Specifies a comma-delimited list of disks to use with the MapR filesystem. With the `-D` option, you cannot specify partitions. By default, the `configure.sh` script automatically starts cluster services, after the configuration finishes successfully. If you do not want cluster services to be restarted, include the `-no-autostart` option along with the `-D` option.

-d

The host and port of the MySQL database to use for storing MapR Metrics data.

-dare

Enables on-disk encryption at the cluster-level. When run on the first CLDB node with the `-genkeys` option, the utility generates the data-at-rest encryption master key file at `/opt/mapr/conf/dare.master.key`.

-defaultdb	Sets the default database (HBase or MapR Database) to which the HBase clients connect. If you do not explicitly configure this option, it defaults to `hbase` (HBase) when you have `mapr-hbase-regionserver` or `mapr-hbase-master` installed on the node. Otherwise, it defaults to `maprdb` (MapR Database). You can also change the database setting using `hbase-site.xml` or the HBase client connection. For more information, see Configure the Default Database for HBase Clients on page 3389.
-disk-opts	Denotes disksetup formatting options. Do not include spaces or commas between the disksetup options. For example, you can specify `-disk-opts FW5` to format the disks (F), and configure five disks per storage pool (W5).
-dp	Specifies the password for logging into the MySQL database used for storing MapR Metrics data.
-ds	Specifies the name of the database schema to use for the MySQL database used for storing MapR Metrics data. The default schema name is *metrics*.
-du	Specifies the username for logging into the MySQL database used for storing MapR Metrics data.

-EC	Specifies a host or hosts that contain the Hive Metastore. Use this parameter and the `-hiveMetastoreHost` argument to configure an ecosystem component, such as Drill, to communicate with the Hive Metastore. Use the following format to specify a list of hosts:
	`hostname[:port_no]`
	`[,hostname[:port_no]...]`
	See the `-EC` parameter example later on this page. If you do not specify a host port number, Drill uses the default Hive Metastore port number (9083) for every host.

-EP	Specifies an option that is passed directly to an ecosystem `configure.sh` script. These commands follow the form `-EP<ecosystem component name> <option>`. In general, `-EP` options are not documented, and should be used only if the documentation specifically instructs you to use them.
	In MapR 6.0 and later, some ecosystem components have their own `configure.sh` scripts. The server `configure.sh` script or a user, can pass options directly to the ecosystem component by using the `-EP` syntax. For example, in the following command:
	`/opt/mapr/server/`
	`configure.sh -R -EPkibana`
	`'-kibanaPort 5610'`
	`-EPkibana '-kibanaPort 5610'` changes the default port for Kibana to 5610.
	As ecosystem components are updated more frequently than MapR Core (which contains the server `configure.sh` script), implementing some

last-updated: Apr 11, 2022

`configure.sh` functions through an ecosystem `configure.sh` script can accelerate the introduction of new features.

`-ES`

Specifies a comma-separated list of host names or IP addresses that identify the Elasticsearch nodes. The Elasticsearch nodes can either be part of the current MapR cluster, or part of a different MapR cluster. Do not use this option when you configure a node for the first time. Use this option along with the `-R` parameter.

The list is in the following format:

```
hostname/IPaddress[:port_no]
[,hostname/IPaddress[:port_no]...]
```

Note: The default Elasticsearch port is `9200`. If you want to use a different port, specify the port number when you list the Elasticsearch nodes.

`-ESDB`

Specifies a non-default location for writing index data on Elasticsearch nodes. To configure an index location, you only need to include this parameter on Elasticsearch nodes.

Elasticsearch requires a lot of disk space. Therefore, a separate filesystem for the index is recommended. It is not recommended to store index data under the `/` or the `/var` file system.

For more information, see Log Aggregation and Storage on page 1391.

`-F`

Specifies a path to a text file that lists the disks and partitions to use with the MapR filesystem. By default, the `configure.sh` script automatically starts cluster services after the configuration finishes successfully. If you do not want cluster services to be restarted, include the `-no-autostart` option along with the `-F` option.

`-f`

Specifies that the node should be configured without performing the system prerequisite check.

`-forceSecurityDefaults`

Instructs `configure.sh` to undo any custom security settings for a cluster, and reconfigure security to the default MapR values for `-unsecure` or `-secure`. You must specify either the `-secure` or the `-unsecure` option. Using the `-forceSecurityDefaults` option removes the `/opt/mapr/conf/.customSecure` file. Use the following syntax:

```
/opt/mapr/server/
configure.sh -forceSecurityDefaults
[ -unsecure | -secure ] -C
<CLDB_node> -Z <ZK_node>
```

For more information, see Customizing Security in MapR on page 1474.

	Important: It is possible that the `-forceSecurityDefaults` operation might not undo all custom security settings since `configure.sh` cannot know all of the custom settings that were implemented. Therefore, you might have to edit some configuration files and settings to restore the cluster to full functionality.
-G	The group ID to use when creating $MAPR_USER with the `-create-user` or `-a` option; corresponds to the `-g` or `-gid` option of the `useradd` command in Linux.
-g	The group name under which MapR services run.
-genkeys	Generates needed keys and certificates for the initial CLDB node in a secure cluster. If specified with the `-dare` option, the `-genkeys` option generates a master key at `/opt/mapr/conf/dare.master.key` on the first CLDB node. Without the master key, you cannot start the cluster, nor can you access the data.
-H	Specifies the HTTPS port number for connecting to the CLDB node. The default port is `7443`.
-HS	Specifies the IP or hostname of the node in the cluster that performs the HistoryServer role. This parameter is required only when a node in the cluster performs the HistoryServer role. In MapR 5.1 and later, this parameter is expanded to support the Mesos DNS-style name with format for Job History. The format is <myriad-fwk-name>.mesos. For example, if the `-MF` parameter is myriadA, the name is: `jobhistory.myriadA.mesos`.
--isvm	Specifies the virtual machine setup. Required when `configure.sh` is run on a cluster node, that is on a virtual machine. This option configures the script to use less memory.
-J	Specifies the JMX port for the CLDB. Default: `7220`
-K | -kerberosEnable	Indicates that Kerberos security has been enabled. Kerberos security is disabled by default.
-L	Specifies a log file. If not specified, `configure.sh` logs errors to `/opt/mapr/logs/configure.log`.
--logHTTPFS	Specifies the hostname to enable centralized logging using `fluentd`.
-MCL	Specifies the top-level directory where all the staging data as well as shuffle data is written for a specific Myriad framework. Used when multiple clusters are implementing Myriad.
-MP	Specifies the name of the Myriad framework that is displayed in the Mesos UI.
-MHA	Enables Myriad high availability.
-M7	Deprecated as of MapR 4.0.1.
-maprpam	When specified, the `configure.sh` script installs the MapR version of Pluggable Authentication Modules (PAM). This option is ignored if `-S` is not set.

last-updated: Apr 11, 2022

-N	Specifies the cluster name. If you do not specify a name, `configure.sh` applies a default name (my.cluster.com) to the cluster. Whenever you run `configure.sh`, be aware of the existing cluster name or names in `mapr-clusters.conf` and specify the `-N` parameter accordingly. If you specify a name that does not exist, a new line is created in `mapr-clusters.conf` and is treated as a configuration for a separate cluster. Subsequent runs of `configure.sh` without the `-N` parameter operate on this default cluster. If you specify a name when you first run `configure.sh`, you can modify the CLDB and ZooKeeper settings corresponding to the named cluster by specifying the same name and running `configure.sh` again. Whenever you need to re-run `configure.sh` on a given cluster (to add or rename nodes, for example), be sure to specify the same cluster name that you used when you ran `configure.sh` for the first time.
-no-autostart	Specifies that the script should not start Zookeeper or Warden when you run `configure.sh`.
-no-auto-permission-update	Pass this option to prevent MapR from silently altering permissions in `/etc/shadow`.
-nocerts	When specified, the `configure.sh` script does not generate SSL certificates even when the `-genkeys` option is specified.
-noDB	Specifies that MapR Database is not in use.
-noRecalcMem	Skips recalculating memory settings when refreshing roles. Can be used only with the `-R` option.
-OT	Specifies a comma-separated list of host names or IP addresses that identify the OpenTSDB nodes. The OpenTSDB nodes can be part of the current MapR cluster or part of a different MapR cluster. Do not use this option when you configure a node for the first time. Use this option along with the `-R` parameter. The Warden service must be running when you use `configure.sh -R -OT`. Use the following format to list the hostnames: `hostname/IP address[:port_no] [,hostname/IP address[:port_no]...]` **Note:** The default OpenTSDB port is `4242`. If you want to use a different port, specify the port number when you list the OpenTSDB nodes.
-on-prompt-cont	Specify: • y to automatically respond Yes to all prompts. • n to automatically respond No to all prompts.
-P	Specifies the Kerberos instance that is used to form a CLDB Kerberos principal in the form of `mapr/<instance-name>@<realm-name>`. Enclose this value in quotes ("). This value is ignored if Kerberos security is not enabled.

last-updated: Apr 11, 2022

-QS	Use the `-QS` option to configure the OJAI Distributed Query Service. See Configure the OJAI Distributed Query Service on page 182.
-RM	In MapR 5.1, this parameter is expanded to support the Mesos DNS-style hostname for Myriad configuration. The Mesos-style hostname is `<application name>.marathon.mesos`. When starting ResourceManager from Marathon, the `.<application name> rm`, for example, is `rm.marathon.mesos`. In MapR 4.0.2, this parameter is not required unless you want to configure manual or automatic failover; zero configuration failover is enabled by default. In MapR 4.0.1, this parameter specifies the nodes in the cluster with the ResourceManager role. List the nodes in the following format: `hostname[,hostname]...]` For more information, see ResourceManager High Availability on page 1508.
-S | -secure	Specifies that this cluster is a secure cluster, and configures security on the platform and on all ecosystem components that support security. Default: `insecure`.
-syschk	Configures the system checks to be enabled or disabled. Value: Y/N.
-TL	Specifies the single node on which the timeline server is installed for the Hive-on-Tez user interface. When you install Tez manually, you must also install the timeline server and run `configure.sh -TL <timeline_server_node>` on all nodes to indicate where the timeline server resides.
-U	The user ID to use when creating $MAPR_USER with either the `--create-user` or `-a` option; corresponds to the `-u` or `--uid` option of the `useradd` command in Linux.
-u	The user name under which MapR services run.
-unsecure	Specifies that this cluster is not secure. Default: `unsecure`.
-v	In addition to logging information, also prints to `stdout`.

Examples

1. **Add a node (not CLDB or ZooKeeper) to a cluster that is running the CLDB and ZooKeeper on three nodes:**

   On the new node, run the following command:

   ```
   /opt/mapr/server/configure.sh -C nodeA,nodeB,nodeC -Z nodeA,nodeB,nodeC
   ```

2. **Configure a client to work with cluster my.cluster.com, which has one CLDB at nodeA:**

   On a Linux client, run the following command:

   ```
   /opt/mapr/server/configure.sh -N my.cluster.com -c -C nodeA
   ```

   On a Windows 7 client, run the following command:

   ```
   C:\opt\mapr\server\configure.bat -N my.cluster.com -c -C nodeA
   ```

3. **Add a second cluster to the configuration:**

   On a node in the second cluster your.cluster.com, run the following command:

   ```
   /opt/mapr/server/configure.sh -C nodeZ -N your.cluster.com -Z
   <zkNodeA,zkNodeB,zkNodeC>
   ```

4. **Add CLDB servers with multiple IP addresses to a cluster:**

   In this example, the cluster my.cluster.com has CLDB servers at nodeA, nodeB, nodeC, and nodeD. The CLDB servers nodeB and nodeD have two NICs each at *eth0* and *eth1*.

   On a node in the cluster `my.cluster.com`, run the following command:

   ```
   /opt/mapr/server/configure.sh -N my.cluster.com -C
   nodeAeth0,nodeCeth0 -M \
            nodeBeth0,nodeBeth1 -M nodeDeth0,nodeDeth1 -Z zknodeA
   ```

5. **Start a cluster in secure mode using configure.sh**

   In this example, the cluster `my.cluster.com` has two CLDB servers at nodeA and nodeB. The ZooKeeper node for this cluster is at nodeC. To start the cluster in secure mode, run the following command on nodeA:

   ```
   /opt/mapr/server/configure.sh -N my.cluster.com -C nodeA,nodeB -Z
   nodeC -secure \
            -genkeys -F <disklist file>
   ```

   This command creates the `ssl_truststore`, `ssl_keystore`, `maprserverticket`, and `cldb.key` files. Copy these files from nodeA's `/opt/mapr/conf` directory to nodeB's `/opt/mapr/conf` directory.

   On nodeB, change the permissions on the `ssl_keystore`, `maprserverticket`, and `cldb.key` files to 600 (the `mapr` user) by using the following command:

   ```
   chmod 600 ssl_keystore maprserverticket cldb.key
   ```

   On the `ssl_truststore` file, change the permissions to 644 (world readable):

   ```
   chmod 644 ssl_truststore
   ```

   On nodeB, run the following command:

   ```
   /opt/mapr/server/configure.sh -N mycluster.com -C nodeA,nodeB -Z
   nodeC -secure -F \
            <disklist file>
   ```

6. **Configure the Drill storage plugin to communicate with a Hive Metastore:**

   This example uses the `-EC` parameter to configure the Drill storage plugin to communicate with a Hive Metastore located on `nodeA`:

   ```
   /opt/mapr/server/configure.sh -EC '-hiveMetastoreHost nodeA'
   ```

7. **Configure HSM:**

   A sample session transcript using the `/opt/mapr/server/configure.sh` script with DARE enabled is as follows. The portions in **bold** relate to the common HSM features, while the portions in *italics* relate to the DARE-specific features:

```
# /opt/mapr/server/configure.sh  -secure -genkeys -N
test96.cluster.com -C perfnode96.lab:7222 -Z perfnode96.lab:5181 -F
disks.txt -dare -hsm -hsmip 10.10.30.129 -hsmlabel "SafeNet
KeySecure" -hsmsopin 12345678 -hsmclientcert /root/safenet-keysecure/
client.pem -hsmcacert /root/safenet-keysecure/CA.pem -hsmclientkey /root/
safenet-keysecure/key.pem
create /opt/mapr/conf/conf.old

Troubleshooting configure.sh

When you run `configure.sh` with the `-OT` option for the first time, you might encounter an error message such as **directory /opt/mapr/conf/proxy is not owned by root**. You must ignore this transient error

message. If you repeatedly see this error during client operations, then re-run `configure.sh` with the `-R` option.

configure-crosscluster.sh

Use the `configure-crosscluster.sh` utility to set up cross-cluster security between two clusters.

You can use the `configure-crosscluster.sh on page 2065` utility to set up cross-cluster security between two clusters. When you run this utility with the `create` subcommand, it establishes security between the local cluster and a remote cluster. After the setup, communication between the two clusters is bi-directional. You can run this utility on any node in the source cluster to grant secure access to users and servers (for replication, or mirroring) on the destination cluster.

The utility prompts for the passwords for both the local and remote clusters. All hosts on a cluster must have the same password. Alternatively, you can use `ssh` public key authentication between the current node and the other nodes in the local and remote clusters.

Prerequisites

Before running this utility, you must:

- Enable wire-level security for both the local and remote clusters.

  Set `secure=true` in your cluster entry for `/opt/mapr/conf/mapr-clusters.conf`, for both the local and remote clusters.

- Install the `pssh` (Parallel SSH) package from EPEL.

- Install the `expect` package.

If you plan to use a user other than the `mapr` administrative user for mirroring or gateway/streams replication, that user must already exist on both the local and remote clusters.

Syntax

```
/opt/mapr/server/configure-crosscluster.sh create <cross-cluster-type>
    [ -localcrossclusteruser <user> ]
    [ -localhosts <path_to_file> ]
    [ -localport <port_number> ]
    [ -localuser <user> ]
    [ -recover <id> ]
    [ -remotecrossclusteruser <user> ]
    [ -remotehosts <port_number> ]
    -remoteip <ip_address>
    [ -remoteport <port_number> ]
    [ -remoteuser <user> ]
```

Type Parameters

The <cross-cluster-type> parameter specifies the type of entity for which cross-cluster access must be established. The value can be one of the following:

user

Used for direct data access for the given user. When you run the utility with the `user` parameter, it performs the following tasks on both the clusters:

1. Updates the `/opt/mapr/conf/mapr-clusters.conf` file to include the first entry from the `/opt/mapr/conf/mapr-clusters.conf` file on the other cluster.
2. Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.

server

Used for MapR server access such as mirroring and replication. When you run the utility with the `server` parameter, it performs the following tasks on both the clusters:

1. Generates a cross-cluster ticket on this cluster for the other cluster, and copies the ticket to the CLDB node on the other cluster.
2. Merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node on the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all the other CLDB nodes on the other cluster.

all

Used for both user and server access. When you run the utility with the `all` parameter, it performs the following actions on both the clusters:

1. Updates the `/opt/mapr/conf/mapr-clusters.conf` file to include the first entry from the `/opt/mapr/conf/mapr-clusters.conf` file on the other cluster.
2. Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.
3. Generates a cross-cluster ticket for the other cluster, copies the ticket to the CLDB node on the other cluster, merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node in the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all other CLDB nodes on the other cluster.

Options

The configure-crosscluster.sh on page 2065 utility supports the following options:

localcrossclusteruser

Default value: `local user`

This option applies only to the server parameter. Specifies the name of the local cross-cluster user if different from the local user, for mirroring and replication of tables, and streams.

localhosts

Default value: `No Default Value`

Contains the full or relative path to the file containing the list of IP addresses or host names of the hosts to update in the local cluster. Specify one host per line in the file, excluding the current host. If you specify this option, the utility updates the configuration, both on the host on which you are running the utility, and on the other nodes specified in the file. If you do not specify this option, the utility copies both the:

- Updated server security configuration in the `/opt/mapr/conf/maprserverticket` file to only the CLDB nodes in the local cluster.
- Updated user security configuration in the `/opt/mapr/conf/mapr-clusters.conf` file, and the `/opt/mapr/conf/ssl_truststore` file, to all the nodes in the local cluster.

localport

Default value: `22`

Indicates the port to use to connect (using `ssh` or `scp`) to local cluster hosts.

localuser

Default value: `mapr`

Specifies the name of the user for the local cluster.

recover

Default value: `No Default Value`

Defines the option to recover from the failure to copy files to nodes in the local or remote cluster, due to failed cluster nodes. Use the special ID keyword `latest` to run with the contents of the most recent run. See Troubleshooting and Recovery on page 2071 for more information.

remotecrossclusteruser

Default value: `remote user`

This option applies only to the server parameter. Specifies the name of the remote cross-cluster user, if different from the remote user.

remotehosts

Default value: `No Default Value`

Contains the full or relative path to the file containing the list of IP addresses or host names of the hosts to update in the remote cluster. Specify one host per line in the file. If you do not specify this option, the utility copies both the:

- Updated server security configuration in the `/opt/mapr/conf/maprserverticket` file to only the CLDB nodes in the remote cluster.
- Updated user security configuration in the `/opt/mapr/conf/mapr-clusters.conf` file, and the `/opt/mapr/conf/ssl_truststore` file, to all the nodes in the remote cluster.

For example, if you have a file `myhosts.txt` in the current directory with the following contents:

```
10.10.20.100
10.10.20.101
10.10.20.102
```

then, specify `-remotehosts myhosts.txt` for this parameter.

Attention: All hosts specified in this file must be directly reachable from the local hosts from which you run the `configure-crosscluster.sh` on page 2065 utility.

remoteip

Default value: `No Default Value`

This option is mandatory. Specifies the host name or IP address of a host in the remote cluster.

remoteport

Default value: `22`

Indicates the port to use to connect (using `ssh` or `scp`) to remote cluster hosts.

remoteuser

Default value: `local user`

Designates the name of the user for the remote cluster.

Verification

To verify that cross-cluster security is correctly set up, perform one of the following actions:

- If you ran the utility using the cross-cluster type `user` or `all`, and the utility completed successfully, you should be able to run remote commands from the local node after obtaining a user ticket using the `maprlogin` on page 2130 utility. See Configuring Secure Clusters for Running Commands Remotely on page 1484 for more information.
- If you ran the utility using the cross-cluster type `server` or `all`, and the utility completed successfully, you should be able to perform various service operations from the local to the remote cluster and vice versa, including mounting volumes over NFS, mirroring volumes, and replicating tables and streams. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486 for more information.

Sample Session

To configure cross-cluster security, run the utility on a CLDB host with wire-level security enabled, :

```
# /opt/mapr/server/configure-crosscluster.sh create all -remoteip
10.10.30.96
Remote IP is 10.10.30.96
WARNING: Strict host key checking will be disabled for this script.
Local user unset, defaulting to mapr
Remote user unset, defaulting to local user mapr
Enter password for mapr user (mapr) for local cluster:
Enter password for mapr user (mapr) for remote cluster:
Local cross-cluster user unset, defaulting to local user mapr
Remote cross-cluster user unset, defaulting to remote user mapr
Verifying connectivity to 10.10.30.96 and presence of mapr-clusters.conf
MapR credentials of user 'mapr' for cluster 'myCluster.cluster.com' are
written to '/tmp/maprticket_0'
Local host is running the CLDB
```

```
chyelin101.cluster.com secure=true qa-cnode101.lab:7222

Generating cross-cluster ticket for mirroring for user mapr
MapR credentials of user 'mapr' for cluster 'myCluster.cluster.com' are
written to '/tmp/mapr-xcs/29668/local_crosscluster_ticket'
SUCCESS
This script has logged in to both the local and remote clusters. Please log
out of
the clusters if needed.
```

Cleanup

After running the utility, you must perform two cleanup actions:

1. Log out of the local and remote clusters if needed, using the `maprlogin logout` command.
2. Delete the `/tmp/mapr-xcs` directory, if it is present, after verifying that the cross-cluster setup is correct.

   If you run this utility without the `-recover` option, the utility creates temporary files in the `/tmp/mapr-xcs` directory under the current process ID. These directories contain sensitive information such as server tickets that are protected by Unix permissions. The utility preserves these tickets, so that you can perform troubleshooting and recovery actions, as needed. You must delete this directory after verifying that the cross-cluster setup is correct:

   ```
   $ /bin/rm -rf /tmp/mapr-xcs
   ```

Post-Configuration Tasks

After you run this utility, cross-cluster security should be successfully set up between the local and the remote cluster. If you specified either the `user` or `all` cross-cluster type when running the utility, to perform any operations on the remote cluster from the local node, login to the remote cluster to obtain a user ticket using the `maprlogin` `on page 2130` command.

```
$ maprlogin password -cluster <remote-cluster-name>
```

Note: You must obtain a new ticket when your current ticket expires.

Examples of Using the Cross-Cluster Utility

For examples on how to run the `configure-crosscluster.sh` `on page 2065` utility, see Configure-crosscluster.sh Examples on page 2069.

Troubleshooting and Recovery on page 2071

Configure-crosscluster.sh Examples

Demonstrates how to use the `configure-crosscluster.sh` utility.

last-updated: Apr 11, 2022

Example 1

Suppose both the local and remote cluster administrator usernames are `mapr`, and both the local and remote cross-cluster users for mirroring and gateway/streams replication are also `mapr`, specify only the `-remoteip` argument for a fresh run:

```
$ /opt/mapr/server/configure-crosscluster.sh create server -remoteip
10.10.1.1
```

Example 2

Assume that the local MapR administrator username defaults to `mapr`, and the remote MapR administrator username defaults to the local MapR administrator username. Specify different user names for the local and remote MapR administrator using the `-localuser` and `-remoteuser` arguments. For example, if the local MapR administrator username is `admin` and the remote MapR administrator username is `mapr`:

```
$ /opt/mapr/server/configure-crosscluster.sh create server -remoteip
10.10.1.1 -localuser admin -remoteuser mapr
```

Example 3

Assume that the local cross-cluster user defaults to the local MapR administrative user, and the remote cross-cluster user defaults to the remote MapR administrative user. To use a different cross-cluster user for mirroring or gateway/streams replication, specify the `-localcrossclusteruser` and/or `-remotecrossclusteruser` parameters. For example, if the local cross-cluster username is `crosscluster`, run the utility as follows:

```
$ /opt/mapr/server/configure-crosscluster.sh create server -remoteip
10.10.1.1 -localcrossclusteruser crosscluster
```

Example 4

By default, the utility performs `ssh` and `scp` operations between the node where the utility is running and the other nodes in the local and remote clusters, using the default SSH port 22. To use a non-default SSH port, either for the local or remote clusters, specify the port number using the `-localport` or the `-remoteport` option. For example, if the SSH port for the local cluster is 10022, run the utility as follows. The remote SSH port is the default value of 22 if the `-remoteport` argument is not specified:

```
$ /opt/mapr/server/configure-crosscluster.sh create server -remoteip
10.10.1.1 -localport 10022
```

Example 5

By default, the utility runs the `maprcli node list` command on both the local and remote nodes to determine the list of hosts in the local and remote clusters, and updates the configuration for all the nodes in the local and remote clusters. To update the configuration only for a subset of nodes in either the local or remote cluster, such as when you want to update only the CLDB nodes, specify the path to the file containing the list of hosts, one per line, using the `-localhosts` and `-remotehosts` options respectively. For example, to update the configuration for only the local nodes specified in the file `/tmp/local` and the remote nodes specified in the file `/tmp/remote`, run:

```
$ /opt/mapr/server/configure-crosscluster.sh create server -remoteip
10.10.1.1 -localhosts /tmp/local -remotehosts /tmp/remote
```

Example 6

To configure cross-cluster functionality for a user without setting up server cross-cluster functionality, specify `user` as the parameter. This parameter allows users to run commands such as `maprcli node list` using the `-cluster` parameter, and the remote cluster name:

```
$ /opt/mapr/server/configure-crosscluster.sh create user -remoteip 10.10.1.1
```

Example 7

To configure both user and server cross-cluster functionality, specify `all` as the parameter, instead of user or server:

```
$ /opt/mapr/server/configure-crosscluster.sh create all -remoteip 10.10.1.1
```

Example 8

To copy the configuration files from the most recently failed run, use the `-recover` option. To update the configuration for a specified list of local or remote hosts, use the `-recover` option together with the `-localhosts` and `-remotehosts` options.

```
$ /opt/mapr/server/configure-crosscluster.sh create server -remoteip
10.10.1.103 -localuser admin -remoteuser mapr -recover latest -localhosts
local -remotehosts remote
```

See Sample Failure, Troubleshooting, and Recovery Session on page 2075 for more information.

Troubleshooting and Recovery

Typically, the utility succeeds and if the utility fails partially or completely, try the troubleshooting and recovery steps described here.

Completely Failed Runs

A completely failed run indicates that the utility did not set up cross-cluster communication between any of the local or remote nodes. Typical reasons for complete failure include:

- The prerequisites for running thes utility were not met.

  Refer to Prerequisites on page 2065 for running this utility.

- The utility was not run as `mapr` or administrative user.

  The user running the utility must be able to run commands like `maprlogin password`, `maprlogin generateticket`, and `maprcli node list`.

- The `-localuser` option was not specified when there was a non-default username (like `admin`) for the `mapr` user on the local node.

- The `-remoteuser` option was not specified when there was a non-default username (like `admin`) for the `mapr` user on the remote node.

- The username specified in the `-localcrosscluster` option does not exist in the local cluster.

  This utility requires that the username specified in the `-localcrossclusteruser` option to exist before running the utility.

- The username specified in the `-remotecrosscluster` option does not exist in the remote cluster.

  This utility requires that the username specified in the `-remotecrossclusteruser` option to exist before running the utility.

- The wrong password was specified for the local `mapr` user for the local cluster.

  This utility uses commands like `ssh` and `scp` to access other nodes in the local cluster. So, if the public key authentication between the local node and the other nodes in the local cluster is not setup, you must have set a password for the mapr administrative user specified in the `-localuser` argument.

- The wrong password was specified for the remote `mapr` user for the remote cluster.

  This utility uses commands like `ssh` and `scp` to access other nodes in the local cluster. So, if the public key authentication between the local node and the node specified in the `-remoteip` option is not setup, there must be a password for the `mapr` administrative user specified in the `-remoteuser` option.

For completely failed runs, examine the log file in `/opt/mapr/logs/crosscluster.log` and the output of the latest run in `/tmp/mapr-xcs` directory. The `crosscluster.log` looks something like the following:

```
Script started at Fri Sep 29 15:56:33
PDT 2017
Entering recovery mode. Using
cross-cluster directory /tmp/mapr-xcs/
13194
Verifying that pssh is present ... ok

 -o GlobalKnownHostsFile=/dev/null -o
LogLevel=quiet -p 22 mapr@10.10.1.103
ls /
opt/mapr/conf/mapr-clusters.conf
Logging in to local cluster
...
```

Partially Failed Runs

The utility may also report partial success. The utility does not fail due to inability to copy the updated files to the nodes in the local or remote clusters, so the most likely cause of partial failure is improperly configured or failed cluster nodes.

For partially failed runs, examine the contents of the latest run in `/tmp/mapr-xcs` directory in addition to the contents of the `/opt/mapr/logs/crosscluster.log` file.

In the following example, the latest run of the utility is in `/tmp/mapr-xcs/13194`, since this directory has the most recent modification date:

```
[admin@node95 ~]# ls -lt /tmp/mapr-xcs
total 8
drwx------ 14 mapr mapr 4096 Sep 29
15:49 13194
drwx------ 30 mapr mapr 4096 Sep 29
14:44 23802
```

The following is the sample content in `/tmp/mapr-xcs/13194`:

```
[admin@node95 mapr-xcs]# ls -l 13194
total 52

15:56 STATUS
```

Troubleshooting

1. Look at `/tmp/mapr-xcs/<latest>/STATUS`. A non-zero value indicates an overall error.
2. If you encounter a non-zero overall status, look at the `STATUS` files in each of the subdirectories.
3. For the subdirectories reporting a non-zero status, look at the contents of the files in that subdirectory.
4. If there is an error in updating the local cluster hosts, and you did not use the `-localhosts` option when running the script, also look at `/tmp/mapr-xcs/<latest>/localclusterhosts.txt` file.

   The `/tmp/mapr-xcs/<latest>/localclusterhosts.txt` file contains the list of IP addresses of the local cluster hosts, which is the first IP address of each node if there are multiple IP addresses, obtained from the following command:

   ```
   maprcli node list -cluster <local-cluster-name> -columns hostname
   ```

   Verify the contents of the file to ensure that the list of local cluster hosts is correct. The original output of the above command is in `/tmp/mapr-xcs/<latest>/localclusterhosts_full.txt`, and you should also check the output to ensure that the list is correct. Otherwise, fix the errors and re-run the script with the `-localhosts` option.

5. If there is an error in updating the remote cluster hosts, and you did not use the `-remotehosts` option when running the script, you should also look at `/tmp/mapr-xcs/<latest>/remoteclusterhosts.txt` file.

   The `/tmp/mapr-xcs/<latest>/remoteclusterhosts.txt` file contains the list of IP addresses of remote cluster hosts, which is the first IP address of each node if there are multiple IP addresses, obtained from the following command:

   ```
   ssh <remoteuser>@<remote-ip> maprcli node list -cluster
   <remote-cluster-name> -columns hostname
   ```

   Verify the contents of the file to ensure that the list of remote cluster hosts is correct. The original output of the above command is in `/tmp/mapr-xcs/<latest>/remoteclusterhosts_full.txt`, and you should also check the output to ensure that the list is correct. Otherwise, fix the errors and re-run the script with the `-remotehosts` option.

6. If you have an error copying to some or all of the local or remote cluster hosts, try doing an `ssh` to the local or remote cluster host (respectively) to ensure that it is accessible using the supplied username and password. If this fails, the copy operation in the script will also fail, since it relies on either public key authentication or username/password authentication to access the nodes. Specify the correct username and/or password and then re-run the script.

Sample Failure, Troubleshooting, and Recovery Session

Suppose the utility is run where one of the nodes in the local cluster (10.10.30.96) has a password that is different from other local cluster nodes, causing the `ssh` and `scp` commands to this node to fail.

1. Run the utility on the local node (10.10.30.95).

   The highlighted text below are the warning messages. The utility continues to run, despite the warnings, to update the cross-cluster configuration on as many nodes as possible:

```
[admin@node95 cross-cluster]$ /opt/mapr/server/configure-crosscluster.sh
create server -remoteip 10.10.1.103 -localuser admin -remoteuser mapr
Remote IP is 10.10.1.103
WARNING: Strict host key checking will be disabled for this script.
Enter password for mapr user (admin) for local cluster:
Enter password for mapr user (mapr) for remote cluster:
Local cross-cluster user unset, defaulting to local user admin
Remote cross-cluster user unset, defaulting to remote user mapr
Verifying connectivity to 10.10.1.103 and presence of mapr-clusters.conf
MapR credentials of user 'admin' for cluster 'node95.cluster.com' are
written to '/tmp/maprticket_0'
node95.cluster.com secure=true node95.perf.lab:7222
WARNING: Copying local /opt/mapr/conf/mapr-clusters.conf to all hosts in
local cluster complete, but the operation failed for at least one node
in the cluster.
For details, look at the output directory /tmp/mapr-xcs/
14043/lpscp_clusterhosts_odir or error directory /tmp/mapr-xcs/14043/
lpscp_clusterhosts_edir.
Configuring cross-cluster communication for server-side operations
Generating cross-cluster ticket for user mapr on remote node
WARNING: Changing permissions of local maprserverticket complete, but
the operation failed for at least one node in the cluster.
For details, look at the output directory /tmp/mapr-xcs/
14043/lpssh_server_odir or error directory /tmp/mapr-xcs/14043/
lpssh_server_edir
WARNING: Cannot change permissions for local MapR server ticket for at
least 1 node
WARNING: Copy local maprserverticket to all hosts in local cluster
complete, but the operation failed for at least one node in the cluster.
For details, look at the output directory /tmp/mapr-xcs/
14043/lpscp_server_odir or error directory /tmp/mapr-xcs/14043/
lpscp_server_edir.
WARNING: Cannot copy local MapR server ticket for at least 1 node
Generating cross-cluster ticket for mirroring for user admin
MapR credentials of user 'admin' for cluster 'node95.cluster.com' are
written to '/tmp/mapr-xcs/14043/local_crosscluster_ticket'
An error has been encountered in configuring cross-cluster communication.
For more information, refer to the log file at /opt/mapr/logs/
crosscluster.log.
If the error is caused by non-functioning local and remote cluster
nodes, more information on the precise errors can be found in /tmp/
mapr-xcs/14043. The list of local cluster hosts is in /tmp/mapr-xcs/
14043/localclusterhosts.txt, and the list of remote cluster hosts is
in /tmp/mapr-xcs/14043/remoteclusterhosts.txt.
In such cases, you can normally fix the error by editing the list
of local and/or remote cluster hosts file and then re-run the script
using the -r option, specifying the local or remote hosts file in
the -localhosts or -remotehosts option respectively.
This script has logged in to both the local and remote clusters. Please
log out of the clusters if needed.
```

2. Look at the specified directory, `/tmp/mapr-xcs/14043`, because the utility resulted in an error.

   The overall status is 1 (indicating an error) as shown in bold below:

```
$ cat /tmp/mapr-xcs/14043/STATUS
1
```

3. Look at the STATUS files in each of the subdirectories to determine the content reporting error.

   Content has non-zero status as shown in bold below:

```
[admin@node95 14043]$ find /tmp/mapr-xcs/14043 -print | grep STATUS |
xargs more
::::::::::::::
./rpscp_clusterhosts_edir/STATUS
::::::::::::::
0
::::::::::::::
./lpscp_clusterhosts_edir/STATUS
::::::::::::::
1               ←FAIL
::::::::::::::
./lpssh_server_edir/STATUS
::::::::::::::
1               ←FAIL
::::::::::::::
./lpscp_server_edir/STATUS
::::::::::::::
1               ←FAIL
::::::::::::::
./rpssh_server_edir/STATUS
::::::::::::::
0
::::::::::::::
./rpscp_server_edir/STATUS
::::::::::::::
0
::::::::::::::
./STATUS
::::::::::::::
1               ←Overall status is FAIL
```

4. Look at each of the files in the subdirectories reporting a non-zero status, for example, `lpscp_clusterhosts_edir`.

   The error “lost connection” for 10.10.30.96 indicates that the local node 10.10.30.95 could not run the `scp` command to that node:

```
[admin@node95 14043]$ more lpscp_clusterhosts_edir/*
::::::::::::::
lpscp_clusterhosts_edir/10.10.30.95
::::::::::::::
::::::::::::::
lpscp_clusterhosts_edir/10.10.30.96
::::::::::::::
lost connection
::::::::::::::
lpscp_clusterhosts_edir/STATUS
::::::::::::::
1
```

5. Try to `ssh` to that node (10.10.30.96), using the same local password used for running the utility.

   The `ssh` (and therefore also `scp`) command fails:

```
[admin@node95 14043]$ ssh admin@10.10.30.96 ls
Password:
Password:
Password:
admin@10.10.30.96's password:
Permission denied, please try again.
admin@10.10.30.96's password:
Received disconnect from 10.10.30.96: 2: Too many authentication
failures for admin
```

6. Run the utility again.

   The utility detects that the previous run did not complete successfully and prompts you to run the utility with the recovery option. It also detects the directories that contain the detailed error information as shown below:

```
[admin@node95 cross-cluster]$ /opt/mapr/server/configure-crosscluster.sh
create server -remoteip 10.10.1.103 -localuser admin -remoteuser mapr
Remote IP is 10.10.1.103
WARNING: Strict host key checking will be disabled for this script.
The previous run of this script with ID 14043 did not complete
successfully. Examine the error directories in /tmp/mapr-xcs/14043
for details of the error:
/tmp/mapr-xcs/14043/lpscp_clusterhosts_edir
/tmp/mapr-xcs/14043/lpscp_server_edir
/tmp/mapr-xcs/14043/lpssh_server_edir
If the failure is down to partially failed nodes, you should exit now,
and re-run this script in recovery mode using the -recover option to
copy the configured tickets and files to the remaining nodes, instead of
continuing and generating new tickets.
Exit now? Enter y to exit, or n to continue: y

Exiting. Re-run this script with the -recover option.
```

7. Fix the error (in this example, by setting/changing the password for 10.10.30.96), and run the utility again with the `-recover` option to update the configuration for the previously failed operation for the local cluster node.

   To copy the configuration again to all the nodes in the local and remote clusters, run the utility without the `-localhosts` and `-remotehosts` option. To rerun the utility to update the configuration for the failed nodes only, specify the IP addresses of the failed nodes only.

   

   Note: Specify at least one node in the `-localhosts` and `-remotehosts` option. You can use hostnames instead of IP addresses, as long as you ensure that DNS is working properly between the local node you are running the utility on, and the nodes you specify in the `-localhosts` and `-remotehosts` options.

   The output of the recovery session is shown below. Note that the utility returned a SUCCESS result:

```
[admin@node95 cross-cluster]$ cat local
10.10.30.96
[admin@node95 cross-cluster]$ cat remote
10.10.1.101
[admin@node95 cross-cluster]$ /opt/mapr/server/configure-crosscluster.sh
create server -remoteip 10.10.1.103 -localuser admin -remoteuser
mapr -recover latest -localhosts local -remotehosts remote
Remote IP is 10.10.1.103
WARNING: Strict host key checking will be disabled for this script.

This script has logged in to both the local and remote clusters. Please
log out of the clusters if needed.
```

Multiple Runs of the Utility

When running the utility with the `all` or `user` argument, you may see the following error if you run the utility multiple times:

```
keytool error: java.lang.Exception: Certificate not imported, alias
<remote.cluster.com> already exists
ERROR: Unable to import remote cluster certificate from /tmp/mapr-xcs/17056/
remote_mapcert into local SSL trust store
Please delete the certificate with the same alias remote.cluster.com from
the truststore first
```

Certificates with the same alias should be imported to the trust store only once. If you are able to run commands like `maprcli volume mount` on the remote cluster from the local cluster, you can ignore this error. If you really want to re-import the remote cluster certificate into the trust store, contact MapR support.

Also, note that when you run the utility multiple times, there are at least 2 entries with the same alias in `/opt/mapr/conf/maprserverticket` file. The utility generates a new cross-cluster ticket (useful for volume mirroring and table and streams replication) every time it is run, and does not delete any tickets in `/opt/mapr/conf/maprserverticket` file. Service tickets have a long lifetime, so this can be ignored if you are able to successfully perform volume mirroring, and table and streams replication operations. However, if you want to clean up the tickets, you can do the following:

1. Delete all the tickets with the remote cluster alias in the `/opt/mapr/conf/maprserverticket` file on the local node.
2. Delete all the tickets with the local cluster alias in the `/opt/mapr/conf/maprserverticket` file on the remote node referenced in the `-remoteip` parameter.
3. Re-run the utility with the `server` argument to set up the service tickets again.

cldbguts
Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

Monitoring the progress of the *container location database (CLDB)* may be useful when troubleshooting cluster issues.

The `cldbguts` utility prints information about active container reports, full container reports, registration requests, MapR filesystem heartbeats, NFS server heartbeats, and containers. You can run `cldbguts` from any *container location database (CLDB)* node; however, running this command from the *container location database (CLDB)* master node provides the most relevant information.

Note: After you run `cldbguts`, it continues to print the output until you kill the process. To prevent `cldbguts` from printing indefinitely, specify the `-n` parameter that denotes the number of times `cldbguts` should print the output.

Syntax:

```
/opt/mapr/bin/cldbguts [[acr | rpc | heartbeat | containers | alarms |
table | all] [-n iterations-count]
```

Output Fields:

Note: When you run `cldbguts` without any parameters, only the `fcr`, `clrpc`, `regn`, `mfs hb`, `nfs hb`, `assigns`, `roles`, `progress`, and the `con-chain` fields are displayed.

acr	Represents active container requests (ACR). This column includes the following information: • `nr`: Number of ACRs completed in the previous second. The first entry displays the total number of ACRs completed since the start of the CLDB service on the node.

- `pt`: Processing time (in milliseconds) for the ACRs completed in the previous second. The first entry displays the total time (in milliseconds) spent processing the ACRs since the start of the CLDB service on the node.
- `to`: Number of ACRs that took longer than expected in the previous second. The first entry displays the total number of ACRs that took longer than expected since the start of the CLDB service on the node.
- `d`: Number of duplicate ACRs received in the previous second. The first entry displays the total number of duplicate ACRs since the start of the CLDB service on the node.
- `dp`: Number of duplicate ACRs that required additional work in the previous second. The first entry displays the total number of duplicate ACRs that required additional work since the start of the CLDB service on the node.

fcr

Represents full container report (FCR).

This column includes the following information:

- `nr`: Number of FCRs completed in the previous second. The first entry displays the total number of FCRs completed since the start of the CLDB service on the node.
- `pt`: Processing time (in milliseconds) for the FCRs completed in the previous second. The first entry displays the total time (in milliseconds) spent processing the FCRs since the start of the CLDB service on the node.
- `to`: Number of FCRs that took longer than expected in the previous second. The first entry displays the total number of FCRs that took longer than expected since the start of the CLDB service on the node.

regn

Represents registration requests.

This column includes the following information:

- `nr`: Number of registration requests completed in the previous second. The first entry displays the total number of registration requests completed since the start of the CLDB service on the node.
- `pt`: Processing time (in milliseconds) for the registration requests completed in the previous second. The first entry displays the total time (in milliseconds) spent processing the registration requests since the start of the CLDB service on the node.

last-updated: Apr 11, 2022

- `to`: Number of registration requests that took longer than expected in the previous second. The first entry displays the total number of registration requests that took longer than expected since the start of the CLDB service on the node.
- `d`: Number of duplicate registration requests received in the previous second. The first entry displays the total number of duplicate registration requests since the start of the CLDB service on the node.
- `dp`: Number of duplicate registration requests that required additional work in the previous second. The first entry displays the total number of duplicate registration requests that required additional work since the start of the CLDB service on the node.

mfs hb

Information about MapR filesystem heartbeats.

This column includes the following information:

- `nr`: Number of MapR filesystem heartbeats completed in the previous second. The first entry displays total number of MapR filesystem heartbeats completed since the start of the CLDB service on the node.
- `pt`: Processing time (in microseconds) for the MapR filesystem heartbeats completed in the previous second. The first entry displays total time (in microseconds) spent processing MapR filesystem heartbeats since the start of the CLDB service on the node.
- `to`: Number of MapR filesystem heartbeats that took longer than expected in the previous second. The first entry displays total number of MapR filesystem heartbeats that took longer than expected since the start of the CLDB service on the node.
- `bmc`: Number of times the Become Master Command (`bmc`) has been sent to this MFS.
- `otc`: Number of times the other commands (apart from `bmc`) has been sent to this MFS.

nfs hb

Information about NFS server heartbeats.

This column includes the following information:

- `nr`: Number of NFS server heartbeats completed in the previous second. The first entry displays total number of NFS server heartbeats completed since the start of the CLDB service on the node.
- `pt`: Processing time (in microseconds) for the NFS server heartbeats completed in the previous second. The first entry displays the total time (in microseconds) spent processing MapR filesystem heartbeats since the start of the CLDB service on the node.

last-updated: Apr 11, 2022

assigns

This column includes the following information:

- `nr`: Number of container assign requests in the previous second. The first entry displays the total number of container assign requests since the start of the CLDB service on the node.
- `nc`: Number of containers created as part of the above container assign requests in the previous second. The first entry displays the total number of containers created since the start of the CLDB service on the node.
- `nrt`: Number of container assign requests for tablets in the previous second. The first entry displays the total number of container assign requests for tablets since the start of the CLDB service on the node.
- `nct`: Number of containers created as part of the above container assign requests for tablets in the previous second. The first entry displays the total number of container created in tablets since the start of the CLDB service on the node.
- `pt`: Time taken by container assignment RPC in milliseconds
- `tpt`: Time taken by container assignment tablet RPC in milliseconds
- `cas`: Number of storage pools scanned for container assignment requests

roles

Represents the roles of the various replica containers.

This column includes the following information:

- `bm`: Number of replica containers that are in the process of becoming master
- `ms`: Number of replica containers that the CLDB thinks have valid masters
- `wr`: Number of replica containers that are waiting for CLDB to assign a role to them
- `rs`: Number of replica containers that are re-syncing
- `vr`: Number of non-master replica containers that have finished resynchronization
- `uu`: Number of replica containers that are unused. For example, the number of replica containers that are on nodes or storage pools which have been offline or unavailable for more than an hour.

Attention: It may take some time for the CLDB to be aware of role changes.

progress

This column includes the following information:

last-updated: Apr 11, 2022

	• `m%`: Percentage of containers that have valid masters • `uc`: Number of unique containers • `v%`: Percentage of replica containers that are valid (that is, have completed resynchronization) • `tr`: Total number of replica containers
con-chain	This column includes the following information: • `ms`: Number of unique containers that have a master • `1r`: Number of unique containers that have 2 valid copies of the data • `2r`: Number of unique containers that have 3 valid copies of the data
location	This column includes the following information: • `lu`: Number of container location lookups • `up`: Number of container location updates • `dl`: Number of container location deletes • `sc`: Number of container location scans
size	This column includes the following information: • `lu`: Number of container size lookups • `up`: Number of container size updates • `dl`: Number of container size deletes • `sc`: Number of container size scans
sptable	This column includes the following information: • `lu`: Number of lookups on the SP-Container-Vol table • `up`: Number of updates on the SP-Container-Vol table • `dl`: Number of deletes on the SP-Container-Vol table • `sc`: Number of scans on the SP-Container-Vol table
nodes	This column includes the following information: • `nn`: Number of nodes in the cluster • `of`: Number of offline nodes

- `nsp`: Number of storage pools
- `of`: Number of offline storage pools

Example Output:

```
/opt/mapr/bin/cldbguts all  -n 3

Retrieving Tiering Statistics Using guts on page 943
Explains how to use the `guts` utility to retrieve tiering statistics.

guts on page 2110
`guts` is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. `guts` is an internal utility, and is subject to change without notice.

cldbguts acr

The `acr` option displays active container requests (ACR).

Syntax

```
/opt/mapr/bin/cldbguts acr
```

Output Fields

Field	Description
`nr`	Number of ACRs completed in the previous 1 second. The first entry displays the total number of ACRs completed since the start of the CLDB service on the node.
`pt`	Processing time (in milliseconds) for the ACRs completed in the previous 1 second. The first entry displays the total time (in milliseconds) spent processing the ACRs since the start of the CLDB service on the node.

last-updated: Apr 11, 2022

Field	Description
to	Number of ACRs that took longer than expected in the previous 1 second. The first entry displays the total number of ACRs that took longer than expected since start of the CLDB service on the node.
d	Number of duplicate ACRs received in the previous 1 second.The first entry displays the total number of duplicate ACRs since start of the CLDB service on the node.
dp	Number of duplicate ACRs that required additional work in the previous 1 second. The first entry displays the total number of duplicate ACRs that required additional work since start of the CLDB service on the node.

Example Output

```
# /opt/mapr/bin/cldbguts acr
2017-09-01 15:15:25,034
             acr
    nr      pt   to  d  dp
  269644  63338   0  0   0
     1      0     0  0   0
     0      0     0  0   0
```

cldbguts containers

The `containers` option displays information on the containers.

Syntax

```
/opt/mapr/bin/cldbguts containers
```

Output Fields

assigns

This column includes the following information:

Field	Description
nr	Number of ContainerAssign requests in the previous 1 second. The first entry displays the total number of ContainerAssign requests since the start of the CLDB service on the node.
nc	Number of containers created as part of the above ContainerAssign requests in the previous 1 second. The first entry displays the total number of containers created since the start of the CLDB service on the node.

Field	Description
nrt	Number of ContainerAssign requests for tablets in the previous 1 second. The first entry displays total number of ContainerAssign requests for tablets since the start of the CLDB service on the node.
nct	Number of containers created as part of the above ContainerAssign requests for tablets in previous 1 second. The first entry displays the total number of container created in tablets since the start of the CLDB service on the node.

roles

Represents the roles of the various replica containers. This column includes the following information:

Field	Description
bm	Number of replica containers that are in the process of becoming master
ms	Number of replica containers that the CLDB thinks have valid masters
wr	Number of replica containers that are waiting for CLDB to assign a role to them
rs	Number of replica containers that are re-syncing
vr	Number of non-master replica containers that have finished resynchronization
uu	Number of replica containers that are unused. For example, the number of replica containers that are on nodes or storage pools which have been offline or unavailable for more than an hour.

Attention: It may take some time for the CLDB to be aware of any role changes.

progress

This column includes the following information:

last-updated: Apr 11, 2022

Field	Description
m%	Percentage of containers that have valid masters
uc	Number of unique containers
v%	Percentage of master + replica containers that are valid container copies
tr	Total number of replica containers

con-chain

This column includes the following information:

Field	Description
ms	Number of unique containers that have a master
1r	Number of unique containers that have 2 valid copies of the data
2r	Number of unique containers that have 3 valid copies of the data

Example Output

```
# /opt/mapr/bin/cldbguts containers

2019-10-03 03:05:15,846

```

cldbguts heartbeat

The `heartbeat` option displays information on the heartbeat sent by the MapR File System and NFS.

Syntax

```
/opt/mapr/bin/cldbguts heartbeat
```

Output Fields

mfs hb

Information about MapR filesystem heartbeats. This column includes the following information:

Field	Description
nr	Number of MapR filesystem heartbeats completed in the previous 1 second. The first entry displays the total number of MapR filesystem heartbeats completed since the start of the CLDB service on the node.
pt	Processing time (in microseconds) for the MapR filesystem heartbeats completed in the previous 1 second. The first entry displays total time (in microseconds) spent processing MapR filesystem heartbeats since the start of the CLDB service on the node.
to	Number of MapR filesystem heartbeats that took longer than expected in the previous 1 second. The first entry displays total number of MapR filesystem heartbeats that took longer than expected since the start of the CLDB service on the node.
bmc	Number of Become Master commands (such as resync, reconnect, etc.) sent by CLDB since the start of CLDB.

nfs hb

Information about NFS server heartbeats. This column includes the following information:

Field	Description
nr	Number of NFS server heartbeats completed in the previous 1 second. The first entry displays total number of NFS server heartbeats completed since the start of the CLDB service on the node.

last-updated: Apr 11, 2022

Field	Description
pt	Processing time (in microseconds) for the NFS server heartbeats completed in the previous 1 second.The first entry displays the total time (in microseconds) spent processing MapR filesystem heartbeats since the start of the CLDB service on the node.

Example Output

```
# /opt/mapr/bin/cldbguts heartbeat

2019-10-03 03:14:56,811
         mfs hb           nfs hb

   0   0   0   0    0     0   0
   0   0   0   0    0     0   0
   0   0   0   0    0     0   0
```

cldbguts rpc

The `rpc` option returns a count of the RPCs that CLDB is processing from clients.

Syntax

```
/opt/mapr/bin/cldbguts rpc
```

Output Fields

clrpc

Represents a count of the client RPCs per second. This count includes:

1. ClusterInfoProc
2. ContainerLookupProc
3. ContainerRootLookupProc

This column includes the following information:

Field	Description
nr	Number of Client RPC's completed in the previous 1 second. The first entry displays total number of client RPCs completed since the start of the CLDB service on the node.

Field	Description
pt	Processing time (in milliseconds) for the Client RPCs completed in the previous 1 second. The first entry displays total time (in milliseconds) spent processing the client RPCs since the start of the CLDB service on the node.
to	Number of Client RPCs that took longer than expected in the previous 1 second. The first entry displays the total number of client RPCs that took longer than expected since the start of the CLDB service on the node.

fcr

Represents full container report (FCR). This column includes the following information:

Field	Description
nr	Number of FCRs completed in the previous 1 second. The first entry displays total number of FCRs completed since the start of the CLDB service on the node.
pt	Processing time (in milliseconds) for the FCRs completed in the previous 1 second. The first entry displays total time (in milliseconds) spent processing the FCRs since the start of the CLDB service on the node.
to	Number of FCRs that took longer than expected in the previous 1 second. The first entry displays the total number of FCRs that took longer than expected since the start of the CLDB service on the node.

regn

Represents registration requests. This column includes the following information:

last-updated: Apr 11, 2022

Field	Description
nr	Number of registration requests completed in the previous 1 second. The first entry displays total number of registration requests completed since the start of the CLDB service on the node.
pt	Processing time (in milliseconds) for the registration requests completed in the previous 1 second. The first entry displays the total time (in milliseconds) spent processing the registration requests since the start of the CLDB service on the node.
to	Number of registration requests that took longer than expected in the previous 1 second. The first entry displays total number of registration requests that took longer than expected since the start of the CLDB service on the node.

Example Output

```
# /opt/mapr/bin/cldbguts rpc

2019-10-03 03:17:48,863
      fcr             clrpc            regn
  nr  pt  to      nr     pt   to    nr  pt  to
   0   0   0   16116  74239   0     0   0   0
   0   0   0       0      0   0     0   0   0
   0   0   0       0      0   0     0   0   0
```

disksetup
Describes the `disksetup` command that formats disks for use by MapR storage.

Description

Note: The `disksetup` command must be run as `root`.

The `disksetup` command formats specified disks for use by MapR storage, and adds those disks to the disktab file.

You do not need to set up Redundant Array of Independent Disks (RAID) on disks used by the MapR File System. MapR uses `disksetup` to set up storage pools. In most cases, you should let MapR calculate storage pools using the default *stripe width* of two or three disks. If you anticipate a high volume of random-access I/O, you can use the `-W` option to specify larger storage pools of up to 8 disks each.

See Setting Up Disks for MapR for more information about when and how to use `disksetup`.

Important: On RHEL 8.1, run the following command to symlink `/usr/bin/python` to `/usr/bin/python3`. The disksetup command fails if `/usr/bin/python` is not found.

```
sudo alternatives --set python /usr/bin/python3
```

Syntax

```
/opt/mapr/server/disksetup
    [-F]
    [-G]
    [-X]
    [-M]
    [-W <stripe_width>]
    <disk list file>
```

Options

Option	Description
`-F`	Forces formatting of all specified disks. Disks that are already formatted for MapR are not reformatted by `disksetup` unless you specify this option. The `-F` option fails when a filesystem has an entry in the `disktab` file, is mounted, or is in use. Call `maprcli disk remove` to remove a disk entry from the `disktab` file.
`-G`	Generates the `disktab` file contents from input disk list, but does not format disks. Use this option if the `disktab` file is completely lost, and you need to regenerate it based on an input list of disks assigned to MapR-FS. This option reads the GUID from the provided disks, and generates the `disktab` output to stdout. You can redirect the output to a file.
`-X`	Fixes `disktab` contents from `/proc/partitions`, but does not format disks. Use this option if there is a change in the names of the disk devices referenced by `disktab`, but the disks themselves are still usable. For example, if `/dev/sdb` has been renamed to `/dev/sdf` but the device itself has the same GUID, only the `disktab` contents need to be updated to point to `/dev/sdf`.
`-M`	Uses the maximum available number of disks per storage pool.
`-W`	Specifies the number of disks per storage pool.

Examples

Setting up disks specified in the file /tmp/disks.txt:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Reformatting all disks

To reformat all disks, remove the `disktab` file and issue the `disksetup -F` command to format the disk:

```
/opt/mapr/server/disksetup -F
```

last-updated: Apr 11, 2022

To reformat a particular disk from the `disktab`, use the `maprcli disk remove` on page 1608 and `maprcli disk add` on page 1602 commands. For more information, see Setting Up Disks for MapR on page 835.

Specifying disks

To specify the disks to be formatted for use by the MapR cluster, create a text file `/tmp/disks.txt` listing the disks and partitions for use by MapR on the node. Each line lists either a single disk, or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run `disksetup` to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Important:

The `disksetup` command removes all data from the specified disks. Ensure that you specify the disks correctly, and that you have backed up any data that you wish to keep.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

Warning: Run `disksetup` on page 2092 only after you run the `configure.sh` on page 2053 .

Test Purposes Only: Using a Flat File for Storage

When setting up a small cluster for evaluation purposes, if a particular node does not have physical disks or partitions available to dedicate to the cluster, you can use a flat file on an existing disk partition as the node's storage. Create at least a 16GB file, and include a path to the file in the disk list file for the `disksetup` on page 2092 script.

The following example creates a 20 GB flat file (`bs=1G` specifies 1 gigabyte blocks, multiplied by `count=20`) at `/root/storagefile`:

```
dd if=/dev/zero of=/root/storagefile bs=1G count=20
```

Next, add the following entry to the disk list file `/tmp/disks.txt` to be used by `disksetup`:

```
/root/storagefile
```

ectool

Dumps or checks the validity of the stripelets in the backend volume that is associated with the volume configured for warm tiering.

You can use the `/opt/mapr/server/tools/ectool` utility to dump or check the validity of the stripelets in the backend volume that is associated with the volume configured for warm tiering.

Pre-Requirements

Before you run the utility, you must ensure that the node on which you plan to run this utility meets the following requirements:

- Set the path to the library (`libjvm.so`) in the `LD_LIBRARY_PATH` environment variable. If the path is not already set, use the `export` command to set the environment variable. For example:

```
export LD_LIBRARY_PATH=/opt/jdk1.8.0_141/jre/lib/amd64/server/
```

Syntax

```
/opt/mapr/server/tools/ectool <cmd> <params>
```

Commands

Command	Description
`dumpStripelet`	Dumps the content of a stripelet to the given file.
`listStripes`	Lists all the stripes in a given container.
`validateStripe`	Validates if the given parity stripelet is valid and matches with other stripelets of the stripe.
`validateCG`	Iterates over all the stripes of the Container Group and checks the validity using the rebuild operation.
`getFid`	Returns the fid for a Virtual Cluster Descriptor (VCD) ID.

Parameters

Parameter	Description
`cid`	The ID of the container.
`fid`	The ID of the file.
`file`	The path to the file.

`volid`	The ID of the (backend) volume, referred to as `ecstorevolume` in the CLI output, associated with the tier. The ID can be retrieved using the `volume info` on page 1965 command. For example:
	`/opt/mapr/bin/maprcli volume info -name a4 -json | grep ecstorevolume`
	`"ecstorevolume":"mapr.internal.ec.a4.87379483",`
	`/opt/mapr/bin/maprcli volume info -name mapr.internal.ec.a4.87379483 -json | grep volumeid`
	`"volumeid":105118862,`

vcdid	The ID of the Virtual Cluster Descriptor (VCD).

Usage

```
/opt/mapr/server/tools/ectool dumpStripelet volid fid file
/opt/mapr/server/tools/ectool listStripes volid cid
/opt/mapr/server/tools/ectool validateStripe volid fid
/opt/mapr/server/tools/ectool validateCG volid cid
/opt/mapr/server/tools/ectool getFid cid vcdid
```

last-updated: Apr 11, 2022

Examples

Dump the stripelet content to the file `/tmp/t` for the file specified by ID 2271.160.131606 in the volume specified by ID 116581327:

```
# /opt/mapr/server/tools/ectool dump 116581327 2271.160.131606 /tmp/t
Stripelet Read done!
```

List all the stripes in the container specified by ID 2271 for the volume specified by ID 116581327:

```
# /opt/mapr/server/tools/ectool list 116581327 2271
Inum:160 Uniq:131606 Size:4194304
Inum:161 Uniq:131608 Size:4194304
Inum:162 Uniq:131610 Size:4194304
```

Validates if the given stripelet matches with other stripelets of the stripe for the file specified by ID 2271.160.131606 in the volume specified by ID 116581327

```
# /opt/mapr/server/tools/ectool validateStripe 116581327 2271.160.131606
Valid Stripe
```

For the container specified by ID 2271, validate if all stripelets match with other stripelets of the corresponding stripe:

```
# /opt/mapr/server/tools/ectool validateCG 116581327 2271
Inum:160 Valid Stripe
Inum:161 Valid Stripe
Inum:162 Valid Stripe
```

expandaudit

Describes how to use the `expandaudit` utility to expand IDs captured in the audit logs to their corresponding names.

As you perform operations on the directories, files, and tables that you are auditing, the audit logs capture records of those operations. Those records identify the affected directories, files, and tables by means of file IDs, the volumes on which the operations took place by means of volume identifiers, and the users who performed the operations by means of user IDs. These IDs are used instead of names in the audit records because fetching the actual names of these objects and users in real-time is costly in terms of performance.

You can use the `expandaudit` utility to create copies of your logs files in which the IDs are resolved into names and inserted into the audit records.

This utility acts on audit logs that exist in the current MapR cluster at the time that the utility is run.

Restrictions

This utility operates on audit logs for filesystem operations and MapR Database operations, which are logged in a local MapR volume on each node where the operations are performed. These operations are logged in `FSAudit` and `DBAudit` log files.

File identifiers are converted to names only when either of the following conditions is met:

- The file exists at the time that `expandaudit` is run.
- The file has been deleted but the deletion of the file was logged and the log files being processed by `expandaudit` include the record of the file deletion.

If a volume is deleted, `expandaudit` does not convert identifiers for files that were in the volume unless the creation of the volume and files were logged.

If the creation of a file is audited and the file is later renamed, the file ID is converted to the current name.

Permissions

Although the permissions on the tool are `755`, the tool generates output only when run by `root` or the user `mapr`.

Syntax

```
/opt/mapr/bin/expandaudit
    [-volumename volume name]
    [-volumeid volume ids. Either volume name or id must be specified]
    -o output directory
    [-d Specify for deleted volumes only]
    [-cluster cluster name]
    [-t number of threads used for parallel expansion across cluster nodes.
default 10]
```

Parameters

Parameter	Description
`cluster`	The name of the cluster on which to run the command.
`d`	Required for deleted volumes as it indicates that the volume is deleted. If you specify this parameter, you must specify a volume ID to be used during expansion. The deleted volume is tracked by the specified volume ID. You can optionally specify a volume name. This specified volume name is used for the expanded output.
`o`	The directory in the MapR filesystem in which to create the copies of the audit logs. The directory must already exist. The directory structure is: `<output directory>/<volume id>/<node>/<day>/<expanded audit log files>` The file names are the same as the names of the input files, though you might see the following extensions: • `.part`: If present, this extension is on the log file with the most recent date. The input log file that corresponds to this output file might still have been receiving new audit records at the time that the `expandaudit` utility was run. If the utility is run again with the same output directory, the utility will update the .`part` file by including the most recent records and converting the identifiers in those records. • `.pending`: This extension indicates files that contain one or more identifiers that the utility could not convert. **Note:** Sometimes, you might see a combination of these two types of files, `part.pending`, which indicates that there is a problem converting identifiers in the most recent audit file.
`t`	The number of threads to use for parallel expansion across cluster nodes. The default value is 10.

last-updated: Apr 11, 2022

Parameter	Description
`volumename`	The name of the volume being audited. You must specify either the `volumename` or the `volumeid` parameter.
`volumeid`	The ID of the volume being audited. You must specify either the `volumename` or the `volumeid` parameter.

Sample Expansion of a Record for Filesystem Operations

Original record

```
{"timestamp":
{"$date":"2015-06-06T13:02:23.746Z"},"operation":"GETATTR","uid":"1","ipAddr
ess":
"10.10.104.53","srcFid":"2049.652.263696","volumeId":68048396,"status":0}
```

Record processed by the expandaudit utility

```
{"timestamp":
{"$date":"2015-06-06T13:02:23.746Z"},"operation":"GETATTR","user":
"userA","uid":"1","ipAddress":"10.10.104.53","srcPath":"/customers/
US_Western_Region.json",
"srcFid":"2049.3296.268968","volumeName":"data_analysis","volumeId":68048396
,"status":0}
```

Attention: Here, `uid` expands to `user`, `srcFid` expands to `srcPath`, and `volumeID` expands to `volumeName`. The original fields are also preserved in the output.

Sample Expansion of a Record for MapR Database Table Operations

Original record

```
{"timestamp":
{"$date":"2015-06-06T13:08:54.474Z"},"operation":"DB_PUT","uid":"1","ipAddre
ss":
"10.10.104.51","volumeId":68048396,"columnFamily":"fam63","columnQualifier":
"col_96","tableFid":
"2049.56.262518","status":0}
```

Record processed by the expandaudit utility

```
{"timestamp":"{$date=2015-06-06T13:08:54.474Z}","operation":"DB_PUT","user":
"userA","uid":
"1","ipAddress":"10.10.104.51","volumeName":"mapr.cluster.root","volumeId":"
68048396",
"columnFamily":"fam63","columnQualifier":"col_96","tablePath":"/
mytable","tableFid":"2049.56.262518",
"status":"0"}
```

Attention: Here, `uid` expands to `user`, `volumeID` expands to `volumeName`, and `tableFid` expands to `tablePath`. The original fields are also preserved in the output.

fcdebug
Dynamically sets the log level to debug a library.

You can modify the `core-site.xml` file to set the log level of all modules using the `fs.mapr.trace` property. However, you must restart FUSE for the change to take effect. As an alternative, you can use the `fcdebug` utility to debug a specific library (at runtime) without restarting FUSE.

last-updated: Apr 11, 2022

Note: You may have to run this command once per library (to debug).

Syntax

```
/opt/mapr/server/tools/fcdebug [-i] [-p <process ID>] [-s <shm ID>][-m
<module>] [-l <level>] [-o <slowOpsTraceThreshold>]
```

Parameters

Parameter	Description
`-i`	Lists the current debug level of all modules.
`-l`	Specifies the log level. Value can be one of the following: FATAL, ERROR, WARN, INFO, DEBUG. **Note:** If you do not specify the log level, the default level is applied for the module.
`-m`	Specifies the module for which the log level is to be set. You can retrieve the list of modules with the `fcdebug -i -p <process ID>` or the `fcdebug -i -s <shmid>` command. **Note:** If you do not specify the module, the log level is set on all modules.
`-p`	Specifies the process ID of either the file client, or the FUSE-based POSIX client.
`-s`	Specifies the shared memory ID (shmid) of either the file client, or the FUSE-based POSIX client.

Attention: Specify either the `process ID (-p)` or the `shmid (-s)` option. If you specify both the options, only the `shmid (-s)` option is used.

Examples

The following command retrieves the list of modules:

```
Note: Use either the -p or the -s option.

/opt/mapr/server/tools/fcdebug -i -p 196614  (OR)
/opt/mapr/server/tools/fcdebug -i -s 335020032
```

Note: You can run this command after dynamically setting the log level to verify the setting.

The following command dynamically sets the log level to DEBUG on the given module:

```
Note: Use either the -p or the -s option.

/opt/mapr/server/tools/fcdebug -p 196614 -m FuseOps -l DEBUG (OR)
/opt/mapr/server/tools/fcdebug -s 335020032 -m FuseOps -l DEBUG
```

Note: It may take up to30 seconds for the changes to take effect.

last-updated: Apr 11, 2022

The following command sets the log level to DEBUG on all the modules:

```
Note: Use either the -p or the -s option.

/opt/mapr/server/tools/fcdebug -p 196614 -l DEBUG (OR)
/opt/mapr/server/tools/fcdebug -s 335020032 -l DEBUG
```

The following command resets the log level to the default value on all the modules:

```
Note: Use either the -p or the -s option.

/opt/mapr/server/tools/fcdebug -p 196614 (OR)
/opt/mapr/server/tools/fcdebug -s 335020032
```

fsck
Detects and fixes inconsistencies in the filesystem.

Use the filesystem check (fsck) utility to detect and fix inconsistencies in the filesystem.

Every storage pool has its own log to journal updates to the storage pool. The system performs all operations to a storage pool transactionally by journaling all operations to the log, before applying them to storage pool metadata. If MapR File System is not shutdown cleanly, some metadata blocks may not persist. However, on the next load of the storage pool, log recovery takes care of these metadata blocks by replaying the records in the log. The fsck utility also replays the log before it checks the metadata consistency in a storage pool. The `fsck` utility walks the storage pool in question to verify all MapR filesystem metadata (and data correctness if specified on the command line), and reports all potentially lost or corrupt containers, directories, tables, files, filelets, and blocks in the storage pool. The `fsck` utility:

- Checks whether all files and directories are reachable and all directory entries are valid.
- Checks whether BTrees are consistent for various inode types (such as files and directories).
- Walks the container file and visits every inode in the container to check that no block is owned by two inodes. Aso, verifies the consistency of bitmaps of inodes and blocks.
- Checks consistency of snapshots.
- Visits every allocated block in the storage pool and recovers any blocks that are part of corrupted inodes.
- Checks consistency of MapR Database metadata.
- Checks consistency of tabletmap, tablets, buckets, and spill files.

The `fsck` utility can be used on an offline storage pool after a node failure, after a disk failure, or after a MapR filesystem process crash, or simply to verify the consistency of data for suspected software bugs.

Typical process flow:

- Take the affected storage pools offline with the mrconfig sp offline on page 2175 command.
- Execute the `fsck` command on the storage pools (or disks) as specified in the following discussion.
- Bring the storage pools back online with the mrconfig sp online on page 2176 command.
- Execute the gfsck on page 2102 command on the cluster, volumes, or snapshots that were affected.

You can run the `fsck` command in two modes:

- Verification mode - `fsck` only reports errors; it does not attempt to fix or modify any data on disk. You can run `fsck` in verification mode on an offline storage pool at any time, and it will report errors if there is inconsistency. If it does not report any errors, you can bring up the storage pool online without any risk of data loss. To run the `fsck` utility in verification mode, use any parameter *except* the `-r` parameter.
- Repair mode - `fsck` attempts to repair a bad storage pool. When you run the `fsck` utility in repair mode on a storage pool, some volumes might need a global fsck (gfsck on page 2102) after bringing the storage pool online. There is potential for loss of data in this case. To run the `fsck` utility in repair mode, use the `-r` parameter.

Using the `/opt/mapr/server/fsck` utility with the `-r` option produces different results depending on the scenario. The `fsck` utility does not interpret the scenario nor does it have a safe mode.

- If a disk is offline because of an imbalanced b-tree, using `fsck -r` may result in data loss from bad containers, and data loss if additional replicas are unavailable.
- If a disk is offline because of an I/O error, using `fsck -r` produces indeterminate results. A disk that is returning I/O errors is questionable in terms of data content and reliability. For example, an operation that completed on the disk but was never returned, may have partial data remaining on the disk. Using `fsck -r` retains any partial data.
- If a disk is offline because of slow I/O, using `fsck -r` does not produce data loss.

The most conservative usage of `fsck` is to first run `fsck` without the `-r` option (verification mode) and check the output. If the output returns errors, then run `fsck` with the `-r` option.

Syntax

```
/opt/mapr/server/fsck [{<device-paths>}] or [-n <sp name>]
     -l <log filename> ; default /opt/mapr/logs/fsck.log.<ts>.<pid>
     -p <mfs port> ; default 5660
     -N to disable status bar
     -P to purge deleted containers in repair
     -h for help
     -j to skip log replay
     -m <memory in MB> to set cache size for blocks
     -d to check data blocks crc
     -b to check db consistency
     -C to specify the container-id when using -d
     -I to specify inode-number when using -d and -C
     -r to repair ; USE WITH CAUTION AS IT CAN LEAD TO LOSS OF DATA
```

Parameters

Parameter	Description
-b	Checks database consistency.
-C	Optional with the `-d` option. Specifies the read-write container ID on which CRC (cyclic redundancy check) must be performed. If this option is not specified with the `-d` option, the CRC is performed on all the containers on the storage pool.
-d	Performs a CRC on data blocks. By default, `fsck` will not validate the CRC of user data pages. Enabling this check causes the check to take a while to complete.

last-updated: Apr 11, 2022

Parameter	Description

<device-paths>	Paths to the disks that make up the storage pool.
	  **Note:** Before running `fsck`, use the mrconfig disk remove on page 2151 command to remove all the disks from MapR File System. For example:
	`/opt/mapr/server/mrconfig disk remove /dev/sdb`
	`/opt/mapr/server/fsck /dev/sdb`

-h	Help
-I	Optional with the `-C` option. Specifies the inode number on which CRC (cyclic redundancy check) must be performed on the container specified by the `-C` option. If this option is not specified with the `-C` option, the CRC is performed on all the inodes.
-j	Skips log replay. Should be set only when log recovery fails. Log recovery can fail if the damaged blocks of a disk belong to the log, or if log recovery finds some CRC errors in the metadata blocks. *Using this parameter will typically lead to larger data loss. *
-l	The log filename. Default: `/opt/mapr/logs/fsck.log.<ts>.<pid>`
-m	Sets the cache size for blocks (MB).
-n	Storage pool name. This option works only if all the disks are in `disktab`. Otherwise, you must individually specify all the disks that make up the storage pool, using the `<device-paths>` parameter.
-N	Disables the status bar.
-p	The MapR File System port. Default: `5660`
-P	Purges deleted containers in repair.
-r	Runs in repair mode. **USE WITH CAUTION AS THIS CAN LEAD TO LOSS OF DATA.**

gfsck

Describes how you can use the `gfsck` command, under the supervision of Map R Support or Engineering, to perform consistency checks and appropriate repairs on a volume, or a volume snapshot.

You can use the `gfsck` command when the local `fsck` either repairs or loses some containers at the highest epoch.

For an overview of using the GFSCK command, see Using Global File System Checking on page 980.

 **Important:** You need to install a patch to use some options such as `-Dfull` and `--crc`

Permissions Required

Although you need to be the *root* user to run this command, checking tiering-enabled volumes requires you to be the *mapr* user.

last-updated: Apr 11, 2022

Syntax

```
/opt/mapr/bin/gfsck
    [-h] [--help]
    [-c] [--clear]
    [-d] [--debug]
    [-b] [--dbcheck]
    [-r] [--repair]
    [-y] [--assume-yes]
    [-Gquick] [--check-tiermetadata-only]
    [-Gfull]  [--check-tiermetadata-full]
    [-Dquick] [--check-tierdata-presence]
    [-Dfull]  [--check-tierdata-crc]
    [-J] [--skip-tier-log-replay]
    [-D] [--crc]

    [cluster=cluster-name (default=default)]
    [rwvolume=volume-name (default=null)]
    [snapshot=snapshot-name (default=null)]
    [snapshotid=snapshot-id (default=0)]
    [fid=fid (default=null)]
    [cid=cid (default=0)]

    [rIdx=<repl index>] (replication index, only enabled with [-D]  [--crc]
    [fidThreads=<check crc thread count for fid>] (default:16, max:128)
    [cidThread=<check crc thread count for cid>] (default:16, max:128)
    [scanthreads=inode scanner threads count (default:10, max:1000)]
```

Parameters

-h|--help	*Description*: Prints usage text *User who must use this option*: Either `root` or `mapr`.
-c|--clear	*Description*: Clears previous warnings before performing the global filesystem check. *User who must use this option*: Either `root` or `mapr`.
-d|--debug	*Description*: Provides information for debugging. *User who must use this option*: Either `root` or `mapr`.
-b|--dbcheck	*Description*: Checks that every key in a tablet is within that tablet's startKey and endKey range. This option is I/O intensive, so use this option only if you suspect database inconsistency. *User who must use this option*: `root` When used with S3 volumes , this option validates that *versionIds* of objects in a given partition are less than *maxVersionId* stored in Partition Map Entry. *User who must use this option*: `mapr`.
-r|--repair	*Description*: Indicates and repairs the inconsistencies detected by `-GQuick`, `-GFull`, `-DQuick`, and `-DFull`. Repair is not supported for snapshots and mirrors. *User who must use this option*: `root`
-y|--assume-yes	*Description*: If specified, assumes that containers without valid copies (as reported by CLDB) are deleted automatically. If not specified, `gfsck` pauses for user input: **yes** to delete, **no** to exit `gfsck`, or **ctrl-C** to quit.

last-updated: Apr 11, 2022

	User who must use this option: Either `root` or `mapr`.
-D|--crc	*Description*: Provides validation of the CRC of the data present in the volume. The data can either be local or offloaded. You can use this option at the volume, container, snapshot, and the filelet levels. `gfsck` reports corruption found at each level. *User who must use this option*: `root`
cluster	*Description*: Specifies the name of the cluster (default: default cluster) *User who must use this option*: Either `root` or `mapr`.
rwvolume	*Description*: Specifies the name of the volume (default: default cluster) *User who must use this option*: Either `root` or `mapr`.
fid	*Description*: Checks data CRC for the master copy of the specified fid. To check any other copy, use the `rIdx` option. You must use **fid** only with the `--crc` option. *User who must use this option*: `mapr`
cid	*Description*: Checks data CRC for the master copy of the specified container ID. To check any other copy, use the `rIdx` option. The default value of `0` denotes that all containers are checked. You must use **cid** only with the `--crc` option. *User who must use this option*: `mapr`
rIdx	*Description*: Specifies the index (either `fid` or `cid`) of the copy of the data to check for errors. Use only with `-D` or `--crc` and either `fid` or `cid`. For example, `-D fid:2510.32.131204 rIdx=0` only checks the data for copy 1 of the specified fid. *User who must use this option*: `mapr`
fidThreads	*Description*: Specifies the number of threads for scanning fids (default:16, max:128). You must use **fidThreads** only with the `--crc` option. *User who must use this option*: `mapr`
cidThreads	*Description*: Specifies the number of threads for scanning container IDs (default:16, max:128). You must use **cidThreads** only with the `--crc` option. *User who must use this option*: `mapr`
scanthreads	*Description*: Specifies the number of threads for scanning inodes (default:10, max:1000) *User who must use this option*: Either `root` or `mapr`.
snapshot	*Description*: Specifies the name of the snapshot (default: null) *User who must use this option*: Either `root` or `mapr`.
snapshotid	*Description*: Specifies the snapshot ID (default: 0) *User who must use this option*: Either `root` or `mapr`.

Tier Options

last-updated: Apr 11, 2022

-Gquick|--check-tiermetadata-only	*Description*: Checks if the entries in the meta data tables maintained internally for objects and tiers (the mapping between the Virtual Cluster Descriptor (VCD) map and object map) , are consistent, and reports an error if not. *User who must use this option*: `mapr`
-Gfull|--check-tiermetadata-full	*Description*: Checks if the entries in the meta data tables maintained internally for objects and containers (the mapping between the VCD map and object map, along with the mapping between the VCD map and the MFS meta data), are consistent and reports an error if not. *User who must use this option*: `mapr`
-Dquick|--check-tierdata-presence	*Description*: Specified with either `-Gquick` or `-Gfull`. Checks and reports if the object in the meta data tables exists in the tier or not. *User who must use this option*: `mapr`
-Dfull|--check-tierdata-crc	*Description*: Specified with either `-Gquick` or `-Gfull`. Validates the data CRC for the object in the meta data tables. *User who must use this option*: `mapr`
-J|--skip-tier-log-replay	*Description*: Skips replaying transactions from internal dot files if a tier operation ends abruptly. MapR recommends that you use this option when running the GFSCK utility on tiered volumes. *User who must use this option*: Either `root` or `mapr`.

last-updated: Apr 11, 2022

Examples

1. **Debug Mode**

   In debug mode, run the `gfsck` command on the read/write volume named `mapr.cluster.root`:

```
/opt/mapr/bin/gfsck rwvolume=mapr.cluster.root -d
```

   Sample output is as follows:

```
Starting GlobalFsck:
  clear-mode            = false
  debug-mode            = true
  dbcheck-mode          = false
  repair-mode           = false
  assume-yes-mode       = false
  cluster               = my.cluster.com
  rw-volume-name        = mapr.cluster.root
  snapshot-name         = null
  snapshot-id           = 0
  user-id               = 0
  group-id              = 0

  get volume properties ...
    rwVolumeName = mapr.cluster.root (volumeId = 205374230,
rootContainerId = 2049, isMirror = false)

  put volume mapr.cluster.root in global-fsck mode ...

  get snapshot list for volume mapr.cluster.root ...

  starting phase one (get containers) for volume
mapr.cluster.root(205374230) ...
    container 2049 (latestEpoch=3, fixedByFsck=false)
    got volume containers map
  done phase one

  starting phase two (get inodes) for volume
mapr.cluster.root(205374230) ...
    get container inode list for cid 2049

2. Verifying CRC of FIlelet

```
# /opt/mapr/bin/gfsck  -D fid=2085.32.131412  --debug
verifying data crc
  mode          =       fid
  fid           =       2085.32.131412
  debug-mode    =       true
  repair-mode   =       false
  cluster       =       default
  replication index     =       -1
  user-id       =       0
  group-id      =       0

crc validate result for fid : 2085.32.131412
  total local cluster/vcds verified : 51
  total local cluster/vcds corrupted : 0
  total local cluster/vcds skipped: 0
  total purged cluster/vcds verified : 0
  total purged cluster/vcds corrupted : 0
  total purged cluster/vcds skipped: 0
```

3. **Verifying CRC at a Container Level**

   For CRC checks at the container level, the output is not displayed on the terminal. Instead it is written to the `/opt/mapr/log/gfsck.log` file. Sample output is as follows:

```
/opt/mapr/bin/gfsck  -D rwvolume=rocky
verifying data crc
  mode          =       volume
  rwVolumeName          =       rocky
  fid thread count      =       16
  cid thread count      =       16
  debug-mode    =       false
  repair-mode   =       false
  cluster       =       default
  replication index     =       -1
  user-id       =       0
  group-id      =       0
  total containers : 6
  total container skipped : 0
  data crc verification completed with no errors
```

Using Global File System Checking on page 980
Describes how to use the `gfsck` command to check and repair filesystem errors.

guts

`guts` is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. `guts` is an internal utility, and is subject to change without notice.

`guts` provides information on entities such as:

CPU	Indicates whether the CPU is idle or busy
RPCs	Number of RPCs, RPCs-in, RPCs-out, bytes-in, and bytes-out
MFS	Number of local-writes, local-reads, and other operations (such as lookup, create and remove)
Log	Number of log writes, log flushes, and log force-flushes
IO	Number of disk-operations/second (read/write), and the disk-io/second in MB (read/write)

Syntax

```
/opt/mapr/bin/guts
    guts
    -help
  instance:<id>  time:unix time:all time:none (add timestamp to output)
  key:5660 (is server port)
  shmid:<shared memory id> (client's shared memory id, check ipcs)
  threadcpu:core threadcpu:all
  cpu:none  cpu:all
  net:sum  net:msum  net:ksum  net:all  net:none
  disk:none disk:ops disk:mb disk:all
  diskMajor:major# of disk
  ssd:none ssd:all
  cache:none cache:small cache:med cache:all
  cleaner:small  cleaner:all  cleaner:none
```

```
  fs:rw   fs:all  fs:none
  kv:all  kv:none
  btree:all  btree:none
  allocator:all allocator:none
  rpc:none  rpc:op  rpc:all rpc:debug
  db:none db:op db:get db:put db:scan db:all
  dbrepl:none dbrepl:op dbrepl:all
  streams:none streams:op streams:all
  dsec:infinity (run time in sec.)
  period:n (output every n sec.)
  cache:small  cache:med  cache:all  cache:none
  log:all  log:none
  btree:all btree:none
  resync:all resync:none
  io:all io:small
  hb:all io:none
  gateway:all gateway:op gateway:lc gateway:none
  mastgateway:all mastgateway:tier mastgateway:db mastgateway:mfsops
mastgateway:none
  fstier:all fstier:none
  nfs:all nfs:none
  moss:all moss:basic moss:none
  client:none client:db client:fs client:all (requires shmid parameter)
  clientpid:<process id of a running client process>
  nfs4client:all
  fuse:all shmid:<shared memory id> (posix client's shared memory id, check
fuse logs)
  header:all  header:none (doesn't seem to work)
  flush:none  flush:line (if line, then output is flushed on every output
line)
defaults: time:none net:none disk:none rpc:op db:op db:put dbrepl:none
streams:none fs:rw cache:small kv:none
  cleaner:short log:none btree:none resync:none period:1
```

Interpreting Output

The prefix *c* identifies client metrics. The suffix *P* refers to the number of pending RPCs. The suffix *C* denotes the number of completed RPCs.

The pending metrics are a snapshot of pending RPCs when the output is printed. The completed metrics are the increase that happened in the last print interval.

Parameters and Output

CPU	cpu:`all` — Percentage of idle time of each CPU on the system in the last second.
IO	The metrics are `ior` and `iow`, which are displayed by default. • `ior` — The first number reports the number of I/O reads for a machine in the last second. The second number reports the amount of I/O reads in MB in the last second. • `iow` — The first number reports the number of I/O writes for a machine in the last second. The second number reports the amount of I/O writes in MB in the last second.

Disk

- `disk:ops` — Number of I/O requests (read+write) for each disk in the last second.
- `disk:mb` — Amount of I/O in MB (read+write) for each disk in the last second.
- `disk:all` — The preceding two numbers for each disk in the last second. The first number is from `disk:ops`, the second number is from `disk:mb`.

Filesystem

`fs:rw` — Reports MFS file system activities. Reported metrics are:

- `read` — The first number reports the number of remote reads in the last second. The second number reports the amount of data read in MB in the last second.
- `write` — The first number reports the number of remote writes in the last second. The second number reports the amount of data written in MB in the last second.
- `lread` / `lwrite` — are similar to the `read` and `write` metrics, but are applicable for local reads/ writes.

In addition, `guts` displays the following *filesystem* metrics:

- `crP` — Total pending *read* RPCs in the last second.
- `crC` — Total completed *read* RPCs in the last second.
- `cwP` — Total pending *write* RPCs in the last second.
- `cwC` — Total completed *write* RPCs in the last second.
- `ccP` — Total pending *create* RPCs in the last second.
- `ccC` — Total completed *create* RPCs in the last second.
- `cuP` — Total pending *unlink* RPCs in the last second.
- `cuC` — Total completed *unlink* RPCs in the last second.

RPC

Reports the following metrics:

- `rpc:none` — Does not display any RPC related metrics.
- `rpc:op` — *rpc* metric
- `rpc:all` — *rpc*, *im*, and *om* metrics.

- `rpc` — Number of RPC calls received in the last second.
- `im` — Amount of RPC calls received in MB in the last second.
- `om` — Amount of RPC calls sent in MB in the last second.

Cache

`cache:small` — Metrics on *inode* and *dentry* cache, which are displayed by default. The metrics reported are:

- `icache` (inode cache) — The first number reports the number of inode cache lookups in the last second. The second number reports the number of inode cache lookup misses in the last second.
- `dcache` (dentry cache) — The first and second numbers report dcache lookups and lookup misses in the last second, respectively.

Network

- `net:sum` — Total network traffic in bytes received and transmitted from all network interfaces for a machine.
- `net:msum` — Total network traffic in megabytes.
- `net:ksum` — Total network traffic in kilobytes.
- `net:all` — Not yet implemented.
- `net:none` — Does not display any network related metrics.

Metrics returned are:

- `nI` — Total amount of network traffic *received* in bytes in the last second. This is a summation of network traffic from all network interfaces for a machine.
- `nO` — Total amount of network traffic *sent* in bytes in the last second. This is a summation of network traffic from all network interfaces in a machine.

Database

`db:get` — Metrics related to `gets`. The output columns are as follows:

- `rOP` — Number of RPCs completed for type OP in the last second.
- `rOPR` — Number of rows processed from all RPCs of type OP in the last second.
- `tOPR` — Number of rows processed from all RPCs in the last second.
- `cOP` — Number of in-progress RPCs for the OP (not differential).

Cleaner Metrics

`guts` displays the following *cleaner* metrics:

last-updated: Apr 11, 2022

- `di` — Number of inodes dirtied by update operations in the last second.
- `ic` — Number of inodes cleaned by the drainer in the last second.
- `dd` — Number of data blocks dirtied by update operations in the last second.
- `dc` — Number of data blocks cleaned by the drainer in the last second.

Operational Metrics

`guts` displays the following *operational* metrics:

- `rput` — Number of *put* RPCs completed in the last second.
- `rputR` — Sum of *put* rows completed in the last second, from all *put* rpcs.
- `tputR` — Sum of *put* rows completed in the last second, from **all** rpcs (*put*, *increment*, *checkAndPut*, *Append* ..)
- `cput` — Number of *put* RPCs in progress currently. This is not a differential, but displays the number of outstanding *put* RPCs at that particular instant.
- `rget` — Number of *get* RPCs completed in the last second.
- `rgetR` — Sum of *get* rows completed in the last second, from all *get* RPCs.
- `tgetR` — Sum of *get* rows completed in the last second, from **all** rpcs (*get*, *increment*, *checkAndPut*, *Append* ..)
- `cget` — Number of *get* RPCs in progress currently. This is not a differential, but displays the number of outstanding *get* RPCs at that particular instant.
- `rsc` — Number of scan RPCs completed in the last second.
- `rscR` — Sum of scan rows returned in the last second, from **all** scan RPCs.
- `csc` — Number of scan RPCs currently in progress. This is not a differential, but shows the number of outstanding scan RPCs at that particular instant.
- `rinc` — Number of increment RPCs completed in the last second.
- `cinc` — Number of increment RPCs currently in progress. This is not a differential, but shows the number of outstanding increment RPCs at that particular instant.
- `rchk` — Number of *checkAndPut*/*checkAndDelete* RPCs completed in the last second.

- `rapp` — Number of append RPCs completed in the last second.
- `rtlk` — Number of tablet lookup RPCs completed in the last second.
- `ctlk` — Number of tablet lookup RPCs currently in progress. This is not a differential, but shows the number of outstanding lookup RPCs at that particular instant.
- `rbulkb` — Number of bulk-import-bucket RPCs completed in the last second.
- `rbulks` — Number of bulk-import-segment RPCs completed in the last second.

Put Metrics

`guts` displays the following *put* metrics:

- `rput` — Number of *put* RPCs completed in the last second.
- `rputR` — Sum of *put* rows completed in the last second, from all *put* rpcs.
- `tputR` — Sum of *put* rows completed in the last second, from **all** rpcs (*put*, *increment*, *checkAndPut*, *Append* ..)
- `cput` — Number of *put* RPCs in progress currently. This value is not a differential, but displays the number of outstanding *put* RPCs at that particular instant.
- `rsf` — Reserved free memory in MemIndex in MB. If this value falls very low, *put* RPCs can get throttled. This value is not a differential.
- `bucketWR`:
  - Column1 : Number of bucket writes (calls to MFS) in the last second.
  - Column2 : Amount of bucket writes in MB in the last second.
- `fl` — Number of bucket flushes fired in the last second.
- `ffl` — Number of force-flushes of buckets in the last second. If the bucket was flushed before it reached its optimal size, then the flush is counted as a force-flush.
- `sfl` — Number of segments touched by the bucket-flushes in the last second.
- `mcom` — Number of segments mini-packed in the last second.
- `fcom` — Number of segments packed fully in the last second.

last-updated: Apr 11, 2022

- `ccom` — Number of segment packs running currently. This value is not a differential.
- `scr` — Number of segment creates in the last second.
- `spcr` — Number of spill creates in the last second.

Get Metrics

`guts` displays the following *get* metrics:

- `rget` — Number of *get* RPCs completed in the last second.
- `rgetR` — Sum of *get* rows completed in the last second, from all *get* RPCs.
- `tgetR` — Sum of *get* rows completed in the last second, from **all** rpcs (*get*, *increment*, *checkAndPut*, *Append* ..)
- `cget` — Number of *get* RPCs currently in progress. This is not a differential, but displays the number of outstanding *get* RPCs at that particular instant.
- `vcM` — Size of the value-cache in MB. This value is not differential.
- `cL` — Number of value-cache lookups in the last second.
- `vcH` — Number of value-cache hits in the last second.
- `bget` — Number of bucket *gets* in the last second. Will be 0 if there are no active buckets.
- `sg` — Number of segment *gets* in the last second. Will normally be equal to `tgetR minus the number of value-cache hits`.
- `spg` — Number of spill *gets* in the last second. This value is calculated as `sigma(segments * spill-per-segment) - bloomFilterSkips`
- `bskp` — Number of spill *gets* that were avoided/ saved by the bloom filter in the last second.

Scan Metrics

`guts` displays the following *scan* metrics:

- `rsc` — Number of scan RPCs completed in the last second.
- `rscR` — Sum of scan rows returned in the last second, from **all** scan RPCs.
- `csc` — Number of scan RPCs currently in progress. This is not a differential, but shows the number of outstanding scan RPCs at that particular instant.
- `bsc` — Number of buckets scanned in the last second.

- `ssc` — Number of segments scanned in the last second.
- `spsc` — Number of spills scanned in the last second.
- `spscR` — Number of rows scanned from spills in the last second.
- `ldbr` — Number of *ldb* blocks read in the last second.
- `blkr` — Number of data blocks read in the last second (over *spills*, *buckets* ..)
- `raSg` — Number of segments for which read-ahead was done in the last second.
- `raSp` — Number of spills for which read-ahead was done in the last second.
- `nAdv` — Number of *fadvise* calls made to MFS for scan read-ahead in the last second.
- `raBl` — Sum of blocks in the *fadvise* calls made to MFS for scan read-ahead in the last second.

Cumulative Metrics

`guts` displays the following *cumulative* metrics:

- cmP — Total pending RPCs from the client in the last second.
- cmC — Total completed RPCs from the client in the last second.

DB Metrics

`guts` displays the following *database* metrics:

- `cgP` — Total pending *get* RPCs.
- `cgC` — Total completed *get* RPCs.
- `cpP` — Total pending *put* RPCs.
- `cpC` — Total completed *put* RPCs.
- `csP` — Total pending *scan* RPCs.
- `csC` — Total completed *scan* RPCs.
- `ciP` — Total pending *increment* RPCs.
- `ciC` — Total completed *increment* RPCs.
- `caP` — Total pending *append* RPCs.
- `caC` — Total completed *append* RPCs.
- `cgR` — Total client *get* rows.
- `cpR` — Total client *put* rows.
- `csR` — Total client *scan* rows.

last-updated: Apr 11, 2022

- `ciR` — Total client *increment* rows.
- `caR` — Total client *append* rows.

Example Usage

The following example demonstrates viewing client metrics. Perform the following steps:

1. Find the process ID of the client program.
2. Find all the shared memory segments (*shmem*) for this program:

```
ipcs -mp | grep <pid>
  998080521  root       30030      21850
  998113290  root       30030      30030
  ^^^^^^^^^
  shmem ID
```

   Here, there are two shared memory segments — one between the client and MFS, and the other between the client and `guts`.

3. Identify the correct *shmem* segment for `guts`:

```
ipcs | grep 998113290
  0x00000000 998113290  root       666        2288       1          dest
ipcs | grep 998080521
  0x00000000 998080521  root       660        20971520   1          dest
                                              ^^^^^^^^
                                              size
```

   The *shmem* with size 20M is between client and MFS. Here, we select *shmem* with ID 998113290.

4. Run `guts`:

```
/opt/mapr/bin/guts client:all shmid:998113290
  Printing only client statistics
  cmP    cmC    cgP    cgC    cpP    cpC    csP    csC    ciP    ciC
caP   caC    crP    crC    cwP    cwC    ccP    ccC    cuP    cuC
    0      0      0      0      0      0      0      0      0
0      0      0      0      0      0      0      0      0      0      0
    0      0      0      0      0      0      0      0      0
0      0      0      0      0      0      0      0      0      0      0
```

   Pass the *shmem* ID and one of the client options. Client options are one of:

   - `none` — Used when printing MFS/dbserver statistics
   - `db` — Prints client statistics for DB operations
   - `fs` — Prints client statistics for filesystem operations
   - `all` — Prints all client statistics

CLDB Guts

The `cldbguts` utility prints information about active container reports, full container reports, registration requests, MapR-FS heartbeats, NFS server heartbeats, and containers. For more information, see cldbguts on page 2080.

last-updated: Apr 11, 2022

NFS Guts

`guts` displays the following *NFS* metrics:

- `req` — Number of requests received from all the NFS clients to this NFS server in the last second.
- `dpC` — Number of dropped calls from NFS client due to running out of ONC handles (probably cluster is responding slow OR NFS client is bombarding the NFS server).
- `inReadReq` — Number of incoming read requests from NFS clients.
- `outReadResp` — Number of outgoing read request responses to NFS Clients.
- `inReadDataReq` — Size/Length of incoming read requests (buffer size) from NFS Clients.
- `outReadDataResp` — Size/Length of outgoing read request response (buffer size) to NFS Clients.
- `inWriteReq` — Number of incoming write requests from NFS clients.
- `outWriteResp` — Number of outgoing read request responses to NFS clients.
- `inWriteDataReq` — Size/Length of incoming write request (buffer size) from NFS clients.
- `outWriteDataResp` — Size/Length of outgoing write request response (buffer size) to NFS Clients.

Running Guts

Start `guts` on the node for which you need to collect metrics.

```
/opt/mapr/bin/guts
  00 01 02 03 04 05 06 07   rpc   lpc     write   lwrite   bwrite
read    lread      icache       dcache     di  ic    dd  dc       ior
iow  rput  rputR  cput  tputR  rget  rgetR  cget  tgetR   rsc    rscR  csc
  86 90 84 84 87 93 81 84     5     6     0   0    1   0    0   0     0
0    3   0     8     0    163     1    337  22    13  16     1   0   73
4     0      0     0      1     0      0     0      0     0       0    0
  62 77 70 82 93 61 50 84    12    20     0   0    3   0    0   0     0
0   10   0    27     0     41     0      6   0     3   0     0   0    0
0     0      0     0      3     0      0     0      0     0       0    0
  63 78 59 56 84 64 32 86     4     5     0   0    5   0    0   0     0
0    0   0     5     0     27     0      8   0    22   0     0   0    0
0     3   1506     0   1506     0      0     0      0     0       0    0
  83 76 77 82 68 69 82 67     1     0     0   0    0   0    0   0     0
0    0   0     0     0      0     0      0   0     0   0     0   0    0
0     0      0     0      0     0      0     0      0     0       0    0
  94 49 91 56 75 48 57 92     1     0     0   0    0   0    0   0     0

Retrieving Tiering Statistics Using guts on page 943
Explains how to use the `guts` utility to retrieve tiering statistics.

manageSSLKeys.sh
Use the `manageSSLKeys.sh` utility to create and manage SSL certificates.

Syntax

```
# /opt/mapr/server/manageSSLKeys.sh
manageSSLKeys.sh is a tool to create and manage the SSL certificates.
it is run once on the first node from configure.sh
Usage: manageSSLKeys and one of
     create [-d DNSDOMAIN] [-N clustername]
        creates the SSL key and trust stores needed for HTTPS traffic
        -d specifies DNS domain used in wildcard certificate. Default is
detected from Local OS
        -N clustername
        -ug MapR user/group, e.g., mapr:mapr
     merge <in trust store> <out trust store>
        merges the certificates from the in trust store into the existing
out trust store
     convert [-N <clustername> ] [-k] [-n] [-p <passwd>] [-srcType JKS|
pkcs12] [-dstType JKS|pkcs12] <in key/trust store> <out key/trust store>
        converts an existing key/trust store into a new PEM type key/trust
store
        if srcType and dstType are not specified, it is assumed that you
are
        converting from JKS to PEM(via pkcs12)
        -N <clustername>
        -k denotes you are converting a keystore
        -n Skips creating the PEM file when converting the key/trust store
from JKS to PKCS12 format
        -p <passwd> store password - needed if you are converting custom
stores
        -srcType JKS|pkcs12 denotes the source format of the store
        -dstType JKS|pkcs12 denotes the destination format of the store
```

Operations

`manageSSLKeys.sh` performs the following operations:

create

Description: Creates the SSL key and trust stores needed for HTTPS traffic.

Format: `create [-d DNSDOMAIN] [-N clustername] -ug <maprUserGroup>`

Parameters:

- `d`: DNS domain used for the wildcard certificate. The default domain is detected from the Local OS.
- `N`: Name of the cluster.
- ug: *User:Group* to use for the key. For example: *mapr:mapr*.

merge

Description: Merges the SSL certificates from the *in trust* store into the existing *out trust* store.

Format: `merge <in trust store> <out trust store>`

Parameters:

last-updated: Apr 11, 2022

- `in trust store`: Source trust store from which to obtain the SSL certificates.
- `out trust store`: Destination trust store to merge the SSL certificates.

convert

Description: Converts an existing key/trust store into a new PEM type key/trust store. If you do not specify the type of the source and the destination key/trust store, it is assumed that you are converting from JKS to PEM (via `pkcs12`).

Format:
```
convert [-N <clustername> ] [-k] [-n] [-p <passwd>] [-srcType JKS|pkcs12] [-dstType JKS|pkcs12] <in key/trust store> <out key/trust store>
```

Parameters:

- `N`: Cluster name.
- `k`: Indicates that a keystore is being converted.
- `n`: Skips creating the PEM file when converting the key/trust store from JKS to PKCS12 format
- `p <passwd>`: store password - needed if you are converting custom stores.
- `srcType`: Format of the source key/trust store - either `JKS` or `pkcs12`.
- `dstType`: Format of the destination key/trust store - either `JKS` or `pkcs12`.
- `in key/trust store`: The existing key/trust store to convert.
- `out key/trust store`: The name to use for the converted key/trust store.

Examples

The following links demonstrate using the `manageSSLKeys.sh` utility.

- Merge trust store: Configuring Secure Clusters for Running Commands Remotely on page 1484
- Generate trust store and key store files: Step 1: Restart and Check Cluster Services on page 323 and Configuring Encryption for ODBC Connection on page 3535
- Convert type of keystore file: Upgrading the MapR Data Access Gateway on page 361

mapr-support-collect.sh
Collects information about a cluster's recent activity, to help MapR Support diagnose problems.

The "mini-dump" option limits the size of the support output. When the `-m` or `--mini-dump` option is specified along with a size, `mapr-support-collect.sh` collects only a head and tail, each limited to the specified size, from any log file that is larger than twice the specified size. The total size of the output is therefore limited to approximately 2 * size * number of logs. The size can be specified in bytes, or using the following suffixes:

- b - bytes

last-updated: Apr 11, 2022

- k - kilobytes (1024 bytes)
- m - megabytes (1024 kilobytes)

Syntax

```
 /opt/mapr/support/tools/mapr-support-collect.sh
       -h, --hosts HOST_FILE
          hosts file, each line has entries [user@]host[:port]
       -H, --host HOST_ENTRY
          additional host entry of the form [user@]host[:port], multiple
can be specified
       -Q, --no-cldb
          do not query CLDB for list of nodes
       -n, --name NAME
          name of output file
       -d, --output-dir DIR_PATH
          absolute path of output directory
       -l, --no-logs
          do not include log files
       --no-hadoop-logs
          do not include hadoop log files
       --hbase-logs
          include hbase log files
       --sqoop-logs
          include sqoop log files
       --eco-logs
          include all ecosystem log files
       --oozie-logs
          include oozie log files
       --spark-logs
          include spark log files
       --pig-logs
          include pig log files
       --impala-logs
          include impala log files
       --hue-logs
          include hue log files
       --hive-logs
          include hive log files
       --flume-logs
          include flume log files
       --drill-logs
          include drill log files
       --no-kibana-logs
          do not include kibana log files
       --no-grafana-logs
          do not include grafana log files
       --no-elasticsearch-logs
          do not include elasticsearch log files
       --no-opentsdb-logs
          do not include opentsdb log files
       --no-collectd-logs
          do not include collectd log files
       --no-fluentd-logs
          do not include fluentd log files
       --no-vol-info
          do not collect volume information
       -L, --libraries
          include libraries
       -s, --no-statistics
          do not include statistics
       -c, --no-conf
```

```
          do not include configurations
       -i, --no-sysinfo
          do not include system information
       -x, --exclude-cluster
          do not collect cluster diagnostics
       -u, --user USER
          username for ssh connections
       -K, --strict-hostkey
          check for strict host key in ssh connection
       -p, --par PAR
          maximum number of nodes from which support dumps will be gathered
concurrently (default: 10)
       -t, --dump-timeout DUMPTIMEOUT
          timeout for execution of mapr-support-dump command on a node
(default: 3600 seconds, 0 = no limit)
       -T, --scp-timeout SCPTIMEOUT
          timeout for copy of support dump output from a remote node to
local filesystem (default: no limit)
       -y, --yes
          do not require acknowledgement of the number of nodes that will
be affected
       -O, --online
          Leverage MapR APIs to gather support dumps. When not specified,
SSH and SCP will be used.
       -S, --scp-port SCPPORT
          the local port to which remote nodes will establish an SCP session
       --collect-cores
          Collect cores of running mfs processes from all nodes (off by
default)
       --move-cores
          Move mfs and nfs cores from coresDir from all nodes (off by
default)
       --use-hostname
          Use hostname to ssh instead of IP addresses (off by default)
       --cldb CLDBNODE
          Use this option when the CLDB Service is down to point to a CLDB
node
       --port PORT
          port number used by FileServer (default: 5660)
       --nfsport NFS_MGMT_PORT
          port number used by NFSServer (default: 9998)
       -m, --mini-dump SIZE
          Collects only first and last number of bytes of each log file if
file is greater then 2*SIZE.
          SIZE may have a multiplier suffix: b 512, k 1024, m 1024*1024
       -A, --logs-age DAYS
          Use this option to collect logs newer than specified DAYS
          (default: 7, nolimit: 0)
       -f, --filter FILTER_STRING
          Use this option to filter nodes for which support dump should be
collected
       -?, --help
          display usage
```

Parameters

Parameter	Description
-h or --hosts	A file containing a list of hosts. Each line contains one host entry, in the format `[user@]host[:port]`.

last-updated: Apr 11, 2022

Parameter	Description
-H or --host	One or more hosts in the format `[user@]host[:port]`.
-Q or --no-cldb	If specified, the command does not query the CLDB for list of nodes.
-n or --name	Specifies the name of the output file. If not specified, the default is a date-named file in the format `YYYY-MM-DD-hh-mm-ss.tar`.
-d or --output-dir	The absolute path to the output directory. The default path is `/opt/mapr/support/collect/`.
-l or --no-logs	If specified, the command output does not include any log files.
--no-hadoop-logs	If specified, the command output does not include Hadoop log files.
--hbase-logs	If specified, the command output includes HBase log files.
--sqoop-logs	If specified, the command output includes Sqoop log files.
--eco-logs	If specified, the command output includes the log files for all MapR ecosystem components.
--oozie-logs	If specified, the command output includes Oozie log files.
--spark-logs	If specified, the command output includes Spark log files.
--pig-logs	If specified, the command output includes Apache Pig log files.
--impala-logs	If specified, the command output includes Apache Impala log files.
--hue-logs	If specified, the command output includes Apache Hue log files.
--hive-logs	If specified, the command output includes Apache Hive log files.
--flume-logs	If specified, the command output includes Apache Flume log files.
--drill-logs	If specified, the command output includes Apache Drill log files.
--no-kibana-logs	If specified, the command output does not include Kibana log files.
--no-grafana-logs	If specified, the command output does not include Grafana log files.
--no-elasticsearch-logs	If specified, the command output does not include Elasticsearch log files.
--no-opentsdb-logs	If specified, the command output does not include OpenTSDB log files.
--no-collectd-logs	If specified, the command output does not include Collectd log files.
--no-fluentd-logs	If specified, the command output does not include Fluentd log files.

last-updated: Apr 11, 2022

Parameter	Description
--no-vol-info	If specified, the command output does not include any volume information.
-L or --no-libraries	If specified, the command output does not include libraries.
-c or --no-conf	If specified, the command output does not include configurations.
-i or --no-sysinfo	If specified, the command output does not include system information.
-x or --exclude-cluster	If specified, the command does not collect cluster diagnostics. Even if cluster diagnostics are excluded, the script still collects local logs and local system diagnostic information.
-u or --user	The username for ssh connections.
-K or --strict-hostkey	If specified, checks for strict host key in the SSH connection. When specified, ssh never automatically adds host keys to the `~/.ssh/known_hosts` file, and refuses to connect to a host whose host key has changed. This provides maximum protection against trojan horse attacks, but can be troublesome when the `/etc/ssh/ssh_known_hosts` file is poorly maintained or connections to new hosts are frequently made. This option forces the user to manually add all new hosts.
-p or --par	The maximum number of nodes from which support dumps are gathered concurrently (default: 10).
-t or --dump-timeout	The timeout in seconds for execution of the `mapr-support-dump` command on a node (default: 3600 seconds or 0 = no limit).
-T or --scp-timeout	The timeout in seconds for copy of support dump output from a remote node to the local filesystem (default: no limit).
-y or --yes	If specified, the command does not require acknowledgement of the number of nodes that are affected.
-O or --online	Specifies a space-separated list of nodes from which to gather support output, and uses the MapR APIs instead of ssh for transmitting the support data.
-S or --scp-port	The local port to which remote nodes establish a SCP session. The default port is 22.
--collect-cores	If specified, the command collects cores of running MFS processes from all nodes (default: off).
--move-cores	If specified, the command moves MFS and NFS cores from /opt/cores to /opt/mapr/logs/cores/ on all nodes (default: off).

last-updated: Apr 11, 2022

Parameter	Description
--use-hostname	If specified, uses hostnames instead of IP address for SSH (default: off).
--cldb <cldbnode>	Use this option when the CLDB Service is down to point to a CLDB node.
--port	The port number used by FileServer (default: 5660).
--nfsport	The port number used by NFSServer (default: 9998).
-m or --mini-dump <size>	For any log file greater than 2 * <size>, collects only a head and tail each of the specified size. The <size> may have a suffix specifying units: • b - blocks (512 bytes) • k - kilobytes (1024 bytes) • m - megabytes (1024 kilobytes)
-A or --logs-ag	Use this option to collect logs newer than specified days (default: 7, nolimit: 0)
-f or --filter <filter string>	Use this option to specify a filter string. Support information is only collected for nodes with names that match the filter string.
-? or --help	Displays usage help text

Examples

Collect support information and dump it to the file /opt/mapr/support/collect/mysupport-output.tar:

```
/opt/mapr/support/tools/mapr-support-collect.sh -n mysupport-output
2019-09-16 21:37:28.884 INFO Creating nodes file
2019-09-16 21:37:28.907 INFO Querying CLDB for nodes in the cluster
2019-09-16 21:37:31.883 INFO Created nodes file
Diagnostics will be collected from 1 nodes. Press enter to continue:

Password:
2019-09-16 21:44:25.137 INFO Making a tarball of all the dumps

--------------------------------------------------------------------------------

------------------ Finished collecting diagnostics
information --------------------
--------------------------------------------------------------------------------

Successfully collected support information on cluster from CLDB.

Total no. of nodes from which dump collection was attempted: 1
Nodes from which support information gathering succeeded:    1
Number of nodes from which dump collection failed:           0
Number of nodes from which dump file could not be copied:    0

The tar ball of the dumps is available at: /opt/mapr/support/collect/
mysupport-output.tar
```

last-updated: Apr 11, 2022

mapr-support-dump.sh
Collects node and cluster-level information for the node on which you invoke the script.

The information collected is used to help MapR Support diagnose problems. Use mapr-support-collect.sh on page 2121 to collect diagnostic information from all nodes in the cluster.

The "mini-dump" option limits the size of the support output. When you specify the `-m` or `--mini-dump` option along with a size, `mapr-support-dump.sh` collects only a head and tail, each limited to the specified size, from any log file that is larger than twice the specified size. The total size of the output is therefore limited to approximately 2 * size * number of logs. You can specify the size using the following suffixes:

- b - bytes
- k - kilobytes (1024 bytes)
- m - megabytes (1024 kilobytes)

Syntax

```
/opt/mapr/support/tools/mapr-support-dump.sh
      [ -n| --name <name> ]
      [ -l| --no-logs ]
      [ --no-hadoop-logs ]
      [ --hbase-logs ]
      [ --sqoop-logs ]
      [ --eco-logs ]
      [ --oozie-logs ]
      [ --spark-logs ]
      [ --pig-logs ]
      [ --impala-logs ]
      [ --hue-logs ]
      [ --hive-logs ]
      [ --flume-logs ]
      [ --drill-logs ]
      [ -L| --libraries ]
      [ -d| --output-dir <path> ]
      [ -s| --no-statistics ]
      [ -c| --no-conf ]
      [ -i| --no-sysinfo ]
      [ -o| --exclude-cluster ]
      [ -O| --online ]
      [ -z| --only-cluster ]
      [ --collect-cores ]
      [ --move-cores ]
      [ --port <port> ]
      [ --nfsport <port> ]
      [ -m| --mini-dump <size> ]
      [ -A| --logs-age <days> ]
      [ -?| --help ]
```

Parameters

Parameter	Description
-n or --name	Specifies the name of the output file. If not specified, the default is a date-named file in the format YYYY-MM-DD-hh-mm-ss.tar
-l or --no-logs	Does not include log files.

last-updated: Apr 11, 2022

Parameter	Description
--no-hadoop-logs	Does not include Hadoop log files
--hbase-logs	Includes Hbase log files.
--sqoop-logs	Includes Sqoop log files
--eco-logs	Includes all ecosystem log files.
--oozie-logs	Includes Oozie log files.
--spark-logs	Includes Spark log files.
--pig-logs	Includes Pig log files.
--impala-logs	Includes Impala log files.
--hue-logs	Includes Hue log files.
--hive-logs	Includes Hive log files.
--flume-logs	Includes Flume log files.
--drill-logs	Includes Drill log files.
-L or --libraries	Includes libraries.
-d or --output-dir	The absolute path to the output directory. If not specified, the default is `/opt/mapr/support/collect/`
-s or --no-statistics	Does not include statistics.
-c or --no-conf	Does not include configurations.
-i or --no-sysinfo	Does not include system information.
-o or --exclude-cluster	Does not collect cluster diagnostics.
-O or --online	Saves the support dump output file to the /var/mapr/cluster/support directory in maprfs. When not specified, the output file is stored at /opt/mapr/support/dump on the local machine filesystem. Specifies a space-separated list of nodes from which to gather support output, and uses the warden instead of ssh for transmitting the support data.
-z or --only-cluster	Collects diagnostic information at the cluster level only.
--collect-cores	Collects cores of running mfs processes from all nodes (off by default)
--move-cores	Moves mfs and nfs cores from /opt/cores from all nodes (off by default)
--port	The port number used by the FileServer. Default: 5660
--nfs-port	The port used by the NFS server. Default: 9998

Parameter	Description
-m, --mini-dump <size>	For any log file greater than 2 * <size>, collects only a head and tail each of the specified size. The <size> may have a suffix specifying units: • b - blocks (512 bytes) • k - kilobytes (1024 bytes) • m - megabytes (1024 kilobytes)
-A or --logs-age <days>	Collects logs newer than the specified number of days. The default value for this parameter is 7. Specify a value of 0 to have the `mapr-support-dump.sh` script collect logs of any age.
-? or --help	Displays usage help text

Output

The example produces a tar file at `/opt/mapr/support/dump/mysupport-output.tar`. To extract the tar file, use `tar -xf mysupport-output.tar`. The directory structure is as follows:

```
$ ls
mysupport-output    mysupport-output.tar

$ ls mysupport-output
MapRBuildVersion       hostid            mfsstate_commands
cluster                hostname          roles
cluster_summary.txt    linux-release     support_dump.log
conf                   logs              system_info
conf_file_metadata     mapr-clusters.conf
```

- **mfsstate_commands** - Contains all information collected about the state of the filesystem are stored the the mfsstate_commands directory.
- **cluster** - Contains information associated with maprcli_commands, resourcemanager, and volume_dumps.
- **system_info** - Contains all information related to the system state and configuration.
- **support_dump.log** - Contains console output of the individual commands launched by the support dump script.
- Commonly required files - cluster_summary.txt, conf_file_metadata, hostid, hostname, linux-release, MapRBuildVersion, mapr-clusters.conf, and support_dump.log are place in the dump root for easier access.

Example

Collect support information and dump it to the file /opt/mapr/support/collect/mysupport-output.tar:

```
/opt/mapr/support/tools/mapr-support-dump.sh -n mysupport-output
```

Example Output

```
/opt/mapr/support/tools/mapr-support-dump.sh -n mysupport-output
2015-06-25 11:51:38.397 INFO Starting Support dump collection. For
```

maprlogin
Authenticates logins to secure MapR clusters.

The `/opt/mapr/bin/maprlogin` command line tool enables users to log into secure MapR clusters. Users authenticate themselves to the cluster with a `maprticket` that can be generated in the following ways:

- Run `maprlogin password` to authenticate with username and password.
- Run `maprlogin generateticket` to request a service, tenant, or cross-cluster ticket for use by an external application or user account (based on the current user's ticket).
- Run `maprlogin kerberos` after generating a Kerberos ticket with the `kinit` command.

Note: Tickets contain keys, and are used to authenticate users and MapR servers. Every user who wants to access a cluster must have a MapR user ticket (`maprticket_<uid>`) and every node in the cluster must have a MapR server ticket (`maprserverticket`).

For more details about different ways to generate tickets, see Tickets.

Syntax

```
/opt/mapr/bin/maprlogin <argument> <option>
```

Arguments

Argument	Description
`authtest`	Simulates runtime behavior during authentication. The following is the syntax for running the `maprlogin` command with this argument: `/opt/mapr/bin/maprlogin authtest [ -cluster mapr cluster name ]` For more information, see Options on page 2132.
`end|logout`	Logs out of the cluster. The following is the syntax for running the `maprlogin` command with this argument: `/opt/mapr/bin/maprlogin end|logout [ -cluster mapr cluster name ]` For more information, see Options on page 2132.

Argument	Description

`generateticket`	Generates a ticket for another user or application. The user who runs the `maprlogin` command with this option must already have a user ticket and must have `fc` (full control) ACL authorization on the cluster. See acl set.
	The following is the syntax for running the `maprlogin` command with this argument:
	`/opt/mapr/bin/maprlogin generateticket`
	`-type service|crosscluster|servicewithimpersonation|tenant`
	`-user <UNIX user name>`
	`[ -cluster <cluster name> ]`
	`-out <ticket location>`
	`[ -duration <[Days:]Hours:Minutes OR -duration Seconds> ]`
	`[ -renewal <[Days:]Hours:Minutes OR -duration Seconds> ]`
	`[ -impersonateduids <uids to impersonate> ]`
	`[ -impersonatedgids <gids to impersonate> ]`
	For more information, see Options on page 2132.

`kerberos`	Indicates the presence of a Kerberos ticket. The following is the syntax for running the `maprlogin` command with this argument:
	`/opt/mapr/bin/maprlogin kerberos`
	`[ -cluster <cluster name> ]`
	`[ -duration <ticket duration> ]`
	For more information, see Options on page 2132.

`password`	The user's UNIX password. The following is the syntax for running the `maprlogin` command with this argument:
	`/opt/mapr/bin/maprlogin password`
	`[ -cluster <cluster name> ]`
	`[ -user <user name> ]`
	`[ -duration <ticket duration> ]`
	`[ -out <ticket location> ]`
	For more information, see Options on page 2132.

`print`	Prints ticket of any type and contains information including the cluster name, the user ID, the date when the ticket was created, the ticket expiration date, and whether user can impersonate other users, and whether the ticket is for a tenant.
	In the service tickets, the value for `CanImpersonate` is `true` if impersonation is enabled for user and `false` if impersonation is disabled for the user. In the regular cluster ticket for the user, the value of `CanImpersonate` is always `false`. In the tenant ticket, the value for `CanImpersonate` is always `true`.
	The following is the syntax for running the `maprlogin` command with this argument:
	`/opt/mapr/bin/maprlogin print`
	`[ -ticketfile <location of ticket file> ]`
	For more information, see Options on page 2132.

last-updated: Apr 11, 2022

Argument	Description

`renew`	Renews the ticket, given a duration that does not cause the ticket to exceed its maximum lifetime. The original `-renewal` value for the ticket determines its maximum lifetime. The following is the syntax for running the `maprlogin` command with this argument:
	`/opt/mapr/bin/maprlogin renew`
	`[ -cluster <cluster name> ]`
	`[ -duration <ticket renew duration> ]`
	`[ -ticketfile <input ticket file> ]`
	`[ -out <ticket location> ]`
	For more information, see Options on page 2132.

Options

Option	Description	Default
`-cluster`	Name of the cluster to log into.	First cluster name in the `/opt/mapr/conf/mapr-clusters.conf` file.

`-duration`	Length of time before the ticket expires, specified in one of the following formats:
	`-duration [Days:]Hours:Minutes`
	`- duration Seconds`
	Password-generated tickets are bounded by the CLDB duration and renewal properties that are set for the cluster:
	• `cldb.security.user.ticket.duration.seconds` (default=`1209600`) is used if duration is not specified while generating the ticket.
	• `cldb.security.user.ticket.max.duration.seconds` (default=`2592000`) is the maximum duration allowed for a ticket.
	For password-generated tickets, if `-duration` is not set with the `maprlogin` command, the CLDB duration property is used by default.
	See config.
	Note: The `service`, `servicewithimpersonation`, tenant, and `crosscluster` tickets may have a very long lifetime; their duration is not bounded by these properties. For service and crosscluster tickets, the default value is LIFETIME.
		• 1209600 seconds (14 days) for user tickets
		• LIFETIME for service and cross-cluster tickets

last-updated: Apr 11, 2022

Option	Description	Default
`-impersonatedgids`	The comma-separated list of GIDs to impersonate. This can only be specified when generating a servicewithimpersonation ticket. If this is specified, the ticket owner can only impersonate the specified groups or users belonging to the specified groups. If `impersonatedgids` and `impersonareduids` are not specified, the ticket holder can impersonate all users on the cluster except the root user or the mapr user.	No default
`-impersonateduids`	The comma-separated list of UIDs to impersonate. This can only be specified when generating a servicewithimpersonation ticket. If this is specified, the ticket owner can only impersonate the specified users. If `impersonatedgids` and `impersonareduids` are not specified, the ticket holder can impersonate all users on the cluster except the root user or the mapr user.	No default
`-out`	A safe directory location where the ticket will be stored. Can be used with `generateticket`, `password`, and `renew` commands. You must specify a location when generating service and tenant tickets. (This requirement ensures that other tickets are not overwritten.)	`/tmp/maprticket_<uid>` (default applies to non-service tickets only)

`-renewal`	Total lifetime of the ticket, specified in one of the following formats:
	`-renewal [Days:]Hours:Minutes`
	`-renewal Seconds`
	If `-renewal` is not set with the `maprlogin` command, the CLDB renewal property is set by default (`cldb.security.user.ticket.renew.duration.seconds`). You can also set the `cldb.security.user.ticket.renew.max.duration.seconds` property, which is the maximum duration (7776000, by default) allowed for a ticket renewal.
	Note: Service, tenant, and crosscluster tickets are not bounded by these properties.
	For example, assume that the `maprlogin` command passes the following options for a service ticket:
	`-duration 30:0:0 -renewal 90:0:0`
	The ticket will expire after 30 days unless it is renewed. If a `maprlogin renew` command is submitted for the ticket before the initial 30 days pass, the ticket's lifetime may be extended up to a total maximum lifetime of 90 days. Tickets do not renew automatically; administrators must renew them with the `maprlogin renew` command, specifying a valid renewal period, and they must do this before the duration period ends. The renewal period must be less than or equal to the remaining amount of time allowed on the ticket.
	Using the same example, if you renew a ticket on the 29th day of its life, you can renew it for up to 61 days. You can renew a ticket incrementally, for some number of days at a time, as long as you do not exceed the original renewal value.
		2592000 seconds (30 days)

Option	Description	Default
`-ticketfile`	Optional with `print` and `renew` commands. Specifies the path to ticket file, if different from default. If this is not specified, the command looks for the ticketfile (`maprticket_<uid>`) in the default location, which is `/tmp` on Linux and `%TEMP%` on Windows systems or in the location specified by the environment variable, `$MAPR_TICKETFILE_LOCATION`.	• Linux: `/tmp` • Windows: `%TEMP%`
`-type`	Required ticket type for the `generateticket` command; value must be `service`, `servicewithimpersonation`, `tenant`, or `crosscluster`: • `service` is used to generate service tickets for regular cluster operations. • `servicewithimpersonation` is used to generate tickets for regular cluster operations, including allowing user to impersonate other users. • `tenant` is used to generate tickets for tenant users/hosts. • `crosscluster` is used to generate tickets for inter-cluster operations, such as remote mirroring. The `crosscluster` option only works with the `mapr` user.	No default; `-type` must be set in the `maprlogin generateticket` command.
`-user`	Required with the `generateticket` command. The UNIX user name of the user on the MapR cluster. For `crosscluster` tickets, the user must be `mapr`.	No default

maprlogin Command Examples
Describes common scenarios associated with `maprlogin` usage.

Generating and Displaying User Ticket

Generate a user ticket:

```
$ maprlogin password
[Password for user 'juser' at cluster 'my.cluster.com': ]
MapR credentials of user 'juser' for cluster 'my.cluster.com'
are written to '/tmp/maprticket_1000'
```

Display the ticket for the current user. Sample output is shown below.

```
$ maprlogin print
Opening keyfile /tmp/maprticket_1000
my.cluster.com: user = juser,
created = 'Mon Sep 17 08:30:26 PDT 2018', expires = 'Mon Oct 01 08:30:26
PDT 2018',
RenewalTill = 'Wed Oct 17 08:30:26 PDT 2018', uid = 20001, gids = 54261,
CanImpersonate = false
```

Generating and Displaying mapr User Ticket

Generate a ticket for the `mapr` user:

```
# su mapr
$ maprlogin password
[Password for user 'mapr' at cluster 'test.cluster.com': ]
MapR credentials of user 'mapr' for cluster 'test.cluster.com'
are written to '/tmp/maprticket_5000'
```

Display the ticket for the current user. Sample output is as follows.

```
$ maprlogin print
Opening keyfile /tmp/maprticket_5000
test.cluster.com: user = mapr, created = 'Mon Sep 17 09:18:19 PDT 2018',
expires = 'Mon Oct 01 09:18:19 PDT 2018', RenewalTill = 'Wed Oct 17
09:18:19 PDT 2018',
uid = 5000, gids = 5000, 0, 5001, CanImpersonate = true
```

Generating and Displaying Service Ticket

Generate a service ticket, *longlived_ticket*, in `/tmp` for *maprUser1*:

```
$ maprlogin generateticket -type service -out /tmp/longlived_ticket
-duration 30:0:0 -renewal 90:0:0 -user maprUser1
MapR credentials of user 'maprUser1' for cluster 'JSKCluster129_secure'
are written to '/tmp/longlived_ticket'
```

Display the service ticket in a specified location:

```
$ maprlogin print -ticketfile /tmp/ticketwithduration
Opening keyfile /tmp/ticketwithduration
JSKCluster129_secure: user = maprUser1,
created = 'Tue Jun 14 11:12:01 PDT 2017', expires = 'Thu Jul 14 11:12:01
PDT 2017',
RenewalTill = 'Mon Sep 12 11:12:01 PDT 2017',
uid = 0, gids = 0, CanImpersonate = false
```

Generating and Printing Service with Impersonation Ticket

Generate a service with impersonation ticket (in `/var/tmp`) for *maprUser1*:

```
$ maprlogin generateticket -type servicewithimpersonation -user maprUser1
-out /var/tmp/impersonationTicketMapRuser1
```

After generating the ticket, ensure that `maprUser1` has read permissions on the ticket. If you move the ticketfile to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable.

Display the service with impersonation ticket in the specified location:

```
$ maprlogin print -ticketfile /var/tmp/impersonationTicketMaprUser1
Opening keyfile /var/tmp/impersonationTicketMaprUser1
JSKCluster129_secure: user = maprUser1,
created = 'Mon Apr 18 13:46:38 PDT 2017', expires = 'Mon May 02 13:46:38
PDT 2017',
RenewalTill = 'Wed May 18 13:46:38 PDT 2017',
uid = 501, gids = 502, CanImpersonate = true
```

To allow a user to impersonate only specific users and/or groups, use the `impersonateduids` and/or `impersonatedgids` options with the `maprlogin` command. For example:

```
$ maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration
30:0:0 -impersonateduids 1002,1003 -impersonatedgids 1005,1006 -renewal
90:0:0
```

The command generates a service with impersonation ticket. The ticket holder can impersonate users whose UIDs are 1002 and 1003, and users in the groups with GIDs 1005 and 1006. The ticket expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time within 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Generating a Tenant Ticket that is Valid for Specific IPs

Generate a tenant ticket (in `/tmp`) for user *test* that is valid for specific IPs:

```
$ maprlogin generateticket -type tenant -out /tmp/ticketip -ips
10.9.0.1,10.9.0.2 -user test
MapR credentials of user 'test' for cluster 'my.cluster.com' are written to
'/tmp/ticketip'
```

Note: The `-ips` argument is only valid for the `tenant` ticket type.

Display the generated tenant ticket:

```
$ maprlogin print -ticketfile /tmp/ticketip
Opening keyfile /tmp/ticketip
my.cluster.com: user = test, created = 'Tue Aug 25 00:34:14 PDT 2020',
expires = 'Tue Aug 25 00:34:14
PDT 12020', RenewalTill = 'Tue Aug 25 00:34:14 PDT 12020', uid = 5001, gids
= 7001,
CanImpersonate = true, isExternal = true, ips = 10.9.0.1,10.9.0.2,,
IsTenant = true
```

Generating and Displaying Cross-Cluster Ticket

Generate a cross-cluster ticket (in `/tmp`) for *maprUser1*:

```
$ maprlogin generateticket -type crosscluster -out /tmp/
crossclusterTicket -user maprUser1
MapR credentials of user 'maprUser1' for cluster 'JSKCluster128_secure'
are written to '/tmp/crossclusterTicket'
```

Display the contents of a cross-cluster ticket in the specified location:

```
$ maprlogin print -ticketfile /tmp/crossclusterTicket
Opening keyfile /tmp/crossclusterTicket
ClusterSecure: user = root,
created = 'Fri May 27 14:29:40 PDT 2017', expires = 'Fri May 27 14:29:40
PDT 12017',
RenewalTill = 'Fri May 27 14:29:40 PDT 12017',
uid = 0, gids = 0, CanImpersonate = false
```

Running an Authentication Test

`authtest`: This troubleshooting option simulates the behavior of the runtime during authentication, going through the authentication flow.

Options: [`-cluster`] Specifies the name of the cluster.

Ending a Session Before the Ticket Expires

`end` or `logout`: Destroys tickets and logs out.

Options: [`-cluster`] Specifies the name of the cluster. By default, deletes all tickets for all clusters.

Renewing a Ticket Before It Expires

`renew`: Renews an existing ticket for a specified time period.

Options:

- `[ -cluster ]` - Specifies the name of the cluster.
- `[ -duration ]` - Specifies the ticket duration.

The duration you specify must be valid for the ticket in question, given the original `-renewal` value for the ticket and the life of the ticket when the renew command is run:

- You cannot renew a ticket that has already expired.
- You can renew the same ticket multiple times.
- The renewal period (or periods) cannot exceed the available time left for the ticket.

For example, assume that a ticket is created with a duration of 10 days and a renewal of 30 days:

```
maprlogin password -duration 10:0:0 -renewal 30:0:0
```

- On the 11th day, the ticket expires and cannot be renewed at all.
- On the 9th day, you can renew the ticket for any number of days up to a maximum of 21.
- On the 23rd day, you can renew the ticket for any number of days up to a maximum of 7.

Example: Renew a ticket and display the renewed ticket in the specified location:

```
$ maprlogin renew -out /tmp/RenewedsecureClusterTicket
-ticketfile /tmp/secureClusterTicket -duration 1:0:0

$ maprlogin print -ticketfile /tmp/RenewedsecureClusterTicket
Opening keyfile /tmp/RenewedsecureClusterTicket
JSKCluster129_secure: user = root,
created = 'Tue Jun 07 11:53:29 PDT 2017',
expires = 'Wed Jun 08 11:56:56 PDT 2017',
RenewalTill = 'Thu Jul 07 11:53:29 PDT 2017',
uid = 0, gids = 0, CanImpersonate = false
```

Troubleshooting maprlogin Failures

While the root causes of most failure cases with maprlogin can be quickly diagnosed, the following cases can prove challenging:

- When security is enabled for a cluster, the cluster's CLDB listens for connections on port 7443. If security for the cluster is disabled, the `maprlogin` utility is unable to reach the CLDB.

- The utility's connection uses HTTPS, which requires the file `conf/ssl_truststore` to exist on the client. If the file is not present, a secure connection cannot be negotiated.

Detailed error logs for `maprlogin` connection attempts are kept at `logs/maprlogin-<USERID>-nnnn.log`.

mrconfig
The `mrconfig` commands let you create, remove, and manage storage pools, disk groups, and disks; and provide information about containers.

Warning: The `mrconfig` commands provide direct control and low-level access to the MapR filesystem. If you are not careful, or do not know what you are doing, you can irrevocably destroy valuable data.

mrconfig cntr
Discusses the `mrconfig cntr` commands that allow you to manage containers and container replicas.

mrconfig cntr disablethrottle
Permits disabling throttling for resync of a container.

The `mrconfig cntr disablethrottle` command allows you to disable throttling for resync of a container (specified by ID). Run this command on the node that is the source for the resync.

Note: By default, throttling is disabled if resync is not complete after 30 minutes, or when there is only one replica container.

Syntax

```
/opt/mapr/server/mrconfig cntr disablethrottle <cid>
```

Parameters

Parameter	Description
`cid`	The ID of the container.

Example

Command

```
/opt/mapr/server/mrconfig cntr disablethrottle 2049
```

Output

```
----------------------
|From Instance 5660::|
----------------------
Changing throttling on container 2049 throttle flag disable
```

mrconfig cntr resetthrottle
Permits resetting the throttle setting for resync of a container.

The `mrconfig cntr resetthrottle` command allows you to reset the throttle setting for resync of a container (specified by ID).

Note: Run this command only after the resync operation (on the specified container) is complete.

Syntax

```
/opt/mapr/server/mrconfig cntr resetthrottle <cid>
```

Parameters

Parameter	Description
`cid`	The ID of the container.

Example

Command

```
# /opt/mapr/server/mrconfig cntr resetthrottle 2049
```

Output

```
----------------------
|From Instance 5660::|
----------------------
Changing throttling on container 2049 throttle flag reset
```

mrconfig cntr resyncprogress
Retrieves the status of a resync operation for containers or volumes.

The `mrconfig cntr resyncprogress` command allows you to get the status of a resync operation for containers or volumes (specified by IDs).

Syntax

```
/opt/mapr/server/mrconfig cntr resyncprogress --cids|--volids <id,...>
```

Parameters

Parameter	Description
`--cids`	The comma-separated list of container IDs.
`--volids`	The comma-separated list of volume IDs.

Example

Command

```
# /opt/mapr/server/mrconfig cntr resyncprogress --cids 2104
```

Output

```
----------------------
|From Instance 5660::|
----------------------
List of Source Container Ids: 2104
List of Volume Ids:
Resync Progress Info
--------------------
Cid: 2104, Snapshot Cid: 4069905785, Vol Id: 233969254, Location: Source,
Peer Addr: 10.20.30.40:5660
```

```
ResyncType: Container Resync, Status: Resync In Progress, Total Inodes:
4095, Resync Complete: 4095
```

mrconfig dbinfo
Each instance of the file server on a node is responsible for processing and tracking activities that result from running database commands. The `mrconfig dbinfo` command displays information about the activities, including information related to containers, tablets, storage pools, tags, and threads processing operations on tables.

See `mrconfig` for instructions about running `mrconfig` commands.

mrconfig dbinfo arena
The `mrconfig dbinfo arena` command displays all the database related arenas (contiguous piece of memory), including the arena count and byte allocated.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo arena
```

Example

Display arena information.

```
/opt/mapr/server/mrconfig dbinfo arena

mrconfig dbinfo autosetup
The `mrconfig dbinfo autosetup` command displays information about replica autosetup for database tables.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo autosetup
```

Example

Display replica autosetup information for database tables.

```
/opt/mapr/server/mrconfig dbinfo autosetup
----------------------
Time: 2020-08-18 14:49:10,4851 Instance 5660
----------------------
table 2049.557.263820 replicaIdx 1 replicaState 4 event 0 schedState 0

mrconfig dbinfo cidmapcache
The `mrconfig dbinfo cidmapcache` command displays the number of entries in the container ID cache and the number of successful and unsuccessful lookups performed by each instance of the file server on the cache.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo cidmapcache
```

Example

Display container ID information.

```
/opt/mapr/server/mrconfig dbinfo cidmapcache
----------------------
Time: 2020-08-17 11:58:27,2761 Instance 5660
----------------------
entries 88138
numLookups 0
numMisses 0
----------------------
Time: 2020-08-17 11:58:27,2769 Instance 5661
----------------------
entries 88138
numLookups 0
numMisses 0
```

mrconfig dbinfo copyregiontrackers
The `mrconfig dbinfo copyregiontrackers` command displays information about copy region progress for tables upon a replica autosetup.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo copyregiontrackers
```

Example

Display the copy region progress for tables upon replica autosetup.

```
/opt/mapr/server/mrconfig dbinfo copyregiontrackers
----------------------
Time: 2020-08-18 14:50:32,0558 Instance 5660

```

mrconfig dbinfo copyregionworkers
The `mrconfig dbinfo copyregionworkers` command displays information about the worker threads for parallel copy regions.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo copyregionworkers
```

Example

Display the

```
/opt/mapr/server/mrconfig dbinfo copyregionworkers
----------------------

```

mrconfig dbinfo mem
The `mrconfig dbinfo mem` command displays memory information related to storage pools and buckets.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo mem
```

Example

Display memory information.

```
/opt/mapr/server/mrconfig dbinfo mem

pendingBucketFlushes 0
numActiveBuckets 0
totalActiveBucketsSz 0
```

mrconfig dbinfo replbuckets
The `mrconfig dbinfo replbuckets` command displays the replication progress information for the data in each bucket for each replica of a table.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo replbuckets
```

Example

Display replication progress.

```
/opt/mapr/server/mrconfig dbinfo replbuckets
----------------------
Time: 2020-08-18 15:01:00,5833 Instance 5660

backoff 7 lastAttemptAt 1597788059
```

mrconfig dbinfo repltable
The `mrconfig dbinfo repltable` command displays information about all the replicas setup on a table.

See mrconfig for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo [-v] repltable <tableFid>
```

Parameters

Parameter	Description
-V	Sets the verbose option.
tableFid	The file identifier for the table.

Example

Display the information about all the replicas setup on a table.

```
/opt/mapr/server/mrconfig dbinfo repltable 2049.557.263820
----------------------
Time: 2020-08-18 15:05:43,2650 Instance 5660

maxPendingTS 0 bucketsPending 0 bytesPending 0 putsPending 0
```

mrconfig dbinfo tablets
The `mrconfig dbinfo tablets` command displays information about tablets (table regions).

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo tablets
```

last-updated: Apr 11, 2022

Example

Display information about tablets.

```
/opt/mapr/server/mrconfig dbinfo tablets

```

mrconfig dbinfo tabletsplits
The `mrconfig dbinfo tabletsplits` command displays information about the tablets (table regions) being split.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo tabletsplits
```

Example

Display information about the tablets currently being split.

```
/opt/mapr/server/mrconfig dbinfo tabletsplits
----------------------
Time: 2020-08-18 15:09:34,9493 Instance 5660

stabilizeState PAUSE_PARTITION_SPLITS
```

mrconfig dbinfo threads
The `mrconfig dbinfo threads` command displays information about the throttling queue for each thread processing BatchGet operations, such as the number of free and maximum slots. The command also displays the work areas (WA) for the RPCs being processed by the file server.

You can configure the number of operations that run in parallel in mfs.conf through the `mfs.db.max.concurrent.internal.ops` option. See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dbinfo threads
```

Example

Display the throttling queue information for BatchGet operations and work areas (WA) for the RPCs currently being processed by the file server.

```
/opt/mapr/server/mrconfig dbinfo threads
----------------------
Time: 2020-08-13 12:08:33,9402 Instance 5662

mrconfig dg

This section discusses the `mrconfig dg` commands that allow you to configure disk groups.

mrconfig dg create

Facilitiates creation of disk groups.

The `mrconfig dg create` commands let you create disk groups (after you initialize disks with the `mrconfig disk init` command and add them to the node with the `mrconfig disk load` command).

You can create a disk group with one of two formats:

- Use the `mrconfig dg create raid0` command to create a striped disk group with a RAID 0 format.
- Use the `mrconfig dg create concat` command to create a concatenated disk group (one disk after another).

After you create disk groups you will be ready to create storage pools on the disk groups.

See `mrconfig` for instructions about running `mrconfig` commands.

mrconfig dg create concat

last-updated: Apr 11, 2022

The `mrconfig dg create concat` command creates a concatenated disk group. When a disk group is created MapR assigns one of the disks as the device path of the disk group. After you create a disk group you will be ready to create a storage pool on the disk group.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dg create concat <path>
```

Parameters

Parameter	Description
path	The device path of each of the disks to add to the disk group; example /dev/sdc /dev/sdd /dev/sde

Examples

Create a concatenated disk group on a local node

```
/opt/mapr/server/mrconfig dg create concat /dev/sdc /dev/sdd /dev/sde
```

mrconfig dg create raid0

Creates a disk group striped for RAID 0.

The `mrconfig dg create raid0` command creates a disk group striped for RAID 0. When you create a disk group, MapR assigns one of the disks as the device path of the disk group. After you create a disk group, you are ready to create a storage pool on the disk group.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dg create raid0 [-d <stripeDepth>] <path>
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`
-d	The stripe depth in 8K blocs; default `128` (1 MB)
path	The device path of each of the disks to add to the disk group; example /dev/sdc /dev/sdd /dev/sde

Examples

Create a disk group striped for RAID 0 with a stripe depth of 24 on a local node

```
/opt/mapr/server/mrconfig dg create raid0 -d 24 /dev/sdc /dev/sdd /dev/sde
```

mrconfig dg help

The `mrconfig dg help` command displays online help for disk group commands.

last-updated: Apr 11, 2022

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dg help
```

Examples
Display online help for `mrconfig dg` commands on a local node

```
/opt/mapr/server/mrconfig dg help
```

mrconfig dg list
The `mrconfig dg list` command lists the disk groups on all the MapR File System disks on a node.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dg list
```

Examples
List the disk groups on all the MapR File System disks on localhost

```
/opt/mapr/server/mrconfig disk list
```

mrconfig disk
This section discusses the `mrconfig disk` commands.
mrconfig disk help

The `mrconfig disk help` command displays the help text for `mrconfig disk` commands.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig disk help
```

Example
Display the help text for `mrconfig disk` commands on a local node

```
/opt/mapr/server/mrconfig disk help
```

mrconfig disk init

The `mrconfig disk init` command initializes a disk and formats it for the MapR filesystem.

Note:

Warning: Initializing a Disk Causes Data Loss

Initializing a disk destroys the data on the disk, so be sure that all data on a disk is backed up and replicated before initializing the disk.

After executing the `mrconfig disk init` command, add the disk to the node with the `mrconfig disk load` command.

See `mrconfig` for instructions about running `mrconfig` commands. **Tip:**

To initialize, format, and load one or more disks in one step using:

- The MapR Control System, see Adding Disks to MapR File System on page 837.
- The CLI, see `disk add` on page 1602 command.

Syntax

```
/opt/mapr/server/mrconfig disk init <path>
    [-F]
    <path>
```

Parameters

Parameter	Description
-F	Forces formatting of the disk for MapR File System, regardless of prior formatting or existing data.
path	The device path of the disk; example /dev/sdc

Examples
Initialize a disk for MapR File System on a local node

```
/opt/mapr/server/mrconfig disk init /dev/sdc
```

Initialize and format a disk for MapR File System on a local node

```
/opt/mapr/server/mrconfig disk init -F /dev/sdc
```

Initialize and format a disk for MapR File System on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx disk init -F /dev/sdc
```

mrconfig disk list

The `mrconfig disk list` command lists all of the disks on a node that have a MapR filesystem.

It also shows information about the disk groups and storage pools on the node including whether or not the storage pools are online.

See `mrconfig` for instructions about running `mrconfig` commands.

Tip:

To list system disks and other available disks on a node in addition to MapR File System disks using:

- The MapR Control System, see Viewing the List of Disks on page 834.
- The CLI, see `disk list` on page 1604 command.

Syntax

```
/opt/mapr/server/mrconfig disk list [<path>]
```

Parameters

Parameter	Description
path	The path of the disk; if not included shows information about all disks on the node, if included only shows information about the specified disk; example: /dev/sdc

Examples
List information about all MapR File System disks on a local node

```
/opt/mapr/server/mrconfig disk list
```

List information about MapR File System disk `/dev/sdc` on a local node

```
/opt/mapr/server/mrconfig disk list /dev/sdc
```

mrconfig disk load

After initializing a disk with the `mrconfig disk init` command, load the disk into memory with the `mrconfig disk load` command.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig disk load <path>

    <path>
```

Parameters

Parameter	Description
path	The device path of the disk; example /dev/sdc

Examples
Load a disk on a local node

```
/opt/mapr/server/mrconfig disk load /dev/sdc
```

mrconfig disk remove

The `mrconfig disk remove` command removes a disk from MapR File System. A disk cannot be removed unless its storage pool is offline.

Note: Warning: Removing a Disk Causes Data Loss

Removing a disk destroys the data on the disk, so be sure that all data on a disk is backed up and replicated before removing a disk.

The `mrconfig disk remove` command is typically used when replacing a failed disk on a node.

Syntax

```
/opt/mapr/server/mrconfig disk remove [<path>]
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
path	The device path of the disk; example /dev/sdc

Examples
Remove a disk from a local node

```
/opt/mapr/server/mrconfig disk remove /dev/sdc
```

Removing Disks Using mrconfig

Suppose one of three disks in a storage pool has failed, and the storage pool has gone offline.

To remove a disk with `mrconfig disk remove`:

1. Ensure that the data on the surviving disks is backed up/replicated.
2. Remove the failed disk from the node's disktab with the `mrconfig disk remove` command.
3. Physically remove the failed disk.
4. Physically attach the replacement disk.
5. Run the `mrconfig disk init` command on the replacement disk and on the other two disks that were in the disk group.
6. Run the `mrconfig disk load` command on each of the three disks.
7. Use the `mrconfig dg create` command to create a new disk group with the three disks.
8. Use the `mrconfig sp make` command to create a storage pool on the new disk group.

mrconfig info
The `mrconfig info` commands provide information about memory, threads, volumes, containers and other information about the MapR filesystem.

See `mrconfig` for instructions about running `mrconfig` commands.

mrconfig info containerchain

The `mrconfig info containerchain` command displays the containerchain for a given container. Example:

```
$ /opt/mapr/server/mrconfig info containerchain 2050
Container 2050 prev 256000049 next 0.
Container 256000049 prev 0 next 2050.
```

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig [-h <host>] [-p <port>] info containerchain <cid>

    <cid>
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`
cid	The container identifier

Tip:

Use the `mrconfig info dumpcontainers` command to find the container identifiers on a node.

Examples
Find the containerchain for a container with a cid of 2049 on a local node

```
/opt/mapr/server/mrconfig info containerchain 2049
```

Find the containerchain for a container with a cid of 2049 on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info containerchain 2049
```

mrconfig info containerlist

The `mrconfig info containerlist` command lists read/write container IDs for a specified volume. Example:

```
$ /opt/mapr/server/mrconfig info containerlist volume1
Volume containers
2050
```

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info containerlist
<volName>
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`
volName	The name of the volume

Tips:

You can see the names of volumes using:

- The **Volumes** view in the in the MapR Control System.
- The `maprcli volume list` command.

Examples
Display information about the containers in a volume named `marketing` on a local node

```
/opt/mapr/server/mrconfig info containerlist marketing
```

Display information about the containers on a volume named `marketing` on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info containerlist marketing
```

mrconfig info containers
The `mrconfig info containers` command displays information about containers.

Example:

```
$ /opt/mapr/server/mrconfig info containers rw
RW containers: 1 2049 2050
$ /opt/mapr/server/mrconfig info containers resync
$ /opt/mapr/server/mrconfig info containers snapshot
Snapshot containers: 256000049
```

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info containers
<container-type> [path]

    <container-type>
    [path]
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`
container-type	When specified, lists only containers of the specified type. Possible values: • `rw` • `resync` • `snapshot`
path	The path to a service pool (obtained with `mrconfig sp list`). When specified, lists only containers on the specified service pool.

Examples
Display a list of read/write containers on a local node

```
/opt/mapr/server/mrconfig info containers rw
```

Display a list of read/write containers on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info containers rw
```

mrconfig info dumpcontainers

The `mrconfig info dumpcontainers` command displays information about containers including container identifiers, volume identifiers, storage pools, total and free inodes per container.

Example:

```
$ /opt/mapr/server/mrconfig info dumpcontainers
cid:2352 volid:165226505 sp:SP2:/dev/sde

```

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info dumpcontainers
```

Input Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`

Output Fields

Field	Description
cid	Container ID
volid	Volume ID of the volume to which this container belongs.
sp	Storage pool to which this container belongs. For example: SP2:/dev/sde Here, SP2 is the name of the storage pool. /dev/sde is the disk on which the container resides.
spid	Storage pool ID
prev	Pointer to the previous snapshot cid or rw cid (for a clone container), in a snapshot chain.
next	Pointer to the next snapshot cid or rw cid (for a clone container), in a snapshot chain.
issnap	Indicates whether container is a snapshot or not, in a snapshot chain. • 0 - rw container (Not a snapshot container) • 1 - Snapshot
isclone	Indicates whether this container is a clone container created as part of the resync operation. • 0 - Not a clone • 1 - Is a clone
deleteinprog	Indicates whether this container is marked for deletion. • 0 - Not marked for deletion • 1 - Marked for deletion
fixedbyfsck	Indicates whether fsck was run on this container to fix any data or metadata errors. • 0 - fsck was not run on the container • 1 - fsck was run on the container

Field	Description
stale	Indicates whether the current cid is a stale cid or not. Container is marked as stale when it is yet to be processed for cleanup. • 0 - Not stale • 1 - Stale
querycldb	Indicates whether the container is awaiting its role from CLDB at the time of bringing up a cluster. • 0 - Not waiting as CLDB has already defined the role for the container • 1 - Waiting for CLDB to specify the role for the container
resyncinprog	Indicates if the container is resyncing from another container in the container chain. • 0 - Resyncing in progress • 1 - No resyncing
shared	Indicates whether the container is hosting any shared data. The value is the number of shared data blocks (each of size 8K).
owned	Indicates the number of data blocks (each of size 8K) that the container owns.
logical	Indicates the number of logical data blocks (each of size 8K) that are present in the container.
snapusage	Indicates the number of container blocks (each of size 8K) that are used for storing snapshot data.
snapusageupdated	Internal field.
ismirror	Indicates if this container is of a mirror volume or not. 0 - Is not of a mirror volume 1- Is of a mirror volume
isrwmirrorcapable	Indicates if the container belongs to a mirror volume, and if the volume can be converted to a rw volume, in case the primary volume goes down. • 0 - Volume cannot be converted • 1 - Volume can be converted
role	Role of the container, in the container chain. • 0 - Master • 1 - Not the master
totalInodes	Indicates the total number of inodes that can be created on the container.

last-updated: Apr 11, 2022

Field	Description
freeInodes	Indicated the number of inodes that are still available to be used.
dare	Indicates whether the container belongs to a volume that is dare-enabled or not. • 0 - Volume is not dare-enabled • 1 - Volume is dare-enabled
istiered	Indicates whether the container belongs to a tiered (either cold-tiered or EC enabled) volume. • 0 - Container belongs to a tiered volume • 1 - Container does not belong to a tiered volume
numtotalblocks	Applicable only for tiered volumes, this parameter indicates the total number of data blocks present in the container.
numpurgedblocks	Applicable only for tiered volumes, this parameter indicates the number of data blocks that are offloaded and not locally present. This value decreases in case of recalls.
numoffloadedblocks	Applicable only for tiered volumes, this parameter indicates the number of data blocks that are off-loaded to the tier.
maxUniq	Internal field.
isResyncSnapshot	Indicates whether the container belongs to the resync snapshot. • 0 - Container does not belong to the resync snapshot • 1 - Container belongs to the resync snapshot
snapId	Indicates the snapshot ID to which this container belongs, if the ID is a snap cid.
port	Indicates the MFS port number used by the container.

Examples

Display information about containers on a local node

```
/opt/mapr/server/mrconfig info dumpcontainers
```

Display information about containers on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info dumpcontainers
```

mrconfig info fsstate

The `mrconfig info fsstate` command displays information about the status of the MapR filesystem, for example whether or not storage pools are loaded. See `mrconfig` for instructions about running `mrconfig` commands.

last-updated: Apr 11, 2022

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info fsstate
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`

Examples
Display information about the state of the MapR filesystem on a local node

```
/opt/mapr/server/mrconfig info fsstate
```

Display information about the state of the MapR filesystem on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info fsstate
```

mrconfig info fsthreads

The `mrconfig info fsthreads` command displays information about threads running on MapR File System disks on a node. See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info fsthreads
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`

Examples
Display information about MapR filesystem threads on a local node

```
/opt/mapr/server/mrconfig info fsthreads
```

Display information about MapR filesystem threads on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info fsthreads
```

mrconfig info mastgateway

The `mrconfig info mastgateway` command must be run on a CLDB node. The command displays the status of the MAST Gateways, the total number of volumes assigned to them, and the number of active, inflight, and pending volumes.

See `mrconfig` `on page 2138` for instructions about running `mrconfig` commands.

last-updated: Apr 11, 2022

Syntax

```
/opt/mapr/server/mrconfig info mastgateway [<gwid>]
```

Parameters

Parameter	Description
gwid	The ID of the MAST Gateway for which to display information.

Examples

Display information about MAST Gateways on the cluster:

```
# /opt/mapr/servermrconfig -h 10.20.30.400 info mastgateway
Num MastGateways: 2

Gateway : atsqa8c46.qa.lab ( 6322920922584906487 )
Active : Yes
Active Vn : 101, Inflight Vn : 101
Num Active Vols : 4
Num Inflight Vols, Adds : 0, Removes : 0
Num Pending Vols, Adds : 0, Removes : 0

Active Vols :
153675213
97789611
23539482
45553484

Gateway : atsqa8c48.qa.lab ( 8723754106996643487 )
Active : Yes
Active Vn : 100, Inflight Vn : 100
Num Active Vols : 0
Num Inflight Vols, Adds : 0, Removes : 0
Num Pending Vols, Adds : 0, Removes : 0
No vols assigned to gateway.
```

mrconfig info nfsthreads

The `mrconfig info nfsthreads` command displays information about in-progress NFS operations.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info nfsthreads
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The NFS port; default `2049`

Output

The output shows the NFS operations currently running (in progress) including the IP address of the client and the type of operation. For example:

```
# /opt/mapr/server/mrconfig info nfsthreads
NFS Threads in progress = 15

Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
```

Examples

Display information about the NFS processes currently running:

```
/opt/mapr/server/mrconfig info nfsthreads
```

Display information about NFS operations in-progress on a remote node with an IP address of `xx.xx.xx.xx`:

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info nfsthreads
```

mrconfig info orphanagecount

The `mrconfig info orphanagecount` command displays orphan entries for a given container (specified by ID).

Syntax

```
/opt/mapr/server/mrconfig info orphanagecount <cid>
```

Parameters

Parameter	Description
cid	The ID of the container.

Examples

Display the number of orphan entries for container 2067:

```
~# /opt/mapr/server/mrconfig info orphanagecount 2067
----------------------
Time: 2017-03-31 18:00:49,1085 Instance 5660
----------------------
orphanagecount cid 2067 count 812
```

mrconfig info orphanlist

The `mrconfig info orphanlist` command displays information about a container's orphans. See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info orphanlist <cid>
    <cid>
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`
cid	The container identifier

Tip:

Use the `mrconfig info dumpcontainers` command to find the container identifiers on a node.

Examples
Display information about the orphans of a container with an identifier of 2049 on a local node

```
/opt/mapr/server/mrconfig info orphanlist 2049
```

Display information about the orphans of a container with an identifier of 2049 on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info orphanlist 2049
```

mrconfig info replication

The `mrconfig info replication` command displays information about container replication. See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info replication
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`

Examples
Display information about container replication on a local node

```
/opt/mapr/server/mrconfig info replication
```

Display information about container replication on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info replication
```

mrconfig info slabs

The `mrconfig info slabs` command displays a report about memory usage.

This report is sometimes used for troubleshooting by MapR customer support and is typically not used by customers.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info slabs
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`

Examples
Display information about memory usage on a local node

```
/opt/mapr/server/mrconfig info slabs
```

Display information about memory usage on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info slabs
```

mrconfig info threads

The `mrconfig info threads` command displays information about threads running on MapR File System. See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info threads
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`

last-updated: Apr 11, 2022

Examples
Display information about MapR filesystem threads on a local node

```
/opt/mapr/server/mrconfig info threads
```

Display information about MapR filesystem threads on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info threads
```

mrconfig info volume snapshot

The `mrconfig info volume snapshot` command displays information about volume snapshots.

Snapshot and this command require an upgrade to a MapR Enterprise Edition license if you don't already have it. See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info volume snapshot
<volName> <snapName>

    <volName>
    <snapName>
```

Parameters

Parameter	Description
-h	host IP address; default `127.0.0.1`
-p	The MapR File System port; default `5660`
volName	The name of the volume
snapName	The name of the snapshot

Tips:

To find volume and snapshot names:

- Navigate to the **Volume** view and the **Snapshot** view respectively in the MapR Control System, or
- Execute the `maprcli volume snapshot list` command, which creates a report that displays volume names and snapshot names.

Examples
Display information about snapshot "snap-2012-01-01" of volume "myVolume" on a local node

```
/opt/mapr/server/mrconfig info volume snapshot myVolume snap-2012-01-01
```

Display information about snapshot "snap-2012-01-01" of volume "myVolume" on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info volume snapshot myVolume
snap-2012-01-01
```

mrconfig info volume mastgateway

The `mrconfig info volume mastgateway` command displays the volume assignment information. This command must be run on a CLDB node.

See `mrconfig` on page 2138 for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig info volume mastgateway [<volName>]
```

Parameters

Parameter	Description
`volName`	The name of the volume for which to retrieve the volume assignment information.

Examples

Display the volume assignment information:

```
# ./mrconfig -h 10.20.30.400 info volume mastgateway
Num volumes : 4

Volume : vol2 ( 153675213 )
State: ASSIGNED
Curr: atsqa8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No

Volume : vol1 ( 45553484 )
State: ASSIGNED
Curr: atsqa8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No

Volume : vol4 ( 97789611 )
State: ASSIGNED
Curr: atsqa8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No

Volume : vol3 ( 23539482 )
State: ASSIGNED
Curr: atsqa8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No
```

mrconfig mastgateway

This section describes the mrconfig mastgateway commands that allow you to test PUT, GET, and DELETE operations on the corresponding tier.

mastgateway infomem

Returns memory information on the MAST Gateway node.

Syntax

```
mrconfig mastgateway infomem
```

last-updated: Apr 11, 2022

Parameters

None

Output

Name	The name of the memory pool in the gateway. Each pool has a number of memory objects (not S3 objects) that are used by the MAST Gateway as needed.
Max Free	The maximum number of objects from this pool that can be free.
Active	The number of memory objects from this pool that are allocated and used by the MAST Gateway.
Avail	The number of memory objects that are free, and can be reused when needed.
Obj Size	The size of the object.
Num Objs	The number of objects on the tier.
TierType	The type of tier. Value can be: • Cold • Ec

Example

```
# /opt/mapr/server/mrconfig mastgateway infomem
MASTGw mem info on 127.0.0.1:8660
    Name           Max Free  Active     Avail     Obj Size
     WriteFragBufsS3       128      0     0     8388616
    FullReadFragBufs       64       0     0     8388616
    FragReadFragBufs       1024     0     0     1048576

    Name             Num Objs       Obj Size     TierType
ColdTiering, Recall Frag       0       8388608       Cold
ColdTiering, Recall Full       0       8388608       Cold
ColdTiering, Offload           0       8388608       Cold
ErasureCoding, Recall Frag     0       25165824       Ec
ErasureCoding, Recall Full     0       25165824       Ec
ErasureCoding, Offload         0       25165824       Ec
```

mastgateway infothreads
Returns information on the threads processing the offload or recall operation.

Syntax

```
mrconfig mastgateway infothreads
```

Parameters

None

Output

The command returns the following if it is run during an ongoing offload or recall operation.

`threadId`	The ID of the thread processing the operation.
`volId`	The ID of the volume being offloaded.
`cid`	The ID of the container associated with the volume.
`cgid`	The gateway ID of the container associated with the volume.
`op`	The operation being processed. Value can be: • VolumeOffload • VolumeRecall

Example

Retrieve information on the threads processing the offload:

```
~# /opt/mapr/server/mrconfig -p 8660 mastgateway infothreads
InfoThreads on 127.0.0.1:8660
threadId: 0
volId: 23315726
cid: 2128

op: VolumeOffload

threadId: 1
volId: 23315726
cid: 2130

op: VolumeOffload

threadId: 10
volId: 23315726
cid: 2127

op: VolumeOffload

threadId: 11
volId: 23315726
cid: 2129

op: VolumeOffload

threadId: 12
volId: 23315726
cid: 2131

op: VolumeOffload
```

mastgateway refreshvolassignment
Triggers CLDB to re-assign specified volume to the least utilized MAST Gateway to rebalance tiering operations.

This can be used when new MAST Gateways are added or when MAST Gateways are removed from the cluster.

Note: You must run this command once for each volume to reassign. Run this command for all volumes if MAST Gateway is either newly added to the cluster or permanently removed from the cluster.

last-updated: Apr 11, 2022

Syntax

```
mrconfig mastgateway refreshvolassignment <volname>
```

Parameters

Parameter	Description
`volname`	The name of the volume to reassign.

Result

If the volume is successfully re-assigned, a success message (similar to the one shown in the Examples on page 2168 below) is printed on the console where the command was triggered.

In case of an error, the volume might or might not be assigned to the newly added MAST Gateway. However, the volume would either continue to be assigned to the same MAST Gateway or would be assigned to a different gateway. You can re-run the command in case of a failure.

Examples

Refresh the assignment of the containers associated with volume named vold23:

```
# /opt/mapr/server/mrconfig mastgateway refreshvolassignment vold23
volume assignment refreshed successfully.
```

mastgateway resumevolume
Resume tiering activities and allow reads and writes on the volume data.

Syntax

```
mrconfig mastgateway resumevolume <volname> [forceresume] [forcereset]
```

Parameters

Parameter	Description
`volname`	The name of the volume.
`forceresume`	This parameter is internal-only.
`forcereset`	This parameter is internal-only.

Examples

```
# /opt/mapr/server/mrconfig mastgateway resumevolume volTSECNEW9_3
2018-08-06 02:47:14,8585 ERROR Global mrconfig.cc:2120 ResumeVolume succeed
for volume : volTSECNEW9_3
```

mastgateway suspendvolume
Revoke and suspend a volume assigned to a MAST Gateway.

When the command is run:

1. The volume assignment to the MAST Gateway is revoked.
2. All tiering activities and client reads and overwrites on the volume are suspended.

3. The volume is reassigned to another MAST Gateway.

You must manually run the `mastgateway resumevolume` on page 2168 command to resume tiering activities, including reads and overwrites, on the volume data.

Syntax

```
/opt/mapr/server/mrconfig mastgateway suspendvolume <volname>
[ignoreflusherr deletcpfiles]
```

Parameters

Parameter	Description
`volname`	The name of the volume to reassign.
`ignoreflusherr`	This parameter is internal-only.
`deletcpfiles`	This parameter is internal-only.

Examples

Revoke volume assignment to MAST Gateway and suspend tiering activities on the volume:

```
# /opt/mapr/server/mrconfig mastgateway suspendvolume volTSECNEW9_3
2018-08-06 02:38:15,9360 INFO Global mrconfig.cc:2085 SuspendVolume :
success for volume volTSECNEW9_3
```

mastgateway tierget
Test retrieving an object from the storage tier.

Syntax

```
mrconfig mastgateway tierget
        <tierName>
        <objectID>
        <isSecure>
        [ <objectSize> ]
```

Parameters

Parameter	Description
`isSecure`	Specifies whether to use HTTPs or HTTP protocol. Value can be one of the following: • `true` - for HTTPs protocol • `false` - for HTTP protocol
`objectID`	The ID of the object to get frp, the storage tier. The ID must be the same ID (in string format) specified when offloading the object (using tierput command).
`objectSize`	The size of the object to get from the storage tier. The default value is 64KB.

last-updated: Apr 11, 2022

Parameter	Description
tierName	The name of the storage tier. If necessary, run the tier list on page 1880 command to retrieve the names of the tiers.

Example

Retrieve the object named sampleamazonobj of size 20971520 on the tier named amazonTier:

```
# /opt/mapr/server/mrconfig  mastgateway tierget amazonTier sampleamazonobj
true 20971520
time take for the operation: 8.748000 seconds
tierget successful
```

mastgateway tierdelete
Test deleting an object on the storage tier.

Syntax

```
mrconfig mastgateway tierdelete
        <tierName>
        <objectID>
        <isSecure>
```

Parameters

Parameter	Description
isSecure	Specifies whether to use HTTPs or HTTP protocol. Value can be one of the following: • true - for HTTPs protocol • false - for HTTP protocol
objectID	The ID of the object to get frp, the storage tier. The ID must be the same ID (in string format) specified when offloading the object (using tierput command).
tierName	The name of the storage tier. If necessary, run the tier list on page 1880 command to retrieve the names of the tiers.

Example

Delete the object named sampleamazonobj of size 20971520 KB in the tier named amazonTier:

```
# /opt/mapr/server/mrconfig mastgateway tierdelete amazonTier
sampleamazonobj true 20971520
time take for the operation: 0.339000 seconds
tierdelete successful
```

mastgateway tierput
Test offloading an object to the storage tier.

Syntax

```
mrconfig mastgateway tierput
    <tierName>
```

last-updated: Apr 11, 2022

```
    <objectID>
    <isSecure>
    [ <objectSize> ]
```

Parameters

Parameter	Description
`isSecure`	Specifies whether to use HTTPs or HTTP protocol. Value can be one of the following: • `true` - for HTTPs protocol • `false` - for HTTP protocol
`objectID`	The ID of the object to put on the storage tier. Value must be a string.
`objectSize`	The size of the object to put on the storage tier. The default value is 64KB.
`tierName`	The name of the storage tier. If necessary, run the `tier list on page 1880` command to retrieve the names of the tiers.

Example

Test offload of an object, whose ID is sapleamazonobj and size is 20971520, to the tier named amazonTier:

```
# /opt/mapr/server/mrconfig mastgateway tierput amazonTier sampleamazonobj
true 20971520
time take for the operation: 4.291000 seconds
tierput successful
```

mrconfig sp
The `mrconfig sp` commands create and control storage pools.

Storage pools are created on disk groups, so disk groups must be created before storage pools can be created.

MapR File System reads and writes data (and metadata) to and from logical storage units called volumes. Volumes store data in containers in storage pools.

Initially storage pools don't have any containers, the containers are automatically created for a volume as needed. When a container is created it is assigned a container identifier (cid).

Storage pools aren't associated with any particular volume – storage pools may hold containers for multiple volumes. Large files may be distributed across multiple containers, and therefore across multiple storage pools. Data replication happens at the container level.

Data cannot be written directly to containers, a volume is required.

You can create volumes in one of two ways:

- Click the **Create Volume** button in the **Data** > **Volumes** page in the MapR Control System, or
- Execute the `maprcli volume create` command.

See `mrconfig` for instructions about running `mrconfig` commands.

mrconfig sp help

The `mrconfig sp help` command displays the online help for storage pool commands.

last-updated: Apr 11, 2022

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp help
```

Examples
Display the online help for storage pools on a local node

```
/opt/mapr/server/mrconfig sp help
```

mrconfig sp list
Displays information about configured storage pools.

The `mrconfig sp list` command displays information about storage pools including the name, size, free space and path of each storage pool, whether or not each storage pool is online or offline, and the total number of storage pools. See mrconfig for instructions on running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig sp list [-v] [sp path]
```

Parameters

Parameter	Description
path	The device path of the storage pool. If you do not specify the path, information about all storage pools is displayed. If you specify the path, only information about the specified storage pool is displayed; example `/dev/sdc`
-v	Print storage pool and cluster GUID information including whether or not the storage pool is enabled for data-at-rest encryption (DARE), and service pool log (journal) size.

Examples

Display information about all storage pools on a local node:

```
/opt/mapr/server/mrconfig sp list
```

Display information about a storage pool with a path `/dev/sdc` on a local node:

```
/opt/mapr/server/mrconfig sp list /dev/sdc
```

Display storage pool information including whether or not the storage pool is DARE-enabled:

```
# /opt/mapr/server/mrconfig sp list -v
ListSPs resp: status 0:2
No. of SPs (2), totalsize 3518339 MB, totalfree 691937 MB

SP 0: name SP1, Online, size 1761217 MB, free 377127 MB, path /dev/
sdb, log 200 MB, port 5660, guid 9dd586829e179476005b0ce23f0dae3c,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sdb /dev/
sdd, dare 1
SP 1: name SP2, Online, size 1757121 MB, free 314809 MB, path /dev/
sde, log 200 MB, port 5660, guid daa5916af8909118005b0ce2430d6d54,
```

```
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sde /dev/
sdf, dare 1
```

mrconfig sp load

The `mrconfig sp load` command loads all of the disks associated with a storage pool.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp load <sp name>
```

Parameters

Parameter	Description
sp name	The name of the storage pool; example SP2

Tips:

- Use the `mrconfig sp list` command to see storage pool names (examples SP1, SP2) and the device paths of the storage pools (example `/dev/sdc`).
- Use the `mrconfig disk list` command to see storage pool names (examples SP1, SP2), the device paths of the storage pools (example `/dev/sdc`), and the disks associated with each storage pool (examples `/dev/sdc`, `/dev/sdd`, `/dev/sde`).

Examples
Load the disks associated with the storage pool named SP2 on the local node

```
/opt/mapr/server/mrconfig sp load SP2
```

mrconfig sp make

The `mrconfig sp make` command creates a storage pool on a concat disk group.

Warning: Creating a Storage Pool Causes Data Loss

Creating a storage pool on a disk group destroys the data on the disks in the disk group, so be sure that all data on the disks in the disk group is backed up and replicated before creating a storage pool.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp make <dg path>

    [ -P <yes/no> ]
    [ -l <LogSize> ]
    [ -s <deviceSize> ]
    [ -L <Lable> ]
    [ -F ]
    [ -I <cid> ]
    <dg path>
```

Parameters

Parameter	Description
-P	Primary partition or not; yes/no
-l	Log size in number of blocks; Note that this is a lowercase letter "l" (ell), not the number "1".
-s	Disk size in GB
-L	Label for this storage pool
-F	Force the overwrite of any existing storage pool
-I	Initialize the storage pool with one container with the specified container identifier, one directory, and one file. Note that this is an uppercase letter "I" (eye), not the letter "l" (ell) or the number "1".
dg path	The device path of the disk group; example /dev/sdc

Examples

Create a storage pool on a disk group with a path of `/dev/sdc` on a local node

```
/opt/mapr/server/mrconfig sp make /dev/sdc
```

Creating a Storage Pool Using mrconfig

To create a storage pool using mrconfig:

1. Assume the disks `/dev/sdb`, `/dev/sdc`, and `/dev/sdd` are available; initialize them with `mrconfig disk init`:

   ```
   /opt/mapr/server/mrconfig disk init /dev/sdb
   /opt/mapr/server/mrconfig disk init /dev/sdc
   /opt/mapr/server/mrconfig disk init /dev/sdd
   ```

2. Create a disk group with `mrconfig dg create`:

   ```
   /opt/mapr/server/mrconfig dg create raid0 -d
   128 /dev/sdb /dev/sdc /dev/sdd
   ```

3. Create a concatenated disk group with `mrconfig dg create concat` by specifying the primary drive.

   ```
   /opt/mapr/server/mrconfig dg create concat /dev/sdb
   ```

4. At this point, you can use `mrconfig dg list` to see the layout of the disk group, and which disk is the primary disk. The primary disk can be used in other commands to refer to the disk group as a whole. Example:

   ```
   /opt/mapr/server/mrconfig dg list
   ```

last-updated: Apr 11, 2022

5. From the disk group, create a storage pool with `mrconfig sp make`:

```
/opt/mapr/server/mrconfig sp make /dev/sdb
```

mrconfig sp offline

The `mrconfig sp offline` command takes a loaded storage pool offline. When a storage pool is offline it remains loaded into memory but it is not available to MapR filesystem for reads and writes.

The main use of the `mrconfig sp offline` command is to take a storage pool offline so the `fsck` (filesystem check) command can be run on one or more disks or storage pools if there are lost or corrupt containers, directories, tables, files, filelets, or blocks.

After running `fsck` the storage pool is brought back online with the `mrconfig sp online` command, and then typically the `gfsck` (global filesystem check) command would be run on the affected cluster, volumes, or snapshots.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp offline <sp path>
```

Parameters

Parameter	Description
sp path	The device path of the storage pool; example /dev/sdc

Examples
Offline a loaded storage pool with a path of `/dev/sdc` on localhost

```
/opt/mapr/server/mrconfig sp offline /dev/sdc
```

mrconfig sp offline all

The `mrconfig sp offline all` command takes all of a node's loaded storage pools offline. When a storage pool is offline it remains loaded into memory, but it is not available to MapR filesystem for reads and writes.

The main use of the `mrconfig sp offline all` command is to take all storage pools on a node offline so the `fsck` (filesystem check) command can be run on disks or storage pools if there are lost or corrupt containers, directories, tables, files, filelets, or blocks.

After running `fsck` the storage pools are brought back online with the `mrconfig sp online` command, and then typically the `gfsck` (global filesystem check) command would be run on the affected cluster, volumes, or snapshots.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp offline all
```

Examples
Offline all storage pools on a local node

```
/opt/mapr/server/mrconfig sp offline all
```

mrconfig sp online

The `mrconfig sp online` command makes an offline storage pool online.

When a storage pool is taken offline with the `mrconfig sp offline` command, the storage pool is not available for reads and writes. Typically this is done so the `fsck` (filesystem check) command can be run to check for or repair filesystem inconsistencies.

After the storage pool is put back online with the `mrconfig sp online` command, the storage pool is once again available for reads and writes, and the `gfsck` (global filesystem check) command can be run on the affected cluster, volumes or snapshots.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp online <sp path>
```

Parameters

Parameter	Description
sp path	The device path of the storage pool; example /dev/sdc

Examples
Online a storage pool with a path of `/dev/sdc` on a local node

```
/opt/mapr/server/mrconfig sp online /dev/sdc
```

mrconfig sp refresh

The `mrconfig sp refresh` command reloads the `disktab` file and adds any new disks to MapR File System.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp refresh
```

Examples
Refresh the storage pools on the local node

```
/opt/mapr/server/mrconfig sp refresh
```

mrconfig sp shutdown

The `mrconfig sp shutdown` command offlines all storage pools and stops the MapR filesystem on their disks.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp shutdown
```

Examples
Offline all storage pools on the local node and stop MapR filesystem on their disks

```
/opt/mapr/server/mrconfig sp shutdown
```

mrconfig sp unload

The `mrconfig sp unload` command unloads all of the disks associated with a storage pool.

See `mrconfig` for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp unload <sp name>
```

Parameters

Parameter	Description
sp name	The name of the storage pool; example SP2

Tips:

- Use the `mrconfig sp list` command to see storage pool names (examples SP1, SP2) and the device paths of the storage pools (example `/dev/sdc`).
- Use the `mrconfig disk list` command to see storage pool names (examples SP1, SP2), the device paths of the storage pools (example `/dev/sdc`), and the disks associated with each storage pool (examples `/dev/sdc`, `/dev/sdd`).

Examples
Unload the disks associated with the storage pool named SP2 on a local node

```
/opt/mapr/server/mrconfig sp unload SP2
```

mrdirectorystats
Prints the space usage for each directory, for a container.

The `mrdirectorystats` utility, when run for a container, prints the space usage information for all directories, starting from the root of the container. This utility is considerably faster than running `ls -R` command on the root of the container and is useful, for example, in identifying directories which need to be moved out to a different volume while trying to reduce the size of the current namespace container.

Syntax

```
/opt/mapr/server/mrdirectorystats
     -c <container_id>
     [ -p ]
     [ -h ]
```

Parameters

Parameter	Description
`c`	The ID of the container.
`h`	Prints help for running the command.
`p`	Prints only parent file ID (PFid) and other information about the file IDs (fids) in the container.

Output

When you specify the `-c` option, the utility prints the following information per directory to the console:

`DirFid`	The directory inode number.
`files`	The number of regular files under the directory.
`subdir`	The number of sub-directories inside the directory.
`others`	The number of other types of files (except directories and regular files), such as device, symlinks, kvstores, tables, etc., inside the directory.
`tfiles`	The total number of regular files stored in the entire directory tree.
`tsubdir`	The total number of sub-directories stored in the entire directory tree.
`tothers`	The total number of other type of files stored in the entire directory tree.
`cntrBlocks`	The space occupied in block size (8k) by the direct blocks of the total regular files (tfiles) in the directory tree, for the current container.
`fieletBlocks`	A rough estimation of the sum of all the data blocks of all the filelets of regular files spread across different data containers.

Note: The utility also shows volume links if any volume exists in the container.

The utility prints the following if `-p` is specified with `-c`:

`Inode`	The inode of the file.
`PFid`	The parent file ID.
`Type`	The type of entity in the container. Value can be one of the following: • Directory — indicates the entity is a directory. • VolLink — indicates entity is a volume link. • KvStore — indicates entity is KvStore.

last-updated: Apr 11, 2022

SubType	The sub-type of the entity in the container. Value can be one of the following: • Directory — indicates entity is directory. • VolLink — indicates entity is a volume link. • Table — indicates entity is a table. Entity can be table only if type is KvStore. • Tabletmap — indicates entity is a tabletmap. Entity can be tabletmap only if type is KvStore. • Schema — indicates entity is a schema. Entity can be schema only if type is KvStore.

Example

Retrieve the disk space usage information for a container by running the utility with the `-c` option:

```
#  ./mrdirectorystats -c 2245
DirFid          files     subdir   others  tfiles    tsubdir  tothers
cntrBlocks  fileletBlocks
2245.16.2       5         3        3       6         4        3
0           65536
2245.39.131308  1         0        0       1         0        0
0           0
2245.40.131310  0         1        0       0         1        0
0           0
2245.41.131312  0         0        0       0         0        0
0           0
2245.45.131320  0         0        0       0         0        0
0           0
symlinks 2 fidmaps 1 tables 1 schemas 1 tabletmaps 1
```

Retrieve information about the file IDs in the container by running the utility with the `-c` and `-p` option:

```
# ./mrdirectorystats  -p -c 2049
Inode :32       PFid: 2049.16.2         Type: VolLink   SubType: VolLink
Inode :33       PFid: 2049.16.2         Type: VolLink   SubType: VolLink
Inode :34       PFid: 2049.16.2         Type: Directory SubType: Directory
Inode :35       PFid: 2049.34.131372    Type: VolLink   SubType: VolLink
Inode :36       PFid: 2049.16.2         Type: VolLink   SubType: VolLink
Inode :37       PFid: 2049.16.2         Type: VolLink   SubType: VolLink
Inode :38       PFid: 2049.16.2         Type: VolLink   SubType: VolLink
Inode :39       PFid: 2049.16.2         Type: KvStore   SubType: Table
Inode :40       PFid: 2049.16.2         Type: VolLink   SubType: VolLink
Inode :41       PFid: 2049.39.262468    Type: KvStore   SubType: Tabletmap
Inode :42       PFid: 2049.39.262468    Type: KvStore   SubType: Schema
```

mrfscmd

Returns the path to the file specified by ID (fid).

Before running the utility, ensure that the `LD_LIBRARY_PATH` environment variable is set for the path to the `libjvm.so` file. If necessary, run the following command to set the `LD_LIBRARY_PATH`:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/java/jre/lib/amd64/server/
```

Syntax

```
/opt/mapr/server/mrfscmd fid path -fid <file-ID>
```

Parameters

Parameter	Description
fid	The ID of the file.

Output

On success, returns path to the file specified by ID (fid).

On failure, returns error.

Examples

The following examples show file path (on success) and errors returned by the utility.

```
# ./mrfscmd fid path -fid 2115.33.131412
/var/mapr/file1
```

```
# ./mrfscmd fid path -fid  2071.33.1313445
Error: Getting Path for Fid 2071.33.1313445 Failed - Stale file handle
(116).
```

```
# ./mrfscmd fid path -fid  2071.33.
Error: Invalid Fid 2071.33.
```

pullcentralconfig
Pulls master configuration files from `/var/mapr/configuration` on the cluster to the local disk, on each node.

The script `/opt/mapr/server/pullcentralconfig` pulls master configuration files from `/var/mapr/configuration` on the cluster to the local disk, on each node.

- If the master configuration file is newer, the local copy is overwritten by the master copy
- If the local configuration file is newer, no changes are made to the local copy

The volume `mapr.configuration` (normally mounted at `/var/mapr/configuration`) contains directories with master configuration files:

- Configuration files in the `default` directory are applied to all nodes
- To specify custom configuration files for individual nodes, create directories corresponding to individual hostnames. For example, the configuration files in a directory named `/var/mapr/configuration/nodes/host1.r1.nyc` are applied only to the machine with the hostname `host1.r1.nyc`.

The following parameters in `warden.conf` control whether central configuration is enabled, and how often `pullcentralconfig` runs:

- `centralconfig.enabled` — Specifies whether to enable central configuration.
- `pollcentralconfig.interval.seconds` — The frequency to check for configuration updates, in seconds.

stubfuse
Simulates a FUSE mount point to determine its read and write performance.

Simulates a FUSE mount point and creates a large test file named `hello`. Use the `dd` command to print the maximum read and write performance of this mount point. The values give you a fair idea of the performance to expect from a MapR POSIX FUSE client. For more information, see MapR FUSE-Based POSIX Client on page 1238

Note: Use an empty directory for the test, as the contents of this directory are emptied during the test. The files that are created during the test are not present after the test.

Attention: Export the path to `libfuse.so` before running this command. Run:

```
export LD_LIBRARY_PATH="/opt/mapr/lib"
```

Syntax

```
/opt/mapr/bin/stubfuse <mountpoint> [<options>] [-h|--help]
```

Parameters

Parameter	Description
`-h|--help`	Prints syntax and all supported options.
mountpoint	The simulated FUSE mount point. This parameter is required.
options	The options that can be specified with the command. Use `-h` or `--help` to retrieve the list of supported options.

Example

Retrieve the read and write performance for the mount point, `/tmp/egmnt`:

- For a write test: `dd if=/dev/zero of=/tmp/egmnt/hello count=100k bs=128k oflag=direct`

  Note: The name of the output file has to be `hello`. Else, the command will fail.

- For a read test: `dd if=/tmp/egmnt/hello of=/dev/null count=100k bs=128k`

  Note: The name of the input file has to be `hello`. Else, the command will fail.

The output will look similar to the following results:

```
100+0 records in
100+0 records out
5120 bytes (5.1 kB) copied, 0.000233249 s, 22.0 MB/s
```

Configuration Files

This section contains reference information about various configuration files.

last-updated: Apr 11, 2022

Configuration File Permissions

Files located in `/opt/mapr/hadoop-2.x.x/etc/hadoop` are owned by the root user account. To edit these files, you must be logged in as `root` user.

Automatic Rolloff of Old Configuration Files

Whenever you run `configure.sh`, the current `warden.conf`, `mapr-clusters.conf`, `hibernate.cfg.xml`, and `db.conf` configuration files are saved with the current timestamp appended to the name. They are saved to the following directory:

```
/opt/mapr/conf/conf.old
```

These configuration files are saved for backup purposes.

cldb.conf
Contains the configuration for CLDB nodes.

The file `/opt/mapr/conf/cldb.conf` specifies the configuration parameters for the CLDB nodes and the cluster topology.

cldb.containers.cache.entries	*Default Value*: 1000000 *Description*: The maximum number of read/write containers available in the CLDB cache.
cldb.default.topologyfileserver	*Default Value*: `/data` *Description*: The default topology for newly-created volumes.
cldb.detect.dup.hostid.enabled	*Default Value*: `false` *Description*: When `true`, CLDB disables *all* nodes with duplicate hostid, including new nodes that try to register with duplicate hostid *and* the existing node. Alarm NODE_ALARM_DUPLICATE_HOSTID is raised. This case requires administrator intervention to correct the hostid confusion. If duplicate hostid occurs on nodes running CLDB, the cluster may fail to start. Therefore, the alarm is not raised, but the `cldb.log` file in `/opt/mapr/logs/` contains an error message.
cldb.enable.memory.tracker	*Default Value*: `false` *Description*: Utility that monitors CLDB for memory usage and deadlocks. If `true`, memory allocations in CLDB are tracked. If memory usage of CLDB goes above certain limits, the utility generates core and shuts down the CLDB. Memory limit is configured as: `Xmx+non heap memory costant(default:3072MB)` You can change the non-heap memory usage by setting `cldb.memory.max.nonheap.mb` to any custom value. If CLDB memory usage goes beyond 130% of this limit, the utility dumps and shuts down CLDB. The default value is `false`.
cldb.ignore.posix.only.hb.alarm	*Default Value*: 1 *Description*: By default, this parameter is set to `1` to consider all nodes except edge nodes (nodes that

	have only POSIX clients and loopback NFS installed) for the No Heartbeat alarm . Set this parameter to `0` to include both edge as well as cluster nodes for the No Heartbeat alarm. **Note:** The edge nodes that went down before changing this parameter are not visible in alarms. However, edge nodes that go down after changing this parameter to `0` will be visible in alarms. See the `-nfsnodes` option of the node list on page 1705 command to view edge nodes.
cldb.ignore.stale.zk	*Default Value*: `false` *Description*: When this setting is `true`, the CLDB ignores the ZooKeeper's information regarding the most recent copy of CLDB data. Change this setting to `true` when the ZooKeeper information is stale. Restart the CLDB with this setting. After the CLDB starts, change the setting back to `false` then restart the CLDB again. Only change this setting on CLDB nodes that are known to have the most recent copy of the CLDB data. Shut down all CLDB processes before changing this variable.
cldb.jmxremote.port	*Default Value*: 7220 *Description*: The CLDB JMX remote port
cldb.max.security.policies	*Default Value*: 10000 *Description*: Defines the maximum number of configured security policies. To prevent users from arbitrarily creating numerous security policies and draining CLDB performance, the maximum number of security policies is limited to 10000 by default.
cldb.min.fileservers	*Default Value*: 1 *Description*: Number of file servers that must register with the CLDB before the root volume is created.
cldb.numthreads	*Default Value*: 10 *Description*: The number of threads reserved for use by the CLDB.
cldb.pbs.global.master	*Default Value*: 0 *Description*: Indicates the global primary cluster for the global namespace. Only the global primary security policy cluster can create/modify security policies. All other secondary security policy clusters can only view or import security policies.
cldb.port	*Default Value*: 7222 *Description*: The port on which the CLDB listens.
cldb.security.blacklist.cleanup.duration.seconds	*Default Value*: 36000 *Description*: Ticket blacklist cleanup interval.
cldb.security.resolve.user	*Default Value*: 0 *Description*: Resolve UID:GID on client OS or on CLDB.

last-updated: Apr 11, 2022

cldb.security.user.ticket.duration.seconds	*Default Value*: 1209600 *Description*: Default ticket duration
cldb.security.user.ticket.max.duration.seconds	*Default Value*: 2592000 *Description*: Maximum ticket duration
cldb.security.user.ticket.renew.duration.seconds	*Default Value*: 2592000 *Description*: Default ticket renew duration
cldb.security.user.ticket.renew.max.duration.seconds	*Default Value*: 7776000 *Description*: Maximum ticket renew duration
cldb.snap.cntr.count.alarm.threshold	*Default Value*: 100000000 *Description*: The threshold (in minutes) for raising the `CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS` alarm.
cldb.snap.cntr.count.disable.threshold	*Default Value*: 128000000 *Description*: The maximum number of snapshots to allow before disabling snapshot creation.
cldb.snap.cntr.count.monitor.interval.minutes	*Default Value*: 60 *Description*: The interval of time (in minutes) to elapse between checking the number of snapshots on the cluster.
cldb.v2.features.enabled	*Default Value*: 1 *Description*: Enables new features added in MapR version 2.0. Used only during the upgrade process from v1.x to 2.x to control when new features become active. Once enabled, cannot be disabled.
cldb.v3.features.enabled	*Default Value*: 1 *Description*: Enables new features added in MapR version 3.0. Used only during the upgrade process from a pre-3.0 version to control when new features become active. Once enabled, cannot be disabled.
cldb.web.port	*Default Value*: 7221 *Description*: The port that the CLDB uses for the webserver.
cldb.zookeeper.servers	*Default Value*: Not Applicable *Description*: The nodes that are running ZooKeeper, in the format `\<host:port\>`.
hadoop.version	*Default Value*: Not Applicable *Description*: The version of Hadoop supported by the cluster.
net.topology.script.file.name	*Default Value*: Not Applicable *Description*: The path to a script that associates IP addresses with physical topology paths. The script takes the IP address of a single node as input and returns the physical topology that should be associated with the specified node. This association is used only at the time a node is initially added to the cluster. To change topology for nodes already in the cluster, use the `maprcli node move` command.
net.topology.table.file.name	*Default Value*: Not Applicable *Description*: The path to a text file that associates IP addresses with physical topology paths. Each line of

	the text file is of format `<hostname/ip> <rack>`, with the IP address or hostname of one node, followed by the topology to associate with the node. This association is used only at the time a node is initially added to the cluster. To change topology for nodes already in the cluster, use the `maprcli node move` command.
num.volmirror.threads	*Default Value*: 1 *Description*: The number of (volume mirror) threads to create to process mirroring requests. The specified number of threads will be created to process requests in parallel; the remaining requests will be in the queue till they are picked up by volume mirror thread.

Example cldb.conf file

```
#
# CLDB Config file.
# Properties defined in this file are loaded during startup
# and are valid for only CLDB which loaded the config.
# These parameters are not persisted anywhere else.
#
# Wait until minimum number of fileserver register with
# CLDB before creating Root Volume
cldb.min.fileservers=1
# CLDB listening port
cldb.port=7222
# Number of worker threads
cldb.numthreads=10
# CLDB webport
cldb.web.port=7221
# CLDB https port
cldb.web.https.port=7443
# Disable duplicate hostid detection
cldb.detect.dup.hostid.enabled=false
# Deprecated: This param is no longer supported. To configure
# the container cache, use the param cldb.containers.cache.percent
# Number of RW containers in cache
#cldb.containers.cache.entries=1000000
#
# Percentage (integer) of Xmx setting to be used for container cache
#cldb.containers.cache.percent=20
#
#Frequency of the heartbeat interval

# Topology script to be used to determine
# Rack topology of node
# Script should take an IP address as input and print rack path
# on STDOUT. eg
# $>/home/mapr/topo.pl 10.10.10.10
# $>/mapr-rack1
# $>/home/mapr/topo.pl 10.10.10.20
# $>/mapr-rack2
#net.topology.script.file.name=/home/mapr/topo.pl
#
# Topology mapping file used to determine
# Rack topology of node
# File is of a 2 column format (space separated)
# 1st column is an IP address or hostname
# 2nd column is the rack path
# Line starting with '#' is a comment
# Example file contents
```

last-updated: Apr 11, 2022

```
# 10.10.10.10 /mapr-rack1
# 10.10.10.20 /mapr-rack2
# host.foo.com /mapr-rack3
#net.topology.table.file.name=/home/mapr/topo.txt
#
# ZooKeeper address
cldb.zookeeper.servers=10.10.82.22:5181
# Hadoop metrics jar version
hadoop.version=2.7.0
# CLDB JMX remote port
cldb.jmxremote.port=7220
num.volmirror.threads=1
# Set this to set the default topology for all volumes and nodes
# The default for all volumes is /data by default
# UNCOMMENT the below to change the default topology.
# For e.g., set cldb.default.topology=/mydata to create volumes
# in /mydata topology and to place all nodes in /mydata topology
# by default
#cldb.default.topology=/mydata
enable.replicas.invariant.check=false
```

Related concepts

Security Certificate Expiry Alarm on page 2233
Describes the NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION alarm.

core-site.xml

Describes the `core-site.xml` file that contains the configuration that overrides the default core parameters.

The `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/core-site.xml` file contains configuration that override the default core parameters.

Note: `/opt/mapr/hadoop/hadoop-0.20.2/conf/core-site.xml` is a symlink to `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml`.

To override a default value, specify the new value within the `<configuration>` tags, using the following format:

```
<property>
  <name> </name>
  <value> </value>
  <description> </description>
</property>
```

Default core Parameters describes the possible entries to place in the `<name>` and `<value>` tags. The `<description>` tag is optional but recommended for maintainability.

Warning: You can examine the current configuration information for this node by using the `hadoop conf -dump` command from a command line.

Default core-site.xml file

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

<!-- Put site-specific property overrides in this file. -->

<configuration>

</configuration>
```

Core Parameters

See Default core Parameters.

daemon.conf

The file `/opt/mapr/conf/daemon.conf` specifies the user and group under which MapR services run, and whether all MapR services run as the specified user/group, or only ZooKeeper and FileServer. The configuration parameters operate as follows:

- If `mapr.daemon.user` and `mapr.daemon.group` are set, the ZooKeeper and FileServer run as the specified user/group. Otherwise, they run as `root`.
- If `mapr.daemon.runuser.warden=1`, all services started by the warden run as the specified user. Otherwise, they run as `root`.

Sample daemon.conf file

```
mapr.daemon.user=mapr
mapr.daemon.group=mapr
mapr.daemon.runuser.warden=1
```

db.conf

The file `/opt/mapr/conf/db.conf` specifies configuration parameters for the Metrics database.

Warning: Any time you make changes to the `db.conf` file, you must restart the `hoststats` service and Warden for those changes to take effect.

Field	Default	Description
db.url	localhost:3306	The URL and port for the MySQL server that stores Metrics data. This machine does not need to be a node in the cluster.
db.user	root	The MySQL user name.
db.passwd	mapr	The MySQL password. If the password contains the & character, it is replaced with the `&` string in the `hibernate.cfg.xml` file (following XML parsing standards).
db.schema	metrics	The name of the MySQL schema.
db.mode	mysql	Reserved for future use.
db.driverclass	com.mysql.jdbc.Driver	Reserved for future use.

last-updated: Apr 11, 2022

Field	Default	Description
db.joblastacessed.limit.hours	48	Task and task attempt data for a job are purged for jobs that have not been accessed in a number of hours equal to this parameter's value. **Note:** Note that there is an error in this parameter's name. Instead of `db.joblastaccessed.limit.hours`, spelled as the English word *accessed*, the parameter is written `db.joblastacessed.limit.hours`.
db.partition.finest.count.days	3	Integer number of days for which the finest data granularity is kept. Finest granularity is a ten-second resolution.
db.partition.fine.count.days	15	Integer number of days for which fine data granularity is kept. Fine granularity is a five-minute average of the finest resolution.
db.partition.coarse.count.years	100	Integer number of years for which the coarse data granularity is kept. Coarse granularity is a 24-hour average of the fine resolution.
metric.file.rotate	365	Integer number of days for which metrics files are kept in the local volume for each node.
metric.file.cleanupthreshold	512	Specifies a size in GB. When the total size of the metrics files exceeds the value of this parameter, all data over 30 days old is cleaned up.

Example db.conf file

```
db.url=localhost:3306
db.user=root
db.passwd=mapr
db.schema=metrics
db.mode=mysql
db.driverclass=com.mysql.jdbc.Driver
db.joblastacessed.limit.hours=48
db.partition.finest.count.days=3
db.partition.fine.count.days=15
db.partition.coarse.count.years=100
### How many files with raw node metrics data to keep
metric.file.rotate=365
```

.dfs_attributes

Each directory in MapR storage contains a hidden file called `.dfs_attributes` that controls compression and chunk size. To change these attributes, change the corresponding values in the file.

Example:

```
# lines beginning with # are treated as comments
Compression=lz4
ChunkSize=268435456
```

Valid values:

- Compression: `lz4`, `lzf`, `zlib`, or `false`
- Chunk size (in bytes): a multiple of 65535 (64 K) or zero (no chunks). Example: `131072`

You can also set compression and chunksize using the hadoop mfs command.

disktab
Describes the use of the disktab file.

On each node, the file `/opt/mapr/conf/disktab` lists all of the physical drives and partitions that have been added to the MapR File System. The `disktab` file is created by the `disksetup` command, and automatically updated when disks are added or removed (either using the MapR Control System, or with the `disk add` and `disk remove` commands).

Sample disktab file

```
# MapR Disks Mon Nov 28 11:46:16 2011

exports

Access control for hosts

On each node, the file `/opt/mapr/conf/exports` lists the clusters and mount points available to mount with NFS.

Specify access control for hosts with a space-separated list of hosts, appending `(rw)` for read-write or `(ro)` for read-only access after each host. To specify a default access for all hosts not otherwise specified, add `(rw)` or `(ro)` after a space at the end of a line. The `exports` file follows the same semantics as a standard UNIX exports table. The following export options are supported:

last-updated: Apr 11, 2022

Export option	Definition
ro	Provides read-only access.
rw	Provides read-write access.
root_squash	Squashes root privileges for remote users. For example, you can use: `/mapr (rw,root_squash)` This entry prevents the `/mapr` directory from being written to by the root user on remote hosts.
no_root_squash	Turns off root squashing for remote users.
all_squash	Squashes every remote user, including root.
anonuid, anongid	Specifies user and group IDs to use with remote users from a particular host.

Restricting clusters to specific hosts

To restrict access to a specific export path to particular hosts, use the following format:

```
<Path> <space-separated list of hosts and access rights>
```

For example, the line `/mapr/cluster1 host01(rw) host02(ro)` restricts read-write access to the cluster in `/mapr/cluster1` to host `host01`, and restricts read-only access to host `host02`. No other hosts have access.

Note: After making changes to this file, you do not have to restart the NFS server. You can run a maprcli command to refresh the exports definition without a restart. See nfsmgmt refresh exports.

Enabling Central Configuration

To enable Central Configuration for `exports`, specify a value for the `AutoRefreshExportsTimeInterval` parameter in the `/opt/mapr/conf/nfsserver.conf` file. The value of the `AutoRefreshExportsTimeInterval` parameter determines the number of minutes after which the NFS server refreshes the `exports` file. The default value of 0 disables central configuration for NFS exports.

Sample exports file

```
# Sample Exports file

# for /mapr exports
# <Path> <exports_control>

#access_control -> order is specific to default
# list the hosts before specifying a default for all
#  host01(ro) host02(ro) host03(ro) (rw)
#  enforces ro for a.b.c.d & 1.2.3.4 and everybody else is rw

# special path to export clusters in mapr-clusters.conf. To disable
exporting,
# comment it out. to restrict access use the exports_control
#
/mapr (rw)

#to export only certain clusters, comment out the /mapr & uncomment.
```

last-updated: Apr 11, 2022

```
# Note: this will cause /mapr to be unexported
#/mapr/clustername (rw)

#to export /mapr only to certain hosts (using exports_control)
#/mapr a.b.c.d(rw) e.f.g.h(ro)

# export /mapr/cluster1 rw to a.b.c.d & ro to e.f.g.h (denied for others)
#/mapr/cluster1 a.b.c.d(rw) e.f.g.h(ro)

# export /mapr/cluster2 only to e.f.g.h (denied for others)
#/mapr/cluster2 e.f.g.h(rw)

# export /mapr/cluster3 rw to e.f.g.h & ro to others
#/mapr/cluster2 e.f.g.h(rw) (ro)
```

FileMigrate.properties

Properties		Default Value	Description
UI Setting	**Property File**		
Full Scan Frequency	`upload.fullScanFrequencyMin`	60	Frequency, in minutes, at which full scan of all files detect changes missed by lite scans and purge (per the configured policy) uploaded files. **Note:** The actual time of a full scan is computed on a per directory basis and spread randomly around the specified fullScanFrequency. Thus specifying 60 minutes does not mean that all directories get a full scan at exactly 60 minutes. Instead, directories randomly get a full scan on average every 60 minutes (somewhere between 30 and 90 minutes). This approach avoids load spikes.
Upload Scan Frequency	`upload.scanFrequencySec`	60	Frequency, in seconds, at which light scans of directories detect changes since the last scan. This value cannot be below 10 seconds.

last-updated: Apr 11, 2022

Properties		Default Value	Description
UI Setting	**Property File**		
Completion Scan Frequency	`upload.completionScanFrequencySec`	3	Frequency, in seconds, for checking upload status. This impacts the time delay before the queue is cleared for more uploads, the reporting time for completion, and statistics collection. **Note:** Values below the default may consume extra system resources.
Minimum Wait Before Upload	`upload.minWaitBeforeUploadSecs`	15	Length of time, in seconds, to wait for uploading a file since the file was last modified. Set a higher value to avoid uploading a file still being modified.
Maximum Active Uploads	`upload.maxActiveUploads`	10	Maximum number of files to upload concurrently. The scanning component of the file migration service is paused when 10 times this many files are waiting for upload.
Minimum Wait After Failure	`upload.minWaitAfterFailureSecs`	300	Amount of time, in seconds, to wait (pause) before retrying if upload fails or if there is an error in the filesystem.
Maximum Retries Per File	`upload.maxErrorsOnOneFileBeforeGiveUp`	10	Maximum number of times to attempt to upload a file. If the limit is reached, the file is dequeued to allow other files to be uploaded and the file modification time does not change. The dequeued file is rediscovered and queued for upload during the next full scan.
Maximum System Retries	`upload.maxErrorsBeforeAssumeSystemIssue`	10	Maximum number of errors to allow before pausing all uploads. If this limit is reached, uploads continue only after the amount of time specified as value for the `minWaitAfterFailureSecs` property has elapsed.
Minimum Idle Time Before Error	`upload.minIdleTimeBeforeErrorSec`	300	Amount of time, in seconds, to wait before logging a warning (in the `filemigrate.log` file) if all uploads are not progressing.

Properties		Default Value	Description
UI Setting	**Property File**		
Bucket Location Region	`aws.region`		Region information as defined here. For: • Older regions, specify the short region name. • New regions, specify the short region name and the region endpoint. The following regions can be specified using just the region name: us-east-1, us-west-1, us-west-2, ap-northeast-1, ap-southeast-1, ap-southeast-2, sa-east-1, eu-west-1, cn-north-1, us-gov-west-1. For all other regions, you might have to specify the endpoint as well. **Note:** When you create a bucket in a region, verify that the bucket is really in that region; in some cases, buckets for one region are actually hosted elsewhere.
Region Endpoint	`aws.regionendpoint`		The AWS region endpoint.
Proxy Host	`aws.proxyHost`		(Optional) Proxy host information.
Proxy Port	`aws.proxyPort`		
Proxy Username	`aws.proxyUsername`		
Proxy Password	`aws.proxyPassword`		
Access Key	`aws.accessKey`		Credentials to use for accessing the S3 bucket.
Secret Key	`aws.secretKey`		
Directory Path	`dir<N>.path`		The path from which the scan of the directory or root directory starts. Replace `<N>` with an integer; for each additional directory tree, increment the number and specify a unique path. **Note:** Do not create multiple policies or directory configurations pointing to the same filesystem location.
Target Bucket	`dir<N>.bucket`		The Amazon S3 bucket to upload to.

last-updated: Apr 11, 2022

Properties		Default Value	Description
UI Setting	**Property File**		
Purge Interval	`dir<N>.purgepolicy.hours`	0	Amount of time, in hours, after the file was last modified to wait before deleting the file. The default value is never delete (`0`). **Note:** Deletion is delayed until after the file upload occurs, regardless of the purge time set.
Delete Empty Directories	`dir<N>.deleteEmptyDirectoryDelayMins`	0	Amount of time to wait, in minutes, before deleting empty directories. The default value is never delete (`0`).
Server Side Encryption	`dir<N>.serverSideEncrypt`	false	Specify whether (`true`) or not (`false`) S3 server side encryption should be used. If the value is `true` (enabled), the TransferManager API that specifies AES256 encryption is used automatically for each uploaded file.

Properties		Default Value	Description
UI Setting	**Property File**		
Ignore Files Regex	`dir<N>.ignoreFilesRegex`		File and directory names to ignore, specified as regex pattern, as defined by `java.util.regex`. For example: • `.*\.TEMP$` - ignore all files/directories ending in .TEMP • `.*TEMP.*` - ignore all files/directories that contain the phrase TEMP • `^TEMP.*` - ignore all files/directories that start with TEMP Specify a single regular expression that matches multiple patterns, as shown in the following examples: • `dir2.ignoreFilesRegex=^IGNORE.*\|.*\.TMP$` • `dir2.ignoreFilesRegex=^IGNORE.*|.*\.TMP$\|.*\\.TXT$|.*\\.txt$` • `dir2.ignoreFilesRegex=^temp$`

Properties		Default Value	Description
UI Setting	**Property File**		
X-Attributes	`dir<N>.xattrs`		The space-separated list of AWS S3 attributes to copy from MapR File System to AWS S3 bucket when uploading a file. Make a note of the following: • While MapR File System attributes can be strings or binary, AWS S3 attributes must be strings. • While MapR File System attribute names are case sensitive, AWS S3 attribute names are case insensitive. **Note:** Only extended attributes from MapR filesystem that start with `user.` are considered for upload (since all user settable attributes begin with `user.`). The attribute must be specified without `user.`. For example, to upload a file with the extended attribute name `user.foo`, the value for this property must be foo because the `user.` is implicit. Extended attributes are uploaded when the file is first uploaded. If extended attributes are set after file upload, the extended attributes are not sent to AWS S3 unless the file modification timestamp changes.

Properties		Default Value	Description
UI Setting	**Property File**		
Authorized Users	`authorized.users`	mapr	The comma-separated list of users who can login and use the File Migration Service. The UI authorizes the following users to login and use the service: • The owner of the file migrate process (on the cluster, this is MAPR_USER). • Any users belonging to the comma-separated list of authorized users specified here. • Any users belonging to any group in the comma-separated list specified using `authorized.groups` property. The default value is the MAPR_USER (who is mapr, by default) specified with the `configure.sh` on page 2053 utility.
Authorized Groups	`authorized.groups`	mapr	The comma-separated list of groups authorized to login and use the service. The default value is the MAPR_USER (mapr, by default) specified with the `configure.sh` on page 2053 utility.

gateway.conf

Describes configuration parameters for the MapR gateway.

The `/opt/mapr/conf/gateway.conf` file specifies configuration parameters for the gateway that supports table and stream replication.

Warning: Changing the default settings in the `gateway.conf` file is not recommended and is not likely to improve performance. If you still need to make changes to the `gateway.conf` file, you must restart the gateway after doing so. See Configuring Gateways for Table and Stream Replication on page 1152.

Field	Default	Description
gateway.port	7660	The gateway listening port.
gateway.receive.numthreads	128	The number of worker threads to receive replication stream requests.
gateway.flush.numthreads	128	The number of flush threads to send put requests to replicas.

Field	Default	Description
gateway.put.mem.mb	128	The maximum size limit (in MB) of the putbuffer memory.
gateway.logfile.size.mb	1024	The maximum size limit (in MB) of the MapR gateway log file. When the size limit is reached, the logs get rolled over.
gateway.es.request.maxsize.kb	128	The maximum size limit (in KB) of replication requests distributed by MapR source clusters. *This property is no longer supported.*
gateway.es.cluster.maxClients	1	Max number of clients for the MapR Event Store For Apache Kafka. *This property is no longer supported.*

Example `gateway.conf` **file**

```
#
# Gateway Config file.
# Properties defined in this file are loaded during startup
# and are valid for only Gateway which loaded the config.
# These parameters are not persisted anywhere else.
#
# Gateway listening port
#gateway.port=7660
# Number of worker threads to receive replication stream requests
#gateway.receive.numthreads=128
# Number of flush threads to send put requests to replicas
#gateway.flush.numthreads=128
#
# Max limit on putbuffer memory in MB
#gateway.put.mem.mb=128
#
# Max limit on log file size
#gateway.logfile.size.mb=1024
#
#
# Gateway ES properties
#gateway.es.request.maxsize.kb=128
#gateway.es.cluster.maxClients=1
```

Related concepts

Administering MapR Gateways on page 1150
A MapR gateway mediates one-way communication between a source MapR cluster and a destination cluster. You can replicate MapR Database tables (binary and JSON) and MapR Event Store For Apache Kafka streams. MapR gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1152
Configuring gateways involves installing the `mapr-gateway` package on nodes on a MapR destination cluster and then configuring the MapR source cluster to communicate with the destination cluster. The MapR source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

Gateways for Replicating MapR Database Tables on page 621
In MapR Database table replication, MapR Database replicates updates to tables (binary and JSON) on source MapR clusters to replicas of those tables on destination MapR clusters. Gateways are services that

receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Related tasks

Specifying the Location of Gateways on page 782
Describes how to set the location of the MapR gateways using either the Control System or the CLI.

Related reference

cluster gateway delete on page 1564
Deletes the list of MapR gateways from a source MapR cluster.

cluster gateway get on page 1565
Lists the MapR gateways that a source MapR cluster is using.

cluster gateway list on page 1567
Lists all of the gateways that a source MapR cluster is using.

cluster gateway local on page 1569
Lists the gateways that are configured on the MapR cluster where this command is run.

cluster gateway resolve on page 1571
Lists the gateways configured on a MapR cluster that are up and running at the time that the command is issued.

cluster gateway set on page 1573
Specifies the locations of the MapR gateways that a source MapR cluster can use for table replication to a destination MapR cluster, or for indexing table data in an Elasticsearch cluster.

Managing Gateways on page 1154
Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

mapr.login.conf

The MapR Converged Data Platform uses the Java Authentication and Authorization Service (JAAS) to control security features. The `/opt/mapr/conf/mapr.login.conf` file specifies configuration parameters for JAAS. Contact MapR support before changing any parameters in this file other than the ones listed in this document.

The MAPR_SERVER_KERBEROS Stanza

The CLDB uses this stanza to verify users that are authenticating with Kerberos. This stanza requires the `com.sun.security.auth.module.Krb5LoginModule` module.

Attribute	Default Value	Description
keyTab	"/opt/mapr/conf/mapr.keytab"	File path to the keytab file.
principal	"mapr/my.cluster.com"	The Kerberos principal to use.

The MAPR_WEBSERVER_KERBEROS Stanza

Web UIs on the cluster use this stanza to evaluate SPNEGO requests. This stanza requires the `com.sun.security.auth.module.Krb5LoginModule` module.

Attribute	Default Value	Description
keyTab	"/opt/mapr/conf/mapr.keytab"	File path to the keytab file.

Attribute	Default Value	Description
principal	"HTTP/*yourhost*"	The principal *must* be HTTP. This principal is used to negotiate authentication for Web services over SPNEGO. You can set the value for *yourhost* manually, but be aware that you must set the principal in the `mapr.keytab` file to match this value.

The jpamLogin Stanza

The MapR cluster uses this stanza to verify user ID and password authentication to all the servers on the cluster. You can modify this stanza to alter the PAM configuration used by the cluster. The `net.sf.jpam.jaas.JpamLoginModule` module is sufficient for this stanza. There are three provided default services. The order of the `serviceName` in the stanza (at cluster startup) determines which PAM configuration file to use. If a failure occurs with a configuration, MapR ignores the error and proceeds with the next entry.

Attribute	Provided Default Values	Description
serviceName	• `sudo` • `sshd` • `mapr-admin`	The PAM configurations to use for validating passwords, shown in their order of use. The configuration files are typically in `/etc/pam.d`.

Other Stanzas

The `Server`, `Client`, `Server_simple`, `Client_simple`, and `hadoop_maprsasl` stanzas control important aspects of your cluster's stability. Consult with MapR support before modifying these stanzas.

mapr-clusters.conf
Provides information and instructions for configuring clusters to create the global namespace.

You can define one or more clusters in the `/opt/mapr/conf/mapr-clusters.conf` file on a node or client. To define a cluster, you specify the CLDB nodes in the cluster. Defining a cluster creates the global namespace. Note that the `mapr-clusters.conf` file on each node or client must have the same cluster configuration and naming convention to create the global namespace.

The following section describes the configuration format of the `mapr-clusters.conf` file:

Format:

```
<cluster-name1> secure=false  <CLDB> <CLDB> ... <CLDB>
[ clustername2  <CLDB> <CLDB> <CLDB> ]
[ ... ]
```

The <CLDB> string format can contain multiple space-separated instances of the following:

- `host;ip:port` - Host, IP, and port (uses DNS to resolve hostnames, or provided IP if DNS is down)
- `host:port` - Hostname and IP (uses DNS to resolve host, specifies port)
- `ip:port` - IP and port (avoids using DNS to resolve hosts, specifies port)
- `host` - Hostname only (default, uses DNS to resolve host, uses default port)
- `ip` - IP only (avoids using DNS to resolve hosts, uses default port)

You can edit `mapr-clusters.conf` manually to add more clusters. For example:

```
<cluster-name3>  <CLDB> <CLDB> <CLDB>
```

Security enabled, with and without Kerberos

With security enabled, without Kerberos, the format for the mapr-clusters.conf file is:

```
<clustername1> secure=true  <CLDB> <CLDB> ... <CLDB>
            [ <clustername2>  <CLDB> <CLDB> ... <CLDB> ]
            [ ... ]
```

With Kerberos enabled, the format for the `mapr-clusters.conf` file is:

```
<clustername1> secure=true kerberosEnable=true <CLDB> <CLDB> ... <CLDB>
            [ <clustername2>  <CLDB> <CLDB> ... <CLDB> ]
            [ ... ]
```

Note: Before renaming a cluster using the `mapr-clusters.conf` file, stop the warden on all the nodes.

Adding multihomed CLDB entries to mapr-clusters.conf with configure.sh

In this example, the cluster `my.cluster.com` has CLDB servers at `nodeA`, `nodeB`, `nodeC`, and `nodeD`. The CLDB servers `nodeB` and `nodeD` have two NICs each at `eth0` and `eth1`. The entries in `mapr-clusters.conf` are separated by spaces for each server's entry. Within a server's entry, individual interfaces are separated by semicolons (`;`).

The command

```
configure.sh -N my.cluster.com -C nodeAeth0,nodeCeth0 -M
nodeBeth0,nodeBeth1 -M nodeDeth0,nodeDeth1 -Z zknodeA
```

generates the following entry in `mapr-clusters.conf`:

```
my.cluster.com nodeAeth0 nodeBeth0;nodeBeth1 nodeCeth0 nodeDeth0;nodeDeth1
```

Cluster Limits

There is no limit for the number of clusters for HDFS and NFSv3. However, the maximum number of clusters for FUSE is 16.

mapred-site.xml
Lists the parameters for MapReduce configuration.

MapReduce is a type of application that can run on the Hadoop 2.x framework. MapReduce configuration options are stored in the `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/mapred-site.xml` file and are editable by the `root` user. This file contains configuration information that overrides the default values for MapReduce parameters. Overrides of the default values for core configuration properties are stored in the MapR Parameters on page 2245 file.

To override a default value for a property, specify the new value within the `<configuration>` tags, using the following format:

```
<property>
 <name> </name>
 <value> </value>
 <description> </description>
</property>
```

Configurations for MapReduce Applications

The configuration comprises the following parameters:

mapreduce.framework.name	*Value*: yarn *Description*: Execution framework set to Hadoop YARN.
mapreduce.input.fileinputformat.split.maxblocknum	*Value*: 0 *Description*: Number of blocks that can be added to one split. A value of *0* means that a single split is generated per node. This functionality requires a patch. To install patches, see Applying a Patch.
mapreduce.map.memory.mb	*Value*: 1024 *Description*: Larger resource limit for maps.
mapreduce.map.java.opts	*Value*: -Xmx1024M *Description*: Larger heap-size for child jvms of maps.
mapreduce.reduce.memory.mb	*Value*: 3072 *Description*: Larger resource limit for reduces.
mapreduce.reduce.java.opts	*Value*: -Xmx2560m *Description*: Larger heap-size for child jvms of reduces.
mapreduce.task.io.sort.mb	*Value*: 512 *Description*: Higher memory limit while sorting data for efficiency.
mapreduce.task.io.sort.factor	*Value*: 100 *Description*: More streams merged at once while sorting files.
mapreduce.reduce.shuffle.parallelcopies	*Value*: 50 *Description*: Higher number of parallel copies run by reduces to fetch outputs from very large number of maps.

Configurations for MapReduce JobHistory Server

The configuration comprises the following parameters:

mapr.localspill.expiration.date	*Value*: *days* *Description*: Property to determine spill files expiration date in days. Default value is 30 days.
mapreduce.jobhistory.address	*Value*: MapReduce JobHistory Server *host:port* *Description*: Default port is 10020.
mapreduce.jobhistory.webapp.address	*Value*: MapReduce JobHistory Server Web UI *host:port* *Description*: Default port is 19888.
mapreduce.jobhistory.intermediate-done-dir	*Value*: `/mr-history/tmp` *Description*: Directory where history files are written by MapReduce applications.

mapreduce.jobhistory.intermediate-done-scan-timeout	*Value*: *milliseconds* *Description*: Timeout in milliseconds for rescanning the `done_intermediate` user directory to reduce JobHistory Server loading. Information about a job is received with a delay equal to the timeout. Adjust the setting based on the cluster load. Start with 5000 ms and increase timeout as needed. **Note:** This functionality requires a patch. To install patches, see Applying a Patch on page 437.
mapreduce.jobhistory.done-dir	*Value*: `/mr-history/done` *Description*: Directory where history files are managed by the MapReduce JobHistory Server.
mapreduce.jobhistory.webapp.https.address	*Value*: Secure MapReduce JobHistory Server Web UI *host:port* (HTTPS) *Description*: Default port is 19890.

Sample Hadoop 2.x mapred-site.xml File

The following `mapred-site.xml` file defines values for two job history parameters.

```
<configuration>
  <property>
    <name>mapreduce.jobhistory.address</name>
    <value>__HS_IP__:10020</value>
  </property>
  <property>
    <name>mapreduce.jobhistory.webapp.address</name>
    <value>__HS_IP__:19888</value>
  </property>
</configuration>
```

Configuration for Apache Shuffle

You can disable Direct Shuffle and enable Apache Shuffle for MapReduce applications through the following settings:

mapreduce.job.shuffle.provider.services	*Value*: `mapreduce_shuffle`
mapreduce.job.reduce.shuffle.consumer.plugin.class	*Value*: `org.apache.hadoop.mapreduce.task.reduce.Shuffle`
mapreduce.job.map.output.collector.class	*Value*: `org.apache.hadoop.mapred.MapTask$MapOutputBuffer`
mapred.ifile.outputstream	*Value*: `org.apache.hadoop.mapred.IFileOutputStream`
mapred.ifile.inputstream	*Value*: `org.apache.hadoop.mapred.IFileInputStream`
mapred.local.mapoutput	*Value*: `true`
mapreduce.task.local.output.class	*Value*: `org.apache.hadoop.mapred.YarnOutputFiles`

mfs.conf
Lists the parameters of the MFS configuration file.

The configuration file `/opt/mapr/conf/mfs.conf` specifies the following parameters about the MapR File System server on each node.

Warning: You must restart the File Server after making changes to this file.

Parameters

`mfs.server.ip`	*Default Value:* Not applicable Description: IP address of the File Server. For example, `192.168.10.10`.
`mfs.server.port`	*Default Value:* 5660 Description: Port used for communication with the server.
`mfs.cache.lru.sizes`	*Default Value:* • For version 4.0.1: `inode:6:log:6:meta:10:dir:40:small:15` • For version 4.0.2 and later versions: `inode:3:meta:6:small:27:dir:15:db:20:valc:3` Description: LRU cache configuration. See the section, **Notes on LRU Cache Configuration** for more information.
`mfs.on.virtual.machine`	*Default Value:* false Description: Specifies whether the MapR File System is running on a virtual machine.
`mfs.io.disk.timeout`	*Default Value:* 60 seconds Description: Timeout, in seconds, after which a disk is considered failed and taken offline. You can increase the timeout to tolerate slow disks.
`mfs.max.disks`	*Default Value:* 48 Description: Maximum number of disks supported on a single node.
`mfs.max.logfile.size.in.mb`	*Default Value:* 1000 MB Description: The maximum amount of disk space that the MFS logs can consume before the oldest log file is deleted; based on the following calculation: `maxSizePerLogFile = maxLogSize / MAX_NUM_OF_LOG_FILES` where • `maxLogSize` = total amount of space that MFS log files can consume • `MAX_NUM_OF_LOG_FILES` = total number of MFS log files
`mfs.max.resync.count`	*Default Value:* 16 Description: The number of parallel resync operations.
`mfs.subnets.whitelist`	*Default Value:* Not Applicable

	Description: A list of subnets (up to 256 characters) that are allowed to make requests to the File Server service and access data on the cluster.
mfs.disk.iothrottle.count	*Default Value:* 100 Description: The maximum number of outstanding requests on disk.  **Note:** You can disable throttling by setting a high value. This option is disabled if you set the value for `mfs.disk.is.ssd` to `1`.
mfs.disk.resynciothrottle.factor	*Default Value:* 20 Description: Controls the amount of time to wait before submitting a request to disk. Increasing this value reduces the wait time, and decreasing this value increases the wait time. For example, setting the value to 40, halves the wait time, while setting the value to 10, doubles the wait time.
mfs.network.resynciothrottle.factor	*Default Value:* 20 Description: Controls the amount of time to wait before sending a resync operation over the network. Increasing this value reduces the wait time, and decreasing this value increases the wait time. For example, setting the value to 40, halves the wait time, while setting the value to 10, doubles the wait time.
mfs.ssd.trim.enabled	*Default Value:* 0 Description: Set this parameter to `1` to enable TRIM operations for SSD devices.  **Note:** Enable TRIM only if it is recommended by the SSD vendor.
mfs.disk.is.ssd	*Default Value:* 0 Description: Specifies whether (`1`) or not (`0`) the drives are SSD. If the value is `0`, the drives are assumed to be rotations. If the value is `1`, the noop scheduler on the SSD is automatically enabled, and I/O throttling is disabled.
mfs.mem.debug.enabled	*Default Value:* 0 Description: Specifies whether file server should (1) or should not (0) track all memory allocations. The default value is `0`. If value is `1` , you can determine the root cause for high memory allocation, or determine the component consuming the most memory.
mfs.numrpcthreads	*Default Value:* 2 Description: Specifies the number of RPC threads per MFS instance. The valid range of values is from 1 to 4.
mfs.db.max.concurrent.internal.ops	*Default Value:* 73728 (72 * 1024) *Max Value:* 131072 (128 *1024) *Min Value:* 36864 (36*1024) Description: Regulates how many BatchGet operations can run in parallel when secondary indexes are present on the table. PUT operations on tables with secondary indexes convert to BatchGet operations on the tables. PUT operations that convert to a high volume of BatchGets can degrade performance. BatchGet operations are spread equally across

last-updated: Apr 11, 2022

	three threads (73728/3). Run `mrconfig dbinfo threads` to evaluate the throttling queue for each thread. **Important:** This parameter is only available with a patch for MapR Core-6.1.0. To install patches, see Applying a Patch.
`mfs.num.compress.threads`	*Default Value:* 1 Description: Reserved for internal use.
`mfs.max.aio.events`	*Default Value:* 5000 Description: Reserved for internal use.
`mfs.disable.periodic.flush`	*Default Value:* 0 Description: Reserved for internal use.
`mfs.ignore.container.delete`	*Default Value:* 0 Description: Reserved for internal use.
`mfs.ignore.readdir.pattern`	*Default Value:* 0 Description: Reserved for internal use.
`mfs.disable.IO.affinity`	*Default Value:* 0 Description: Reserved for internal use.
`mfs.deserialize.length`	*Default Value:* 8192 Description: Reserved for internal use.
`mfs.enable.nat`	*Default Value:* 0 Description: Reserved for internal use.
`mfs.bulk.writes.enabled`	*Default Value:* 0 Description: Reserved for internal use.

Example

```
mfs.server.ip=192.168.10.10
mfs.server.port=5660
mfs.cache.lru.sizes=inode:3:meta:6:small:27:dir:15:db:20:valc:3
mfs.on.virtual.machine=0
mfs.io.disk.timeout=60
mfs.max.disks=48
```

Notes on LRU Cache Configuration

The cache values are expressed as percentages, which vary based on the expected size of the data that the node is required to cache. The goal is to achieve a state in which most of the required data comes directly from the cache. You may need to tune the cache percentages based on your cluster configuration and the workload on specific nodes. Non-default allocations tend to work better for nodes that run only CLDB and nodes that do not have CLDB but do have a heavy MapR Database workload. Note the following recommendations.

- For CLDB-only nodes, increase the size of the cache for Dir LRU to 40%: change `dir:15` to `dir:40`A CLDB-only node is a file server node that hosts only the CLDB volume `mapr.cldb.internal` (no user volume data is hosted on the node). Dir LRU is used to host B-tree pages.
- For non-CLDB nodes with no MapR Database workload, optimize the cache to host as many file pages as possible. Change the value of the parameter to: `inode:3:meta:6:small:27:dir:6`

The remainder of the cache is used to cache file data pages.

Note: You need to restart MFS for the change in `mfs.conf` to take effect.

nfsserver.conf
Lists the parameters for the MapR NFS server.

The file `/opt/mapr/conf/nfsserver.conf` controls parameters related to MapR services and the warden. Most of the parameters are not intended to be edited directly by users. The following list shows the parameters of interest:

Compression	*Default Value*: `true` *Description*: Indicates whether compression is on (`true`) or off (`false`).
ChunkSize	*Default Value*: `67108864 bytes (64 MB)` *Description*: Size of each chunk.
CompThreads	*Default Value*: `2` *Description*: Number of threads for compression or decompression.
DrCacheSize	*Default Value*: `20480` *Description*: Duplicate request cache size.
DrCacheTimeout	*Default Value*: `62 seconds` *Description*: Duplicate request cache timeout in seconds.
DRCacheTimeOutOpt	*Default Value*: `0.5` *Description*: If the operations take more than `DrCacheTimeout * DRCacheTimeOutOpt`, the operations are not cached. For example, by default, if the operation takes more than 31 seconds — `(62 * .5) = 31` seconds — the operation is not cached. A value of `0` disables the cache.
HighMemLimitMB	*Default Value*: `disabled` (Parameter is commented out in the file) *Description*: The maximum amount of memory (in MB) that the NFS server process can use. If the NFS server process uses more memory than this value, then the server is automatically shutdown, and a Core file is generated for debugging. For example: `HighMemLimitMB=10000` indicates that the NFS server is shutdown if it consumes more than 10GB of memory. This parameter is effective only if you enable the `MemDebugEnable` parameter.
LogLevel	*Default Value*: `INFO` *Description*: Sets the level of log messages displayed in the output. Levels include: • DEBUG • INFO • WARN

last-updated: Apr 11, 2022

- ERROR
- CRITICAL
- OFF

MaxLogFileSize

Default Value: `1024 MB`

Description: The maximum amount of disk space that the NFS server logs can consume before the oldest log file is deleted, based on the following calculation:

```
maxSizePerLogFile = maxLogFileSize /
MAX_NUM_OF_LOG_FILES
```

where:

- `maxLogFileSize` is the total amount of space that NFS server log files may consume
- `MAX_NUM_OF_LOG_FILES` is the total number of NFS server log files

Logrotate support for both the `.log` and the `.err` files honor this setting.

Attention: `MaxLogFileSize` is not a combined size of `.log` and `.err` files. The `.log` and `.err` files can individually grow up to this size.

MemDebugEnable

Default Value: `false` (Parameter is commented out in the file)

Description: Set this parameter to `true` to enable memory tracking for the NFS server. This parameter works along with the `HighMemLimitMB` parameter.

MinLenForDeserialization

Default Value: `8192`

Description:Deserialize (if value is > 0) or do not deserialize (if value = 0) the response in the compression thread. If value is greater than 0, MapR deserializes requests with length >= value in the compression thread. If value is 0, requests of length < value are deserialized in the RPC thread itself..

RamfsMntDir

Default Value: `/ramfs/mapr`

Description: Mount point for the `ramfs` file for `mmap`.

RamfsSize

Default Value: `0.25`

Description: Size of the ramfile to use (percent of total physical memory). A value of `0` disables the use of ramfs.

WindowsAceSupport

Default Value: `false`

Description: Allow (`true`) or deny (`false`) access to a Windows client when ACEs are set. If `true`, the mode bits are set to `777`, the Windows client is granted access, and the operation is allowed based on the permissions enforced using mode bits and/or ACEs. If value is `false`, the mode bits are set to 000

and the Windows client is denied access. For more information, see Mounting NFS on a Windows Client on page 1188.

> **Tip:** Use separate NFS servers for Windows clients and non-Windows clients.

warden.conf

Lists the configuration parameters for Warden.

The file `/opt/mapr/conf/warden.conf` controls parameters related to MapR services and the Warden. Most of the parameters are not intended to be edited directly by users. The following list describes the parameters of interest:

Note: When defining heapsize values for services, keep in mind that `service.heapsize.percent` is bound by `service.heapsize.min`, if defined, and `service.heapsize.max`.

centralconfig.enabled

Sample Value: true

Description: Specifies whether to enable central configuration.

cldb.port

Sample Value: 7222

Description: The port to use for communicating with the CLDB.

enable.overcommit

Sample Value: true

Description:Set this value to `true` to allow services to start up, even if their memory demands exceed the memory provided by the node.

hoststats.port

Sample Value: 5660

Description: The port to use for communicating with the HostStats service.

hs.port

Sample Value: 1111

Description: Hoststats listening port for Metrics RPC activity.

hs.rpcon

Sample Value: true

Description: Indicates whether or not to configure Job Management.

hs.host

Sample Value: localhost

Description: Hoststats hostname for RPC activity.

isDB

Sample Value: true

Description: Specifies if MapR Database is in use. When this value is `false`, the `service.command.mfs.heapsize.percent` is set to 20. Do not manually edit this value. For more information, see Allocating Memory for Nodes on page 818..

kvstore.port

Sample Value: 5660

Description: The port for communicating with the Key/Value Store.

log.retention.exceptions

Sample Value: `mfs.log-*`

last-updated: Apr 11, 2022

	Description: Retains the following log files instead of removing them during the log file cleanup that occurs every ten days: `cldb.log`, `hoststats.log`, `configure.log` and `mfs.log-*`. You can modify the list. This parameter accepts partial file names and asterisks. Log files listed as exceptions are retained indefinitely. To disable all exceptions, comment out this parameter, that is, `#log.retention.exceptions`. When this parameter is null, that is, `log.retention.exceptions=`, no files are picked for log cleanup.
log.retention.time	*Sample Value*: 864000000 *Description*: All `.log` and `.out` files in the cluster are kept for a time period defined in milliseconds by the value of the `log.retention.time` parameter. The default value is ten days. Restart the Warden after changing this value.
mapr.home.dir	*Sample Value*: `/opt/mapr` *Description*: MapR installation directory.
mfs.port	*Sample Value*: 7222 *Description*: The port to use for communicating with the Fileserver.
pollcentralconfig.interval.seconds	*Sample Value*: 300 *Description*: The frequency (in seconds) to check for central configuration updates.
rpc.drop	*Sample Value*: false *Description*: Drop outstanding metrics when the queue to send to hoststats is too large.
service.command.cldb.heapsize.max	*Sample Value*: 4000 *Description*: The maximum heap space, specified in MB, that the CLDB can use.
service.command.cldb.heapsize.min	*Sample Value*: 256 *Description*: The minimum heap space, specified in MB, that the CLDB can use.
service.command.cldb.heapsize.percent	*Sample Value*: 8 *Description*: The percentage of heap space reserved for CLDB.
service.command.cldb.retryinterval.time.sec	*Sample Value*: 600 *Description*: Specifies an interval in seconds. The warden attempts to restart a failed CLDB service when this interval expires.

Note: The warden restarts the CLDB service only if the service has been stopped unintentionally - for example, the service crashed. Warden does not restart a CLDB service that has been stopped intentionally using the `maprcli node services` command.

service.command.mfs.heapsize.maxpercent

Sample Value: 85

Description: The maximum percentage of heap space that can be allocated to the MapR File System. Restart the Warden after modifying this setting.

service.command.mfs.heapsize.min

Sample Value: 512

Description: The minimum heap space, specified in MB, that can be allocated to the MapR File System. Restart the Warden after modifying this setting.

service.command.mfs.heapsize.percent

Sample Value: 35

Description: The percentage of heap space reserved for the MapR File System. If the value for `isDB` is `true`, you cannot set this property to a value lower than 35. If you set this parameter to a value lower than 35, the value reverts to 35 when the Warden restarts, to ensure that when the MapR Database is enabled, corresponding cache allocation occurs. If you want to lower the heapsize allocated to the MapR File System, you must change `service.command.mfs.heapsize.maxpercent` instead. Restart the Warden after modifying this setting.

service.command.nfs.heapsize.max

Sample Value: 1000

Description: The maximum heap space, specified in MB, that the NFS can use.

service.command.nfs.heapsize.min

Sample Value: 64

Description: The minimum heap space, specified in MB, that the NFS can use.

service.command.nfs.heapsize.percent

Sample Value: 3

Description: The percentage of heap space reserved for the NFS.

service.command.os.heapsize.max

Sample Value: 750

Description: The maximum heap space, specified in MB, that can be used by the operating system.

service.command.os.heapsize.min

Sample Value: 256

Description: The minimum heap space, specified in MB, for use by the operating system.

service.command.os.heapsize.percent

Sample Value: 3

Description: The percentage of heap space reserved for the operating system.

service.command.webserver.heapsize.min

Sample Value: 512

last-updated: Apr 11, 2022

	Description: The minimum heap space, specified in MB, for use by the MapR Control System.
service.command.webserver.heapsize.percent	*Sample Value*: 3 *Description*: The percentage of heap space reserved for the MapR Control System.
service.nice.value	*Sample Value*: -10 *Description*: The `nice` priority under which all services run.
services.memoryallocation.alarm.threshold	*Sample Value*: 95 *Description*: The maximum amount of system memory that services running on the node can use before triggering the NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED alarm.
services.resetretries.time.sec	*Sample Value*: 3600 *Description*: Specifies a time interval in seconds. The `services.retries` parameter sets the number of times that the warden attempts to restart failing services within this interval.
services.retries	*Sample Value*: 3 *Description*: The number of times the Warden tries to restart a service that fails.
services.retryinterval.time.sec	*Sample Value*: 1800 *Description*: The number of seconds after which the warden attempts several times to start a failed service. The number of attempts after each interval is specified by the parameter `services.retries`.
warden.enable.jmxremote	*Sample Value*: `false` *Description*: Set to `true` to enable the Warden JMX server.
zookeeper.servers	*Sample Value*: 10.250.1.61:5181 10.10.1.230:5181 *Description*: Space separated list of Zookeeper servers.

For information on configuration files for additional services, see warden.<servicename>.conf.

warden.<servicename>.conf

Describes the service configuration files that Warden supports.

The `warden.conf` configuration file is associated with the standard services that are provided by MapR. Warden supports service monitoring for additional services.

Each of these supported services requires a configuration file, `warden.<servicename>.conf`, which is included with the package for that service. When you install any of these service packages, its corresponding configuration file is stored in `/opt/mapr/conf/conf.d`. The configuration files and their packages are as follows:

collectd	*Configuration File*: `warden.collectd.conf` *Description*: Installed with the `mapr-collectd` package. This package is supported only for internal MapR Monitoring uses cases.

last-updated: Apr 11, 2022

drill	*Configuration File*: `warden.drill-bits.conf` *Description*: Installed with the `mapr-drill` package.
elasticsearch	*Configuration File*: `warden.elasticsearch.conf` *Description*: Installed with the `mapr-elasticsearch` package. This package is supported only for internal MapR Monitoring uses cases.
fluentd	*Configuration File*: `warden.fluentd.conf` *Description*: Installed with the `mapr-fluentd` package. This package is supported only for internal MapR Monitoring uses cases.
gateway	*Configuration File*: `warden.gateway.conf` *Description*: Installed with the `mapr-gateway` package.
grafana	*Configuration File*: `warden.grafana.conf` *Description*: Installed with the `mapr-grafana` package. This package is supported only for internal MapR Monitoring uses cases.
hue	*Configuration File*: `warden.hue.conf` *Description*: Installed with the `mapr-hue` package.
httpfs	*Configuration File*: `warden.httpfs.conf` *Description*: Installed with the `mapr-httpfs` package.
hbase thrift server	*Configuration File*: `warden.hbasethrift.conf` *Description*: Installed with the `mapr-hbasethrift` package.
hbase rest gateway	*Configuration File*: `warden.hbase-rest.conf` *Description*: Installed with the `mapr-hbase-rest` package.
historyserver	*Configuration File*: `warden.historyserver.conf` *Description*: Installed with the `mapr-historyserver` package.
hive metastore	*Configuration File*: `warden.hivemeta.conf` *Description*: Installed with the `mapr-hivemetadata` package.
hiveserver2	*Configuration File*: `warden.hs2.conf` *Description*: Installed with the `mapr-hiveserver2` package.
kibana	*Configuration File*: `warden.kibana.conf` *Description*: Installed with the `mapr-kibana` package. This package is supported only for internal MapR Monitoring uses cases.
nodemanager	*Configuration File*: `warden.nodemanager.conf`

last-updated: Apr 11, 2022

	Description: Installed with the `mapr-nodemanager` package.
oozie	*Configuration File*: `warden.oozie.conf` *Description*: Installed with the `mapr-oozie` package.
opentsdb	*Configuration File*: `warden.opentsdb.conf` *Description*: Installed with the `mapr-opentsdb` package. This package is supported only for internal MapR Monitoring uses cases.
resourcemanager	*Configuration File*: `warden.resourcemanager.conf` *Description*: Installed with the `mapr-resourcemanager` package.
sentry	*Configuration File*: `warden.sentry.conf` *Description*: Installed with the `mapr-sentry` package. However, Sentry is not automatically monitored by the Warden. When Sentry is configured to use the database storage model, you can manually copy the `/opt/mapr/sentry/sentry-<version>/conf.d/warden.sentry.conf` file to the `/opt/mapr/conf/conf.d` directory to add Sentry to the list of services that the Warden monitors.
spark master	*Configuration File*: `warden.spark-master.conf` *Description*: Installed with the `spark-master` package.

Configuring Service Properties

You can configure the following properties in the `warden.<servicename>.conf` file:

services	*Description*: Service name and number of nodes this service should run on, along with service dependencies. Format is `serviceName:N[depServiceName]`. Values for N = `1` or `all`
service.alarm.label	*Description*: Specifies the alarm name for this service. This is the alarm name that appears in the CLI when you do not request a terse output. Once tWarden starts the service, you cannot edit this value.
service.alarm.tersename	*Description*: Specifies the abbreviated alarm name for this service. This is the alarm name that appears in the Control System. Once Warden starts the service, you cannot edit this value.
service.command.monitor	*Description*: Monitor string (if the service monitor command does not provide sufficient monitoring).
service.command.monitorcommand	*Description*: Specifies a command that checks whether the service is running.
service.command.start	*Description*: Service `start` command.
service.command.stop	*Description*: Service `stop` command.

service.command.type	*Description*: Indicates whether the script runs in background (and exits) or inline (script does not exit). Type is either `BACKGROUND` or `INLINE`.
service.depends.local	*Description*: Indicates whether the service depends on a service instance locally, or on the master. Values = 1 (local) or 0 (master).
service.displayname	*Description*: The name of the service to display.
service.env	*Description*: Specifies environment variables to be use by the service. By default, it may include `MAPR_MAPREDUCE_MODE=default`. You can include a comma-separated list of environment variables. For example, `service.env=MAPR_MAPREDUCE_MODE=default, ABC=1,XYZ=2`.
service.heapsize.max	*Description*: Maximum heapsize in MB.
service.heapsize.min	*Description*: Minimum heapsize in MB.
service.heapsize.percent	*Description*: Specifies heapsize percent.
service.logs.location	*Description*: Location of the service log files.
service.port	*Description*: Port where the service is running (for example, the hue webserver runs on port 8888).
service.process.type	*Description*: Specifies the type of process. For example, `service.process.type=JAVA` indicates that the process is a Java process.
service.uri	*Description*: To include a link to a user interface associated with this service in the Control System, enter a Uniform Resource Identifier (URI) in this property, and specify the port in the `service.ui.port` property. For example, enter `/service1` for this property and then enter `8080` in the `service.ui.port` property to provide the following UI link for this service in the MCS: `http://<hostname>:8080/service1`
service.uri.port	*Description*: If you want to include a link to the user interface associated with this service in the Control System, enter the port in this property and also specify the URI in the `service.uri` property.

Memory Management for Services

The following memory parameters are used to reserve memory for the service:

- The `service.<servicename>.heapsize.percent` parameter controls the percentage of system memory allocated to the named service.
- The `service.<servicename>.heapsize.max` parameter defines the maximum heapsize used when invoking the service.
- The `service.<servicename>.heapsize.min` parameter defines the minimum heapsize used when invoking the service.

For example, the `service.command.gateway.heapsize.percent`, `service.command.gateway.heapsize.max`, and `service.command.gateway.heapsize.min` parameters in the `warden.gateway.conf` file control the amount of memory that Warden allocates to the gateway service before allocating memory to other services.

The actual heap size used when invoking a service is a combination of the three parameters according to the formula `max(heapsize.min, min(heapsize.max, total-memory * heapsize.percent / 100))`.

warden.hs2.conf Example

The hiveserver2 configuration file, `warden.hs2.conf`, looks like this:

```
services=hs2:1
service.displayname=HiveServer2
service.command.start=/opt/mapr/hive/hive-0.13/bin/hive --start --service
hiveserver2
service.command.stop=/opt/mapr/hive/hive-0.13/bin/hive --stop --service
hiveserver2
service.command.type=BACKGROUND
service.command.monitorcommand=/opt/mapr/hive/hive-0.13/bin/
hive --status --service hiveserver2
service.port=9083
service.ui.port=9083
service.uri=about
service.logs.location=/tmp/mapr
service.process.type=JAVA
```

When `hiveserver2` is installed, the `warden.hs2.conf` file is placed in the directory `/opt/mapr/conf/conf.d`. If Warden is running, it detects the file and starts the service. If Warden is not running, the file is picked up when Warden starts. Warden monitors the service and displays the status on the Control System UI.

yarn-site.xml

Describes the YARN configuration options.

YARN configuration options are stored in the `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml` file and are editable by the `root` user. This file contains configuration information that overrides the default values for YARN parameters. Overrides of the default values for core configuration properties are stored in the Default YARN parameters file.

To override a default value for a property, specify the new value within the `<configuration>` tags, using the following format:

```
<property>
 <name> </name>
   <value> </value>
 <description> </description>
</property>
```

The following configuration lists describe the possible entries that you can place between the `<name>` tags and between the `<value>` tags. The `<description>` tag is optional but recommended for maintainability.

Configuration for ResourceManager

Comprises the following parameters:

yarn.resourcemanager.hostname	The hostname of the ResourceManager.

	The configure.sh command automatically sets this value to the IP address that you provide with the `-RM` option. *Default value*: `{IP Address}`
yarn.resourcemanager.scheduler.address	The hostname and port of the Scheduler Interface. *Example value*: `${yarn.resourcemanager.hostname}:8030`
yarn.resourcemanager.resource-tracker.address	The hostname and port of the Resource Manager. *Example value*: `${yarn.resourcemanager.hostname}:8025`
yarn.resourcemanager.address	The address of the Applications Manager interface that is contained in the Resource Manager. *Example value*: `${yarn.resourcemanager.address}:8041`

Configuration for NodeManager

Comprises the following parameters:

yarn.nodemanager.container-localizer.log.level	*Default Value:*INFO *Description:*You can change the log level for the container localizer by setting the configuring options in this property. Different configuring options available are INFO, DEBUG, and WARN. By default logs will be available in the Application Master logs location but based on your cluster configuration, they will be available in the application's localized log directory. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch on page 437.
yarn.nodemanager.max-retry-file-delete	*Default Value:* 2 *Description:* Defines how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the /tmp directory on the local filesystem. Increasing the value for this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch on page 437.
yarn.nodemanager.kill-container-child-process	*Default Value:* `false` *Description:* Enables NodeManager to automatically run the `kill -9` command to end processes that hang after YARN stops containers. Set to `true` to enable this behavior. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch on page 437.
yarn.nodemanager.container-executor.class	*Default Value*: `org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor` *Description*: Identifies how containers are executed.

	Set to `LinuxContainerExecutor` by default, so that jobs can run as the user that submits the job. **Note:** If a system user (a user with *userID<500*) wants to submit a job, you must add the user in the *container-executor.cfg* file. The user `mapr` is already configured as an allowed system user.
yarn.nodemanager.aux-services	*Default Value*: `mapreduce_shuffle, mapr_direct_shuffle` *Description*: Selects a shuffle service that needs to be set for MapReduce to run.
yarn.nodemanager.aux-services.mapreduce_shuffle.class	*Default Value*: `org.apache.hadoop.mapred.ShuffleHandler` *Description*: This property, in conjunction with other properties, sets *direct shuffle* as the default shuffle for MapReduce.
yarn.nodemanager.aux-services.mapr_direct_shuffle.class	*Default Value*: `com.mapr.hadoop.mapred.LocalVolumeAuxService` *Description*: This property, in conjunction with other properties, sets *direct shuffle* as the default shuffle for MapReduce.

Configuration for Timeline Server Security with MapR-SASL

Comprises the following parameter:

yarn.timeline-service.http-authentication.type	*Default Value*: `com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHand ler` *Description*: The authentication used for the timeline server HTTP endpoint.

Configuration for Timeline Server Security with Kerberos

Comprises the following parameter:

yarn.timeline-service.http-authentication.type	*Default Value*: `com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHand ler` *Description*: The authentication used for the timeline server HTTP endpoint.
yarn.timeline-service.http-authentication.kerberos.principal	*Default Value*: `principal(HTTP/nodex@NODEx)` *Description*: The Kerberos service principal for the timeline server HTTP endpoint.
yarn.timeline-service.http-authentication.kerberos.keytab	*Default Value*: `path to keytab(/opt/mapr/conf/mapr.keytab)` *Description*: The Kerberos keytab for the timeline server HTTP endpoint.
yarn.timeline-service.principal	*Default Value*: `mapr/nodex@NODEX` *Description*: The Kerberos principal for the timeline reader. NodeManager principal is used for the timeline collector as it runs as an auxiliary service inside NodeManager.

yarn.timeline-service.keytab

Default Value: `path to keytab(/opt/mapr/conf/mapr.keytab)`

Description: The Kerberos keytab for the timeline reader. NodeManager keytab is used for the timeline collector as it runs as an auxiliary service inside NodeManager.

Configuration for MapReduce

Comprises the following parameter:

mapreduce.job.shuffle.provider.services

Default Value: `mapr_direct_shuffle`

Description: This is the default shuffle handler for MapReduce. Contains a value from the `yarn.nodemanager.aux-services` property.

Configuration for Container Logs

Comprises the following parameters:

yarn.nodemanager.log-dirs

Default Value: `/opt/mapr/hadoop/hadoop-<version>/logs/userlogs/<applicationID>/<containerID>/<filename>.log`

Description: The location to store container logs on the node. An application's log directory is `${yarn.nodemanager.log-dirs}/application_${appid}`. Individual containers' log directories are named `container_{$contid}`. Each container directory will contain the files *stderr*, *stdin*, and *syslog* generated by that container.

Note: You can find the application ID associated with your job in the Control System.

yarn.log-aggregation-enable

Default Value: `false`

Description: Indicates whether the logs are aggregated.

yarn.nodemanager.log.retain-seconds

Default Value: `10800 (3 hours)`

Description: Specifies the duration for which user logs are maintained, when log aggregation is disabled.

yarn.log-aggregation.retain-seconds

Default Value: `-1`

Description: Specifies the number of seconds to retain logs, when log aggregation is enabled. The default value of *-1*, disables the deletion of logs.

yarn.log-aggregation.retain-check-interval-seconds

Default Value: `-1`

Description: The interval between aggregated log retention checks. If set to *0* or a negative value, then the value is computed as one-tenth of the aggregated log retention time.

Note: Setting this to a low value may cause unnecessary log retention checks.

yarn.nodemanager.remote-app-log-dir

Default Value: `/tmp/logs`

last-updated: Apr 11, 2022

	Description: The location on the filesystem where the logs are aggregated.
yarn.nodemanager.remote-app-log-dir-suffix	*Default Value*: `logs` *Description*: The suffix for the directory that stores the aggregated logs for each user.

Configuration for Oozie

Comprises the following parameter:

yarn.resourcemanager.principal	*Default Value*: `mapr` *Description*: The name of the administrative user.

Configuration for Apache Shuffle

You can disable Direct Shuffle and enable Apache Shuffle for MapReduce applications through the following setting:

yarn.nodemanager.aux-services	*Value*: `mapreduce_shuffle`

zoo.cfg
Lists the ZooKeeper configuration file.

Example zoo.cfg File

The file `/opt/mapr/zookeeper/zookeeper-`*`$version`*`/conf/zoo.cfg` specifies ZooKeeper configuration parameters.

```
# The number of milliseconds of each tick
tickTime=2000
# The number of ticks that the initial
# synchronization phase can take
initLimit=20
# The number of ticks that can pass between
# sending a request and getting an acknowledgement
syncLimit=10
# the directory where the snapshot is stored.
dataDir=/opt/mapr/zkdata
# the port at which the clients will connect
clientPort=5181
# max number of client connections
maxClientCnxns=1000
#autopurge interval - 24 hours
autopurge.purgeInterval=24
#superuser to allow zk nodes delete
superUser=mapr
#readuser to allow read zk info for authenticated clients
readUser=anyone
# cldb key location
mapr.cldbkeyfile.location=/opt/mapr/conf/cldb.key
#security provider name
authMech=MAPR-SECURITY
# security auth provider
authProvider.1=org.apache.zookeeper.server.auth.SASLAuthenticationProvider
# use maprserverticket not userticket for auth
mapr.usemaprserverticket=true
#
# ZK-to-ZK server authentication using MAPR-SASL
# Set quorum.auth.enableSasl=false for insecure cluster, =true for secure
cluster
```

```
quorum.auth.enableSasl=true
quorum.auth.learnerRequireSasl=true
quorum.auth.serverRequireSasl=true
quorum.auth.learner.loginContext=QuorumLearner
quorum.auth.server.loginContext=QuorumServer
quorum.cnxn.threads.size=20
server.0=xxx.xxx.xxx.xxx:2888:3888
server.1=xxx.xxx.xxx.xxx:2888:3888
server.2=xxx.xxx.xxx.xxx:2888:3888
```

Warning: `maxClientCnxns` limits the number of concurrent ZooKeeper connections that a single client machine may make. This value does not set a limit for the whole cluster. The default is 100. If you plan to run more than 100 jobs from a single node, increase this value.

Attention: By default, only **authenticated** users (users with a valid ticket) are allowed to execute ZooKeeper related commands. To allow **all** users to execute ZooKeeper related commands, add the entry `sessionRequireClientSASLAuth=false` to this file and restart ZooKeeper.

Related tasks

Enabling Security on page 1405
Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

zookeeper-env.sh
Use this file to load or unload JMX parameters for ZooKeeper.

Important: MapR version 6.0.x, and MapR version 6.1.x require a patch to use this functionality.

By default, in all MapR versions, the ZooKeeper JMX parameters are not loaded.

To load ZooKeeper JMX parameters, set the JMXDISABLE parameter to `false` in the `zookeeper-env.sh` file within the `/opt/mapr/zookeeper/zookeeper-$version/conf` directory.

```
JMXDISABLE=false
```

Restart the ZooKeeper process: `service mapr-zookeeper restart`.

To unload ZooKeeper JMX parameters, set:

```
JMXDISABLE=true
```

in `zookeeper-env.sh`. Restart the ZooKeeper process: `service mapr-zookeeper restart`.

Alarms Reference

The pages in this section provide details about all of the types of alarms.

User/Group Alarms

User/group alarms indicate problems with user or group quotas. The following tables describe the MapR user/group alarms.

- Entity Advisory Quota Alarm
- Entity Quota Alarm

Entity Advisory Quota Alarm

UI Column	User Advisory Quota Alarm

Logged As	AE_ALARM_AEADVISORY_QUOTA_EXCEEDED
Meaning	A user or group has exceeded its advisory quota. See Setting Quota Defaults for Users and Groups on page 781 for more information about user/group quotas.
Resolution	No immediate action is required. To avoid exceeding the hard quota, clear space on volumes created by the user or group, or stop further data writes to those volumes.
Configuration	Configurable when setting/modifying entity properties. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Entity Quota Alarm

UI Column	User Quota Alarm
Logged As	AE_ALARM_AEQUOTA_EXCEEDED
Meaning	A user or group has exceeded its quota. Further writes by the user or group will fail. See Setting Quota Defaults for Users and Groups on page 781 and Set or Modify Quotas for Users and/or Groups on page 952 for more information about user/group quotas.
Resolution	Free some space on the volumes created by the user or group, or increase the user or group quota.
Configuration	Configurable when setting/modifying entity properties. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Cluster Alarms

Cluster alarms indicate problems that affect the cluster as a whole. The following sections describe the data-fabric cluster alarms.

CLDB Low Memory Alarm

UI Column	Cluster freespace above CLDB heapsize
Logged As	CLUSTER_ALARM_CLDB_HEAPSIZE
Meaning	The CLDB process needs more memory to cache containers.
Resolution	The CLDB heap size is no longer sufficient for the CLDB to cache containers. The solution is to increase the CLDB memory settings on all CLDB nodes, using the same value for the minimum and maximum heap sizes. The text the alarm code provides will include the minimum amount of memory required to be sufficient; however, to accommodate future growth, you should set these values to a somewhat higher number. For example, if the alarm indicates that the CLDB needs 4000 MB, you should set the minimum and maximum heap sizes to a larger value such as 4400 MB. The CLDB memory settings are controlled by the following parameters in the `warden.conf` file located in `$MAPR_HOME/conf/:`:

	`service.command.cldb.heapsize.max=<max heap size>`
	`service.command.cldb.heapsize.min=<min heap size>`
	Restart the Warden service on each CLDB node after you edit the `warden.conf file`.

License Near Expiration

UI Column	License Near Expiration Alarm
Logged As	CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION
Meaning	The Enterprise Edition license associated with the cluster is within 30 days of expiration.
Resolution	Renew the Enterprise Edition license.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

License Expired

UI Column	License Expiration Alarm
Logged As	CLUSTER_ALARM_LICENSE_EXPIRED
Meaning	The Enterprise Edition license associated with the cluster has expired. Enterprise Edition features have been disabled.
Resolution	Renew the Enterprise Edition license.

Cluster Almost Full

UI Column	Cluster Almost Full
Logged As	CLUSTER_ALARM_CLUSTER_ALMOST_FULL
Meaning	The cluster storage is almost full. The percentage of storage used before this alarm is triggered is 90% by default, and is controlled by the configuration parameter `cldb.cluster.almost.full.percentage`.
Resolution	Reduce the amount of data stored in the cluster. If the cluster storage is less than 90% full, check the `cldb.cluster.almost.full.percentage` parameter via the `config load` command, and adjust it if necessary via the `config save` command.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Cluster Full

UI Column	Cluster Full
Logged As	CLUSTER_ALARM_CLUSTER_FULL
Meaning	The cluster storage is full. MapReduce operations have been halted.
Resolution	Free up some space on the cluster.

Maximum Licensed Nodes Exceeded alarm

UI Column	Licensed Nodes Exceeded Alarm
Logged As	CLUSTER_ALARM_LICENSE_MAXNODES_EXCEEDED
Meaning	The cluster has exceeded the number of nodes specified in the license.
Resolution	Remove some nodes, or upgrade the license to accommodate the added nodes.

New Cluster Features Disabled

UI Column	New Cluster Features Disabled
Logged As	CLUSTER_ALARM_NEW_FEATURES_DISABLED
Meaning	Features added in version 2.0 or 3.0 are not enabled on the cluster.
Resolution	Enable the latest features for the data-fabric version that you are currently running.

Upgrade in Progress

UI Column	Software Installation & Upgrades
Logged As	CLUSTER_ALARM_UPGRADE_IN_PROGRESS
Meaning	A rolling upgrade of the cluster is in progress.
Resolution	No action is required. Performance may be affected during the upgrade, but the cluster should still function normally. After the upgrade is complete, the alarm is cleared.

VIPAssignment Failure

UI Column	VIP Assignment Alarm
Logged As	CLUSTER_ALARM_UNASSIGNED_VIRTUAL_IPS
Meaning	Core software was unable to assign a VIP to any NFS servers.
Resolution	Check the VIP configuration, and make sure at least one of the NFS servers in the VIP pool are up and running. See Setting Up VIPs for NFS. This alarm can also indicate that a VIP's hostname exceeds the maximum allowed length of 16. Check the log file `/opt/mapr/logs/nfsmon.log` for additional information.

DARE Enabled

UI Column	DARE Enabled Alarm
Logged As	CLUSTER_ALARM_DARE_COPY_MASTER_KEY
Meaning	Data-at-rest encryption (DARE) is enabled on the cluster.
Resolution	When DARE is enabled on the cluster, a data-at-rest encryption master key file is generated and stored in `/opt/mapr/conf/dare.master.key` on the

	CLDB node. Before dismissing the alarm, make a copy of the master key file because loss of the master key file can be catastrophic and irreversible and might result in loss of data.

DARE Incompatible

UI Column	DARE Incompatible Alarm
Logged As	CLUSTER_ALARM_DARE_INCOMPATIBLE
Meaning	Not all nodes on the cluster are enabled for data-at-rest encryption (DARE).
Resolution	When DARE is enabled on certain nodes in the cluster, there may still be some nodes that are not (yet) enabled for DARE. Enable DARE on all the nodes before dismissing the alarm.

Too Many Snapshots

UI Column	Too Many Snapshots
Logged As	CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS
Meaning	There are too many snapshots on this cluster.
Resolution	Delete snapshots from the cluster before dismissing the alarm.

Node Alarms

Node alarms indicate problems in individual nodes. The following tables describe the MapR node alarms.

CLDB Service Alarm

UI Column	CLDB Alarm
Logged As	NODE_ALARM_SERVICE_CLDB_DOWN
Meaning	The CLDB service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the CLDB service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 2209. If the warden successfully restarts the CLDB service, the alarm is cleared. If the warden is unable to restart the CLDB service, see more troubleshooting information.

Core Present Alarm

UI Column	Core Present
Logged As	NODE_ALARM_CORE_PRESENT
Meaning	A service on the node has crashed and created a core dump file. When all core files are removed, the alarm is cleared.

last-updated: Apr 11, 2022

Resolution	See troubleshooting information.

Debug Logging Active

UI Column	Excess Logs Alarm
Logged As	NODE_ALARM_DEBUG_LOGGING
Meaning	Debug logging is enabled on the node.
Resolution	Debug logging generates enormous amounts of data, and can fill up disk space. If debug logging is not absolutely necessary, turn it off: use the `setloglevel on page 1751` command. If it is absolutely necessary, make sure that the logs in `/opt/mapr/logs` are not in danger of filling the entire disk.

Disk Failure

UI Column	Disk Failure Alarm
Logged As	NODE_ALARM_DISK_FAILURE
Meaning	A disk has failed on the node.
Resolution	Check the disk health log (`/opt/mapr/logs/faileddisk.log`) to determine which disk failed and view any SMART data provided by the disk. See Managing Disks on page 834.

Duplicate Host ID

UI Column	Duplicate Host Id
Logged As	NODE_ALARM_DUPLICATE_HOSTID
Meaning	Two or more nodes in the cluster have the same host ID.
Resolution	Multiple nodes with the same host ID are prevented from joining the cluster, in order to prevent addressing problems that can lead to data loss. To correct the problem and clear the alarm, make sure all host IDs are unique and use the `maprcli node allow-into-cluster` command to un-ban the affected host IDs.

FileServer Service Alarm

UI Column	FileServer Alarm
Logged As	NODE_ALARM_SERVICE_FILESERVER_DOWN
Meaning	The FileServer service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the FileServer service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the

	warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 2209 file. If the warden successfully restarts the FileServer service, the alarm is cleared. If the warden is unable to restart the FileServer service, see more troubleshooting information.

Heartbeat Processing Slow

UI Column	Heartbeat Processing Slow Alarm
Logged As	NODE_ALARM_HB_PROCESSING_SLOW
Meaning	The time that has elapsed since the CLDB processed the previous heartbeat from the MapR File System node has exceeded 5 seconds.
Resolution	When the CLDB is processing a heartbeat from a node, it will compare the current time to the time at which the previous heartbeat from that node was processed. If the elapsed time exceeds 5 seconds then this alarm is raised. If this alarm occurs frequently, investigate what might be causing the relevant node or nodes to be busy, or whether the CLDB nodes have enough resources to handle their load.

HBMaster Service Alarm

UI Column	HBase Master Alarm
Logged As	NODE_ALARM_SERVICE_HBMASTER_DOWN
Meaning	The HBMaster service on the node has stopped running.
Resolution	To check whether the HBMaster service is running, go to the node information page or the **Services** page in the Control System. Warden will try three times to restart the service automatically. After an interval (30 minutes by default), Warden will again try three times to restart the service. The interval can be configured using the `services.retryinterval.time.sec` parameter in the `warden.conf` file. If Warden successfully restarts the HBMaster service, the alarm is cleared. If Warden is unable to restart the HBMaster service, it might be necessary to contact technical support.

HBRegion Service Alarm

UI Column	Hbase RegionServer Alarm
Logged As	NODE_ALARM_SERVICE_HBREGION_DOWN
Meaning	The HBRegion service on the node has stopped running.
Resolution	To check whether the HBRegion service is running, go to the node information page or the **Services** page in the Control System. Warden will try three times to

	restart the service automatically. After an interval (30 minutes by default), Warden will again try three times to restart the service. The interval can be configured using the `services.retryinterval.time.sec` parameter in the `warden.conf` file. If Warden successfully restarts the HBRegion service, the alarm is cleared. If Warden is unable to restart the HBRegion service, it might be necessary to contact technical support.

High MAST Gateway Memory Alarm

UI Column	High Memory Usage
Logged As	NODE_ALARM_HIGH_MASTGATEWAY_MEMORY
Meaning	Memory consumption of MAST Gateway exceeds the memory allocated for MAST Gateway.
Resolution	Tune the percentage of node memory allocated for MAST Gateway in the `/opt/mapr/conf/conf.d/warden.mastgateway.conf` file. See Configuring MAST Gateway for more information. If core is generated for this error, contact MapR support.

HistoryServer Alarm

UI Column	HistoryServer Alarm
Logged As	NODE_ALARM_SERVICE_HISTORYSERVER_DOWN
Meaning	The HistoryServer on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether HistoryServer is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 2209 file. If warden successfully restarts the HistoryServer, the alarm is cleared. If Warden is unable to restart the HistoryServer, see more troubleshooting information.

HiveMeta Alarm

UI Column	HiveMeta Alarm
Logged As	NODE_ALARM_SERVICE_HIVEMETA_DOWN
Meaning	The HiveMeta service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether Hive Metastore is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 2209 file.

	If Warden successfully restarts the Hive Metastore service, the alarm is cleared. If Warden is unable to restart the Hive Metastore service, see more troubleshooting information.

HiveServer 2 Alarm

UI Column	HiveServer 2 Alarm
Logged As	NODE_ALARM_SERVICE_HS2_DOWN
Meaning	The HiveServer 2 service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether HiveServer 2 is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 2209 file. If Warden successfully restarts the HiveServer 2 service, the alarm is cleared. If Warden is unable to restart the HiveServer 2 service, see more troubleshooting information.

Hoststats Alarm

UI Column	HostStats
Logged As	NODE_ALARM_SERVICE_HOSTSTATS_DOWN
Meaning	The Hoststats service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the Hoststats service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 2209 file. If the warden successfully restarts the service, the alarm is cleared. If the warden is unable to restart the service, review more troubleshooting information.

Incorrect Topology Alarm

UI Column	CLDB Alarm
Logged As	NODE_ALARM_INCORRECT_TOPOLOGY_ALARM
Meaning	The `mapr.cldb.internal` volume's topology (normally `/cldb`) must include all CLDB nodes. This alarm signifies that one or more CLDB nodes are outside the CLDB volume's topology.
Resolution	There are two ways to resolve this alarm:

last-updated: Apr 11, 2022

- Move any stray CLDB nodes into the topology in which `mapr.cldb.internal` resides. See Setting Up Volume Topology on page 915 for more information.
- Change the volume topology of `mapr.cldb.internal` to include the stray CLDB nodes. See Administering Volumes on page 856 for more information.

Installation Directory Full Alarm

UI Column	Installation Directory Full
Logged As	NODE_ALARM_OPT_MAPR_FULL
Meaning	The partition `/opt/mapr` on the node is running out of space (95% full).
Resolution	Free up some space in `/opt/mapr` on the node.

Instance Mismatch Alarm

UI Column	Instance Mismatch Alarm
Logged As	NODE_ALARM_NUM_INSTANCES_MISMATCH
Meaning	The number of MapR File System instances is not as configured.
Resolution	Restart warden on the node by running the following command: `service mapr-warden restart`

High FileServer Memory Alarm

UI Column	High FileServer Memory Alarm
Logged As	NODE_ALARM_HIGH_MFS_MEMORY
Meaning	Memory consumed by **fileserver** service on the node is in excess of the allotted amount.
Resolution	Log on as root to the node for which the alarm is raised, and restart the Warden: `service mapr-warden restart`
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

MapR User Mismatch

UI Column	MapR User Mismatch Alarm
Logged As	NODE_ALARM_MAPRUSER_MISMATCH
Meaning	The cluster nodes are not all set up to run MapR services as the same user (for example, some nodes

	are running MapR as `root` while others are running as `mapr_user`.
Resolution	For the nodes on which the User Mismatch alarm is raised, follow the steps in Changing the User for MapR Services from the Command-Line on page 832.

Memory Allocation Alarm

UI Column	Memory Allocation Alarm
Logged As	NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED
Meaning	The percentage of system memory required to run services on the node exceeds the set threshold and could potentially overload the node. If you installed a service on the node that causes the sum of memory used by the services on the node to exceed the threshold set, the system raises the alarm.
Resolution	To clear the alarm, you can add more memory to the node, stop a service from running on the node, or remove a service from the node. You can run the `service list` command to see the memory allocated to each service on the node. See service list for more information. The `services.memoryallocation.alarm.threshold` property in `warden.conf` defines the maximum amount of system memory that services running on the node can use before triggering the alarm. The default setting for this property is 95 percent: `services.memoryallocation.alarm.threshold=95` The percentage of system memory that services can use on the node should not exceed 95. Restart the Warden service on the node after you edit the `warden.conf` file.

Memory Usage Alarm

UI Column	Memory Usage Alarm
Logged As	NODE_ALARM_MEMORY_SWAPPING
Meaning	The HostStats service raises this alarm for swap space when the delta of swap in memory and the delta of swap out memory exceeds the threshold set over a specific time period.
Resolution	To clear the alarm, you can increase the physical memory or reduce the load running on the node. You can run the `service list` command to see the memory allocated to each service on the node. See `service list` for more information. The memory swapping alarm is controlled by the following properties in `/opt/mapr/conf/hoststats.conf`:

last-updated: Apr 11, 2022

	• `alarm.swapping.threshold` • `alarm.swapping.counter` The memory threshold for swap in and swap out is defined by the `alarm.swapping.threshold` property, which is set to 100MB by default. The duration over which HostStats checks the delta of the memory is defined by the `alarm.swapping.counter`, which is set to 100 seconds by default.

NFS Gateway Alarm

UI Column	NFS Service Down
Logged As	NODE_ALARM_SERVICE_NFS_DOWN
Meaning	The NFS service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the NFS service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 2209 file. If the warden successfully restarts the NFS service, the alarm is cleared. If the warden is unable to restart the NFS service, see more troubleshooting information.

NFSv4 Service Alarm

UI Column	NFSv4 Service Down
Logged As	NODE_ALARM_SERVICE_NFS4_DOWN
Meaning	The NFSv4 service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the NFS service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 2209 file. If the warden successfully restarts the NFS service, the alarm is cleared. If the warden is unable to restart the NFS service, refer to NFSv4 Troubleshooting on page 1219 to restart the service.

NodeManager Alarm

Explains how to resolve the issue with the Node Manager service stopping on the node.

UI Column	NodeManager Alarm
Logged As	NODE_ALARM_SERVICE_NODEMANAGER_DOWN

Meaning	The NodeManager service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether NodeManager is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 2209 file. If warden successfully restarts the NodeManager, the alarm is cleared. If warden is unable to restart the NodeManager, see more troubleshooting information.

No Disk Attached Alarm

UI Column	No Disk Attached Alarm
Logged As	NODE_ALARM_NO_DISK_ATTACHED
Meaning	There are one or more MapR File System instances on a node with no SP assigned to them.
Resolution	To clear the alarm, assign at least one SP per MapR File System.

No Heartbeat Alarm

Describes the NODE_ALARM_NO_HEARTBEAT alarm.

UI Column	No Heartbeat Alarm
Logged As	NODE_ALARM_NO_HEARTBEAT
Meaning	Node is not undergoing maintenance, and no heartbeat detected for over 5 minutes.
Resolution	Check the status of the node manually.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

This alarm is raised when a node is down for more than 5 minutes. By default, this alarm is not raised if an edge node is down. To raise an alarm for edge nodes as well, set the CLDB parameter `cldb.ignore.posix.only.hb.alarm` to `0` using the command:

```
/opt/mapr/bin/maprcli config save -values
'{cldb.ignore.posix.only.hb.alarm:"0"}'
```

Security Certificate Expiry Alarm

Describes the NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION alarm.

Note: On MapR version 6.1, you need to install the latest patch to enable this functionality.

UI Column	SSL Certificate Expiry
Logged As	NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION
Meaning	SSL certificates are expiring within the number of days denoted by the CLDB setting

last-updated: Apr 11, 2022

	`cldb.ssl.cert.expiring.alarm.days`. See cldb.conf on page 2182 for more information.
Resolution	Renew the SSL certificates. See Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster for more information.
Configuration	None.

Specification	This alarm is raised when any of the first ten security certificates in `/opt/mapr/conf/ssl_keystore` or in `/opt/mapr/conf/ssl_truststore` are set to expire within the number of days denoted by the CLDB setting `cldb.ssl.cert.expiring.alarm.days`. Once the alarm is raised, the administrator needs to find out the certificates that are expiring, and renew them.
	To find out the certificates that are expiring, use the `/opt/mapr/server/getSSLExpiryCerts.py` Python script. For example:
	`python /opt/mapr/server/getSSLExpiryCerts.py -print`
	`Below certificates expiring in the next 120 days`
	`Truststore:`
	`Alias: 100day valid until: Mon Jul 13 04:04:15 PDT 2020`
	`Alias: 65day valid until: Mon Jun 08 03:45:44 PDT 2020`
	`Alias: 70day valid until: Sat Jun 13 03:46:00 PDT 2020`
	`Alias: 80day valid until: Tue Jun 23 03:46:14 PDT 2020`
	`Alias: 90day valid until: Fri Jul 03 04:03:57 PDT 2020`
	`Keystore:`
	`Alias: 3daymay17 valid until: Thu May 21 04:20:26 PDT 2020`

Related reference

cldb.conf on page 2182
Contains the configuration for CLDB nodes.

Node Too Many Containers

UI Column	Too Many Containers Alarm
Logged As	NODE_ALARM_TOO_MANY_CONTAINERS
Meaning	Number of containers on this node reached the maximum limit.
Resolution	Delete unused volumes or Snapshots. You can reset the maximum with: `maprcli config save -values {"pernode.numcntrs.alarm.thr":"<number>"}`
Configuration	Configurable at cluster level.

	This alarm is also raised when total number of containers (including snap containers) exceed 10 times the value of `pernode.numcntrs.alarm.thr`. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Oozie Alarm

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

UI Column	Oozie Alarm
Logged As	NODE_ALARM_SERVICE_OOZIE_DOWN
Meaning	The Oozie service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether Oozie is running. Warden will try three times to restart Oozie automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 2209 file. If Warden successfully restarts Oozie, the alarm is cleared. If Warden is unable to restart Oozie, see more troubleshooting information.

PAM Misconfigured Alarm

UI Column	Pam Misconfigured Alarm
Logged As	NODE_ALARM_PAM_MISCONFIGURED
Meaning	The PAM authentication on the node is configured incorrectly.
Resolution	See PAM Configuration.

ResourceManager Alarm

UI Column	ResourceManager Alarm
Logged As	NODE_ALARM_SERVICE_RESOURCEMANAGER_DOWN
Meaning	The ResourceManager service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether ResourceManager is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 2209 file. If warden successfully restarts the ResourceManager, the alarm is cleared. If warden is unable to restart the ResourceManager, see more troubleshooting information.

last-updated: Apr 11, 2022

Root Partition Full Alarm

UI Column	Root Partition Full
Logged As	NODE_ALARM_ROOT_PARTITION_FULL
Meaning	The root partition ('/') on the node is running out of space (99% full).
Resolution	Free up some space in the root partition of the node.

Tiny Buckets Flush Alarm

UI Column	Lot of Tiny Buckets Flushed
Logged As	NODE_ALARM_TINY_BUCKET_FLUSH
Meaning	Indicates lot of small buckets (<= 8mb) are getting flushed in DB resulting in performance degradation. You may see put operation performance going down during this phase and will need to take corrective actions to fix it. This will not bring down the cluster and data is still accessible.
Resolution	Increase memory for MapR File System as number of active tablets is very high.

Time Skew Alarm

UI Column	Time Skew Alarm
Logged As	NODE_ALARM_TIME_SKEW
Meaning	The clock on the node is out of sync with the master CLDB by more than 20 seconds.
Resolution	Use NTP to synchronize the time on all the nodes in the cluster.

Version Alarm

UI Column	Version Alarm
Logged As	NODE_ALARM_VERSION_MISMATCH
Meaning	One or more services on the node are running an unexpected version or there is a mismatch in the MapR File System patch versions on the nodes.
Resolution	Stop the node, Restore the correct version of any services you have modified, and re-start the node. See Administering Nodes on page 797.

WebServer Service Alarm

UI Column	Webserver Alarm
Logged As	NODE_ALARM_SERVICE_WEBSERVER_DOWN
Meaning	The WebServer service on the node has stopped running.

Resolution	Go to the node information page or the **Services** page in the Control System to check whether the WebServer service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 2209. If the warden successfully restarts the WebServer service, the alarm is cleared. If the warden is unable to restart the WebServer service, see more troubleshooting information.

Table-Replication Alarms

You can view table-replication alarms using the Control System and the CLI. See Viewing Active Table Replication Alarms on page 1318 for more information.

Table Replication Errors
Explains the alarm that is raised when there are table replication errors.

Logged As	VOLUME_ALARM_TABLE_REPL_ERROR
Meaning	This alarm displays the paths and names of the source tables for which the alarms were issued. Up to ten (10) source tables, that have encountered an error, are displayed.

Diagnostics

To identify the cause of the alarm, run the maprcli table replica list command. This command displays an `errors` field with additional information about the error.

```
maprcli table replica list -path <table path>
```

The `errors` field provides the following information:

- Code - table replication error code:
- Host - host that the error occurred on
- Msg - error message information

For additional information about possible causes of the error, see the following log files (located in the **/opt/mapr/logs** directory):

- mfs.log-5 - for the nameserver node of the source table
- mfs.log-5 - for the nameserver node of the destination table
- gateway.log

last-updated: Apr 11, 2022

Error Conditions

Possible Error Conditions	Description
A missing table or column family on the destination cluster	If a column family no longer exists in the replica, pause replication with the `maprcli table replica pause` command, recreate the column family with the `maprcli table cf create`command, run the CopyTable utility to copy data from the source table into the column family, and then resume replication with the `maprcli table replica resume` command.
A mismatch in column family names for the table on the destination cluster	If the column family still exists in the replica but the name of the column family was changed, run the `maprcli table cf edit` command with the parameter `-newcfname` set to the correct name. Replication will resume automatically.
Unreachable gateways on the destination cluster	This error occurs only if none of the gateways on the cluster are reachable.
Autosetup with directcopy has failed while copying data from the source to the replica	This error could be raised under the following conditions: • If this error occurs due to a connection failure, this alarm should get resolved once the connection is restored. • If this error occurs due to other error conditions such as missing tables, mis-matched column families, or an unreachable gateway, the error condition may not get resolved on its own and may need administration action. For example, if a PUT operation fails on destination cluster due to an Out-Of-Space condition, the administrator will need to add more storage before the PUT retry succeeds.

Table Replication Lag High

Logged As

VOLUME_ALARM_TABLE_REPL_LAG_HIGH

Meaning

These alarms display the paths and names of the source tables for which the replication lag is high. High lag times might be caused by these conditions:

- High load on the source or replica
- Low network bandwidth between the source and replicas
- Miscellaneous error conditions that prevent replication from proceeding
- Replication explicitly paused on the source cluster

Configuration

Configurable at the volume level. See volume create on page 1931 for more information.

Table Replication Asynchronous

Logged As

VOLUME_ALARM_TABLE_REPL_ASYNC

Meaning

These alarms display the pathnames of the source tables that are involved.

	If MapR Database is replicating synchronously and it judges the latency of the replication stream to be too high, it will switch to asynchronous replication temporarily. After a new gateway is created, an existing gateway is restarted, or after latency is sufficiently reduced, MapR Database switches the mode of replication back to synchronous. You can also check whether a source table is being replicated synchronously or asynchronously by running the command `table replica list` on page 1863 .

Elasticsearch Formatting Alarm

Logged As	NODE_ALARM_SERVICE_ELASTICSEARCH_EXCP
Meaning	The put of primary table cannot be converted/ formatted for pushing to ElasticSearch. If the primary table has ElasticSearch as one of its replicas, that may miss updates on some rows as they could not be converted to a supported format for ElasticSearch.
Resolution	Check for rows that could not be formatted for pushing to ElasticSearch in MapR File System logs and insert row with data that can be pushed to ElasticSearch.

Secondary Index Alarms

Secondary index alarms indicate issues that MapR Database might encounter while updating secondary indexes. It is important that you understand what the alarms indicate, and how to resolve the issue causing them.

Secondary Index Update Lag High

Logged As	VOLUME_ALARM_TABLE_INDEX_LAG_HIGH
Meaning	This alarm displays the paths and names of the source tables for which replication lag is high. High lag times might be caused by these conditions: • High load on the source or replica • Low network bandwidth between the source and replicas • Miscellaneous error conditions that prevent replication from proceeding • Replication explicitly paused on the source cluster
Resolution	If you have configured the threshold for this alarm too low, you can increase the theshhold. You configure this lag at the volume level by specifying the `dbindexlagsecalarmthresh` parameter. See volume modify on page 2005 for more information.

Secondary Index Update Error

Logged As	VOLUME_ALARM_TABLE_INDEX_ERROR

Meaning	This alarm occurs if the JSON table regions cannot connect to any of the internal gateways used to update fields in a secondary index. This might be caused by these conditions: • The replication gateway failed. • You have configured too few replication gateway instances.
Resolution	If the gateway failed, restart it. Otherwise, add more gateways. See Managing Gateways on page 1154 for further information.

Secondary Index Encoding Error

Logged As	VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR
Meaning	This alarm occurs when any of the following encoding errors occur during index updates: • The indexed rowkey size is too big (> 32 Kb). • The indexed field contains a CAST function, and a failure occurs evaluating the CAST function.
Resolution	You must either correct your underlying data or redefine the index to avoid missing rows. See Troubleshooting Secondary Index Encoding Errors on page 1101 for details about how to identify these errors and possible corrective actions. You also must manually clear this alarm, even if you drop the index or the table.

Volume Alarms

Volume alarms indicate problems in individual volumes. The following sections describe the MapR volume alarms.

Compaction Failed

UI Column	Volume Compaction Failed
Logged As	VOLUME_ALARM_COMPACTION_FAILURE
Meaning	Data could not be purged as the compactor did not complete the run.
Resolution	Wait for the compactor to run again or manually trigger the compactor using the `volume compact` on page 1927 command.

Data Unavailable

UI Column	Data Alarm
Logged As	VOLUME_ALARM_DATA_UNAVAILABLE
Meaning	This is a potentially very serious alarm that may indicate data loss. Some of the data on the volume

	cannot be located. This alarm indicates that enough nodes have failed to bring the replication factor of part or all of the volume to zero. For example, if the volume is stored on a single node and has a replication factor of one, the Data Unavailable alarm will be raised if that volume fails or is taken out of service unexpectedly. If a volume is replicated properly (and therefore is stored on multiple nodes) then the Data Unavailable alarm can indicate that a significant number of nodes is down.
Resolution	Investigate any nodes that have failed or are out of service. • You can see which nodes have failed by looking at the Node Health pane in the **Overview** page in the Control System. • Check the cluster(s) for any snapshots or mirrors that can be used to re-create the volume. For additional troubleshooting information, see how to handle this alarm.

Data Under-Replicated
Describe the alarm that is triggered when a volume is under replicated.

UI Column	Replication Alarm
Logged As	VOLUME_ALARM_DATA_UNDER_REPLICATED
Meaning	The volume replication factor is lower than the desired replication factor set for the volume. This can be caused by failing disks or nodes, or the cluster may be running out of storage space.
Resolution	Investigate any nodes that are failing. You can see which nodes have failed by looking at the Node Health pane in the **Overview** page on the Control System. Determine whether it is necessary to add disks or nodes to the cluster. This alarm is generally raised when the nodes that store the volumes or replicas have not sent a heartbeat for five minutes. To prevent re-replication during normal maintenance procedures, MapR waits a specified interval (by default, one hour) before considering the node dead and re-replicating its data. You can control this interval by setting the `cldb.fs.mark.rereplicate.sec` parameter using the `config save` command. For additional troubleshooting information, see how to handle this alarm.

Warm-Tier Data Node Down
Provides the resolution for the Warm-Tier Data Node Down alarm.

UI Column	Warm-Tier Data Node Down
Logged As	VOLUME_ALARM_DEGRADED_EC_STRIPES
Meaning	One of the nodes or SPs, on which either the data or parity fragments associated with the tiering enabled volume resides, is offline or down.

last-updated: Apr 11, 2022

Resolution	MapR tolerates failure of nodes equal to the number of parity fragments. However, to ensure the availability of data, add nodes to the topology or cluster.

Data Under-Encoded

UI Column	Volume Data Under-Encoded
Logged As	VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES
Meaning	The number of nodes that are down is equal to the number of parity fragments.
Resolution	MapR tolerates failure of nodes equal to the number of parity fragments. However, to ensure the availability of data, add nodes to the topology or cluster.

Data Below-Parity

UI Column	Volume Data Below-Parity
Logged As	VOLUME_ALARM_EC_DATA_UNAVAILABLE
Meaning	The number of SPs or nodes that are offline or down exceed the number of parity fragments set for the tiering-enabled volume. MapR only tolerates failure of nodes equal to the number of parity fragments set for the tiering-enabled volume.
Resolution	Add more nodes to the topology or cluster.

Offload/Recall Failed

UI Column	Volume Offload/Recall Failed
Logged As	VOLUME_ALARM_OFFLOAD_RECALL_FAILURE
Meaning	The volume data could not be offloaded or could not be recalled.
Resolution	Check the log file for more information on the error. For some errors, CLDB tries to offload the data again after a brief wait. For more information, see Retrying Failed Operation on page 939.

Inodes Limit Exceeded

UI Column	Inodes Exceeded Alarm
Logged As	VOLUME_ALARM_INODES_EXCEEDED
Meaning	The volume contains too many files or the size of the namespace container size has exceeded the configured limit.
Resolution	This alarm indicates that not enough volumes are set up to handle the number of files stored in the cluster or the size of the name container exceeds the limit. Typically, each user or project should have a separate volume. To resolve the name container issue, investigate the cause for the alarm. After careful

	consideration, create one or more volumes and move data into the new volumes. See How to handle the VOLUME_ALARM_INODES_EXCEEDED alarm in MapR for more information on resolving this alarm.
Configuration	Configurable at cluster and volume level. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Large Row

UI Label	Large Row
Logged As	VOLUME_ALARM_TABLE_LARGE_ROW_WARNING
Meaning	A row in a table within the specified volume has reached 75% of the maximum supported row size of 2 GB. The alarm provides the rowkey and the name of the table. If the rowsize exceeds 2 GB, subsequent MapR Database operations on the corresponding table region will fail with an I/O error.
Resolution	Ensure that client applications that access the table are managing row data correctly, so that no row exceeds 2 GB. The method of resolving the alarm depends on the way in which client applications were managing row data. For example, if client applications allowed too many versions of cell data, delete excess versions. If client applications neglected to remove old columns or column families, remove those manually.

Mirror Failure

UI Column	Mirror Alarm
Logged As	VOLUME_ALARM_MIRROR_FAILURE
Meaning	A mirror operation failed.
Resolution	Make sure the CLDB is running on both the source cluster and the destination cluster. Look at the CLDB log (`/opt/mapr/logs/cldb.log`) and the MapR filesystem log (`/opt/mapr/logs/mfs.log`) on both clusters for more information. If the attempted mirror operation was between two clusters, make sure that both clusters are reachable over the network. Make sure the source volume is available and reachable from the cluster that is performing the mirror operation. For more troubleshooting information, see how to handle this alarm.

No Nodes in Topology

UI Column	No Nodes in Vol Topo
Logged As	VOLUME_ALARM_NO_NODES_IN_TOPOLOGY
Meaning	The path specified in the volume's topology no longer corresponds to a physical topology that contains any nodes, either due to node failures or changes to node

	topology settings. While this alarm is raised, MapR places data for the volume on nodes outside the volume's topology to prevent write failures.
Resolution	Add nodes to the specified volume topology, either by moving existing nodes or adding nodes to the cluster. See Understanding Topology on page 457.

Snapshot Failure

UI Column	Snapshot Alarm
Logged As	VOLUME_ALARM_SNAPSHOT_FAILURE
Meaning	A snapshot operation failed.
Resolution	Make sure the CLDB is running. Look at the CLDB log (`/opt/mapr/logs/cldb.log`) and the MapR filesystem log (`/opt/mapr/logs/mfs.log`) on both clusters for more information. If the attempted snapshot was a scheduled snapshot that was running in the background, try a manual snapshot. For more troubleshooting information, see how to handle thi alarm.

Topology Almost Full

UI Column	Vol Topo Almost Full
Logged As	VOLUME_ALARM_TOPOLOGY_ALMOST_FULL
Meaning	The nodes in the specified topology are running out of storage space.
Resolution	Move volumes to another topology, enlarge the specified topology by adding more nodes, or add disks to the nodes in the specified topology.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Topology Full Alarm

UI Column	Vol Topo Full
Logged As	VOLUME_ALARM_TOPOLOGY_FULL
Meaning	The nodes in the specified topology have out of storage space.
Resolution	Move volumes to another topology, enlarge the specified topology by adding more nodes, or add disks to the nodes in the specified topology.

Volume Advisory Quota Alarm

UI Column	Vol Advisory Quota Alarm
Logged As	VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED
Meaning	A volume has exceeded its advisory quota.

Resolution	No immediate action is required. To avoid exceeding the hard quota, clear space on the volume or stop further data writes.
Configuration	Configurable in volume properties. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

Volume Become Master Stuck

UI Column	VOLUME BECOME MASTER STUCK
Logged As	VOLUME_ALARM_BECOME_MASTER_STUCK
Meaning	This means that there are some containers (associated with the volume) that don't have Master role. The alarm description displays the containers on which Master role is not assigned.
Resolution	Run `dump containerinfo` on page 1616 command to determine the node on which role is not assigned and restart that node. If you see the alarm after the node is restarted, contact MapR support.

Volume with Non-Local Containers

UI Column	Local Volume containers non-local
Logged As	VOLUME_ALARM_DATA_CONTAINERS_NONLOCAL
Meaning	This is a local volume and its containers should all reside on the same node. Some containers were created on another node, which may cause performance issues in MapReduce applications.
Resolution	Recreate the local volume or review information on how to handle this alarm.

Volume Quota Alarm

UI Column	Vol Quota Alarm
Logged As	VOLUME_ALARM_QUOTA_EXCEEDED
Meaning	A volume has exceeded its quota. Further writes to the volume will fail.
Resolution	Free some space on the volume or increase the volume hard quota.
Configuration	Configurable in volume properties. See Configuring the Alarm Threshold Using the CLI on page 786 for more information.

MapR Environment

This section provides information associated with the MapR environment.

MapR Parameters

The following table lists user-configurable parameters and their default values. These default values reflect those in the default configuration files, plus any overrides shipped out-of-the-box in `core-site.xml`, `mapred-site.xml`, or other configuration files. You can override these values by editing or adding them

in `mapred-site.xml` or `core-site.xml`, using the `-D` option to the `hadoop jar` command when submitting a job, or by setting them explicitly in your code.

Parameter	Default
fs.mapr.bailout.on.library.mismatch	true
fs.mapr.bind.retries	false
fs.mapr.working.dir	
fs.maprfs.impl	
fs.ramfs.impl	
fs.s3.block.size	33554432
fs.s3.blockSize	33554432
fs.s3.buffer.dir

Default MapR Configurations

The default values for configuration parameters can come for various sources:

- marpred-default.xml
- core-default.xml
- yarn-default.xml
- MapR code
- Hadoop code

The topics in this section include the default values for each parameter and the source of the default.

Note: For each parameter, an entry in the <name>-site.xml file overrides the default.

Default core Parameters

Property	Description
dfs.bytes-per-checksum	Default value: 512 Default source: code
dfs.ha.fencing.ssh.connect-timeout	Default value: 30000 Default source: core-default.xml
dfs.namenode.checkpoint.dir	Default value:${hadoop.tmp.dir}/dfs/namesecondary Default source: code
dfs.namenode.checkpoint.edits.dir	Default value: ${fs.checkpoint.dir} Default source: code
dfs.namenode.checkpoint.period	Default value: 3600 Default source: code
file.blocksize	Default value: 67108864 Default source: core-default.xml
file.bytes-per-checksum	Default value: 512 Default source: core-default.xml
file.client-write-packet-size	Default value: 65536 Default source: core-default.xml
file.replication	Default value: 1 Default source: core-default.xml
file.stream-buffer-size	Default value: 4096 Default source: core-default.xml
fs.AbstractFileSystem.file.impl	Default value: org.apache.hadoop.fs.local.LocalFs Default source: core-default.xml

fs.AbstractFileSystem.ftp.impl	Default value: org.apache.hadoop.fs.ftp.FtpFs Default source: core-default.xml
fs.AbstractFileSystem.har.impl	Default value: org.apache.hadoop.fs.HarFs Default source: core-default.xml
fs.AbstractFileSystem.hdfs.impl	Default value: com.mapr.fs.MFS Default source: code
fs.AbstractFileSystem.maprfs.impl	Default value: com.mapr.fs.MFS Default source: code
fs.AbstractFileSystem.viewfs.impl	Default value: org.apache.hadoop.fs.viewfs.ViewFs Default source: core-default.xml
fs.automatic.close	Default value: TRUE Default source: core-default.xml
fs.checkpoint.size	Default value: 67108864 Default source: code
fs.client.resolve.remote.symlinks	Default value: TRUE Default source: core-default.xml
fs.defaultFS	Default value: maprfs:/// Default source: code
fs.df.interval	Default value: 60000 Default source: core-default.xml
fs.du.interval	Default value: 600000 Default source: core-default.xml
fs.file.impl	Default value: org.apache.hadoop.fs.LocalFileSystem Default source: code
fs.ftp.host	Default value: 0.0.0.0 Default source: core-default.xml
fs.ftp.host.port	Default value: 21 Default source: core-default.xml
fs.ftp.impl	Default value: org.apache.hadoop.fs.ftp.FTPFileSystem Default source: code
fs.har.impl	Default value: org.apache.hadoop.fs.HarFileSystem Default source: code
fs.har.impl.disable.cache	Default value: TRUE Default source: core-default.xml

fs.hdfs.impl	Default value: com.mapr.fs.MapRFileSystem Default source: code
fs.hftp.impl	Default value: org.apache.hadoop.hdfs.HftpFileSystem Default source: code
fs.hsftp.impl	Default value: org.apache.hadoop.hdfs.HsftpFileSystem Default source: code
fs.kfs.impl	Default value: org.apache.hadoop.fs.kfs.KosmosFileSystem Default source: code
fs.mapr.flush.unaligned	Default value: false Default source: code
fs.mapr.rathreads	Default value: 0 Default source: code
fs.mapr.working.dir	Default value: /user/$USERNAME/ Default source: code
fs.mapr.write.idleflush.timeout	Default value: 3 seconds Default source: code
fs.maprfs.impl	Default value: com.mapr.fs.MapRFileSystem Default source: code
fs.permissions.umask-mode	Default value: 22 Default source: core-default.xml
fs.ramfs.impl	Default value: org.apache.hadoop.fs.InMemoryFileSystem Default source: code
fs.s3.block.size	Default value: 33554432 Default source: code
fs.s3.blockSize	Default value: 33554432 Default source: code
fs.s3.buffer.dir	Default value: ${hadoop.tmp.dir}/s3 Default source: core-default.xml
fs.s3.impl	Default value: org.apache.hadoop.fs.s3native.NativeS3FileSystem Default source: code
fs.s3.maxRetries	Default value: 4 Default source: core-default.xml

fs.s3.sleepTimeSeconds	Default value: 10 Default source: core-default.xml
fs.s3a.attempts.maximum	Default value: 10 Default source: core-default.xml
fs.s3a.buffer.dir	Default value: ${hadoop.tmp.dir}/s3a Default source: core-default.xml
fs.s3a.connection.establish.timeout	Default value: 5000 Default source: core-default.xml
fs.s3a.connection.maximum	Default value: 15 Default source: core-default.xml
fs.s3a.connection.ssl.enabled	Default value: TRUE Default source: core-default.xml
fs.s3a.connection.timeout	Default value: 50000 Default source: core-default.xml
fs.s3a.fast.buffer.size	Default value: 1048576 Default source: core-default.xml
fs.s3a.fast.upload	Default value: FALSE Default source: core-default.xml
fs.s3a.impl	Default value: org.apache.hadoop.fs.s3a.S3AFileSystem Default source: core-default.xml
fs.s3a.max.total.tasks	Default value: 1000 Default source: core-default.xml
fs.s3a.multipart.purge	Default value: FALSE Default source: core-default.xml
fs.s3a.multipart.purge.age	Default value: 86400 Default source: core-default.xml
fs.s3a.multipart.size	Default value: 104857600 Default source: core-default.xml
fs.s3a.multipart.threshold	Default value: 2147483647 Default source: core-default.xml
fs.s3a.paging.maximum	Default value: 5000 Default source: core-default.xml
fs.s3a.threads.core	Default value: 15 Default source: core-default.xml
fs.s3a.threads.keepalivetime	Default value: 60 Default source: core-default.xml

last-updated: Apr 11, 2022

fs.s3a.threads.max	Default value: 256 Default source: core-default.xml

s3native.bytes-per-checksum	Default value: 512 Default source: core-default.xml
s3native.client-write-packet-size	Default value: 65536 Default source: core-default.xml
s3native.replication	Default value: 3 Default source: core-default.xml
s3native.stream-buffer-size	Default value: 4096 Default source: core-default.xml
tfile.fs.input.buffer.size	Default value: 262144 Default source: core-default.xml
tfile.fs.output.buffer.size	Default value: 262144 Default source: core-default.xml
tfile.io.chunk.size	Default value: 1048576 Default source: core-default.xml

Default YARN Parameters

Parameter	Description
mapreduce.job.hdfs-servers	Default value: ${fs.defaultFS} Default source: yarn-default.xml
yarn.acl.enable	Indicates whether ACLs are enabled. Default value: FALSE Default source: yarn-default.xml
yarn.admin.acl	ACL of who can be admin of the YARN cluster. Default value: * Default source: yarn-default.xml
yarn.am.liveness-monitor.expiry-interval-ms	The expiry interval for application master reporting. Default value: 600000 Default source: yarn-default.xml

yarn.app.mapreduce.job.update-status-max-retries	The number of job status update retries. Default value: 0 (retried only 1 time) For a value N, the update is retried 1+N times.
yarn.app.mapreduce.job.update-status-retry-interval	The interval in milliseconds for job status update retries. Default value: 2000 (2000 millisecond or 2 seconds delay is observed before each retry attempt)
yarn.client.application-client-protocol.poll-interval-ms	The interval that the yarn client library uses to poll the completion status of the asynchronous API of application client protocol. Default value: 200 Default source: yarn-default.xml
yarn.client.failover-proxy-provider	When HA is enabled, the class to be used by Clients, AMs and NMs to failover to the Active RM. It should extend org.apache.hadoop.yarn.client.RMFailoverProxyProvider. Default value: org.apache.hadoop.yarn.client.ConfiguredRMFailoverProxyProvider Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties.
yarn.client.failover-retries	When HA is enabled, the number of retries per attempt to connect to a ResourceManager. In other words, it is the ipc.client.connect.max.retries to be used during failover attempts. Default value: 0 Default source: yarn-default.xml
yarn.client.failover-retries-on-socket-timeouts	When HA is enabled, the number of retries per attempt to connect to a ResourceManager on socket timeouts. In other words, it is the ipc.client.connect.max.retries.on.timeouts to be used during failover attempts. Default value: 0 Default source: yarn-default.xml

last-updated: Apr 11, 2022

yarn.client.max-nodemanagers-proxies	Maximum number of proxy connections for node manager. It should always be more than 1. NMClient and MRAppMaster will use this to cache connection with node manager. There will be at max one connection per node manager. Ex. configuring it to a value of 5 will make sure that client will at max have 5 connections cached with 5 different node managers. These connections will be timed out if idle for more than system wide idle timeout period. The token if used for authentication then it will be used only at connection creation time. If new token is received then earlier connection should be closed in order to use newer token. This and (yarn.client.nodemanager-client-async.thread-pool-max-size) are related and should be sync (no need for them to be equal). Default value: 0 Default source: yarn-default.xml
yarn.client.nodemanager-client-async.thread-pool-max-size	Max number of threads in NMClientAsync to process container management events. Default value: 500 Default source: yarn-default.xml
yarn.client.nodemanager-connect.max-wait-ms	Default value: 900000 Default source: yarn-default.xml
yarn.client.nodemanager-connect.retry-interval-ms	Default value: 10000 Default source: yarn-default.xml
yarn.dfs-logging.dir-glob	Default value: maprfs:////var/mapr/local/*/logs/yarn/userlogs Default source: Code
yarn.dfs-logging.handler-class	Default value:com.mapr.hadoop.yarn.util.MapRFSLoggingHandler Default source: Code
yarn.external.token.manager	Default value: com.mapr.hadoop.yarn.security.MapRTicketManager Default source: Code
yarn.http.policy	Configures the HTTP endpoint for YARN Daemons.The following values are supported: -HTTP_ONLY : Service is provided only on http -HTTPS_ONLY : Service is provided only on https Default value: HTTP_ONLY Default source: yarn-default.xml
yarn.ipc.rpc.class	RPC class implementation. Default value: org.apache.hadoop.yarn.ipc.HadoopYarnProtoRPC Default source: yarn-default.xml

yarn.log-aggregation.retain-check-interval-seconds	How long to wait between aggregated log retention checks. If set to 0 or a negative value, then the value is computed as one-tenth of the aggregated log retention time. Default value: -1 Default source: yarn-default.xml See YARN Log Aggregation.
yarn.log-aggregation.retain-seconds	How long to keep aggregation logs before deleting them. -1 disables. Default value: 2592000 Default source: code See YARN Log Aggregation.
yarn.log-aggregation-enable	Whether to enable log aggregation. Default value: FALSE Default source: yarn-default.xml See YARN Log Aggregation.
yarn.mapr.ticket.expiration	Default value: 604800000 Default source: code
yarn.nm.liveness-monitor.expiry-interval-ms	How long to wait until a NodeManager is considered dead. Default value: 600000 Default source: yarn-default.xml
yarn.nodemanager.container-localizer.log.level	Configuring container localizer logs Default value: INFO Default source: code
yarn.nodemanager.address	The address of the container manager in the NM. Default value: ${yarn.nodemanager.hostname}:0 Default source: yarn-default.xml
yarn.nodemanager.admin-env	Environment variables that should be forwarded from the NodeManager's environment to the container's environment. Default value: MALLOC_ARENA_MAX=$MALLOC_ARENA_MAX Default source: yarn-default.xml
yarn.nodemanager.aux-services	The valid service name should only contain a-zA-Z0-9_ and can not start with numbers. Default value: mapreduce_shuffle,mapr_direct_shuffle Default source: code
yarn.nodemanager.aux-services.mapr_direct_shuffle.class	Default value: com.mapr.hadoop.mapred.LocalVolumeAuxService Default source: code

last-updated: Apr 11, 2022

yarn.nodemanager.aux-services.mapreduce_shuffle.class	Default value: org.apache.hadoop.mapred.ShuffleHandler Default source: yarn-default.xml
yarn.nodemanager.container-executor.class	Identifies who will execute (launch) the containers. Default value: org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor Default source: code
yarn.nodemanager.container-manager.thread-count	Number of threads the container manager uses. Default value: 20 Default source:yarn-default.xml
yarn.nodemanager.container-monitor.interval-ms	How often to monitor containers. Default value: 3000 Default source: yarn-default.xml
yarn.nodemanager.container-monitor.procfs-tree.smaps-based-rss.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.delete.debug-delay-sec	Number of seconds after an application finishes before the NodeManager's DeletionService will delete the application's localized file directory and log directory. To diagnose Yarn application problems, set this property's value large enough (for example, to 600 = 10 minutes) to permit examination of these directories. After changing the property's value, you must restart the NodeManager in order for it to have an effect. The roots of Yarn applications' work directories are configurable with the yarn.nodemanager.local-dirs property (see below), and the roots of the Yarn applications' log directories is configurable with the yarn.nodemanager.log-dirs property (see also below). Default value: 0 Default source: yarn-default.xml
yarn.nodemanager.delete.thread-count	Number of threads used in cleanup. Default value: 4 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.interval-ms	Frequency of running disk health checker code. Default value: 1200000 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.max-disk-utilization-per-disk-percentage	Default value: 90 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.min-free-space-per-disk-mb	Default value: 0 Default source: yarn-default.xml

yarn.nodemanager.disk-health-checker.min-healthy-disks	The minimum fraction of number of disks to be healthy for the nodemanager to launch new containers. This correspond to both yarn-nodemanager.local-dirs and yarn.nodemanager.log-dirs. i.e. If there are less number of healthy local-dirs (or log-dirs) available, then new containers will not be launched on this node. Default value: 0.25 Default source: yarn-default.xml
yarn.nodemanager.docker-container-executor.exec-name	Default value: /usr/bin/docker Default source: yarn-default.xml
yarn.nodemanager.env-whitelist	Environment variables that containers may override rather than use NodeManager's default. Default value: JAVA_HOME,HADOOP_COMMON_HOME,HADOOP_HDFS_HOME,HADOOP_CONF_DIR,HADOOP_YARN_HOME Default source: yarn-default.xml
yarn.nodemanager.external.token.localizer	Default value: com.mapr.hadoop.yarn.nodemanager.MapRTicketLocalizer Default source: code
yarn.nodemanager.health-checker.interval-ms	Frequency of running node health script. Default value: 600000 Default source: yarn-default.xml
yarn.nodemanager.health-checker.script.timeout-ms	Script time out period. Default value: 1200000 Default source: yarn-default.xml
yarn.nodemanager.hostname	The hostname of the NM. Default value: 0.0.0.0 Default source: yarn-default.xml
yarn.nodemanager.keytab	Keytab for NM. Default value: /etc/krb5.keytab Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.cgroups.hierarchy	The cgroups hierarchy under which to place YARN proccesses (cannot contain commas). If yarn.nodemanager.linux-container-executor.cgroups.mount is false (that is, if cgroups have been pre-configured), then this cgroups hierarchy must already exist and be writable by the NodeManager user, otherwise the NodeManager may fail. Only used when the LCE resources handler is set to the CgroupsLCEResourcesHandler. Default value: /hadoop-yarn Default source: yarn-default.xml

yarn.nodemanager.linux-container-executor.cgroups.mount	Whether the LCE should attempt to mount cgroups if not found. Only used when the LCE resources handler is set to the CgroupsLCEResourcesHandler. Default value: false Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.cgroups.strict-resource-usage	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users	Default value: TRUE Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user	Default value: nobody Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.nonsecure-mode.user-pattern	The allowed pattern for UNIX user names enforced by Linux-container-executor when used in nonsecure mode (use case for this is using cgroups). The default value is taken from /usr/sbin/adduser. Default value: ^[_.A-Za-z0-9][-@_.A-Za-z0-9]{0,255}?[$]?$ Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.resources-handler.class	The class which should help the LCE handle resources. Default value: org.apache.hadoop.yarn.server.nodemanager.util.DefaultLCEResourcesHandler Default source: yarn-default.xml
yarn.nodemanager.local-cache.max-files-per-directory	It limits the maximum number of files which will be localized in a single local directory. If the limit is reached then sub-directories will be created and new files will be localized in them. If it is set to a value less than or equal to 36 [which are sub-directories (0-9 and then a-z)] then NodeManager will fail to start. For example; [for public cache] if this is configured with a value of 40 (4 files + 36 sub-directories) and the local-dir is /tmp/local-dir1, then it will allow 4 files to be created directly inside /tmp/local-dir1/filecache. For files that are localized further, it will create a sub-directory "0" inside /tmp/local-dir1/filecache and will localize files inside it until it becomes full. If a file is removed from a sub-directory that is marked full, then that sub-directory will be used back again to localize files. Default value: 8192 Default source: yarn-default.xml
yarn.nodemanager.local-dirs	List of directories to store localized files in. An application's localized file directory will be found in: ${yarn.nodemanager.local-dirs}/usercache/${user}/appcache/application_${appid}. Individual containers' work directories, called container_${contid}, will be subdirectories of this. Default value: ${hadoop.tmp.dir}/nm-local-dir Default source: yarn-default.xml

yarn.nodemanager.localizer.address	Address where the localizer IPC is. Default value: ${yarn.nodemanager.hostname}:8040
yarn.nodemanager.localizer.cache.cleanup.interval-ms	Interval in between cache cleanups. Default value: 60000 Default source: yarn-default.xml
yarn.nodemanager.localizer.cache.target-size-mb	Target size of localizer cache in MB, per local directory. Default value: 10240 Default source: yarn-default.xml
yarn.nodemanager.localizer.client.thread-count	Number of threads to handle localization requests. Default value: 5 Default source: yarn-default.xml
yarn.nodemanager.localizer.fetch.thread-count	Number of threads to use for localization fetching. Default value: 4 Default source: yarn-default.xml
yarn.nodemanager.log.retain-seconds	Time in seconds to retain user logs. Only applicable if log aggregation is disabled. Default value: 10800 Default source: yarn-default.xml
yarn.nodemanager.log-aggregation.compression-type	T-file compression types used to compress aggregated logs. Default value: none Default source: yarn-default.xml
yarn.nodemanager.log-aggregation.roll-monitoring-interval-seconds	Default value: -1 Default source: yarn-default.xml
yarn.nodemanager.log-dirs	Where to store container logs. An application's localized log directory will be found in ${yarn.nodemanager.log-dirs}/application_${appid}. Individual containers' log directories will be below this, in directories named container_{$contid}. Each container directory will contain the files stderr, stdin, and syslog generated by that container. Default value: ${yarn.log.dir}/userlogs Default source: yarn-default.xml
yarn.nodemanager.pmem-check-enabled	Whether physical memory limits will be enforced for containers. Default value: true Default source: yarn-default.xml
yarn.nodemanager.process-kill-wait.ms	Max time to wait for a process to come up when trying to cleanup a container. Default value: 2000 Default source: yarn-default.xml

yarn.nodemanager.recovery.enabled	Default value: TRUE Default source: yarn-default.xml
yarn.nodemanager.remote-app-log-dir	Where to aggregate logs to. Default value: /tmp/logs Default source: yarn-default.xml
yarn.nodemanager.remote-app-log-dir-suffix	The remote log dir will be created at {yarn.nodemanager.remote-app-log-dir}/${user}/{thisParam} Default value: logs Default source: yarn-default.xml
yarn.nodemanager.resource.cpu-vcores	Number of CPU cores that can be allocated for containers. Default value: ${nodemanager.resource.cpu-vcores} Default source: code
yarn.nodemanager.resource.io-spindles	Default value: ${nodemanager.resource.io-spindles} Default source: code
yarn.nodemanager.resource.memory-mb	Amount of physical memory, in MB, that can be allocated for containers. Default value: ${nodemanager.resource.memory-mb} Default source: code
yarn.nodemanager.resource.percentage-physical-cpu-limit	Default value: 100 Default source: yarn-default.xml
yarn.nodemanager.resourcemanager.minimum.version	The minimum allowed version of a resourcemanager that a nodemanager will connect to. The valid values are NONE (no version checking), EqualToNM (the resourcemanager's version is equal to or greater than the NM version), or a Version String. Default value: NONE Default source: yarn-default.xml
yarn.nodemanager.sleep-delay-before-sigkill.ms	Number of ms to wait between sending a SIGTERM and SIGKILL to a container. Default value: 250 Default source: yarn-default.xml
yarn.nodemanager.vmem-check-enabled	Whether virtual memory limits will be enforced for containers. Default value: false Default source: yarn-default.xml

yarn.nodemanager.vmem-pmem-ratio	Ratio between virtual memory to physical memory when setting memory limits for containers. Container allocations are expressed in terms of physical memory, and virtual memory usage is allowed to exceed this allocation by this ratio. Default value: 2.1 Default source: yarn-default.xml
yarn.nodemanager.webapp.address	NM Webapp address. Default value: ${yarn.nodemanager.hostname}:8042 Default source: yarn-default.xml
yarn.nodemanager.windows-container.cpu-limit.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.windows-container.memory-limit.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.resourcemanager.address	The address of the applications manager interface in the ResourceManager. Default value: ${yarn.resourcemanager.hostname}:8032 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.admin.address	The address of the ResourceManager admin interface. Default value: ${yarn.resourcemanager.hostname}:8033 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.admin.client.thread-count	Number of threads used to handle the ResourceManager admin interface. Default value: 1 Default source: yarn-default.xml
yarn.resourcemanager.am.max-attempts	The maximum number of application attempts. This is a global setting for all ApplicationMasters. Each ApplicationMaster can specify its individual maximum number of application attempts via the API, but the individual number cannot be more than the global upper bound. If it is, the ResourceManager will override it. The default number is set to 2, to allow at least one retry for the ApplicationMaster. Default value: 2 Default source: yarn-default.xml

last-updated: Apr 11, 2022

yarn.resourcemanager.application-tokens.master-key-rolling-interval-secs	Interval for the roll over for the master key used to generate application tokens. Default value: 86400 Default source: yarn-default.xml
yarn.resourcemanager.aux-services	Default value: RMVolumeManager Default source: code
yarn.resourcemanager.aux-services.HSVolumeManager.class	Default value: com.mapr.hadoop.yarn.resourcemanager.RMVolumeManager Default source: code
yarn.resourcemanager.aux-services.RMVolumeManager.class	Default value: com.mapr.hadoop.yarn.resourcemanager.RMVolumeManager Default source: code
yarn.resourcemanager.client.thread-count	The number of threads used to handle applications manager requests. Default value: 50 Default source: yarn-default.xml
yarn.resourcemanager.configuration.provider-class	Default value: org.apache.hadoop.yarn.LocalConfigurationProvider Default source: yarn-default.xml
yarn.resourcemanager.connect.max-wait.ms	Maximum time to wait to establish connection to the ResourceManager. Default value: 900000 Default source: yarn-default.xml
yarn.resourcemanager.connect.retry-interval.ms	How often to retry connecting to the ResourceManager. Default value: 30000 Default source: yarn-default.xml
yarn.resourcemanager.container.liveness-monitor.interval-ms	How often to check that containers are still alive. Default value: 600000 Default source: yarn-default.xml
yarn.resourcemanager.container-tokens.master-key-rolling-interval-secs	Interval for the roll over for the master key used to generate container tokens. It is expected to be much greater than yarn.nm.liveness-monitor.expiry-interval-ms and yarn.rm.container-allocation.expiry-interval-ms. Otherwise the behavior is undefined. Default value: 86400 Default source: yarn-default.xml
yarn.resourcemanager.delayed.delegation-token.removal-interval-ms	Interval at which the delayed token removal thread runs. Default value: 30000 Default source: yarn-default.xml

yarn.resourcemanager.dir	Default value: /var/mapr/cluster/yarn/rm Default source: code
yarn.resourcemanager.fs.state-store.num-retries	Default value: 0 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.retry-interval-ms	Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.retry-policy-spec	hdfs client retry policy specification. hdfs client retry is always enabled. Specified in pairs of sleep-time and number-of-retries and (t0, n0), (t1, n1), ..., the first n0 retries sleep t0 milliseconds on average, the following n1 retries sleep t1 milliseconds on average, and so on. Default value: 2000, 500 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.uri	URI pointing to the location of the FileSystem path where RM state will be stored. This must be supplied when using org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore as the value for yarn.resourcemanager.store.class Default value: /var/mapr/cluster/yarn/rm/system Default source: code
yarn.resourcemanager.ha.automatic-failover.embedded	Enable embedded automatic failover. The embedded elector relies on the RM state store to handle fencing, and is primarily intended to be used in conjunction with ZKRMStateStore. Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.ha.automatic-failover.enabled	Enable automatic failover. Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.ha.automatic-failover.zk-base-path	The base znode path to use for storing leader information, when using ZooKeeper based leader election. Default value: /yarn-leader-election Default source: yarn-default.xml
yarn.resourcemanager.ha.custom-ha-rmaddressfinder	Default value: org.apache.hadoop.yarn.client.MapRZKBasedRMAddressFinder Default source: code

last-updated: Apr 11, 2022

yarn.resourcemanager.ha.enabled	Enable RM high-availability. When enabled, (1) The RM starts in the Standby mode by default, and transitions to the Active mode when prompted to. (2) The nodes in the RM ensemble are listed in yarn.resourcemanager.ha.rm-ids (3) The id of each RM comes from yarn.resourcemanager.ha.id (4) The actual physical addresses come from the configs of the pattern - {rpc-config}.{id} Default value: false Default source: yarn-default.xml
yarn.resourcemanager.hostname	The hostname of the ResourceManager. Default value: 0.0.0.0 Default source: yarn-default.xml
yarn.resourcemanager.keytab	The keytab for the ResourceManager. Default value: /etc/krb5.keytab Default source: yarn-default.xml
yarn.resourcemanager.leveldb-state-store.path	Default value: ${hadoop.tmp.dir}/yarn/system/rmstore Default source: yarn-default.xml
yarn.resourcemanager.max-completed-applications	The maximum number of completed applications RM keeps. Default value: 10000 Default source: yarn-default.xml
yarn.resourcemanager.nodemanager.minimum.version	The minimum allowed version of a connecting nodemanager. The valid values are NONE (no version checking), EqualToRM (the nodemanager's version is equal to or greater than the RM version), or a Version String. Default value: NONE Default source: yarn-default.xml
yarn.resourcemanager.nodemanagers.heartbeat-interval-ms	The heart-beat interval in milliseconds for every NodeManager in the cluster. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.principal	The Kerberos principal for the ResourceManager. Default value:mapr Default source: code
yarn.resourcemanager.proxy-user-privileges.enabled	Default value: FALSE Default source: yarn-default.xml

yarn.resourcemanager.recovery.enabled	Enable RM to recover state after starting. If true, then yarn.resourcemanager.store.class must be specified. Default value: false When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.resource-tracker.address	Default value: ${yarn.resourcemanager.hostname}:8031 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.resource-tracker.client.thread-count	Number of threads to handle resource tracker calls. Default value: 50 Default source: yarn-default.xml
yarn.resourcemanager.scheduler.address	The address of the scheduler interface. Default value: ${yarn.resourcemanager.hostname}:8030 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.scheduler.class	The class to use as the resource scheduler. Default value: org.apache.hadoop.yarn.server.resourcemanager.scheduler.fair.FairScheduler Default source: code
yarn.resourcemanager.scheduler.client.thread-count	Number of threads to handle scheduler interface. Default value: 50 Default source: yarn-default.xml
yarn.resourcemanager.scheduler.monitor.enable	Enable a set of periodic monitors (specified in yarn.resourcemanager.scheduler.monitor.policies) that affect the scheduler. Default value: false Default source: yarn-default.xml
yarn.resourcemanager.scheduler.monitor.policies	The list of SchedulingEditPolicy classes that interact with the scheduler. A particular module may be incompatible with the scheduler, other policies, or a configuration of either. Default value: org.apache.hadoop.yarn.server.resourcemanager.monitor.capacity.ProportionalCapacityPreemptionPolicy Default source: yarn-default.xml

last-updated: Apr 11, 2022

yarn.resourcemanager.staging	Default value: /var/mapr/cluster/yarn/rm/staging Default source: code
yarn.resourcemanager.state-store.max-completed-applications	The maximum number of completed applications RM state store keeps, less than or equals to ${yarn.resourcemanager.max-completed-applications}. By default, it equals to ${yarn.resourcemanager.max-completed-applications}. This ensures that the applications kept in the state store are consistent with the applications remembered in RM memory. Any values larger than ${yarn.resourcemanager.max-completed-applications} will be reset to ${yarn.resourcemanager.max-completed-applications}. Note that this value impacts the RM recovery performance.Typically, a smaller value indicates better performance on RM recovery. Default value: ${yarn.resourcemanager.max-completed-applications} Default source: yarn-default.xml
yarn.resourcemanager.store.class	The class to use as the persistent store. If org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore is used, the store is implicitly fenced; meaning a single ResourceManager is able to use the store at any point in time. More details on this implicit fencing, along with setting up appropriate ACLs is discussed under yarn.resourcemanager.zk-state-store.root-node.acl. Default value: org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore Default source: yarn-default.xml
yarn.resourcemanager.system	Default value: /var/mapr/cluster/yarn/rm/system Default source: code
yarn.resourcemanager.system-metrics-publisher.dispatcher.pool-size	Default value: 10 Default source: yarn-default.xml
yarn.resourcemanager.system-metrics-publisher.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.resourcemanager.webapp.address	The http address of the ResourceManager web application. Default value: ${yarn.resourcemanager.hostname}:8088 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.webapp.delegation-token-auth-filter.enabled	Default value: TRUE Default source: yarn-default.xml

yarn.resourcemanager.webapp.https.address	The https adddress of the ResourceManager web application. Default value: ${yarn.resourcemanager.hostname}:8090 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1518.
yarn.resourcemanager.work-preserving-recovery.enabled	Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.work-preserving-recovery.scheduling-wait-ms	Default value: 10000 Default source: yarn-default.xml
yarn.resourcemanager.zk-acl	ACL's to be used for ZooKeeper znodes. Default value: world:anyone:rwcda Default source: yarn-default.xml
yarn.resourcemanager.zk-num-retries	Number of times RM tries to connect to ZooKeeper. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.zk-retry-interval-ms	Retry interval in milliseconds when connecting to ZooKeeper. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.zk-state-store.parent-path	Full path of the ZooKeeper znode where RM state will be stored. This must be supplied when using org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore as the value for yarn.resourcemanager.store.class Default value: /rmstore Default source: yarn-default.xml
yarn.resourcemanager.zk-timeout-ms	ZooKeeper session timeout in milliseconds. Session expiration is managed by the ZooKeeper cluster itself, not by the client. This value is used by the cluster to determine when the client's session expires. Expirations happens when the cluster does not hear from the client within the specified session timeout period (i.e. no heartbeat). Default value: 10000 Default source: yarn-default.xml
yarn.scheduler.maximum-allocation-mb	The maximum allocation for every container request at the RM, in MBs. Memory requests higher than this won't take effect, and will get capped to this value. Default value: 8192 Default source: yarn-default.xml

last-updated: Apr 11, 2022

yarn.scheduler.maximum-allocation-vcores	The maximum allocation for every container request at the RM, in terms of virtual CPU cores. Requests higher than this won't take effect, and will get capped to this value. Default value: 4 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-mb	The minimum allocation for every container request at the RM, in MBs. Memory requests lower than this won't take effect, and the specified value will get allocated at minimum. Default value: 1024 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-vcores	The minimum allocation for every container request at the RM, in terms of virtual CPU cores. Requests lower than this won't take effect, and the specified value will get allocated the minimum. Default value: 1 Default source: yarn-default.xml
yarn.resourcemanager.zk-timeout-ms	Default value: 10000 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-mb	Default value: 1024 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-vcores	Default value: 1 Default source: yarn-default.xml
yarn.sharedcache.admin.address	Default value: 0.0.0.0:8047 Default source: yarn-default.xml
yarn.sharedcache.admin.thread-count	Default value: 1 Default source: yarn-default.xml
yarn.sharedcache.app-checker.class	Default value: org.apache.hadoop.yarn.server.sharedcachemanager.RemoteAppChecker Default source: yarn-default.xml
yarn.sharedcache.checksum.algo.impl	Default value: org.apache.hadoop.yarn.sharedcache.ChecksumSHA256Impl Default source: yarn-default.xml
yarn.sharedcache.cleaner.initial-delay-mins	Default value: 10 Default source: yarn-default.xml
yarn.sharedcache.cleaner.period-mins	Default value: 1440 Default source: yarn-default.xml
yarn.sharedcache.cleaner.resource-sleep-ms	Default value: 0 Default source: yarn-default.xml

yarn.sharedcache.client-server.address	Default value: 0.0.0.0:8045 Default source: yarn-default.xml
yarn.sharedcache.client-server.thread-count	Default value: 50 Default source: yarn-default.xml
yarn.sharedcache.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.sharedcache.nested-level	Default value: 3 Default source: yarn-default.xml
yarn.sharedcache.nm.uploader.replication.factor	Default value: 10 Default source: yarn-default.xml
yarn.sharedcache.nm.uploader.thread-count	Default value: 20 Default source: yarn-default.xml
yarn.sharedcache.root-dir	Default value: /sharedcache Default source: yarn-default.xml
yarn.sharedcache.store.class	Default value: org.apache.hadoop.yarn.server.sharedcachemanager.store.InMemorySCMStore Default source: yarn-default.xml
yarn.sharedcache.store.in-memory.check-period-mins	Default value: 720 Default source: yarn-default.xml
yarn.sharedcache.store.in-memory.initial-delay-mins	Default value: 10 Default source: yarn-default.xml
yarn.sharedcache.store.in-memory.staleness-period-mins	Default value: 10080 Default source: yarn-default.xml
yarn.sharedcache.uploader.server.address	Default value: 0.0.0.0:8046 Default source: yarn-default.xml
yarn.sharedcache.uploader.server.thread-count	Default value: 50 Default source: yarn-default.xml
yarn.sharedcache.webapp.address	Default value: 0.0.0.0:8788 Default source: yarn-default.xml
yarn.timeline-service.address	Default value: ${yarn.timeline-service.hostname}:10200 Default source: yarn-default.xml
yarn.timeline-service.client.max-retries	Default value: 30 Default source: yarn-default.xml

last-updated: Apr 11, 2022

yarn.timeline-service.client.best-effort	Default value: FALSE Default source: yarn-default.xml To enable an application to run successfully after it is retried, set this to TRUE
yarn.timeline-service.client.retry-interval-ms	Default value: 1000 Default source: yarn-default.xml
yarn.timeline-service.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.timeline-service.generic-application-history.aux-services	Default value: HSVolumeManager Default source: code
yarn.timeline-service.handler-thread-count	Default value: 10 Default source: yarn-default.xml
yarn.timeline-service.hostname	Default value: 0.0.0.0 Default source: yarn-default.xml
yarn.timeline-service.http-authentication.simple.anonymous.allowed	Default value: TRUE Default source: yarn-default.xml

Environment Variables
Describes the environment variables specific to the MapR Data Platform.

For core release 6.0 and later, environment variables should be set in `/opt/mapr/conf/env_override.sh`. Editing `/opt/mapr/conf/env.sh` is no longer recommended. For more information, see About env_override.sh on page 2290.

Variable	Example Values	Description
`CLDB_EXTERNAL_RPC_PORT`	`5000`	If clients outside the cluster cannot reach CLDB on the default port, use the `CLDB_EXTERNAL_RPC_PORT` environment variable to specify the port on which CLDB can be reached.
`JAVA_HOME`	`/usr/lib/jvm/java-7-sun`	The directory where the correct version of Java is installed.
`MAPR_HOME`	`/opt/mapr` (default)	The directory in which the core software is installed.
`MAPR_EXTERNAL`	`10.10.123.25,10.10.123.30`	If your cluster nodes have multiple NICs, use the MAPR_EXTERNAL environment variable to grant external clients access to a cluster node on specific IP addresses. The value of the MAPR_EXTERNAL environment variable on a node is a comma-separated list of up to four IP addresses with no spaces.

Variable	Example Values	Description
MAPR_SUBNETS	10.10.123.0/24,10.10.124.0/24	MAPR_SUBNETS is used for MapR RPC to RPC communication. The MFS, CLDB, NFS, and LOOPBACKNFS modules use this environment variable. The NFS and LOOPBACKNFS modules use this environment variable when registering with CLDB. If you do not want MapR to use all NICs on each node, use this environment variable to restrict MapR traffic to specific NICs. Set MAPR_SUBNETS to a comma-separated list of up to four subnets in CIDR notation with no spaces. If you do not set MAPR_SUBNETS,MapR uses all NICs present on the node. When MAPR_SUBNETS is set, make sure that the node can reach all nodes in the cluster (servers and clients) using the specified subnets.
MAPR_USER	mapr (default)	Used with configure.sh on page 2053 to specify the user under which MapR runs its services. If not explicitly set, it defaults to the user mapr. After configure.sh is run, the value is stored in daemon.conf on page 2187 .
MAPR_ECOSYSTEM_LOGIN_OPTS	*hybrid*	Specifies the JAAS configuration to use with installed open source components.

About env_override.sh
Describes the purpose of the env_override.sh file.

env_override.sh is a file that you can create to store custom settings for environment variables. By default, /opt/mapr/conf/env.sh contains environment variables for a MapR cluster, but upgrading to a new MapR release causes the env.sh file to be replaced. (A backup is stored as /opt/mapr/conf/env.sh<timestemp>). When env.sh is replaced, any custom settings are removed.

For MapR 6.0 and later, keep any custom settings in /opt/mapr/conf/env_override.sh. It is no longer necessary to modify env.sh.

Upgrading a cluster does not remove or modify env_override.sh. /opt/mapr/conf/env.sh reads the env_override.sh file at the end of its execution. If the same parameter is listed in both env.sh and env_override.sh, the value specified in env_override.sh is used. If env_override.sh is not present, the values in env.sh are used.

You create env_override.sh from a blank file and insert export statements into the file. For example:

Sample env_override.sh File

```
export CLDB_EXTERNAL_RPC_PORT=5000
export JAVA_HOME=/usr/lib/jvm/java-7-sun
export MAPR_HOME=/opt/mapr
export MAPR_EXTERNAL=10.10.123.25,10.10.123.30
export MAPR_SUBNETS=10.10.123.0/24,10.10.124.0/24
export MAPR_USER=mapr
export MAPR_ECOSYSTEM_LOGIN_OPTS=*hybrid*
```

Ports Used by MapR Software
Lists the ports used by MapR services.

Avoiding Port Conflicts

To avoid trouble with port conflicts on your MapR clusters, try these tips:

- Remap the ports for the HBaseMaster and HBaseRegionServer services to ports below 32768.
- Set the ephemeral port range to stop at 50029 by changing the value in the file /proc/sys/net/ipv4/ip_local_port_range. Note that this setting changes the available number of ephemeral ports from the default of 28233 ports to 17233.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the MapR filesystem. You need to open the relevant ports for TCP connectivity from POSIX clients to the MapR file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports, as detailed in the following section.

Services and Ports Quick Reference

The following list defines the ports used by a MapR cluster, along with the default port numbers. All the ports used by MapR software are **TCP** ports.

API Server (apiserver)	*Source IP*: Cluster nodes running apiserver *Destination IP*: Cluster nodes running apiserver *Ports*: • 5701 • 5702 *Purpose*:Clustering support *Parameter and File where Port is Configured*: Not Applicable
CLDB	*Source IP*: Nodes running any MapR services, clients interacting with the file system *Destination IP*: Cluster nodes running CLDB services *Ports*: 7222 A client reads CLDB IP and port number from the /opt/mapr/conf/mapr-clusters.conf file. The client initially tries to communicate with CLDB on port 7222. Once it establishes the connection, it fetches the additional CLDB IPs and ports from the connected CLDB. By default, CLDB listens on ports 7222 and 7223. For performance reasons, additional ports may be opened, depending on the configuration parameter cldb.num.rpc.threads in the /opt/mapr/conf/cldb.conf file. For example, setting cldb.num.rpc.threads=3, opens up ports 7222, 7223 and 7224. **Note:** The cldb.num.rpc.threads parameter is hard-coded with a default value of 3. To change this value, add this parameter with the new value to the /opt/mapr/conf/cldb.conf file. **Note:** When you upgrade from MapR Core 5.2.x or Core 6 to Core 6.1 and above, the value of cldb.num.rpc.threads is not changed. The default remains as 3, which means three ports are open for each CLDB node.

last-updated: Apr 11, 2022

	The client tries connecting to the CLDBs till timeout occurs in the case of soft mount, while the client indefinitely retries in the case of hard mount. If a client cannot connect to a CLDB port, the CLDB is marked unreachable. For example, assume a CLDB with IP 10.10.10.10 and 3 ports `7222`, `7223` and `7224`. If a client fails to connect to the CLDB say on port `7223`, the CLDB 10.10.10.10 is marked unreachable, and the client will not try the two other ports for the next few minutes. It tries to connect with the next CLDB entry in the list. For load balancing at CLDB, a client will always pick a random port among the available CLDB ports. *Purpose*: MapR File System API calls *Parameter and File where Port is Configured*: • `/opt/mapr/conf/cldb.conf` • `/opt/mapr/conf/warden.conf` • `/opt/mapr/conf/mapr-clusters.conf`
CLDB JMX Monitor Port	*Source IP*: Nodes running CLDB services *Destination IP*: CLDB JMX monitor port *Ports*: 7220 *Purpose*: The port on which `Collectd` gathers CLDB metrics through JMX. *Parameter and File where Port is Configured*: Not Applicable
CLDB web port	*Source IP*: Nodes/clients connecting to the CLDB GUI *Destination IP*: Cluster nodes running CLDB services *Ports*: 7221 *Purpose*: CLDB GUI for a cluster with security disabled. For a secure cluster, the port is `7443` as defined by the `maprlogin` utility. *Parameter and File where Port is Configured*: `/opt/mapr/conf/cldb.conf`
maprlogin utility	*Source IP*: Connections using the maprlogin utility *Destination IP*: Cluster nodes running CLDB services *Ports*: 7443 *Purpose*: When security is enabled for a cluster, the CLDB listens for connections on port 7443. If security is disabled, the `maprlogin` utility is unable to reach the CLDB. *Parameter and File where Port is Configured*: Not Applicable
Data Access Gateway	*Source IP*: Clients using the MapR Database JSON REST API with HTTPS *Destination IP*:Not Applicable *Ports*: 8243 *Purpose*: The port used to connect to the Data Access Gateway using HTTPS

	Parameter and File where Port is Configured: `rest.https.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Node.js OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Python OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Go OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: C# OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Java OJAI thin client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Drill JMX Port	*Source IP*: Nodes running the Drillbit service *Destination IP*: Drill JMX Port *Ports*: 6090

last-updated: Apr 11, 2022

	Purpose: The port on which `Collectd` gathers Drill metrics via JMX. *Parameter and File where Port is Configured*: Not Applicable
Drill Web UI	*Source IP*: Nodes running the Drillbit service *Destination IP*: Nodes running the Drillbit service *Ports*: 8047 *Purpose*: TCP port needed for the Drill Web UI and clients using REST API and nodes running the Drillbit service. *Parameter and File where Port is Configured*: `drill.exec.http.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (User Port)	*Source IP*: Nodes running the Drillbit service and clients using JDBC/ODBC *Destination IP*: Nodes running the Drillbit service *Ports*: 31010 *Purpose*: TCP user port address. Used between nodes in a Drill cluster. Needed for an external client, such as Tableau, to connect into the cluster nodes. Also needed for the Drill Web UI. You can also use this port to connect directly to a Drillbit. *Parameter and File where Port is Configured*: `drill.exec.rpc.user.server.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (Control Port)	*Source IP*: Nodes running the Drillbit service *Destination IP*: Nodes running the Drillbit service *Ports*: 31011 *Purpose*: TCP port that controls the port address. Used between nodes in a Drill cluster. Needed for multi-node installation of Drill. *Parameter and File where Port is Configured*: `drill.exec.rpc.bit.server.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (Data Port)	*Source IP*: Nodes running the Drillbit service *Destination IP*: Nodes running the Drillbit service *Ports*: 31012 *Purpose*: TCP data port address. Used between nodes in a Drill cluster. Needed for multi-node installation of Drill. *Parameter and File where Port is Configured*: `drill.exec.rpc.bit.server.port + 1` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (ZooKeeper Port)	*Source IP*: Clients using JDBC/ODBC and nodes running ZooKeeper services *Destination IP*: Nodes running the Drillbit service *Ports*: 5181 *Purpose*: ZooKeeper port used to connect to Drill through the JDBC driver.

	Parameter and File where Port is Configured: See `the ZooKeeper entry in this list.`
Elasticsearch (Components Communication Port)	*Source IP*: Non-Elasticsearch components, such a web browser, curl, and Kibana, that connect to Elasticsearch. *Destination IP*: Nodes running Elasticsearch for monitoring use cases *Ports*: 9200 *Purpose*: Non-Elasticsearch components use this port when communicating with Elasticsearch. *Parameter and File where Port is Configured*: You can configure a different port for monitoring use cases when you run the configure.sh on page 2053 script with the `-ES` parameter.
Elasticsearch (Daemons Communication Port)	*Source IP*: Nodes running Elasticsearch *Destination IP*: Nodes running Elasticsearch for monitoring use cases *Ports*: 9300 *Purpose*: Elasticsearch uses this port for communications between Elasticsearch daemons. *Parameter and File where Port is Configured*: Not Applicable
File Migration Service	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9444 *Purpose*: File Migration service UI *Parameter and File where Port is Configured*: `/opt/mapr/conf/conf.d/warden.filemigrate.conf`
Gateway	*Source IP*: Nodes sending operations to replicate *Destination IP*: Nodes running the gateway service *Ports*: 7660 *Purpose*: The port used by gateway services to listen for incoming replication operations. *Parameter and File where Port is Configured*: Not Applicable
Grafana	*Source IP*: Web Browsers *Destination IP*: Nodes running Grafana for monitoring *Ports*: 3000 *Purpose*: Web browsers use this port when connecting to Grafana. *Parameter and File where Port is Configured*: Not Applicable
HBase Master	*Source IP*: HBase Clients *Destination IP*: Nodes running HBase Master services *Ports*: 16000 *Purpose*: HBase API and HBase shell use this port to connect to HBase Master *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`

HBase Master Web UI	*Source IP*: HBase Master Web UI clients *Destination IP*: Nodes running HBase Master services *Ports*: 16010 *Purpose*: Information Web UI of HBase Master *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Thrift Server	*Source IP*: HBase Thrift Server clients *Destination IP*: Nodes running HBase Thrift Server *Ports*: 9090 *Purpose*: The HBase client uses this port to connect to HBase, using the Thrift protocol *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Thrift Web UI	*Source IP*: HBase Thrift Web UI clients *Destination IP*: Nodes running HBase Thrift *Ports*: 9095 *Purpose*: Information Web UI of HBase Thrift *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase REST Server	*Source IP*: HBase REST Server clients *Destination IP*: Nodes running HBase REST Server *Ports*: 8080 *Purpose*: The HBase client uses this port to connect to HBase using the HTTP protocol *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase REST Web UI	*Source IP*: HBase REST Web UI clients *Destination IP*: Nodes running HBase REST *Ports*: 8086 *Purpose*: Information Web UI of HBase REST *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Regionserver	*Source IP*: HBase Clients *Destination IP*: Nodes running HBase Regionserver services *Ports*: 16020 *Purpose*: HBase API and HBase shell use this port to connect to HBase RegionServer *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Regionserver UI	*Source IP*: HBase Regionserver Web UI clients *Destination IP*: Nodes running HBase Regionserver *Ports*: 16030

	Purpose: Information Web UI of HBase Regionserver *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HistoryServer RPC	*Source IP*: Not Applicable *Destination IP*: Nodes running MapReduce JobHistory Server *Ports*: 10020 *Purpose*: Not Applicable *Parameter and File where Port is Configured*: Not Applicable
HistoryServer Web UI and REST APIs	*Source IP*: Clients that access Job History Server UI in a *non-secure* cluster *Destination IP*: Secure nodes running MapReduce JobHistory Server in a non-secure cluster *Ports*: 19888 *Purpose*: Non-secure HistoryServer Web UI and REST APIs *Parameter and File where Port is Configured*: See mapred-site.xml on page 2201
HistoryServer Web UI and REST APIs	*Source IP*: Clients that access Job History Server UI in a *secure* cluster *Destination IP*: Secure nodes running MapReduce JobHistory Server in a secure cluster *Ports*: 19890 *Purpose*: Secure HistoryServer Web UI and REST APIs *Parameter and File where Port is Configured*: See mapred-site.xml on page 2201
Hive Metastore	*Source IP*: Nodes/clients performing Hive queries/ operations *Destination IP*: Nodes running the Hive metastore services *Ports*: 9083 *Purpose*: Used by Hive clients to query/access the Hive metastore *Parameter and File where Port is Configured*: `/opt/mapr/hive/hive-<version>/conf/hive-site.xml`
Hiveserver2	*Source IP*: Nodes or clients performing hive queries using JDBC/ODBC *Destination IP*: Nodes running Hiveserver2 *Ports*: 10000 *Purpose*: Port through which clients perform hive queries *Parameter and File where Port is Configured*: Not Applicable
Hiveserver2 Web UI	*Source IP*: Not Applicable *Destination IP*: Nodes running Hiverserver2 Web UI *Ports*: 10002

last-updated: Apr 11, 2022

	Purpose: Provides access to Hive configuration settings, local logs, metrics, and information about active sessions and queries. *Parameter and File where Port is Configured*: Not Applicable
Hoststats	See `hoststats.port` and `hs.port` in the Warden configuration file.
Httpfs	*Source IP*: Nodes/clients accessing httpfs services *Destination IP*: Nodes running httpfs services *Ports*: 14000 *Purpose*: Used by httpfs file clients to access the httpfs server *Parameter and File where Port is Configured*: • `/opt/mapr/httpfs/httpfs-<version>` • `/etc/hadoop/httpfs-env.sh`
Hue Webserver	*Source IP*: Nodes/clients accessing Hue web services *Destination IP*: Nodes running Hue web services *Ports*: 8888 *Purpose*: Used by Hue webserver clients to access the Hue webserver *Parameter and File where Port is Configured*: `/opt/mapr/hue/hue*/desktop/conf/hue.ini`
Impala Catalog Daemon	*Source IP*: Nodes running Impala Daemon *Destination IP*: Nodes running Impala Catalog Daemon *Ports*: 25020 *Purpose*: Catalog service web interface for monitoring and troubleshooting. Available in Impala 1.2 and higher. *Parameter and File where Port is Configured*: Not Applicable
Impala Daemon	*Source IP*: Clients using JDBC/ODBC and nodes running Impala Daemon *Destination IP*: Nodes running Impala Daemon *Ports*: 21000 *Purpose*: Used to transmit commands and receive results by `impala-shell` *Parameter and File where Port is Configured*: Not Applicable
Impala Daemon	*Source IP*: Nodes running Impala Daemon *Destination IP*: Nodes running Impala Daemon *Ports*: 21050 *Purpose*: Used by applications, such as Business Intelligence tools, to transmit commands and receive results using JDBC. *Parameter and File where Port is Configured*: Not Applicable

Impala Daemon	*Source IP*: Nodes running Impala Daemon *Destination IP*: Nodes running Impala Daemon *Ports*: 25000 *Purpose*: Impala web interface for monitoring and troubleshooting. *Parameter and File where Port is Configured*: Not Applicable
Impala StateStoreDaemon	*Source IP*: Nodes running Impala Daemon *Destination IP*: Nodes running Impala StateStore Daemon *Ports*: 25010 *Purpose*: StateStore web interface for monitoring and troubleshooting *Parameter and File where Port is Configured*: Not Applicable
KSQL	*Source IP*: All cluster nodes *Destination IP*: Nodes running KSQL *Ports*: 8084 *Purpose*: KSQL *Parameter and File where Port is Configured*: `$KSQL_INSTALL_DIR/etc/ksql/ksqlserver.properties`
Kafka Connect	*Source IP*: All cluster nodes *Destination IP*: Nodes running Kafka Connect *Ports*: 8083 *Purpose*: Kafka Connect REST API calls *Parameter and File where Port is Configured*: `/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties`
Kafka REST	*Source IP*: All cluster nodes *Destination IP*: Nodes running Kafka REST *Ports*: 8082 *Purpose*: Kafka Connect REST API calls *Parameter and File where Port is Configured*: `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties`
Kafka Schema Registry	*Source IP*: All cluster nodes *Destination IP*: Nodes running Kafka Schema Registry *Ports*: 8087 *Purpose*: Kafka Schema Registry API calls *Parameter and File where Port is Configured*: `/opt/mapr/schema-registry/schema-registry-<version>/config/schema-registry.properties`
Kibana	*Source IP*: Web browsers *Destination IP*: Nodes running Kibana for monitoring use cases *Ports*: 5601

	Purpose: Web browsers use this port when connecting to Grafana. *Parameter and File where Port is Configured*: Not Applicable
MAST Gateway	*Source IP*: Nodes running MAST Gateway service *Destination IP*: Nodes running MAST Gateway service *Ports*: 8660 *Purpose*: MapR clients use this port to connect to the MAST Gateway *Parameter and File where Port is Configured*: `/opt/mapr/conf/mastgateway.conf`
MapR File System server	*Source IP*: Nodes running any MapR services, clients interacting with the file system *Destination IP*: Nodes running FileServer services *Ports*: 5660, 5692, 5724, and 5756 *Purpose*: The filesystem is a random read-write distributed filesystem that allows applications to concurrently read and write directly to disk. Clients use these ports to access the file-system server. *Parameter and File where Port is Configured*: Not Applicable
MapR File System server	*Source IP*: Nodes running the gateway service *Destination IP*: Nodes running the MapR File System *Ports*: 6660 *Purpose*: The port on which gateway nodes send replicated operations to nodes in destination clusters. *Parameter and File where Port is Configured*: Not Applicable
MapR File System server instances	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: See Working with Multiple Instances of the File System on page 790 *Purpose*: Multiple MapR File System instances *Parameter and File where Port is Configured*: Not Applicable
Object Store	*Source IP*: Nodes accessing the MOSS server *Destination IP*: Nodes running the MOSS server *Ports*: 9000 *Purpose*: Port for the MOSS server *Parameter and File where Port is Configured*: The *moss.port* option in `/opt/mapr/conf/moss.conf`. **CAUTION:** The default port for S3 Gateway is also 9000. If you run S3 Gateway and Object Store, change one of the ports to avoid conflicts.
S3 Gateway	*Source IP*: Nodes accessing the S3 Gateway server *Destination IP*: Nodes running the S3 Gateway server *Ports*: 9000 *Purpose*: Port for the S3 Gateway server

last-updated: Apr 11, 2022

	Parameter and File where Port is Configured: The *ports* option in `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json`
NFS	*Source IP*: Nodes/clients accessing the filesystem via the NFS protocol *Destination IP*: Nodes running MapR NFS Services *Ports*: 2049 *Purpose*: NFSv3 or NFSv4 access to the MapR File System *Parameter and File where Port is Configured*: Not Applicable
NFS	*Source IP*: Nodes running NFS services *Destination IP*: Nodes running NFS services *Ports*: 9997, 9998 *Purpose*: NFS VIP Management *Parameter and File where Port is Configured*: `/opt/mapr/conf/nfsserver.conf`
NodeManager JMX Port	*Source IP*: Nodes running NodeManager *Destination IP*: NodeManager JMX Port *Ports*: 8027 *Purpose*: The port on which Collectd gathers metrics from NodeManager nodes via JMX. *Parameter and File where Port is Configured*:Not Applicable
NodeManager	*Source IP*: Nodes running NodeManager *Destination IP*: Not Applicable *Ports*: 8099 *Purpose*: The node manager manages the health of each node in the cluster. *Parameter and File where Port is Configured*:`yarn.nodemanager.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
NodeManager Localizer RPC	*Source IP*: Nodes running NodeManager *Destination IP*: Not Applicable *Ports*: 8040 *Purpose*: The port that node manager uses to localize resources for a node. With localization, remote resources are downloaded to the local filesystem for access. *Parameter and File where Port is Configured*: `yarn.nodemanager.localizer.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
NodeManager Web UI and REST APIs	*Source IP*: External Web browsers and REST clients accessing NodeManager services in a non-secure cluster *Destination IP*: Nodes running NodeManager services in a non-secure cluster *Ports*: 8042

last-updated: Apr 11, 2022

	Purpose: NodeManager HTTP port *Parameter and File where Port is Configured*: `yarn.nodemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
NodeManager Web UI and REST APIs	*Source IP*: External Web browsers and REST clients accessing NodeManager services in a secure cluster *Destination IP*: Nodes running NodeManager services in a secure cluster *Ports*: 8044 *Purpose*: NodeManager HTTPS port *Parameter and File where Port is Configured*: `yarn.nodemanager.webapp.https.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
Oozie	*Source IP*: Nodes/clients accessing Oozie services in a *non-secure* cluster *Destination IP*: Nodes running Oozie services in a non-secure cluster *Ports*: 11000 *Purpose*: Used by Oozie clients to access the Oozie server in a non-secure cluster *Parameter and File where Port is Configured*: `/opt/mapr/oozie/oozie-<version>/conf/oozie-env.sh`
Oozie	*Source IP*: Nodes/clients accessing Oozie services in a *secure* cluster *Destination IP*: Nodes running Oozie services in a secure cluster *Ports*: 11443 *Purpose*: Used by Oozie clients to access the Oozie server in a secure cluster *Parameter and File where Port is Configured*: `/opt/mapr/oozie/oozie-<version>/conf/oozie-env.sh`
OpenTSDB	*Source IP*: OpenTSDB clients, such as `Collectd`. *Destination IP*: Nodes running OpenTSDB for monitoring use cases. *Ports*: 4242 *Purpose*: `Collectd` uses this port to write metrics to OpenTSDB. *Parameter and File where Port is Configured*: You can configure a different port for monitoring use cases when you run configure.sh on page 2053 script with the `-OT` parameter.
Port Mapper	*Source IP*: Nodes running MapR NFS Services *Destination IP*: Nodes/clients accessing the filesystem using the NFS protocol *Ports*: 111 *Purpose*: RPC Portmap services used to connect to the MapR File System using NFSv3

	Parameter and File where Port is Configured: Not Applicable
ResourceManager JMX Port	*Source IP*: Nodes running ResourceManager *Destination IP*: ResourceManager JMX port *Ports*: 8025 *Purpose*: The port on which `Collectd` gathers metrics from the ResourceManager using JMX. *Parameter and File where Port is Configured*: Not Applicable
ResourceManager Admin RPC	*Source IP*: Applications that access the ResourceManager *Destination IP*: Nodes running ResourceManager *Ports*: 8033 *Purpose*: The port that applications use to access the ResourceManager RPC *Parameter and File where Port is Configured*: `yarn.resourcemanager.admin.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
ResourceManager Client RPC	*Source IP*: Clients that submit YARN applications *Destination IP*: Nodes running ResourceManager *Ports*: 8032 *Purpose*: The port that clients use to access the YARN applications *Parameter and File where Port is Configured*: `yarn.resourcemanager.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
ResourceManager Resource Tracker RPC (for NodeManagers)	*Source IP*: Applications that access the ResourceManager *Destination IP*: Nodes running ResourceManager *Ports*: 8031 *Purpose*: The port that applications use to access the Resource Manager Tracker RPC *Parameter and File where Port is Configured*: `yarn.resourcemanager.resource-tracker.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
ResourceManager Scheduler RPC (for ApplicationMasters)	*Source IP*: Applications that access the ResourceManager *Destination IP*: Nodes running ResourceManager *Ports*: 8030 *Purpose*: The port on which the applications in the cluster talk to the ResourceManager. *Parameter and File where Port is Configured*: `yarn.resourcemanager.scheduler.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
ResourceManager Web UI (HTTP)	*Source IP*: Clients that access ResourceManager UI in a *non-secure* cluster

	Destination IP: Nodes running ResourceManager master in a non-secure cluster *Ports*: 8088 *Purpose*: ResourceManager Web UI *Parameter and File where Port is Configured*: `yarn.resourcemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
ResourceManager Web UI (HTTPS)	*Source IP*: Clients that access ResourceManager UI in a *secure* cluster *Destination IP*: Nodes running ResourceManager master in a secure cluster *Ports*: 8090 *Purpose*: ResourceManager Web UI *Parameter and File where Port is Configured*: `yarn.resourcemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
Shuffle HTTP	*Source IP*: Not Applicable *Destination IP*: Shuffle HTTP *Ports*: 13562 *Purpose*: The port that MapReduce Shuffle uses. Transferring the map outputs to reducer inputs in sorted form is the shuffle operation. *Parameter and File where Port is Configured*: Not Applicable
Spark Standalone Master (RPC)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 7077 *Purpose*: The port on which to submit jobs in a Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_MASTER_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Standalone Master (Web UI)	*Source IP*: Nodes/clients accessing Spark services in a *non-secure* cluster *Destination IP*: Nodes running Spark services in a non-secure cluster *Ports*: 8580 *Purpose*: The port on which browsers connect to Spark master in a non-secure Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_MASTER_WEBUI_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Standalone Master (Web UI)	*Source IP*: Nodes/clients accessing Spark services in a *secure* cluster *Destination IP*: Nodes running Spark services in a secure cluster *Ports*: 8980 *Purpose*: The port on which browsers connect to a Spark master in a secure Spark standalone cluster.

	Parameter and File where Port is Configured: `SPARK_MASTER_WEBUI_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Standalone Worker	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 8081 *Purpose*: The port on which browsers connect to Spark workers in a Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_WORKER_WEBUI_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Thrift Server (if start and stop server using Spark scripts)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 10000 *Purpose*: The port on which JDBC clients connect to Spark Thrift server. *Parameter and File where Port is Configured*: `hive.server2.thrift.port` in `SPARK_HOME/conf/hive-site.xml`
Spark Thrift Server (if start and stop server through Warden, starting in EEP 4.0)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 2304 *Purpose*: The port on which JDBC clients connect to Spark Thrift server. *Parameter and File where Port is Configured*: `hive.server2.thrift.port` in `SPARK_HOME/conf/hive-site.xml`
Spark History Server	*Source IP*: Clients that access Spark Job History in a *non-secure* cluster *Destination IP*: Nodes running Spark History Server in a non-secure cluster *Ports*: 18080 *Purpose*: The port on which browsers connect to a non-secure Spark history server. *Parameter and File where Port is Configured*: `spark.history.ui.port` in `SPARK_HOME/conf/spark-default.conf"`
Spark History Server	*Source IP*: Clients that access Spark Job History in a *secure* cluster *Destination IP*: Nodes running Spark History Server in a secure cluster *Ports*: 18480 *Purpose*: The port on which browsers connect to a secure Spark history server. *Parameter and File where Port is Configured*: `spark.ssl.historyServer.port` in `SPARK_HOME/conf/spark-defaults.conf (starting from Spark-2.2.1)`
Spark External Shuffle Service	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 7337

	Purpose: The port on which Spark jobs connect to External Shuffle server. *Parameter and File where Port is Configured*: `spark.shuffle.service.port` in `SPARK_HOME/conf/spark-default.conf`
Sqoop2 Server	*Source IP*: Nodes/clients accessing Sqoop2 services *Destination IP*: Nodes running Sqoop2 services *Ports*: 12000 *Purpose*: Used by Sqoop2 clients to access the Sqoop2 server *Parameter and File where Port is Configured*: Not Applicable
Tez Shuffle	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 13563 *Purpose*: Port to communicate with the Tez Shuffler. A Tez specific shuffle handler allows data to be shuffled in a way that takes advantage of the new features in Tez *Parameter and File where Port is Configured*: Not Applicable
Timeline Server	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 10200 *Purpose*: Hadoop IPC port used for internal communication in Hadoop *Parameter and File where Port is Configured*: Not Applicable
Timeline Server Web Interface (HTTP)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 8188 *Purpose*: Non-secure web access for the Timeline Server. The Timeline Server allows storage and retrieval of an application's current and historic information in a generic fashion. *Parameter and File where Port is Configured*: Not Applicable
Timeline Server Web Interface (HTTPS)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 8190 *Purpose*: Secure web access for the Timeline Server *Parameter and File where Port is Configured*: Not Applicable
Tomcat Port (Hive-on-Tez UI)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9383 *Purpose*: The non-secure port to access the Tez UI. Hive-on-Tez speeds up execution of Hive queries. *Parameter and File where Port is Configured*: Not Applicable

Tomcat SSL Port (Hive-on-Tez UI)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9393 *Purpose*: The secure port to access the Tez UI. *Parameter and File where Port is Configured*: Not Applicable
Web UI	*Source IP*: External web browser accessing either a *non-secure* or a *secure* cluster *Destination IP*: Nodes running the Control System Web UI in a non-secure or a secure cluster *Ports*: 8443 *Purpose*: Control System Web UI *Parameter and File where Port is Configured*: `/opt/mapr/apiserver/conf/properties.cfg`
Zeppelin	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9995 *Purpose*: The port to connect to the Zeppelin Docker container *Parameter and File where Port is Configured*: Configurable by setting `ZEPPELIN_SSL_PORT` when running the Zeppelin Docker image
ZooKeeper	*Source IP*: Nodes running ZooKeeper services, clients executing ZooKeeper API calls *Destination IP*: Nodes running ZooKeeper services *Ports*: 5181 *Purpose*: ZooKeeper API calls *Parameter and File where Port is Configured*: • `/opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg` • `/opt/mapr/conf/warden.conf, /opt/mapr/conf/cldb.conf` • `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` • `/opt/mapr/hive/hive-<version>/conf/hive-site.xml`
ZooKeeper follower-to-leader Communication	*Source IP*: Nodes running ZooKeeper services *Destination IP*: Nodes running ZooKeeper services *Ports*: 2888 *Purpose*: ZooKeeper Server > Server Communication *Parameter and File where Port is Configured*: `/opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg`
ZooKeeper Leader Election	*Source IP*: Nodes running ZooKeeper services *Destination IP*: Nodes running ZooKeeper services *Ports*: 3888 *Purpose*: ZooKeeper Server > Server Communication

last-updated: Apr 11, 2022

Parameter and File where Port is Configured: `/opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg`

Log Files

Lists the log files for each MapR component.

The table below provides information on the log files for the components.

Component	Type of Log	Log File	Configuration File	Rotation	Maximum File Size	# of Backups	Expiration Period
CLDB	Main	/opt/mapr/logs/cldb.log	/opt/mapr/conf/log4j.cldb.properties	By Size	100MB	9	-
	Disk Balancer	/opt/mapr/logs/cldbdiskbalancer.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Role Balancer	/opt/mapr/logs/cldbrolebalancer.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Time Skew	/opt/mapr/logs/timeskew.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	MapR filesystem Summary	/opt/mapr/logs/cldbfssummary.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Audit	/opt/mapr/logs/cldbaudit.log.json	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	-
	Guts	/opt/mapr/logs/cldbguts.log	/opt/mapr/conf/log4j.properties	-	-	-	10 days
	Proxy	/opt/mapr/logs/cldbproxy.log	/opt/mapr/conf/log4j.properties	-	-	-	10 days

Component	Type of Log	Log File	Configuration File	Rotation	Maximum File Size	# of Backups	Expiration Period
WebServer	Main	/opt/mapr/apiserver/logs/apiserver.log	/opt/mapr/apiserver/conf/properties.cfg	Every Startup	-	10	10 days
			/opt/mapr/conf/log4j.mcs.properties	Daily	-	-

Increasing Log Retention

To increase log retention for specific component, you can modify the configuration file and reset the value of the properties.

Increasing Log Retention for MapR File System

In the `/opt/mapr/conf/mfs.conf` file, increase the value for the `mfs.max.logfile.size.in.mb` property. The value for this property is computed using the following formula:

```
maxSizePerLogFile = maxLogSize / MAX_NUM_OF_LOG_FILES
```

Here:

- `maxLogSize` specifies the total amount of space that MapR File System log files can consume.
- `MAX_NUM_OF_LOG_FILES` specifies the total number of MapR File System log files (5 hard coded).

For example, for a value of 10 GB, there will be 5 log files (`mfs.log-3` to `mfs.log-3.4`) of 2GB each.

Increasing Log Retention for CLDB

In the `/opt/mapr/conf/log4j.cldb.properties` file, modify the value for the following properties:

- `log4j.appender.R.MaxFileSize` — specifies the size of each `cldb.log` before rolling over
- `log4j.appender.R.MaxBackupIndex` — specifies the number of `cldb.log*` before the oldest one is deleted.

For example, suppose the following configuration:

- `log4j.appender.R.MaxFileSize` = 1024MB
- `log4j.appender.R.MaxBackupIndex` = 10

The CLDB log files will grow to 10GB before they are purged.

Note: This setting does not impact audit logging.

Increasing Log Retention for Hadoop Services

You can increase log retention for ResourceManager, NodeManager, HistoryServer, and TimelineServer by modifying the following properties in the `/opt/mapr/hadoop/hadoop-<Version>/etc/hadoop/log4j.properties` file:

- `hadoop.log.maxfilesize` — specifies the size of each `<service-name>-hostname>.log` before rolling over.
- `hadoop.log.maxbackupindex` — specifies the number of `<service-name>-<hostname>.log*` before the oldest one is deleted.

For example, suppose the following configuration:

- `hadoop.log.maxfilesize` = 1024Mb
- `hadoop.log.maxbackupindex` = 10

There will be 10 GB of total service-specific logs (1GB per file) before the oldest file is purged.

Setting the Tracing Level

last-updated: Apr 11, 2022

To check all the modules and their current logging levels, run the following command:

```
maprcli trace info
```

To set the tracing level for a module, run the `maprcli trace setlevel` command. For example:

```
maprcli trace setlevel -module FuseMonitor -level DEBUG
```

Configuring Profiling for Operations

To check the amount of time it took to complete each operation (from the time of submission), enable profiling for client RPC and MapR File System operations. To enable profiling for:

- Client RPC, run the following command:

  ```
  fcdebug -s <shmid> -m ClntProfileRpc -1 DEBUG
  ```

  Tip: For more information, see `fcdebug`.

  Enabling profiling for the client RPC will allow you to determine, for each RPC, the amount of time it took to receive a response after submitting the request.

- MapR File System operations, run the following command:

  ```
  maprcli trace setlevel -module FSProfile -level debug
  ```

  Tip: For more information, see `maprcli`.

  Enabling profiling for MapR File System operations will allow you to determine the amount of time it took MapR File System to process each operation.

By default, profiling is disabled for both client RPC and MapR File System operations. Once enabled, the log for:

- Client RPC should look similar to the following:

  ```
  2016-06-16 10:58:04,6404 DEBUG ClntProfileRpc
  fs/client/fileclient/cc/client.cc:3483 Thread: 32188 Profile: CltRpcDone:

  server 10.10.100.196:5692 took 1 msec error 0 FID 2125.16.2  PathWalkPlus
  path
  abc
  ```

- MapR File System should look similar to the following:

```
2016-06-19 15:51:05,0231 DEBUG FSProfile unlink.cc:2456 OP unlink:
localTm 34
elapsedTm 34 client 10.10.100.196 err 0 PFID: 1.32.131398 name

2016-06-19 15:51:08,1184 DEBUG FSProfile readdir.cc:505 OP ReadDir:
elapsedTm
28 client 10.10.100.196 err 0 FID: 2121.16.2 Isplus true
```

For example, to check the time it took for a read RPC, run the following command:

```
# cat /opt/mapr/logs/ffs.log* | grep -nrui "CltRpcDone" | grep -nrui "read"
| less
1009:1014:2016-06-16 11:21:51,8203 DEBUG ClntProfileRpc

2182.32.131232
off 7143424 len 131072 name 2125.34.262486
```

Archiving CLDB Logs

The CLDB logs can be archived by setting the value for the configuration parameter, `cldb.logarchiver.enabled`, using the maprcli config save command. The value can be:

- 0 — disable
- 1 — enable

To:

- Enable archiving, run the following command:

```
maprcli config save -values '{"cldb.logarchiver.enabled":"1"}'
```

- Disable archiving, run the following command:

```
maprcli config save -values '{"cldb.logarchiver.enabled":"0"}'
```

The default value for this parameter is 2, which indicates that the CLDB log archiving is disabled; but on clusters with 50 or more MapR File System nodes, the CLDB log archiving will be automatically enabled unless the value is explicitly set to 0.

If/when archiving is enabled:

- All static CLDB log files, except the active `cldb.log` file, are periodically scanned and archived in `/var/mapr/cldblog/<hostname>` directory.

- The filename for the archived log file is autogenerated based on the date and timestamp on the first log line in the file chosen for archival.

  For example, suppose a log file with the following first line:

  ```
  2017-04-06 12:42:16,020 INFO CLDB [main]: Loading properties file : /opt/
  mapr/conf/cldb.conf
  ```

  The archived log filename in `/var/mapr/cldblog/<hostname>` directory will be:
  `2017-04-06_12.42.16.020`

Enabling Runtime Logging

To enable logging at runtime for the file client (`libfsalmapr.so` library), run the `fcdebug` utility:

```
/opt/mapr/server/tools/fcdebug -s <shmid> -m <module> [-l <level>]
/opt/mapr/server/tools/fcdebug -i -s <shmid>
```

Before running this command, make a note of the following:

- If necessary, run `maprcli trace info` to retrieve the list of modules.

  The default value for module is all.

- Level should be one of FATAL, ERROR, WARN, INFO, DEBUG.

  If level is not specified, default level is applied for the module.

- The `-i` lists the current debug level of all modules.

- The `shmid` is available in the `fsal.log-*` files when `libMapRClient` is loaded.

  For example, the first line in the log file is something similar to the following:

  ```
  2017-02-13 11:56:32,6809 ERROR FuseAPI fs/client/fileclient/cc/
  fuse_api.cc:1371
  Thread: 428 Shmid to be used by fcdebug 512720897
  ```

  This `shmid` can be used with `fcdebug`.

Note: Run `fcdebug` once for every library (every library has a separate shared memory). The `shmids` can be found in the respective `fsal` log files.

Viewing Audit Logs

The following sections describe audit logs for execution of any maprcli command, REST API call, or action in Control System, and audit logs for cluster administration, filesystem, table, and stream operations.

Viewing Log Entries for Audited maprcli Command Executions
Describes where audit records of operations performed using the CLI are stored and how to view them.

The execution of any `maprcli` command on the cluster is logged in the local filesystem on the node on which the execution happened. The log file is `/opt/mapr/mapr-cli-audit-log/audit.log.json`. Auditing of CLI operations is always enabled, whether or not auditing is enabled for cluster-level operations with the `maprcli audit cluster` command.

Typical log entries provide a timestamp of the execution, the UID of the user who ran the command, the IP address from which the user ran the command, the command itself, and the status of the execution. Status codes are 0 for success and 1 for failure. The error messages field provides the reasons for failures.

Below are some typical log entries:

```
{"timestamp":
{"$date":"2015-06-15T11:45:56.434Z"},"uid":2147483632,"ipAddress":
"10.10.20.12","command":"volume info","arguments":
{"name":"mapr.opt"},"status":
1,"errors": ["Volume lookup of mapr.opt failed, No such volume"]}
{"timestamp":
{"$date":"2015-06-15T11:49:34.434Z"},"uid":2147483632,"ipAddress":
"10.10.20.12","command":"alarm add","arguments":{"baseService":"1","alarm":
"NODE_ALARM_SERVICE_GATEWAY_DOWN","service":"gateway","displayName":"Gateway
ServiceDown",
"serviceName":"GatewayService","terse":"nagwsd"},"status":1,"errors":
["Terse name of
nagwsd already exists in the system.","Alarm
NODE_ALARM_SERVICE_GATEWAY_DOWN already
exists in the system."]}
{"timestamp":
{"$date":"2015-06-15T11:49:52.598Z"},"uid":2147483632,"ipAddress":
"10.10.20.12","command":"volume create","arguments":
{"name":"mapr.hbase","path":"/hbase",
"replicationtype":"low_latency"},"status":1,"errors":["Volume Name
mapr.hbase, Already In Use"]}
```

Viewing Audit Logs for Cluster Administration
Describes where audit records of cluster administration operations are stored and how to view them.

Entries for audit logs are initially held in memory until 128 operations have been logged or 10 seconds have elapsed, whichever happens first. At that point, the new log entries are flushed to disk.

Audit logs are in JSON format, so they can be queried by Drill or processed by other third-party tools or your own scripts.

Audit logs are readable only by the `mapr` and `root` users on the cluster where the logs are located. These users can also copy and delete audit logs.

The `status` field in every log entry shows the status of the attempted operation. The status codes are taken from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

Audit logs use Coordinated Universal Time (UTC) in the records of audited operations.

The cleanup of old audit log files is handled by Warden either when they are older than 10 days (the default retention time) or when they are older than the number of days set for the `log.retention.time` parameter in the `/opt/mapr/conf/warden.conf` file. To prevent Warden from removing the log files, by default, `cldbaudit*` and `authaudit*` are listed under the `log.retention.exceptions` parameter in the `warden.conf` file.

To enable Warden to automatically cleanup log files, remove `cldbaudit*` and `authaudit*` from the `log.retention.exceptions` parameter in the `warden.conf` file and, if you want a shorter cleanup time, set the value for `log.retention.time` parameter in the `warden.conf` file. The value for `log.retention.time` must be specified in milliseconds.

To disable all exceptions, comment out the `log.retention.exceptions` parameter, that is, `#log.retention.exceptions`. When this parameter is null, that is, `log.retention.exceptions=`, no files are picked for log cleanup.

Viewing Audit Logs for File System, Table, and Stream Operations
Describes where MapR File System, MapR Database, and MapR Event Store For Apache Kafka audit logs are stored and how to view them.

Operations on data-fabric file, database, and event data are captured and recorded in the audit logs. The operations take place within volumes and have effects at the level of the file system.

These audit logs are stored in a system volume created specifically to store them. This volume is created automatically during cluster installations and upgrades. Operations are logged on the nodes on which the operations are executed, which could differ from the nodes where operations are initiated. Logs are stored in the file system at `/var/mapr/local/<node_name>/audit/`. By default, only root and the cluster administrator (typically `mapr`) can read the log files. To allow other users to read the logs, set ACEs on the directory granting `readfile` (`rf`), `readdir` (`rd`), and `lookupdir` (`ld`) permissions to the users. For example:

```
~# hadoop mfs -setace -R -aces "rf:u:root|u:mapr|u:m7user1,rd:u:root|u:mapr|
u:m7user1,ld:u:root|u:mapr|u:m7user1" /var/mapr/local/sample.qa.lab/audit/
```

Note: For more information, see Enabling Volume, Directory, and File Authorizations with ACEs on page 1452.

Audit logs for operations on directories and files

Operations on directories and files, as well as the deletion of MapR Database tables, are logged in files that have this naming convention: `FSAudit.log.json-dd-mm-yyyy-<001-999>`

To see what information is recorded in typical log entries, see Example Log Entries for Audited File System Operations.

Audit logs for operations on MapR Database tables and MapR streams

All operations on MapR Database tables and streams are logged in files that have this naming convention: `DBAudit.log.json-dd-mm-yyy-<001-999>`

Operations that result from maprcli commands, REST calls, or activity in MCS are also logged in `/opt/mapr/mapr-cli-audit-log/audit.log.json` in the local file system on the nodes where the operations are processed.

To see what information is recorded in typical log entries, see Example Log Entries for Audited Operations on MapR Database Tables.

Note: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Common Features of Audit Logs for File System, Table, and Stream Operations

Entries for audit logs are initially held in memory until 128 operations have been logged or 10 seconds have elapsed, whichever happens first. At that point, the new log entries are flushed to disk, depending on the *coalesce* interval.

The coalesce interval represents the interval of time during which READ, WRITE, or GETATTR operations on one file from one client IP address and UID/GID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly. To change the coalesce interval, see volume audit on page 1922.

Audit logs are in JSON format, so they can be queried by Drill or processed by other third-party tools or your own scripts.

Audit logs are readable only by the `mapr` and `root` users on the cluster where the logs are located. These users can also copy and delete audit logs.

The status field in every log entry shows the status of the attempted operation. The status codes are taken from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

Audit logs use Coordinated Universal Time (UTC) in the records of audited operations.

When operations are performed on directories, files, or tables that are being audited, the full names for those objects, as well as the current volume and the name of the user performing the operation, are not immediately available to the auditing feature. What are immediately available are IDs for those objects and users. Converting IDs to names at run-time would be costly for performance. Therefore, audit logs contain file identifiers (FIDs) for directories, files, and tables; volume identifiers for volume; and user identifiers (UIDs) for users.

You can resolve identifiers into names by using the expandaudit utility. This utility creates a copy of the log files for a specified volume, and in that copy are the names of the file system objects, users, and volumes that are in the audit log records. You can then query or process the copy.

A sample of the logs is as follows:

```
{"timestamp":
{"$date":"2021-07-14T13:05:01.506Z"},"resource":"test-audit-logs","operation
":"volumeMirrorPermCheck","username":"root","uid":0,"clientip":"10.163.167.2
14","status":0}
{"timestamp":
{"$date":"2021-07-14T08:44:01.553Z"},"resource":"255","operation":"volumeLoo
kup","username":"root","uid":0,"clientip":"10.163.167.214","status":2}
```

Note: There will be an entry in the audit log for each IP address on a node. For example, suppose there is a node with multiple IP addresses. The audit log on this node may show multiple entries of the same operation, each associated with a different IP address.

Note: The number of bytes read or written is not recorded.

Example Log Entries for Audited File System Operations

When auditing of file system operations is enabled at the cluster level, volume level, and file system level, each operation on a directory or file is logged on the node on which the operation was initiated.

Typical log entries provide a timestamp of the operation, the type of operation, the UID of the user who ran the command, the IP address from which the user ran the command, identifiers of the affected resources, the volume identifier, and the status of the operation. Status codes come from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

Note: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Below are some typical log entries:

```
{"timestamp":
{"$date":"2015-06-06T10:44:22.800Z"},"operation":"MKDIR","uid":0,"ipAddress"
:
```

last-updated: Apr 11, 2022

```

```

Example Log Entries for Audited Operations on MapR Database Binary and JSON Tables

When auditing of table operations is enabled at the cluster level, volume level, and file system level, each operation on a table is logged on the node where the operation was executed, which could differ from the node where the operation was initiated.

Typical log entries provide a timestamp of the operation, the type of operation, the UID of the user who ran the command, the IP address from which the user ran the command, identifiers of the affected resources,

and the status of the operation. Fields such as “ColumnFamily” and “Column” for some operations are also included when applicable. Row keys are not included. Status codes come from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

Note: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Note: Audit logs do not display the indices of array elements when there are put or update operations on arrays that are in documents within JSON tables.

Below are some typical log entries:

```
{"timestamp":
{"$date":"2015-06-06T11:31:02.621Z"},"operation":"DB_GET","uid":0,"ipAddress
":
"10.10.105.51","volumeId":48210891,"tableFid":"2751.77.131402","status":0}
{"timestamp":

ycsbTable0","status":0}
```

Managing Audit Logs for File System and Table Operations

There are three parameters that you can use to manage audit logs for file system and table operations:

- `-maxSize`
- `-retention`
- `-coalesce`

You can set the first two parameters with the maprcli audit data command. You can set the third parameter with the maprcli volume audit command.

last-updated: Apr 11, 2022

Effects of the -maxSize parameter

When you enable auditing with the audit data on page 1553`maprcli audit data` command, you can use the `-maxSize` parameter to specify the size at which an alarm is raised concerning the size of the audit volume. The alarm is displayed on the dashboard in the Control System and in the output of the alarm list on page 1545`maprcli alarm list` command. This alarm simply means that the threshold size has been reached. Audited operations are still logged to the audit volume in question.

There are three actions that you can take:

- If you decide that you want to be notified when the audit volume reaches a smaller or larger size, you can change the threshold by running the `maprcli audit data` command and changing the value of the `-maxSize` parameter.
- If you want to try preventing audit log files from growing as quickly as they are, you can change the number of identical operations that are logged within a number of minutes. Run the `maprcli audit data` command and increase the value of the `-coalesce` parameter. This parameter is described subsequently.
- If you are concerned about longer-term space requirements for storing audit log files, you can change the number of days to keep old log files before they are deleted. Run the `maprcli audit data` command and decrease the value of the `-retention` parameter. This parameter is also described below.

Effects of the -retention parameter

When you enable auditing with the `maprcli audit data` command, you can use the `-retention` parameter to specify how many days to keep old log files.

Audit logs are rotated every night at midnight UTC time . The saved audit logs are kept until the retention period expires.

For example, suppose the retention period is 30 days. The node 192.168.10.15 in the volume `/myVolume` contains 30 days of saved log files for file-system operations and the current date is March 30, 2016. The directory `/var/mapr/local/102.168.10.15/audit/` contains these log files:

```
FSAudit.log.json-30-03-2016-001
FSAudit.log.json-29-03-2016-001
FSAudit.log.json-28-03-2016-001
...
FSAudit.log.json-01-03-2016-001
```

Note: If MFS is restarted on the same day, audit logs gets rotated, and new files with convention -002, -003, and so on are created with each restart.

If there is no more disk space for new entries in audit logs, audit logging stops.

If the size of the audit log volume exceeds its quota, an alarm is raised, though logging continues. The alarm is `VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED`. You can view alarms in the Control System or by running the command `maprcli alarm list`. The default quota is 32 GB.

Effects of the -coalesce parameter

The coalesce on page 6594parameter represents the interval of time during which READ, WRITE, or GETATTR operations on one file from one client IP address and UID/GID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at

least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly.

Status Codes That Can Appear in Audit Logs

In the `status` field in entries in audit logs, numeric codes other than 0 for success can appear. For the list of possible codes, their keyword equivalents, and descriptions, refer to the standard Linux `errno-base.h` and `errno.h` files. The `authaudit.log.json` file contains HTTP status codes. See HTTP Status Codes for more information.

Viewing Application Logs

You can use logs to view the status and analyze the execution of applications in a cluster.

To view the status or to access logs for running applications, you can use the user interface associated with the YARN framework.

- For MapReduce version 2 or non-MapReduce applications, access the ResourceManager user interface from the Control System to view the status and logs for a particular application.

For completed applications, the distributed nature of YARN frameworks can make analyzing the execution of applications difficult because tasks and containers are scattered throughout the cluster. Without centralized or aggregated logging, you must manually access all the log files for a completed application by merging the log details for a particular application across multiple nodes in the cluster. With centralized or aggregated logging, you can can access all the logs for a completed application in a centralized location. However, the steps to access logs for completed applications differ based on the configured logging option.

Logging Options

In a data-fabric cluster, the logging option that you configure defines how the logs are stored and accessed.

- **Centralized logging.** The logs are written to local volumes on the file system.
- **YARN log aggregation.** The logs are written to the local file system and then the container logs from each node are aggregated and stored on the file system.
- **Local logging.** The log files for each job or application are written to the local file system. This is the default behavior for MapReduce version 2 (MRv2) applications and non-MapReduce applications.
  - For MRv2 or other applications that run on YARN, the logs are written to the following directory on the local file system: `/opt/mapr/hadoop/hadoop-2.x.x/logs/userlogs/`

The logging options that you can choose from are determined by the type of jobs or applications that you run:

Type of Job or Application	Available Logging Options
MRv2	• Centralized logging • YARN log aggregation • Local logging (default)

Type of Job or Application	Available Logging Options
YARN applications (non-MapReduce)	• YARN log aggregation • Local logging (default)

If you enable centralized logging for MRv2, the MapReduce applications will use centralized logging, while the other YARN applications in the cluster will use local logging.

Note: Select a logging option that stores the logs on the file system for the following reasons:

- Prevent job or application failures due to a lack of space on the local file system for logs.
- Prevent the loss or inaccessibility of logs due to node failure. Logs stored in a local volume are two-way replicated.

YARN Log Aggregation

The YARN Log Aggregation option aggregates and moves log files for completed applications from the local filesystem to the MapR File System. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

By default, YARN container logs are not aggregated on the MapR File System. Instead, the logs are retained for 3 hours on the local filesystem before they are deleted. To enable YARN log aggregation or to edit the configuration of YARN log aggregation, you must edit the yarn-site.xml file in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`

Enabling YARN Log Aggregation

To enable YARN log aggregation, add or edit the following properties in `yarn-site.xml`:

- Set the value of the `yarn.log-aggregation-enable` to `true`.
- Configure the `yarn.log.server.url` property to contain the URL of the YARN HistoryServer, which should look like the following:

secure cluster	`https://<historyserver-host>:19890/jobhistory/logs`
non-secure cluster	`http://<historyserver-host>:19888/jobhistory/logs`

- Optional: Set the value of `yarn.nodemanager.remote-app-log-dir` to a location in the MapR filesystem. By default, the location is `maprfs:///tmp/logs`.
- Optional: Set the value of `yarn.nodemanager.remote-app-log-dir-suffix` to the name of the folder that should contain the logs for each user. By default, the folder name is `logs`.

On a non-secure cluster, you also need to add the following property to `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/yarn-env.sh` on the Node Manager nodes:

```
export MAPR_IMPERSONATION_ENABLED=1
```

Then restart the Node Manager services. This setting enables impersonation for Node Manager processes so that log files can be created with the correct user ownership.

Aggregated logs are owned by the user who runs the job. For example, when user admin runs a job, the logs are stored to `maprfs:///tmp/logs/admin`. If user analyst runs a job, the logs are stored to `maprfs:///tmp/logs/analyst`. If these two users do not share the same UNIX group, they will not be able to see each other's logs.

last-updated: Apr 11, 2022

Note: If centralized logging and YARN log aggregation are enabled, the logs for MapReduce version 2 applications will be managed by Centralized Logging while the logs for non-MapReduce applications will be managed by YARN log aggregation.

Enabling YARN Local-Node Log Aggregation

The steps in this procedure configure log aggregation for NodeManager processes, enabling you to store the logs on nodes (node-local volumes) where the YARN containers are launched.

To enable YARN local-node log aggregation, add or edit the following properties in the `yarn-site.xml` file:

1. Set the value of `yarn.node-local-log-aggregation.enable` to `true`.

   Note: The default setting for YARN Log Aggregation (`yarn.log-aggregation-enable`) should be removed or set to `false` in the `yarn-site.xml` file.

2. Optional: Set the value of `yarn.node-local-log-aggregation.metadata-path` to a location in the system. By default the location is `maprfs:///NM_REMOTE_APP_LOG_DIR/<user>/logsMeta`. `NM_REMOTE_APP_LOG_DIR` should match the `yarn.nodemanager.remote-app-log-dir` property.

   Note: The location should not be an absolute path (the location begins from `/`). In the MapR File System (`maprfs`), the default setting for NM_REMOTE_APP_LOG_DIR is `/tmp/logs`.

3. Optional: Set the value of `node-local-log-aggregation.metadata-filename` to the name of the metafile that should contain the information about containers for each node. By default, the file name is `containers.seq`, so if you use the default paths, the file will be stored at `/tmp/logs/${user}/logsMeta/<appId>/<nodeName>/containers.seq`.

4. Restart the NodeManager and HistoryServer services.

Aggregated logs are owned by the user who runs the job.

Different users cannot see each other's logs. For example, when the data-fabric user **`admin`** runs a job, the logs are stored in `maprfs:///var/mapr/local/<nodeNames>/mapred/nodeManager/logs/admin/<appId>`. If a user **`analyst`** runs a job, the logs are stored in `maprfs:///var/mapr/local/<nodeNames>/mapred/nodeManager/logs/analyst/<appId>`.

Viewing Logs for Completed Applications

With YARN log aggregation, you can use yarn commands or the HistoryServer UI to access logs for completed applications.

View Application Logs from the Command Line

Get the application ID and then view log files for the application.

Get the Application ID

To get the application ID for an application that is in a "running" state, you can run the following command:

```
yarn application -list
```

However, if you run `yarn application -list` after a job completes, the command will not return any information.

last-updated: Apr 11, 2022

To get the application ID for an application in any state (submitted, accepted, or running), run the following command:

```
yarn application -list -appStates ALL
```

The `yarn appication -list` command returns information similar to the following, including the application ID:

```
20/10/19 14:57:51 INFO
client.MapRZKBasedRMFailoverProxyProvi
der: Updated RM address to
node1.cluster.com/192.168.33.11:8032
Total number of applications
(application-types: [] and states:
[SUBMITTED, ACCEPTED, RUNNING]):1
Application-Id Application-Name
Application-Type User Queue State
Final-State Progress Tracking-URL
application_1603118361219_0002
QuasiMonteCarlo MAPREDUCE mapr
root.mapr ACCEPTED UNDEFINED 0% N/A
```

View Application Logs

Run the following command to view log files for an application:

```
yarn logs -applicationId
<application-ID>

//Example: yarn logs -applicationId
application_1603118361219_0002
```

Using UI to View Logs for Completed Applications

Explains how to view HistoryServer logs using the graphical interface.

You can view the logs for completed applications through the Control System and by directly accessing the HistoryServer UI.

Using the Control System to View the HistoryServer Logs for Completed Applications

1. Log on to the Control System and click **Services** to display the list of services.

   Note: The **Services** menu is not available on the Kubernetes version of the Control System.

2. Click the **History Server** link in the list of services to display the **JobHistory** page in a new tab.
3. Click the job ID link for the job you want to view the logs for.
4. Click the logs link in the **Logs** column of the **Application Master** section.

Using the HistoryServer UI to View Logs for Completed Applications

1. Open a browser and go to the following URL to open the JobHistory page:

Non-secure cluster

```
http://<IP address of HistoryServer
node>:19888
```

last-updated: Apr 11, 2022

Secure cluster	`https://<IP address of HistoryServer node>:19890`

2. Click the job ID link for the job for which you want to view the logs.
3. Click the logs link in the **Logs** column of the **Application Master** section.

Editing the Retention Settings of Aggregated Logs

By default, aggregate logs are stored on the MapRMapR Data Platform filesystem for 30 days. The retention time for aggregated logs also applies to centralized logs.

To edit the retention settings, add or edit the following properties in the *yarn-site.xml* file:

1. Set the value of `yarn.log-aggregation.retain-seconds` to set the duration that the logs are maintained. If you set a negative value for `yarn.log-aggregation.retain-seconds`, logs will not be deleted.

   Note: The duration specified by `yarn.log-aggregation.retain-seconds` starts from the time that the application starts running. Therefore, when you configure the duration, consider how long you want the log to remain in addition to the amount of time that the application will take to run. For example, if you expect most applications to take 20 seconds to run, do not set the value of this property to 20 seconds because the log might be deleted as soon as the applications completes.

2. Optionally, set the `yarn.log-aggregation.retain-check-interval-seconds` to specify how often the log retention check should be run. By default, it is one-tenth of the log retention time.

For more details about the properties that impact the YARN container logs and the aggregation option, see yarn-site.xml.

Centralized Logging

Describes the centralized logging feature of MapR.

MapR's Centralized Logging feature provides a job-centric or application-centric view of all log files generated by a MapReduce program. With centralized logging, the log files are written to local volumes in the MapR filesystem. You can run the `maprcli job linklogs` command for running or completed jobs to create a centralized log directory populated with symbolic links to all log files pertaining to the specified jobs or to the application.

Managing Centralized Logs for MapReduce Version 2 Applications

To manage centralized logs for MapReduce Version 2 applications, enable centralized logging, configure log retention, and view application logs.

Enabling Centralized Logging for MapReduce Version 2

Describes how to enable central logging for MapReduce version 2 applications.

As of MapR version 4.0.2, you can use centralized logging for MapReduce version 2 applications. However, this feature is disabled by default. In MapR version 4.0.1, centralized logging is not supported for MapReduce version 2 applications.

- Configure the `yarn.use-central-logging-for-mapreduce-only` property in the `yarn-site.xml` file to enable or disable centralized logging.

  The `yarn-site.xml` file is located in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`.

last-updated: Apr 11, 2022

- To disable centralized logging, remove the property `yarn.use-central-logging-for-mapreduce-only` from the `yarn-site.xml` file, or set the value of `yarn.use-central-logging-for-mapreduce-only` to `false` in the `yarn-site.xml` file.
- To enable centralized logging, set the value of `yarn.use-central-logging-for-mapreduce-only` to `true` in the `yarn-site.xml` file. If you enable centralized logging while applications are running, restart all ResourceManagers. In a production cluster, restart ResoureManagers one at a time to prevent interruption to the running applications. The applications running during this process may not have centralized logging enabled.

Configuring Log Retention Time for MapReduce Version 2 Applications

Lists the parameter that controls the log retention time for MapReduce applications.

- Set the value of `yarn.log-aggregation.retain-seconds` to the number of seconds you want to retain the logs once the application starts in the `yarn-site.xml` file.

  The value defaults to 30 days. The value that you set for this property also applies to the retention of aggregated YARN logs.

  The `yarn-site.xml` file is in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

Viewing Logs for Completed MapReduce Version 2 Applications

With centralized logging, you can use maprcli or the HistoryServer user interface to access completed logs.

Using the Command Line to View Logs for Completed Applications

Describes how to view logs from the CLI.

1. Use the `maprcli job linklogs` command to create centralized logs for completed applications. For example, you can run the following `maprcli job linklogs` command to create centralized logs for `application_1434605941718_0001:`

   ```
   maprcli job linklogs -jobid application_1434605941718_0001 -todir /logsdir
   ```

   The centralized log directory contains symbolic links that are organized by hostname and containerID.

2. To determine where the logs are located, run the following command on the directory that contains the symlinks to the log files for a specific container:

   ```
   hadoop mfs -ls <todir>/<applicationID>/hosts/<hostName>/<containerID>
   ```

   For example, if you specified `logsdir` as the directory, you might issue a command similar to the following example. The system then displays the location of the log files:

   ```
   hadoop mfs -ls /logsdir/application_1434605941718_0001/hosts/
   qa-node178.qa.lab/container_e02_1434605941718_0001_01_000003

   Found 1 items
   lrwxrwxrwx U U U 3 root root 138 2015-06-18 05:50 0
   /logsdir/application_1434605941718_0001/hosts/qa-node178.qa.lab/
   container_e02_1434605941718_0001_01_000003
   ->
   ../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/userlogs/
   application_1434605941718_0001/container_e02_1434605941718_0001_01_000003
   p 2068.40.262432 qa-node178.qa.lab:5660 qa-node175.qa.lab:5660
   ```

   The link location appears after the arrow.

last-updated: Apr 11, 2022

3. To determine the types of log files that are available for this container and the path to each available log file, run the following command:

   ```
   hadoop fs -ls <link location>
   ```

   For example:

   ```
   hadoop fs -ls ../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/
   userlogs/application_1434605941718_0001/
   container_e02_1434605941718_0001_01_000003

   -rw-r-----   2 root root       2337 2015-06-18 05:48
   ../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/userlogs/
   application_1434605941718_0001/
   container_e02_1434605941718_0001_01_000003/syslog
   ```

   In this example, the path to the syslog is the only one that is displayed in the output. However, the stdout or stderr may also be available depending on what is generated by the application.

4. Run one of the following options to view the contents of a log file:
   a) To view the end of the log file, run `hadoop fs -tail <path to log file>`.

      ```
      hadoop fs -tail ../../../../var/mapr/local/
      qa-node178.qa.lab/logs/yarn/userlogs/application_1434605941718_0001/
      container_e02_1434605941718_0001_01_000003/syslog
      ```

   b) To view the entire log file, run `hadoop fs- cat <path to log file>`.

      ```
      hadoop fs- cat ../../../../var/mapr/local/
      qa-node178.qa.lab/logs/yarn/userlogs/application_1434605941718_0001/
      container_e02_1434605941718_0001_01_000003/syslog
      ```

Using the HistoryServer UI to View Logs for Completed Applications

Describes how to view logs using the HistoryServer interface.

You can view the logs in the HistoryServer interface.

View Logs in the HistoryServer Interface Launched Using the Control System

1. Log on to the Control System and click **Services** to display the list of services installed on the cluster.
2. Click the HistoryServer link in the list of services to open the **Job History** page in a new tab.
3. Click the Job ID link for the job for which you want to view the logs.
4. Click the logs link in the **Logs** column of the **Application Master** section.

View Logs Using the HistoryServer Interface

1. Go the URL similar to the following example, to open the Job History page:

   ```
   <IP address of HistoryServer node>:19888
   ```

2. Click the Job ID link for the job for which you want to view the logs.
3. Click the logs link in the **Logs** column of the **Application Master** section.

last-updated: Apr 11, 2022

Viewing the Service Log

Esplains how to view service logs using Kibana.

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

1. Log in to the Control System and do one of the following:
   - Click **Services** to display the list of services installed on the cluster.
   - Go to the **Summary** tab in the service information page for the service.
2. Click  in the **Log Viewer** column to view the log for the associated service in the Kibana UI.
   See Kibana User Guide for more information.

Cluster Maintenance Schedule

Lists a sample maintenance schedule for the cluster.

A maintenance schedule shows which tasks a cluster administrator should perform daily, weekly, monthly, and quarterly, along with the initial setup tasks. This sample schedule is offered as a template that you can customize to suit your needs.

Initial Setup	Daily	Weekly	Monthly	Quarterly
Perform hardware checks	Check alarms	Check logs (cluster and job logs)	Clean up logs	Audit storage use
Check Prerequisites	Onboard new users	Check for zombie jobs	Reevaluate node and volume topology	Perform security audit
Verify Installation	Offboard users	Perform simple performance test	Check performance (jobs, I/O)	Upgrade MapR core, Hive, HCatalog
High Availability planning	Check cluster health	Verify snapshots	Verify mirrors	
Set up VIPs for NFS	Perform hardware maintenance (disks)	Remove old snapshots	Clean up data	
Benchmark and tuning		Failbacks to restore service layout	MapR File System balancing	
Set up node and volume topologies				
Capacity planning			Upgrade ecosystem components (other than Hive and HCatalog, which are done quarterly)	
Set up user permissions (ACLs, directory permissions, users, home directories)				
Set up quotas				
Set up compression				
Configure cluster queues for MapReduce jobs				

Initial Setup	Daily	Weekly	Monthly	Quarterly
Set up schedules (fair scheduler, capacity scheduler, job placement)				
Set up snapshots and mirrors				
Configure NICs				
Set up monitoring tools				
Set up security				
Create a disaster recovery plan				

Language Support for MapR Database Tables

This section lists the human languages that MapR Database tables can store, retrieve, and process.

MapR Database tables can store, retrieve, and process data in the following languages:

A

Abaza Abkhazian Achinese Acoli Adangme Adyghe Afar Afrikaans Aghem Ainu Akan Akkadian Akoose Albanian Aleut Amharic Amo Ancient Egyptian Ancient Greek Angika Arabic Aragonese Aramaic Arapaho Arawak Armenian Aromanian Assamese Assyrian Neo-Aramaic Asturian Asu Atikamekw Atsam Avaric Avestan Awadhi Aymara Azerbaijani

Metering Data Descriptions

This table lists the metrics collected by the metering feature.

Table

JSON Field Name	Description
clusterId	Randomly generated ID created when the cluster is installed
collectionDate	Epoch timestamp for the latest metric collection
mapRCoreBuildVersion	MapR core software build version
signature	Digital signature of the metering JSON file
version	Version of the metering program used to capture this JSON result

Table (Continued)

JSON Field Name	Description
isSecure	Identifies whether the cluster is secure or not Options: `true` or `false`.
numberOfNodes	Number of nodes in the cluster
clusterDiskCapacityInGB	Total data in the cluster at that time
clusterDiskCapacityUsedInGB	Total data consumed in the cluster at that time
totalAmountOfDataOffloadedToColdTiersInGB	Data offloaded to the cloud, using Object Tiering You can display this metric using the `maprcli dashboard info` command.
cpuCoreInSeconds	CPU core hours consumed by all MapR Services across all nodes Also, CPU core-hours used by all Apache ecosystem components, as well as MapR File System, CLDB, API servers, REST gateways, replication gateways, and so on.
clients	Number of active instances at that moment
numberOfactiveUniquePlatinumPosixClients	Number of monthly active unique Platinum POSIX clients You can display this metric using the `maprcli node list -clientsonly` command.
numberOfactiveUniqueDSROrPACCInstances	Number of monthly active unique DSR instances, using Gold POSIX clients

Troubleshooting Cluster Administration

Lists the common errors and their solutions.

The following list identifies how to address several cluster administration issues:

The URL reported by YARN for tracking job details does not load.

This URL uses the output of the `hostname -f` command, which must be the fully qualified domain name (FQDN) for the node. On Ubuntu, make sure that the */etc/hostname* file is configured with the node's FQDN. On CentOS/Redhat, make sure that the */etc/sysconfig/network* file is configured with the node's FQDN, then restart the node.

The ResourceManager does not start.

If the ResourceManager does not come up, check the following:

- Check that you supplied the correct ResourceManager hostname or IP address in the `-RM` parameter when running configure.sh on each node at installation time. If you are not sure, you can re-run configure.sh to correct the problem.
- Do not specify a ResourceManager port with the hostname or IP address in the `-RM` parameter; there is no `<port>` option.

last-updated: Apr 11, 2022

- Make sure that you specified the same ResourceManager hostname or IP address on all nodes when running configure.sh.
- For more information about what might be causing a problem, check the ResourceManager logs:*/opt/mapr/hadoop/hadoop-<version>/logs*

The NodeManager does not start.

If the NodeManager does not come up, check the following:

- Make sure that the fileserver role is installed on the node by looking in the */opt/mapr/roles* directory.
- Make sure that the fileserver service is running, using either the service list command or the MapR Control System.
- For more information about what might be causing a problem, check the NodeManager logs:*/opt/mapr/hadoop/hadoop-2.3.0/logs*

Job history is not available.

If job history is not recorded, check the following:

- Make sure that the HistoryServer role is installed on the desired node by looking in the */opt/mapr/roles* directory. Note that only one node in the cluster can have the HistoryServer role.
- Make sure the HistoryServer is running on the desired node, using either the service list command or the MapR Control System.
- Check that you supplied the correct HistoryServer hostname or IP address in the `-HS` parameter when running configure.sh on each node at installation time. If you are not sure, you can re-run configure.sh to correct the problem.

Submitted applications do not show up in the ResourceManager.

If you submit an application and it does not appear in the ResourceManager, check the following:

- Make sure the application is running in YARN and not as a local application (check for *app_local* or *job_local* in the application output).
- Check the class path on which the application was invoked, and make sure that */opt/mapr/hadoop/hadoop-<version>/etc/hadoop* includes the class paths.
- Make sure that you are running the correct version of Hadoop. Example:

```
ls -l /usr/bin/hadooplrwxrwxrwx 1
root root 40
   Mar
4 11:38 /usr/bin/hadoop -> /opt/
mapr/hadoop/hadoop-2.3.0/bin/hadoop
```

The application throws a ClassNotFound exception at job submission time.

If you submit an application and it throws the ClassNotFound exception, check the following:

last-updated: Apr 11, 2022

- Check that the application jar is correctly packaged with the required class.
- Make sure that you are running the correct version of Hadoop. Example:

```
ls -l /usr/bin/hadooplrwxrwxrwx 1
root root 40
   Mar
4 11:38 /usr/bin/hadoop -> /opt/
mapr/hadoop/hadoop-2.3.0/bin/hadoop
```

I want to move the HistoryServer and ResourceManager to different nodes.

If you have installed the HistoryServer and the ResourceManager on the same node (when you initially ran configure.sh you did not specify the `-HS` parameter, or you specified the same IP address or hostname for both the `-RM` and `-HS` parameters), you can use configure.sh to move one or both services to different nodes. Make sure to specify both the `-HS` parameter and the `-RM` parameter, because if you only specify the `-RM` parameter the HistoryServer will move to the ResourceManager node.

Timing issue prevents services from starting on a secure cluster.

If your cluster has security features enabled, you may encounter a timing issue that results in services failing to start during initial configuration with the `-F` option. (This issue does not arise if you are bringing up a cluster that has already been installed and configured.)

When you run the configure.sh script with the `-F` option, the ZooKeeper and Warden services start up on the primary node first, then as other nodes are installed, services are automatically started on those nodes. However, because of this timing issue, Warden may fail to communicate with ZooKeeper, and the cluster may fail to come up.

If you encounter this problem, do not use the `-F` option. Instead, stop all ZooKeeper and Warden services on all nodes, then start the ZooKeeper services on all of the ZooKeeper nodes (that is, the nodes where the ZooKeeper packages are installed). Finally, start the Warden services on all nodes.

How to find a node's serverid.

Some `maprcli` commands take an argument `serverid`, which is an unique identifier for each node in a cluster. This id is also sometimes referred to as the *node id*.

To find the `serverid`, use the maprcli node list command, which lists information about all nodes in a cluster. The `id` field is the value to use for `serverid`.

For example:

```
maprcli node list -columns hostname,id
   id                   hostname
ip
   4800813424089433352  node-28.lab
10.10.20.28
   6881304915421260685  node-29.lab
10.10.20.29
   4760082258256890484  node-31.lab
```

```
10.10.20.31
   8350853798092330580  node-32.lab
10.10.20.32
   2618757635770228881  node-33.lab
10.10.20.33
```

You can also get this listing as a JSON object by using the `-json` option. For example:

```
maprcli node list -columns
id,hostname -json
   {
        "timestamp":1358537735777,
        "status":"OK",
        "total":5,
        "data":[
                {

"id":"4800813424089433352",

"ip":"10.10.20.28",

"hostname":"node-28.lab"
                },
                {

"id":"6881304915421260685",

"ip":"10.10.20.29",

"hostname":"node-29.lab"
                },
                {

"id":"4760082258256890484",

"ip":"10.10.20.31",

"hostname":"node-31.lab"
                },
                {

"id":"8350853798092330580",

"ip":"10.10.20.32",

"hostname":"node-32.lab"
                },
                {

"id":"2618757635770228881",

"ip":"10.10.20.33",

"hostname":"node-33.lab"
                }
        ]
   }
```

Error 'mv Failed to rename maprfs...' when moving files across volumes.

Prior to version 2.1, you cannot move files across volume boundaries in the MapR Platform. You can

move files within a volume using the `hadoop fs -mv` command, but attempting to move files to a different volume results in an error of the form "`mv: Failed to rename maprfs://<source path> to <destination path>`".

As a workaround, you can copy the file(s) from source volume to destination volume, and then remove the source files.

The example below shows the failure occurring. In this example directories `/a` and `/b` are mount-points for two distinct volumes.

```
hadoop fs -ls /
   Found 2 items
   drwxrwxrwx   - root root
0 2011-12-02 15:14 /a
   drwxrwxrwx   - root root
0 2011-12-02 15:09 /b

hadoop fs -put testfile /a
hadoop fs -ls /a
   Found 1 items
   -rwxrwxrwx   3 root root
2048000 2011-12-02 15:18 /a/testfile

root@node1:~# hadoop fs -mv /a/
testfile /b
   mv: Failed to rename maprfs://
10.10.80.71:7222/a/testfile to /b
```

The following example shows the work-around, moving a file `/a/testfile` to directory `/b`, and then removing the source file.

```
hadoop fs -cp /a/testfile /b/testfile
hadoop fs -ls /b
   Found 1 items
   -rwxrwxrwx   3 root root
2048000 2011-12-02 15:19 /b/testfile

hadoop fs -rmr /a/testfile
   Deleted maprfs://
10.10.80.71:7222/a/testfile

hadoop fs -ls /a
```

This workaround is only necessary if `/a` and `/b` correspond to different volumes.

'ERROR com.mapr.baseutils.cldbutils.CLDBRpcCommonUtils' in cldb.log, caused by mixed-case cluster name in mapr-clusters.conf.

MapR cluster names are case sensitive. However, some versions of MapR v1.2.x have a bug in which the cluster names specified in `/opt/mapr/conf/mapr-clusters.conf` are not treated as case sensitive. If you have a cluster with a mixed-case name, after upgrading from v1.2 to v2.0+, you may experience CLDB errors (in particular for mirror volumes) which generate messages like the following in `cldb.log`:

```
2012-07-31 04:43:50,716 ERROR
com.mapr.baseutils.cldbutils.CLDBRpcCo
```

```
mmonUtils
[VolumeMirrorThread]: Unable to reach
cluster with name: qacluster1.2.9. No
entry found in file /conf/
mapr-clusters.conf for cluster
qacluster1.2.9.
Failing the CLDB RPC with status 133
```

(The path given in this message is relative to `/opt/mapr/`, which might be misleading.)

As a work-around after upgrading, to continue working with mirror volumes created in v1.2, duplicate any lines with upper-case letters in `mapr-clusters.conf`, converting all letters to lower case.

Mirror volumes created in v2.0+ do not exhibit this behavior.

MapR Control System does not display on Internet Explorer.

The MapR Control System supports Internet Explorer version 9 and above. In IE9, **Compatibility View** under the **Tools** menu must be turned off, or else the user interface will not display correctly.

Unable to kill a job using the Metrics UI.

The following error displays when the root user tries to kill a job using the Metrics UI: `Failed to get Job information for job_x, Error: mapr is not allowed to impersonate root`

To resolve this issue, add the following properties to core-site.xml in directory `/opt/mapr/hadoop/hadoop-0.20.2/etc/` :

```
<property>
<name>hadoop.proxyuser.mapr.groups</
name>
<value>*</value>
<description>Allow the superuser mapr
to impersonate any member of any
group</description>
</property>

<property>
<name>hadoop.proxyuser.mapr.hosts</
name>
<value>*</value>
<description>The superuser can
connect from any host to impersonate a
user</description>
</property>
```

YARN logs are deleted before the application completes.

The duration that YARN container logs are maintained starts from the time that the application starts running.

When YARN container logs are not aggregated, the YARN container logs are retained for 3 hours on each node. To update the duration, edit the value of `yarn.nodemanager.log.retain-seconds` in the yarn-site.xml file.

When YARN container log aggregation is enabled, by default, the aggregated logs are not deleted. However, this setting can be overridden in yarn-site.xml

	file. To update the duration, edit the value of `log-aggregation.retain-seconds` in the yarn-site.xml file. You must consider how long you want the log to remain past the amount of time that the application will take to run. For example, if you expect most applications to take 20 seconds to run, do not set the value of this property to 20 seconds because the log may be deleted before the applications competes.
YARN applications fail because /tmp subdirectories have been deleted.	Some RHEL and CentOS platforms include the `tmpwatch` service by default. This service cleans up the `/tmp` directory on a regular basis. However, this operation causes the deletion of directories that are needed for applications to run (for example, `nm-local-dir` for YARN). The running NodeManager process does not re-create these missing directories, causing applications to fail.
Jobs fail when the timeline server is down	The timeline server for the Hive-on-Tez user interface does not support high availability. Jobs fail when the resource manager cannot connect to the timeline server. However, you can change the `yarn.timeline-service.client.best-effort` property to TRUE in the yarn-site.xml file to allow applications to run successfully even when the timeline server is down.

Best Practices for Backing Up MapR Information

Lists the best practices and performance considerations to follow when backing up MapR information.

To back up configuration information and data from your MapR cluster, you must install the appropriate Linux backup client from your backup software provider on your servers in your MapR cluster. Your backup client user must have the proper filesystem, and volume permissions. For details on how to configure MapR volume permissions see Creating Volume-level ACLs on page 1447 and Managing Access Controls on page 1445.

Backup Configuration Data

By default, all installation files on the cluster, for each server in the cluster, are stored in a single directory on each server in the MapR cluster. To ensure that you backup all the configuration files, MapR supported applications, as well as log files, back up the `/opt/mapr` directory for all servers in the cluster.

Note that the `/opt/mapr` location includes all log files. Log files can add a significant amount of data to your backup environment, so evaluate if they are needed for your business continuity requirements. To backup just the configuration files for the cluster, backup the `/opt/mapr/conf` directory from all servers in the cluster.

Backup Volume Data

MapR's recommended way to backup and restore data, is to enable and configure snapshots and volume mirroring for your data, to another MapR cluster. This step ensures that your business continuity and disaster recovery needs are met.

See the following links for setting up Snapshots, Mirroring, Table and Streams replications.

- Snapshots: Managing Snapshots on page 947
- Mirrors: Mirror Volumes on page 459

last-updated: Apr 11, 2022

- MapR-DB Table Replication: Managing Table Replication on page 1065
- MapR-ES Streams Replication: Stream Replication on page 656

If you do not have a secondary cluster to mirror your data, back up your volumes by specifying the following path in your Linux backup agent: `/mapr/cluster_name/` - For example: `/mapr/my.cluster.com/`.

Performance Considerations When Backing Large Data Sets

You could run into bandwidth and performance limitations when you specify only one path to your MapR cluster, where your data in your volumes is stored on only one Linux host agent. The bottleneck can occur due to the size of that data you are backing up (large file sizes), or due to the number of files you have in your directory structure (millions of files in one directory).

To mitigate performance issues, break up the volumes across multiple Linux backup agents, with specific mount paths. For example:

```
MapR Linux Host 1 (hostname1):
          /mapr/my.cluster.com/volume1
          /mapr/my.cluster.com/volume2
          /mapr/my.cluster.com/volume3
```

```
MapR Linux Host 2 (hostname2):
          /mapr/my.cluster.com/volume4
          /mapr/my.cluster.com/volume5
          /mapr/my.cluster.com/volume6
```

```
MapR Linux Host 3 (hostname3):
          /mapr/my.cluster.com/volume7
          /mapr/my.cluster.com/volume8
          /mapr/my.cluster.com/volume9
```

Preserve Metadata About the Volumes

To preserve metadata such as permissions and *ACE* rules, run a pre-script process as the `mapr` user, in your backup agent. For example in your pre-script configuration for your host agent for your cluster, you would run:

```
maprcli volume dump create
        -name volume1 -dumpfile volume1_fulldump1 -e statefile1
```

Some backup software may need "stderr" or "stdout" codes to run pre or post processing scripts within their product. In that case, you may need to write a bash script to dump the file to a location of your choice, and ensure that your backup agent is configured to backup that directory. Consult your backup software provider's documentation. For information on creating volume dumps, see Create and Maintain Volume Dump File on page 1961.

6.1 Development

This section contains information related to application development for Ezmeral ecosystem components and MapR Data Platform products, including Filesystem, Database (Key-Value and JSON), and Event Streams.

Application Development Process

Before you start developing applications on the MapR Data Platform platform, consider how you will get the data into the platform, the storage format of the data, the type of processing or modeling that is required, and how the data will be accessed.

At a high-level, building an application comes down to the following steps:

1. Step 1: Select a Data Storage Format on page 2359
2. Step 2: Write Data to MapR Data Platform on page 2362
3. Step 3: Explore Ways to Work With the Data on page 2362
4. Step 4: Set Up the Development Environment on page 2365
5. Step 5: Build the Application on page 2374

Step 1: Select a Data Storage Format

Consider the data format options and determine how you want to use to store your data.

Keep in mind that a single application can access data from a variety of data formats. The following data formats are available.

MapR XD Distributed File and Object Store

MapR XD Distributed File and Object Store is a random read-write distributed filesystem that allows applications to concurrently read and write directly to files. This data store is great for storing and scanning large data sets of historical data, and for sharing files between various services and applications. Any node with access to the filesystem can access files on it.

Consider the following examples:

- Write large amounts of user click-stream data for a web site in a simple directory structure based on the date, and then process that data using tools like Spark, Drill, Hive or another MapReduce application.
- Store various types of images, audio files, and video files in one shared directory so that web or mobile applications can render the content as required.
- Share configuration files or internationalized resources among various applications by storing these files in a shared directory.
- Simplify the deployment of new applications by adding java libraries (.jar files) to a shared directory and then including the directory in the classpath of one or more applications.

last-updated: Apr 11, 2022

- Store the Docker files and images in a shared location which can be accessed by various servers. This provides a single, shared location from which users can launch containers.

When you store large data sets, use a file format in which the data can be consumed efficiently. For example, Parquet, ORC, sequence files are good for storing and scanning. Parquet is great for storing data on the filesystem because it stores data in columnar format, which can be partitioned. Parquet also works well for use cases where you query the data with Drill or process the data with Spark applications. Note that you can use CSV or JSON formats, but they scanning these formats is less efficient.

For more information about the MapR File System, see File System on page 452.

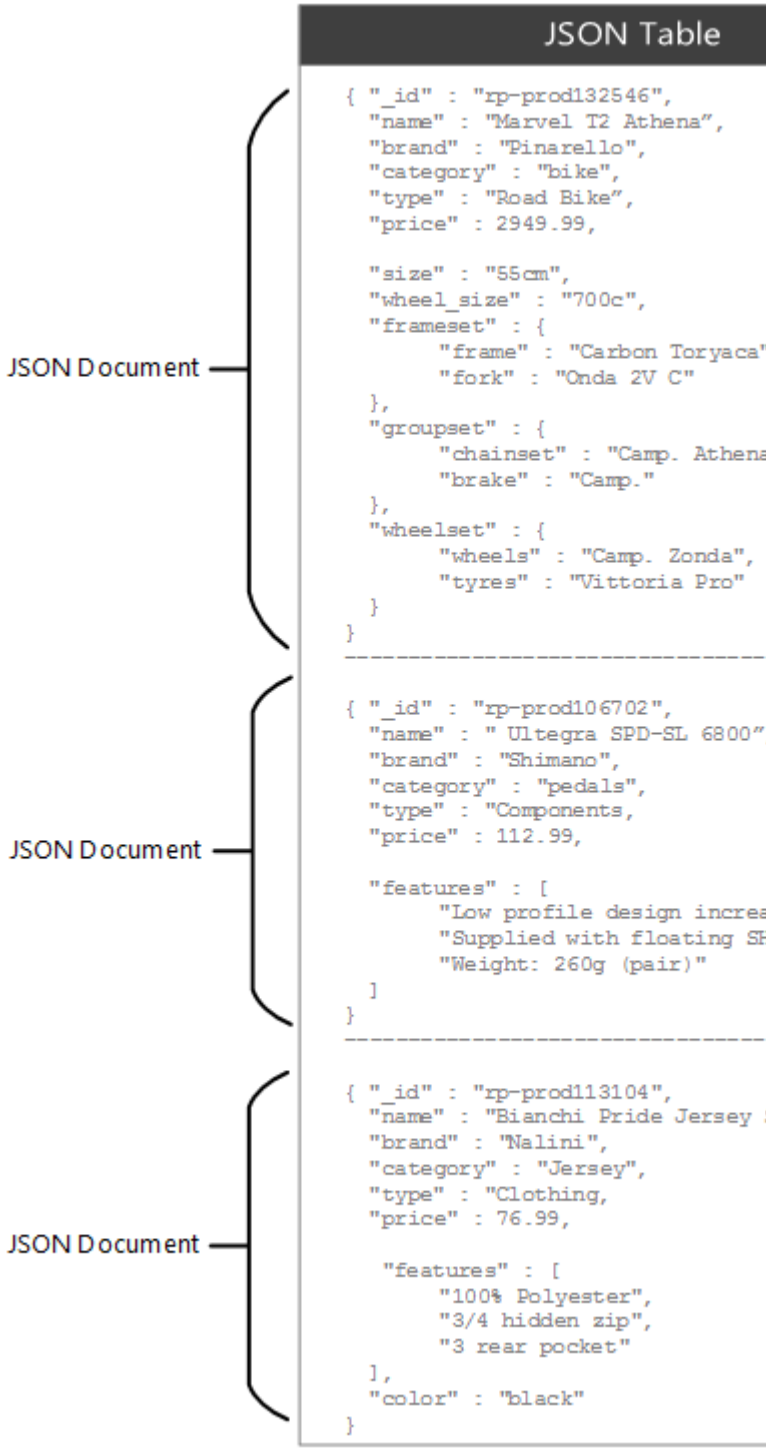
MapR Database

MapR Database is an enterprise-grade, high performance, NoSQL database management system that supports both binary and JSON tables. Consider using MapR Database tables when you want to query and organize large amounts data. It also integrates with Drill, Apache Spark, Hive and other MapReduce tools to provide applications the ability to scan or query large data sets in an efficient, distributed way.

MapR Database provides the following features:

- **A flexible schema.** Each row or document can have its own set of attributes.
- **Efficient random access.** Applications can quickly access one or more records using a row key, document ID, or a conditional queries.
- **Easy and efficient data mutation.** Applications can insert, update, and delete rows or documents.

MapR Database Binary Tables	MapR Database binary tables consist of rows that are identified by primary keys and row data is identified by key/value pairs. MapR Database tables are similar to HBase tables in that MapR Database does not determine or store the datatype of each value in the table. But, MapR Database tables perform operations more efficiently than HBase table. You might want to use binary tables when you want to create or use an existing HBase application. However, on the Converged Data Platform, JSON tables are usually preferred due to their flexibility.
MapR Database JSON Tables	A MapR Database JSON tables provide a flexible, powerful schema that you can customize based on the data that you want to represent. Each row in a JSON table corresponds to an JSON document with an unique _id and each JSON document can have a different set of columns. MapR Database JSON tables determine the datatype of each value based on the type of data written to the document. The following example lists three JSON documents from a single JSON table. Note that the attributes associated with each document varies.



For more information, see MapR Database on page 496.

MapR Event Store For Apache Kafka

MapR Event Store For Apache Kafka is a publish/subscribe messaging solution that uses the Apache Kafka API. MapR Event Store For Apache Kafka writes events as messages in a topic and topics are part of a stream. Producer applications can publish events to a stream and consumer applications can read all or a subset of the messages in a stream. By default, messages are stored in a topic for 7 days and then automatically purged. However, you can shorten or extend the time-to-live (ttl) for messages in a stream based on your use case.

For more information, see MapR Event Store For Apache Kafka on page 627.

Step 2: Write Data to MapR Data Platform

Depending on your use case, move existing data onto the MapR Data Platform platform or write data directly to the platform.

You can write batch data or streaming data to MapR Data Platform. Batch data refers to data that is already in a data-store while streaming data refers to the continuous flow of real-time messages that have yet to be written to a data-store. Streaming data is generally processed as it is received while batch data is processed after a set of data is written to the datastore. There are many ways to write batch and streaming data to the platform, the following sections provide a few examples.

Write Batch Data to the Platform

You can use an NFS client, hadoop command, or ecosystem components to write batch data to MapR File System. Basic POSIX filesystem operations can be used to move data to MapR File System. For example, you can use NFS clients, POSIX clients, or applications that utilize libraries such as java.io to access the filesystem. Hadoop commands and hdfs APIs can be used to add or update files on the MapR File System. For example, you can use the hadoop `distcp` command to copy data from HDFS to MapR File System. Hadoop Ecosystem components, such as Apache Flume, can also be used to push log files to MapR File System.

You can also write, update, or delete batch data to MapR Database tables. Applications can use the OJAI API to write to JSON tables or the HBase API to write to binary tables.

Write Streaming Data to the Platform

Write streaming event data as messages in HPE Ezmeral Data Fabric Event Data Streams topics using Kafka APIs or a REST client application. C, Java, or Python applications can produce messages to one or more topics in event streams. Additionally, applications written in any language can use the REST Proxy to produce messages to one or more topics in an event stream. For example, a financial service application, written in Java, could produce messages about stock market activity to an event stream topic.

Step 3: Explore Ways to Work With the Data

Once the data is in the MapR Data Platform platform, explore the various features and components available on the platform and determine your path. You may want to access data in its initial format or perform some data modeling or processing prior to accessing the data.

The following sections provide some examples to help you determine which approach will work for your particular use case.

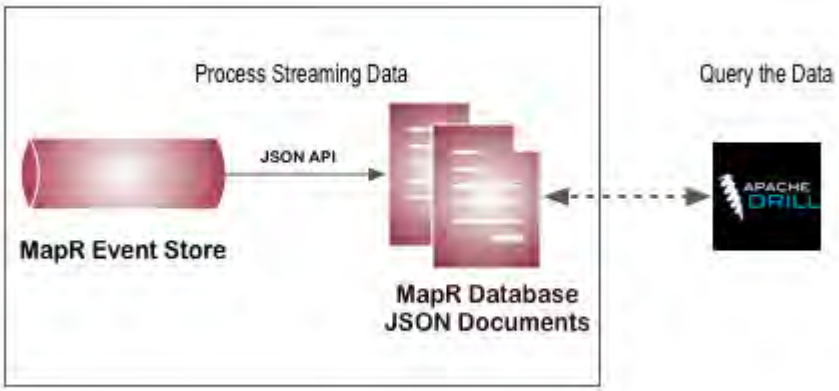
Process Data

When developing applications that ingest data, consider if the data requires some processing before the data can be consumed or stored.

Consider the following scenarios:

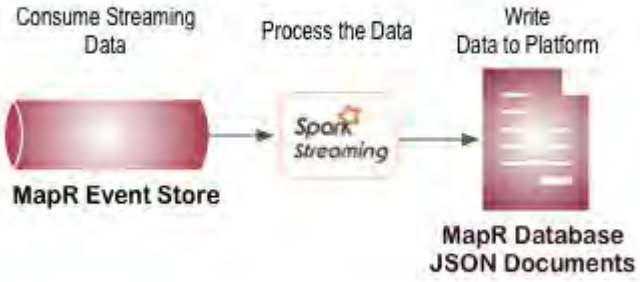
- **Process the Data Before Querying the Data**

  To efficiently query data, you may want to convert the data into a different format. For example, if you want to use Drill to query event data, you can convert streaming data from topics to a JSON table to enable more efficient querying. To do this, ingest event data using MapR Event Store For Apache Kafka, use the MapR Event Store For Apache Kafka API to read the data from topics and the JSON API to store the data in a JSON table, then use Drill to query the JSON tables.



- **Process Data before Storing the Data**

  You may also want to process the data based on business needs to perform some pre-processing before long term storage. For example, you can consume streaming data from a MapR Event Store For Apache Kafka topic with a Spark Streaming application which performs calculations or adds additional data before storing the data in a different data-store such as a MapR Database JSON table.



- **Perform Calculations as the Data is Stored**

  You may want to modify a single row in a table and then incrementally aggregate data. For example, you can use MapR Database tables to store large amounts of customer information or product catalog data and then read and write to a subset of that data. Then, modify a single row in a table to incrementally aggregate data. For example, to aggregate the number of clicks on a page, you can have a row key for each date and page. Internally, you can design the table to increment based on timestamp. The following example shows a row of data for the info page on 2017-02-22:

```
2017-01-22-info.html => key
Total : 1230 +1
H00 :   100
M1:1
M2: 5
...
M30 : 10
...
H20 : 50 +1
M1:1
...
M25: 1
```

- **Process Large Sets of Data**

  There are also many methods to process files in their initial state. To process large sets of data on the MapR XD Distributed File and Object Store, it is common to use Spark or MapReduce applications. MapReduce applications perform parallel,distributed processing of data in batches and are therefore a great way to process large datasets. Spark applications can be used to iteratively process large sets of data with machine learning algorithms. For an example of using a machine learning algorithm with a Spark application, see Building a Recommendation Engine with Spark.

Access Data

There are many use cases for why you might want to access data and many methods to access the data. Operational applications or E-commerce services may want to access data on the MapR Data Platform platform to provide customers a view of transactional data. Business users may want to view user profile data or submit queries through a BI tool to visually analyze the data.

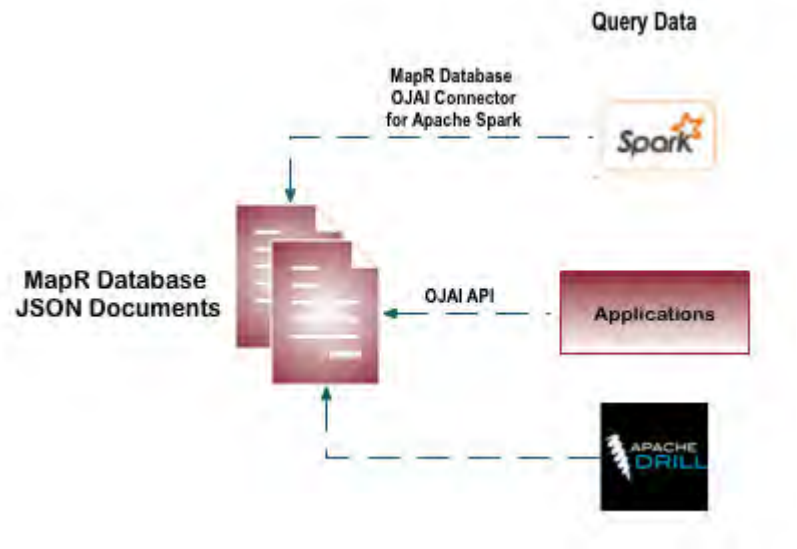
The following sections will provide some examples for how to access the data so that you can envision that will work for your use case.

- **Access Data in MapR XD Distributed File and Object Store**

  The most common way to access data in the MapR XD Distributed File and Object Store is via a NFS mount point that is remote or local to the cluster. You can use HDFS commands as well but they are generally only used for migrating hadoop applications to the MapR Data Platform platform. If you require high throughput, security, and scalability, consider installing the MapR POSIX client as this provides a more efficient way to access data in the MapR XD Distributed File and Object Store. You can also query the data directly using Drill.

- **Access Data in MapR Database**

  The methods that you can use to access MapR Database table data differs based on the table type. You can access MapR Database binary table data with the HBase shell and applications that use the HBase API. You can access MapR Database JSON table data with the mapr dbshell, and java applications that use the OJAI API. You can also use Drill or Spark to query MapR Database binary and JSON table data directly.



- **Access Data in MapR Event Store For Apache Kafka**

  Data in MapR Event Store For Apache Kafka can be accessed by one or more stream consumers and the number of consumers can change over time depending on business needs.

  Similar to the various ways you can write data to topics a stream, data in stream topics can be accessed by applications that utilize the Kafka API or a REST interface. You can also use Spark to query streams for new messages at a given interval and access any new messages that are available.

  MapR Event Store For Apache Kafka provides flexibility to add new consumers without making changes to the producer application. For example, you have a MapR Event Store For Apache Kafka producer that writes all twitter feeds to a stream. Today, this stream is accessed by a single consumer application that provides access to twitter feeds with content related to IOT. The next week, there may be a request check for how many tweets originate from a specific account. Providing access to different data in an existing stream can be achieved by creating a new consumer which reads from the same stream.

Step 4: Set Up the Development Environment

Before you start building the application, figure out how your the application will connect to the cluster and what the library dependencies and installation requirements are.

last-updated: Apr 11, 2022

Applications are often run on edge nodes which are nodes that are not part of the cluster. Setting up an edge node so that it can be used to develop and run applications consists of the following steps:

- Selecting a client that you will use to connect to the cluster.
- Installing additional clients required for your use case.
- Determining the application dependencies.

Note: The dependencies to build and run applications differ based on your use case and the various types of data or tools that are part of an application.

The following sub-topics include the various methods to connect to the cluster, and minimal requirements to build and run applications.

Connect to the Cluster

Application are often run on nodes that are not part of the MapR Data Platform cluster. There are many methods to connect to a MapR cluster; this section briefly describes each option.

MapR Data Platform Client	The MapR Data Platform client includes the libraries and utilities required on an edge node to perform the following: connect to the cluster, submit MapReduce applications, submit YARN applications, run hadoop fs commands, and run hadoop mfs commands. However, to run applications that access data from MapR Database or MapR Event Store For Apache Kafka, you must configure additional dependencies. For more information about the MapR Data Platform client, see MapR Client on page 388 and How MapR clients Connect to the cluster on page 746. **Note:** Although it is not recommended, you can include the MapR File System JAR file in the application instead of installing the MapR Data Platform client. However, there are caveats and specific requirements to make this work. For information, see Using the File System JAR to Connect to the Cluster on page 2367.
MapR Data Platform Persistent Application Client Container (PACC)	The MapR Data Platform Persistent Application Client Container (PACC) is a Docker-based container image that includes a container-optimized MapR Data Platform client. The PACC provides seamless access to MapR Data Platform Converged Data Platform services, including MapR File System, MapR Database, and MapR Event Store For Apache Kafka. The PACC includes the POSIX client, the MapR Data Platform client, and the libraries required to build MapR Database and MapR Event Store For Apache Kafka applications. For more information, see About the MapR Persistent Application Client Container (PACC) on page 403.
MapR Data Platform POSIX Clients	MapR Data Platform POSIX clients enable app servers, web servers, and other client nodes and applications to read and write directly and securely to the filesystem. For more information about the POSIX clients, see POSIX Clients on page 492 and MapR POSIX Clients on page 399.
MapR Data Platform NFS Clients	You can mount the cluster itself via NFS so that your applications can read and write data directly. For more information, see Managing the MapR NFS Service on page 1176.

last-updated: Apr 11, 2022

Using the File System JAR to Connect to the Cluster

The MapR File System JAR file includes the data-fabric client libraries required to connect to the cluster. While this is strongly discouraged, application developers can bundle the MapR File System JAR file in data-fabric file system, MapR Database, and MapR Event Store For Apache Kafka applications instead of installing the data-fabric client on the edge node (node that runs the application). Applications should not bundle the MapR File System JAR file unless the application meets certain requirements.

Important: When bundling the MapR File System JAR file, if there is a binary mismatch between the bundled JAR file and the version that the cluster expects, this can result in failures. In release 5.2.2 and later, the system detects the mismatch and prevents the application from starting. In releases earlier than 5.2.2, nodes running applications may run out of memory or shut down unexpectedly.

Requirements

You can bundle the MapR File System JAR (`maprfs-<version>-mapr.jar`) with applications that meet all of the following requirements:

- The application communicates directly with the MapR File System, MapR Database, or MapR Event Store For Apache Kafka
- The application does not run as a MapReduce or YARN job/application on the cluster.
- The application does not include MapR File System JARs on the local machine in its classpath.
- The application accesses a cluster that is not secure.

Configuring the Cluster Connection

When you include the MapR File System JAR in an application instead of installing the data-fabric client on the edge node, you must create and configure a `mapr-clusters.conf` file on node that runs the application.

1. Set a `MAPR_HOME` environment variable to a location such as `/opt/mapr`.
2. Create the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory.
3. Configure the `mapr-clusters.conf` file with the cluster name and the list of CLDB nodes.

   For example, the `mapr-clusters.conf` on an edge node would contain the following content if it was connecting to a cluster named `my.cluster` with CLDB nodes on centos765, centos234, and centos123:

   ```
   my.cluster secure=false centos765 centos234 centos123
   ```

   For more information about how to configure `mapr-clusters.conf`, see mapr-clusters.conf on page 2200.

For more information about how the data-fabric client connects to the cluster, see How MapR clients Connect to the cluster on page 746.

Using Maven to Include MapR File System JAR as a Dependency

If you use Maven to bundle the MapR File System JAR file with an application and you plan to run the application on a data-fabric cluster where a patch has been applied, ensure that you specify both a system scope and a local system path to the file.

For example, to bundle the MapR File System JAR file, the `pom.xml` file may include the following:

```
...
 <groupId>com.mapr.hadoop</groupId>
        <artifactId>maprfs</artifactId>
        <version>${mapr.core.version}</version>
        <scope>system</scope>
        <systemPath>/opt/mapr/lib/maprfs-5.2.0-mapr.jar</systemPath>
...
```

By default, the data-fabric Maven repository includes JAR files from https://repository.mapr.com/maven/. This default Maven repository includes JAR files associated with the GA packages for each data-fabric release. Therefore, when a patch has been applied to the cluster, failure to specify a system scope may result in errors due to a binary mismatch between the MapR File System JAR files used by the application and the cluster.

Known Issues

Nodes running applications with a bundled MapR File System JAR file may run out of memory or shut down unexpectedly in the following scenarios:

The version of the MapR File System JAR included in the application differs from the version that is available on the cluster.	This may occur when a patch was applied to some, but not all the nodes in the cluster. It can also occur when Maven is bundling the GA version of the JAR file when the cluster expects a newer, patched version.
Two versions of the JAR are available on the node.	For YARN applications, the NodeManager nodes that run the tasks or containers store local versions of the dependencies included with the application. In this scenario, since both the cluster's MapR File System JAR and the version included in the application are available on the node, it is unknown which JAR will be used when processing the application.

MapR Database JSON Application Requirements

The following tables include the minimal node requirements for building and running MapR Database JSON table applications.

Java Applications

Node Requirements	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. • Use the MapR File System JAR to connect to the cluster. For more information, see Connect to the Cluster on page 2366.
The OJAI Query Service is installed	To use secondary indexes, you may need to enable this service. See Preparing Clusters for Querying using Secondary Indexes on JSON Tables on page 1089 for more information.

Node Requirements	Method(s) to Meet Requirement
MapR Database libraries are configured as a dependency.	When you build an application, use the Maven Repository to determine the dependencies. The POM file should include the MapR Repository and the MapR OJAI Driver project. When you run the application, provide the dependencies in the application's classpath. For more information, see Compiling and Running Java OJAI Applications on page 2666
Other items to consider.	If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file. For example, to use the MapR Database OJAI Connector for Apache Spark, see Configuring the MapR Database OJAI Connector for Apache Spark on page 4052

MapR Database Binary Application Requirements

The following tables include the minimal node requirements for building and running MapR Database binary table applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. • Use the MapR File System JAR to connect to the cluster. For more information, see Connect to the Cluster on page 2366.
The HBase client is installed.	Install the HBase client. The HBase client is as part of the EEP installation. For more information, see 6.1 Installation on page 107. **Note:** The HBase client is include when you install PACC.
HBase client library files are configured as an application dependency.	When you build the application, use the Maven Repository to determine the dependencies. The POM file should include the MapR Repository and the HBase client dependency. When you run an application, include the `hbase classpath` script and additional dependencies in the application's classpath. For more information, see Compiling and Running MapR Database Binary Applications on page 2478
Other Items	If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.

C Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. • Use the MapR File System JAR to connect to the cluster. For more information, see Connect to the Cluster on page 2366.
The HBase Client is installed.	Install the HBase client. The HBase client is as part of the EEP installation. For more information, see 6.1 Installation on page 107. **Note:** The HBase client is include when you install PACC.
The libMapRClient library and libjvm shared libraries are in the application's library search path and the `libMapRClient` header files are in this directory:`/opt/mapr/include/hbase`	For more information, see Building and Launching C Applications on page 2472.

MapR Event Store For Apache Kafka Application Requirements

The following tables include the minimal node requirements for building and running MapR Event Store For Apache Kafka consumer and producer applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. • Use the MapR File System JAR to connect to the cluster. For more information, see Connect to the Cluster on page 2366.
The MapR Streams Java Client is installed.	Install the MapR Event Store For Apache Kafka Java Client. The MapR Event Store For Apache Kafka Java client (mapr-kafka) is available as part of the EEP installation. For more information, see 6.1 Installation on page 107. **Note:** The MapR Streams Java Client is include when you install PACC.

last-updated: Apr 11, 2022

Node Requirement	Method(s) to Meet Requirement
MapR Streams Java client and the MapR Streams project library files are configured as an application dependency.	When you build the application, use the Maven Repository to determine the dependencies. The POM file should include the MapR Repository, the MapR Event Store For Apache Kafka Java Client dependency, and the MapR Event Store For Apache Kafka project dependency. When you run an application, include the dependencies in the application's classpath. For more information, see Compiling and Running MapR Event Store For Apache Kafka Java Apps on page 2777
Other Items	If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.

MapR File System Application Requirements

The following tables include the minimal node requirements for building and running MapR File System applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. • Use the MapR File System JAR to connect to the cluster. For more information, see Connect to the Cluster on page 2366.

Node Requirement	Method(s) to Meet Requirement

Include hadoop-common libraries as a dependency.	When you compile the application, use the Maven Repository to determine the dependencies.The POM file should include the MapR Repository and the hadoop-common dependency:
	
	`<repositories>`
	`<repository> <id>mapr-releases</id>`
	`<url>https://repository.mapr.com/maven/</url>`
	`<snapshots><enabled>false</enabled></snapshots> <releases><enabled>true</enabled></releases>`
	`</repository>`
	`</repositories>`
	
	`<dependencies>`
	`<dependency>`
	`<groupId>org.apache.hadoop</groupId>`
	`<artifactId>hadoop-common</artifactId>`
	`<version>${hadoop.version}</version>`
	`</dependency>`
	`</dependencies>`
	
	When you run the application, include the following in the application's classpath: `` `hadoop classpath` ``
	
	For more information, see Compiling and Running a Java Application on page 2436.

Note:

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your MapR cluster expects, this can result in failures. The failures differ depending on the version of MapR you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 2367.

C Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. For more information, see Connect to the Cluster on page 2366.

Node Requirement	Method(s) to Meet Requirement
Include the libhdfs libraries and MapR libraries when you compile the application.	The MapR libraries are available in the following location: `/opt/mapr/lib` Link to the libhdfs libraries in the following location: `MAPR_HOME/hadoop/hadoop-2.x/` For more information, see Compiling and Running C Applications on File System Clients on page 2379

YARN Application Requirements

The following tables include the minimal node requirements for building and running YARN applications.

Node Requirement	Method(s) to Meet Requirement
A connection to the MapR cluster.	Select one of the following options: • Install and configure the MapR client. • Install the PACC and run an application container. For more information, see Connect to the Cluster on page 2366.

Hadoop libraries are configured as an application dependency.	When you compile the application, use the Maven Repository to determine the dependencies. The POM file should include the MapR Repository and the hadoop-common dependency:
	`<repositories>`
	`<repository>`
	`<id>mapr-releases</id> <url>https://repository.mapr.com/maven/</url>`
	`<snapshots><enabled>false</enabled></snapshots>`
	`<releases><enabled>true</enabled></releases>`
	`</repository>`
	`</repositories>`
	
	`<dependencies>`
	`<dependency>`
	`<groupId>org.apache.hadoop</groupId>`
	`<artifactId>hadoop-common</artifactId>`
	`<version>${hadoop.version}</version>`
	`</dependency>`
	`</dependencies>`
	When you run the application, include the following in the application's classpath: `` `hadoop classpath` ``
	Note: Based on how you submit the application, the classpath locations and requirements differ. See External Applications and Classpath on page 3030 and Classpath Construction on page 3031.

last-updated: Apr 11, 2022

Node Requirement	Method(s) to Meet Requirement
Other Items	• If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file. • Any third-party library that is required by a MapReduce program must be accessible to this node and the data node that processes the job or application. For more information, see Managing Third-Party Libraries on page 3031.

Step 5: Build the Application

Start building an application! This section lists a few of the sample applications available in MapR Data Platform.

Note: When building and running your application, you may want to use a classpath for printing to standard output. The following classpaths are available:

mapr classpath	Prints CLASSPATH to standard output. This classpath could be used to build your application classpath to runMapR Data Platform applications for YARN and other components.
mapr clientclasspath	Prints CLASSPATH for MapR Database clients to standard output. The clientclasspath could be used to build the classpath to run your MapR Database (binary and JSON) and MapR Event Store For Apache Kafka applications.

MapR Database JSON

Build Your Java Application on page 2519	This section shows how to build a Java application that uses OJAI and accesses MapR Database JSON tables.
Managing JSON Tables on page 2522	This section describes how to create, list, and delete JSON tables as well as set permissions and manage column families using either the MapR Data Platform Java API library or the MapR Database Shell commands.
Creating JSON Documents in Java OJAI on page 2545	This section provides several Java examples of creating a document.
Examples: Inserting JSON Documents on page 2554	This section shows how to insert a document or data into a document store (MapR Database JSON table) with Java and dbshell.
Examples: Querying JSON Documents on page 2624	This section provides several examples of querying documents.
MapR Database JSON MapReduce: Sample App on page 2715	This sample Java application extends the Apache Hadoop MapReduce framework to read records (JSON documents) from a JSON table and inserts new documents into another JSON table. This API library allows you to write your own MapReduce applications to write data from one JSON table to another.

last-updated: Apr 11, 2022

MapR Database Binary

C API Examples on page 2455	This section provides examples using the MapR Database libMapRClient C API to operate on MapR Database binary tables.
MapR Database Sample C Application on page 2459	This section provides additional sample C applications that accesses and performs operations on MapR Database binary tables.

MapR Event Store For Apache Kafka Streams

Sample Java Consumer on page 2721	This sample Java consumer application iterates through the returned records, extracts the value of each message, and prints the value to standard output.
Sample Java Producer on page 2722	This sample Java producer application publishes messages to a stream topic.
Developing a MapR Event Store For Apache Kafka C Application on page 2797	These sample C applications publish messages to a stream topic and consumes the messages.
Developing MapR Event Store For Apache Kafka Python Applications on page 2999	These sample Python applications publish messages to a stream topic and consumes the messages.

MapR File System

Sample Applications on page 2440	This sample Java application demonstrates how to set, get, modify, and delete ACEs on files using the Java APIs.
hdfs_write_revised.c on page 2384	This C application demonstrates how to write to files by using the hdfsWrite() and hdfsPwrite() APIs.
hdfs_read_revised.c on page 2391	This C application demonstrates how to read from files by using the hdfsRead() and hdfsPread() APIs.
hdfs_connect_as_user.c on page 2398	This C application demonstrates how to create and write to files impersonating another user by using the hdfsConnectAsUser() API.

Github Repo

You can find additional sample code on the MapR Demos Github repository.

MapR XD and Apps

The following sections provide information about accessing the MapR XD with C and Java applications.

Copying Data from Apache Hadoop to a MapR Cluster

Describes the procedure to copy data from an Apache Hadoop to a MapR cluster.

You can use the hdfs protocol, webhdfs protocol, or NFS to copy data from Apache Hadoop to a MapR cluster.

The following table describes these methods:

last-updated: Apr 11, 2022

Method	Description
hdfs:// protocol	You can use the `hadoop distcp` command with the `hdfs://` protocol to copy data from a HDFS cluster into a MapR cluster if the HDFS cluster and the MapR cluster use the same RPC protocol version. For all other scenarios, use the `webhdfs://` protocol or NFS gateway to copy data to a MapR cluster.
webhdfs:// protocol	You can use the `hadoop distcp` command with the `webhdfs://` protocol to copy data from a HDFS cluster into a MapR cluster.
NFS	You can mount a MapR cluster to a HDFS cluster using NFS mount and then use the `hadoop distcp` command to copy data between the two clusters.

Refer to the following sections for information about how to copy data from Hadoop to a MapR cluster:

Copy Data Using the hdfs:// Protocol
Describes the procedure to copy data from a HDFS cluster to a MapR cluster using the *hdfs://* protocol.

Before you can copy data from an HDFS cluster to a MapR cluster using the *hdfs://* protocol, you must configure the MapR cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a MapR Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and MapR clusters, and then complete the steps listed under Verifying Access to an HDFS Cluster.

You also need the following information:

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>` - the port for connecting to the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<MapRFilesystem path>` - the path in the MapR cluster to which you plan to copy HDFS data
- `<file>` - a file in the HDFS path

To copy data from HDFS to MapR filesystem using the `hdfs://` protocol, complete the following steps:

1. Run the following Hadoop command to determine if the MapR cluster can read the contents of a file in a specified directory on the HDFS cluster:

   ```
   hadoop fs -cat <NameNode>:<NameNode port>/<HDFS path>/<file>
   ```

   Example

   ```
   hadoop fs -cat hdfs://nn1:8020/user/sara/contents.xml
   ```

2. If the MapR cluster can read the contents of the file, run the `distcp` command to copy the data from the HDFS cluster to the MapR cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> maprfs://
   <MapRFilesystem path>
   ```

   Example

   ```
   hadoop distcp hdfs://nn1:8020/user/sara maprfs:///user/sara
   ```

Copying Data Using the webhdfs:// Protocol

Describes how to copy data from a HDFS cluster to a MapR cluster using the *webhdfs://* protocol.

Before you can copy data from an HDFS cluster to a MapR cluster using the *webhdfs://* protocol, you must configure the MapR cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a MapR Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and MapR clusters, and then complete the steps listed under Verifying Access to an HDFS Cluster.

The HDFS cluster must have WebHDFS enabled. Verify that the following parameter exists in the `hdfs-site.xml` file and that the value is set to `true`.

```
<property>
<name>dfs.webhdfs.enabled</name>
<value>true</value>
</property>
```

You also need the following information:

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode HTTP Port>` - the HTTP port on the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<MapR filesystem path>` - the path in the MapR cluster to which you plan to copy HDFS data

To copy data from the HDFS to the MapR filesystem using the `webhdfs://` protocol, complete the following step:

Run the following command from a node in the MapR cluster:

```
hadoop distcp webhdfs://<NameNode>:<NameNode HTTP Port>/<HDFS path>
maprfs:///<MapR filesystem path>
```

Example

```
hadoop distcp webhdfs://nn2:50070/user/sara maprfs:///user/sara
```

Note: The triple slashes in `maprfs:///...` are required.

Copying Data Using NFS

Describes how to copy files from one MapR cluster to another using NFS.

If NFS is installed on the MapR cluster, you can mount the MapR cluster to the HDFS cluster and then copy files from one cluster to the other using `hadoop distcp`. If you do not have NFS installed and a mount point configured, see Accessing Data with NFS v3 on page 1183 and Managing the MapR NFS Service on page 1176.

To perform a copy using distcp via NFS, you need the following information:

- `<MapR NFS Server>` - the IP address or hostname of the NFS server in the MapR cluster
- `<maprfs_nfs_mount>` - the NFS export mount point configured on the MapR cluster; default is `/mapr`
- `<hdfs_nfs_mount>` - the NFS mount point configured on the HDFS cluster
- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>` - the port on the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data

last-updated: Apr 11, 2022

- `<MapR filesystem path>` - the path in the MapR cluster to which you plan to copy HDFS data

To copy data from HDFS to the MapR filesystem using NFS, complete the following steps:

1. **Mount HDFS.**

   Issue the following command to mount the MapR cluster to the HDFS NFS mount point:

   ```
   mount <MapR NFS Server>:/<maprfs_nfs_mount> /<hdfs_nfs_mount>
   ```

   Example

   ```
   mount 10.10.100.175:/mapr /hdfsmount
   ```

2. **Copy data.**

   a. Issue the following command to copy data from the HDFS cluster to the MapR cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> file:///
   <hdfs_nfs_mount>/<MapR filesystem path>
   ```

   Example

   ```
   hadoop distcp hdfs://nn1:8020/user/sara/file.txt file:///hdfsmount/
   user/sara
   ```

   b. Issue the following command from the MapR cluster to verify that the file was copied to the MapR cluster:

   ```
   hadoop fs -ls /<MapR filesystem path>
   ```

   Example

   ```
   hadoop fs -ls /user/sara
   ```

Accessing the File System with C Applications

MapR Data Platform provides a modified version of `libhdfs` that supports access to the data-fabric file system. You can develop applications with C that read files, write to files, change file permissions and file ownership, create and delete files and directories, rename files, and change the access and modification times of files and directories.

`libMapRClient` supports and makes modifications to hadoop-2.x version of `libhdfs`. The API reference notes which APIs are supported by hadoop-2.x.

`libMapRClient`'s version of `libhdfs` contains the following changes and additions:

- There are no calls to a JVM, so applications run faster and more efficiently.
- Changes to APIs
  - *hadoop-2.x:* Support for `hdfsBuilder` structures for connections to HDFS is limited. Some of the parameters are ignored.
  - *hadoop-2.x:* `hdfsGetDefaultBlockSize()`: If the file system that the client is connected to is an instance of MapR File System, the returned value is 256 MB, regardless of the actual setting.
  - *hadoop-2.x:* `hdfsCreateDirectory()`: The parameters for buffer size, replication, and block size are ignored for connections to the data-fabric file system.

  - *hadoop-2.x:* `hdfsGetDefaultBlockSizeAtPath()`: If the file system that the client is connected to is an instance of MapR File System, the returned value is 256 MB, regardless of the actual setting.
  - *hadoop-2.x:* `hdfsOpenFile()`: The parameters for buffer size and replication are ignored for connections to the data-fabric file system.
- APIs that are unique to `libMapRClient` for hadoop-2.x
  - `hdfsCreateDirectory2()`
  - `hdfsGetNameContainerSizeBytes()`
  - `hdfsOpenFile2()`
  - `hdfsSetRpcTimeout()`
  - `hdfsSetThreads()`

Installing and Configuring MapR File System C Clients

Install the `mapr-client` package on the nodes on which you plan to build and run client applications. This package installs the `libMapRClient` library. See Setting Up the Client.

Note: The package `mapr-core` contains the files that are in the mapr-client package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

The modified versions of `libhdfs` are installed in this directory:

`MAPR_HOME/hadoop/hadoop-2.x/`

Compiling and Running C Applications on File System Clients

MapR File System exposes the HDFS API; if you already have a client program built to use `libhdfs`, you do not have to relink your program just to access the MapR file system. However, re-linking to the MapR-specific shared library `libMapRClient.so` will give you better performance on MapR file system, because it does not make any Java calls to access the file system (unlike `libhdfs.so`).

The script below sets environment variables to necessary values and compiles one of the sample applications. Use this script as an example for building and launching your own applications.

When you set HADOOP_HOME for your own client applications, set it to the path for the version of `libhdfs` that your application uses. The path is:

`MAPR_HOME/hadoop/hadoop-2.x/`

Also, set the path to your application in the `gcc` command, of course.

This script assumes that `MAPR_HOME` is set to the default value of `/opt/mapr`.

```
#!/bin/bash
#Setup environment
export HADOOP_HOME=${MAPR_HOME}/hadoop/hadoop-2.7.0/
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:${MAPR_HOME}/lib/native/
export LD_RUN_PATH=${LD_RUN_PATH}:${MAPR_HOME}/lib
GCC_OPTS="-Wl,--allow-shlib-undefined -I. -I{$HADOOP_HOME}/include/"

#Compile and Link
gcc ${GCC_OPTS} ${HADOOP_HOME}src/c++/libhdfs/hdfs_read.c -o hdfs_read -L$
{MAPR_HOME}/lib -lMapRClient
```

```
#Launch the application
./hdfs_read
```

Note:

- The compiled `libMapRClient` is statically linked to the following third-party libraries:
  - Crypto++: `libcryptoapp.a` (v5.6.2)
  - Protobuf: `libprotobuf-lite.a` (v2.5.0)
- If a client application connects to the local fileserver, before launching the application you can set the MAPR_CLIENT_SHMEM environment variable to control how much of the local system's memory should be devoted to the resources and buffers used for communication between the client application and the local fileserver. By default, the size of the shared memory is 20 MB. If you want to change this value, specify it as a number of pages. For example, to set the shared memory at 128 MB, multiply 128 by 10242 bytes and then divide the product by 8192 bytes. In this case, the value would be 16384 pages.

Overview of the File System C APIs in libMapRClient

Although you can use the file system C APIs to perform other tasks, the most common use of the file system C APIs is to write to and read from files.

Review the following information for an overview of the steps required to use MapR File System C APIs in libMapRClient:

1. Create a connection to the MapR file system running on a MapR cluster. For information about connections, see Establishing Connections to Filesystems.
2. Create or open a file. You can create explicitly or by calling one of the `hdfsOpen()` APIs and specifying a file that doesn't exist. Opening a file sets the current offset to 0, the first byte in the file. You can move file offset explicitly with the `hdfsSeek()` API. Writes done by `hdfsWrite()` and reads done by `hdfsRead()` increment the offset by the number of bytes written or read.

   Use `hdfsTell()` to find out what the current offset is.

   For information about how to specify the location of a file to create or open, see Specifying Paths to Files and Directories.
3. Write to or read from the file. When you write to a file, you pass a buffer that contains the data that you want to write. Writes can be done from the default offset, which is 0 when the file is opened, appended to the end of the file, or done from an offset that you specify. Write buffers are flushed to the server periodically. For more information about writes, seeWriting to Files.

   When you read from a file, you pass a pointer to a buffer for storing the data that is read. Reads can be done from the default offset or from an offset that you specify. For more information about reads, see Reading from Files.
4. Close the file.

   Closing a file implicitly flushes any remaining write buffers to the server. It also frees resources that are associated with the file.
5. Disconnect from the file system.

For more detailed information about these steps, see:

Establishing Connections to the File System

The APIs for establishing connections to the MapR File System and returning file system handles are:

- hadoop-2.x: `hdfsConnect()`
- hadoop-2.x: `hdfsConnectAsUser()`

  Note: This API ignores the impersonation request and therefore is equivalent to hdfsConnect().

- hadoop-2.x: `hdfsConnectNewInstance()`

The API `hdfsConnectAsNewUserInstance()` is not supported for connections to MapR File System fileservers.

These APIs behave in the same way:

- If "`default`" is specified for the `host` parameter, the APIs connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to /opt/mapr.)
- If a hostname or IP address is specified for the `host` parameter:
  1. Look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
  2. If they find a match, they try to connect to the cluster and all standard features for connections to MapR clusters are available. These features include high availability across CLDBs and secure connections.
  3. If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to MapR clusters are not available. For example, if the cluster is secured, the connection will fail.

It is possible to have more than one open connection at a time. For each connection, simply return the file system handle to a different instance of `hdfsFS`, as in this example:

```
    //Connect to Cluster 1 (picked up from /opt/mapr/conf/
mapr-clusters.conf)
        hdfsFS fs1 = hdfsConnectNewInstance("default", 7222);
    //Connect to Cluster 2
        hdfsFS fs2 = hdfsConnectNewInstance("n1c", 7222);
    //Connect to Cluster 3
        hdfsFS fs3 = hdfsConnectNewInstance("n1d", 7222);
```

You can then obtain file handles for files in each connected cluster, as in this example. For each cluster, this example code calls `hdfsOpenFile()`, passing in the handle to the file system, the absolute path to a file (and the file is created before being opened, if it doesn't already exist) and a file-access flag that specifies to open the file in write-only mode. This mode truncates existing files to offset 0, deleting their content.

Ignore the last three parameters for this example. `hdfsOpenFile()` returns a handle to the file or an error message, if the open operation fails.

```
     //Create files for write operations on all clusters
        const char* writePath = "/tmp/write-file1.txt";
        hdfsFile writeFile1 = hdfsOpenFile(fs1, writePath, O_WRONLY, 0, 0,
0);
        if (!writeFile1) {
        fprintf(stderr, "Failed to open %s for writing on Cluster 1!\n",
writePath);
            exit(-2);
     }
        hdfsFile writeFile2 = hdfsOpenFile(fs2, writePath, O_WRONLY, 0, 0,
```

last-updated: Apr 11, 2022

```
0);
        if (!writeFile2) {
        fprintf(stderr, "Failed to open %s for writing on Cluster 2!\n",
writePath);
            exit(-2);
     }
         hdfsFile writeFile3 = hdfsOpenFile(fs3, writePath, O_WRONLY, 0, 0,
0);
     if (!writeFile3) {
        fprintf(stderr, "Failed to open %s for writing on Cluster 3!\n",
writePath);
            exit(-2);
     }
         fprintf(stderr, "Opened %s for writing successfully on all 3
clusters...\n", writePath);
```

After working with the files, close them and disconnect from the file systems, as in this example:

```
// Close all files
if (writeFile1)
        hdfsCloseFile(fs1, writeFile1);
if (writeFile2)
        hdfsCloseFile(fs2, writeFile2);
if (writeFile3)
        hdfsCloseFile(fs3, writeFile3);

// Disconnect from all clusters
hdfsDisconnect(fs1);
hdfsDisconnect(fs3);
hdfsDisconnect(fs3);
```

Specifying Paths to Files and Directories

Many of the APIs require clients to pass a path to a file or directory. You can specify absolute paths or relative paths. Absolute paths must begin with a forward slash. Relative paths are relative to the working directory, which you can set by calling `hdfsSetWorkingDirectory()` and find out by calling `hdfsGetWorkingDirectory()`. Any path that does not begin with a forward slash is considered to be relative to the working directory.

The maximum length of paths is 4096 bytes.

You cannot specify paths to a cluster other than the cluster for the current connection. All paths are local to the cluster connected to. You can, however, explicitly connect to multiple clusters, as described in Establishing Connections to the File System on page 2380.

Writing to Files

There are two APIs for writing to files: `hdfsWrite()` and `hdfsPwrite()`. With both APIs, you pass a buffer that contains the data to write. You also pass the length of the buffer in bytes. There maximum length of the buffer is the maximum size of the datatype that is used to specify the buffer length. The datatype is a custom datatype: `tSize`, a signed 32-bit integer.

Both APIs return the number of bytes that were written. Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

For an example of both APIs in action, see `hdfs_write_revised.c`.

Note: The `core-site.xml` flags:

- `fs.mapr.flush.unaligned` default setting (`false`) enables flushes to the server in 8K boundaries. Unaligned flushes can happen only if idle flusher (`fs.mapr.write.idleflush.timeout`) is triggered. If this behavior is not desired, set the value for `fs.mapr.flush.unaligned` to `true`, which will enable flushing of unaligned write buffers (so that even small writes can be flushed on every subsequent write call).
- `fs.mapr.write.idleflush.timeout` automatically flushes the buffer, by default, after 3 seconds for all the open files. This can be disabled by setting the value to `0`. If value is specified, buffer is flushed automatically between *n* to *n*+1 seconds. For example, if value is 3 seconds, the write buffer is not cached after 4 seconds.

See also: Default core Parameters.

Using hdfsWrite()

When a file is opened in write-only mode or read-write mode, the file is truncated from offset 0, effectively deleting the content of the file. Therefore, the initial write to the file begins at offset 0. You can start subsequent writes anywhere in the file after first calling `hdfsSeek()` to move to the desired offset. After a write operation, the offset is located at the last written byte.

If the file is opened in append mode, data is appended to the end of the file only.

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo`.()

On error, pending write buffers are flushed to the server.

Using hdfsPwrite()

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

On error, pending write buffers are flushed to the server.

Reading from Files

There are two APIs for reading from files: `hdfsRead()` and `hdfsPread()`. With both `hdfsRead()` and `hdfsPRead()`, you pass a pointer to a buffer for the runtime to read bytes into and the length of the buffer. There maximum length of the buffer is the maximum size of the datatype that is used to specify the buffer length. The datatype is a custom datatype: `tSize`, a signed 32-bit integer.

Both functions return the number of bytes that are actually read.

For an example of both APIs in action, see `hdfs_read_revised.c`.

Using hdfsRead()

Whenever you open a file, the file pointer is placed at offset 0. If you want to start reading at an offset other than 0, call `hdfsSeek()` to move the file pointer forward to that offset before you call `hdfsRead()`.

last-updated: Apr 11, 2022

When you call `hdfsSeek()`, you specify the offset as a value of type `tOffset`, which is a fixed-width, signed 64-byte integer type for storing offsets. `tOffset` is defined in `hdfs.h`.

If a file is already open and you are not sure what the current offset is, you can find out by calling `hdfsTell()`.

After `hdfsRead()` finishes a read operation, the current offset is set to the last byte read plus one.

Using hdfsPread()

With `hdfsPread()`, you specify the offset at which you want to start reading, so you don't first have to call `hdfsSeek()` to move to that offset.

However, the offset that you specify does not change the current offset in the file. After `hdfsPread()` finishes the read operation, the current offset is not set to the last byte read plus one. Instead, the current offset remains as it was before the read operation.

Sample Applications

The following applications demonstrate how to write to and read from files using the APIs:

hdfs_write_revised.c

Sample Application

This application demonstrates how to write to files by using the APIs `hdfsWrite()` and `hdfsPwrite()`: `hdfs_write_revised.c`

Before running this application:

- Ensure that you have access either to a cluster running MapR File System.
- Ensure that a text-based file that you have access to exists on the cluster. Note the path to the file and the size of the file in bytes.
- The content of the file will be deleted before the first write is performed by the application.
- Decide on the length in bytes of a string to write to the file.

To build and run it, download it from this page to a MapR client or to a system with the `mapr-core` package installed. Then, modify the `run.sh` script in Building and Running C Applications on MapR File System Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `errno.h`
- `fcntl.h`

The APIs are defined in `hdfs.h`. The file `fcntl.h` defines the file-access flags.

The application performs the actions that are described in the following sections.

Takes a filename, file size, and buffer size as input	When you launch the application, provide the path and name of the file, the size of the file, and the number of bytes to write. `hdfs_write <filename> <filesize> <buffersize>`

Sets an RPC timeout

`hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
  fprintf(stderr, "Failed to set rpc
timeout!\n");
  exit(-1);
}
```

Connects to a filesystem, using an API that is supported in the hadoop-2.x version of libhdfs

The application tries to connect to the first MapR File System cluster that is specified in the `mapr-clusters.conf` file in the `MAPR_HOME/conf` directory on the client. After connecting to the filesystem, the application returns a handle to the filesystem.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
  fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
  exit(-1);
}
```

Stores the values of the arguments

The application stores the values of the arguments in a character array and in two variables of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize fileSize = strtoul(argv[2],
NULL, 10);
tSize bufferSize = strtoul(argv[3],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the filesystem
- The name of the file, which you supplied when you launched the application.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY`. This flag creates the file if the file does not exist and truncates the file if the file does exist. If the file existed and you wanted to preserve the content of the file, you would specify `O_WRONLY | O_APPEND` for flag. These flags are defined in the header file `fcntl.h`.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs` ignores them.

```
hdfsFile writeFile = hdfsOpenFile(fs,
rfile, O_WRONLY, 0, 0, 0);
if (!writeFile) {
   fprintf(stderr, "Failed to open %s
for writing!\n", rfile);
   exit(-2);
}
```

Creates a buffer of the size that you specified and populates the buffer

At this point that the application, creates a string to populate the buffer. This is the data that the application will write.

```
char* buffer = malloc(sizeof(char) *
bufferSize);
if(buffer == NULL) {
  fprintf(stderr, "Failed to allocate
memory!\n");
  return -2;
}
int i;
  for (i=0; i<bufferSize; i++) {
  buffer[i] = 'a' + i%26;
}
```

Writes an entire file with hdfsWrite()

The application calls the function `writeLength()`:

```
int ret = writeLength(fs, writeFile,
buffer, bufferSize, fileSize);
if (ret < 0) {
  goto done;
}
```

This function writes the content of the buffer to the file, starting at offset 0.

```
int
writeLength(hdfsFS fs, hdfsFile
writeFile, char *buffer, tSize
bufferSize, tSize writeSize)
{
  tSize writeBytes = 0;
  tSize ret = 0;
  uint64_t totalWrite = 0;
  if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
    return -1;
  }
  if (writeSize == 0) {
    return 0;
  }
  for
(writeBytes=0; writeBytes<writeSize;
writeBytes+=bufferSize) {
    ret = hdfsWrite(fs, writeFile,
(void*)buffer, bufferSize);
    if (ret > 0) {
```

```
      totalWrite += ret;
    } else {
      fprintf(stderr, "hdfsWrite
failed with error %d \n", errno);
      hdfsCloseFile(fs, writeFile);
      return -1;
    }
  }
  return 0;
}
```

Seeks an offset and writes from that offset with hdfsWrite()

The application next calls the function `writeAtOffse()`:

```
  tSize writeBytes =
writeAtOffset(fs, writeFile, 0,
buffer, bufferSize);
if (writeBytes < 0) {
  goto done;
}
```

This function writes the content of the buffer to the file, starting at the specified offset. If the file already exists, the file is first truncated to this offset before the write operation begins. In this case, the specified offset is 0.

The difference between this function and the previous function is that, before writing, it calls `hdfsSeek()` to move to the specified offset in the file.

```
tSize
writeAtOffset(hdfsFS fs, hdfsFile
writeFile, tOffset offset,
              char *buffer, tSize
bufferSize)
{
  tSize ret = 0;
  if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
    return -1;
  }
  ret = hdfsSeek(fs, writeFile,
offset);
  if (!ret) {
    //hdfsWrite will return -1 if
ret != number of bytes asked to
    //be written.
    ret = hdfsWrite(fs, writeFile,
buffer, bufferSize);
    if (ret < 0) {
      fprintf(stderr, "hdfsWrite
failed with error %d \n", errno);
    }
  } else {
    fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
  }
  if (ret < 0) {
    //hdfsWrite does a flush in case
of an error, explicit flush
    //is not required.
    hdfsCloseFile(fs, writeFile);
```

```
  }
  //Current offset within the file
will be positioned at (offset +
writeBytes)th byte.
  return ret;
}
```

Performs a positional write with hdfsPwrite()

The application next calls the function `positionalWrite()`:

```
writeBytes = positionalWrite(fs,
writeFile, 20, buffer, bufferSize);
if (writeBytes < 0) {
  goto done;
}
```

This function writes the content of the buffer to the file, starting at the offset that you specify.

```
tSize
positionalWrite(hdfsFS fs, hdfsFile
writeFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
  tSize writeBytes = 0;
  if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
    return -1;
  }
  writeBytes = hdfsPwrite(fs,
writeFile, offset, buffer,
bufferSize);
  if (writeBytes < 0) {
    fprintf(stderr, "hdfsPwrite
failed with error %d \n", errno);
    hdfsCloseFile(fs, writeFile);
  }
  //Current offset within the file
will not be advanced if hdfsPwrite is
used
  return writeBytes;
}
```

Closes the file

```
hdfsCloseFile(fs, writeFile);
```

Frees the buffer

```
free(buffer);
```

Disconnects from the filesystem

```
hdfsDisconnect(fs);
```

hdfs_read_revised.c

Sample Application

This application demonstrates how to read from files by using the APIs `hdfsRead()` and `hdfsPread()`: `hdfs_read_revised.c`

Before running this application:

- Ensure that you have access to a cluster running MapR File System.

- Ensure that a text-based file that you have access to exists on the cluster. Note the path to the file.
- Decide on the number of bytes to read from the file.

To build and run it, download it from this page and copy it to a MapR client. Then, modify the `run.sh` script in Building and Running C Applications on MapR File System Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `errno.h`
- `fcntl.h`

The APIs are defined in `hdfs.h`. The file `fcntl.h` defines the file-access flags.

The application performs the actions that are described in the following sections.

Takes a filename and buffer size as input

After compiling the application, type the following command to launch the application and pass in the path and name of the file, as well as the size of the buffer to read data into:

```
hdfs_read <filename> <buffer size>
```

Sets an RPC timeout

`hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
  fprintf(stderr, "Failed to set rpc
timeout!\n");
  exit(-1);
}
```

Connects to a filesystem, using an API that is supported in the hadoop-2.x version of libhdfs

The application tries to connect to the first MapR File System cluster that is specified in the `mapr-clusters.conf` file in the `MAPR_HOME/conf` directory on the client. After connecting to the filesystem, the application returns a handle to the filesystem.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
  fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
  exit(-1);
}
```

Stores the values of the arguments

The application stores them in a character array and in a variable of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer

type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize bufferSize = strtoul(argv[2],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the filesystem
- The name of the file, which you supplied when you launched the application.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_RDONLY`, which specifies read-only mode.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs`ignores them.

```
hdfsFile readFile = hdfsOpenFile(fs,
rfile, O_RDONLY, 0, 0, 0);
if (!readFile) {
  fprintf(stderr, "Failed to open %s
for reading!\n", rfile);
  exit(-2);
}
```

Creates a buffer of the size that you specified

This is the buffer that the application will read data into.

```
  char* buffer = malloc(sizeof(char)
* bufferSize);
if(buffer == NULL) {
  fprintf(stderr, "Failed to allocate
memory!\n");
  return -2;
}
```

Reads an entire file with hdfsRead

The application calls the function `readEntireFile()`:

```
//Read entire file from the beginning
int ret = readEntireFile(fs,
readFile, buffer, bufferSize);
if (ret < 0) {
  goto done;
}
```

This function uses a WHILE loop. In each loop iteration, the function reads an amount of data that is equal to the size of the buffer. When the amount of bytes read is less than the size of the buffer, the end of the file has been reached and the function breaks the

loop. The number of bytes read is added to a total in each iteration.

```
int
readEntireFile(hdfsFS fs, hdfsFile
readFile, char *buffer, tSize
bufferSize)
{
  tSize readBytes = bufferSize;
  uint64_t totalRead = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  while (readBytes == bufferSize) {
    readBytes = hdfsRead(fs,
readFile, (void*)buffer, bufferSize);
    if (readBytes > 0) {
      totalRead += readBytes;
    } else {
      if (readBytes < 0) {
        fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
        hdfsCloseFile(fs, readFile);
        return -1;
      }
      break;
    }
  }
  return 0;
}
```

Seeks an offset and reads from that offset with hdfsRead()

The application next calls the function `readAtOffset()`, passing in 0 as the offset from which to start reading the file.

```
//Read file at a particular offset
//In this case, we are reading from
offset 0
tSize readBytes = readAtOffset(fs,
readFile, 0, buffer, bufferSize);
if (readBytes < 0) {
  goto done;
}
```

This function calls `hdfsSeek()` to move to the specified offset in the file.

If the seek is successful, the function reads from that offset until the buffer is full. The function then returns the number of bytes that were read.

If the seek or the read is not successful (meaning `hdfsSeek()` or `hdfsRead()` returned -1), the function closes the file and returns -1.

The offset in the file is the next byte after the end of the data that was read.

```
tSize
readFromOffset(hdfsFS fs, hdfsFile
readFile, tOffset offset,
               char *buffer, tSize
```

```
bufferSize)
{
  tSize ret = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  ret = hdfsSeek(fs, readFile,
offset);
  if (!ret) {
    ret = hdfsRead(fs, readFile,
buffer, bufferSize);
    if (ret < 0) {
      fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
    }
  } else {
    fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
  }
  if (ret < 0) {
    hdfsCloseFile(fs, readFile);
  }
  //Current offset within the file
will be positioned at (offset +
readBytes)th byte.
  return ret;
}
```

Performs a positional read with hdfsPread()

The application calls `positionalRead()`, passing 100 as the offset from which to start the read.

```
  readBytes = positionalRead(fs,
readFile, 100, buffer, bufferSize);
if (readBytes < 0) {
  goto done;
}
```

The function reads data into the buffer, starting at offset 100, without first calling `hdfsSeek()` to move the offset to that position. The offset is not moved to 100 before the read begins. The offset stays where it is, the read begins at offset 100, and (after the read) the offset remains where it was before the read. The offset in the file is ignored by the positional read.

```
tSize
positionalRead(hdfsFS fs, hdfsFile
readFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
  tSize readBytes = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  readBytes = hdfsPread(fs, readFile,
offset, buffer, bufferSize);
  if (readBytes < 0) {
    fprintf(stderr, "hdfsPread failed
```

with error %d \n", errno);
    hdfsCloseFile(fs, readFile);
  }
  //Current offset within the file
will not be advanced if hdfsPread is
used
  return readBytes;
}
```

Closes the file

```
hdfsCloseFile(fs, readFile);
```

Frees the buffer

```
free(buffer);
```

Disconnects from the filesystem

```
hdfsDisconnect(fs);
```

hdfs_connect_as_user.c

last-updated: Apr 11, 2022

Sample Application

This application demonstrates how to create and write to files impersonating another user by using the API `hdfsConnectAsUser()`.

Before running this application, ensure that you have access to a cluster running MapR filesystem.

To build and run it, download it from this page and copy it to a MapR client or to a system with the mapr-core package installed. Then, modify the `run.sh` script in Building and Running C Applications on MapR File System Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `stdlib.h`
- `string.h`

Note: The impersonation APIs are defined in `hdfs.h`.

The application performs the actions that are described in the following sections.

Takes two usernames and a hostname as input

After compiling the application, type the following command to launch the application and pass in the two usernames (to impersonate) and host name:

```
hdfs_connect_as_user <username1>
<username2> <hostname>if (argc < 4) {
  fprintf (stderr, "Provide two
usernames to impersonate and the host
name\n");
  printf ("USAGE: ./
hdfs_connect_as_user mapruser1
mapruser2 10.10.xx.xxx\n");
  exit(EXIT_FAILURE);
}
```

Stores the values of the arguments

The application stores the values of the arguments in character arrays. The application uses the port, 7222, to connect to the given host, and uses character arrays for user directory and file path.

```
char *impersonate_user1 = argv[1];
char *impersonate_user2 = argv[2];
char *host_addr = argv[3];
int port_num = 7222;
char user1_dir[100];
char writePath[100];
int ret_val;
```

Populates the directory path and file path

The application creates a default path for the user directory and file.

```
sprintf(user1_dir, "/tmp/%s_dir",
impersonate_user1);
sprintf(writePath, "%s/test_file",
user1_dir);
```

last-updated: Apr 11, 2022

Sets an RPC timeout

The `hdfsSetRpcTimeout()` is specific to the libMapRClient version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
  fprintf(stderr, "Failed to set rpc
timeout!\n");
  exit(-1);
}
```

Connects to the filesystem as the impersonated user

The application connects to the filesystem as the impersonated user (<username1>) using `hdfsConnectAsUser()`. If successful, this operation returns a handle to the filesystem.

```
printf("Impersonate user: %s\n",
impersonate_user1);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user1);
hdfsFS fs_handle =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user1);
if (fs_handle == NULL) {
    printf("hdfsConnectAsUser()
failed.\n");
    exit(EXIT_FAILURE);
}
```

Creates a directory as the impersonated user

The application creates a directory under `/tmp` as the impersonated user (<username1>).

```
printf("User1: Create a directory :
%s\n", user1_dir);
ret_val =
hdfsCreateDirectory(fs_handle,
user1_dir);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsCreateDirectory()
failed.\n");
  exit(EXIT_FAILURE);
}
```

Creates and opens a file

The application creates a file and opens the file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the filesystem.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY|O_CREAT`. This flag creates the file and opens it for writing.

For more details, see `hdfsOpenFile()` documentation.

```
printf("User1: Create and write to
the file as user1 : %s\n", writePath);
```

```
hdfsFile writeFile =
hdfsOpenFile(fs_handle, writePath,
O_WRONLY|O_CREAT, 0, 0, 0);
if(!writeFile) {
  printf("hdfsOpenFile() failed.\n");
  exit(EXIT_FAILURE);
}
```

Writes to the open file

The application writes to the open file as the impersonated user (<username1>).

```
char* buffer = "Hello, from user 1!";
tSize num_written_bytes =
hdfsWrite(fs_handle, writeFile,
(void*)buffer, strlen(buffer)+1);
if (hdfsFlush(fs_handle, writeFile)) {
  printf("failed to flush %s\n",
writePath);
  exit(EXIT_FAILURE);
}
```

Closes the file

The application closes the file after successfully writing to the file as the impersonated user (<username1>).

```
printf("User1: Close file %s.\n",
writePath);
hdfsCloseFile(fs_handle, writeFile);
```

Connects to the filesystem as the impersonating user

The application connects to the filesystem as the second user (<username2>) using `hdfsConnectAsUser()` and returns a handle to the filesystem.

```
printf("Impersonate user: %s\n",
impersonate_user2);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user2);
hdfsFS fs_handle2 =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user2);
if (fs_handle2 == NULL) {
  printf("hdfsConnectAsUser()
failed.\n");
  exit(EXIT_FAILURE);
}
```

Tries to write to the file as the impersonating user

The application tries to open the file created by the impersonated user (<username1>) and write to the file as the impersonating user (<username2>). This operation fails as the impersonating user (<username2>) is denied access to the file created by the impersonated user (<username1>) and the application returns error EACCES.

```
printf("User2: Try opening file
created by user1 for writing : %s\n",
writePath);
hdfsFile writeFile2 =
hdfsOpenFile(fs_handle2, writePath,
```

last-updated: Apr 11, 2022

```
O_WRONLY, 0, 0, 0);
int errNum = errno;
if(writeFile2) {
    printf("User2: hdfsOpenFile()
should have failed for %s.\n",
impersonate_user2);
    exit(EXIT_FAILURE);
} else {
    if (errNum == EACCES) {
        printf("User2: As expected
hdfsOpenFile() with EACCES.\n");
    } else {
        printf("User2: hdfsOpenFile()
failed with errno:%d expected %d.\n",
errNum, EACCES);
        exit(EXIT_FAILURE);
    }
}
```

Deletes a directory

The application deletes a directory as the impersonated user (<username1>) using the filesystem handle created for this user.

```
printf("Delete directory : %s\n",
user1_dir);
ret_val = hdfsDelete(fs_handle,
user1_dir, 1);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDelete() failed.\n");
  exit(EXIT_FAILURE);
}
```

Disconnects the impersonating user

The application disconnect the impersonating user (<username2>) from the filesystem.

```
printf("Disconnect the impersonation
user2.\n");
ret_val = hdfsDisconnect(fs_handle2);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDisconnect()
failed.\n");
  exit(EXIT_FAILURE);
}
```

Disconnects the impersonated user

The application disconnect the impersonated user (<username1>) from the filesystem.

```
printf("Disconnect the impersonation
user1.\n");
ret_val = hdfsDisconnect(fs_handle);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDisconnect()
failed.\n");
  exit(EXIT_FAILURE);
}
```

Reference for the MapR File System C APIs

The following sections describe the custom datatypes, structures, and APIs in the `libMapRClient` version of `libhdfs`:

Type Definitions

`libhdfs` defines the following custom data types, which are supported by `libMapRClient`:

tObjectKind

An enumeration, the values of which are ‘F’ for file and ‘D’ for directory. Used to specify whether an object is a file or directory.

tOffset

A signed 64-bit integer that is used to specify an offset within a file and the size of a file.

tPort

An unsigned 16-bit integer that is used to specify a port to use in connections to filesystems.

tSize

A signed 32-bit integer that is used to specify the size of data in bytes to read or write.

tTime

A data type of `time_t` that is used to specify a time in seconds.

Structures

`libhdfs` defines these structures, which are supported by `libMapRClient`.

hdfsBuilder

Supported by libhdfs for hadoop-2.x

This structure can be passed to `hdfsBuilderConnect()` for creating connections to MapR File System clusters. In the `libMapRClient`, four of the parameters are ignored. `forceNewInstance` is ignored, though the header file does not indicate this.

```
struct hdfsBuilder {
    int forceNewInstance;
    const char *nn;
    tPort port;
    const char *kerbTicketCachePath; // Ignored
    const char *userName;            // Ignored
    struct hdfsBuilderConfOpt *opts; // Ignored
};
```

Parameters

`nn`

Specifies the CLDB node to connect to when `hdfsBuilderConnect()` is called. This value is set by `hdfsBuilderSetNameNode()`.

- If `default` is specified for the `host` parameter, `hdfsBuilderConnect()` will connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to `/opt/mapr`.)
- If a hostname or IP address is specified for the `host` parameter, `hdfsBuilderConnect()`, look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
  - If they find a match, they try to connect to the cluster and all standard features for connections to MapR clusters are available. These features include high availability across CLDBs and secure connections.
  - If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to MapR clusters are not available. For example, if the cluster is secured, the connection will fail.

`port`

Specifies the port to connect to on the CLDB node. This value is set by `hdfsBuilderSetNameNodePort()`.

hdfsFileInfo

Supported by libhdfs for hadoop-2.x

This structure is returned by `hdfsGetPathInfo()` and deleted by `hdfsFreeFileInfo()`. It contains information about the file or directory that is specified in the call to `hdfsGetPathInfo()`.

`ParameterstObjectKind mKind`

Specifies whether the object is a file or directory.

`char *mName`

Specifies the name of the object.

`tTime mLastMod`

Specifies the epoch time in milliseconds of the last modification to the object.

`tOffset mSize`

Specifies the size of the object in bytes.

`short mReplication`

Specifies the count of replicas of the object.

`tOffset mBlockSize`

Specifies the block size for the object.

`char *mOwner`

Specifies the owner of the object.

`char *mGroup`

Specifies the group that is associated with the object.

`short mPermissions`

Specifies the permissions on the object.

`tTime mLastAccess`

Specifies the epoch time in milliseconds at which the object was created.

APIs

The following sections provide information about the hdfs APIs:

hdfsAvailable()

Supported by `libMapRClient` for hadoop-2.x

Returns the number of bytes that can be read from an input stream without blocking. This number is simply the size of the file in bytes.

Signature

```
int hdfsAvailable(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns the size of the file in bytes, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the arguments provided are invalid.

hdfsBuilderConnect()

Supported by `libMapRClient` for hadoop-2.x

Connects to a MapR filesystem using the parameters that are specified in an `hdfsBuilder` structure.

Signature

```
hdfsFS hdfsBuilderConnect(struct hdfsBuilder *bld)
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
bld	The builder to use for the connection. This value cannot be NULL.

Return Value

Returns the handle to the filesystem or NULL on error.

hdfsBuilderSetForceNewInstance()

Not supported for MapR File System

This API is ignored.

hdfsBuilderSetKerbTicketCachePath()

Not supported for MapR File System

This API is ignored.

hdfsBuilderSetNameNode()

Supported by `libMapRClient` for hadoop-2.x

Specifies a CLDB node for an `hdfsBuilder` structure.

Signature

```
void hdfsBuilderSetNameNode(struct hdfsBuilder *bld, const char *nn)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. This value cannot be NULL.
nn	The hostname or IP address of a name node. Use NULL to connect to the local filesystem. Use `default` to connect to the first MapR File System cluster that is listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

hdfsBuilderSetNameNodePort()

Supported by `libMapRClient` for hadoop-2.x

Sets the port in an `hdfsBuilder` structure.

Signature

```
void hdfsBuilderSetNameNodePort(struct hdfsBuilder *bld, tPort port)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. This value cannot be NULL.
port	The port to use for connections. If the CLDB node is set to NULL or `default`, use 0.

last-updated: Apr 11, 2022

hdfsBuilderSetUserName()

Not supported for MapR File System

This API is ignored.

hdfsChmod()

Supported by `libMapRClient` for hadoop-2.x

Changes permissions on a file or directory in the manner of the `chmod` command.

Signature

```
int hdfsChmod(hdfsFS fs, const char* path, short mode)
```

Parameters

Parameter	Description
fs	The handle to the filesystem. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory.
mode	The bitmask for the new permissions.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsChown()

Supported by `libMaprClient` for hadoop-2.x

Changes ownership of a file or directory in the manner of the `chown` command.

Attention:

- To permit a client to resolve user or group from a server, set the `fs.mapr.server.resolve.user` parameter to `true` in `core-site.xml`, for both secure and non secure clusters. Setting this is essential when the client does not belong to the same domain as the mapr cluster nodes, and does not have any knowledge of users present in that domain.
- To permit CLDB to resolve user or group, set the `cldb.security.resolve.user` configuration parameter to `1` on a non-secure cluster as follows:

  ```
  maprcli config save -values {"cldb.security.resolve.user":1}
  ```

  You do not have to set this parameter for a secure cluster, as it is already set to `1`.

Signature

```
int hdfsChown(hdfsFS fs, const char* path, const char *owner, const char
*group)
```

Parameters

Parameter	Description
fs	The handle to the filesystem. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory
owner	The user to own the file or directory. Set to NULL to keep the owner as is.
group	The group to own the file or directory. Set to NULL to keep the owner as is.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsCloseFile()

Supported by `libMapRClient` for hadoop-2.x

Closes an open file. Flushes all pending write buffers for the file and releases resources that are associated with the file.

Signature

```
int hdfsCloseFile(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsConnect()

Supported by `libMapRClient` for hadoop-2.x

Connects to a MapR File System cluster.

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a handle to a new connection instance.

Note that if `default` is used for the `host` parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to MapR File System.

Signature

```
hdfsFS hdfsConnect(const char* host, tPort port)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a MapR File System cluster. To connect to the first MapR File System cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value `default` and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.

Return Value

Returns a handle to the connected filesystem, or NULL on error.

Check errno for error codes and meanings.

hdfsConnectAsUser()

Supported by `libMapRClient` for hadoop-2.x

Connects to a MapR File System cluster as specified user.

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a unique handle to a connection instance for each user.

Note: If `default` is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to MapR File System.

Signature

```
hdfsFS hdfsConnectAsUser(const char* host, tPort port, const char* user)
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a MapR File System cluster. To connect to the first MapR File System cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user`	The user connected to the cluster.

Return Value

Returns a handle to the connected filesystem, or NULL on error.

hdfsConnectAsUid()
Connects to a MapR File System cluster as specified user ID.

Supported by `libMapRClient` for hadoop-2.x

Attention: You need to install a patch for version 6.1 to use this command.

If a connection to the cluster in which the remote host is located already exists, the function returns a handle to this existing connection.

If a connection to the cluster does not already exist, the function returns a unique handle to a connection instance for the specified user ID.

Note: To connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client, use `default` as the value for the `host` parameter.

For more information about connections, see Establishing Connections to the File System on page 2380.

Signature

```
hdfsFS hdfsConnectAsUid(const char* host, tPort port, uid_t uid)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a MapR File System cluster. To connect to the first MapR File System cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user ID`	The ID of the user connected to the cluster.

Return Value

Returns a handle to the connected filesystem, or NULL on error.

hdfsConnectAsUserNewInstance()

Supported by libMapRClient for hadoop-2.x

Connects to a MapR File System cluster as specified user.

The function returns a handle to a new connection instance.

Note: If default is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to MapR File System.

Signature

```
hdfsFS hdfsConnectAsUserNewInstance(const char* host, tPort port, const
char* user)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a MapR File System cluster. To connect to the first MapR File System cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.

Return Value

Returns a handle to the connected filesystem, or NULL on error.

hdfsConnectNewInstance()

Supported by `libMapRClient` for hadoop-2.x

Connects to a MapR File System cluster.

The function returns a handle to a new connection instance.

Note: If `default` is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to MapR File System.

Signature

```
hdfsFS hdfsConnectNewInstance(const char* host, tPort port)
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a MapR File System cluster. To connect to the first MapR File System cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user`	The user connected to the cluster.

Return Value

Returns a handle to the connected filesystem, or NULL on error.

hdfsCopy()

This API is not supported.

hdfsCreateDirectory()

Supported by `libMapRClient` for hadoop-2.x

Creates a file or directory at the specified path. Intermediate directories in the path that do not exist are created.

Signature

```
int hdfsCreateDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the filesystem in which to create the file or directory. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are not valid, EEXIST if the directory already exists, or EACCES if the parent directory does not allow the user write permission.

hdfsCreateDirectory2()

Supported by `libMapRClient` for hadoop-2.x

Makes the given file and all non-existent parents into directories. Stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB,

operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int hdfsCreateDirectory2(hdfsFS fs, const char* path, tSize
*nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the filesystem in which to create the file or directory. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsDelete()

Supported by `libMapRClient` for hadoop-2.x

Deletes the specified directory or file.

Signature

```
int hdfsDelete(hdfsFS fs, const char* path, int recursive)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file or directory to delete is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the file.
recursive	A value of 0 deletes the specified directory, if the directory is empty. If the directory is not empty, an error is returned. A non-zero value deletes the specified directory and all of its subdirectories. If the specified object is a file, not a directory, this parameter is ignored.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings. Some of the key errors are ESTALE, EACCES, and EPERM.

last-updated: Apr 11, 2022

hdfsDisconnect()

Supported by `libMapRClient` for hadoop-2.x

Disconnects from the specified filesystem.

Even if there is an error, the resources that are associated with the filesystem handle are freed.

Signature

```
int hdfsDisconnect(hdfsFS fs)
```

Parameter

Parameter	Description
fs	The handle of the filesystem to disconnect from. Obtain this handle with one of the `hdfsConnect()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsExists()

Supported by `libMapRClient` for hadoop-2.x

Checks whether a given directory or file exists on the filesystem.

Signature

```
int hdfsExists(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The filesystem handle. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsExists2()

Supported by `libMapRClient` for hadoop-2.x

Checks the filesystem directly (avoiding a client cache) to determine whether a given file or directory exists.

Signature

```
int hdfsExists2(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The filesystem handle. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsFileFreeReadStatistics()

This API is not supported.

hdfsFileGetReadStatistics()

This API is not supported.

hdfsFileIsOpenForRead()

This API is not supported.

hdfsFileIsOpenForWrite()

This API is not supported.

hdfsFlush()

Supported by `libMapRClient` for hadoop-2.x

Flushes the write buffer for the specified file to the server

Signature

```
int hdfsFlush(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The filesystem handle. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsFreeBuilder()

Supported by `libMapRClient` for hadoop-2.x

Frees the memory that was used by an `hdfsBuilder` structure and its parameter values.

Signature

```
void hdfsFreeBuilder(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. The value cannot be NULL.

hdfsFreeFileInfo()

Supported by `libMapRClient` for hadoop-2.x

Frees up the array of `hdfsFileInfo` structures that is returned by `hdfsListDirectory()`, including allocated fields.

Signature

```
void hdfsFreeFileInfo(hdfsFileInfo *hdfsInfo, int numEntries)
```

Parameters

Parameter	Description
hdfsInfo	The array of dynamically-allocated `hdfsFileInfo` structures.
numEntries	The size of the array.

hdfsFreeHosts()

Supported by `libMapRClient` for hadoop-2.x

Frees an array that was returned by `hdfsGetHosts()`.

Signature

```
void hdfsFreeHosts(char ***blockHosts)
```

Parameters

Parameter	Description
blockHosts	The two-dimensional array that was returned by `hdfsGetHosts()`.

hdfsGetCapacity()

Supported by `libMapRClient` for hadoop-2.x

Returns the capacity in bytes of the connected filesystem.

Signature

```
tOffset hdfsGetCapacity(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The filesystem handle. Obtain this handle by calling one of the `hdfsConnect()` APIs.

Return Value

Returns the capacity in bytes of the connected filesystem, -1 on error.

Check errno for error codes and meanings.

errno can be set to EINVAL in case of error.

hdfsGetDefaultBlockSize()

Supported by libMapRClient for hadoop-2.x

Gets the default size of blocks for the connected filesystem.

Signature

```
tOffset hdfsGetDefaultBlockSize(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The handle of filesystem. Obtain this handle with one of the `hdfsConnect()` APIs.

Return Value

Returns 256 MB.

Returns -1 on error.

Check errno for error codes and meanings.

hdfsGetDefaultBlockSizeAtPath()

Supported by `libMapRClient` for hadoop-2.x

Gets the block size of a file at the specified path.

Signature

```
tOffset hdfsGetDefaultBlockSizeAtPath(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
fs	The handle of the filesystem. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The location and name of the file.

Return Value

Returns 256 MB.

last-updated: Apr 11, 2022

Check errno for error codes and meanings.

hdfsGetHosts()

Supported by `libMapRClient` for hadoop-2.x

Gets hostnames where a particular block, as determined by the offset and block size, is stored. Due to replication, a single block could be present on multiple hosts.

This function can be useful for understanding the performance implications of file access, and to validate or verify changes to the replication factor.

Signature

```
char*** hdfsGetHosts(hdfsFS fs, const char* path, tOffset start, tOffset
length)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the file.
start	The start of the block.
length	The length of the block.

Return Value

If successful, returns a dynamically-allocated two-dimensional array of hostnames. The last element in the array is NULL.

Returns NULL on error.

Check errno for error codes and meanings.

hdfsGetNameContainerSizeBytes()

Unique to libMapRClient

Get the size of the container hosting the path.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int tSize hdfsGetNameContainerSizeBytes(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
path	Path of the file or directory residing on the container.

Return Value

Returns size of the container on success; -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsGetPathInfo()

Supported by libMapRClient for hadoop-2.x

Returns a dynamically-allocated `hdfsFileInfo` structure that contains information about the given path.

Call `hdfsFreeFileInfo()` when the structure is no longer needed.

See `hdfsFileInfo()` for information about the information that this object contains.

Signature

```
hdfsFileInfo * hdfsGetPathInfo(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The filesystem handle. Obtain this by calling one of the `hdfsConnect()` APIs.
path	The path of the file.

Return Value

Returns a dynamically-allocated `hdfsFileInfo` structure on success, and NULL on error.

errno is set to EINVAL for invalid arguments and to EACCES for invalid access.

hdfsGetUsed()

Supported by libMapRClient for hadoop-2.x

Returns the total number of bytes bytes that are being used by all of the files in the filesystem.

Signature

```
tOffset hdfsGetUsed(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The filesystem handle.

Return Value

Returns the total size in bytes or -1 on error.

Check errno for error codes and meanings.

hdfsGetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

last-updated: Apr 11, 2022

Gets the current working directory for the filesystem. Before calling this method, the application must have called `hdfsSetWorkingDirectory()`.

Signature

```
char* hdfsGetWorkingDirectory(hdfsFS fs, char *buffer, size_t bufferSize)
```

Parameters

Parameter	Description
fs	The filesystem handle.
buffer	The buffer in which to copy path of current working directory.
bufferSize	The length of user-buffer.

Return Value

Returns the buffer on success, NULL on error.

errno is set to EINVAL for invalid arguments.

hdfsGetXattr()

Supported by libMapRClient for hadoop-2.x

Gets extended attribute values from a file.

Signature

```
int hdfsGetXattr(hdfsFS fs, const char* path, const char *name, char
*value,  size_t size);
```

Parameters

Parameter	Description
`fs`	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
`name`	The name of the extended attribute.
`path`	The path to the file.
`size`	The size of the buffer.
`value`	The value for the extended attribute that is read from the system and written to the buffer.

Return Value

Returns:

- Current size of the value of the extended attribute on success
- -1 on error

  Check `errno` for error codes and meanings.

hdfsListDirectory()

Supported by `libMapRClient` for hadoop-2.x

Gets list of files and directories for a given path. Returns the information in a dynamically allocated array of `hdfsFileInfo` structures.

`hdfsFreeFileInfo()` should be called to deallocate memory when this structure is no longer needed.

This method is the equivalent of the `ls -l` command.

Signature

```
hdfsFileInfo *hdfsListDirectory(hdfsFS fs, const char* path, int
*numEntries)
```

Parameters

Parameter	Description
fs	The handle of the filesystem. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.
numEntries	Set to the number of files/directories in path. Cannot be 0 or NULL.

Return Value

Returns a dynamically-allocated array of `hdfsFileInfo` structures on success and NULL on error.

Check errno for error codes and meanings.

hdfsMove()

This API is not supported.

hdfsNewBuilder()

Supported by `libMapRClient` for hadoop-2.x

Returns an `hdfsBuilder` structure. You can set values for its parameters and then pass it to `hdfsBuilderConnect()`.

Signature

```
struct hdfsBuilder *hdfsNewBuilder(void)
```

Return Value

Returns a new `hdfsBuilder` structure.

Returns ENOMEM if unable to allocate memory for a new `hdfsBuilder` structure.

hdfsOpenFile()

Supported by `libMapRClient` for hadoop-2.x

Opens a file in the specified mode. Creates the file and intermediate directories if they do not exist.

Requires a valid filesystem handle, which one of the `hdfsConnect()` APIs can provide.

Before the call to `hdfsOpenFile()`, `hdfsExists()` can check that the file exists, if a check is needed.

last-updated: Apr 11, 2022

After finishing work on a file, call `hdfsCloseFile()` to free the memory that is associated with the file.

Signature

```
hdfsFile hdfsOpenFile(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blocksize)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The full path to the file.
flags	One of the following values. These flags are included in the fcntl.h header file. **O_RDONLY** — Opens the file in read-only mode with the current offset at 0. **O_RDWR** — Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file to offset 0. **O_RDWR | O_APPEND** — Opens the file in read-write mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API. **O_WRONLY** — Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_WRONLY | O_APPEND** — Opens the file in write-only mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API.
bufferSize	*Ignored for files on MapR filesystem*
replication	*Ignored for files on MapR filesystem*

Parameter	Description
blocksize	The size of chunks for the file in bytes. Specify 0 if you want to use the value that is specified for the `fs.mapr.block.size` parameter in the `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml` file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in `core-site.xml`, the default value is taken from the directory's `.dfs_attrributes` file.

Return Value

Returns the handle to the open file or NULL on error.

Check errno for error codes and meanings.

hdfsOpenFile2()

Supported by `libMapRClient` for hadoop-2.x

Opens a file in a given mode. Creates the file if the file does not exist.

If `hdfsOpenFile2()` creates a file, it stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Before the call to `hdfsOpenFile2()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the resources that are associated with the file.

Signature

```
hdfsFile hdfsOpenFile2(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blocksize, tSize *nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The full path to the file.

Parameter	Description
flags	One of the following values. These flags are included in the fcntl.h header file. **O_RDONLY** — Opens the file in read-only mode with the current offset at 0. **O_RDWR** — Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_RDWR** | **O_APPEND** — Opens the file in read-write mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API. **O_WRONLY** — Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_WRONLY** | **O_APPEND** — Opens the file in write-only mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API.
bufferSize	*Ignored for files on MapR filesystem*
replication	*Ignored for files on MapR filesystem*
blocksize	The size of chunks for the file in bytes. Use 0 if you want to use the value that is specified for the `fs.mapr.block.size` parameter in the `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml` file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in `core-site.xml`, the default value is taken from the directory's `.dfs_attrributes` file.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container. The value is returned only if `hdfsOpenFile2()` creates the specified file because the file does not already exist.

last-updated: Apr 11, 2022

Return Value

Returns the handle to the open file or NULL on error.

Check errno for error codes and meanings.

hdfsPread()

Supported by libMapRClient for hadoop-2.x

Reads an open file from a specified offset.

Whereas `hdfsRead()` increments the current offset in the file by the number of bytes that are read, `hdfsPread()` does not change the current offset. For example, if the current offset is 0 and `hdfsPread()` starts reading from offset 100, after the read the current offset is still 0.

Signature

```
tSize  hdfsPread(hdfsFS fs, hdfsFile file, tOffset position, void* buffer,
tSize length)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.
position	Offset from which to read.
buffer	The buffer to copy read bytes into.
length	The length of the buffer. The maximum size of `tSize` is the maximum buffer length.

Return Value

Returns the number of bytes actually read, which can be less than than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

On error, errno is set to one of the following values:

- EACCES if the access permissions are violated.
- ESTALE if the file doesn't exist on the server.
- EINVAL if the arguments are invalid or if the file type doesn't support read operations.

To recover from errors, close the file by calling `hdfsCloseFile()`.

hdfsPwrite()

Supported by libMapRClient for hadoop-2.x

Writes starting at a specified position in an open file.

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

last-updated: Apr 11, 2022

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tSize hdfsPwrite(hdfsFS fs, hdfsFile file, tOffset position, const void*
buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle of the file. Obtain this handle with one of the `hdfsOpenFile()` APIs.
position	The offset at which to start writing.
buffer	The data to write.
length	The number of bytes to write. The maximum length is the maximum size of `tSize`.

Return Value

Returns the number of bytes written, -1 on error.

Check errno for error codes and meanings.

hdfsRead()

Supported by libMapRClient for hadoop-2.x

Reads data from the current offset in an open file. After the read, the current offset is incremented by the number of bytes read.

To read from a specific offset, first call `hdfsSeek()` to move to that offset in the file. Then, call `hdfsRead()`.

Alternatively, call `hdfsPread()`, specifying an offset in the call. `hdfsPread()` does not increment the current offset in the file. The offset that you specify in the call is used only for the read.

Signature

```
tSize hdfsRead(hdfsFS fs, hdfsFile file, void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The filesystem handle. Filesystem handle can be obtained using one of the `hdfsConnect()` APIs.

Parameter	Description
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.
buffer	The buffer to copy bytes into during the read.
length	The length of the buffer. The maximum length of the buffer is the maximum size of `tSize`.

Returned Value

Returns the number of bytes actually read, which can be less than than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

Check errno for error codes and meanings.

hdfsReadStatisticsGetRemoteBytesRead()

This API is not supported.

hdfsRename()

Supported by libMapRCient for hadoop-2.x

Renames the specified file. For information about the format to use for paths, see Specifying Paths to Files and Directories.

Signature

```
int hdfsRename(hdfsFS fs, const char* oldPath, const char* newPath)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
oldPath	The path of the source file.
newPath	The path of the destination file.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSeek()

Supported by `libMapRClient` for hadoop-2.x

Moves the current offset to another offset in the specified file.

Signature

```
int hdfsSeek(hdfsFS fs, hdfsFile file, tOffset desiredPos)
```

last-updated: Apr 11, 2022

Parameters

Parameter	Description
fs	The handle for the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle to the file. Obtain this handle with one of the `hdfsConnect()` APIs.
desiredPos	The offset to move forward to.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetTicketAndKeyFile()
Dynamically loads a ticket file

Supported by `libMapRClient` for hadoop-2.x

Use this API to dynamically load a ticket file to connect to newly added clusters and nodes, without restarting your application.

Signature

```
int hdfsSetTicketAndKeyFile(const char *fname)
```

Parameters

Parameter	Description
fname	The name of the ticket file to reload.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetReplication()

This API is not supported.

hdfsSetRpcTimeout()

Unique to libMapRClient

Sets the RPC timeout in seconds. Before creating a connection to a MapR File System cluster, you can set an RPC timeout for your connections to CLDB nodes and fileservers, passing the number of seconds for the timeout as an integer.

Signature

```
int hdfsSetRpcTimeout(int seconds)
```

Parameters

Parameter	Description
seconds	The time in seconds to wait before timing out. The default is 99 seconds. If you change the value, set it either to 0 or to greater than 30 seconds. If RPC timeout is set to 0, remote procedure calls will continue to be retried until they are successful.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetThreads()

Unique to libMapRClient

Configures the number of threads for flushing write buffers. This number is specific to individual clients. The default number is 8.

The number of threads must be positive. If it isn't, EINVAL is returned.

Signature

```
int hdfsSetThreads(int threads)
```

Parameters

Parameter	Description
threads	The number of threads for flushing write buffers.

Return Value

Returns the current number of flush threads for the client, -1 on error. Check errno for error codes and meanings.

hdfsSetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Set the working directory. All relative paths will be resolved relative to it.

For example, if you call this API to set the working directory to `/mycluster/myvolume` and subsequently call `hdfsOpenFile()` with the path `/temp/tmp.txt`, the full path to the file to open is assumed to be `/mycluster/myvolume/temp/tmp.txt`.

Signature

```
int hdfsSetWorkingDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the directory is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the new working directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL for invalid arguments.

hdfsSetXattr()

Supported by libMapRClient for hadoop-2.x

Sets extended attribute on a file.

Signature

```
int hdfsSetXattr(hdfsFS fs, const char* path, const char *name, int
nameLen, char *value, int valueLen);
```

Parameters

Parameter	Description
`fs`	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
`name`	The name of the extended attribute.
`nameLen`	The length of the name of the extended attribute.
`path`	The path to the file.
`value`	The value for the extended attribute.
`valueLen`	The length of the value of the extended attribute.

Return Value

Returns `0` on success, `-1` on error.

Check `errno` for error codes and meanings.

hdfsTell()

Supported by libMapRClient for hadoop-2.x

Gets the current offset in the file in bytes.

Signature

```
tOffset hdfsTell(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns the current offset in bytes, or -1 on error.

Check errno for error codes and meanings.

hdfsUtime()
Changes the access and modification times of a file or directory.

Supported by libMapRClient for hadoop-2.x

Signature

```
int hdfsUtime(hdfsFS fs, const char* path, tTime mtime, tTime )
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file or directory is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory.
mtime	The new modification time or 0 (if you want to set only the access time) in seconds.

Return Value

Returns 0 on success, -1 on error.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsWrite()

Supported by libMapRClient for hadoop-2.x

Writes to the specified open file.

If the file is opened in write-only mode, writes start at offset 0 because write-only mode causes the content of the file to be truncated when the file is opened.

If the file is opened in append mode, data is appended to the end of the file.

If there are concurrent writes that start at the same offset, only the last write to finish persists.

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tsize hdfsWrite(hdfsFS fs, hdfsFile file, const void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the filesystem where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle of the file. Obtain this handle with one of the `hdfsOpenFile()` APIs.
buffer	The buffer containing the data to be written.
length	The number of bytes to write. This value cannot be zero. The maximum length of the buffer is the maximum size of the `tSize` data type.

Return Value

Returns the number of bytes written, -1 on error.

Check errno for error codes and meanings.

Accessing MapR XD Distributed File and Object Store in Java Applications

As a high-performance filesystem, portions of the MapR XD Distributed File and Object Store file client are based on a native maprfs library. When developing an application, specifying dependence on the JAR file that includes the maprfs library enables you to build applications without having to manage platform-specific dependencies.

The following sections describe how to access the MapR XD Distributed File and Object Store in a Java program.

Writing a Java Application

In your Java application, you will use a Configuration object to interface with the filesystem. When you instantiate a Configuration object, it is created with values from Hadoop configuration files.

If the program is built with JAR files from the MapR Data Platform installation, the Hadoop 1 configuration files are in the `$MAPR_HOME/hadoop/hadoop-<version>/conf` directory, and the Hadoop 2 configuration files are in the `$HADOOP_HOME/etc/hadoop` directory. This Hadoop configuration directory is in the hadoop classpath that you include when you compile and run the Java program.

If the program is built through maven using mapr maven artifacts, the default Hadoop configuration files are included in the maven artifacts. The user needs to programmatically update the Hadoop configuration to match the Hadoop configuration files on the MapR cluster.

Sample Code

The following sample code shows how to interface with MapR filesystem using Java. The example creates a

last-updated: Apr 11, 2022

directory, writes a file, then reads the contents of the file.

```
/* Copyright (c) 2009 & onwards. MapR
Tech, Inc., All rights reserved */

//package com.mapr.fs;

import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

/**
* Assumes mapr installed in /opt/mapr
*
* Compilation:
* javac -cp $(hadoop classpath)
MapRTest.java
*
* Run:
* java -cp .:$(hadoop classpath)
MapRTest /test
*/
public class MapRTest
{
 public static void main(String
args[]) throws Exception {
        byte buf[] = new
byte[ 65*1024];
        int ac = 0;
        if (args.length != 1) {

System.out.println("usage: MapRTest
pathname");
        return;
        }

        // maprfs:/// -> uses
the first entry in /opt/mapr/conf/
mapr-clusters.conf
        // maprfs:///mapr/
my.cluster.com/
        // /mapr/my.cluster.com/

        // String uri = "maprfs:///";
        String dirname = args[ac++];

        Configuration conf = new
Configuration();

        //FileSystem fs =
FileSystem.get(URI.create(uri),
conf); // if wanting to use a
different cluster
        FileSystem fs =
FileSystem.get(conf);

        Path dirpath = new
Path( dirname + "/dir");
        Path wfilepath = new
Path( dirname + "/file.w");
        //Path rfilepath = new
```

```
Path( dirname + "/file.r");
        Path rfilepath = wfilepath;

        // try mkdir
        boolean res =
fs.mkdirs( dirpath);
        if (!res) {

System.out.println("mkdir failed,
path: " + dirpath);
        return;
        }

        System.out.println( "mkdir( "
+ dirpath + ") went ok, now writing
file");

        // create wfile
        FSDataOutputStream ostr =
fs.create( wfilepath,
                true, // overwrite
                512, // buffersize
                (short) 1, //
replication
                (long)
(64*1024*1024) // chunksize
                );
        ostr.write(buf);
        ostr.close();

        System.out.println( "write( "
+ wfilepath + ") went ok");

        // read rfile
        System.out.println( "reading
file: " + rfilepath);
        FSDataInputStream istr =
fs.open( rfilepath);
        int bb = istr.readInt();
        istr.close();
        System.out.println( "Read
ok");
        }
}
```

Compiling and Running a Java Application

You can compile and run the Java application using JAR files from the mapr maven repository or from the Data Fabric installation.

Using JARs from the Maven Repository

Maven artifacts from version 2.1.2 onward are published to https://repository.mapr.com/maven/. When compiling for MapR Data Platform core version 6.1, add the following dependency to the `pom.xml` file for your project:

```
<dependency>
   <groupId>org.apache.hadoop</
groupId>
  <artifactId>hadoop-common</
```

```
artifactId>
  <version>2.7.0-mapr-1808</version>
</dependency>
```

This dependency adds the dependencies from the mapr maven repository the next time you do a `mvn clean install`. The JAR that includes the `maprfs` library is a dependency for the `hadoop-common` artifact.

For a complete list of artifacts and further details, see Maven Artifacts for MapR on page 4155.

Using JARs from the MapR Data Platform Installation

The `maprfs` library is included in the hadoop classpath. Add the hadoop classpath to the JAVA classpath when you compile and run the Java application.

- To compile the sample code, use the following command:

```
javac -cp $(hadoop classpath)
MapRTest.java
```

- To run the sample code, use the following command:

```
java -cp .:$(hadoop classpath)
MapRTest /test
```

Loading the MapR Data Platform Native Library

By default, the root class loader will load the native library to allow all children to see and access it. If the native library is loaded by a child class, other classes will not be able to access the library. To allow applications and associated child classes to access the symbols and variables in the native library, we recommend loading the native library via the root loader.

The loading of the native library via the root class loader is accomplished by injecting code into the root loader. If MapR Data Platform runs on top of applications (such as Tomcat) where it does not have access to the root class loader, the native library will not be loaded. Child classes that try to access the symbols under the assumption that the root class loader successfully loaded the native library will fail.

The parameter `-Dmapr.library.flatclass`, when specified with Java, disables the injection of code via the root class loader, thus disabling the loading of the native library using the root class loader. Instead, the application trying to access the symbols can load the native library themselves. However, since the native library can be loaded only once and can only be seen by the application loading it, ensure that only one application within the JVM attempts to load and access the native library.

Garbage Collection in MapR Data Platform

The garbage collection (GC) algorithms in Java provide opportunities for performance optimizations for your application. Java provides the following GC algorithms:

- *Serial* GC. This algorithm is typically used in client-style applications that don't require low pause times. Specify `-XX:+UseSerialGC` to use this algorithm.
- *Parallel* GC, which is optimized to maximize throughput. Specify `-XX:+UseParNewGC` to use this algorithm.

last-updated: Apr 11, 2022

- *Mostly-Concurrent* or *Concurrent Mark-Sweep* GC, which is optimized to minimize latency. Specify `-XX:+UseConcMarkSweepGC` to use this algorithm.
- *Garbage First* GC, a new GC algorithm intended to replace Concurrent Mark-Sweep GC. Specify `-XX:+UseG1GC` to use this algorithm.

Consider testing your application with different GC algorithms to determine their effects on performance.

Flags for GC Debugging

Set the following flags in Java to log the GC algorithm's behavior for later analysis:

```
-verbose:gc
-Xloggc:<filename>
-XX:+PrintGCDetails
-XX:+PrintGCDateStamps
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
```

For more information, see the Java Garbage Collection Tuning document or the Java Garbage Collection links.

Converting fid and volid

The following MapR File System APIs are available in `com.mapr.fs.MapRFileSystem` for converting fid to file path and volid to volume name:

- `public String getMountPathFidCached(String fidStr) throws IOException`
- `public String getVolumeNameCached(int volId) throws IOException`
- `public String getVolumeName(int volId) throws IOException`
- `public String getMountPathFid(String fidStr) throws IOException`

Converting fid to File Path

The `getMountPathFid(string)` and `getMountPathFidCached(string)` APIs can be used for converting file ID to the full path to the file. The `getMountPathFid()` API makes a call to CLDB and MapR File System to get the file path from the fid. Because this API does not cache or store this information locally, it might make repeated requests to CLDB and MapR File System for the same fid and this might result in many RPCs to both CLDB and MapR File System. The `getMountPathFidCached()` API makes a call the CLDB and MapR File System one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the file path from the fid. However, if there are many files in the volume, there might still be a large number of calls to CLDB and MapR File System to determine the file path for each fid in the volume. The caching is useful if the API attempts to determine the file path for the same fid repeatedly. The cache is purged after 15 seconds. If the file name changes before the cache is purged, you will see the old name for the file until the cache expires. You can use these APIs to convert the fid to the file path.

For example, the sample consumer application and the sample uncached consumer application for consuming

last-updated: Apr 11, 2022

audit logs as stream messages use these methods as shown below.

- **Sample Cached Consumer**

```
{
     String token =
st1.nextToken();
     /* If the field has fid,
expand it using Cached API */
     if (token.endsWith("Fid")) {
       String lfidStr =
st1.nextToken();
       String path= null;
       try {
           path =
fs.getMountPathFidCached(lfidStr);
// Expand FID to path
       } catch (IOException e){
     }
     lfidPath =
"\"FidPath\":\""+path+"\",";
     // System.out.println("\nPAth
for fid " + lfidStr +  "is " +
path);
}
```

- **Sample Uncached Consumer**

```
{
     String token =
st1.nextToken();
     if (token.endsWith("Fid")) {
         String lfidStr =
st1.nextToken();
         String path= null;
         try {
           path =
fs.getMountPathFid(lfidStr);//
Expand FID to path
         } catch (IOException e){
         }
     lfidPath =
"\"FidPath\":\""+path+"\",";
     // System.out.println("\nPAth
for fid " + lfidStr +  "is " +
path);
}
```

Converting volid to Volume Name

The `getVolumeName()` and `getVolumeNameCached()` APIs can be used for converting volume IDs to volume name. The `getVolumeName()` API makes a call to the CLDB every time to get the volume name from the volid and this may result in too many RPCs to CLDB. The `getVolumeNameCached()` API makes a call to the CLDB one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the volume name from the volid. The cache is purged after

last-updated: Apr 11, 2022

15 seconds. You can use these APIs to convert the volid to volume name.

For example, the sample consumer application and the sample uncached consumer application for consuming audit logs as stream messages uses these methods as shown below.

- **Sample Cached Consumer**

```
if (token.endsWith("volumeId")) {
       String volid =
st1.nextToken();
       String name= null;
       try {
         int volumeId =
Integer.parseInt(volid);
           // Cached API to
convert volume Id to volume Name
           name =
fs.getVolumeNameCached(volumeId);
         }
       catch (IOException e){
       }
       lvolName =
"\"VolumeName\":\""+name+"\",";
       //
System.out.println("\nVolume Name
for volid " + volid +  "is " +
name);
}
```

- **Sample Uncached Consumer**

```
if (token.endsWith("volumeId")) {
       String volid =
st1.nextToken();
       String name= null;
       try {
         int volumeId =
Integer.parseInt(volid);
           // API to convert
volume Id to volume Name
           name =
fs.getVolumeName(volumeId);
         }
       catch (IOException e){
       }
       lvolName =
"\"VolumeName\":\""+name+"\",";
       //
System.out.println("\nVolume Name
for volid " + volid +  "is " +
name);
}
```

Sample Applications
Demonstrates how to set ACEs using the Java APIs.

Sample Application

The sample application demonstrates how to set, get, modify, and delete ACES on files using the Java APIs.

Before running this application, verify that you have access to a cluster running MapR File System. To build and run this application:

1. Set the classpath:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the java file:

```
javac FileAceTest.java
```

3. Run the final `FileAceTest.class` file.

The application imports the following libraries:

- `java.io.*`
- `java.net.*`
- `java.util.*`

The application performs the actions described in the following sections.

Connects to a filesystem

The application tries to connect to the first MapR File System cluster that is specified in the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory on the client. After connecting to the filesystem, the application returns a handle to the filesystem.

```
Configuration conf = new
Configuration();
FileSystem fs = FileSystem.get(conf);
//MapRFileSystem fs =
getMapRFileSystem();
```

Creates a new directory and a new file in the directory

The application creates a new directory and a file in the directory.

```
Path testDir = new Path(rootDir +
"FileAceTest");
mkDir(fs, testDir);

Path testFile = new Path(testDir + "/
testFile");
createFile(fs, testFile);
```

Sets ACEs on the new directory and the file

The application then sets ACEs to grant m7user1 user or the root user permissions to list the contents of the directory, which is required for the user to write and/or execute files in the directory. In addition, the

application sets ACEs on the file in the directory to grant the m7user1 user read access on the file.

```
MapRFileAce ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DFILE);
ace.setBooleanExpression("u:m7user1");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root");
aces.add(ace);
((MapRFileSystem)fs).setAces(testDir,
aces);
((MapRFileSystem)fs).setAces(testFile,
 aces);
```

Verifies the ACEs set on the directory and file

The application then prints the ACEs set on the directory and file.

```
List<MapRFileAce> newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

List<MapRFileAce> newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Modifies the ACEs on the directory and file

The application modifies the ACEs on the directory to grant m7user2 user also permissions to list the contents of the directory, which is required for the users to write and/or execute files in the directory. It also modifies the ACEs on the file to grant write access on the file to m7user2 user. Please note that when modifying ACEs on the file to grant write access

to m7user2 user, the application does not change read access, which was granted to m7user1 user.

```
aces = new ArrayList<MapRFileAce>();
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root|u:m7user2");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.WRI
TEFILE);
ace.setBooleanExpression("u:m7user2");
aces.add(ace);
((MapRFileSystem)fs).modifyAces(testDi
r, aces);
((MapRFileSystem)fs).modifyAces(testFi
le, aces);
```

Verifies the changes to ACEs on the directory and file

The application prints the changes in ACEs on the directory and the file.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Deletes ACEs on directory and file

The application deletes all ACEs on the directory and the file.

```
((MapRFileSystem)fs).deleteAces(testDi
r);
((MapRFileSystem)fs).deleteAces(testFi
le);
```

Verifies the ACEs on the directory and the file

The application prints the ACEs on the directory and the file after they are deleted.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
if (newDirAces == null ||
newDirAces.size() == 0)
  System.out.println("AceCount: 0");
else
  System.out.println("AceCount: " +
newDirAces.size());
System.out.println("");
newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
if (newFileAces == null ||
newFileAces.size() == 0)
  System.out.println("AceCount: 0");
else
  System.out.println("AceCount: " +
newFileAces.size());
```

Example FileAceTest.java File

```
import java.io.*;
import java.net.*;
import java.util.*;

import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

import com.mapr.fs.MapRFileAce;
import com.mapr.fs.MapRFileSystem;

public class FileAceTest {
  public FileSystem fs = null;

  public static void mkDir(FileSystem fs, Path path) throws IOException {
    boolean res = fs.mkdirs(path);
    if (!res) {
      throw new IOException("mkdir failed, path: " + path);
    }
  }

  public static void createFile(FileSystem fs, Path path) throws Exception {
    byte buf[] = new byte[1024];

    FSDataOutputStream ostr = fs.create(path,
                                        true, // overwrite
                                        512, // buffersize
                                        (short) 1, // replication
                                        (long)(64*1024*1024) // chunksize
                                       );
    ostr.write(buf);
    ostr.close();
  }
```

```
  public static void rmR(FileSystem fs, Path path) throws IOException {
    boolean res = fs.delete(path, true /*recursive*/);
    if (!res) {
      throw new IOException("rmR failed, path: " + path);
    }
  }

  public static void main(String args[]) throws Exception {

    rmR(fs, testDir);
  }
}
```

Troubleshooting

My application that includes maprfs-0.1.jar is now missing dependencies and fails to link.

As of version 2.1.2 , the contents of `maprfs-0.1.jar` are now in two JAR files:

- `maprfs-<version>.jar`

- `maprfs-jni-<version>.jar`

The `<version>` refers to the version of the distribution. For example, if you have an existing application written for `maprfs-0.1.jar` and you update it to load `maprfs-2.1.2.jar`, you must also include `maprfs-jni-2.1.2.jar`. This change was made to enable loading on distributed class-loader environments that use the `maprfs` libraries to access the filesystem from multiple contexts.

These JAR files are installed in the `/opt/mapr/hadoop/hadoop<version>/lib/` directory, or can be accessed via the Maven Central Repository.

MapR Database and Apps

This section contains information about developing client applications for JSON and key-value tables.

Why use MapR Database?

From a developer's point-of-view, MapR Database provides the following capabilities:

- **Extreme scale for CRUD operations**: Enabled by the integration of MapR Database with the MapR Data Platform Filesystem, CRUD operations are extremely fast and efficient.
- **Flexible data model**: MapR Database can be used as both a document database and a column-oriented database. So if the content structure changes, the applications do not need to be re-written.
- **Rich query**: Integration with Apache Drill on page 3185 for MapR Database provides a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data.
- **Integration with Apache Spark**: MapR Database provides MapR Database Connectors for Apache Spark on page 4050 that allow you to access MapR Database tables through Spark applications.
- **Strong data consistency**: Consistently fast response with strong data consistency with row/document level ACID transactions and in-memory database options for faster speeds.

MapR Database JSON provides additional benefits:

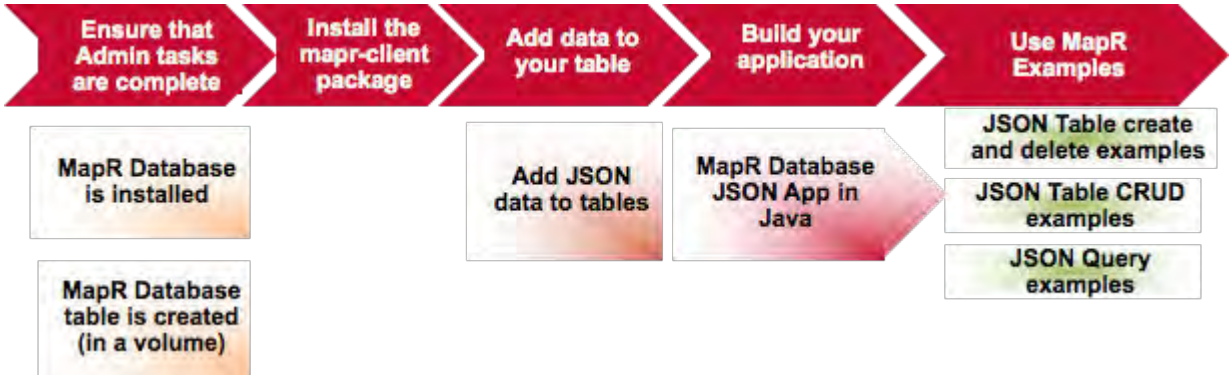
- **High performance via Secondary Indexes on page 544**: No memory copying. No need to retrieve the full document to make updates due the log-based database architecture. No application changes needed to leverage secondary indexes for efficient query execution.
- **Easy application development**: JSON constructs such as maps, arrays, and data types are supported natively.
- **Language-specific client APIs:** Java, Python, and Node.js client APIs

Note: MapR Data Platform has a universal namespace which means that the same namespace is used for files, tables, and streams. A universal namespace streamlines application development for different operations.

How Do I Get Started with MapR Database JSON?

The following diagram illustrates an end-to-end flow associated with getting started with MapR Database JSON.

last-updated: Apr 11, 2022



1. Ensure that the administrative tasks are complete as described in the introduction to MapR Database Administration.
2. Describes how to install the MapR Client package. This package allows you to run applications from your client machine.
3. This topics describes the methods available for loading OJAI documents into JSON tables.
4. This topic describes how to use mapr dbshell to create JSON tables and add JSON document to JSON tables.
5. This topic provides information on how to develop Java client applications for MapR Database JSON tables.
6. This topic provides examples creating, listing, and deleting MapR Database JSON tables.
7. This topic provides examples performing CRUD operations on JSON documents in MapR Database JSON tables.
8. Installing MapR describes how to install MapR software and Ecosystem components. You can install manually, with the MapR Installer, or with the MapR Installer Stanza.
9. This topic describes the different methods for creating tables and provides examples.
10. This topic provides examples querying JSON documents in MapR Database JSON tables.

Note: *This flow is not the only way to get started!*

You can also run through end-to-end examples using preconfigured, single node MapR Data Platform clusters. The following table describes two options:

MapR Sandbox	The MapR Sandbox is a virtual machine (VM) that runs a single node MapR cluster. Sandbox Tutorial for JSON on page 2516 describes how to use that VM with MapR Database JSON to do the following: • Install and configure MapR Database in the VM • Run a sample Java OJAI application • Use MapR Database Shell to perform simple MapR Database JSON operations
Container for Developers	MapR Container for Developers on page 96 is a Docker container that runs a single node cluster. Using MapR Database JSON: Getting Started, you can do the following:

- Set up the Docker container
- Import data into MapR Database JSON tables
- Use MapR Database Shell to query, insert, and update JSON documents in MapR Database JSON tables
- Use Drill to query MapR Database JSON tables
- Run sample Java OJAI applications
- Run a sample Spark application using the MapR Database OJAI Connector for Apache Spark

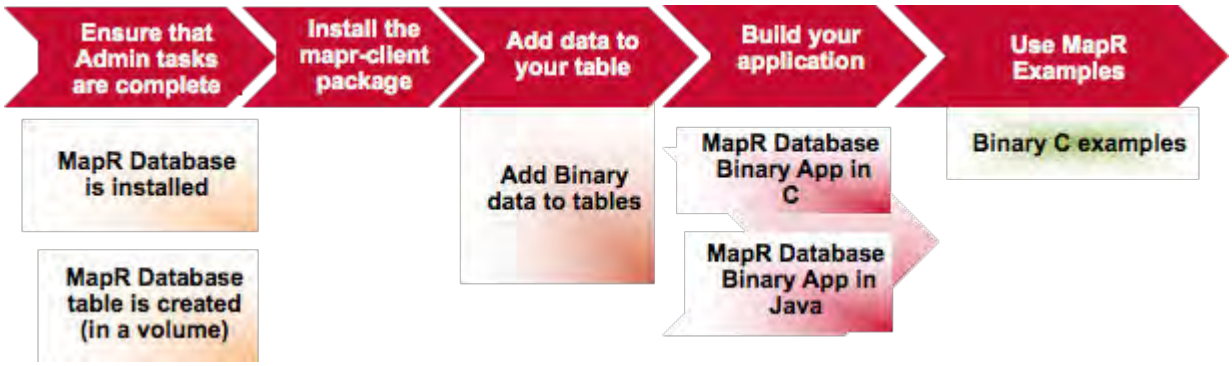
How Do I Get Started with MapR Database Binary?

The following diagram illustrates an end-to-end flow associated with getting started with MapR Database Binary.



1. Ensure that the administrative tasks are complete as described in the introduction to MapR Database Administration.
2. Describes how to install the MapR Client package. This package allows you to run applications from your client machine.
3. This topic describes how to bulk load data into binary tables.
4. This topic provides information on creating C applications for MapR Database binary tables.
5. This topic provides information on creating Java application for MapR Database binary tables.
6. This topics provides a step-by-step C application example that performs CRUD operations on a MapR Database binary tables.
7. Installing MapR describes how to install MapR software and Ecosystem components. You can install manually, with the MapR Installer, or with the MapR Installer Stanza.
8. This topic describes the different methods for creating tables and provides examples.
9. This topic provides information for developing client applications for MapR Database Binary tables.

Useful MapR Database Binary Developer Resources

Getting Started and Examples	Tools, Utilities, and Applications	General (Blogs, etc)
MapR Database Sample C Application on page 2459 - C application example for binary tables	maprcli and REST API Syntax on page 1522	High Performance C APIS on MapR Database
	Utilities for MapR Database Binary Tables on page 5329	
	Apache Drill on page 3185	
	MapR Database Binary Connector for Apache Spark on page 4101	

Installing the mapr-client Package

The `mapr-client` package must be installed on each node where you will be building and running your applications. This package installs all of the MapR Libraries needed for application development regardless of programming language or type of MapR Database table (binary or JSON).

last-updated: Apr 11, 2022

Note: The package `mapr-core` contains the files that are in the `mapr-client` package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

Complete the following steps to install the `mapr-client` package from a repository:

1. Configure the repository to point to `https://package.mapr.hpe.com/releases/<release version>/<operating system>`

   For example, if your VM has a CentOS operating system, edit the **/etc/yum.repos.d/mapr_core.repo** file and add the location.

2. Based on your operating system, run one of the following commands to install the package:
   - On Red Hat /Centos: `yum install mapr-client`
   - On Ubuntu: `apt-get install mapr-client`
   - On SLES: `zypper install mapr-client`

Passing the MapR Database Table Path

This topic describes the methods for passing a MapR Database table name. Binary table names can be passed by either specifying the table path in the API or by setting the table path in the **core-site.xml** file. JSON table names are passed by specifying the table path in the API.

Specifying the Table Path in the API

With this method, you provide the complete path to the table using the following format: `/mapr/<cluster>/<volume>/<table>`

Note: This format is independent of the programming language. This method is used for both MapR Database binary and JSON tables.

For example, if you were adding a new column family to a table and you had the following information:

- Cluster name: `newyork`
- Volume name: `vol1`
- Table name: `table1`

The table path would be `/mapr/newyork/vol1/table1`

Specifying the Table Path in the core-site.xml File

With this method, you specify the table path with `hbase.table.namespace.mappings` property in the **/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml** file.

Note: This method is specific to MapR Database binary tables only. This method is independent of the programming language.

In the following example, all tables that you create and access via the API, will be in the `/tables_dir1` directory. If you specified the table name `table1` in the API, the full path to the table would be `/tables_dir1/table1`.

```
<property>
   <name>hbase.table.namespace.mappings</name>
   <value>*:/tables_dir1</value>
</property>
```

last-updated: Apr 11, 2022

Tuning Parameters for Client Apps

Though tuning client applications is generally not necessary, MapR does offer tuning parameters to change the behavior of client-side caching.

Client application cache pending puts in buffers that are unique to each tablet (*region*, in HBase terminology). Individual put buffers are flushed when they are full or idle. As a result of this architecture and behavior, client applications tend to send RPCs of 128KB when flushing puts to disk, which results in better performance than flushing a single global buffer would, as that could result in a large number of small RPCs.

You can change the values of parameters that affect how put buffers are flushed. Set values for them in the `hbase-site.xml` file or `core-site.xml` file in your MapR installation. If a non-default value for a parameter is set in both files, the value in the `hbase-site.xml` file is used.

db.mapr.putbuffer.threshold.mb	Specifies the size of the cumulative put buffer for all tablets in the client application. When this threshold is reached, the put buffer that is most full is flushed to its tablet. The default value is 32MB. Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.
db.mapr.putbuffer.threshold.sec	Specifies the number of seconds that MapR Database should wait before flushing an idle put buffer. The default value is 3. This parameter has no effect if automatic flushing is enabled.
fs.mapr.tabletlru.size.kb	Specifies the size of the metadata cache for all tables in a client application.. The metadata for each tablet is 128 bytes. The default value of this parameter is 512KB, which allows for the caching of the metadata of 4,096 tablets. When this metadata cache is full, any operation on a tablet for which the metadata is not cached requires an RPC to fetch that tablet's metadata. Moreover, caching the newly retrieved metadata removes from the cache the metadata of a different tablet. Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.
fs.mapr.threads	Specifies the number of threads to use when flushing put buffers. Each thread makes synchronous RPCs when flushing. The default value is 64.

Developing Applications for Binary Tables

MapR Database provides a C API, `libMapRClient` and partially supports the Apache HBase 1.1 Java APIs for performing operation on MapR Database binary tables.

The MapR Database C API, `libMapRClient`, runs more efficiently on MapR Database and performs faster against MapR Database tables than the open source library of C APIs, `libhbase`, that is used to create and access Apache HBase tables. The `libMapRClient` header files are in this directory: **/opt/mapr/include/hbase**

MapR Database also supports all of the Apache HBase 1.1 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

You can easily port existing applications that use the open-source version of `libhbase` or the HBase Java APIs to use MapR Database binary tables.

Current Limitations

- Custom HBase filters are not supported.
- HBase co-processors are not supported.

Note: Filters used with Scan operations support regular expressions. When you filter scans on MapR Database tables, you can use regular expressions that comprise the Perl Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in java.util.regex.pattern. See HBase Java Regular Expressions Support on page 2506 for a list of supported regular expressions.

Creating C Apps - Binary Tables

MapR provides a library of C APIs – `libMapRClient` – for performing operations on MapR Database binary tables.

The MapR Database `libMapRClient` C API library is MapR's extension of the `libhbase` C API library. The `libMapRClient` header files are in this directory: **/opt/mapr/include/hbase**

`libMapRClient` uses the following conventions:

- All data types are prefixed with 'hb_'.
- All exported functions are annotated with HBASE_API, prefixed with 'hb_' and named using the following convention: `'hb_<subject>_<operation>_[<object>|<property>]'`
- All asynchronous APIs take a callback which is triggered when a request completes. This callback can be triggered in the caller's thread or in another thread. To avoid any potential deadlock or starvation, applications should not block in the callback routine.
- All callbacks take a void pointer for application developers to supply their own data. This void pointer is passed when callback is triggered.

Note: No explicit batching is supported for asynchronous APIs.

Warning: It is the responsibility of applications to free up all backing data buffers. However, for asynchronous APIs, applications must wait before freeing buffers until after receiving callbacks or manipulating results. For better performance of asynchronous APIs, `libMapRClient` does not copy data buffers that are allocated for mutations, gets, and scans. These buffers hold table names, name space identifiers, row keys, column-family names, and column names or qualifiers. Instead, libMaprClient temporarily takes ownership of the buffers and references them with pointers until the callback is triggered. Therefore, applications should not free memory buffers before receiving callbacks for mutations. Applications also should not free memory buffers before receiving results for gets and scans. If applications must read results, the applications should not free memory buffers until the results are destroyed.

last-updated: Apr 11, 2022

Note: When one of these asynchronous APIs is invoked, a work item is created and queued for processing on the client:

- `hb_client_destroy()`
- `hb_get_send()`
- `hb_mutation_send()`
- `hb_scanner_destroy()`
- `hb_scanner_next()`

The work item is picked up as soon as possible by a thread in a thread pool.

Client applications can often call these asynchronous APIs faster than the work items are processed. To ensure that the queue of work items does not grow without bound, the configuration parameter `fs.mapr.pool.queue.max_size` is set by default to 10,000. You can modify this parameter in the `/opt/mapr/conf/dbclient.conf` file for a client.

Whenever the number of work items in the queue reaches this limit, `libMapRClient` returns the `ENOBUFS` error for each asynchronous call. Client applications are expected to handle this error, and can try the call again later.

libMapRClient C APIs

This section provides the MapR Database `libMapRClient` C API library. This library is MapR's extension of the `libhbase` C API library. The `libMapRClient` header files are in the directory: **/opt/mapr/include/hbase**.

The `libMapRClient` API implements functions in addition to the functions in the `libhbase` API.

Note: Your applications need include only the `hbase.h` header file. The header files are provided for display purposes.

admin.h	Describes the APIs for Apache HBase table administration operations such as creating and enabling tables, checking if tables exist, and deleting tables, to name a few .
client.h	Describes the APIs for Apache HBase client side operations such as creating and terminating client connections, and flushing buffered client-side writes to Apache HBase.
coldesc.h	Describes the APIs for performing operations such as creation, deletion, and setting the maximum and minimum number of cell versions to be retained for each Apache HBase column family.
connection.h	`libMapRClient` includes a function in the `connection.h` header file: `hb_connection_create_as_user()`. This function provides support for impersonation, so that you can connect to a MapR cluster and access MapR Database tables by using a specific username. The user that is passed with the `hb_connection_create_as_user()` API must have permissions on the tables that the application accesses. For example, to read from a table, the user must have the `readperm` permission. To write to a table, the user must have the `writeperm` permission.

last-updated: Apr 11, 2022

	See Enabling Table and Stream Authorizations with ACEs on page 1461. For `hb_connection_create()` and `hb_connection_create_as_user()`, the standard C APIs for Apache HBase require a list of ZooKeeper nodes. For MapR Database, this list is interpreted as a list of CLDB nodes. The `zk_root` parameter is ignored. If `zk_quorum` is NULL, then the connection is created to the default cluster that is listed in the `mapr-clusters.conf` file.
get.h	Describes the APIs to query and fetch data from Apache HBase tables.
hbase.h	Describes the APIs and data structures of a C client for Apache HBase.
log.h	Describes the APIs to manage Apache HBase logs.
macros.h	Defines internal macros that Apache HBase uses for its operations.
multiget.h	Describes the APIs to queue and manage multiple GET requests to fetch data from Apache HBase tables.
mutations.h	Describes the APIs for row and column mutations on Apache HBase tables.
result.h	Describes the buffers for internal temporary storage of results.
scanner.h	Describes the APIs for the client side scanner to scan and request rows from the Apache HBase server.
types.h	Defines the data types and error codes that Apache HBase uses.

C API Examples

This section provides examples using the MapR Database `libMapRClient` C API to operate on MapR Database binary tables.

The MapR Database `libMapRClient` C API library is MapR's extension of the `libhbase` C API library. The libMapRClient header files are in this directory: `/opt/mapr/include/hbase`

Filtering SCAN Operation Results Example

This example shows filtering on the results of a SCAN operation.

```
for (uint32_t i = 0; i < num_filters; ++i) {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3);  // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_set_filter(scanner, (byte_t *)filters[i],
strlen(filters[i]));
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
    wait_for_scan();
 }
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
       "ColumnCountGetFilter(2)",
       "ColumnPaginationFilter(1)",
       "ColumnPrefixFilter('column-a')",
       "FamilyFilter(=,'binaryprefix:f')",
       "PrefixFilter('row_') AND QualifierFilter(<,'binaryprefix:g')",
       "SKIP TimestampsFilter(1392222222222)",
       "WHILE ValueFilter(=,'binaryprefix:cell2_value_v1')",
       "FuzzyRowFilter('row00','00001')",
       "TimestampsFilter(1430937732000,1431024132000)"};
       }
```

Note: For more information about suppport for HBase Java Filters by the MapR Database C API, see HBase Java Filters Support on page 2473

Filtering GET Operation Results Example
This example shows filtering on the results of a GET operation.

```
{
    bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
    hb_get_t get = NULL;
    hb_get_create(rowKey->buffer, rowKey->length, &get);
    hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
    hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
    hb_get_set_table(get, table_name, table_name_len);
    hb_get_set_num_versions(get, 10); // up to ten versions of each column
    hb_get_set_filter(get, (byte_t *)filters[9], strlen(filters[9]));
    get_done = false;
    hb_get_send(client, get, get_callback, rowKey);
    wait_for_get();
 }
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
       "ColumnCountGetFilter(2)",
       "ColumnPaginationFilter(1)",
       "ColumnPrefixFilter('column-a')",
       "FamilyFilter(=,'binaryprefix:f')",
       "PrefixFilter('row_') AND QualifierFilter(<,'binaryprefix:g')",
       "SKIP TimestampsFilter(1392222222222)",
       "WHILE ValueFilter(=,'binaryprefix:cell2_value_v1')",
       "FuzzyRowFilter('row00','00001')",
       "TimestampsFilter(1430937732000,1431024132000)"};
       }
```

Note: For more information about suppport for HBase Java Filters by the MapR Database C API, see HBase Java Filters Support on page 2473

Impersonation Example
This sample application demonstrates the capabilities of the new C API for impersonation.

The sample also shows how to use the API in your own programs. The application is located in the `/opt/mapr/examples/interactive` directory.

Prerequisite for compiling and running this sample application

Install the `mapr-client` package on the node where you will build the application. See Installing the MapR Client on page 389. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

Compiling this sample application

To compile and run this sample application, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true` and then read the instructions in the `README` file in the `/opt/mapr/examples/interactive` directory.

Though the application links against `libjvm`, a Java virtual machine (JVM) is not spawned. However, the `libMapRClient` does have Java dependencies.

Set Time Range Example
This example scans MapR Database binary tables and sets the time range.

```
int32_t scanWithTimeranges( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                std::string end_row_key, int64_t min_ts, int64_t max_ts,
std::string name_space, std::string column_name) {
        hb_scanner_t scanner = NULL;
        int32_t retCode;

        scan_num_rows = 0;
        scan_cell_count = 0;
        scan_done = false;
        // scanner object create
        hb_scanner_create(client, &scanner);

        scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

        // set the table to scan
        scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
        hb_scanner_set_table(scanner, (char *)
scan_data->table_name_->buffer, scan_data->table_name_->length));

        // start and end row - optional
        scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
        hb_scanner_set_start_row(scanner, scan_data->start_row_key_->buffer,
                        scan_data->start_row_key_->length);

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                        scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName   = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName   = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner,(byte_t
*)cfName->buffer,cfName->length,columnName->buffer,columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timerange
```

last-updated: Apr 11, 2022

```
        hb_scanner_set_timerange(scanner, min_ts, max_ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}
```

Set Time Stamp Example
This example scans MapR Database binary tables and sets the time stamp.

```
int32_t scanWithTimestamp( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                std::string end_row_key, int64_t ts, std::string
name_space, std::string column_name) {
        hb_scanner_t scanner = NULL;
        int32_t retCode;

        scan_num_rows = 0;
        scan_cell_count = 0;
        scan_done = false;

        // scanner object create
        hb_scanner_create(client, &scanner);

        scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

        // set the table to scan
        scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
        hb_scanner_set_table(scanner, (char *)
scan_data->table_name_->buffer, scan_data->table_name_->length));

        // start and end row - optional
        scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
        hb_scanner_set_start_row(scanner, scan_data->start_row_key_->buffer,
                        scan_data->start_row_key_->length);

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                        scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName   = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName   = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner,(byte_t
*)cfName->buffer,cfName->length,columnName->buffer,columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timestamp
        hb_scanner_set_timestamp(scanner, ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}
```

Delete Specific Cells Example
This example deletes specific cells that correspond to a specific timestamp.

```
nt32_t deleteRowExactTS(std::string table_name, std::string row_key,
        std::vector<std::string> data, int64_t ts) {

        int32_t retCode = 0;
        // initialize delete object
        hb_delete_t del = NULL;

        row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
        row_data->key = bytebuffer_printf("%s", row_key.c_str());
        row_data->tablename = bytebuffer_printf("%s",table_name.c_str());

        // create delete object
        hb_delete_create(row_data->key->buffer, row_data->key->length,
&del);

        cell_data_t *prevCell=NULL;
        // add cells that needs to be deleted
        for(int t=0; t < (int)data.size(); t++) {
             vector<string> data_qualifier = split(data.at(t),':');
             cell_data_t *cell_data= new_cell_data();
             if(t==0)
                row_data->first_cell = cell_data;
             else
                prevCell->next_cell = cell_data;

             cell_data->columnFamily =
bytebuffer_printf("%s",data_qualifier[0].c_str());
             cell_data->columnName =
bytebuffer_printf("%s",data_qualifier[1].c_str());

             //add column, fam/column/ts to delete the exact version
             retCode=hb_delete_add_column_exact(del,
cell_data->columnFamily->buffer, cell_data->columnFamily->length,

cell_data->columnName->buffer,cell_data->columnName->length,ts);
             prevCell = cell_data;
        }

        // set the table name in delete mutation object
        hb_mutation_set_table(del, (const char
*)row_data->tablename->buffer,row_data->tablename->length);

        //send the delete request
        retCode = hb_mutation_send(client, del, delete_callback, row_data);
        return retCode;
}
```

MapR Database Sample C Application
MapR provides a sample C application that accesses and performs operations on MapR Database binary tables. This section describes the various operation performed by the application.

The sample C application is located in the `/opt/mapr/examples/sample` directory.

Prerequisites

In order to compile and run the sample application, install the `mapr-client` package on the node where you will build the application. See Impersonation Example on page 2456. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

Compiling

To compile and run the sample application, read the instructions in the `README` file in the `/opt/mapr/examples/sample` directory.

Set the log level and specify the log stream

APIs used

These two APIs are defined in the header file `log.h`:

- `hb_log_set_level()`: Sets the log output level. The levels are defined in the header file types.h.
- `hb_log_set_stream()`: Sets the location of the log output. By default, log messages are sent to stderr.

Code

```
hb_log_set_level(HBASE_LOG_LEVEL_DEBUG); // defaults to INFO
const char *logFilePath = getenv("HBASE_LOG_FILE");
if (logFilePath != NULL) {
  FILE* logFile = fopen(logFilePath, "a");
  if (!logFile) {
    retCode = errno;
    fprintf(stderr, "Unable to open log file \"%s\"", logFilePath);
    perror(NULL);
    goto cleanup;
  }
  hb_log_set_stream(logFile); // defaults to stderr
}
```

Log levels are specified in the header file `types.h`.

```
/**
 *  Log levels
 */
typedef enum {
  HBASE_LOG_LEVEL_INVALID = 0,
  HBASE_LOG_LEVEL_FATAL   = 1,
  HBASE_LOG_LEVEL_ERROR   = 2,
  HBASE_LOG_LEVEL_WARN    = 3,
  HBASE_LOG_LEVEL_INFO    = 4,
  HBASE_LOG_LEVEL_DEBUG   = 5,
  HBASE_LOG_LEVEL_TRACE   = 6
} HBaseLogLevel;
```

Create a connection

API used: `hb_connection_create()`

Use this function to connect to the MapR cluster.

This API takes three parameters:

```
const char *zk_ensemble,     /* [in] NULL terminated, comma separated
                                     *   string of CLDB servers. e.g.
                                     *   "<server1[:port]>,...".
const char *zk_root,              /* [in] Ignored for MapR-DB. */
hb_connection_t *connection_ptr); /* [out] pointer to hb_connection_t */
```

There are two methods by which you can use the `zk_ensemble` parameter to determine how the MapR client connection locates the MapR cluster to connect to:

Set `zk_ensemble` to NULL to connect to the default cluster that is defined in the `mapr-clusters.conf` file.	MapR recommends this method, which uses the configuration information that is listed for the cluster in the `mapr-clusters.conf` file.
Set `zk_ensemble` to a string that includes hostnames or IP addresses.	With this method, the client application can connect to a non-default cluster explicitly. The client application searches through the `mapr-clusters.conf` file to find a cluster entry with a matching hostname/IP address. The first entry that is found to contain a matching hostname[:port]/IP address[:port} is used for the connection, as is the configuration information for that entry. If none of the hostnames or IP addresses specified for `zk_ensemble` are located in entries in `mapr-clusters.conf`, or if `mapr-clusters.conf` does not exist, the client application tries to connect to the first specified hostname[:port]/IP address[:port]. If the client application cannot make a connection, it moves to the next specified hostname[:port]/IP address[:port].  **Warning:** Because no `mapr-clusters.conf` file is involved, no additional configuration information is used for connections. For example, connections made in this way cannot be secure because no security parameters are provided.

Examples

```
//connect to default cluster specified in mapr-clusters.conf (preferred)
if ((err = hb_connection_create(NULL,
                                NULL,
                                &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
  goto cleanup;
}

//Connect directly to cluster with these specified IP addresses.
//Typically this means there is no mapr-clusters.conf and security not used.
if ((err = hb_connection_create("192.168.1.1:7222,192.168.1.2:7222",
                                NULL /* ignored */,
                                &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
  goto cleanup;
}
```

Code in the sample application

```
if ((retCode = hb_connection_create(zk_ensemble,
                                    zk_root_znode,
                                    &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create HBase connection : errorCode = %d.",
retCode);
  goto cleanup;
}
```

last-updated: Apr 11, 2022

This API is defined in the header file `connection.h`:

Create a table

The sample application creates a table by calling a function named ensureTable.

APIs used

The definition of this function uses these APIs:

APIs defined in the header file `admin.h`.

- `hb_admin_table_create()`: Creates a table. Returns 0 on success or an error code.
- `hb_admin_table_delete()`: Deletes a table. Returns 0 on success or an error code.
- `hb_admin_destroy()`: Disconnects the hb_admin object, releasing any internal objects or connections that were created in the background.
- `hb_admin_table_disable()`: Disables an HBase table. Returns 0 on success or an error code. Only sets a flag in memory to say that the table is disabled.

  Note: Tables never need to be disabled or enabled in MapR Database, which has no notion of disabling or enabling tables. However, applications ported from HBase to MapR Database will attempt to disable and enable tables. By placing a flag in memory, MapR Database allows those applications to proceed without error when performing admin functions on tables.
- `hb_admin_table_enable()`: Enables an HBase table. Returns 0 on success or an error code. As with hb_admin_table_enable, this function sets a flag in memory and performs no other operation.
- `hb_admin_table_enabled()`: Checks whether an HBase table is enabled. Returns 0 if the table is enabled. If the table is disabled, returns either the error message HBASE_TABLE_DISABLED or an error code, if an error occurs. In MapR Database, this API only checks for the existence of an in-memory flag that indicates whether to consider a table as disabled or enabled.
- `hb_admin_table_exists()`: Checks whether a table exists. Returns 0 on success or an error code.

APIs defined in the header file `coldesc.h`.

- `hb_coldesc_create()`: Creates a column-family descriptor. Returns a handle to an hb_columndesc object or NULL, if unsuccessful.
- `hb_coldesc_set_maxversions()`: Sets the maximum number of cell versions to be retained for the column family. The default is 3.
- `hb_coldesc_set_minversions()`: Sets the minimum number of cell versions to be retained for the column family. The default is 0.
- `hb_coldesc_set_ttl()`: Sets the time-to-live value in seconds for data in column cells. The default is forever.

- `hb_coldesc_set_inmemory()`: Boolean. Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.

  For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if its `inmemory` parameter is set to `false`, but preference will be given to column families where this parameter is set to `true`. A column family can have more than 32 bytes stored inline if its `inmemory` parameter is set to `true`.

  If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have the `inmemory` parameter set to `true`. All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data at all will be stored in-line for that column family.

  The default value for the `inmemory` parameter is `false`.

- `hb_coldesc_destroy()`: Releases resources that are held by a column-family descriptor.

Sequence of steps in the ensureTable function

1. Create an admin handle from the connection.
2. Using the admin handle, check whether the specified table exists.
3. If the table exists, delete it.
4. Specify columns and column families for the table.
5. Create the table.
6. Check whether the table is enabled. If it isn't enabled, enable it.
7. Disable the table and then enable it again.
8. Destroy the column descriptors.
9. Destroy the `hb_admin` structure.

Code for the ensureTable function at line 325

```
static int
ensureTable(hb_connection_t connection, const char *table_name) {
  int32_t retCode = 0;
  hb_admin_t admin = NULL;

  if ((retCode = hb_admin_create(connection, &admin)) != 0) {
    HBASE_LOG_ERROR("Could not create HBase admin : errorCode = %d.",
retCode);
    goto cleanup;
  }

  if ((retCode = hb_admin_table_exists(admin, NULL, table_name)) == 0) {
    HBASE_LOG_INFO("Table '%s' exists, deleting...", table_name);
    if ((retCode = hb_admin_table_delete(admin, NULL, table_name)) != 0) {
      HBASE_LOG_ERROR("Could not delete table %s[%d].", table_name,
retCode);
```

```
      goto cleanup;
    }
  } else if (retCode != ENOENT) {
    HBASE_LOG_ERROR("Error while checking if the table exists: errorCode =
%d.", retCode);
    goto cleanup;
  }

  hb_coldesc_create(FAMILIES[0], 1, &HCD[0]);
  hb_coldesc_set_maxversions(HCD[0], 2);
  hb_coldesc_set_minversions(HCD[0], 1);
  hb_coldesc_set_ttl(HCD[0], 2147480000);
  hb_coldesc_set_inmemory(HCD[0], 1);

  hb_coldesc_create(FAMILIES[1], 1, &HCD[1]);

  HBASE_LOG_INFO("Creating table '%s'...", table_name);
  if ((retCode = hb_admin_table_create(admin, NULL, table_name, HCD, 2)) ==
0) {
    HBASE_LOG_INFO("Table '%s' created, verifying if enabled.", table_name);
    retCode = hb_admin_table_enabled(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Table '%s' is %senabled, result %d.", table_name, retCode?"not
":"");
    retCode = hb_admin_table_disable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to disable table '%s', result %d.", table_name);
    retCode = hb_admin_table_disable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to disable table '%s' again, result %d.", table_name);
    retCode = hb_admin_table_enable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to enable table '%s', result %d.", table_name);
    retCode = hb_admin_table_enable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to enable table '%s' again, result %d.", table_name);
  }
  hb_coldesc_destroy(HCD[0]);
  hb_coldesc_destroy(HCD[1]);

cleanup:
  if (admin) {
    hb_admin_destroy(admin, NULL, NULL);
  }
  return retCode;
}
```

Code to call the ensureTable function

```
if ((retCode = ensureTable(connection, table_name)) != 0) {
  HBASE_LOG_ERROR("Failed to ensure table %s : errorCode = %d", table_name,
retCode);
  goto cleanup;
}
```

Create a client

API used

`hb_client_create()`: Initializes a handle to `hb_client_t` object that can be passed to other APIs. You need to use this method only once per cluster. The returned handle is thread-safe. This API is defined in the `client.h` header file.

Code

```
if ((retCode = hb_client_create(connection, &client)) != 0) {
  HBASE_LOG_ERROR("Could not connect to HBase cluster : errorCode = %d.",
retCode);
  goto cleanup;
}
```

Asynchronously put ten rows of one cell each

APIs used in this operation

The first 6 APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the name of the table for the put operation.
- `hb_mutation_set_bufferable()`: Sets whether or not the RPC call for the put operation can be buffered on the client side.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

The last API is defined in the header file `client.h`:

- `hb_client_flush()`: Flushes any buffered client-side write operations to the server. The callback is invoked after everything that was buffered at the time of the call is flushed. Invocation of the callback is a guarantee that all outstanding RPC calls are complete.

Sequence of steps in this code extract

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Set whether or not the RPC call for the put operation can be buffered on the client side.
5. Create cell data.
6. Create a cell.
7. Add the cell to the row.

last-updated: Apr 11, 2022

8. Queue the put.
9. After following the steps above 10 times, flush the puts to the server.
10. Wait for the RPC calls to complete.

Code

```
// let's send a batch of 10 puts with single cell asynchronously
outstanding_puts_count += num_puts;
for (int i = 0; i < num_puts; ++i) {
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key   = bytebuffer_printf("%s%02d", rowkey_prefix, i);
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SKIP_WAL);
  hb_mutation_set_bufferable(put, false);

  cell_data_t *cell_data = new_cell_data();
  row_data->first_cell = cell_data;
  cell_data->value = bytebuffer_printf("%s%02d", value_prefix, i);

  hb_cell_t *cell = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell_data->hb_cell = cell;

  cell->row = row_data->key->buffer;
  cell->row_len = row_data->key->length;
  cell->family = FAMILIES[rand() % 2];
  cell->family_len = 1;
  cell->qualifier = column_a->buffer;
  cell->qualifier_len = column_a->length;
  cell->value = cell_data->value->buffer;
  cell->value_len = cell_data->value->length;
  cell->ts = HBASE_LATEST_TIMESTAMP;

  hb_put_add_cell(put, cell);
  HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                 cell->row_len, cell->row);
  hb_mutation_send(client, put, put_callback, row_data);
}
hb_client_flush(client, client_flush_callback, NULL);
wait_for_flush();

wait_for_puts(); // outside the loop, wait for 10 puts to complete
```

Asynchronously put two cells in a single row

APIs used

These APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the first cell.
7. Add the first cell to the row.
8. Create cell data for the second cell.
9. Create the second cell.
10. Add the data to the second cell.
11. Add the second cell to the row.
12. Queue the put.
13. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

`wait_for_puts()` without `hb_client_flush()`: Waits for all outstanding put requests to be flushed. If hb_client_flush() is not called before wait_for_puts(), it can take up to three seconds for outstanding put requests to be flushed.

Code

```
// now, let's put two cells in a single row
outstanding_puts_count++;
{
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key = bytebuffer_printf("row_with_two_cells");
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

  // first cell
  cell_data_t *cell1_data = new_cell_data();
  row_data->first_cell = cell1_data;
  cell1_data->value = bytebuffer_printf("cell1_value_v1");

  hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell1_data->hb_cell = cell1;

  cell1->row = row_data->key->buffer;
  cell1->row_len = row_data->key->length;
  cell1->family = FAMILIES[0];
  cell1->family_len = 1;
  cell1->qualifier = column_a->buffer;
  cell1->qualifier_len = column_a->length;
  cell1->value = cell1_data->value->buffer;
  cell1->value_len = cell1_data->value->length;
  cell1->ts = 1391111111111L;
  hb_put_add_cell(put, cell1);
```

last-updated: Apr 11, 2022

```
    // second cell
    cell_data_t *cell2_data = new_cell_data();
    cell1_data->next_cell = cell2_data;
    cell2_data->value = bytebuffer_printf("cell2_value_v1");

    hb_cell_t *cell2 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell2_data->hb_cell = cell2;

    cell2->row = row_data->key->buffer;
    cell2->row_len = row_data->key->length;
    cell2->family = FAMILIES[1];
    cell2->family_len = 1;
    cell2->qualifier = column_b->buffer;
    cell2->qualifier_len = column_b->length;
    cell2->value = cell2_data->value->buffer;
    cell2->value_len = cell2_data->value->length;
    cell2->ts = 1391111111111L;
    hb_put_add_cell(put, cell2);

    HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                   cell1->row_len, cell1->row);
    hb_mutation_send(client, put, put_callback, row_data);
    wait_for_puts();
  }
```

Asynchronously put a second version in one column of one row

APIs used

These APIs are defined in the header file mutations.h:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the cell, using a later timestamp than in the previous operation.
7. Add the first cell to the row.
8. Queue the put.

9. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

Code

```
  // now, let's put second version in one column
  outstanding_puts_count++;
  {
    row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
    row_data->key = bytebuffer_printf("row_with_two_cells");
    hb_put_create(row_data->key->buffer, row_data->key->length, &put);
    hb_mutation_set_table(put, table_name, table_name_len);
    hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

    // first cell
    cell_data_t *cell1_data = new_cell_data();
    row_data->first_cell = cell1_data;
    cell1_data->value = bytebuffer_printf("cell1_value_v2");

    hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell1_data->hb_cell = cell1;

    cell1->row = row_data->key->buffer;
    cell1->row_len = row_data->key->length;
    cell1->family = FAMILIES[0];
    cell1->family_len = 1;
    cell1->qualifier = column_a->buffer;
    cell1->qualifier_len = column_a->length;
    cell1->value = cell1_data->value->buffer;
    cell1->value_len = cell1_data->value->length;
    cell1->ts = 1392222222222L;
    hb_put_add_cell(put, cell1);

    HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                   cell1->row_len, cell1->row);
    hb_mutation_send(client, put, put_callback, row_data);
    wait_for_puts();
  }
```

Scan the entire table

APIs used

These APIs and more are defined in the header file `scanner.h`:

- `hb_scanner_create()`: Creates a client side row scanner. The returned scanner is not thread safe. No RPC will be invoked until the call to fetch the next set of rows is made. You can set the various attributes of this scanner until that point. @returns 0 on success, non-zero error code in case of failure.
- `hb_scanner_next()`: Request the next set of results from the server. You can set the maximum number of rows returned by this call using hb_scanner_set_num_max_rows().
- `hb_scanner_num_max_rows()`: Sets the maximum number of rows to scan per call to hb_scanner_next().
- `hb_scanner_num_versions()`: Sets the maximum versions of a column to fetch.
- `hb_scanner_set_table()`: Sets the name of the table to scan.

Sequence of steps

1. Create the scanner object.

2. Set the name of the table to scan.
3. Set the number of rows to scan at a time.
4. Set the number of versions to scan.
5. Request the next set of results from the server.
6. `wait_for_scan()`: wait for the rpc call to complete.

Code

```
  // now, scan the entire table
  {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3);  // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
    wait_for_scan();
  }
```

Fetch a row that has two cells

APIs used

- `hb_get_add_column()`: Adds a column family and optionally a column qualifier to an hb_get_t object.
- `hb_get_create()`: Creates an `hb_get_t` object and populates the handle `get_ptr`.
- `hb_get_send()`: Queues the get request. The callback specified by `cb` is called on completion. Any buffers attached to the get object can be reclaimed only after the callback is received.
- `hb_get_set_num_versions()`: Sets maximum number of latest values of each column to be fetched. This API is optional.
- `hb_get_set_table()`: Sets the name of the table to get data from.

Sequence of steps

1. Create a row object named `rowKey`.
2. Create a get object.
3. Specify the column families and optional column qualifiers to get values from.
4. Specify the name of the table.
5. Specify the number of versions of the column values to get.
6. Queue the get request.
7. Wait for the get to complete.

Code

```
// fetch a row with row-key="row_with_two_cells"
{
  bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
  hb_get_t get = NULL;
  hb_get_create(rowKey->buffer, rowKey->length, &get);
  hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
  hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
  hb_get_set_table(get, table_name, table_name_len);
  hb_get_set_num_versions(get, 10); // up to ten versions of each column
  get_done = false;
  hb_get_send(client, get, get_callback, rowKey);
  wait_for_get();
}
```

Delete a specific version of a column in the row that was fetched

APIs used

The APIs that are used are defined in the header file `mutations.h`.

- `hb_delete_add_column()`: Set the column criteria for hb_delete_t object. Set the qualifier to NULL to delete all columns of a family. Only the cells with timestamp less than or equal to the specified timestamp are deleted. Set the timestamp to `INT64_MAX` to delete all versions of the column. This API is optional for deletes.
- `hb_delete_create()`: Creates a structure for delete operation and return its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a delete object for a row with a particular row key.
2. Add a column to the delete object.
3. Specify the name of the table from which to delete the cell version.
4. Queue the delete.
5. Wait three seconds for the delete to be flushed, then wait for the RPC call to complete.

Code

```
// delete a specific version of a column
{
  bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
  hb_delete_t del = NULL;
  hb_delete_create(rowKey->buffer, rowKey->length, &del);
  hb_delete_add_column(del, FAMILIES[0], 1,
      column_a->buffer, column_a->length, 1391111111112L);
  hb_mutation_set_table(del, table_name, table_name_len);
  delete_done = false;
  hb_mutation_send(client, del, delete_callback, rowKey);
```

```
    wait_for_delete();
  }
```

Destroy the client and the connection

APIs used

- `hb_client_destroy()`: Cleans up `hb_client_t` handle and releases any held resources. The callback is called after the connections are closed, but just before the client is freed. This API is defined in the header file `client.h`.
- `hb_connection_destroy()`: Destroys the connection and frees all resources allocated at creation time. This API is defined in the header file `connection.h`.

Sequence of steps

1. Destroy the client.
2. Destroy the connection.

Code

```
  if (client) {
    HBASE_LOG_INFO("Disconnecting client.");
    hb_client_destroy(client, client_disconnection_callback, NULL);
    wait_client_disconnection();
  }
  if (connection) {
    hb_connection_destroy(connection);
  }
```

Building and Launching C Applications

This topic describes basic setup for building and launching C application using the MapR `libMapRClient` C API library

Prerequisites

The MapR Database `libMapRClient` C API library is MapR's extension of the `libhbase` C API library). The libMapRClient header files are in this directory: **/opt/mapr/include/hbase**

- Verify that the `mapr-client` package is installed on the node. The `mapr-client` package must be installed on each node that builds an application. The `libMapRClient` header files are in this directory: `/opt/mapr/include/hbase`.
- Verify that both the `libMapRClient` library and `libjvm` shared libraries are in the application's library search path.

Building Applications

When building applications that use `libMapRClient`, run this command:

```
gcc -o <application_name> <source_file> -I/opt/mapr/include/hbase -L/opt/
mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/include/hbase -L/opt/
mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

Note:

- The compiled libMapRClient is statically linked to the following third-party libraries: Crypto++: libcryptoapp.a (v5.6.2)Protobuf: libprotobuf-lite.a (v2.5.0)
- The `libMapRClient` library has dependencies on `libjvm`, though a JVM is not instantiated. In general, the `libjvm` library is located within the JDK/JRE installation directory.

Launching Applications

Before launching an application, set this value for the environment variable `LD_LIBRARY_PATH`:

```
/opt/mapr/lib:/usr/lib/jvm/java-6-openjdk-amd64/jre/lib/amd64/server
```

If the client is on Windows, append the following directories to the `PATH` environment variable:

- `$MAPR_HOME/lib`
- `$JAVA_HOME/bin/server`

If the application uses the `hb_connection_create_as_user` API for impersonation, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true`.

What To Do Next

Launch the application!

HBase Java Filters Support
The hb_get_set_filter() and hb_scanner_set_filter() C APIs are used to filter the results of GET and SCAN operations. These APIs are in the **get.h** and **scanner.h** header files.

They both take filters that are passed as strings, as well as the length of these strings. MapR Database parses the strings to construct filters.

Their signatures are:

```
int32_t hb_get_set_filter(hb_get_t get, const byte_t *filter, const int32_t
filterLen);
int32_t hb_scanner_set_filter(hb_scanner_t scanner, const byte_t *filter,
const int32_t filterLen);
```

For examples, see Filtering GET Operation Results Example on page 2456 and Filtering SCAN Operation Results Example on page 2455.

Filter Format and Arguments
Filters are specified in the Thrift Filter Language and are in this format: `FilterName (argument, argument,... , argument)`. Arguments that represent strings are enclosed in single quotation marks (‘). Arguments that represent booleans, integers, or comparison operators (<, <=, =, !=, >, >=) are not enclosed in single quotation marks.

Binary Operators

You can combine filters by using the binary operators `AND` and `OR`. For example, `PrefixFilter ('Row') AND PageFilter (1) AND FirstKeyOnlyFilter ()` returns all key-value pairs that match the following conditions:

- The row containing the key-value must start with the prefix "Row".
- The key-value must be located in the first row of the table.
- The key-value must be the first key-value pair in the row.

For another example, `(RowFilter (=, 'binary:Row 1') AND TimeStampsFilter (74689, 89734)) OR ColumnRangeFilter ('abc', true, 'xyz', false))` returns all key-value pairs that

Match both of the following conditions:

- The key-value is in a row for which the row key is "Row 1".
- The key-value has a timestamp of either 74689 or 89734.

Or match this condition:

- The key-value is located in a column that is lexicographically greater than or equal to "abc" and less than "xyz".

Unary Operators

You can also use the following unary operators with filters:

- SKIP

  For a particular row, if any of the key-values don't pass the filter condition, the entire row is skipped. For example, `SKIP ValueFilter (0)` omits rows in which any values are not 0.

- WHILE

  Rows are tested in order against the filter condition. Rows that meed the condition are included in the result set. When a row fails to meet the condition, filter processing stops and no more rows are tested.

Evaluation of Filters

When filters are combined with the binary operators, unary operators, or both, they are evaluated according to these rules:

1. First, evaluate the contents of parentheses.
2. Next, evaluate filters that use unary operators. Both SKIP and WHILE operators have the same precedence.
3. Finally, evaluate filters that use the binary operators. AND has higher precedence than OR.

For example, in a filter of the form `Filter1 AND Filter2 OR Filter`, `Filter1 AND Filter2` is evaluated and the result is *X*. Then, *X* `OR Filter3` is evaluated.

For another example, a filter of the form `Filter1 AND SKIP Filter2 OR Filter3` is evaluated in these steps:

1. Evaluate `SKIP Filter2` with the result being *X*.
2. Evaluate `Filter1 AND` *X* with the result being *Y*.
3. Evaluate *Y* `OR Filter3`.

Compare Operators and Comparators
This topic describesthe compare operators and comparators for comparison filters.

The comparison filters DependentColumnFilter, FamilyFilter, QualifierFilter, RowFilter, and ValueFilter use the following syntax:

```
filter(<compareOperator>, <comparatorType:Value>)
```

Compare Operators

The following compare operators are supported: <,<=, =, !=, >, >=

Comparators

There are four comparators:

Comparator	Description
BinaryComparator	This comparator lexicographically compares against the specified byte array . Values are byte arrays. For example, `binary:abc` matches values that are lexicographically greater than "abc".
BinaryPrefixComparator	This comparator lexicographically compares against a specified byte array. It only compares up to the length of this byte array. Values are byte arrays. For example, `binaryprefix:abc` matches values in which the first 3 characters are lexicographically equal to "abc"
RegexStringComparator	This comparator compares against the specified byte array using the given regular expression. You can use only the = and != compare operators with this comparator. Values are regular expressions. For example, `regexstring:ab*yz` matches values that begin with "ab" and end with "yz".
SubStringComparator	This comparator tests whether the given substring appears in a specified byte array. The comparison is case insensitive. You can use only the = and != compare operators with this comparator. Values are strings. For example, `substring:abc123` matches values that contains the substring "abc123".

Supported Filters

Filter	Format	Description
ColumnCountGetFilter	`ColumnCountGetFilter(`*x*`)`	Returns the first x columns in a row. Used for GET operations.

Filter	Format	Description
ColumnPaginationFilter	`ColumnPaginationFilter(x,y)`	Returns the first x columns after the number y of columns that is specified for the offset.
ColumnPrefixFilter	`ColumnPrefixFilter('prefix')`	Returns only those key-values in columns that have names that start with the specified prefix. The column prefix must be of the form “qualifier”.
ColumnRangeFilter	`ColumnRangFilter('minColumn','maxColumn',boolean,boolean)`	Returns only those key-values that are in columns that have names between minColumn and maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', the filter returns key-values from columns named 'ana', 'bad', but not from columns named 'bed' or'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. This filter also takes two boolean variables to indicate whether to include the minColumn and maxColumn.
DependentColumnFilter	`DependentColumnFilter('family','qualifier')`	Tries to locate the specified column in each row and returns all key-values that have the same timestamp in that column. If a row does not contain the specified column, none of the key-values in that row are returned.
FamilyFilter	`FamilyFilter(compareOperator,'comparator:value')`	Filters by column family. If the comparison returns true, the filter returns all of the key-values in the matching column family.
FirstKeyOnlyFilter	`FirstKeyOnlyFilter()`	Returns the first key-value from each row.
FirstKeyValueMatchingQualifiersFilter	`FirstKeyValueMatchingQualifier('qualifier_1', 'qualifier_2',...'qualifier_n')`	Serially compares each qualifier in a row with the given qualifiers. If the current qualifier matches any of the given qualifiers, the filter stops and includes the current row (up to the current qualifier) in the result set.

Filter	Format	Description
FuzzyRowFilter	`FuzzyRowFilter('rowkey','fuzzy_info')`	Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values: 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key Example: Let's assume row key format is userId_actionId_year_month. Length of userId is fixed and is 4, length of actionId is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" I.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.
InclusiveStopFilter	`InclusiveStopFilter('rowKey')`	Returns all key-values that are in the rows up to and including the specified row that has the specified row key.
KeyOnlyFilter	`KeyOnlyFilter()`	Returns the key component of each key-value.
MultipleColumnPrefixFilter	`MultipleColumnPrefixFilter('prefix_1','prefix_2',...,'prefix_n')`	Returns the key-values from columns that have names that begin with any of the specified prefixes.
PageFilter	`PageFilter(pageSize)`	Returns the number of rows that is equivalent to the specified page size..
PrefixFilter	`PrefixFilter('rowKey_prefix')`	Returns the key-values from a row that has a key which starts with the specified row-key prefix.
QualifierFilter	`QualifierFilter(compareOperator,'comparator:value')`	Filters by column. If the comparison returns true, the filter returns all of the key-values in the matching column.
RandomRowFilter	`RandomRowFilter(probability)`	Filters by probability. For example, RandomRowFilter(0.25) means that there is a 1 in 4 chance that the filter will pick the first row, a 1 in 4 chance that the filter will pick the next row, and so on until all rows in the table have been processed in this way.

last-updated: Apr 11, 2022

Filter	Format	Description
RowFilter	`RowFilter(compareOperator,'comparator:value')`	Filters by row key. If the comparison returns true, the filter returns all of the key-values in the matching row.
SingleColumnValueExcludeFilter	`SingleColumnValueExcludeFilter('columnFamily','qualifier', compareOperator,'comparator:value')`	This filter takes the same arguments and behaves the same as SingleColumnValueFilter: however, if the column is found and the condition passes, all of the columns of the row will be returned except for the tested column value.
SingleColumnValueFilter	`SingleColumnValueFilter('columnFamily','qualifier', compareOperator,'comparator:value')`	This filter takes a column family, a qualifier, a compare operator and a comparator. If the specified column is not found: all of the columns of that row will be emitted. If the column is found and the comparison with the comparator returns true, all of the columns of the row will be emitted. If the condition fails, the row will not be returned.
SkipFilter	`SKIP filter`	See the description of the SKIP unary operator above .
TimeStampsFilter	`TimeStampsFilter('timestamp_1','timestamp_2',..., 'timestamp_n')`	Returns the key-values that have timestamps that match any of the specified timestamps.
ValueFilter	`ValueFilter(compareOperator,'comparator:value')`	Filters by key-value. If the comparison returns true, the filter returns the matching key-value.
WhileMatchFilter	`WHILE filter`	See the description of the WHILE unary operator above .

Creating Java Apps - Binary Tables

This topics describes the supported Apache HBase Java APIs used for CRUD operations on MapR Database binary tables.

MapR Database supports all of the Apache HBase 1.0 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

Code written for Apache HBase can be easily ported to use MapR Database binary tables.

MapR Database binary tables do not support low-level HBase API calls that are used to manipulate the state of an Apache HBase cluster. HBase API calls that are not supported by MapR Database tables report successful completion to allow legacy code written for Apache HBase to continue executing, but do not perform any actual operations.

Note: For the list of supported HBase v0.98 APIs, refer to the HBase Java API Support on page 2480.

Compiling and Running MapR Database Binary Applications

For applications that use the MapR Database Java API for binary tables, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

last-updated: Apr 11, 2022

Compile and Determine Dependencies

1. Add MapR's maven repository to the list of repositories in your application's `pom.xml`, if it is not there already:

```
<repository>
      <id>mapr-releases</id>
      <url>https://repository.mapr.com/maven/</url>
      <snapshots><enabled>true</enabled></snapshots>
      <releases><enabled>true</enabled></releases>
</repository>
```

2. Add a dependency to the HBase client project:

```
<dependencies>
<dependency>
  <groupId>org.apache.hbase</groupId>
  <artifactId>hbase-client</artifactId>
  <version><version selected from the repository></version>
</dependency>
<dependencies>
```

Note:

- The hbase-client version mentioned above is an example. The actual version that your application requires is based on the current EEP and MapR version that you are running.The file versions are listed in the following location: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-client/ Ensure that the version tags include reference to m7-<maprversion>. Otherwise, your applications will not be able to access MapR Database binary tables.
- If your application uses both the MapR Database JSON and MapR Database Binary APIs, you may encounter a conflict in the netty library used by each API. To avoid this, exclude the netty library from your `hbase-client` dependency as follows:

```
<dependency>
   <groupId>org.apache.hbase</groupId>
   <artifactId>hbase-client</artifactId>
   <version><version selected from the repository></version>
   <exclusions>
     <exclusion>
        <artifactId>netty-all</artifactId>
           <groupId>io.netty</groupId>
     </exclusion>
   </exclusions>
</dependency>
```

3. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Running Applications

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that do the following instead:

1. Compile the Java application without including dependencies

2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your MapR cluster expects, this can result in failures. The failures differ depending on the version of MapR you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 2367.

If the cluster is secure, the node must also have a mapr ticket configured for the user that runs the application.

You can use the following command to launch MapR Database binary applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Note: The classpath should include items that are part of the 'hbase classpath' script plus any other required dependencies.

HBase Java API Support
This topic describes the methods in the Apache HBase Java API library that are supported for MapR Database tables.
Admin Method Support
This topic lists the methods that the MapR Database supports in the HBase interface `Admin`.

The MapR Database tables support the following HBase methods, except where noted.

`abort(String why, Throwable e)`	*Modifier and Type*: `void` *Purpose*: Aborts the server or client *Supported*: No
`addColumn(TableName tableName, HColumnDescriptor column)`	*Modifier and Type*: `void` *Purpose*: Adds a column to an existing table *Supported*: Yes
`assign(byte[] regionName)`	*Modifier and Type*: `void` *Purpose*: Assigns a region *Supported*: No
`balancer()`	*Modifier and Type*: `boolean` *Purpose*: Invokes the balancer **Note:** The MapR Database does not require balancing. Therefore, the method is ignored. *Supported*: No
`cloneSnapshot(byte[] snapshotName, TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Creates a new table by cloning the snapshot content *Supported*: No
`cloneSnapshot(String snapshotName, TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Creates a new table by cloning the snapshot content *Supported*: No
`close()`	*Modifier and Type*: `void` *Purpose*: Releases any resources held *Supported*: Yes

closeRegion(byte[] regionname, String serverName)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegion(ServerName sn, HRegionInfo hri)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegion(String regionname, String serverName)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegionWithEncodedRegionName(String encodedRegionName, String serverName)	*Modifier and Type*: `boolean` *Purpose*: For expert administrators. *Supported*: No
compact(TableName tableName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a table *Supported*: No
compact(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Compacts a table *Supported*: No
compactRegion(byte[] regionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a region *Supported*: No
compactRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Compacts an individual region *Supported*: No
compactRegionServer(ServerName sn, boolean major)	*Modifier and Type*: `void` *Purpose*: Compacts all regions on the region server *Supported*: No
coprocessorService()	*Modifier and Type*: `CoprocessorRpcChannel` *Purpose*: Creates and returns a RpcChannel instance connected to the active master *Supported*: No
coprocessorService(ServerName sn)	*Modifier and Type*: `CoprocessorRpcChannel` *Purpose*: Creates and returns a RpcChannel instance connected to the active master *Supported*: No
createNamespace(NamespaceDescriptor descriptor)	*Modifier and Type*: `void` *Purpose*: Creates a new namespace *Supported*: No
createTable(HTableDescriptor desc, byte[] startKey, byte[] endKey, int numRegions)	*Modifier and Type*: `void` *Purpose*: Creates a new table with the specified number of regions *Supported*: Yes
createTable(HTableDescriptor desc, byte[][] splitKeys)	*Modifier and Type*: `void`

last-updated: Apr 11, 2022

	Purpose: Creates a new table with an initial set of empty regions defined by the specified split keys *Supported*: Yes
`createTable(HTableDescriptor desc)`	*Modifier and Type*: `void` *Purpose*: Creates a new table *Supported*: Yes
`createTableAsync(HTableDescriptor desc, byte[][] splitKeys)`	*Modifier and Type*: `void` *Purpose*: Creates a new table but does not block and wait for it to come online  **Note:** The MapR Database treats this method as synchronous and returns null when the table is created. *Supported*: Yes
`deleteColumn(String tableName, String columnName)`	*Modifier and Type*: `void` *Purpose*: Deletes a column from a table *Supported*: Yes
`deleteColumn(TableName tableName, byte[] columnName)`	*Modifier and Type*: `void` *Purpose*: Deletes a column from a table *Supported*: Yes
`deleteNamespace(String name)`	*Modifier and Type*: `void` *Purpose*: Deletes an existing namespace. *Supported*: No
`deleteSnapshot(byte[] snapshotName)`	*Modifier and Type*: `void` *Purpose*: Deletes an existing snapshot *Supported*: No
`deleteSnapshot(String snapshotName)`	*Modifier and Type*: `void` *Purpose*: Deletes an existing snapshot *Supported*: No
`deleteSnapshots(Pattern pattern)`	*Modifier and Type*: `void` *Purpose*: Deletes existing snapshots whose names match the specified pattern *Supported*: No
`deleteSnapshots(String regex)`	*Modifier and Type*: `void` *Purpose*: Deletes existing snapshots whose names match the specified pattern *Supported*: No
`deleteTable(String tableName)`	*Modifier and Type*: `void` *Purpose*: Deletes a table *Supported*: Yes
`deleteTable(byte[] tableName)`	*Modifier and Type*: `void` *Purpose*: Deletes a table *Supported*: Yes
`deleteTable(TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Deletes a table

	Supported: Yes
deleteTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Delete tables that match the passed-in pattern, and waits on completion *Supported*: Yes
deleteTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Delete tables that match the passed-in regular expression, and waits on completion *Supported*: Yes
disableTable (String tableName)	*Modifier and Type*: `void` *Purpose*: Disables table, and waits for completion **Note:** The MapR Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation. *Supported*: Yes
disableTable(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Disables table, and waits for completion **Note:** The MapR Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation. *Supported*: Yes
disableTableAsync (String tableName)	*Modifier and Type*: `void` *Purpose*: Disables the table, but does not block and wait for it be completely disabled *Supported*: Yes
disableTableAsync(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Disables the table, but does not block and wait for it be completely disabled *Supported*: Yes
disableTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Disables tables that match the passed-in pattern, and waits on completion *Supported*: Yes
disableTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Disable tables that match the passed-in regular expression, and waits on completion *Supported*: Yes
enableCatalogJanitor(boolean enable)	*Modifier and Type*: `boolean` *Purpose*: Enables/Disables the catalog janitor *Supported*: No
enableTable(String tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table

last-updated: Apr 11, 2022

	Note: The MapR Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTable(bye[] tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **Note:** The MapR Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTable(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **Note:** The MapR Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTableAsync (String tableName)	*Modifier and Type*: `void` *Purpose*: Enables the table, but does not block and wait for it be completely enabled *Supported*: Yes
enableTableAsync(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Enables the table, but does not block and wait for it be completely enabled *Supported*: Yes
enableTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Enable tables that match the passed-in pattern, and waits on completion *Supported*: Yes
enableTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Enable tables that match the passed-in regular expression. and waits on completion *Supported*: Yes
execProcedure(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `void` *Purpose*: Executes a distributed procedure on a cluster *Supported*: No
execProcedureWithRet(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `>byte[]` *Purpose*: Executes a distributed procedure on a cluster. *Supported*: No
flush(TableName tableName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table

	Supported: Yes
flush(byte[] tableNameOrRegionName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flush(String tableNameOrRegionName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flushRegion(byte[] regionName)	*Modifier and Type*: `>void` *Purpose*: Flushes an individual region *Supported*: Yes
getAlterStatus(byte[] tableName)	*Modifier and Type*: `Pair<Integer,Integer>` *Purpose*: Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation  **Note:** The MapR Database always returns (0,0). *Supported*: No
getAlterStatus(TableName tableName)	*Modifier and Type*: `Pair<Integer,Integer>` *Purpose*: Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation  **Note:** The MapR Database always returns (0,0). *Supported*: No
getClusterStatus()	*Modifier and Type*: `ClusterStatus` *Purpose*: Gets the status of the cluster *Supported*: No
getCompactionState(String tableNameOrRegionName)	*Modifier and Type*: `CompactionState` *Purpose*: Get the current compaction state of a table *Supported*: No
getCompactionState(TableName tableName)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState` *Purpose*: Gets the current compaction state of a table *Supported*: No
getCompactionStateForRegion(byte[] regionName)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState` *Purpose*: Gets the current compaction state of a region *Supported*: No
getConfiguration()	*Modifier and Type*: `org.apache.hadoop.conf.Configuration` *Purpose*: Gets the configuration used by the instance *Supported*: Yes

last-updated: Apr 11, 2022

getConnection()	*Modifier and Type*: `Connection` *Purpose*: Gets the connection used by this object *Supported*: Yes
getMasterCoprocessors()	*Modifier and Type*: `String[]` *Purpose*: Helper delegate to getClusterStatus().getMasterCoprocessors() *Supported*: No
getMasterInfoPort()	*Modifier and Type*: `int` *Purpose*: Gets the information port of the current master, if one is available *Supported*: No
getNamespaceDescriptor(String name)	*Modifier and Type*: `NamespaceDescriptor` *Purpose*: Gets a namespace descriptor by name *Supported*: No
getOnlineRegions(ServerName sn)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets all the online regions on a region server *Supported*: No
getOperationTimeout()	*Modifier and Type*: `int` *Purpose*: The MapR Database never uses the timeout value **Note:** If you use the v1.1 API with the MapR Database, the method is ignored. *Supported*: No
getQuotaRetriever(QuotaFilter filter)	*Modifier and Type*: `QuotaRetriever` *Purpose*: Returns a QuotaRetriever to list the quotas based on the filter *Supported*: No
getTableDescriptor (byte[] tableName)	*Modifier and Type*: `HTableDescriptor` *Purpose*: Gets the table descriptor *Supported*: Yes
getTableDescriptor(TableName tableName)	*Modifier and Type*: `HTableDescriptor` *Purpose*: Gets the table descriptor *Supported*: Yes
getTableDescriptors(List<String> names)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets table descriptors *Supported*: Yes
getTableDescriptorsByTableName(List<TableName> tableNames)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets table descriptors *Supported*: Yes
getTableRegions (byte[] tableName)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets the regions of a given table *Supported*: Yes
getTableRegions(TableName tableName)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets the regions of a given table

last-updated: Apr 11, 2022

	Supported: Yes
isAborted()	*Modifier and Type*: `boolean` *Purpose*: Queries on the catalog janitor state. The MapR Database always returns false. *Supported*: No
isCatalogJanitorEnabled()	*Modifier and Type*: `boolean` *Purpose*: Queries on the catalog janitor state. The MapR Database always returns false. *Supported*: No
isProcedureFinished(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `boolean` *Purpose*: Checks the current state of the specified procedure *Supported*: No
isSnapshotFinished(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `boolean` *Purpose*: Checks the current state of the passed snapshot *Supported*: No
isTableAvailable(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if all regions of the table are available *Supported*: Yes
isTableAvailable(TableName tableName, byte[][] splitKeys)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table has been created with the specified number of splitkeys that was used while creating the given table *Supported*: No
isTableAvailable(TableName tableName)>	*Modifier and Type*: `boolean` *Purpose*: Returns true if all regions of the table are available *Supported*: Yes
isTableDisabled(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is offline  **Note:** Although the MapR Database supports this method, it only checks the flag. *Supported*: Yes
isTableDisabled(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is offline  **Note:** Although the MapR Database supports this method, it only checks the flag. *Supported*: Yes
isTableEnabled(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is online  **Note:** Although the MapR Database supports this method, it only checks the flag, and does not change the flag.

last-updated: Apr 11, 2022

	Supported: Yes
isTableEnabled(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is online **Note:** Although the MapR Database supports this method, it only checks the flag, and does not change the flag. *Supported*: Yes
listNamespaceDescriptors()	*Modifier and Type*: `NamespaceDescriptor[]` *Purpose*: Lists available namespace descriptors *Supported*: No
listSnapshots()	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists completed snapshots *Supported*: No
listSnapshots(Pattern pattern)	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists all the completed snapshots that match the given pattern *Supported*: No
listSnapshots(String regex)	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists all the completed snapshots that match the given regular expression *Supported*: No
listTableDescriptorsByNamespace(String name)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets the list of table descriptors by namespace *Supported*: No
listTableNames()	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables *Supported*: Yes
listTableNames(Pattern pattern, boolean includeSysTables)	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified pattern *Supported*: Yes
listTableNames(Pattern pattern)	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified pattern *Supported*: Yes
listTableNames(String regex, boolean includeSysTables)	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified regular expression *Supported*: Yes
listTableNames(String regex)	*Modifier and Type*: `TableName[]`

last-updated: Apr 11, 2022

	Purpose: Lists all the names of userspace tables that match the specified regular expression *Supported*: Yes
listTableNamesByNamespace(String name)	*Modifier and Type*: `TableName[]` *Purpose*: Gets the list of table names by namespace *Supported*: Yes
listTables()	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables *Supported*: Yes
listTables(Pattern pattern, boolean includeSysTables)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the tables that match the given pattern.  **Note:** The MapR Database does not have system tables and therefore, the boolean value is ignored. *Supported*: Yes
listTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables matching the given pattern. *Supported*: Yes
listTables(String regex, boolean includeSysTables)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the tables matching the given pattern.  **Note:** The MapR Database does not have system tables and therefore, the boolean value is ignored. *Supported*: Yes
listTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables that match the given regular expression. *Supported*: Yes
majorCompact(byte[] tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region. *Supported*: Deprecated
majorCompact(String tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region. *Supported*: Deprecated
majorCompact(byte[] tableNameOrRegionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a table, or a region *Supported*: Deprecated
majorCompact(String tableNameOrRegionName, String columnFamily)	*Modifier and Type*: `void` *Purpose*: Compact a column family within a table, or a region *Supported*: Deprecated

last-updated: Apr 11, 2022

majorCompactRegion(byte[] regionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a region *Supported*: No
majorCompactRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region *Supported*: No
mergeRegions(byte[] nameOfRegionA, byte[] nameOfRegionB, boolean forcible)	*Modifier and Type*: `void` *Purpose*: Merges two regions *Supported*: No
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	*Modifier and Type*: `void` *Purpose*: Modifies an existing column family on a table *Supported*: Yes
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	*Modifier and Type*: `void` *Purpose*: Modifies an existing column family on a table *Supported*: Yes
modifyNamespace(NamespaceDescriptor descriptor)	*Modifier and Type*: `void` *Purpose*: Modifies an existing namespace *Supported*: No
modifyTable (byte[] tableName, HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table *Supported*: Yes
modifyTable(final String tableName, final HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table *Supported*: Yes
modifyTable(TableName tableName, HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table. This method is the more IRB friendly version. *Supported*: Yes
move(byte[] encodedRegionName, byte[] destServerName)	*Modifier and Type*: `void` *Purpose*: Moves the region to the destination *Supported*: No
offline(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Offlines specified region from master's in-memory state *Supported*: No
restoreSnapshot(byte[] snapshotName, boolean takeFailSafeSnapshot)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(byte[] snapshotName)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No

last-updated: Apr 11, 2022

restoreSnapshot(String snapshotName, boolean takeFailSafeSnapshot)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(String snapshotName)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
rollWALWriter(ServerName serverName)	*Modifier and Type*: `void` *Purpose*: Rolls the log writer. *Supported*: No
runCatalogScan()	*Modifier and Type*: `int` *Purpose*: Requests a scan of the catalog table *Supported*: No
setBalancerRunning(boolean on, boolean synchronous)	*Modifier and Type*: `boolean` *Purpose*: Turns the load balancer on or off **Note:** The MapR Database does not require balancing. Therefore, the method just sets a flag. There is no impact on the MapR table. *Supported*: No
setQuota(QuotaSettings quota)	*Modifier and Type*: `void` *Purpose*: Applies the new quota settings *Supported*: No
shutdown()	*Modifier and Type*: `void` *Purpose*: Shuts down the HBase cluster *Supported*: No
snapshot(byte[] snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Creates a timestamp consistent snapshot for the given table *Supported*: No
snapshot(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `void` *Purpose*: Takes a snapshot, and waits for the server to complete that snapshot (blocking). *Supported*: No
snapshot(String snapshotName, TableName tableName, org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription.Type type)	*Modifier and Type*: `void` *Purpose*: Creates a typed snapshot of the table *Supported*: No
snapshot(String snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Takes a snapshot for the given table *Supported*: No
split(byte[] tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Splits a table

	Note: The tableNameOrRegionName parameter has a different format when used with MapR tables than with Apache HBase tables. With MapR tables, specify both the table path and the FID as a comma-separated list. *Supported*: Yes
split(TableName tableName, byte[] splitPoint)	*Modifier and Type*: `void` *Purpose*: Splits a table. **Note:** The tableNameOrRegionName parameter has a different format when used with MapR tables than with Apache HBase tables. With MapR tables, specify both the table path and the FID as a comma-separated list. *Supported*: No
split(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Splits a table. **Note:** The tableNameOrRegionName parameter has a different format when used with MapR tables than with Apache HBase tables. With MapR tables, specify both the table path and the FID as a comma-separated list. *Supported*: Yes
splitRegion(byte[] regionName, byte[] splitPoint)	*Modifier and Type*: `void` *Purpose*: Splits an individual region. *Supported*: No
splitRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Splits an individual region *Supported*: Yes
stopMaster()	*Modifier and Type*: `void` *Purpose*: Shuts down the current HBase master only *Supported*: No
stopRegionServer(String hostnamePort)	*Modifier and Type*: `void` *Purpose*: Stops the designated region server *Supported*: No
tableExists(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
tableExists(byte[] tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
tableExists(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes

last-updated: Apr 11, 2022

takeSnapshotAsync(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.MasterProtos.SnapshotResponse` *Purpose*: Takes a snapshot without waiting for the server to complete that snapshot (asynchronous). Ensure that you take only a single snapshot at a time, or the results may be undefined. *Supported*: No
truncateTable(TableName tableName, boolean preserveSplits)	*Modifier and Type*: `void` *Purpose*: Truncates a table *Supported*: Yes
unassign(byte[] regionName, boolean force)	*Modifier and Type*: `void` *Purpose*: Unassigns a region from the current hosting region server *Supported*: No
updateConfiguration()	*Modifier and Type*: `void` *Purpose*: Updates the configuration, and triggers an online configuration change on all the region servers *Supported*: No
updateConfiguration(ServerName server)	*Modifier and Type*: `void` *Purpose*: Updates the configuration, and triggers an online configuration change on all the region servers *Supported*: No

BufferedMutator Method Support

This table indicates which methods MapR Database supports in the HBase interface `BufferedMutator`.

The following HBase methods are supported with MapR Database tables, except where noted.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Performs a flush() and releases any resources held.	Yes
`flush()`	void	Executes all the buffered, asynchronous Mutation operations and waits until they are done.	Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of the table that this BufferedMutator writes to.	Yes
`getWriteBuffer()`	long	Get the internal write buffer.	No
`getWriteBufferSize()`	long	Returns the maximum size in bytes of the write buffer for this HTable.	No
`mutate(List<? extends Mutation> mutations)`	void	Send some Mutation objects to the table.	Yes

last-updated: Apr 11, 2022

Method Name	Modifier and Type	Description	Supported?
`mutate(Mutation mutation)`	void	Sends a Mutation to the table.	Yes
`setWriteBufferSize()`	long	Sets the maximum size (in bytes) of the write buffer for this HTable	No

Connection Method Support
This table indicates which methods MapR Database supports in the HBase interface `Connection`.

The following HBase methods are supported with MapR Database tables, except where noted. For full details about this interface, see `Interface Connection`.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Close this connection.	Yes
`getAdmin()`	Admin	Retrieve an Admin implementation to administer an HBase cluster.	Yes
`getBufferedMutator(BufferedMutatorParams params)`	BufferedMutator	Retrieve a BufferedMutator for performing client-side buffering of writes.	Yes
`getBufferedMutator(TableName tableName)`	BufferedMutator		Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Retrieve the Configuration object used by this connection.	Yes
`getRegionLocator(TableName tableName)`	RegionLocator	Retrieve a RegionLocator implementation to inspect region information on a table.	Yes
`getTable(TableName tableName)`	Table	Retrieve a Table implementation for accessing a table.	Yes
`getTable(TableName tableName, ExecutorService pool)`	Table		Yes
`isClosed()`	boolean	Returns whether the connection is closed or not.	Yes

ConnectionFactory Method Support
This table indicates which methods MapR Database supports in the HBase class `ConnectionFactory`.

The following HBase methods are supported with MapR Database tables, except where noted. For full details about this class, see the `ConnectionFactory` class in the Client package..

Method Name	Modifier and Type	Description	Supported?
`createConnection()`	static Connection	Create a new Connection instance using default HBaseConfiguration.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes

Method Name	Modifier and Type	Description	Supported?
`createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool, User user)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, User user)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes

RegionLocator Method Support
This table indicates which methods MapR Database supports in the HBase interface `RegionLocator`.

The following HBase methods are supported with MapR Database tables, except where noted. For full details about this interface, see `Interface RegionLocator` interface in the Client package.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Close this connection.	Yes
`getAllRegionLocations()`	List<HRegionLocation>	Retrieves all of the regions associated with this table.	Yes
`getConfiguration()`	Configuration	Retrieve the Configuration Object used by this RegionLocator.	Yes
`getEndKeys()`	byte[][]	Gets the ending row key for every region in the currently open table.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of this table.	Yes
`getRegionLocation(byte[] row)`	HRegionLocation	Finds the region on which the given row is being served.	Yes
`getRegionLocation(byte[] row, boolean reload)`	HRegionLocation		Yes
`getStartEndKeys()`	Pair<byte[][],byte[][]>	Gets the starting and ending row keys for every region in the currently open table.	Yes
`getStartKeys()`	byte[][]	Gets the starting row key for every region in the currently open table.	Yes

Table Method Support
This table indicates which methods MapR Database supports in the HBase interface `Table`.

The following HBase methods are supported with MapR Database tables, except where noted. For full details about this interface, see `Interface Table` in the Client package.

last-updated: Apr 11, 2022

Method Name	Modifier and Type	Description	Supported?
`append(Append append)`	Result	Appends values to one or more columns within a single row.	Yes
`batch(List<? extends Row> actions)`	Object[]	A batch call on Deletes, Gets, Puts, Increments, Appends and RowMutations.	Deprecated
`batch(List<? extends Row> actions, Object[] results)`	void	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends.	Yes
`batchCallback(List<? extends Row> actions, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	Object[]	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends with a callback.	YesFootnote.
`batchCallback(List<? extends Row> actions, Object[] results, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<R> void	Same as batch(List, Object[]), but with a callback. MapR Database ignores the callback.	YesFootnote.
`batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor methodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<R extends com.google.protobuf.Message> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), all the invocations to the same region server will be batched into one call.	No
`batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor methodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype)`	<R extends com.google.protobuf.Message> Map<byte[],R>		No

[1] Not fully supported. When used with MapR Database, the callback is ignored.
[2] Not fully supported. When used with MapR Database, the durability is ignored.

Method Name	Modifier and Type	Description	Supported?
`checkAndDelete(byte[] row, byte[] family, byte[] qualifier, byte[] value, Delete delete)`	boolean	Atomically checks if a row/family/qualifier value matches the expected value.	Yes
`checkAndDelete(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Delete delete)`	boolean		Yes
`checkAndMutate(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, RowMutations mutation)`	boolean		Yes
`checkAndPut(byte[] row, byte[] family, byte[] qualifier, byte[] value, Put put)`	boolean		Yes
`checkAndPut(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Put put)`	boolean		Yes
`close()`	void	Releases any resources held or pending changes in internal buffers.	Yes
`coprocessorService(byte[] row)`	CoprocessorRpcChannel	Creates and returns a RpcChannel instance connected to the table region containing the specified row.	No

last-updated: Apr 11, 2022

Method Name	Modifier and Type	Description	Supported?
`coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<T extends com.google.protobuf.Service,R> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), and invokes the passed Batch.Call.call(T) method with each Service instance.	No
`coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable)`	<T extends com.google.protobuf.Service,R> Map<byte[],R>		No
`delete(Delete delete)`	void	Deletes the specified cells/row.	Yes
`delete(List<Delete> deletes)`	void	Deletes the specified cells/rows in bulk.	Yes
`exists(Get get)`	boolean	Test for the existence of columns in the table, as specified by the Get.	Yes
`existsAll(List<Get> gets)`	boolean[]	Test for the existence of columns in the table, as specified by the Gets, in batch.	Yes
`get(Get get)`	Result	Extracts certain cells from a given row.	Yes
`get(List<Get> gets)`	Result[]	Extracts certain cells from the given rows, in batch.	Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of this table.	Yes
`getScanner(byte[] family, byte[] qualifier)`	ResultScanner	Gets a scanner on the current table for the given family and qualifier.	Yes
`getScanner(byte[] family)`	ResultScanner	Gets a scanner on the current table for the given family.	Yes
`getScanner(Scan scan)`	ResultScanner	Returns a scanner on the current table as specified by the Scan object.	Yes
`getTableDescriptor()`	HTableDescriptor	Gets the table descriptor for this table.	Yes
`getWriteBufferSize()`	long	Returns the maximum size in bytes of the write buffer for this HTable.	No

last-updated: Apr 11, 2022

Method Name	Modifier and Type	Description	Supported?
`increment(Increment increment)`	Result	Increments one or more columns within a single row.	Yes
`incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount, Durability durability)`	long	Atomically increments a column value.	YesFootnote.
`incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount)`	long	See incrementColumnValue(byte[], byte[], byte[], long, Durability).	Yes
`mutateRow(RowMutations rm)`	void	Performs multiple mutations atomically on a single row.	Yes
`put(List<Put> puts)`	void	Puts some data in the table, in batch.	Yes
`put(Put put)`	void	Puts some data in the table.	Yes
`setWriteBufferSize(long writeBufferSize)`	void	Sets the size of the buffer in bytes.	No

HColumnDescriptor and HTableDescriptor Support
This section describes the supported fields in the HColumnDescriptor and the HTableDescriptor classes.

MapR Database supports all of the methods that are in these classes. However, it supports only a subset of their fields.

HColumnDescriptor Class

Field	Description
BLOCKSIZE	Size of blocks in files stored to the filesytem (hfiles).
BLOOMFILTER	Whether or not to use bloomfilters.
COMPRESSION	Compression type.
IN_MEMORY	Whether to serve from memory or not.
MIN_VERSIONS	Minimum number of versions to keep.
NAME	Name of the column family.
TTL	Time to live of cell contents.
VERSIONS	Number of versions to keep.

HTableDescriptor Class

Field	Description
AUTOSPLIT	Specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the`regionsizemb` parameter. The default value is `true`.

Field	Description
BULKLOAD	Boolean. Specifies whether to perform a full bulk load of the table. The default is `false`. For more information, see Bulk Loading and MapR Tables.

last-updated: Apr 11, 2022

Field	Description
DELETE_TTL	Used for multi-master replication. Normally, delete operations are purged after the affected table cells are updated. Whereas the result of an update is saved in a table until another change overwrites or deletes it, the result of a delete is not saved. In multi-master replication, this difference can lead to tables being unsynchronized. Example Suppose that you have set up multi-master replication between table `customers` in the cluster `sanfrancisco` and table `customers` in the cluster `newyork`. Client applications then make these two changes: **1.** On `/mapr/sanfrancisco/customers`, put row A at 10:00:00 AM. **2.** On `/mapr/newyork/customers`, delete row A at 10:00:01 AM. On `/mapr/sanfrancisco/customers`, the order of operations is: **1.** Put row A with a timestamp of 10:00:00 AM **2.** Delete row A with a timestamp of 10:00:01 AM (This operation is repllicated from `/mapr/newyork/customers`.) On `/mapr/newyork/customers`, the order of operations is: **1.** Delete row A with a timestamp of 10:00:01 AM **2.** Put row A with a timestamp of 10:00:00 AM (This operation is replicated from `/mapr/sanfrancisco/customers`.) Now, though the put happened on `/mapr/sanfrancisco/customers` at 10:00:00 AM, the put reaches `/mapr/newyork/customers` several seconds after that. Suppose that the actual time that the put arrives at `/mapr/newyork/customers` is 10:00:03 AM. To ensure that both tables stay synchronized, `/mapr/newyork/customers` should preserve the delete until after the put is replicated. Then, the delete can be applied after the put. Therefore, the time-to-live for the delete should be at least long enough for the put to arrive at `/mapr/newyork/customers`. In this case, the time-to-live should be at least 3 seconds. In general, the time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours. For example, suppose (to extend the scenario above) that you pause replication during weekdays and resume it on weekends. The put takes place on Monday morning `/mapr/sanfrancisco/customers` at 10:00:00 AM and the delete takes place at `/mapr/newyork/customers` at 10:00:01 AM. Replication does not resume until 12:00:00 AM Saturday morning. Given the volume of operations to be replicated and the potential for network problems, it is possible that these operations will not be replicated until Sunday. In this scenario, a value of 7 days for DELETE_TTL (7 multiplied by 24 hours) should provide sufficient margin.

Field	Description
NAME	Name of the table.

Support for HBase Java Filters Support

MapR Database supports the following Java filters, which work identically to their Apache HBase versions. See the Apache HBase API for more information, specifically, the Apache HBase Filter package.

Filter	Description
`ColumnCountGetFilter`	Simple filter that returns first N columns on row only. This filter was written to test filters in Get and as soon as it gets its quota of columns, `filterAllRemaining()` returns true. This makes this filter unsuitable as a Scan filter.
`ColumnPaginationFilter`	A filter, based on the `ColumnCountGetFilter`, takes two arguments: limit and offset. This filter can be used for row-based indexing, where references to other tables are stored across many columns, in order to efficient lookups and paginated results for end users. Only most recent versions are considered for pagination.
`ColumnPrefixFilter`	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys with columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
`ColumnRangeFilter`	This filter is used for selecting only those keys with columns that are between minColumn to maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', it will pass keys with columns like 'ana', 'bad', but not keys with columns like 'bed', 'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. minColumnInclusive and maxColumnInclusive specify if the ranges are inclusive or not.
`DependentColumnFilter`	A filter for adding inter-column timestamp matching Only cells with a correspondingly timestamped entry in the target column will be retained Not compatible with Scan.setBatch as operations need full rows for correct filtering
`FamilyFilter`	This filter is used to filter based on the column family. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column family portion of a key. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList` . If an already known column family is looked for, use `Get.addFamily(byte[])` directly rather than a filter.

last-updated: Apr 11, 2022

Filter	Description
`FilterList`	Implementation of `Filter` that represents an ordered List of Filters which will be evaluated with a specified boolean operator `FilterList.Operator.MUST_PASS_ALL` (`AND`) or `FilterList.Operator.MUST_PASS_ONE` (`OR`). Since you can use Filter Lists as children of Filter Lists, you can create a hierarchy of filters to be evaluated. `FilterList.Operator.MUST_PASS_ALL` evaluates lazily: evaluation stops as soon as one filter does not include the KeyValue. `FilterList.Operator.MUST_PASS_ONE` evaluates non-lazily: all filters are always evaluated. Defaults to `FilterList.Operator.MUST_PASS_ALL` .
`FirstKeyOnlyFilter`	A filter that will only return the first KV from each row. This filter can be used to more efficiently perform row count operations.
`FirstKeyValueMatchingQualifiersFilter`	The filter looks for the given columns in KeyValue. Once there is a match for any one of the columns, it returns ReturnCode.NEXT_ROW for remaining KeyValues in the row. **Note**: It may emit KVs which do not have the given columns in them, if these KVs happen to occur before a KV which does have a match. Given this caveat, this filter is only useful for special cases like `RowCounter` .
`FuzzyRowFilter`	Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values: • 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match • 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key Example: Let's assume row key format is userId_actionId_year_month. Length of userId is fixed and is 4, length of actionId is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" I.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.
`InclusiveStopFilter`	A Filter that stops after the given row. There is no "RowStopFilter" because the Scan spec allows you to specify a stop row. Use this filter to include the stop row, eg: [A,Z].
`KeyOnlyFilter`	A filter that will only return the key component of each KV (the value will be rewritten as empty). This filter can be used to grab all of the keys without having to also grab the values.

last-updated: Apr 11, 2022

Filter	Description
`MultipleColumnPrefixFilter`	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys will columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
`PageFilter`	Implementation of Filter interface that limits results to a specific page size. It terminates scanning once the number of filter-passed rows is > the given page size. Note that this filter cannot guarantee that the number of results returned to a client are <= page size. This is because the filter is applied separately on different region servers. It does however optimize the scan of individual HRegions by making sure that the page size is never exceeded locally.
`PrefixFilter`	Pass results that have same row prefix.
`QualifierFilter`	This filter is used to filter based on the column qualifier. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column qualifier portion of a key. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList` . If an already known column qualifier is looked for, use `Get.addColumn(byte[], byte[])` directly rather than a filter.
`RandomRowFilter`	A filter that includes rows based on a chance.
`RowFilter`	This filter is used to filter based on the key. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the row, and column qualifier portions of a key. This filter can be wrapped with `WhileMatchFilter` to add more control. Multiple filters can be combined using `FilterList`. If an already known row range needs to be scanned, use `CellScanner` start and stop rows directly rather than a filter.
`SingleColumnValueExcludeFilter`	A `Filter` that checks a single column value, but does not emit the tested column. This will enable a performance boost over `SingleColumnValueFilter` , if the tested column value is not actually needed as input (besides for the filtering itself).

Filter	Description
`SingleColumnValueFilter`	This filter is used to filter cells based on value. It takes a `CompareFilter.CompareOp` operator (equal, greater, not equal, etc), and either a byte [] value or a ByteArrayComparable. If we have a byte [] value then we just do a lexicographic compare. For example, if passed value is 'b' and cell has 'a' and the compare operator is LESS, then we will filter out this cell (return true). If this is not sufficient (eg you want to deserialize a long and then compare it to a fixed long value), then you can pass in your own comparator instead. You must also specify a family and qualifier. Only the value of this column will be tested. When using this filter on a `CellScanner` with specified inputs, the column to be tested should also be added as input (otherwise the filter will regard the column as missing). To prevent the entire row from being emitted if the column is not found on a row, use `setFilterIfMissing(boolean)` . Otherwise, if the column is found, the entire row will be emitted only if the value passes. If the value fails, the row will be filtered out. In order to test values of previous versions (timestamps), set `setLatestVersionOnly(boolean)` to false. The default is true, meaning that only the latest version's value is tested and all previous versions are ignored. To filter based on the value of all scanned columns, use `ValueFilter`.
`SkipFilter`	A wrapper filter that filters an entire row if any of the Cell checks do not pass. For example, if all columns in a row represent weights of different things, with the values being the actual weights, and we want to filter out the entire row if any of its weights are zero. In this case, we want to prevent rows from being emitted if a single key is filtered. Combine this filter with a `ValueFilter`: `scan.setFilter(new SkipFilter(new ValueFilter(CompareOp.NOT_EQUAL, new BinaryComparator(Bytes.toBytes(0))));` Any row which contained a column whose value was 0 will be filtered out (since ValueFilter will not pass that Cell). Without this filter, the other non-zero valued columns in the row would still be emitted.
`TimestampsFilter`	Filter that returns only cells whose timestamp (version) is in the specified list of timestamps (versions). Note: Use of this filter overrides any time range/time stamp options specified using `Get.setTimeRange(long, long)`, `Scan.setTimeRange(long, long)`, or `Scan.setTimeStamp(long)`. See the Apache HBase API, Client package for detailed information.

last-updated: Apr 11, 2022

Filter	Description
`ValueFilter`	This filter is used to filter based on column value. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the cell value. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList`. To test the value of a single qualifier when scanning multiple qualifiers, use `SingleColumnValueFilter`.
`WhileMatchFilter`	A wrapper filter that returns true from `filterAllRemaining()` as soon as the wrapped filters `Filter.filterRowKey(byte[], int, int)`, `Filter.filterKeyValue(org.apache.hadoop.hbase.Cell)`, `Filter.filterRow()` or `Filter.filterAllRemaining()` methods returns true.

HBase Java Regular Expressions Support

This topics defines the subset of Java regular expressions that are supported for MapR Database tables.

Filters used with Scan operations support regular expressions. When you filter scans on MapR Database tables, you can use regular expressions that comprise the Perl-Compatible Regular Expressions library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`.

Characters

Pattern	Description
x	The character x
\\	The backslash character
\0n	The character with octal value 0n (0 <= n <= 7)
\0nn	The character with octal value 0nn (0 <= n <= 7)
\xhh	The character with hexadecimal value 0xhh
\t	The tab character ('\u0009')
\n	The newline (line feed) character ('\u000A')
\r	The carriage-return character ('\u000D')
\f	The form-feed character ('\u000C')
\a	The alert (bell) character ('\u0007')
\e	The escape character ('\u001B')
\cx	The control character corresponding to x

Character Classes

Pattern	Description
[abc]	a, b, or c (simple class)
[Supported Regular Expressions in MapR Tables^abc]	Any character except a, b, or c (negation)
[a-zA-Z]	a through z or A through Z, inclusive (range)

Predefined Character Classes

Pattern	Description
.	Any character (may or may not match line terminators)
\d	A digit: [0-9]
\D	A non-digit: [Supported Regular Expressions in MapR Tables^0-9]
\s	A whitespace character: [\t\n\x0B\f\r]
\S	A non-whitespace character: [Supported Regular Expressions in MapR Tables^\s]
\w	A word character: [a-zA-Z_0-9]
\W	A non-word character: [Supported Regular Expressions in MapR Tables^\w]

Classes for Unicode Blocks and Categories

Pattern	Description
\p{Lu}	An uppercase letter (simple category)
\p{Sc}	A currency symbol

Boundaries

Pattern	Description
^	The beginning of a line
$	The end of a line
\b	A word boundary
\B	A non-word boundary
\A	The beginning of the input
\G	The end of the previous match
\Z	The end of the input but for the final terminator, if any

last-updated: Apr 11, 2022

Pattern	Description
\z	The end of the input

Greedy Quantifiers

Pattern	Description
X?	X, once or not at all
X*	X, zero or more times
X+	X, one or more times
X{n}	X, exactly n times
X{n,}	X, at least n times
X{n,m}	X, at least n but not more than m times

Reluctant Quantifiers

Pattern	Description
X??	X, once or not at all
X*?	X, zero or more times
X+?	X, one or more times
X{n}?	X, exactly n times
X{n,}?	X, at least n times
X{n,m}?	X, at least n but not more than m times

Possessive Quantifiers

Pattern	Description
X?+	X, once or not at all
X*+	X, zero or more times
X++	X, one or more times
X{n}+	X, exactly n times
X{n,}+	X, at least n times
X{n,m}+	X, at least n but not more than m times

Logical Operators

Pattern	Description
XY	X followed by Y
X|Y	Either X or Y
(X)	X, as a capturing group

Back References

Pattern	Description
\n	Whatever the nth capturing group matches

Quotation

Pattern	Description
\	Nothing, but quotes the following character
\Q	Nothing, but quotes all characters until \E
\E	Nothing, but ends quoting started by \Q

Special Constructs

Pattern	Description
(?:X)	X, as a non-capturing group
(?=X)	X, via zero-width positive lookahead
(?!X)	X, via zero-width negative lookahead
(?<=X)	X, via zero-width positive lookbehind
(?<!X)	X, via zero-width negative lookbehind
(?>X)	X, as an independent, non-capturing group

HBase Java Comparators Support

MapR Database supports the following Java filters, which work identically to their Apache HBase versions. See the Apache HBase API for more information, specifically, the Apache HBase Filter package.

Comparator	Description
`>BinaryComparator`	A binary comparator which lexicographically compares against the specified byte array using `Bytes.compareTo(byte[], byte[])`.
`BinaryPrefixComparator`	A comparator which compares against a specified byte array, but only compares up to the length of this byte array. For the rest it is similar to BinaryComparator.

last-updated: Apr 11, 2022

Comparator	Description
`BitComparator`	A bit comparator which performs the specified bitwise operation on each of the bytes with the specified byte array. Then returns whether the result is non-zero.
`NullComparator`	A binary comparator which lexicographically compares against the specified byte array using `Bytes.compareTo(byte[], byte[])`.
`RegexStringComparator`	This comparator is for use with `CompareFilter` implementations, such as `RowFilter` , `QualifierFilter` , and `ValueFilter` , for filtering based on the value of a given column. Use it to test if a given regular expression matches a cell value in the column. Only EQUAL or NOT_EQUAL comparisons are valid with this comparator. For example: `ValueFilter vf = new ValueFilter(CompareOp.EQUAL, new RegexStringComparator(// v4 IP address "(((25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\\.){3,3}" + "(25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?))(\\/[0-9]+)?" + "|" + // v6 IP address "((([\\dA-Fa-f]{1,4}:){7}[\\dA-Fa-f]{1,4})(:([\\d]{1,3}.)" + "{3}[\\d]{1,3})?)(\\/[0-9]+)?"));`
`SubstringComparator`	This comparator is for use with SingleColumnValueFilter, for filtering based on the value of a given column. Use it to test if a given substring appears in a cell value in the column. The comparison is case insensitive. Only EQUAL or NOT_EQUAL tests are valid with this comparator. For example: `SingleColumnValueFilter scvf = new SingleColumnValueFilter("col", CompareOp.EQUAL, new SubstringComparator("substr"));`

Unsupported HBase Java Methods

This topic identifies the HBase Java methods that are not supported for MapR Database tables. Attempts to call any of these methods results in an `UnsupportedOperationException` exception.

Methods for ACLs for cells:

- `Put.setACL(String user, org.apache.hadoop.hbase.security.access.Permission perms)`
- `Append.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`

- `Delete.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`
- `Increment.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`

Methods for cell visibility:

- `Put.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Append.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Delete.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Increment.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`

Methods for time-to-live for cell values:

- `Put.setTTL(long ttl)`
- `Append.setTTL(long ttl)`
- `Delete.setTTL(long ttl)`
- `Increment.setTTL(long ttl)`

Other methods

- `Delete.deleteFamilyVersion(byte[] family, long timestamp)`
- `Scan.setReversed(boolean reversed)`
- `Scan.setBatch()`
- `Scan.setCaching()`
- `Scanner.next(int nbRows)`

Impersonation via HBase REST Gateway

Impersonation enables access to tables via user IDs other than the user that runs the Gateway.

You can enable user impersonation to access MapR Database tables via the HBase REST Gateway. This feature is not supported in earlier combinations of MapR and HBase packages.

Impersonation is only supported if the REST Gateway is running as the mapr user (MAPR_USER).

You can enable impersonation via the Gateway on both non-secure and secure MapR clusters (secured using either MapR SASL or Kerberos). MapR Database does not support gateway impersonation using a Thrift interface.

Note: Impersonation for HBase REST Gateway is enabled by default on secure clusters.

last-updated: Apr 11, 2022

Enabling Impersonation on a Non-Secure Cluster

To enable impersonation on a non-secure cluster, follow these steps:

1. Install the `mapr-hbase` package on a cluster that is running version 4.0.2 or later. This package contains all of the HBase binaries. For installation details, see HBase Client and MapR Database.
2. Enable simple authentication via the REST Gateway by appending the following property to the `hbase-site.xml` file (`/opt/mapr/hbase/hbase<hbase_version>/conf/hbase-site.xml`): The simple authentication protocol is a Hadoop pseudo authenticator that serves as an example and is part of the hadoop-common package.

   ```
   <property>
   <name>hbase.rest.authentication.type</name>
   <value>simple</value>
   </property>
   ```

3. Set the following environment variable to enable impersonation:

   ```
   export MAPR_IMPERSONATION_ENABLED=1
   ```

4. Start the REST Gateway server as the MAPR_USER.

   ```
   /opt/mapr/hbase/hbase<hbase_version>/bin/hbase-daemon.sh start rest -p
   port
   ```

Using Custom Authentication

This section describes how to use Hadoop pseudo authentication for custom authentication.

Editing the `hbase-site.xml` file is the procedure to follow if you want to use Hadoop pseudo authentication. Alternatively, you can write and use your own authenticator to substitute for the "simple" configuration by implementing the Hadoop AuthenticationHandler interface. If you are using custom authentication, place your authenticator jar in the following directory:

```
/opt/mapr/hbase/hbase-<hbase_version>/lib/
```

Then start the REST Gateway.

Mapping to HBase Table Namespaces

This section describes mapping table namespaces between Apache HBase tables and MapR Database binary tables.

The MapR implementations of the HBase Java API and libhbase differentiate between Apache HBase tables and MapR Database tables according to table names. In certain cases, such as migrating code from Apache HBase tables to MapR Database tables, users need to force the API they are using to access a MapR Database table, even though the table name could map to an Apache HBase table. The `hbase.table.namespace.mappings` property allows you to map Apache HBase table names to MapR Database tables. This property is typically set in the configuration file `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml`.

In general, if a table name includes a slash (`/`), the name is assumed to be a path to a MapR Database table, because slash is not a valid character for Apache HBase table names. In the case of "flat" table names without a slash, namespace conflict is possible, and you might need to use table mappings.

Table Mapping Naming Conventions

A table mapping takes the form *name*`:`*map* , where *name* is the table name to redirect and *map* is the modification made to the name. The value in *name* can be a literal string or contain the * wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Mappings and Table Listing Behaviors

When you use the `list` command without specifying a directory, the command's behavior depends on two factors:

- Whether a table mapping exists
- Whether Apache HBase is installed and running

Here are three different scenarios and the resulting `list` command behavior for each.

- There is a table mapping for *, as in `*:/tables`. In this case, the `list` command lists the tables in the mapped directory.
- There is no mapping for *, and Apache HBase is installed and running. In this case, the `list` command lists the HBase tables.
- There is no mapping for *, and Apache HBase is not installed or is not running.
  - For HBase 0.98.12, the shell will try to connect to an HBase cluster but it will return an error instead.
  - For HBase 1.1 or above, if the `mapr.hbase.default.db` property in the hbase-site.xml is set to `hbase`, the list command will return an error stating that HBase is not available. If the `mapr.hbase.default.db` property is set to `maprdb`, list command will list the MapR Database tables under the user's home directory.

Example 1: Map all HBase tables to MapR Database tables in a directory

In this example, any flat table name `foo` is treated as a MapR Database table in the directory `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>*:/tables_dir</value>
        </property>
```

Example 2: Map specific Apache HBase tables to specific MapR Database tables

In this example, the Apache HBase table name `mytable1` is treated as a MapR Database table at `/user/aaa/mytable1`. The Apache Hbase table name `mytable2` is treated as a MapR Database table

last-updated: Apr 11, 2022

at `/user/bbb/mytable2`. All other Apache HBase table names are treated as stock Apache HBase tables.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/</value>
        </property>
```

Example 3: Combination of specific table names and wildcards

Mappings are evaluated in order. In this example, the flat table name `mytable1` is treated as a MapR Database table at `/user/aaa/mytable1`. The flat table name `mytable2` is treated as a MapR Database table at `/user/bbb/mytable2`. Any other flat table name `foo` is treated as a MapR Database table at `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/,*:/tables_dir</value>
        </property>
```

Thread-pool Settings for Performance

The MapR Database C APIs internally have one thread pool per client. Threads work on the async tasks enqueued by a client application. There are two thread-pool parameters that you can modify in the `/opt/mapr/conf/dbclient.conf` file for better application performance.

fs.mapr.pool.threads

This parameter controls the number of connections that a client application makes with MapR Database for append, increment, read, and scan requests. For a higher rate of throughput to MapR Database, you can increase this value. The default value is 10.

fs.mapr.highpri.pool.threads

This parameter controls the number of threads that invoke application-provided callbacks. If an application's callbacks are not lightweight but instead perform complex calculations that require significant processing, increase this value to avoid delays in invoking callbacks. The default value is 2.

Building MapReduce Applications

This section provides information about building and running custom MapReduce application that access MapR Database binary tables.

The steps for building and running custom MapReduce applications that run against MapR Database are the same as the steps for building and running custom MapReduce applications that run against Apache HBase. The steps are documented in the Apache HBase Reference Guide at http://hbase.apache.org/book.html#mapreduce.

However, you must use an HBase JAR file from MapR's Maven repository at https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-server/. The name of the JAR file that you use must contain the version of HBase and the version of MapR that you are using.

For example, if you are using HBase 1.1 and MapR version 5.1, you would use the file `hbase-server-1.1.1-mapr-1602.jar`.

Performing Bulkloads with MapReduce

This section describes custom MapReduce applications used to perform bulkloads for MapR Database binary tables.

You can use the `HFileOutputFormat configureIncrementalLoad()` method for writing custom MapReduce applications to perform bulk loads. Although the name of the method implies that you can use

it only for incremental bulk loads, the method also works for full bulk loads, provided that the `-bulkload`, `BULKLOAD`, or `Bulkload` parameter for a table is set to true, as described in Bulk Loading and MapR Database Tables.

If you have a custom MapReduce applications that does not use `HFileOutputFormat.configureIncrementalLoad()`, simply use the path to the MapR Database table that you want to load. Using `HFileOutputFormat.configureIncrementalLoad()` provides at least two advantages:

This method performs a number of tasks that your application would otherwise need to do explicitly:

1. Inspects the table to configure a total order partitioner
2. Uploads the partitions file to the cluster and adds it to the DistributedCache
3. Sets the number of reduce tasks to match the current number of regions
4. Sets the output key/value class to match `HFileOutputFormat`'s requirements
5. Sets the reducer up to perform the appropriate sorting (either `KeyValueSortReducer` or `PutSortReducer`)

This method turns off Speculative Execution automatically. For details, see the note below.

Warning: Turning off Speculative Execution

Speculative Execution of MapReduce tasks is on by default. For custom applications that load MapR Database binary tables, it is recommended to turn Speculative Execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `HFileOutputFormat.configureIncrementalLoad()`, you do not have to turn off Speculative Execution manually. `HFileOutputFormat.configureIncrementalLoad()` turns it off automatically. Speculative Execution is automatically turned off for MapReduce utilities such as `CopyTable` and `ImportTsv`.

If you are writing a custom MapReduce application that does not use the `HFileOutputFormat configureIncrementalLoad()` method for bulk loading, you must turn off Speculative Execution manually.

Turn off Speculative Execution by setting the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`

If the job is programmatically written, you can turn off Speculative Execution at the code level: `job.setSpeculativeExecution(false);`

Setting for OJAI Applications to Use MapR Client Features

Describes how to set the classpath for OJAI applications to use MapR client features.

When you launch an OJAI application that needs to access MapR client features, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Developing Applications for JSON Tables

As part of its support for JSON tables, MapR Database implements the OJAI API. The OJAI API provides methods for creating, reading, updating, and deleting JSON documents in MapR Database JSON tables. It is available in Java, and starting in EEP 6.0, also available in Node.js, Python, C#, and Go. MapR

Database also provides a MapR Database JSON Client API for managing JSON tables and a MapR Database JSON REST API for performing basic operations using HTTP calls.

The following shows the general flow for developing an OJAI client application that accesses MapR Database JSON tables:

1. Make a connection to MapR Database using the OJAI Connection and Driver interfaces.
2. Request a MapR Database JSON table using the JSON DocumentStore.
3. Specify the table, document, or column family operation.
4. Perform the operation on the table.
5. Return the results.

For additional information about OJAI, refer to the following:

- OJAI wiki page
- OJAI github repository - The README file provides an introduction to OJAI

The MapR Database JSON Client API, implemented in Java, enables you to create, drop, and alter MapR Database JSON tables and column families.

You can also use HTTP calls to create, delete, and query MapR Database JSON tables Using the MapR Database JSON REST API on page 2696.

API Documentation

The following are links to the detailed API pages:

- Java OJAI Client API
- Node.js OJAI Client API
- Python OJAI Client API
- C# OJAI Client API
- Go OJAI Client API
- MapR Database JSON Client API

Note: Beginning with MapR version 6.0, the MapR Database `Table` interface in the MapR Database JSON Client API is deprecated and replaced by the `DocumentStore` interface in the OJAI API.

Sandbox Tutorial for JSON

This section provides a tutorial that will help you build a Java application using the MapR Database JSON Java API library.

This tutorial is an implementation of the Open JSON Application Interface (OJAI) API library. Basic information about using the MapR Database Shell (JSON Tables) on page 5286 utility for JSON tables is also included in this document.

About OJAI

The MapR Database JSON Java API library leverages MapR Database support for OJAI in many areas, including:

- Tables

- Sub-documents
- Efficient access to data
- Large document support
- Security

Key features of the API library include:

- APIs for manipulating JSON documents
- Extensions to the Hadoop ecosystem:
  - Efficient parsing of large files
  - MapReduce integration

JSON Support

MapR Database, in addition to its support of the key-value model (column family), now offers a Document Model. This means that applications can use a JSON document to represent data. JSON is built on two structures:

- A collection of name/value pairs. In various languages, this is realized as an object, record, struct, dictionary, hash table, keyed list, or associative array.
- An ordered list of values. In most languages, this is realized as an array, vector, list, or sequence.

A document looks like this:

```
{
    "_id" : "001",
    "first_name" : "John",
    "last_name" : "Doe",
    "age" : 45,
    "email" : "jd@mydoc.com",
    "interests" : ["sports", "movies"],
    "address" : {
        "street" : "1015 Main Street",
        "city" : "San Jose",
        "state" : "CA",
        "zip" : "95106"
    }
}
```

MapR Database stores the documents in tables. An interesting aspect of MapR Database JSON is that inside a table, documents can have a different structure.

Documents inside MapR Database must have a unique identifier stored in the `_id` field.

MapR Database does not store the documents as a whole in a single location. Instead, MapR Database creates fields for each attribute and nested documents/attributes. This allows MapR Database to access the information very efficiently. When you read, for example using projection, or when you edit a document, only the necessary fields will be modified. MapR Database can store very large documents, for example, multi-GB documents, if the application requires it.

Prerequisites

- Download MapR Sandbox (Version 5.1)
- Configure OJAI in your Maven project.

- Sample Projects
  - OJAI 101
  - REST API & AngularJS

Installation

Follow these steps to install and configure MapR Database.

Install MapR Database

The MapR Sandbox is available as a virtual machine (VM) so the installation is straightforward.

The VM is configured to use a host-only network. Check that you have a host-only network configured in your environment.

Add the IP address of the VM to your `/etc/hosts` file. On Windows:

```
Windows\System32\drivers\etc\hosts
```

In the `/etc/hosts` file, use the MapR Database machine name `maprdemo`.

The VM is a CentOS Linux. You can connect to it using SSH:

```
# password is mapr
ssh mapr@maprdemo
```

Set MAPR_HOME on Your Host

On your host Windows, Mac OSX, or Linux machine where you will write and run your Java applications, follow these steps:

1. Create the following directory structure:

   ```
   /opt/mapr/conf  (for Linux and OSX)
   C:\opt\mapr\conf (for Windows)
   ```

2. If you have a MapR client installed on your machine (existing `/opt/mapr` folder), use it; otherwise, create a new folder. Use an arbitrary name for the folder. For example:`/opt/mapr_51`
3. Create a file in this folder named `mapr-clusters.conf`.
4. Add the following line to this file:

   ```
   demo.mapr.com maprdemo:7222
   ```

   Note: `maprdemo` is the host name or IP address of the VM where the MapR Sandbox is running.

Java Library

In the sample application, you will see the entries required in your Maven `pom.xml` file:

```
<repositories>
    <repository>
        <id>mapr-releases</id>
        <url>https://repository.mapr.com/maven/</url>
        <snapshots><enabled>true</enabled></snapshots>
        <releases><enabled>true</enabled></releases>
    </repository>

</repositories>
```

```
<dependencies>
  <dependency>
    <groupId>com.mapr.db</groupId>
    <artifactId>maprdb</artifactId>
    <version>5.1.0-mapr</version>
  </dependency>
</dependencies>
```

Build Your Java Application

Follow the instructions in this section to build a Java application that uses OJAI and accesses MapR Database JSON tables.

1. Prepare the Directory Structure

This application uses the JSON tables that are mapped to the filesystem and uses the POSIX permission model (read/write for users and groups), and more. In this tutorial we do not use any advanced security features. To read more about security, see Performing File System Operations on MapR Database Tables on page 1041.

A particular directory structure is needed on the VM for this application. Change the permissions for the `apps` directory, and add a `blog` folder (used by the Java REST Sample application).

```
ssh mapr@maprdemo
cd /mapr/demo.mapr.com/
ls -la
chmod 777 apps
mkdir apps/blog
chmod 777 apps/blog
```

2. MapR Database and Java: Overview

The OJAI 101 repository contains the full application that shows the core operations of MapR Database and OJAI.

Before running any Java application, you have to set the library path to point to the MapR client library. For example:

```
-Dmapr.home.dir=/opt/mapr
```

If you used a different name for the folder in `opt`, use that name.

Code Snippets

Create a table:

```
Table table = MapRDB.createTable("/apps/user_profiles");
```

Create an JSON document (JSON):

```
Document doc = MapRDB.newDocument()
                          .set("firstName", "John")
                          .set("lastName", "Doe")
                          .set("age", 50);
```

This document is very simple, but you can use the API to create any valid JSON document, including nested documents and arrays. The JSON document looks like this:

```
{
  "firstName" : "John",
```

last-updated: Apr 11, 2022

```
  "lastName" : "Doe",
  "age" : 50
}
```

You can now insert the document into MapR Database using the `insert()` method. You just need to set the Document ID (or rowkey):

```
table.insert("jdoe", doc);
```

The Document ID is unique within a table. If you try to insert a document using an existing key, a `DocumentExistsException` will be raised. You can also use the `insertOrReplace` method; with this method, if the document with the ID exists, it will be replaced.

You can also retrieve the document with a simple get operation:

```
Document doc2  = table.findById("jdoe");
System.out.println(  doc2  );
System.out.println(
       doc2.getString("firstName") +":"+ doc2.getInt("age")
);
```

To update a document, you have to do the following operations:

```
DocumentMutation mutation = MapRDB.newMutation()
                                  .increment("age", 1)
                                  .set("interests",
Arrays.asList("sports", "movies"));
table.update("jdoe", mutation);
```

As you can see, not only can you update an existing attribute, such as the age increment, but you can also modify the structure of the document. For example, we added the `interests` field to the document.

We won't go into all the capabilities of the database, but let's take a look at a simple query. For example, return all the profiles with an age greater than 50:

```
QueryCondition condition = MapRDB.newCondition()
                                 .is("age", Condition.Op.GREATER, 50)
                                 .build();

DocumentStream rs = table.find(condition);
Iterator<Document> itrs =  rs.iterator();
while (itrs.hasNext()) {
    System.out.println( itrs.next() );
}
rs.close();
```

Finally let's delete a document:

```
table.delete("jdoe");
```

Let's also delete the table:

```
MapRDB.deleteTable("/apps/user_profiles");
```

You have now learned the basics of OJAI and you can see how to store, retrieve, and delete a document from a MapR Database table.

You can now start building your own application or look at the different sample applications available.

3. MapR Database and Java: Sample Application

Clone the following git repository: https://github.com/mapr-demos/maprdb-ojai-101

Look at the com.mapr.db.samples.basic.Ex01SimpleCRUD.run() method.

This method calls three other methods:

- `createDocuments()`, which shows different ways of creating documents
- `queryDocuments()`, which shows different ways of querying documents
- `updateDocuments()`, which shows different ways of updating documents

Execute the following Maven commands:

```
mvn clean package
mvn exec:java -Dexec.mainClass="com.mapr.db.samples.basic.Ex01SimpleCRUD"
```

You can use the MapR Database Shell described at the end of this document to query JSON documents, including the one created by running the sample application.

4. MapR Database and Java: REST API Sample

Clone the following git repository: https://github.com/mapr-demos/maprdb-ojai-rest-sample

This web application exposes a MapR Database document using a REST API (using JAX-RS and Swagger).

Execute the following Maven commands:

```
mvn clean package
mvn exec:java -Dexec.mainClass="com.mapr.db.samples.rest.Main"
```

Look at com.mapr.db.samples.rest.Main.

Start the application and go to: `http://localhost:8080`

Using the mapr dbshell Utility

This section assumes that you performed the following tasks described earlier in this document:

- Downloaded the MapR 5.1 Sandbox.
- Installed the VM.
- Connected to the MapR host using a terminal.

Assuming you are connected to your MapR host using a terminal, you can run the following command to launch the shell:

```
mapr dbshell
```

You can list all the commands of the shell by using `help`. Use the shell as shown in the following examples.

Create a table:

```
create /apps/my_users
```

Add a new document in the table:

```
insert /apps/my_users --id "001" --value '{"first_name":"John",
"last_name":"Doe", "age" : 34 }'
```

Get one document by ID:

```
findbyid /apps/my_users --id 001
```

Get all documents:

```
find /apps/my_users
```

Delete a document:

```
delete /apps/my_users --id "001"
```

Drop a table:

```
drop /apps/my_users
```

Managing JSON Tables
This section describes how to create, list, and delete JSON tables, alter JSON table attributes, set permissions, and manage column families. You can perform these operations using either the MapR Database JSON Client API library or MapR Database Shell commands.

MapR Database JSON Client API

The MapR Database JSON Client API is a Java library. There is not a Python implementation of the library, but you can create and drop MapR Database JSON tables in the Python OJAI client.

Admin API

Use the methods in this interface to perform these tasks:

- Create JSON tables
- Alter JSON tables
- Delete JSON tables
- List JSON tables in a folder
- See if a JSON table exists

For a full list of methods, see the MapR Admin interface

TableDescriptor API

Use the methods in this interface to perform these tasks:

- Create tables with non-default values for one or more of their parameters
- Alter tables

For a full list of interfaces and methods, see the MapR TableDescriptor interface.

MapR Database Shell

The mapr dbshell is a tool for the creation and lightweight manipulation of JSON tables and documents. To run dbshell, enter `mapr dbshell` on the command line after logging into a node in a MapR cluster. See MapR Database Shell (JSON Tables) on page 5286 for more information.

Creating JSON Tables

This topic describes how to create MapR Database JSON tables using either programmatic APIs or dbshell.

Note: Before creating a table, you typically create a directory and MapR volume. This is not required; however, it is a good practice. For example, assuming both the directory and volume names are `sample`, the command would be:

```
// Create directories with hadoop
hadoop fs -mkdir /sample

// Create a MapR volume using maprcli create volume
maprcli volume create -name sample -path /sample -type rw
```

Java

The following Java code examples show you how to create a table in the following ways:

- By using the default values for the table attributes,
- By setting specific values for the table attributes.

See the Admin and TableDescriptor APIs for more information.

The following example shows how to create a table by calling an `Admin` object's `createTable()` `method` and passing, as an argument, the path that you want to use for the new table:

```
public void createJSONTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tablePath);
         }
    }
}
```

Tables created with this version of the `createTable()` method use the default values for their attributes.

Alternatively, the following example how to create a table by passing a `TableDescriptor` object as an argument to the `createTable() method`:

```
/* Create a TableDescriptor for the table to create,
 * passing in the path of the table.
 */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Pass the TableDescriptor object and the path to the table
 * to the Admin.createTable() method.
 */
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tableDescriptor);
        }
```

```
    }
}
```

This alternative allows you to set values for some of the table's attributes.

Node.js

To create a table in the Node.js OJAI client, call the `Connection.createStore()` method:

```
connection.createStore(table_path)
    .then((store) => {
        // Process result
        ...
    });
```

The method returns a `DocumentStore` object.

Python

To create a table in the Python OJAI client, call the `Connection.create_store()` method:

```
store = connection.create_store(store_path=table_path)
```

The method returns a `DocumentStore` object.

dbshell

The following **dbshell** command shows code syntax for creating a table:

```
# mapr dbshell
maprdb root:> create /<tablePath>/<tableName>
```

C#

To create a table in the C# OJAI client, call the `connection.CreateStore(string storePath)` method:

```
var store = connection.CreateStore(string storePath);
```

The method returns a `DocumentStore` object.

Go

To create a table in the Go OJAI client, call the `connection.CreateStore()` function:

```
store, error := connection.CreateStore("/store_path")
```

The function returns a new `DocumentStore` and an error.

Listing JSON Tables

This topic describes how to list the JSON tables by using either the MapR Database JSON Client API or MapR Database Shell.

Permission Required

The `readAce` permission on the volumes where the JSON tables are located. Setting Whole Volume ACEs on page 1459

Java

The table is listed by calling MapR Database JSON Client API `Admin` object's `listTables()` method and passing, as an argument, the path of the folder.

Use a conditional loop to iterate through the returned list and retrieve the names of the tables.

```
public void listTables(String parentFolder) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        for(Path tablePath : admin.listTables(parentFolder)) {
            System.out.println(tablePath);
        }
    }
}
```

Note: The parameter `parentFolder` provides a path to a folder that is in the MapR filesystem. See "**Table Paths**" in MapR Database JSON Tables for examples.

dbshell

```
# mapr dbshell
maprdb root:> list /demo
/demo/user
/demo/checkin
/demo/review
/demo/business
/demo/tip
5 table(s) found.
```

See dbshell list on page 5303 for further details.

Altering JSON Table Attributes

This topic describes how to change the values of table attributes by using the MapR Database JSON Client API.

In this example, the code turns off the `bulkload` flag on the table. Applications will typically need to turn off this flag after a bulk load of the table with the `import`, `importJSON`, or `copytable` utility.

Create a `TableDescriptor` object for an existing table by passing the path of the table to the `Admin` interface's `getTableDescriptor()` method.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Example

Tables are altered a by using the `TableDescriptor` object and then passing that object to the `Admin` interface's `altertable()` method.

```
public void alterTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);
        // set bulk load to false
        tableDesc.setBulkLoad(false);
        admin.alterTable(tableDesc);
    }
}
```

last-updated: Apr 11, 2022

Deleting JSON Tables

This topic describes how to delete MapR Database JSON tables using either programmatic APIs or dbshell.

Java

To delete a table in the Java OJAI client, call an `Admin` object's `deleteTable()` method and pass, as an argument, the path of the table to delete:

```
public void deleteTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (admin.tableExists(tablePath)) {
            admin.deleteTable(tablePath);
        }
    }
}
```

Node.js

To delete a table in the Node.js OJAI client, call the `Connection.deleteStore()` method:

```
connection.deleteStore(table_path)
    then((deleteResponse) => {
        // Process deleteReponse
        ...
    });
```

Python

To delete a table in the Python OJAI client, call the `Connection.delete_store()` method:

```
rc = connection.delete_store(store_path=table_path)
```

dbshell

```
# mapr dbshell
maprdb root:> drop <table path>
```

See dbshell drop on page 5290 for additional details.

C#

To delete a table in the C# OJAI client, call the `connection.DeleteStore(string storePath)` method:

```
connection.DeleteStore(string storePath);
```

Go

To delete a table in the Go OJAI client, call the `connection.DeleteStore()` function:

```
err := connection.DeleteStore("/store_path")
```

Permissions Required

You must have both the `readAce` and `writeAce` permissions on the volumes where the JSON tables are located to delete it. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Permission Types for Fields and Column Families in JSON Tables

By using access-control expressions (ACEs), you can grant or deny access to fields and column families that are in JSON tables.

For an explanation of the syntax of ACEs, see ACE Syntax.

There are three types of permission:

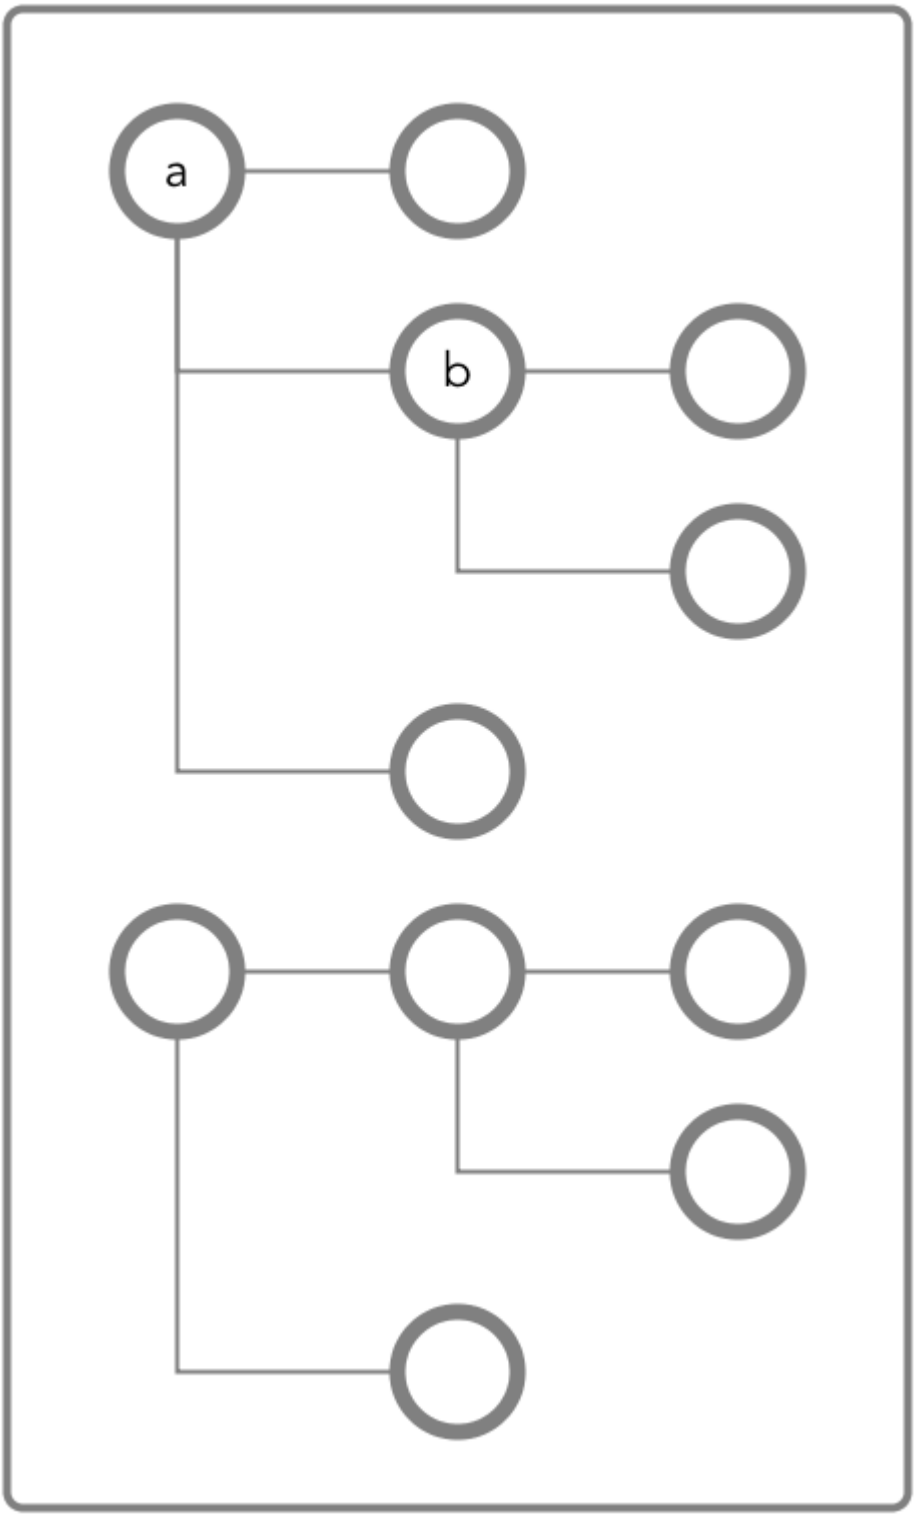
- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access the fields that the grantee has write or read permission on.

For example, suppose that a user has read and write access only on field b in this document.

last-updated: Apr 11, 2022

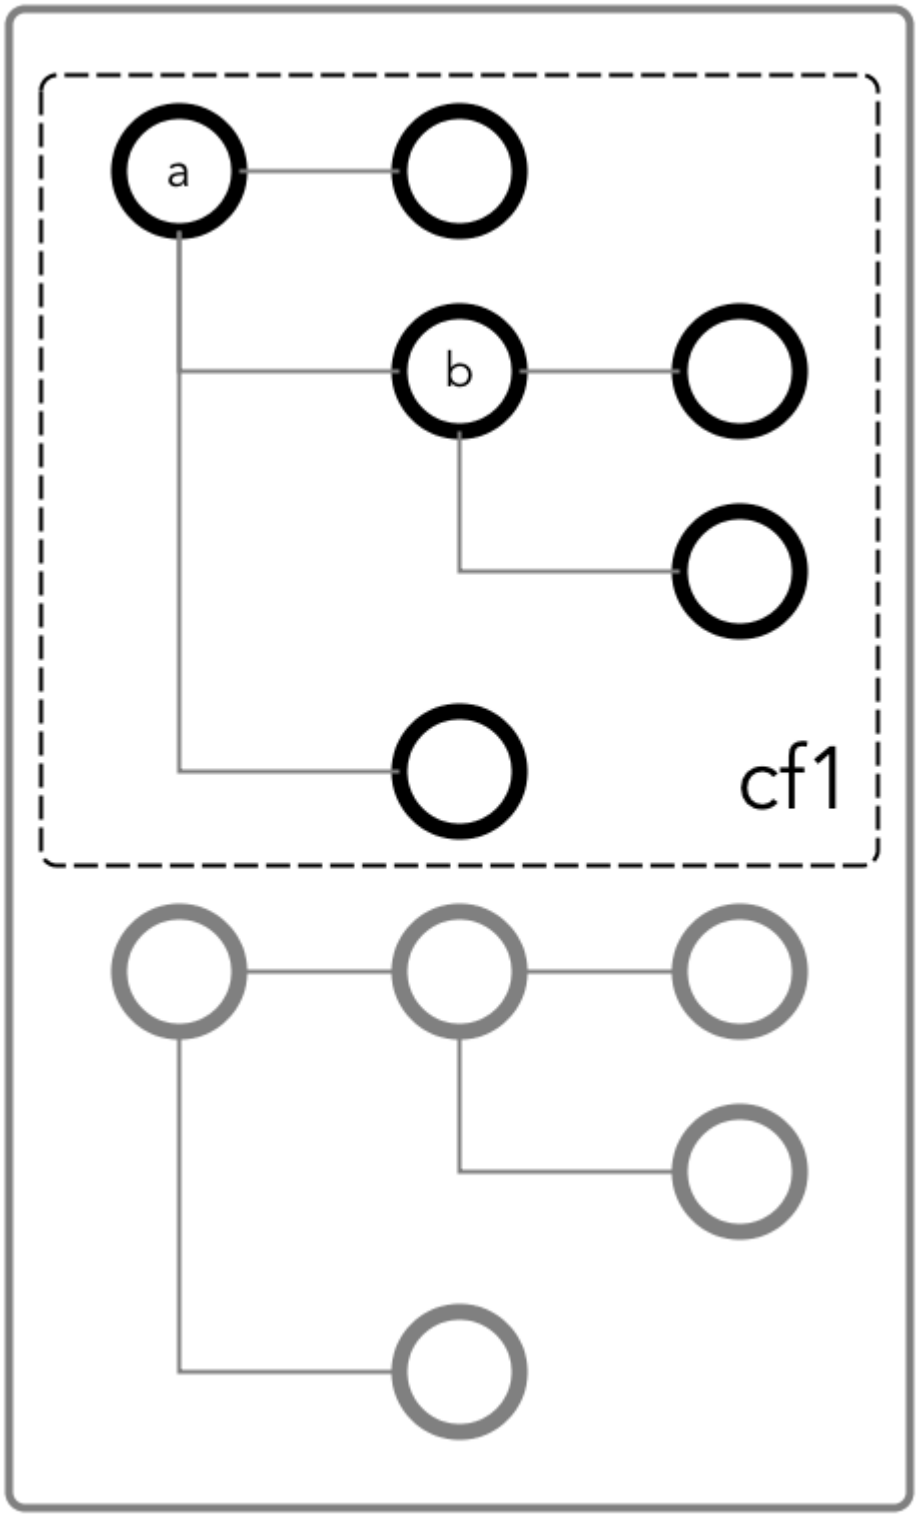


To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If traverse permission on the default column family were denied the user, it would not be possible for the user to access field b. Granting traverse permission on field a in this case would have no effect.

last-updated: Apr 11, 2022

In the next example, field a is a column family named `cf1`.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

last-updated: Apr 11, 2022

Read (`readperm`)

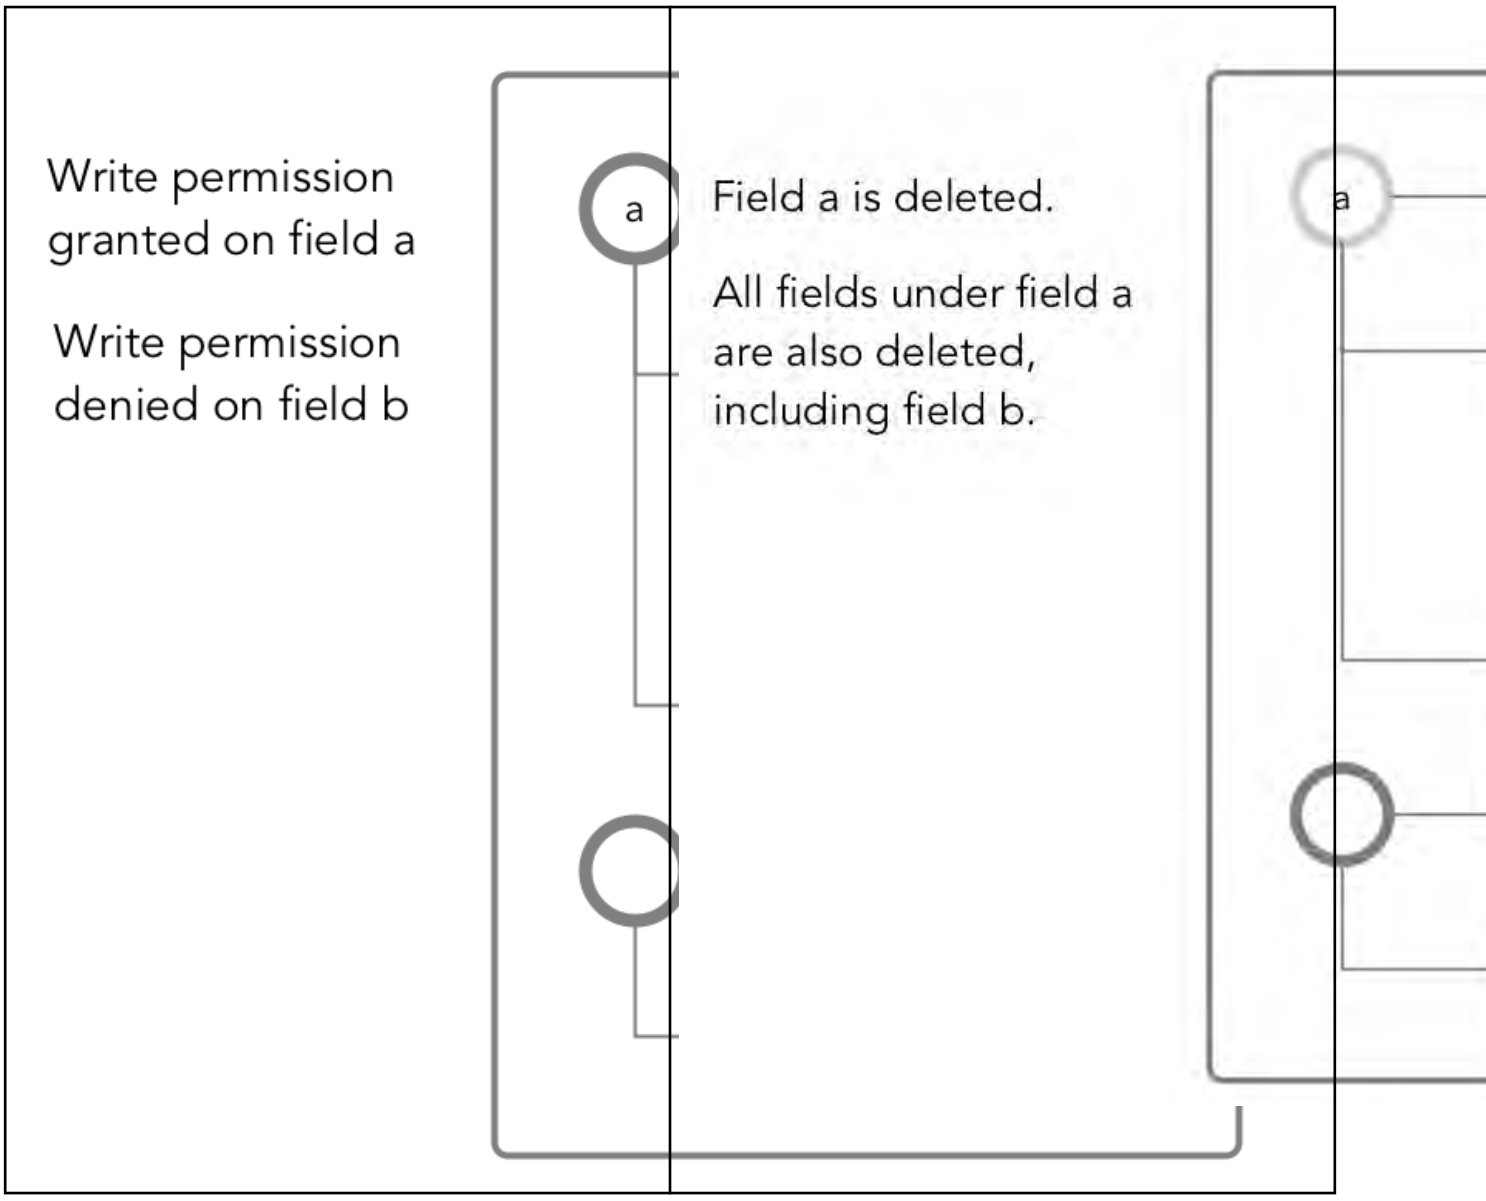
This permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field that the permission was granted on. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite a field's value.

As illustrated in the following two diagrams, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Obtaining `readperm` and `writeperm` on Fields
In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

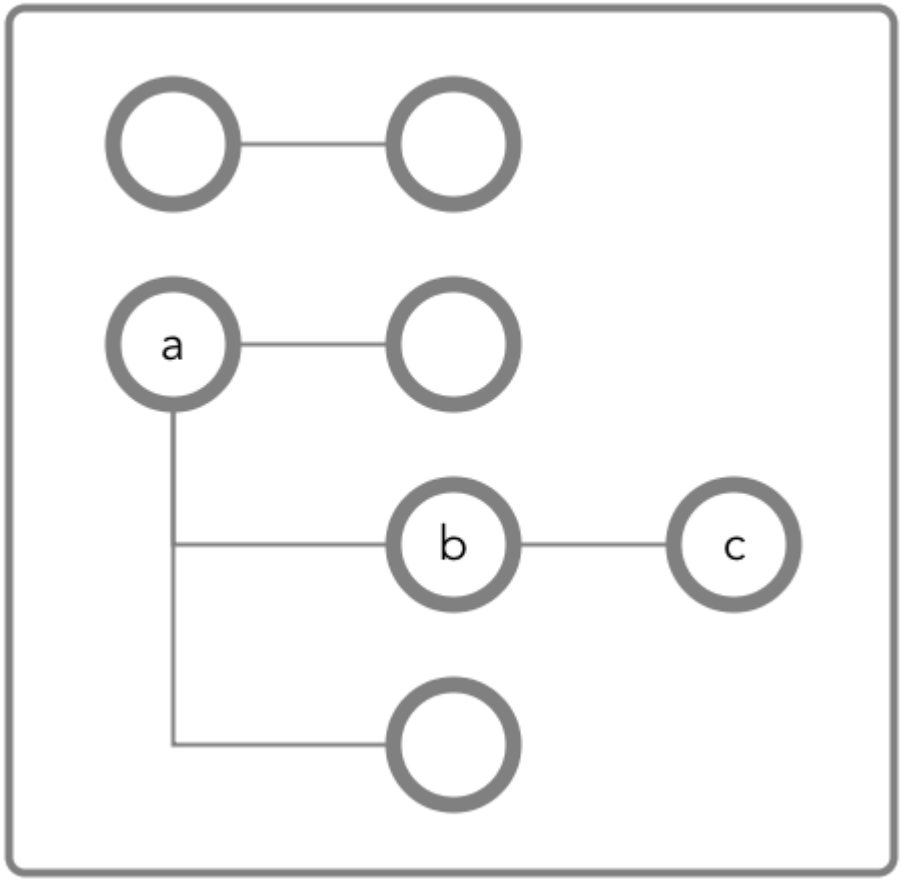


Figure 23: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field c.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of MapR Database's native JSON support. For information about them, see Column Families in JSON table.

In the following document, you want to perform an operation on field c, which is in the column family `cf1` that is defined at field b with the path `a.b`.

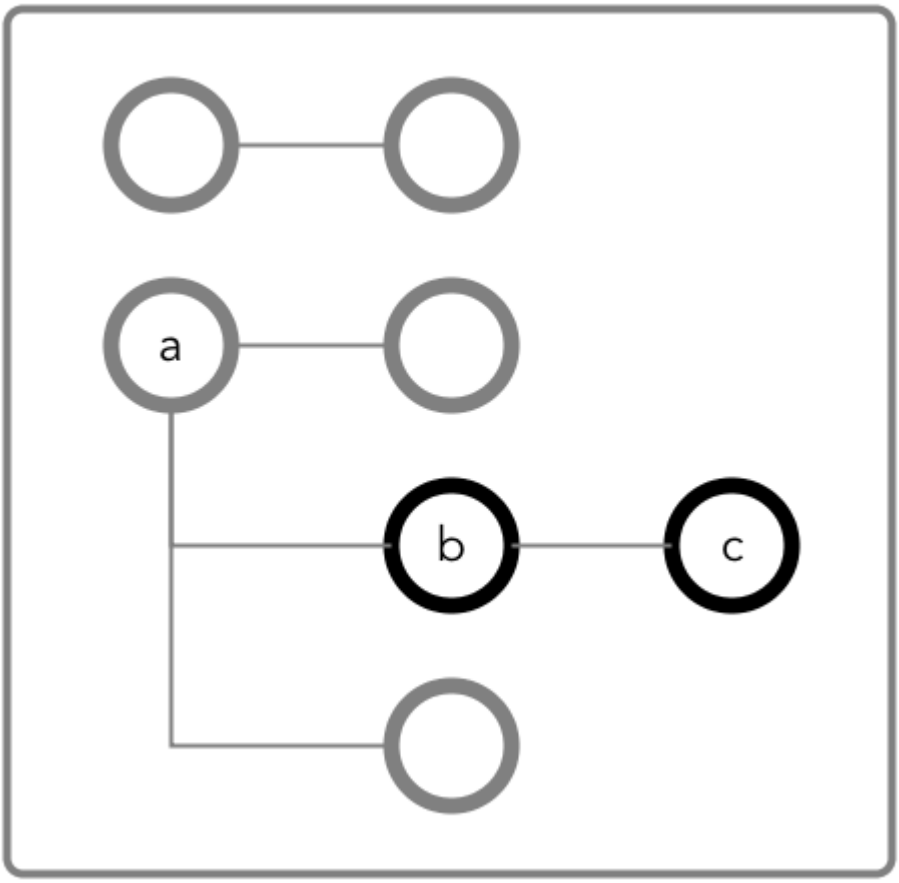

Figure 24: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`	You need `traverseperm` on field b and both `readperm` and `writeperm` on field c. You can be granted these permissions with commands similar to these:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field> -writeperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have `readperm` and `writeperm` on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Obtaining `readperm` or `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the following document, you want to perform an operation on field `c,` which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

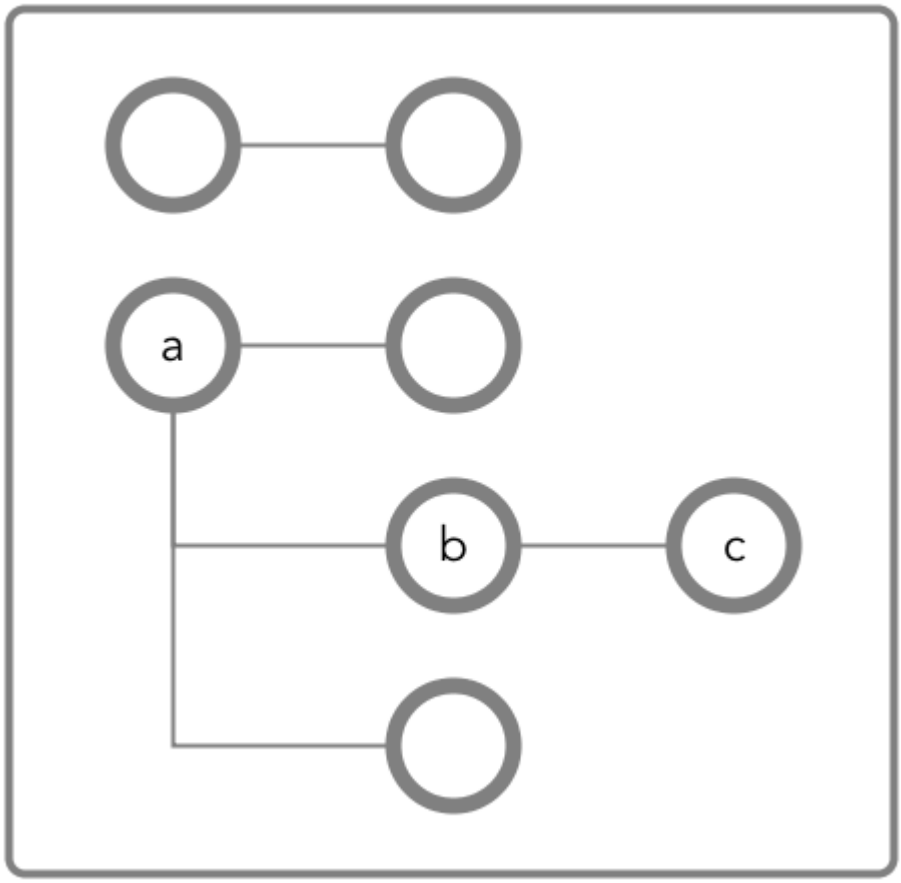

Figure 25: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family

In this case, field c inherits the permission, assuming that the permission was not denied on field a or b.

If you do not have `readperm` or `writeperm` on field a or b, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field c.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
```

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of MapR Database's native JSON support. For information about them, see Column Families in JSON Tables.

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field `b` with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

last-updated: Apr 11, 2022

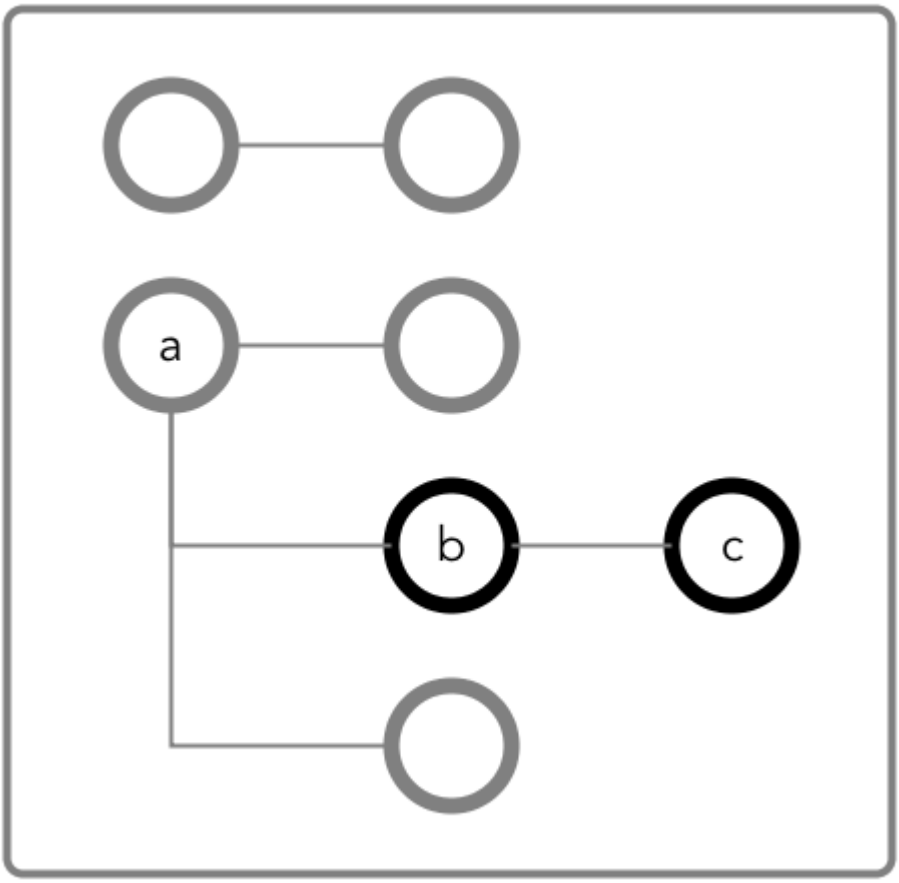

Figure 26: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`	You need `traverseperm` on field b, and you need `readperm` or `writeperm` granted to you explicitly on field c.
	Example commands to grant these permissions:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Setting Permissions on Arrays

When granting permissions on a field, if the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

Note: This topic describes the behavior of permissions in MapR Database version 6.1 and later, regardless of the MapR version you used to grant the permissions. To understand how permissions on arrays behave in earlier releases, see Operational Changes (MapR 6.1.0) - Permissions on Arrays in MapR Database JSON.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person`, to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents, for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

last-updated: Apr 11, 2022

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables
This page summarizes the default access-control expressions for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	`-defaultreadperm -defaulttraversepe rm -defaultwriteperm`	`u:<ID of the process>`
	`maprcli table create`		`u:<user ID of table creator>`
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	`maprcli table edit`		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	`maprcli table cf create`	`-readperm -traverseperm -writeperm -indexperm`	ACEs for `-defaultreadperm`, `-defaulttraverseperm`, and `-defaultwriteperm`
	Control System		
Set permissions on a column family when editing the column family.	`maprcli table cf edit`		Current ACEs
	Control System		
Set permissions on individual fields.	`maprcli table cf colperm set`		Inherited from column family or parent field
	Control System		

Managing Column Families
JSON tables store data in column families, which are collections of fields that are stored together on disk.

Each table has a default column family, which is default storage for all fields in the documents of a table. You can create additional column families to store data for a collection of fields in a separate location on disk. Queries that operate only on data that is stored in a column family are more efficient and better performing than queries on the same data when that data is stored with other data in a table. You can also cache values from a column family in memory.

Applications do not need to be aware of the existence of column families. They perform CRUD operations by using the paths of fields in a document. For example, to update any of the fields below `a.c`, an application does not need to be aware that the field is in the column family at the path `a.c`. The application simply moves through the document along the path to the field.

For more information, see Column Families in JSON Tables on page 527.

Creating Column Families
You can create column families with the MapR Database JSON Java API library by using the `Admin.createTable(TableDescriptor tableDescriptor)` method.

Add a column family to the `TableDescriptor` object before passing that object to the `createTable()` method.

Restriction

If any existing column family in a JSON table, including the default column family, uses a time-to-live that is greater than 0, you cannot create any additional column families in that table. See Setting TTL for Data.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to create two column families -- the default column family and a custom column family -- during the creation of a table:

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor();
tableDescriptor.addFamily(defaultfamilyDesc);

/* Create a FamilyDescriptor for the custom column family
   to create. The setJsonFieldPath() method specifies the field
   at which to create the column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor familyDescriptor = MapRDB.newFamilyDescriptor()
  .setName("CF1")
  .setJsonFieldPath("a.b");
tableDescriptor.addFamily(familyDescriptor);

// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {
    if (!admin.tableExists(tablePath)) {
      admin.createTable(tableDescriptor);
    }
  }
}
```

Alternative Method

You can also create column families in JSON tables by running the command `table cf create`.

Altering Column Families
You can alter column families, including the default column family for a table, by using the `Admin.alterFamily()` method in the MapR Database JSON Java API library.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to change the name of a column family:

```
public void alterColumnFamily(String tablePath, String familyName,
  String newFamilyName) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {

    /* Get a TableDescriptor object for the table. This object
       gives access to the column families that are in the table. */
    TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);

    /* Get a FamilyDescriptor object for the column family to
       change the name of. /
    FamilyDescriptor familyDesc = tableDesc.getFamily(familyName);

    // Rename the column family.
    familyDesc.setName(newFamilyName);

    /* Call alterFamily(), passing in the path of the table,
       the original name of the column family, and the
       FamilyDescriptor in which the new name was set. */
    admin.alterFamily(tablePath, familyName, familyDesc);
  }
}
```

Alternative Method

You can also edit column families in JSON tables by running the command `table cf edit`.

Deleting Column Families
You can delete a column family (except for the default column family) in a JSON table with the `Admin.deleteFamily()` Java method.

Important: Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Behavior

The data that is in the specified column family is deleted. If the column family is followed by one or more column families in a hierarchy, the other column families in the hierarchy are unaffected and still accessible. For example, if column family `CF1` at path `a.c` is followed by column family `CF2` at path `a.c.f`, `CF2` remains accessible and only the data in `CF1` is deleted.

Before deleting the column family `CF1` at `a.c`	After deleting the column family `CF1` at `a.c`

<pre>{
 "a" : {
  "b" : "value_b",
  "c" : {
  "d" : "value_d",
  "e" : "value_e",
  "f" : {
  "g" :
"value_g",
  "h" : "value_h"
  }
  }
  }
}</pre>
	<pre>{
	 "a" : {
	  "b" : "value_b",
	  "c" : {
	  "d" : "",
	  "e" : "",
	  "f" : {
	  "g" :
	"value_g",
	  "h" : "value_h"
	  }
	  }
	  }
	}</pre>

Example of using the `Admin.deleteFamily()` method

```
public void deleteColumnFamily(String tablePath, String familyName) throws
DBException {
    try (Admin admin = MapRDB.newAdmin()) {
      if (admin.tableExists(tablePath)) {
        admin.deleteFamily(tablePath, familyName);
      }
    }
}
```

Parameter	Description
`tablePath`	The path of the table in the MapR filesystem. See the "Table Paths" section in MapR Database JSON Tables on page 524.
`familyName`	The name of the column family to delete. You cannot delete the default column family. If familyName is equal to "default", the API returns an exception.

Setting TTL for Data

You can delete stale JSON documents in JSON tables automatically by setting a time-to-live (TTL) value on the column family.

TTL is set only on the default column family in a JSON table. The duration that you set applies to each entire JSON document in the JSON table.

Note: Only the default column family can exist in order to set TTL; no other column families can exist in the JSON table. You also cannot set the TTL for a JSON table if it has secondary indexes.

Data can become stale. If the data in an JSON document has not been updated within a certain period of time, you might want to delete the document. In the case of a large amount of JSON documents, applications should not have to track the time between updates and then delete the expired documents.

Because the time-to-live that is set on a column family affects an entire JSON table, only the default column family is allowed to have a non-default time-to-live value. In addition, to prevent multiple column families from having non-default time-to-live values, additional column families can not be created in a table if the default column family has a non-default value. This is because if more than one column family had a non-default TTL value, fragments of documents would expire at different times, leading to inconsistent views of data.

last-updated: Apr 11, 2022

Permission Required

The `writeAce` permission on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.

Example: Setting the default column family to a non-default time-to-live value
If you set the time-to-live parameter for the default column family to 864,000 seconds, JSON documents in that table are considered to be stale if the document's data has not been updated within 10 days and are automatically deleted.

The following code example creates a JSON table, the default column family and sets the TTL to a non-default value of 10 days (864,000 seconds).

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   Set the TTL to 10 days.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor()
   .setTTL(864000);
tableDescriptor.addFamily(defaultfamilyDesc);

// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {
    if (!admin.tableExists(tablePath)) {
      admin.createTable(tableDescriptor);
    }
  }
}
```

Managing JSON Documents
To perform CRUD operations (create, read, update, and delete) on JSON documents in MapR Database JSON tables using the OJAI API, you use `Document`, `DocumentStore`, and `DocumentMutation` objects.

You can also perform these operations using MapR Database Shell (JSON Tables) on page 5286.

`Document`

To create a JSON document, you must create a `Document` object. See the following for information specific to each language:

Java	To create a JSON document in Java OJAI, use the Document interface. See Creating JSON Documents in Java OJAI on page 2545 to learn about the different ways to create `Document` objects in Java.
Node.js	To create a `Document` object in Node.js OJAI, simply create a JSON object.

	See Sample OJAI Code for Creating JSON Documents on page 2550 for an example of how to do this.
Python	The preferred approach is to create a `Document` object in Python is to create a Python dictionary. You can also use the Document interface. See Creating JSON Documents in Python OJAI on page 2549 to learn about these two ways to create JSON documents in Python.
C#	To create a `Document` object in C# OJAI, create a C# object. See Sample OJAI Code for Creating JSON Documents on page 2550 for an example of how to do this. For C# OJAI examples, see this Github page.
Go	To create a `Document` object in Go OJAI, create a Go structure. See Sample OJAI Code for Creating JSON Documents on page 2550 for an example of how to do this.

`DocumentStore`

After you create a `Document` object, you can pass it to the `DocumentStore` interface. The interface has methods to perform the following tasks:

- Delete documents from tables
- Insert documents into tables
- Replace documents in tables

See the following for API links to the `DocumentStore` interface in each language:

Java	DocumentStore **Note:** By default, OJAI implements non-buffered writes. If you want buffered writes instead, use the `ojai.mapr.documentstore.buffer-writes` option and with the `Document` object. This option is available only in the Java OJAI API. See Enabling Buffered Writes in Java OJAI on page 2670 for more information.
Node.js	DocumentStore
Python	DocumentStore
C#	DocumentStore For C# OJAI examples, see this Github page.
Go	DocumentStore

last-updated: Apr 11, 2022

`DocumentMutation`

To make changes to JSON documents, create a `DocumentMutation` object. A `DocumentMutation` enables you to perform OJAI mutations, which includes replacing, updating, combining, and deleting fields in a JSON document. For a list of available mutations, see Using OJAI Mutation Syntax on page 2561.

Java	To create a `DocumentMutation` object, call the methods in the `DocumentMutation` class corresponding to the mutation operations you want to perform. See DocumentMutation for a list of available methods. Pass the `DocumentMutation` object to either the DocumentStore.checkAndUpdate or DocumentStore.update method to apply the changes to the document. The first method accepts a QueryCondition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
Node.js	To create a `DocumentMutation` object, create a JSON object Using OJAI Mutation Syntax on page 2561. Pass the `DocumentMutation` object to either the DocumentStore.checkAndUpdate or DocumentStore.update method to apply the changes to the document. The `DocumentStore.checkAndUpdate()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
Python	To create a `DocumentMutation` object, create a Python dictionary object Using OJAI Mutation Syntax on page 2561. Pass the `DocumentMutation` object to either the DocumentStore.check_and_update or DocumentStore.update method to apply the changes to the document. The `DocumentStore.check_and_update()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
C#	To create a `DocumentMutation` object, create a C# object Using OJAI Mutation Syntax on page 2561. Pass the `DocumentMutation` object to either the `DocumentStore.CheckAndUpdate` or `DocumentStore.Update` method to apply the changes to the document. The `DocumentStore.CheckAndUpdate` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated. For C# OJAI examples, see this Github page.
Go	To create a `DocumentMutation` object, create a Go structure Using OJAI Mutation Syntax on page 2561.

Pass the `DocumentMutation` structure to either the `DocumentStore.CheckAndUpdate` or `DocumentStore.Update` method to apply the changes to the document. The `DocumentStore.CheckAndUpdate` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

By default, the default maximum size of a JSON document is 32 MB. A `DocumentMutation` does not enforce this limit. MapR Database enforces the limit when you pass your `DocumentMutation` object to the `DocumentStore` method. See JSON Document Size on page 510 for information about how to increase this limit.

See Examples: Updating JSON Documents on page 2569 for examples that use mutations.

Creating JSON Documents in OJAI

The way you create a JSON document in your OJAI application depends on the language you use.

Creating JSON Documents in Java OJAI

There are several ways to create JSON documents in your Java OJAI application. They all require you to call the `Connection.newDocument` method to create a `Document` object.

Related information

Connection

Document

Create a Document Using a Document Object in Java OJAI

You can create a new JSON document in your Java OJAI client by first calling the `Connection.newDocument()` method to create a `Document` object, and then calling methods on the object to specify document fields and values.

The following shows the detailed sequence of steps:

1. Create a new JSON document by calling the `newDocument()` method in the `Connection` class.
2. Specify the ID of the document with the `setId()` method.
3. Specify field names and their values with the `set()` or `setArray()` method.
4. Return the results in a `Document` object.

For example, suppose you want to create the following JSON document:

```
{
    "_id" : "movie0000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
```

last-updated: Apr 11, 2022

The following method creates the document:

```
public Document buildDocument() {
    return connection.newDocument()
        .setId("movie0000001")
        .set("title", "OJAI -- The Documentary")
        .set("studio", "MapR Technologies, Inc.")
        .set("release_date", Values.parseDate("2015-09-29"))
        .set("trailers.teaser", "https://10.10.21.90/trailers/teaser")
        .set("trailers.theatrical", "https://10.10.21.90/trailers/
theatrical")
        .setArray("characters",
            ImmutableList.of(
                "Heroic Developer", "Evil Release Manager", "Mad
Development Manager"))
        .set("box_office_gross", 1000000000L);
}
```

Create a Document from a JSON String in Java OJAI

You can create a new JSON document in your Java OJAI client by passing a JSON string to the `Connection.newDocument()` method.

To create the following JSON document:

```
{
    "_id":"id001",
    "a":1,
    "b":"aString",
    "array":[
        1,
        2,
        "arrStr",
        {
            "c":"arrMapStr"
        }
    ]
}
```

Call `Connection.newDocument()`, passing in a JSON string with escaped quotes:

```
Document pojoDoc = connection.newDocument(
    "{\"_id\":\"id001\",\"a\":1,\"b\":\"aString\",\"array\":[1,2,\"arrStr\",
{\"c\":\"arrMapStr\"}]}");
```

Create a Document from a JavaBean

You can create a new JSON document in your Java OJAI client by passing a JavaBean to the `Connection.newDocument(Object bean)` method. Through an example, the content shows you a sample JavaBean class, how to create a bean for that class, how to create a JSON document from the bean, and how to convert a JSON document back to a bean.

Sample JavaBean Class

Suppose that you are using a JavaBean class named `ExampleJson`:

```
package com.example;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import javax.annotation.Generated;
```

```
import com.fasterxml.jackson.annotation.JsonAnyGetter;
import com.fasterxml.jackson.annotation.JsonAnySetter;
import com.fasterxml.jackson.annotation.JsonIgnore;
import com.fasterxml.jackson.annotation.JsonInclude;
import com.fasterxml.jackson.annotation.JsonProperty;
import com.fasterxml.jackson.annotation.JsonPropertyOrder;

@JsonInclude(JsonInclude.Include.NON_NULL)
@Generated("org.jsonschema2pojo")
@JsonPropertyOrder({
    "a",
    "b",
    "array"
})

public class ExampleJson {

    @JsonProperty("a")
    private Double a;
    @JsonProperty("b")
    private String b;
    @JsonProperty("array")
    private List<Object> array = new ArrayList<Double>();
    @JsonIgnore
    private Map<String, Object> additionalProperties = new HashMap<String,
Object>();

    /**
      *
      * @return
      * The a
      */
    @JsonProperty("a")
    public Double getA() {
        return a;
    }

    /**
      *
      * @param a
      * The a
      */
    @JsonProperty("a")
    public void setA(Double a) {
        this.a = a;
    }

    /**
      *
      * @return
      * The b
      */
    @JsonProperty("b")
    public String getB() {
        return b;
    }

    /**
      *
      * @param b
      * The b
      */
    @JsonProperty("b")
    public void setB(String b) {
```

```
        this.b = b;
    }

    /**
      *
      * @return
      * The array
      */
    @JsonProperty("array")
    public List<Object> getArray() {
        return array;
    }

    /**
      *
      * @param array
      * The array
      */
    @JsonProperty("array")
    public void setArray(List<Object> array) {
        this.array = array;
    }

    @JsonAnyGetter
    public Map<String, Object> getAdditionalProperties() {
        return this.additionalProperties;
    }

    @JsonAnySetter
    public void setAdditionalProperty(String name, Object value) {
        this.additionalProperties.put(name, value);
    }
}
```

Create a Bean

You can create a bean for the `ExampleJson` class with the following code:

```
ExampleJson bean = new ExampleJson();

bean.setA(1);
bean.setB("aString");

List arrList = new ArrayList();
arrList.add(1);
arrList.add(2);
arrList.add("arrStr");

Map arrMap = new HashMap();
arrMap.put("c","arrMapStr");
arrList.add(arrMap);
bean.setArray(arrList);
```

Create a New Document from a Bean

After creating the `ExampleJson` bean, you can create a JSON document using the bean with the following call:

```
Document pojoDoc = connection.newDocument(bean);
```

The document will have the following structure:

```
{
    "a":1,
    "b":"aString",
    "array":[
        1,
        2,
        "arrStr",
        {
            "c":"arrMapStr"
        }
    ]
}
```

Create a JavaBean from a JSON Document

You can also create a JavaBean from a JSON document. For example, suppose you modify the document that you created earlier:

```
pojoDoc.set("d","10");
```

The following converts the modified document back into an `ExampleJson` bean:

```
ExampleJson bean = pojoDoc.toJavaBean(ExampleJson.class);
```

Creating JSON Documents in Python OJAI
There are two ways to create JSON documents in your Python OJAI application, one of which is the preferred approach.

The preferred way to create a Python dictionary object and then pass it to the `Connection.new_document()` method:

```
json_dict = {
    "_id" : "movie0000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
new_document = connection.new_document(dictionary=json_dict)
```

Alternatively, you can call `Document` interface methods to set fields and values:

```
doc = connection.new_document()
        .set_id("movie0000001")
        .set('title', 'OJAI - The Documentary')
        .set('studio', 'MapR Technologies, Inc.')
        .set('release_date', ODate.parse(date_str='2015-09-29'))
        .set('trailers.teaser', 'https://10.10.21.90/trailers/teaser')
        .set('trailers.theatrical', 'https://10.10.21.90/trailers/
theatrical')
```

```
        .set('characters', ['Heroic Developer', 'Evil Release Manager',
'Mad Development Manager'])
        .set('box_office_gross', 1000000000)
```

See the following for more details about the APIs:

- Connection
- Document

Sample OJAI Code for Creating JSON Documents
The sample code in this section shows you how to create a JSON document.

Java

The code is available at OJAI_001_GetConnectionCreateDocument.java.

```
/**

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((connection) => {
    // create new document as a JavaScript object
    const newDocument = {
      "_id": "id001",
      "name": "Joe",
      "age": 50,
      "address": {
        "street": "555 Moon Way",
        "city": "Gotham"
      }
    };

    // Print the OJAI Document
    console.log(JSON.stringify(newDocument));

    // close the OJAI connection and release any resources held by the
connection
    connection.close();
  });
```

Python

The code is available at 001_get_connection_create_document.py.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Json string or json dictionary
json_dict = {"_id": "id001",
             "name": "Joe",
             "age": 50,
             "address": {
                 "street": "555 Moon Way",
                 "city": "Gotham"}
             }

# Create new document from json_document
new_document = connection.new_document(dictionary=json_dict)

# Print the OJAI Document
print(new_document.as_json_str())

# close the OJAI connection
connection.close()
```

C#

The code is available at 001_GetConnectionCreateDocument.cs.

```
using System;
using MapRDB.Driver;

public class GetConnectionCreateDocument
{
    public void GetConnectionCreateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Json string
        var jsonStr =
            @"{" +
                @""""_id"":""id001""," +
                @""""name"":""Joe""," +
                @""""age"":{""$numberInt"":""50""}," +
                @""""address"":" +
                    @"{" +
                        @""""street"":""555 Moon Way""," +
                        @""""city"":""Gotham""" +
                    @"}" +
            @"}";
```

```
        // Create a document from jsonStr
        var documentJson = connection.NewDocument(jsonStr);

        // Print the OJAI Document
        Console.WriteLine(documentJson.ToJsonString());

        // Create new document with the same fields using constructor
        var documentConstructed = connection.NewDocument()
            .SetID("id001")
            .Set("name", "Joe")
            .Set("age", 50)
            .Set("address.street", "555 Moon Way")
            .Set("address.city", "Gotham");

        // Print the OJAI Document
        Console.WriteLine(documentConstructed.ToJsonString());

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The code is available at 001_get_connection_create_document.go.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    // Create a connection to data access server
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Json string or map from which the Document will be created
    newMap := map[string]interface{}{
        "_id":  "id001",
        "name": "Joe",
        "age":  50,
        "address": map[string]interface{}{
            "street": "555 Moon Way",
            "city":   "Gotham",
        },
    }

    // Create new document from json_document
    newDocument := connection.CreateDocumentFromMap(newMap)
```

```
    // Print the new OJAI Document
    fmt.Println(newDocument.AsJsonString())

    // Close connection
    connection.Close()
}
```

Examples: Inserting JSON Documents
This section contains sample code that inserts a JSON document into a MapR Database JSON table. It also shows the MapR Database Shell syntax for inserting documents.

Java

The following code is available at OJAI_002_GetStoreAndInsertDocuments.java.

After you create the JSON document, call the DocumentStore.insertOrReplace method to insert the document into MapR Database.

```
/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.
 * You may obtain a copy of the License at
 *
 *   http://www.apache.org/licenses/LICENSE-2.0
 *
 * Unless required by applicable law or agreed to in writing, software
 * distributed under the License is distributed on an "AS IS" BASIS,
 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

import com.mapr.ojai.examples.data.Dataset;
import com.mapr.ojai.examples.data.User;

public class OJAI_002_GetStoreAndInsertDocuments {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI
    final DocumentStore store = connection.getStore("/demo_table");

    for (final User someUser : Dataset.users) {
      // Create an OJAI Document form the Java bean (there are other ways
too)
      final Document userDocument = connection.newDocument(someUser);

      System.out.println("\t inserting "+ userDocument.getId());
```

```
      // insert the OJAI Document into the DocumentStore
      store.insertOrReplace(userDocument);
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js

The following code is available at OJAI_002_GetStoreAndInsertDocuments.js.

The following code creates a list of JSON objects and then calls the DocumentStore.insertOrReplace method to insert the document into MapR Database.

```
/*
 * Copyright (c) 2018 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");

        'age': 45,
        'firstName': 'Simon',
        'lastName': 'Davis',
        'address': {
          'street': '38 De Mattei Court',
          'city': 'San Jose',
          'state': 'CA',
          'zipCode': 95142
        },
        'phoneNumbers': [
          {'areaCode': 555, 'number': 5425639},
          {'areaCode': '555', 'number': '542-5656'}]
      }
    ];
    const promiseList = documentList.map((doc) => {
      // Print the OJAI Document
      console.log(JSON.stringify(doc));
      // Insert the OJAI Document into the DocumentStore
      return store.insertOrReplace(doc);
    });
    return Promise.all(promiseList);
  })
  .then(() => {
    // close the OJAI connection
    connection.close();
  });
```

Python

The following code is available at 002_get_store_and_insert_documents.py.

The following code creates a list of JSON dictionary objects, creates Document objects, and calls the DocumentStore.insert_or_replace method to insert the documents into MapR Database.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
```

```
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
if connection.is_store_exists('/demo_table'):
    store = connection.get_store('/demo_table')
else:
    store = connection.create_store('/demo_table')

document_list = [{'_id': 'user0000',
                  'age': 35,
                  'firstName': 'John',
                  'lastName': 'Doe',
                  'address': {
                      'street': '350 Hoger Way',
                      'city': 'San Jose',
                      'state': 'CA',
                      'zipCode': 95134
                  },
                  'phoneNumbers': [
                      {'areaCode': 555, 'number': 5555555},
                      {'areaCode': '555', 'number': '555-5556'}]
                  },
                 {'_id': 'user0001',
                  'age': 26,
                  'firstName': 'Jane',
                  'lastName': 'Dupont',
                  'address': {
                      'street': '320 Blossom Hill Road',
                      'city': 'San Jose',
                      'state': 'CA',
                      'zipCode': 95196
                  },
                  'phoneNumbers': [
                      {'areaCode': 555, 'number': 5553827},
                      {'areaCode': '555', 'number': '555-6289'}]
                  },
                 {'_id': 'user0002',
                  'age': 45,
                  'firstName': 'Simon',
                  'lastName': 'Davis',
                  'address': {
                      'street': '38 De Mattei Court',
                      'city': 'San Jose',
                      'state': 'CA',
                      'zipCode': 95142
                  },
                  'phoneNumbers': [
                      {'areaCode': 555, 'number': 5425639},
                      {'areaCode': '555', 'number': '542-5656'}]
                  }
                 ]

for doc_dict in document_list:
    # Create new document from json_document
    new_document = connection.new_document(dictionary=doc_dict)
    # Print the OJAI Document
    print(new_document.as_json_str())

    # Insert the OJAI Document into the DocumentStore
    store.insert_or_replace(new_document)
```

```
# close the OJAI connection
connection.close()
```

dbshell

The following shows the syntax to insert a document with MapR Database Shell. See dbshell insert on page 5302 for more information and examples.

```
# mapr dbshell
maprdb root:>

// Syntax for inserting a document using the document ID
maprdb root:> insert <table path> --value '{"_id": "<row-key", < table
field >}'

// Syntax for inserting a document using document value
maprdb root:> insert <table path> --id <row-key> --value '{"_id":
"<row-key", < table field >}'
```

C#

The following code is available at 002_GetStoreAndInsertDocuments.cs.

The following code creates a list of JSON strings, creates Documents from the list, and calls the `DocumentStore.InsertOrReplace` method to insert the documents into the MapR Database.

```
using System;
using MapRDB.Driver;
using System.Collections.Generic;

public class GetStoreAndInsertDocuments
{
    public void GetStoreAndInsertDocuments()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        if (!connection.StoreExist("/demo_table"))
            connection.CreateStore("/demo_table");
        var store = connection.GetStore("/demo_table");

        var documentList = new List<string>
            {
                @"{""_id"":""user0000"","" +
                @""age"":{""$numberInt"":""35""},"" +
                @""firstName"":""John"","" +
                @""lastName"":""Doe"","" +
                @""address"":{"" +
                    @""street"":""350 Hoger Way"","" +

                @"""lastName"":""Davis""," +
                @"""address"":{" +
                    @"""street"":""38 De Mattei Court""," +
                    @"""city"":""San Jose""," +
                    @"""state"":""CA""," +
                    @"""zipCode"":{""$numberLong"":""95142""}" +
                    @"}," +
                @"""phoneNumbers"":[" +
                    @"{""areaCode"":{""$numberInt"":""555""},""number"":
{""$numberLong"":""5425639""}}," +
                    @"{""areaCode"":""555"",""number"":""542-5656""}]" +
                @"}"
            };

        foreach (var doc in documentList)
        {
            // Create new document from json string
            var document = connection.NewDocument(doc);

            // Print the OJAI Document
            Console.WriteLine(document.ToJsonString());

            // Insert the OJAI Document into the DocumentStore
            store.InsertOrReplace(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following code is available at 002_get_store_and_insert_documents.go.

The following code creates a list of JSON dictionary objects, creates Document objects, and calls the DocumentStore.InsertOrReplaceDocument function to insert the documents into MapR Database.

```
package main

import (
    "fmt"
```

last-updated: Apr 11, 2022

```
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    isExists, err := connection.IsStoreExists(storeName)
    if err != nil {
        panic(err)
    }
    var store *client.DocumentStore
    if isExists {
        store, err = connection.GetStore(storeName)
        if err != nil {
            panic(err)
        }
    } else {
        store, err = connection.CreateStore(storeName)
        if err != nil {
            panic(err)
        }
    }

    // Slice of maps from which the Document will be created
    documentArray := []map[string]interface{}{
        {
            "_id":       "user0000",
            "age":       35,
            "firstName": "John",
            "lastName":  "Doe",
            "address": map[string]interface{}{
                "street":  "350 Hoger Way",
                "city":    "San Jose",
                "state":   "CA",
                "zipCode": 95134,
            },
            "phoneNumbers": []interface{}{
                map[string]interface{}{"areaCode": 555, "number": 5555555},
                map[string]interface{}{"areaCode": "555", "number":
"555-5556"},
            },
        },
        {
            "_id":       "user0001",
            "age":       26,
            "firstName": "Jane",
            "lastName":  "Dupont",
            "address": map[string]interface{}{
```

```
                "street":  "320 Blossom Hill Road",
                "city":    "San Jose",
                "state":   "CA",
                "zipCode": 95196,
            },
            "phoneNumbers": []interface{}{
                map[string]interface{}{"areaCode": 555, "number": 5553827},
                map[string]interface{}{"areaCode": "555", "number":
"555-6289"},
            },
        },
        {
            "_id":       "user0002",
            "age":       45,
            "firstName": "Simon",
            "lastName":  "Davis",
            "address": map[string]interface{}{
                "street":  "38 De Mattei Court",
                "city":    "San Jose",
                "state":   "CA",
                "zipCode": 95142,
            },
            "phoneNumbers": []interface{}{
                map[string]interface{}{"areaCode": 555, "number": 5425639},
                map[string]interface{}{"areaCode": "555", "number":
"542-5656"},
            },
        },
    }

    for _, docMap := range documentArray {
        // Create new document from json_document
        newDocument := connection.CreateDocumentFromMap(docMap)
        // Print the new OJAI Document
        fmt.Println(newDocument.AsJsonString())
        //Insert the OJAI Document into the DocumentStore
        store.InsertOrReplaceDocument(newDocument)
    }

    // Close connection
    connection.Close()
}
```

Using OJAI Mutation Syntax

To perform updates using OJAI, you specify the document you want to update using its `_id` field, create *mutations* for that document, and then update it in your document store. OJAI defines a syntax for specifying mutations. Mutations allow you to append, decrement, delete, increment, combine, replace, and update fields in a document. This topic describes the syntax for the supported mutation operations and provides examples.

The following table lists the mutations OJAI supports. Each entry in the table contains a brief description of the mutation and a link to a section in this topic that describes the mutation in more detail.

Mutation Operation	Description
Append	Appends values to binary, string, and array fields
Decrement	Decrements field values
Delete	Deletes fields
Increment	Increments field values
Merge	Combines a nested document with an existing document

last-updated: Apr 11, 2022

Mutation Operation	Description
Put	Replaces field values or adds new fields
Set	Updates field values or adds new fields

The examples in this topic use the following sample JSON document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Append Mutations

Syntax

```
{"$append":{"fieldpath":value}}
```

```
{"$append":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$append` mutation is a read-modify-write operation. Use it to append specified values to existing binary, string, or array type fields. If there is type mismatch in any intermediate field specified in a *fieldpath* for the document, the mutation fails with an error. For example, an append mutation on field path `a.b.c` fails if the field `a` is a scalar.

To append multiple field paths, use an array notation to list the field paths.

Example

The following mutation appends an element to the array `a.b` and appends the string `" MapR"` to the end of the string already in the field path `a.c.e`:

```
{"$append":[{"a.b":{"appd":1}},
{"a.c.e":" MapR"}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 }, { "appd" :
1 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello MapR"
    }
  },
```

```
  "m" : "MapR wins"
}
```

OJAI Decrement Mutations

Syntax

```
{"$decrement":"fieldpath"}
```

```
{"$decrement":
{"fieldpath":decrementValue}}
```

```
{"$decrement":
[{"fieldpath1":decrementValue1},
{"fieldpath2":decrementValue2},...]}
```

Description

The `$decrement` mutation decrements the value in the *fieldpath*. To decrement multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *decrementValue*.

The *decrementValue* is optional and defaults to -1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 5 by using the decrement mutation:

```
{"$decrement":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 5,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Delete Mutations

Syntax

```
{"$delete":"fieldpath"}
```

```
{"$delete":
["fieldpath1","fieldpath2",...]}
```

last-updated: Apr 11, 2022

Description

The `$delete` mutation removes either a single field or a list of fields from a document. If the field does not exist, the delete ignores that field.

Example

The following mutation removes two fields from the document:

```
{"$delete":["a.b[1]","a.c.e"]}
```

The mutation results in the following document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false } ],
    "c" : {
      "d" : 10
    }
  },
  "m" : "MapR wins"
}
```

OJAI Increment Mutations

Syntax

```
{"$increment":"fieldpath"}
```

```
{"$increment":
{"fieldpath":incrementValue}}
```

```
{"$increment":
[{"fieldpath1":incrementValue1},
{"fieldpath2":decrementValue2},...]}
```

Description

The `$increment` mutation increments the value in the *fieldpath*. To increment multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *incrementValue*.

The *incrementValue* is optional and defaults to 1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 15 by using the increment mutation:

```
{"$increment":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
```

last-updated: Apr 11, 2022

```
      "d" : 15,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Merge Mutations

Syntax

```
{"$merge":
{"fieldpath":nestedDocument}}
```

Description

The `$merge` mutation combines a *nestedDocument* with an existing document at a specified *fieldpath*. If the original document already contains subfields specified in the *nestedDocument*, then the mutation replaces the values for those subfields. Otherwise, it adds new subfields to the document.

Note: The `$merge` mutation does not support the array notation that other mutation operations provide.

To specify more than one merge operation in a single mutation, use the syntax described at either Specifying Multiple Mutation Operations on page 2567 or OJAI Mutations Without Explicit Mutation Operation Names on page 2569. When using these syntax variations, avoid specifying overlapping field paths. MapR Database treats these as conflicting mutations and discards conflicts.

Examples

The following mutation replaces the pre-existing field path `a.c.d` with the value 11. It adds a new subfield y to the nested document `a.c`.

```
{"$merge":{"a.c":{"d":11,"y":"yo"}}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello",
      "y" : "yo"
    }
  },
  "m" : "MapR wins"
}
```

The following mutation replaces the value in the field path `a.b` and adds a new subfield `a.d`:

```
{"$merge":{"a":{"b":1,"d":"MapR"}}}
```

last-updated: Apr 11, 2022

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : 1,
    "c" : {
      "d" : 10,
      "e" : "Hello"
    },
    "d" : "MapR"
  },
  "m" : "MapR wins"
}
```

OJAI Put Mutations

Syntax

```
{"$put":{"fieldpath":value}}
```

```
{"$put":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$put` mutation is a replace operation. It is not a read-modify-write operation; it does no validation on the data. If the specified *fieldpath* exists, the mutation replaces the *fieldpath*'s value with the new *value,* regardless of the type of the original value. For example, you can update a field `a.b` from an array to a nested document. If the *fieldpath* does not exist, the mutation creates a new field with the given *value*. Because the operation does no data validation, it is significantly faster than the set operation.

To replace multiple field paths, use an array notation to list the field paths.

Example

The following example replaces the pre-existing fields `a.b` and `a.c.d` with values whose types differ from the original types. It also adds a new field `a.x`.

```
{"$put":[{"a.b":{"boolean":true}},
{"a.c.d":"eureka"},{"a.x":1}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : { "boolean" : true },
    "c" : {
      "d" : "eureka",
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

The mutation behaves as follows for the pre-existing fields:

- For `a.b`, the mutation replaces the original array of nested documents with a single nested document.
- For `a.c.d`, the mutation changes the field from an integer to a string.

OJAI Set Mutations

Syntax

```
{"$set":{"fieldpath":value}}
```

```
{"$set":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$set` mutation updates one or more fields in a document. It is a read-modify-write operation. It validates the type of the existing value before applying the mutation. If the specified *fieldpath* does not exist in a document, the mutation creates a new field. If the *fieldpath* exists but is not of the same type as the type of new *value*, then the entire mutation fails.

To update multiple field paths, use an array notation to list the field paths.

Example

The following example updates the pre-existing fields `a.b.[0]` and `a.c.d`. It also adds a new field `a.x`.

```
{"$set":[{"a.b[0].boolean":true},
{"a.c.d":11},{"a.x":1}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : true },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

Specifying Multiple Mutation Operations

You can specify more than one operation in a single mutation by specifying each operation separated by a comma.

The following is a mutation with six operations:

```
{
   "$set":{"x":[1,2,3]},
```

```
   "$put":{"a.c.e":{"$binary":"AAAADg=="}},
   "$increment":"a.b[1].decimal",
   "$delete":"a.b[0]",
   "$merge":{"newDoc":{"k":"MapR DBShell rocks!!"}},
   "$append":{"m":"!!!"}
}
```

It results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "decimal" : 124.456 } ],
    "c" : {
      "d" : 10,
      "e" : { "$binary" : "AAAADg==" }
    }
  },
  "m" : "MapR wins!!!",
  "newDoc" : { "k" : "MapR DBShell rocks!!" },
  "x" : [ 1, 2, 3 ]
}
```

The mutation applies the updates in the following manner:

- The `$set` mutation adds a new array field `x` with the value `[1, 2, 3]`.
- The `$put` mutation replaces the string `"Hello"` with the nested document `{"$binary":"AAAADg=="}`.
- The `$increment` mutation increments the value `123.456` in the second element of the array `a.b`.
- The `$delete` mutation deletes the field path `a.b[0]`, resulting in a single element array `a.b`.
- The `$merge` mutation adds a new field `newDoc` with the nested document `{"k":"MapR DBShell rocks!!"}` as its value.
- The `$append` mutation appends the string `"!!!"` to the end of the string `"MapR wins"`.

Conflicting Mutations

When you specify a mutation with field paths that are overlapping, MapR Database detects the conflict, discards the previous conflicting operation, and proceeds with the next operation.

For example, suppose you have the following document:

```
{"_id":"id1", "a":{"b":{"c":5}}}
```

The following mutation has two operations with overlapping fields `a.b`:

```
{"$delete":"a.b","$set":{"a.b.d":10}}
```

You may have intended for the mutation to first delete `a.b` and then to replace it with `a.b.d` as follows:

```
{"_id":"id1", "a":{"b":{"d":"10"}}}
```

But the *actual* result is the following:

```
{"_id":"id1", "a":{"b":{"c":5,"d":"10"}}}
```

In this case, the set operation on **`a.b.d`** causes the delete operation on **`a.b`** to be discarded.

Note: In the earlier example in this section, the `$increment` and `$delete` operations are not conflicting because one operates on `a.b[1]`, while the other operates on `a.b[0]`. On the other hand, the following are conflicting operations:

```
{"$increment":"a.b[1].decimal","$delete":"a.b"}
```

OJAI Mutations Without Explicit Mutation Operation Names

You can specify a mutation without using an explicit mutation name. These mutations run as merge operations.

For example, the following mutation merges the fields `k` and `a.c.d` to the document by adding a new field `k` and updating `a.c.d`:

```
{"k":"eureka","a":{"c":{"d":1234}}}
```

The mutation results in the following document, with updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 1234,
      "e" : "Hello"
    }
  },
  "k" : "eureka",
  "m" : "MapR wins"
}
```

Examples: Updating JSON Documents

This section contains sample code that updates a JSON document in a MapR Database JSON table using an OJAI mutation. It also shows the MapR Database Shell syntax for updating documents.

See Using OJAI Mutation Syntax on page 2561 for more details about OJAI mutations.

Java

The following code is available at OJAI_012_UpdateDocument.java. It does the following:

- Finds a document using the DocumentStore.findById method
- Creates a DocumentMutation that updates a field
- Updates the document by calling the DocumentStore.update method

```

package com.mapr.ojai.examples;

import org.ojai.store.Connection;
import org.ojai.store.DocumentMutation;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_012_UpdateDocument {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    String docId = "user0002";

    // Print the document before update
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Create a DocumentMutation to update the zipCode field
    DocumentMutation mutation = connection.newMutation()
        .set("address.zipCode", 95196L);

    System.out.println("\tUpdating document "+ docId);

    // Update the Document with '_id' = "user0002"
    store.update(docId, mutation);

    // Print the document after update
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js - Update

The following code is available at OJAI_011_UpdateDocument.js. It does the following:

- Finds a document using the DocumentStore.findById method

- Creates an OJAI mutation that updates a field
- Updates the document by calling the DocumentStore.update method

```

```

Python - Update

The following code is available at 012_update_document.py. It does the following:

- Finds a document using the DocumentStore.find_by_id method
- Creates an OJAI mutation that updates a field
- Updates the document by calling the DocumentStore.update method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0002'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)

# Create mutation to update the zipCode field
mutation = {'$set': {'address.zipCode': 95196}}

# Execute update
store.update(_id=doc_id, mutation=mutation)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

Python - Check and Update

The following code is available at 013_check_and_update_document.py. It does the following:

- Finds a document using the DocumentStore.find_by_id method

- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the DocumentStore.check_and_update method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
                 "ssl=true;" \
                 "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
                 "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0001'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)

# Create mutation to update the zipCode field
mutation = {'$put': {'address.zipCode': 99999}}

# Create condition
condition = {'$eq': {'address.street': '320 Blossom Hill Road'}}

# Execute check_and_update.
# Returns True if condition True and document was updated.
update_result = store.check_and_update(_id=doc_id,
                                       mutation=mutation,
                                       query_condition=condition)

print(update_result)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

dbshell

The following dbshell command is equivalent to the code examples. See dbshell update on page 5305 for more information and examples.

```
# mapr dbshell
maprdb root:> update /demo_table --id user002 --m {"$set":
{"address.zipCode":95196}}
```

C# - Update

The following code is available at 012_UpdateDocument.cs. It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.

- Updates the document by calling the `DocumentStore.Update` method.

```
using System;
using MapRDB.Driver;

public class UpdateDocument
{
    public void UpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0002";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
connection.NewDocumentMutation().Set("address.zipCode", (long)95196);

        // Execute update
        store.Update(docId, mutation);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - Check and Update

The following code is available at 013_CheckAndUpdateDocument.cs. It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Creates an OJAI condition to apply in the check and update.
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;
```

```
public class CheckAndUpdateDocument
{
    public void CheckAndUpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0001";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
connection.NewDocumentMutation().SetOrReplace("address.zipCode", 99999);

        // Create condition
        var condition = connection
            .NewQueryCondition()
                .Is("address.street", QueryOp.EQUAL, "320 Blossom Hill
Road")
                .Close()
            .Build();

        // Execute CheckAndUpdate.
        // Returns True if condition True and document was updated
        var updateResult = store.CheckAndUpdate(docId, condition, mutation);

        Console.WriteLine(updateResult);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Update

The following code is available at 012_update_document.go. It does the following:

- Finds a document using the `DocumentStore.FindByIdString` function to print the document before update
- Creates an OJAI mutation that updates a field

last-updated: Apr 11, 2022

- Updates the document by calling the `DocumentStore.Update` function

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"
    documentId := "user0002"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Print the document before update
    documentBeforeUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v before update.\n %v", documentId,
documentBeforeUpdate.AsJsonString())

    // Create mutation to update the zipCode field
    mutation := map[string]interface{}{"$set": map[string]interface{}
{"address.zipCode": 95196}}

    // Execute update
    err = store.Update(client.BosiFromString(documentId),
client.MosmFromMap(mutation))
    if err != nil {
        panic(err)
    }

    // Print the document after update
    documentAfterUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v after update.\n %v", documentId,
documentAfterUpdate.AsJsonString())

    // Close connection
```

```
    connection.Close()
}
```

Go - Check and Update

The following code is available at 013_check_and_update_document.go. It does the following:

- Finds a document using the DocumentStore.FindByIdString function to print the document before update
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` function

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"
    documentId := "user0001"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Print the document before update
    documentBeforeUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v before update.\n %v\n", documentId,
documentBeforeUpdate.AsJsonString())

    // Create mutation to update the zipCode field
    mutation := map[string]interface{}{"$put": map[string]interface{}
{"address.zipCode": 99999}}

    // Create condition
```

```
    condition := map[string]interface{}{"$eq": map[string]interface{}
{"address.street": "320 Blossom Hill Road"}}

    // Execute update
    // Returns True if condition True and document was updated.
    res, err := store.CheckAndUpdate(
        client.BosiFromString(documentId),
        client.MoscFromMap(condition),
        client.MosmFromMap(mutation))
    if err != nil {
        panic(err)
    }

    // Print the document after update
    documentAfterUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Update result: %v.\nDocument with id %v after update.\n
%v\n",
        res,
        documentId,
        documentAfterUpdate.AsJsonString())

    // Close connection
    connection.Close()
}
```

Querying JSON Documents

This section describes how to query JSON documents in MapR Database JSON tables using the OJAI API library and MapR Database Shell. It includes sample programs using the OJAI API library and shows how to run the same queries in MapR Database Shell.

Querying in OJAI Applications

To query MapR Database JSON tables in your OJAI applications, you use the OJAI `Query` interface. The typical flow of your application involves creating a connection, obtaining a handle to the MapR Database JSON table you want to query, constructing the query, performing the query, and then processing the results.

Note: The Node.js, Python, C#, and Go OJAI clients are supported starting in EEP 6.0.

Description

The `DocumentStore` interface includes a `Query` interface. The `Query` interface allows you to build a query programmatically.

Java

To construct an OJAI query, call the following methods in the `Query` interface:

- Query.select
- Query.where
- Query.orderBy
- Query.offset
- Query.limit

To run the query, pass the `Query` object to the DocumentStore.find method.

last-updated: Apr 11, 2022

Node.js

To construct an OJAI query, create a Node.js JSON object using OJAI Query Syntax on page 2603.

To run the query, pass the `Query` object to the DocumentStore.find method.

Python

To construct an OJAI query, create a Python dictionary object using OJAI Query Syntax on page 2603.

To run the query, pass the `Query` object to the DocumentStore.find method.

Note: The following `Query` methods are available in the Python OJAI API, but creating a Python dictionary is the preferred approach:

- Query.select
- Query.where
- Query.order_by
- Query.offset
- Query.limit

C#

To construct an OJAI query, create a C# object.

To run the query, pass the `Query` object to the `DocumentStore.Find` method.

Note: The following `Query` methods are available in the C# OJAI API:

- Query.Select
- Query.Where
- Query.OrderBy
- Query.Offset
- Query.Limit

Go

To construct an OJAI query, create a Go object.

To run the query, pass the `Query` object to the `DocumentStore.FindQuery` function.

Note: The following `Query` functions are available in the Go OJAI API:

- `Query.Select`
- `Query.WhereCondition`
- `Query.OrderBy`
- `Query.Offset`
- `Query.Limit`

last-updated: Apr 11, 2022

Basic Application Flow

The following steps describe the basics in developing client applications that query MapR Database JSON tables using the OJAI API.

Java

1. Create a Connection instance to your MapR cluster using the DriverManager class:

```
Connection connection =
DriverManager.getConnection("ojai:m
apr:");
```

Note: Do not omit the ending colon in the connection string.

2. Obtain a DocumentStore handle to a MapR Database JSON table using the connection object:

```
DocumentStore store =
connection.getStore(tablePath);
```

3. Create a Query object using the connection object:

```
Query query =
connection.newQuery();
```

4. Perform the query operation on the table:

```
QueryResult result =
store.find(query);
```

last-updated: Apr 11, 2022

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a JSON string:

```
for (final Document userDocument :
result) {
    // Print the OJAI Document

System.out.println(userDocument.asJ
sonString());
}
```

   To process individual fields within a document, use the DocumentReader interface. The following code snippet iterates through the fields in a document and prints the fields that are strings:

```
Iterable it =
result.documentReaders();
for (DocumentReader reader : it) {
    EventType et = null;
    while ((et = reader.next()) !=
null) {
        if (et ==
EventType.STRING) {

System.out.println("Value of field
" + reader.getFieldName() + ": " +
reader.getString());
        }
    }
}
```

6. Close the result stream, the connection to the document store, and the connection to MapR:

```
result.close();
store.close;
connection.close();
```

Node.js

1. Create a connection:

```
ConnectionManager.getConnection('lo
calhost:5678?;user=mapr;password=ma
pr;ssl=false')
    .then((connection) => {
        // Process connection
        ...
    });
```

2. Obtain a handle to a MapR Database JSON table using the connection object:

```
connection.getStore(tablePath)
    .then((store) => {
        // Process store
        ...
    });
```

3. Create a query object:

```
const query = {};
```

4. Perform the query operation on the table:

```
const stream = store.find(query)
```

5. Process the results:

```
stream.on('data', (document) =>
console.log(document));
```

6. Close the connection to MapR:

```
stream.on('end', () => {
  console.log('end');
  connection.close();
});
```

Python

1. Create a Connection instance to your MapR cluster using the `ConnectionFactory` class:

```
connection_str =
'localhost:5678?;user=mapr;password
=mapr;ssl=false'
connection =
ConnectionFactory.get_connection(co
nnection_str=connection_str)
```

2. Obtain a DocumentStore handle to a MapR Database JSON table using the connection object:

```
store =
connection.get_store(table_path)
```

3. Create a Query object using the connection object:

```
query =
connection.new_query().build()
```

4. Perform the query operation on the table:

```
query_result = store.find(query)
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a Python dictionary:

```
for doc in query_result:
    print(doc)
```

6. Close the connection to MapR:

```
connection.close()
```

C#

1. Create a `Connection` instance to your MapR cluster using the `ConnectionFactory` class:

```
var connectionStr =
$"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/
ssl_truststore.pem;" +

$"sslTargetNameOverride=node1.mapr.
com";
var connection =
ConnectionFactory.CreateConnection(
connectionStr);
```

2. Obtain a `DocumentStore` handle to a MapR Database JSON table using the connection object:

```
var store =
connection.GetStore(storePath);
```

3. Create a `Query` object using the connection object:

```
var query =
connection.NewQuery().Build();
```

4. Perform the query operation on the table:

```
var queryResult =
store.Find(query);
```

last-updated: Apr 11, 2022

5. Process the results.

   The following code snippet iterates through the `QueryResult` and prints each document as a JSON:

```
var documentStream = await
queryResult.GetDocumentAsyncStream(
).GetAllDocuments();
foreach (var document in
documentStream)
{

Console.WriteLine(document.ToJsonSt
ring());
}
```

6. Close the connection to MapR:

```
connection.Close();
```

Go

1. Create a `Connection` instance to your MapR cluster:

```
connectionString :=
"localhost:5678?
auth=basic;user=mapr;password=mapr;
ssl=false"
connection, error :=
client.MakeConnection(connectionStr
ing)
```

2. Obtain a `DocumentStore` handle to a MapR Database JSON table using the connection object:

```
store,
error := connection.CreateStore("/
store_path")
```

3. Create a Query object:

```
query, err := client.MakeQuery()
query.Build()
```

4. Perform the query operation on the table:

```
queryResult, err :=
store.FindQuery(query,
&client.FindOptions{})
```

last-updated: Apr 11, 2022

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a JSON:

```
    for _, doc := range
queryResult.DocumentList() {
        fmt.Println(doc)
    }
```

6. Close the connection to MapR:

```
connection.Close()
```

See Examples: Querying JSON Documents on page 2624 for complete code examples.

Related concepts

OJAI Distributed Query Service on page 505
OJAI queries either directly access MapR Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for MapR Database JSON, powered by Apache Drill. The MapR client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of MapR Drill.

Comparisons and Sorts in OJAI Queries

When running OJAI queries with comparisons and sorts, you need to be aware of how different data types behave. You also need to understand how sorting works in MapR-DB queries. Depending on the component that runs the sort, you may encounter unexpected behavior.

OJAI supports comparisons using the `QueryCondition` interface. For information about how to use this interface, see Query Conditions in OJAI Applications on page 2590.

When using the OJAI `Query` `where` and `orderby`, and comparing and sorting across different data types, there are subtleties you should take into consideration. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 513 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 514 for more information.

If you do not have a secondary index defined that can generate your query's specified `orderby`, then your query requires an explicit sort. If you have installed the OJAI Distributed Query Service on page 505, the service performs the sort. If you have not, the MapR client performs the sort, but restricts the amount of data it can sort. The default sort limit is 5000 documents. For example, if your query returns 10,000 documents, and you specify a query result `limit` of 5000 documents, the MapR client can perform the sort.

Important: The MapR client returns an error if your query result size exceeds the client's sort limit.

You can avoid errors due to the client sort limitation by adhering to the following guidelines:

- If you know the largest possible query result size when your queries specify an `order by`, you can increase the sort limit of your client to that maximum size by setting the `ojai.mapr.query.max-client-sort-limit` parameter.

  The following code snippets increase the limit to 6000:

Java

```
query.setOption("ojai.mapr.query.ma
x-client-sort-limit", 6000);
```

Note: This option is not applicable to the Java OJAI Thin Client.

Node.js

```
const query
= {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
const stream = store.find(query)
```

Python

```
query = {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
query_result = store.find(query)
```

C#

```
            var query =
connection.NewQuery()
                .Select("col")
                .SetMaxClientSortLimi
t(6000)
                .Build();

            var queryResult =
store.Find(query);
```

Go

```
query := map[string]interface{}{
    "$select":"col",
    "$options":map[string]interface{}
{
        "ojai":map[string]interface{}
{

"mapr":map[string]interface{}{

"query":map[string]interface{}{

"max-client-sort":6000}}}}
queryResult, err :=
store.FindQueryMap(query,
&client.FindOptions{})
```

You can also set this option across all your OJAI clients by modifying a MapR Data Access Gateway property. See Administering the MapR Data Access Gateway - Application Properties for details.

- If you do not know the largest possible query result size, specify a `limit` in your queries. If your query result size exceeds that `limit`, the client sorts the entire result set but returns only a subset of the rows up to the specified limit. This avoids the error, but may result in unintended behavior if your application is not expecting a truncated result. You should take corrective action if necessary.

  See Querying with Order By on page 2655 for an example of how to set a query `limit`.

Permissions and OJAI Queries
You need to understand permission requirements because they affect filter conditions in your OJAI queries.

MapR Database enforces permissions when your application processes the query result. In the basic application flow shown in the previous section, this corresponds to step 5. In an application, if user1 performs the query while user2 processes the result, then the result corresponds to user2's permissions.

You should create a separate OJAI connection for each unique user. Sharing a connection across users can result in non-optimal queries or invalid permission errors.

The following permissions are required to query documents:

- The `readAce` permission on the volumes where the JSON tables that contain the documents are located. See Setting Whole Volume ACEs on page 1459.
- The `readperm` permission on the JSON table's column families containing fields being queried. See Enabling Table and Stream Authorizations with ACEs on page 1461.

If the user does not have the `readperm` permission on a field, MapR Database treats the field as non-existent for that user. When a query selects a non-existent field, MapR Database ignores the field. If a query filters on a non-existent field, the query behaves as follows:

Filter Condition on Non-existent Field	Behavior
Filter for specific values in the field	No documents qualify the filter because a non-existent field does not match any value.
Filter for non-matches in the field	All documents qualify the filter because a non-match on a non-existent field is a no-op.

The exception is the rowkey field. Access control on the rowkey is not available. Users can always select and filter on rowkey.

For information about setting permissions, see Permission Types for Fields and Column Families in JSON Tables on page 1462.

OJAI Query Options
OJAI supports query options that enable you to modify the behavior of your queries. This includes an option to force secondary index usage and options to influence the behavior of sorts.

Available Query Options

The following table lists available query options. Some options may or may not apply, depending on whether your query uses the OJAI Distributed Query Service. The detailed descriptions make a note of this.

Option Name	Description	Details
`ojai.mapr.query.hint-using-index`	Forces the MapR client to use a particular index, regardless of cost considerations	Forcing Secondary Index Usage in OJAI on page 2589
`ojai.mapr.query.force-noncovering-sort`	Enables sort behavior to avoid partial sorts due to secondary index lags	Avoiding Partial Sorts with Secondary Indexes in OJAI on page 2589
`ojai.mapr.query.max-client-sort-limit`	Sets the MapR client sort limit	Comparisons and Sorts in OJAI Queries on page 2586

last-updated: Apr 11, 2022

Option Name	Description	Details
`ojai.mapr.query.force-drill`	When set to `true`, forces the MapR client to use the OJAI Distributed Query Service	Forcing Usage of the OJAI Distributed Query Service on page 2589
`ojai.mapr.drill.<OJAI Distributed Query Service Property Name>`	Sets options for the OJAI Distributed Query Service	Setting OJAI Distributed Query Service Properties on page 2590

Setting Query Options

To set these options in your OJAI application, see the following topics:

Java	Setting Query Options in Java OJAI on page 2670
Node.js	Setting Query Options in Node.js Using OJAI Query Syntax on page 2678
Python	Setting Query Options in Python Using OJAI Query Syntax on page 2688
C#	Setting Query Options in C# OJAI on page 2692
Go	Setting Query Options in Go OJAI on page 2696

Forcing Secondary Index Usage in OJAI

To force the MapR client to use an index, specify the name of the index with the `ojai.mapr.query.hint-using-index` option.

Regardless of cost considerations, the MapR client attempts to use the specified index. To use the index, the index must benefit filter conditions, the order by, or projections in the query as described at Queries that Benefit from Secondary Indexes on page 570. Otherwise, the MapR client ignores the option.

To force the MapR client to *not* use any indexes, specify the table name without the full path as the second parameter in the calls shown earlier. For example, if the full path of your table is `/mapr/sanfrancisco/volume1/customer`, pass the name `customer` as the second parameter.

Note: Setting this option in your OJAI application has no effect if you are using the OJAI Distributed Query Service.

Avoiding Partial Sorts with Secondary Indexes in OJAI

Partial sorts can occur due to secondary index lags. To avoid these lags, set the `ojai.mapr.query.force-noncovering-sort` option to TRUE.

This option forces the OJAI Distributed Query Service to explicitly sort the data. Do not set this option if you do not expect to encounter index lags. Otherwise, you lose the ordering advantage that secondary indexes provide.

For more information about why partial sorts occur, see Partial Sorts with Non-Covering Indexes on page 579.

Forcing Usage of the OJAI Distributed Query Service

When set to `true`, the MapR client uses the OJAI Distributed Query Service execution path, rather than selecting an execution path that it determines to be most optimal. See OJAI Distributed Query Service on page 505 for more information about the different query execution paths.

last-updated: Apr 11, 2022

Setting OJAI Distributed Query Service Properties

OJAI queries may leverage the OJAI Distributed Query Service. To modify OJAI Distributed Query Service property settings in your OJAI application, prefix the OJAI Distributed Query Service property name with `ojai.mapr.drill`.

For example, the option `ojai.mapr.drill.planner.enable_index_planning` disables using secondary indexes when queries use the Query Service.

See Index Planning and Execution Configuration Options on page 3352 for the list of available OJAI Distributed Query Service properties.

Related concepts

OJAI Distributed Query Service on page 505
OJAI queries either directly access MapR Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for MapR Database JSON, powered by Apache Drill. The MapR client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of MapR Drill.

Query Conditions in OJAI Applications

You can create a query condition in an OJAI application in either of two ways. One way is to create an OJAI `QueryCondition` object and call methods in the class to construct your query condition. Another way is to create an OJAI query condition in a JSON format.

Creating an OJAI QueryCondition Object

The Java and Python OJAI clients support a `QueryCondition` interface. After you create a `QueryCondition` object, call methods in the class to construct your query condition.

Creating a `QueryCondition` Object

Java

Java OJAI provides a `QueryCondition.is()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryCondition.Op`
- The value to compare the field path against

The field path is either a field in a JSON document, a subfield within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. See OJAI Query Conditions Using Container Field Paths on page 2615 for details.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Java typed value (for example, `int`, `float`, or `String`) or a Java OJAI object. The API supports the following OJAI types:

- `ODate`
- `OInterval`

last-updated: Apr 11, 2022

	• `OTime` • `OTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Java `Map` object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Java `List` object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`equals()` `notequals()`	Match for equality or non-equality on nested documents and arrays
`in()`	Search for individual elements in an array
`like()`	Search for string values using SQL LIKE expressions
`matches()`	Search for string values using regular expressions. You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support on page 2506 for a list of supported regular expressions.
`and()`	Begins a new AND condition block
`or()`	Begins a new OR condition block

last-updated: Apr 11, 2022

QueryCondition Method	Description
`elementAnd()`	Begins a new `elementAnd` block. See OJAI Query Condition Operators on page 2606 for a detailed description of this operator.
`close()`	Closes a compound condition block
`build()`	Builds the condition

Note: The material described in this section is a subset of the `QueryCondition` API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.

Python

Python OJAI provides a `QueryCondition.is_()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryConditionOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. See OJAI Query Conditions Using Container Field Paths on page 2615 for details.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Python scalar value (for example, `int`, `float`, or `str`) or a Python OJAI object. The API supports the following OJAI types:

- `ODate`
- `OInterval`
- `OTime`
- `OTimestamp`

Nested Documents

You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Python `dictionary` object. In the case of equality, all of the fields in the nested

	document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Python `list` object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is_()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`equals_()` `not_equals_()`	Match for equality or non-equality on nested documents and arrays
`in_()`	Search for individual elements in an array
`like_()`	Search for string values using SQL LIKE expressions
`matches_()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support on page 2506 for a list of supported regular expressions.
`and_()`	Begins a new `AND` condition block
`or_()`	Begins a new `OR` condition block
`element_and()`	Begins a new `elementAnd` block. See OJAI Query Condition Operators on page 2606 for a detailed description of this operator.
`close()`	Closes a compound condition block
`build()`	Builds the condition

Note:

- The material described in this section is a subset of the `QueryCondition` API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.
- The preferred approach for creating query conditions in Python is to create the condition in a JSON format. See Creating an OJAI Query Condition Using a JSON String on page 2601

C#

C# OJAI provides a `QueryCondition.ls()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see OJAI Query Conditions Using Container Field Paths on page 2615.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data	You can specify the value using either a C# scalar value (for example, `int`, `float`, or `string`) or a C# OJAI object. The API supports the following OJAI types: • `OjaiDate` • `OjaiInterval` • `OjaiTime` • `OjaiTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a C# object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using

a C# `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`Condition()`	Search for values using a specific condition.
`Equals()` `NotEquals()`	Match for equality or non-equality on nested documents and arrays.
`Exists()` `NotExists()`	Search for a field if the given field path exists, or verify that a field path does not exist.
`In()` `NotIn()`	Search for individual elements in an array or verify their absence.
`Like()` `NotLike()`	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.
`Matches()` `NotMatches()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 2506.
`SizeOf()`	Search for a value of the specified size. The value must be one of the following types: • `string` • `binary` • `iDictionary` • `iList`
`TypeOf()` `NotTypeOf()`	Search for value of the specified Type or verify its absence.

last-updated: Apr 11, 2022

QueryCondition Method	Description
`And()`	Begins a new `AND` condition block.
`Or()`	Begins a new `OR` condition block.
`ElementAnd()`	Begins a new `ElementAnd` block. For a detailed description of this operator, see OJAI Query Condition Operators on page 2606.
`Close()`	Closes a compound condition block.
`Build()`	Builds the condition.

Note:

- The material described in this section is a subset of the QueryCondition API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.
- The preferred approach for creating query conditions in C# is to create the condition in a JSON format. See 009_FindQueryWithSelectAndCondition.cs or Example: Creating a QueryCondition Object on page 2598.

Go

Go OJAI provides a `QueryCondition.ls()` function for specifying query conditions. The function takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see OJAI Query Conditions Using Container Field Paths on page 2615.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Go scalar value (for example, `int`, `float64`, or `string`) or a Go OJAI object. The API supports the following OJAI types:

- `OjaiDate`
- `OjaiTime`

last-updated: Apr 11, 2022

	• `OjaiTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Go object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Go `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following functions:

`QueryCondition` Function	**Description**
`AddCondition()`	Search for values using a specific condition.
`Equals()` `NotEquals()`	Match for equality or non-equality on nested documents and arrays.
`Exists()` `NotExists()`	Search for a field if the given field path exists, or verify that it does not exist.
`In()` `NotIn()`	Search for individual elements in an array or verify their absence.
`Like()` `NotLike()`	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.
`Matches()` `NotMatches()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 2506.

last-updated: Apr 11, 2022

QueryCondition Function	Description
`TypeOf()` `NotTypeOf()`	Search for value of the specified Type or verify its absence.
`And()`	Begins a new `AND` condition block.
`Or()`	Begins a new `OR` condition block.
`ElementAnd()`	Begins a new `ElementAnd` block. For a detailed description of this operator, see OJAI Query Condition Operators on page 2606.
`Close()`	Closes a compound condition block.
`Build()`	Builds the condition.

Note:

- The material described in this section is a subset of the `Query` API. It introduces you to the basics of the API. For the complete API, see the Query interface.
- The preferred approach for creating query conditions in Go is to create the condition in a JSON format. See 009_find_query_with_select_and_condition.go or Example: Creating a QueryCondition Object on page 2598.

Example: Creating a `QueryCondition` Object

The following example shows how to define a `QueryCondition` object for this query condition:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

```
QueryCondition qc =
connection.newCondition()
    .and()
        .is("a.b[0].boolean",
Op.EQUAL, false)
        .or()
            .is("a.c.d",
Op.NOT_EQUAL, 5)
            .is("a.b[1].decimal",
Op.GREATER, 1)
            .is("a.b[1].decimal",
Op.LESS, 10)
            .close()
    .close()
    .build();
```

Pass the `QueryCondition` object to the Query.where method. For a complete Java code example, see the *Java - OJAI QueryCondition Object* example at Querying with Conditions on page 2642.

Python

```
qc = connection.new_condition()
    .and_()
        .is_('a.b[0].boolean',
QueryConditionOp.EQUAL, False)
        .or_()
            .is_('a.c.d',
QueryConditionOp.NOT_EQUAL, 5)
            .is_('a.b[1].decimal',
QueryConditionOp.GREATER, 1)
            .is_('a.b[1].decimal',
QueryConditionOp.LESS, 10)
            .close()
    .close()
    .build()
```

Pass the `QueryCondition` object to the Query.where method. For a complete Python code example, see the *Python - OJAI QueryCondition Object* example at Querying with Conditions on page 2642.

C#

```
var condition =
connection.NewQueryCondition()
    .And()
        .Is("a.b[0].boolean",
QueryOp.EQUAL, false)
        .Or()
            .Is("a.c.d",
QueryOp.NOT_EQUAL, 5)
            .Is("a.b[1].decimal",
QueryOp.GREATER, 1)
            .Is("a.b[1].decimal",
QueryOp.LESS, 10)
            .Close()
    .Close()
    .Build();
```

Pass the `Condition` object to the `Query.Where` method. For a complete C# code example, see the *C# - OJAI QueryCondition Object* example at Querying with Conditions on page 2642.

Go

```
    condition, err :=
client.MakeCondition(
        client.And(),

client.Is("a.b[0].boolean",
client.EQUAL, false),
            client.Or(),
                client.Is("a.c.d",
client.NOT_EQUAL, 5),

client.Is("a.b[1].decimal",
client.GREATER, 1),

client.Is("a.b[1].decimal",
```

```
client.LESS, 10),
            client.Close(),
        client.Close())
    condition.Build()
```

Pass the `Condition` object to the `Query.WhereCondition` function. For a complete Go code example, see the *Go - OJAI QueryCondition Object* example at Querying with Conditions on page 2642.

Examples: Using the `QueryCondition.elementAnd` Method

The following example shows how to write the `elementAnd` condition described at Using elementAnd with Nested Documents on page 2619, using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("grades[]")
        .is("course",
QueryConditionOp.EQUALS, "history")
        .is("score",
QueryConditionOp.EQUALS, 12)
        .close()
    .build();
```

Python

```
qc = connection.new_condition()
    .element_and("grades[]")
        .is_("course",
QueryConditionOp.EQUALS, "history")
        .is_("score",
QueryConditionOp.EQUALS, 12)
        .close()
    .build()
```

C#

```
var condition =
connection.NewQueryCondition()
    .ElementAnd("grades[]")
        .Is("course", QueryOp.EQUALS,
"history")
        .Is("score", QueryOp.EQUALS,
12)
        .Close()
    .Build();
```

Go

```
    condition, err :=
client.MakeCondition(
        client.ElementAnd("grades[]"),
            client.Is("course",
client.EQUAL, "history"),
            client.Is("score",
client.EQUAL, 12),
        client.Close())
    condition.Build()
```

The following code corresponds to the example described at Using elementAnd with Scalar Values on page 2620 using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("values[]")
        .is("$",
QueryConditionOp.GREATER, 7)
        .is("$",
QueryConditionOp.LESS, 14)
        .close()
    .build();
```

Python

```
qc = connection.new_condition()
    .element_and("values[]")
        .is_("$",
QueryConditionOp.GREATER, 7)
        .is_("$",
QueryConditionOp.LESS, 14)
        .close()
    .build()
```

C#

```
var condition =
connection.NewQueryCondition()
    .EementAnd("values[]")
        .Is("$", QueryOp.GREATER, 7)
        .Is("$", QueryOp.LESS, 14)
        .Close()
    .Build();
```

Go

```
    condition, err :=
client.MakeCondition(
        client.ElementAnd("values[]"),
            client.Is("$",
client.EQUAL, 7),
            client.Is("$",
client.EQUAL, 14),
        client.Close())
    condition.Build()
```

Creating an OJAI Query Condition Using a JSON String
You can create a query condition using OJAI syntax to specify the condition in JSON format. This is the preferred approach for the Node.js, Python, C#, and Go OJAI clients.

The following example shows you how to create the following query condition using the syntax:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

This is a Java string for the condition:

```
String jc = new String(
    '{ \
        "$and":[ \
            {"$eq":
{"a.b[0].boolean":false}}, \
```

last-updated: Apr 11, 2022

```
            {"$or":[ \
                {"$ne":{"a.c.d":5}}, \
                {"$gt":
{"a.b[1].decimal":1}}, \
                {"$lt":
{"a.b[1].decimal":10}} \
            ]} \
        ]} \
    )';
```

Pass the string to the Query.where method. See the *Java - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 2642 for a complete Java code example.

Node.js

This is a Node.js JSON object for the condition:

```
query =
    {"$where":
        {"$and":[
            {"$eq":
{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":
{"a.b[1].decimal":1}},
                {"$lt":
{"a.b[1].decimal":10}}
            ]}
        ]}
    };
```

See the *Node.js - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 2642 for a complete Node.js code example.

Python

This is a Python dictionary for the condition:

```
query =
    {"$where":
        {"$and":[
            {"$eq":
{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":
{"a.b[1].decimal":1}},
                {"$lt":
{"a.b[1].decimal":10}}
            ]}
        ]}
    }
```

See the *Python - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 2642 for a complete Python code example.

C#

This is a JSON string for the condition:

```
var query =
    @"{""$where"":" +
        @"{""$and"":[" +
```

```
            @"{""$eq"":
{""a.b[0].boolean"":false}}," +
            @"{""$or"":["
+
                @"{""$ne"":{""a.c.d"":
{""$numberInt"":""5""}}}," +

@"{""$gt"":{""a.b[1].decimal"":
{""$decimal"":""1""}}}," +

@"{""$lt"":{""a.b[1].decimal"":
{""$decimal"":""10""}}}" +
            @"]}" +
        @"]" +
   @"}";
```

Go

This is a JSON string for the condition:

```
query := "{\"$where\": +
              "{\"$and\":[" +
                    "{\"$eq\":
{\"a.b[0].boolean\":false}}," +
                    "{\"$or\":[" +
                         "{\"$ne\":
{\"a.c.d\":5}}," +
                         "{\"$gt\":
{\"a.b[1].decimal\":1}}," +
                         "{\"$lt\":
{\"a.b[1].decimal\":10}}" +
                    "]}" +
              "]}" +
         "}"
```

To learn about the complete OJAI syntax for query conditions, see OJAI Query Condition Syntax on page 2606.

Note: The OJAI clients are supported starting in EEP 6.0.0.

OJAI Query Syntax

OJAI defines a syntax for specifying queries on JSON documents. You can use this syntax in Node.js and Python OJAI client applications and MapR Database shell.

See Query with --query on page 5292 to learn about how to use this syntax in MapR Database shell.

An OJAI query can include the following components:

- Projection
- Condition
- Order by
- Limit
- Offset
- Options

You can specify some or all these components in a query, separating each component with a comma.

OJAI Query Projection

Syntax

```
"$select":"fieldpath"
```

```
"$select":
["fieldpath1","fieldpath2",...]
```

Description

The projection is the list of field paths to select in your query. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths.

See JSON Document Field Paths on page 515 for more information about the syntax of different JSON document field paths.

Examples

Single field path:

```
"$select":"a.c.d"
```

Multiple field paths:

```
"$select":["a.c.d", "a.c.e", "m[0]"]
```

OJAI Query Condition

Syntax

```
"$where":OJAIQueryCondition
```

Description

The condition filters your query result. See OJAI Query Condition Syntax on page 2606 for more information about the syntax of an *OJAIQueryCondition*.

Example

If you have the following condition:

```
(a.b.[0].boolean == false && (a.c.d !
= 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

This is the OJAI JSON syntax for the condition:

```
"$where":{
    "$and":[
        {"$eq":
{"a.b[0].boolean":false}},
        {"$or":[
            {"$ne":{"a.c.d":5}},
            {"$gt":
{"a.b[1].decimal":1}},
            {"$lt":
{"a.b[1].decimal":10}}
            ]
        }
    ]
}
```

last-updated: Apr 11, 2022

OJAI Query Order By

Syntax

```
"$orderby":"fieldpath"
```

```
"$orderby":{"fieldpath":"order"}
```

```
"$orderby":[fieldpath1,fieldpath2,...]
```

```
"$orderby":[{"fieldpath1":"order"},
{"fieldpath2":"order"},...]
```

Description

The order by specifies the field paths on which to sort your query result. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths. For each field path, you can optionally specify an *order* of either `asc` or `desc`. Both *order* keywords are case insensitive. The default is `asc`. When specifying an *order*, enclose the *fieldpath* and *order* with curly braces.

Examples

Order on a single field path in the default `asc` order:

```
"$orderby":"a.c.e"
```

Order on a single field path in the `desc` order:

```
"$orderby":{"a.c.e":"desc"}
```

Order on two field paths, where the second specifies a `desc` order:

```
"$orderby":["a.c.d",{"a.c.e":"desc"}]
```

OJAI Query Limit

Syntax

```
"$limit":positive-integer
```

Description

The number of documents to return from the query.

Example

Return only ten documents:

```
"$limit:10
```

OJAI Query Offset

Syntax

```
"$offset":positive-integer
```

Description

The number of documents to skip before returning results to the client. The offset value has a direct effect on query time; as the offset value increases, query time also increases.

last-updated: Apr 11, 2022

Example

Process the query and skip the first five documents in the result set before returning the results to the client.

```
"$offset":5
```

OJAI Query Options

Syntax

```
"$options":{optionName:optionValue}
```

```
"$options":
[{optionName1:optionValue1},
{optionName2:optionValue2},...]
```

Description

Settings that influence a query's execution path. See OJAI Query Options on page 2588 for a list of available options.

When specifying the *optionName*, you must separate the components of the option name, replacing the dots with curly braces and colons and enclosing each component in quotes.

Example

Force the query to use the OJAI Distributed Query Service by setting the `ojai.mapr.query.force-drill` option:

```
"$options":{"ojai":{"mapr":{"query":
{"force-drill":true}}}}
```

OJAI Query Condition Syntax

OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

When writing an OJAI application, you can also apply query conditions by calling OJAI API methods, corresponding to specific operators. This section does not discuss this alternative. For details on that alternative, see Query Conditions in OJAI Applications on page 2590.

Note: Using the JSON format is the preferred approach for Python and Node.js OJAI clients.

OJAI Query Condition Operators

OJAI supports comparison, existence, between, match, like, type of, size of, in, and logical operators.

Click the name in the following box to navigate to the section that provides details on each operator.

last-updated: Apr 11, 2022

Comparison Operators

Operators

Operator	Syntax
Equals	`{"$eq": {"fieldpath":value}}`
Greater Than	`{"$gt": {"fieldpath":value}}`
Greater Than or Equals	`{"$ge": {"fieldpath":value}}`
Less Than	`{"$lt": {"fieldpath":value}}`
Less Than or Equals	`{"$le": {"fieldpath":value}}`
Not Equals	`{"$ne": {"fieldpath":value}}`

Description

Compares the data in *`fieldpath`* against *`value`* for the specified operator.

Float and double data are approximate representations of decimal values. They may not return true in equality comparisons against their equivalent decimal values.

You can specify only equality and non-equality conditions on nested documents and arrays.

In the case of equality on nested documents, all of the fields in the nested document must match. The order of the fields is not relevant.

In the case of equality on arrays, both the order of the elements and the element values must match.

last-updated: Apr 11, 2022

Existence Operators

Exists

Syntax

```
{"$exists":"fieldpath"}
```

Description

Checks for existence of *fieldpath*.

Not Exists

Syntax

```
{"$notexists":"fieldpath"}
```

Description

Checks for non-existence of *fieldpath*.

See Existence Conditions with Container Field Paths on page 2617 for details about how these operators behave when you use them with container field paths.

Between

Syntax

```
{"$between":{"fieldpath":
[startValue,endValue]}}
```

Description

Checks if the value in *fieldpath* is in the range specified by *startValue* and *endValue*, where the values are inclusive.

Matches Operators

Operators

Operator	Syntax
Matches	`{"$matches": {"fieldpath":matchValue}}`
Not Matches	`{"$notmatches": {"fieldpath":matchValue}}`

Description

Performs a regular expression match on *fieldPath* using *matchValue*.

You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support for a list of supported regular expressions.

Like Operators

Operators

Operator	Syntax
Like	`{"$like": {"fieldpath":likeValue}}`
Not Like	`{"$notlike": {"fieldpath":likeValue}}`

Description

Performs a SQL LIKE comparison on `fieldPath` where *`likeValue`* is a string with wildcard characters '%' and '_'.

Special-Purpose Characters for the Like Operators

The OJAI API allows you to use four special-purpose characters or patterns with `$like` operator expressions:

Special-Purpose Character	Description	Example
%	Matches any string of zero or more characters.	`"abc%"` matches `"abc"`, `"abcd"`, `"abcde232136"`, etc. `"%abc"` matches `"abc"`, `"pqrabc"`, etc.
_	Matches a single character.	`"_am"` matches `"ram"`, `"sam"`, `"Sam"`, `"cam"`.
[]	Matches a single character in the specified set or range.	`"[r-t]am"` matches `"ram"`, `"sam"`, and `"tam"` but not `"Sam"` or `"cam"`.
[^]	Matches a single character **not** in the specified set or range.	`"[^r-t]am"` matches `"Sam"`, `"pam"`, `"jam"`, or `"cam"` but not `"ram"`, `"sam"` and `"tam"`.

When any of these special characters is used as a literal, the character can be enclosed within `[]`:

Literal	Corresponding Like Expression
`"[a]"`	`"[[]a]"`

last-updated: Apr 11, 2022

Literal	Corresponding Like Expression
`"a%"`	`"a[%]"`
`"a_c"`	`"a[_]c"`

Note that `"^"` and `"]"` need not be escaped.

Type of Operators

Type Of

Syntax

```
{"$typeof":{"fieldpath":"typeValue"}}
```

Description

Checks whether *`fieldpath`* is of type *`typeValue`*.

Not Type Of

Syntax

```
{"$nottypeof":{"fieldpath":"typeValue"}}
```

Description

Checks whether *`fieldpath`* is not of type *`typeValue`*.

`typeValue` can be any of `map`, `array`, `binary`, `date`, `time`, `timestamp`, `interval`, `double`, `float`, `long`, `int`, `short`, `byte`, `string`, `boolean`, or `null`.

Size Of

Syntax

```
{"$sizeof":{"fieldpath":{"comparisonOp":intValue}}}
```

Description

Compares the size of the data in *`fieldpath`* against *`intValue`*, using *`comparisonOp`* . The size varies depending on the type of *`fieldPath`*:

String	Length of string
Array	Number of elements in the array
Nested document	Number of subfields in the nested document

last-updated: Apr 11, 2022

comparisonOp can be any of `$eq`, `$lt`, `$le`, `$gt`, `$ge`, or `$ne`.

In Operators

In

Syntax

```
{"$in":
{"fieldpath":inOp
Values}}
```

Description

Checks whether the data in *fieldpath* is in the list specified by *inOpValues*.

Not In

Syntax

```
{"$notin":
{"fieldpath":inOp
Values}}
```

Description

Checks whether the data in *fieldpath* is not in the list specified by *inOpValues*

Logical Operators

And

Syntax

```
{"$and":
[OJAIQueryConditi
ons]}
```

Description

Applies logical AND on a list of conditions. *OJAIQueryConditions* is a comma-separated list of OJAI query conditions.

Or

Syntax

```
{"$or":
[OJAIQueryConditi
ons]}
```

Description

Applies logical OR on a list of conditions. *OJAIQueryConditions* is a comma-separated list of OJAI query conditions.

Element And

Syntax

```
{

"$elementAnd":{
```

```
"containerFieldPath":

[OJAIQueryConditions]
    }
}
```

Note: Supported starting in MapR 6.1.

Description

Applies multiple conditions as part of a group. All conditions must be true for a common array element.

OJAIQueryConditions is the comma-separated list of the OJAI query conditions.

containerFieldPath exhibits the following behaviors:

- *containerFieldPath* specifies the container path prefix of the common container element.
- If *containerFieldPath* refers to a container of nested documents, then you must use field paths relative to the common prefix in your *OJAIQueryConditions* .
- If the *containerFieldPath* refers to a container of scalar values, then you use the $ symbol to refer to individual elements in your *OJAIQueryConditions*.

Note: There is no `elementOr` operator because it is semantically equivalent to an OR operator.

Related concepts

OJAI Query Condition Examples on page 2613

last-updated: Apr 11, 2022

This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

OJAI Query Conditions Using Container Field Paths on page 2615
Starting in MapR 6.1, MapR Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

OJAI Query Conditions Using elementAnd on page 2619
The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

OJAI Query Condition Examples
This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

The examples in this section use the following JSON documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Example	Documents Returned
`{"$exists":"tags.v"}` Matches documents where `tags` is a nested document that has a `v` subfield.	008
`{"$eq":{"tags":10}}` Matches documents where `tags` equals the scalar value 10.	003
`{"$eq":{"tags.t":"ipod"}}` Matches documents where `tags` is a nested document with a subfield `t` equal to "ipod".	005, 008
`{"$eq":{"tags":{"t":"ipod"}}}` Matches documents where `tags` is a nested document with a single subfield `t` equal to "ipod".	005
`{"$eq":{"tags":{"v":10,"t":"ipod"}}}` Matches documents where `tags` is a nested document with two subfields, `v` and `t`. `v` is equal to 10, and `t` is equal to "ipod". The order of subfields in the condition does not matter.	008

last-updated: Apr 11, 2022

Example	Documents Returned
`{"$eq":{"tags":["electronics","ipod","apple"]}}` Matches documents where `tags` is an array with the three elements listed.	001
`{"$eq":{"tags":["ipod","electronics","apple"]}}` This example does not match any document, whereas the previous does, because the order of the elements in this example does not match the order in document 001.	None
`{"$between":{"tags":[5,15]}}` Matches documents where `tags` is a scalar value between 5 and 15.	003
`{"$like":{"tags[1]":"ip%"}}` Matches documents where the first array element in `tags` qualifies the wildcard string `"ip%"`	001, 004
`{"$typeof":{"tags":"map"}}` Matches documents where `tags` is a nested document.	005, 008
`{"$typeof":{"tags":"array"}}` Matches documents where `tags` is an array.	001, 004, 006, 007
`{"$sizeof":{"tags":{"$ge":3}}}` Matches documents where the size of the data in `tags` is greater than or equal to three. • 001 matches because the array has three elements • 002 matches because the string is of length four • 004 matches because the nested document has three subfields	001, 002, 004
`{"$in":{"tags":["ipod", 10, {"t":"ipod"}]}}` Matches documents where `tags` equals any of the values listed. Note that the values can be of different types.	002, 003, 005
`{ "$and":[ {"$lt":{"tags[1].v":10}}, {"$matches":{"tags[1].t":"ap{2}"}} ] }` Matches documents where the first array element in `tags` has a nested document with a subfield v less than one, and the same nested document also matches the regular expression `"ap{2}"`.	007

Example	Documents Returned

<pre>{
    "$or":[
        {"$exists":"tags.v"},
        {"$typeof":{"tags":"string"}}
    ]
}</pre> Matches documents where either `tags` is a nested document with a subfield `v`, or `tags` is a scalar string.
	002, 008

Note: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 570 for more details.

OJAI Query Conditions Using Container Field Paths

Starting in MapR 6.1, MapR Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

Conditions with Container Field Paths on Arrays

If you have a field that has a single value rather than an array of values, when using the container notation, MapR Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values. The array elements and scalar values can be of any type.

Suppose you have the following set of documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
```

last-updated: Apr 11, 2022

```
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

To find all documents that contain the tag named `"ipod"`, you can use the following OJAI query condition, where you reference `tags` using a container field path:

```
{"$eq":{"tags[]":"ipod"}}
```

The expression matches the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
```

Note that the matching documents have the following characteristics:

- In 001 and 004, `tags` are array fields.
- In 002, `tags` is a scalar value.
- In 001 and 004, the `tags` arrays have elements in addition to `"ipod"`.

You can also use the `AND` operator to match multiple container field path conditions.

For example, the following condition finds all documents that have both `"ipod"` and `"apple"` tags:

```
{
    "$and":[
        {"$eq":{"tags[]":"ipod"}},
        {"$eq":{"tags[]":"apple"}}
    ]
}
```

The expression matches the following document, with the matching conditions highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ]
```

Conditions with Container Field Paths on Nested Documents

You can also use the container field path in combination with a nested document subfield reference.

For example, using the same set of documents shown earlier, the following OJAI query condition finds all documents in which `"ipod"` is specified in the subfield named `t` within the `tags` nested document:

```
{"$eq":{"tags[].t":"ipod"}}
```

This expression returns the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" : "ipod"
} ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Note that the matching documents have the following characteristics:

- In 005 and 008, `tags` is a single nested document.
- In 006 and 007, `tags` is an array of nested documents.
- In 004, the `tags` array has both scalar data and a nested document.
- In 004 and 006, the `tags` array have other array elements that do not match the nested document subfield `t`.

Existence Conditions with Container Field Paths

Existence Operators on page 2608 check for the existence and non-existence of a specified field path. When you use `$exists` with a container field path, the specified field path can be any element in an array.

Using the same set of documents shown earlier, the following OJAI query condition finds all documents where the `tags` array has a nested document with a subfield `t`:

```
{"$exists":"tags[].t"}
```

The expression matches the following documents with the matching condition highlighted in bold:

```
{"_id":"004","name":"Ipod 004","tags":[10,"ipod",{"t":"ipod"}]}
{"_id":"005","name":"Ipod 005","tags":{"t":"ipod"}}
{"_id":"006","name":"Ipod 006","tags":[{"t":"ipod"},{"t":"apple"}]}
{"_id":"007","name":"Ipod 007","tags":[{"t":"ipod","v":10},
{"t":"apple","v":9}]}
```

When you use `$notexists` with a container field path, it matches *any* element in the array that does not meet the existence condition:

```
{"$notexists":"tags[].t"}
```

The expression returns the following documents with the matching condition highlighted in bold:

```
{"_id":"001","name":"Ipod 001","tags":["electronics","ipod","apple"]}
{"_id":"002","name":"Ipod 002","tags":"ipod"}
{"_id":"003","name":"Ipod 003","tags":10}
{"_id":"004","name":"Ipod 004","tags":[10,"ipod",{"t":"ipod"}]}
```

Even document `004` has a `tags[].t` element, the other elements in that document's `tags` array do not; therefore, the document qualifies the condition.

Conditions with Container Field Paths Across Multiple Levels of Nested Documents

The following are examples of query conditions that match the sample document shown at Container Field Paths Across Multiple Levels of Nested Documents:

```
{"$eq":{"projects[].customer.contacts[].emails[].value":"jdoe@gmail.com"}}
```

```
{"$eq":{"projects[].customer.contacts[].role":"CEO"}}
```

Conditions with Container Field Paths on Multidimensional Arrays

The following examples reference documents that store the high and low temperatures for each day in a week. They use a two-dimensional array to store this data. The first element of each nested array element is the high temperature for a day, and the second element is the low. Typically, the two-dimensional array

last-updated: Apr 11, 2022

has seven array pairs, one for each day of the week. But in cases where data is unavailable, the document has only the days available.

For example, document 002 has a single dimensional array because it has data for only one day that week.

```
{
   "_id" : "001",
   "temps" : [[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]],
   "weekOf" : "4/29/2018"
}
{
   "_id" : "002",
   "temps" : [81,60],
   "weekOf" : "5/12/2018"
}
{
   "_id" : "003",
   "temps" : [[80,55],[78,54],[79,54],[77,53],[79,54],[77,54],[78,54]],
   "weekOf" : "5/13/2018"
}
```

As described at Container Field Paths with Multidimensional Arrays, you can specify a container field path in a dimension only if it does not precede a dimension that specifies an explicit element. For example, the following condition is not allowed because the first dimension specifies a container field path and precedes element 1 in the second dimension:

```
// Invalid condition
{"$ge":{"temps[][1]":60}}
```

The following table shows examples of conditions on multidimensional arrays that MapR Database supports:

Example	Documents Returned
`{"$ge":{"temps[][]":60}}` Matches documents that have any temperature greater than 60. • Documents 001 and 003 match because all days have high temperatures above 60. • Document 002 matches because day 1 has a low temperature of 60. Although `temps` in this document is a one-dimensional array, the container notation treats it as a two-dimensional array.	001, 002, 003
`{"$ge":{"temps[1][]":75}}` Matches documents that have any temperature greater than 75 on the second day of the week	003
`{"$eq":{"temps[]":[78,54]}}` Matches documents that have a high and low temperature of 78 and 54 on the same day. • Day 5 from document 001 matches this condition. • Days 2 and 7 from document 003 match this condition.	001, 003

OJAI Query Conditions Using `elementAnd`

The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

Using `elementAnd` with Nested Documents

Assume that you have the following set of documents that reflect student scores on courses. Each document has an array of `grades`. `Grades` is a nested document that reflects how the students scored on each course they took.

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"score":12,"course":"history"},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
{"_id":"005","grades":[{"course":"math","score":15.5},
{"course":"history","score":10},{"course":"physics","score":11}]}
```

If you want to find the students who scored 12 in history, you use the following `elementAnd` condition:

```
{
    "$elementAnd":{
        "grades[]":[
            {"$eq":{"course":"history"}},
            {"$eq":{"score":12}}
        ]
    }
}
```

The condition matches the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

The example illustrates the following behavior:

- The positions of the subfields in the nested document are not significant.

- In document 002, there are other subfields in the nested document that do not match the specified conditions.

In contrast, the following example expresses a different condition, using `and` instead of `elementAnd`:

```
{
    "$and":[
        {"$eq":{"grades[].course":"history"}},
        {"$eq":{"grades[].score":12}}
    ]
}
```

This condition returns documents corresponding to students who have taken history and scored 12 on *any* course. The following are the matching documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

The example illustrates the following behavior:

- Besides returning the same documents as the previous `elementAnd` example, this condition also returns document 003.
- Document 003 matches because that student took history and scored 12 on english, rather than history.
- Document 005 does not match because although the student took history, the student did not score 12 on any courses.

Using `elementAnd` with Scalar Values

If you apply `elementAnd` to a container of scalar values, you use the `$` symbol to denote an unspecified container element.

Suppose you have the following documents:

```
{"_id" : "001", "name" : "a", "values" : [1, 2, 3, 6, 15] }
{"_id" : "002", "name" : "b", "values" : [3, 6, 9, 10, 15] }
{"_id" : "003", "name" : "c", "values" : [14] }
{"_id" : "004", "name" : "c", "values" : 11 }
```

To find all documents where `values[]` contains a number between 7 and 11 (inclusive), you can use the following condition:

```
{
    "$elementAnd":{
        "values[]":[
            {"$ge":{"$":7}},
            {"$le":{"$":11}}
        ]
    }
}
```

The condition returns the following documents, with the matching numbers highlighted in bold:

```
{"_id":"002","name":"b","values":[3,6,9,10,15]}
{"_id":"004","name":"c","values":11}
```

The example illustrates the following behavior:

- In document 002, multiple elements in the array match the condition.
- In document 004, `values` is a scalar value.

Suppose you apply the following condition that uses `and` instead of `elementAnd`:

```
{
    "$and":[
        {"$ge":{"values[]":7}},
        {"$le":{"values[]":11}}
    ]
}
```

All documents except 003 match this `and` condition because in the matching documents, `values[]` contains *some* number greater than or equal to 7 and *some* number less than or equal to 11. The difference is that the same number does not need to match both conditions, which is the case for document 001.

Using `between` with `elementAnd`

You cannot use a container field path in a `between` condition. To use the `between` operator to match against an arbitrary array element, you must include the `between` condition in an `elementAnd` condition.

The following table shows the proper way to specify a `between` condition that is equivalent to the `elementAnd` example from the previous section:

Correct Condition	Incorrect Condition
`{ "$elementAnd":{ "values[]":[ {"$between":{"$":[7,11]}} ] } }`	`{"$between":{"values[]":[7,11]}}`

This example uses `between` to match against an arbitrary scalar array element. You can also use `between` to match against a subfield in a nested document, in which the nested document is an arbitrary array element.

For example, using the sample documents shown earlier, the following table shows the correct way to apply the `between` operator on the subfield `score` in the nested documents that are elements in the `grades` array:

Correct Condition	Incorrect Condition

<pre>{
    "$elementAnd":{
        "grades[]":[
            {"$between":{"score":
[15.5,20]}}
        ]
    }
}</pre>
	<pre>{"$between":{"grades[].score":
	[15.5,20]}}</pre>

The condition returns the following documents, with the matching conditions highlighted in bold:

<pre>{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"cmts":"...","course":"history","score":12},
{"course":"english","score":18}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","details":{"info":"..."},"score":12}]}
{"_id":"005","grades":[{"course":"math","score":15.5},
{"course":"history","score":10},{"course":"physics","score":11}]}</pre>

Using Other Operators in `elementAnd` Conditions

You can also use operators like `or` in `elementAnd`'s query condition list.

For example, the following condition finds all students who scored 12 in either history or english:

<pre>{
    "$elementAnd":{
        "grades[]":[
            {"$or":[
                {"$eq":{"course":"history"}},
                {"$eq":{"course":"english"}}
            ]},
            {"$eq":{"score":12}}
        ]
    }
}</pre>

The condition returns the following documents, with the matching conditions highlighted in bold:

<pre>{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"cmts":"...","course":"history","score":12},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}</pre>

Combining `elementAnd` with Other Operators

You can combine `elementAnd` with other operators like `and`.

last-updated: Apr 11, 2022

For example, using the sample documents shown earlier, suppose you want to find all students who scored 12 in history as well scored 15.5 in math. The following condition expresses this criteria:

```
{
   "$and":[
      {
         "$elementAnd":{
            "grades[]":[
               {"$eq":{"course":"history"}},
               {"$eq":{"score":12}}
            ]
         }
      },
      {
         "$elementAnd":{
            "grades[]":[
               {"$eq":{"course":"math"}},
               {"$eq":{"score":15.5}}
            ]
         }
      }
   ]
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

Querying with MapR Database Shell

This section describes how to query JSON documents using either the `find` or `findbyid` command in MapR Database Shell (dbshell). It introduces the functionality the `find` command supports and describes the two ways to specify your queries. It also provides links to reference pages and examples.

The `findbyid` command allows you to retrieve a single document with a specified id from a MapR Database JSON table.

The `find` command allows you to specify projections and filter conditions (using JSON strings) to retrieve specific documents. It also allows you to specify the following options:

- Range of document IDs to retrieve
- Offset from which to start retrieval
- Order by to sort fields in the document
- Limit on the number of documents to retrieve

To invoke MapR Database shell, run the following command on a MapR cluster node:

```
% mapr dbshell
```

last-updated: Apr 11, 2022

For a complete list and description of options available, see dbshell find or findbyid on page 5290.

Alternatives for Writing Dbshell Query Commands

You can construct your dbshell queries in one of two ways:

- Use individual options in the `find` command
- Use the `--query` option in the `find` command and specify keywords as arguments to `--query`

The following example illustrates the differences between the two alternatives.

Suppose you want to query the table `/apps/tab` with the following criteria:

- Select fields `f1` and `f2`
- Limit the result to ten documents
- Skip the first two documents
- Filter documents where the field `f3` equals 15
- Sorts on field `f1`

Click on each of the following tabs to see the syntax for each alternative:

Use Individual Options in `find`

```
find /apps/tab --fields f1,f2 --limit
10 --offset 2 --where {"$eq":
{"f3":15}} --orderby f1
```

Use the `--query` Option in `find`

```
find /apps/tab --query {"$select":
["f1","f2"],"$limit":10,"$offset":2,"$
where":{"$eq":
{"f3":15}},"$orderby":"f1"}
```

For more examples on how to use the two query alternatives, see the following links:

Use Individual Options in `find`	Use the `--query` Option in `find`
Query Examples with Other Options on page 5297	• Query with --query on page 5292 • Query with --orderby on page 5296

Note: With both options, you need to specify the query condition using OJAI Query Condition Syntax on page 2606.

Examples: Querying JSON Documents

This section provides query examples using the OJAI API. The examples include querying by document ID, retrieving all documents in a store, selecting individual fields, specifying query conditions, and ordering your query result. For reference, the examples also include the equivalent MapR Database Shell (dbshell) commands.

If you hover over the right hand side of all code examples, you can use the 
icon to copy and paste the code.

You can also download the code examples from github at https://github.com/mapr-demos/ojai-examples.git.

last-updated: Apr 11, 2022

Querying By ID

The examples in this section show you how to query for a single document ID.

Java

This example retrieves a single document identified by the ID `user001`.

Note: To query for a range of document IDs, you must specify an OJAI QueryCondition. See Querying with Conditions on page 2642 for examples of the syntax.

 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // fetch the OJAI Document by its '_id' field
    return store.findById('user0001');
  })
  .then((doc) => {
    // Print the OJAI Document
    console.log(doc);
    connection.close();
  });
```

Python

This example retrieves a single document identified by the ID `user0001`.

Note: To query for a range of document IDs, you must specify an OJAI QueryCondition. See Querying with Conditions on page 2642 for examples of the syntax.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
```

```
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# fetch the OJAI Document by its '_id' field
doc = store.find_by_id("user0001")

# Print the OJAI Document
print(doc)

# close the OJAI connection
connection.close()
```

dbshell

The following is the equivalent of the code examples using dbshell. See dbshell find or findbyid on page 5290 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> findbyid /demo_table --id user0001
```

C#

This example retrieves a single document identified by the ID `user0001`.

Note: To query for a range of document IDs, you must specify an OJAI `QueryCondition`. See Querying with Conditions on page 2642 for examples of the syntax.

```
using System;
using MapRDB.Driver;

public class FindById
{
    public void FindById()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch the OJAI Document by its '_id' field
        var document = store.FindById("user0001");

        // Print the OJAI Document
        Console.WriteLine(document);

        // Close the OJAI connection
        connection.Close();
```

last-updated: Apr 11, 2022

```
    }
}
```

Go

This example retrieves a single document identified by the ID `user0001`.

Note: To query for a range of document IDs, you must specify an OJAI Condition. See Querying with Conditions on page 2642 for examples of the syntax.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Fetch the OJAI Document by its '_id' field
    doc, err := store.FindByIdString("id0001")
    if err != nil {
        panic(err)
    }

    // Print the OJAI Document
    fmt.Println(doc.AsJsonString())

    // Close connection
    connection.Close()
}
```

Querying and Returning All Documents

The examples in this section show you two ways of retrieving all documents from a document store.

Java - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.
 * You may obtain a copy of the License at
 *
 *   http://www.apache.org/licenses/LICENSE-2.0
 *
 * Unless required by applicable law or agreed to in writing, software
 * distributed under the License is distributed on an "AS IS" BASIS,
 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_004_FindAll {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    // fetch all OJAI Documents from this store
    final DocumentStream stream = store.find();

    for (final Document userDocument : stream) {
      // Print the OJAI Document
      System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Java - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.findQuery method.

```
/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License"); you may
not use this file except in compliance with
 * the License. You may obtain a copy of the License at

 * http://www.apache.org/licenses/LICENSE-2.0
 *
 * Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on
 * an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either
express or implied. See the License for the
 * specific language governing permissions and limitations under the
License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;
import org.ojai.store.Query;

public class OJAI_005_FindAllQuery {

  public static void main(final String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    // Build an OJAI query
    final Query query = connection.newQuery().build();

    // fetch all OJAI Documents from this store
    final DocumentStream stream = store.find(query);

    for (final Document userDocument : stream) {
      // Print the OJAI Document
      System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }
```

```
}
```

Node.js - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
/*

 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // fetch all OJAI Documents from table
    return store.find({});
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => console.log(document));
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Node.js - Example 2

The following example queries a document store and returns all documents. It creates an empty query and passes that to the DocumentStore.find method.

```
/*
 * Copyright (c) 2018 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.

 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // options for find request
    const options = {
      'ojai.mapr.query.include-query-plan': true,
      'ojai.mapr.query.timeout-milliseconds': 10000
    }
    // fetch all OJAI Documents from table
    return store.find({}, options)
  })
  .then((queryResult) => {
    // get query plan
    console.log(queryResult.queryPlan);

    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Python - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# fetch all OJAI Documents from table
query_result = store.find()

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()
```

Python - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.find method.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Build an OJAI query
query = connection.new_query().build()

# options for find request
options = {
    'ojai.mapr.query.include-query-plan': True,
    'ojai.mapr.query.result-as-document': True,
    'ojai.mapr.query.timeout-milliseconds': 10000
}

# fetch all OJAI Documents from table
query_result = store.find(query, options=options)

# get query plan
print(query_result.get_query_plan())

doc_stream = query_result
# Print OJAI Documents from document stream
```

last-updated: Apr 11, 2022

```
for doc in doc_stream:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following is the equivalent of the code examples using dbshell. See dbshell find or findbyid on page 5290 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table
```

C# - Example 1

The following example queries a document store and returns all documents by using the `GetAllDocuments` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllDocuments
{
    public async void FindAllDocuments()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch all OJAI Documents from table
        var queryResult = store.Find();
        var documentStream = await queryResult.GetAllDocuments();

        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

last-updated: Apr 11, 2022

C# - Example 2

The following example queries a document store and returns all documents. It creates a `Query` object and passes that to the `DocumentStore.Find` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllQuery
{
    public async void FindAllQuery()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Build an OJAI query
        var query = connection.NewQuery().Build();

        // Options for find request
        var options = new QueryOptions()
        {
            IncludeQueryPlan = true,
            Timeout = 1000
        };

        // Fetch all OJAI Documents from table
        var queryResult = store.Find(query, options);

        // Get query plan
        Console.WriteLine(queryResult.GetQueryPlan());

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.FindAll function.

```
package main

import (
```

last-updated: Apr 11, 2022

```
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindAll(&client.FindOptions{IncludeQueryPlan:
false, ResultAsDocument: true})

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.FindQuery function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"
```

```
    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{IncludeQueryPlan: true,
ResultAsDocument: true}

    // Build an OJAI query
    query, err := client.MakeQuery()
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Get query plan
    fmt.Println(findResult.QueryPlan())

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Paginating Your Result

An alternative to returning all documents from a store is to specify a limit in the query. Another alternative is to paginate the result using offset and limit. Querying with Order By on page 2655 contains an example that shows you how to use offset and limit. Although the example also uses order by, you can use offset and limit independent of order by.

Querying with Select

The examples in this section query a document store and retrieve specific fields from the documents.

Note: Selecting a specific field is also known as a *projection*. You can improve the performance of projection queries by using secondary indexes. See Using Indexes to Optimize Projections in Queries on page 580 for more details.

Java

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using the Query.select method.

```
/**

  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // Create an OJAI query
    const query = {"$select": ["_id", "address.zipCode"]};
    // fetch OJAI Documents by query
    return store.find(query);
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Python

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["_id", "address.zipCode"]}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5290 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table --query {"$select":["_id","address.zipcode"]}

maprdb root:> find /demo_table --fields _id,address.zipcode
```

C#

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithSelect
{
    public async void FindQueryWithSelect()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
```

last-updated: Apr 11, 2022

```
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        //Create an OJAI query
        var query = connection.NewQuery().Select("_id",
"address.zipCode").Build();

        // Options for find request
        var options = new QueryOptions(1000, true);

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query, options);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
```

```
    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"address.zipCode"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Conditions

The examples in this section query a document store and return documents that have specific conditions.

For more information about how to specify query conditions in OJAI, see Query Conditions in OJAI Applications on page 2590.

Note: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 570 for more details.

Java - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the Query.where method. It uses an OJAI QueryCondition to specify the condition.

```

```

```
# Create an OJAI query
query = connection.new_query()\
    .where(connection.new_condition()
           .is_('address.zipCode', QueryOp.EQUAL, 95196)
           .close()
           .build())\
    .build()

# fetch the OJAI Documents by query
query_result = store.find(query)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()
```

Python - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$where": {"$eq": {"address.zipCode": 95196}}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5290 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table --q {"$where":{"$eq":
{"address.zipCode":95196}}}
```

```
maprdb root:> find /demo_table --where {"$eq":
{"address.zipCode":95196}}
```

C# - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the `Query.Where` method. It uses an OJAI QueryCondition to specify the condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithCondition
{
    public async void FindQueryWithCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        //Create an OJAI query
        var query = connection
            .NewQuery()
                .Where(connection
                        .NewQueryCondition()
                            .Is("address.zipCode", QueryOp.EQUAL, 95196)
                            .Close()
                        .Build())
                 .Build();

        // Fetch the OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithConditionJson
{
    public async void FindQueryWithConditionJson()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query =
            @"{" +
                @"""$where"":" +
                    @"{" +
                        @"""$eq"":{""address.zipCode"":
{""$numberLong"":""95196""}}" +
                    @"}" +
            @"}";

        // Fetch OJAI Documents by query
        var queryResult = store.FindQuery(query);

        var documentStream = await queryResult.GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the `Query.WhereCondition` function. It uses an OJAI Condition to specify the condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)
```

```
func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create a condition
    condition, err := client.MakeCondition(client.Is("address.zipCode",
client.EQUAL, 95196), client.Close())
    if err != nil {
        panic(err)
    }
    condition.Build()

    // Create an OJAI query
    query, err := client.MakeQuery(client.WhereCondition(condition))
    if err != nil {
        panic(err)
    }
    query.Build()

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
package main

import (
```

```
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{
        "$where": map[string]interface{}{
            "$eq": map[string]interface{}{
                "address.zipCode": 95196}}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Select and Conditions
The examples in this section query a document store and return specific fields from documents that have specific conditions.

For more information about how to specify query conditions in OJAI, see Query Conditions in OJAI Applications on page 2590.

Note: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 570 for more details.

Java

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses the Query.select and Query.where methods, specifying the query condition as a JSON string.

```

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    // Build an OJAI query with the condition specified as a JSON string
    final Query query = connection.newQuery()
        .select("name",
"address.zipCode").select("age").select("phoneNumbers[0]")
        .where("{\"$eq\": {\"address.zipCode\": 95196}}")
        .build();

    // fetch all OJAI Documents from this store
    final DocumentStream stream = store.find(query);

    for (final Document userDocument : stream) {
      // Print the OJAI Document
      System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
```

```
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```

  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // Create an OJAI query
    const query = {"$select": ["name",
        "adress.zipCode",
        "age",
        "phoneNumbers[0]"],
      "$where": {"$eq": {"address.zipCode": 95196}}};
    // fetch OJAI Documents by query
    return store.find(query);
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
```

```
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Python

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["name",
                     "adress.zipCode",
                     "age",
                     "phoneNumbers[0]"],
         "$where": {"$eq": {"address.zipCode": 95196}}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query,
                          options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5290 for more details about the syntax dbshell provides.

```
find /demo_table --query {
   "$select":["name","address.zipCode","age","phoneNumber[0]"],
   "$where":{"$eq":{"address.zipCode":95196}}
}

find /demo_table
   --fields name,address.zipCode,age,phoneNumber[0]
   --where {"$eq":{"address.zipCode":95196}}
```

Note: The commands are shown split across multiple lines for readability. When using dbshell, you must enter them in a single line.

C#

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithSelectAndCondition
{
    public async void FindQueryWithSelectAndCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI condition
        var condition = connection
            .NewQueryCondition()
                .Is("address.zipCode", QueryOp.EQUAL, 95196)
                .Close()
            .Build();

        // Create an OJAI query
        var query = connection
            .NewQuery()
                .Select("name", "adress.zipCode", "age", "phoneNumbers[0]")
                .Where(condition)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"firstName",
"address.zipCode", "age", "phoneNumbers[0]"},
        "$where": map[string]interface{}{
            "$eq": map[string]interface{}{"address.zipCode": 95196}}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Order By

The examples in this section query a document store and return specific fields from the documents, sorted in a specific order. One of the examples also uses offset and limit.

last-updated: Apr 11, 2022

Note: You can improve the performance of order by queries by using secondary indexes. See Using Indexes to Optimize ORDER BY Queries on page 577 for more information.

Java - Order By

The following example shows how to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sorting the documents by `_id`. It uses the Query.select and Query.orderBy methods.

Note: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` method call as follows:

```
orderBy("_id", SortOrder.DESC)
```

```

            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query = connection
            .NewQuery()
```

```
                .Select("_id", "firstName", "lastName", "address.zipCode")
                .Offset(2)
                .Limit(1)
                .OrderBy("_id", SortOrder.ASC)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Order By

The following example uses an OJAI query to return the `_id` and `firstName` fields from documents in a store and to sort the documents by `_id`.

The example sorts in the default ascending order. To sort in descending order, modify the `orderby` specification as follows:

```
"$orderby": map[string]interface{}{"_id": "desc"}}
```

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
```

```
    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName"},
        "$orderby": map[string]interface{}{"_id": "asc"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - Order By with Offset and Limit

The following example uses an OJAI query to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sort the documents by `_id`, offset the result by two documents, and limit the result to a single document.

The example sorts in the default ascending order. To sort in descending order, modify the `orderby` function call as follows:

```
"$orderby": map[string]interface{}{"_id": "desc"}}
```

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
```

```
    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName", "lastName", "address.zipCode"},
        "$offset":  2,
        "$limit":   1,
        "$orderby": map[string]interface{}{"_id": "asc"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Using the Java OJAI Client
This topic describes MapR Database functionality that is applicable to only the Java OJAI client. This includes instructions on how to compile your Java OJAI application, enable buffered writes, use the read your own writes feature, and enable available query options.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples

Compiling and Running Java OJAI Applications
For applications that use the Java OJAI API, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

Use Maven to compile and determine the application dependencies.

1. Add MapR's Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
    <repository>
        <id>mapr-releases</id>
        <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
        <snapshots><enabled>true</enabled></snapshots>
        <releases><enabled>true</enabled></releases>
    </repository>
</repositories>
```

2. Add a dependency to the MapR OJAI driver project:

```
<dependencies>
    <dependency>
        <groupId>com.mapr.ojai</groupId>
        <artifactId>mapr-ojai-driver</artifactId>
        <version>6.0.0-mapr</version>
    </dependency>
</dependencies>
```

Note: Replace the `<version>` property with the MapR Database version that you are using.

3. Use Maven to compile the application and resolve dependencies.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your MapR cluster expects, this can result in failures. The failures differ depending on the version of MapR you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 2367.

When the cluster is secure, the node must also have a MapR ticket configured for the user that runs the application.

You can use the following command to launch MapR Database JSON applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Enable OJAI Tracing

To help debug your Java OJAI application, you can enable OJAI tracing. MapR uses the `log4j` API to log tracing messages. To enable writing these messages to standard output, follow these steps:

1. Set the following property in your `/opt/mapr/conf/log4j.properties` file:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

2. Add the following to your `java` launch command:
   - In your java classpath, add the library that includes custom MapR `log4j` classes:

     ```
     -cp /opt/mapr/lib/central-logging-6.1.1-mapr.jar:<other classpaths>:.
     ```

   - Define the location of the `log4j.properties` file:

     ```
     -Dlog4j.configuration=file:/opt/mapr/conf/log4j.properties
     ```

last-updated: Apr 11, 2022

Reading Your Own Writes in Java OJAI

The Java OJAI `DocumentStore` and `Query` APIs provide the ability to track writes to JSON tables. Use these APIs to ensure your application reads recent writes on JSON tables with secondary indexes.

Description

You should use this feature if it is important for your query results to reflect synchronized data between a JSON table and its secondary indexes. Because MapR Database updates secondary indexes asynchronously, it is possible for a JSON table and its secondary indexes to become out-of-sync while the index update is in progress.

For example, consider the following scenario:

- Your application updates a JSON table.
- The JSON table includes an `address` field that is a nested document with a `zipCode` subfield.
- You have a secondary index on `zipCode`.
- Later in your application, you query the JSON table filtering on `zipCode`.

You want your query result to reflect the updates from earlier in your application. To achieve this, use the `DocumentStore` and `Query` APIs that enable you to retrieve up-to-date information from the index. The APIs synchronize write operations on the JSON table with read operations on a secondary index.

See Asynchronous Secondary Index Updates on page 587 for more information about index updates.

Note: The Python and Node.js OJAI APIs do not support this feature.

API Details

The OJAI `DocumentStore` and `Query` interfaces provide the following methods to support this functionality.

`DocumentStore.beginTrackingWrites`	Begins tracking the write operations performed through this instance of `DocumentStore`. The method takes an optional `previousWritesContext` parameter. If you specify this parameter, the tracking uses that context as the base state.
`DocumentStore.endTrackingWrites`	Flushes any buffered writes operations for this `DocumentStore` and returns a `writesContext`. Use this context to ensure that writes are visible to later queries. You can use the context across `DocumentStore` objects in the same, as well as different, client processes, when the stores refer to the same JSON table. For example, you can pass the `writesContext` returned by one `DocumentStore` to a second `DocumentStore`, to begin write tracking on the second store.
`DocumentStore.clearTrackedWrites`	Stops the write tracking and clears any state on this `DocumentStore` instance.
`Query.waitForTrackedWrites`	Sets the `writesContext` parameter for this query. A `writesContext` allows this query to "see" all the writes that happened inside the `writesContext` of a `DocumentStore`.

For the complete API, see Java OJAI Client API.

last-updated: Apr 11, 2022

Read Your Own Writes Example

A complete code example is available on github at OJAI_013_ReadYourOwnWrite.java. The following are code snippets from that example. Each step contains links to corresponding lines of code in the github example:

1. Call beginWriteTracking to set the starting point for the commit context on the JSON table `/demo_table`:

```
// Create an OJAI connection to MapR cluster
final Connection connectionNode1 =
DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode1 = connectionNode1.getStore("/demo_table");

// initiate tracking of commit-context
storeNode1.beginTrackingWrites();
```

2. Update the `zipCode` of an existing user and insert a new user in `/demo_table`:

```
// issue a set of mutations/insert/delete/etc
storeNode1.update("user0000",
connectionNode1.newMutation().set("address.zipCode", 95110L));
storeNode1.insertOrReplace(connectionNode1.newDocument(
    "{\"_id\": \"user0004\", \"firstName\": \"Joel\",
\"lastName\": \"Smith\", \"age\": 56, \"address\": {\"zipCode\":
{\"$numberLong\":95110}}}"));
```

3. Call endWriteTracking to flush the write operations after step 1, including updates to the secondary index:

```
final String commitContext = storeNode1.endTrackingWrites();
```

   The call also returns a `commitContext`.

4. Issue a query that calls waitForTrackedWrites with the `commitContext` from step 3:

```
/*
 * Next section of the code can run on the same or on a different node,
 * the `commitContext` obtained earlier needs to be propagated to that
node.
 */

// Create an OJAI connection to MapR cluster
final Connection connectionNode2 =
DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode2 = connectionNode2.getStore("/demo_table");

// Build an OJAI query and set its commit context with timeout of 2
seconds
final Query query = connectionNode2.newQuery()
    .select("_id", "firstName", "lastName", "address.zipCode")
    .where("{\"$gt\": {\"address.zipCode\": 95110}}")
    .waitForTrackedWrites(commitContext)
    .build();
```

   The query filters on the indexed subfield `address.zipCode`. The `commitContext` ensures that the query result includes the changes made in step 2.

Setting Query Options in Java OJAI
This topic describes how to set query options in your Java OJAI application.

See OJAI Query Options on page 2588 for a list of available query options.

To set an option, pass the option name as the first parameter to the Query.setOption method:

```
query.setOption("ojai.mapr.query.hint-using-index", indexName);
```

Enabling Buffered Writes in Java OJAI
By default, MapR Database JSON does not buffer writes. You can improve performance by enabling buffered writes in your Java OJAI application.

Description

The buffered writes option can be set in the Connection.getStore method. You pass the option setting through a `Document` object in the second parameter to the method. The `Document` object sets `ojai.mapr.documentstore.buffer-writes` to either `true` or `false`. The default value is `false`, which means that writes are not buffered.

Example Code Snippet

The following code sample enables buffered writes:

```
final DocumentStore store =
    connection.getStore(
        "/demo_table",

connection.newDocument().set("ojai.mapr.documentstore.buffer-writes",
true));
```

Using the Java OJAI Thin Client
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write MapR Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You

can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Java OJAI Thin Client Benefits

The client provides you with the following benefits:

- Easy installation and use
- Access to MapR Database JSON through the OJAI interface
- An OJAI interface that is tailored to Java developers
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

Comparing the Java OJAI Client and the Java OJAI Thin Client

Note these considerations when deciding whether to use the Java OJAI Client or the Java OJAI Thin Client:

- Both the Java OJAI client and Java OJAI Thin Client use the same API (Java OJAI Client API).
- The Java OJAI client is more scalable, more performant, and more fault tolerant, but also more complicated to deploy. See Using the Java OJAI Client on page 2666.
- The Java OJAI Thin Client requires you to specify the service (MapR Data Access Gateway) to which you will connect.
- The Java OJAI Thin Client is a pure Java client, while the Java OJAI client requires a JNI library.

Installing the MapR Data Access Gateway

To use the Java OJAI Thin Client, you must install the MapR Data Access Gateway on your MapR cluster. The gateway serves as a proxy for translating requests between the Java OJAI Thin Client and the MapR cluster. To administer the gateway and configure load balancing, see Administering the MapR Data Access Gateway on page 1492.

Java OJAI Thin Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure MapR cluster, the client uses:

- X.509 certificates to authenticate with the MapR Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Java OJAI Thin Client Connection String

The string you use to connect your OJAI client to a MapR cluster must have the following format:

```
"ojai:mapr:thin:@<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

<hostname>	Name of the MapR Data Access Gateway host
<port>	Port number (see Ports Used by MapR Software on page 2290) that gRPC clients use to connect to the MapR Data Access Gateway Default: 5678

last-updated: Apr 11, 2022

auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and cluster security settings. The default for this option is `true`, which is the required setting if connecting to a secure MapR cluster. If connecting to a nonsecure MapR cluster, set it to `false`. If set to `false`, the other SSL parameters are ignored.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. Must be set if the `ssl` option is `true`.

Here is an example of a connection string:

```
"ojai:mapr:thin:@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
```

Advanced Parameters

Advanced parameters such as `maxmsgsize` are optional for the Java OJAI Thin Client connection string:

maxmsgsize	If you use thin-client version `1.0.2-mapr` and later, `maxmsgsize` sets the maximum message size that the gRPC client accepts. The default is set to 32 MB, as this is the default maximum document size for MapR Database JSON tables. The value specified in the connection string should be less than or equal to the value set in the Data Access Gateway configuration on the server side (see Administering the MapR Data Access Gateway on page 1492).

Maven Coordinates

The Maven coordinates are:

```
<dependency>
    <groupId>com.mapr.ojai</groupId>
    <artifactId>mapr-ojai-driver-thin</artifactId>
    <version>1.0.2-mapr</version>
</dependency>
```

Additional Resources

The Java OJAI Client examples at the following location also apply to the Java OJAI Thin Client. Only the connection string and the Maven artifact name will be different for the thin client: https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples

Using the Node.js OJAI Client

Starting with EEP 6.0, you can use the Node.js OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON from middleware components, and add, update, and query documents in a MapR Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to MapR Database JSON through the OJAI interface in Node.js
- An OJAI interface that is tailored to Node.js developers
- Support for Callback and Promise/Async Node.js asynchronous programming models
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing
- Use of JavaScript to manipulate MapR Database JSON documents

To use the Node.js OJAI client, you must install the MapR Data Access Gateway on your MapR cluster. The gateway serves as a proxy for translating requests between the Node.js client and the MapR cluster. The gateway also performs data processing to keep the client lightweight. See Administering the MapR Data Access Gateway on page 1492 for information about how to administer the gateway and configure load balancing.

Important: MapR does not support running the Node.js OJAI client in a web browser.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/nodejs

Source Code: https://github.com/mapr/maprdb-node-client

Getting Started with the Node.js OJAI Client

This section describes the software required to run the Node.js OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Node.js OJAI applications.

The Node.js OJAI client is available starting in the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Node.js	Supported versions: • 6.x • 8.x • 9.x • 10.x
Node.js OJAI client	Install the client by using the following command: `npm install node-maprdb`

You also must have access to the following software:

last-updated: Apr 11, 2022

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a Node.js OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1492
- Modifying Configuration Settings for the Data Access Gateway Service on page 1493

Node.js OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure MapR cluster, the client uses:

- X.509 certificates to authenticate with the MapR Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Node.js OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the MapR Data Access Gateway host
<port>	Port number (see Ports Used by MapR Software on page 2290) that gRPC clients use to connect to the MapR Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the MapR Data Access Gateway on page 1492.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format.

	Must be set if the `ssl` option is `true`.
`sslTargetNameOverride=<CA certificate common name>`	Fully qualified domain name specified in the CA certificate, which is different from the `<hostname>` in the connection string. For example, imagine that you are using the following: • Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`. • Internal DNS is `node1.mydomain.com`. • CA signed certificate is issued to `node1.mydomain.com`. Using these names, you must specify the following connection string: `"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

Node.js OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`ojai.mapr.rpc.wait-multiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`ojai.mapr.rpc.wait-max-attempt`	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
`ojai.mapr.rpc.max-retries`	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	

	Default Parameters:
	`{`
	`'ojai.mapr.rpc.wait-multiplier': 1000,`
	`'ojai.mapr.rpc.wait-max-attempt': 18000,`
	`'ojai.mapr.rpc.max-retries': 7`
	`}`
		`{`
		`'ojai.mapr.rpc.wait-multiplier': 2,`
		`'ojai.mapr.rpc.wait-max-attempt': 90,`
		`'ojai.mapr.rpc.max-retries': 5`
		`}`

1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionManager.getConnection` call:

```
const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';
const options = {
  'ojai.mapr.rpc.wait-multiplier': 5,
  'ojai.mapr.rpc.wait-max-attempt': 50,
  'ojai.mapr.rpc.max-retries': 3
}

let connection;

ConnectionManager.getConnection(connectionString,options)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
```

Writing Node.js OJAI Applications

For information about writing a Node.js OJAI application, see the Node.js sections in the following topics:

Querying in OJAI Applications on page 2579	Provides an introduction to the basic flow of an OJAI application that queries a MapR Database JSON table
Examples: Querying JSON Documents on page 2624	Contains code samples of OJAI applications that query MapR Database JSON tables
Managing JSON Documents on page 2542	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in MapR Database JSON tables

Node.js OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Node.js OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`ConnectionManager`	Manages connections to MapR Database JSON.
`Connection`	Provides a logical connection to an OJAI data source: for example, MapR Database JSON.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, MapR Database JSON tables.
`QueryResult`	Encapsulates the stream of result sets for an OJAI query.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.

See Node.js OJAI Client API for details about each class, including the methods available in each class.

Setting Query Options in Node.js OJAI

There are two categories of options you can set in your Node.js OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Node.js OJAI Method Call

Option Name	Description
`ojai.mapr.query.include-query-plan`	Enables or disables availability of the query plan for retrieval Value: `true|false` Default: `false`
`ojai.mapr.query.timeout-milliseconds`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
const docStream = store.find(
    query,
    { 'ojai.mapr.query.timeout-milliseconds': 3000 }
);
```

last-updated: Apr 11, 2022

Setting Query Options in Node.js Using OJAI Query Syntax

OJAI Query Options on page 2588 describes query options that are available in all OJAI clients. To use these options in Node.js OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the Python OJAI Client

Starting with EEP 6.0, you can use the Python OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to MapR Database JSON through the OJAI interface in Python
- An OJAI interface that is tailored to Python developers
- Use of Python types to manipulate MapR Database JSON documents
- Support for Python multiprocessing and multithreading modules
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Python OJAI client, you must install the MapR Data Access Gateway on your MapR cluster. The gateway serves as a proxy for translating requests between the Python client and the MapR cluster. The gateway also performs data processing to keep the client lightweight. See Administering the MapR Data Access Gateway on page 1492 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/python

Source Code: https://github.com/mapr/maprdb-python-client

Getting Started with the Python OJAI Client

This section describes the software required to run the Python OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Python OJAI applications.

The Python OJAI client is available starting with the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Python	Use Python 2.7 or later
pip	See https://pip.pypa.io/en/stable/installing/ for instructions specific to your environment.
Python OJAI client	Install the client by using the following command: `pip install maprdb-python-client`

You also must have access to the following software:

- MapR cluster 6.1 or later

- MapR Data Access Gateway 2.0 or later

To run a Python OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1492
- Modifying Configuration Settings for the Data Access Gateway Service on page 1493

Python OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure MapR cluster, the client uses:

- X.509 certificates to authenticate with the MapR Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Python OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the MapR Data Access Gateway host
<port>	Port number (see Ports Used by MapR Software on page 2290) that gRPC clients use to connect to the MapR Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the MapR Data Access Gateway on page 1492.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. Must be set if the `ssl` option is `true`.

last-updated: Apr 11, 2022

sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the CA certificate, which is different from the <hostname> in the connection string. For example, imagine that you are using the following: • Public network host name is ec2-203-0-113-25.compute-1.amazonaws.com. • Internal DNS is node1.mydomain.com. • CA signed certificate is issued to node1.mydomain.com. Using these names, you must specify the following connection string: `"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

Python OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
ojai.mapr.rpc.wait-multiplier	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
ojai.mapr.rpc.wait-max-attempt	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
ojai.mapr.rpc.max-retries	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	

	Default Parameters:
	`{`
	`'ojai.mapr.rpc.wait-multiplier': 1000,`
	`'ojai.mapr.rpc.wait-max-attempt': 18000,`
	`'ojai.mapr.rpc.max-retries': 7`
	`}`
		`{`
		`'ojai.mapr.rpc.wait-multiplier': 2,`
		`'ojai.mapr.rpc.wait-max-attempt': 90,`
		`'ojai.mapr.rpc.max-retries': 5`
		`}`

1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionFactory.get_connection` call:

```
connection_str = 'localhost:5678?auth=basic;user=mapr;password=mapr;' \
    'ssl=true;' \
    'sslCA=/opt/mapr/conf/ssl_truststore.pem;' \
    'sslTargetNameOverride=node1.mapr.com'
options = {
    'ojai.mapr.rpc.wait-multiplier': 5,
    'ojai.mapr.rpc.wait-max-attempt': 50,
    'ojai.mapr.rpc.max-retries': 3
}
connection =
ConnectionFactory.get_connection(connection_str=connection_str,options=optio
ns)
```

Writing a Python OJAI Application

For information about writing a Python OJAI application, see the Python sections in the following topics:

Querying in OJAI Applications on page 2579	Provides an introduction to the basic flow of an OJAI application that queries a MapR Database JSON table
Examples: Querying JSON Documents on page 2624	Contains code samples of OJAI applications that query MapR Database JSON tables
Managing JSON Documents on page 2542	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in MapR Database JSON tables

last-updated: Apr 11, 2022

Python OJAI Client Classes and Methods
This topic lists and describes the classes supported by the Python OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`Connection`	Provides a logical connection to an OJAI data source: for example, MapR Database JSON.
`ConnectionDriver`	Provides a connection handler, which enables you to get and check connections
`ConnectionManager`	Manages connections to MapR Database JSON.
`Document`	Provides the primary, DOM-based interface for inspecting OJAI documents.
`DocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, MapR Database JSON tables.
`DocumentStream`	Encapsulates the result set of an OJAI query.
`QueryResult`	Encapsulates the result set of an OJAI query.
`Query`	Encapsulates an OJAI query.
`QueryCondition`	Encapsulates a query condition; similar to a SQL `where` clause.
`Value`	Encapsulates the value of a field, scalar, or complex type in an OJAI document.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.
`OInterval`	Encapsulates the OJAI `INTERVAL` type.

See Python OJAI Client API for details about each class, including the methods available in each class.

Multiprocessing and Multithreading in Python OJAI Applications
Python supports multiprocessing and multithreading modules that enable you to spawn either multiple processes or multiple threads in a Python program. This section contains examples that show you how to use these modules in your Python OJAI application.

Multiprocessing in Python OJAI Applications

The following code example spawns multiple processes using the Python `multiprocessing` module. When you use the module, you must create a separate OJAI connection for each process.

The code example is available at 014_multiprocessing_example.py.

```
"""Following example works with Python Client"""

import multiprocessing
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

"""Create a connection, get store, insert_or_replace/update document in
 store via multiprocessing"""

# Create a connection string using path:user@password
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
```

```
# Create method which will be used for multiprocessing
def sample():
    # Create connection from connection_url
    # Cannot share connection for processes,
    # so need to create connection for each process.
    connection =
ConnectionFactory().get_connection(connection_str=connection_str)

    # Get a store and assign it as a DocumentStore object
    store = connection.get_or_create_store('/tmp/store_name')

    # Insert 15 documents, represented as Python dictionaries,
    # into DocumentStore
    for i in range(15):
        store.insert_or_replace(doc={'_id': str(i), 'name': 'Greg'})

    # Create DocumentMutation object using the OJAIConnection object
    mutation = connection.new_mutation()

    # Set mutation value
    mutation.set_or_replace(field_path='name', value='T')

    # Update 15 Document in store
    for i in range(15):
        store.update(_id=str(i), mutation=mutation)

# Create simple method for run process from Pool
def run(unused_var):
    pass

# Create data for multiprocessing
proces_count = 7
map_iterable = [1]  # simple iterator

# Create Pool object using the function and process_count value
p = multiprocessing.Pool(proces_count, initializer=sample)

# Run processes from the Pool
p.map(run, map_iterable)
```

Multithreading in Python OJAI Applications

You can use either the Python `thread` or `threading` module to spawn multiple threads in your Python application. When you use these modules, you can share an OJAI connection across threads.

Thread Module

The following code example uses the `thread` module. It is available at 015_thread_example.py.

```
"""Following example works with
Python Client"""
import thread
import time
from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
 store via thread using same
connection"""
```

```
# Create method which will be used
for threads
def run_thread(name, conn):
    # Print that thread started with
threadName
    print('\n Start thread ', name)

    # Get a store and assign it as a
DocumentStore object
    store =
conn.get_or_create_store('/tmp/
store_name')

    # Insert 15 documents,
represented as Python dictionaries,
    # into DocumentStore
    for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

    # Create DocumentMutation object
using the OJAIConnection object
    mutation = conn.new_mutation()

    # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

    # Update 15 Document in store
    for index in range(15):
        store.update(_id=str(index),
mutation=mutation)

    # Print that thread done with
threadName
    print('\n Done thread ', name)

# Create a connection string using
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \

"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(conne
ction_str)

# Create 10 threads using the same
```

```
connection instance
for i in range(10):
    thread_name =
'Thread-{}'.format(str(i))

thread.start_new_thread(run_thread,
(thread_name, connection,))

# This thread implementation doesn't
return thread object
# so thread status cannot be checked
# Wait 10 seconds
time.sleep(10)

# Close connection
connection.close()
```

Threading Module

The following code example uses the `threading` module. It is available at 016_threading_example.py.

```
"""Following example works with
Python Client"""
import threading
import time

from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
 store via thread using same
connection"""

# Create a connection string using
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \

"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(conne
ction_str)

# Create child for sample threading
implementation
class MyThread(threading.Thread):
    # Implement __init__() method,
which takes thread name and
    # connection object
    def __init__(self, name,
```

```
connection):

threading.Thread.__init__(self)
        self.name = name
        self.connection = connection

    # Implement run() method
    def run(self):
        # Print that thread started
with threadName
        print('\n Start thread ',
self.name)

        # Get a store and assign it
as a DocumentStore object
        store =
connection.get_or_create_store('/tmp/
store_name')

        # Insert 15 documents,
represented as Python dictionaries,
        # into DocumentStore
        for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

        # Create DocumentMutation
object using the OJAIConnection object
        mutation =
connection.new_mutation()

        # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

        # Update 15 Document in store
        for index in range(15):

store.update(_id=str(index),
mutation=mutation)

        # Print that thread done with
threadName
        print('\n Done thread ',
self.name)

# This thread implementation return
thread object
# so thread status can be checked via
native methods
# Simple thread waiter for thread
list:
def waiter(threads):
    for my_thread in threads:
        # Check that current thread
is alive
        if my_thread.is_alive():
            time.sleep(1)
            # Wait until current
```

```
thread finished
            waiter(threads)
        # Move to the next thread if
this is not alive
        elif not my_thread.is_alive():
            pass

# Create list instance for storing
created threads objects
thread_list = []

# Create and run 10 threads
for i in range(10):
    # Create thread instance using
MyThread and OJAIConnection object
    thread =
MyThread(name='Thread-{0}'.format(str(
i)),

connection=connection)

    # Start current thread
    thread.start()

    # Append thread object into
thread_list
    thread_list.append(thread)

# Wait until all threads will finished
waiter(thread_list)

# Close connection
connection.close()
```

Setting Query Options in Python OJAI

There are two categories of options you can set in your Python OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Python OJAI Method Call

Option Name	Description
`ojai.mapr.query.include-query-plan`	Enables or disables availability of the query plan for retrieval Value: `True`|`False` Default: `False`
`ojai.mapr.query.result-as-document`	Enables or disables returning the query result as an OJAI `Document` class object versus a Python dictionary Value: `True`|`False` Default: `False`; returns query result as a Python dictionary
`ojai.mapr.query.timeout-milliseconds`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

last-updated: Apr 11, 2022

To set any of these query options, you must pass the option as the second parameter in the DocumentStore.find method.

The following code snippet sets the option to return the query result as a Document object:

```
options = {'ojai.mapr.query.result-as-document': True}
query_result = store.find(query, options=options)
```

Setting Query Options in Python Using OJAI Query Syntax

OJAI Query Options on page 2588 describes query options that are available in all OJAI clients. To use these options in Python OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the C# OJAI Client

Starting with EEP 6.1.0, you can use the C# OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to MapR Database JSON through the OJAI interface in C#
- An OJAI interface that is tailored to C# developers
- Use of C# types to manipulate MapR Database JSON documents
- Support for C# asynchronous programming and threading mechanism
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the C# OJAI client, you must install the MapR Data Access Gateway on your MapR cluster. The gateway serves as a proxy for translating requests between the C# client and the MapR cluster. The gateway also performs data processing to keep the client lightweight. See Administering the MapR Data Access Gateway on page 1492 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/csharp

Getting Started with the C# OJAI Client

This section describes the software required to run the C# OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write C# OJAI applications.

The C# OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Visual Studio 2017	https://visualstudio.microsoft.com/vs/

Client Software	Installation Notes

C# OJAI client	• Install the client by using the NuGet Command Line Interface (CLI).
	• Install the `MapRDB.Driver` using the NuGet Package Manager Console:
	`Install-Package MapRDB.Driver -Version 1.0.0`
	• Use the dotnet command line interface:
	`dotnet add package MapRDB.Driver`
	• Use the NuGet Package Manager UI. For instructions, follow this link.

You also must have access to the following software:

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a C# OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1492
- Modifying Configuration Settings for the Data Access Gateway Service on page 1493

C# OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure MapR cluster, the client uses:

- X.509 certificates to authenticate with the MapR Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

C# OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>`	Name of the MapR Data Access Gateway host
`<port>`	Port number (see Ports Used by MapR Software on page 2290) that gRPC clients use to connect to the MapR Data Access Gateway Default: 5678
`auth=<scheme_name>`	The authentication scheme for the current connection; currently, only `basic`
`user=<username>`	The user name for `basic` authentication
`password=<password>`	The password for `basic` authentication

last-updated: Apr 11, 2022

ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the MapR Data Access Gateway on page 1492.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. Must be set if the `ssl` option is `true`.
sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the CA certificate, which is different from the `<hostname>` in the connection string. For example, imagine that you are using the following: • Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`. • Internal DNS is `node1.mydomain.com`. • CA signed certificate is issued to `node1.mydomain.com`. Using these names, you must specify the following connection string: `"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

C# OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`retryExponentialMultiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000

last-updated: Apr 11, 2022

Connection Option Parameter	Description	Default Value
`retryCount`	Maximum number of retry attempts	7

To set these retry options, you must pass them in the `ConnectionFactory.CreateConnection` call:

```
var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
var connection = ConnectionFactory.CreateConnection(connectionStr, 3, 5);
```

Writing a C# OJAI Application

For information about writing a C# OJAI application, see the C# sections in the following topics:

Querying in OJAI Applications on page 2579	Provides an introduction to the basic flow of an OJAI application that queries a MapR Database JSON table
Examples: Querying JSON Documents on page 2624	Contains code samples of OJAI applications that query MapR Database JSON tables
Managing JSON Documents on page 2542	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in MapR Database JSON tables

C# OJAI Client Classes and Methods

This topic lists and describes the classes supported by the C# OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`Value`	Encapsulates the value of a field, scalar, or complex in an OJAI document.
`OjaiDocument`	Provides the primary, DOM-based interface for inspecting OJAI documents
`OjaiDocumentStream`/ `QueryResult`	Encapsulates the result set of an OJAI query.
`OjaiDocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`Query`	Encapsulates an OJAI query.
`QueryCondition`	Encapsulates a query condition; similar to a SQL `where` clause.
`ConnectionFactory`	Provides a logical connection to an OJAI data source: for example, MapR Database JSON.
`MapRDBConnection`	Provides a connection handler, which enables you to get and check connections.
`OjaiDocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, MapR Database JSON tables.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.
`OInterval`	Encapsulates the OJAI `INTERVAL` type.

See the C# OJAI Client API for details about each class, including the methods available in each class.

Setting Query Options in C# OJAI

There are two categories of options you can set in your C# OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a C# OJAI Method Call

Option Name	Description
`IncludeQueryPlan`	Enables or disables availability of the query plan for retrieval Value: `true|false` Default: `false`
`Timeout`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.Find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
var queryResult = store.Find(query, new QueryOptions() { Timeout = 3000 });

var queryResult = store.Find(query, new QueryOptions(3000));
```

Setting Query Options in C# Using OJAI Query Syntax

OJAI Query Options on page 2588 describes query options that are available in all OJAI clients. To use these options in C# OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the Go OJAI Client

Starting with EEP 6.0.0, you can use the Go OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to MapR Database JSON through the OJAI interface in Go
- An OJAI interface that is tailored to Go developers
- Use of Go types to manipulate MapR Database JSON documents
- Support for Go multithreading using Goroutines
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Go OJAI client, you must install the MapR Data Access Gateway on your MapR cluster. The gateway serves as a proxy for translating requests between the Go client and the MapR cluster. The gateway also performs data processing to keep the client lightweight. To administer the gateway and configure load balancing, see Administering the MapR Data Access Gateway on page 1492.

Blog: CRUD with the New Golang Client for MapR Database

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/golang

Source Code: https://github.com/mapr/maprdb-go-client

Getting Started with the Go OJAI Client

This section describes the software required to run the Go OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Go OJAI applications.

The Go OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Golang 1.10 (or later)	
Go OJAI client	Install the client using the following command: `go get github.com/mapr/maprdb-go-client`

You also must have access to the following software:

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a Go OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1492
- Modifying Configuration Settings for the Data Access Gateway Service on page 1493

For some sample code, see https://github.com/magpierre/mapr_go_client_mqtt. `main.go` shows a simple Go client that reads from an MQTT messaging protocol and writes to a MapR JSON database.

Go OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure MapR cluster, the client uses:

- X.509 certificates to authenticate with the MapR Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Go OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>` Name of the MapR Data Access Gateway host

last-updated: Apr 11, 2022

<port>	Port number (see Ports Used by MapR Software on page 2290) that gRPC clients use to connect to the MapR Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the MapR Data Access Gateway on page 1492.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. Must be set if the `ssl` option is `true`.
sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the CA certificate, which is different from the <`hostname`> in the connection string. For example, imagine that you are using the following: • Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`. • Internal DNS is `node1.mydomain.com`. • CA signed certificate is issued to `node1.mydomain.com`. Using these names, you must specify the following connection string: `"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

Go OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`MaxAttempt`	Maximum number of retry attempts	9
`WaitBetweenSeconds`	Maximum wait time between attempts	12 s
`CallTimeoutSeconds`	Maximum call timeout	60 s

To set these retry options, you must pass them in the `client.MakeConnectionWithRetryOptions` call:

```
    connectionString := "localhost:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"
    options := &client.ConnectionOptions{MaxAttempt:3,
WaitBetweenSeconds:10, CallTimeoutSeconds:60}
    connection, _ :=
client.MakeConnectionWithRetryOptions(connectionString, options)
```

Writing a Go OJAI Application

For information about writing a Go OJAI application, see the Go sections in the following topics:

Querying in OJAI Applications on page 2579	Provides an introduction to the basic flow of an OJAI application that queries a MapR Database JSON table
Examples: Querying JSON Documents on page 2624	Contains code samples of OJAI applications that query MapR Database JSON tables
Managing JSON Documents on page 2542	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in MapR Database JSON tables

Go OJAI Client Structures and Functions

This topic lists and describes the structures supported by the Go OJAI client and provides a link to document pages that describe the functions in each structure.

Structure Name	Description
`Document`	Provides the primary, DOM-based interface for inspecting OJAI documents.
`QueryResult`	Encapsulates the result set of an OJAI query.
`DocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`Query`	Encapsulates an OJAI query.
`Condition`	Encapsulates a query condition; similar to a SQL `where` clause.
`Connection`	Provides a logical connection to an OJAI data source: for example, MapR Database JSON.

last-updated: Apr 11, 2022

Structure Name	Description
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, MapR Database JSON tables.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.

For details about each structure, including the functions available in each structure, see the Go OJAI Client API.

Setting Query Options in Go OJAI
There are two categories of options you can set in your Go OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Go OJAI Function Call

Option Name	Description
`IncludeQueryPlan`	Enables or disables availability of the query plan for retrieval. Value: `true`|`false` Default: `false`
`ResultAsDocument`	Enables or disables returning the query result as an OJAI `Document` object list versus a Go map list. Value: `True`|`False` Default: `False`: returns query result as a Go map list
`Timeout`	Query timeout in milliseconds. Maximum allowed value is 2147483647 Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.FindQueryWithContext` function.

The following code snippet sets the query timeout to 3000 milliseconds:

```
timeoutCtx, cancel := context.WithTimeout(context.Background(),
time.Duration(3*time.Second))
result, err := suite.store.FindQueryWithContext(query, findOptions,
timeoutCtx)
cancel()
```

Setting Query Options in Go Using OJAI Query Syntax

OJAI Query Options on page 2588 describes query options that are available in all OJAI clients. To use these options in Go OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the MapR Database JSON REST API
Starting in the EEP 5.0 release, you can use a REST API to access MapR Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on MapR Database JSON tables.

The API supports the following operations:

last-updated: Apr 11, 2022

- Create and delete MapR Database JSON tables
- Insert, update, and delete documents from a table
- Retrieve documents while specifying filter conditions and projections

The REST API has the following characteristics:

- Operations are stateless
- Operations are synchronous
- Request responses are not buffered
- Web connections are secure when connecting to secure MapR clusters
- Supports the following methods of authentication:
  - Basic authentication
  - Token-based authentication using JSON Web Tokens (JWT)
- Supports user impersonation - All data access calls are run on behalf of the authenticated user
- Returns HTTP error codes and detailed error responses in the response message body

When connecting to a MapR cluster, you must use HTTPS in your requests.

With basic authentication, you pass a username and password in your Web client. With token based authentication, you generate a token and then pass the token in the header of subsequent API requests.

The MapR Data Access Gateway is the service that supports this web API. You should configure multiple instances of this service across your MapR cluster to distribute request processing. To achieve load balancing, you must install an external load balancer. Using token based authentication and an external load balancer, you can achieve high availability and failover. Because the REST API is stateless, you do not have to regenerate your authentication token when different service instances process your API request. This applies even in the event of failovers and service restart. You must regenerate your token when it expires.

The API does not support the following features:

- MapR Database JSON administrative commands, except the commands noted earlier
- Read Your Own Writes

To modify properties that the MapR Database JSON REST API uses, see Application Properties.

Related concepts

Understanding the MapR Data Access Gateway on page 750
The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster.

Administering the MapR Data Access Gateway on page 1492
The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Getting Started with the MapR Database JSON REST API

A simple way to invoke the MapR Database JSON REST API is to use cURL commands. This section contains a sequence cURL commands that demonstrate the basic functionality of the API.

last-updated: Apr 11, 2022

Note: The MapR Database JSON REST API is available starting in the EEP 5.0 release.

The operations shown are the following:

- Create a MapR Database JSON table
- Insert documents into the table
- Retrieve documents from the table, including retrievals that contain field projections and conditions
- Update individual documents and fields within a document

To learn about the complete API, see the reference material at Understanding the MapR Database JSON REST API on page 2703.

The examples in this section assume that you installed the MapR Data Access Gateway on the host `10.10.100.42`. The examples use HTTPS with the default HTTPS port of `8243`. For information about installing the Data Access Gateway, see Installing the Data Access Gateway Service on page 1492.

Note: The examples URL encode the slashes in the table path (`%2F`) to differentiate them from the slashes in the command API.

Using Basic Authentication

The commands in this section use basic authentication. To use this form of authentication, you must pass the username and password in all commands, using the `-u` option.

1. Create a MapR Database JSON table in the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. Insert 3 documents into the table:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
 {"_id":"user002","first_name":"Jane","last_name":"Doe"},
 {"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

3. Retrieve all of the documents:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

4. Limit the `GET` request to 2 documents starting at offset 1:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
offset=1&limit=2' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

5. Retrieve only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "first_name": "John"
        },
        {
            "first_name": "Jane"
        },
        {
            "first_name": "Simon"
        }
    ]
}
```

6. Retrieve all documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
  -u root:mapr
```

Note: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

The command returns 2 documents:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        }
    ]
}
```

7. Retrieve the id and first name of documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
  -u root:mapr
```

Note: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ]
}
```

8. Run the same command, also retrieving the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
  -u root:mapr
```

The output includes the query plan:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ],
    "QueryPlan": [
        [
            {
                "streamName": "DBDocumentStream",
                "parameters": {
                    "queryConditionPath": true,
                    "projectionPath": [
                        "_id",
                        "first_name"
                    ],
                    "primaryTable": "/apps/employees"
                }
            }
        ]
    ]
}
```

9. Update the first name in one of the documents, specifying the `id` in the command:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"$set":{"first_name":"Jay"}}'
```

10. Retrieve the updated document, specifying the `id` in the command:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -u root:mapr
```

    The document contains an updated first name:

```
{
    "_id": "user001",
    "first_name": "Jay",
    "last_name": "Doe"
}
```

11. Replace the same document, but this time with a user who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"_id":"user001","first_name":"Jonathan"}'
```

12. Retrieve the new document by passing the `id` in the request:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -u root:mapr
```

    The document contains only a first name:

```
{
    "_id": "user001",
    "first_name": "Jonathan"
}
```

Using Token-Based Authentication

To use token-based authentication, you first create a token, authenticating with a username and password. You then pass the generated token in all subsequent commands.

1. Generate a token using the following command:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

   The command returns the following token:

```
{
    "token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiYXVkIjoid2ViIiwiZXhwIjoxNTIwMjY
5MTQwLCJpYXQiOjE1MjAyNjczNDB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1Zs
oI1ar09it7-XwNtRqfL_I29IHLyfmuHcT5eSIpwq6ng"
}
```

2. Pass the token in your cURL command, as shown in the following GET:

```
curl -X GET \
  https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees \
  -H 'Authorization:
Bearer
eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiYXVkIjoid2ViIiwiZXhwIjoxNTIwMjY5
MTQwLCJpYXQiOjE1MjAyNjczNDB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1Zso
I1ar09it7-XwNtRqfL_I29IHLyfmuHcT5eSIpwq6ng'
```

Understanding the MapR Database JSON REST API
The section describes the details of the MapR Database JSON REST API.

The following table summarizes the commands the API supports. Click on the command for details about the command parameters and examples.

Category	REST API Command	Description
Authentication	POST /auth/v2/token on page 2703	Creates an authentication token
Table Operations	PUT /api/v2/table/{path} on page 2704	Creates a MapR Database JSON table
	DELETE /api/v2/table/{path} on page 2704	Drops a MapR Database JSON table
Table Document Operations	POST /api/v2/table/{path} on page 2705	Adds one or more documents to a MapR Database JSON table
	PUT /api/v2/table/{path}/document/{id} on page 2706	Updates a document by id in a MapR Database JSON table
	POST /api/v2/table/{path}/document/{id} on page 2707	Updates a partial document by id in a MapR Database JSON table using mutations
	DELETE /api/v2/table/{path}/document/{id} on page 2707	Deletes a single document by id in a MapR Database JSON table
	GET /api/v2/table/{path} on page 2708	Retrieves one or more documents from a MapR Database JSON table
	GET /api/v2/table/{path}/document/{id} on page 2711	Retrieves a single document by id from a MapR Database JSON table

POST /auth/v2/token
Authenticates a user. If successful, creates an authentication token that you use in subsequent API requests. By default, the token expires in 30 minutes. After a token expires, you must rerun this command to generate a new token.

last-updated: Apr 11, 2022

Request Example

The following creates an authentication token for user `root`:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

Response Example

```
200 OK

{
  "token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJtYXByIiwiYXVkIjoid2ViIiwiZXhwIjoxNTE2NzQ2MD
c4LCJpYXQiOjE1MTY3NDQyNzh9.6YXWX72UP9_U9DPmT8c-_DQRDwY_TL0DEdsBaBqoaLf8iK0qH
NctyBTbFO5ktUJMTubVOj6D7pFOEyEuV8lhjA"
}
```

For an example that shows how to use the token returned by this API call in a subsequent `GET` command, see Using Token-Based Authentication on page 2702.

PUT /api/v2/table/{path}
Creates a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the new MapR Database JSON table

Request Example

The following creates a table with the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps/employees' \
  -u root:mapr
```

Response Example

```
201 Created
```

DELETE /api/v2/table/{path}
Drops a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table

Request Example

The following drops a table with the path `/apps/employees`:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}
Adds or replaces one or more documents in a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table
fieldAsKey `string` *(query)*	The name of the field that serves as the key in the JSON document
mode `string` *(query)*	Defines the behavior of the operation. The following are the possible values: • `insertOrReplace` - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. • `insert` - Inserts new document; if the specified document ID already exists, returns an error. • `replace` - Replaces document with specified ID; returns an error if document does not exist. Default: `insertOrReplace`
body *(body)*	The body of the documents to add or replace

Request Example

The following inserts 3 documents into `/apps/employees`:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
 {"_id":"user002","first_name":"Jane","last_name":"Doe"},
 {"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

last-updated: Apr 11, 2022

Response Example

```
200 OK
```

PUT /api/v2/table/{path}/document/{id}
Updates a single document by id in a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table
id `string` *(path)*	**Required**: Id of the document to update. If the document with the specified id does not exist, the mode parameter determines the behavior.
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndReplace` evaluation. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.
mode `string` *(query)*	Defines the behavior of the operation. The following are the possible values: • `insertOrReplace` - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. • `insert` - Inserts new document; if the specified document ID already exists, returns an error. • `replace` - Replaces document with specified ID if it exists Default: `insertOrReplace`
body *(body)*	**Required**: The body of the new document

Request Example

The following replaces the document with id `user001` in `/apps/employees` with an employee who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"_id":"user001","first_name":"Jonathan"}'
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}/document/{id}
Updates a partial document by id in a MapR Database JSON table using mutations

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table
id `string` *(path)*	**Required**: Id of the document to update. If the document does not exist, inserts a new document.
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndUpdate` evaluation. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.
body *(body)*	**Required**: The mutation specifying updates to the document. See Using OJAI Mutation Syntax on page 2561 for a description of the syntax.

Request Example

The following updates the `first_name` field the document in `/apps/employees` with id `user001`, replacing the field with the value `Jay`:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"$set":{"first_name":"Jay"}}'
```

Response Example

```
200 OK
```

DELETE /api/v2/table/{path}/document/{id}
Deletes a single document by id in a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table
id `string` *(path)*	**Required**: Id of the document to delete

last-updated: Apr 11, 2022

Name	Description
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndDelete` evaluation. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.

Request Example

The following deletes the document with id `user003` in `/apps/employees`:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user003' \
  -u root:mapr
```

Response Example

```
200 OK
```

GET /api/v2/table/{path}
Retrieves one or more documents from a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table
condition `string` *(query)*	Query condition (in JSON format) to evaluate on documents retrieved. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.
fields `string` *(query)*	The fields from the document to retrieve. See JSON Document Field Paths on page 515 for details about how to specify field paths.
fromId `string` *(query)*	Starting id of the range of documents to retrieve (inclusive)
toId `string` *(query)*	Ending id of the range of documents to retrieve (exclusive)
getPlan `string` *(query)*	If set to `true`, returns the query plan used to retrieve the documents Value: True|False Default: False

Name	Description
limit `integer` *(query)*	The maximum number of documents to retrieve
offset `integer` *(query)*	The number of documents to skip past before returning results
orderBy `string` *(query)*	The fields on which to sort the result. Specify the fields in a comma separated list, in the format `<field name>:<sort order>` where `<sort order>` is either `asc` or `desc`. `<sort order>` is optional and defaults to `asc`.
query `string` *(query)*	Query string with predefined keywords that define the behavior of the query. See Query with --query on page 5292 for syntax details.
withTags `string` *(query)*	Enables or disables output with extended type tags Value: True|False Default: True

Request Examples

1. The following retrieves all documents from `/apps/employees`:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. The following specifies an offset and limit in the GET request:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
offset=1&limit=2' \
  -u root:mapr
```

3. The following retrieves only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
  -u root:mapr
```

4. The following retrieves all documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
  -u root:mapr
```

Note: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

5. The following retrieves the id and first name of documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
  -u root:mapr
```

6. The following runs the same command and includes a request for the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
  -u root:mapr
```

Response Examples

```
200 OK

{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

If you have configured the MapR Data Access Gateway to limit the number of documents in retrieval requests, and your result set exceeds the limit, the API response includes a warning. In the following example, the limit is set to 2:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        }
    ],
    "WARNING": "result truncated due to limit set to 2."
}
```

The following shows an example of output that includes a query plan. It corresponds to the output from example #6 in the previous section:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ],
    "QueryPlan": [
        [
            {
                "streamName": "DBDocumentStream",
                "parameters": {
                    "queryConditionPath": true,
                    "projectionPath": [
                        "_id",
                        "first_name"
                    ],
                    "primaryTable": "/apps/employees"
                }
            }
        ]
    ]
}
```

GET /api/v2/table/{path}/document/{id}
Retrieves a single document by id from a MapR Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the MapR Database JSON table
id `string` *(path)*	**Required**: Id of the document to retrieve
condition `string` *(query)*	Query condition (in JSON format) to evaluate on document retrieved. See OJAI Query Condition Syntax on page 2606 for a description of the syntax.
fields `string` *(query)*	The fields from the document to retrieve. See JSON Document Field Paths on page 515 for details about how to specify field paths.
withTags `string` *(query)*	Enables or disables output with extended type tags Value: True|False Default: True

Request Example

The following retrieves the document with id `user003` from `/apps/employees`:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user003' \
  -u root:mapr
```

Response Example

```
200 OK

{
    "_id": "user003",
    "first_name": "Simon",
    "last_name": "Davis"
}
```

MapR Database JSON MapReduce API

This API library extends the Apache Hadoop MapReduce framework, so that you can write your own MapReduce applications to write data from one JSON table to another.

Prerequisites to using this API Library

- Ensure that you have a firm grasp of MapReduce concepts and experience writing MapReduce applications.
- Before running a MapReduce application that uses this API, ensure that the destination JSON table or tables already exist and that any column families other than the default are already created on the destination tables.

Classes

The following table summarizes the information that is in the MapR Database JSON MapReduce API, which you can refer to for complete details of the classes.

Category	Class	Description
Utility	`MapRDBMapReduceUtil`	Simplifies the use of the API for most use cases.
Input formatters	`TableInputFormat`	Describes how to read documents from MapR Database JSON tables.
Record reader	`TableRecordReader`	Reads documents (records) from MapR Database JSON tables.
	`TableRecordReaderImpl`	Iterates over MapR Database JSON table data. Returns key-value pair as `ByteBufWritableComparable` and `Document` respectively.
Record writers	`BulkLoadRecordWriter`	Bulk loads documents into MapR Database JSON tables.
	`TableMutationRecordWriter`	Modifies documents that are in MapR Database JSON tables.
	`TableRecordWriter`	Writes documents to MapR Database JSON tables.

last-updated: Apr 11, 2022

Category	Class	Description
Output formatters	`BulkLoadOutputFormat`	Describes how to bulk load documents into MapR Database JSON tables.
	`TableOutputFormat`	Describes how to write documents to MapR Database JSON tables.
	`TableMutationOutputFormat`	Writes `DocumentMutation` from the MapReduce phase to JSON tables . The key is of type `Value` and the value is a `DocumentMutation`.
Serializers	`DocumentSerialization`	Defines the serializer and deserializer for passing data from `Document` objects between map and reduce phases.
	`DBDocumentSerialization`	Converts a JSON document from MapR Database format to binary SequenceFile format.
	`ValueSerialization`	Serializes a JSON key and passes it between MapReduce phases.
Partitioner	`TablePartitioner`	Specifies how to partition data from the source JSON table.
	`TotalOrderPartitioner<K,V>`	Globally sorts data according to row key and then partitions the sorted data. This class is useful when the destination table has been pre-split into two or more tablets.

Using MapRDBMapReduceUtil to Set Default Values in Configurations and Jobs

The centerpiece of this API is the `MapRDBMapReduceUtil` class, which you can use in the `createSubmittableJob()` method of your applications to perform these actions:

- Set default values in the configuration for a MapReduce application and set the input and output format classes.
- Set default types for output keys and values.
- Configure a `TotalOrderPartitioner` and return the number of reduce tasks to use for a job.

To set default values in the configuration for a MapReduce application and set the input and output format classes, use the following methods:

```
configureTableInputFormat(org.apache.hadoop.mapreduce.Job job, String
srcTable)
```

The `configureTableInputFormat` method performs the following actions:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.

last-updated: Apr 11, 2022

- Set the input format class for the job to `TableInputFormat`.

```
configureTableOutputFormat(org.apache.hadoop.mapreduce.Job job, String
destTable)
```

The `configureTableOutputFormat` method performs the following actions:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.
- Set the output format class for the job to `TableOutputFormat`.

If you want to set values for other fields in `TableInputFormat` or `TableOutputFormat`, or write your own logic for them, you can pass field values to configurations and specify these classes for jobs as you would in common MapReduce applications.

To set default types for output keys and values, use the following methods:

```
setMapOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
setOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
```

Note: You can also set types for output keys and values from the map phase, if those types will differ from the final output types.

To configure `TotalOrderPartitioner` and return the number of reduce tasks to use for a job, you can use a code line similar to the following in your application's method for creating a job:

```
int numReduceTasks =
MapRDBMapReduceUtil.setPartitioner(org.apache.hadoop.mapreduce.Jobjob,
String destPath);
```

The `setPartitioner()` method finds out whether a table has been pre-split into two or more tablets, counts the number of tablets, writes the number to a partitioner file, and sends that file to an instance of `TotalOrderPartitioner`. This line also returns the number of tablets to `numReduceTasks`. Your code can then use that variable to set the number of reducers, like the following:

```
job.setNumReduceTasks(numReduceTasks);
```

Note: The sample application gives an example of how to use `MapRDBMapReduceUtil`.

Mutating Rows in Destination Tables

Use the `TableMutationRecordWriter` class when you need to mutate rows.

For example, suppose that you are tracking the number of users who are performing various actions on your retail website. To do this, at intervals you run your MapReduce application and save the results in JSON documents in MapR Database. Suppose that you count the number of users who went through the order process but abandoned their orders. After every run of the application, you want to update an JSON document by adding the current count to the total count and by updating a field that tracks the date and time that the MapReduce application was last run.

You could do that by setting values in a DocumentMutation object (see the OJAI (Open JSON Application Interface) Javadoc. You would then serialize that and write it to the table with `TableMutationRecordWriter`.

Compiling and Running Applications

You can compile applications that use the MapR Database Java API by using the required JAR file from the MapR installation. Run applications with the mapr command.

To compile an application, use the following command:

```
javac -cp 'mapr classpath' <Application jars>
```

To launch an application, use the following command

```
mapr <Main class jar> <commandline arguments>
```

Note: If you want to add JAR files to the classpath that the mapr command uses, add them with the environment variable MAPR_CLASSPATH. For example:

```
export MAPR_CLASSPATH=/home/apps/awesome-1.0.jar
         mapr com.company.MyAwesomeApp
```

Important: Turn off speculative execution

Speculative execution of MapReduce tasks is on by default. For custom applications that load MapR Database tables, it is recommended to turn speculative execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `MapRDBMapReduceUtil.configureTableOutputFormat()`, you do not have to turn off speculative execution manually. This method turns it off automatically.

Turn off speculative execution by using either of these methods:

- Set the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`
- Include the following line in the method in your application that sets parameters for jobs:

  ```
  job.setSpeculativeExecution(false);
  ```

MapR Database JSON MapReduce: Sample App

This sample application reads records (JSON documents) from a JSON table and inserts new documents into another JSON table.

After reading records from a JSON table, the application aggregates data within those records, creates new JSON documents that contain the aggregated records, and then inserts the new documents into another JSON table. Each record contains the name of an author and the name of a book that the author has written.

The JSON documents have this structure:

```
{
    "_id" : <string or binary>,
    "authorid":"<string>",
    "name":"<string>",
    "book":{
        "id":<int>,
        "title":"<string>"
    }
}
```

last-updated: Apr 11, 2022

The structure of each aggregate record will look like this:

```
{
    "_id" : <string or binary>,
    "authorid":"<string>",
    "book":{
        [
            "title":"<string>",
            "title":"<string>",
            ...
        ]
    }
}
```

Prerequisites

- Ensure that your user ID has the `-readAce` and `-writeAce` privileges on the volumes where you plan to create the source and destination tables.
- Create the source JSON table. You can create the source table and populate it with sample records by running sample_dataset.txt from the `mapr dbshell` utility.

  ```
  $ mapr dbshell < sample_dataset.txt
  ```

- Create the destination JSON table. A simple way to create this table is to use the `create` command in the MapR Database Shell (JSON Tables) on page 5286 utility.

Compiling and Running

To compile an application, use the following command:

```
javac -cp <classpath> <java source file(s)>
```

To launch an application, use the following command:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class>
<command line arguments>
```

To run the application, supply the paths and names of the source and destination tables as arguments:

```
CombineBookList <source_table> <destination_table>
```

Code Walkthrough

```
  private static Job createSubmittableJob(Configuration conf, String[]
otherArgs)
      throws IOException {

    srcTable = otherArgs[0];
    destTable = otherArgs[1];

    Job job = new Job(conf, NAME + "_" + destTable);
    job.setJarByClass(CombineBookList.class);
    MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);
    job.setMapperClass(CombineBookListMapper.class);
    MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);
    MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);
    job.setReducerClass(CombineBookListReducer.class);
```

```
    MapRDBMapReduceUtil.setOutputKeyValueClass(job);
    job.setNumReduceTasks(1);
    return job;
  }
```

The `createSubmittableJob()` method uses methods that are in the `MapRDBMapReduceUtil` class to perform the following tasks:

Set the input format to the default table input format

You can call the `configureTableInputFormat()` method, passing in the job and also passing in the path and name of the source table:

```
MapRDBMapReduceUtil.configureTableInput
tFormat(job, srcTable);
```

The default behavior is to do the following:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.
- Set the input format class for the job to `TableInputFormat`.

If you want to customize `TableInputFormat` , you can call it as you would normally set the input format for a job:

```
job.setInputFormatClass(TableInputForm
at.class);
```

Set the type for keys and values that are output from the mapper

You can call the `setMapOutputKeyValueClass()` method to use the default type for keys and values:

```
MapRDBMapReduceUtil.setMapOutputKeyVal
ueClass(job);
```

If you want to customize the output keys and values, you can call `Job.setMapOutputKeyClass()` and `Job.setMapOuputValueClass()` as you would normally for MapReduce applications.

Set the output format to the default table output format

You can call the `configureTableOutputFormat()` method, passing in the job and also passing in the path and name of the destination table, which must already exist at runtime:

```
MapRDBMapReduceUtil.configureTableOutp
utFormat(job, destTable);
```

The default behavior is to do the following:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.

last-updated: Apr 11, 2022

	• Set the output format class for the job to `TableOutputFormat`. If you want to customize `TableOutputFormat`, you can call it as you would normally set the output format for a job: `job.setOutputFormatClass(TableOutputFormat.class);` You also have the option of using the `BulkLoadOutputFormat` class for bulk loading.
Set the type of the keys and values that are output from the reducer	You can call the `setOutputKeyValueClass()` method to use the default type for keys and values: `MapRDBMapReduceUtil.setOutputKeyValueClass(job);` If you want to customize the output keys and values, you can call `Job.setOutputKeyClass()` and `Job.setOuputValueClass()` as you would normally for MapReduce applications.

The `map()` method in the mapper class `CombineBookListMapper` takes the value of the `_id` field in a document as a key and the JSON document with that `_id` field value as a `Document`. The mapper does nothing with the `Value` object. For each `record`, the mapper writes the value of the `authorid` field and the full JSON document itself to the context.

```
  public static class CombineBookListMapper extends Mapper<Value, Document,
Value, Document> {
    @Override
    public void map(Value key, Document record, Context context) throws
IOException, InterruptedException {
      context.write(record.getValue("authorid"), record);
    }
  }
```

Both the `Value` and `Document` interfaces are part of the OJAI (Open JSON Application Interface) API. The javadoc for the OJAI API is here.

The `reduce()` method in the reducer class `CombineBookListReducer` takes the map output key, which is the value of the `authorid` field, and the map output value, which is an iterator of `Document` objects that each contain a full record. For each author ID, the reducer creates a document. For each document in the iterator, the reducer extracts the value of the `book` field and adds that value to the list `books` within a new JSON document.

```
  public static class CombineBookListReducer extends Reducer<Value,
Document, Value, Document> {

    @Override
    public void reduce(Value key, Iterable<Document> values,
        Context context) throws IOException, InterruptedException {
      Document d = MapRDB.newDocument();
      List<Document> books = new ArrayList<Document>();

      for (Document b : values) {
        books.add((Document)b.getValue("book"));
      }

      d.setId(key);
```

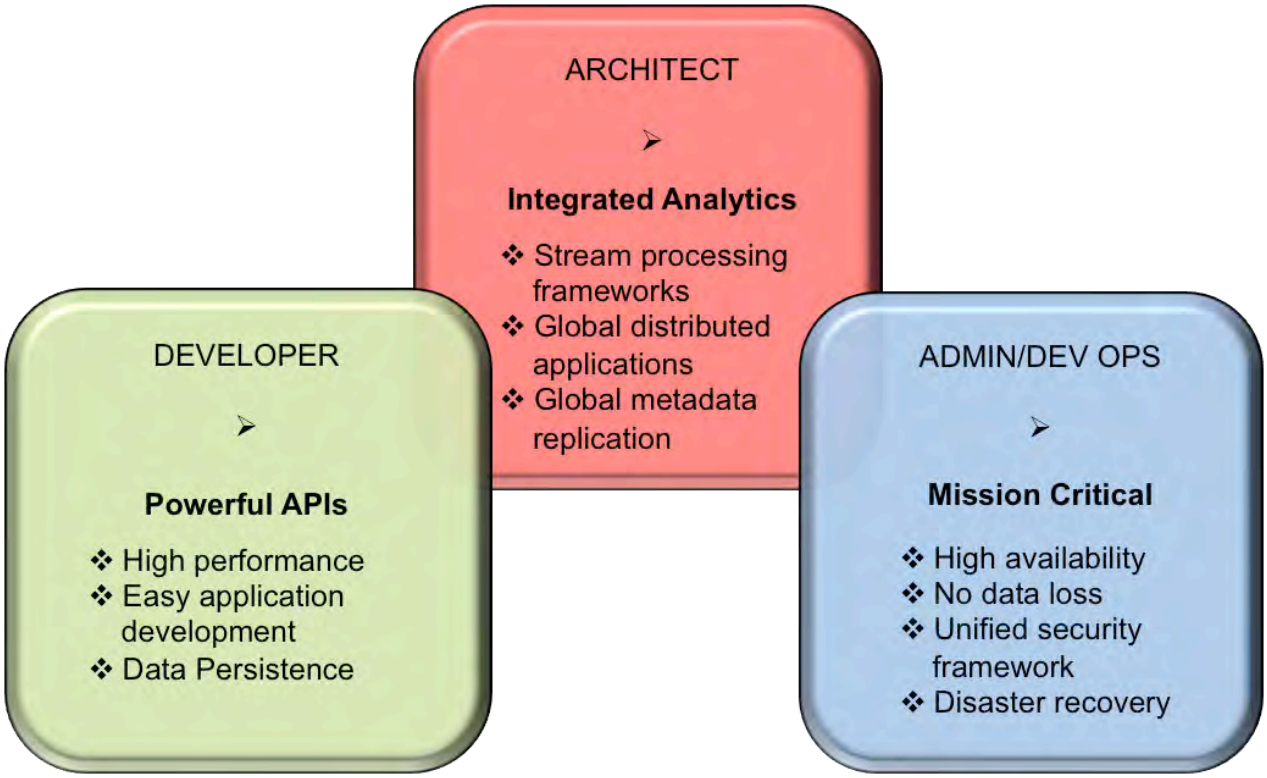
```
      d.set("books", books);
      context.write(key, d);
    }
  }
```

The MapRDB class is part of the MapR Database JSON API, not the MapR Database JSON MapReduce API.

MapR Event Store For Apache Kafka and Apps

MapR Event Store For Apache Kafka brings integrated publish and subscribe messaging to MapR Data Platform.

MapR Event Store For Apache Kafka is built into the MapR Data Platform. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



1. The Getting Started with MapR Event Store For Apache Kafka section provides overall instructions for setting up, producing, and consuming streams.
2. The MapR Event Store For Apache Kafka section provides conceptual information.
3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

Attention: As of core version 6.1, the MapR Event Store For Apache Kafka API enforces a maximum of 4096 partitions for a topic. If you create an application with the MapR Event Store For Apache Kafka 6.1 API, the maximum number of partitions is 4096. If you previously created an application with MapR Event Store For Apache Kafka 6.0.1 API (or older) and you have upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in core version 6.0.1 or earlier, you can continue with the same number of partitions after upgrading.

last-updated: Apr 11, 2022

Getting Started with MapR Event Store For Apache Kafka

If you have a basic understanding of MapR Event Store For Apache Kafka components and the typical flow of messages from producers to consumers, you can get started.

- Ensure that your Linux, Windows, or OS X system has Java SDK 7 or later installed.
- Install the latest version of MapR Data Platform on a cluster.
- Install the core client (mapr-client) package, if you want to run the producer and consumer from a machine outside the cluster. See Installing the MapR Client on page 389 for more information.

1. On a node in the MapR Data Platform cluster, follow these steps:

a) Create a stream.

- Run this command if you plan to run the producer and consumer with the same user ID that you are using to create the stream:

  ```
  maprcli stream create -path /<path to and name of the stream>
  ```

- Run this command if you plan to run the producer and consumer with user IDs that are different from the user ID that you are using to create the stream:

  ```
  maprcli stream create -path /<path to and name of the
  stream> -consumeperm u:<user ID> -produceperm u:<user ID>
  ```

  The two additional parameters grant security permissions. By default, these permissions are granted to the user ID that ran the `maprcli stream create` command.

`-consumeperm`	Grants permission to read messages from topics that are in the stream.
`-produceperm`	Grants permission to publish messages to topics that are in the stream.

b) Create a topic.

Run this command to create the topic:

```
maprcli stream topic create -path <path and name of the stream> -topic
<name of the topic>
```

2. On the system where the mapr-client is installed, compile and launch the Java consumer first and then launch the Java producer.

In both the consumer and producer, change this text to the path and name of your stream and to the name of the first of the topics:

```
/<path to and name of the stream>:<name of topic>
```

For the steps of compiling and launching, see Compiling and Running MapR Event Store For Apache Kafka Java Apps on page 2777.

Launch the consumer first, and then launch the producer. If you launch the producer first and then the consumer, the producer publishes 50 messages, but the consumer (as consumers do by default) starts reading from the head of the partition, which is after the 50 messages.

Note: As of MapR 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the MapR Database/MapR Event Store For Apache Kafka feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).

last-updated: Apr 11, 2022

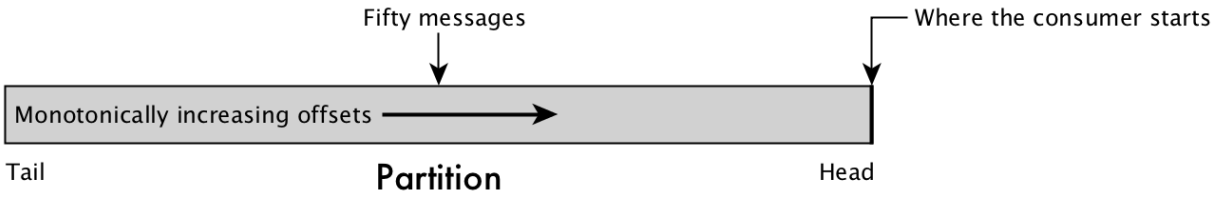


Figure 27: Result of starting the producer before starting the consumer for this step

If you launch the consumer first, the partition is empty and the consumer continuously polls for new messages.

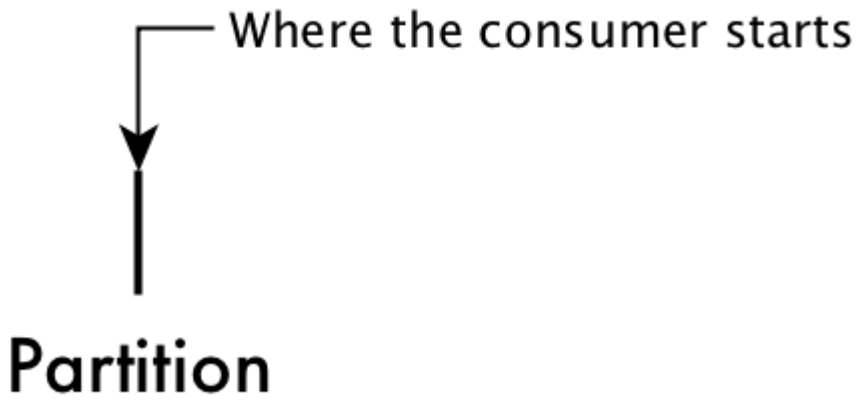

Figure 28: The position of a consumer on an empty partition

After you launch the producer, the fifty messages are published to the partition, and the consumer can move forward in the partition, reading the messages.

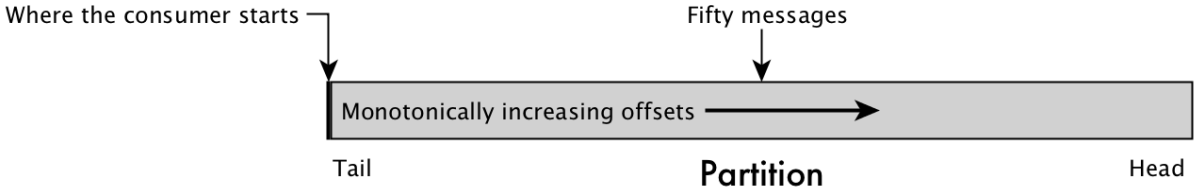

Figure 29: Result of starting the consumer first and then starting the producer for this step

Sample Java Consumer

You need to first add the following dependency to the POM file:

```
<dependency>
  <groupId>commons-logging</groupId>
  <artifactId>commons-logging</artifactId>
  <version>1.1.1</version>
</dependency>
```

```
/* This code is successfully tested for common-logging version 1.11 and
1.2. */
```

```
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;

public class SampleConsumer {
    // Set the stream and topic to read from
    public static String topic = "/<path to and name of the stream>:<name
of topic>";

    // Declare a new consumer.
    public static KafkaConsumer<Integer, String> consumer;

    public static void main(String[] args) {
        configureConsumer();

        // Subscribe to the topic.
        consumer.subscribe(Collections.singletonList(topic));

        // Set the timeout interval for requests for unread messages.
        Duration pollTimeout = Duration.ofMillis(1000);

        try {
            while (true) {
                ConsumerRecords<Integer, String> records =
consumer.poll(pollTimeout);
                records.forEach(record -> {
                    System.out.printf("%s %d %d %s %s \n", record.topic(),
                            record.partition(), record.offset(),
record.key(), record.value());

                });
            }
        } finally {
            consumer.close();
        }
    }

    /* Set the value for a configuration parameter.
       This configuration parameter specifies which
       class to use to deserialize the value of each message. */
    public static void configureConsumer() {
        Properties props = new Properties();
        props.put(ConsumerConfig.GROUP_ID_CONFIG, "consumer-group");
        props.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");
        props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,

"org.apache.kafka.common.serialization.IntegerDeserializer");
        props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
                "org.apache.kafka.common.serialization.StringDeserializer");
        consumer = new KafkaConsumer(props);
    }
}
```

Sample Java Producer

```
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
```

```
import java.util.Properties;

public class SampleProducer {
    // Set the stream and topic to publish to.
    public static String topic = "/<path to and name of the stream>:<name
of topic>";
    // Set the number of messages to send.
    public static int numMessages = 50;

    // Declare a new producer.
    public static KafkaProducer<Integer, String> producer;

    public static void main(String[] args) {
        configureProducer();

        for(int i = 0; i < numMessages; i++) {
            // Set content of each message.
            String messageText = "Msg " + i;

           /* Add each message to a record. A ProducerRecord object
              identifies the topic or specific partition to publish
           a message to. */
            ProducerRecord<Integer, String> rec = new ProducerRecord(topic,
i, messageText);

            // Send the record to the producer client library.
            producer.send(rec);
            System.out.println("Sent message number " + i);
        }
        producer.close();
        System.out.println("All done.");
    }

    /* Set the value for a configuration parameter.
       This configuration parameter specifies which class
       to use to serialize the value of each message. */
    public static void configureProducer() {
        Properties props = new Properties();
        props.put(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
                "org.apache.kafka.common.serialization.IntegerSerializer");
        props.put(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
                "org.apache.kafka.common.serialization.StringSerializer");
        producer = new KafkaProducer(props);
    }
}
```

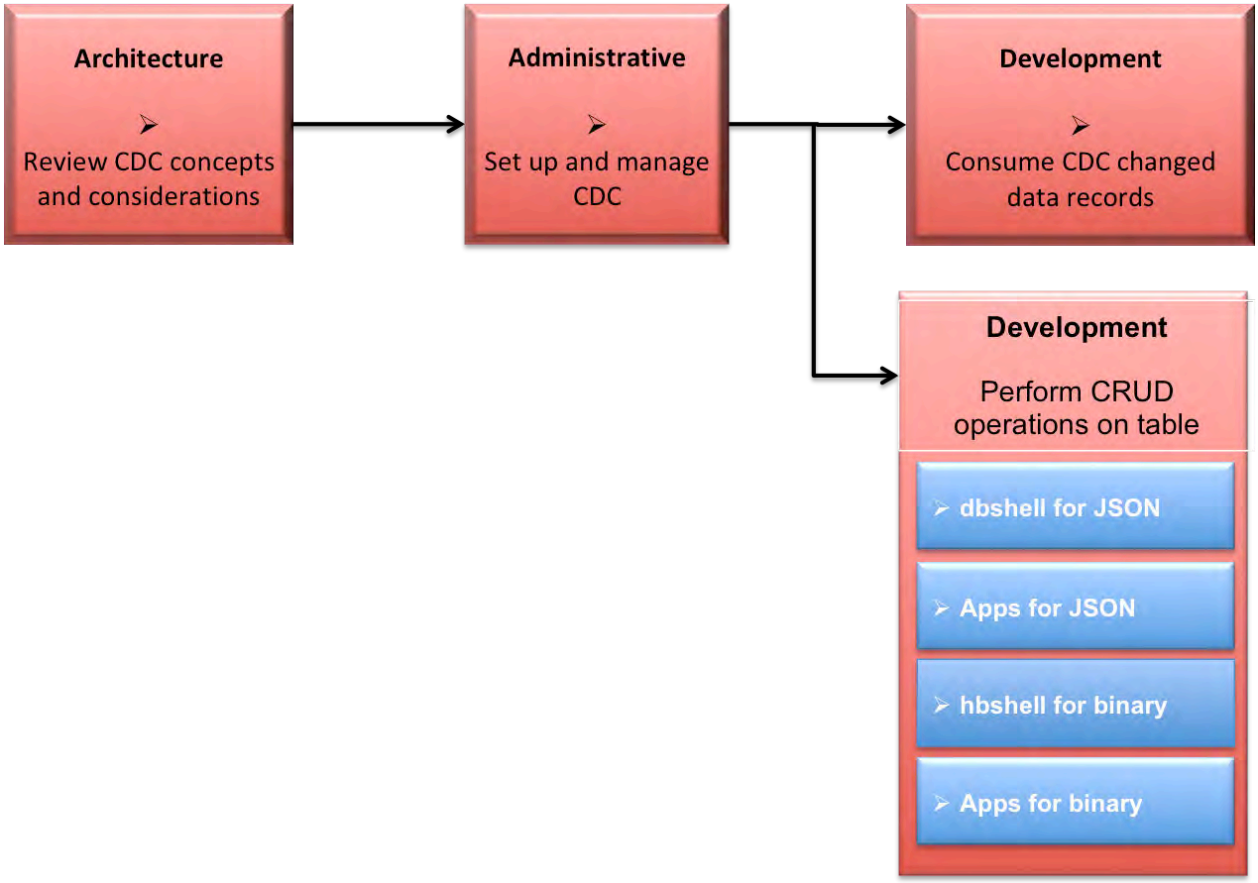
Consuming CDC Records

The OJAI changelog interfaces are used to consume changed data records (propagated by the Change Data Capture feature).

The general CDC flow of understanding architectural concepts, performing administrative tasks to set up and use CDC, performing CRUD operations on a database table, and developing applications for consuming CDC changed data records. This diagram provides hotspot links to help you navigate to the applicable documentation.



1. Learning about CDC
2. Administering Change Data Capture
3. Building a consumer app for CDC
4. Using dbshell to perform CRUD operations on MapR Database JSON tables
5. Developing client applications for MapR Database JSON tables.
6. Using hbshell to perform CRUD operations on MapR Database binary tables.
7. Developing client applications for MapR Database binary tables.

Javadoc

See the following Java documentation for detailed information about CDC APIs.

Java OJAI CDC API

Deserializer for consuming CDC records

The deserializer converts stream messages into individual change data records. When your application creates a CDC consumer, you must also register the ChangeData deserializer by setting the `value.deserializer` configuration parameter to `com.mapr.db.cdc.ChangeDataRecordDeserializer`.

last-updated: Apr 11, 2022

Note: When applications consume from a CDC change topic, the record key retrieved from `poll()` is not deserialized. The record key is not equal to the `_id` field of the document. If you want to retrieve the exact `_id` of the document, you must call the `ChangeDataRecord.getId()` method.

Interfaces for working with CDC records

The following OJAI interfaces and enumerations create consumers for CDC changed data.

ChangeNode	Contains the change to a single field in a document.
ChangeEvent	Identifies the change event associated with the current change node. The value of ChangeEvent can be one of the following: • NULL (no event) • NODE (a change with real value) • START_MAP (a node representing the beginning of a map) • END_MAP (a node representing the end of a map) • START_ARRAY (a node representing the beginning of an array) • END_ARRAY (a node representing the end of an array)
ChangeOp	Identifies the type of the operation performed on the current field. The values of ChangeOp can be one of the following: • NULL (no operation) • SET (replace the current field with the given value) • PUT (add an extra version of the value) • MERGE (combine the given value with the existing values in the table) • DELETE (delete all values older than or equal to the delete operation timestamp) • DELETE_EXACT (delete the version of the value with the given timestamp)
ChangeDataRecord	Contains all the changes made on a single document/row in the source table.
ChangeDataRecordType	Specifies the mode of change for the change data record. The following values are specified: • RECORD_INSERT • RECORD_UPDATE • RECORD_DELETE
ChangeDataReader	Is a parser that traverses over the individual change tree nodes on a change data record. It provides cursor-like semantics that can be moved, one tree node at a time, by invoking the `next` method. The APIs retrieve the properties of individual change nodes

last-updated: Apr 11, 2022

(for example: data type, field name, field value, and so on).

Open Data Format

The CDC Open Format feature allows you to create applications in languages other then Java that consume CDC (Change Data Capture) changed data records. For example, C/C++, Python, and C#/.NET) are supported.

This functionality is provided with an open format decoder/serializer in the MapR Event Store For Apache Kafka C library. The decoder translates the internal format to the open data format, decodes/deserializes the data, and returns the value of the changed data record as a human readable JSON string.

All languages that are binding through the MapR Event Store For Apache Kafka C library can retrieve the open data format and, with a simple JSON parser, consume changed data records.

Building Consumers for CDC

MapR Event Store For Apache Kafka consumers read and process CDC changed data records. The consumer is built with the OJAI API library.

Description

When building a consumer, the general steps are to:

- Set the consumer properties using Apache Kafka and MapR Data Platform configuration parameters.
- Subscribe to the stream topic.
- Consume the events and determine record type.
- Process the change data records.

The following examples refer to the MapR CDC Sample. See the Java OJAI CDC API for specific API information.

Set Configuration

This code snippet configures the consumer properties using the Apache Kafka configuration parameters. See MapR Event Store For Apache Kafka Configuration Parameters for Consumers. This could be externalized in a file or hard coded in the application code. The following code examples show both methods.

Note: CDC uses a optimized serialization format for all the events, so `value.deserializer` must be set to **com.mapr.db.cdc.ChangeDataRecordDeserializer**.

```
// Consumer configuration parameters specified in application

    Properties consumerProperties = new Properties();
    consumerProperties.setProperty("group.id",
"cdc.consumer.demo_table.fts_geo");
    consumerProperties.setProperty("enable.auto.commit", "true");
    consumerProperties.setProperty("auto.offset.reset", "latest");
    consumerProperties.setProperty("key.deserializer",
"org.apache.kafka.common.serialization.ByteArrayDeserializer");
    consumerProperties.setProperty("value.deserializer",
"com.mapr.db.cdc.ChangeDataRecordDeserializer");
```

```
// Consumer configuration parameters specified in an external file
```

last-updated: Apr 11, 2022

```
key.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
value.deserializer=com.mapr.db.cdc.ChangeDataRecordDeserializer
enable.auto.commit=true
auto.offset.reset=latest
group.id=cdc.consumer.demo_table.fts_geo
```

Subscribe to topic

This code snippet creates the consumer and subscribes to the MapR Event Store For Apache Kafka topic that contains the change data records. The consumer is created using a key (bytes[]) and a `ChangeDataRecord` object for the value.

```
// Consumer used to consume MapR-DB CDC events

KafkaConsumer<byte[], ChangeDataRecord> consumer = new
KafkaConsumer<byte[], ChangeDataRecord>(consumerProperties);
consumer.subscribe(Arrays.asList("/demo_changelog:demo_table"));
```

Consume the events and determine record type

This code snippet polls the topic to determine whether there are any changes and, if so, iterates through the change data records to retrieve the change data record IDs based on the change data record type. The ChangeDataRecordType interface is used to determine the type of record and the ChangeDataRecord interface is used to retrieve the record type and record ID.

```
    while (true) {
      ConsumerRecords<byte[], ChangeDataRecord> changeRecords =
consumer.poll(500);
      Iterator<ConsumerRecord<byte[], ChangeDataRecord>> iter =
changeRecords.iterator();

      while (iter.hasNext()) {
        ConsumerRecord<byte[], ChangeDataRecord> crec = iter.next();
        // The ChangeDataRecord contains all the changes made to a document
        ChangeDataRecord changeDataRecord = crec.value();
        String documentId = changeDataRecord.getId().getString();

        if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_INSERT) {
          System.out.println("\n\t Document Inserted " + documentId);
          insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_UPDATE) {
          System.out.println("\n\t Document Updated " + documentId);
          insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_DELETE) {
          System.out.println("\n\t Document Deleted " + documentId);
          deleteDocument(changeDataRecord, producer);
        }

      }
    }

  }
```

last-updated: Apr 11, 2022

Process the records

This code snippet processes the change data records and based on the type of event (insert, update, delete), using the `ChangeDataRecordType` class and the `changeDataRecord.getType()` method, checks and retrieves the record type.

```
// Use the ChangeNode Iterator to capture all the individual changes

    Iterator<KeyValue<FieldPath, ChangeNode>> cdrItr =
changeDataRecord.iterator();

    while (cdrItr.hasNext()) {
      Map.Entry<FieldPath, ChangeNode> changeNodeEntry = cdrItr.next();
      String fieldPathAsString = changeNodeEntry.getKey().asPathString();
      ChangeNode changeNode = changeNodeEntry.getValue();
      ...
      ...
    }
```

To process and retrieve an inserted new document, you can check to see if the field path is NULL or empty. When *a new document is inserted*, all the changes are made in a single object represented as a Map. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString == null || fieldPathAsString.equals("")) { // Insert
        Map<String, Object> documentInserted = changeNode.getMap();

        if (documentInserted.containsKey("firstName")) {
          fieldToIndex.put("firstName", (String)
documentInserted.get("firstName"));
          sendIndexingMessage = true;
        }

        if (documentInserted.containsKey("lastName")) {
          fieldToIndex.put("lastName", (String)
documentInserted.get("lastName"));
          sendIndexingMessage = true;
        }

        if (documentInserted.containsKey("address")) {
          addressMessage.set("address",
jsonMapper.convertValue((Map)documentInserted.get("address"),
JsonNode.class) );
          sendAddressMessage = true;
        }
     }
```

To process and retrieve updated documents, you can check the field path and retrieve the value depending on the expected value type. When *a document is updated*, the iterator contains one ChangeNode by updated field. You can then access the field path and value directly. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString.equalsIgnoreCase("firstName")) {
          fieldToIndex.put("firstName", changeNode.getString());
          sendIndexingMessage = true;
        }
          else if (fieldPathAsString.equalsIgnoreCase("lastName")) {
          fieldToIndex.put("lastName", changeNode.getString());
          sendIndexingMessage = true;
        }
```

```
          else if (fieldPathAsString.equalsIgnoreCase("address")) {
          addressMessage.set("address",
jsonMapper.convertValue( changeNode.getMap(), JsonNode.class) );
          sendAddressMessage = true;
        }
```

To process delete operations, you can directly retrieve the document ID using the `changeDataRecord.getId()` method and process the document deletion with the `deleteDocument` method. The delete operation is a single change data record.

Consumer Application for CDC JSON Data
This example consumes changed data records from MapR Database JSON tables.

Example of Consuming JSON Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and MapR configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Retrieve the properties of individual change node (for example: data type, field name, field value, and so on) by using various methods of the `ChangeDataReader` interface.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from MapR Database JSON table data, the following are unique:

- There are multiple property values that can be retrieved through the `ChangeDataReader` interface. For example, getDouble or getFloat.
- There are multiple values for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `Value value = changeNode.getValue();`

Consumer Application for CDC Binary Data
This example consumes changed data records from MapR Database Binary tables.

Example of Consuming Binary Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and MapR Data Platform configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from MapR Database Binary table data, the following are unique:

- An additional package must be imported: `java.nio.ByteBuffer`
- There is single value for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `ByteBuffer value = changeNode.getBinary();`

```
package com.mapr.qa.cdc.tests.binary;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
```

```
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.ojai.*;
import org.ojai.store.Connection;
import org.ojai.store.Driver;
import org.ojai.store.DriverManager;
import org.ojai.store.cdc.*;

import java.nio.ByteBuffer;
import java.util.*;

Open Format
Describes the CDC open format.

Open Format Mapping

The following shows the mapping between the MapR Data Platform CDC data types and the JSON open format data types.

```
{
        "map": {
        "null": null,
        "boolean" : true,
        "string": "eureka",
        "byte" : {"$numberByte": 127},
        "short": {"$numberShort": 32767},
        "int": {"$numberInt": 2147483647},
        "long": {"$numberLong":9223372036854775807},
        "float" : {"$numberFloat":3.4028235E38},
        "double" : 1.7976931348623157e308,
        "decimal": {"$decimal":
"12345678901234567890189012345678901.23456789"},
        "date": {"$dateDay": "yyyy-mm-dd"},
        "time" : {"$time" : "HH:mm:ss[.sss]"},
        "timestamp" : {"$date" : "yyyy-MM-ddTHH:mm:ss.SSSXXX"},
        "interval" : {"$interval" : number_of_millisecods},
        "binary" : {"$binary" : "base64_encoded_binary_value"},
        "array" : [42, "open sesame", 3.14, {"$dateDay": "2015-01-21"}]
        }
}
```

JSON Record Format

When the consumer retrieves the changed data record (by the key-value pair), the record is returned as a string in JSON format (a readable open format). The information about the mutation is returned as an array where each array element is one (1) change.

Note: If you use the default print, the string returns float values of up to six (6) digits of precision and double values of up to fifteen (15) digits. If the data exceeds this default and you want the exact number returned, use the CDC API that returns a float or double value.

The following example changed data record shows two (2) mutations.

```
{
        "_id":"row1"
        "$opType":"$RECORD_UPDATE",
        "$opTime":1518654391801,

        "$mutations":[
        {"$fieldPath":"arrayB,
        "$fieldOp":"$SET",
        "$fieldValue":[{"$numberInt":100},false,"set a map"]
        }
        {"$fieldPath":"arrayC,
        "$fieldOp":"$SET",
        "$fieldValue":[{"$numberInt":200},false,"set a map"]
        }
        ]
}
```

   List<String> topicList = new ArrayList<>();
   topicList.add(topic);
   consumer.subscribe(topicList);

   ConsumerRecords<String, String> consumerRecords =
consumer.poll(pollTimeout);
   Iterator<ConsumerRecord<String, String>> iterator =
consumerRecords.iterator();
   while (iterator.hasNext())

      { ConsumerRecord<String, String> record = iterator.next(); String
cdcResult = record.value(); }

}
```

Consuming Audit Logs

Audit Streaming (available from v6.0.1) provides a way to process the audit data in real-time.

When audit streaming is enabled, the MapR Data Platform generates audit logs that are sent as an audit stream, opening the possibility of real-time processing of the audit data. See Streaming Audit Logs on page 701 for more information.

Use the sample consumer application, or build your custom consumer application, to consume the audit logs that are available as a stream topic, when audit streaming is enabled.

The sample application uses filesystem APIs to get the file path and name from the FID, and the volume name from the volume ID.

Determine When to use Cached or Uncached Version of the Filesystem API

Caching the file path and file name, along with the volume name at the initial API call, reduces the load on CLDB for subsequent API calls.

However, there could be cases when the uncached version of the application is more suitable for use. Consider the following example:

For the initial API call, File1 is returned as the file name for FID 1. The result is cached.

The file is then renamed to File2. For subsequent API calls, to get the file name for FID 1, the result from the cache is used. The cache, unaware of the rename operation, returns the name as File1, which is incorrect, as the file is already renamed to File2. For such a case, use the uncached version.

Evaluate your use case, and then use the cached, or the uncached version, as appropriate.

Sample Cached Consumer Application for Audit Stream
The Consumer.java application demonstrates how to connect to the MapR Filesystem filesystem, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running MapR File System. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp .:`mapr classpath` Consumer.java
```

3. Run the final `Consumer.class` file. For example:

```
java -cp .:`mapr classpath` Consumer
```

This application requires the following imports:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`
- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The configuration parameters for the consumer are stored in `consumer.props` file. This file should be present in the current directory or mapr classpath. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.comm
on.serialization.StringDeserializer
value.deserializer=org.apache.kafka.co
mmon.serialization.StringDeserializer
# fast session timeout makes it more
fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
avoid consumer switching to
# a mode where it processes one
bufferful every 5 seconds with
multiple
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException,InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
        Properties properties = new
Properties();
        properties.load(props);
        if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
        }
        consumer = new
KafkaConsumer<>(properties);
    }
}
```

Subscribes to the topic to read from

The application initializes the filesystem object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent

to the `ExpandAudit.json.log` file used by the `expandaudit on page 2096` utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:my.cluster.com`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);
Pattern pattern =
Pattern.compile("/var/mapr/
auditstream/
auditlogstream:my.cluster.com.auth.+")
;
consumer.subscribe(pattern,null);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
    ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
    Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
    if (iterator.hasNext()) {
      while (iterator.hasNext()) {
        ConsumerRecord<String,
String> record = iterator.next();
        String value = record.value();
        String rvalue =
value.replace("\"","");
        String recordValue
= processRecord(fs, rvalue,
value);
        System.out.println(("
Consumed Record: " + recordValue));
      }
    } else {
      Thread.sleep(1000);
      //stop = true;
    }
}
```

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the `getMountPathFidCached()` API and

volid in the message to volume name using the `getVolumeNameCached()` API.

```
while (st.hasMoreTokens()) {
    String field = st.nextToken();
    StringTokenizer st1 = new
StringTokenizer(field, ":");
    while (st1.hasMoreTokens()) {
        String token =
st1.nextToken();
        if (token.endsWith("Fid")) {
           String lfidStr =
st1.nextToken();
           String path= null;
           try {
              path =
fs.getMountPathFidCached(lfidStr); //
Expand FID to path
           } catch (IOException e){
        }
        lfidPath =
"\"FidPath\":\""+path+"\",";
        // System.out.println("\nPAth
for fid " + lfidStr +  "is " +  path);
    }
    if (token.endsWith("volumeId")) {
        String volid =
st1.nextToken();
        String name= null;
        try {
            int volumeId =
Integer.parseInt(volid);
            name =
fs.getVolumeNameCached(volumeId); //
Cached API to convert volume Id to
volume Name
        } catch (IOException e){
        }
        lvolName =
"\"VolumeName\":\""+name+"\",";
        //
System.out.println("\nVolume Name for
volid " + volid +  "is " +  name);
    }
}
```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value,",");
while (st2.hasMoreTokens()) {
     String tokens = st2.nextToken();
     result = result + tokens + ",";
     if (tokens.contains("Fid")) {
         result = result + lfidPath;
     }
     if (tokens.contains("volumeId"))
{
         result = result + lvolName;
```

```
    }
}
return result.substring(0,
result.length() - 1);
```

Sample Uncached Consumer Application for Audit Stream

The ConsumerUncached.java application demonstrates how to connect to the MapR Data Platform file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running MapR File System. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp .:`mapr classpath` ConsumerUncached.java
```

last-updated: Apr 11, 2022

3. Run the final `ConsumerUncached.class` file. For example:

```
java -cp .:`mapr classpath` ConsumerUncached
```

This application requires the following:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`
- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The configuration parameters for the consumer are stored in `consumer.props` file. This file should be present in the current directory or mapr classpath. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.comm
on.serialization.StringDeserializer
value.deserializer=org.apache.kafka.co
mmon.serialization.StringDeserializer

# fast session timeout makes it more
fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
avoid consumer switching to
# a mode where it processes one
bufferful every 5 seconds with
multiple
```

```
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException,InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
          Properties properties = new
Properties();
          properties.load(props);
          if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
          }
      consumer = new
KafkaConsumer<>(properties);
      }
}
```

Subscribes to the topic to read from

The application initializes the filesystem object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent to the `ExpandAudit.json.log` file used by the `expandaudit` on page 2096 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:my.cluster.com`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);

Pattern pattern =
Pattern.compile("/var/mapr/
auditstream/
auditlogstream:my.cluster.com.+");
consumer.subscribe(pattern,null);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
      ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
      Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
      if (iterator.hasNext()) {
          while (iterator.hasNext()) {
              ConsumerRecord<String,
String> record = iterator.next();
              String value =
record.value();
              String rvalue =
value.replace("\"","");
              String recordValue =
processRecord(fs, rvalue, value);
              System.out.println(("
Consumed Record: " + recordValue));
          }
      } else {
                  //stop = true;
      }
}
```

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the `getMountPathFid()` API and volid in the message to volume name using the `getVolumeName()` API.

```
public static String
processRecord(MapRFileSystem fs,
String rvalue, String value)
  {
     StringTokenizer st = new
StringTokenizer(rvalue, ",");
     String lfidPath = "";
     String lvolName = "";

     while (st.hasMoreTokens()) {
          String field =
st.nextToken();
          StringTokenizer st1 = new
StringTokenizer(field, ":");
          while (st1.hasMoreTokens())
{
               String token =
st1.nextToken();
               if
(token.endsWith("Fid")) {
             String lfidStr =
st1.nextToken();
             String path= null;
             try {
                   path =
```

```
fs.getMountPathFid(lfidStr);
            } catch (IOException e)
{ }
            lfidPath =
"\"FidPath\":\""+path+"\",";
             if
(token.endsWith("volumeId")) {
          String volid =
st1.nextToken();
          String name= null;
          try {
              int volumeId =
Integer.parseInt(volid);
                name =
fs.getVolumeName(volumeId);
            }
          catch (IOException e){ }
          lvolName =
"\"VolumeName\":\""+name+"\",";
             }
       }
    }
```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value,",");
while (st2.hasMoreTokens()) {
    String tokens = st2.nextToken();
    result = result + tokens + ",";
    if (tokens.contains("Fid")) {
       result = result + lfidPath;
    }
    if (tokens.contains("volumeId")) {
       result = result + lvolName;
    }
    return result.substring(0,
result.length() - 1);
}
```

          String recordValue = processRecord(fs, rvalue, value);

          System.out.println((" Consumed Record: " + recordValue));
          //System.out.println((" Consumed Record: " + value));
        }
      } else {
    Thread.sleep(1000);
        //stop = true;
      }
```

```
    }
    consumer.close();
    System.out.println("All done.");
  }
  public static String processRecord(MapRFileSystem fs, String rvalue,
String value)
  {
     StringTokenizer st = new StringTokenizer(rvalue, ",");
     String lfidPath = "";
     String lvolName = "";

     while (st.hasMoreTokens())
     {
       String field = st.nextToken();
       StringTokenizer st1 = new StringTokenizer(field, ":");
       while (st1.hasMoreTokens())
       {
         String token = st1.nextToken();
         if (token.endsWith("Fid")) {
           String lfidStr = st1.nextToken();
           String path= null;
           try {
               path = fs.getMountPathFid(lfidStr);
           } catch (IOException e){
           }
           lfidPath = "\"FidPath\":\""+path+"\",";
           // System.out.println("\nPAth for fid " + lfidStr +  "is " +
path);
         }

         if (token.endsWith("volumeId")) {
           String volid = st1.nextToken();
           String name= null;
           try {
             int volumeId = Integer.parseInt(volid);
               name = fs.getVolumeName(volumeId);
             }
           catch (IOException e){
           }
           lvolName = "\"VolumeName\":\""+name+"\",";
           //  System.out.println("\nVolume Name for volid " + volid +  "is
" +  name);
         }
       }
     }
     String result = "";
     StringTokenizer st2 = new StringTokenizer(value,",");
     while (st2.hasMoreTokens()) {
       String tokens = st2.nextToken();
       result = result + tokens + ",";
       if (tokens.contains("Fid")) {
         result = result + lfidPath;
       }
       if (tokens.contains("volumeId")) {
         result = result + lvolName;
       }
     }
     return result.substring(0, result.length() - 1);
  }
}
```

MapR Event Store For Apache Kafka Java Applications

This section contains information on developing client applications with Java including information about the MapR Event Store For Apache Kafka and Apache Kafka Java APIs, configuration parameters, and compiling and running producers and consumers.

Apache Kafka Support

MapR Data Platform supports the following Apache Kafka Java API versions:

Table

Core version	Apache Kafka API
As of 6.2	2.1
As of 6.1	1.1
As of 6.0.1	1.0
6.0.0 and earlier	0.9.0

Log Compaction

As of MapR Data Platform 6.1, log compaction is supported. Log compaction can be enabled for streams created with MapR Data Platform core 6.1 and later. In addition, clients older thanMapR Data Platform 6.1 are prevented from consuming from streams that have had log compaction enabled on them at least once in their lifetime.

When a stream on a source cluster has both log compaction and replication enabled, the replica cluster does not automatically have log compaction enabled. You must explicitly enable log compaction on the replica cluster.

- If a replica cluster has been upgraded and the stream data for a source cluster is compacted (that is, one or more messages have been deleted), then the source cluster replicates the compacted data to the replica cluster.
- If a replica cluster has ***not*** been upgraded, then the source cluster fails the replication and an error is generated that requests an replica cluster upgrade.

In the context of a scan by a client that is **not** upgraded, the (upgraded) server inspects the row header to check if it is serving a compacted row. If it is serving a compacted row, then the server fails the consumer request. This behavior applies both to a stream that is explicitly configured for compaction and a replica that has received a compacted row.

Important: To perform log compaction on older streams, the `-force` option can be used. The `-force` option should only be used when ALL clients have been upgraded to MapR Data Platform 6.1.

last-updated: Apr 11, 2022

Idempotent Producer

As of MapR Data Platform 6.1, the idempotent producer (exactly once) feature is supported. You can implement the idempotent producer with MapR Data Platform core 6.1 and later.

When creating a producer instance, use the following configuration:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true)
```

The idempotent producer feature is supported by EEP MapR Data Platform 6.0 clients and MapR Data Platform 6.1.0 servers.

- You must upgrade all servers to v6.1.0 and enable all the v6.1.0 features, before you enable the idempotent producer.
- If you use a pre-MapR Data Platform 6.1 client and a MapR Data Platform 6.1 server, and if a group of messages are atomically persisted without a valid producer ID, the server treats the request as a non-idempotent producer.
- If you use a MapR Data Platform 6.1 client and a pre-MapR Data Platform 6.1 server, the idempotent producer is not supported. In this case, the idempotent producer fails to produce to the stream and the following exception is thrown:

```
Exception in thread "main" java.util.concurrent.ExecutionException:
org.apache.kafka.common.errors.UnknownTopicOrPartitionException:
Operation not permitted (1) null
        at

Caused by:
org.apache.kafka.common.errors.UnknownTopicOrPartitionException:
Operation not permitted (1) null
```

TimestampType Permissions

The following discussion describes the *ACE* permissions that you need when using the timestamp type parameter. See Stream Security on page 664 for general information about MapR Event Store For Apache Kafka streams security.

A MapR Event Store For Apache Kafka stream topic inherits the default timestamp type value from its stream. To override the stream's default value, set the timestamp type for the topic to a different value.

- Setting the value at the stream-level requires `adminperm` permissions. The stream-level timestamp type parameter is `defaulttimestamptype`. See stream create on page 1758 and stream edit on page 1765 for more information on setting this parameter using the `maprcli` command.
- Setting the `timestamptype` at the topic-level requires `topicperm` permissions. The topic-level timestamp type parameter is `timestamptype`. See stream topic create on page 1781 and stream topic edit on page 1784 for more information on setting this parameter using the `maprcli` command.

User Impersonation

As of MapR Data Platform 6.0, user impersonation is supported for MapR Event Store For Apache Kafka.

last-updated: Apr 11, 2022

You can set up user impersonation programmatically. To do so, use the `UserGroupInformation.doAs()` method in the Hadoop documentation. See Class UserGroupInformation for more information.

If you are setting up user impersonation in a secure cluster, you need to generate an impersonation ticket. See the Generating and Printing Service with Impersonation Ticket section in the maprlogin Command Examples on page 2134 topic.

After generating the ticket:

1. Ensure that user `mapruser1` has read permissions on the ticket.
2. If you moved the ticket file to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable with the appropriate path.

For more information about impersonation, see:

- How Impersonation Works on page 1478
- Generating a Service with Impersonation Ticket on page 1428
- Managing Impersonation on page 1476

Backward Compatibility

As of MapR Data Platform 6.0.1, along with the support of Apache Kafka, the `java.util.Collection` interface is being used. This impacts applications using certain APIs. See MapR Event Store For Apache Kafka Java API Library on page 2756 for detailed information.

MapR Event Store For Apache Kafka Java API Library

Use the MapR Event Store For Apache Kafka Admin Java API library as an alternative to `maprcli` commands and the REST APIs for performing administrative tasks on streams and topics. This library can also be used for analysis of the contents of streams.

Javadoc

The following Apache Kafka Java API versions are supported:

Table

Core version	Apache Kafka API
As of 6.1	1.1
As of 6.0.1	1.0
6.0.0 and earlier	0.90

See the following APIs for detailed information:

- MapR Event Store For Apache Kafka Java API Library (6.1)
- Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka (6.1)

Java Interfaces, Classes, and Enums

The MapR Event Store For Apache Kafka Java API library consists of the following interfaces and class:

Admin	Provides methods for performing administrative tasks on streams and topics, as well as for obtaining `StreamDescriptor` and `TopicDescriptor` objects.
StreamDescriptor	Provides methods for setting and retrieving values for stream attributes. `StreamDescriptor` is passed into methods when performing operations on streams, for example, creating a new stream and editing an existing stream. `StreamDescriptor` is also used to find attribute values for an existing stream.
TopicDescriptor	**Note:** TopicDescriptor is new as of 6.0.1. Provides methods for setting and retrieving topic values. `TopicDescriptor` is passed into methods when performing operations on topics, for example, setting and retrieving topic partitions and timestamp type. The available timestamp type can be either `createtime` or `logappendtime`. When a producer writes a message to a MapR Event Store For Apache Kafka topic, a timestamp is included that is part of the message record. This timestamp can be used to implement time-based indexing. Time-based indexing enables consumers to find the offsets for messages based on timestamps. The returned message offset corresponds to the *earliest* topic-partition message whose timestamp is equal to or greater than the provided timestamp. **Note:** APIs that support timeout semantics will adhere to the specified timeouts only if the client is configured for soft mount.
Streams Class	Streams class is also required to create an instance of Admin, which is used for all admin operations on streams. It can also be used to create a StreamDescriptor or TopicDescriptor objects. Provides the entry point to accessing MapR Event Store For Apache Kafka streams for analytics purposes.
TimestampType Enum	Provides the timestamp type of the records.
TopicRefreshListListener / TopicRefreshRegexListener	**Note:** Internal; not for public usage.

MapR Event Store For Apache Kafka Java APIs (as of 6.1)

The following MapR Event Store For Apache Kafka Java APIs are available as of MapR Data Platform 6.1:

Table

Interface	Method	Description
`StreamDescriptor`	`void setCompact(boolean compact)`	Sets log compaction on a stream.
`StreamDescriptor`	`boolean getCompact()`	Gets the log compaction on a stream. Returns true if the stream has log compaction on the stream.

last-updated: Apr 11, 2022

Table (Continued)

Interface	Method	Description
`StreamDescriptor`	`void setMinCompactionLagMS(long ts)`	Sets the time in (milliseconds) that a message should remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`long getMinCompactionLagMS()`	Returns the minimum time (in milliseconds) a message will remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`void setDeleteRetentionMS(long ts)`	Sets the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`long getDeleteRetentionMS()`	Returns the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
`Producer`	`ProducerConfig` class	The idempotence producer option is set by setting the `enable.idempotence` value of **true** passed through the ProducerConfig class.

MapR Event Store For Apache Kafka Java APIs (as of 6.0.1)

The following table lists the new Interfaces and APIs for MapR Data Platform 6.0.1. They are the delta between MapR Data Platform 6.0.1 and 6.0.0, meaning, they are applicable to MapR Data Platform6.0.1 but not MapR Data Platform 6.0.0.

Table

Interface and Methods	Description
Admin.close	Long duration for TimeUnit.
Admin.createTopic	TopicDescriptor array for topic attributes.
Admin.editTopic	TopicDescriptor array for topic attributes.
Admin.getTopicDescriptor	Method for retrieving topic attributes.
Admin.listTopic	Method for listing all the topics in a stream.
Admin.streamExists	Method for determining whether a stream exists.
StreamDescriptor.getDefaultTimestampType	Method for retrieving the timestamp type.
StreamDescriptor.setDefaultTimestampType	Method for setting the timestamp type.
TopicDescriptor	New MapR Data Platform interface.
TopicDescriptor.getPartitions	Method associated with the new interface.
TopicDescriptor.setPartitions	Method associated with the new interface.
TopicDescriptor.getTimestampType	Method associated with the new interface.
TopicDescriptor.setTimestampType	Method associated with the new interface.
Enum TimestampType	New Enum class and associated methods.

last-updated: Apr 11, 2022

Backward Compatibility

As of MapR Data Platform 6.0.1, Apache Kafka 1.0 is supported. The following `pause`, `resume`, `seekToBeginning`, and `seekToEnd` APIs support the Collection Interface. The deprecated APIs will continue to run unchanged, however, they may be removed in a future release.

Table

Replacement Collection APIs	Deprecated APIs
void pause(Collection<TopicPartition> partitions);	void pause(TopicPartition... partitions);
void resume(Collection<TopicPartition>partitions);	void resume(TopicPartition... partitions);
void seekToBeginning(Collection<TopicPartition>);	void seekToBeginning(TopicPartition... partitions);
void seekToEnd(Collection<TopicPartition>);	void seekToEnd(TopicPartition... partitions);

The following `subscribe` and `assign` APIs support the Collection Interface (which is more generalized) as well as the List Interface. Support for the List Interface has been retained for backward binary compatibility.

Table

Replacement Collection APIs	Retained APIs
void subscribe(Collection<String> topics);	void subscribe(java.util.List<java.lang.String> topics);
void subscribe(Collection<String> topics, ConsumerRebalanceListener);	void subscribe(java.util.List<java.lang.String> topics, ConsumerRebalanceListener listener);
void assign(Collection<TopicPartition> partitions);	void assign(java.util.List<TopicPartition> partitions);

Stream and Topic Operations Summary

Provides a summary of stream topic operations and the interface, class, or method used for the operation.

The following stream and topic operations is not an inclusive list, but a sampling. For detailed information, see the following libraries:

- MapR Event Store For Apache Kafka Java API Library (6.1)
- Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka (6.1)

Table

Operation	Interface/Method Used
Creating streams	`StreamDescriptor` is used to set the attributes for streams that you plan to create. `Admin.createStream(String streamPathAndName, StreamDescriptor desc)` - create the stream.
Editing stream attributes	`StreamDescriptor` is used to edit the stream's attribute values. `Admin.editStream(String streamPathAndName, StreamDescriptor desc)` - set or modify the stream's attribute values.
Retrieving the default timestamp type on a stream	`StreamDescriptor.getDefaultTimestampType()` - retrieves the default timestamp type on the stream. **Note:** This method is new as of 6.0.1
Sets the default timestamp type on a stream	`StreamDescriptor.setDefaultTimestampType(TimestampType logAppendTime)` - sets the default timestamp type on the stream. **Note:** TimestampType Enum is new as of 6.0.1

last-updated: Apr 11, 2022

Table (Continued)

Operation	Interface/Method Used
Deleting streams	`Admin.deleteStream(String streamPathAndName)`
Determining stream existence	`Admin.streamExists(String streamPathAndName)` - determines whether a stream exists or not. Returns: true | false  **Note:** This method is new as of 6.0.1
Creating topics	`Admin.createTopic(String streamPathAndName, String topicName, TopicDescriptor desc)` is used when creating a topic with the defaults for partitions and timestamp type.  **Note:** TopicDescriptor is new as of 6.0.1 `Admin.createTopic(String streamPathAndName, String topicName)` is used when accepting the default number of partitions. `Admin.createTopic(String streamPathAndName, String topicName, int npartitions)` - creates a topic with a specific number of partitions.  **Note:** If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.
Editing topics	`Admin.editTopic(String streamPathAndName, String topicName, TopicDescriptor desc)` - sets the partitions and timestamp type attributes of a topic.  **Note:** TopicDescriptor is new as of 6.0.1 `Admin.editTopic(String streamPathAndName, String topicName, int npartitions)`
Retrieving topic attributes	`Admin.getTopicDescriptor(String streamPathAndName, String topicName)` - retrieves topic attributes.  **Note:** This method is new as of 6.0.1
Deleting topics	`Admin.deleteTopic(String streamPathAndName, String topicName)` - deletes topics.
Listing topics	`Admin.listTopics(String streamPathAndName)` - lists all topics in a stream.  **Note:** This method is new as of 6.0.1
Counting topics	`Admin.countTopics(String streamPathAndName)` - counts the number of topics in a stream.
Gets/Sets topic timestamp type	`TopicDescriptor` is used to retrieve the timestamp type attribute value of a topic.  **Note:** TopicDescriptor is new as of 6.0.1 `TopicDescriptor.getTimestampType()` - retrieves the default timestamp type of a topic. `TopicDescriptor.setTimestampType(TimestampType timestampType)` - sets the default timestamp type of a topic.

last-updated: Apr 11, 2022

Table (Continued)

Operation	Interface/Method Used
Gets/Sets topic partitions	`TopicDescriptor` is used to retrieve the partition attribute value of a topic.  **Note:** TopicDescriptor is new as of 6.0.1 `TopicDescriptor.getPartitions()` - retrieves the partitions of a topic. `TopicDescriptor.setParitions(int numPartitions)` - sets the partitions of a topic.
Enabling and tuning log compaction	`TopicDescriptor` is used to enable and tune log compaction at the stream-level. • `setCompact(boolean compact)` - sets log compaction. • `getCompact()` - returns **true** if log compaction is set on the stream. • `setMinCompactionLagMS(long ts)` - set the lag time (in milliseconds) that a message should remain uncompacted. • `getMinCompactionLagMS()` - retrieves the value of the lag time. • `setDeleteRetentionMS(long ts)` - sets the time (in milliseconds) for which deleted records are retained. • `getDeleteRetentionMS()` - returns the time value of which deleted records are retained. In addition, the `Admin` interface is used with the following method to set compaction at the topic-level: • `compactTopic(java.lang.String streamPath, java.lang.String topicName)`
Enabling an Idempotent Producer	The `Producer` interface along with the `ProducerConfig` class is used to enable idempotence (exact-once message delivery semantics) publishing.

Managing Streams with Java

Provides Java code snippets for performing CRUD operations on MapR Event Store For Apache Kafka streams.

Creating Streams

`StreamDescriptor` is used to set attributes for streams that you want to create.

```
public StreamDescriptor createStreamDescriptor(int numPartitions, String
adminUsers, String producerUsers, String consumerUsers, String copyUsers,
String topicUsers) {
        StreamDescriptor desc = Streams.newStreamDescriptor();
        desc.setDefaultPartitions(numPartitions);
        desc.setCompressionAlgo("zlib");
        desc.setAutoCreateTopics(false);
        desc.setAdminPerms(adminUsers);
        desc.setConsumePerms(consumerUsers);
        desc.setCopyPerms(copyUsers);
        desc.setTopicPerms(topicUsers);

        return desc;
}
```

last-updated: Apr 11, 2022

`Admin` is used with the `createStream` method to create the stream with the pre-established attribute values.

```
public void createStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createStream(streamPathAndName, desc);
        streamAdmin.close();
}
```

Editing Stream Attributes

`StreamDescriptor` is used to retrieve the stream's attribute values. `Admin` with the `editStream` method is used to set or modify the stream's attribute values.

```
Admin.editStream(String streamPathAndName, StreamDescriptor desc)
```

```
Configuration conf = new Configuration();
Admin streamAdmin = Streams.newAdmin(conf);
        StreamDescriptor desc =
streamAdmin.getStreamDescriptor(streamPathAndName);
```

```
public void editStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.editStream(streamPathAndName, desc);
        streamAdmin.close();
}
```

Deleting Streams

```
public void deleteStreamUtilFunction(String streamPathAndName) throws
IllegalArgumentException, IOException{
          Configuration conf = new Configuration();
          Admin streamAdmin = Streams.newAdmin(conf);
          streamAdmin.deleteStream(streamPathAndName);
          streamAdmin.close();
}
```

Managing Topics with Java

Provides Java code snippets for performing CRUD operations on MapR Event Store For Apache Kafka stream topics.

Creating Topics

The `createTopic` API is used to create a topic with the default number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName)
```

Note: If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.

```
public void createTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
        Configuration conf = new Configuration();
```

```
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createTopic(streamPathAndName, topicName);
        streamAdmin.close();
}
```

The `createTopic` API is used to create a topic with a specific number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName, int
npartitions)
```

```
public void createTopicWithPartitionsUtilFunction(String streamPathAndName,
String topicName, int npartitions) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createTopic(streamPathAndName, topicName, npartitions);
        streamAdmin.close();
}
```

Editing Topics

The `editTopic` API is used to change timestamp type and the number of partitions for a topic.

```
Admin.editTopic(String streamPathAndName, String topicName, int npartitions)
```

```
public void editTopicUtilFunction(String streamPathAndName, String
topicName, int npartitions) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.editTopic(streamPathAndName, topicName, npartitions);
        streamAdmin.close();
}
```

Retrieving Topic Attributes

The `getTopicDescriptor` API is used to get or set the topic's attribute values. `TopicDescriptor` is passed into methods to set and retrieve topic partitions and timestamp type. The `Enum TimestampType` values are CREATE_TIME and LOG_APPEND_TIME.

Note: `TopicDescriptor` is available as of MapR 6.0.1.

Deleting Topics

The `deleteTopic` API is used to delete a topic from a stream.

```
Admin.deleteTopic(String streamPathAndName, String topicName)
```

```
public void deleteTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.deleteTopic(streamPathAndName, topicName);
        streamAdmin.close();
}
```

Counting Topics

The `countTopics` API is used to count the number of topics in a stream. See the mapr streamanalyzer on page 5348 utility for a sample application that counts and queries topic messages.

```
Admin.countTopics(String streamPathAndName)
```

```
public int countTopicsUtilFunction(String streamPathAndName){
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        int count = streamAdmin.countTopics(streamPathAndName);
        streamAdmin.close();

        return count;
}
```

Using Timestamps on Streams and Topics

Provides a code example for using timestamps on MapR Event Store For Apache Kafka streams and topics.

Passing Timestamp Value

The timestamp value can be passed as part of the `ProducerRecord`, for example:

```
ProducerRecord<String, String> producerRecord =
        new ProducerRecord<String, String>(topicName, partition, timestamp,
key, value);
```

Note: The timestamp value is retained if the timestamp type is `createtime`. If the timestamp type is `logappendtime`, then the timestamp value is ignored and instead the server timestamp is used.

Retrieving Timestamp Type

This example sets and retrieves the timestamp type. The following code example performs the following:

- Creates a stream with a default timestamp type of LogAppendTime.
- Creates a topic with a specific timestamp type of CreateTime.
- Retrieves the topics's timestamp type.

```
// Create stream with default timestamp type as "LogAppendTime"
// Create a topic with timestamp type as "CreateTime"
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);

// Create a stream
        StreamDescriptor sDesc = Streams.newStreamDescriptor();
        sDesc.setDefaultTimestampType(TimestampType.LOG_APPEND_TIME);
        streamAdmin.createStream(streamName, sDesc);

// Create a topic
        TopicDescriptor tDesc = Streams.newTopicDescriptor();
        tDesc.setTimestampType(TimestampType.CREATE_TIME);
        streamAdmin.createTopic(streamName, topicName, tDesc);

// Get topic timestamp type
        TopicDescriptor rDesc = streamAdmin.getTopicDescriptor(streamName,
```

```
topicName);
        System.out.println(rDesc.getTimestampType().name);
```

Enabling Log Compaction
Provides a code example for using timestamps on MapR Event Store For Apache Kafka streams and topics.

Log compaction is enabled through the MapR Event Store For Apache Kafka `StreamDescriptor` interface with the `setCompact` method where the compact value is set to **true**. Additionally, use the `setDeleteRetentionMS` and `setMinCompactionLagMS` methods to set the time delay before compacting records and the time that deleted records are retained.

Configuration values include:

- compact - used to set log compaction at the stream-level.
- min.compaction.lag.ms - used to set a **minimum** time delay (milliseconds) before starting to compact records after they are written. Records won't get compacted until after this period. The setting gives consumers time to retrieve every record.
- delete.retention.ms - used to set the **minimum** time (milliseconds) that deleted records are retained.

Note: You can set not set log compaction when creating the stream; only when editing the stream configuration. The configuration parameters, `min.compaction.lag.ms` and `delete.retention.ms` can be set when both creating and editing streams.

Enabling Log Compaction

The following code example performs the following:

- Enables log compaction at the stream-level.
- Sets the minumum time delay before log compaction starts
- Set the minimum time that deleted record are retained.

```
// Creates a stream
// Sets log compaction on the stream
// Sets the minimum time for a message to stay uncompacted
// Sets the time that deleted records are retained.

(Admin streamAdmin = Streams.newAdmin(conf))
    StreamDescriptor streamDescriptor = Streams.newStreamDescriptor();
       streamDescriptor.setCompact(true);
       streamDescriptor.setDeleteRetentionMS(deleteRetentionMs);
    streamDescriptor.setMinCompactionLagMS(minCompactionLagMs);
       streamAdmin.editStream(streamName, streamDesc);
}
```

For More Information

See the following topics for more information:

- Log Compaction on page 641
- maprcli stream create on page 1758 and stream edit on page 1765

Enabling an Idempotent Producer
Describes how to enable an idempotent producer. Idempotence refers to exactly-once message delivery semantics.

To enable idempotence, the `enable.idempotence` configuration must be set to **true**. When set, the retries configuration defaults to Integer.MAX_VALUE and the Acks configuration defaults to all.

The idempotence producer option is set by setting the `enable.idempotence` value of true passed through the `ProducerConfig` class.

Constant Field Values
`org.apache.kafka.clients.producer.ProducerConfig`

Modifier and Type	Constant Field	Value
`public static final java.lang.String`	`ENABLE_IDEMPOTENCE_CONFIG`	enable.idempotence

Example Code Snippet:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true);
```

Note: The default is false, which retains at-least-once message delivery semantics.

Tip: There are no API changes for the Idempotent Producer functionality, so existing applications do not need to be modified except to enable the producer configuration property.

Example: Subscribing and Querying with Timestamps
This sample Java consumer application uses the `subscribe` API to subscribe to the input topics and queries offsets upon partition-assignment.

In the query, the `offsetsForTimes` API returns the earliest offset in a topic-partition with a timestamp greater than or equal to the input timestamp. The consumer then seeks to that offset if it is greater than the consumer's current position. Following this, the consumer polls for messages. If there are messages following that offset with timestamps earlier than the input timestamp, then those messages are skipped by the consumer.

```

      }
```

```
      // for each assigned partition, find the earliest offset in that
partition with a timestamp
      // greater than or equal to the input timestamp
      Map<TopicPartition, OffsetAndTimestamp> outOffsets =
consumer.offsetsForTimes(timestampsToSearch);
      for (TopicPartition partition : partitions) {
        Long seekOffset = outOffsets.get(partition).offset();
        Long currentPosition = consumer.position(partition);
        // seek to the offset returned by the offsetsForTimes API
        // if it is beyond the current position
        if (seekOffset.compareTo(currentPosition) > 0) {
          consumer.seek(partition, seekOffset);
        }
      }
    }

    @Override
    public void onPartitionsRevoked(Collection<TopicPartition> partitions) {
    }

  }

}
```

Querying Topic Messages
Describes how MapR Event Store For Apache Kafka topic messages can be queried.

Time-based Querying

The **consumer.offsetsForTimes**API is used to get offsets in a topic-partition. This API takes in a `Map` of `TopicPartition` and timestamp. The offset is returned in an `OffsetAndTimestamp` object when `offsetsForTime` is called.

The following shows how the Map is constructed:

```
Long timestamp = 1522195205L;
TopicPartition topicPartition = new TopicPartition(topic,partition);

HashMap<TopicPartition, Long> offsetsForTimesMap = new
HashMap<TopicPartition, Long>();
offsetsForTimesMap.put(topicPartition, timestamp);

// Invocation to offsetsForTimes
Map<TopicPartition, OffsetAndTimestamp> offsetForTimesResultMap =
consumer.offsetsForTimes(offsetsForTimesMap);
```

Direct Querying

The `Streams` class is used to directly query topic messages. See the mapr streamanalyzer on page 5348 utility for a sample application that counts and queries topic messages.

- The `getMessageStore()` APIs are used to get the `DocumentStore` object which represents the underlying topic messages for a specified stream.
- The `DocumentStore.find()` APIs are used to query the messages that are in the `DocumentStore` object. While running `find()` on the returned DocumentStore object, message fields can be projected based on the specified field name.

Note: DocumentStore is a part of the open-source OJAI API.

The logical schema of each message is the same, where analytics applications can run queries on these fields. See Logical Schema of Messages on page 635 for more information.

```
{
        "_id":<STRING>,
        "topic":<STRING>,
        "partition":<SHORT>,
        "offset":<LONG>,
        "timestamp":<LONG>,
        "producer":<VARCHAR>,
        "key":<BINARY>,
        "value":<VARBINARY>
}
```

Apache Kafka Java APIs

MapR Event Store For Apache Kafka supports these Apache Kafka Java APIs.

Javadoc

As of MapR Data Platform 6.1.0, Apache Kafka 1.1 is supported.

See the following APIs for detailed information:

- MapR Event Store For Apache Kafka Java API Library
- Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka

Admin APIs

The following Admin APIs, `org.apache.kafka.clients.admin` package, are applicable to MapR Data Platform support of Apache Kafka. These APIs are supported as of MapR Data Platform 6.1.0.

- AdminClient

Note: For MapR 6.1, the following Apache Kafka API is not supported:

- deleteRecords()

Note: The AdminClient API options (CreateTopicsOptions, DeleteTopicsOptions, DescribeTopicsOptions, ListTopicsOptions, CreatePartitionsOptions, and DescribeTopicsOptions), are ignored. All of the methods assume that a topic belongs to the default stream unless a stream path is specified in the topic name.

If a default stream name is not specified and the topic path does not contain a stream name, the an exception is reported via the Result object. For example:

- If the topic name is specified as `topic1`, then the API assumes the full topic path as `/defaultStream:topic1`.
- If the topic name is specified as `/defaultStream:topic1`, then that will be the full topic path.

Note: The `AdminClient` default stream configuration parameter is `streams.admin.default.stream`. See Configuration Parameters on page 2772 for more information.

Table

Modifier and Type	Method
static AdminClient	create(java.util.Properties props)

last-updated: Apr 11, 2022

Table (Continued)

Modifier and Type	Method
static AdminClient	create(java.util.Map<java.lang.String,java.lang.Object> conf)
void	close()
CreateTopicsResult	createTopics(java.util.Collection<NewTopic> newTopics)
DeleteTopicsResult	deleteTopics(java.util.Collection<NewTopic> newTopics)
DescribeTopicsResult	describeTopics(java.util.Collection<java.lang.String> topicNames)
ListTopicsResult	listTopics()
ListTopicsResult	listTopics((java.lang.String streamPath))
CreatePartitionsResult	createPartitions(java.util.Map<java.lang.String,NewPartitions> newPartitions)
DescribeClusterResult	describeCluster()

Note: For a complete list of supported APIs, see Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka

Consumer APIs

The following Consumer APIs, `org.apache.kafka.clients.consumer` package, are applicable to MapR Data Platform support of Apache Kafka 1.1. These APIs are supported as of MapR Data Platform 6.1.0..

- Interface ConsumerInterceptor<K,V>
- Class ConsumerRecord
- Class KafkaConsumer

Table

Modifier and Type	Method
long	timestamp()
long	timestamptype()

Table

Modifier and Type	Method
void	pause(Collection<TopicPartition> partitions)
void	resume(Collection<TopicPartition>partitions)
void	seekToBeginning(Collection<TopicPartition>)
void	seekToEnd(Collection<TopicPartition>)
void	subscribe(Collection<String> topics);
void	subscribe(Collection<String> topics, ConsumerRebalanceListener)
void	assign(Collection<TopicPartition> partitions)

Table (Continued)

Modifier and Type	Method
java.util.Map<TopicPartition,OffsetAndTimestamp>	offsetsForTimes(java.util.Map<TopicPartition,java.lang.Long> timestampsToSearch)
java.util.Map<TopicPartition,java.lang.Long>	beginningOffsets(Collection<TopicPartition>)
java.util.Map<TopicPartition,java.lang.Long>	endOffsets(Collection<TopicPartition> partitions)
ConsumerRecords<K,V>	poll(long timeout)
void	commitSync()
void	commitAsync()

The following consumer interface and classes are applicable to MapR Data Platform support of Apache Kafka.

- org.apache.kafka.clients.consumer.ConsumerConfig
- org.apache.kafka.clients.consumer.ConsumerRebalanceCallback (interface)
- org.apache.kafka.clients.consumer.ConsumerRecord<K,V>
- org.apache.kafka.clients.consumer.ConsumerRecords<K,V>
- org.apache.kafka.clients.consumer.KafkaConsumer<K, V> implements Consumer<K, V>

Note: For a complete list of supported APIs, see Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka

Producer APIs

The following producer interface and classes, `org.apache.kafka.clients.producer` package, are applicable to MapR Data Platform support of Apache Kafka 1.1. These APIs are supported as of MapR Data Platform 6.1.0..

- Interface ProducerInterceptor<K,V>
- Class RecordMetadata
- Class ProducerRecord

Table

Modifier and Type	Method
java.util.concurrent.Future<RecordMetadata>	send(ProducerRecord<K,V> record)
void	flush()
void	close()

The following producer interface and classes are applicable to MapR Data Platform support of Apache Kafka.

- org.apache.kafka.clients.producer.Callback (Interface)
- org.apache.kafka.clients.producer.KafkaProducer<K,V>

last-updated: Apr 11, 2022

- org.apache.kafka.clients.producer.ProducerConfig
- org.apache.kafka.clients.producer.ProducerRecord<K,V>
- org.apache.kafka.clients.producer.RecordMetadata

Note: For a complete list of supported APIs, see Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka

Common APIs

The following common APIs, `org.apache.kafka.clients.common` packages, are applicable toMapR Data Platform support of Apache Kafka 1.1. These APIs are supported as of MapR Data Platform 6.1.0..

- Interface Header

Table

Modifier and Type	Method
java.lang.String	key()
byte[]	value()

The following APIs are applicable to MapR Data Platform support for Apache Kafka.

- org.apache.kafka.common.PartitionInfo

  Supported methods in PartitionInfo:

  - int partition()
  - java.lang.String topic()
  - java.lang.String toString()
- org.apache.kafka.common.serialization.Serializer<T> (Interface)
- org.apache.kafka.common.serialization.Deserializer<T> (interface)
- org.apache.kafka.common.TopicPartition

Note: For a complete list of supported APIs, see Apache Kafka 1.1 APIs used with MapR Event Store For Apache Kafka

Configuration Parameters
This topic describes configuration parameters that are either specific to MapR Event Store For Apache Kafka or supported from Apache Kafka.

AdminClient

Table

Parameter	Description
`streams.admin.default.stream`	This parameter, when set during creation of the AdminClient instance, ensures that the specified stream is using the the AdminClient instance for all administrative operations. Syntax: `/mapr/<cluster name>/<volume name>/<stream name>`
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the MapR Event Store For Apache Kafka server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000 **Note:** Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout` For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Consumer

Table

Parameter	Description
`streams.consumer.buffer.memory`	Specifies how much memory to use for caching pre-fetched messages. Messages that are in subscribed topics and partitions are pre-fetched and cached to improve performance. Default 64MB
`streams.consumer.default.stream`	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. This default value is also used for the `KafkaConsumer.listTopics() method`.
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the MapR Event Store For Apache Kafka server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000 For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Table

Parameter	Description
`auto.commit.interval.ms`	The frequency in milliseconds that the offsets are committed. Default: 1000ms

Table (Continued)

Parameter	Description
`auto.offset.reset`	Specifies what MapR Event Store For Apache Kafka should do when there is no initial offset, such as when a consumer starts reading from a partition. Default: latest **`earliest`** — Reset the offset to the offset of the earliest message in the partition. **`latest`** — Reset the offset to the offset of the latest message in the partition. **none** — Throws a `NoOffsetForPartitionException` exception when the consumer next polls for messages in its subscription and no offset exists. The consumer must unsubscribe from the partition before polling functions correctly. Any other value throws an error to the consumer.
`enable.auto.commit`	If true, periodically commits the highest offsets of the messages fetched by the consumer in all of the partitions for the topics that the consumer is subscribed to. Default: true
`fetch.min.bytes`	The minimum amount of data the server should return for a fetch request. If insufficient data is available, the server will wait for this minimum amount of data to accumulate before answering the request. This minimum applies to the totality of what a consumer has subscribed to. Works in conjunction with the timeout interval that is specified in the poll function. If the minimum number of bytes is not reached by the time that the interval expires, the poll returns with nothing. For example, suppose the value is set to 6 bytes and the timeout on a poll is set to 100ms. If there are 5 bytes available and no further bytes come in before the 100ms expire, the poll returns with nothing. Default: 1 byte
`fetch.max.bytes`	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **Note:** This parameter is new as of MapR 6.0.1.
`fetch.max.wait.ms`	The maximum amount of time the MapR Event Store For Apache Kafka server will block before answering the fetch request if there isn't sufficient data to satisfy the requirement given by `fetch.min.bytes`.

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description
`group.id`	A string 2457 up to bytes long that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group ID, multiple consumer processes indicate that they are all part of the same consumer group. Putting consumers into groups provides benefits that are described in Consumer Groups. It is possible for a single consumer to be in a group.
`key.deserializer`	The class that implements the `Deserializer` interface for deserializing keys.
`max.poll.records`	Places an upper bound on the number of records returned from each call. **Note:** This parameter is new as of MapR 6.0.1.
`max.partition.fetch.bytes`	The number of bytes of message data to attempt to fetch for each partition in each poll request. These bytes will be read into memory for each partition, so this parameter helps control the memory that the consumer uses. Default: 64KB The size of the poll request must be at least as large as the maximum message size that the server allows or else it is possible for producers to send messages that are larger than the consumer can fetch. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **Note:** This is a behavior change as of MapR 6.0.1.
`value.deserializer`	The name of the appropriate deserialization class in the `org.apache.kafka.common.serialization` package or a class that implements the `Deserializer` interface for deserializing values.

Producer

Table

Parameter	Description
`streams.buffer.max.time.ms`	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec create default stream
`streams.parallel.flushers.per.partition`	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true create default stream
`streams.partitioner.class`	The class that implements the `StreamsPartitioner` interface. This interface lets you write custom algorithms for determining which topic and partition to use for messages that match specific criteria. Use this configuration parameter only for producers that are written in Java. create default stream

last-updated: Apr 11, 2022

Table (Continued)

Parameter	Description
`streams.producer.default.stream`	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. Syntax: `/mapr/<cluster name>/<volume name>/<stream name>` create default stream
`fs.mapr.hardmount`	Specifies whether to use a hard mount or a soft mount for connections to the MapR Streams server. The default is to use a hard mount and the value is `true`. If a value for this parameter is set in the `core-site.xml` file, the value in that file is ignored. create default stream
`fs.mapr.rpc.timeout`	Specifies the length of time in seconds to wait for a response from the MapR Event Store For Apache Kafka server if the configuration parameter `fs.mapr.hardmount` is set to false. Default: 300. Minimum value: 30. **Note:** Applicable to MapR 6.0.0 and earlier. As of MapR 6.0.1, use `streams.mapr.timeout.ms`. If a soft mount is used, the time expires while a producer waits for a response from the MapR Event Store For Apache Kafka server, and the producer used the `KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)` method, the callback is invoked with the error `EAGAIN`, which means "Resource temporarily unavailable." create default stream
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the MapR Event Store For Apache Kafka server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000 For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Table

Parameter	Description
`buffer.memory`	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are generated faster than they can be delivered to the server the producer will block. Default: 33554432
`client.id`	Producers can tag records with a client ID that identifies the producer. Consumers can then be aware of which producer sent a message or set of messages. Apache Drill or other analytic tools querying messages can include this ID in the filters for their queries. Default: No client ID.

Table (Continued)

Parameter	Description
`key.serializer`	The name of the appropriate serialization class in the `org.apache.kafka.common.serialization` package or a class that implements the `Serializer` interface for serializing keys.
`metadata.max.age.ms`	The producer generally refreshes the topic metadata from the server when there is a failure. It will also poll for this data regularly. Default: 300 * 1000 msec
`value.serializer`	The class that implements the `Serializer` interface for serializing values.

Compiling and Running MapR Event Store For Apache Kafka Java Apps

For producer and consumer applications that use the MapR Event Store For Apache Kafka Java API, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

See MapR Event Store For Apache Kafka Streams Sample Programs on GitHub for an example pom.xml file.

1. Add MapR's Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
    <repository>
      <id>mapr-releases</id>
      <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
      <snapshots><enabled>true</enabled></snapshots>
      <releases><enabled>true</enabled></releases>
    </repository>
</repositories>
```

2. Add a dependency to the MapR Streams Java client (kakfa-clients) project:

```
<dependency>
      <groupId>org.apache.kafka</groupId>
      <artifactId>kafka-clients</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

Note: The kafka-clients version mentioned above is an example. The actual version that your application requires is based on the current EEP and MapR version that you are running. The versions are listed in the following location: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/kafka/kafka-clients/

last-updated: Apr 11, 2022

3. Add a dependency to the MapR Streams project:

```
<dependency>
      <groupId>com.mapr.streams</groupId>
      <artifactId>mapr-streams</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

Note: The MapR Streams project version mentioned above is an example. The actual version that your application requires is based on the current EEP and MapR version that you are running. The versions are listed in the following location:https://repository.mapr.com/nexus/content/groups/mapr-public/com/mapr/streams/mapr-streams/

4. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your MapR cluster expects, this can result in failures. The failures differ depending on the version of MapR you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 2367.

When the cluster is secure, the node must also have a mapr ticket configured for the user that runs the application.

You can use the following command to launch MapR Event Store For Apache Kafka applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Migrating Apache Kafka Java Applications to MapR Event Store For Apache Kafka
There are only two steps that you need to follow to migrate applications written with the Apache Kafka Java API to MapR Event Store For Apache Kafka.

The following steps assume that migration is from either:

- Apache Kafka 2.1.1 to MapR Event Store For Apache Kafka 6.2 or higher
- Apache Kafka 1.1 to MapR Event Store For Apache Kafka 6.1 or higher
- Apache Kafka 1.0 to MapR Event Store For Apache Kafka 6.0.1 or higher
- Apache Kafka 0.9.0 to MapR Event Store For Apache Kafka 6.0.0 or earlier

Important: For information on backward compatibility, see MapR Event Store For Apache Kafka Java API Library on page 2756

1. Change the names of topics to include the path and name of the MapR Stream stream in which the topic is located.

   Here is the syntax to use:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a MapR cluster that is named `stream_A`, and the stream might be in a volume named `IoT` and in a directory named `automobile_sensors`. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this:

   ```
   /mapr/IoT/automobile_sensors/stream_A:<name of topic>
   ```

2. If a producer application uses the Kafka interface Partitioner to compute which partitions to publish messages to, revise the application so that it uses the Kafka StreamsPartitioner interface instead.

Differences between MapR Event Store For Apache Kafka and Apache Kafka Configuration
Describes the MapR Event Store For Apache Kafka supportability of Apache Kafka configuration parameters for producers and consumers.

Kafka Producer

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...` Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file `mapr-clusters.conf`.
`key.serializer`	`Serializer` class for key that implements the `Serializer` interface.	Yes
`value.serializer`	`Serializer` class for value that implements the `Serializer` interface.	Yes

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`acks`	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common:	Ignored, all writes in MapR Event Store For Apache Kafka are synchronous, and number of replicas is determined at the volume level, with a default of 3.
	`acks=0` If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to -1.	
	`acks=1` This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost.	
	`acks=all` This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	
`buffer.memory`	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by `block.on.buffer.full`.	Yes
	This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`compression.type`	The compression type for all data generated by the producer. The default is none (i.e. no compression). Valid values are `none`, `gzip`, `snappy`, or `lz4`. Compression is of full batches of data, so the efficacy of batching will also impact the compression ratio (more batching means better compression).	Ignored. Compression is configured per stream.
`retries`	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	Ignored. MapR Event Store For Apache Kafka always does automatic retries on transient errors.
`ssl.key.password`	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.keystore.location`	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.keystore.password`	The store password for the key store file.This is optional for client and only needed if `ssl.keystore.location` is configured.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.truststore.location`	The location of the trust store file.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.truststore.password`	The password for the trust store file.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`batch.size`	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes.	Ignored. MapR Data Platform always batches records for optimal performance.
	No attempt will be made to batch records larger than this size.	
	Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent.	
	A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	
`client.id`	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
`connections.max.idle.ms`	Close idle connections after the number of milliseconds specified by this config.	Ignored.

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`linger.ms`	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay—that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting linger.ms=5, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absense of load.	Ignored.
`max.block.ms`	The configuration controls how long {@link KafkaProducer#send()} and {@link KafkaProducer#partitionsFor} will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable.This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a send(). In case of partitionsFor(), this configuration imposes a maximum time threshold on waiting for metadata	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
`max.request.size`	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	Ignored.

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`partitioner.class`	Partitioner class that implements the Partitioner interface.	Use the Kafka StreamsPartitioner interface.
`receive.buffer.bytes`	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.
`request.timeout.ms`	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
`sasl.kerberos.service.name`	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`security.protocol`	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`send.buffer.bytes`	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
`ssl.enabled.protocols`	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored.
`ssl.keystore.type`	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.protocol`	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.provider`	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.truststore.type`	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.

last-updated: Apr 11, 2022

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`timeout.ms`	The configuration controls the maximum amount of time the server will wait for acknowledgments from followers to meet the acknowledgment requirements the producer has specified with the acks configuration. If the requested number of acknowledgments are not met when the timeout elapses an error will be returned. This timeout is measured on the server side and does not include the network latency of the request.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
`block.on.buffer.full`	When our memory buffer is exhausted we must either stop accepting new records (block) or throw errors. By default this setting is true and we block, however in some scenarios blocking is not desirable and it is better to immediately give an error. Setting this to false will accomplish that: the producer will throw a BufferExhaustedException if a recrord is sent and the buffer space is full.	Ignored.
`max.in.flight.requests.per.connection`	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.parallel.flushers.per.partition`
`metadata.fetch.timeout.ms`	The first time data is sent to a topic we must fetch metadata about that topic to know which servers host the topic's partitions. This fetch to succeed before throwing an exception back to the client.	Ignored.
`metadata.max.age.ms`	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
`metric.reporters`	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
`metrics.num.samples`	The number of samples maintained to compute metrics.	No.
`metrics.sample.window.ms`	The number of samples maintained to compute metrics.	No.

last-updated: Apr 11, 2022

Name	Description	Supported for producers in MapR Event Store For Apache Kafka?
`reconnect.backoff.ms`	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
`retry.backoff.ms`	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
`sasl.kerberos.kinit.cmd`	Kerberos kinit command path. Default is /usr/bin/kinit	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`sasl.kerberos.min.time.before.relogin`	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`sasl.kerberos.ticket.renew.jitter`	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`sasl.kerberos.ticket.renew.window.factor`	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.cipher.suites`	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.endpoint.identification.algorithm`	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.keymanager.algorithm`	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
`ssl.trustmanager.algorithm`	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.

last-updated: Apr 11, 2022

Kafka Consumer

Name	Description	Supported for consumers in MapR Event Store For Apache Kafka?
bootstrap.servers	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form host1:port1,host2:port2,.... Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file `mapr-clusters.conf`.
key.deserializer	Deserializer class for key that implements the Deserializer interface.	Yes
value.deserializer	Deserializer class for value that implements the Deserializer interface.	Yes
fetch.min.bytes	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request. The default setting of 1 byte means that fetch requests are answered as soon as a single byte of data is available or the fetch request times out waiting for data to arrive. Setting this to something greater than 1 will cause the server to wait for larger amounts of data to accumulate which can improve server throughput a bit at the cost of some additional latency.	Yes
fetch.max.bytes	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.  **Note:** This is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
group.id	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using subscribe(topic) or the Kafka-based offset management strategy.	Yes

last-updated: Apr 11, 2022

Name	Description	Supported for consumers in MapR Event Store For Apache Kafka?
heartbeat.interval.ms	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	No
max.poll.records	Places an upper bound on the number of records returned from each call.  **Note:** This parameter is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
max.partition.fetch.bytes	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be #partitions * max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.  **Note:** This is a behavior change as of MapR 6.0.1.	Yes
session.timeout.ms	The timeout used to detect failures when using Kafka's group management facilities.	Ignored
ssl.key.password	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.keystore.location	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.

Name	Description	Supported for consumers in MapR Event Store For Apache Kafka?
ssl.keystore.password	The store password for the key store file.This is optional for client and only needed if ssl.keystore.location is configured.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.truststore.location	The location of the trust store file.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.truststore.password	The password for the trust store file.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
auto.offset.reset	What to do when there is no initial offset in Kafka or if the current offset does not exist any more on the server (e.g. because that data has been deleted): **earliest** automatically reset the offset to the earliest offset **latest** automatically reset the offset to the latest offset **none** throw exception to the consumer if no previous offset is found for the consumer's group **anything else** throw exception to the consumer.	Yes
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	Ignored
enable.auto.commit	If true the consumer's offset will be periodically committed in the background.	Yes
partition.assignment.strategy	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used	Ignored. MapR Event Store For Apache Kafka distributes partitions equally among the consumers in a group.
receive.buffer.bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.

Name	Description	Supported for consumers in MapR Event Store For Apache Kafka?
request.timeout.ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
sasl.kerberos.service.name	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
security.protocol	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
send.buffer.bytes	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
ssl.enabled.protocols	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.keystore.type	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.protocol	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.provider	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.truststore.type	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
auto.commit.interval.ms	The frequency in milliseconds that the consumer offsets are auto-committed to Kafka if enable.auto.commit is set to true.	Yes

Name	Description	Supported for consumers in MapR Event Store For Apache Kafka?
check.crcs	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	Ignored. MapR Event Store For Apache Kafka always does end-to-end crc computation and verification.
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
fetch.max.wait.ms	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy the requirement given by fetch.min.bytes.	No
metadata.max.age.ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
metrics.num.samples	The number of samples maintained to compute metrics.	No
metrics.sample.window.ms	The number of samples maintained to compute metrics.	No
reconnect.backoff.ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
retry.backoff.ms	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. MapR Event Store For Apache Kafka has a similar parameter: `streams.rpc.timeout.ms`
sasl.kerberos.kinit.cmd	Kerberos kinit command path. Default is /usr/bin/kinit	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.

last-updated: Apr 11, 2022

Name	Description	Supported for consumers in MapR Event Store For Apache Kafka?
sasl.kerberos.min.time.before.relogin	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
sasl.kerberos.ticket.renew.jitter	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
sasl.kerberos.ticket.renew.window.factor	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.cipher.suites	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.keymanager.algorithm	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.
ssl.trustmanager.algorithm	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through MapR Data Platform security. See Security on page 683 for more information.

MapR Event Store For Apache Kafka Parameters

The following MapR Event Store For Apache Kafka parameters are for the Admin API.

Table

MapR Event Store For Apache Kafka Parameter	Description	Kafka Parameter Replaced

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the MapR Event Store For Apache Kafka server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000
	  **Note:** Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`request.timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

The following MapR Event Store For Apache Kafka parameter are for the Producer API:

Table

MapR Event Store For Apache Kafka Parameter	Description	Kafka Parameter Replaced
`streams.buffer.max.time.ms`	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec	`linger.ms`
`streams.parallel.flushers.per.partition`	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true	`max.in.flight.requests.per.connection`
`streams.partitioner.class`	The class that implements the `StreamsPartitioner` interface. This interface lets you write custom algorithms for determining which topic and partition to use for messages that match specific criteria. Use this configuration parameter only for producers that are written in Java.	Not applicable.

Table (Continued)

MapR Event Store For Apache Kafka Parameter	Description	Kafka Parameter Replaced
`streams.producer.default.stream`	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>/<topic> However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, MapR Event Store For Apache Kafka assumes that the topic specified is in Apache Kafka and does nothing.	Not applicable.

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the MapR Event Store For Apache Kafka server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000
	If the time expires while a producer waits for a response from the MapR Event Store For Apache Kafka server, and the producer used the `KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)` method, the callback is invoked with the error `EAGAIN`, which means "Resource temporarily unavailable."
	Note: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`max.block.ms`
		`request.timeout.ms`
		`timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

The following MapR Event Store For Apache Kafka parameters are for the Consumer API:

Table

MapR Event Store For Apache Kafka Parameter	Description	Kafka Parameter Replaced
`streams.consumer.default.stream`	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. This default value is also used for the KafkaConsumer.listTopics() method.	Not applicable.

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the MapR Event Store For Apache Kafka server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000
	Note: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`request.timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

MapR Event Store For Apache Kafka C Applications

C applications can be developed for MapR Event Store For Apache Kafka (as of MapR 5.2.1). The MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka. The MapR Event Store For Apache Kafka C Client is available in MapR Ecosystem Pack (EEP) 3.0 or higher.

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of 6.0.1	As of 5.0	0.11.3
As of 5.2.1 through 6.0.0	As of 3.0	0.9.0

The MapR Event Store For Apache Kafka C Client supports a majority of the librdkafka C APIs plus additional configuration properties that are available only with MapR Event Store For Apache Kafka. When developing applications for MapR Event Store For Apache Kafka or migrating Kafka applications to MapR Event Store For Apache Kafka, see the list of librdkafka APIs Supported by MapR Event Store For Apache Kafka C Client on page 2811 which also describes API behavior. Reference rdkafka.h for API signatures.

When developing and running MapR Event Store For Apache Kafka C applications, note the following:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- As of MapR Data Platform 6.0, the MapR Event Store For Apache Kafka offset values start at 0.
- MapR Data Platform Security is supported. Kafka application-level security is not supported. See Security on page 683.
- User impersonation is not supported.

CAUTION: As of MapR Data Platform 6.1, the mapr-core package has a dependency on mapr-librdkafka. If the mapr-librdkafka package is installed, do not remove it manually. Doing so could result in the removal of MapR Data Platform core packages, rendering the node unusable.

last-updated: Apr 11, 2022

Configuring the MapR Event Store For Apache Kafka C Client

After installing the MapR Data Platform Client and before developing applications, you must configure your client C library by setting the library path.

Linux

For Linux installations, add `/opt/mapr/lib` to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib
```

Important: For MapR Data Platform 6.0.1, the libjvm.so configuration is *not* required.

For MapR Data Platform 6.0.0 and earlier, add the /opt/mapr/lib *and the path to the directory that contains libjvm.so* to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/
lib:<path_to_libjvm.so_directory>
```

The location of the libjvm.so differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the libjvm.so file is in the following location:

```
/usr/lib/jvm/java-7-openjdk-amd64/jre/lib/amd64/server/libjvm.so
```

Then, you set the library path like this:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib:/usr/lib/jvm/
java-7-openjdk-amd64/jre/lib/amd64/server/
```

Mac

For Mac installations, add `/opt/mapr/lib` to the end of DYLD_LIBRARY_PATH.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib
```

Important: For MapR Data Platform 6.0.1, the libjvm.so configuration is *not* required.

For MapR Data Platform 6.0.0 and earlier, add /opt/mapr/lib *and the path to the directory that contains libjvm.dylib* to the end of DYLD_LIBRARY_PATH.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/
lib:<path_to_libjvm.dylib_directory>
```

The location of the libjvm.dylib differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the libjvm.dylib file is in the following location:

```
/Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/
Home/jre/lib/server/libjvm.dylib
```

Then, you set the library path like this:

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib:/Library/Java/
JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/jre/lib/server
```

Windows

Note: As of MapR Data Platform 6.0.1, the MapR Data Platform C client is available on Windows.

For Windows installations, no additional configuration is required. Link your application and run your programs against the MapR Data Platform Client dynampic link libraries (dll) located at: `C:\opt\mapr\lib`. The corresponding librdkafka header is `C:\opt\mapr\include\librdkafka`.

Developing a MapR Event Store For Apache Kafka C Application

This topic includes basic information about how to develop a MapR Event Store For Apache Kafka C application. Sample applications are provided.

Before you Begin

Confirm that your environment meets the following requirements:

- The MapR Data Platform cluster version is 5.2.1 or greater.
- MapR Data Platform core client (mapr-client) packagei s installed on the node and it is configured to access the cluster. Or, it is a MapR Data Platform cluster node. See Installing the MapR Client on page 389 for more information.
- The MapR Event Store For Apache Kafka C Client is installed and configured on the node. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.
- GNU Compiler Collection (GCC) is installed on the node.

Creating, Compiling and Running C Apps

The following sections describes how to create a producer and consumer in C, compile the source code, generate executables, and run the applications.

Create Producer

This topic describes how to create a MapR Event Store For Apache Kafka streams producer in C. While the code to generate a MapR Event Store For Apache Kafka stream producer varies depending on the use case, in general, the producer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h)
2. Use `rd_kafka_conf_new()` to create the producer configuration.
3. Use `rd_kafka_new ()` to create the producer handle.
4. Use `rd_kafka_topic_conf_new()` to create the topic configuration.
5. Use `rd_kafka_topic_new ()` to create a topic handle for the producer.
6. Use `rd_kafka_produce()` to produce messages.
7. Optionally, use `rd_kafka_poll()`to poll for callbacks. This is useful to see if there are messages that have yet to be sent to the server.
8. Use `rd_kafka_topic_destroy ()` to destroy the topic handle destroy
9. Use `rd_kafka_destroy ()` to destroy the producer handle.

Note: For more details on the APIs, see Supported APIs for MapR Event Store For Apache Kafka C Client and rdkafka.h on page 2892

last-updated: Apr 11, 2022

For example, the following source code produces 5 messages to topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the producer function.
 *
 */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <rdkafka.h>
#include <errno.h>

/* msgDeliveryCB: Is the delivery callback.
 * The delivery report callback will be called once for each message
 * accepted by rd_kafka_produce() with err set to indicate
 * the result of the produce request. An application must call
rd_kafka_poll()
 * at regular intervals to serve queued delivery report callbacks.
 */
static void msgDeliveryCB (rd_kafka_t *rk,
                           const rd_kafka_message_t *rkmessage, void
*opaque) {
    if (rkmessage->err != RD_KAFKA_RESP_ERR_NO_ERROR) {
        printf("FAILURE: Message not delivered to partition.\n");
        printf("ERROR: %s", rd_kafka_err2str(rkmessage->err));
    } else {
        printf("Produced: %.*s\n",(int)rkmessage->len, (const
char*)rkmessage->payload);
    }
}

/*
 * Method      : int producer(int nummsgs_p, const char *fullTopicName)
 * Description : This is a simple producer method. In this method the
producer
 *               produces messages to a topic.
 */

\n", nummsgs_p, fullTopicName);
  }
}
```

Create Consumer

This topic describes how to create a MapR Event Store For Apache Kafka streams consumer in C. While the code to generate a MapR Event Store For Apache Kafka stream consumer varies depends on the use case, in general, the consumer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h).
2. Use `rd_kafka_conf_new()` to create the consumer configuration.

3. Use `rd_kafka_conf_set()` to set the configuration parameters. For this API, you must set the "group.id."
4. Use `rd_kafka_new ()` to create the consumer handle.
5. Use `rd_kafka_subscribe()` or `rd_kafka_assign()` to specify which topics to consume.
6. Use `rd_kafka_consumer_poll()` to poll for messages that are ready to be consumed.
7. Use `rd_kafka_consumer_close()` to perform auto commits and prepare to destroy the consumer handle.
8. Use `rd_kafka_destroy ()` to destroy the consumer handle.

For example, the following source code consumes 5 messages from topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the consumer function.
 *
 */

#include <stdio.h>
#include <stdlib.h>
#include <rdkafka.h>
#include <string.h>

/*
 * Method      : int consumer(int expected_nummsgs, const char
*fullTopicName)
 * Description : This is a simple consumer method. In this method the
consumer
 *               consumes messages from a topic.
 */

int consumer(int expected_nummsgs, const char *fullTopicName) {
    printf("*********  CONSUMER START  *********\n");
    rd_kafka_t *consHndle;
    rd_kafka_conf_t *consCfg;
    rd_kafka_topic_conf_t *consTopicCfg;
    char errstr[1000];
    rd_kafka_resp_err_t errCode;

    printf("Create new consumer configuration object\n");
    /*
    * rd_kafka_conf_new(): This API creates default rd_kafka_conf_t object
to
    * be passed at the time of consumer object creation using rd_kafka_new
call.
    */
    consCfg = rd_kafka_conf_new();
    if(consCfg == NULL) {
        printf("Failed to create consumer conf\n");
        return(EXIT_FAILURE);
    }
    /*
    * rd_kafka_conf_set(): This API is used to set config parameters in the
    * rd_kafka_conf_t object. group.id Must be set for all the consumers.
    * All changes to the consCfg must be done before creating consumer
object.
    */
    if(RD_KAFKA_CONF_OK != rd_kafka_conf_set(consCfg,
                      "group.id", "consumerGroup",
```

```
                        errstr, sizeof(errstr))) {
        printf("rd_kafka_conf_set() failed with error: %s\n", errstr);
        return (EXIT_FAILURE);
    }
   /*
    * rd_kafka_topic_conf_new(): This API Creates topic conf object
    * required to set the default topic configuration.
    */
    printf("Set topic configurations\n");
    consTopicCfg = rd_kafka_topic_conf_new();

    /* rd_kafka_topic_conf_set(): This API sets the config property by name.
    * consTopicCfg should have been previously set up with
`rd_kafka_topic_conf_new()`
    * property set in this call is 'auto.offset.reset', when set to
    * earliest will return messages on rd_kafka_consumer_poll from
beginning of
    * time (for the very first time consumption) or from last commited
offset
    * for online consumer. If property is set to 'latest' it will return the
    * messages produced after consumer has started(for first time consumer)
or
    * from the last committed offset for online consumer
    */
    if (RD_KAFKA_CONF_OK != rd_kafka_topic_conf_set(consTopicCfg,
"auto.offset.reset",
                            "earliest" ,errstr, sizeof(errstr))) {

    /*
     * rd_kafka_new():Creates a new Kafka handle and starts its operation
     * according to the specified type (RD_KAFKA_CONSUMER or
RD_KAFKA_PRODUCER).
     * consCfg object passed here is freed by this function and must not be
used
     * or destroyed by the application subsequently. errstr must be a
pointer to
     * memory of at least size errstr_size where
     * `rd_kafka_new()` may write a human readable error message in case the
     * creation of a new handle fails. In which case the function returns
NULL.
     */

    consHndle = rd_kafka_new(RD_KAFKA_CONSUMER, consCfg, errstr,
sizeof(errstr));
    if(consHndle == NULL) {
        printf("Failed to create consumer:%s", errstr);
        return (EXIT_FAILURE);
    }

    /* rd_kafka_poll_set_consumer() is used to redirect the main queue
which is
    *  serviced using rd_kafka_poll() to the rd_kafka_consumer_poll(). With
```

```
one api
    *  'rd_kafka_consumer_poll()' both callbacks and message are serviced.
    *  Once queue is forwarded using this API, it is not permitted to call
    *  rd_kafka_poll to service non message delivery callbacks.
    */
    rd_kafka_poll_set_consumer(consHndle);

    /* Topic partition list (tp_list) is supplied as an input to the
consumer
    *  subscribe(using rd_kafka_subscribe()). The api rd_kafka_subscribe()
expects
    *  that the partition argument to be set to RD_KAFKA_PARTITION_UA and
internally
    *  all partitions are assigned to the consumer.
    *  Note: partition balancing/assignment is done if more consumers are
part
    *  of the same consumer group.
    */

    printf("Create topic partition list for topic: %s\n", fullTopicName);
    rd_kafka_topic_partition_list_t *tp_list =
rd_kafka_topic_partition_list_new(0);
    rd_kafka_topic_partition_t* tpObj =
rd_kafka_topic_partition_list_add(tp_list,
                                                fullTopicName,
RD_KAFKA_PARTITION_UA);
    if (NULL == tpObj) {
        printf("Could not add the topic partition to the list.\n");
        return (EXIT_FAILURE);
    }

    printf("Subscribe consumer to the topic:\n");
    /*
    * rd_kafka_subscribe(): This API subscribes given consumer to the topic
list
    * provided in tp_list, depending upon number of consumers in a consumer
group
    * partitions will be balanced and assigned to each consumer.
    */
    errCode = rd_kafka_subscribe(consHndle, tp_list);
    if (errCode  != RD_KAFKA_RESP_ERR_NO_ERROR) {

        * rd_kafka_consumer_poll(): This API returns one message or
callback at
        * a time. An application should make sure to call consumer_poll()
at regular
        * intervals, even if no messages are expected, to serve any
        * queued callbacks waiting to be called.  When the application is
finished
        * with a message it must call rd_kafka_message_destroy() to destroy
```

```
and
        * message.
        */
        rd_kafka_message_t *msg = rd_kafka_consumer_poll(consHndle, 1000);
        if (msg != NULL) {
            if (msg->err == RD_KAFKA_RESP_ERR_NO_ERROR) {
                msg_count++;
                printf("%d Consumed: %.*s\n", msg_count,(int) msg->len,
                   (const char*)msg->payload);
                if (msg_count == expected_nummsgs){
                    rd_kafka_message_destroy(msg);
                    break;
                }
            }
            rd_kafka_message_destroy(msg);
        }
    }

    printf("\nCommit the offsets before closing the consumer\n");
    /*
    * Commit offsets on broker for the provided list of topic partitions.
    * when input is NULL the current partition assignment will be used
instead.
    * If async is false this operation will block until the offset commit
    * is done, returning the resulting success or error code.
    * This call is made to be sure that offsets are committed before
closing
    * consumer.
    */
    int retVal = rd_kafka_commit(consHndle, NULL, false/*async*/);
    if(retVal != RD_KAFKA_RESP_ERR_NO_ERROR) {
        printf("rd_kafka_commit() failed");
        return(EXIT_FAILURE);
    }

    printf("\nClose and destroy consumer handle\n");
    /*
    * Consumer shutdown sequense:
    * 1. rd_kafka_consumer_close(): This is blocking call. It makes sure to
revoke
    *    assignments, commit offsets, leave consumer group.
    *    The application still needs to call rd_kafka_destroy() after
    *    this call finishes to clean up the underlying handle resources.
    * 2. rd_kafka_destroy(): This API destroys the consumer handle created
using
    *    rd_kafka_new call and frees resources
    */

  if (EXIT_SUCCESS != ret_val) {
    printf("\nFAIL: consumer failed\n");
  } else {
    printf("\nPASS: %d messages consumed from topic %s\n",
expected_nummsgs, fullTopicName);
  }
}
```

Note: For more details on the APIs, see Supported APIs for MapR Event Store For Apache Kafka C Client and rdkafka.h on page 2892

Compile the Apps

This topic describes how to compile MapR Event Store For Apache Kafka streams producers and consumers in C. When you compile a MapR Event Store For Apache Kafka C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path and include the header file directory to ensure that your application references the header file included with MapR Event Store For Apache Kafka C Client.

Important: For MapR 6.0.0 and earlier, When you compile a MapR Event Store For Apache Kafka C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path, *the libjvm library*, and include the header file directory to ensure that your application references the header file included with MapR Event Store For Apache Kafka C Client.

The following steps compile the source code and generate executables in the same directory as the Makefile. For example, in the **librdkafka_example** directory, the `consumer` and `producer` executables are generated from the producer.c and consumer.c source files.

1. On your node, create a directory. For example: **librdkafka_example**.
2. In your directory (**librdkafka_example**), create a producer application. For example, if you are using the provided sample producer application:
   a. Create a file named producer.c.
   b. Copy the contents of the sample producer application into that file.
3. In your directory (**librdkafka_example**), create a consumer application. For example, if you are using the provided sample consumer application:
   a. Create a file named consumer.c.
   b. Copy the contents of the sample consumer application into that file.

4. In your directory (**librdkafka_example**), create a file named Makefile with the following content:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

export LD_LIBRARY_PATH=/opt/mapr/lib

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

Important: For MapR 6.0.0 and earlier, use the following Makefile:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

#Edit JAVA_HOME to be appropriate for your environment
JAVA_HOME=/usr/lib/jvm/java-7-openjdk-amd64/
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

5. Complete the following edits to the Makefile:

   For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib
```

   Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib
```

last-updated: Apr 11, 2022

Important: For MapR 6.0.0 and earlier, the following steps apply:

a. For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server
```

Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/server
```

b. Based on your environment, edit JAVA_HOME. This ensures that LD_LIBRARY_PATH or DYLD_LIBRARY_PATH will include the full path to the directory containing the libjvm library.

Note: You can use `find / -name libjvm*` to determine the JAVA_HOME directory on your machine. However, note that the results of this command include the full path to the libjvm file not just the JAVA_HOME directory.

For example, JAVA_HOME may be set to `Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/` on a Mac and JAVA_HOME may be set to `/usr/lib/jvm/java-1.7.0-openjdk-1.7.0.79.x86_64/` on Linux.

6. From your directory (**librdkafka_example**), run the following commands to compile the source code:

```
make clean
```

```
make all
```

Run the Apps

Once you have the application executables, complete the following steps to run the application:

1. On a cluster node, use the maprcli to create a stream. For example, **MapR_Streams**.

```
maprcli stream create -path /MapR_Streams
```

Note: As long as autocreate is enabled for the stream when you run `stream create`,the producer will create the topic. By default, autocreate is enabled. For more information, see stream create on page 1758.

2. At the command line, set the library path to include **/opt/mapr/lib** and the path to the directory that contains the **libjvm** library. For more information, see Configuring the MapR Event Store For Apache Kafka C Client on page 2796.

Note: You must complete this step at the command line even though you already set the library path in the Makefile. If you do not complete the step, an error similar to the following displays when you run the application in the next step: `error while loading shared libraries: librdkafka.so.1: cannot open shared object file: No such file or directory`

last-updated: Apr 11, 2022

3. From your directory (**librdkafka_example**), run the producer application from the command line. For example, if the application is called producer:

```
./producer
```

   The following appears on the console assuming that the stream name is MapR_Streams:

```
********************** PRODUCER ***********************
Create producer configuration object
Create Producer Kafka handle
Create topic handle
Send/Produce message to topic: /MapR_Streams:MapR-Topic1
Wait for messages to be delivered
Produced: Welcome to MapR Streams CAPI
Produced: MapR Streams CAPI Message Payload 1
Produced: MapR Streams CAPI Message Payload 2
Produced: MapR Streams CAPI Message Payload 3
Produced: MapR Streams CAPI Message Payload 4

Destroy topic handle
Destroy producer handle

PASS: 5 messages produced and sent to topic partition /
MapR_Streams:MapR-Topic1
```

4. From your directory (**librdkafka_example**), run the consumer application from the command line. For example, if the application is called consumer:

```
./consumer
```

   The following appears on the console assuming that the stream name is MapR_Streams:

```
*********  CONSUMER START  *********
Create new consumer configuration object
Set topic configurations
Create consumer Kafka handle
Create topic partition list for topic: /MapR_Streams:MapR-Topic1
Subscribe consumer to the topic:
Destroy topic partition list:

Start message consumption:
1 Consumed: Welcome to MapR-ES CAPI
2 Consumed: MapR Streams CAPI Message Payload 1
3 Consumed: MapR Streams CAPI Message Payload 2
4 Consumed: MapR Streams CAPI Message Payload 3
5 Consumed: MapR Streams CAPI Message Payload 4

Commit the offsets before closing the consumer

Close and destroy consumer handle

PASS: 5 messages consumed from topic /MapR_Streams:MapR-Topic1
```

Migrating Kafka C Applications to MapR Event Store For Apache Kafka

With some modification, you can use existing Kafka C applications to consume and produce topics in MapR Event Store For Apache Kafka. The MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that is compatible with MapR Event Store For Apache Kafka.

1. Install and configure the MapR Streams C Client.

last-updated: Apr 11, 2022

2. When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a MapR Data Platform cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

   Note: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream. To use these MapR Data Platform-specific parameters in your application, compile your application with the rdkafka.h file (/opt/mapr/include/librdkafka/rdkafka.h) that was installed with the MapR Event Store For Apache Kafka C Client. See the Compile the Apps on page 2806 section of Developing a MapR Event Store For Apache Kafka C Application on page 2797.

3. See Configuration Properties for MapR Event Store For Apache Kafka C Client on page 2882 for the list of supported configuration parameters, including a few parameters that are MapR Data Platform-specific. Make changes to your application, as needed.

   Note: SSL-related configuration parameters are ignored. When you set these parameters, the MapR Event Store For Apache Kafka Client issues a warning indicating that the parameters are not supported.

4. Review the list of librdkafka APIs that are **not** supported by the MapR Event Store For Apache Kafka C Client and make changes to your application, as needed.

Simple/low level consumer APIs that are not supported	• rd_kafka_queue_new • rd_kafka_queue_destroy • rd_kafka_consume_start • rd_kafka_consume_start_queue • rd_kafka_consume_stop • rd_kafka_consume • rd_kafka_consume_batch • rd_kafka_consume_callback • rd_kafka_consume_queue • rd_kafka_consume_batch_queue • rd_kafka_consume_callback_queue • rd_kafka_offset_store • rd_kafka_pause_partitions • rd_kafka_resume_partitions
Producer/Consumer common APIs that are not supported	• rd_kafka_conf_set_dr_cb

last-updated: Apr 11, 2022

- rd_kafka_conf_set_throttle_cb
- rd_kafka_conf_set_stats_cb
- rd_kafka_conf_set_socket_cb
- rd_kafka_conf_set_open_cb
- rd_kafka_conf_dump
- rd_kafka_conf_dump_free
- rd_kafka_name
- rd_kafka_set_log_level
- rd_kafka_mem_free
- rd_kafka_set_log_level
- rd_kafka_mem_free

Topic APIs that are not supported

- rd_kafka_query_watermark_offsets

  Note: As of MapR Data Platform 6.0.1, this API *is* supported.

- rd_kafka_get_watermark_offsets

  Note: As of MapR Data Platform 6.0.1, this API *is* supported.

Cluster APIs that are not supported

- rd_kafka_memberid
- rd_kafka_metadata
- rd_kafka_metadata_destroy

Miscellaneous APIs that are not supported

- rd_kafka_version
- rd_kafka_version_str
- rd_kafka_get_debug_contexts
- rd_kafka_dump
- rd_kafka_thread_cnt
- rd_kafka_message_timestamp

librdkafka APIs Supported by MapR Event Store For Apache Kafka C Client

This topic lists the librdkafka APIs supported by the MapR Event Store For Apache Kafka C Client. It also describes behavior differences between librdkafka and the MapR Event Store For Apache Kafka C Client.

Table

Core release	EEP Release	Kafka librdkafka version
As of MapR Data Platform 6.0.1	As of 5.0	0.11.3
As of MapR Data Platform 5.2.1 through 6.0.0	As of 3.0	0.9.0

last-updated: Apr 11, 2022

This topic contains the following supported APIs:

Producer APIs

API	Behavior
rd_kafka_flush	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_poll	Same as librdkafka.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_produce	When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.
rd_kafka_produceva	Same as librdkafka. This API should be used with either RD_KAFKA_V_TOPIC or RD_KAFKA_V_RKT. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_produce_batch	When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.

API	Behavior
rd_kafka_outq_len	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker.

Consumer APIs

API	Behavior
rd_kafka_assign	If this API is called for a consumer that is already subscribed to topics, no operation is performed.
rd_kafka_assignment	This API returns the number of topic partitions the consumer is assigned to. However, it returns 0 when topic partitions have yet to be created by the producer. librdkafka returns the number of partitions assigned to a consumer even when the partitions have not been created. **Note:** For this API to work, the argument partitions must be explicitly allocated or initialized with either `rd_kafka_topic_partition_list_t *parts = NULL` or `rd_kafka_topic_partition_list_new(0);`. For example: `RD_EXPORT rd_kafka_resp_err_t rd_kafka_assignment (rd_kafka_t *rk, rd_kafka_topic_partition_list_t **partitions);`

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_commit	Same as librdkafka.
rd_kafka_commit_message	Same as librdkafka.
rd_kafka_committed	Same as librdkafka. **Note:** The MapR Event Store For Apache Kafka offset starts at 1.

API	Behavior
rd_kafka_consumer_close	Same as librdkafka.
rd_kafka_consumer_poll	Same as librdkafka. **Note:** For librdkafka 0.9: If the consume callback was set and messages were polled using rd_kafka_consumer_poll(), then the consume callback gets called and the messages can be consumed in the callback. For librdkafka 0.11.3: If the consume callback is set and messages are polled using rd_kafka_consumer_poll(), the consume callback is not called. The result is that you cannot consume messages in the consume callback when using rd_kafka_consumer_poll().

API	Behavior
rd_kafka_group_list_destroy	Same as librdkafka.
rd_kafka_list_groups	This API can only be used by consumers that are subscribed to at least one stream on the cluster and have a default stream configured with the streams.consumer.default.stream parameter. It returns the group list of subscribed consumers associated with the default stream. librdkafka returns all consumer groups from the cluster instead. **Note:** This API returns RD_KAFKA_RESP_ERR__TIMED_OUT when the querying consumer is not subscribed to any topic.

API	Behavior
rd_kafka_message_destroy	Same as librdkafka.
rd_kafka_poll_set_consumer	Same as librdkafka.

API	Behavior
rd_kafka_position	This API returns 0 when the messages have not yet been consumed from partitions. librdkafka returns -1001 instead.
rd_kafka_seek	Same as librdkafka.
rd_kafka_subscribe	Same as librdkafka.

API	Behavior
rd_kafka_subscription	This API allows either a list of topics from one or more streams or a regex expression for topics from a single streams. For example, regex expression `/streamA:^t*a,/streamA:^t*b` is supported but `/streamA:^t*a,/_streamB:^t*a` is not supported. librdkafka accepts both options in the same call. **Note:** You cannot use the rd_kafka_subscribe API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error RD_KAFKA_RESP_ERR__CONFLICT is returned.
rd_kafka_unsubscribe	Same as librdkafka.

Producer/Consumer Common APIs

API	Behavior
rd_kafka_conf_destroy	Same as librdkafka.
rd_kafka_conf_dup	Same as librdkafka.
rd_kafka_conf_get	Same as librdkafka.

API	Behavior
rd_kafka_conf_new	Same as librdkafka.
rd_kafka_conf_set	Same as librdkafka.

API	Behavior
rd_kafka_conf_set_consume_cb	Same as librdkafka.
rd_kafka_conf_set_dr_msg_cb	Same as librdkafka.

API	Behavior
rd_kafka_conf_set_error_cb	Same as librdkafka.
rd_kafka_conf_set_offset_commit_cb	Same as librdkafka.

API	Behavior
rd_kafka_conf_set_opaque	Same as librdkafka.
rd_kafka_conf_set_rebalance_cb	Same as librdkafka.

API	Behavior
rd_kafka_conf_set_throttle_cb	Same as librdkafka.
rd_kafka_destroy	Same as librdkafka.
rd_kafka_new	Same as librdkafka.

API	Behavior
rd_kafka_opaque	Same as librdkafka.
rd_kafka_wait_destroyed	Same as librdkafka.
rd_kafka_yield	Same as librdkafka.

last-updated: Apr 11, 2022

Topic APIs

API	Behavior
rd_kafka_conf_set_default_topic_conf	Same as librdkafka.

API	Behavior
rd_kafka_topic_conf_destroy	Same as librdkafka.
rd_kafka_topic_conf_dup	Same as librdkafka.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_topic_conf_new	Same as librdkafka.
rd_kafka_topic_conf_set	Same as librdkafka.

API	Behavior
rd_kafka_topic_conf_set_opaque	Same as librdkafka.

API	Behavior
rd_kafka_topic_conf_set_partitioner_cb	Same as librdkafka.
rd_kafka_topic_destroy	Same as librdkafka.

API	Behavior
rd_kafka_topic_name	Same as librdkafka.
rd_kafka_topic_new	Same as librdkafka..

API	Behavior
rd_kafka_topic_partition_list_add	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_add_range	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_copy	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_del	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_del_by_idx	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_destroy	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_find	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_new	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_set_offset	Same as librdkafka.

Queue APIs

API	Behavior
rd_kafka_queue_new	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_queue_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_queue_get_main	For this API, produce events are batched as well as the APIs that use this API, such as, `rd_kafka_event_message_count` and `rd_kafka_event_message_next`. The messages produce events can be consumed together in batches, wheras, opensource librdkafka events are obtained one at a time. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_queue_get_consumer	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_queue_length	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_queue_poll	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_queue_poll_callback	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_commit_queue	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_queue_forward	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_set_log_queue	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_queue_length	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_queue_to_event_enable	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_queue_get_partition	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

Event APIs

API	Behavior
rd_kafka_event_type	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_event_name	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_event_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_event_message_array	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_event_message_count	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_event_error	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_event_error_string	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_event_topic_partition_list	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.
rd_kafka_event_message_next	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_event_opaque	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform6.0.1.

Timestamp APIs

API	Behavior
rd_kafka_offsets_for_times	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_message_timestamp	Same as librdkafka. Available as of librdkafka 0.9.1. Supported as of MapR Data Platform 6.0.1.

Interceptors APIs

Attention: Modifying the message in interceptors is not supported and can result in undefined behavior.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_interceptor_f_on_conf_set_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_conf_dup	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_interceptor_f_on_conf_destroy_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_new_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_destroy_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_send_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_offset_store_message_interceptor_f_on_acknowledgement_f	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_consume_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_commit_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_conf_set	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_conf_dup	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_conf_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_new	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_add_on_send	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_add_on_acknowledgement	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_interceptor_add_on_consume	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

API	Behavior
rd_kafka_interceptor_add_on_commit	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

Cluster Configuration APIs

API	Behavior
rd_kafka_brokers_add	This API has no impact on MapR Event Store For Apache Kafka since MapR Event Store For Apache Kafka does not utilize Kafka brokers. When this API is called, the MapR Event Store For Apache Kafka client may print a `_brokers are down error` message to the console.

last-updated: Apr 11, 2022

Miscellaneous API

API	Behavior
rd_kafka_err2name	Same as librdkafka.
rd_kafka_err2str	Same as librdkafka.
rd_kafka_errno	Same as librdkafka.

API	Behavior
rd_kafka_err_no2err	Same as librdkafka.
rd_kafka_get_err_descs	Same as librdkafka.
rd_kafka_last_error	Same as librdkafka.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_log_print	Same as librdkafka.
rd_kafka_log_syslog	Same as librdkafka.
rd_kafka_message_errstr	Same as librdkafka.

API	Behavior
rd_kafka_set_logger	Same as librdkafka.
rd_kafka_query_watermark_offsets	When you are querying or retrieving a topic that is non-existent topic/partition (using `rd_kafka_query_watermark_offsets()` and `rd_kafka_get_watermark_offsets()` APIs), the timeout is honored even though you still receive the correct error message. Supported as of MapR Data Platform 6.0.1.

last-updated: Apr 11, 2022

API	Behavior
rd_kafka_get_watermark_offsets	When you are querying or retrieving a topic that is non-existent topic/partition (using `rd_kafka_query_watermark_offsets()` and `rd_kafka_get_watermark_offsets()` APIs), the timeout is honored even though you still receive the correct error message. Supported as of MapR Data Platform 6.0.1.

Additional Information

For more information and API signatures, see rdkafka.h on page 2892.

librdkafka APIs NOT Supported by MapR Event Store For Apache Kafka C Client
This topic lists the librdkafka APIs that are *not* supported by the MapR Event Store For Apache Kafka C Client.

These APIs are also documented in the rdkafka.h on page 2892 as not support by MapR Event Store For Apache Kafka. If you want to see the list of supported librdkafka APIs, see librdkafka APIs Supported by MapR Event Store For Apache Kafka C Client on page 2811.

Note: This list of librdkafka APIs *not* supported is applicable to MapR Data Platform 6.0.1 and librdkafka 0.11.3.

Table

Core release	EEP Release	Kafka librdkafka version
As of MapR Data Platform 6.0.1	As of 5.0	0.11.3
As of MapR Data Platform 5.2.1 through 6.0.0	As of 3.0	0.9.0

Configuration Properties for MapR Event Store For Apache Kafka C Client

This topic describes the configuration properties supported by the MapR Event Store For Apache Kafka C Client. This includes librdkafka configuration properties that MapR Event Store For Apache Kafka supports and additional properties that are specific to MapR Event Store For Apache Kafka.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka.
message.max.bytes	See Configuring Properties for Message Size on page 3029.

Property Name	Behavior
receive.message.max.bytes	See Configuring Properties for Message Size on page 3029.
topic.blacklist	Same as librdkafka.
error_cb	Same as librdkafka.

Property Name	Behavior
opaque	Same as librdkafka.
queue.buffering.max.ms	Same as librdkafka.
enable.partition.eof	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

Property Name	Behavior
queue.buffering.max.kbytes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

Consumer Configuration Properties

Property Name	Behavior
default_topic_conf	Same as librdkafka.
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.

Property Name	Behavior
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.

Property Name	Behavior
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

Topic Configuration

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of MapR Data Platform 6.0.1, beginning and end are supported. **Note:** librdkafka additionally supports error.

MapR Data Platform-Specific Configurations

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **Note:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.

Property Name	Behavior
streams.parallel.flushers.per.partition	Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, MapR Event Store For Apache Kafka assumes that the topic specified is in Apache Kafka and does nothing.

Additional Information

For more information, see rdkafka.h on page 2892.

rdkafka.h
This rdkafka header file has been updated to be compatible with MapR Event Store For Apache Kafka. After you install the MapR Event Store For Apache Kafka C Client, this file is available in the following directory: /opt/mapr/include/librdkafka/

librdkafka 0.11.3

Apache librdkafka 0.11.3 is supported as of MapR Data Platform 6.0.1/EEP5.0.

Important: With this release, the RD_KAFKA_MSG_F_BLOCK call provides *blocking* behavior, whereas, the RD_KAFKA_MSG_F_COPY and RD_KAFKA_MSG_F_FREE calls are *non-blocking* (this is a behavior change from previous releases.

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
 *                              rd_kafka_topic_partition_list_t *partitions,
 *                              void *opaque) {
 *
 *        switch (err)
 *        {
 *          case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
```

```
 *              // application may load offets from arbitrary external
 *              // storage here and update \p partitions
 *
 *              rd_kafka_assign(rk, partitions);
 *              break;
 *
 *          case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
 *              if (manual_commits) // Optional explicit manual commit
 *                  rd_kafka_commit(rk, partitions, 0); // sync commit
 *
 *              rd_kafka_assign(rk, NULL);
 *              break;
 *
 *          default:
 *              handle_unlikely_error(err);
 *              rd_kafka_assign(rk, NULL); // sync state
 *              break;
 *         }
 *    }
 * @endcode

/**
 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynch non-blocking API.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *    RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 *                           \p queue.buffering.max.messages or
 *                           \p queue.buffering.max.kbytes are exceeded.
 *                           Messages are considered in-queue from the
point they
 *                           are accepted by produce() until their
corresponding
 *                           delivery report callback/event returns.
 *                           It is thus a requirement to call
```

```
 *                            rd_kafka_poll() (or equiv.) from a separate
 *                            thread when F_BLOCK is used.
 *                            See WARNING on \c RD_KAFKA_MSG_F_BLOCK above.
 *
 *    RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
 *                          with it.
 *    RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
 *                          \p payload pointer will not be used by rdkafka
 *                          after the call returns.
 *
 *    ..._F_FREE and ..._F_COPY are mutually exclusive.
 *
 *    If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
 *    the memory associated with the payload is still the caller's
 *    responsibility.
 *
 * \p payload is the message payload of size \p len bytes.
 *
 * \p key is an optional message key of size \p keylen bytes, if non-NULL it
 * will be passed to the topic partitioner as well as be sent with the
 * message to the broker and passed on to the consumer.
 *
 * \p msg_opaque is an optional application-provided per-message opaque
 * pointer that will provided in the delivery report callback (`dr_cb`) for
 * referencing this message.
 *
 * @remark on_send() and on_acknowledgement() interceptors may be called
 *         from this function. on_acknowledgement() will only be called if
the
 *         message fails partitioning.
 *
 * @returns 0 on success or -1 on error in which case errno is set
accordingly:
 *  - ENOBUFS  - maximum number of outstanding messages has been reached:
 *               "queue.buffering.max.messages"
 *               (RD_KAFKA_RESP_ERR__QUEUE_FULL)
 *  - EMSGSIZE - message is larger than configured max size:
 *               "messages.max.bytes".
 *               (RD_KAFKA_RESP_ERR_MSG_SIZE_TOO_LARGE)
 *  - ESRCH    - requested \p partition is unknown in the Kafka cluster.
 *               (RD_KAFKA_RESP_ERR__UNKNOWN_PARTITION)
 *  - ENOENT   - topic is unknown in the Kafka cluster.
 *               (RD_KAFKA_RESP_ERR__UNKNOWN_TOPIC)
 *
 * @sa Use rd_kafka_errno2err() to convert `errno` to rdkafka error code.

/**
 * @name Miscellaneous APIs
 * @{
 *
 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or
 *         \c bootstrap.servers configuration property (preferred method).

/**
 * @name Interceptors
 *
 * @{
 *
 * @brief A callback interface that allows message interception for both
 *        producer and consumer data pipelines.
 *
 * Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
 * interceptors, interceptors are added to the
 * newly created rd_kafka_t client instance. These interceptors MUST only
 * be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
 *
 * The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
 * are added to the configuration object which is later passed to
 * rd_kafka_new() where on_new() is called to allow addition of
 * other interceptors.
 *
 * Each interceptor reference consists of a display name (ic_name),
 * a callback function, and an application-specified opaque value that is
 * passed as-is to the callback.
 * The ic_name must be unique for the interceptor implementation and is used
 * to reject duplicate interceptor methods.
 *
 * Any number of interceptors can be added and they are called in the order
 * they were added, unless otherwise noted.
 * The list of registered interceptor methods are referred to as
 * interceptor chains.
 *
 * @remark Contrary to the Java client the librdkafka interceptor interface
 *         does not support message modification. Message mutability is
 *         discouraged in the Java client and the combination of
 *         serializers and headers cover most use-cases.
 *
 * @remark Interceptors are NOT copied to the new configuration on
 *         rd_kafka_conf_dup() since it would be hard for interceptors to
 *         track usage of the interceptor's opaque value.
 *         An interceptor should rely on the plugin, which will be copied
 *         in rd_kafka_conf_conf_dup(), to set up the initial interceptors.
 *         An interceptor should implement the on_conf_dup() method
 *         to manually set up its internal configuration on the newly
created
```

```
 *         configuration object that is being copied-to based on the
 *         interceptor-specific configuration properties.
 *         conf_dup() should thus be treated the same as conf_init().
 *
 * @remark Interceptors are keyed by the interceptor type (on_..()), the
 *         interceptor name (ic_name) and the interceptor method function.
 *         Duplicates are not allowed and the .._add_on_..() method will
 *         return RD_KAFKA_RESP_ERR__CONFLICT if attempting to add a
duplicate
 *         method.
 *         The only exception is on_conf_destroy() which may be added
multiple
 *         times by the same interceptor to allow proper cleanup of
 *         interceptor configuration state.
 */

/**
 * @brief on_conf_set() is called from rd_kafka_*_conf_set() in the order
 *        the interceptors were added.

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
```

```
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
 *                              rd_kafka_topic_partition_list_t *partitions,
 *                              void *opaque) {
 *
 *        switch (err)
 *        {
 *          case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
 *             // application may load offets from arbitrary external
 *             // storage here and update \p partitions
 *
 *             rd_kafka_assign(rk, partitions);
 *             break;
 *
 *          case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
 *             if (manual_commits) // Optional explicit manual commit
 *                 rd_kafka_commit(rk, partitions, 0); // sync commit
 *
 *             rd_kafka_assign(rk, NULL);
 *             break;
 *
 *          default:
 *             handle_unlikely_error(err);
 *             rd_kafka_assign(rk, NULL); // sync state
 *             break;
 *         }
 *    }
 * @endcode

 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynch non-blocking API.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
```

```
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *    RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
 *                          with it.
 *    RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
 *                          \p payload pointer will not be used by rdkafka
 *                          after the call returns.
 *
 *    ..._F_FREE and ..._F_COPY are mutually exclusive.
 *
 *    If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
 *    the memory associated with the payload is still the caller's
 *    responsibility.
 *
 * \p payload is the message payload of size \p len bytes.
 *
 * \p key is an optional message key of size \p keylen bytes, if non-NULL it
 * will be passed to the topic partitioner as well as be sent with the
 * message to the broker and passed on to the consumer.
 *
 * \p msg_opaque is an optional application-provided per-message opaque
 * pointer that will provided in the delivery report callback (`dr_cb`) for
 * referencing this message.
 *
 * Returns 0 on success or -1 on error in which case errno is set
accordingly:
 *  - ENOBUFS  - maximum number of outstanding messages has been reached:

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or
 *         \c bootstrap.servers configuration property (preferred method).
 */

MapR Event Store For Apache Kafka Python Applications

As of MapR Data Platform 5.2.1, you can create python applications for MapR Event Store For Apache Kafka using the MapR Event Store For Apache Kafka Python client. The MapR Event Store For Apache Kafka Python client is a binding for librdkafka and the MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka.

The MapR Event Store For Apache Kafka Python client is available in a MapR Ecosystem Pack (EEP) starting with EEP 3.0.

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of MapR Data Platform 6.0.1	As of 5.0	0.11.3
As of MapR Data Platform 5.2.1 through 6.0.0	As of 3.0	0.9.0

Note: Because the MapR Event Store For Apache Kafka Python Client is dependent on the MapR Event Store For Apache Kafka C Client, the MapR Event Store For Apache Kafka C Client must be configured before using the MapR Event Store For Apache Kafka Python Client.

When developing and running MapR Event Store For Apache Kafka Python applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- MapR Event Store For Apache Kafka offset values start at 1, not 0.
- MapR Data Platform security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See Security on page 683 for more information about MapR Data Platform security features.
- User impersonation is not supported.

Developing MapR Event Store For Apache Kafka Python Applications

This topic includes basic information about how to develop a MapR Event Store For Apache Kafka Python application and an example program that you can run.

Before you Begin

Confirm that your environment meets the following requirements:

- MapR Data Platform cluster version 5.2.1 or greater.
- MapR Data Platform core client (mapr-client) package. See Installing the MapR Client on page 389 for more information.
- MapR Event Store For Apache Kafka C Client (mapr-librdkafka) is installed and configured on the node. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.
- MapR Event Store For Apache Kafka Python Client (mapr-streams-python) is installed on the node. See Installing MapR Event Store For Apache Kafka Python Client on page 198.
- Python installed on the node (Python version 2.7.x and above, up to version 3.6.x).

Create a MapR Event Store For Apache Kafka Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

last-updated: Apr 11, 2022

As of EEP 5.0 MapR Event Store For Apache Kafka Python Client: In the following example code, three messages are produced to a topic named `mytopic` in a stream named `my_stream`.

```
from confluent_kafka import Producer
p = Producer({'streams.producer.default.stream': '/my_stream'})
some_data_source= ["msg1", "msg2", "msg3"]
for data in some_data_source:
     p.produce('mytopic', data.encode('utf-8'))
     p.flush()
```

As of EEP 3.0 MapR Event Store For Apache Kafka Python Client: In the following example code, three messages are produced to a topic named `mytopic` in a stream named `my_stream`.

```
from mapr_streams_python import Producer
p = Producer({'streams.producer.default.stream': '/my_stream'})
some_data_source= ["msg1", "msg2", "msg3"]
for data in some_data_source:
    p.produce('mytopic', data.encode('utf-8'))
    p.flush()
```

Create a MapR Event Store For Apache Kafka Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

As of EEP 5.0 MapR Event Store For Apache Kafka Python Client: In following example code, the MapR Event Store For Apache Kafka consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
from confluent_kafka import Consumer, KafkaError
c = Consumer({'group.id': 'mygroup',
              'default.topic.config': {'auto.offset.reset': 'earliest'}})
c.subscribe(['/my_stream:mytopic'])
running = True
while running:
  msg = c.poll(timeout=1.0)
  if msg is None: continue
  if not msg.error():
    print('Received message: %s' % msg.value().decode('utf-8'))
  elif msg.error().code() != KafkaError._PARTITION_EOF:
    print(msg.error())
    running = False
c.close()
```

As of EEP 3.0 MapR Event Store For Apache Kafka Python Client: In following example code, the MapR Event Store For Apache Kafka consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
from mapr_streams_python import Consumer, KafkaError
c = Consumer({'group.id': 'mygroup',
              'default.topic.config': {'auto.offset.reset': 'earliest'}})
c.subscribe(['/my_stream:mytopic'])
running = True
```

```
while running:
  msg = c.poll(timeout=1.0)
  if msg is None: continue
  if not msg.error():
    print('Received message: %s' % msg.value().decode('utf-8'))
  elif msg.error().code() != KafkaError._PARTITION_EOF:
    print(msg.error())
    running = False
c.close()
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named `mystream`.
2. Create a file named producer.py.
3. Add the producer example code into the producer.py file.
4. Create a file named consumer.py.
5. Add the consumer example code into the consumer.py file.
6. Verify that you have completed the steps to configure the MapR Event Store For Apache Kafka C client or complete the steps now. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.

   Note: The MapR Event Store For Apache Kafka Python Client is dependent on the MapR Event Store For Apache Kafka C Client. Therefore, the MapR Event Store For Apache Kafka C Client must be configured before you can run the application.

7. Run producer.py from the command line to generate messages.

   ```
   $ python producer.py
   ```

8. Run consumer.py from the command line:

   ```
   $ python consumer.py
   ```

Migrating Kafka Python Applications to MapR Event Store For Apache Kafka

With some modification, you can use existing confluent-kafka python applications to consume and produce topics in MapR Event Store For Apache Kafka. The MapR Event Store For Apache Kafka Python Client is a binding for Apache librdkafka that works with MapR Event Store For Apache Kafka.

1. Install the MapR Event Store For Apache Kafka Python Client.

   Note: This required that you also install and configure the MapR Event Store For Apache Kafka C Client. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.

2. Do one of the following depending on whether you are using the EEP 5.0 (or higher) MapR Event Store For Apache Kafka Python Client or the EEP 3.0 (or higher) MapR Event Store For Apache Kafka Python Client.
   - If you are using MapR Event Store For Apache Kafka Python EEP 5.0 (or higher), skip this step. The references to `confluent_kafka` should be retained.

last-updated: Apr 11, 2022

- If you are using MapR Event Store For Apache Kafka Python EEP 3.0 (or higher), update import statements to refer to the MapR Stream Python API. References to `confluent_kafka` should be updated to `mapr_streams_python`.

  Note: For example, update `from confluent_kafka import Consumer` to `from mapr_streams_python import Consumer`.

3. When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a MapR Data Platform cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

   Note: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

4. Review the APIs that are supported and make changes to your application, as needed. See API for MapR Event Store For Apache Kafka Python Client on page 3002.

5. See Configuration Properties for MapR Event Store For Apache Kafka Python Client on page 3008 for the list of supported configuration parameters and make changes to your application, as needed.

   Note: SSL-related configuration parameters are ignored. When you set these parameters, the MapR Event Store For Apache Kafka Client issues a warning indicating that the parameters are not supported.

API for MapR Event Store For Apache Kafka Python Client

MapR Event Store For Apache Kafka Python Client is a binding for librdkafka and it supports the following APIs.

As of MapR Data Platform 5.2.1, you can create python applications for MapR Event Store For Apache Kafka using the MapR Event Store For Apache Kafka Python client. The MapR Event Store For Apache Kafka Python client is a binding for librdkafka and the MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka.

Table

Core release	EEP Release	Kafka librdkafka version
As of MapR Data Platform 6.0.1	As of 5.0	0.11.3
As of MapR Data Platform 5.2.1 through 6.0.0	As of 3.0	0.9.0

class mapr_streams_python.Consumer

A high-level Kafka Consumer.

Method	Behavior
Consumer(**kwargs)	Create new Consumer instance using provided configuration dictionary.

Method	Behavior
assign(partitions)	Set consumer partition assignment to the provided list of TopicPartition and starts consuming. Parameters(s): • partitions (list(TopicPartition)) – List of topic+partitions and optionally initial offsets to start consuming
unassign()	Unassign from all TopicPartitions that have been assigned with the `.assign(*topic_partition_list) method.`  **Note:** This method is applicable as of MapR Event Store For Apache Kafka Python Client EEP 5.0 which is associated with librdkafka 0.11.3.
assignment()	Return a list of assignments for a consumer object.  **Note:** This method is applicable as of MapR Event Store For Apache Kafka Python Client EEP 5.0 which is associated with librdkafka 0.11.3.
close()	Close down and terminate the Kafka Consumer. Actions(s): • Stops consuming • Commits offsets • Leave consumer group
commit([message=None][, offsets=None][, async=True])	Commit a message or a list of offsets. Message and offsets are mutually exclusive, if neither is set the current partition assignment's offsets are used instead. Parameters(s): • message (confluent_kafka.Message) – Commit message's offset+1. • offsets (list(TopicPartition)) – List of topic+partitions+offsets to commit. • async (bool) – Asynchronous commit, return immediately.

last-updated: Apr 11, 2022

Method	Behavior
committed(partitions[, timeout=None])	Retrieve committed offsets for the list of partitions. Parameters(s): • partitions (list(TopicPartition)) - List of topic+partitions to query for stored offsets. • timeout (float) – Request timeout Returns: List of topic+partitions with offset and possibly error set. Return type: list(TopicPartition) Raises: KafkaException **Note:** As of MapR Data Platform 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the MapR Database/MapR Event Store For Apache Kafka feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).
on_commit(err, partitions)	A callback for Consumer.commit() that triggers custom actions when a commit request completes. Parameters(s): • err (KafkaError) – Commit error object, or None on success. • Partitions (list(TopicPartition)) – List of partitions with their committed offsets or per-partition errors
poll([timeout=None])	Consume messages, calls callbacks and returns events. The application must check the returned Message object's Message.error() method to distinguish between proper messages (error() returns None), or an event or error (see error().code() for specifics). Parameter(s): timeout (*float*) – Maximum time to block waiting for message, event or callback Returns: A Message object or None on timeout Return type: Message or None
position(partitions[, timeout=None])	Retrieve current positions (offsets) for the list of partitions. Parameter(s): partitions (list(TopicPartition)) – List of topic+partitions to return current offsets for. The current offset is the offset of the last consumed message + 1 Returns: List of topic+partitions with offset and possibly error set. Return type: list(TopicPartition) Raises: KafkaException This function returns 0 when the messages have not yet been consumed from partitions. librdkafka returns -1001 instead.

Method	Behavior
subscribe(topics[, listener=None])	Set subscription to supplied list of topics This replaces a previous subscription. Parameters: • topics (list(str)) – List of topics (strings) to subscribe to. • on_assign (callable) – callback to provide handling of customized offsets on completion of a successful partition re-assignment. • on_revoke (callable) – callback to provide handling of offset commits to a customized store on the start of a rebalance operation. Raises: KafkaException **Note:** You cannot use the rd_kafka_subscribe API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error RD_KAFKA_RESP_ERR__CONFLICT is returned.
on_assign(consumer, partitions)	Same as librdkafka.
unsubscribe()	Same as librdkafka.
on_revoke(consumer, partitions)	Parameter(s): • consumer (Consumer) – Consumer instance. • partitions (list(TopicPartition)) – Absolute list of partitions being assigned or revoked.
get_watermark_offsets(confluent_kafka.TopicPartition)	Get WatermarkOffsets for a given Topic Partition. Parameter(s): TopicPartition - Gets the watermark offset **Note:** This method is applicable as of MapR Event Store For Apache Kafka Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.Producer

Asynchronous Kafka Producer.

Method	Behavior
Producer(**kwargs)	Create new Producer instance using provided configuration dict.
len()	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker. Return type: int

Method	Behavior
flush()	Wait for all messages in the Producer queue to be delivered. This is a convenience method that calls poll() until len()is zero.
poll([timeout])	Polls the producer for events and calls the corresponding callbacks (if registered). Parameter(s): • timeout (float) – Maximum time to block waiting for events Returns: Number of events processed (callbacks served). Return type: int
produce(topic[, value][, key][, partition][, callback])	Produce message to topic. This is an asynchronous operation, an application may use the callback(alias on_delivery) argument to pass a function (or lambda) that will be called from poll() when the message has been successfully delivered or permanently fails delivery. Parameters: • topic (str) – Topic to produce message to • value (str|bytes) – Message payload • key (str|bytes) – Message key • partition (int) – Partition to produce to, else uses the configured partitioner. • on_delivery(err,msg) (func) – Delivery report callback to call (from poll() or flush()) on successful or failed deliver Raises: • BufferError – if the internal producer message queue is full (queue.buffering.max.messages exceeded) • KafkaException – for other errors, see exception code **Note:** When this function is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.

class mapr_streams_python.Message

The Message object represents either a single consumed or produced message, or an event . An application must check with error() to see if the object is a proper message (error() returns None) or an error/event. This class is not user-instantiable.

Method	Behavior
len()	Returns: Message value (payload) size in bytes. Return type: int

Method	Behavior
error()	The message object is also used to propagate errors and events. Applications must check error() to determine if the Message is a proper message (error() returns None) or an error or event (error() returns a KafkaError object) Return type: None or KafkaError
key()	Returns: message key or None if not available Return type: str|bytes or None
offset()	Returns: message offset or None if not available Return type: int or None
partition()	Returns: partition number or None if not available Return type: int or None
topic()	Returns: topic name or None if not available Return type: str or None
value()	Returns: message value (payload) or None if not available Return type: str|bytes or None
timestamp()	Returns: message timestamp  **Note:** This method is applicable as of MapR Event Store For Apache Kafka Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.TopicPartition

TopicPartition is a generic type to hold a single partition and various information about it. It is typically used to provide a list of topics or partitions for various operations, such as Consumer.assign().

Method	Behavior
TopicPartition(topic[, partition][, offset])	Instantiate a TopicPartition object. Parameter(s) • topic (string) – Topic name • partition (int) – Partition id • offset (int) – Initial partition offset Return type: TopicPartition
error	Attribute that indicates an error (with KafkaError) unless None.
offset	Attribute for offset.
partition	Attribute for partition number.
topic	Attribute for topic name.

last-updated: Apr 11, 2022

class mapr_streams_python.KafkaError

Kafka error and event object.

The KafkaError class serves multiple purposes:

- Propagation of errors
- Propagation of events
- Exceptions

This class is not user-instantiable.

Method	Behavior
code()	Returns the error/event code for comparison toKafkaError.<ERR_CONSTANTS>. Returns: error/event code Return type: int
name()	Returns the enum name for error/event. Returns: error/event enum name string Return type: str
str()	Returns the human-readable error/event string. Returns: error/event enum message string Return type: str

Configuration Properties for MapR Event Store For Apache Kafka Python Client
In the instance constructor of a MapR Event Store For Apache Kafka Python application, you can use a dictionary to set the following configuration properties. MapR Event Store For Apache Kafka Python client supports a superset of the configuration properties supported by the MapR Event Store For Apache Kafka C client.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka
default.topic.config	A dictionary of topic-level configuration properties that are applied to all used topics for the instance.
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.
receive.message.max.bytes	Same as librdkafka
topic.blacklist	Same as librdkafka
error_cb	A callback for generic/global error events. This callback is served by poll().
opaque	Same as librdkafka.

Consumer Configuration Properties

Property Name	Behavior
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.
on_commit	A callback used to indicate success or failure of commit requests.

Topic Configuration Properties

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: earliest, latest, none, smallest, and largest. librdkafka also supports biggest, end and error.

Producer Configuration Properties

Property Name	Behavior
on_delivery(kafka.KafkaError, kafka.Message)	A Python function reference that is called once for each produced message to indicate the final delivery result (success or failure). This property may also be set per-message by passing callback=callable (or on_delivery=callable) to the confluent_kafka.Producer.produce() function.

MapR Data Platform-Specific Configuration Properties

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **Note:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.
streams.parallel.flushers.per.partition	Enables the producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order.

last-updated: Apr 11, 2022

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, MapR Event Store For Apache Kafka assumes that the topic specified is in Apache Kafka and does nothing.

Additional Information

Here is a consumer configuration example:

```
conf = {'group.id': 'mygroup',

'session.timeout.ms': 6000,

'on_commit': my_commit_callback,

'default.topic.config': {'auto.offset.reset': 'smallest'}}

consumer = mapr_streams_python.Consumer(**conf)
```

MapR Event Store For Apache Kafka C#/.NET Applications

As of MapR Data Platform 6.0.1/EEP5.0, you can create C#/.NET applications for MapR Event Store For Apache Kafka using the MapR Event Store For Apache Kafka C#/.NET client. The MapR Event Store For Apache Kafka C#/.NET client is a binding for librdkafka and the MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka.

Requirements

- MapR Data Platform Client on Windows 7 (or higher) x64 operating systems
- MapR Data Platform cluster version 6.0.1 or greater
- Java 8 SDK and set Java HOME
- MapR Event Store For Apache Kafka C Client (mapr-librdkafka 0.11.3)
- MapR Event Store For Apache Kafka C#/.NET Client (mapr-streams-dotnet)
- .NET SDK 4.5.x or 4.6.x or .NET Core SDK 1.1
- nuget.exe

See Installing MapR Event Store For Apache Kafka C#/.NET Client on page 200 for installation information.

General Information

When developing and running MapR Event Store For Apache Kafka C#/.NET applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- MapR Event Store For Apache Kafka offset values start at 1, not 0.
- MapR Data Platform security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See Security on page 683 for more information about MapR Data Platform security features.
- User impersonation is not supported.

Developing MapR Event Store For Apache Kafka C#/.NET Applications

Describes general tasks for developing C#/.NET applications.

Before Your Begin

Confirm that your environment meets the following requirements:

- MapR Data Platform cluster version 6.0.1 or greater.
- MapR Event Store For Apache Kafka C Client (mapr-librdkafka 0.11.3) is installed and configured on the node. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.
- MapR Event Store For Apache Kafka C#/.NET Client (mapr-streams-dotnet) is installed on the node.
- .NET SKD 4.5.x or 4.6.x
- .NET Core SDK 1.1
- nuget.exe

Create a Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

In the following example code, three messages are produced to a topic named mytopic in a stream named my_stream.

```
class Producer
    {
        public static async void Produce()
        {
            string stream = "/my_stream";
            string topicName = "mytopic";

            var config = new Dictionary<string, object>
{ { "streams.producer.default.stream", stream } };
            var messages = new string[] { "Msg1", "Msg2", "Msg3" };
```

last-updated: Apr 11, 2022

```
            using (var producer = new Producer<Null, string>(config, null,
new StringSerializer(Encoding.UTF8)))
            {
                foreach (var msg in messages)
                {
                    var deliveryReport = await
producer.ProduceAsync(topicName, null, msg);
                    Console.WriteLine($"Delivery report:
{deliveryReport.TopicPartitionOffset}");
                }

                producer.Flush(TimeSpan.FromSeconds(1));
            }
        }
    }
```

Create a Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

In following example code, the MapR Event Store For Apache Kafka consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
using Confluent.Kafka;
using Confluent.Kafka.Serialization

    class Consumer
    {
        public static void Consume()
        {
            var stream = "/mystream";
            var topic = "mytopic";

            var config = new Dictionary<string, object>
            {
                { "group.id", "simple-csharp-consumer" },
                { "streams.consumer.default.stream", stream }
            };

            bool running = true;

            using (var consumer = new Consumer<Ignore, string>(config,
null, new StringDeserializer(Encoding.UTF8)))
            {
                var l = new List<TopicPartitionOffset> { new
TopicPartitionOffset(topic, 0, 0) };
                consumer.Assign(l);

                // Raised on critical errors, e.g. connection failures.
                consumer.OnError += (_, error) =>
                {
                    Console.WriteLine($"Error: {error}");
```

```
                    running = false;
                };

                // Raised on deserialization errors or when a consumed
message has an error != NoError.
                consumer.OnConsumeError += (_, error) =>
                {
                    Console.WriteLine($"Consume error: {error}");
                    running = false;
                };

                while (running)
                {
                    Message<Ignore, string> msg;
                    if (consumer.Consume(out msg, TimeSpan.FromSeconds(10)))
                    {
                        Console.WriteLine($"Topic: {msg.Topic} Partition:
{msg.Partition} Offset: {msg.Offset} {msg.Value}");
                    }
                }
            }
        }
    }
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named **mystream**.
2. Create a folder application.
3. Create a file named **example.cs**.
4. Add producer example code into the **example.cs** file.
5. Add consumer example code into the **example.cs** file.
6. Add an entry point for your application:

```
    class Demo
              {
              public static void Main(string[] args)
              {
              Producer.Produce();
              Consumer.Consume();
              }
              }
```

7. Create a project file named **example.csproj**.

8. Add the following dependency properties into the **example.csproj** file:

```
<?xml version="1.0" encoding="utf-8"?>
<Project ToolsVersion="15.0" xmlns="http://schemas.microsoft.com/
developer/msbuild/2003">
  <Import Project="$(MSBuildExtensionsPath)\$(MSBuildToolsVersion)
\Microsoft.Common.props" Condition="Exists('$(MSBuildExtensionsPath)\$
(MSBuildToolsVersion)\Microsoft.Common.props')" />
  <PropertyGroup>
    <Configuration Condition=" '$(Configuration)' == '' ">Debug</
Configuration>
    <Platform Condition=" '$(Platform)' == '' ">AnyCPU</Platform>
    <ProjectGuid>{99EDBA4B-D7DA-48BB-8D0C-AF4B12387935}</ProjectGuid>
    <OutputType>Exe</OutputType>
    <RuntimeIdentifiers>win10-x64</RuntimeIdentifiers>
    <RootNamespace>app</RootNamespace>
    <AssemblyName>app</AssemblyName>
    <TargetFrameworkVersion>v4.6.1</TargetFrameworkVersion>
    <FileAlignment>512</FileAlignment>
    <AutoGenerateBindingRedirects>true</AutoGenerateBindingRedirects>
  </PropertyGroup>
  <PropertyGroup Condition=" '$(Configuration)|$(Platform)' == 'Debug|
AnyCPU' ">
    <PlatformTarget>AnyCPU</PlatformTarget>
    <DebugSymbols>true</DebugSymbols>
    <DebugType>full</DebugType>
    <Optimize>false</Optimize>
    <OutputPath>bin\Debug\</OutputPath>
    <DefineConstants>DEBUG;TRACE</DefineConstants>
    <ErrorReport>prompt</ErrorReport>
    <WarningLevel>4</WarningLevel>
  </PropertyGroup>
  <ItemGroup>
    <Compile Include="app.cs" />
  </ItemGroup>
  <ItemGroup>
    <PackageReference Include="mapr-streams-dotnet" Version="0.11.3" />
  </ItemGroup>
    <Import Project="$(MSBuildToolsPath)\Microsoft.CSharp.targets" />
</Project>
```

9. Verify that you have completed the steps to configure the MapR Event Store For Apache Kafka C client or complete the steps now. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.

   Note: The MapR Event Store For Apache Kafka C#/.NET Client is dependent on the MapR Event Store For Apache Kafka C Client. Therefore, the MapR Event Store For Apache Kafka C Client must be configured before you can run the application.

10. Open your project folder on the command line and run:

```
dotnet run
```

Migrating Kafka C#/.NET Applications to MapR Event Store For Apache Kafka

With some modification, you can use existing confluent-kafka C#/.NET applications to consume and produce topics in MapR Event Store For Apache Kafka. The MapR Event Store For Apache Kafka C#/.NET Client is a binding for Apache librdkafka that works with MapR Event Store For Apache Kafka.

Migrating a .NET 4.5 or 4.6 Application

Note: This migration information is applicable for Windows (Win7-x64) platform *only*.

To migrate an existing .NET 4.5 or 4.6 application:

1. Install and configure the MapR Event Store For Apache Kafka C Client. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.
2. Replace the librdkafka.dll with the MapR Data Platform librdkafka 0.11.3 from **/bin/.../runtimes/<win7-x64>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application1

Note: This migration information is applicable for Windows (Win7-x64) and Linux platforms.

To migrate an existing .NET Core application:

1. Install and configure the MapR Event Store For Apache Kafka C Client. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.
2. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application2

Note: This migration information is applicable for Linux platforms *only*.

To migrate an existing .NET Core application:

1. Remove all **.so** files from the **~/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>** directory.
2. Install and configure the MapR Event Store For Apache Kafka C Client. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.
3. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/** directory.
4. If the MapR Client doesn not install into the ID search path, add a symlink from the **MapRClient.dll** to the **l/usr/local/lib**.
5. Restart the application.

last-updated: Apr 11, 2022

General Migration Information

- When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

  ```
  /<path and name of stream>:<name of topic>
  ```

  For example, you might have a stream in a MapR cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

  

  Note: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

- Review the APIs that are supported and make changes to your application, as needed. See API for MapR Event Store For Apache Kafka C#/.NET on page 3016.

- See Configuration Properties for MapR Event Store For Apache Kafka C#/.NET Client on page 3018 for the list of supported configuration parameters and make changes to your application, as needed.

  

  Note: SSL-related configuration parameters are ignored. When you set these parameters, the MapR Event Store For Apache Kafka Client issues a warning indicating that the parameters are not supported.

API for MapR Event Store For Apache Kafka C#/.NET

MapR Event Store For Apache Kafka C#/.NET Client is a binding for librdkafka and the MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka.

Table

Core release	EEP Release	Kafka librdkafka version
As of MapR Data Platform 6.0.1	As of 5.0	0.11.3

Classes

Classes	Descripton
CommittedOffsets	Encapsulates information provided to a Consumer's OnOffsetsCommitted event - per-partition offsets and success/error together with overall success/error of the commit operation.
Consumer	Implements a high-level Apache Kafka consumer (without deserialization).
Consumer<TKey, TValue>	Implements a high-level Apache Kafka consumer (with key and value deserialization).
Error	Represents an error that occured when interacting with a Kafka broker or the librdkafka library.
ErrorCodeExtensions	Provides extension methods on the ErrorCode enumeration.
GroupInfo	Encapsulates information describing a particular Kafka group.

last-updated: Apr 11, 2022

Classes	Descripton
GroupMemberInfo	Encapsulates information describing a particular member of a Kafka group.
Ignore	A type for use in conjunction with that enables message keys or values to be read as null, regardless of their value.
KafkaException	Represents an error that occured during an interaction with Kafka.
Library	Methods that relate to the native librdkafka library itself (do not require a Producer or Consumer broker connection).
Loggers	OnLog callback event handler implementations.
LogMessage	Encapsulates information provided to the Producer/ Consumer OnLog event.
Message	Represents a message stored in Kafka.
Message<TKey, TValue>	Represents a (deserialized) message stored in Kafka.
Metadata	Kafka cluster metadata.
Null	A type for use in conjunction with and that enables null key or values to be enforced when producing or consuming messages.
PartitionMetadata	Metadata pertaining to a single Kafka topic partition.
Producer	Implements a high-level Apache Kafka producer (without serialization).
Producer<TKey, TValue>	Implements a high-level Apache Kafka producer with key and value serialization.
TopicMetadata	Metadata pertaining to a single Kafka topic.
TopicPartition	Represents a Kafka (topic, partition) tuple.
TopicPartitionError	Represents a Kafka (topic, partition, error) tuple.
TopicPartitionOffset	Represents a Kafka (topic, partition, offset) tuple.
TopicPartitionOffsetError	Represents a Kafka (topic, partition, offset, error) tuple.
TopicPartitionTimestamp	Represents a Kafka (topic, partition, timestamp) tuple.
WatermarkOffsets	Represents the low and high watermark offsets of a Kafka topic/partition.

Interfaces

Interface	Description
IDeliveryHandler	This interface is implemented by types that handle delivery report callbacks as a result of calls to Producer.ProduceAsync().
IDeliveryHandler<TKey, TValue>	This interface is implemented by types that handle delivery report callbacks as a result of calls to Producer<TKey,TValue>.ProduceAsync().

last-updated: Apr 11, 2022

Interface	Description
ISerializingProducer<TKey, TValue>	This interface describes the minimum functionality to be provided by a high level (serializing) Kafka producer.

Structs

Struct	Descripton
Offset	Represents a Kafka partition offset value.
Timestamp	Encapsulates a Kafka timestamp and its type.

Enums

Enum	Descripton
ErrorCode	Enumeration of local and broker generated error codes.
TimestampType	Enumerates the different meanings of a message timestamp value.

Configuration Properties for MapR Event Store For Apache Kafka C#/.NET Client

Describes the C#/.NET client configuration properties.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka.

Property Name	Behavior
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.
receive.message.max.bytes	Same as librdkafka.

Property Name	Behavior
topic.blacklist	Same as librdkafka.
error_cb	Same as librdkafka.
opaque	Same as librdkafka.
enable.partition.eof	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

Property Name	Behavior
queue.buffering.max.kbytes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of MapR Data Platform 6.0.1.

Consumer Configuration Properties

Property Name	Behavior
default_topic_conf	Same as librdkafka.
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.

Property Name	Behavior
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.

Property Name	Behavior
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

Topic Configuration

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of MapR Data Platform 6.0.1, beginning and end are supported.  **Note:** librdkafka additionally supports error.

last-updated: Apr 11, 2022

MapR Data Platform-Specific Configurations

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **Note:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.

last-updated: Apr 11, 2022

Property Name	Behavior
streams.parallel.flushers.per.partition	Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, MapR Event Store For Apache Kafka assumes that the topic specified is in Apache Kafka and does nothing.

Utilities for MapR Event Store For Apache Kafka

MapR Event Store For Apache Kafka provides the utilities for operating on streams and topics.

Note: MapR Event Store For Apache Kafka cannot use MapR Database Shell to perform operations on streams or topics.

`mapr copystream`	This utility copies data from one MapR Stream to another MapR Stream. You can use it, for example, if you want to set up replication manually from one stream to another.
`mapr diffstreams`	This utility compares the message IDs, metadata, and data in two MapR Streams. Then, generates two

	directories that contain sequence files that you can use to merge the rows from the two MapR Streams.
mapr diffstreamswithcrc	This utility uses a cyclic redundancy check to detect differences between sets of messages in the specified MapR Streams. Then, for each set of non-identical messages, it performs a detailed comparison. Finally, it generates one or more directories of sequence files.
mapr exportstream and mapr importstream	Use these utilities together to export data from MapR Streams into binary sequence files, and then import the data from the binary sequence files into other MapR Streams. You can also use the `mapr importstream` utility to import changes that are specified in sequence files output by the `mapr diffstreams` utility.
mapr perfconsumer	This utility runs a consumer reading messages from topics in a MapR Stream. Use this utility to run consumers when you want to estimate the performance of consumers for your MapR Streams applications, given your network configuration.
mapr perfproducer	This utility runs a producer, generating messages and publishing them to a MapR Stream. Use this utility to run producers when you want to estimate the performance of producers for your MapR Streams applications, given your network configuration.
mapr streamanalyzer	This light-weight utility, which is a sample application for the `Streams` Java class for analytics on MapR Streams, lets you count the messages in a stream or a subset of the topics in a stream. The utility also lets you print either whole retrieved messages or a subset of the fields in each message.

Configuring Properties for Message Size

Describes the `message.max.bytes` and `receive.message.max.bytes` properties for configuring message size.

message.max.bytes	For a C producer, the `message.max.bytes` value is 1000000 B by default. The minimum value is 1000 B and maximum value is 32000000 B. The maximum message size produced by a C API is decided by the `message.max.bytes` value set on the C producer. From C, Python, and C# APIs, the maximum message size that can be produced is 32000000 B. If a C consumer needs to consume a message that is greater than 32000000 B in size, which may be produced by a Java client, the consumer needs to update the `message.max.bytes` or `receive.message.max.bytes` properties to a higher value to consume it. If the `message.max.bytes` property is set to greater than 32000000 B, it is by default capped at 32000000 B. Though a consumer can consume messages greater than 32000000 B (produced say by a Java client), only up to 32000000 B is produced from the MapR C client. The maximum message size consumed by a C API is limited by the value that is higher among the `message.max.bytes` and `receive.message.max.bytes` values.

last-updated: Apr 11, 2022

receive.message.max.bytes	For a C consumer, the `receive.message.max.bytes` is 1000000 B by default. The minimum value is 1000 B and maximum value is 1000000000 B.

Using a Java API, a larger message size can be produced if the cluster-side property is changed using the following `maprcli config save` command:

```
Cluster side:

maprcli config save -values
{"mfs.db.max.rowsize.kb":<value in KB>}
```

In this case, the row size is 32 MB by default and the maximum is a little less than 2 GB.

The `mfs.db.max.rowsize.kb` setting is a cluster-wide setting that applies to MapR Database (Binary+JSON) and MapR Event Store for Apache Kafka, and it is not configurable per stream or topic.

MapReduce and Apps

This section contains information associated with developing YARN applications.

External Applications and Classpath

Describes how to configure the class path for external applications.

MapReduce version 2 applications require the hadoop 2.x or the yarn classpath, and other applications that can run on YARN require the yarn classpath.

The method to specify the classpath differs based on how the job or application is submitted:

Method used to Submit the Job	Method to Specify Classpath
The external application uses the `hadoop jar` or the `yarn jar` command.	YARN applications (MapReduce or custom applications) that are submitted using the `yarn jar` command will automatically use the yarn classpath. If the external application has a service that submits the job, you can set the CLASSPATH environment variable to point to a different classpath prior to starting the service. In this case, the hadoop classpath that you set in the CLASSPATH environment variable takes priority over the hadoop classpath for the `hadoop jar` command.
The external application does not use the `hadoop jar` or the `yarn jar` command.	Set the classpath using one of the following options: • If the external application has a service that submits the job or application, you can set the CLASSPATH environment variable to point to the hadoop or yarn classpath prior to starting the service. • Set the classpath within the application. Use one of the following methods to get the classpath: • `hadoop2 classpath` or `hadoop -yarn classpath`: Gets the classpath for MRv2 applications. • `yarn classpath`: Gets the classpath for YARN applications (MRv2 or other applications that can run on YARN).

Important: When you launch a spring boot application, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Classpath Construction

This section describes how the MapReduce classpath is constructed.

The classpath that is used to run a MapReduce program is constructed based on how the program is submitted.

When you submit an application from the command line, the classpath used to process the program is based on the following items in this order of priority:

1. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
2. JARs specified with the `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

If an external application submits the application, the classpath that is used to process the jar file is based on the following items in this order of priority:

1. JARs in the classpath of the external application.
2. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
3. JARs specified with `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

Managing Third-Party Libraries

Any third-party library that is required by a MapReduce program must be accessible to the data node that processes the application.

A data node is a node in the cluster that includes the NodeManager role. You can provide the third-party libraries when you submit the program, or you can install the third-party libraries on each node that processes the application.

Include the third-party libraries with each program

Including the third-party libraries with each program is the preferred method.

Perform one the following operations to include the third-party jars when you submit the program:

- Package the third-party libraries with the MapReduce jar file. The benefit of this method is that the node from which you submit the program and the node that runs the program are not required to have the libraries files.
- Use the `-libjars` parameter to specify the third-party libraries on the command line. With this option, the library files are submitted to the data node along with the program. The benefit of this method is that the node that runs the program does not need to have the library files installed. However, the node that submits the program must have the library files installed.

Install the third-party libraries on each node that runs the program

You can also install the third-party libraries on each data node. However, this may not be preferred as there could be conflicts between library versions or library files.

To install the third-party libraries on each data node, perform one of the following operations:

- Install the third-party libraries in the following directory on each Node Manager node: `/opt/mapr/hadoop/hadoop-2.x/share/hadoop/common`

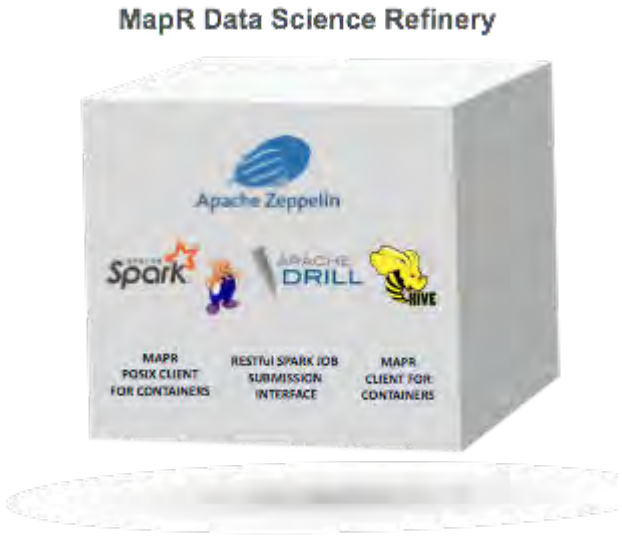
last-updated: Apr 11, 2022

- On each node with the NodeManager role, install the required third-party libraries and then specify the location(s) of the third-party libraries with the HADOOP_CLASSPATH env variable in the `env_override.sh` file. The `env_override.sh` file is located in the following directory: `/opt/mapr/conf`. For more information about the file, see About env_override.sh on page 2290.

MapR Data Science Refinery

The MapR Data Science Refinery is an easy-to-deploy and scalable data science toolkit with native access to all platform assets and superior out-of-the-box security.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.



The MapR Data Science Refinery offers:

Access to All Platform Assets	The MapR FUSE-based POSIX Client allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a MapR cluster, like a Linux filesystem. In addition, connectors are provided for interacting with both MapR Database and MapR Event Store For Apache Kafka via Apache Spark connectors.
Superior Security	The MapR Platform provides enhanced security. Apache Zeppelin on MapR leverages and integrates with this security layer using the built-in capabilities provided by the MapR Persistent Application Container (PACC).
Extensibility	Apache Zeppelin is paired with the Helium framework to offer pluggable visualization capabilities.
Simplified Deployment	A preconfigured Zeppelin Docker container provides the ability to leverage MapR as a persistent data store.

Getting Started Using the Data Science Refinery with Zeppelin

You can deploy the Apache Zeppelin Docker container included in the Data Science Refinery on any of the following, listed in order of recommendation for best practice, starting with the most preferable option:

- Container orchestration engines; for example: Docker Swarm, Kubernetes, OpenShift

- Cloud instances
- Shared edge node
- Personal computers

Note: Starting in version 1.2, you can deploy the Data Science Refinery on a MapR cluster node. Make sure you take into consideration the resource requirements of the Data Science Refinery, if you choose this deployment mode.

If you are already familiar with Apache Zeppelin on MapR and want to skip to the deployment instructions, see Running the Zeppelin Container on page 3034.

Related information

MapR Data Science Refinery Product Page

Zeppelin on MapR

The MapR Data Science Refinery includes a preconfigured Apache Zeppelin notebook, packaged as a Docker container. Apache Zeppelin is an open source web-based data science notebook. You can use it with MapR components to conduct data discovery, ETL, machine learning, and data visualization.

You can run the Zeppelin container either on your laptop or on MapR edge nodes. Out of box, the Zeppelin container image is integrated with open source data processing engines like Apache Spark, Apache Drill, and Apache Hive, as well as with native MapR engines (MapR File System, MapR Database, and MapR Event Store For Apache Kafka). Using the notebook simply requires running the Docker image and connecting to the container through your browser.

Zeppelin provides the following benefits for your data engineering and data science use cases:

- An interactive development environment for writing, testing, and sharing data processing code snippets
- The ability to run the notebooks in a local client environment, such as on a laptop
- Support for a variety of interpreters for integrating with different backend components
- Support for extensible visualization libraries

The Zeppelin notebook included with the Data Science Refinery provides additional benefits:

- A small footprint, pre-built, certified data science container that is easy to deploy and run
- An isolated environment where you can experiment with libraries and packages without affecting other users' work
- Secure authentication at the container level across a secure Web connection
- Preconfigured JDBC interpreters for accessing query engines like Apache Drill and Apache Hive
- The MapR FUSE-Based POSIX Client on page 1238, which you need to access File System on page 452 using shell commands

last-updated: Apr 11, 2022

- All client side services that you need to submit Apache Spark jobs, including jobs that access MapR Event Store For Apache Kafka on page 627
- MapR connectors, which you need to access MapR Database on page 496 (both binary and JSON tables)

See Zeppelin Release Notes on page 5641 for release specific information.

For additional information about Zeppelin, you can also refer to the open source documentation.

Running the Zeppelin Container

To run the Apache Zeppelin container, you must access the Zeppelin Docker image from MapR's public repository, run the Docker image, and access the deployed container from your web browser. From your browser, you can create Zeppelin notebooks.

To pull and run the Docker image, you must first install `Docker` on the host where you want to run the container. You can download the software from https://docs.docker.com/engine/installation/.

Docker is a tool that you use to package an application and its dependencies into a virtual container. You can deploy and run the container on any node. MapR uses this technology to package Apache Zeppelin with all software you need to integrate with various engines. After you deploy the container, all software and services used by Zeppelin are started and ready for you to use.

Important: After installing Docker, if you configure a memory limit, ensure that it is at least 3.5 GB of memory. Otherwise, you may not be able to start the Zeppelin container or may encounter log in problems.

See https://docs.docker.com/ for additional information about Docker and https://docs.docker.com/docker-hub/ for information about running Docker images from cloud-based repositories.

Accessing the Zeppelin Docker Image

To access a container image through Docker, you specify the image name and a tag. In the case of the MapR Data Science Refinery, the tag specifies the operating system of the running container. This operating system does not need to match your host operating system.

The image name and available tags for the latest release are:

Image Name	Operating System Version of Running Container	Tag
maprtech/data-science-refinery	CentOS 7	v1.4.1_6.1.0_6.3.0_centos7
	Ubuntu 16	v1.4.1_6.1.0_6.3.0_ubuntu16

For a complete list of all available tags, see https://hub.docker.com/r/maprtech/data-science-refinery/tags/.

1. Download the Docker image, referencing the image name and tag. The following downloads the image for CentOS:

   ```
   docker pull maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
   ```

   Note: A best practice is to choose the image OS that matches the OS running in your MapR cluster.

2. Verify that you have downloaded the Docker image by listing the Docker images on your machine:

   ```
   docker images
   ```

Running the Zeppelin Docker Image

To run a Docker image, you use the `docker run` command. You must specify various parameters, including parameters indicating the MapR cluster you want to access from your notebook. You must also specify a user name and password. Only that user can access the running container.

If you are running the MapR Data Science Refinery as a Kubernetes service, follow the steps at Running MapR Data Science Refinery as a Kubernetes Service on page 3049.

Important: If you plan to use the FUSE-based POSIX client, make sure you have a MapR POSIX Client for Containers license on your MapR cluster before performing the steps described in this topic.

1. Determine what parameters you want to pass to Docker

   Note: You cannot access the container as the `root` user. Make sure to specify an alternative user name for the `MAPR_CONTAINER_USER` environment variable.

2. Pass the parameters you have selected to `docker run` by using one of the following options:

   Command Line

   Specify all your parameters in the command line:

   ```
   docker run -it <parameters> \
      maprtech/
   data-science-refinery:v1.4.1_6.1.0_6
   .3.0_centos7
   ```

   Env File

   Specify your environment variable (`-e`) parameters in a file and the remaining parameters in the command line.

   Pass the file to `docker run` using `--env-file`.

   In the following example, the file `env.list` contains your environment variable parameters:

   ```
   docker run -it --env-file ./
   env.list \
      -p 9995:9995 \
      -p 10000-10010:10000-10010 \
      -p 11000-11010:11000-11010 \
      -v /home/mapruser1/
   mapr_ticket:/tmp/mapr_ticket:ro \
      --cap-add SYS_ADMIN \
      --cap-add SYS_RESOURCE \
      --device /dev/fuse \
      --security-opt
   apparmor:unconfined \
      maprtech/
   data-science-refinery:v1.4.1_6.1.0_6
   .3.0_centos7
   ```

   The following shows an example of the contents of `env.list`:

   ```
   HOST_IP=172.24.9.151
   MAPR_CLUSTER=my.cluster.com
   MAPR_CLDB_HOSTS=172.24.11.84,172.24.
   8.72,172.24.9.248
   MAPR_CONTAINER_USER=mapuser1
   MAPR_CONTAINER_PASSWORD=SeCreTpAsSw0
   MAPR_CONTAINER_GROUP=mapr
   MAPR_CONTAINER_UID=5000
   ```

last-updated: Apr 11, 2022

```
MAPR_CONTAINER_GID=5000
MAPR_TICKETFILE_LOCATION=/tmp/
mapr_ticket
MAPR_MOUNT_PATH=/mapr
MAPR_HS_HOST=172.24.9.248
ZEPPELIN_NOTEBOOK_DIR=/mapr/
my.cluster.com/user/mapruser1/
notebook
MAPR_TZ=US/Pacific
```

3. Verify that Zeppelin is running:

```
docker ps
```

If you want to run a second Docker image on a host machine, follow the instructions at Running Multiple Zeppelin Containers on a Single Host on page 3045.

Understanding Zeppelin Docker Parameters

There are a set of key parameters to use when running Apache Zeppelin containers. This includes parameters related to the connection port, bridge networking, specifying your MapR cluster, enabling security through MapR ticketing, and enabling the FUSE-based POSIX client.

The general syntax for running the Apache Zeppelin Docker image is the following:

```
docker run -it -p 9995:9995 \
    -e HOST_IP=<docker-host-ip> \
      -p 10000-10010:10000-10010 \
      -p 11000-11010:11000-11010 \
    -e MAPR_CLUSTER=<cluster-name> \
      -e MAPR_CLDB_HOSTS=<cldb-ip-list> \
    -e MAPR_CONTAINER_USER=<user-name> \
      -e MAPR_CONTAINER_PASSWORD=<password> \
      -e MAPR_CONTAINER_GROUP=<group-name> \
      -e MAPR_CONTAINER_UID=<uid> \
      -e MAPR_CONTAINER_GID=<gid> \
      -e MAPR_TICKETFILE_LOCATION=<ticket-file-container-location> \
      -v <ticket-file-host-location>:<ticket-file-container-location>:ro \
    -e MAPR_MOUNT_PATH=<path-to-fuse-mount-point> \
      --cap-add SYS_ADMIN \
      --cap-add SYS_RESOURCE \
      --device /dev/fuse \
      --security-opt apparmor:unconfined \
    -e MAPR_HS_HOST=<historyserver-ip> \
    -e ZEPPELIN_NOTEBOOK_DIR=<path-for-notebook-storage> \
    -e MAPR_TZ=<time-zone> \
    maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
```

Following is a sample command:

```
docker run -it -p 9995:9995 \
    -e HOST_IP=172.24.9.151 \
      -p 10000-10010:10000-10010 \
      -p 11000-11010:11000-11010 \
    -e MAPR_CLUSTER=my.cluster.com \
      -e MAPR_CLDB_HOSTS=172.24.11.84,172.24.8.72,172.24.9.248 \
    -e MAPR_CONTAINER_USER=mapuser1 \
      -e MAPR_CONTAINER_PASSWORD=SeCreTpAsSw0 \
      -e MAPR_CONTAINER_GROUP=mapr \
      -e MAPR_CONTAINER_UID=5000 \
      -e MAPR_CONTAINER_GID=5000 \
      -e MAPR_TICKETFILE_LOCATION=/tmp/mapr_ticket \
```

```
      -v /home/mapruser1/mapr_ticket:/tmp/mapr_ticket:ro \
    -e MAPR_MOUNT_PATH=/mapr \
      --cap-add SYS_ADMIN \
      --cap-add SYS_RESOURCE \
      --device /dev/fuse \
      --security-opt apparmor:unconfined \
    -e MAPR_HS_HOST=172.24.9.248 \
    -e ZEPPELIN_NOTEBOOK_DIR=/mapr/my.cluster.com/user/mapruser1/notebook \
    -e MAPR_TZ=US/Pacific \
    maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
```

The following sections describe each category of parameters in more detail. Where appropriate, the descriptions reference the sample command.

For a list of all MapR-specific environment variables, refer to the MapR-Specific Environment Variables on page 3044 section at the end of this topic.

Connection Port

By default, the Zeppelin notebook runs on port 9995. To use a different port number, pass the `ZEPPELIN_SSL_PORT` environment variable in your `docker run` command and specify the `<port-number>`:

```
docker run -it \
    ...
    -e ZEPPELIN_SSL_PORT=<port-number> \
    -p <port-number>:<port-number> \
    ...
```

Important: If you are running on Mac, you must publish the container port by specifying `-p <port-number>:<port-number>` in your `docker run` command.

Bridge Networking

By default, Docker uses bridge networking. In general, bridge networking provides better isolation from the host machine and other containers.

You must set the `HOST_IP` environment variable, the `-p 10000-10010:10000-10010` and `-p 11000-11010:11000-11010` parameters when using bridge networking:

```
docker run -it \
    ...
    -e HOST_IP=<docker-host-ip> \
    -p 10000-10010:10000-10010 \
    -p 11000-11010:11000-11010 \
    ...
```

The `<docker-host-ip>` must be an actual IP address. If you are running the container on your laptop, you cannot specify `localhost` as the IP address.

Specifying the 10000-10010 port range reserves the range for the Livy launcher. If you are already using these ports for other reasons, use the `LIVY_RSC_PORT_RANGE` environment variable to specify a different range.

If you plan to use Spark interpreter, you must reserve the 11000-11010 port range for Spark. To reserve a different port range, use the `SPARK_PORT_RANGE` environment variable.

For example, the following command reserves two different sets of port ranges for Livy and Spark:

```
docker run -it \
    ...
```

last-updated: Apr 11, 2022

```
    -e HOST_IP=<docker-host-ip> \
    -p 10011-10021:10011-10021 \
    -e LIVY_RSC_PORT_RANGE="10011~10021" \
    -p 13011-13021:13011-13021 \
    -e SPARK_PORT_RANGE="13011~13021" \
    ...
```

Note: Use tilde (~) rather than dash (-) when specifying the range with the `LIVY_RSC_PORT_RANGE` and `SPARK_PORT_RANGE` environment variables.

If you prefer to use host networking, specify the following parameter in your `docker run` command instead:

```
docker run -it \
    ...
    --network=host \
    -e HOST_IP=<docker-host-ip> \
    ...
```

Note: You do not need to reserve port ranges when using host networking.

See https://docs.docker.com/engine/userguide/networking/ for more details about Docker networking.

MapR Cluster

Identify the MapR cluster you want your container to access by specifying the name of your MapR cluster and a comma separated list of the IP addresses of the cluster's CLDB nodes. The following specifies three CLDB nodes:

```
docker run -it \
    ...
    -e MAPR_CLUSTER=my.cluster.com \
    -e MAPR_CLDB_HOSTS=172.24.11.84,172.24.8.72,172.24.9.248 \
    ...
```

MapR Ticketing

If your MapR cluster is secure, you need a copy of the MapR ticket on your local host so you can specify a mount point in your `docker run` command. This makes the ticket visible to the Zeppelin container. The sample command shown earlier uses MapR tickets.

To determine whether your cluster is secure, view the contents of the file `/opt/mapr/conf/mapr-clusters.conf` on your MapR cluster. For example, the following shows a secure cluster:

```
my.cluster.com secure=true ip-172-24-11-84
```

If your cluster is secure, follow these steps to make the ticket visible to the Zeppelin container:

1. Generate a service ticket for the container user by following the instructions at Generating a Service Ticket on page 1428.
2. Copy the generated ticket file to your local host machine. This is your source ticket file.
3. Change the owner and group on your source ticket so it matches the UID and GID in the ticket file.
4. Specify the source ticket path in the Docker mount point, as described in the table below.

The table lists the parameters related to MapR tickets and their values in the sample command:

Parameter	Sample Parameter Value	Details
`MAPR_CONTAINER_USER`	`mapruser1`	The only user who can access the notebook
`MAPR_CONTAINER_PASSWORD`	`SeCreTpAsSw0`	The password you use to log in to your Zeppelin notebook. This password does not need to match the password in your MapR cluster. If not specified, it defaults to the value of `MAPR_CONTAINER_USER`.
`MAPR_CONTAINER_GROUP`	`mapr`	Name of the container user's group
`MAPR_CONTAINER_UID`	5000	UID of the container user; must be consistent with the value in the ticket file
`MAPR_CONTAINER_GID`	5000	GID of the container user; must be consistent with the value in the ticket file
`MAPR_TICKETFILE_LOCATION`	`/tmp/mapr_ticket`	Location of the ticket file in the container
`-v <ticket-file-host-location>:<ticket-file-container-location>:ro`	`-v /home/mapruser1/mapr_ticket:/tmp/mapr_ticket:ro`	Docker mount point for the source and destination of your ticket file **`<ticket-file-location>`**: • Source ticket file • Location of the ticket file on your local host **`<ticket-file-container-location>`**: • Destination ticket file • Location of the ticket file in the container • Must match the value of the `MAPR_TICKETFILE_LOCATION` parameter

See Security Considerations for the MapR PACC on page 406 for further information.

FUSE-Based POSIX Client

With the FUSE POSIX Client for File-Based Applications on page 403, you can access MapR filesystem using POSIX shell commands instead of Hadoop commands. To do so, you must specify the MapR filesystem mount point environment variable (`MAPR_MOUNT_PATH`) and other FUSE parameters in your `docker run` command. In the sample command shown earlier, the following are the relevant parameters and their settings:

Parameter	Sample Parameter Value
`MAPR_MOUNT_PATH`	`/mapr`
`--cap-add`	`SYS_ADMIN`
`--cap-add`	`SYS_RESOURCE`
`--device`	`/dev/fuse`
`--security-opt`	`apparmor:unconfined`

All of these parameters are required except `security-opt`. You must specify `security-opt` if you are running on an Ubuntu host.

last-updated: Apr 11, 2022

Important: You must have a MapR POSIX Client for Containers license on your MapR cluster to use the FUSE-based POSIX client. Without a license, the MapR filesystem mount point you specified will be empty. You can confirm a missing license by checking for errors in `/opt/mapr/logs/posix-client-container.log` inside your container.

Pig, Livy, and Spark Interpreters

If you plan to use the Pig, Livy, or Spark interpreters, you should set the `MAPR_HS_HOST` environment variable to the IP address of your MapR cluster's HistoryServer:

```
docker run -it ... -e MAPR_HS_HOST=172.24.9.248 ...
```

This enhances the performance of those interpreters. If your MapR cluster does not have a HistoryServer, your Pig and Spark jobs will run, but they may perform poorly.

Notebook Storage

The environment variable `ZEPPELIN_NOTEBOOK_DIR` specifies where to store your notebooks. If you do not specify `ZEPPELIN_NOTEBOOK_DIR`, Zeppelin stores your notebooks in the directory `/opt/mapr/zeppelin/zeppelin-0.8.0/notebook`.

Storage Options

You can store your notebooks either in MapR File System or your container's local filesystem:

MapR File System using the FUSE-based POSIX client

In the sample command shown earlier, MapR Data Science Refinery stores your notebooks in a directory named `/user/mapruser1/notebook` in MapR filesystem using the FUSE-Based POSIX Client on page 3039.

The example assumes your MapR filesystem mount point is `/mapr` and your cluster name is `my.cluster.com`:

```
docker run -it ... \
   -e ZEPPELIN_NOTEBOOK_DIR=/
mapr/my.cluster.com/user/mapruser1/
notebook ...
```

Important: You must specify the parameters used by the FUSE-Based POSIX Client on page 3039. If Docker is unable to start the FUSE-based client, you cannot open Zeppelin in your browser. Your browser will return the following error:

```
HTTP ERROR: 503
```

MapR File System without the FUSE-based POSIX client

Starting in MapR Data Science Refinery 1.3, you can store your notebooks in MapR filesystem without using the FUSE-based POSIX client. To use this option, specify the full MapR filesystem path in the `ZEPPLIN_NOTEBOOK_DIR` variable.

last-updated: Apr 11, 2022

The following example is equivalent to the previous:

```
docker run -it ... \
   -e ZEPPELIN_NOTEBOOK_DIR=maprfs:///
user/mapruser1/notebook ...
```

Local filesystem

To store your notebooks in your local filesystem, specify the container's local path in `ZEPPELIN_NOTEBOOK_DIR`:

```
docker run -it ... \
   -e ZEPPELIN_NOTEBOOK_DIR=/opt/mapr/
notebook ...
```

Zeppelin Tutorial Notebook

If you set `ZEPPELIN_NOTEBOOK_DIR`, perform the following steps to enable access to the tutorial:

1. Manually move the tutorial notebook from the default directory to your specified notebook directory.

   The following command to move the tutorial from the default location to MapR filesystem path should be run from inside the container running Zeppelin:

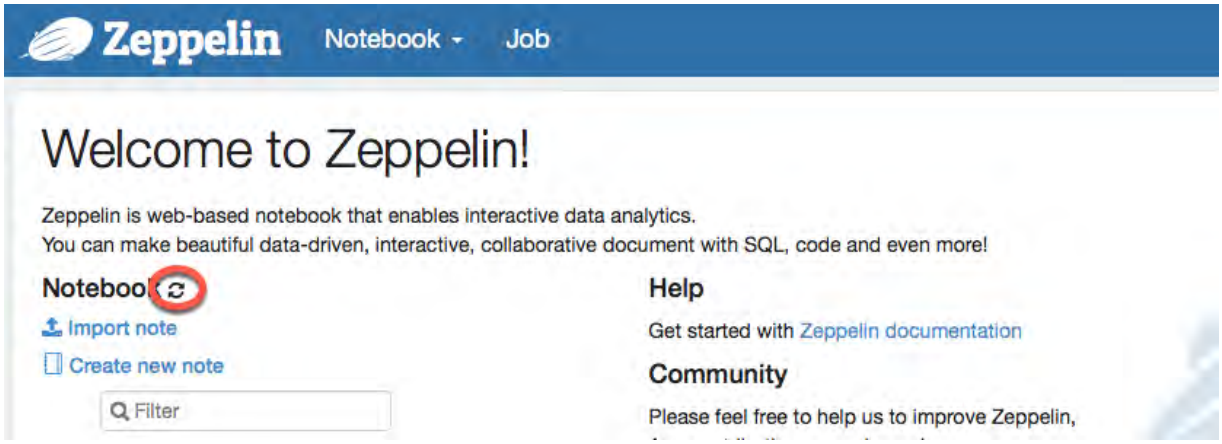
   POSIX

   ```
   cp -r /opt/mapr/zeppelin/
   zeppelin-0.8.0/notebook/* /mapr/
   my.cluster.com/user/mapruser1/
   notebook/
   ```

   Hadoop

   ```
   hadoop fs -put /opt/mapr/zeppelin/
   zeppelin-0.8.0/notebook/* maprfs:///
   user/mapruser1/notebook/
   ```

2. After moving the notebook, make sure you reload your notebooks from storage by clicking on the icon circled in red below:



Python Version

By default, when you use Python with either the Livy or Spark interpreters, the interpreters use Python 2. Although you can run only one version of Python with MapR Data Science Refinery, you can switch

last-updated: Apr 11, 2022

to Python 3, by setting the PYSPARK_PYTHON environment variable to the absolute path of the Python 3 executable on your MapR cluster:

```
docker run -it ... -e PYSPARK_PYTHON=/usr/local/bin/python3.6 ...
```

You can also install custom Python packages. See Installing Custom Packages for PySpark on page 3066

Idle Interpreter Timeout Threshold

Starting with the 1.3 release, by default, MapR Data Science Refinery terminates interpreters that have been idle for one hour. To modify this idle timeout threshold, specify the ZEPPELIN_INTERPRETER_LIFECYCLE_MANAGER_TIMEOUT_THRESHOLD environment variable. The parameter value is in milliseconds.

The following example sets the idle timeout to 10 minutes:

```
docker run -it ... \
   -e ZEPPELIN_INTERPRETER_LIFECYCLE_MANAGER_TIMEOUT_THRESHOLD=600000 ...
```

If a Spark job terminates due to the Spark interpreter reaching the timeout threshold, the job shows a status of FAILED in the YARN UI.

Configuration Storage

By default, the following Zeppelin configuration files are stored in /opt/mapr/zeppelin/zeppelin-0.8.0/conf/:

- interpreter.json
- notebook-authorization.json

Starting with MapR Data Science Refinery 1.3, you can store these files in MapR filesystem by specifying the ZEPPELIN_CONFIG_FS_DIR environment variable. You can also specify a local system for this variable.

The following shows sample commands for the three available options:

MapR File System using the FUSE-based POSIX client

This example assumes your MapR filesystem mount point is /mapr and your cluster name is my.cluster.com:

```
docker run -it ... \
   -e ZEPPELIN_CONFIG_FS_DIR=/mapr/
my.cluster.com/user/mapruser1/dsrconf
...
```

Important: You must specify the parameters used by the FUSE-Based POSIX Client on page 3039 to use this option.

MapR File System without the FUSE-based POSIX client

The following example is equivalent to the previous:

```
docker run -it ... \

-e ZEPPELIN_CONFIG_FS_DIR=maprfs:///
user/mapruser1/dsrconf ...
```

last-updated: Apr 11, 2022

Local filesystem

The following specifies a local filesystem path:

```
docker run -it ... \
   -e ZEPPELIN_CONFIG_FS_DIR=/opt/
mapr/dsrconf ...
```

If all of the following apply, then you must restart all containers to enable the new configuration settings:

- `ZEPPELIN_CONFIG_FS_DIR` is set to a MapR filesystem path
- Multiple containers share the two configuration files
- You make a change in either of the configuration files that requires a container restart

Default Drill JDBC Connection URL

The default Drill JDBC connection URL is `jdbc:drill:drillbit=drillbitnode:31010`. Starting with MapR Data Science Refinery 1.3, you can configure this default URL using one of the following two environment variables:

`MAPR_DRILLBITS_HOST`

Description

Comma separated list of Drillbit servers and optional port numbers.

Use if you want to connect to Drill through a Drillbit server. If you do not specify port numbers, they default to 31010.

Sample commands

```
docker run -it ... \
  -e
MAPR_DRILLBITS_HOSTS=node1.cluster.com
,node2.cluster.com ...

docker run -it ... \
  -e
MAPR_DRILLBITS_HOSTS=node1.cluster.com
:31010,node2.cluster.com:31010 ...
```

Resulting URL

```
jdbc:drill:drillbit=node1.cluster.com:
31010,node2.cluster.com:31010
```

`MAPR_ZK_QUORUM`

Description

Comma separated list of servers and optional port numbers in your Zookeeper cluster.

Use if you want to connect to Drill through a Zookeeper cluster. If you do not specify port numbers, they default to 5181.

Sample commands

```
docker run -it ... \
  -e
MAPR_ZK_QUORUM=node1.cluster.com,node2
.cluster.com,node3.cluster.com \
  ...

docker run -it ... \
  -e
```

last-updated: Apr 11, 2022

```
MAPR_ZK_QUORUM=node1.cluster.com:5181,
node2.cluster.com:5181,node3.cluster.c
om:5181 \
  ...
```

Resulting URL

```
jdbc:drill:zk=node1.cluster.com:5181,n
ode2.cluster.com:5181,node3.cluster.co
m:5181/drill/my.cluster.com-drillbits
```

You should specify only one of the two environment variables. If you mistakenly specify both, `MAPR_DRILLBITS_HOST` takes precedence.

See Start the Drill Shell (SQLLine) on page 3270 for more information about the Drill JDBC connection URL. See Drill JDBC on page 3071 for more information about setting other options in your Drill JDBC connection string for MapR Data Science Refinery.

MapR-Specific Environment Variables

The following table lists all MapR-specific environment variables you can use in your `docker run` command. The second column contains a short description of each variable. The third column provides links to detailed descriptions, including situations where you need to use each variable.

Environment Variable	Description	Documentation Link
`HOST_IP`	IP address of your Docker host machine	Bridge Networking on page 3037
`LIVY_RSC_PORT_RANGE`	Port range reserved for the Livy launcher	Bridge Networking on page 3037 Running Multiple Zeppelin Containers on a Single Host on page 3045
`MAPR_CLUSTER`	Name of your MapR cluster	MapR Cluster on page 3038
`MAPR_CLDB_HOSTS`	List of CLDB host IPs	MapR Cluster on page 3038
`MAPR_CONTAINER_GID`	GID of the container user	MapR Ticketing on page 3038
`MAPR_CONTAINER_GROUP`	Group name of the container user	MapR Ticketing on page 3038
`MAPR_CONTAINER_PASSWORD`	Password used to log in to the container UI	MapR Ticketing on page 3038
`MAPR_CONTAINER_UID`	UID of the container user	MapR Ticketing on page 3038
`MAPR_CONTAINER_USER`	Name of the container user	MapR Ticketing on page 3038
`MAPR_DRILLBITS_HOSTS`	Comma separated list of Drillbit servers for connecting to Drill	Default Drill JDBC Connection URL on page 3043
`MAPR_HS_HOST`	IP address of your MapR cluster's HistoryServer	Pig, Livy, and Spark Interpreters on page 3040
`MAPR_MOUNT_PATH`	Path of the mount point for MapR filesystem	FUSE-Based POSIX Client on page 3039
`MAPR_TICKETFILE_LOCATION`	Location of MapR ticket file in your container	MapR Ticketing on page 3038
`MAPR_TZ`	Time zone inside the container	Running the MapR PACC Using Docker on page 413

Environment Variable	Description	Documentation Link
`MAPR_ZK_QUORUM`	Comma separated list of servers in your Zookeeper cluster for connecting to Drill	Default Drill JDBC Connection URL on page 3043
`PYSPARK_PYTHON`	Location of Python 3 executable on your MapR cluster	Python Version on page 3041
`SPARK_PORT_RANGE`	Port range reserved for the Spark interpreter	Bridge Networking on page 3037 Running Multiple Zeppelin Containers on a Single Host on page 3045
`ZEPPELIN_ARCHIVE_PYTHON`	Path containing your archive with custom Python packages	Installing Custom Packages for PySpark on page 3066
`ZEPPELIN_CONFIG_FS_DIR`	Path containing the following Zeppelin configuration files: • `interpreter.json` • `notebook-authorization.json`	Configuration Storage on page 3042
`ZEPPELIN_DEPLOY_MODE`	Set to `kubernetes` if running Zeppelin as a Kubernetes service	Running MapR Data Science Refinery as a Kubernetes Service on page 3049
`ZEPPELIN_INTERPRETER_LIFECYCLE_MANAGER_TIMEOUT_THRESHOLD`	Timeout threshold that determines when to terminate idle interpreters	Idle Interpreter Timeout Threshold on page 3042
`ZEPPELIN_NOTEBOOK_DIR`	Location to store your Zeppelin notebooks	Notebook Storage on page 3040
`ZEPPELIN_SSL_PORT`	Port number for connecting to the Zeppelin UI	Connection Port on page 3037

Running Multiple Zeppelin Containers on a Single Host

To run multiple Apache Zeppelin containers on a single host, you must modify certain parameters in your `docker run` command. If you are using version 1.0 of the MapR Data Science Refinery, you also must modify the Livy interpreter's configuration and restart the Livy service.

Important: You cannot use host networking when running multiple Zeppelin containers on a single host. You must use the default Bridge Networking on page 3037.

1. Select different port numbers for your new container:
   a) Choose a different connection port number; for example, 9996
   b) Choose a different port range for the Livy launcher; for example, 10011-10021
   c) Choose a different port range for the Spark interpreter; for example, 13011-13021
2. Issue your `docker run` command with the port numbers you selected in Step 1 using one of the following two commands, depending on the version of the MapR Data Science Refinery you are using:

- Version 1.1 or later:

```
docker run -it ... \
   -e ZEPPELIN_SSL_PORT=9996 -p 9996:9996 \
   -p 10011-10021:10011-10021 -e LIVY_RSC_PORT_RANGE="10011~10021" \
   -p 13011-13021:13011-13021 -e SPARK_PORT_RANGE="13011~13021" \
   ... \
   maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
```

  If you are not using the Spark interpreter, you can omit the following parameters:

```
-p 13011-13021:13011-13021 -e SPARK_PORT_RANGE="13011~13021"
```

  Use tilde (~) rather than dash (-) when specifying the range with the `LIVY_RSC_PORT_RANGE` and `SPARK_PORT_RANGE` environment variables.

- Version 1.0:

```
docker run -it ... \
   -e ZEPPELIN_SSL_PORT=9996 -p 9996:9996 \
   -p 10011-10021:10011-10021 \
   ... \
   maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
```

3. If you are using Version 1.1 or later of the MapR Data Science Refinery, skip to Step 8. Otherwise, continue to Step 4.
4. Determine your `container-id` using the output from the following command:

```
docker ps
```

5. Log in to your container as the user running the container using the `container-id`:

```
docker exec -it --user <MAPR_CONTAINER_USER> <container-id> bash -l
```

6. Update the following property in `/opt/mapr/livy/livy-<version>/conf/livy-client.conf` to match the port range you chose in Step 1b:

```
livy.rsc.launcher.port.range = 10011~10021
```

   Note: Make sure to use tilde (~) rather than dash (-) when specifying the range.

7. Restart the Livy service:

```
/opt/mapr/livy/livy-<version>/bin/livy-server stop
/opt/mapr/livy/livy-<version>/bin/livy-server start
```

8. Connect to the new container using the port number you chose in Step 1a. The following URL assumes you are running the container on your local machine:

```
https://localhost:9996
```

Connecting MapR Data Science Refinery to MapR Sandbox
To connect MapR Data Science Refinery to MapR Sandbox, install MapR Sandbox, configure resource settings in your virtual machine (if needed), and then set the parameters corresponding to your virtual machine environment in your `docker run` command.

1. Install the sandbox using a virtual machine player
   a) You can use one of the following virtual machine players:
      - Installing the Sandbox on VirtualBox on page 106
      - Installing the Sandbox on VMware Player or VMware Fusion on page 104

   b) If you are installing VirtualBox, you must configure a second network adapter using either **Host-only Adapter** or **Bridged Adapter**. For the VMware players, you can use the default network configuration.

   c) You may also need to increase the default processor and memory configurations, depending on the workload you plan to run.

2. Determine the parameters you want to pass to Docker:
   a) See Understanding Zeppelin Docker Parameters on page 3036 to determine your initial parameters.

   b) Then determine the value of parameters that are specific to connecting to MapR Sandbox:

<table>
<tr><th>Parameter Name</th><th>Parameter Value</th></tr>
<tr><td>MAPR_CLDB_HOSTS</td><td>IP address of your virtual machine</td></tr>
<tr><td>MAPR_HS_HOST</td><td>IP address of your virtual machine</td></tr>
<tr><td>HOST_IP</td><td>Set this variable based on the network adapter and virtual machine player you are using:
<table>
<tr><th colspan="2">VirtualBox</th><th>VMware</th></tr>
<tr><td>Host-only Adapter</td><td>IP address of the gateway interface to the virtual machine's internal network</td><td rowspan="2">Output from the following command:
<pre>ip r get 8.8.8.8 | awk 'NR==1 {print $NF}'</pre></td></tr>
<tr><td>Bridged Adapter</td><td>Output from the following command:
<pre>ip r get 8.8.8.8 | awk 'NR==1 {print $NF}'</pre></td></tr>
</table></td></tr>
<tr><td>--add-host</td><td>"<hostname>":<IP address> of your virtual machine</td></tr>
</table>

3. Construct your `docker run` command based on Step 3.

   The following are examples of `docker run` commands that use VirtualBox with the different network adapters. Note the parameters highlighted in bold:

   Host-only Adapter

```
docker run -it -p 9995:9995 \
    -e HOST_IP=192.168.192.1  \
      -p 10000-10010:10000-10010 \
      -p 11000-11010:11000-11010 \
```

last-updated: Apr 11, 2022

```
    -e MAPR_CLUSTER=demo.mapr.com \
      -e
MAPR_CLDB_HOSTS=192.168.192.100 \
    -e MAPR_CONTAINER_USER=mapr \
      -e
MAPR_CONTAINER_PASSWORD=mapr \
      -e MAPR_CONTAINER_GROUP=mapr \
      -e MAPR_CONTAINER_UID=2000 \
      -e MAPR_CONTAINER_GID=2000 \
    -e MAPR_MOUNT_PATH=/mapr \
      --cap-add SYS_ADMIN \
      --cap-add SYS_RESOURCE \
      --device /dev/fuse \
    -e MAPR_HS_HOST=192.168.192.100
\
    --add-host="maprdemo:192.168.192
.100" \
    --add-host="maprdemo.local:192.1
68.192.100" \
    maprtech/
data-science-refinery:v1.4.1_6.1.0_6
.3.0_centos7
```

Bridged Adapter

```
docker run -it -p 9995:9995 \
    -e HOST_IP=$(ip r get 8.8.8.8 |
awk 'NR==1 {print $NF}')  \
      -p 10000-10010:10000-10010 \
      -p 11000-11010:11000-11010 \
    -e MAPR_CLUSTER=demo.mapr.com \
      -e
MAPR_CLDB_HOSTS=10.2.13.163 \
    -e MAPR_CONTAINER_USER=mapr \
      -e
MAPR_CONTAINER_PASSWORD=mapr \
      -e MAPR_CONTAINER_GROUP=mapr \
      -e MAPR_CONTAINER_UID=2000 \
      -e MAPR_CONTAINER_GID=2000 \
    -e MAPR_MOUNT_PATH=/mapr \
      --cap-add SYS_ADMIN \
      --cap-add SYS_RESOURCE \
      --device /dev/fuse \
    -e MAPR_HS_HOST=10.2.13.163 \
    --add-host="maprdemo:10.2.13.163
" \
    --add-host="maprdemo.local:10.2.
13.163" \
    maprtech/
data-science-refinery:v1.4.1_6.1.0_6
.3.0_centos7
```

After following these steps, you can refer to other MapR Data Science Refinery topics that describe how to use the resulting container.

If you encounter resource errors or hangs, you may need to increase the processor and memory configuration settings in your virtual machine player.

Important: Also, due to resource constraints, you cannot run both the Livy on page 3060 and Spark on page 3060 interpreters.

Running MapR Data Science Refinery as a Kubernetes Service

This topic contains sample snippets from YAML files that enable you to run MapR Data Science Refinery as a Kubernetes service. The samples show you how to use various Kubernetes features. This includes specifying your MapR ticket as a Kubernetes secret, using a `ConfigMap` to define environment variables, mapping ports to route external traffic, passing the container password as a Kubernetes secret, exposing MapR Data Science Refinery as a service, and running MapR Data Science Refinery as a deployment for high availability.

The simplest way to run MapR Data Science Refinery as a Kubernetes service is to expose it to Kubernetes by including it in your Kubernetes pod manifest file. The following shows a sample file:

```
apiVersion: v1
kind: Pod
metadata:
  name: dsr-kube
  labels:
      app: dsr-svc
spec:
  containers:
  - name: dsr
    imagePullPolicy: Always
    image: maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
    securityContext:
      capabilities:
        add: ["SYS_ADMIN" , "SYS_RESOURCE"]
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    env:
    - name: MAPR_MOUNT_PATH
      value: /mapr
    - name: MAPR_CLUSTER
      value: cluster1
    - name: MAPR_CLDB_HOSTS
      value: 10.10.102.95
    - name: MAPR_CONTAINER_USER
      value: mapr
    - name: MAPR_CONTAINER_GROUP
      value: mapr
    - name: MAPR_CONTAINER_PASSWORD
      value: mapr
    - name: HOST_IP
      valueFrom:
        fieldRef:
          fieldPath: status.hostIP
    - name: ZEPPELIN_DEPLOY_MODE
      value: kubernetes
    volumeMounts:
    - mountPath: /dev/fuse
      name: fuse
  volumes:
  - name: fuse
    hostPath:
      path: /dev/fuse
```

Make sure you include the following lines in your manifest file:

```
- name: ZEPPELIN_DEPLOY_MODE
      value: kubernetes
```

You can run MapR Data Science Refinery with Kubernetes 1.9 and later.

last-updated: Apr 11, 2022

Specifying your MapR Ticket as a Kubernetes Secret when Running MapR Data Science Refinery
To specify your MapR ticket as a Kubernetes Secret, you must create a secret and mount the secret in your MapR Data Science Refinery container. This topic describes the steps to do this.

1. Follow the instructions at Configuring a Secret on page 3167 to create a Kubernetes secret with your MapR ticket base64 encoded.

   The following is a sample YAML file named `dsr-ticket.yaml`:

```
apiVersion: v1
kind: Secret
metadata:
  name: dsr-ticket-secret
type: Opaque
data:
  CONTAINER_TICKET:
Y2x1c3RlcjMgMEpHTktQMWlBSU1td05wVWF4SXp5V0VLSjBvS080TndPSkU0SFVyazN6M3JVK
zVhcllDaWhqZ3Q2TDZNMmg4UnF4VGEzMU9IaDMvUmplYytTM0F3WVRlNTdjQ2kzL1dKYTJTbl
JEWkE4M2h2UEFqZkwyVUlzaVcydDJXdVZhT2xtSVIydmNwa3pMNVlqYUtIbm55RlpvbmJ4SUd
jQVRMTDJSaEdmL3JiY091Qk1wbzIxdlY3MnNYRHo5RXY5S1Fma0tKdElRTVNaK1JpTWwyZllC
MWtHa2hhdHJ3dE5qd2tqRlB6dUpQUEU2N2hDSnRLN1pRM0NuN01KM1JhRVliWkJlRjRFVVVxU
VVKSXV5T0VSV0RJbFJORCt3PT0K
```

2. In your Kubernetes pod manifest file, specify the following lines to mount the Kubernetes secret in your container.

   The example below mounts the ticket in `/tmp/mapr_ticket/CONTAINER_TICKET`:

```
env:
- name: MAPR_TICKETFILE_LOCATION
      value: "/tmp/mapr_ticket/CONTAINER_TICKET"

volumeMounts:
- mountPath: /tmp/mapr_ticket
      name: maprticket
      readOnly: true

volumes:
  - name: maprticket
    secret:
      secretName: dsr-ticket-secret
```

The following table summarizes the parameters that you must set in your YAML file and pod manifest. The values are highlighted in bold in the examples:

Parameter Description	Value in Example
Name of ticket file in your container	`CONTAINER_TICKET`
Mount path for the ticket file in your container	`/tmp/mapr_ticket`
Name of Kubernetes secret	`dsr-ticket-secret`
Name of volume for mounting the secret	`maprticket`

Using `ConfigMap` to Define MapR Data Science Refinery Variables in Kubernetes

You can use a `ConfigMap` to define your MapR Data Science Refinery environment variables. `ConfigMaps` enable you to decouple configuration artifacts from image content, providing more portable containerized applications. This topic describes the steps to define and deploy a `ConfigMap`.

1. Define your environment variables in a `ConfigMap` (`dsrconfigmap.yaml`):

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: dsr-configmap
data:
  MAPR_CLUSTER: "my.cluster.com"
  MAPR_CLDB_HOSTS: "1.1.1.1"
  MAPR_HS_HOST: "2.2.2.2"
  MAPR_CONTAINER_USER: "mapr"
  MAPR_CONTAINER_UID: "5000"
  MAPR_CONTAINER_GROUP: "mapr"
  MAPR_CONTAINER_GID: "5000"
  MAPR_MOUNT_PATH: /mapr
```

2. Create the `configMap` before deploying your MapR Data Science Refinery container by running the following command:

```
kubectl create -f dsrconfigmap.yaml
```

3. Modify your deployment YAML file and use `configMapKeyRef` to reference variables from the `ConfigMap` defined in step 1, as shown in the following sample:

```
env:
    - name: MAPR_MOUNT_PATH
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_MOUNT_PATH
    - name: MAPR_CLUSTER
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_CLUSTER
    - name: MAPR_CLDB_HOSTS
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_CLDB_HOSTS
    - name: MAPR_CONTAINER_USER
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_CONTAINER_USER
    - name: MAPR_CONTAINER_UID
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_CONTAINER_UID
    - name: MAPR_CONTAINER_GID
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_CONTAINER_GID
    - name: MAPR_CONTAINER_GROUP
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_CONTAINER_GROUP
    - name: MAPR_CONTAINER_PASSWORD
      valueFrom:
        secretKeyRef:
          name: dsr-container-secret
          key: password
    - name: HOST_IP
      valueFrom:
        fieldRef:
          fieldPath: status.hostIP
    - name: MAPR_HS_HOST
      valueFrom:
        configMapKeyRef:
          name: dsr-configmap
          key: MAPR_HS_HOST
```

Mapping MapR Data Science Refinery Ports for External Access

To access MapR Data Science Refinery through the internet, when it is running as a Kubernetes service, you must map the ports using `nodePort`. This topic provides a sample that shows you how to do this.

last-updated: Apr 11, 2022

Assume you have the following `configMap` settings for ports:

```
apiVersion: v1
  kind: ConfigMap
  metadata:
    name: dsr-confs
    namespace: dsr-ns
  data:
    ZEPPELIN_SSL_PORT: "9995"
    LIVY_RSC_PORT_RANGE: "30000~30009"
    SPARK_PORT_RANGE: "30010~30019"
```

The following defines mappings for these ports:

```
apiVersion: v1
kind: Service
metadata:
  name: dsr-svc
  namespace: dsr-ns
spec:
  type: LoadBalancer
  ports:
    - { name: dsr-ui, port: 9995, nodePort: 32000 }

  selector:
    app: dsr-app

---
apiVersion: v1
kind: Service
metadata:
  name: dsr-svc-ports
  namespace: dsr-ns
spec:
  type: NodePort
  selector:
    app: dsr-app
  ports:

    - { name: dsr-livy-0, port: 30000, nodePort: 30000 }
    - { name: dsr-livy-1, port: 30001, nodePort: 30001 }
    - { name: dsr-livy-2, port: 30002, nodePort: 30002 }
    - { name: dsr-livy-3, port: 30003, nodePort: 30003 }
    - { name: dsr-livy-4, port: 30004, nodePort: 30004 }
    - { name: dsr-livy-5, port: 30005, nodePort: 30005 }
    - { name: dsr-livy-6, port: 30006, nodePort: 30006 }
    - { name: dsr-livy-7, port: 30007, nodePort: 30007 }
    - { name: dsr-livy-8, port: 30008, nodePort: 30008 }
    - { name: dsr-livy-9, port: 30009, nodePort: 30009 }

    - { name: dsr-spark-0, port: 30010, nodePort: 30010 }
    - { name: dsr-spark-1, port: 30011, nodePort: 30011 }
    - { name: dsr-spark-2, port: 30012, nodePort: 30012 }
    - { name: dsr-spark-3, port: 30013, nodePort: 30013 }
    - { name: dsr-spark-4, port: 30014, nodePort: 30014 }
    - { name: dsr-spark-5, port: 30015, nodePort: 30015 }
    - { name: dsr-spark-6, port: 30016, nodePort: 30016 }
    - { name: dsr-spark-7, port: 30017, nodePort: 30017 }
    - { name: dsr-spark-8, port: 30018, nodePort: 30018 }
    - { name: dsr-spark-9, port: 30019, nodePort: 30019 }
```

last-updated: Apr 11, 2022

The example exposes the Livy and Spark ports through `NodePort`, using the same port numbers inside and outside the container.

It exposes the MapR Data Science Refinery UI port through a `LoadBalancer` service. To access the UI, use the following URL with port 32000, as defined in the mapping:

```
https://<k8s-worker-ip>:32000
```

`<k8s-worker-ip>` is the public IP address of any Kubernetes worker node. The worker node proxies the port into the MapR Data Science Refinery service.

Note: You must map port 9995 to a number in the range of 30000-32767 because `NodePort` supports only that port range.

Passing MapR Data Science Refinery Password as a Secret in Kubernetes
To avoid passing your `MAPR_CONTAINER_PASSWORD` in clear text, you can use a Kubernetes secret. This topic shows you how to do this.

1. Create a secret (`dsr-container-secret.yaml`) where you have base64 encoded `MAPR_CONTAINER_PASSWORD`:

   ```
   apiVersion: v1
   kind: Secret
   metadata:
     name: dsr-container-secret
   type: Opaque
   data:
     password: azhzUm9ja3M=
   ```

   `azhzUm9ja3M=` is the base64 encoding of `k8sRocks`.

2. Create the secret before deploying your MapR Data Science Refinery container by running the following command:

   ```
   kubectl create -f dsr-container-secret.yaml
   ```

3. Reference the secret in your deployment YAML file as follows:

   ```
   - name: MAPR_CONTAINER_PASSWORD
         valueFrom:
           secretKeyRef:
             name: dsr-container-secret
             key: password
   ```

Related information

https://kubernetes.io/docs/concepts/configuration/secret/

Exposing MapR Data Science Refinery as a Service in Kubernetes
You can expose MapR Data Science Refinery as a Kubernetes service. For example, if you run the service in a cloud Kubernetes deployment, you can expose it as a Kubernetes `LoadBalancer` service. This topic provides a sample that shows you how to do this. It also discusses the alternative where you are running in a non-cloud Kubernetes deployment.

The following sample YAML file exposes a `LoadBalancer` service:

```
apiVersion: v1
kind: Service
metadata:
  name: dsr-web-svc
  namespace: dsr-ns
spec:
  type: LoadBalancer
  ports:
    - { name: dsr-ui, port: 9995, nodePort: 32000 }

  selector:
    app: dsr-app
```

If you are running in a cloud Kubernetes deployment, run the following command to retrieve the external IP of the `LoadBalancer` service:

```
kubectl get service -n dsr-ns
```

Use the value in the `EXTERNAL-IP` column as the IP to connect to the MapR Data Science Refinery UI:

```
https://<EXTERNAL-IP>:9995
```

If you are running in a non-cloud Kubernetes deployment, the `EXTERNAL-IP` column returns `<pending>`, due to unavailability of a `LoadBalancer` service. You can still connect to the MapR Data Science Refinery UI by using the IP of any Kubernetes worker node and the `nodePort` specified in your YAML file:

```
https://<k8s-worker-ip>:32000
```

Running MapR Data Science Refinery as a Deployment in Kubernetes
This topic provides a sample YAML file that shows you how to run MapR Data Science Refinery as a Kubernetes `Deployment`. Doing so enables the Kubernetes deployment controller to spawn a new pod when a pod is killed or dies.

To run MapR Data Science Refinery as a Kubernetes `Deployment`, include the following configuration settings in your YAML file:

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: dsr-app
spec:
  replicas: 1
  template:
    metadata:
          labels:
            app: dsr-app
    spec:
      containers:
      - name: dsr
```

last-updated: Apr 11, 2022

```
        imagePullPolicy: Always
        image:  maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
```

The remainder of your YAML file is similar to a YAML file that specifies a Pod. The YAML file at Running MapR Data Science Refinery as a Kubernetes Service on page 3049 is an example.

Using MapR Data Fabric for Kubernetes with MapR Data Science Refinery

You can integrate MapR Data Fabric for Kubernetes with your MapR Data Science Refinery deployment. This provides persistent storage to MapR Filesystem, which you can use as an alternative to the MapR FUSE-Based POSIX Client. You have two integration options: use the Kubernetes Flexvolume driver, or use Kubernetes Persistent Volumes (PV) and Persistent Volume Claims (PVC).

Regardless of your integration choice, you must follow the instructions at Installing MapR and Kubernetes Software on Separate Nodes on page 241 to install MapR Data Fabric for Kubernetes.

Note: If you decide to use MapR Data Fabric for Kubernetes, do not set the `MAPR_MOUNT_PATH` variable. Otherwise, it enables the MapR FUSE-Based POSIX Client, which you do not need.

Using the Flexvolume Driver

The following sample shows you how to configure the Flexvolume driver:

```
            volumeMounts:
              - mountPath: /dev/fuse
                name: fuse
              - mountPath: /sys/fs/cgroup
                name: cgroup
              - mountPath: /tmp/maprticket_secret
                name: maprticket-secret
              - mountPath: /mapr-vol
                name: maprflex-volume

          volumes:
            - name: fuse
              hostPath:
                path: /dev/fuse
            - name: cgroup
              hostPath:
                path: /sys/fs/cgroup
            - name: maprticket-secret
              secret:
                secretName: mapr-ticket-secret
            - name: maprflex-volume
              flexVolume:
                driver: "mapr.com/maprfs"
                readOnly: true
                options:
                  cluster: "my.cluster.com"
                  cldbHosts: "cldb1 cldb2"
                  securityType: "secure"
                  ticketSecretName: "mapr-ticket-secret"
                  ticketSecretNamespace: "ns-mydsr"
```

last-updated: Apr 11, 2022

Using Persistent Volumes (PV) and Persistent Volume Claims (PVC)

The following defines the namespace used in subsequent configuration snippets:

```
apiVersion: v1
kind: Namespace
metadata:
  name: ns-mydsr
  labels:
    name: ns-mydsr
```

The following defines your PV and PVC:

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: dsr-pv
  namespace: ns-mydsr
spec:
  capacity:
    storage: 5Gi
  accessModes:
    - ReadWriteOnce
  flexVolume:
    driver: "mapr.com/maprfs"
    readOnly: true
    options:
      cluster: "my.cluster.com"
      cldbHosts: "cldb1 cldb2"
      securityType: "secure"
      ticketSecretName: "mapr-ticket-secret"
      ticketSecretNamespace: "ns-mydsr"

---
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: dsr-pvc
  namespace: ns-mydsr
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

The following references the previously defined PV and PVC:

```
            volumeMounts:
              - mountPath: /dev/fuse
                name: fuse
              - mountPath: /sys/fs/cgroup
                name: cgroup
              - mountPath: /tmp/maprticket_secret
                name: maprticket-secret
              - mountPath: /mapr-pvc
                name: maprflex-pv-pvc
        volumes:
          - name: fuse
            hostPath:
              path: /dev/fuse
          - name: cgroup
            hostPath:
```

last-updated: Apr 11, 2022

```
            path: /sys/fs/cgroup
        - name: maprticket-secret
          secret:
            secretName: mapr-ticket-secret
        - name: maprflex-pv-pvc
          persistentVolumeClaim:
            claimName: dsr-pvc
```

Accessing and Creating Notebooks in Zeppelin

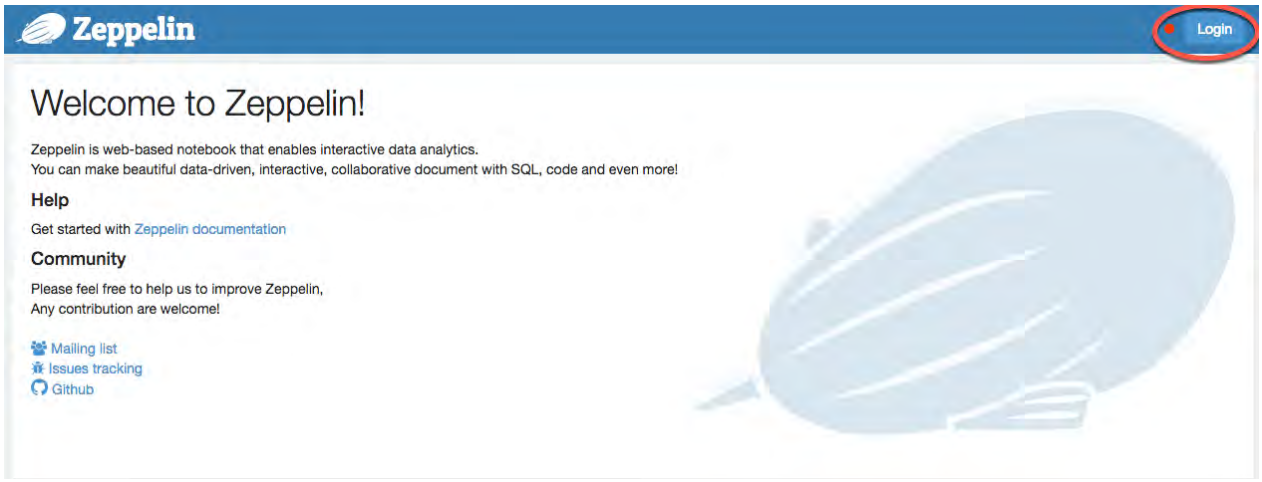
1. After the Apache Zeppelin Docker image is running, access the Zeppelin notebook in your browser by specifying the following URL:

   ```
   https://localhost:9995
   ```

   This URL loads the Zeppelin notebook's home page. You must specify a secure URL.

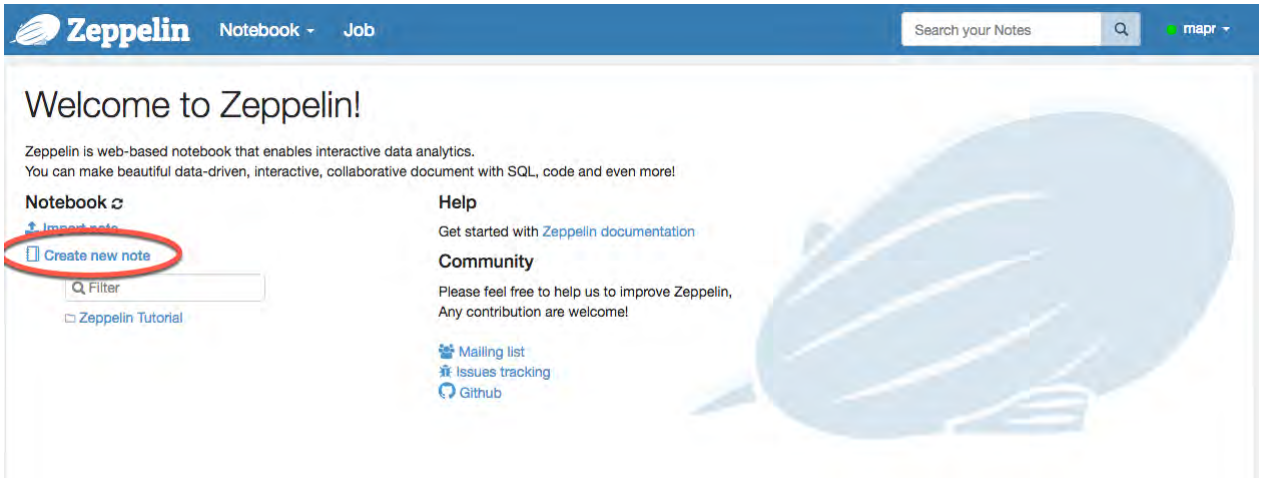
   If the Docker image is running on a remote node, such as a MapR edge node, replace `localhost` with the host name or IP address of the remote node. If you specified a different port number in your `docker run` command, replace 9995 with your port number.

2. Log in to Zeppelin using the user name and password you specified in your `docker run` command:



3. Create your notebook:

last-updated: Apr 11, 2022



See Understanding Zeppelin Interpreters on page 3059 for details on interpreters you can use.

Stopping Your Zeppelin Container

If you no longer need to use your Zeppelin container, you can stop the running image.

1. Determine the container id of your Docker instance by listing all running Docker containers:

   ```
   docker ps
   ```

   The output includes the following fields:

   ```
   CONTAINER ID
   IMAGE

   23b60c2720dd        maprtech/
   data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
   ```

2. Stop the running container specifying the revealed container id:

   ```
   docker stop 23b60c2720dd
   ```

Understanding Zeppelin Interpreters

Apache Zeppelin interpreters enable you to access specific languages and data processing backends. This section describes the interpreters you can use with MapR and the use cases they serve.

Supported Zeppelin Interpreters

Apache Zeppelin on MapR supports the following interpreters:

Shell	With the Shell interpreter, you can invoke system shell commands. If you have a MapR File System mount point, you can access MapR File System using shell commands like `ls` and `cat` by using the FUSE-Based POSIX Client on page 3039. See Running Shell Commands in Zeppelin on page 3085 for examples that use this interpreter.
Pig	The Apache Pig interpreter enables you to run Apache Pig scripts and queries. See Running Pig Scripts in Zeppelin on page 3086 for examples that use this interpreter.

JDBC - Drill and Hive

Apache Zeppelin on MapR provides preconfigured Apache Drill and Apache Hive JDBC interpreters. See Running Drill Queries in Zeppelin on page 3087 and Running Hive Queries in Zeppelin on page 3087 for examples that use these interpreters.

Livy

The Apache Livy interpreter is a RESTful interface for interacting with Apache Spark. With this interpreter, you can run interactive Scala, Python, and R shells, and submit Spark jobs.

The Spark jobs run in YARN cluster mode so they run inside an application master process managed by YARN. This has the following implications:

- Allows you to close your Zeppelin notebook without killing your Spark jobs.
- Supports Spark Dynamic Resource Allocation, which allows you to set idle timeouts in your Spark context to recapture wayward memory.

Starting in the 1.3 release, MapR Data Science Refinery uses a shared Livy session to run all Spark variations. In prior releases, it uses separate Livy sessions for Spark, PySpark, and SparkR jobs.

The Livy interpreter does not support ZeppelinContext and Angular Display System. See the description of the Spark interpreter for details about these features.

Although MapR Data Science Refinery includes Livy, you cannot run the Livy UI inside your Zeppelin container.

The following topics contain examples that use the Livy interpreter to access different backend engines:

- Running Spark Jobs in Zeppelin on page 3089
- Accessing MapR Database in Zeppelin Using the MapR Database Binary Connector on page 3093
- Accessing MapR Event Store For Apache Kafka in Zeppelin Using the Livy Interpreter on page 3097

Note: See MapR Data Science Refinery Support by MapR Core Version on page 5638 for limitations in version support when accessing MapR Event Store.

Spark

The Apache Spark interpreter is available starting in MapR Data Science Refinery 1.1. It provides an alternative to the Livy interpreter.

The Spark interpreter supports the following features not supported by the Livy interpreter:

- ZeppelinContext - Allows you to create dynamic forms and share objects between Spark Scala and PySpark code
- Angular Display System - Allows you to display charts using data returned from Spark and to pass variables from the Spark interpreter to the Angular interpreter

last-updated: Apr 11, 2022

Starting in MapR Data Science Refinery 1.3, Spark jobs run in YARN cluster mode. In prior releases, they run in YARN client mode. Running in YARN cluster mode avoids heavy resource consumption on your container host machine because the Spark driver process does not run on the container host. It also provides the advantages noted earlier for the Livy interpreter.

The following topics contain examples that use the Spark interpreter to access different backend engines:

- Running Spark Jobs in Zeppelin on page 3089
- Accessing MapR Database in Zeppelin Using the MapR Database Binary Connector on page 3093
- Accessing MapR Database in Zeppelin Using the MapR Database OJAI Connector on page 3095
- Accessing MapR Event Store For Apache Kafka in Zeppelin Using the Spark Interpreter on page 3100

  Note: See MapR Data Science Refinery Support by MapR Core Version on page 5638 for limitations in version support when accessing MapR Event Store.

MapR Database Shell

The MapR Database Shell interpreter allows you to run commands available in MapR Database Shell (JSON Tables) on page 5286 in the Zeppelin UI. Using dbshell commands, you can access MapR Database JSON tables without having to write Spark code. The interpreter supports all dbshell commands except `find` commands that specify an ordering.

The interpreter is available starting in MapR Data Science Refinery 1.2. You do not have to run any new additional configuration steps to use this interpreter.

Specify the following in the Zeppelin UI to invoke the interpreter:

```
%maprdb
```

See Running MapR Database Shell Commands in Zeppelin on page 3092 for examples that use this interpreter.

Livy vs Spark Interpreters

Starting in MapR Data Science Refinery 1.3, since both the Livy and Spark interpreters run in YARN cluster mode, the primary reason for choosing the Spark interpreter over the Livy interpreter is support for visualization features in the former.

Note: Neither interpreter supports Spark standalone mode.

Zeppelin Interpreter Use Cases

The table below summarizes which interpreters to use to access different backend engines for different data processing goals:

last-updated: Apr 11, 2022

Data Processing Goal	Zeppelin Interpreter	Backend Engine
Data discovery, exploratory querying	Livy, Spark	Spark SQL
	JDBC	Hive, Drill
	Shell	MapR File System
	MapR Database Shell	MapR Database JSON
ETL, preparation	Livy, Spark	Spark, PySpark, SparkSQL, SparkStreaming,
	Livy, Spark	MapR Database (through the MapR Database Connectors for Apache Spark on page 4050)
	Livy, Spark	MapR Event Store For Apache Kafka (through Spark jobs that query MapR Event Store For Apache Kafka) **Note:** See MapR Data Science Refinery Support by MapR Core Version on page 5638 for limitations in version support when accessing MapR Event Store.
	JDBC	Hive
	Pig	MapReduce
Machine and deep learning, data science	Livy, Spark	SparkML
Reporting, visualization	JDBC	Hive, Drill

The following are general guidelines for choosing between the Livy and Spark interpreters:

- Use Livy for jobs that are long running or resource intensive
- Use Spark if you use visualization features that Livy does not support

Unsupported Zeppelin Interpreters

Apache Zeppelin on MapR does not support the HBase interpreter. To access MapR Database binary tables, use the MapR Database Binary Connector for Apache Spark on page 4101 with either the Livy or Spark interpreter.

Sequential Execution of Notebook Paragraphs

Starting in the 1.3 release, MapR Data Science Refinery runs paragraphs in a notebook sequentially rather than in parallel. This allows paragraphs to run properly when they have dependencies on earlier paragraphs in the same notebook.

Related information

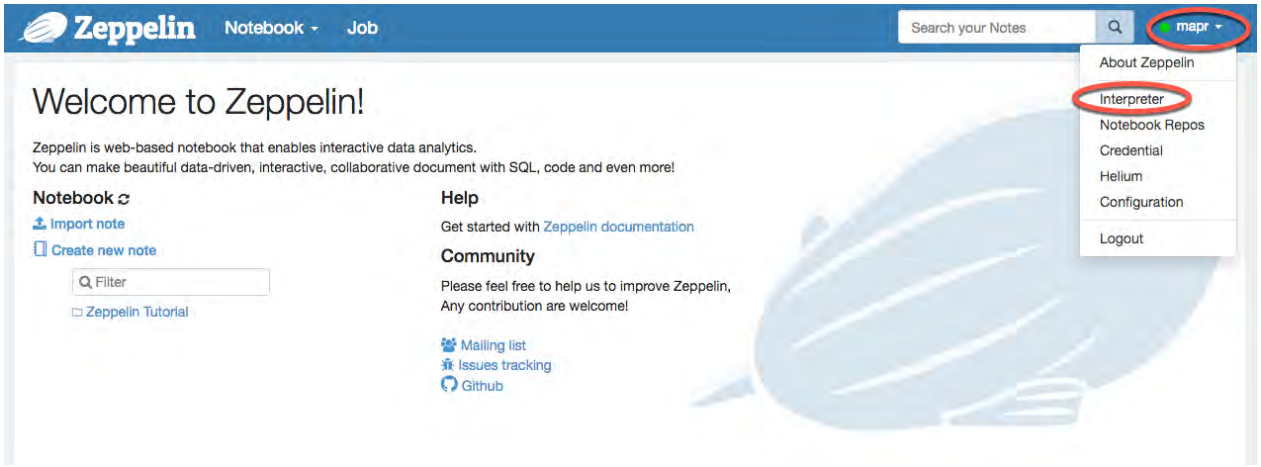
https://zeppelin.apache.org/docs/0.7.3/manual/interpreters.html

Configuring Zeppelin Interpreters

Out-of-box, the interpreters in Apache Zeppelin on MapR are preconfigured to run against different backend engines. You may need to perform manual steps to configure the Livy, Spark, and JDBC interpreters. No additional steps are needed to configure and run the Pig and Shell interpreters. You can configure the idle timeout threshold for interpreters.

last-updated: Apr 11, 2022

To configure an interpreter, click on your login name in the top right corner of the Zeppelin home screen and select **Interpreter**:



Configuring the Livy Interpreter

The Livy interpreter provides support for Spark Python, SparkR, Basic Spark, and Spark SQL jobs. To use the Livy interpreter for these variations of Spark, you must take certain actions, including configuring Zeppelin and installing software on your MapR cluster.

You must also issue your `docker run` command with the parameters the Livy interpreter requires. See the following material for details about these parameters:

- Bridge Networking on page 3037
- Pig, Livy, and Spark Interpreters on page 3040
- Python Version on page 3041

Spark Python

The Apache Livy interpreter supports both Python 2 and Python 3, but you can run only one or the other in your container. You must install the Python packages on your MapR cluster to use them through Livy. You do not need to install them in your container.

To use Python, specify the following in your notebook:

```
%livy.pyspark
```

By default, this invokes Python 2. To switch Python versions, see Python Version on page 3041.

To install custom Python packages, see Installing Custom Packages for PySpark on page 3066.

SparkR

You must install R on your MapR cluster to use Apache SparkR through Livy.

To install custom packages for SparkR, run the R interpreter and execute R commands to install the target package. You must install the packages on each node where SparkR will execute. This are the nodes that contain a YARN NodeManager. By default, the Livy interpreter submits Spark jobs in YARN cluster mode.

The following example installs the `data.table` and `googleVis` packages using the R interpreter:

```
sudo R
> install.packages("data.table")
> install.packages("googleVis")
```

To verify these installs, run the following code in your Zeppelin UI:

```
%livy.sparkr

print(packageVersion("data.table"))
print(packageVersion("googleVis"))
```

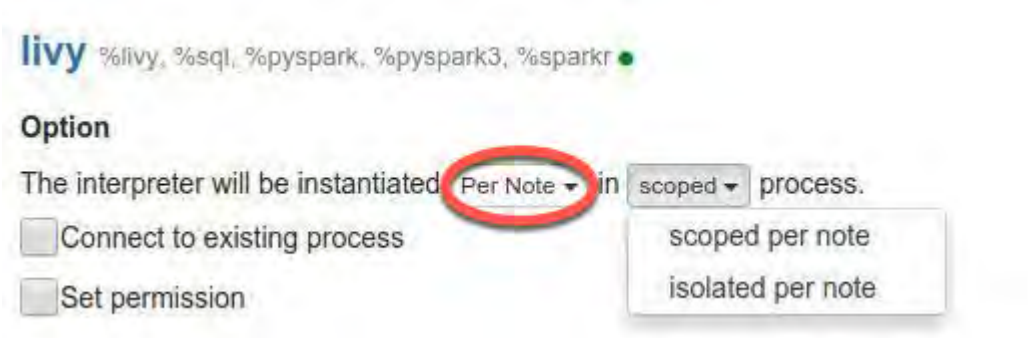
Your output should look similar to the following, depending on your package versions:

```
[1] '1.10.4.3'
[1] '0.6.2'
```

Spark Jobs

By default, the Livy interpreter is configured to submit Apache Spark jobs in YARN cluster mode.

To run Spark jobs in parallel, you must modify the Livy interpreter to instantiate **Per Note**:



You can set **scoped** to either of the two options.

Hive Tables

To use Apache Spark SQL with Apache Hive, follow the steps described at Integrate Spark-SQL (Spark 2.0.1 and later) with Hive on page 4115. As described on that page, to access Hive tables through Spark, you must make the `hive-site.xml` configuration file from your Hive cluster available to Spark running in your Zeppelin container.

One way to make the file available is through a volume mount when you start Docker:

1. Copy the file `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` from your Hive cluster to the local host on which you are running the Docker container.
2. Add a volume mount argument to your `docker run` command.

   In the following example, the local `hive-site.xml` file is in `/tmp`:

   ```
   docker run -it -p 9995:9995 -e MAPR_CLUSTER=<cluster-name> … \
   -v /tmp/hive-site.xml:/opt/mapr/spark/spark-2.3.1/conf/hive-site.xml:ro \
   maprtech/data-science-refinery:v1.4.1_6.1.0_6.3.0_centos7
   ```

Another way to make the file available is to copy it into your running container:

1. Copy the file `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` from your Hive cluster to the local host on which you are running the Docker container.

2. Determine your `container-id` using the output from the following command:

```
docker ps
```

3. Copy `hive-site.xml` from your local host into your Docker container:

```
docker cp /tmp/hive-site.xml <container-id>:/opt/mapr/spark/spark-2.3.1/
conf
```

4. Log in to your container as the user running the container using the `container-id`:

```
docker exec -it --user <MAPR_CONTAINER_USER> <container-id> bash -l
```

5. Restart the Livy service running in your container:

```
/opt/mapr/livy/livy-<version>/bin/livy-server stop
/opt/mapr/livy/livy-<version>/bin/livy-server start
```

Configuring the Spark Interpreter

The Spark interpreter is available starting in the 1.1 release of the MapR Data Science Refinery. It provides support for Spark Python, SparkR, Basic Spark, and Spark SQL jobs. To use the Spark interpreter for these variations of Spark, you must take certain actions, including configuring Zeppelin and installing software on your MapR cluster.

You must also issue your `docker run` command with the parameters the Spark interpreter requires. See the following material for details about these parameters:

- Bridge Networking on page 3037
- Pig, Livy, and Spark Interpreters on page 3040
- Python Version on page 3041

Spark Python

You must install Python in your MapR cluster to run Python code with the Spark interpreter. You do not need to install it in your container since Spark runs in YARN cluster mode.

To use Python in the Spark interpreter, specify the following in your notebook:

```
%spark.pyspark
```

By default, this invokes Python 2. To switch Python versions, see Python Version on page 3041.

To install custom Python packages, see Installing Custom Packages for PySpark on page 3066. This also describes how to use Python 3 with custom packages.

Note: Although the 1.3 release includes IPython with the Spark interpreter, MapR Data Science Refinery does not support this feature.

SparkR

The Zeppelin container includes R. Some Apache SparkR jobs require you to install R on your MapR cluster nodes to run these jobs in the Spark interpreter.

last-updated: Apr 11, 2022

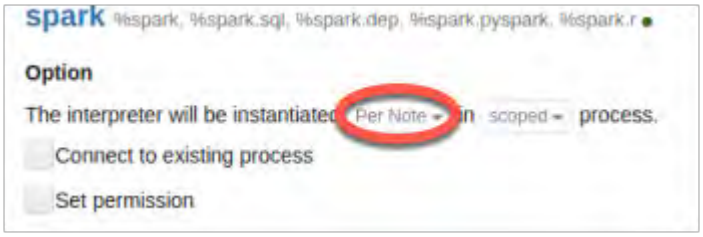
To use R in the Spark interpreter, specify the following in your notebook:

```
%spark.r
```

Spark Jobs

By default, the Spark interpreter is configured to submit Apache Spark jobs in YARN client mode. The interpreter does not support YARN cluster mode. Make sure you follow the steps described at Installing Spark on YARN on page 218 to install Spark on your MapR cluster.

To run Spark jobs in parallel, you must modify the Spark interpreter to instantiate **Per Note**:



You can set **scoped** to either of the two options.

Hive Tables

To access Apache Hive tables using the Spark interpreter, you must make the `hive-site.xml` configuration file from your Hive cluster available to Spark running in your Zeppelin container. Follow the same steps that describe how to access Hive tables with the Livy interpreter.

Installing Custom Packages for PySpark
You can install custom Python packages either by manually installing packages on each node in your MapR cluster or by using Conda. Using Conda allows you to perform the install from your Zeppelin host node without having to directly access your MapR cluster. The topics in this section describe the instructions for each method as well as instructions for Python 2 vs Python 3.

You can run only version of Python in your Zeppelin notebook.

Important: MapR supports the Python libraries included in the Zeppelin container, but does not support the libraries in custom Python packages. You should use Python versions that match the versions installed on your MapR cluster nodes. Choosing a Zeppelin Docker image OS that matches the OS running in your MapR cluster minimizes library version differences.

Manually Installing Custom Packages for PySpark
Use the Python package manager `pip` (or `pip3` for PySpark3) to manually install custom packages on each node in your MapR cluster. You need administrative access on your cluster nodes to install the packages.

1. Install the package manager using one of the following commands, depending on your operating system:
   a) RedHat:

Python 2

```
sudo yum install -y python-devel
python-setuptools
sudo easy_install pip
```

Python 3

```
sudo yum install -y python34-devel
python34-setuptools
sudo easy_install-3.4 pip
```

b) SLES:

Python 2

```
sudo zypper install -y
python-devel python-setuptools
sudo easy_install pip
```

Python 3

```
sudo zypper install -y
python3-devel python3-setuptools
sudo easy_install-3.4 pip
```

c) Ubuntu:

Python 2

```
sudo apt-get install -y python-dev
python-setuptools
sudo easy_install pip
```

Python 3

```
sudo apt-get install -y
python3-dev python3-setuptools
sudo easy_install3 pip
```

2. Install the custom package using the utility you downloaded in Step 1.

The following example installs the `matplotlib` package:

Python 2

```
sudo pip install matplotlib
```

Python 3

```
sudo pip3 install matplotlib
```

You must install the package on each node in your MapR cluster where PySpark jobs will run. These are the nodes that contain a YARN NodeManager.

3. To verify successful installs, run the following code snippet in your Zeppelin UI:

```
%livy.pyspark

import sys
print(sys.version)

import matplotlib
print(matplotlib.__version__)
```

The code snippet returns output similar to the following:

Python 2

```
2.7.5 (default, Nov 6 2016,
00:28:07)
[GCC 4.8.5 20150623 (Red Hat
4.8.5-11)]
2.1.0
```

Python 3

```
3.4.5 (default, May 29 2017,
15:17:55)
```

```
[GCC 4.8.5 20150623 (Red Hat
4.8.5-11)]
2.1.0
```

The minor versions of Python and `matplotlib` may differ depending on the versions you install.

Related information

https://mapr.com/blog/how-to-using-tensorflow-with-the-mapr-data-science-refinery/

Installing Custom Packages for PySpark Using Conda

To install custom packages for Python 2 (or Python 3) using Conda, you must create a custom Conda environment and pass the path of the custom environment in your `docker run` command.

To install Conda, follow the instructions at https://conda.io/docs/user-guide/install/index.html.

For each step of the following steps, select the tab corresponding to the Python version you want to install.

1. Create your custom Conda environment and archive it as a zip archive.

Python 2

The following example creates a custom Conda environment with Python 2 and three packages (`matplotlib`, `numpy`, and `pandas`):

```
mkdir custom_pyspark_env
conda create -p ./
custom_pyspark_env python=2 numpy
pandas matplotlib
cd custom_pyspark_env
zip -r custom_pyspark_env.zip ./
```

Python 3

The following example creates a custom Conda environment with Python 3 and three packages (`matplotlib`, `numpy`, and `pandas`):

```
mkdir custom_pyspark3_env
conda create -p ./
custom_pyspark3_env python=3 numpy
pandas matplotlib
cd custom_pyspark3_env
zip -r custom_pyspark3_env.zip ./
```

Important: Do not create an archive named `pyspark.zip`. This name is reserved for PySpark internals.

2. Launch the Zeppelin container, specifying the path of the Python archive in your `docker run` command.

Python 2

You can specify the archive in one of the following ways:

- **Option 1**: Specify the archive from MapR File System by uploading the archive to MapR File System
- **Option 2**: Specify the archive from your local filesystem using a Docker mount point

last-updated: Apr 11, 2022

Option 1

```
hadoop fs -put
custom_pyspark_e
nv.zip /
python_envs/
custom_pyspark_e
nv.zip
docker
run -it ... \
   -e
ZEPPELIN_ARCHIVE
_PYTHON=/
python_envs/
custom_pyspark_e
nv.zip \
   ... \
   maprtech/
data-science-ref
inery:v1.4.1_6.1
.0_6.3.0_centos7
```

Option 2

```
docker
run -it ... \
   -v /local/
path/
custom_pyspark_e
nv.zip:/tmp/
custom_pyspark_e
nv.zip:ro \
   -e
ZEPPELIN_ARCHIVE
_PYTHON=/tmp/
custom_pyspark_e
nv.zip \
   ... \
   maprtech/
data-science-ref
inery:v1.4.1_6.1
.0_6.3.0_centos7
```

The path parameters in the sample command correspond to the following:

Full Path to Archive from Step 1	Mount Point of the Archive in your Container
`/local/path/custom_pyspark_env.zip`	`/tmp/custom_pyspark_env.zip`

Python 3

If you want to use Python 3 instead of Python 2, set >>>>>>> Brought back DSR 1.3 content `ZEPPELIN_ARCHIVE_PYTHON` in one of the following ways:

last-updated: Apr 11, 2022

- **Option 1**: Specify the archive from MapR File System by uploading the archive to MapR File System
- **Option 2**: Specify the archive from your local file system using a Docker mount point

Option 1

```
hadoop fs -put
custom_pyspark3_
env.zip /
python_envs/
custom_pyspark3_
env.zip
docker
run -it ... \
   -e
ZEPPELIN_ARCHIVE
_PYTHON=/
python_envs/
custom_pyspark3_
env.zip \
   ... \
   maprtech/
data-science-ref
inery:v1.4.1_6.1
.0_6.3.0_centos7
```

Option 2

```
docker
run -it ... \
   -v /local/
path/
custom_pyspark3_
env.zip:/tmp/
custom_pyspark3_
env.zip:ro \
   -e
ZEPPELIN_ARCHIVE
_PYTHON=/tmp/
custom_pyspark3_
env.zip \
   ... \
   maprtech/
data-science-ref
inery:v1.4.1_6.1
.0_6.3.0_centos7
```

The path parameters in the sample command correspond to the following:

Full Path to Archive from Step 1	Mount Point of the Archive in your Container
`/local/path/custom_pyspark3_env.zip`	`/tmp/custom_pyspark3_env.zip`

3. To verify that you have successfully installed the `matplotlib` package, run the following code snippet in your Zeppelin UI:

Livy PySpark

```
%livy.pyspark

import sys
print(sys.version)

import matplotlib
print(matplotlib.__version__)
```

Spark PySpark

```
%spark.pyspark
import sys
print(sys.version)

import matplotlib
print(matplotlib.__version__)
```

The code snippet returns output similar to the following:

Python 2

```
2.7.14 |Anaconda, Inc.| (default,
Oct 27 2017, 18:21:12)
[GCC 7.2.0]
2.1.0
```

Python 3

```
3.6.3 |Anaconda, Inc.| (default,
Oct 27 2017, 19:41:01)
[GCC 7.2.0]
2.1.0
```

The minor versions of Python and `matplotlib` may differ depending on the versions you install.

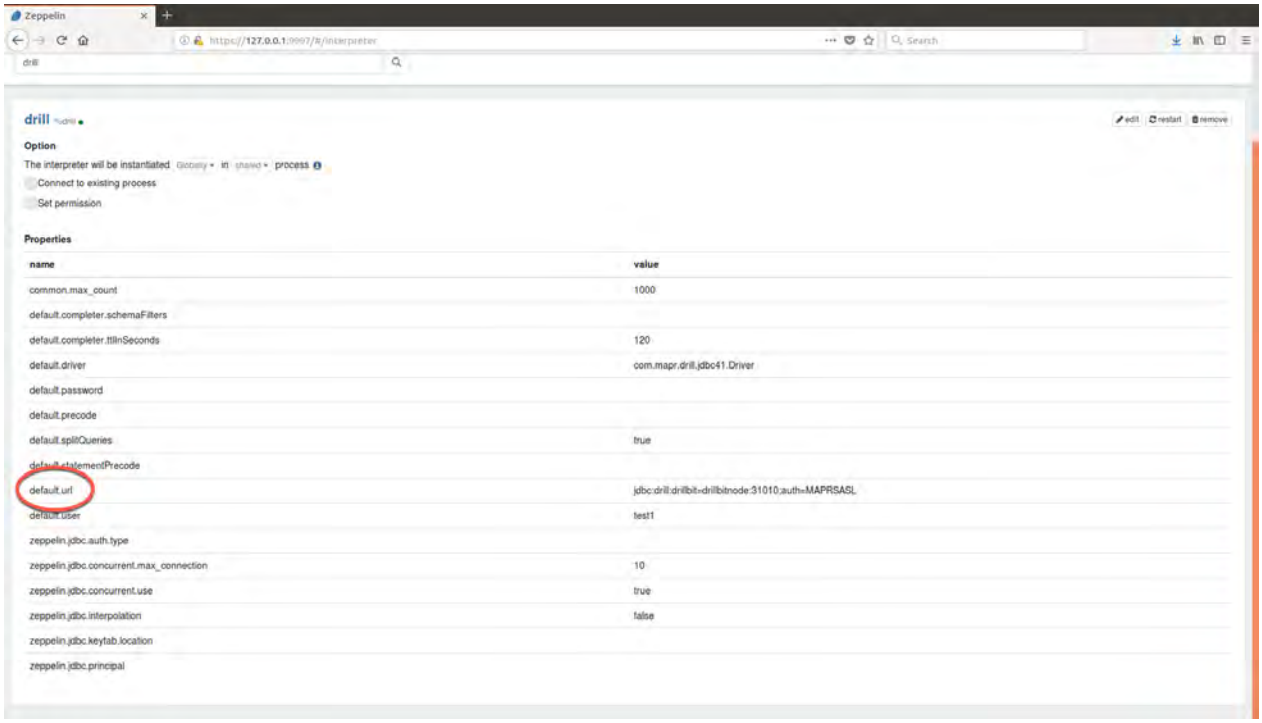
Configuring the JDBC Interpreter for Apache Drill and Apache Hive

Apache Zeppelin on MapR includes custom JDBC interpreters for Apache Drill and Apache Hive. Fields in each interpreter are prepopulated, but you need to customize them for your environment.

In particular, you must modify the JDBC URL, as described in the following sections.

Drill JDBC

You can set the default Apache Drill JDBC URL by specifying environment variables in your `docker run` command. See Default Drill JDBC Connection URL on page 3043 for details. To make additional changes to the URL, modify the `default.url` property:



The following is an example of a URL when MapR-SASL is enabled:

```
jdbc:drill:drillbit=drillbitnode:31010;auth=maprsasl
```

If MapR-SASL is not enabled, the URL is the following:

```
jdbc:drill:drillbit=node1:31010
```

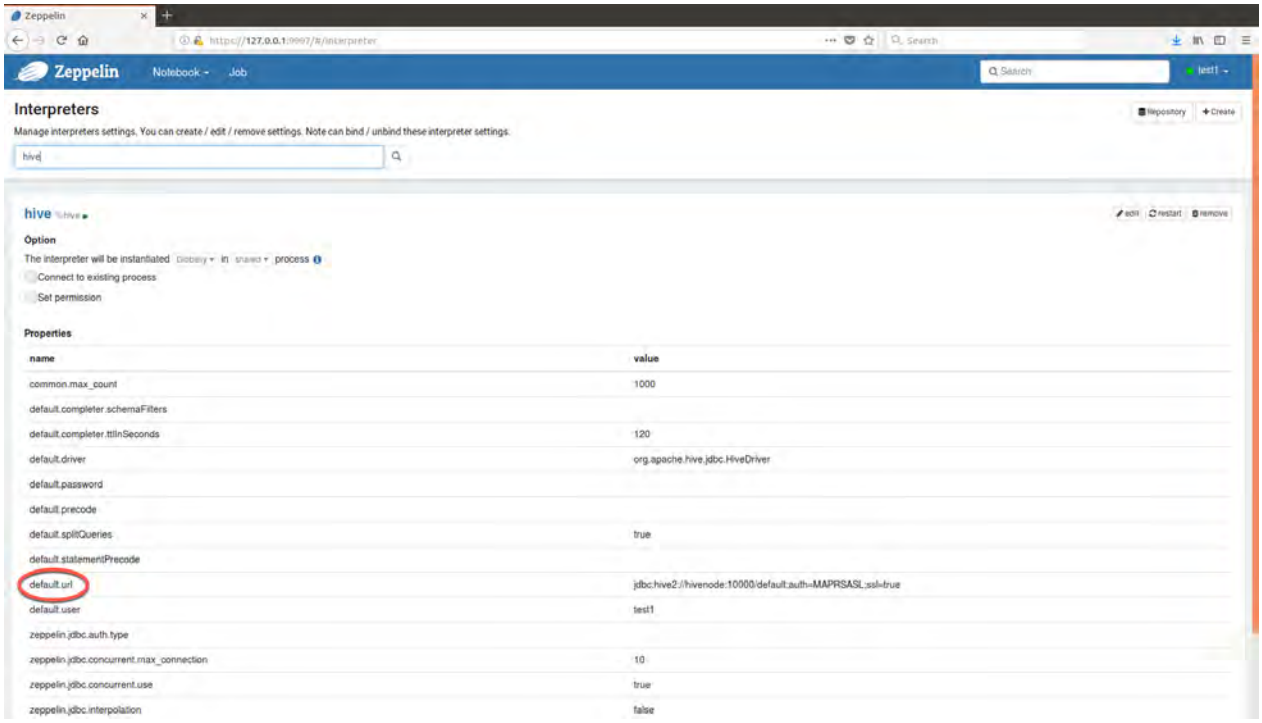
For non-secure clusters, `default.user` is prepopulated with the user running the container (`MAPR_CONTAINER_USER`). You can modify this property and `default.password`, as needed. Zeppelin submits your Drill queries using this user name and password (if specified).

For secure clusters, Zeppelin always submits Drill queries using the user name and password from your MapR ticket. You do not need to modify the `default.user` and `default.password` properties.

Hive JDBC

You must specify the Apache Hive JDBC URL in the `default.url` property:

last-updated: Apr 11, 2022



The following is an example of a URL when MapR-SASL is enabled:

```
jdbc:hive2://hivenode:10000/default;auth=maprsasl;ssl=true
```

Note: Starting with MapR Data Science Refinery 1.3, you must specify `ssl=true` when MapR-SASL is enabled.

If MapR-SASL is not enabled, the URL is the following:

```
jdbc:hive2://node2:10000/default
```

Troubleshooting Zeppelin

This section describes how to resolve common problems you may encounter when using Apache Zeppelin.

Problems Starting Zeppelin

Problem	Your `docker run` command fails with the following message: `Zeppelin start [FAILED]`
Possible Cause	You have configured Docker with too little memory
Resolution	Reconfigure Docker with at least 3.5 GB of memory

last-updated: Apr 11, 2022

Problems Connecting to Zeppelin UI

Problem

You specify storing your notebooks in MapR File System and encounter the following error when trying to connect to Zeppelin in your browser:

```
HTTP ERROR: 503
```

Possible Cause	Resolution
`ZEPPELIN_NOTEBOOK_DIR` is set to an incorrect MapR filesystem directory in your `docker run` command	Verify that you have set `ZEPPELIN_NOTEBOOK_DIR` to a valid MapR filesystem directory
Problems with the FUSE-Based POSIX Client on page 3039	Apply the MapR POSIX Client for Containers license if you are missing this license
Problems with your MapR ticket file	Make sure you have correctly set up your MapR ticket file, including setting the proper owner and group on your source ticket file. See MapR Ticketing on page 3038 for details.

See Notebook Storage on page 3040 for further details.

Problems Logging into the Zeppelin UI

Problem

Log in fails even though you have specified a correct username and password

Possible Cause

You have configured Docker with too little memory

Resolution

Reconfigure Docker with at least 3.5 GB of memory

Navigation Problems in Zeppelin UI

Problem

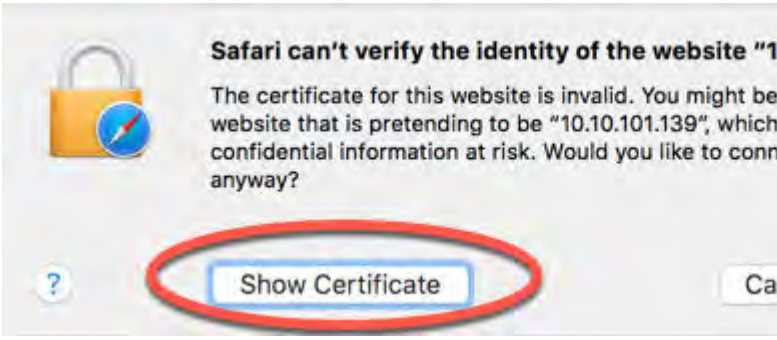
Zeppelin UI screens do not display correctly in your browser

Possible Cause

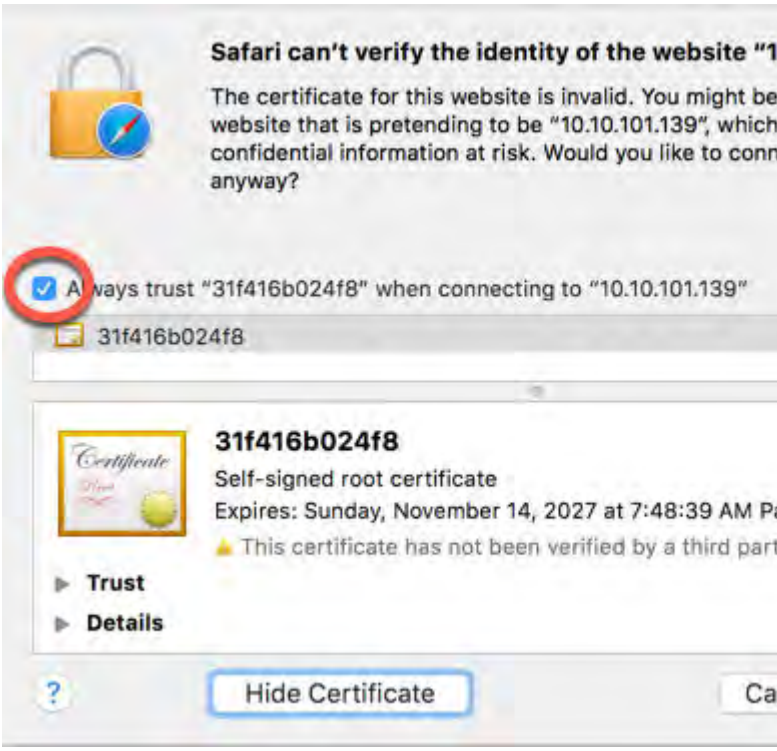
Due to security requirements, connecting to Zeppelin requires self-signed certificates

Resolution

Make sure you accept any certificates when connecting to Zeppelin. The following shows the prompts you need to click in the Safari browser:



last-updated: Apr 11, 2022



Unable to Access MapR File System

Problem	You are using the FUSE-based POSIX client to access MapR filesystem and your MapR filesystem mount point is empty.
Possible Cause	Missing MapR POSIX Client for Containers license
Resolution	Install the necessary license. See FUSE-Based POSIX Client on page 3039 for further details.

`FileClient` Errors

Problem	Running `ls` either in the Zeppelin shell interpreter or inside your container returns the following error: `ls: Could not create FileClient`
Possible Cause	Invalid MapR ticket
Resolution	Make sure you have a valid ticket with the proper permissions. You must generate a unique ticket for each MapR cluster. See MapR Ticketing on page 3038 for further details.

last-updated: Apr 11, 2022

Livy Errors when Using Bridge Networking

Problem

You are using bridge networking, and all commands you run in the Livy interpreter return errors. You see an error similar to the following in the Zeppelin UI:

```
org.apache.zeppelin.livy.LivyException
: Session 0 is finished, appId:
application_1511983726844_0005, log:
[ at
java.util.concurrent.ThreadPoolExecuto
r$Worker.run(ThreadPoolExecutor.java:6
24), at
java.lang.Thread.run(Thread.java:748),
 , Shell output: main : command
provided 1, main : user is mapr,
main : requested yarn user is
mapr, , , Container exited with a
non-zero exit code 15, Failing this
attempt. Failing the application.]
```

Possible Cause

You have not correctly specified the `HOST_IP` or Livy launcher's port range as described at bridge networking.

Solution

Make sure your `docker run` command includes the noted parameters. In particular, make sure you do not specify `localhost` as the `HOST_IP` if you are running the container and Zeppelin UI on the same machine. If you are running multiple Zeppelin containers on a single host, make sure you specify unique port ranges for the Livy launcher as described at Running Multiple Zeppelin Containers on a Single Host on page 3045.

Livy and Pig Errors when Using Bridge Networking

Problem

You are using bridge networking and encounter errors when using the Livy and Pig interpreters.

Possible Cause

The errors may be due to DNS issues. Bridge networking, which is the Docker default, may override your DNS settings. Examine your Zeppelin Log Files on page 3083 to see if there are errors related to unknown hosts.

Sample of errors in the case of Livy are the following:

- Livy interpreter output in the Zeppelin UI:

```
org.apache.zeppelin.livy.LivyExcept
ion: Session 0 is finished, appId:
null, log:
[java.lang.RuntimeException:
Unable to create proxy to the
ResourceManager null,
org.apache.hadoop.yarn.client.MapRZ
KBasedRMFailoverProxyProvider.getPr
oxy(MapRZKBasedRMFailoverProxyProvi
der.java:135)
...
```

last-updated: Apr 11, 2022

- Exceptions in the Livy log file (`/opt/mapr/livy/livy-0.5.0/logs/livy-mapruser1-server.out`):

```
17/11/08 14:41:02 INFO
ContextLauncher: 17/11/08 14:41:02
FATAL zookeeper.ZKDataRetrieval:
Could not create ZooKeeper
instance. Due to IOException. No

```

Samples of errors in the case of Pig are the following:

last-updated: Apr 11, 2022

- Pig interpreter output in the Zeppelin UI:

```
org.apache.pig.impl.logicalLayer.Fr
ontendException: ERROR 1066:
Unable to open iterator for alias
paragraph_20161228_140730_190334287

    at
org.apache.pig.PigServer.openIterat
or(PigServer.java:1032)
...
```

- Exceptions in the Pig log file (`/opt/mapr/zeppelin/zeppelin-0.8.0/logs/zeppelin-interpreter-pig-mapruser1-a384f3320c46.log`):

```
INFO [2017-11-08 14:30:13,346]
({pool-2-thread-3}
ZooKeeper.java[<init>]:438) -
Initiating client connection,
connectString=node1:5181
sessionTimeout=30000
watcher=com.mapr.util.zookeeper.ZKD
ataRetrieval@5de4a6da
FATAL [2017-11-08 14:30:13,544]
({pool-2-thread-3}
ZKDataRetrieval.java[init]:105) -
Could not create ZooKeeper
instance. Due to IOException. No
data from ZK with connect string:
node1:5181 will be returned.
java.net.UnknownHostException:
node1: Name or service not known
        at
java.net.Inet4AddressImpl.lookupAll
HostAddr(Native Method)
```

Resolution

Add the following parameter to `docker run`:

```
--dns=<nameserver-that-resolves-cluste
r-hosts>
```

Problems Running PySpark or SparkR Code

Problem

You are unable to run PySpark or SparkR code in either the Livy or Spark interpreter.

Possible Cause

You have different versions of the Python or R libraries in your Zeppelin container and your MapR cluster.

Resolution

Install matching versions of the libraries in your MapR cluster.

Or, choose the Zeppelin Docker image OS that matches the OS running in your MapR cluster. This minimizes version differences between the libraries running in your container vs your MapR cluster.

NPE Using the Spark Interpreter

Problem

You encounter an NPE when you use the Spark interpreter.

Possible Cause

The directory `/apps/spark` is missing in your MapR cluster. If this is the case, you will see the following error in your Zeppelin Spark interpreter log file:

```
ERROR [2018-03-23 16:40:22,120]
({pool-2-thread-2}
Utils.java[invokeMethod]:40) -
java.lang.reflect.InvocationTargetExce
ption

last-updated: Apr 11, 2022

Resolution

Create the directory `/apps/spark` on your MapR cluster as described at Installing Spark on YARN on page 218.

Possible Cause

The credentials on your MapR ticket are incorrect. If this is the case, you will see the following errors in your Zeppelin Spark interpreter log file:

```
ERROR [2018-03-26 22:47:48,967]
({pool-2-thread-2}

```

Resolution

Make sure you have correctly set up your MapR ticket file, including setting the proper owner and group on your source ticket file. See MapR Ticketing on page 3038 for details.

Hangs when Using the Spark Interpreter

Problem

You encounter hangs when running code using the Spark interpreter.

Possible Cause

You are using bridge networking and have not reserved the ports used by the Spark driver.

Resolution

Add the following to your `docker run` command:

```
-p 11000-11010:11000-11010
```

See Bridge Networking on page 3037 for further details.

MapR Credential Errors

Problem

Your MapR cluster is secure and you encounter the following error while trying to access the cluster:

```
Unable to obtain MapR credentials
```

Possible Cause

This is likely a problem with your MapR ticket.

Resolution

As described in the MapR Ticketing on page 3038 section that discusses `docker run` parameters, make sure the following are true:

- All identity parameters (user name, group name, UID, and GID) are consistent with the values specified in the ticket file.
- The owner and group on the source ticket file match the UID and GID specified in the ticket file.

Note that it is not necessary for the user and group names to exist on the Docker host. If that is the case, to change the owner and group on the source ticket file, use the UID and GID in the `chown` command:

```
sudo chown
<MAPR_CONTAINER_UID>:<MAPR_CONTAINER_G
ID> <path on Docker host to MapR
ticket>
```

Access Control Errors when Creating Hive Tables

Problem	When creating Hive tables, you encounter an `AccessControlException`.
Possible Cause	This is likely a permission issue. Check the permissions on the Hive Warehouse Directory on page 3410 whose default location is `/user/hive/warehouse`. The permissions on the directory must be 777.
Resolution	Update the permissions if not already set to 777: `hadoop fs -chown 777 /user/hive/warehouse`

Zeppelin Log Files

Apache Zeppelin generates log files for each interpreter you use. Each interpreter also generates its own log files. This section describes the location and naming conventions of these files.

Zeppelin Interpreter Logs

Zeppelin stores these log files in the `/opt/mapr/zeppelin/zeppelin-0.8.0/logs` directory. The names of the files have the following pattern:

```
zeppelin-interpreter-<INTERPRETER_ID>-<MAPR_CONTAINER_USER>-<CONTAINER_ID>.log
```

This is an example of a Pig log file name:

```
/opt/mapr/zeppelin/zeppelin-0.8.0/logs/
zeppelin-interpreter-pig-mapruser1-a384f3320c46.log
```

The following table summarizes the tags used in the name:

Tag Name	Description	Value in Example
<INTERPRETER_ID>	The interpreter family name, e.g., livy, jdbc	pig
<MAPR_CONTAINER_USER>	The user running the container	mapruser1
<CONTAINER_ID>	The container ID generated by Docker for your Zeppelin container	a384f3320c46

Interpreter Log Files

These log files are specific to each interpreter. You can find them in the directories corresponding to each interpreter. For example, in the case of Livy, the log files are in the `/opt/mapr/livy/livy-0.5.0/logs` directory. The names of the Livy log files have the following pattern:

```
livy-<MAPR_CONTAINER_USER>-server.out
```

where `<MAPR_CONTAINER_USER>` is the name of the user running the container.

This is an example of a Livy log file name:

```
/opt/mapr/livy/livy-0.5.0/logs/livy-mapruser1-server.out
```

last-updated: Apr 11, 2022

Using Visualization Packages in Zeppelin

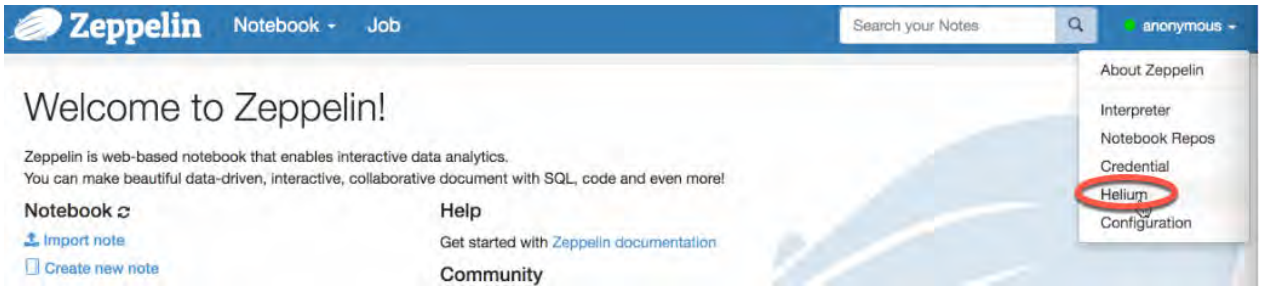
Apache Zeppelin supports the Helium framework. Using visualization packages, you can view your data through area charts, bar charts, scatter charts, and other displays. To use a visualization package, you must enable it through the Helium repository browser in the Zeppelin UI. Like Zeppelin interpreters, Helium is automatically installed in your Zeppelin container.

The example in this section assumes that you are using Zeppelin 0.8.0 and are enabling the `ultimate-pie-chart` package. Zeppelin 0.8.0 is supported starting in MapR Data Science Refinery 1.3. If you are using an earlier release of MapR Data Science Refinery, see earlier versions of the documentation for instructions.

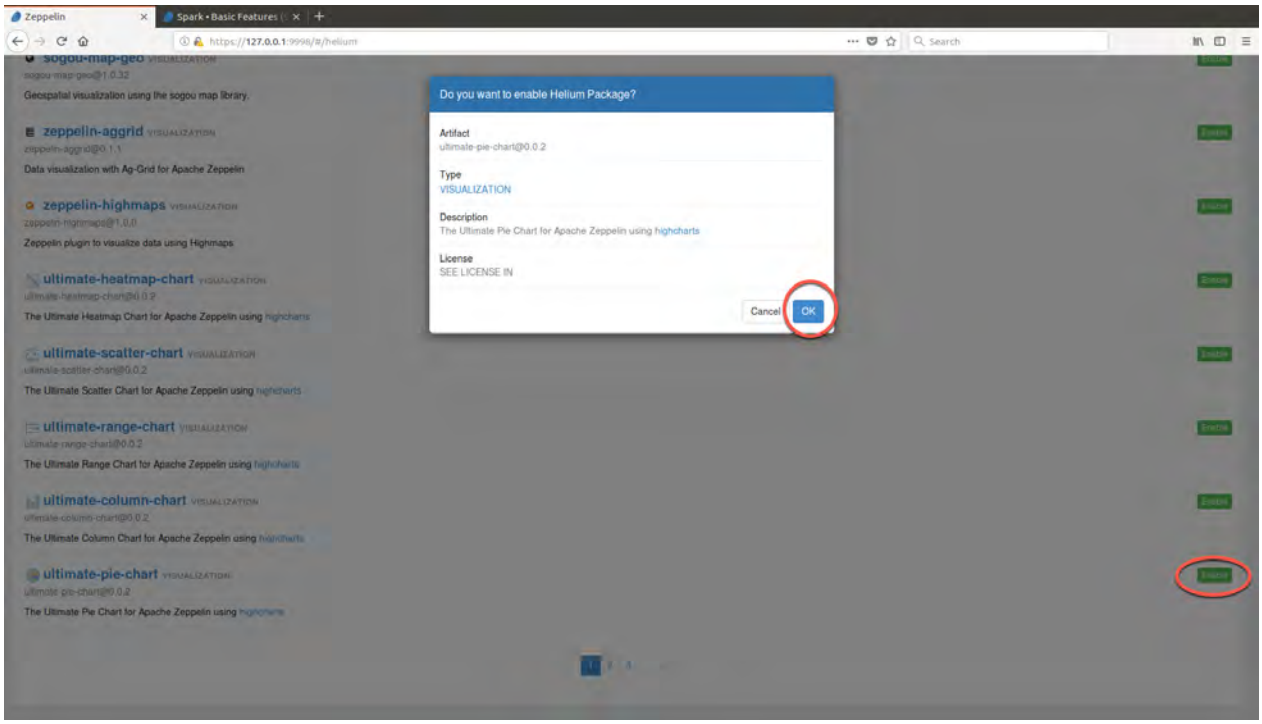
Important: The Apache Community provides and supports the visualization packages available through the Helium repository browser. MapR does not provide support for these packages.

Follow these steps to enable a package:

1. Open the Helium repository browser by selecting the **Helium** tab in the main menu of the Zeppelin UI:



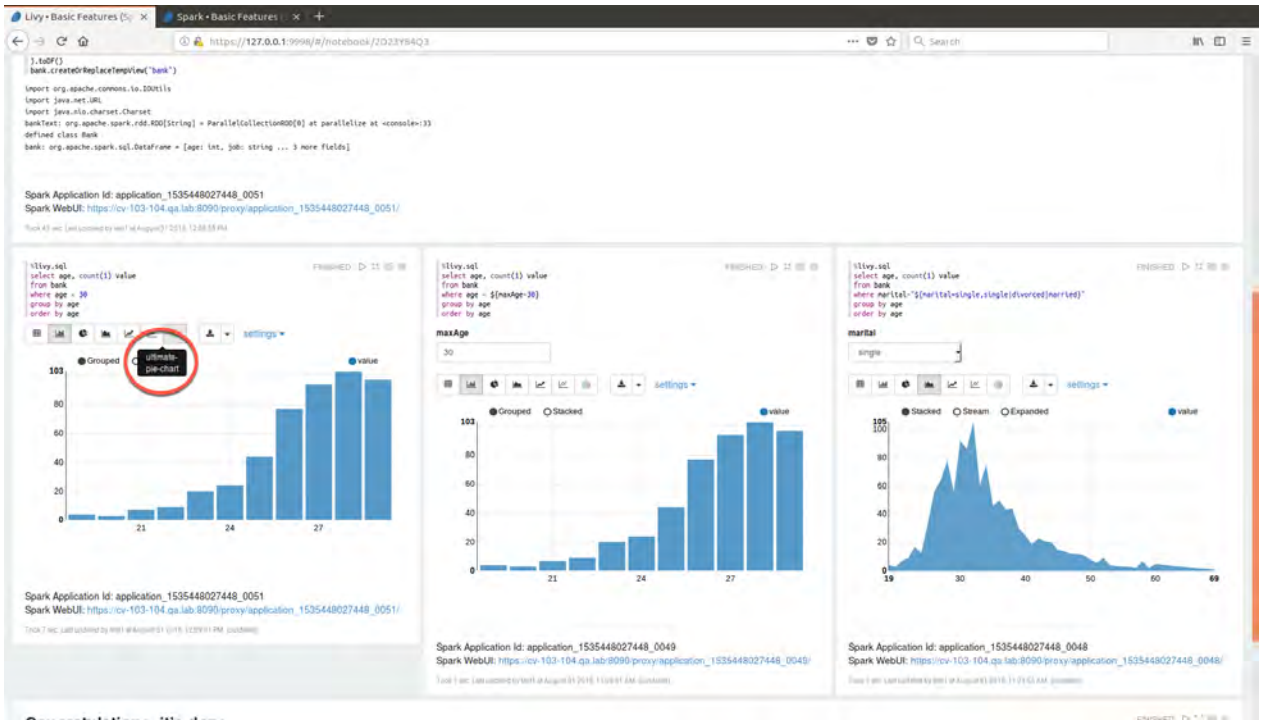
2. Locate your package, click **Enable**, and then click **OK** in the popup window:



The time it takes to enable a package depends on your internet connection speed.

After enabling the package and refreshing your browser to reload notebook content, you can use the package. The following shows output that uses the `ultimate-pie-chart` package:

last-updated: Apr 11, 2022



Using Zeppelin to Access Different Backend Engines

This section contains examples of how to use Apache Zeppelin interpreters to access the different backend engines. This includes running Apache Pig scripts, Apache Drill queries, Apache Hive queries, and Apache Spark jobs, as well as accessing MapR Database and MapR Event Store For Apache Kafka.

Note:

The Data Science Refinery includes the libraries that allow you to access MapR Event Store For Apache Kafka through the MapR Event Store For Apache Kafka Java and C APIs. You must run these applications inside your container. To log in to your container, follow these steps:

1. Determine your `container-id` using the output from the following command:

   ```
   docker ps
   ```

2. Log in to your container as the user running the container using the `container-id`:

   ```
   docker exec -it --user <MAPR_CONTAINER_USER> <container-id> bash -l
   ```

See MapR Event Store For Apache Kafka Java Applications on page 2754 and MapR Event Store For Apache Kafka C Applications on page 2795 for details about how to use these APIs.

Running Shell Commands in Zeppelin

This section shows you how to access files in your local filesystem and MapR File System by using shell commands in your Apache Zeppelin notebook.

To use POSIX shell commands to access MapR File System, you must have a MapR File System mount point in your container. The FUSE-Based POSIX Client on page 3039 provides this functionality.

In the following example, your MapR File System mount point is in `/mapr` and your cluster name is `my.cluster.com`. You can find the name of your cluster in the file `/opt/mapr/conf/mapr-clusters.conf` on your MapR cluster.

1. Create a file of test data in `/tmp`:

```
%sh
cat > /tmp/test.data << EOF
John,Smith
Brian,May
Rodger,Taylor
John,Deacon
Max,Plank
Freddie,Mercury
Albert,Einstein
Fedor,Dostoevsky
Lev,Tolstoy
Niccolo,Paganini
EOF
```

2. Copy the file to your home directory in MapR File System (`/user/mapruser1`) and display the contents of the file:

POSIX

```
%sh
cp /tmp/test.data /mapr/
my.cluster.com/user/mapruser1
cat /mapr/my.cluster.com/user/
mapruser1/test.data
```

Hadoop

```
%sh
hadoop fs -put /tmp/test.data /user/
mapruser1
hadoop fs -cat /user/mapruser1/
test.data
```

Running Pig Scripts in Zeppelin

This section contains a sample of an Apache Pig script that you can run in your Apache Zeppelin notebook.

This example reads the contents of your password file and outputs the first field in the file: the user name.

1. Using the shell interpreter, copy the password file to MapR File System:

POSIX

To use POSIX shell commands like `cp`, you must have a MapR File System mount point in your container. The example below assumes your mount point is `/mapr` and your cluster name is `my.cluster.com`:

```
%sh
cp /etc/passwd /mapr/my.cluster.com/
user/mapruser1
```

Hadoop

```
%sh
hadoop fs -put /etc/passwd /user/
mapruser1/
```

2. Load the password file in Pig and output the first field in each line in the file:

```
%pig
A = load 'passwd' using PigStorage(':');
B = foreach A generate $0 as id;
dump B;
```

There are other examples of using Pig in the Zeppelin tutorial, including running Pig queries.

Running Drill Queries in Zeppelin

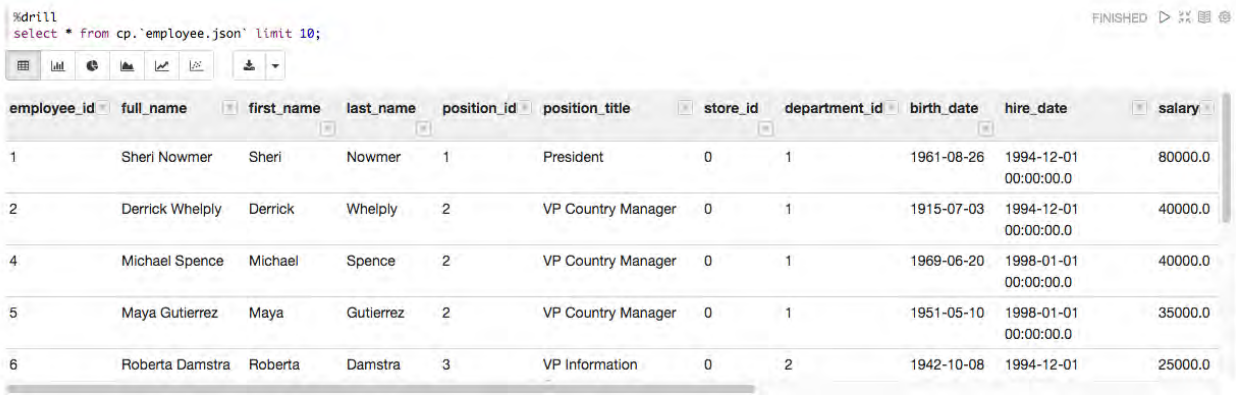
This section contains samples of Apache Drill queries that you can run in your Apache Zeppelin notebook.

Before running Drill queries, make sure you have configured the Drill JDBC interpreter.

The following example queries a JSON file:

```
%drill
select * from cp.`employee.json` limit 10;
```

The output looks like the following:



employee_id	full_name	first_name	last_name	position_id	position_title	store_id	department_id	birth_date	hire_date	salary
1	Sheri Nowmer	Sheri	Nowmer	1	President	0	1	1961-08-26	1994-12-01 00:00:00.0	80000.0
2	Derrick Whelply	Derrick	Whelply	2	VP Country Manager	0	1	1915-07-03	1994-12-01 00:00:00.0	40000.0
4	Michael Spence	Michael	Spence	2	VP Country Manager	0	1	1969-06-20	1998-01-01 00:00:00.0	40000.0
5	Maya Gutierrez	Maya	Gutierrez	2	VP Country Manager	0	1	1951-05-10	1998-01-01 00:00:00.0	35000.0
6	Roberta Damstra	Roberta	Damstra	3	VP Information	0	2	1942-10-08	1994-12-01	25000.0

This example creates a table from a JSON source file and queries it:

```
%drill
use dfs.tmp;
create table drill_one as select * from cp.`employee.json`;
select * from dfs.tmp.drill_one limit 10;
```

Running Hive Queries in Zeppelin

This section contains samples of Apache Hive queries that you can run in your Apache Zeppelin notebook.

last-updated: Apr 11, 2022

Before running Hive queries, make sure you have configured the Hive JDBC interpreter. Also, see MapR Data Science Refinery Support by MapR Core Version on page 5638 for limitations when connecting to a secure MapR 6.1 cluster.

1. Using the shell interpreter, create a source data file:

```
%sh
cat > /tmp/test.data << EOF
John,Smith
Brian,May
Rodger,Taylor
John,Deacon
Max,Plank
Freddie,Mercury
Albert,Einstein
Fedor,Dostoevsky
Lev,Tolstoy
Niccolo,Paganini
EOF
```

2. Copy the file to MapR File System:

POSIX

To use POSIX shell commands like `cp`, you must have a MapR filesystem mount point in your container. The example below assumes your mount point is `/mapr` and your cluster name is `my.cluster.com`:

```
%sh
cp /tmp/test.data /mapr/
my.cluster.com/user/mapruser1
```

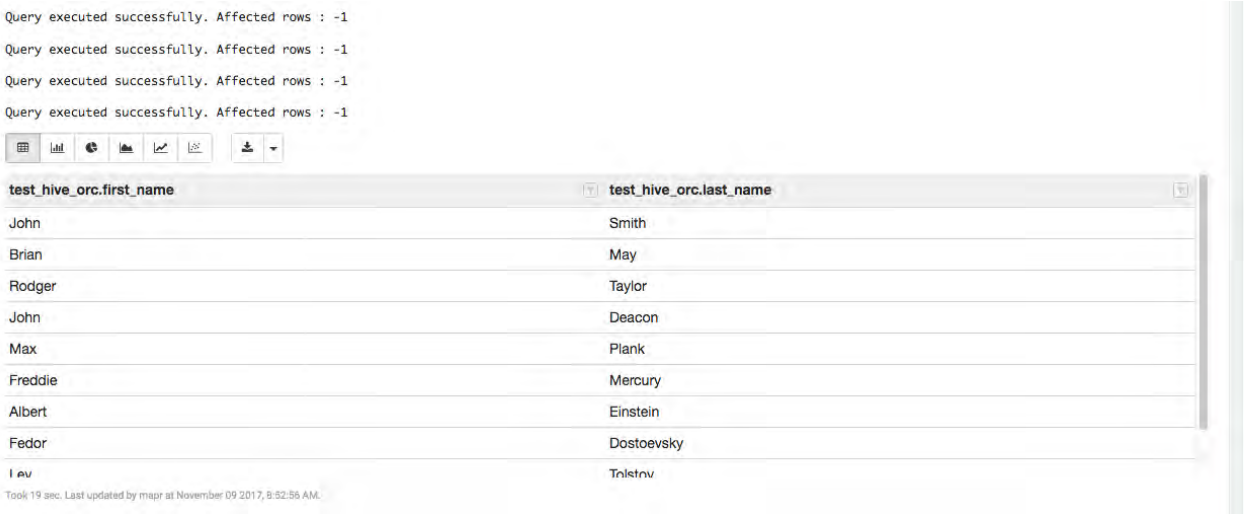
Hadoop

```
%sh
hadoop fs -put /tmp/test.data /user/
mapruser1
```

3. Run the Hive code using the Hive JDBC interpreter:

```
%hive
-- create and load Hive table
create table test_hive(first_name string, last_name string) ROW FORMAT
DELIMITED FIELDS TERMINATED BY ',';
load data inpath '/user/mapruser1/test.data' overwrite into table
test_hive;
-- create and load Hive ORC table
create table test_hive_orc(first_name string, last_name string) stored
as orc tblproperties ("orc.compress"="NONE");
insert overwrite table test_hive_orc  select * from test_hive;
-- query the Hive ORC table
select * from test_hive_orc;
```

The output looks like the following:



4. Drop the Hive tables created in the example:

```
%hive
drop table test_hive;
drop table test_hive_orc;
```

Running Spark Jobs in Zeppelin

This section contains code samples for different types of Apache Spark jobs that you can run in your Apache Zeppelin notebook. You can run these examples using either the Livy or Spark interpreter. The Spark interpreter is available starting in the 1.1 release of the MapR Data Science Refinery.

Before running these examples, depending on whether you are using the Livy or Spark interpreter, make sure you have configured the interpreter.

Note: The examples in this section use Hadoop commands to access files in MapR File System. If you have a MapR File System mount point in your container, you can replace the Hadoop commands with standard shell commands. Refer to Running Shell Commands in Zeppelin on page 3085 for an example of how to do this.

Running a Spark Job Using PySpark

The following example shows how to run a Spark job using Python. Make sure you have installed Python on your MapR cluster.

1. Before running the sample PySpark code, copy the files that the code references to MapR File System:

```
%sh
hadoop fs -mkdir -p /user/mapruser1/examples/src/main/resources/
hadoop fs -put /opt/mapr/spark/spark-2.3.1/examples/src/main/resources/
people.txt /user/mapruser1/examples/src/main/resources/
hadoop fs -put /opt/mapr/spark/spark-2.3.1/examples/src/main/resources/
people.json /user/mapruser1/examples/src/main/resources/
```

2. Run the PySpark code specifying either `%livy.pyspark` or `%spark.pyspark` as your interpreter:

```
from pyspark.sql.types import *
sc = spark.sparkContext
lines = sc.textFile("examples/src/main/resources/people.txt")
parts = lines.map(lambda l: l.split(","))
people = parts.map(lambda p: (p[0], p[1].strip()))
schemaString = "name age"
fields = [StructField(field_name, StringType(), True) for field_name in
schemaString.split()]
schema = StructType(fields)
schemaPeople = spark.createDataFrame(people, schema)
schemaPeople.createOrReplaceTempView("people")
schemaPeople.createOrReplaceTempView("people")
results = spark.sql("SELECT name FROM people")
results.show()
```

Running a Spark Job Using SparkR

The following SparkR code example creates a table and queries it using HiveQL. Make sure you have installed SparkR on your MapR cluster. Set your interpreter to either `%livy.sparkr` or `%spark.r`, depending on whether you are using Livy or Spark.

```
sqlContext <- sparkR.session(sc)
sql("CREATE TABLE IF NOT EXISTS src (key INT, value STRING)")
sql("LOAD DATA LOCAL INPATH '/opt/mapr/spark/spark-2.3.1/examples/src/main/
resources/kv1.txt' INTO TABLE src")

# Queries can be expressed in HiveQL.
results <- collect(sql("FROM src SELECT key, value"))
print(results)
```

Reading a JSON File Using Spark

Set your interpreter to either `%livy.spark` or `%spark`, depending on whether you are using Livy or Spark.

The following example loads a JSON file into a Spark DataFrame and then displays it:

```
val pathJSON = "file:/opt/mapr/spark/spark-2.3.1/examples/src/main/
resources/people.json"
val df = spark.read.json(pathJSON)
df.show()
```

Querying Using Spark

Set your interpreter to either `%livy.spark` or `%spark`, depending on whether you are using Livy or Spark.

The following example extends the JSON file reading example by issuing various queries on the data read into the DataFrame:

```
import spark.implicits._
val pathJSON = "file:/opt/mapr/spark/spark-2.3.1/examples/src/main/
resources/people.json"
val df = spark.read.json(pathJSON)
df.printSchema()
df.select("name").show()
df.select($"name", $"age" + 1).show()
```

```
df.filter($"age" > 21).show()
df.groupBy("age").count().show()
```

Querying Hive Tables Using Spark SQL

The following two examples query Hive tables using Spark SQL queries. Make sure the `hive-site.xml` configuration file from your Hive cluster is available in your Zeppelin container. Hive Tables on page 3064 describes the detailed steps.

If the code snippets in these examples do not specify an interpreter, specify `%livy.spark` to use the Livy interpreter or `%spark` to use the Spark interpreter.

Example 1

1. Run the following code to create Hive tables and issue various select statements against them:

```
import org.apache.spark.sql.Row
import org.apache.spark.sql.SparkSession
case class Record(key: Int, value: String)
import spark.implicits._
import spark.sql

// Create table, loading data from text file
sql("CREATE TABLE IF NOT EXISTS src (key INT, value STRING)")
sql("LOAD DATA LOCAL INPATH '/opt/mapr/spark/spark-2.3.1/examples/src/
main/resources/kv1.txt' INTO TABLE src")
sql("SELECT * FROM src").show()
sql("SELECT COUNT(*) FROM src").show()

// Find records where key < 10, ordering the result
val sqlDF = sql("SELECT key, value FROM src WHERE key < 10 ORDER BY key")

// Create a second table and join with the first
val stringsDS = sqlDF.map {case Row(key: Int, value: String) => s"Key:
$key, Value: $value"}
stringsDS.show()
val recordsDF = spark.createDataFrame((1 to 100).map(i => Record(i,
s"val_$i")))
recordsDF.createOrReplaceTempView("records")
sql("SELECT * FROM records r JOIN src s ON r.key = s.key").show()
```

2. Drop the table created in the previous code snippet:

```
sql("DROP TABLE src").show()
```

Example 2

1. Using the shell interpreter, create the source data file that you will use to load your Hive table:

```
%sh
cat > /tmp/test.data << EOF
John,Smith
Brian,May
Rodger,Taylor
John,Deacon
Max,Plank
Freddie,Mercury
Albert,Einstein
Fedor,Dostoevsky
Lev,Tolstoy
Niccolo,Paganini
EOF
hadoop fs -put /tmp/test.data /user/mapruser1/
```

2. Create, load, and query the Hive table:

```
sql ("create table test_hive(first_name string, last_name string) ROW
FORMAT DELIMITED FIELDS TERMINATED BY ','")
sql("load data inpath '/user/mapruser1/test.data' overwrite into table
test_hive")
sql("CREATE TABLE test_hive_parquet (first_name string, last_name
string) STORED AS PARQUET")
sql("INSERT OVERWRITE TABLE test_hive_parquet SELECT first_name,
last_name FROM test_hive")
sql("SELECT * from test_hive_parquet").show()
```

Running MapR Database Shell Commands in Zeppelin
This section contains a sample of MapR Database shell commands that you can run in your Apache Zeppelin notebook.

1. Invoke the MapR Database shell:

```
%maprdb.shell
```

2. Create a MapR Database JSON table in your home directory on MapR filesystem:

```
create ./sample_table
```

3. Insert some documents in to the table:

```
insert ./sample_table --value '{"_id": "FYWN1w","name":"Dental by
Design","city":"Ahwatukee","stars":4.0}'
insert ./sample_table --value '{"_id": "He-G7v","name":"Stephen Szabo
Salon","city":"McMurray","stars":3.0}'
insert ./sample_table --value '{"_id": "KQPW8l","name":"Western Motor
Vehicle","city":"Phoenix","stars":1.5}'
insert ./sample_table --value '{"_id": "8DShNS","name":"Sports
Authority","city":"Tempe","stars":3.0}'
insert ./sample_table --value '{"_id": "PfOCPj","name":"Brick House
Tavern + Tap","city":"Cuyahoga Falls","stars":3.5}'
insert ./sample_table --value '{"_id":
"o9eMRC","name":"Messina","city":"Stuttgart","stars":4.0}'
insert ./sample_table --value '{"_id": "kCoE3j","name":"BDJ
Realty","city":"Las Vegas","stars":4.0}'
insert ./sample_table --value '{"_id": "OD2hnu","name":"Soccer
Zone","city":"Las Vegas","stars":1.5}'
insert ./sample_table --value '{"_id": "EsMcGi","name":"Any Given
Sundae","city":"Wexford","stars":5.0}'
insert ./sample_table --value '{"_id": "TGWhGN","name":"Detailing Gone
Mobile","city":"Henderson","stars":5.0}'
```

4. Retrieve the documents with at least a 4 star rating:

```
find ./sample_table  --where '{"$ge":{"stars":4}}'
```

   The query returns the following:

```
{"_id": "EsMcGi","name":"Any Given Sundae","city":"Wexford","stars":5.0}
{"_id": "FYWN1w","name":"Dental by
Design","city":"Ahwatukee","stars":4.0}
{"_id": "TGWhGN","name":"Detailing Gone
Mobile","city":"Henderson","stars":5.0}
{"_id": "kCoE3j","name":"BDJ Realty","city":"Las Vegas","stars":4.0}
{"_id": "o9eMRC","name":"Messina","city":"Stuttgart","stars":4.0}
5 document(s) found.
```

Accessing MapR Database in Zeppelin Using the MapR Database Binary Connector

This section contains an example of an Apache Spark job that uses the MapR Database Binary Connector for Apache Spark to write and read a MapR Database Binary table. You can run this example using either the Livy or Spark interpreter. The Spark interpreter is available starting in the 1.1 release of the MapR Data Science Refinery.

Before running the example, make sure you have configured either your Livy or Spark interpreter to run Spark jobs.

This example is derived from the example at SparkSQL and DataFrames on page 4108. That page provides a more detailed explanation of the code.

The Zeppelin on MapR Tutorial also includes a notebook with Scala code examples using the MapR Database Binary Connector.

1. Set your interpreter to either `%livy.spark` or `%spark`, depending on whether you are using Livy or Spark.

2. Run the following code in your notebook:

```
import org.apache.spark.sql.{DataFrame, SQLContext}
import org.apache.spark.{SparkContext, SparkConf}
import org.apache.spark.sql.datasources.hbase.HBaseTableCatalog
case class HBaseRecordClass(
  col0: String,
  col1: Boolean,
  col2: Double,
  col3: Float,
  col4: Int,
  col5: Long,
  col6: Short,
  col7: String,
  col8: Byte)
object HBaseRecord {
  def apply(i:Int): HBaseRecordClass = {
    val s = "row" + "%03d".format(i)
    new HBaseRecordClass(s,
      i % 2 == 0,
      i.toDouble,
      i.toFloat,
      i,
      i.toLong,
      i.toShort,
      s"String$i extra",
      i.toByte)
  }
}
val tableName = "/user/mapruser1/test1"
val cat = s"""{
          |"table":{"namespace":"default", "name":"$tableName"},
          |"rowkey":"key",
          |"columns":{
            |"col0":{"cf":"rowkey", "col":"key", "type":"string"},
            |"col1":{"cf":"cf1", "col":"col1", "type":"boolean"},
            |"col2":{"cf":"cf2", "col":"col2", "type":"double"},
            |"col3":{"cf":"cf3", "col":"col3", "type":"float"},
            |"col4":{"cf":"cf4", "col":"col4", "type":"int"},
            |"col5":{"cf":"cf5", "col":"col5", "type":"bigint"},
            |"col6":{"cf":"cf6", "col":"col6", "type":"smallint"},
            |"col7":{"cf":"cf7", "col":"col7", "type":"string"},
            |"col8":{"cf":"cf8", "col":"col8", "type":"tinyint"}
            |}
          |}""".stripMargin
val sqlContext = new SQLContext(sc)
import sqlContext.implicits._

def withCatalog(cat: String): DataFrame = {
  sqlContext
    .read
    .options(Map(HBaseTableCatalog.tableCatalog->cat))
    .format("org.apache.hadoop.hbase.spark")
    .load()
}
val data = (0 to 255).map { i =>
  HBaseRecord(i)
}
sc.parallelize(data).toDF.write.options(
  Map(HBaseTableCatalog.tableCatalog ->
cat, HBaseTableCatalog.newTable ->
"5")).format("org.apache.hadoop.hbase.spark").save()
```

```
val df = withCatalog(cat)
df.show
```

The output looks like the following:

```
+----+--------------+-----+----+----+------+----+----+----+
|col4|          col7| col1|col3|col6|  col0|col8|col2|col5|
+----+--------------+-----+----+----+------+----+----+----+
|   0| String0 extra| true| 0.0|   0|row000|   0| 0.0|   0|

+----+--------------+-----+----+----+------+----+----+----+
only showing top 20 rows
```

Note: Zeppelin displays only the first 20 rows in the output.

See MapR Database Binary Connector for Apache Spark on page 4101 for additional information about this connector.

Accessing MapR Database in Zeppelin Using the MapR Database OJAI Connector

This section contains examples of Apache Spark jobs that use the MapR Database OJAI Connector for Apache Spark to read and write MapR Database JSON tables. The examples use the Spark Python interpreter. The Spark interpreter is available starting in the 1.1 release of the MapR Data Science Refinery. The Python API in the MapR Database OJAI Connector is available starting in the EEP 4.1 release.

Before running the examples, make sure you have configured your Spark interpreter to run Spark jobs.

Inserting a Spark DataFrame into a MapR Database JSON Table

The following code sample creates a Spark DataFrame, inserts it into a MapR Database JSON table that is created as part of the insert, and then loads it into another DataFrame:

```
%spark.pyspark
df = sc.parallelize([ { "_id": "rsmith", "address": { "city": "San
Francisco", "line": "100 Main Street", "zip": 94105 }, "dob": "1982-02-03",
"first_name": "Robert", "interests": [ "electronics", "music", "sports" ],
"last_name": "Smith" }, { "_id": "mdupont", "address": { "city": "San
Jose", "line": "1223 Broadway", "zip": 95109 }, "dob": "1982-02-03",
"first_name": "Maxime", "interests": [ "sports", "movies", "electronics" ],
"last_name": "Dupont" }, { "_id": "jdoe", "address": None, "dob":
"1970-06-23", "first_name": "John", "interests": None, "last_name":
"Doe" }, { "_id": "dsimon", "address": None, "dob": "1980-10-13",
"first_name": "David", "interests": None, "last_name": "Simon" }, { "_id":
```

```
"alehmann", "address": None, "dob": "1980-10-13", "first_name": "Andrew",
"interests": [ "html", "css", "js" ], "last_name": "Lehmann" } ]).toDF()

# Insert into MapR-DB table
spark.insertToMapRDB(df, "/user/mapruser1/table1", create_table=True)

# Load previously inserted data from MapR-DB table
df_loaded = spark.loadFromMapRDB("/user/mapruser1/table1").show()
```

Inserting a Spark DataFrame into a MapR Database JSON Table Using Bulk Insert

To bulk insert into a MapR Database JSON table that is created as part of the insert operation, you must order the records in the DataFrame as shown in the following example:

```
%spark.pyspark
df = sc.parallelize([ { "_id": "rsmith", "address":{ "city": "San
Francisco", "line": "100 Main Street", "zip": 94105 }, "dob": "1982-02-03",
"first_name": "Robert", "interests": [ "electronics", "music", "sports" ],
"last_name": "Smith" }, { "_id": "mdupont", "address":{ "city": "San Jose",
"line": "1223 Broadway", "zip": 95109 }, "dob": "1982-02-03", "first_name":
"Maxime", "interests": [ "sports", "movies", "electronics" ], "last_name":
"Dupont" },{ "_id": "jdoe", "address": None, "dob": "1970-06-23",
"first_name": "John", "interests": None, "last_name": "Doe" },{ "_id":
"dsimon", "address": None, "dob": "1980-10-13", "first_name": "David",
"interests": None, "last_name": "Simon" },{ "_id": "alehmann", "address":
None, "dob": "1980-10-13", "first_name": "Andrew", "interests": [ "html",
"css", "js" ], "last_name": "Lehmann" }]).toDF().orderBy("_id")

# Bulk insert into MapR-DB table
spark.insertToMapRDB(df, "/user/mapruser1/table2", create_table=True,
bulk_insert=True)

# Load previously inserted data from MapR-DB table
df_loaded = spark.loadFromMapRDB("/user/mapruser1/table2").show()
```

Selecting and Filtering Data when Loading a Spark DataFrame

The following code sample uses projection and filtering when loading a Spark DataFrame from a MapR Database JSON table:

```
%spark.pyspark

from pyspark.sql.functions import col, asc

df = sc.parallelize([{ "_id": "rsmith", "address": { "city": "San
Francisco", "line": "100 Main Street", "zip": 94105 }, "dob": "1982-02-03",
"first_name": "Robert", "interests": [ "electronics", "music", "sports" ],
"last_name": "Smith" }, { "_id": "mdupont", "address": { "city": "San
Jose", "line": "1223 Broadway", "zip": 95109 }, "dob": "1982-02-03",
"first_name": "Maxime", "interests": [ "sports", "movies", "electronics" ],
"last_name": "Dupont" }]).toDF()

spark.saveToMapRDB(df, "/user/mapruser1/table3", create_table=True)

# Load previously saved data from the MapR-DB table
df_loaded_select = spark.loadFromMapRDB("/user/mapruser1/table3")\
    .select("_id","first_name","address")\
    .filter(col("first_name") == "Maxime").show()
```

Joining DataFrames when Loading a Spark DataFrame

The following code sample loads a Spark DataFrame from a MapR Database JSON table and joins the DataFrame with a second DataFrame:

```
%spark.pyspark
df = sc.parallelize([ { "_id": "rsmith", "address": { "city": "San
Francisco", "line": "100 Main Street", "zip": 94105 }, "dob": "1982-02-03",
"first_name": "Robert", "interests": [ "electronics", "music", "sports" ],
"last_name": "Smith" }, { "_id": "mdupont", "address": { "city": "San
Jose", "line": "1223 Broadway", "zip": 95109 }, "dob": "1982-02-03",
"first_name": "Maxime", "interests": [ "sports", "movies", "electronics" ],
"last_name": "Dupont" }, { "_id": "jdoe", "address": None, "dob":
"1970-06-23", "first_name": "John", "interests": None, "last_name":
"Doe" }, { "_id": "dsimon", "address": None, "dob": "1980-10-13",
"first_name": "David", "interests": None, "last_name": "Simon" }, { "_id":
"alehmann", "address": None, "dob": "1980-10-13", "first_name": "Andrew",
"interests": [ "html", "css", "js" ], "last_name": "Lehmann" } ]).toDF()
dfProfessions = sc.parallelize([ { "_id": "rsmith", "profession":
"Engineer" }, { "_id": "alehmann", "profession": "Doctor" }, { "_id":
"alehmann", "profession": "Accountant" }, { "_id": "fake", "profession":
"Software developer" } ]).toDF()

# Save to MapR-DB table
spark.saveToMapRDB(df, "/user/mapruser1/table4", create_table=True)

# Load previously saved data from MapR-DB Table and join with another
DataFrame
df_loaded_select = spark.loadFromMapRDB("/user/mapruser1/table4")\
    .join(dfProfessions, "_id").show()
```

Tutorial Examples

The Zeppelin on MapR Tutorial includes notebooks with Python and Scala code examples using the MapR Database OJAI Connector.

Related concepts

Understanding the MapR Database OJAI Connector for Spark on page 4050
Using the MapR Database OJAI connector for Spark enables you build real-time and batch pipelines between your data and MapR Database JSON. Before getting started, it is important that you understand Spark terminology and workflow, system requirements and support, and OJAI connector and API features.

Accessing MapR Event Store For Apache Kafka in Zeppelin Using the Livy Interpreter

This section contains a MapR Event Store For Apache Kafka streaming example that you can run in your Apache Zeppelin notebook using the Livy interpreter.

Note: See MapR Data Science Refinery Support by MapR Core Version on page 5638 for limitations in version support when accessing MapR Event Store.

The example references a stream named `test_stream` created in the path `/streaming_test/test_stream`. The stream contains a topic called `test_topic`. You can use the following commands to create this stream and topic, but you cannot run them in Zeppelin; they must be run in a MapR cluster.

```
hadoop fs -mkdir /streaming_test
hadoop fs -chown <user>:<group> /streaming_test
sudo su - <user>
maprcli stream create -path /streaming_test/test_stream
maprcli stream topic create -path /streaming_test/test_stream -topic
test_topic
```

last-updated: Apr 11, 2022

When the stream and topic are available, perform the following actions in your notebook:

1. Configure the Livy interpreter. Make sure to follow the steps described in the Spark Jobs on page 3064 section to allow Spark jobs to run in parallel.

2. Create a streaming consumer in your notebook using the `%livy.spark` interpreter:

```
import org.apache.kafka.clients.consumer.ConsumerConfig

import org.apache.spark.SparkConf
import org.apache.spark.streaming.{Seconds, StreamingContext}
import org.apache.spark.streaming.kafka09.{ConsumerStrategies,
KafkaUtils, LocationStrategies}

val ssc = new StreamingContext(sc, Seconds(1))

val topicsSet = Set("/streaming_test/test_stream:test_topic")
val kafkaParams = Map[String, String](
  ConsumerConfig.BOOTSTRAP_SERVERS_CONFIG -> "localhost:9092",
  ConsumerConfig.GROUP_ID_CONFIG -> "none",
  ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> "earliest",
  ConsumerConfig.ENABLE_AUTO_COMMIT_CONFIG -> "false"
)

val consumerStrategy =
      ConsumerStrategies.Subscribe[String, String](topicsSet,
kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
      ssc,
      LocationStrategies.PreferConsistent,
      consumerStrategy)

val lines = messages.map(_.value())
val words = lines.flatMap(_.split(" "))
val wordCounts = words.map(x => (x, 1L)).reduceByKey(_ + _)
wordCounts.print()

ssc.start()
ssc.awaitTerminationOrTimeout(3 * 60 * 1000)
```

3. Create a streaming producer in another notebook, also with the `%livy.spark` interpreter:

```
import java.util.Properties
import org.apache.kafka.clients.producer.{KafkaProducer, ProducerRecord}

val props = new Properties()
props.put("bootstrap.servers", "localhost:9092")
props.put("acks", "all")
props.put("retries", "0")
props.put("batch.size", "16384")
props.put("linger.ms", "1")
props.put("buffer.memory", "33554432")
props.put("key.serializer",
"org.apache.kafka.common.serialization.StringSerializer")
props.put("value.serializer",
"org.apache.kafka.common.serialization.StringSerializer")

val producer = new KafkaProducer[String, String](props)

for (i <- 1 to 1000) {
    val message = new ProducerRecord[String, String]("/streaming_test/
test_stream:test_topic", i.toString(), i.toString())
    producer.send(message)
}
```

4. Start running the consumer notebook from Step 2.

   Wait until the Livy session in YARN for this consumer is initialized and running. You can determine this by locating the session in the YARN resource manager UI:

   The URL for the YARN resource manager is one of the following:

   - Secure cluster:

     ```
     https://<resource-manager-host>:8090
     ```

   - Non-secure cluster:

     ```
     http://<resource-manager-host>:8088
     ```

5. Run the producer notebook from Step 3 several times.

   The consumer notebook has a three-minute timeout that was set by the following line:

   ```
   ssc.awaitTerminationOrTimeout(3 * 60 * 1000)
   ```

   You will see output in the consumer notebook after the timeout has expired.

Accessing MapR Event Store For Apache Kafka in Zeppelin Using the Spark Interpreter
This section contains a MapR Event Store For Apache Kafka streaming example that you can run in your Apache Zeppelin notebook using the Spark interpreter. The Spark interpreter is available starting in the 1.1 release of the MapR Data Science Refinery.

Note: See MapR Data Science Refinery Support by MapR Core Version on page 5638 for limitations in version support when accessing MapR Event Store.

The example references a stream named `test_stream` created in the path `/streaming_test/test_stream`. The stream contains a topic called `test_topic`. You can use the following commands to create this stream and topic, but you cannot run them in Zeppelin; they must be run in a MapR cluster.

```
hadoop fs -mkdir /streaming_test
hadoop fs -chown <user>:<group> /streaming_test
sudo su - <user>
maprcli stream create -path /streaming_test/test_stream
maprcli stream topic create -path /streaming_test/test_stream -topic
test_topic
```

When the stream and topic are available, perform the following actions in your notebook:

1. Configure the Spark interpreter. Make sure to follow the steps described in the Spark Jobs on page 3066 section to allow Spark jobs to run in parallel.

2. Create a streaming consumer in your notebook using the `%spark` interpreter:

```
import org.apache.kafka.clients.consumer.ConsumerConfig

import org.apache.spark.SparkConf
import org.apache.spark.streaming.{Seconds, StreamingContext}
import org.apache.spark.streaming.kafka09.{ConsumerStrategies,
KafkaUtils, LocationStrategies}

val ssc = new StreamingContext(sc, Seconds(1))

val topicsSet = Set("/streaming_test/test_stream:test_topic")
val kafkaParams = Map[String, String](
  ConsumerConfig.BOOTSTRAP_SERVERS_CONFIG -> "localhost:9092",
  ConsumerConfig.GROUP_ID_CONFIG -> "none",
  ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> "latest",
  ConsumerConfig.ENABLE_AUTO_COMMIT_CONFIG -> "false"
)

val consumerStrategy =
      ConsumerStrategies.Subscribe[String, String](topicsSet,
kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
      ssc,
      LocationStrategies.PreferConsistent,
      consumerStrategy)

val lines = messages.map(_.value())
val words = lines.flatMap(_.split(" "))
val wordCounts = words.map(x => (x, 1L)).reduceByKey(_ + _)
wordCounts.print()

ssc.start()
ssc.awaitTermination()
```

3. Create a streaming producer in another notebook, also with the `%spark` interpreter:

```
import java.util.Properties
import org.apache.kafka.clients.producer.{KafkaProducer, ProducerRecord}

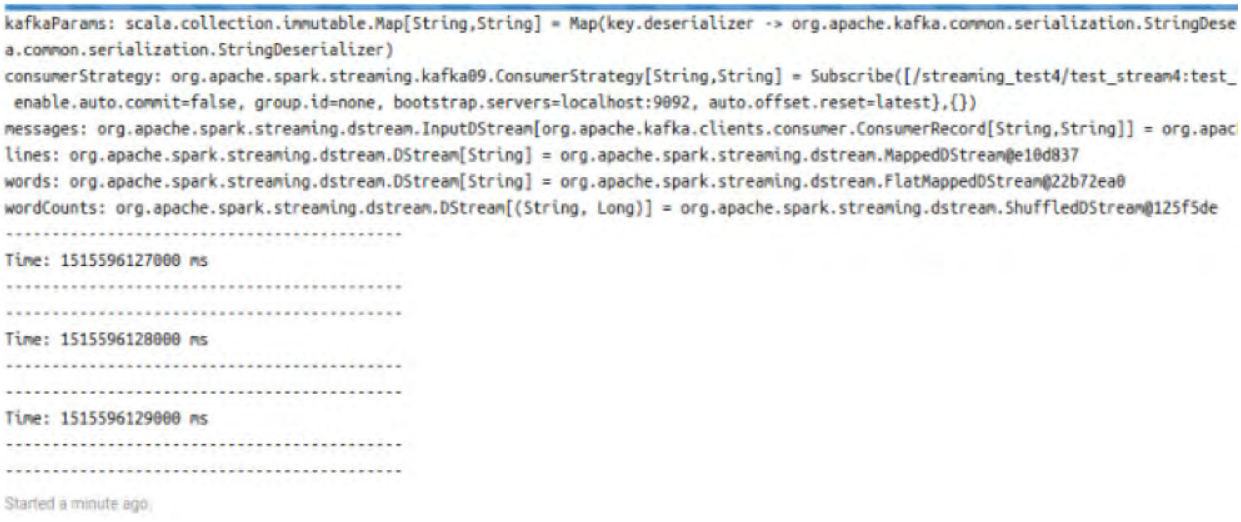
val props = new Properties()
props.put("bootstrap.servers", "localhost:9092")
props.put("acks", "all")
props.put("retries", "0")
props.put("batch.size", "16384")
props.put("linger.ms", "1")
props.put("buffer.memory", "33554432")
props.put("key.serializer",
"org.apache.kafka.common.serialization.StringSerializer")
props.put("value.serializer",
"org.apache.kafka.common.serialization.StringSerializer")

val producer = new KafkaProducer[String, String](props)

for (i <- 1 to 1000) {
    val message = new ProducerRecord[String, String]("/streaming_test/
test_stream:test_topic", i.toString(), i.toString())
    producer.send(message)
}
```

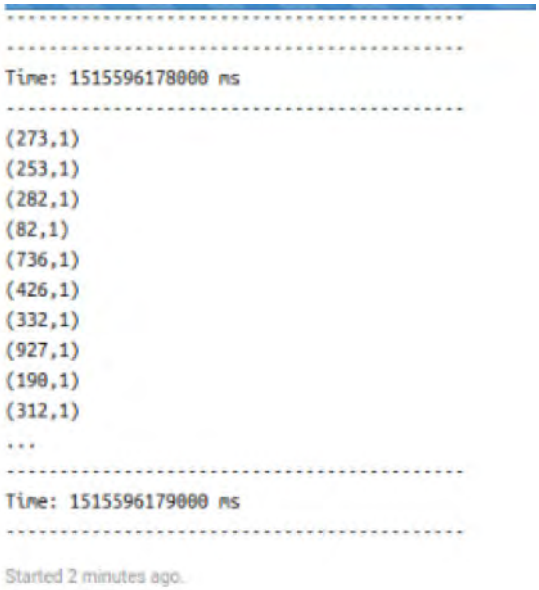
4. Start running the consumer notebook from Step 2.

   Wait until this consumer session is initialized and running. The following sample output in your notebook indicates the session is running:



5. Run the producer notebook from Step 3.

   The consumer notebook displays the following sample output after you run the producer:



Sharing Zeppelin Notebook Content
By default, Zeppelin stores notebooks in the local filesystem in your container. An alternative is to store them in MapR File System. This allows you to share the notebooks with other users.

To store notebooks in MapR File System, see Notebook Storage on page 3040.

For information about other available storage options, see https://zeppelin.apache.org/docs/0.8.0/.

Building your own MapR Data Science Refinery Docker Image

MapR provides a preconfigured and prepackaged Docker image for the MapR Data Science Refinery. Starting with the1.3 release, you can build your own custom Docker image.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Determine the OS of the Docker image you want to build:

Operating System	URL
CentOS	https://package.mapr.com/labs/data-science-refinery/v1.4.0/redhat/
Ubuntu	https://package.mapr.com/labs/data-science-refinery/v1.4.0/ubuntu/

2. Download the Dockerfile corresponding to your OS:

```
wget https://package.mapr.com/labs/data-science-refinery/v1.4.0/redhat/Dockerfile
```

3. Build the Docker image:

```
docker build -t my_custom_dsr .
```

Note: The sample command specifies the current working directory (`.`) as the build path.

4. Confirm that the image appears in the following command's output:

```
docker image list
```

last-updated: Apr 11, 2022

To run and configure the image, see Zeppelin on MapR on page 3033.

MapR Data Fabric for Kubernetes

This section describes how to leverage the capabilities of the MapR Data Fabric for Kubernetes.

MapR Container Storage Interface (CSI) Storage Plugin Configuration

This section describes how to use and troubleshoot the MapR Container Storage Interface (CSI) Storage Plugin.

See MapR Container Storage Interface (CSI) Storage Plugin Overview on page 666 for more information.

Using the MapR Container Storage Interface (CSI) Storage Plugin

This section describes how to configure for static and dynamic provisioning and mounting using example configuration files.

For an overview of the MapR Container Storage Interface (CSI) Storage Plugin, see MapR Container Storage Interface (CSI) Storage Plugin Overview on page 666.

Before You Begin CSI Configuration

Before configuring the MapR Container Storage Interface (CSI) Storage Plugin, be sure to review the following notes about supported and unsupported features and parameters. For an overview of the MapR Container Storage Interface (CSI) Storage Plugin, see MapR Container Storage Interface (CSI) Storage Plugin Overview on page 666.

MapR Parameters for Static and Dynamic Provisioning

In dynamic provisioning, you can specify parameters for the MapR volume to be created. For a list of the parameters that you can use, see `volume create` on page 1931. Note these considerations for using the parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute will generate an error because the value (`1`) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following parameters are ignored because they are redundant, and the CSI Driver configures these parameters automatically during volume creation:
  - `mount`
  - `quota*`
  - `createparent`
  - `path`
  - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) makes it unnecessary to set the `quota` parameter. For an example, see Example: Statically Provisioning a Volume Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3111.

last-updated: Apr 11, 2022

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. Access modes can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. MapR Container Storage Interface (CSI) Storage Plugin supports ROX (ReadOnlyMany), RWO (ReadWriteOnce) and RWX (ReadWriteMany) access modes for the PV and PVC spec. See Kubernetes CSI documentation for more information.

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes CSI Drivers, so it cannot be used with the Kubernetes Interfaces for Data Fabric. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the MapR volume are deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported
Retain	The PersistentVolume and the MapR volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported

For more information about the reclaim policy, see Change the Reclaim Policy of a PersistentVolume.

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the MapR Container Storage Interface (CSI) Storage Plugin.

Configuring Static and Dynamic Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin

This page summarizes the high-level steps for configuring the MapR Container Storage Interface (CSI) Storage Plugin after installation to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see Static and Dynamic Volume Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin on page 667.

Static Provisioning

1. Create the ticket secret and deploy the secret in the Pod only if the volume is on a secure MapR cluster.

   See Configuring a Secret on page 3167 for more information.

2. Configure a PersistentVolume in your Pod spec or as part of a separate configuration file and provide information about the MapR volume.

   See Example: Statically Provisioning a Volume Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3111, Persistent Volumes, and Example: Mounting a PersistentVolume for Static Provisioning on page 3113.

3. Configure a PersistentVolumeClaim in your Pod spec or as part of a separate configuration file.

   See PersistentVolumeClaims.

4. Run the Pod spec using `kubectl` commands.

   See Overview of kubectl.

last-updated: Apr 11, 2022

Dynamic Provisioning

1. Create the REST and ticket secrets and deploy the secrets in the Pod only if the volume is on a secure MapR cluster.
   See Configuring a Secret on page 3167 for more information.
2. Create a storage class in your Pod spec or in a separate configuration file.
   See Storage Classes and Example: Mounting a PersistentVolume for Dynamic Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin on page 3120.
3. Configure a PersistentVolumeClaim in your Pod spec or in a separate configuration file.
   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin on page 3120.
4. Run the Pod spec using `kubectl` commands.
   See Overview of kubectl.

Configuring Static and Dynamic Provisioning for a Raw Block Volume

Raw block volumes are supported for both static and dynamic provisioning. To request a raw-block PersistentVolumeClaim, set `volumeMode: Block`. If not specified, `volumeMode` defaults to `Filesystem` in the PersistentVolumeClaimSpec. PersistentVolumes also have a `volumeMode` field in the PersistentVolumeSpec that is used for static provisioning. `Block`-type PVCs can only bind to `Block`-type PVs.

All the features supported on `Filesystem`-persistent volumes are supported on `Block` volumes. For example:

- Create and Delete Volumes
- Expand Volumes
- Clone Volumes
- Create and Delete Snapshot
- Snapshot Restore

Block volumes are supported only in single-node-writer access modes. At any given time, they can only be published once as read/write on a single node. For `Block` volumes, the CSI driver does not format the block device; it just binds the block device to the target path. The application pod can choose to format the block device to any required Linux file system, such as ext4, xfs, btrfs, and others.

Each block volume is stored in an HPE Ezmeral Data Fabric file. Statically provisioned block files are located at the path designated in the `volumePath` specified in the persistent volume definition. Dynamically provisioned block files are located at the path designated by the `mountPrefix` in the storage class. For fast, random block-write performance, these files should not be erasure coded (warm tiering) or tiered off to an objectstore (cold tiering).

Static Provisioning Example

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-blockpv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  volumeMode: Block
```

last-updated: Apr 11, 2022

```
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5G
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/user/guest/myblockvolume"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      platinum: "true"
      capacityBytes: "5000000000"
```

Note: For the Loopback NFS CSI driver, change `driver` to `com.mapr.csi-nfskdf`.

Dynamic Provisioning Example

Note that no change in the StorageClass is required:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-block-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  volumeMode: Block
  resources:
    requests:
      storage: 5G
```

Pod Specification

In the pod specification, you must specify `volumeDevices` and `devicePath` for the block volume instead of `volumeMounts` and `mountPath`.

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-block-pod
spec:
  containers:
    - name: fc-container
      image: fedora:26
      command: ["/bin/sh", "-c"]
      args: [ "tail -f /dev/null" ]
      volumeDevices:
        - name: data
          devicePath: /dev/xvda
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: test-secure-block-pvc
```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. For more information about Secrets, see Secrets.

last-updated: Apr 11, 2022

The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. For more information about security and Secrets, see Security Properties. Specifically, it is important to turn on encryption at rest for Secrets. See Encrypting Secret Data at Rest.

During installation of the Driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see Secrets in the Kubernetes documentation.

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a MapR user to the provisioner. This user must have privileges to create and delete a MapR volume. The credentials allow the provisioner to make REST calls to the MapR webserver. Secrets are protected by the Kubernetes RBAC.

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
 MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example.

Parameter	Notes
`MAPR_CLUSTER_USER`	The base64 representation of a MapR user that has the ability to create and delete MapR volumes. See Converting a String to Base64 on page 3169.

MAPR_CLUSTER_PASSWORD	The base64 representation of the password for the user defined by the MAPR_CLUSTER_USER parameter. See .Converting a String to Base64 on page 3169
MAPR_CLUSTER_TICKET	The base64 representation of the ticket contents generated on the data-fabric cluster using the maprlogin utility. For dynamic provisioning, with the latest CSI drivers, you can configure a data-fabric ticket to authenticate to the data-fabric webserver to make REST calls. This parameter is provided as a Beta feature.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure MapR cluster. The ticket for the POSIX client can be generated on the MapR cluster using the maprlogin on page 2130 utility.

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the CONTAINER_TICKET field in the ticket Secret example.

Parameter	Notes
CONTAINER_TICKET	Base64-encoded ticket value. See Converting a String to Base64 on page 3169.

To create the secret:

1. Run the following command to create the Secret file:

   ```
   kubectl create -f <secret-file-name>.yaml
   ```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

   See Converting a String to Base64 on page 3169.

3. Add the base64 representation of sensitive data in the Secret file.

   For more information about the format of the Secret files, see REST Secrets on page 3108 and Ticket Secrets on page 3109 earlier in this section.

4. Deploy the secret on the pod by running the following command:

   ```
   kubectl apply -f <secret-file-name>.yaml
   ```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

last-updated: Apr 11, 2022

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name `mapr` is `bWFwcg==`.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTXOqsXYPTnqRJl6/
mlWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRUOtKBG9gp65bsZN9Kphnr/
Wp15z8D3O2go951CANes/
7QQllYVP7l2BOpGR6I1zIrC3XGwI8OQWT61qpsjSVZv8zO5oQ5GDYQTkPttI/yAk/
uJBES1ohCz38n9HgYALLvMALVsBPtUtG+cNGc1ktUDDMR2q1EgVzdJbuYsOuHnZX3LO3euKDGl4C
4MCmrv9DWiWJxwiZ1yZu69GbZJlXxqLOQBlkdMoTXk=" | base64

Y2x1c3RlcjIgUHVHMGxwdVBYdUR4ajlFUmdLQ1RYT3FzWFlQVG5xUkpsNi9tbFdKamRWS3ZFNXI0
NlFTMkJoOW5DK0k0UmN1MEd0bldSVU90S0JHOWdwNjVic1pOOUtwaG5yL1dwMTV6OEQzTzJnbzk1
MUNBTmVzLzdRUWxsWVZQN2wyQk9wR1I2STF6SXJDM1hHd0k4T1FXVDYxcXBzalNWWnY4ek81b1E1
R0RZUVRrUHR0SS95QWsvdUpCRVMxb2hDejM4bjlIZ1lBTEx2TUFMVnNCUHRVdEcrY05HYzFrdFVE
RE1SMnExRWdWemRKYnVZc091SG5aWDNMTzNldUtER2w0QzRNQ21ydjlEV2lXSnh3aVoxeVp1NjlH
YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

Note: Another method for converting values to base64 is to use an Internet tool such as https://www.base64encode.org to encode or decode data.

Best Practices for Using Tickets

When using secure MapR clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see How Impersonation Works on page 1478 and maprlogin on page 2130.
- Match the security context `runAsUser:` ID and `fsGroup:` group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

last-updated: Apr 11, 2022

Example: Statically Provisioning a Volume Using the MapR Container Storage Interface (CSI) Storage Plugin

You can designate a volume for use with Kubernetes by specifying the volume parameters directly inside the PersistentVolume spec.

Suppose you want to get an application container up and running quickly in the MapR Data Platform. You already have a file-system path that you want to use for the application. You only need the data accessible to read. To make this work, you must do the following:

1. Generate a service ticket and set the `securityType` parameter in the PersistentVolume spec to `secure` if the volume to mount is on a secure cluster.

   See Generating a Service Ticket on page 1428 for more information. For example:

```
kind: PersistentVolume
metadata:
  name: pv-securepv-test
  namespace: test-csi
  spec:
    accessModes:
    …
    csi:
      …
      volumeAttributes:
        …
        securityType: "secure"
```

2. If the volume to mount is on a secure cluster, configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret.

   For more information, see Configuring a Secret on page 3167. The following table describes the properties of the Secret file:

Property	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`namespace`	The namespace in which the Secret runs.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.
`CONTAINER_TICKET`	The contents of the ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3169. You may remove the ticket if the cluster is not secure.

3. Set the `runAsUser` and the `fsGroup` parameters in the pod spec to the UID and GID of the user that created the ticket.

   For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv1
  namespace: test-csi
spec:
  ...
  securityContext:
    runAsUser: 1000
```

last-updated: Apr 11, 2022

```
    fsGroup:2000
  ...
```

The following table lists the properties specified in the sample pod spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. For clarity, the example uses a naked pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs.
`numrpcthreads`	Sets the number of RPC threads for the data-fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.

4. Point the `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information.

   For the complete list of volume attributes, see `volume create` on page 1931; however, note that volume attributes like `mount`, `quota`, `createparent`, `path`, and `name` are ignored when provisioning a volume. For more information, see MapR Parameters for Static and Dynamic Provisioning on page 3104.

   For example:

   FUSE

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      platinum: "true"
```

   Loopback NFS

```
apiVersion: v1
kind: PersistentVolume
metadata:
```

```
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-nfskdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
```

The following table lists the properties shown in the sample PersistentVolume spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`accessModes`	How the PersistentVolume is mounted on the host. All modes work the same.  **Note:** The PV and PVC modes must be the same so that they can bind. For more information, see Access Modes.
`csi: driver`	The CSI Driver being used. Call it using one of these drivers: • FUSE driver: `com.mapr.csi-kdf` • Loopback NFS driver: `com.mapr.csi-nfskdf`
`csi: volumeHandle`	The existing volume name or unique volume name for static provisioning.
`volumePath`	The mount point within the filesystem. This parameter specifies an existing MapR path.
`cluster`	The cluster name.
`cldbHosts`	The DNS names or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether tickets are used or not used. If tickets are used, specify `secure`. Otherwise, specify `unsecure`.

Example: Mounting a PersistentVolume for Static Provisioning

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a pod spec:

- The configuration file can be shared for use by multiple pod specs.

last-updated: Apr 11, 2022

- The configuration file enables the PersistentVolume to be mounted and available even when the pod spec that references it is removed.

For example, suppose a marketing volume exists in the secure MapR File System under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must do the following:

1. Create a PersistentVolume (PV) (if you have already not statically provisioned a MapR volume as described in this example) and set the following volumeAttributes:
   - `accessMode` of the PV to `ReadWriteOnce`
   - `securityType` parameter to `secure` because the volume is on a secure MapR cluster
   - `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information
   - `platinum` parameter to use the POSIX platinum client or the `license` parameter to select from three POSIX clients

   For example:

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
  labels:
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.102.96"
      securityType: "secure"
      platinum: "true"
```

   The preceding example specifies the high-performance Platinum POSIX license by including `platinum: "true"` in the `volumeAttributes`.

   If you have a Platinum FUSE POSIX license, Release 1.0.2 and later provide another way to control the POSIX client. Instead of specifying `platinum: "true"`, you can specify `license: "<license-name>"` and select one of three POSIX licenses (Basic, Container, or Platinum). Release 1.0.2 also adds support for a `startupConfig` line that lets you pass custom startup parameters to the FUSE process. The following example shows these options:

```
apiVersion: v1
kind: PersistentVolume
metadata:
```

last-updated: Apr 11, 2022

```
  name: test-simplepv
  namespace: test-csi
  labels:
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteMany
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterB"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      license: "container"
      startupConfig: "-o allow_other -o big_writes -o auto_unmount -o
async_dio -o max_background=24 -o auto_inval_data --disable_writeback"
```

The following table shows the properties defined in the sample PersistentVolume:

Parameter	Notes
`metadata: name`	The PersistentVolume name.
`metadata: namespace`	The namespace in which the PersistentVolume is stored.
`accessModes`	How the PersistentVolume is mounted on the host. All modes work the same. The example uses `ReadWriteOnce`. Note that `ReadOnlyMany` does not mount read-only. **Note:** The accessMode is not used to set the access mode bit on the volume. The accessMode of the PV and PVC should be the same so that they can bind. For more information, see Access Modes.
`persistentVolumeReclaimPolicy`	Specifies what happens to the volume when it is released by its claim. The `Retain` value keeps the PVC around for manual cleanup. `Delete` deletes the PV from Kubernetes. **Note:** If this volume was created using dynamic provisioning, `Delete` causes the underlying volume to be deleted. For more information, see Reclaiming.
`capacity`	Specifies how big the allocated storage should be. This value is not validated against the MapR quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
`csi: nodePublishSecretRef`	The Ticket Secret for the CSI driver.
`nodePublishSecretRef:name`	The name of the Ticket Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3167.
`nodePublishSecretRef:namespace`	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the PersistentVolume.
`csi: driver`	The MapR CSI driver being used. Call it by specifying driver: `mapr.com/maprfs`.

last-updated: Apr 11, 2022

`volumeHandle`	The existing volume name or unique volume name for static provisioning.
`volumePath`	The mount point within the MapR File System. This parameter specifies an existing MapR path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`cluster`	The MapR cluster name.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`platinum`	If set to `platinum: "true"`, the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and MapR Platinum licenses.
`license` (FUSE POSIX)	Release 1.0.2 and later support the `license: "<license-name>"` parameter in addition to the `platinum: "<true | false>"` parameter for the FUSE POSIX plugin. The `license: "<license-name>"` parameter can have one of three values that control the number of host resources that are consumed: • `"container"` for the Container driver (one binary, 8 threads) • `"basic"` for the Basic driver (one binary, 64 threads) • `"platinum"` for the Platinum driver (multiple binaries, each running 64 threads) Note the following considerations for using the `license: "<license-name>"` parameter: • To use the `license: "<license-name>"` parameter, you must have a Platinum license. • If you specify both the `platinum: "<true | false>"` parameter and the `license: "<license-name>"` parameter, the `platinum: "<true | false>"` parameter overrides the `license: "<license-name>"` parameter. • If neither the `platinum: "<true | false>"` nor the `license:` parameter is specified, the `container` driver is implemented.

`startupConfig` (FUSE POSIX)	Release 1.0.2 and later support specifying the `startupConfig` line. The `startupConfig` line allows you to specify FUSE configuration parameters that are passed to the `fuse.conf` file. For the parameters that can be passed, see Configuring the MapR FUSE-Based POSIX Client on page 1240.
	If no `startupConfig` line is specified, these default startup settings are used:
	`"-o allow_other -o big_writes -o auto_unmount"`
	The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the filesystem when the process is terminated.
	The following example includes the three default settings and adds some additional settings (shown in **bold**):
	`startupConfig: "-o allow_other -o big_writes -o auto_unmount` **`-o async_dio -o max_background=24 -o auto_inval_data --disable_writeback`**`"`
	The additional settings enable asynchronous direct I/O, set the maximum number of asynchronous requests to 24, automatically invalidate the kernel FUSE cache for any data change that causes a change in the files, and disable the writeback cache.

last-updated: Apr 11, 2022

`startupConfig` (Loopback NFS)	The `startupConfig` line allows you to specify configuration parameters that are passed to the `nfsserver.conf` file. For the parameters that can be passed, see nfsserver.conf on page 2207. The `startupConfig` values supported for Loopback NFS are all the configs supported in the `nfsserver.conf` file. Values must be separated by a space. If no `startupConfig` line is specified, these default startup settings are used: `startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"`
`trackMemory`	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is `false`.
`logLevel`	Sets the log level to one of the following values: `error`, `warn`, `info`, or `debug`. For the FUSE POSIX driver (`com.mapr.csi-kdf`), the default value is `error`. For the Loopback NFS driver (`com.mapr.csi-nfskdf`), the default value is `info`.
`retainLogs`	Retains the logs for the pod on the host machine. The default value is `false`.

See Example: Statically Provisioning a Volume Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3111 for more information.

2. Create a PersistentVolumeClaim (PVC) spec and set the `accessMode` of the PVC to `ReadWriteOnce`.

   For example:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-simplepvc
  namespace: test-csi
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

   The following table shows the properties used in the sample PersistentVolumeClaim:

Parameter	Notes
`metadata: name`	The PersistentVolumeClaim name.
`metadata: namespace`	The namespace in which the PersistentVolumeClaim is configured.
`accessMode`	How the requested PersistentVolume is mounted on the host. All modes work the same. The example uses `ReadWriteOnce`. Note that `ReadOnlyMany` does not mount read-only.  **Note:** The PV and PVC modes should be the same so that they can bind. For more information, see Access Modes.

3. Generate a service ticket, and create and deploy a ticket secret on the pod (if you have already not done it as described in steps 1 and 2 of this example).

   See `maprlogin on page 2130` for information on generating a ticket and Configuring a Secret on page 3167 for information on creating and deploying a ticket secret.

4. Create the pod spec and set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.

last-updated: Apr 11, 2022

For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv
  namespace: test-csi
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "1000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-simplepvc
```

The following table shows the properties defined in the sample pod spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. The example uses a naked pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs.
`numrpcthreads`	Sets the number of RPC threads for the data-fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. Matches with `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

last-updated: Apr 11, 2022

5. Deploy the `.yaml` file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each Pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the MapR cluster. You can run the `node list` on page 1705 command on the MapR cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientsonly true
clienttype       clienthealth hostname
ip                                        lasthb  id
posixclientbasic Inactive     4f3d34fe-2007-11e9-8980-0cc47ab39644

  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

Example: Mounting a PersistentVolume for Dynamic Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin

This example also uses a PersistentVolume. However, unlike the previous example, when you use the dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want MapR and Kubernetes cluster administrators to create storage manually to store the pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes administrator has created a storage class called `test-secure-sc` for pod creators to use when they want to create persistent storage for their pods. In this example, it is important for the created pod storage to survive the deletion of a pod.

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX provisioner (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS provisioner (`com.mapr.csi-nfskdf`).

last-updated: Apr 11, 2022

To dynamically provision a volume, you must do the following:

1. Generate a user ticket, and create and deploy a ticket secret on the pod. See:
   - Best Practices for Using Tickets on page 3170 to select the right ticket
   - maprlogin on page 2130 for information about generating a ticket
   - Configuring a Secret on page 3167 for information about creating and deploying a ticket secret
2. Create the REST secret and deploy the secret on the pod.
   See Configuring a Secret on page 3167 for information about creating and deploying a ticket secret.
3. Create a StorageClass similar to the following:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: test-secure-sc
  namespace: test-csi
provisioner: com.mapr.csi-kdf
allowVolumeExpansion: true
reclaimPolicy: Delete
parameters:
    csiProvisionerSecretName: "mapr-provisioner-secrets"
    csiProvisionerSecretNamespace: "test-csi"
    csiNodePublishSecretName: "mapr-ticket-secret"
    csiNodePublishSecretNamespace: "test-csi"
    restServers: "10.10.10.210:8443"
    cldbHosts: "10.10.10.210:7222"
    cluster: "clusterA"
    securityType: "secure"
    namePrefix: "csi-pv"
    mountPrefix: "/csi"
    advisoryquota: "100M"
    trackMemory: "false"
    logLevel: "error"
    retainLogs: "false"
```

   For more information, see Storage Classes. The following table shows the properties defined in the sample StorageClass:

Property	Description
`apiVersion`	The Kubernetes API version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the StorageClass. Administrators should specify the name carefully because it will be used by pod authors to help select the right StorageClass for their needs.
`metadata: namespace`	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and pod, since the StorageClass namespace can be a cross-namespace resource.
`provisioner`	The provisioner being used. For the FUSE POSIX provisioner, specify `com.mapr.csi-kdf`. For the Loopback NFS provisioner, specify `com.mapr.csi-nfskdf`.
`csiNodePublishSecretName`	The name of the Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3167.

last-updated: Apr 11, 2022

Property	Description
`csiNodePublishSecretNamespace`	The namespace that contains the Secret. Use the same namespace as the namespace used by the pod.
`csiProvisionerSecretName` (deprecated) `csi.storage.k8s.io/provisioner-secret-name`	The name of the Kubernetes Secret that is used to store MapR administrative credentials (user, password, and ticket information for the MapR webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 3167.
`csiProvisionerSecretNamespace` (deprecated) `csi.storage.k8s.io/provisioner-secret-namespace`	The namespace for the Secret containing the MapR administrative credentials (user name and password information for a MapR user that has the privileges to create volumes). This namespace can be different from the namespace used by the pod, since a pod author or namespace admin might not be trusted to create administration Secrets for the MapR cluster.
`restServers`	A space-separated list of MapR webservers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`cluster`	The MapR cluster name.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`namePrefix`	A prefix for the MapR volume to be created. For example, if you specify PV as the `namePrefix`, the first dynamically created volume might be named `PV.bevefsescr`. The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.
`mountPrefix`	The parent path of the mount in the MapR filesystem. If you do not specify a mount prefix, the provisioner mounts your volume under the MapR root. **Note:** User provisioning a volume under this `mountPrefix` requires read-write permissions to mount the newly created volume; otherwise, the volume provision will fail.
`advisoryquota`	The advisory storage quota for the volume. The `advisoryquota` is one of the MapR parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 3151.
`trackMemory`	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is `false`.
`logLevel`	Sets the log level to one of the following values: `error`, `warn`, `info`, or `debug`. For the FUSE POSIX driver (`com.mapr.csi-kdf`), the default value is `error`. For the Loopback NFS driver (`com.mapr.csi-nfskdf`), the default value is `info`.
`retainLogs`	Retains the logs for the pod on the host machine. The default value is `false`.

4. Configure a PersistentVolumeClaim similar to the following:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
```

```
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

The following table shows the properties defined in the sample PersistentVolumeClaim:

Property	Description
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. This is a PersistentVolumeClaim (PVC).
`metadata: name`	The PVC name.
`metadata: namespace`	The namespace in which the PVC runs. This should be the same namespace used by the pod.
`storageClassName`	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes.
`accessModes`	How the PersistentVolume is mounted on the host. For more information, see Access Modes.
`requests: storage`	The storage resources being requested, or that were requested and have been allocated. The pod author can use this parameter to specify how much quota is needed for the MapR volume. For the units, see Resource Model.

5. Create the pod spec similar to the following:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-pod
  namespace: test-csi
spec:
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "1000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc
```

The following table shows the properties defined in the sample pod spec:

Property	Description
`apiVersion`	The Kubernetes API version for the pod spec.

last-updated: Apr 11, 2022

Property	Description
`kind`	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs. It should be the same namespace in which the PVC runs.
`numrpcthreads`	Sets the number of RPC threads for the data-fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. The value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

6. Deploy the `.yaml` file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the MapR cluster. You can run the `node list on page 1705` command on the cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientsonly true
clienttype clienthealth hostname ip lasthb id

Example: Volume Cloning for Dynamic Provisioning

last-updated: Apr 11, 2022

You can clone a volume from an existing volume by configuring a PersistentVolumeClaim that specifies the volume PVC as the data source. In the following example, the PVC named `testcsi-secure-pvc` serves as the data source for creating a new volume named `testcsi-secure-pvc-clone`:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: testcsi-secure-pvc-clone
 namespace: test-csi
spec:
 storageClassName: testcsi-secure-sc
 accessModes:
    - ReadWriteOnce
 resources:
 requests:
 storage: 10G
 dataSource:
 kind: PersistentVolumeClaim
 name: testcsi-secure-pvc
```

When cloning extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to clone the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting for the `csi-provisioner` sidecar container. See the `--timeout` argument in the latest `csi-maprkdf-<version>.yaml`.

For more information, see CSI Volume Cloning.

Example: Volume Expansion for Dynamic Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin

The following versions of the MapR Container Storage Interface (CSI) Storage Plugin support a volume expansion feature for dynamically provisioned volumes:

- FUSE POSIX plugin versions 1.1.0 and later
- Loopback NFS plugin versions 1.0.0 and later

Volume expansion means you can increase the storage quota of volumes created by the CSI driver. Note that the `StorageClass` must have `allowVolumeExpansion` set to `true` for volume expansion to succeed. For more information about volume expanssion, see Expanding Persistent Volume Claims.

To use volume expansion, increase the storage value and reapply the PersistentVolumeClaim configuration. For example, in the following PVC configuration, to increase the storage quota for the volume from 5G to 10G, change `storage: 5G` to `storage: 10G`, and run the `kubectl apply -f <path_to_pvc>.yaml` command:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

Once the pod spec is installed, you can verify the status of a PersistentVolumeClaim and/or a PersistentVolume by using the `kubectl` command. For example:

1. Run the Kubernetes `get` command to verify the status of the PersistentVolumeClaim:

   Note: The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

Static Provisioning

```

```

Managing Snapshots Using the MapR Container Storage Interface (CSI) Storage Plugin

This section describes how to create and delete one or more snapshots of volumes dynamically provisioned by the MapR Container Storage Interface (CSI) Storage Plugin on the MapR cluster.

The MapR Container Storage Interface (CSI) Storage Plugin v1.x.x uses the `csi-snapshotter` to support snapshot provisioning.

CSI now supports snapshot restore, which allows you to create a new volume from the snapshot data of another volume. See Creating a Volume from a Snapshot on page 3146. To manually restore a volume, see Copying From a Snapshot Using the CLI on page 951.

Creating a Snapshot Using the MapR Container Storage Interface (CSI) Storage Plugin

You can create one or more snapshots of a dynamically provisioned volume using the MapR Container Storage Interface (CSI) Storage Plugin.

Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster

1. Verify that the volume was successfully provisioned by checking the PersistentVolume (PV) and PersistentVolumeClaim (PVC) for the volume.

   For example, run the describe `kubectl command` to verify the PV and then the PVC.

```
# kubectl describe pv -n test-csi
Name:            mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Labels:          <none>
Annotations:     pv.kubernetes.io/provisioned-by: com.mapr.csi-kdf
Finalizers:      [kubernetes.io/pv-protection]
StorageClass:    test-secure-sc
Status:          Bound
Claim:           test-csi/test-secure-pvc
Reclaim Policy:  Delete
Access Modes:    RWO
VolumeMode:      Filesystem
Capacity:        5Gi
Node Affinity:   <none>
Message:
Source:
    Type:              CSI (a Container Storage Interface (CSI) volume
source)
    Driver:            com.mapr.csi-kdf
    VolumeHandle:      csisc-securesc.txiqvsdxwu

test-secure-pvc"
  Normal     ProvisioningSucceeded  3m40s
com.mapr.csi-kdf_csi-controller-kdf-0_69805ad1-2010-11e9-88dc-d610076b9fb
3  Successfully provisioned volume
mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Mounted By:  test-secure-pod
```

2. Deploy the REST secret `.yaml` file by running the following command:

```
kubectl apply -f <secret filename>.yaml
```

   The Secret file should look similar to the following:

```
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
apiVersion: v1
kind: Secret
metadata:
  name: mapr-snapshot-secrets
  namespace: test-csi
type: Opaque
data:
  MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

   For more information, see Configuring a Secret on page 3167.

3. Create a snapshot class for provisioning a snapshot of the volume. For example, the snapshot class file should look similar to the following:

   FUSE

```
apiVersion: snapshot.storage.k8s.io/v1beta1
kind: VolumeSnapshotClass
metadata:
 name: testcsi-snapshotclass
 namespace: test-csi
driver: com.mapr.csi-kdf
deletionPolicy: Delete
parameters:
 restServers: "10.10.102.95:8443"
 cluster: "mycluster"
 csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
 csi.storage.k8s.io/snapshotter-secret-namespace: test-csi
```

   Loopback NFS

```
apiVersion: snapshot.storage.k8s.io/v1beta1
kind: VolumeSnapshotClass
metadata:
 name: testcsi-snapshotclass
 namespace: test-csi
driver: com.mapr.csi-nfskdf
```

```
deletionPolicy: Delete
parameters:
 restServers: "10.10.102.95:8443"
 cluster: "mycluster"
 csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
 csi.storage.k8s.io/snapshotter-secret-namespace: test-csi
```

The sample snapshot class file shown above contains the following properties:

Property	Description
`apiVersion`	The Kubernetes APi version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the snapshot calss. Administrators should specify the name carefully because it will be used by Pod authors to help select the right snapshot class for their needs.
`metadata: namespace`	The namespace in which the snapshot class runs.
`driver`	The CSI volume plugin to use for provisioning the volume snapshots. For example: `com.mapr.csi-kdf`.
`restServers`	A space-separated list of webservers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cluster`	The cluster name.
`csiSnapshotterSecretName` (deprecated) `csi.storage.k8s.io/snapshotter-secret-name`	The name of the Kubernetes Secret that is used to store administrative credentials (user, password, and ticket information for the webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 3167.
`csiSnapshotterSecretNamespace` (deprecated) `csi.storage.k8s.io/snapshotter-secret-namespace`	The namespace for the Secret containing the administrative credentials (user name and password information for a user that has the privileges to create volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the cluster.

4. Deploy the snapshot class by running the following command:

```
kubectl apply -f <snapshot class>.yaml
```

5. Verify whether the snapshot class was successfully deployed by running one of the following commands:

```
# kubectl get volumesnapshotclass -n test-csi
NAME                 AGE
test-snapshotclass   41s
root@qa102-92:~/csi-kdf-3/csi-kdf/examples/snapshot# kubectl describe
volumesnapshotclass -n test-csi
Name:         test-snapshotclass
Namespace:
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
                {"apiVersion":"snapshot.storage.k8s.io/
v1alpha1","kind":"VolumeSnapshotClass","metadata":{"annotations":
{},"name":"test-snapshotclass"},"p...
API Version:  snapshot.storage.k8s.io/v1alpha1
Kind:         VolumeSnapshotClass
Metadata:
  Creation Timestamp:  2019-01-24T21:13:35Z
  Generation:          1
  Resource Version:    1039219
  Self Link:           /apis/snapshot.storage.k8s.io/v1alpha1/

  Csi Snapshotter Secret Namespace:     test-csi
  Name Prefix:                          test-snapshot
  Rest Servers:                         10.10.10.210:8443
Snapshotter:                            com.mapr.csi-kdf
Events:                                 <none>
```

```
# kubectl get volumesnapshotclass -n test-csi -o yaml
apiVersion: v1
items:
- apiVersion: snapshot.storage.k8s.io/v1alpha1
  kind: VolumeSnapshotClass
  metadata:
    annotations:
      kubectl.kubernetes.io/last-applied-configuration: |
        {"apiVersion":"snapshot.storage.k8s.io/
v1alpha1","kind":"VolumeSnapshotClass","metadata":{"annotations":
{},"name":"test-snapshotclass"},"parameters":
{"cluster":"clusterA","csiSnapshotterSecretName":"mapr-snapshot-secrets",
"csiSnapshotterSecretNamespace":"test-csi","namePrefix":"test-snapshot","
restServers":"10.10.10.210:8443"},"snapshotter":"com.mapr.csi-kdf"}
    creationTimestamp: "2019-01-24T21:13:35Z"
    generation: 1
    name: test-snapshotclass
    resourceVersion: "1039219"
    selfLink: /apis/snapshot.storage.k8s.io/v1alpha1/
volumesnapshotclasses/test-snapshotclass
    uid: e94a1fc8-201c-11e9-84c0-0cc47ab39644
  parameters:
    cluster: clusterA
    csiSnapshotterSecretName: mapr-snapshot-secrets
    csiSnapshotterSecretNamespace: test-csi
    namePrefix: test-snapshot
    restServers: 10.10.10.210:8443
  snapshotter: com.mapr.csi-kdf
kind: List
```

last-updated: Apr 11, 2022

```
metadata:
  resourceVersion: ""
  selfLink: ""
```

6. Associate the snapshot class with the PersistentVolumeClaim (for the volume to take a snapshot of) by creating a VolumeSnapshot. For example, the VolumeSnapshot file should look similar to the following:

```
apiVersion: snapshot.storage.k8s.io/v1beta1
kind: VolumeSnapshot
metadata:
 name: testcsi-secure-snapshot
 namespace: test-csi
spec:
 volumeSnapshotClassName: testcsi-snapshotclass
 source:
    persistentVolumeClaimName: testcsi-secure-pvc
```

   The sample VolumeSnapshot file shown above contains the following properties:

Property	Description
`metadata: name`	The VolumeSnapshot name.
`metadata: namespace`	The namespace in which the VolumeSnapshot runs.
`snapshotClassName`	The volumeSnapshotClassName.
`source: name`	The persistentVolumeClaimName.

7. Deploy the VolumeSnapshot by running the following command:

```
kubectl apply -f <volume snapshot>.yaml
```

8. Verify whether VolumeSnapshot was successfully deployed by doing the following:

last-updated: Apr 11, 2022

a) Run one of the following commands to retrieve the VolumeSnapshot:

```
# kubectl get volumesnapshot -n test-csi -o yaml
apiVersion: v1
items:
- apiVersion: snapshot.storage.k8s.io/v1alpha1
  kind: VolumeSnapshot
  metadata:
    annotations:
      kubectl.kubernetes.io/last-applied-configuration: |
        {"apiVersion":"snapshot.storage.k8s.io/
v1alpha1","kind":"VolumeSnapshot","metadata":{"annotations":
{},"name":"test-snapshot","namespace":"test-csi"},"spec":
{"snapshotClassName":"test-snapshotclass","source":
{"kind":"PersistentVolumeClaim","name":"test-secure-pvc"}}}
    creationTimestamp: "2019-01-24T21:16:21Z"
    finalizers:
    - snapshot.storage.kubernetes.io/volumesnapshot-protection
    generation: 5
    name: test-snapshot
    namespace: test-csi
    resourceVersion: "1039445"
    selfLink: /apis/snapshot.storage.k8s.io/v1alpha1/namespaces/
test-csi/volumesnapshots/test-snapshot
    uid: 4c5293bc-201d-11e9-84c0-0cc47ab39644
  spec:

```

9. Log in to the cluster and verify by running the `volume snapshot list` on page 2030 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365090744,
    "timeofday":"2019-01-24 01:24:50.744 GMT-0800 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Creating Multiple Snapshots of a Dynamically Provisioned Volume

1. Perform steps 1 - 5 described in the Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 3135 section.

last-updated: Apr 11, 2022

2. Create a VolumeSnapshot similar to the one shown in step 6 of the Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 3135 section for each additional snapshot to create for the volume.

   For example:

   ```
   apiVersion: snapshot.storage.k8s.io/v1alpha1
   kind: VolumeSnapshot
   metadata:
     name: test-snapshot1
     namespace: test-csi
   spec:
     snapshotClassName: test-snapshotclass
     source:
       name: test-secure-pvc
       kind: PersistentVolumeClaim
   ```

3. Repeat step 7 in Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 3135 for each additional volume snaphots you have created.

4. Log in to the cluster and verify by running the `volume snapshot list` on page 2030 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365359138,
    "timeofday":"2019-01-24 01:29:19.138 GMT-0800 PM",
    "status":"OK",
    "total":2,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        },
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000052",

"snapshotname":"mapr-snapshot-19282d27-201f-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:29:15 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Deleting a Snapshot of a Dynamically Provisioned Volume

You can delete snapshots you created using MapR Container Storage Interface (CSI) Storage Plugin. To delete:

1. Run the following command:

```
kubectl delete -f <volume snapshot>.yaml
```

   For example:

```
# kubectl delete -f test-snapshot1.yaml
volumesnapshot.snapshot.storage.k8s.io "test-snapshot1" deleted
```

2. Log in to the cluster and verify that the snapshot was deleted by running the `volume snapshot list` on page 2030 command.

   For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365417772,
    "timeofday":"2019-01-24 01:30:17.772 GMT-0800 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Creating a Volume from a Snapshot

You can restore a volume from a volume snapshot by configuring a PersistentVolumeClaim that specifies the volume snapshot as the data source.

In the following example, the snapshot named `testcsi-secure-snapshot` serves as the data source for creating a new volume named `testcsi-secure-pvc-restore`:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: testcsi-secure-pvc-restore
  namespace: test-csi
spec:
  storageClassName: testcsi-secure-sc
```

```
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 10G
  dataSource:
    kind: VolumeSnapshot
    apiGroup: snapshot.storage.k8s.io
    name: testcsi-secure-snapshot
```

When creating a volume from snapshots of extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to create the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting of the `csi-snapshotter` sidecar container. See the `--timeout` argument in the latest `csi-maprkdf-<version>.yaml`.

For more information, see Persistent Volumes.

Enabling the Platinum POSIX Client for MapR Container Storage Interface (CSI) Storage Plugin

When you install the MapR Container Storage Interface (CSI) Storage Plugin, the Container FUSE-based POSIX client package is installed on the CSI Driver container. The CSI Driver also supports the use of the Basic, Container, and Platinum FUSE-based POSIX client. For a comparison of the POSIX client packages, see Preparing for Installation (MapR POSIX Client) on page 400.

Note: Enabling the Platinum POSIX client is not required for the Loopback NFS plug-in.

To install the Platinum POSIX client, include the `platinum` parameter in your pod spec. For example:

```
volumeAttributes:
    volumePath: "/"
    cluster: "clusterA"
    cldbHosts: "10.10.102.96"
    securityType: "secure"
    platinum: "true"
```

Release 1.0.2 and later support another method for specifying the POSIX client. You can use the `license` parameter and specify the Container, Basic, or Platinum driver. For example:

```
volumeAttributes:
    volumePath: "/"
    cluster: "clusterA"
    cldbHosts: "10.10.102.96"
    securityType: "secure"
    license: "platinum"
```

For more information, see Example: Mounting a PersistentVolume for Static Provisioning on page 3113.

Logging for the CSI Driver and Provisioner
Describes the event logs for the CSI driver and provisioner for both FUSE and Loopback NFS plugins.

Logs for the MapR Container Storage Interface (CSI) Storage Plugin can be found in `/var/log/csi-maprkdf/`. The following table shows the new log-file format. Before the FUSE 1.2.2 and Loopback NFS 1.0.2 drivers were introduced, the log files included a version in the file name.

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Driver events log	FUSE	`csi-plugin.log`	Captures CSI Driver events such as registering the driver and CSI Driver logs for node mount and unmount operations.	All Kubernetes nodes.
	Loopback NFS	`csi-nfsplugin.log`		

last-updated: Apr 11, 2022

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Provisioner events log	FUSE	`csi-provisioner.log`	Captures provisioner events such as registering the CSI provisioner and CSI Controller events such as Create/Delete volumes, Create/Delete Snapshots etc.	The Kubernetes node where the provisioner StatefulSet pod is running.
	Loopback NFS	`csi-nfsprovisioner.log`		

Note: The directory must grant `rw` permissions for creating the logs and must grant write/append permissions to the plug-in and provisioner.

Troubleshooting the MapR Container Storage Interface (CSI) Storage Plugin
This section describes how to resolve common problems you might encounter when installing and using the MapR Container Storage Interface (CSI) Storage Plugin.

Troubleshooting CSI Driver installation

Run the following commands to get the pods that are deployed for the CSI plugin and provisioner:

FUSE

```
kubectl get pods -n mapr-csi
```

Loopback NFS

```
kubectl get pods -n mapr-nfscsi
```

The installation is considered successful if the `get pods` command shows the pods in the `Running` state. For example, your output should look similar to the following when CSI plugin is deployed on three worker nodes:

FUSE

```
mapr-csi       csi-controller-kdf-0         5/5     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-2kfrf     3/3     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-lq5nw     3/3     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-pkrzt     3/3     Running     0
4h25m
```

Loopback NFS

```
csi-controller-nfskdf-0       7/7     Running   0          22h
csi-nodeplugin-nfskdf-5rjt2   3/3     Running   0          18h
csi-nodeplugin-nfskdf-7d9cs   3/3     Running   0          22h
csi-nodeplugin-nfskdf-qw7kg   3/3     Running   0          22h
```

The preceding output shows the following:

FUSE

- `csi-nodeplugin-kdf-*`: Daemonset pods deployed on all the Kubernetes worker nodes
- `csi-controller-kdf-0`: StatefulSet pod deployed on a single Kubernetes worker node

Loopback NFS

- `csi-nodeplugin-nfskdf-*`: Daemonset pods deployed on all the Kubernetes worker nodes
- `csi-controller-nfskdf-0`: StatefulSet pod deployed on a single Kubernetes worker node

Troubleshoot MapR CSI Plugin Deployment Failures

If the pods show a failure in the deployment, run the following kubectl command to see the container logs:

FUSE

```
kubectl logs <csi-nodeplugin-*> -n mapr-csi -c <nodeplugin-pod-container>
```

Loopback NFS

```
kubectl logs <csi-nodeplugin-*> -n mapr-nfscsi -c <nodeplugin-pod-container>
```

If the pods show a failure in the deployment, run the following kubectl commands to see the container logs:

FUSE

```
kubectl logs <csi-nodeplugin-*> -n mapr-csi -c <nodeplugin-pod-container>
```

Loopback NFS

```
kubectl logs csi-controller-nfskdf-0 -n mapr-nfscsi -c
<controller-pod-container>
```

Here, replace `<nodeplugin-pod-container>` with the container that is failing. You can also run the following kubectl command to see the controller logs:

```
kubectl logs csi-controller-kdf-0 -n mapr-csi -c <controller-pod-container>
```

Here, replace `<controller-pod-container>` with the container which is failing.

Troubleshooting Volume Provisioning

Check the provisioner log and check for any provisioner errors:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsprovisioner.log
```

Troubleshooting Mount Operation

Check the CSI Storage plug-in log for any mount/unmount errors:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-plugin.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsplugin.log
```

last-updated: Apr 11, 2022

If you don't see any errors, see the kubelet logs on the node where the pod is scheduled to run. Check the MapR CSI Storage plugin logs for specific errors.

Troubleshooting MapR CSI Storage Plugin Discovery with kubelet

Check the kubelet path for kubernetes deployment from the kubelet process running with `--root-dir`. The `--root-dir` is a string that contains the directory path for managing kubelet files (such as volume mounts, etc.,) and defaults to `/var/lib/kubelet`. If the Kubernetes environment has a different kubelet path, modify the CSI driver deployment `.yaml` file with the new path, and redeploy the MapR CSI Storage Plugin again.

Troubleshooting Snapshot Provisioning

See the provisioner log and check for any provisioner errors:

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

If there are no errors, run the following kubectl command to check the snapshot:

```
kubectl describe volumesnapshot.snapshot.storage.k8s.io <snapshot-name> -n
<namespace-name>
```

Here:

- `<snapshot-name>`: Name of the VolumeSnapshot Object defined in yaml
- `<namespace-name>`: Namespace where the VolumeSnapshot object is created

Troubleshooting No Space on Disk Error

The devicemapper storage driver used for Docker allows only 10 GB by default resulting in "no space left on device" errors when writing to new directories for a new volume mount request. If `--maxvolumepernode` is configured to be greater than 20 and underlying docker is using devicemapper storagedriver, do the following to increase the storage size:

1. Change storagedriver to be other than devicemapper, which restricts container storage to 10 GB by default.
2. Increase default container storage to more than the default of 10 GB for devicemapper storagedriver for the Docker container running on Kubernetes worker node.

For example, do the following to increase the storage size to 50 GB:

1. In `/etc/sysconfig/docker-storage` file, add `--storage-opt dm.basesize=50G` under `DOCKER_STORAGE_OPTIONS` section.
2. Restart Docker.
3. Confirm that the setting is correctly applied by running the following command:

   ```
   docker info | grep "Base Device Size"
   ```

Kubernetes FlexVolume Driver Configuration

This section describes how to use and troubleshoot the MapR Data Platform for Kubernetes FlexVolume Driver.

For more information about the MapR Data Platform for Kubernetes, see MapR Data Fabric for Kubernetes FlexVolume Driver Overview on page 671.

Using the MapR Data Fabric for Kubernetes FlexVolume Driver

This section describes how to configure Kubernetes objects to enable persistent storage and includes example configuration files for static and dynamic provisioning.

Before You Begin

Before configuration, be sure to review the following notes about supported and unsupported features and parameters:

MapR Parameters for Dynamic Provisioning

In dynamic provisioning, you can specify MapR parameters for the MapR volume to be created. For a list of the MapR parameters that you can use, see volume create on page 1931. Note these considerations for using the MapR parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute will generate an error because the value (`1`) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following MapR parameters are ignored because they are redundant or not supported in the Kubernetes implementation:
  - `mount`
  - `quota*`
  - `createparent`
  - `path`
  - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) (see Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 3155) makes it unnecessary to set the MapR `quota` parameter.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. Access modes can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. Unfortunately, beyond the PVC/PV binding behavior, PVs using FlexVolume drivers ignore these access modes in the current version of Kubernetes. All access modes will work with the MapR Data Fabric for Kubernetes. However, they will appear the same. This means the ROX mode will not make the volume read only. If you want read-only behavior, specify `readOnly:` in the FlexVolume driver flags.

PersistentVolumeClaim Protection

PVC protection is a Kubernetes 1.9 alpha feature that restricts the user from deleting a PVC while it is being used by an active Pod. Alpha features are not tested for use with the volume plug-in and provisioner. However, without PVC protection, you should not delete a PVC that is still attached to Pods. If you have not turned on PVC protection, ensure that you do not delete PVC's that are in use. In the current release of the MapR Data Fabric for Kubernetes, deleting a PVC causes undefined behavior.

last-updated: Apr 11, 2022

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes FlexVolume Drivers, so it cannot be used with KDF. The Retain Policy is currently broken in Kubernetes 1.9 StoragePolicies but not in static PersistentVolumes. The MapR Data Fabric for Kubernetes has a workaround that allows Retain policy on dynamically provisioned volumes by passing the `reclaimPolicy:` in the parameters rather than in the standard place that FlexVolumes ignore. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the MapR volume are deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported
Retain	The PersistentVolume and the MapR volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported*
Recycle	Performs a basic scrub on a PersistentVolume and makes it available for a new PersistentVolumeClaim.	Not Supported by Kubernetes Flexvolumes

*Not supported for dynamic provision without a workaround.

For more information about the reclaim policy, see Change the Reclaim Policy of a PersistentVolume.

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the MapR Data Fabric for Kubernetes because it is not supported for use with the FlexVolume plug-in.

Steps for Configuring the MapR Data Fabric for Kubernetes FlexVolume Driver

This page summarizes the high-level steps for configuring the MapR Data Fabric for Kubernetes FlexVolume Driver to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see Static and Dynamic Provisioning Using FlexVolume Driver on page 673.

Static Provisioning

1. Install the MapR Data Fabric for Kubernetes.

   See Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241.

2. In your Pod spec or as part of a separate configuration file, configure a PersistentVolume.

   See Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 3155 and Persistent Volumes.

3. Do *one* of the following:

   - Annotate the Pod spec to provide information about the MapR volume.

     See Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in on page 3153.

   - In your Pod spec or as part of a separate configuration file, configure a PersistentVolumeClaim.

     See PersistentVolumeClaims.

4. Run the Pod spec by using `kubectl` commands. See Overview of kubectl.

last-updated: Apr 11, 2022

Dynamic Provisioning

1. Install the MapR Data Fabric for Kubernetes.

   See Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241.

2. In your Pod spec or in a separate configuration file, create a storage class.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver on page 3159 and Storage Classes.

3. In your Pod spec or in a separate configuration file, configure a PersistentVolumeClaim.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver on page 3159.

4. Run the Pod spec by using `kubectl` commands. See Overview of kubectl.

Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in

You can designate a MapR volume for use with Kubernetes by specifying the MapR FlexVolume parameters directly inside the Pod spec. In the Pod spec, you define a Kubernetes volume and add the MapR FlexVolume information to it. You can supply path information by using the `volumePath` parameter. The Kubernetes volume is only as persistent as the Pod. By defining the volume this way, when the Pod is removed, the Kubernetes volume is also immediately unmounted and removed. This approach to static provisioning is most appropriate when you want to get up and running quickly or when you want the Pod and Kubernetes volume lifecycle to be the same.

For example, a developer wants to get her application container up and running quickly with MapR. She already has a MapR path that she wants to use for the application. She only needs the data accessible to read. To make this work, she must:

1. Generate a MapR service ticket, and set the `securityType` parameter in the Pod spec to `secure`. See Generating a Service Ticket on page 1428.

2. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See Configuring a Secret on page 3167.

3. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.

4. Point the `volumePath` in the `flexVolume` setting to the desired path, and fill in the `cldbHosts` and `cluster` information.

Note: The following example works for on-premise deployments. For GKE and AWS deployments, you must set a default StorageClass to the `maprfs` StorageClass. If a default StorageClass is not provided for GKE and AWS deployments, the volume is created using your default StorageClass, which might not be a good fit. For information about changing the default StorageClass, see Change the default StorageClass.

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
  containers:
  - name: mycontainer
```

last-updated: Apr 11, 2022

```
    image: myrepo/myorg/mycontainer
    args:
    - sleep
    - "1000000"

    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprvolume
  volumes:
    - name: maprvolume
      flexVolume:
        driver: "mapr.com/maprfs"
        readOnly: true
        options:
          volumePath: "/path/to/data/in/mapr"
          cluster: "mycluster"
          cldbHosts: "cldb1 cldb2 cldb3"
          securityType: "secure"
          ticketSecretName: "mapr-ticket-secret"
          ticketSecretNamespace: "mapr-examples"
---
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>
```

The following tables describe the parameters in the example:

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. For clarity, the example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. Matches with `Volumes: name`.

last-updated: Apr 11, 2022

`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. Matches with `volumeMounts: name`.
`flexVolume: driver`	The MapR FlexVolume driver being used. Call it using this driver: `mapr.com/maprfs`.
`flexVolume: readOnly`	Specifies that the FlexVolume driver should tell the MapR POSIX Client to mount the volume with the read-only flag.
`volumePath`	The mount point within the MapR filesystem. This parameter specifies an existing MapR path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`cluster`	The MapR cluster name.
`cldbHosts`	The DNS names or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3167.
`ticketSecretNamespace`	The namespace that contains the Secret. See Configuring a Secret on page 3167

Secret

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`namespace`	The namespace in which the Secret runs.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.
`CONTAINER_TICKET`	The contents of the MapR ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3169. You may remove the ticket if the MapR cluster is not secure.

Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a Pod spec:

- The configuration file can be shared for use by multiple Pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the Pod spec that references it is removed.

last-updated: Apr 11, 2022

For example: A marketing volume exists in the MapR filesystem under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must:

1. Create a PersistentVolume (PV).
2. Set the `AccessMode` of the PV to `ReadWriteOnce`.
3. Create a PersistentVolumeClaim (PVC) spec.
4. Set the `AccessMode` of the PVC to `ReadWriteOnce`.
5. Create the Pod spec.
6. Generate a MapR service ticket, and set the `flexVolume securityType` parameter to `secure`. For information about generating a service ticket, see Generating a Service Ticket on page 1428.
7. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See Configuring a Secret on page 3167.
8. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.
9. Set the `platinum` parameter in the Pod spec to `platinum: "true"`. See Enabling the Platinum Posix Client for MapR Data Fabric for Kubernetes FlexVolume Driver on page 3166.
10. Point the `volumePath` in the `flexVolume` setting to the desired MapR path.
11. Fill in the `cldbHosts` and `cluster` information.

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv-testsecure1
  namespace: mapr-examples
spec:
  capacity:
    storage: 5Gi
  accessModes:
    - ReadWriteOnce
  persistentVolumeReclaimPolicy: Retain
  claimRef:
    namespace: mapr-examples
    name: pvc-testsecure1
  flexVolume:
    driver: "mapr.com/maprfs"
    options:
      platinum: "true"
      cluster: "mycluster"
      cldbHosts: "cldb1 cldb2 cldb3"
      volumePath: "/path/in/mapr"
      securityType: "secure"
      ticketSecretName: "mapr-ticket-secret"
      ticketSecretNamespace: "mapr-examples"
---
apiVersion: v1
kind: Pod
metadata:

PersistentVolume (PV)

Parameter	Notes
`Capacity`	Specifies how big the allocated storage should be. This value is not validated against the MapR quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
`accessModes`	How the PersistentVolume is mounted on the host. All modes work the same. The example uses `ReadWriteOnce`. Note that `ReadOnlyMany` does not mount read-only. (To implement a read-only mount, use the Flexvolume flag for `readOnly`, as shown in Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in on page 3153.) It's important that the PV and PVC modes are the same so that they can bind. For more information, see Access Modes.

last-updated: Apr 11, 2022

`persistentVolumeReclaimPolicy`	Specifies what happens to the volume when it is released by its claim. The `Retain` value keeps the PVC around for manual cleanup. `Delete` deletes the PV from Kubernetes. **Note:** If this volume was created using dynamic provisioning, `Delete` causes the underlying volume to be deleted. `Recycle` is not supported by Kubernetes FlexVolumes. For more information, see Reclaiming.
`claimRef`	Specifies a default PVC to bind to. If unspecified, the PV selected for a PVC is randomly allocated based on the access mode and provides at least as much storage capacity as requested by the PVC.
`flexVolume: driver`	The MapR FlexVolume driver being used. Call it by specifying driver: `mapr.com/maprfs`.
`platinum`	If set to `platinum: "true"`, the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and MapR Platinum licenses.
`cluster`	The MapR cluster name.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`volumePath`	The mount point within the MapR filesystem. This parameter specifies an existing MapR path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Ticket Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3167.
`ticketSecretNamespace`	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the Pod.

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. The example uses a naked Pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.

last-updated: Apr 11, 2022

`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. This value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. This value should match `volumeMounts: name`.

PersistentVolumeClaim (PVC)

Parameter	Notes
`AccessMode`	How the requested PersistentVolume is mounted on the host. All modes work the same. The example uses `ReadWriteOnce`. Note that `ReadOnlyMany` does not mount read-only. (To implement a read-only mount, use the Flexvolume flag for `readOnly`, as shown in Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in on page 3153.) It's important that the PV and PVC modes are the same so that they can bind. For more information, see Access Modes.

Secret

Parameter	Notes
`metadata: name`	The name of the Ticket Secret. See Configuring a Secret on page 3167
`metadata: namespace`	The namespace in which the Ticket Secret runs.
`CONTAINER_TICKET`	The contents of the MapR ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3169. You may remove the ticket if the MapR cluster is not secure.

Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver

This example also uses a PersistentVolume. However, unlike the previous example, when you use the MapR dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want MapR and Kubernetes administrators to create storage manually to store the Pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes Administrator has created a storage class called `secure-maprfs` for Pod creators to use when they want to create persistent storage for their Pods. In this example, it is important for the created Pod storage to survive the deletion of a Pod.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
```

last-updated: Apr 11, 2022

```
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    readOnly: "true"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
    readonly: "1"

```

The following tables describe the parameters in the example:

StorageClass

Parameter	Notes
`apiVersion`	The Kubernetes APi version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the StorageClass. Administrators should specify the name carefully because it will be used by Pod authors to help select the right StorageClass for their needs.
`metadata: namespace`	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and Pod, since the StorageClass namespace can be a cross-namespace resource.
`provisioner`	The provisioner being used. for the MapR provisioner, specify `mapr.com/maprfs`.
`restServers`	A space-separated list of MapR webservers. Specify the hostname or IP address and port number of each REST server for the MapR cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`cluster`	The MapR cluster name.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3167.
`ticketSecretNamespace`	The namespace that contains the Secret. Use the same namespace as the namespace used by the Pod.
`maprSecretName`	The name of the Kubernetes Secret that is used to store MapR administrative credentials (user, password, and ticket information for the MapR webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 3167.
`maprSecretNamespace`	The namespace for the Secret containing the MapR administrative credentials (user name and password information for a MapR user that has the privileges to create MapR volumes). This namespace can be different from the namespace used by the Pod, since a

last-updated: Apr 11, 2022

Parameter	Notes
	Pod author or namespace admin might not be trusted to create administration Secrets for the MapR cluster.
`namePrefix`	A prefix for the MapR volume to be created. For example, if you specify `PV` as the `namePrefix`, the first dynamically created volume might be named `PV.bevefsescr`. The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.
`mountPrefix`	The parent path of the mount in MapR filesystem. If you do not specify a mount prefix, the provisioner mounts your volume under the MapR root.
`readOnly`	This parameter specifies that the POSIX driver should mount the MapR path as read only. This is different from the `readonly` parameter for volume creation that creates the volume as read only.
`reclaimPolicy`	Kubernetes does not currently support passing a non-delete reclaim policy to the StorageClass. This parameter allows you to specify `Retain`. This ensures that provisioned volumes are not automatically deleted when their calling Pods are deleted. If you specify `Retain`, you must clean up your provisioned volumes manually.
`advisoryquota`	The advisory storage quota for the MapR volume. `advisoryquota` is one of the MapR parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 3151.
`readonly`	When the value is `1`, this parameter specifies that the MapR volume should be created as read-only. This is different from the `readOnly` parameter that mounts the MapR path as read only.

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs. It should be the same namespace in which the PVC runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. The value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.

last-updated: Apr 11, 2022

Parameter	Notes
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

PVC

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. This is a PersistentVolumeClaim (PVC).
`metadata: name`	The PVC name.
`metadata: namespace`	The namespace in which the PVC runs. This should be the same namespace used by the Pod.
`accessModes`	How the PersistentVolume is mounted on the host. (This is a limitation of the FlexVolume driver.) For more information, see Access Modes.
`storageClassName`	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes.
`requests: storage`	The storage resources being requested, or that were requested and have been allocated. The Pod author can use this parameter to tell MapR how much quota is needed for the MapR volume. For the units, see Resource Model.

Provisioner Secret

In the mapr-provisioner-secrets Secret:

Parameter	Notes
`MAPR_CLUSTER_USER`	This is the base64-encoded user ID used to log in to the MapR REST server and create or delete volumes. See Converting a String to Base64 on page 3169. For more information about Secrets, see Secrets.
`MAPR_CLUSTER_PASSWORD`	This is the base64-encoded password for the MAPR_CLUSTER_USER. See Converting a String to Base64 on page 3169. For more information about Secrets, see Secrets.

Ticket Secret

In the mapr-ticket-secret Secret:

Parameter	Notes
`CONTAINER_TICKET`	The contents of the MapR ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3169. You may remove the ticket if the MapR cluster is not secure. For more information about Secrets, see Secrets.

Identifying the MapR Volume Created During Dynamic Provisioning

Describes how to find the name of the MapR volume created during dynamic provisioning.

last-updated: Apr 11, 2022

In dynamic provisioning, the provisioner creates a new MapR volume with a name that is randomly generated using lower-case letters. For example, if you specify `PV` as the `namePrefix` in the StorageClass, the first dynamically created volume might be named `PV.bevefsescr`. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.

To find the name of the new MapR volume and the path to the volume:

1. Use the `kubectl describe` command to get information about the PVC:

   ```
   kubectl describe pvc -n <namespace> <pvc-name>
   ```

   The command output shows the name of the PersistentVolume (PV) that was created: For example:

   ```
   kubectl describe pvc -n mapr-examples maprfs-secure-pvc109
   Name:          maprfs-secure-pvc109
   Namespace:     mapr-examples
   StorageClass:  secure-maprfs
   Status:        Bound
   Volume:        pv-ikmqxfwtjh
   Labels:        <none>
   Annotations:   control-plane.alpha.kubernetes.io/
   leader={holderIdentity":"ed60e649-0c68-11e8-acd5-36117e0e7e02","leaseDura
   tionSeconds":15, "acquireTime":"2018-02-09T22:09:43Z"
                  pv.kubernetes.io/bind-competed=yes
                  pv.kubernetes.io/bound-by-controller=yes
                  volume.beta.kubernetes.io/storage-provisioner=mapr.com/
   maprfs
   Finalizers:    []
   Capacity:      300M
   Access Modes:  RWO
   Events:
   ```

2. Use the `kubectl get` command and the PersistentVolume (PV) name to obtain a description of the PersistentVolume:

   ```
   kubectl get pv <pv-name> -o yaml
   ```

   The command output shows the path to the MapR volume. For example:

```
kubectl get pv pv-ikmqxfwtjh -o yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  annotations:
    mapr.com/description: 'Dynamically provisioned PV for MapR-FS:
pv.ikmqxfwtjh'
    mapr.com/maprProvisionerIdentity: mapr.com/maprfs
    mapr.com/provisionerVersion: v1.0.0
    mapr.com/restServers: 10.10.88.214:8443
    mapr.com/secretName: mapr-provisioner-secrets
    mapr.com/secretNamespace: mapr-examples
    mapr.com/volumeName: pv.ikmqxfwtjh
    pv.kubernetes.io/provisioned-by: mapr.com/maprfs
  creationTimestamp: 2018-02-09T22:21:22Z
  name: pv-ikmqxfwtjh
  resourceVersion: "2875820"
  selfLink: /api/v1/persistentvolumes/pv-ikmqxfwtjh
  uid: 8f11aa11-0de7-11e8-bdd6-84a9c4fbf7cb
spec:
  accessModes:
  - ReadWriteOnce

      cluster: Test5
      mountOptions: ""
      platinum: "true"
      readOnly: "false"
      securityType: secure
      ticketSecretName: mapr-ticket-secret
      ticetSecretNamespace: mapr-examples
      volumePath: /pv/pv-ikmqxfwtjh
  persistentVolumeReclaimPolicy: Delete
  storageclassName: secure-maprfs
status:
  phase: Bound
```

Creating a Default StorageClass

As noted in Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in on page 3153, some deployments can require a default StorageClass. A default StorageClass can reduce the effort it takes to create Pods. For example, you could use a default StorageClass to provision storage dynamically to a MapR location for any PersistentVolumeClaim that you create.

last-updated: Apr 11, 2022

If you set the `DefaultStorageClass` admission controller (see PodSecurityPolicy), and you wish to enable a MapR StorageClass as the default, follow the instructions in Change the default StorageClass.

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

Once the Pod spec is installed, you can verify the status of a PersistentVolumeClaim or a PersistentVolume by using the Kubernetes `get` command. For example:

```
$ kubectl get pvc
NAME        STATUS  VOLUME         CAPACITY  ACCESS MODES  STORAGECLASS
AGE
Maprfs-pvc  Bound   pv-rsojpoapxy  8Mi       RWO           simple-maprfs  3d
$ kubectl get pv
NAME           CAPACITY ACCESS MODES  RECLAIM POLICY STATUS
CLAIM             ...
Pv-rsojpoapxy  8Mi      RWO           Delete         Bound  mapr-demo/
maprfs-pvc
```

For an example of creating a PersistentVolumeClaim and a PersistentVolume, see Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 3155.

Enabling the Platinum Posix Client for MapR Data Fabric for Kubernetes FlexVolume Driver

When you install the MapR Data Fabric for Kubernetes FlexVolume Driver, the Basic FUSE-based POSIX client package is installed on all nodes by default. The FlexVolume Driver also supports the use of the Platinum FUSE-based POSIX client. For a comparison of the two POSIX client packages, see Preparing for Installation (MapR POSIX Client) on page 400.

To install the Platinum POSIX client, include the `platinum` parameter in your Pod spec. For example:

```
options:
cluster: "cluster2"
platinum: "true"
cldbHosts: "10.10.102.96"
```

Mounting a Read-Only Volume

This page describes how to specify a volume that should be mounted as read-only.

The following example specifies a volume that should be mounted as read-only in a MapR path or PersistentVolume during static provisioning:

```
flexVolume:
        driver: "mapr.com/maprfs"
        readOnly: true
        options:
          volumePath: "/path/to/data/in/mapr"
          cluster: "mycluster"
          cldbHosts: "cldb1 cldb2 cldb3"
          securityType: "secure"
          ticketSecretName: "mapr-ticket-secret"
          ticketSecretNamespace: "mapr-examples"
```

The following example shows how to specify that the volume should be mounted read-only in a StorageClass for dynamic provisioning. The example specifies that the POSIX driver should mount the MapR path as read only. This is different from the `readonly` parameter for volume creation that creates the volume as `readonly`.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
```

last-updated: Apr 11, 2022

```
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    readOnly: "true"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
```

The following example specifies that the volume should be created as `readOnly` in a StorageClass for dynamic provisioning:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
    readonly: "1"
```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. For more information about Secrets, see Secrets.

The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. For more information about security and Secrets, see Security Properties. Specifically, it is important to turn on encryption at rest for Secrets. See Encrypting Secret Data at Rest.

During installation of the Driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
```

last-updated: Apr 11, 2022

```
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see Secrets in the Kubernetes documentation.

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a MapR user to the provisioner. This user must have privileges to create and delete a MapR volume. The credentials allow the provisioner to make REST calls to the MapR webserver. Secrets are protected by the Kubernetes RBAC.

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
 MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example.

Parameter	Notes
`MAPR_CLUSTER_USER`	The base64 representation of a MapR user that has the ability to create and delete MapR volumes. See Converting a String to Base64 on page 3169.
`MAPR_CLUSTER_PASSWORD`	The base64 representation of the password for the user defined by the `MAPR_CLUSTER_USER` parameter. See .Converting a String to Base64 on page 3169
`MAPR_CLUSTER_TICKET`	The base64 representation of the ticket contents generated on the data-fabric cluster using the `maprlogin` utility. For dynamic provisioning, with the latest CSI drivers, you can configure a data-fabric ticket to authenticate to the data-fabric webserver to make REST calls. This parameter is provided as a Beta feature.

Ticket Secrets
