.toBytes("foo2.b")))))
    val familyHBaseWriterOptions =
      new java.util.HashMap[Array[Byte], FamilyHFileWriteOptions]
    val f1Options = new FamilyHFileWriteOptions("GZ", "ROW", 128, "PREFIX")
    familyHBaseWriterOptions.put(Bytes.toBytes(columnFamily1), f1Options)
    rdd.hbaseBulkLoad(hbaseContext,
      TableName.valueOf(tableName),
      t => {
        val rowKey = t._1
        val family:Array[Byte] = t._2._1
        val qualifier = t._2._2
        val value = t._2._3
        val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
        Seq((keyFamilyQualifier, value)).iterator
      },
      stagingFolder,
      familyHBaseWriterOptions,
      compactionExclude = false,
      HConstants.DEFAULT_MAX_FILE_SIZE)
    val connection = HConnectionManager.createConnection(conf)
    val table = connection.getTable(TableName.valueOf(tableName))
    val load = new LoadIncrementalHFiles(conf)
    load.doBulkLoad(new Path(stagingFolder),
      connection.getAdmin, table,
connection.getRegionLocator(TableName.valueOf(tableName)))
```

Thin-Record Bulk Load Example

The following example shows how to call the thin-record bulk load implementation:

Note: Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{HBaseContext, _}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
val tableName = "table3"
    val stagingFolder = "/home/mapr"
    val columnFamily1 = "cf1"
    @transient val conf = HBaseConfiguration.create()
    val hbaseContext = new HBaseContext(sc, conf)
    conf.set(TableInputFormat.INPUT_TABLE, tableName)
    conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
    conf.setInt("hbase.zookeeper.property.clientPort", 5181)
    val rdd = sc.parallelize(Array(
      ("1",  List(Bytes.toBytes(columnFamily1), Bytes.toBytes("a"),
Bytes.toBytes("foo1"))),
      ("3", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("b"),
Bytes.toBytes("foo2.b")))))
    rdd.hbaseBulkLoadThinRows(hbaseContext,
      TableName.valueOf(tableName),
      t => {
        val rowKey = t._1
        val familyQualifiersValues = new FamiliesQualifiersValues
```

```
        val q = t._2
        val family:Array[Byte] = q.head
        val qualifier = q(1)
        val value:Array[Byte] = q(2)
        println(s"family: $family")
        println(s"qualifier: $qualifier")
        println(s"value: $value")
        familyQualifiersValues +=(family, qualifier, value)
        (new ByteArrayWrapper(Bytes.toBytes(rowKey)),
familyQualifiersValues)}, stagingFolder, new java.util.HashMap[Array[Byte],
FamilyHFileWriteOptions], compactionExclude = false, 20)
    val connection = HConnectionManager.createConnection(conf)
    val table = connection.getTable(TableName.valueOf(tableName))
    val load = new LoadIncrementalHFiles(conf)
    load.doBulkLoad(
      new Path(stagingFolder),
      connection.getAdmin,
      table,
      connection.getRegionLocator(TableName.valueOf(tableName)))
```

The big difference in using bulk load for thin rows is that the function returns a tuple with the first value being the RowKey and the second value being an object of `FamiliesQualifiersValues`. `FamiliesQualifiersValues` contains all the values for this row for all column families.

SparkSQL and DataFrames

The MapR Database Binary Connector for Apache Spark leverages DataSource API (SPARK-3247) introduced in Spark-1.2.0. The connector bridges the gap between simple HBase KV store and complex relational SQL queries and enables users to perform complex data analytical work on top of MapR Database binary tables using Spark. HBase Dataframe is a standard Spark Dataframe, and is able to interact with any other data sources, such as Hive, Orc, Parquet, JSON, and others. The MapR Database Binary Connector for Apache Spark applies critical techniques such as partition pruning, column pruning, predicate pushdown and data locality.

To use the MapR Database Binary Connector for Apache Spark, you need to define the Catalog for the schema mapping between MapR Database binary tables and Spark tables, prepare the data and populate the MapR Database binary table, then load the HBase DataFrame. After that, users can do integrated query and access records in a MapR Database binary table with SQL query. The following examples illustrate the basic procedure.

Define Catalog Example

The `catalog` defines a mapping between MapR Database binary tables and Spark tables. There are two critical parts of this catalog. One is the rowkey definition. The other is the mapping between the table column in Spark and the column family and column qualifier in MapR Database binary table. The following example defines a schema for a MapR Database binary table with name as `my_table`, row key as `key` and a number of columns (`col1 - col8`). Note that the rowkey also has to be defined in details as a column (`col0`), which has a specific `cf (rowkey)`.

```
def catalog = s"""{
       |"table":{"namespace":"default", "name":"/path_to/my_table"},
       |"rowkey":"key",
       |"columns":{
         |"col0":{"cf":"rowkey", "col":"key", "type":"string"},
         |"col1":{"cf":"cf1", "col":"col1", "type":"boolean"},
         |"col2":{"cf":"cf2", "col":"col2", "type":"double"},
         |"col3":{"cf":"cf3", "col":"col3", "type":"float"},
         |"col4":{"cf":"cf4", "col":"col4", "type":"int"},
         |"col5":{"cf":"cf5", "col":"col5", "type":"bigint"},
         |"col6":{"cf":"cf6", "col":"col6", "type":"smallint"},
         |"col7":{"cf":"cf7", "col":"col7", "type":"string"},
```

```
          |"col8":{"cf":"cf8", "col":"col8", "type":"tinyint"}
        |}
     |}""".stripMargin
```

Save the DataFrame Example

Data prepared by the user is a local Scala collection that has 256 HBaseRecord objects. The `sc.parallelize(data)` function distributes data to form an RDD. `toDF` returns a DataFrame. `writefunction` returns a DataFrameWriter used to write the DataFrame to external storage systems (e.g. MapR Database here). Given a DataFrame with a specified schema catalog, the `save` function creates a MapR Database binary table with five (5) regions and saves the DataFrame inside.

```
case class HBaseRecord(
   col0: String,
   col1: Boolean,
   col2: Double,
   col3: Float,
   col4: Int,
   col5: Long,
   col6: Short,
   col7: String,
   col8: Byte)

object HBaseRecord
{

   def apply(i: Int, t: String): HBaseRecord = {
      val s = s"""row${"%03d".format(i)}"""
      HBaseRecord(s,
      i % 2 == 0,
      i.toDouble,
      i.toFloat,
      i,
      i.toLong,
      i.toShort,
      s"String$i: $t",
      i.toByte)
  }
}

val data = (0 to 255).map { i =>  HBaseRecord(i, "extra")}

sc.parallelize(data).toDF.write.options(Map(
    HBaseTableCatalog.tableCatalog -> catalog,
    HBaseTableCatalog.newTable -> "5")
).format("org.apache.hadoop.hbase.spark")
 .save()
```

Load the DataFrame Example

In the `withCatalog` function, `sqlContext` is a variable of `SQLContext`, which is the entry point for working with structured data (rows and columns) in Spark. `read` returns a DataFrameReader that can be used to read data in a DataFrame. The `option` function adds input options for the underlying data source to the DataFrameReader. The `format` function specifies the input data source format for the DataFrameReader. The `load()` function loads input as a DataFrame. The data frame `df` returned by the `withCatalog` function can be used to access the MapR Database binary table, as shown in the Language Integrated Query and SQL Query examples.

```
def withCatalog(cat: String): DataFrame = {
  sqlContext
```

```
  .read
  .options(Map(HBaseTableCatalog.tableCatalog->cat))
  .format("org.apache.hadoop.hbase.spark")
  .load()
}
val df = withCatalog(catalog)
```

Language Integrated Query Example

DataFrame can do various operations, such as `join`, `sort`, `select`, `filter`, `orderBy`, and so on. In the following example, `df.filter` filters rows using the given SQL expression. `select` selects a set of columns: `col0`, `col1` and `col4`.

```
val s = df.filter(($"col0" <= "row050" && $"col0" > "row040") ||
  $"col0" === "row005" ||
  $"col0" <= "row005")
  .select("col0", "col1", "col4")
s.show
```

SQL Query Example

`registerTempTable` registers `df` DataFrame as a temporary table using the table name `table1`. The lifetime of this temporary table is tied to the SQLContext that was used to create `df`. `sqlContext.sqlfunction` allows the user to execute SQL queries.

```
df.registerTempTable("table1")
sqlContext.sql("select count(col1) from table1").show
```

Query with Different Timestamps

In `HBaseSparkConf`, you can set four parameters related to timestamp:

- `TIMESTAMP`
- `MIN_TIMESTAMP`
- `MAX_TIMESTAMP`
- `MAX_VERSIONS`

With `MIN_TIMESTAMP` and `MAX_TIMESTAMP`, you can query records with different timestamps or time ranges. In the meantime, use a concrete value instead of `tsSpecified` and `oldMs` in the following examples. The first example shows how to load `df` DataFrame with different timestamps. `tsSpecified` is specified by the user. `HBaseTableCatalog` defines the HBase and Relation relation schema. `writeCatalog` defines the catalog for the schema mapping.

```
val df = sqlContext.read
      .options(Map(
        HBaseTableCatalog.tableCatalog -> writeCatalog,
        HBaseSparkConf.TIMESTAMP -> tsSpecified.toString)
    ).format("org.apache.hadoop.hbase.spark")
      .load()
```

The following example shows how to load `df` DataFrame with different time ranges. `oldMs` is specified by the user.

```
val df = sqlContext.read
      .options(Map(
```

last-updated: Apr 11, 2022

```
        HBaseTableCatalog.tableCatalog -> writeCatalog,
        HBaseSparkConf.MIN_TIMESTAMP -> "0",
        HBaseSparkConf.MAX_TIMESTAMP -> oldMs.toString)
    ).format("org.apache.hadoop.hbase.spark")
      .load()
After loading df DataFrame, users can query data.
df.registerTempTable("table")
sqlContext.sql("select count(col1) from table").show
```

Native Avro Support

The MapR Database Binary Connector for Apache Spark supports different data formats such as Avro, JSON, and others. The following use case shows how Spark supports Avro. You can persist the Avro record into MapR Database binary tables directly. Internally, the Avro schema is converted to a native Spark Catalyst data type automatically. Note that both key-value parts in a MapR Database binary table can be defined in Avro format.

1. Define the `catalog` for schema mapping. `catalog` is a schema for a MapR Database binary table named `Avrotable`, a row key as `key`, and one column `col1`. The rowkey also has to be defined in details as a column (`col0`), which has a specific `cf` (`rowkey`).

   ```
   def catalog = s"""{
                        |"table":{"namespace":"default", "name":"/path_to/
   avro_table"},
                        |"rowkey":"key",
                        |"columns":{
                        |"col0":{"cf":"rowkey", "col":"key",
   "type":"string"},
                        |"col1":{"cf":"cf1", "col":"col1", "type":"binary"}
                        |}
                        |}""".stripMargin
   ```

2. Prepare the data. `schemaString` is defined first. Then it is parsed to get `avroSchema`. `avroSchema` is used to generate `AvroHBaseRecord`. `data prepared by users` is a local Scala collection that has 256 AvroHBaseRecord objects.

```
object AvroHBaseRecord {
   val schemaString =
     s"""{"namespace": "example.avro",
         |   "type": "record",      "name": "User",
         |    "fields": [
         |        {"name": "name", "type": "string"},
         |        {"name": "favorite_number",  "type": ["int", "null"]},
         |        {"name": "favorite_color", "type": ["string", "null"]},
         |        {"name": "favorite_array", "type": {"type": "array",
"items": "string"}},
         |        {"name": "favorite_map", "type": {"type": "map",
"values": "int"}}
         |      ]    }""".stripMargin

   val avroSchema: Schema = {
     val p = new Schema.Parser
     p.parse(schemaString)
   }

   def apply(i: Int): AvroHBaseRecord = {
     val user = new GenericData.Record(avroSchema);
     user.put("name", s"name${"%03d".format(i)}")
     user.put("favorite_number", i)
     user.put("favorite_color", s"color${"%03d".format(i)}")
     val favoriteArray = new GenericData.Array[String](
    2,
    avroSchema.getField("favorite_array").schema())
     favoriteArray.add(s"number${i}")
     favoriteArray.add(s"number${i+1}")
     user.put("favorite_array", favoriteArray)
     import collection.JavaConverters._
     val favoriteMap = Map[String, Int](("key1" -> i), ("key2" ->
(i+1))).asJava
     user.put("favorite_map", favoriteMap)
     val avroByte = AvroSedes.serialize(user, avroSchema)
     AvroHBaseRecord(s"name${"%03d".format(i)}", avroByte)
   }
 }

 val data = (0 to 255).map { i =>
    AvroHBaseRecord(i)
 }
```

3. Save the DataFrame. Given a data frame with the specified schema catalog, the following example creates a MapR Database binary table with five (5) regions and saves the data frame inside.

```
sc.parallelize(data).toDF.write.options(
     Map(
    HBaseTableCatalog.tableCatalog -> catalog,
    HBaseTableCatalog.newTable -> "5")
    ).format("org.apache.spark.sql.execution.datasources.hbase")
     .save()
```

last-updated: Apr 11, 2022

4. Load the DataFrame. In the `withCatalog` function, `read` returns a DataFrameReader that can be used to read data in as a DataFrame. The `option` function adds input options for the underlying data source to the DataFrameReader. There are two options: one is to set `avroSchema` as `AvroHBaseRecord.schemaString`. The other option is to set `HBaseTableCatalog.tableCatalog` as `avroCatalog`. The `load()` function loads input in as a DataFrame. The date frame df returned by the `withCatalog` function can be used to access the MapR Database binary table.

```
def avroCatalog = s"""{
            |"table":{"namespace":"default", "name":"avrotable"},
            |"rowkey":"key",
            |"columns":{
              |"col0":{"cf":"rowkey", "col":"key", "type":"string"},
              |"col1":{"cf":"cf1", "col":"col1", "avro":"avroSchema"}
            |}
          |}""".stripMargin

 def withCatalog(cat: String): DataFrame = {
     sqlContext
         .read
         .options(Map(
        "avroSchema" -> AvroHBaseRecord.schemaString,
        HBaseTableCatalog.tableCatalog -> avroCatalog)
         ).format("org.apache.spark.sql.execution.datasources.hbase")
         .load()
 }
 val df = withCatalog(catalog)
```

5. Query data using SQL. After loading `df DataFrame`, you can query data. `registerTempTable` registers `df DataFrame` as a temporary table using the table name `avrotable`. The `sqlContext.sql` function allows you to execute SQL queries.

```
df.registerTempTable("avrotable")
val c = sqlContext.sql("select count(1) from avrotable"
```

Integrating Spark

This section includes the following topics about configuring Spark to work with other ecosystem components.

Integrate Spark-SQL (Spark 2.3.1 and later) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 2.3.0 or later users.

Note: For Spark 2.2.1 and 2.3.1 versions, use the 4.0.0 avro version of `com.databricks:spark-avro_2.11`.

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

1. Download the Avro 1.7.7 JAR file to the Spark `jars` (`opt/mapr/spark/spark-<version>/jars`) directory.

   You can download the file from the maven repository: http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7

last-updated: Apr 11, 2022

2. Add the following properties in `spark-defaults.conf`:

```
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
spark.executor.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
```

Integrate Spark-SQL (Spark 1.6.1) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 1.6.1 or earlier users.

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

1. Download the Avro 1.7.7 JAR file to the Spark lib (`opt/mapr/spark/spark-<version>/lib`) directory.

   You can download the file from the maven repository: http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7

2. Use one of the following methods to add the Avro 1.7.7 JAR to the classpath:

   - Prepend the Avro 1.7.7 JAR file to the spark.executor.extraClassPath and spark.driver.extraClassPath in the spark-defaults.conf (`/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf`) file:

     ```
     spark.executor.extraClassPath  /opt/mapr/spark/
     spark-<spark_version>/lib/avro-1.7.7.jar:<rest_of_path>
     spark.driver.extraClassPath  /opt/mapr/spark/spark-<spark_version>/lib/
     avro-1.7.7.jar:<rest_of_path>
     ```

   - Specify the Avro 1.7.7 JAR files with command line arguments on the spark shell:

     ```
     /opt/mapr/spark/spark-<version>/bin/spark-shell \
     --packages com.databricks:spark-avro_2.10:2.0.1 \
     --driver-class-path /opt/mapr/spark/spark-<version>/lib/avro-1.7.7.jar
     \
     --conf spark.executor.extraClassPath=/opt/mapr/spark/
     spark-<version>/lib/avro-1.7.7.jar --master <master-url>
     ```

Integrate Spark with HBase

Integrate Spark with HBase or MapR Database when you want to run Spark jobs on HBase or MapR Database tables.

If you installed Spark with the MapR Installer, these steps are not required.

1. Configure the HBase version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

   ```
   hbase_versions=<version>
   ```

   The HBase version depends on the current EEP and MapR version that you are running.

2. If you want to create HBase tables with Spark, add the following property to `hbase-site.xml`:

   ```
   <property>
   hbase.table.sanity.checks</name>
   <value>false</value>
   </property>
   ```

3. On each Spark node, copy the `hbase-site.xml` to the `{SPARK_HOME}/conf/` directory.

   Tip: Starting in the EEP 7.0.0 release, you do not have to complete step 3. Running `configure.sh` copies the `hbase-site.xml` file to the Spark directory automatically.

4. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

5. To verify the integration, complete the following steps:
   a) Create an HBase or MapR Database table:

```
create '<table_name>' , '<column_family>'
```

   b) Run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
/opt/mapr/spark/spark-<spark_version>/bin/spark-submit --master
<master> [--deploy-mode <deploy-mode>]  --class
org.apache.hadoop.hbase.spark.example.rdd.HBaseBulkPutExample /opt/
mapr/hbase/hbase-<hbase_versrion>/lib/
hbase-spark-<hbase_version>-mapr.jar  <table_name>  <column_family>
```

   The master URL for the cluster is either `spark://<host>:7077`, yarn, or local (without deploy-mode). The deploy-mode is either `client` or `cluster`.

   c) Check the data in the HBase or MapR-DB table:

```
hbase(main):001:0> scan '<table_name>'
```

Integrate Spark-SQL (Spark 2.0.1 and later) with Hive
You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 2.0.1 or later users.

For information about Spark-SQL and Hive support, see Spark Feature Support.

Note: If you installed Spark with the MapR Installer, the following steps are not required.

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration. Do not create a symbolic link instead of copying the file. You may need to edit the file with settings that are specific to the Spark Thrift server.

2. Add `644` permission to the `hive-site.xml` using the following command:

```
sudo chmod 644 /opt/mapr/spark/spark-<sparkVersion>/conf/hive-site.xml
```

3. If Hive is configured on Tez (not on MR), you must remove the Tez property from the Spark conf directory hive-site.xml. Delete this entry:

```
<property>
  <name>hive.execution.engine</name>
  <value>tez</value>
</property>
```

last-updated: Apr 11, 2022

4. If Hive is configured on PAM, set "`hive.metastore.sasl.enabled = true`" in the `hive-site.xml` located in the Spark conf directory.

5. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
spark.yarn.dist.files	For Spark on YARN, specify the location of the `hive-site.xml` file: `/opt/mapr/spark/spark-<spark-version>/conf/hive-site.xml`
spark.sql.hive.metastore.version	Specify the Hive version that you are using. **Note:** If you are using Hive Metastore 2.1, set the version to 1.2.1.

6. Depending on whether you plan to run with impersonation, perform one of the following:
   - Configure user impersonation. See Hive User Impersonation for the steps to configure impersonation in the Spark Thrift server.
   - Set `hive.server2.enable.doAs` to `false` in the `hive-site.xml` file.

7. To verify the integration, run the following command as the mapr user or as a user that mapr impersonates:

```
<spark-home>/bin/run-example --master <master> [--deploy-mode
<deploy-mode>] sql.hive.SparkHiveExample
```

   The master URL for the cluster is either spark://<host>:7077 or yarn. The deploy-mode is either client or cluster.

Note: The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

Note: If you plan to access Hive tables that store data in MapR Database, you need to copy the Hive HBase handler jar into the Spark jars directory. For example:

```
cp /opt/mapr/hive/hive-2.1/lib/hive-hbase-handler-2.1.1-mapr-1707.jar /opt/
mapr/spark/spark-2.1.0/jars/
```

Integrate Spark-SQL (Spark 1.6.1) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 1.6.1 or earlier users.

For information about Spark-SQL and Hive support, see Spark Feature Support.

Note: If you installed Spark with the MapR Installer, the following steps are not required.

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration.

2. Configure the Hive version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hive_versions=<version>
```

3. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements

spark.yarn.dist.files	Option 1: For Spark on YARN, specify the location of the hive-site.xml and the datanucleus JARs:
	`/opt/mapr/hive/hive-<hive-version>/conf/hive-site.xml,/opt/mapr/hive/<version>/lib/datanucleus-api-jdo-<version>.jar,/opt/mapr/hive/<version>/lib/datanucleus-core-<version>.jar,/opt/mapr/hive/hive-1.2/lib/datanucleus-rdbms-<version>.jar`
	Option 2: For Spark on YARN, store hive-site.xml and datanucleus JARs on MapR File System, and use the following syntax:
	`maprfs:///<path to hive-site.xml>,maprfs:///<path to datanucleus jar files>`

spark.sql.hive.metastore.version	Specify the Hive version that you are using. For example, for Hive 1.2.x, set the value to 1.2.0.

spark.sql.hive.metastore.jars	Specify the classpath to JARs for Hive, Hive dependencies, and Hadoop. These files must be available on the node from which you submit Spark jobs:
	`/opt/mapr/hadoop/hadoop-<hadoop-version>/etc/hadoop:/opt/mapr/hadoop/hadoop-<hadoop-version>/share/hadoop/common/lib/*:<rest of hadoop classpath>:/opt/mapr/hive/hive-<version>/lib/accumulo-core-<version>.jar:/opt/mapr/hive/hive-<version>/lib/hive-contrib-<version>.jar:<rest of hive classpath>`
	For example, when you run with Hive 1.2, you can set the following classpath:
	`/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/*:/opt/mapr/hadoop/./hadoop-2.7.0/share/hadoop/mapreduce/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/*:/opt/mapr/hive/hive-1.2/lib/accumulo-core-1.6.0.jar:/opt/mapr/hive/hive-1.2/lib/hive-contrib-1.2.0-mapr-1607.jar:/opt/mapr/hive/hive-1.2/lib/*`
	For more information, see the Apache Spark documentation.

last-updated: Apr 11, 2022

4. To verify the integration, run the following command as the mapr user or as a user that mapr impersonates:

```
MASTER=<master-url> <spark-home>/bin/run-example sql.hive.HiveFromSpark
```

   The master URL for the cluster is either spark://<host>:7077, yarn-client, or yarn-cluster.

Note: The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

Integrate Spark with MapR Event Store For Apache Kafka
Integrate Spark with MapR Streams to enable Spark to query MapR Event Store For Apache Kafka for new messages at a given interval, process any new messages that are available, and also publish messages into MapR Event Store For Apache Kafka.

You can use Spark to access MapR Event Store For Apache Kafka through Spark's receiver-less, direct approach.

For more information, see the Apache Spark documentation.

Note: Before you integrate Spark with MapR Event Store For Apache Kafka, verify that the Streams Client is install on all Spark nodes. For more information, see the Installing MapR and MapR Ecosystem Components on page 128.

Configure Spark 2.2.1 and later to Consume MapR Event Store For Apache Kafka Messages
Using the Kafka 0.9 API, you can configure a Spark application to query MapR Event Store For Apache Kafka for new messages at a given interval. This information is for Spark 2.2.1 and later users.

1. Install the MapR core Kafka package, if you have not already done so.
2. Copy the Kafka client jar into the Spark jars directory as shown below:

```
cp /opt/mapr/lib/kafka-clients-<version>.jar SPARK_HOME/jars
```

3. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-0-9_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

   Note: If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`.

4. Consider the following when you write the Spark application:
   a) Verify that it meets the following requirements:
      - Imports and use classes from `org.apache.spark.streaming.kafka09`. The following code snippet imports three classes.

```
import org.apache.spark.streaming.kafka09.{ConsumerStrategies,
KafkaUtils, LocationStrategies}
```

- Defines key and value deserializers in the kafkaParams map.

```
val kafkaParams = Map[String, String](
   ConsumerConfig.GROUP_ID_CONFIG -> groupId,
   ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
      "org.apache.kafka.common.serialization.StringDeserializer",
   ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
      "org.apache.kafka.common.serialization.StringDeserializer",
   ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> offsetReset)
```

- Does not configure a broker address or Zookeeper as these are not required for MapR Event Store For Apache Kafka.

b) Optionally, define a value for `spark.streaming.kafka.consumer.poll.ms` in the Spark configuration.

Note: You can configure the poll timeout using Spark option `spark.streaming.kafka.consumer.poll.ms`. If you do not configure `spark.streaming.kafka.consumer.poll.ms`, the `spark.network.timeout` property is used. If `spark.network.timeout` is empty, the default is 120 seconds.

```
val sparkConf = new SparkConf()
      .setAppName("v09DirectKafkaWordCount")
      .set("spark.streaming.kafka.consumer.poll.ms", pollTimeout)
```

Example:

https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/V09DirectKafkaWordCount.scala is a sample consumer program.

The `KafkaUtils.createDirectStream` method creates an input stream to read MapR Event Store For Apache Kafka messages. The `ConsumerStrategies.Subscribe` method creates the `consumerStrategy` that will limit the set of topics the stream subscribes to. This is derived from the `topics` parameter passed into the program. Using `LocationStategies.PreferConsistent` will distribute partitions evenly across available executors.

```
val consumerStrategy = ConsumerStrategies.Subscribe[String, String]
(topicsSet, kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
   ssc, LocationStrategies.PreferConsistent, consumerStrategy)
```

Configure Spark to Produce MapR Event Store For Apache Kafka Messages
Using the Kafka 0.9 API, you can configure a Spark application to produce MapR Streams messages.

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

Note: If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`.

last-updated: Apr 11, 2022

2. When you write the Spark program, import and use classes from `org.apache.spark.streaming.kafka.producer._` and `org.apache.spark.streaming.dstream`.

   The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

   ```
   sendToKafka(topic: String, conf: ProducerConf)
   ```

   In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter.

   ```
   val producerConf = new ProducerConf(bootstrapServers =
   kafkaBrokers.split(",").toList)
      .withKeySerializer("org.apache.kafka.common.serialization.ByteArraySer
   ializer")
      .withValueSerializer("org.apache.kafka.common.serialization.StringSeri
   alizer")

   val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
   val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
   val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
   defaultRDD)

   dStream.foreachRDD(_.sendToKafka(topics, producerConf))
   dStream.count().print()
   ```

   The `org.apache.kafka.common.serialization.ByteArraySerializer` and `org.apache.kafka.common.serialization.StringSerializer` properties are used by default, and in case you do not want to use another serializer, `withKeySerializer` and `withValueSerializer` methods are not necessary.

Source code for a sample producer program can be found at https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala

Integrate Spark with R

You integrate Spark with R when you want to run R programs as Spark jobs.

1. On each node that will submit Spark jobs, install R 3.2.2 or greater:

   - On Ubuntu:

     ```
     apt-get install r-base-dev
     ```

   - On CentOS/RedHat:

     ```
     yum install R
     ```

   For more information about installing R, see the R documentation.

2. To verify the integration, run the following commands as the mapr user or as a user that mapr impersonates:

   a) Start Spark R:

- On Spark 2.0.1, 2.1.0, and later:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master>
[--deploy-mode <deploy-mode>]
```

- On Spark 1.6.1:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master-url>
```

b) Run the following command to create a DataFrame using sample data:
On Spark 1.6.1:

```
people <- read.df(sqlContext, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

On Spark 2.0.1, 2.1.0, and later:

```
people <- read.df(spark, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

c) Run the following command to display the data from the DataFrame that you just created:

```
head(people)
```

Integrate Spark with Kafka
From EEP-5.0.0, Spark can be integrated with Kafka-1.0. You can configure a Spark application to produce Kafka messages.

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

2. When you write the Spark program, import and use classes from:

```
org.apache.spark.streaming.kafka.producer._
org.apache.spark.streaming.dstream.
```

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from DStream:

```
sendToKafka(topic: String, conf: ProducerConf)
```

3. In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the topics parameter:

```
val producerConf = new ProducerConf(
bootstrapServers = kafkaBrokers.split(",").toList)

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

Source code for a sample producer program can be found at https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala

Spark JDBC and ODBC Drivers

MapR provides JDBC and ODBC drivers so you can write SQL queries that access the Apache Spark data-processing engine. This section describes how to download the drivers, and install and configure them.

You can download the Spark JDBC driver from https://package.mapr.hpe.com/tools/MapR-JDBC/MapR_Spark/ and the Spark ODBC driver from https://package.mapr.hpe.com/tools/MapR-ODBC/MapR_Spark/.

After downloading the driver, refer to the documentation at Spark JDBC Driver to install and configure the JDBC driver and Spark ODBC Driver for the ODBC driver. A copy of the documentation also is available in each download package. The following table describes the driver versions available for various EEP releases:

	EEP version	Driver version	Driver link	Documentation link
JDBC version	EEP 6.0.0+	2.6.3	Spark JDBC Driver for version 2.6.3	Spark JDBC Documentation for version 2.6.3
	EEP 3.0.1+	1.1.8	Spark JDBC Driver for version 1.1.8	Spark JDBC Documentation for version 1.1.8
ODBC version	EEP 6.0.0+	2.6.1	Spark ODBC Driver for version 2.6.1	Spark ODBC Documentation for version 2.6.1
	EEP 2.0.2+	1.2.5	Spark ODBC Driver for version 1.2.5	Spark ODBC Documentation for version 1.2.5

Note: When connecting to the Spark Thrift Server using `beeline` and the JDBC driver, you might encounter the following error:

```
"Unsupported transaction isolation level: 4"
```

To avoid this error, pass the `isolation` parameter to `beeline` as follows:

```
bin/beeline --isolation=default
```

Spark API Changes
This topic describes the public API changes that occurred for specific Spark versions.

Spark 2.3.1 API Changes
EEP 6.0.0 supports Spark version 2.3.1.

For more information about Spark 2.3.1, see the Spark 2.3.1-1808 (EEP 6.0.0) Release Notes on page 6385 and the Spark 2.3.1 API Documentation.

For a complete list of all new and changed APIs, refer to the open source documentation.

Spark 2.1.0 API Changes
This topic describes the public API changes that occurred between Apache Spark 2.0.1 and Spark 2.1.0.

For more information about Spark 2.1.0, see the Spark Release Notes and the Spark 2.1.0 API Documentation.

New API

- The `DataType` API is now mostly stable. Please see `InterfaceStability` annotations for the classes you need.
- Add the `from_json` and `to_json` functions to SQL.
- `StructType` now accepts Python Dictionaries.
- New ML algorithms have been added for Spark R.
- `SparkContext.addFile` is now supported for SparkR.
- SparkR now supports multinomial logistics regression.
- MLlib supports MLR in DataFrames, LSH.
- MLlib model loading is now backward-compatible with Spark 1.6.

Changed API

- Parquet-MR is bumped to 1.8.1.
- `spark.sql.warehouse.dir` now needs to be set before SparkSession creation and is shared between multiple SparkSessions.
- Values generated by non-deterministic functions will not change after coalesce or union.
- The default `Locale` for `DateFormat/NumberFormat` is now `Locale.US`.
- Function `SIZE` returns -1 when its input parameter is null.

Spark 2.0.1-1703 API Changes
This release does not introduce any changes to public Spark API apart from Structured Streaming, which is not supported by the MapR platform.

Spark 2.0.1-1611 API Changes
This topic describes the public API changes that occurred between Apache Spark 1.6.1 and Spark 2.0.1.

Removed Methods

The following items have been removed from Apache Spark 2.0.1:

- Bagel (the Spark implementation of Google Pregel)

- Most of the deprecated methods from Spark 1.x, including:

Category	Subcategory	Instead of this removed API...	Use...
GraphX		`mapReduceTriplets`	`aggregateMessages`
		`runSVDPlusPlus`	`run`
		`GraphKryoRegistrator`	
SQL	DataType	`DataType.fromCaseClassString`	`DataType.fromJson`
	DecimalType	`DecimalType()`	`DecimalType(precision, scale)` `precision explicitly`
		`DecimalType(Option[PrecisionInfo])`	`DecimalType(precision scale)`
		`PrecisionInfo`	`DecimalType(precision, scale)`
		`precisionInfo`	`precision` and `scale`
		`Unlimited`	(No longer supported)
	Column	`Column.in()`	`isin()`
	DataFrame	`toSchemaRDD`	`toDF`
		`createJDBCTable`	`write.jdbc()`
		`saveAsParquetFile`	`write.parquet()`
		`saveAsTable`	`write.saveAsTable()`
		`save`	`write.save()`
		`insertInto`	`write.mode(SaveMode.Append).s`
	DataframeReader	`DataFrameReader.load(path)`	`option("path", path).load()`
	Functions	`cumeDist`	`cume_dist`
		`denseRank`	`dense_rank`
		`percentRank`	`percent_rank`
		`rowNumber`	`row_number`
		`inputFileName`	`input_file_name`
		`isNaN`	`isnan`
		`sparkPartitionId`	`spark_partition_id`
		`callUDF`	`udf`
Core	SparkContext	Constructors no longer take `prefferedNodeLocationData` param	
		`tachyonFolderName`	`externalBlockStoreFolderName`
		`initLocalProperties`, `clearFiles`, `clearJars`	(No longer needed)
		`runJob` method no longer takes `allowLocal` param	
		`defaultMinSplits`	`defaultMinPartitions`
		`[Double, Int, Long, Float]AccumulatorParam`	implicit objects from `AccumulatorPar`
		`rddTo[Pair, Async, Sequence, Ordered]RDDFunctions`	implicit functions from RDD

last-updated: Apr 11, 2022

Category	Subcategory	Instead of this removed API...	Use...
		`[double, numeric]RDDToDoubleRDDFunctions`	implicit functions from RDD
		`intToIntWritable, longToLongWritable, floatToFloatWritable, doubleToDoubleWritable, boolToBoolWritable, bytesToBytesWritable, stringToText`	implicit functions from `WriteableFact`
		`[int, long, double, float, boolean, bytes, string, writable]WritableConverter`	implicit functions from `WritableConve`
	TaskContext	`runningLocally`	`isRunningLocally`
		`addOnCompleteCallback`	`addTaskCompletionListener`
		`attemptId`	`attemptNumber`
	JavaRDDLike	`splits`	`partitions`
		`toArray`	`collect`
	JavaSparkContext	`defaultMinSplits`	`defaultMinPartitions`
		`clearJars, clearFiles`	(No longer needed)
	PairRDDFunctions	`PairRDDFunctions.reduceByKeyToDriver`	`reduceByKeyLocally`
	RDD	`mapPartitionsWithContext`	`Taskcontext.get`
		`mapPartitionsWithSplit`	`mapPartitionsWithIndex`
		`mapWith`	`mapPartitionsWithIndex`
		`flatMapWith`	`mapPartitionsWithIndex` and `flat`
		`foreachWith`	`mapPartitionsWithIndex` and `fore`
		`filterWith`	`mapPartitionsWithIndex` and `filt`
		`toArray`	`collect`
	TaskInfo	`TaskInfo.attempt`	`TaskInfo.attemptNumber`
	Guava Optional	`Guava Optional`	`org.apache.spark.api.java.Opt`
	Vector	`Vector, VectorSuite`	
Configuration options and params		`--name`	
		`--driver-memory`	`spark.driver.memory`
		`--driver-cores`	`spark.driver.cores`
		`--executor-memory`	`spark.executor.memory`
		`--executor-cores`	`spark.executor.cores`
		`--queue`	`spark.yarn.queue`
		`--files`	`spark.yarn.dist.files`
		`--archives`	`spark.yarn.dist.archives`
		`--addJars`	`spark.yarn.dist.jars`
		`--py-files`	`spark.submit.pyFiles`

last-updated: Apr 11, 2022

Note also the following deprecated configuration options and parameters:

- Methods from Python `DataFrame` that returned `RDD` have been moved to `dataframe.rdd`. For example, `df.map` is now `df.rdd.map`.
- Some streaming connectors (Twitter, Akka, MQTT, and ZeroMQ) have been removed.
- `org.apache.spark.shuffle.hash.HashShuffleManager` no longer exists. `SortShuffleManager` is the default since Spark 1.2.
- `DataFrame` is no longer a class. It is a subtype of `DataSet`.

Behavior Changes

Spark 2.0.1 implements the following behavior changes:

- Spark 2.0.1 uses Scala 2.11 instead of 2.10.
- Floating literals in SQL are now parsed as decimal type instead of double type.
- The Kryo version is now 3.0.
- Jersey version is now 2.
- Java `RDD flatMap` and `mapPartitions` functions now require functions that return Java `iterator` instead of `Iterable`.
- Java `RDD countByKey` and `countApproxDistinctByKey` now return `Map[K => Long]` instead of `Map[K => Object]`.
- When writing Parquet files, the summary files are no longer written (set `parquet.enable.summary-metadata` to `true` to re-enable).
- Lots were changed in MLLib. Follow the Apache Spark Migration Guide.
- `Sparkcontext.emptyRDD` now returns `RDD` instead of `EmptyRDD`.
- Spark Standalone Master no longer serves the jobs history.
- org.apache.spark.api.java.JavaPairRDD methods were changed:
  - `countByKey` and `countApproxDistinctByKey` now return `java.lang.Long` instead of `scala.Long`.
  - `sampleByKey` and `sampleByKeyExact` now return `java.lang.Double` instead of `scala.Double`.
- The Old Application History format that created folders for each application has been removed.
- `org.apache.spark.Logging` is now private. You can use `slf4j` directly instead.

Other Deprecated Items

- Java 7 is now deprecated.
- Python 2.6 is now deprecated.
- TaskContext.isRunningLocally now is always false, as there is no more local execution of *yarn-client* and `yarn-cluster` as masters. Use `--master yarn` and `--deploy-mode client/cluster`.

- Instead of `HiveContext`, use `SparkSession.builder.enableHiveSupport`.
- Instead of `SQLContext`, use `SparkSession.builder`.
- Some methods related to `Accumulators`, `ShuffleWriteMetrics`, `SparklLoop`, `DataSet`, and `SQLContext` are now deprecated. You will see warnings in your application logs if you use them.

Structured Streaming in Spark
Starting in EEP 5.0.0, structured streaming is supported in Spark.

Related Links

Spark streaming is integrated with MapR Event Store For Apache Kafka for Apache Kafka.

- MapR Event Store For Apache Kafka Clients and Tools

Prerequisites for Using Structured Streaming in Spark
To deploy a structured streaming application in Spark, you must create a MapR Streams topic and install a Kafka client on all nodes in your cluster.
Creating a MapR Streams Topic

- Create a MapR Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

Installing a Kafka Client

- Install a kafka-client on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

Using Structured Streaming to Create a Word Count Application
The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.
Using Apache Kafka

Scala

```
val spark = SparkSession
       .builder
       .appName("StructuredKafkaWordCo
unt")
       .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
       .readStream
       .format("kafka")
       .option("kafka.bootstrap.server
s", bootstrapServers)
       .option(subscribeType, topics)
       .load()
       .selectExpr("CAST(value AS
STRING)")
       .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()
//Run the query that prints the
running counts to the console
```

```
val query = wordCounts.writeStream
       .outputMode("complete")
       .format("console")
       .option("checkpointLocation",
checkpointLocation)
       .start()

query.awaitTermination()
```

Java

```
SparkSession spark = SparkSession
              .builder()
              .appName("JavaStructured
KafkaWordCount")
              .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
              .readStream()
              .format("kafka")
              .option("kafka.bootstrap
.servers", bootstrapServers)
              .option(subscribeType,
topics)
              .load()
              .selectExpr("CAST(value
AS STRING)")
              .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
              .outputMode("complete")
              .format("console")
              .start();

query.awaitTermination();
```

Python

```
spark = SparkSession\
          .builder\
          .appName("StructuredKafkaWor
dCount")\
          .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
          .readStream\
          .format("kafka")\
          .option("kafka.bootstrap.ser
vers", bootstrapServers)\
          .option(subscribeType,
```

```
topics)\
          .load()\
          .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
        split(lines.value, ' ')
       ).alias('word')
     )

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
           .writeStream\
           .outputMode('complete')\
           .format('console')\
           .start()

query.awaitTermination()
```

Using MapR Event Store for Apache Kafka

For MapR Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val df1 = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
   "maprdemo:9092").option("subscribe", topic).option("group.id",
   "testgroup").option("startingOffsets",
"earliest").option("failOnDataLoss",
          false).option("maxOffsetsPerTrigger", 1000).load()
```

Writing a Structured Spark Stream to MapR Database JSON Table

The example in this section writes a structured stream in Spark to MapR Database JSON table.

To write a structured Spark stream to MapR Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

Scala

```
import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._
```

```
df.select($"value" as "_id")
  .writeStream
  .format(MapRDBSourceConfig.Format)
  .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
  .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
  .option(MapRDBSourceConfig.CreateTab
leOption, true)
  .option(MapRDBSourceConfig.BulkModeO
ption, true)
  .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
  .outputMode("append")
}
```

Java

```
import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStr
eamReader;
import
org.apache.spark.sql.streaming.DataStr
eamWriter;
import
org.apache.spark.sql.streaming.Streami
ngQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
   return df.selectExpr("CAST(value
AS STRING) as _id")
            .writeStream()
            .format(MapRDBSourceConfig
.Format())
            .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
            .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
            .option(MapRDBSourceConfig
.CreateTableOption(), true)
            .option(MapRDBSourceConfig
.BulkModeOption(), true)
            .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
            .outputMode("append");
 }
```

Python

```
from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
  return df.selectExpr("CAST(value AS
STRING) as _id") \
           .writeStream \
```

```
            .format("com.mapr.db.spark.
streaming") \
            .option("checkpointLocation
", checkpoint_dir) \
            .option("tablePath",
table_path) \
            .option("idFieldPath",
"value") \
            .option("createTable",
True) \
            .option("bulkMode", True) \
            .option("sampleSize", 1000)
```

Writing a Spark Stream Word Count Application to MapR Database
The example in this section writes a Spark stream word count application to MapR Database.

Scala

```
val spark = SparkSession
      .builder
      .appName("StructuredKafkaWordCou
nt")
      .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
      .readStream
      .format("kafka")
      .option("kafka.bootstrap.servers
", bootstrapServers)
      .option(subscribeType, topics)
      .load()
      .selectExpr("CAST(value AS
STRING)")
      .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
      .format(MapRDBSourceConfig.Forma
t)
      .option(MapRDBSourceConfig.Table
PathOption, resultTable)
      .option(MapRDBSourceConfig.Creat
eTableOption, true)
      .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
      .outputMode("complete")
      .start()

query.awaitTermination()
```

Java

```
SparkSession spark = SparkSession
            .builder()
```

```
            .appName("JavaStructuredKaf
kaWordCount")
            .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
             .readStream()
             .format("kafka")
             .option("kafka.bootstrap.s
ervers", bootstrapServers)
             .option(subscribeType,
topics)
             .load()
             .selectExpr("CAST(value
AS STRING)")
             .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
             .format(MapRDBSourceConfig
.Format())
             .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
             .option(MapRDBSourceConfig
.CreateTableOption(), true)
             .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
             .outputMode("complete");
             .start();

query.awaitTermination();
```

Python

```
spark = SparkSession\
            .builder\
            .appName("StructuredKafkaWo
rdCount")\
            .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
           .readStream\
           .format("kafka")\
           .option("kafka.bootstrap.ser
vers", bootstrapServers)\
           .option(subscribeType,
topics)\
           .load()\
           .selectExpr("CAST(value AS
```

```
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
       split(lines.value, ' ')
       ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
              .writeStream\
              .format("com.mapr.db.spa
rk.streaming") \
              .option("tablePath",
table_path) \
              .option("createTable",
True) \
              .option("idFieldPath",
"value") \
              .outputMode('complete')\
              .start()

query.awaitTermination()
```

PAM Authentication for Spark
Spark supports PAM authentication on secure MapR clusters.

In EEP-5.0.0, PAM authentication and encryption is enabled by default for all Spark Web UIs. After running configure.sh, if the cluster is secure and Spark is installed, Spark will be configured using PAM.

Note: Spark PAM is available in Spark-2.2.1 from EEP-5.0 and in Spark-2.1.0 from EEP-4.1.1.

See Configuring PAM on page 1442 for information on how PAM works with MapR.

Read or Write LZO Compressed Data for Spark
This topic provides details for reading or writing LZO compressed data for Spark.

1. Install the LZO library:

```
sudo yum install lzo-devel lzo
```

2. Clone hadoop-lzo and build it:

```
[mapr@node1 ~]$ git clone https://github.com/twitter/hadoop-lzo
[mapr@node1 ~]$ cd hadoop-lzo
[mapr@node1 hadoop-lzo]$ mvn package
```

3. Copy the jar file to hadoop classpath:

```
[mapr@node1 hadoop-lzo]$ sudo
cp target/hadoop-lzo-0.4.21-SNAPSHOT.jar /opt/mapr/hadoop/hadoop-2.7.0/
share/hadoop/yarn/lib/
```

4. Add two LZO compression codes to `core-site.xml`:

```
property: io.compression.codecs
codecs:
com.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec/
```

   It will look like this:

```
<property>
  <name>io.compression.codecs</name>

<value>org.apache.hadoop.io.compress.DefaultCodec,org.apache.hadoop.io.co
mpress.GzipCodec,org.apache.hadoop.io.compress.BZip2Codec,org.apache.hado
op.io.compress.DeflateCodec,org.apache.hadoop.io.compress.SnappyCodec,com
.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec</
value>
</property>

<property>
 <name>io.compression.codec.lzo.class</name>
 <value>com.hadoop.compression.lzo.LzoCodec</value>
</property>
```

5. Run Spark and read LZO compressed data:

```
[mapr@node1 spark]$ ./bin/spark-shell --master yarn
spark.read.csv("/user/mapr/LzoCompressedCsv").show
```

6. Write LZO compressed data with Spark:

```
scala>
df.write.option("codec","com.hadoop.compression.lzo.LzopCodec").csv("csv1
")

[mapr@node1 spark]$ hadoop fs -ls /user/mapr/csv1
Found 2 items
-rwxr-xr-x   3 mapr mapr          0 2017-12-15 12:42 /user/mapr/csv1/
_SUCCESS
-rwxr-xr-x   3 mapr mapr     493366 2017-12-15 12:42 /user/mapr/csv1/
part-00000-256a95a9-eb9c-4048-b7ce-c95dfbef54d7.csv.lzo
```

Ports Used by Spark

To run a Spark job from a client node, ephemeral ports should be opened in the cluster for the client from which you are running the Spark job.

If you do not want to open all the ephemeral ports, you can use the configuration parameter to specify the range of ports.

To set ports to special values, use the `spark.driver.port`, `spark.blockManager.port`, and `spark.port.maxRetries` properties. The `spark.port.maxRetries` property is 16 by default.

For example, if you need to open port 200 for `spark.blockManager.port` from 40000, set `spark.blockManager.port = 40000` and `spark.port.maxRetries = 200`.

For a list of Web UIs ports dynamically used when starting spark contexts, see the open source documentation.

The default port numbers that need to be opened on the firewall behind the client and MapR cluster nodes for Spark jobs to operate in YARN client, YARN cluster, and standalone modes are as follows:

Service	Port Number
Spark Standalone Master (RPC)	7077
Spark Standalone Master (Web UI)	8580, 8980*
Spark Standalone Worker	8581, 8981*
Spark Thrift Server	2304
Spark History Server	18080,18480*
Spark External Shuffle Service (if yarn shuffle service is enabled)	7337
CLDB	7222
ZooKeeper	5181
Nodes running ResourceManager	8032
MapR Filesystem Server	5660, 5692

* refers to ports for secure clusters

ACL Configuration for Spark
Starting in the EEP 6.0 release, the ACL configuration for Spark is disabled by default.

If you are authorized by PAM, you will have access to all Spark UIs. For the Spark History Server, you can only see the logs of your own Spark jobs if PAM is enabled (regardless of ACL being enabled).

Starting in Spark-2.4.4.0, MapR Spark ACLs behave like Apache Spark ACLs. With this change, all users can log in to the Spark History Server UI and see the full list of applications. Only an application owner or the users specified in `spark.ui.view.acls` or `history.ui.admin.acls` can see application details. Users specified in `history.ui.admin.acls` can see the details for all applications.

By default on a secure cluster:

```
spark.acls.enable false
spark.admin.acls mapr
spark.admin.acls.groups mapr
spark.ui.view.acls mapruser1
```

Other Example:

```
spark.acls.enable true - ACL is enabled and restricted access to Spark
master and thriftserver UIs for other users.
spark.admin.acls mapr - Administrator or "sudoer" of ACL access.
spark.admin.acls.groups mapr - Group of administrators.
spark.ui.view.acls mapruser1 - user who can be logged in to Spark master
and thriftserver UIs.
```

Sqoop

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Apache Sqoop™ is a tool designed to efficiently transfer bulk data between Apache Hadoop and structured datastores, such as relational databases.

This documentation provides information for using Sqoop and Sqoop2, but does not duplicate the Apache Sqoop™ documentation on the Apache Sqoop website.

The following table describes the differences between Sqoop1 or Sqoop2:

Feature	Sqoop1	Sqoop2
Specialized connectors for all major RDBMS	Available.	Not available. However, you can use the `generic-jdbc-connector` , which has been tested on these databases: • MySQL • Microsoft SQL Server • Oracle (Not supported in Sqoop 1.99.7) • PostgreSQL The generic JDBC connector should also work with any other JDBC-compliant database, although specialized connectors probably give better performance.
Data transfer from RDBMS to Hive	Done automatically.	Must be done manually in two stages: 1. Import data from RDBMS into MapR File System. 2. Load data into Hive using the `LOAD DATA` command **Note:** As of Sqoop 1.99.7, you can also use the `kite-connector` to load data into Hive.

last-updated: Apr 11, 2022

Feature	Sqoop1	Sqoop2
Data transfer from Hive to RDBMS	Must be done manually in two stages: 1. Extract data from Hive into MapR File System, as a text file or as an Avro file. 2. Export the output of step 1 to an RDBMS using Sqoop.	Must be done manually in two stages: 1. Extract data from Hive into MapR File System, as a text file or as an Avro file. **Note:** As of Sqoop 1.99.7, you can also use the `kite-connector` to extract data from Hive. 2. Export the output of step 1 to an RDBMS using Sqoop.
Integrated Kerberos security	Supported.	Supported.
Password encryption	Not supported.	Supported as of Sqoop 1.99.7.

Sqoop1

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Sqoop transfers data between the MapR File System and relational databases. You can use Sqoop to transfer data from a relational database management system (RDBMS), such as MySQL or Oracle, into the MapR File System and use MapReduce on the transferred data. Sqoop can export this transformed data back into an RDBMS.

The Maven repository contains JAR files for Sqoop that you can download and use for your application:

Version	Core	EEP	Maven Repository Locations
Sqoop 1.4.7	6.1.x	6.3.2	1.4.7-mapr-632/
		6.3.1	1.4.7-mapr-2009/
		6.3.0	1.4.7-mapr-1904/

For more information about Sqoop, see the Apache Sqoop 1.4.7 Documentation.

MapR Connector for Teradata

The MapR Connector for Teradata (powered by the Teradata Connector for Hadoop (TDCH)) is a connector for Sqoop1 that enables the transfer of data between a Teradata MPP database and MapR environments.

Sqoop TDCH Features

The MapR Connector for Teradata supports the following features:

- Import of data to Sqoop in these formats:
  - TextFormat, delimited
  - RCFile
  - ORCFile
  - Avro file
- Hive arguments. The MapR Connector for Teradata supports all standard Hive arguments and all data types except Union.

last-updated: Apr 11, 2022

- Export from and import to HCatalog tables.
- Automatic schema mapping to or from HCatalog.
- Import using a query.

The following features are NOT supported:

- Update table
- Compression
- Parquet format

Supported Product Versions and System Requirements

You must have the following minimum software versions to use the MapR Connector for Teradata:

- Teradata Database 15.10
- Hive 1.2
- MapR 5.2
- Sqoop 1.4.6

The Sqoop 1.4.6-1707 release supports TDCH 1.5.2. Prior releases support TDCH 1.5.1.

The MapR Connector for Teradata also requires JRE/JDK 1.7.x or 1.8.x. Make sure to include the Hive libraries in your Java classpath.

Importing and Exporting Data Using the MapR Connector for Teradata

You can specify MapR Connector for Teradata options using any of these methods:

- Configuration file
- `-D` command line option
- Sqoop options

Some Sqoop options are unsupported in the current release. For a list of unsupported Sqoop options, see Sqoop TDCH Import and Export Options.

This table shows examples for importing and exporting data:

Table

Operation	Example

Import from Hive and HCatalog	Importing from Hive and HCatalog requires that `HIVE_HOME` and `HCAT_HOME` be specified before the Sqoop command is run or using `--hive-home/--hcatalog-home` options. This example shows the environment variable setup:
	`export HIVE_HOME=/opt/mapr/hive/hive-1.2`
	`export HCAT_HOME=/opt/mapr/hive/hive-1.2/hcatalog`
	Or
	`sqoop import --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --hive-import --hive-overwrite --hive-home /opt/mapr/hive/hive-1.2/`

Import from Teradata to MapR File System	`sqoop import --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --target-dir /user/mapr/test`
Import from Teradata into a Hive Table	`sqoop import --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --hive-import --hive-overwrite --hive-home /opt/mapr/hive/hive-1.2/ --fields-terminated-by ';'`
Import from Teradata into an HCatalog Table	`sqoop import --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --hcatalog-table test`

last-updated: Apr 11, 2022

Table (Continued)

Operation	Example
Import from Teradata into a Hive Table Stored as RCFile  **Note:** If you must import to a table stored as an RCFile or ORCFile, the table must be created before data is imported.	`sqoop import -D tdch.fileformat="rcfile" --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --hive-import --hive-overwrite --hive-home /opt/mapr/hive/hive-1.2/`
Export to Teradata	`sqoop export --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --export-dir /user/mapr/test`
Export from an AVRO File to Teradata	`sqoop export -D tdch.fileformat="avrofile" --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --export-dir /user/mapr/avro`

MapR Connector Import and Export Options

Import Options

Import Option	Description

`--as-avrodatafile`, `--as-textfile`	The format of a to-be-imported data file in MapR File System. An 'hcat' or 'hive' job type supports 'rcfile', 'orcfile' and 'textfile' file formats. To set the file format, you need to use the `-D` command line option. For example:
	`sqoop import -D tdch.fileformat="orcfile" --connect jdbc:teradata://<hosname>/database=test --connection-manager org.apache.connectors.td.TeradataManager …`
	  **Note:** If import to MapR File System in Avro format fails, include `-Dmapreduce.job.user.classpath.first=true` in your command.
	`sqoop import --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --as-avrodatafile ...`

`--target-dir`	MapR File System destination directory.

last-updated: Apr 11, 2022

`--num-mappers`	The number of mappers for the import job. The default value is 4.
`--query`	The SQL query to select data from a Teradata database. This option works only with the textfile and avrofile formats.
`--table`	The name of the source table in a Teradata system from which the data is imported.
`--columns`	The names of columns to import from the source table in a Teradata system, in comma-separated format. For example: `sqoop import --connect jdbc:teradata://<hostname>/ database=test --connection-manager org.apache.connectors.td.TeradataManager --username test --password test --table test --columns id,name`
`--hive-table`	The name of the target table in Hive or HCatalog.
`--fields-terminated-by`	The field separator to use with the imported files. This parameter is only applicable with the textfile file format. The default value is `\t`.
`--split-by`	The column of the table used to split work units.
`--map-column-hive`	Override mapping from SQL to Hive type for configured columns.
`--where`	WHERE clause to use during import.
`--staging-table`Footnote.	The table for staging data before insertion into the destination table. Only applicable when using `input-method split.by.partition`
`--num-partitions-for-staging-table`Footnote.	The number of partitions to create when auto-creating the staging table. Only applicable when using `input-method split.by.partition`.
`--staging-database`Footnote.	The database for creating the staging table. Only applicable when using `input-method split.by.partition.`
`--staging-force`Footnote.	Option to force the connector to create a staging table, if supported. Only applicable when using `input-method split.by.partition`.
`--input-method`Footnote.	The input method to use to transfer data from Teradata. Supported values: • `split.by.amp` • `split.by.value` • `split.by,partition` • `split.by.hash`
`--batch-size`Footnote.	The number of row processed per batch.
`--access-lock`Footnote.	Option to apply access lock on the database.
`--query-band`Footnote.	The arbitrary query bands to be set for all queries the connector runs. Specify the query bands using a semicolon-separated `key=value` format.
`--skip-xviews`Footnote.	Option to switch to the non-X version of system views to obtain metadata.
`--date-format`Footnote.	Custom format for date columns.

[1] Only available starting in Sqoop-1.4.6-1707.

last-updated: Apr 11, 2022

`--time-format`Footnote.	Custom format for time columns.
`--timestamp-format`Footnote.	Custom format for timestamp columns.

Only available starting in Sqoop-1.4.6-1707.

Use the `-D` command line option to set the file format. For example:

```
-D tdch.fileformat="fileformat"
```

The following Sqoop import options are unsupported:

- `--append`
- `--compression-codec`
- `--direct`
- `--direct-split-size`
- `--compress, -z`
- `--check-column`
- `--incremental`
- `--last-value`
- `--mysql-delimiters`
- `--optionally-enclosed-by`
- `--hive-delims-replacement`
- `--hive-drop-import-delims`
- `--hive-partition-key`
- `--hive-partition-value`
- `--column-family`
- `--hbase-create-table`
- `--hbase-row-key`
- `--hbase-table`
- `--map-column-java`
- `--fetch-size`
- `--as-sequencefile`

Export Options

Export Option	Description

`--table`	The name of the target table in a Teradata system.
`--export-dir`	The directory of to-be-exported source files in MapR File System.
`--num-mappers`	The number of mappers for the export job. The default value is 4.
`--columns`	The names of fields to export to the target table in a Teradata system, in comma-separated format. For export from MapR File System, you can only use this option with the avrofile format.
`--staging-table`	The table in which data will be staged before being inserted into the destination table.
`--keep-staging-table`Footnote.	Option specifying that the connector retain the staging table after failures.
`--staging-database`Footnote.	The database for creating the staging table.
`--staging-force`Footnote.	Option to force the connector to create a staging table, if supported.
`--output-method`Footnote.	The output method to use to transfer data to Teradata. Supported values: • `batch.insert` • `internal.fastload`
`--query-band`Footnote.	The arbitrary query bands to be set for all queries that the connector runs. Specify the query bands using a semicolon-separated `key=value` format.
`--error-table`Footnote.	Prefix name for error tables. Only applicable when using `output-method internal.fastload`.
`--error-database`Footnote.	Override for the default error database name. Only applicable when using `output-method internal.fastload`.
`--fastload-socket-hostname`Footnote.	Hostname or IP address of the host on which Sqoop runs. If not set, the connector auto-detects the host. Only applicable when using `output-method internal.fastload`.
`--fastload-socket-port`Footnote.	The host port that fastload tasks use to synchronize state. Only applicable when using `output-method internal.fastload`.
`--fastload-socket-timeout`Footnote.	The timeout value the server socket uses for fastload task connections. Only applicable for `output-method internal.fastload`.
`--skip-xviews`Footnote.	Option to switch to the non-X version of system views to obtain metadata.
`--date-format`Footnote.	Custom format for date columns.
`--time-format`Footnote.	Custom format for time columns.
`--timestamp-format`Footnote.	Custom format for timestamp columns.

Use the `-D` command line option to set the file format. For example:

```
-D tdch.fileformat="fileformat"
```

Supported export file format values are:

- textfile (default format)
- avrofile

last-updated: Apr 11, 2022

- orcfile
- refile

The following Sqoop export options are unsupported:

- `--batch`
- `--clear-staging-table`
- `--direct`
- `--update-key`
- `--update-mode`
- `--input-lines-terminated-by`
- `--input-optionally-enclosed-by`
- `--map-column-java`
- `--as-sequencefile`

YARN

YARN is a resource-management and scheduling framework that distributes resource-management and job-management duties. YARN assigns the resource-management and job-management duties as follows:

- ResourceManager: manages cluster resources and tracks resource usage and node health.
- ApplicationMaster: a framework-specific process that negotiates resources for a single application (a single job or a directed acyclic graph of jobs), which runs in the first *container* allocated for the application.
- A YARN component called the HistoryServer archives job metrics and metadata. Status on completed applications is available via REST APIs.

The ResourceManager allocates resources among all the applications running the cluster. The ResourceManager includes a pluggable scheduler, which is responsible for allocating resources according to the resource requirements of the running applications. Current MapReduce schedulers, including the Capacity Scheduler and the Fair Scheduler, can be plugged into the YARN scheduler directly.
