About MapR 6.1

This site contains the main documentation for Version 6.1 of the MapR Converged Data Platform, including installation, configuration, administration, and reference information.

Related concepts

Products Covered in the MapR Data Platform Documentation on page 5390

This section lists the products covered in the MapR Data Platform documentation portal and provides links to the related product documentation.

Version 6.1.0 Release Notes

These release notes contain information about Version 6.1.0 of the MapR Converged Data Platform.

CAUTION: New installations of MapR 6.1.0 are no longer recommended. Because of a known issue with MapR 6.1.0, HPE recommends installing MapR 6.1.1 or MapR 6.2.0 for new installations. The MapR Installer no longer supports installing MapR 6.1.0 and automatically installs MapR 6.1.1. To review the support advisory announcing release 6.1.1, see Announcement of HPE Ezmeral Data Fabric maintenance release 6.1.1 to address 6.1.0 critical defects.

Upgrading to MapR 6.1.0 also is no longer recommended. If you need to upgrade to MapR 6.1.x, upgrade to MapR 6.1.1. See Installation and Upgrade Notes (MapR 6.1.1) on page 74.

If your cluster is currently installed with MapR 6.1.0, HPE recommends that you install the latest 6.1.0 patch. See Downloading a Patch on page 437.

What's New in Version 6.1.0

The 6.1.0 MapR release supplies substantial new features for the components of the data platform.

To see new features delivered as part of the MapR Ecosystem Pack, see What's New in EEP 6.0.0 on page 6532 There are multiple new features for MapR-Drill. See the Drill release notesfor details.

MapR 6.1.0 Is "Secure by Default"

Because MapR 6.1.0 in its default configuration is more secure than MapR 6.0.1, documentation references to "built-in security" have been changed to "secure by default." See Security for Ecosystem Components on page 702.

Streaming Security and Critical Data Asset Protection

ZooKeeper Upgraded	MapR 6.1.0 includes ZooKeeper 3.4.11 (upgraded from Zookeeper 3.4.5 in MapR 6.0.1) to support ZooKeeper server-to-server authentication.
Zookeeper Supports Server-to-Server Authentication	As of MapR 6.1.0, ZooKeeper is automatically configured for server-to-server authentication with new installations of MapR Core. The following ZooKeeper security parameters are set to "true" whenever you use `configure.sh` to perform a new installation (including when `configure.sh` is invoked by the MapR Installer or MapR Installer Stanzas). • `quorum.auth.enableSasl` • `quorum.auth.learnerRequireSasl`

last-updated: Apr 11, 2022

- `quorum.auth.serverRequireSasl`

These parameters enable secure communication between peer servers in the ZooKeeper quorum using SASL.

Simplified Development and Deployment of AI and Analytics Applications

Lightweight Client Architecture

EEP 6.0.0 introduces Node.js and Python OJAI clients that enable you to write MapR Database JSON applications using a language other than Java. These clients use the MapR Data Access Gateway to access your MapR cluster. The Data Access Gateway performs some data processing that otherwise runs in the client. This keeps the clients lightweight and simplifies their installation and use.

See Understanding the MapR Data Access Gateway on page 750 for more details about the Data Access Gateway. See What's New in EEP 6.0.0 on page 6532 for more details about the new clients.

New Features in MapR Filesystem

Storage Tiers Support for Files

MapR Filesystem v6.1.0 includes rule-based automated tiering functionality for businesses looking to leverage low-cost storage solutions either on low-cost hardware or on the cloud to gain limitless storage capacity. MapR's tiering functionality can seamlessly integrate with the following:

- Low-cost hardware to store data that is less frequently accessed, which is referred to as "warm" data
- Cloud resources to store data that is rarely accessed or archived, which is referred to as "cold" data

Enabling warm or cold tiering allows you to use valuable on-premise storage resources for more active or "hot" file data and applications. You can use "warm" or "cold" tiering for file data retained for compliance, historical, or other business reasons.

See Data Tiering on page 469 for more information.

NFSv4 Protocol Support

As of MapR v6.1, the MapR Filesystem includes support for NFSv4 protocol. NFSv4 provides end-to-end secure filesystem access and a much higher throughput compared to NFSv3, improving performance. MapR uses NFS Ganesha, which is an Open Source userspace implementation of the NFS server, for supporting NFSv4 features. See Accessing Data with NFS v4 on page 1193 for more information.

Also supported are mixed-mode NFS configurations in which some nodes of a cluster use NFSv3 and other nodes use NFSv4. See Installing MapR NFS on page 386.

When installed through the MapR Installer, there is no security between the client and the NFS gateway whether or not the cluster is secure. On a secure cluster, the connection between NFSv4 server and

	MapR File System is secure. The following options are supported for configuring Kerberos security for NFSv4: • Kerberos only (users are in the local node database) • LDAP and Kerberos (users are in LDAP) • Active Directory and Kerberos (users are in the Active Directory) For more information, see Configuring NFSv4 Server for Kerberos on page 1209. When configuing NFSv4 for security, make a note of the following: • If NFSv4 is installed on (existing or new) edge nodes, the edge nodes must be part of the Kerberos setup. • If NFSv4 is installed on cluster nodes, then all the cluster nodes must be part of the Kerberos setup. For more information, see Accessing Data with NFS v4 on page 1193.
Secure by Default	The MapR Data Platform v6.1 and EEP v6.0 components are secure out-of-the-box on all new installations, ensuring all network connections require authentication and all data in motion is protected with wire-level encryption. Without requiring an external security manager server or a particular security plug-in for each ecosystem component, MapR provides the ability to apply security protection directly for data as it comes into and moves out of the platform. The security semantics are applied automatically on data being retrieved or stored by any ecosystem component, application, or users. See Security for more information. Because MapR 6.1.0 in its default configuration is more secure than MapR 6.0.1, documentation references to "built-in security" have been changed to "secure by default." See Security for Ecosystem Components on page 702.
Encryption of Data at Rest	MapR v6.1 includes support for encryption of data at rest. Data on disk (or data-at-rest) in a secure MapR cluster can be encrypted, enabling you to protect the data if a disk is compromised. Encryption of data-at-rest not only prevents unauthorized users from accessing sensitive data, but it also protects against data theft via sector-level disk access. See Security for more information.
Client-side Port Binding	MapR now requires only a single source port on the client side. MapR will bind multiple sockets to the same port for establishing connections to all the nodes on the MapR cluster.

Core Data Services Innovations to Speed AI and Analytics and Lower TCO

Complex Types Support in MapR Database JSON	In MapR Database 6.1.0, you can write more expressive queries on complex types, which includes

	arrays of scalar types and arrays of nested documents. MapR Database JSON introduces the notion of a *container field path*. Using a container field path, you can access a field that is either a single value or an arbitrary array element. This is useful if you want to perform one of the following operations: • Perform comparisons on a field path that is either a single value or an arbitrary array element • Access subfields in a nested document, where the nested document is either an arbitrary array element or a single nested document • Access arbitrary elements in an array For example, suppose your JSON document contains an `addresses` field that is an array of nested documents with address details like `street`, `city`, and `state`. You can use a container field path to write a query that filters on *any* element in the `addresses` array that matches a specific `city` and `state`. You can also create secondary indexes using container field paths, improving the performance of these more expressive queries. See the following topics for more details about the feature: • Container Field Paths on page 518 • OJAI Query Conditions Using Container Field Paths on page 2615 • Using Container Field Paths as Indexed Fields on page 562 In MapR Database 6.1.0, you also are no longer restricted to creating secondary indexes on scalar data fields. You can now create indexes on fields with arrays and nested documents. See Data Types and Secondary Index Fields on page 561 for more information. To understand how indexes behave, depending on the version you are using, see Secondary Indexes and Upgrades.
Complex Type Support in Drill	The query planner in Drill can leverage indexes created on MapR Database JSON document fields with complex data types. You must write queries using specific SQL syntax for the query planner in Drill to leverage indexes on complex fields.

New Features in MapR Event Store For Apache Kafka

Idempotent (Exactly-Once) Producer	An "exactly-once" message delivery semantic produces messages without duplication. Each message is delivered once and only once. Exactly-once is insured by uniquely identifying a group of messages that are atomically persisted. Exactly-once message delivery is set with the producer idempotence option. See Enabling an Idempotent Producer on page 2766 for more information.

last-updated: Apr 11, 2022

Log Compaction

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record. See Log Compaction on page 641 for more information.

Apache Kafka 1.1 Support

MapR 6.1.0 introduces support for the Apache Kafka 1.1 API.

Other Enhancements

Security Certificate Expiry Alarm

A new alarm has been added to alert users to security certificates that are expiring within a configurable time period. See Security Certificate Expiry Alarm on page 2233.

MapR Database Enhancements

MapR Database Table Metrics

MapR Database 6.1.0 supports table metrics and enhanced node metrics. Table metrics provide more granular metrics. They enable you to detect and diagnose bottlenecks and performance issues that are specific to individual tables.

MapR enables table metrics by default. You cannot disable metrics on individual tables. During installation, you can disable table metrics across your entire cluster by selecting a minimal configuration for metrics collection.

See MapR Database Metrics on page 1352 for more details. For details about table metrics, including how to disable them, see MapR Database Table Metrics on page 1355. To learn about how to view these metrics in the MapR Control System (MCS), see Visualizing Table Metrics in the Control System on page 1303.

OJAI 3.0 Support

MapR 6.1.0 introduces support for the OJAI 3.0 API. This version includes extensions for new complex types support in MapR Database JSON. See Complex Types Support in MapR Database JSON for an overview of this feature.

last-updated: Apr 11, 2022

Documentation Enhancements	**New Component Versions Matrix**	A new matrix has been added to the list of Interoperability Matrices. The Component Versions for Released EEPs matrix lets you compare the versions of ecosystem and MapR Monitoring components across different EEPs.
	Revised Product Naming	Some components of the MapR Data Platform have been changed. MapR-Streams is now called MapR Event Store For Apache Kafka. MapR-DB is now MapR Database. MapR-FS is now MapR File System.
	Removal of Third-Party Solutions Content	Third-Party Solutions information has been removed from the MapR 6.1 documentation. Installation and usage information for the following products is no longer current and will not be updated: • Datameer • HParser • Pentaho • Vertica Analytics Platform

Installation and Upgrade Notes (MapR 6.1.0)

CAUTION: New installations of MapR 6.1.0 are no longer recommended. Because of a known issue with MapR 6.1.0, HPE recommends installing MapR 6.1.1 or MapR 6.2.0 for new installations. The MapR Installer no longer supports installing MapR 6.1.0 and automatically installs MapR 6.1.1. Installation and upgrade considerations can be found in the support advisory announcing release 6.1.1. See Announcement of HPE Ezmeral Data Fabric maintenance release 6.1.1 to address 6.1.0 critical defects.

Upgrading to MapR 6.1.0 also is no longer recommended. If you need to upgrade to MapR 6.1.x, upgrade to MapR 6.1.1. See Installation and Upgrade Notes (MapR 6.1.1) on page 74.

If your cluster is currently installed with MapR 6.1.0, HPE recommends that you install the latest 6.1.0 patch. See Downloading a Patch on page 437.

List of YARN Enhancements

MapR 6.1 runs the 2.7.0 version of Hadoop. A number of new features have been incorporated into the version of Hadoop that MapR Converged Data Platform 6.1 uses.

- Support for Azure Data Lake Store.
- Support for YARN Resource Calculation Based on Labels on page 1278.

last-updated: Apr 11, 2022

Support for ADLS
Starting with MapR 6.1, you can use Azure Data Lake Store (ADLS) as a data source or destination for all applications.

Prerequisites for Using ADLS
Setting up Azure Data Lake Store (ADLS) on the Azure portal enables you to access ADLS from any application.

- Create an account on the Azure portal.
- Create an Azure Data Lake Store (get started with Azure Data Lake Storage).

Authenticating ADLS Account
To access data stored in Azure Data Lake Store (ADLS), you must first authenticate your ADLS account using your ADLS credentials.

1. Obtain the following properties from your Azure application:
   - `dfs.adls.oauth2.access.token.provider.type`

     `ClientCredential`, `Refresh Tokens`, or `Client Keys` to obtain the authentication type.
   - `dfs.adls.oauth2.client.id`

     Create an Azure Active Directory application and get your application ID and authentication key.
   - `dfs.adls.oauth2.refresh.url`

     Navigate to Azure Active Directory and click on `Endpoints`. Use the `OAUTH 2.0 TOKEN ENDPOINT` value.
   - `dfs.adls.oauth2.credential`

     Obtain the access token key value from `App Registrations` in your Azure account.

2. Add the properties obtained in step 1 to the `core-site.xml` file:

```
<!--ADL-->
<property>
   <name>dfs.adls.oauth2.access.token.provider.type</name>
   <value>ClientCredential</value>
</property>

<property>
   <name>dfs.adls.oauth2.client.id</name>
   <value>f377fab9-c0a3-4531-a1c9-77345105</value>
</property>

<property>
   <name>dfs.adls.oauth2.refresh.url</name>
   <value>https://login.microsoftonline.com/25735fb/oauth2/token</
value>
</property>

<property>
   <name>dfs.adls.oauth2.credential</name>
   <value>WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/d2z2CGiw=</value>
</property>
```

Note: The `core-site.xml` file can be overwritten using the command line. You can also specify these properties at runtime. The syntax for overwriting ADLS properties at runtime using the command line is as follows:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
-Ddfs.adls.oauth2.access.token.provider.type=ClientCredential
-Ddfs.adls.oauth2.client.id=f377fab9-c0a3-4531-a1c9-77345105
-Ddfs.adls.oauth2.refresh.url=https://login.microsoftonline.com/
25735fb/oauth2/token
-Ddfs.adls.oauth2.credential=WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/
d2z2CGiw= adl://testhue.azuredatalakestore.net/some_folder/testfile
adl://testhue.azuredatalakestore.net/some_folder/wordcountout
```

To provide your ADLS credentials securely, see Securely Providing ADLS Credentials on page 42.

3. Provide your application with file access.

4. For secure clusters, MapR-SASL (Simple Authentication and Security Layer), and Kerberos, import the required CA certificate.

- Open source documentation
- Azure documentation
- Azure documentation on authorization and access control
-

last-updated: Apr 11, 2022

Securely Providing ADLS Credentials
You can provide your ADLS credentials securely by hiding the open, readable configuration on the command line using the Hadoop credential provider.

1. Generate a `jceks` file for ADLS authorization:

```
hadoop credential create dfs.adls.oauth2.client.id -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client ID
hadoop credential create dfs.adls.oauth2.credential -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client secret
hadoop credential create dfs.adls.oauth2.refresh.url -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value refresh URL
```

2. Run the `DistCp` example using the `jceks` file:

```
hadoop distcp
[-D hadoop.security.credential.provider.path=localjceks://hdfs/user/
USER_NAME/adlskeyfile.jceks]
hdfs://<NameNode Hostname>:9001/user/foo/007020615
adl://<Account Name>.azuredatalakestore.net/testDir/
```

3. Configure the `core-site.xml` file to use the `jceks` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://hdfs/user/USER_NAME/adlskeyfile.jceks</value>
  <description>Path to interrogate for protected credentials.</
description>
</property>
```

Using ADLS for Data Input or Output
You can use Azure Data Lake Store (ADLS) as a source or destination for your application data.

For general information about the features of ADLS, refer to the Azure Data Lake Store documentation.

For information about configuring ADLS as storage for a Hadoop cluster, refer to the official Apache documentation.

The Azure Data Lake Storage access path syntax is:

```
adl://<Account Name>.azuredatalakestore.net/
```

You can use ADLS the same way as you use MapR File System, substituting an `adl` scheme instead of `maprfs`, `hdfs`, `webhdfs`, and so on.

1. Create a directory and read data:

```
[mapr@node4 ~]$ hadoop fs -mkdir adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/

Found 1 items
drwxr-xr-x - 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:09
adl://<username>.azuredatalakestore.net/testdir
```

2. Put data into ADLS from your local MapR File System:

```
[mapr@node4 ~]$ hadoop fs -put testfile adl://
<username>.azuredatalakestore.net/testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
testdir

Found 1 itemsrw-rr- 1 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:10
adl://<username>.azuredatalakestore.net/testdir/testfile
```

3. Delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

4. Run YARN jobs with your input and output stored in ADLS:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
adl://<username>.azuredatalakestore.net/testdir/testfile adl://
<username>.azuredatalakestore.net/wordcountout
```

Deleting Data from ADLS
You can delete your data from Azure Data Lake Store (ADLS).

- To delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

Operational Changes (MapR 6.1.0)

Lists the functional changes made to existing commands in MapR version 6.1.0.

Note the following functional changes to existing commands in Version 6.1.

MapR Database

OJAI Support	MapR 6.1.0 introduces support for OJAI 3.0. For a list of classes and methods deprecated in OJAI 3.0, see https://docs.datafabric.hpe.com/apidocs/61/ojai/java/deprecated-list.html. MapR 6.1.0 deprecates support for OJAI 1.0. The next release after 6.1.0 will no longer support OJAI 1.0.
Permissions on Arrays in MapR Database JSON	Starting from MapR 6.1.0, when you grant permissions on a field using array syntax (for example, `person[]`), you no longer have to grant separate permissions if the field also contains non-array values. However, this can result in errors if you attempt to define a new permission that conflicts with an existing one.

For example, suppose you have the following two documents in a JSON table:

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith",
"first" : "John"}},
        {"name" : {"last" :
"Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" :
"Doe", "first" : "Jane"}}
}
```

In document `id001`, `person` is an array of nested documents and in `id002`, it is a single nested document.

The following table summarizes the behavior in 6.1 versus pre-6.1 when you grant permissions in the sequence shown:

Permission Grant Sequence	6.1 Behavior	Pre-6.1 Behavior	Key Differences
1. `person[]` **2.** `person`	**1.** Permission granted on `person` in documents `id001` and `id002` **2.** Error - conflicts with permission on `person[]` You do not need to grant this permission. The previous is sufficient.	**1.** Permission granted on `person` in document `id001` **2.** Permission granted on `person` in document `id002`	In 6.1, having permission on `person[]` also gives you permission on `person`. Prior to 6.1, you need two separate permissions.

last-updated: Apr 11, 2022

Permission Grant Sequence	6.1 Behavior	Pre-6.1 Behavior	Key Differences
1. `person` 2. `person[]`	1. Permission granted on `person` in document `id002` 2. Error - conflicts with permission on `person` You (or an administrator with appropriate permissions) must drop the permission on `person` before you grant permission on `person[]`.	1. Permission granted on `person` in document `id002` 2. Permission granted on `person` in document `id001`	In 6.1, if an array permission conflicts with an existing permission, you must remove the conflicting permission.

The new 6.1 behavior applies to permissions granted in earlier versions after you upgrade your MapR cluster.

Note: If you upgrade your cluster using rolling upgrades, whether you encounter pre-6.1 or 6.1 behavior depends on whether the MapR node enforcing the permission has been upgraded.

See Permissions on Arrays on page 538 for more details about the new 6.1 behavior.

Data Types and Secondary Indexes

In MapR Database 6.1.0, you are no longer restricted to creating secondary indexes on scalar data fields. You can now create indexes on fields with arrays and nested documents. As a consequence, a 6.1 index may contain additional rows that are missing in an equivalent pre-6.1 index. If a query uses a covering

last-updated: Apr 11, 2022

index, MapR Database 6.1 returns these additional rows. See Data Types and Secondary Index Fields on page 561 for more information about data type support.

Secondary Indexes and Upgrades

Starting with MapR Database 6.1, you can define secondary indexes using container field paths. Pre-existing indexes created in earlier releases do not support this new functionality, even after you upgrade your MapR cluster to 6.1. After you upgrade your cluster to 6.1, any new indexes you create support this functionality. You can use these indexes in your application if you are using a 6.1 (or later) client.

Note: If your client is running on a MapR cluster node, after you upgrade the cluster node, the client becomes a 6.1 client and supports the new indexing functionality. Your pre-6.1 client can use an index created in a 6.1 cluster if the index does not use the new container field path functionality.

For more information about indexes on complex types, see Complex Types Support in MapR Database JSON.

MapR File System

Data-on-Wire Encryption

Beginning with MapR 6.1, data-on-wire encryption is enabled by default for newly created volumes for secure clusters. Data-on-wire encryption encrypts data in a volume during transmission over the wire. Data-on-wire encryption is not supported for non-secure clusters. You can disable data-on-wire encryption for individual volumes using MCS, the `maprcli`, or REST API commands. For more information, see the `-wiresecurityenabled` parameter of volume create on page 1931 and volume modify on page 2005. See also Creating a Volume on page 864 or Modifying a Volume on page 892.

Impersonation

Beginning with MapR 6.1:

- You cannot generate a ticket with impersonated UID and/or GID as the following:
  - UID `0` and/or GID `0` (user root)
  - UID `mapr_uid` and/or GID `mapr_gid` (user mapr)
- User mapr can impersonate anyone, including user root.

For more information, see Managing Impersonation on page 1476 and `maprlogin on page 2130`.

MapR Tickets

Beginning with MapR 6.1, if the UID and GID in the ticket (without impersonation capability) is different from the UID and GID of the logged-in user, all operations are performed using the UID and GID of the ticket and not that of the logged-in user.

MapR Event Store For Apache Kafka (Streams)

Caution: Do Not Remove mapr-librdkafka In MapR 6.1 and later, the `mapr-core` package has a dependency on `mapr-librdkafka`. If the `mapr-librdkafka` package is installed, do not remove it manually. Doing so might result in the removal of MapR core packages, rendering the node unusable.

Using the **Incremental Install** function of the MapR Installer, you can safely deselect the **Streams Tools** and **Streams Clients** service options. The MapR Installer ensures that the `mapr-librdkafka` package is left intact when the services are removed. For manual operations, removing the `mapr-librdkafka` package is not recommended unless you also plan to remove the MapR software.

Partition Maximum As of MapR 6.1, the MapR Event Store For Apache Kafka API enforces a maximum of 4096 partitions for a topic. If you create an application with the MapR Event Store For Apache Kafka 6.1 API, the maximum number of partitions is 4096. If you previously created an application with MapR Event Store For Apache Kafka 6.0.1 API (or older) and you've upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in MapR 6.0.1 or earlier, you can continue to use the same number of partitions after upgrading.

MapR Installer

Off-Cluster Elasticsearch and OpenTSDB With MapR Installer 1.10, the installer no longer includes an option to support off-cluster Elasticsearch and OpenTSDB when security is turned on. For non-secure clusters, MapR continues to support the option for off-cluster Elasticsearch and OpenTSDB.

Deprecated Features

- None

Known Issues at Release (MapR 6.1.0)

You may encounter the following known issues after upgrading to Version 6.1. This list is current as of the release date. For a dynamic list of all known issues for all MapR product releases, refer to Support notices of known issues

Where available, the workaround for an issue is also documented in this topic. MapR regularly releases maintenance releases and patches to fix issues. We recommend checking the release notes for any subsequent maintenance releases to see if one or more of these issues are fixed.

Installation and Configuration Issues

You can see generic installation issues here: MapR Installer Known Issues.

Keytool error on SLES 12 SP4 Node	Running the `configure.sh` script on a SLES 12 SP 4 node can fail with the following error:
	`keytool error: java.security.ProviderException: Could not initialize NSS`
	The installation fails because the `mozilla-nss` dependency is not installed.
	Workaround: Install the `mozilla-nss` package using the following command, and rerun `configure.sh`:
	`zypper install mozilla-nss`

IN-2637	After a manual installation, Oozie and Hive services can fail to connect to a MySQL or MariaDB database because the server time-zone value is unrecognized

	or represents more than one time zone. The issue affects your installation if you applied the `mapr-patch` released on or after February 21, 2021 (including the latest `mapr-patch`). This issue affects manual installations but is fixed in Installer 1.14.0.0. **Workaround:** For manual installations, you must configure either the server or JDBC driver (using the `serverTimezone` configuration property) to use a more specific time-zone value if you want to utilize time-zone support. After running `configure.sh` but before starting the Oozie or Hive services, update the `serverTimezone` parameter in the `hive-site.xml` or `oozie-site.xml`. For more information, see MySQL Bug #95036.
MFS-6772	Installation of MapR 6.1 fails on Red Hat or CentOS 8.2 and later due to a missing dependency on sdparm. Getting dependency error as sdparm is removed from RHEL8. **Workaround:** See support advisory 4730.
MFS-10783	After a manual installation of release 6.1.0 or 6.1.1 on RHEL or CentOS 8.x, Collectd fails to start. Error messages indicate that `libcrypto.so.10` cannot open a shared object file. **Workaround:** Install the `compat-openssl10` package using the following command, and restart Collectd: `yum install compat-openssl10` Alternatively, you can install the `compat-openssl10` package during the course of manual installation before installing the `mapr-*` packages. See Step 3: Install Cluster Service Packages on page 150.
SPYG-1136	During a manual installation or upgrade, Collectd provided in core 6.1.0 won't start on RHEL / CentOS 8.2 because it expects the Python 2 libraries to be installed, and RHEL / CentOS 8.2 provides the Python 3 libraries instead. This issue does not affect installations or upgrades performed using the Installer. **Workaround:** Before installing the monitoring components, check to see if Python 2 is installed. If the following error is generated, try installing Python 2 on RHEL / CentOS 8.2: `failed: libpython2.7.so.1.0: cannot open shared object file`

Upgrade Issues

INFO-960	**Description:** The Kibana log (`/opt/mapr/kibana/kibana-<version>/var/log/kibana/kibana.*.<#>`) can show the following error if you upgrade Kibana without capturing a snapshot of the Kibana index, as described in Pre-Upgrade Steps for MapR Monitoring on page 342. This issue was

noticed after an upgrade from MapR 6.0.1 with EEP 5.0.3 to EEP 6.1.0 with EEP 6.2.0:

```
{"type":"error","@timestamp":"2019-0
4-25T01:29:26Z","tags":
["fatal","root"],"pid":28300,"level":"
fatal","error":
{"message":"Index .kibana belongs to
a version of Kibana that
cannot be automatically migrated.
Reset it or use the X-Pack upgrade
assistant.","name":"Error","stack":"Er
ror: Index .kibana belongs to a
version of Kibana that cannot be
automatically migrated. Reset it or
use the X-Pack upgrade
assistant.\n
at assertIsSupportedIndex (/opt/mapr/
kibana/kibana-6.5.3/src/server/
saved_objects/migrations/core/
elastic_index.js:237:15)\n
at Object.fetchInfo (/opt/mapr/kibana/
kibana-6.5.3/src/server/saved_objects/
migrations/core/
elastic_index.js:48:12)\n
at
<anonymous>"},"message":"Index .kibana
 belongs to a version of Kibana that
cannot be automatically migrated.
Reset it or use the X-Pack upgrade
assistant."}
```

Resolution: Use this procedure to migrate the Kibana index to version 6.0. Then run Kibana from `/opt/mapr/kibana/kibana-6.5.3/bin`.

MAPRYARN-129

Issue: For some clusters that are upgraded from MapR 6.0.1 to 6.1.0, using any Hadoop command generates the following `java.lang.ClassNotFoundException`:

```
hadoop fs -ls /
log4j:ERROR Could not instantiate
class
[org.apache.hadoop.yarn.WorldWritableL
ogAppender].

```

This issue only affects clusters that use scheduler debug logging as described in **31038** of Known Issues at Release (MapR 6.0.1). The issue occurs because the `hadoop-yarn-common-2.7.0-mapr-1808.jar` in MapR 6.1.0 does not contain the `org.apache.hadoop.yarn.WorldWritableLogAppender` Java class.

Workaround: Remove the following lines from the `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/log4j.properties` file:

```
yarn.debug.controller.logger = INFO,
ED
yarn.debug.controller.log.file=yarn-ma
pr-scheduling-debug.log
yarn.debug.controller.log.maxfilesize=
256MB
yarn.debug.controller.log.maxbackupind
ex=20

log4j.logger.org.apache.hadoop.yarn.se
rver.resourcemanager.scheduler.
DebugController=$
{yarn.debug.controller.logger}
log4j.additivity.org.apache.hadoop.yar
n.server.resourcemanager.scheduler.
DebugController=false

log4j.appender.ED=org.apache.hadoop.ya
rn.WorldWritableLogAppender
log4j.appender.ED.File=$
```

```
{hadoop.log.dir}/$
{yarn.debug.controller.log.file}
log4j.appender.ED.MaxFileSize=$
{yarn.debug.controller.log.maxfilesize
}
log4j.appender.ED.layout=org.apache.lo
g4j.PatternLayout
log4j.appender.ED.layout.ConversionPat
tern=%d{ISO8601} : %m%n
```

30422

Issue: Using the `configure.sh -R` command after an upgrade from 5.2.x to 6.0 or later can return error messages for some MapR Monitoring components. For example:

```
/opt/mapr/server/configure.sh -R
Configuring Hadoop-2.7.0 at /opt/mapr/
hadoop/hadoop-2.7.0 Done configuring
Hadoop Node setup configuration:
drill-bits fileserver hbinternal nfs
nodemanager opentsdb Log can be found
at: /opt/mapr/logs/configure.log
ls: cannot access /opt/mapr/
hbinternal: No such file or directory
Configuring opentsdb
getopt: unrecognized option
'--unsecure'
getopt: unrecognized option '-EC'
usage: /opt/mapr/opentsdb/
opentsdb-2.3.0/bin/configure.sh
[-nodeCount <cnt>] [-nodePort
<port> -nodeZkCount <zkCnt>]
[-nodeZkPort <zkPort>]
[-R] -OT "ip:port,ip1:port," -Z
"ip:port,ip1:port,"

/opt/mapr/server/configure.sh -R
Configuring Hadoop-2.7.0
at /opt/mapr/hadoop/hadoop-2.7.0
Done configuring Hadoop
Node setup configuration:
drill-bits fileserver grafana
hbinternal historyserver
nfs nodemanager spark-historyserver
Log can be found
at: /opt/mapr/logs/configure.log
ls: cannot access /opt/mapr/
hbinternal: No such file or directory
ls: cannot access /opt/mapr/
spark-historyserver: No such
file or directory
Configuring grafana
getopt: unrecognized option
'--unsecure'
getopt: unrecognized option '-EC'
usage: /opt/mapr/grafana/
grafana-4.1.2/bin/configure.sh
[-nodeCount <cnt>] [-nodePort
<port>] [-grafanaPort
<port>] [-secureCluster]
```

```
[-loadDataSourceOnly] [-R] -OT
"ip:port,ip1:port,"
```

These errors are generated because a newer version of the server `configure.sh` uses certain options that do not exist with older ecosystem components.

Workaround: None. The upgrade can succeed in spite of the errors, and the current ecosystem configuration is left unchanged. The error messages can be ignored.

File System

MFS-14890

Issuing `hadoop mfs -lsfid` with a non-`mapr` user ticket returns an `Operation not permitted` error. For example:

```
2022-03-15 18:12:23,6663 DEBUG
Cidcache fc/cidcache.cc:4315 Thread:
18743 Enter GetVolumeMountPoint
138102135
2022-03-15 18:12:23,6663 DEBUG
Cidcache fc/cidcache.cc:4754 Thread:
18743 Sending RPC to CLDB:
10.163.172.130:7222
2022-03-15 18:12:23,6672 DEBUG
Cidcache fc/cidcache.cc:4193 Thread:
18743 GetVolumeProperties returns: 0,
numTries:0
2022-03-15 18:12:23,6673 ERROR
Cidcache fc/cidcache.cc:4277 Thread:
18743 VolumePropertiesLookupRequest
failed, cldb returned err
Operation not permitted(1), CLDB:
10.163.172.130:7222
2022-03-15 18:12:23,6673 DEBUG Client
fc/client.cc:11139 Thread: 18743
GetVolumeMountPoint returns: 0
```

In a secure cluster, this happens because the `hadoop mfs -lsfid` command works only when the UID associated with the ticket has either READ permission or full permission at the cluster level.

Workaround: Assign read permission to the UID by using an ACL to give the non-`mapr` user login permission. For example:

```
# maprcli acl  edit -type
cluster -user user1:login
maprcli acl show -type cluster
Allowed actions            Principal
[login, ss, cv, a, fc, cp]  User mapr
[login, ss, cv, a, fc, cp]  User root
[login]                    User user1
```

Indexing and MapR Drill

MD-2218 (previously 28041)

Running multiple queries in sequence can cause Drillbits to run out of direct memory. Limiting records in large batches to 5KB may prevent this issue

from occurring. Should Drill return an out of memory exception, issue the following command to restart the Drillbits:

```
$ maprcli node services -name
drill-bits -action restart -nodes
<node host names separated by a space>
```

28096

If you use the Google Guava library in your application and encounter the following error:

```
Caused by:
java.lang.NoSuchMethodError:
com.google.common.base.Stopwatch.creat
eStarted()Lcom/google/common/base/
Stopwatch;
```

You must use version 18.0 of the library. If you use Maven, you can use the following dependency:

```
            <dependency>

<groupId>com.google.guava</groupId>
              <artifactId>guava</
artifactId>
              <version>18.0</version>
              </dependency>
```

MapR Database

MAPRDB-1375

If you have a MapR Database JSON table with multiple column families and the table has a secondary index, after you perform a series of update operations (for example: set, increment, decrement, replace, append, etc.) on the table, the index may have duplicate rows.

MAPRDB-1520

If you have an OR condition that references a container field path more than once, and MapR Database uses an index to process the query, then the query may return incorrect results. You can workaround this problem by forcing MapR Database to not use indexes. See Forcing Secondary Index Usage in OJAI on page 2589 for details.

27057

When you issue a maprcli table changelog add command, during the initial sync when the existing data is copied to the change log, the end-to-end latency during the initial 5 minutes can be high. After the initial sync, latency will be small, specifically 2-4 seconds.

MAPRDB-2092

In the MapR Database, adding a table index or replicating a table fails if the cluster administrator (MAPR_USER) does not have write access to the parent volume of the table.

Workaround: For more information, see this support advisory. If a patch is not available or the available patch has not been applied, another workaround is to add the MAPR_USER to the writeACE for the table parent volume.

MapR Client

23624

The same MapR client can access both secure and nonsecure clusters; however, a MapR client that is configured to access a secure cluster can access a nonsecure cluster only if these conditions are met:

- The secure cluster must be listed first in `mapr-clusters.conf`.
- A user must obtain a ticket for the secure cluster even if the user wants to access only the nonsecure cluster.

MapR Control System

MON-4891

Description: The MCS displays an Oops error on the **Admin** > **User Settings** > **SMTP** page when the `mapr.smtp.provider` is not any of the 3 allowed options (Gmail, Office 365, SMTP). This impacts all upgrade from 5.x to 6.x where your SMTP provider setting is "other".

Resolution: Run the following command to resolve this error if your SMTP provider is not Gmail or Office 365:

```
maprcli config save -values
{"mapr.smtp.provider":"smtp"}
```

If your SMTP provider is Office 365, run the following command:

```
maprcli config save -values
{"mapr.smtp.provider":"office"}
```

MON-4874

Description: When MAPR_EXTERNAL environment variable is set, the MCS UI might not be accessible and might return the following error:

```
HTTP ERROR 503
           Problem accessing /app/mcs/
```

Resolution: Remove entries for `tsdbService` and `amazonS3Service` from the `/opt/mapr/apiserver/conf/applicationContext.xml` file. For example:

1. Remove the following and save and close the file:

```
<bean id="tsdbService"
class="com.mapr.admin.service.impl.
TsdbServiceImpl"/>
<bean id="amazonS3Service"
class="com.mapr.admin.service.Amazo
nS3Service"/>
```

2. Restart apiserver.

MON-4862

Description: The MCS does not start after an upgrade to MapR 6.1 if the installed license does not

last-updated: Apr 11, 2022

have table support enabled. See Support Portal for additional information.

MON-4788

Description: When running large number of table (get, scan, index) operations, the API server may become unresponsive and you may see following error: GC overhead limit exceeded.

Resolution: Check the heap size and increase it based on available system resources or set up a load balancer to distribute the HTTP requests (load) to other API servers. To increase heap size:

1. Open `/opt/mapr/apiserver/bin/mapr-apiserver.sh` file.
2. Modify the value for `JVMXMS` and `JVMXMX` (under JVM tuning).

   For example, modify the following in the file:

   ```
   # JVM tuning
   JVMXMS=${JVMXMS:-1024m}
   JVMXMX=${JVMXMX:-1024m}
   ```

3. Save and close the file.
4. Restart apiserver for the changes to take effect.

   For example, run the following command to restart the apiserver:

   ```
   maprcli node services -action
   restart -name apiserver -nodes
   `hostname`
   ```

MON-4776

Description: You cannot mount or unmount multiple volumes at the same time by selecting them from different pages in the **Volumes** pane (of the **Data** > **Volumes** page).

Workaround: Increase the number of rows, if possible, in the **Volumes** pane and select the volumes from the same page to mount or unmount.

MON-4701

Description: The table metrics list view displays metric values calculated using endTime-startTime. If you select a time range like **Today**, **This Week**, **This Month**, where the end time is in the future, no data is displayed in the columns.

Workaround: Choose **Today so far**, **This week so far**, **This month so far** instead to view the most current data.

MON-3922

Description: After upgrading to v6.1.0, editing volumes that have no volumes ACEs is not supported in MCS. You cannot view or edit volumes that were created using MapR Data Platform version <=5.1.

Workaround: To resolve the issue, do the following:

- Use the `volume modify` on page 2005 command to set or modify volume ACEs.
- Download and install the following patches:

last-updated: Apr 11, 2022

- `mapr-apiserver-6.1.0.20190301101733.GA-1.noarch`
- `mapr-webserver-6.1.0.20190301101733.GA-1.noarch`

MON-3817	**Description:** The **Node Health by Topology** pane does not reflect the most recent topology of the node if the node was just moved to a different/new topology. **Workaround:** Navigate to another tab or page and then return to the page to view the updated topology for the node in the **Node Health by Topology** pane.
MON-3709	**Description:** The list of services in the **Services** page do not refresh per the configured refresh rate settings. **Workaround:** To view the latest status for the services, reload the page in the browser.
MON-3476	**Issue:**In the MapR Control System, table permissions can only be modified by the owner/creator of the table. **Workaround:** User, who is not the owner but has table admin permissions, must use the CLI to modify table permissions.
MON-3452	**Issue:** After selecting the **Include System Volumes** checkbox to display system volumes in the **Volumes** list pane, if you set quota (using the link in the **Quota** column), the system volumes are no longer displayed in the list of volumes even though the system volumes checkbox is still selected. **Workaround:** Deselect and then re-select the **Include System Volumes** checkbox to display the system volumes in the list of volumes.
MON-3438	**Issue:** You may experience some latency in the **Admin** > **Cluster Settings** > **Alarms** page when you click the name of an alarm to display the **Alarm Settings** window for the alarm.
MON-3425	**Issue:** When you filter the list of alarms in the **Alarms** summary page, the page does not refresh and display the correct list of alarms if there are muted alarms.
MON-3407	**Issue:** If you are upgrading from a pre-6.0 version, the MapR Control System might display 0 instances of webserver running in the **Services** page. This is because starting from v6.0, the UI static files are in `mapr-webserver` and the `mapr-apiserver` runs the server that sends the queries. For more information on webserver in v6.0, see Setting Up the Control System on page 423.
MON-3404	**Issue:** The topic search field in the **Stream (detail)** > **Topic** tab does not display correctly in Firefox. **Workaround:** Use Chrome (v58 and later) to perform a topic search.
MON-3247	**Issue:** The MapR Control System does not display NFS edge nodes and POSIX client nodes that are currently connected to the cluster when you sort the list of nodes by topology. **Workaround:** Use the `node list` on page 1705 command to retrieve the list of client nodes currently connected to the cluster.

last-updated: Apr 11, 2022

MON-2409	**Issue:** When you try to navigate to another cluster by clicking on the cluster name from the drop-down list at the top of the page, the **Overview** page for the current cluster displays and it takes a few minutes to display the MCS login page for the other cluster.
MON-2374	**Issue:** If a node has multiple IP addresses, the log viewer link for the services in the nodes information page is broken because the Kibana URL contains multiple IP addresses. **Workaround:** Remove all irrelevant IP addresses in the URL and use the modified URL to view logs for the service.
MON-2321	**Issue:** If Elasticsearch fails, the **Services** page does not show the nodes on which Elasticsearch has failed.
MON-2219	**Issue:** If you add Streams license separately, you may not be able to view the **Streams** page. **Workaround:** Contact MapR Support.
MON-2218	**Issue:** When you preserve snapshots, there is no notification (success message) or indication (**Expires On** column still does not show *No Expiration*) even though the operation succeeded. **Workaround:** Refresh the page after preserving a snapshot to see the *No Expiration* setting in the **Expires On** column.
MON-2076	**Issue:** When you select topics to remove, deselect all the topics in the **Remove Topic** confirmation window and click **Cancel**, then select a topic in the page by clicking on the checkbox, the **Remove Topic** window opens again even if you did not click on the **Remove Topic** button. **Workaround:** Refresh the page.
MON-2018	**Issue:** In the **Add Change Log** page, after entering field to add in the **Publish Selected Field Path** text field, the **Add Field** button is disabled. **Workaround:** Click outside the text field to enable the **Add Field** button.
MON-2011	**Issue:** When adding or editing the compression setting on a replica, selecting **Inherited** does not have any effect. The default value is lz4. **Workaround:** Do not select **Inherited** as the compression setting on a replica.
MON-2009	**Issue:** When modifying replica of a binary table with three or more column families, if you select different set of columns to replicate for different column families, the operation might result in an error.
MON-1994	**Issue:** If you adjust the system time, the time stamp associated with the alarm in the **Active Alarms** pane might show negative value.
MON-1968	**Issue:** In the **User Disk Usage** page, you cannot remove the email address after setting an email address for an entity by editing the properties.
MON-1929	**Issue:** The **Save Changes** button in the **Access Control Expression** builder page is disabled after entering user, group, or role name in text field.

last-updated: Apr 11, 2022

	Workaround: Click outside the field to enable the **Save Changes** button.
MON-1810	**Issue:** When editing multiple volumes, you cannot undo changes to **Auditing** and **Accountable Entity** fields by clicking ↶.
MON-1755	**Issue:** When creating a mirror volume, after entering the name of the source volume on the remote cluster and selecting the remote cluster on which the volume resides, you may see an error that the source volume does not exist. **Workaround:** Re-enter the name of the source volume on the remote cluster.
MON-1221	**Issue:** In the **Alarm Settings** window, if you click the cursor in the **Additional email recipients** text field and then press the return/enter key in the keyboard without entering an email address, the **Cluster Settings** page displays once again.

MapR Monitoring

ES-58	**Issue:** After an upgrade from MapR 5.2.x with EEP 3.0.x to MapR 6.1.0 using the MapR Installer, Elasticsearch and Fluentd fail to start, and the Elasticsearch roles file (`/opt/mapr/roles/elasticsearch`) is missing. This issue has been seen on upgrades from MapR 5.2.1 with EEP 3.0.3 to MapR 6.1.0 with EEP 6.0.0 but can affect all upgrades from EEP 3.0.x.
	Workaround: To work around the issue, you must re-create the roles file. On the node where Elasticsearch was upgraded and the roles file was removed:
	1. Re-create the roles file by using this command:
	`touch /opt/mapr/roles/elasticsearch`
	2. Run configure.sh with the `-R` option:
	`/opt/mapr/server/configure.sh -R`
	3. Restart Fluentd using the MapR Control System (MCS) or a terminal.

SPYG-1083	**Issue:** On initial startup, Kibana 6.5.3.0 takes longer to complete its optimization than previous Kibana versions. During this time, if you try to connect to Kibana, the browser can show: `Kibana server is not ready yet` This issue affects EEP 6.1.0 installations. (Kibana 6.5.3.0 was introduced with EEP 6.1.0.) **Workaround:** Wait for the Kibana optimization to complete before trying to connect. To check the progress of startup operations, see the startup log at `/opt/mapr/kibana/kibana-6.5.3/var/log/`

last-updated: Apr 11, 2022

`kibana/kibana_startup.log`. Messages such as the following indicate that startup is still in progress:

```
2019-01-12 13:10:26: Waiting on
Kibana daemon to start
2019-01-12 13:11:26: kibana server
optimizing - waiting for it to
complete
```

The following message indicates that optimization is complete:

```
2019-01-12 13:16:47: kibana server
optimizing completed
```

OTSDB-72

Issue: The memory allocated to OpenTSDB can be insufficient, resulting in empty graphs and out-of-memory or `GC overhead limit exceeded` errors.

Workaround: Increase the default memory for OpenTSDB by making the following changes on all OpenTSDB nodes:

1. Edit the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file to change:

   ```
   service.heapsize.max=2000
   service.heapsize.min=2000
   ```

   to

   ```
   service.heapsize.max=6000
   service.heapsize.min=6000
   ```

2. Edit the `/opt/mapr/opentsdb/opentsdb-*/etc/init.d/opentsdb` file to change:

   ```
   $
   {JVMXMX:=-Xmx2000m -Xss1m -XX:MaxMe
   taspaceSize=128m}
   ```

   to

   ```
   $
   {JVMXMX:=-Xmx6000m -Xss1m -XX:MaxMe
   taspaceSize=128m}
   ```

3. Restart the OpenTSDB service:

   ```
   maprcli node services -name
   opentsdb -nodes <space-separated
   list of OpenTSDB nodes> -action
   restart
   ```

OTSDB-60

Issue: EEPs 6.0.x or earlier with MapR Installer 1.10 or earlier can generate numerous instances of the following streams error in the `opentsdb.err` file:

```
2018-06-22 21:33:55,5510 ERROR
StreamsClient fs/client/marlin/cc/
marlinclient.cc:402 Thread: 2958 /var/
mapr/mapr.monitoring/streams/0 does
not exist
```

The error might be valid for users upgrading from a previous release, but is generated even when users have not upgraded.

Workaround: To stop the error from being generated, use the following workaround:

1. Create the `/var/mapr/mapr.monitoring/streams` directory:

   ```
   hadoop fs -mkdir /var/mapr/
   mapr.monitoring/streams
   ```

2. Use `maprcli` to create a stream that will prevent the error from being generated:

   ```
   maprcli stream create -path /var/
   mapr/mapr.monitoring/steams/0 -ttl
   86400
   ```

SPYG-994

Issue: The time-to-live for MapR Event Store For Apache Kafka metrics is fixed at 30 days and cannot be reduced to lower disk space usage.

SPYG-934

Issue: On secure Ubuntu 14.04 or 16.04 clusters, Elasticsearch fails to generate a keystore password if the `uuid-runtime` package is not installed. `uuid-runtime` is one of the MapR Installer prerequisites.

Workaround: Install the `uuid-runtime` package from the default Ubuntu repository:

```
apt-get install uuid-runtime
```

MapR PACC

CORE-498:

Issue: After installation of the `mapr-thin-client*.tar.gz`, the `mapr-posix-client-container` fails to start, and the following message appears in the `/opt/mapr/logs/posix-client-container.log`:

```
Failed to call init on library /tmp/
libMapRClient_c.so.0
```

This issue is fixed in release 6.2 but might affect earlier PACC releases.

last-updated: Apr 11, 2022

Workaround: Create the following file (the file can be empty), and retry the operation:

```
/opt/mapr/hadoop/hadoop-2.7.4/etc/
hadoop/core-site.xml
```

See also MapR PACC Known Issues on page 417.

NFSv4

32364

Issue: Any running IO on NFSv4 mount (with kerberos) is stuck if the krb5 ticket expires for the current user. The mount point also hangs and becomes inaccessible.

Workaround: Restart rpcgssd service with the new ticket to make the mount point accessible and re-trigger the IO to proceed.

Oozie

29634

Issue: On a secure cluster, Oozie jobs can fail when the timeline server for the Hive-on-Tez user interface is configured with MapR-SASL.

Workaround: Restart the resource manager and timeline server. For more information, see Configuring the Timeline Server to Use the Hive-on-Tez User Interface on page 3507.

YARN

MAPRYARN-185

YARN cgroups are not supported on RHEL 7.x. In RHEL 7.x, libcgroup is deprecated and systemd maintains cgroups. Moving default hierarchies that systemd manages can generate unexpected results.

PJDTest Suite Compliance

28912

Issue: When trying to open a FIFO on a FUSE mounted filesystem, permissions to perform the operation are not checked.

29234

Issue: The FUSE-based POSIX can only trace at millisecond level and the test suite utimensat in pjdtestsuite fails because the test suite sets time in nanoseconds.

29237

Issue: Any user can set time using `touch -t` for any file on a FUSE mounted filesystem.

Timeline Server

See Hive-on-Tez User Interface Known Issues on page 3510.

Resolved Issues

Lists the issues that were resolved in MapR version 6.1.0

The following MapR issues, which were reported by customers, are resolved in Version 6.1.

Component	Number	Description	Resolution

last-updated: Apr 11, 2022

CLDB	31346	Number of resync are large for an extended time after a couple of nodes are stopped/restarted in the cluster	The issue occurs when there are a large number of snapshots on a cluster. There are new alarms to warn about this issue, and are configurable. See the following resources: • Cluster Alarms on page 2222 • cldb.conf on page 2182 • Configuring the Alarm Threshold Using the CLI on page 786
	31620	Volume mirroring floods log with misleading error	The bug occurs when mirroring happens between clusters that have both internal and external IPs set in `mapr-clusters.conf`. The getIPTypeForCluster method in CLDBRpcCommonUtils is unable to determine whether the IP type is internal or external. The workaround is to put in the internal IP in `mapr-clusters.conf` and keep the external IP in the `env.sh` file. See: Starting the Mirror on page 919
Upgrade	31038	Prior to 6.1, the log4j.properties file was not automatically updated in an upgrade	All files update automatically.
Upgrade	29752	Prior to 6.1, if Oozie was not upgraded to the EEP 4.0.0 version, the Oozie process would fail following a manual upgrade from MapR 5.2.x/ EEP 3.0.1 to MapR 6.0	The upgrade process works correctly.

FileClient	31024	When `hadoop fs -rmr` command is run to remove a list of files/directories, if a file/directory is not present at the time of removal, the command returns an error, 'no such file or directory', and terminates without removing remaining files and/or directories from the given list.	When `hadoop fs -rmr` command is run to remove a list of files and/or directories, if a file/directory from the list is not present on the system, the command now removes remaining files and/or directories from the list.
	30987	Memory leak in DoPathWalk	This leak is fixed.
	31026	FileClient should use one source port to connect to any server	This issue occurred because FileClient was using multiple source ports to connect to file servers, thus exhausting all available ports. This issue is now fixed to let FileClient connect on a single source port. See Client Side Port Binding in What's New in Version 6.1.0 on page 34
	31129	File Client crashed at mapr::fs::CidCache::GetBinding	The issue occurred because the assumption was that the number of volume replicas will not exceed 7. This issue is fixed.
	31146	The SQL queries are failing intermittently	The issue occurred because user impersonation was faulty. This issue is fixed.
	31738	Create request should take setattr credentials from ticket	To avoid this issue, all requests should take the credentials from the ticket, and not use the context user. This problem is fixed. See Managing the FUSE-Based POSIX Client on page 1255
	31804	FileClient hangs at WaitUntilEnqueued	This is a backport of the fix in #24266, where the Idle Flusher needed to be disabled to resolve hangs, for MapR version 5.2.2. This fix is backported.

FileServer	26792	createTTVolume.sh needs to reliably determine the MFS state before deciding to recreate the local NM volume	This bug caused rolling updates to fail. This issue is fixed.
	30063	FCR sent during disk I/O error causes all 3 copies of container to be unavailable	This bug occurred because the primary filesystem instance reported incorrect replica chain management information. This issue is fixed.
	30917	EIO on a read op of a local volume cid deletes/offlines the container but local volume in not recreated	This issue was caused because Volume IDs were not being passed in HandleDamagedVolumes() when called from the ContainerOffline case, causing the volumes to be deleted and not recreated automatically. This bug is fixed.
	31007	FUSE clients do not honor impersonation constraints in servicewithimpersonation tickets	This issue was caused when FUSE failed to honor constraints for a servicewithimpersonation ticket which includes impersonatedgids constraints. This issue is fixed, and FUSE now enforces such constraints. A support advisory is available at https://support.datafabric.hpe.com/s/article/FUSE-Clients-do-not-honor-impersonation-constraints-in-servicewithimpersonation-tickets?language=en_US
	31301	Some snapcids on mirror volumes that are marked for delete never get deleted	This issue is fixed.
	31361	Rename operation fails on tables and streams	This issue occurred when a table or stream already existed in a rename operation... that is, in mv x y -> y already exists. This issue is fixed.
	31365	MFS Rpc thread on CLDB node is running out of CPU	This issue occurred because the process that reads from, and writes data to the key-value store, was not offloaded to the compression thread. This issue is fixed.
	31453	MFS on CLDB secondary instances crashed due to failure in kvstorerangedelete (ENOENT)	This bug occurred due to corruption of the structure that holds information about volume containers. This issue occurred due to a large number of containers being present in the volume. This issue is fixed. Appropriate documentation that depicts how to set the alarm for too many containers is available at Configuring the Alarm Threshold Using the CLI on page 786 (see CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS), and cldb.conf on page 2182
	31981	Disk failure on Master (A) container when reporting loss of B to CLDB, can cause all copies to be unavailable	The problem arose because there was no sanity check to check for the validity of a replica, when the reconnection timer expires. This check has been added.
FS::ACE	26280	"hadoop mfs -setace" does not accept groups with spaces in the name	Spaces in AD group names caused the issue. This issue is fixed. Spaces in AD group names are correctly parsed.
	30245	Permission denied error due to aceCache when readdir served by the primary node of NC	This issue occurred due to a null character in the ACE expression, as the ACE for execute file was null. This issue has been resolved.

last-updated: Apr 11, 2022

FS::Audit	30928	expandaudit does not resolve most of fids in a huge volume	This issue is fixed by making logging more explanatory.
FS::Fuse	31662	Fuse : OPEN with O_TRUNC fails with permission denied error	This issue is fixed.
	31730	Fuse: mkdir fails with EBUSY	The issue is caused by inode number reuse. The work around is to set the `fuse.use.compressed.inode.format` parameter to 1 as documented in Configuring the MapR FUSE-Based POSIX Client on page 1240
	32030	Fuse Assert in fs/client/fuse/cc/fuse_special_ll.c	This issue was caused by Fuse reading debugs_assert() from the wrong location. This issue is now fixed.
	32050	Fuse needs to honor prod_build	This issue was caused by Fuse reading debugs_assert() from the wrong location. This issue is now fixed.
	32074	Memory leak in fuse cache	This leak is fixed.
FS::Snapshot	31051	MCS & maprcli command are not showing correct Volume size	This issue occurred because some snapshot containers might have had a delayed deletion. This issue is fixed.
hoststats	31858	Hoststats process is not coming up after changing the default value (5660) of "mfs.server.port" in /opt/mapr/conf/mfs.conf	The problem occurred because the ports were hadcorded in MapR settings. Using a port other than the default, causes the shared memory key to fail. This issue is fixed.
MCS	MON-3709	The list of services in the **Services** page do not refresh per the configured refresh rate settings.	The list of services in the **Services** page refresh per the configured refresh rate settings.
MapR Monitoring	SPYG-1010	The Grafana dashboard shows "No data points" for Volume metrics	Dashboard entries are correct.
	SPYG-916	MapR monitoring index is not loaded correctly.	The MapR monitoring index loads correctly.
MapR Event Store for Apache Kafka	31074	[Kafka 1.0] incorrect behavior for offsetsForTimes when streams.rpc.timeout.ms is configured	Behavior corrected for offsetsForTimes when streams.rpc.timeout.ms
Elasticsearch	ES-27	Elasticsearch fails to start correctly	Elasticsearch starts correctly.

MapR Database	29278	Puts to tablets that failed with out of space errors, continue to fail on the first put, even though there is sufficient space; subsequent puts succeed.	When space becomes available, the very first put no longer returns an error.
	30489	Client rpc trace messages for slow operations are not printing tablet `fid`	The messages include tablet `fid`.
	31092	MapR filesystem nodes are crashing when there is a burst of read requests	Corrected batching of read requests to avoid the condition that was causing the crash.
	31297	Using Python `happyhbase` module to scan a MapR Database table via HBase Thrift causes the Thrift server to hang	Addressed underlying issue that was causing the hang.
	31766	MapR filesystem node crash causes client RPC timeouts during get and put operations	Corrected the underlying logic for notification calls when creating new MapR Database buckets.
	31901	Memory corruption occurs when deleting/ freeing memory	Corrected race conditions that were causing the corruption.
	32262	Incremental bulkload via MapReduce fails to load data, even though it does not report an error	Corrected the underlying logic that was causing the incremental load to fail without returning an error.
NFS	31810	Unable to mount specific volume, when `cldb.reject.root` is enabled	Enabling `cldb.reject.root` caused NFS mounts to fail. This issue is fixed.
security	31935	All versions of MapR have Serious Ticket Vulnerability Enabling Authority Escalation	This issue was caused by CLDB generating tickets from falsified credentials. This issue is fixed. A security bulletin is available at https://support.datafabric.hpe.com/s/article/MapR-Ticket-Credentials-can-become-compromised?language=en_US and the vulnerabilities list is updated and available at Security Vulnerabilities on page 6569
Warden	31628	maprcli urls show the wrong value for hbmaster after shutdown of current HBmaster	This issue occurred because maprcli had stale information on a HBase Master process that was killed. This issue is fixed.

YARN	25473	Aggregated log is written with wrong ownership	Addressed the underlying issue that was causing writing the aggregated log to the wrong user.
	31082	ResourceManager address does not resolve after redirect via a proxy request	Fixed incorrect condition that updated the current ResourceManager address.
	31174	In the primary application log, the following error repeatedly occurred: "Tez AM is trying to access Timeline server and it fails"	TEZ AM is released after job or session is completed.
	31200	YARN job submission using server side uid resolution fails with ownership exception	The problem occurred because the username was not read from the submitted ticket. This issue is fixed.
	31487	Containers fail in LOCALIZING state	Implemented clean up of subprocesses spawned by Shell when the process exits. Localization failures are available in the container diagnostics.
	31679	CVE-2016-6811 user who can escalate to Yarn user can possibly run arbitrary commands as a root user	Fixed the underlying security vulnerability.
	32178	Thread leak when executing a Scoop job	Fixed thread leak.
	32304	Fails to refresh labels for nodes in the cluster	DefaultContainerExecutor sets proper permissions.

Packages and Dependencies for MapR Software

Package and dependency details for MapR 6.1 platform and ecosystem components.

For downloadable packages, see these links:

- MapR Core Packages
- EEP Packages
- MapR Installer Packages

For MapR Installer package dependencies, see:

- MapR Installer Prerequisites and Guidelines

This table shows the MapR 6.1 package dependencies for Red Hat / CentOS and SUSE. A dash (—) indicates no dependency.

	Depends on . . .	
This package . . .	**These MapR packages**	**And these non-MapR packages**
`mapr-apiserver`	`mapr-core`	—
`mapr-cldb`	`mapr-core` `mapr-fileserver`	—

`mapr-client`	`mapr-librdkafka`	`glibc`
		`libgcc`
		`libstdc++`
		`syslinux`

last-updated: Apr 11, 2022

This package . . .	Depends on . . .	
	These MapR packages	**And these non-MapR packages**
mapr-compat-suse	—	/etc/default/useradd /sbin/rpcinfo /usr/sbin/acpidump libffi4 libgcc_s1 libsnappy1 libstdc++6 openssl
mapr-core	mapr-core-internal mapr-hadoop-core mapr-librdkafka (version 0.11.3 or later) mapr-mapreduce2	—
mapr-core-internal	—	dmidecode glibc hdparm initscripts irqbalance libgcc libstdc++ nss (version 3.19 or later) redhat-lsb-core sdparm shadow-utils syslinux
mapr-fileserver	mapr-core	—
mapr-hadoop-core	mapr-core-internal	—
mapr-historyserver	mapr-mapreduce2	—
mapr-loopbacknfs	—	iputils nfs-utils redhat-lsb-core rpcbind
mapr-mapreduce2	mapr-hadoop-core	—
mapr-nfs	mapr-core	/usr/sbin/rpcinfo iputils nfs-utils
mapr-nodemanager	mapr-mapreduce2	—

last-updated: Apr 11, 2022

This package . . .	Depends on . . .	
	These MapR packages	**And these non-MapR packages**
mapr-posix-client	mapr-client	—
mapr-resourcemanager	mapr-mapreduce2	—
mapr-single-node	mapr-cldb mapr-fileserver mapr-nfs mapr-webserver mapr-zookeeper	—
mapr-upgrade	mapr-core	rpmrebuild
mapr-webserver	mapr-apiserver	—
mapr-zk-internal	—	—
mapr-zookeeper	mapr-core mapr-zk-internal	—

These MapR 5.x packages were removed for MapR 6.x:

- mapr-jobtracker
- mapr-mapreduce1
- mapr-metrics
- mapr-tasktracker

This table shows the MapR 6.1 package dependencies for Ubuntu:

This package . . .	Depends on . . .	
	These MapR packages	**And these non-MapR packages**
mapr-client	mapr-librdkafka (version 0.11.3 or later)	awk bash (version 2.05a-11 or later) coreutils (version 5.0-5 or later) grep (version 2.4.2-3 or later) libc6 libgcc1 libstdc++6 perl procps (version 1:2.0.7-8 or later) sed (version 3.02-8 or later) syslinux

This package . . .	Depends on . . .	
	These MapR packages	**And these non-MapR packages**

`mapr-core-internal`	—	`adduser` (version 3.11 or later)
		`awk`
		`bash` (version 2.05a-11 or later)
		`coreutils` (version 5.0-5 or later)
		`dmidecode`
		`grep` (version 2.4.2-3 or later)
		`hdparm`
		`libc6`
		`libgcc1`
		`libstdc++6`
		`lsb-base`
		`irqbalance`
		`perl`
		`procps` (version 1:2.0.7-8 or later)
		`sdparm`
		`sed` (version 3.02-8 or later)
		`syslinux`
		`sysvinit-utils`

`mapr-loopbacknfs`	—	`iputils-arping`
		`lsb-base`
		`rpcbind`

`mapr-nfs`	`mapr-core`	`awk`
		`bash` (version 2.05a-11 or later)
		`coreutils` (version 5.0-5 or later)
		`grep` (version 2.4.2-3 or later)
		`iputils-arping`
		`nfs-common`
		`perl`
		`procps` (version 1:2.0.7-8 or later)
		`sed` (version 3.02-8 or later)

Patches and Documentation

Describes important considerations for patches and patch documentation.

Whenever possible, keep your software up to date by applying the latest patches available on the MapR Support Portal. This practice can help you to resolve issues and minimize downtime.

Some patches enable new features or behaviors that are described in the documentation. However, the MapR documentation does not typically include patch numbers or identify the features or behaviors that are delivered by specific patches. If you see a fix or feature in the documentation that is not available on your platform, you might need to apply a patch in order to use the fix or feature.

last-updated: Apr 11, 2022

To understand which patches apply to your platform, contact your MapR support representative, or visit the Support notices of known issues. For information about applying a patch, see Applying a Patch on page 437.

Version 6.1.1 Release Notes

These release notes contain information about Version 6.1.1 of the MapR Converged Data Platform.

To review the support advisory announcing release 6.1.1, see Announcement of HPE Ezmeral Data Fabric maintenance release 6.1.1 to address 6.1.0 critical defects.

What's New in Version 6.1.1

Describes fixes and new features contained in release 6.1.1.

MapR version 6.1.1 supports SuSE Linux Enterprise Server version 12 SP5 and EEP 6.3.3. In addition to the information on this page, see What's New in EEP 6.3.3 on page 6524.

Filesystem Additions

CORE-517	Added the `-no-auto-permission-update` option to prevent MapR from silently altering the `/etc/shadow` file during reconfiguration.
MFS-2343	Enhanced the node list command. Using the node list command without the `-clientsonly true` or the `-nfsnodes true` option, does not list edge nodes. To include edge nodes, use the `-nfsnodes true` or the `-clientsonly true` option.
MFS-2344	Added a new CLDB parameter cldb.ignore.posix.only.hb.alarm that controls whether this alarm is raised for edge nodes.
MFS-2749	Added a parameter cldb.disable.alarm.history to disable alarm history.
MFS-11243	Added a FUSE tunable (fuse.max.cache.pages) to limit the amount of memory that each FUSE process can use when working with a large number of open files.
MFS-11674	Added a new `-D|--crc` option to enable gfsck to perform CRC checks without blocking the operations on the EC frontend volume.

MCS Additions

MON-5511	Added Snapshot Size as a configurable column in the Volumes List view.

Operating System Support

MapR version 6.1.1 supports SuSE Linux Enterprise Server version 12 SP5.

Performance

MAPRDB-2250	Added a parameter `mfs.db.max.concurrent.internal.ops` to regulate the number of parallel *BatchGet* operations.

last-updated: Apr 11, 2022

MAPRMR-8	Added the parameter mapreduce.input.fileinputformat.split.maxblocknum that determines the number of blocks that can be added to one split.
MFS-2078	Added the `fuse.negative.timeout` parameter to cache negative lookup results, and speed up FUSE path lookups.
MFS-4750	Added a tunable - prevent.volume.skew.by.diskbalancer to let the Disk Balancer allow or prevent volume skew.
MFS-4805	Added the following entities in `/opt/mapr/conf/nfsserver.conf`: • `MemDebugEnable` - Set to true to enable Memory Debugging. • `HighMemLimitMB` - Sets the maximum amount of memory that the NFS Server can use.

Security

CORE-384	Added a parameter `JMXDISABLE` to enable or disable loading ZooKeeper JMX parameters.
MFS-3310	Added the Security Certificate Expiry Alarm.
MFS-5236	Added a new parameter warden.enable.jmxremote that must be explicitly set to `true` to enable the Warden JMX Server.

YARN

MAPRMR-19	Two options have been added to YARN to retry fetching job statuses. • `yarn.app.mapreduce.job.update-status-max-retries` - The number of times to retry. • `yarn.app.mapreduce.job.update-status-retry-interval` - The interval to wait before each retry attempt.
MAPRYARN-210	Added the Local Log Aggregation Feature.
MAPRYARN-221	Added two options: • `yarn.nodemanager.timeout-localizing-container` - The maximum time to wait to localize resources for containers. • `yarn.nodemanager.check-interval-localizing-container.ms` - The frequency at which the ApplicationMaster checks the running time of the localizing container.
MAPRYARN-250	Added a parameter, mapreduce.jobhistory.intermediate-done-scan-timeout

last-updated: Apr 11, 2022

to set the timeout in milliseconds for rescanning the `done_intermediate` user directory.

Other Features

For a list of other features, see What's New in Version 6.1.0 on page 34

Installation and Upgrade Notes (MapR 6.1.1)

Describes considerations for installing and upgrading to MapR 6.1.1.

If you are upgrading from MapR 5.x, be sure to review the Installation and Upgrade Notes (MapR 6.0.0) first. Installation and upgrade considerations can also be found in the support advisory announcing release 6.1.1. See Announcement of HPE Ezmeral Data Fabric maintenance release 6.1.1 to address 6.1.0 critical defects.

Installation Considerations

Installation of MapR 6.1.1 is the same as for other core releases. You may install the packages manually or by using the MapR Installer, as described in:

- Installing with the MapR Installer on page 141
- Installing without the MapR Installer on page 141

However, unlike other releases, MapR 6.1.1 supports only one EEP: EEP 6.3.3. For EEP support information, see EEP Support and Lifecycle Status on page 5531.

Upgrade Considerations (All Upgrade Methods)

Note these considerations for upgrading to MapR 6.1.1, which apply regardless of the method you use to upgrade:

Supported Upgrade Paths	You can upgrade to MapR 6.1.1 from the following releases: • MapR 5.2.2 • MapR 6.0.x • MapR 6.1.0 The upgrade from MapR 6.1.0 to 6.1.1 is a full package upgrade and not simply a patch update. As with any upgrade, HPE recommends applying the latest patches for the release to which you are upgrading. For upgrade instructions, see Upgrading MapR Core or EEP Components on page 284.
Support Advisory for Upgrading to MapR 6.1.x	If you are upgrading a cluster with volumes created from MapR 4.0.1 or earlier, you might be subject to the issue described in Advisory 4176. Be sure to review the advisory before upgrading to MapR 6.1.x.
Upgrading to MapR 6.1.x Might Require an OS Upgrade	If you want to upgrade to MapR 6.1.x but your cluster does not use a supported Linux operating system, you must upgrade your operating system before starting the upgrade. For the list of operating system versions supported by MapR 6.1.x, see Operating System Support Matrix (MapR 6.x).
Patch Required Before Upgrading to EEP 6.3.4	**CAUTION:** EEP 6.3.4 requires a core patch to resolve a Warden defect. The defect is fixed in `mapr-patch-6.1.0.20180926230239.GA-20210512163609.x86_64` and later. Before upgrading to EEP 6.3.4, you must apply the patch. See Patches and Documentation for MapR 6.1.1 on page 96.

Data-on-wire-encryption	Beginning with MapR 6.1.0, data-on-wire encryption is enabled by default for newly created volumes on secure clusters. Data-on-wire encryption encrypts data in a volume during transmission over the wire. Data-on-wire encryption is *not* supported for non-secure clusters. When you upgrade a cluster to a MapR 6.1.1 secure cluster, data-on-wire encryption is enabled by default. You can disable data-on-wire encryption for individual volumes using MCS, the maprcli, or REST API commands.
MapR 6.1.1 and EEP 6.3.3	MapR 6.1.1 requires EEP 6.3.3. EEP 3.0.1 or later can coexist with MapR 6.1.x only temporarily in the context of an upgrade. For EEP compatibility information, see EEP Support and Lifecycle Status on page 5531.
Metrics Monitoring	To support metering, MapR 6.1.1 requires a minimal level of metrics monitoring to be configured. If metrics monitoring is already configured before the upgrade, you must upgrade it as part of the MapR Ecosystem Pack upgrade. If metrics monitoring is not installed, you must install it after the upgrade. When you upgrade to MapR 6.1.1 using the MapR Installer, metrics monitoring is configured and enabled by default. See Installing Metering Using the MapR Installer on page 283. When you upgrade to MapR 6.1.1 using manual steps, you must install metrics monitoring after the upgrade. See Installing Metering Using Manual Steps on page 284.
Log Monitoring Upgrades	If log monitoring is configured on your cluster and you plan to use either the MapR Installer or manual steps to upgrade to MapR 6.1.1, you might need to migrate or back up the Kibana and Elasticsearch indexes to version 6 before starting the upgrade. For more information, see Pre-Upgrade Steps for MapR Monitoring on page 342. Migrating or backing up the indexes is not needed if log monitoring is not configured or if you are performing a new installation.
Regenerating the `maprusserticket` File	Changes to the `CanImpersonate` parameter of the `maprusserticket` file in MapR 6.1.1 require users who upgrade manually to regenerate the file before restarting Warden. See Step 1: Restart and Check Cluster Services on page 323. The file needs to be regenerated to ensure that impersonation works correctly for non-`mapr` users. Prior to MapR 6.1.0, all `maprusserticket` files were generated with `CanImpersonate = false`. MapR 6.1.0 and later enforce the `CanImpersonate` parameter and sets the parameter to `true` for freshly installed clusters. For upgraded clusters, if `CanImpersonate` is not set to `true`, some services will not be able to impersonate.
Upgrade Workflows	The following upgrade workflows can help you understand the scope of activities involved in an upgrade based on the method you use: • Workflow: Manual Rolling Upgrade on page 287 • Workflow: Offline Manual Upgrade on page 289 • Workflow: MapR Installer Upgrade on page 292
OpenTSDB and Upgrades to EEP 6.0.1 or Later	In EEPs 6.0.1 and later, the OpenTSDB service is configured to use a default heap size of 6 GB. In earlier EEPs, the default was 2 GB. Upgrading to EEPs 6.0.1 and later causes the default setting to change to 6 GB. If you configured a custom value for the OpenTSDB service heap size and you want to reinstate the custom value after upgrading to EEP 6.0.1 or later, see Configure the OpenTSDB Service Heap Size on page 1380.

last-updated: Apr 11, 2022

Professional Support for Upgrades	Upgrading can be time-consuming and complicated. Consider engaging HPE professional support services to assist in planning and executing your upgrade. For more information, contact your HPE support representative.

Upgrade Considerations for the MapR Installer

Note these considerations for upgrading to MapR 6.1.1 that are specific to the MapR Installer:

MapR Installer Version	Before upgrading, update the MapR Installer to the latest MapR Installer. Only MapR Installer 1.15.0.1 and later can be used with MapR 6.1.1 and EEP 6.3.3.
Maintenance Update	If your cluster is installed with MapR 6.1.0 and EEP 6.3.3, you can use the maintenance update feature of the MapR Installer to perform the upgrade. Otherwise you must use the MapR Installer version upgrade feature to perform the upgrade. For more information about maintenance updates, see Performing a Maintenance Update on page 5447.
Version Upgrade	Except in cases where a maintenance update is supported, upgrading to MapR 6.1.1 using the MapR Installer requires you to perform a version upgrade.
Changes to Auto-Provisioning Templates	MapR 6.1.0 introduced changes to some auto-provisioning templates. See the "MapR Installer 1.10 Updates" described in Auto-Provisioning Templates.
Special Consideration for MySQL Database	If you are upgrading from MapR 5.x to MapR 6.1.x and your cluster is configured with a MySQL database, the installer prompts you for the MySQL password during the upgrade. You must enter the MySQL password that you specified when you first installed the cluster. If you did not specify a password for MySQL, you must leave the password field blank during the upgrade operation. If you specify the wrong value for the password, the upgrade can fail. See the known issue for IN-1972 in MapR Installer Known Issues.

List of YARN Enhancements

Describes the enhancements in YARN, if any, for MapR version 6.1.1.

No new enhancements for MapR version 6.1.1.

For a list of YARN enhancements in MapR 6.1.0, see List of YARN Enhancements.

Operational Changes (MapR 6.1.1)

Lists the functional changes, if any, made to existing commands in MapR version 6.1.1.

There are no functional changes in MapR 6.1.1.

For a list of functional changes in MapR 6.1.0, see Operational Changes (MapR 6.1.0) on page 43.

Known Issues at Release (MapR 6.1.1)

Lists the known issues that users should be aware of before installing or using release 6.1.1.

You may encounter the following known issues after upgrading to Version 6.1.1. This list is current as of the release date. For a dynamic list of all known issues for all MapR product releases, refer to Support notices of known issues

Where available, the workaround for an issue is also documented in this topic. MapR regularly releases maintenance releases and patches to fix issues. We recommend checking the release notes for any subsequent maintenance releases to see if one or more of these issues are fixed.

last-updated: Apr 11, 2022

Installation and Configuration Issues

You can see generic installation issues here: MapR Installer Known Issues on page 5460.

Keytool error on SLES 12 SP4 Node

Running the `configure.sh` script on a SLES 12 SP 4 node can fail with the following error:

```
keytool error:
java.security.ProviderException:
Could not initialize NSS
```

The installation fails because the `mozilla-nss` dependency is not installed.

Workaround: Install the `mozilla-nss` package using the following command, and rerun `configure.sh`:

```
zypper install mozilla-nss
```

IN-2637

After a manual installation, Oozie and Hive services can fail to connect to a MySQL or MariaDB database because the server time-zone value is unrecognized or represents more than one time zone. The issue affects your installation if you applied the `mapr-patch` released on or after February 21, 2021 (including the latest `mapr-patch`). This issue affects manual installations but is fixed in Installer 1.14.0.0.

Workaround: For manual installations, you must configure either the server or JDBC driver (using the `serverTimezone` configuration property) to use a more specific time-zone value if you want to utilize time-zone support. After running `configure.sh` but before starting the Oozie or Hive services, update the `serverTimezone` parameter in the `hive-site.xml` or `oozie-site.xml`. For more information, see MySQL Bug #95036.

Monitoring

ES-75

Elasticsearch purge jobs fail in MapR 6.1.0 with EEP 6.3.1 because certain curator files are missing.

Workaround: A patch is required for this issue. See Known Issue article 4812 in the Support notices of known issues. To download a patch, see Downloading a Patch on page 437. EEP 6.3.3 and later include the fix for this issue.

ES-76

Running the curator purge script in Elasticsearch in EEP 6.3.2 or EEP 7.0.1 returns a syntax error.

Workaround: A patch is required for this issue. See Known Issue article 4812 in the Support notices of known issues. To download a patch, see Downloading a Patch on page 437. EEP 6.3.3 and later include the fix for this issue.

ES-77

During an upgrade from release 6.1.0 and EEP 6.3.x to release 6.2.0 and EEP 7.0.1, Elasticsearch, Kibana, and Grafana packages do not get upgraded and remain at the EEP 6.3.x package version. The issue occurs because of a misnumbered fourth digit in the EEP 7.0.1 packages for Elasticsearch, Kibana, and Grafana. This issue affects manual upgrades and

last-updated: Apr 11, 2022

	version upgrades using the Installer. This issue does not affect new installations. **Workaround**: After the upgrade, manually uninstall the `mapr-elasticsearch` and `mapr-kibana` packages using a command such as `yum remove`. Then reinstall the packages. If you installed using the Installer, run an **Incremental Install** to reinstall the packages. If you installed the cluster manually, use a command such as `yum install` to reinstall the `mapr-elasticsearch` and `mapr-kibana` packages. For a guide to the component package versions, see Component Versions for Released EEPs on page 5586.
NFSv4	
MFS-11919	`nfs-ganesha` crashes when starting NFSv4 server on SLES 12 sp4/sp5 nodes. However, subsequently NFSv4 is able to come up and work fine. **Workaround**: None.
Upgrade	
IN-2824	During a version upgrade using the Installer, the upgrade fails during the Verification phase with a message that the OS is not supported. Hovering over the error in the right-navigation pane indicates that your OS is not supported for the core version you selected, and the core version is displayed as 5.1.0. Troubleshooting indicates that the `install.json` file includes EEP components but no core services in the services list. This can happen because of a timing issue in the Installer user interface. **Workaround**: You might be able to avoid this issue by incorporating a brief delay when you use the **Maintenance Update** or **Version Upgrade** function. After specifying the core version and the EEP version, wait a minute or two before clicking **Next** to advance to the next screen. This delay gives the Installer time to process the selections that you made. To recover from the upgrade failure: **1.** Reset the Installer database as described in Resetting the Installer Database on page 5459. **2.** Import the last known state by following the steps for importing the cluster state in Importing or Exporting the Cluster State on page 5447. **3.** Retry the upgrade through the Installer.
Impersonation	
MFS-11943	Impersonation does not work by default on insecure clusters because the admin file is not automatically created in the `/opt/mapr/conf/proxy` directory upon initial cluster configuration. **Workaround:** Manually create an empty admin file in `/opt/mapr/conf/proxy`, for example `/opt/mapr/conf/proxy/mapr`, and then restart services.

File System

MFS-14890

Issuing `hadoop mfs -lsfid` with a non-`mapr` user ticket returns an `Operation not permitted` error. For example:

```
2022-03-15 18:12:23,6663 DEBUG
Cidcache fc/cidcache.cc:4315 Thread:
18743 Enter GetVolumeMountPoint
138102135
2022-03-15 18:12:23,6663 DEBUG
Cidcache fc/cidcache.cc:4754 Thread:
18743 Sending RPC to CLDB:
10.163.172.130:7222
2022-03-15 18:12:23,6672 DEBUG
Cidcache fc/cidcache.cc:4193 Thread:
18743 GetVolumeProperties returns: 0,
numTries:0
2022-03-15 18:12:23,6673 ERROR
Cidcache fc/cidcache.cc:4277 Thread:
18743 VolumePropertiesLookupRequest
failed, cldb returned err
Operation not permitted(1), CLDB:
10.163.172.130:7222
2022-03-15 18:12:23,6673 DEBUG Client
fc/client.cc:11139 Thread: 18743
GetVolumeMountPoint returns: 0
```

In a secure cluster, this happens because the `hadoop mfs -lsfid` command works only when the UID associated with the ticket has either READ permission or full permission at the cluster level.

Workaround: Assign read permission to the UID by using an ACL to give the non-`mapr` user login permission. For example:

```
# maprcli acl  edit -type
cluster -user user1:login
maprcli acl show -type cluster
Allowed actions             Principal
[login, ss, cv, a, fc, cp]  User mapr
[login, ss, cv, a, fc, cp]  User root
[login]                     User user1
```

Resolved Issues (MapR 6.1.1)

Lists the issues that were resolved in MapR version 6.1.1.

The following MapR issues, which were reported by customers, are resolved in Version 6.1.1.

Apache Kafka

MS-791

KafkaConsumer position does not honor TTL.

MS-946

Consumer poll returns messages before a subscription or re-balance operation with *ConsumerRebalanceListener* on *PartitionsAssigned* callback is complete.

MS-947

Kafka message headers should not be Null but can be empty.

last-updated: Apr 11, 2022

Control System

MON-4844	Navigating to Usage tab when editing a volume causes OOPS error.
MON-4845	API server fails to start if the user is not *mapr*.
MON-4902	Default snapshot policies and times are incorrect.
MON-5075	Cannot modify existing volume quota due to insufficient permissions.
MON-5102	MCS does not allow configuring SMTP without a username and password.
MON-5131	OOPS error when adding a SMTP provider other than smtp, Office 365, and Gmail.
MON-5169	MCS call to schedule/list returns an error.
MON-5194	Incorrect scale on Y-axis for CPU Utilization graph on Overview page.
MON-5206; MON-5141	Volume modification fails when the metrics feature is not enabled.
MON-5270	Memory leak in API server.
MON-5271	Remove the limit on the number of results returned for MAC addresses when configuring a virtual IP.
MON-5272	User name should not be hardcoded as `mapr` in MCS.
MON-5275	MCS displays MAC addresses incorrectly.
MON-5338	I/O errors occur and the table summary page is not loaded when huge MapR DB tables are queried.
MON-5489	Volume filter options should not be pre-defined but should allow filtering on any volume attribute.
MON-5491	Detailed alarm descriptions were missing in the alarm popup view and the volume details view.
MON-5510	The Disk Space Available column uses the wrong units in the Nodes view.
MON-5517	Enhance the alarm summary command to return the alarm occurrences for each alarm type, indicate whether the alarm is a warning or an error, and specify the total number of occurrences for each alarm type.
MON-5672	The Security Certificate Expiry Alarm (*NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION*) is incorrectly labeled.
MON-5774	API Server crashes when the *tmp* directories are mounted with the `noexec` option.
MON-5900	Resource Manager URL is invalid on Ubuntu.

last-updated: Apr 11, 2022

Flume

MS-770	Array Index Out of Bounds Exception.

Filesystem

CORE-387	MapR user tickets get overwritten when Kerberos authentication is enabled.
CORE-416	The configure.sh script must support environments where root activity is not allowed.
CORE-427	Local Spark shuffle volumes if damaged, need to be automatically recreated when NodeManager starts.
CORE-472	The disk list command runs very slowly and fails to identify the right MapR-FS disk when more than one symlink points to the same disk.
CORE-476	Running configure.sh with the `-R` option, erases the value of the `MAPR_JMXAUTH` variable in the *env_override.sh* file. This prevents NodeManager from starting.
CORE-480	Volume rack path is not updated for volumes with local path set when moving nodes.
CORE-517	The configure.sh script should not silently alter permissions in the `/etc/shadow` file. Added the `-no-auto-permission-update` option as the fix.
CORE-566	The *hoststats* process crashes continuously and causes cluster auditing to fail.
CORE-571	Oozie server does not start because of a missing jar file.
MFS-1984	The maprcli dashboard info command returns incorrect compression statistics.
MFS-1985	POSIX Client service (FUSE) does on auto start on system reboot on Ubuntu 16.
MFS-2015	The maprcli dashboard info command returns incorrect memory statistics.
MFS-2019	API Server hangs intermittently and fails to access CLDB servers, in a multi-NIC environment.
MFS-2051	Improve the clarity of NFS logs.
MFS-2055	CLDB crashes when processing alarms.
MFS-2062	Remote mirroring fails repeatedly even after a source CLDB that went down is restarted and operational.
MFS-2143	MFS does not preserve excluded volume audit data operations on restart.
MFS-2144	Spark streaming tasks are stuck indefinitely when looking up tablets.

last-updated: Apr 11, 2022

MFS-2209	Exception occurs when calling the getVolName() function.
MFS-2211	Name Container master freezes during resync of orphan entries and causes MFS and the resync operation to restart frequently.
MFS-2218	MFS randomly crashes if errors occur when reading data.
MFS-2260	MapR jobs fail since the file client fails to check the MapR filesystem to determine the status of the RPCs sent previously to MFS, before resending them.
MFS-2266	Spark encounters RPC errors when reading files from volumes with `wiresecurity` enabled.
MFS-2273	Storage Pools fail randomly when MFS is restarted, and many containers go offline without a valid replica.
MFS-2275	Spark jobs fail intermittently when trying to retrieve rows from MapR DB tables.
MFS-2294	CLDB crashes when registering NFS version 4 servers.
MFS-2298	CRC errors occur randomly in Storage Pools and cause them to go offline.
MFS-2306	Master CLDB crashes when MFS nodes are added or removed frequently.
MFS-2307	Add an internal cluster level flag to prevent storage pools from going offline when Read CRC errors are encountered.
MFS-2323	NFS Server version 4 boot script should not contain hardcoded user and group (*mapr:mapr*).
MFS-2343	The node list command should not display nodes which contain only the POSIX client (edge node). Using the node list command without the `-clientsonly true` or the `-nfsnodes true` option, does not list edge nodes. To include edge nodes, use the `-nfsnodes true` or the `-clientsonly true` option.
MFS-2344	The NODE_ALARM_NO_HEARTBEAT (No Heartbeat) alarm should not be raised for POSIX clients (edge nodes). CLDB has a new parameter cldb.ignore.posix.only.hb.alarm that controls whether this alarm is raised for edge nodes.
MFS-2392	`gfsck` fails on secure clusters due to a missing library.
MFS-2423	POSIX only clients should be immediately removed when marked dead.
MFS-2444	FUSE process does not remove shared memory segments resulting in volumes failing to mount.
MFS-2462	Crash in MapR DB when looking up role memberships.

last-updated: Apr 11, 2022

MFS-2498	FUSE does not honor the product build value.
MFS-2573	Mirroring fails with a CLBD internal error when an invalid container ID is found on the source cluster.
MFS-2610	Persistent Volume mounts hang when tickets expire.
MFS-2628	Null Pointer Exception in CLDB Server.
MFS-2630	The mrconfig info threads command crashes the MFS process when attempting to retrieve volume aces, when Extended Attributes are not enabled.
MFS-2631	CLDB shuts down when adding or removing NFS servers.
MFS-2632	CLDB operations fail with the Server Retry error.
MFS-2659	MFS process hangs intermittently in environments with multiple NICs.
MFS-2694	Stack overflow in MFS when deleting a container chain.
MFS-2695	Cross cluster mirroring fails after enabling the Snapshot Lite feature.
MFS-2725	NFS Server version 3 crashes randomly when trying to satisfy mount requests.
MFS-2731	MFS does not automatically retry reconnecting to CLDB after a connection reset request.
MFS-2732	RPC connections between MFS and CLDB fail intermittently with Connection Reset by Peer errors.
MFS-2757	MapR service status is displayed incorrectly due to change in `systemd`.
MFS-2767	File client tries to connect to the same failed CLDB node repeatedly.
MFS-4480	NFS Server version 4 crashes intermittently.
MFS-4485	FUSE client fails to work with a scoped impersonation ticket.
MFS-4531	Snapshots of mirrors are not deleted after mirroring completes.
MFS-4551	`loopbacknfs` does not log any messages to the `loopbacknfs.log` file.
MFS-4562	File stat on the FUSE mount indicates the block size as a fixed value (512) instead of the client's block size.
MFS-4585	CLDB exception occurs when a NFS heartbeat reports a failed Virtual IP.
MFS-4597	Warden and the maprcli command intermittently cannot start dependent services.

last-updated: Apr 11, 2022

MFS-4605	CLDB shuts down when ACL size exceeds the threshold value.
MFS-4667	Replicated operations fail and cause frequent resyncs.
MFS-4776	FUSE RPCs fail intermittently.
MFS-5356	The `getAces()` API raises a Null Pointer Exception when called on a non-existing object.
MFS-5405	Client sends the `NODE_ALARM_SERVICE_NODEMANAGER_DOWN` alarm but CLDB raises the `NODE_ALARM_SERVICE_OPENTSDB_DOWN` alarm.
MFS-5422	The `create()` API does not create files with the same permissions as the parent directory.
MFS-5430	NFS Server is unable to parse lines exceeding 8K characters in the exports file.
MFS-5482	Memory leak in CLDB master instance.
MFS-5488	Jobs on random nodes fail to create FileClient.
MFS-5502	Path lookup error occurs when client nodes run a newer version of MapR than the CLDB server nodes.
MFS-5711	Unable to access files on EC tier due to I/O error and StripeletIO failure.
MFS-6585	Applications intermittently fail to detect updates to the ticket file.
MFS-6587	Avoid flooding the CLDB log with invalid snapshot ID messages.
MFS-6667	`hoststats` creates defunct Python processes.
MFS-6748	Automatic offload does not trigger EC offload.
MFS-6873	Cross cluster move operation fails on FUSE.
MFS-6874	Node Manager fails repeatedly during log aggregation.
MFS-8452	Memory leak in loopback NFS.
MFS-8459	Fixed volume access problems for volumes that reused the volume ID of deleted volumes.
MFS-10328	maprlogin renew (ticket renewal) fails to refresh group memberships.
MFS-10743	Node Manager fails to report container failure and loops between slave CLDBs, without contacting the new master CLDB.
MFS-10825	Cluster is unable to self-heal from the VOLUME_ALARM_DEGRADED_EC_STRIPES (Warm-Tier Data Node Down) alarm, and rebuild does not occur.

last-updated: Apr 11, 2022

MFS-10845	Volume creation fails to honor the credentials of the impersonated user while creating the parent directory.
MFS-11002	fsck crashes due to an inode reservation issue.
MFS-11109	Filesystem crashes due to a leak in orphanage reservation.
MFS-11171	Restrict the tenant ticket so that it cannot mount non-tenant volumes in POSIX.
MFS-11221	Drill query crashes in MapR client due to an unexpected exception during fragment initialization.
MFS-11243	Memory leak in FUSE. Added a FUSE tunable (`fuse.max.cache.pages`) to limit the amount of memory that each FUSE process can use when working with a large number of open files.
MFS-11295	Offloading fails when `mastgateway` is stuck in compaction state.
MFS-11442	FUSE client does not honour the location of the cluster configuration file as defined by the parameter `fuse.cluster.conf.location`.
MFS-11609	Hadoop `distcp` jobs fail when using CLDB hostname and port.
MFS-11647	SlowOPs trace function does not work for NFSv3.
MFS-11674	Enable `gfsck` to perform CRC checks without blocking the operations on the EC frontend volume. See gfsck on page 2102 for the new `-D|--crc` option.
MFS-11682	CLDB volume dump fails with an RPC error due to an unknown session key.
MFS-11729	`mrconfig info` threads crash the filesystem when hardlinks are not enabled.
MFS-11731	Suppress redundant incorrect build version alarms.
MFS-11740	Filesystem crashes when compacting memory.
MFS-11779	MFS dumps core due to stack overflow.
MFS-11823	Service ticket renewal does not honour duration.
MFS-11838	Jobs fail with the "Too many open files" error.

Hadoop

MAPRHADOOP-61	Kerberos fails for services when a custom ticket location is set in the `env.sh` file.
MAPRHADOOP-83	Upgrade Tomcat servers to their latest version or remove them if they are not needed.

last-updated: Apr 11, 2022

MAPRHADOOP-102	Error occurs in ACEs when the Hive resource downloader internally copies files from the MapR filesystem to the local filesystem.
MAPRHADOOP-131	Update Jersey to its latest 1.X version.

MapR-DB

MAPRDB-1236	The Tiny Bucket Flush alarm is raised even when the node has sufficient memory.
MAPRDB-1589	Incorrect key sorting when using the `orderby` clause with conditions.
MAPRDB-1719	DB server crashes when columnset is used without initialization.
MAPRDB-1732	Inserting data into MapR-DB fails intermittently with an *Invalid Argument* error.
MAPRDB-1889	The Java API findById() intermittently fails to retrieve complete projection details from JSON documents.
MAPRDB-1985	The `mapr dbshell find` command crashes when run on a table with a huge number of tablets.
MAPRDB-1995	MapR-DB raises intermittent false VOLUME_ALARM_TABLE_REPL_LAG_HIGH alarms for replicated streams.
MAPRDB-2062	Failed to scan table on a remote secure cluster using the `mapr dbshell` utility because of a wrong ticket that was sent to ZooKeeper.
MAPRDB-2072	Data Access Gateway (DAG) fails to fetch indexes as it queries indexes as the `mapr` user instead of the impersonated user.
MAPRDB-2091	MapR-DB hangs due to inodes being recycled even when they are in use.
MAPRDB-2092	In MapR-DB, adding a table index or replicating a table fails if the cluster administrator (MAPR_USER) does not have write access to the parent volume of the table.
MAPRDB-2098	MapR DB crashes when multiple threads modify the *size_* variable while calculating the serialised JSON document size.
MAPRDB-2103	PUT operations on binary tables fail when the values of the `wireSecurityEnabled` field vary between the FileClient and the FileServer.
MAPRDB-2120	Drill query on MapR DB intermittently fails with a DB Scan exception.
MAPRDB-2125	OJAI APIs fail to connect to ZooKeeper.
MAPRDB-2159	DB Autosetup, Indexing, and Replication fail as MFS is unable to reach the local Gateway.

last-updated: Apr 11, 2022

MAPRDB-2201	Memory leak in *BaseJsonTable* caused by a dangling reference of *MetaTable*.
MAPRDB-2254	AppendStream fails when Gateway closes the inactive stream, and raises the replication lag alarm.
MAPRDB-2267	DB crashes during heap memory allocation.
MAPRDB-2303	The Replication Lag alarm does not display the actual lag value.
MAPRDB-2315	MapR-DB scan fails on large tables.
MAPRDB-2323	The Table Replication (**VOLUME_ALARM_TABLE_REPL_ERROR**) alarms are missing information such as the actual bucket FID that produced the alarm, if applicable, and the error code and description of the replication error.

Performance

MS-560	MapR cluster nodes experience high network traffic from mapr-stream clients.
MAPRDB-1727	Delay in data retrieval on MFS nodes with a large number of outstanding active buckets and high usage of DB memory.
MAPRDB-2113	MapR-DB needs to select the most appropriate index in cases where more than one index has been defined over the same field of a MapR-DB table.
MAPRDB-2156	When running queries with a set timeout, the number of threads on the MapR client increases up to 500, exhausting the Thread Pool, and causing the client to stop responding completely, even after all queries time out.
MAPRDB-2250	Too many *BatchGet* operations in parallel when secondary indexes are present on a table, causes MapR DB to crash. Added a parameter `mfs.db.max.concurrent.internal.ops` to regulate the number of parallel *BatchGet* operations.
MAPRMR-8	Reduce the number of input splits that are generated when a job is processed through the `CombineFileInputFormat()` function. Added the parameter mapreduce.input.fileinputformat.split.maxblocknum that determines the number of blocks that can be added to one split.
MFS-2078	Speed up FUSE path lookups. Added the `fuse.negative.timeout` parameter to cache negative lookup results.
MFS-2082	Optimize directory lookup and traversal to avoid overwhelming MFS with RPCs.
MFS-2324	Optimize disk space reserved for tiering operations.
MFS-2608	Priority of child threads do not change when the priority of their parent process is changed.

last-updated: Apr 11, 2022

MFS-2638	Avoid re-sorting results in CLDB for the default output of the maprcli alarm list -sortby alarmtype command.
MFS-2691	Optimize fetching of Muted and Raised Alarms.
MFS-2711	Optimize removal of expired snapshots to free up CLDB CPU from background activity.
MFS-2749	The Alarm History feature needs to be disabled on large clusters as it can degrade performance. Added a parameter cldb.disable.alarm.history to disable alarm history.
MFS-3291	File client does not honor the number of flusher threads set in the `coresite.xml` file. See the fs.mapr.threads parameter.
MFS-4532	Jobs fail with I/O error or are very slow to complete.
MFS-4670	CLDB process consumes 78.8 GB approximately every 6-7 hours and triggers CLDB failover very often.
MFS-4687	Memory leak in CLDB.
MFS-4750	Disk Balancer is unable to move containers from full Storage Pools as they fail the Volume underweight check. Added a tunable - prevent.volume.skew.by.diskbalancer to let the Disk Balancer allow or prevent volume skew.
MFS-4805	Fixed memory leak in NFS Server version 3 that occurs when profiling memory. Added the following entities in `/opt/mapr/conf/nfsserver.conf`: • `MemDebugEnable` - Set to true to enable Memory Debugging. • `HighMemLimitMB` - Sets the maximum amount of memory that the NFS Server can use.
MFS-5227	NFS Server hangs or is very slow and causes replication and resync failures.
MFS-5700	CLDB master failover time is very high.
MFS-6539	NFS Version 3 Server on edge nodes does not have the ulimit setting, as warden is not available on these nodes.
MFS-5724	The MFS configuration parameter mfs.max.restore.count is not being honored causing mirror resync operations to be delayed due to the lack of sufficient restore slots.
MFS-6547	Massive delay in mounting the configured mount points after starting the NFS service.
MFS-6666	NFS server should throttle RPCs to avoid overwhelming CLDB.

last-updated: Apr 11, 2022

MFS-6785	The response from the mrconfig info containers rw command is slow on a cluster with large number of volumes.
MFS-6869	Fuse client should limit the number of RPCs to prevent overwhelming CLDB.
MFS-7181	FileClient defaults to 8KB reads instead of 512KB.
MFS-8475	The `createsystemvolumes.sh` script took hours to complete when adding a new node to a cluster with a large number of volumes.
MFS-11111	Queuing and CLI RPC processing are slow in CLDB.

Security

COMSECURE-331	Security vulnerability in the JNDI-bindable DataSources library.
COMSECURE-334	Security vulnerability in the DOM4j XML framework.
COMSECURE-335	Security vulnerability in the Jasper library.
CORE-290	The `/opt/mapr` directory contains files and directories with insecure permissions.
CORE-293	After upgrading system security packages, `mapr-zookeeper` and `mapr-warden` are not properly started with `systemd`. The `ps` command reports them as started, while `systemd` reports errors when trying to start these services.
CORE-384	Remote Code Execution vulnerability in the ZooKeeper Java JMX server. Added a parameter `JMXDISABLE` to enable or disable loading ZooKeeper JMX parameters.
MAPRDB-2251	Standardize JMX handling for Java processes to prevent vulnerabilities.
MAPRDB-2255	Stream ACE `u:mapr |` has the potential to lock out the administration of the stream.
MAPRHADOOP-63	Security vulnerability in `jackson-databind`.
CORE-562, MAPRHADOOP-123	Security vulnerabilities in MapR 6.x JAR files.
MAPRHADOOP-58, MAPRHADOOP-64, MAPRHADOOP-136, MAPRHADOOP-137	Multiple security vulnerabilities in Hadoop.
MAPRYARN-241	Remote Code Execution vulnerability in the YARN Java JMX Server.
MFS-2336	File Client impersonation does not honour the permissions of the actual user.
MFS-2493	The `/tmp/cldbinfo/unreachableCldbs` is created with insecure permissions.
MFS-2551	Local Privilege Escalation vulnerability in the `maprexecute` command.

last-updated: Apr 11, 2022

MFS-2645	Fixed a buffer overflow in NFS Server version 3.
MFS-2661	Snapshot creation fails due to a permission error.
MFS-2685	The `maprcli` commands use the wrong ticket to communicate with ZooKeeper in secure, cross cluster environments.
MFS-2700	FUSE kernel sends the wrong user credentials to the MapR FUSE Process.
MFS-2708	Disk failure related log files have insecure permissions.
MFS-3310	Need an alert to warn about expiring SSL certificates. Added the Security Certificate Expiry Alarm.
MFS-5229	Remote Code Execution vulnerability in the MAST Gateway JMX Server.
MFS-5234	Remote Code Execution vulnerability in the CLDB JMX Server.
MFS-5235	Remote Code Execution vulnerability in the Gateway JMX Server.
MFS-5236	Remote Code Execution vulnerability in the Warden JMX Server. Added a new parameter warden.enable.jmxremote that must be explicitly set to `true` to enable the Warden JMX Server.

MapR Streams

MS-762	Customer Streams face cursor commit failures.
MS-557	Commits fail for MapR Streams on volumes that were previously mirror volumes but are now standard volumes.

Upgrade

MS-925	After upgrade to EEP 6.2 (Spark 2.4.0), Kafka/ MapR Streams cannot be consumed.
MFS-2079	After upgrading to MapR version 6.1.0, the volume Name Container hangs when assigning volume names for volumes created with MapR version < 4.0.1.
MFS-2469	After upgrading MapR from version 5.2.2 to 6.1.0, slave CLDB nodes are stuck during initialization.
MFS-2553	Ecosystem jobs using ZooKeeper fail after upgrading to the MapR 6.1 EBF patch.
MFS-2560	CLDB on a MapR 5.2.2 cluster gets overwhelmed with RPC calls when mirroring from a MapR 6.1.x cluster.
MFS-2561	The VOLUME_ALARM_DATA_UNDER_REPLICATED alarm is generated frequently after upgrading MapR from version 3.0.1 to version 6.1.0.
MFS-2675	Certify MapR version 6.1.0 on RHEL 7.7

last-updated: Apr 11, 2022

MON-3922	When upgrading to MapR 6.x, ensure that volumes prior to MapR version 6.0, which lack volume aces are handled gracefully after upgrade.
MON-4862	After upgrading from MapR 5.2.1 to MapR 6.1, API server fails to start with an M5 license without tables support installed.
MON-4892	Snapshot tab in MCS indicates that license upgrade is needed after upgrading from MapR 5.2.1 to MapR 6.1 with M5 license installed.

YARN

MAPRMR-4	With centralized logging, YARN does not populate *stderr* and *stdout* logs.
MAPRMR-19	Applications fail with the *Jobstatus not available* exception. The ApplicationMaster has already finished processing each job but the Job History Server has not yet updated job statuses. This causes the failures. Two options have been added to YARN to retry fetching job statuses. • `yarn.app.mapreduce.job.update-status-max-retries` - The number of times to retry. • `yarn.app.mapreduce.job.update-status-retry-interval` - The interval to wait before each retry attempt.
MAPRYARN-127	Resource Manager fails with a Concurrent Modification Exception.
MAPRYARN-155	Containers fail to launch if property names contain a dash (-) in the `launch_container.sh` script.
MAPRYARN-161	Deletion of History Server logs is stopped when an invalid application directory is found within the log aggregation directory.
MAPRYARN-171	YARN preemption does not occur with Fair and DRF scheduling policies.
MAPRYARN-191	YARN API requests via CLI do not return any result when cluster has Label-Based-Scheduling enabled.
MAPRYARN-192	MapReduce jobs fail if their labels contain the logical operand character (*&&*).
MAPRYARN-193	Resource Manager crashes when sorting Collections using the FairShare comparator.
MAPRYARN-195	Resource Manager exits with a FATAL error.
MAPRYARN-203	Resource preemption fails and returns a Null Pointer Exception.
MAPRYARN-210	Use per-node local volumes for YARN log aggregation instead of a single volume. Added the Local Log Aggregation Feature.

last-updated: Apr 11, 2022

MAPRYARN-221	Containers hang in LOCALIZING state. Added two options: • `yarn.nodemanager.timeout-localizing-container` - The maximum time to wait to localize resources for containers. • `yarn.nodemanager.check-interval-localizing-container.ms` - The frequency at which the ApplicationMaster checks the running time of the localizing container.
MAPRYARN-223	Maximum idle time of the Jetty connection should be configurable.
MAPRYARN-244	Resource Manager hangs when trying to shut down after CLDB failover.
MAPRYARN-246	Resource Manager hangs when there is a space in the name of the queue in the *fair-scheduler.xml* file.
MAPRYARN-249	Resources needed to preempt should not have negative vcore values.
MAPRYARN-250	Job History Server (JHS) hangs under heavy load when scanning MFS for job history files. Added a parameter, mapreduce.jobhistory.intermediate-done-scan-timeout to set the timeout in milliseconds for rescanning the `done_intermediate` user directory.
MAPRYARN-258	Publish system metrics in batches so as to avoid overloading the Application Timeline Server (ATS).
MAPRYARN-261	Administrator users who are not part of the `mapr` group are not able to view the logs of the running jobs of another user.
MAPRYARN-276	Resource Manager crashes with a Null Pointer Exception.
MAPRYARN-284	YARN kills container but the task process is not killed.
MAPRYARN-287	When the *ClientRMService* processes an application kill request, the application diagnostics should report the user and the host that issued the kill request.
MAPRYARN-291	On RHEL 8.2, Warden must run Node Manager with umask 022 on MapR Core 6.1.0.

Packages and Dependencies for MapR 6.1.1 Software

Package and dependency details for MapR 6.1.1 platform and ecosystem components.

For downloadable packages, see these links:

- MapR Core Packages
- EEP Packages
- MapR Installer Packages

For MapR Installer package dependencies, see:

- MapR Installer Prerequisites and Guidelines

This table shows the MapR 6.1 package dependencies for Red Hat / CentOS and SLES. A dash (—) indicates no dependency.

	Depends on . . .	
This package . . .	**These MapR packages**	**And these non-MapR packages**
`mapr-apiserver`	`mapr-core`	—
`mapr-cldb`	`mapr-core` `mapr-fileserver`	—

`mapr-client`	`mapr-librdkafka`	`glibc`
		`libgcc`
		`libstdc++`
		`syslinux`

`mapr-compat-suse`	—	`/etc/default/useradd`
		`/sbin/rpcinfo`
		`/usr/sbin/acpidump`
		`libffi4`
		`libgcc_s1`
		`libsnappy1`
		`libstdc++6`
		`openssl`

`mapr-core`	`mapr-core-internal`
	`mapr-hadoop-core`
	`mapr-librdkafka` (version 0.11.3 or later)
	`mapr-mapreduce2`
		—

`mapr-core-internal`	—	`dmidecode`
		`glibc`
		`hdparm`
		`initscripts`
		`irqbalance`
		`libgcc`
		`libstdc++`
		`nss` (version 3.19 or later)
		`redhat-lsb-core`
		`sdparm`
		`shadow-utils`
		`syslinux`

`mapr-fileserver`	`mapr-core`	—
`mapr-hadoop-core`	`mapr-core-internal`	—

last-updated: Apr 11, 2022

This package . . .	Depends on . . .	
	These MapR packages	**And these non-MapR packages**
mapr-historyserver	mapr-mapreduce2	—
mapr-loopbacknfs	—	iputils nfs-utils redhat-lsb-core rpcbind
mapr-mapreduce2	mapr-hadoop-core	—
mapr-nfs	mapr-core	/usr/sbin/rpcinfo iputils nfs-utils
mapr-nodemanager	mapr-mapreduce2	—
mapr-posix-client	mapr-client	—
mapr-resourcemanager	mapr-mapreduce2	—
mapr-single-node	mapr-cldb mapr-fileserver mapr-nfs mapr-webserver mapr-zookeeper	—
mapr-upgrade	mapr-core	rpmrebuild
mapr-webserver	mapr-apiserver	—
mapr-zk-internal	—	—
mapr-zookeeper	mapr-core mapr-zk-internal	—

These MapR 5.x packages were removed for MapR 6.x:

- mapr-jobtracker
- mapr-mapreduce1
- mapr-metrics
- mapr-tasktracker

This table shows the MapR 6.1 package dependencies for Ubuntu:

This package . . .	Depends on . . .	
	These MapR packages	**And these non-MapR packages**

`mapr-client`	`mapr-librdkafka` (version 0.11.3 or later)	`awk`
		`bash` (version 2.05a-11 or later)
		`coreutils` (version 5.0-5 or later)
		`grep` (version 2.4.2-3 or later)
		`libc6`
		`libgcc1`
		`libstdc++6`
		`perl`
		`procps` (version 1:2.0.7-8 or later)
		`sed` (version 3.02-8 or later)
		`syslinux`

`mapr-core-internal`	—	`adduser` (version 3.11 or later)
		`awk`
		`bash` (version 2.05a-11 or later)
		`coreutils` (version 5.0-5 or later)
		`dmidecode`
		`grep` (version 2.4.2-3 or later)
		`hdparm`
		`libc6`
		`libgcc1`
		`libstdc++6`
		`lsb-base`
		`irqbalance`
		`perl`
		`procps` (version 1:2.0.7-8 or later)
		`sdparm`
		`sed` (version 3.02-8 or later)
		`syslinux`
		`sysvinit-utils`

`mapr-loopbacknfs`	—	`iputils-arping`
		`lsb-base`
		`rpcbind`

		`grep` (version 2.4.2-3 or later)
		`iputils-arping`
		`nfs-common`
		`perl`
		`procps` (version 1:2.0.7-8 or later)
		`sed` (version 3.02-8 or later)

Patches and Documentation for MapR 6.1.1

Describes important considerations for patches and patch documentation for MapR 6.1.1.

Whenever possible, keep your software up to date by applying the latest patches available on the MapR Support Portal. This practice can help you to resolve issues and minimize downtime.

Some patches enable new features or behaviors that are described in the documentation. However, the MapR documentation does not typically include patch numbers or identify the features or behaviors that are delivered by specific patches. If you see a fix or feature in the documentation that is not available on your platform, you might need to apply a patch in order to use the fix or feature.

To understand which patches apply to your platform, contact your MapR support representative, or visit the Support notices of known issues. For information about applying a patch, see Applying a Patch on page 437.

MapR Container for Developers

The MapR Container for Developers is a Docker container that enables you to create a single-node MapR cluster. The container is lightweight and designed to run on your laptop. It requires no additional configuration for you to connect your clients, also running on your laptop, to the cluster.

Important: The Development Environment for MapR Data Platform is currently unavailable for use with release 7.0.0. The development environment script will be updated and documented for release 7.0.0 as soon as the updated Docker image is available.

The MapR cluster created by the Docker image includes the following components:

- MapR Core 6.1
  - MapR XD Distributed File and Object Store on page 451
  - MapR Database on page 496
  - MapR Event Store For Apache Kafka on page 627
  - MapR Control System on page 682
  - MapR NFS
- Apache Drill 1.14.0-1808
- Apache Spark 2.3.1-1808

Examples in this section show Mac OS X and Linux support for the container, but you can run the container on any operating system that supports Docker containers.

After you deploy the container, the environment inside the container runs Ubuntu16 and JDK 8. By default, the MapR cluster is configured as non-secure.

The MapR Container for Developers is provided *as is* for development purposes. HPE technical support is not available for this product. However, users may post questions or comments on the Ezmeral Data Fabric Community.

Prerequisites to Running the MapR Container for Developers

To run the MapR Container for Developers, you must first install the MapR client and Docker software.

The instructions in this topic are specific to Mac OS X. The container is supported on all operating systems that support Docker containers.

1. Install a MapR client on your laptop:
   a) Download the MapR 6.1 client from https://package.mapr.hpe.com/releases/v6.1.0/mac/ or for one of the following Linux distributions:
      - Oracle Enterprise Linux: https://package.mapr.hpe.com/releases/v6.2.0/oel/
      - RHEL: https://package.mapr.hpe.com/releases/v6.2.0/redhat/
      - Ubuntu: https://package.mapr.hpe.com/releases/v6.2.0/ubuntu/

   b) On a Mac, extract the client software to the `/opt` directory by running the following commands:

```
sudo mv ~/Downloads/
mapr-client-6.1.0.20180926230239.GA-1.x86_64.tar.gz /opt
cd /opt
sudo tar xvfz mapr-client-6.1.0.20180926230239.GA-1.x86_64.tar.gz
```

   c) On Linux, use the appropriate package manager to install the client. For example:
      - RPM-based Systems:

```
rpm -ivh mapr-client-6.2.0.0.20200915234957.GA-1.x86_64.rpm
```

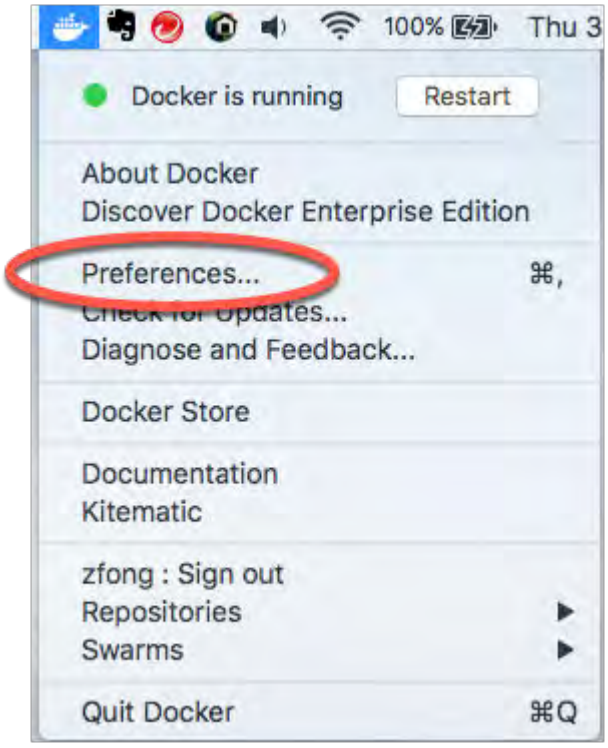
      - On Ubuntu:

```
dpkg -i mapr-client-6.2.0.0.20200915234957.GA-1.amd64.deb
```

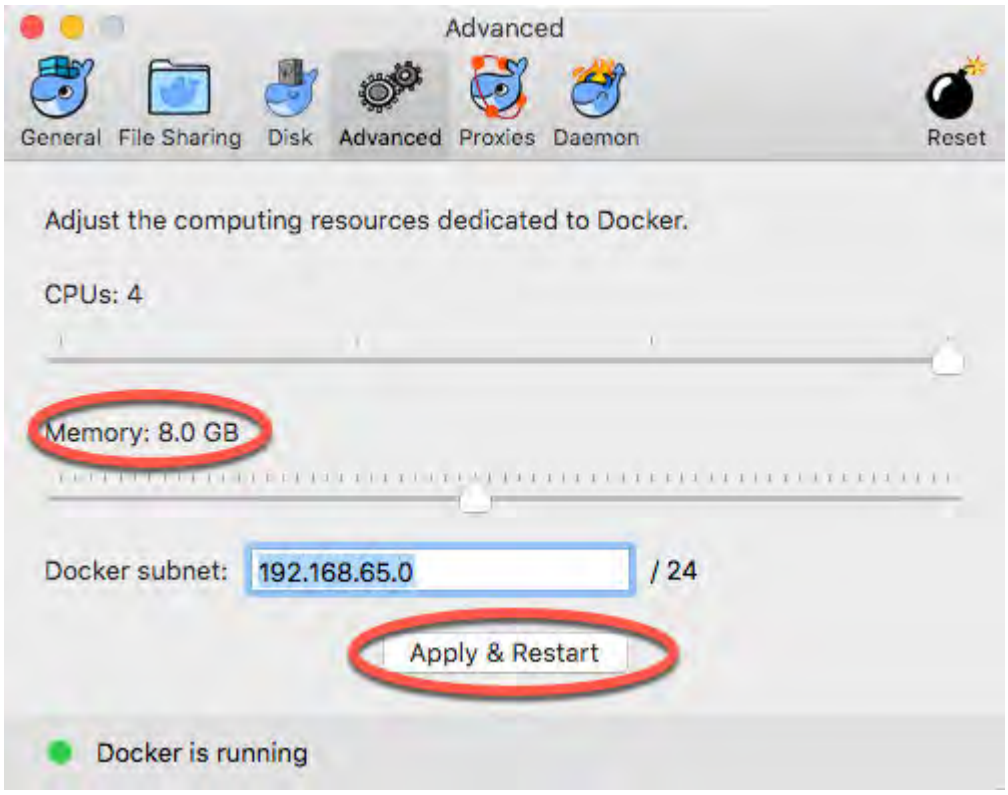
2. Install Docker on your laptop:
   a) Download the software for Mac from https://www.docker.com/docker-mac, or follow the instructions for the appropriate Linux distribution.

   b) Install the software.

   c) On a Mac, verify that Docker is running with at least 8 GB of memory by clicking **Docker->Preferences->Advanced**:



3. Modify the memory settings, if needed, and restart Docker:



Running the MapR Container for Developers Script

The MapR Container for Developers script, `mapr_devsandbox_container_setup.sh`, downloads the Docker image associated with the container and launches the container image that starts the MapR cluster.

It also performs the configuration steps needed to connect local MapR clients to the MapR cluster running in the container.

Important: The Development Environment for MapR Data Platform is currently unavailable for use with release 7.0.0. The development environment script will be updated and documented for release 7.0.0 as soon as the updated Docker image is available.

1. Download `mapr_devsandbox_container_setup.sh` from GitHub.
2. Modify the script so it is executable:

   ```
   chmod +x mapr_devsandbox_container_setup.sh
   ```

3. Run the script:

   ```
   ./mapr_devsandbox_container_setup.sh
   ```

   By default, the script runs the latest version of the container, `maprtech/dev-sandbox-container:latest`,. To run an earlier version, replace `latest` with the tag corresponding to the version you want to use, and pass that as an argument to the script. The following example runs the 6.0.1 version:

   ```
   ./mapr_devsandbox_container_setup.sh maprtech/
   dev-sandbox-container:6.0.1_5.0.0_ubuntu16
   ```

   For a list of available tags, see https://hub.docker.com/r/maprtech/dev-sandbox-container/tags/.

   Note: The script can take 5-10 minutes to run the first time you run it. It requires downloading the Docker image from the Docker repository.

4. When the Docker image is running, you see the following output:

   ```
   Docker Container is coming up....
   Client has been configured with the docker container.

   Please login to the container using (root password mapr): ssh
   root@localhost -p 2222
   Login to the Control System at https://localhost:8443
   ```

5. Log in to the Docker container:

   ```
   ssh root@localhost -p 2222
   ```

6. Wait for the `AdminApplication` java process to start by viewing the output from `jps`:

   ```
   root@maprdemo:~# jps
   3472 WardenMain
   28369 Jps
   5105 CLDB
   13810 RunJar
   28259 FsShell
   13235 AdminApplication
   3232 QuorumPeerManager
   12280 Drillbit
   14122 RunJar
   ```

last-updated: Apr 11, 2022

7. When `AdminApplication` is running, you can access the MapR Control System in your browser using the following URL:

   ```
   https://localhost:8443
   ```

8. After all MapR services are running, you can access the filesystem by using POSIX commands, with `/mapr` as your mount point. The following steps show you how to determine that all services are running:
   a) Determine the id of your Docker container by examining the output from the following command:

      ```
      docker ps
      ```

   b) Examine the contents of the Docker logs using the container id from Step 8a:

      ```
      docker logs ca2c94d9e822
      ```

   c) It can take a few minutes for all services to initialize, depending on the load in your environment. Output similar to the following in your log output indicates that all services are running:

      ```
      This container IP : 172.17.0.2
      ```

   d) Log in to the container using the command from Step 5.

   e) Run the following command to access the MapR filesystem using `ls`:

      ```
      root@maprdemo:~# ls /mapr
      ```

Note: Whenever you change your network environment, you must reconfigure your container. Rerun the `mapr_devsandbox_container_setup.sh` script, and select option 2 when the script shows the following prompt:

```
MapR sandbox container is already running.
1. Kill the earlier run and start a fresh instance
2. Reconfigure the client and the running container for any network
changes
Please enter choice 1 or 2 :
```

Connecting Clients to the MapR Container for Developers

You can access the MapR cluster running in the MapR Container for Developers from your laptop. Simply issue client commands from your laptop.

Setting up New Users

The MapR Container for Developers is setup with only users `mapr` and `root`. If you want to connect clients as some other user, you must add your user name and group to the container.

For example, if running the `id` command on your laptop returns the following:

```
uid=5001(mapruser) gid=5000(maprgroup)
```

Then, run the following commands to add your user name and group to the container:

```
ssh root@localhost -p 2222
groupadd -g 5000 maprgroup
useradd -m -u 5001 -gmaprgroup mapruser
```

Accessing the File System

The following command lists the files in MapR filesystem on the cluster:

```
/opt/mapr/bin/hadoop fs -ls /
```

Accessing MapR Database

To access MapR Database, you can use MapR Database shell:

```
/opt/mapr/bin/mapr dbshell
```

In MapR Database shell, you can create a table, insert into the table, and read from the table:

```
create /tmp/t1
insert /tmp/t1 --v '{"a":"ABC"}' --id "ID1"
find /tmp/t1
```

Accessing Drill

The MapR client that you downloaded in the Prerequisites to Running the MapR Container for Developers on page 97 topic includes a minimum set of clients. To run other clients, you must first copy the client software to your laptop.

The following example shows how to do this for Apache Drill 1.14.0:

1. Determine your Docker `<container-id>` by examining the output of the `docker ps` command
2. Copy Drill from your container to your laptop specifying the `<container-id>`:

   ```
   docker cp <container-id>:/opt/mapr/drill /opt/mapr/drill
   ```

3. Connect to Drill as user `mapr` through JDBC by running `sqlline`:

   ```
   /opt/mapr/drill/drill-1.14.0/bin/sqlline -u
   "jdbc:drill:drillbit=localhost" -n mapr
   ```

   Note: If you are using a different version of Drill, replace the version string with your version.

4. Run a SQL query in `sqlline`:

   ```
   select * from cp.'employee.json' limit 10;
   ```

Demo Applications

Sample applications are available at https://github.com/mapr-demos/mapr-db-60-getting-started. The applications show you how to access a MapR Database JSON table using the following programming interfaces:

- Drill JDBC

last-updated: Apr 11, 2022

- OJAI
- Understanding the MapR Database OJAI Connector for Spark on page 4050

See the README file in the GitHub repository for detailed steps on how to create the data used in the applications and how to run the applications.

Troubleshooting the MapR Container for Developers

This section describes problems you might encounter when deploying, running, and accessing the MapR Container for Developers. It also includes steps to troubleshoot and resolve the problems.

Docker Login Problems

Problem

Attempting to log in to your Docker container returns the following error:

```
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
@@@@@@@@@@@@@@@@@@@@
@    WARNING: REMOTE HOST
IDENTIFICATION HAS CHANGED!    @
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
@@@@@@@@@@@@@@@@@@@@
```

Possible Cause

You have an old ssh key in your `.ssh/known_hosts` file

Solution

Replace the old ssh key with the correct key:

```
ssh-keygen -R [localhost]:2222
```

Docker Failures

Problem

Docker fails to run the container

Possible Cause

Docker encounters problems starting ZooKeeper or Warden

Solution

1. Determine your Docker `<container-id>` by examining the output of the `docker ps` command
2. Examine the Docker log files by running:

   ```
   docker logs <container-id>
   ```

3. Examine the MapR log files specified in the output for further diagnostics. You need to log in to the container to see those files.

Problem

Docker completes its startup as shown by the following output from Docker logs:

```
This container IP : 172.17.0.2
```

But Docker is killed before the MapR processes are running.

Possible Cause	You have not allocated enough memory to Docker
Solution	Make sure you have configured Docker with at least 6 GB of memory as described at Step 2c at Prerequisites to Running the MapR Container for Developers.

MapR Connection Problems

Problem	Unable to connect to Control System in your browser

Possible Cause	Solution
The `AdminApplication` process is not running yet	Run `jps` and wait for `AdminApplication` to appear in the list of running java processes
You are accessing an older, cached copy of the Control System URL	Clear your browser cache and retry connecting to the URL

Unable to Access MapR Database Table

Problem	You cannot access a MapR Database table
Possible Cause	You do not have permissions on the volume where the table is stored
Solution	When creating a volume, make sure you set up the user access controls appropriately. See Creating a Volume on page 864 for details.

Unable to run OJAI Queries Due to Query Service Errors

Problem	When running an OJAI query, you encounter an error indicating that the Query Service is not enabled.
Possible Cause	The MapR Container for Developers is setup with only users `mapr` and `root`. You are running as some other user and your query requires the OJAI Distributed Query Service on page 505.
Solution	Add your user name and group to the container by following the instructions at Setting up New Users on page 100.

MapR Sandbox for Hadoop

The MapR Sandbox for Hadoop is a fully-functional single-node cluster that gently introduces business analysts, current and aspiring Hadoop developers, and administrators (database, system, and Hadoop) to the big data capabilities of Hadoop and its ecosystem.

Use the sandbox to experiment with Hadoop technologies using the Control System and Hue.

Hadoop administrators can launch the Control System and use tutorials to configure, monitor, and manage a cluster.

Hadoop developers or analysts who need to gain an understanding of Hadoop and MapR can:

- Launch the Hue interface.
- Use the tutorials to perform tasks with the provided Hue applications.
- Explore solutions to use cases.

last-updated: Apr 11, 2022

- Run jobs on data in the MapR Sandbox for Hadoop.

To use the MapR Sandbox for Hadoop:

- Verify that the host system meets the prerequisites listed below.
- Download, import, and run the MapR Sandbox for Hadoop, as described in Installing the Sandbox on VMware Player or VMware Fusion or in Installing the Sandbox on VirtualBox.

Prerequisites

Before you install the MapR Sandbox for Hadoop, verify that the host system meets the following prerequisites:

- A supported virtual machine player is installed. The MapR Sandbox for Hadoop runs on the following virtual machine players installed on Windows, Mac, or Linux PCs:
  - VMware Workstation Player (version 12)
  - VMware Fusion (version 8)
  - VirtualBox (version 5.1.22 and later)
  - **Note:** Use of the virtual machine players is subject to the end-user license terms for each player. By downloading and using the virtual machine players, you agree to the terms and conditions.
- At least 20 GB free hard disk space, at least 4 physical cores, and 8 GB of RAM is available. Performance increases with more RAM and free hard disk space.
- Uses one of the following 64-bit x86 architectures:
  - A 1.3 GHz or faster AMD CPU with segment-limit support in long mode
  - A 1.3 GHz or faster Intel CPU with VT-x support
- If you have an Intel CPU with VT-x support, verify that VT-x support is enabled in the host system BIOS. The BIOS settings that must be enabled for VT-x support vary depending on the system vendor. To determine if VT-x support is enabled, see the VMware knowledge base article at http://kb.vmware.com/kb/1003944.

Installing the Sandbox on VMware Player or VMware Fusion

Download the MapR Sandbox for Hadoop, and import the virtual machine into the VMware Player. Configure the network setting, and start the MapR Sandbox for Hadoop to access the MapR Control System and Hue interfaces.

Complete the following steps to install and run the MapR Sandbox for Hadoop:

1. Download the MapR Sandbox for Hadoop file to a directory on your machine. To access the file, go to https://package.mapr.hpe.com/releases/, and select the directory for the latest MapR release. The file is located in the `sandbox/` directory for the release, as shown:

   ```
   https://package.mapr.com/releases/v6.1.0/sandbox/
   MapR-Sandbox-For-Hadoop-6.1.0-vmware.ova
   ```

2. Open the VMware Player, and select the **Open a Virtual Machine** option. If you are running VMware Fusion, select **Import**.

3. Go to the directory where you downloaded the MapR Sandbox for Hadoop file, and select `MapR-Sandbox-For-Hadoop-<version>-vmware.ova`. The *Import Virtual Machine* window appears.
4. In the *Import Virtual Machine* window, click **Import**. The virtual machine player imports the sandbox.
5. Select **Edit virtual machine settings** and then select the **Network Adapter** option.

   Note: The correct setting depends on your network connectivity when you run the sandbox. In general, if you are going to use a wired Ethernet connection, select **NAT**. If you use ODBC or JDBC on a remote host, select **Bridged Adapter**. If you are going to use a wireless network, select **Host-only** or **Bridged Adapter**.
6. Click **OK** to save the settings.
7. Select the `MapR-Sandbox-For-Hadoop-<version>_VM`, and click **Play virtual** machine.
8. When you see the `maprdemo login:_` prompt, enter `mapr` and then enter `mapr` as the password.

   The message, *Welcome to your MapR Demo virtual machine,* appears.
9. Verify that a DNS entry was created on the host machine for the virtual machine. If not, create the entry.
   - For Linux and Mac, create the entry in `/etc/hosts`.
   - For Windows, create the entry in the `%WINDIR%\system32\drivers\etc\hosts` file. To edit and save the hosts file on Windows, you may need to log on as administrator and run an editor, such as Notepad.

   Example: `127.0.0.1 maprdemo`
10. Enter the following URLs in your browser address bar to access the Hue and MapR Control System interfaces, and enter `mapr` as the username and password:
    - **MapR Control System** - Enter https://localhost:8443 or https://127.0.0.1:8443 in the address bar.

      Note: If you encounter a warning message stating that your connection is not private, select the option to accept and continue to the MapR Control System.
    - **Hue** - Enter http://localhost:8888 or http://127.0.0.1:8888 in the address bar.

      Note: If you used a bridged adapter, the network generates and assigns an IP to the sandbox that you must use in place of 127.0.0.1 or localhost in the URL. To get the IP address, log in to the sandbox, using Alt+F2 on Windows or Option+F5 on Mac or Linux. Enter `root` as the username and `mapr` as the password. Run the `ifconfig` command to get the sandbox IP address. The IP address is located in the inet address field. You can access the Control System and Hue interfaces using the IP address, as shown in the following examples:
      - **Control System** - https://192.168.1.104:8443
      - **Hue** - http://192.168.1.104:8888

    Alternatively, you can access the host via SSH using `ssh mapr@localhost -p 2222`.

last-updated: Apr 11, 2022

Installing the Sandbox on VirtualBox

Download the MapR Sandbox for Hadoop, and import the virtual machine into VirtualBox. Configure the network setting, and start the MapR Sandbox for Hadoop to access the MapR Control System and Hue interfaces.

Note: The MapR Sandbox for Hadoop on VirtualBox comes with network address translation (NAT) ports forwarded to `localhost`.

Complete the following steps to install and run the MapR Sandbox for Hadoop:

1. Download the MapR Sandbox for Hadoop file to a directory on your machine. To access the file, go to https://package.mapr.hpe.com/releases/, and select the directory for the latest MapR release. The file is located in the `sandbox/` directory for the release, as shown:

   ```
   https://package.mapr.com/releases/v6.1.0/sandbox/
   MapR-Sandbox-For-Hadoop-6.1.0.ova
   ```

2. Open VirtualBox, and select **File** > **Import Appliance**. The *Import Appliance* window appears.
3. Go to the directory where you downloaded the MapR Sandbox for Hadoop file, select the `MapR-Sandbox-For-Hadoop-<version>.ova` file, and click **Open**. The *Import Virtual Appliance* window appears.
4. Click **Next**.
5. In the *Import Virtual Appliance* window, select the option to **Reinitialize the MAC address of all network cards** and then click **Import**. The Import Appliance imports the sandbox.
6. When the import completes, select the MapR Sandbox for Hadoop and then click **Settings**. The *Settings* window appears.
7. In the *Settings* window, select **Network**. The correct setting depends on your network connectivity when you run the sandbox. In general, if you are going to use a wired Ethernet connection, select **NAT Network**. If you use ODBC or JDBC on a remote host, select **Bridged Adapter**. If you are going to use a wireless network, select **Host-only Adapter** or **Bridged Adapter** with the **Intel(R) Dual Band Wireless-AC 8260** option.
8. Click **OK** to continue.
9. Select the `MapR-Sandbox-For-Hadoop-<version>` in VirtualBox, and click **Start**.
10. When you see `maprdemo login:_` prompt, enter `mapr` and then enter `mapr` as the password.

    The message, *Welcome to your MapR Demo virtual machine,* appears.
11. Verify that a DNS entry was created on the host machine for the virtual machine. If not, create the entry.
    - For Linux and Mac, create the entry in `/etc/hosts`.
    - For Windows, create the entry in the `%WINDIR%\system32\drivers\etc\hosts` file. You may need to run an editor, such as Notepad, as the administrator to edit and save the hosts file on Windows.

    Example: `127.0.0.1 maprdemo`
12. Enter the following URLs in your browser's address bar to access the Hue and MapR Control System interfaces, and enter `mapr` as the username and password:

last-updated: Apr 11, 2022

- **MapR Control System** - Enter https://localhost:8443 or https://127.0.0.1:8443 in the address bar.

  Note: If you encounter a warning message stating that your connection is not private, select the option to accept and continue to the MapR Control System.

- **Hue** - Enter http://localhost:8888 or http://127.0.0.1:8888 in the address bar.

  Note: If you used a bridged adapter, the network generates and assigns an IP to the sandbox that you must use in place of 127.0.0.1 or localhost. To get the IP address, log in to the sandbox, using Alt+F2 on Windows or Option+F5 on Mac or Linux. Enter `root` as the username and `mapr` as the password. Enter `ifconfig` to get the sandbox IP address. The IP address is located in the inet address field. You can access the Control System and Hue interfaces using the IP address, as shown in the following examples:

  - **Control System** - https://192.168.1.104:8443
  - **Hue** - http://192.168.1.104:8888

  If you are unable to access these URLs, upgrade Virtual Box and restart the virtual machine.

Alternatively, you can access the host via SSH using `ssh mapr@localhost -p 2222`.

6.1 Installation

This section contains information about installing and upgrading MapR software. It also contains information about how to migrate data and applications from an Apache Hadoop cluster to a MapR cluster.

The topics in this section assume that you are planning, installing, or upgrading a single cluster. If your environment requires multiple clusters, you must repeat each documented procedure for each cluster.

Planning the Cluster

Describes information and factors used in planning your cluster.

A MapR installation is usually a large-scale set of individual servers, called *nodes*, collectively called a *cluster*. In a typical cluster, most nodes are dedicated to data processing and storage, and a smaller number of nodes run other services that provide cluster coordination and management.

The first step in deploying MapR is planning the servers that will form the cluster, and selecting the services that will run on each node. To determine whether a server is capable of contributing to the cluster, it may be necessary to check the requirements in Preparing Each Node. Each node in the cluster must be carefully checked against these requirements; unsuitability of a node is one of the most common reasons for installation failure.

For an excellent introduction to planning a MapR cluster, see this tech talk.

The objective of a cluster plan is to detail each node's set of services.

Select Services

This section describes some of the services that can be run on a node.

Every installation requires services to manage jobs and applications. **ResourceManager** and **NodeManager** manage MapReduce version 2 and other applications that can run on YARN. In addition, MapR requires the **ZooKeeper** service to coordinate the cluster, and at least one node must run the **CLDB** service. The **WebServer** service is required if the browser-based Control System will be used.

last-updated: Apr 11, 2022

After you install MapR core, you can install ecosystem components that belong to a MapR Ecosystem Pack (EEP). A EEP provides a set of ecosystem components that work together. When a newer version or a revision to a component becomes available, the EEP version is updated to reflect the fact that an update was made. For details on the ecosystem components available in each EEP and the list of EEPs supported by your MapR cluster version, see MapR Ecosystem Packs (EEPs).

The following table shows some of the services that can be run on a node:

Service Category	Service	Description
Management	**Warden**	Warden runs on every node, coordinating the node's contribution to the cluster. Warden is also responsible for managing the service state and its resource allocations on that node.
YARN	**NodeManager**	Hadoop YARN NodeManager service. The NodeManager manages node resources and monitors the health of the node. It works with the ResourceManager to manage YARN containers that run on the node.
MapR Core	**FileServer**	FileServer is the MapR service that manages disk storage for MapR File System and MapR Database on each node.
MapR Core	**CLDB**	Maintains the *container location database (CLDB)* (CLDB) service. The CLDB service coordinates data storage services among MapR File System file server nodes, and access across MapR NFS gateways, and MapR clients.
MapR Core	**NFS**	Provides read-write MapR Direct Access NFS™ access to the cluster, with full support for concurrent read and write access.
Storage	**MapR HBase Client**	Provides access to MapR Database binary tables via HBase APIs. Required on all nodes that will access table data in MapR File System, typically all edge nodes for accessing table data. HBase API can also be accessed through the HBase Thrift and Rest Gateways.
YARN	**ResourceManager**	Hadoop YARN ResourceManager service. The ResourceManager manages cluster resources, and tracks resource usage and node health.
Management	**ZooKeeper**	Internal service. Enables high availability (HA) and fault tolerance for MapR clusters by providing coordination.
YARN	**HistoryServer**	Archives MapReduce application metrics and metadata.

last-updated: Apr 11, 2022

Service Category	Service	Description
Management	**Web Server**	Contains static Control System user interface pages.
Management	**Apiserver**	Allows you to perform cluster administration programmatically, and supports the Control System (see Setting Up the Control System on page 423).
OJAI Distributed Query Service	**Drill**	Provides the distributed query service powered by Apache Drill for MapR Database JSON. Supports the following functionality: • Advanced secondary index selection • Sorts on large data sets • Parallel query execution See OJAI Distributed Query Service on page 505 for more details about the service.
Application	**Hue**	Hue is the Hadoop User Interface that interacts with Apache Hadoop and its ecosystem components, such as Hive, Pig, and Oozie. It also provides interactive notebook access to Spark through Livy.
Application	**Pig**	Pig is a high-level data-flow language and execution framework.
Application	**Hive**	Hive is a data warehouse engine that supports SQL-like adhoc querying and data summarization.
Application	**Flume**	Flume is a service for piping and aggregating large amounts of log data
Application	**Oozie**	Oozie is a workflow scheduler system for managing Hadoop jobs.
Application	**HCatalog**	HCatalog provides applications with a table view of the MapR File System layer of the cluster, expanding your options from read/write data streams to add-[Hive]-table operations such as get row and store row.
Application	**Cascading**	Cascading on page 3185 is an application framework for analyzing and managing big data.

Service Category	Service	Description
Application	**Myriad**	Myriad is an application framework that enables YARN applications and Mesos frameworks to run side-by-side while dynamically sharing cluster resources. When using Myriad, the **ResourceManager** is deployed using Marathon, and **NodeManager** is run as a Mesos task.
Application	**Spark**	Spark is a processing engine for large datasets. While it can be deployed locally or standalone, the recommended deployment is on YARN. The application timeline server component provides a historical view of query details.
Application	**Sqoop**	Sqoop is a library for transferring bulk data between Hadoop and relational databases.

Cluster Design Objectives

This section describes some of the work that your cluster performs, and identifies key design considerations.

Begin by understanding the work that the cluster performs. Establish metrics for data storage capacity, throughput, and characterize the data processing that will typically be performed.

Data Workload

While MapR is relatively easy to install and administer, designing and tuning a large production MapReduce cluster is a complex task that begins with understanding your data needs. Consider the kind of data processing that will occur and estimate the storage capacity and throughput speed required. Data movement, independent of MapReduce operations, is also a consideration. Plan for how data will arrive at the cluster, and how it will be made useful elsewhere.

Network bandwidth and disk I/O speeds are related; either can become a bottleneck. CPU-intensive workloads reduce the relative importance of disk or network speed. If the cluster will be performing a large number of big reduces, network bandwidth is important, suggesting that the hardware plan include multiple NICs per node. The MapR Core can natively take advantage of multiple NICs and distribute workload across them. In general, the more network bandwidth, the faster things will run.

Running NFS on multiple data nodes can improve data transfer performance and make direct loading and unloading of data possible, but multiple NFS instances requires an Converged Enterprise Edition, Hadoop module license. For more information about NFS, see Managing the MapR NFS Service on page 1176.

Plan which nodes will provide NFS access according to your anticipated traffic. For instance, if you need 5Gb/s of write throughput and 5Gb/s of read throughput, the following node configurations would be suitable:

- 12 NFS nodes with a single 1GbE connection each
- 6 NFS nodes with dual 1GbE connections each
- 4 NFS nodes with quadruple 1GbE connections each

When you set up NFS on all of the file server nodes, you enable a self-mounted NFS point for each node. A cluster made up of nodes with self-mounted NFS points enable you to run native applications as

last-updated: Apr 11, 2022

tasks. You can use round-robin DNS or a hardware load balancer to mount NFS on one or more dedicated gateways outside the cluster to allow controlled access.

High Availability

A properly licensed and configured MapR cluster provides automatic failover for continuity throughout the MapR Core stack. Configuring a cluster for HA involves redundant instances of specific services, as well as a correct configuration of the MapR NFS service. HA features are not available with the Converged Community Edition.

The following table describes redundant services used for HA:

Service	Strategy	Min. instances
CLDB	Primary/secondary--two instances in case one fails.	2
ZooKeeper	A majority of ZK nodes (a *quorum*) must be up.	3
ResourceManager	One active and one or more standby instances. If the active one fails, one standby instance takes over. This is configured automatically using Zero Configuration.	2
NFS	The more redundant NFS services, the better.	2
OpenTSDB	At least one instance should be up.	3
Elasticsearch	At least two instances should be up.	3

Note: You should use an odd number of ZooKeeper instances. Setting up more than 5 ZooKeeper instances is not usually needed.

For a high availability cluster, use 5 ZooKeepers, so that the cluster can tolerate 2 ZooKeeper nodes failing and still maintain a quorum.

On a large cluster, you may choose to have extra nodes available in preparation for failover events. In this case, you keep spare, unused nodes ready to replace nodes running control services, such as CLDB or ZooKeeper in case of a hardware failure.

Virtual IP Addresses

You can use virtual IP addresses (VIPs) for load balancing or failover with the Converged Enterprise Edition, Hadoop module. VIPs provide multiple addresses that can be leveraged for round-robin DNS, allowing client connections to be distributed among a pool of NFS nodes. VIPs also enable high availability (HA) NFS. In a HA NFS system, when an NFS node fails, data requests are satisfied by other NFS nodes in the pool. Use a minimum of one VIP per NFS node per NIC that clients will use to connect to the NFS server. If you have four nodes with four NICs each, with each NIC connected to an individual IP subnet, use a minimum of 16 VIPs and direct clients to the VIPs in round-robin fashion. The VIPs should be in the same IP subnet as the interfaces to which they will be assigned. See Managing VIPs for NFS on page 1176 for NFS for details on enabling VIPs for your cluster.

If you plan to use VIPs on your cluster's NFS nodes, consider the following tips:

- Set up NFS on at least three nodes if possible.
- All NFS nodes must be accessible over the network from the machines where you want to mount them.

last-updated: Apr 11, 2022

- To serve a large number of clients, set up dedicated NFS nodes and load-balance between them. If the cluster is behind a firewall, you can provide access through the firewall through a load balancer instead of direct access to each NFS node. You can run NFS on all nodes in the cluster, if needed.
- To provide maximum bandwidth to a specific client, install the NFS service directly on the client machine. The NFS gateway on the client manages how data is sent in or read back from the cluster, using all its network interfaces (that are on the same subnet as the cluster nodes) to transfer data via MapR APIs, balancing operations among nodes as needed.
- Use VIPs to provide High Availability (HA) and failover.

Minimum Cluster Size

All MapR production clusters must have a minimum of four data nodes except for MapR Edge on page 6579.

More Nodes Are Better

In general, it is better to have more nodes. Larger clusters recover faster from disk failures because more nodes are available to contribute. To maximize fault tolerance in the design of your cluster, see Example Cluster Designs on page 118.

A data node is defined as a node running a FileServer process that is responsible for storing data on behalf of the entire cluster. Having additional nodes deployed with control-only services such as CLDB and ZooKeeper is recommended, but they do not count toward the minimum node total because they do not contribute to the overall availability of data.

To understand how to size a MapR cluster, see this video.

Considerations for Clusters Smaller Than 10 Nodes

Note these special considerations for clusters of 10 nodes or fewer:

- Erasure coding and rolling updates are not supported for clusters of four nodes or fewer.
- Erasure coding is not recommended for five- and six-node clusters. See the *Important* note in Erasure Coding Scheme for Data Protection and Recovery on page 926.
- Dedicated control nodes are not needed on clusters with fewer than 10 data nodes.
- As the cluster size is reduced, each individual node has a larger proportional impact on cluster performance. As cluster size drops below 10 nodes, especially during times of failure recovery, clusters can begin to exhibit variable performance depending on the workload, network and storage I/O speed, and the amount of data being re-replicated.
- For information about fault tolerance, see Priority 1 - Maximize Fault Tolerance on page 119 and Cluster Design Objectives on page 110.

For hardware and configuration best practices, see Cluster Hardware on page 112.

Cluster Hardware

Describes important hardware architecture considerations for your cluster.

When planning the hardware architecture for the cluster, make sure all hardware meets the node requirements listed in Preparing Each Node.

The architecture of the cluster hardware is an important consideration when planning a deployment. Among the considerations are anticipated data storage and network bandwidth needs, including intermediate data generated when jobs and applications are executed. The type of workload also is important. Consider whether the planned cluster usage will be CPU-intensive, I/O-intensive, or

last-updated: Apr 11, 2022

memory-intensive. Think about how data will be loaded into and out of the cluster, and how much data is likely to be transmitted over the network.

Planning a cluster often involves tuning key ratios, such as:

- Disk I/O speed to CPU processing power
- Storage capacity to network speed
- Number of nodes to network speed

Typically, the CPU is less of a bottleneck than network bandwidth and disk I/O. To the extent possible, balance network and disk transfer rates to meet the anticipated data rates using multiple NICs per node. It is not necessary to bond or trunk the NICs together. The MapR Data Platform can take advantage of multiple NICs transparently. Each node should provide raw disks to MapR, with no RAID or logical volume manager, as MapR takes care of formatting and data protection.

The following example architecture provides specifications for a recommended standard MapR Hadoop compute/storage node for general purposes. This configuration is highly scalable in a typical data center environment. MapR can make effective use of more drives per node than standard Hadoop, so each node should present enough faceplate area to allow a large number of drives.

Standard Compute/Storage Node

- Dual CPU socket system board
- 2x8 core CPU, 32 cores with HT enabled
- 8x8GB DIMMs, 64GB RAM (DIMM count must be multiple of CPU memory channels)
- 12x2TB SATA drives
- 10GbE network interface
- OS using entire single drive, not shared as data drive

Best Practices

Hardware recommendations and cluster configuration vary by use case. For example, is the application an MapR Database application? Is the application latency-sensitive?

The following recommendations apply in most cases:

Disk Drives	• Drives should be JBOD, using single-drive RAID0 volumes to take advantage of the controller cache. • SSDs are recommended when using MapR Database JSON with secondary indexes. HDDs can be used with secondary indexes only if the performance requirements are thoroughly understood. Performance can be substantially impaired on HDDs because of high levels of disordered I/O requests. SSDs are not needed for using MapR Event Store For Apache Kafka. • SAS drives can provide better I/O latency; SSDs provide even lower latency. • Match aggregate drive throughput to network throughput. 20GbE ~= 16-18 HDDs or 5-6 SSDs or 1 NVMe drive.

last-updated: Apr 11, 2022

Cluster Size	• In general, it is better to have more nodes. Larger clusters recover faster from disk failures because more nodes are available to contribute. For information about fault tolerance, see Example Cluster Designs on page 118. • For smaller clusters, all nodes are likely to fit on a single non-blocking switch. Larger clusters require a well-designed Spine/Leaf fabric that can scale.
Operating System and Server Configuration	• Red Hat Enterprise Linux, SUSE Linux Enterprise Server, Ubuntu, CentOS, and Oracle Enterprise Linux are supported as described in Operating System Support Matrix on page 5522. • Install the minimal server configuration. Use a product like Cobbler to PXE boot and install a consistent OS image. • Install the full JDK (1.8). • For best performance, avoid deploying a MapR cluster on virtual machines. However, VMs are supported for use as clients or edge nodes.
Memory, CPUs, Number of Cores	• Make sure the DIMM count is an exact multiple of the number of memory channels the selected CPU provides. • Use CPUs with as many cores as you can. Having more cores is more important than having a slightly higher clock speed. • MapR Database benefits from lots of RAM: 256GB per node or more. • Filesystem-only nodes can have fewer, faster cores: 6 cores for the first 10GbE of network bandwidth, and an additional 2 cores for each additional 10GbE. For example, dual 25GbE (50GbE) filesystem-only nodes perform best with at least 6+(4*2)=14 cores. • Filesystem-only nodes should have hyperthreading disabled.

Service Layout in a Cluster

Provides an overview of segregating services on different nodes.

How you assign services to nodes depends on the scale of your cluster and the MapR license level. For a single-node cluster – which must not be used in a production environment (see Minimum Cluster Size on page 112) – no decisions are involved. All of the services you are using run on the single node.

On medium clusters, the performance demands of the CLDB and ZooKeeper services require them to be assigned to separate nodes to optimize performance. On large clusters, good cluster performance requires that these services run on separate nodes.

The cluster is flexible and elastic. Nodes play different roles over the lifecycle of a cluster. The basic requirements of a node are not different for management or for data nodes.

As the cluster grows, it becomes advantageous to locate control services (such as ZooKeeper and CLDB) on nodes that do not run compute services. The MapR Converged Community Edition does not include HA

last-updated: Apr 11, 2022

capabilities, which restricts the number of instances that certain services can run. The number of nodes and the services they run evolve over the life cycle of the cluster.

To provide a high-availability, high-performance cluster, the MapR software architecture allows virtually any service to run on any node, or nodes. The following guidelines help you to plan your cluster service layout.

Note: It is possible to install MapR software on a one- or two-node demo cluster. Production clusters can harness hundreds of nodes, but five- or ten-node production clusters are appropriate for some applications.

Node Types

Depending on the size of your cluster, nodes may or may not perform specialized work.

In a production MapR cluster, some nodes are typically dedicated to cluster coordination and management, and other nodes are tasked with data storage and processing duties. An edge node provides user access to the cluster, concentrating open user privileges on a single host. In smaller clusters, the work is not so specialized, and a single node may perform data processing as well as management.

Nodes Running ZooKeeper and CLDB

High latency on a ZooKeeper node can lead to an increased incidence of ZooKeeper quorum failures. A ZooKeeper quorum failure occurs when the cluster finds too few copies of the ZooKeeper service running. If the ZooKeeper node is running other services, competition for computing resources can lead to increased latency for that node. If your cluster experiences issues relating to ZooKeeper quorum failures, consider reducing or eliminating the number of other services running on the ZooKeeper node.

Nodes for Data Storage and Processing

Most nodes in a production cluster are data nodes. FileServer and NodeManager run on data nodes. Data nodes can be added or removed from the cluster as requirements change over time.

Edge Nodes

So-called Edge nodes provide a common user access point for the MapR webserver and other client tools. Edge nodes may or may not be part of the cluster, as long as the edge node can reach cluster nodes. Nodes on the same network can run client services and other services, but edge nodes and client nodes may not host MapR monitoring components.

Related concepts

MapR Monitoring Architecture on page 1331
MapR Monitoring integrates with open-source components to collect, aggregate, store, and visualize metrics and logs.

Service Layout Guidelines for Large Clusters

Describes how to install and segregate services on large clusters.

General Guidelines

The following are guidelines for installing services on large clusters:

- **ResourceManager**: Run the ResourceManager services on dedicated nodes for clusters with over 250 nodes.
- **Elasticsearch:** Elasticsearch consumes significant CPU, disk, and memory resources. Review the following guidelines:
  - Whenever possible, Elasticsearch should have a dedicated disk for its index directory.
  - Depending on the number of indexed logs, you may want to run the Elasticsearch service on five or more dedicated nodes.

last-updated: Apr 11, 2022

  - On production clusters, consider increasing Elasticsearch's memory allocation. After you install MapR Monitoring, see Configure the Elasticsearch Service Heap Size on page 1394.
  - On clusters with high-density racks, run one or more Elasticsearch services on each rack. Also, configure Fluentd to write logs to Elasticsearch services that reside on the same rack as the Fluentd services. After you install MapR Monitoring, see Configure Fluentd Services to Write to Elasticsearch Nodes on the Same Rack on page 1395.
- **OpenTSDB:** Run the OpenTSDB service on five or more nodes for clusters over 100 nodes.

Services to Separate on Large Clusters

The following are guidelines about which services to separate on large clusters:

- **ResourceManager on ZooKeeper nodes:** Avoid running the ResourceManager service on nodes that are running the ZooKeeper service. On large clusters, the ResourceManager service can consume significant resources.
- **Monitoring Services on CLDB Nodes**: Avoid running the OpenTSDB, Elasticsearch, Kibana, or Grafana services on nodes that are running the CLDB service.

Service Layout Guidelines for Replication

Based on the use case, replicating MapR Database tables and MapR Event Store For Apache Kafka may require the installation of MapR Gateways and the HBase client on one or more nodes.

Guidelines for Installing Gateways

When you configure replication for MapR Database tables or MapR Event Store For Apache Kafka, MapR gateways provide one-way communication between a source MapR cluster and a destination cluster. It is recommended to install at least three gateways on the destination cluster. Installing two or more gateways on a destination cluster allows for replication failover in the event that one gateway is unavailable. Installing three gateways on a large cluster enables better throughput for data replication. Installing more than three gateways can improve availability but is not likely to improve replication performance.

Guidelines for Installing HBase Client

When you configure replication for MapR Database tables, the HBase client is not required by default. However, you must install the HBase client to replicate MapR Database tables in the following situations:

- You plan to perform autosetup table replication using the MapR Database C API. In this case, you must install the HBase Client on the node where the C application will run.
- You plan to perform autosetup table replication using the `maprcli table replica autosetup` command without direct copy. In this case, you must install the HBase Client on the node where you submit the `maprcli table replica autosetup` command. For more information about autosetup table replication, see Replica Autosetup for MapR Database Tables on page 624.

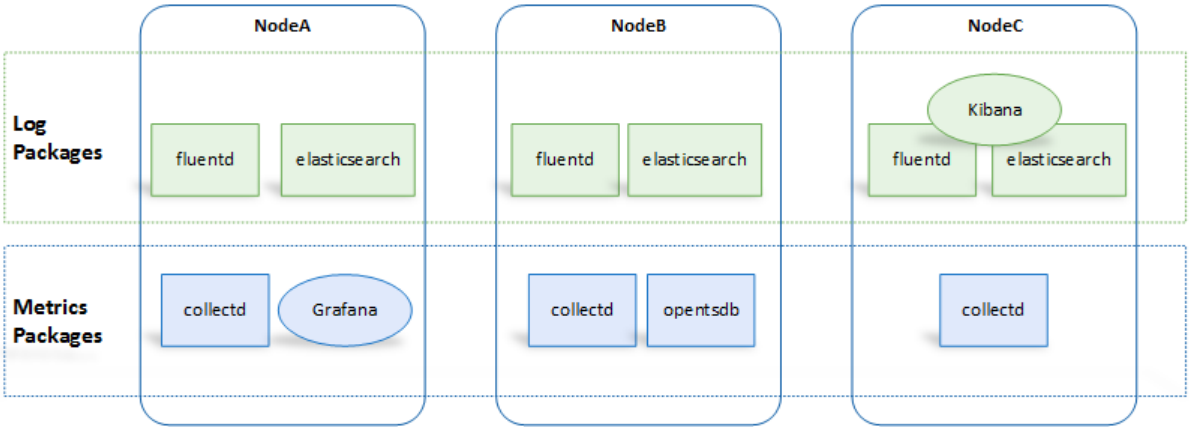
MapR Monitoring Storage Options

Describes various storage options for MapR Monitoring. The Control System relies on MapR monitoring components to display metrics, but can function without the monitoring components. Using MapR monitoring to store logs is optional.

The following installation options are available for metric storage with OpenTSDB and log storage with Elasticsearch. You can store logs and metrics on a non-MapR cluster but this scenario is not supported by MapR.

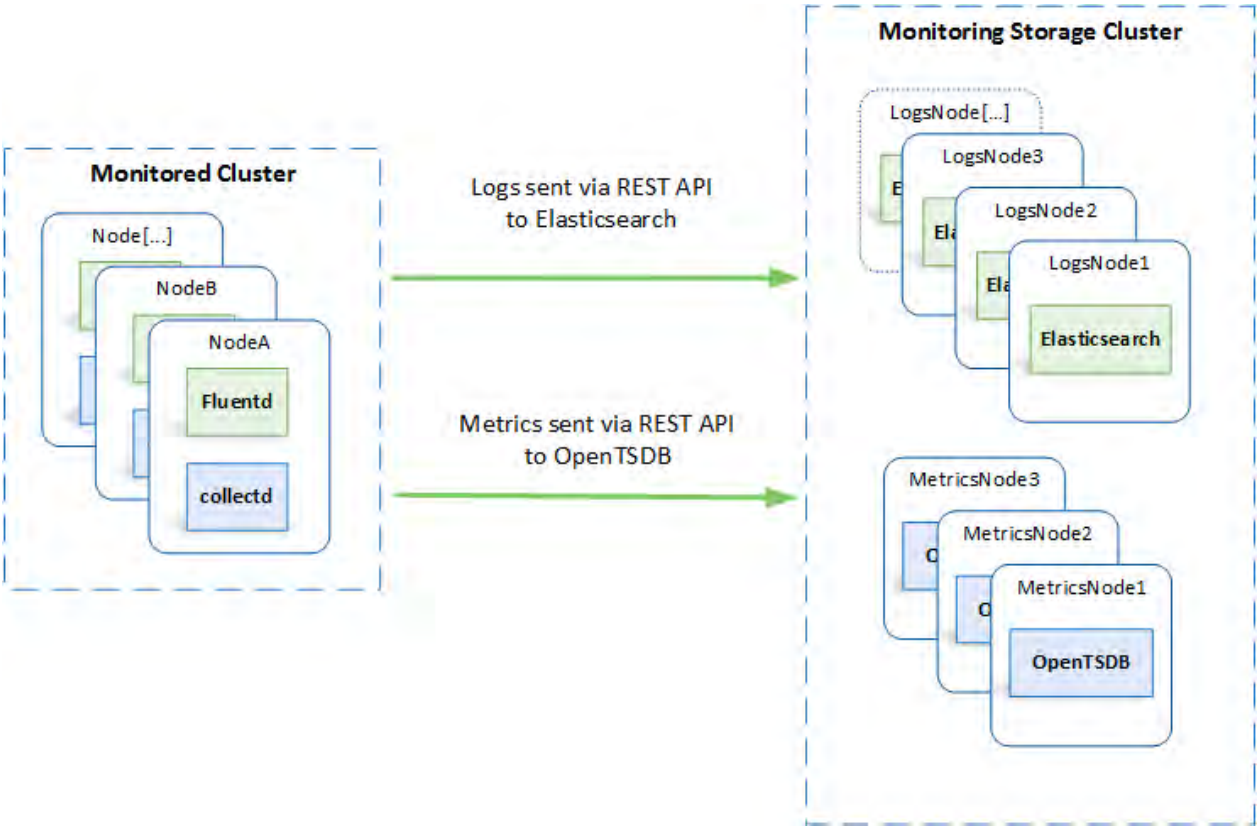
Store Metrics and Logs on the Monitored Cluster

You can store metrics and logs on the nodes in the same MapR cluster that you want to monitor. Note that installing Grafana is optional.



Store Metrics and Logs on a Storage Cluster

You can store metrics and logs for the MapR cluster that you want to monitor, on nodes in a different MapR cluster.

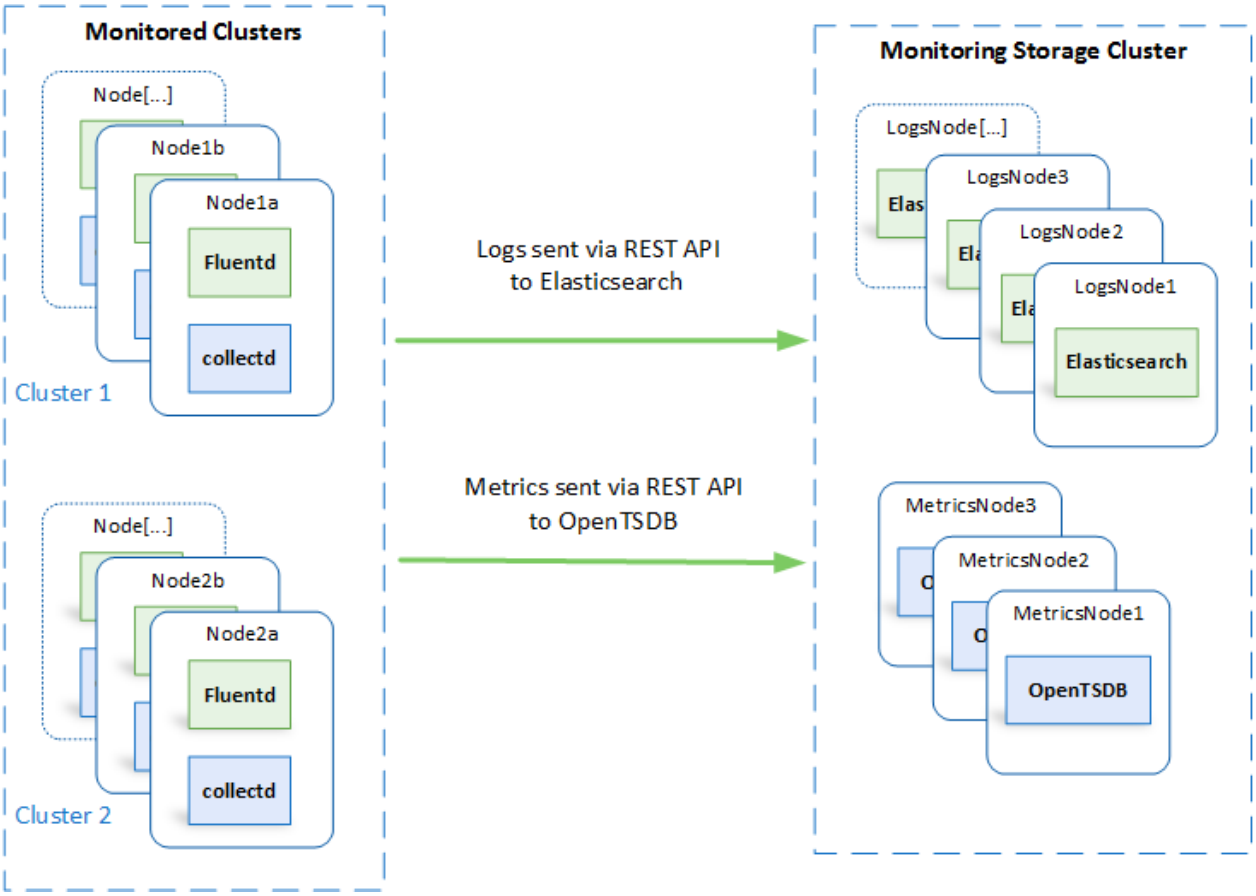


In this case, Kibana and Grafana can be installed on either cluster.

Use a Single Cluster to Store Monitoring Data for Multiple Clusters

You can store metrics and logs for more than one MapR cluster on a shared set of nodes. With this option, a single dashboard can monitor multiple clusters.

last-updated: Apr 11, 2022



In this case, Kibana and Grafana can be installed on any of these clusters.

Example Cluster Designs
Describes how to design a MapR cluster for maximum availability, fault-tolerance, and performance.

The topic includes example cluster designs for 6-node, 12-node, and 50-node clusters:

- Example 1: 6-Node Cluster on page 121
- Example 2: 12-Node Cluster on page 122
- Example 3: 50-Node Cluster on page 123

Design Priorities

Building a cluster requires you to make decisions – and sometimes tradeoffs – that take into account cluster attributes such as:

- Performance
- Fault-tolerance
- Cost
- Ease of use
- Supportability
- Reliability

The following priorities and related best practices can help you plan a durable cluster that includes all or most of these cluster attributes. The priorities are listed in order of importance:

- Priority 1 - Maximize Fault Tolerance on page 119
- Priority 2 - Minimize Resource Contention on page 120
- Priority 3 - Promote High Availability on page 120
- Priority 4 - Use Dedicated Nodes for Key Services for Large Clusters (50-100 Nodes) on page 121

Priority 1 - Maximize Fault Tolerance

Follow these best practices to ensure that your MapR cluster can tolerate failures:

- Ensure an odd number of ZooKeeper services. ZooKeeper fault tolerance depends on a quorum of ZooKeeper services being available. At least three ZooKeeper services are recommended. For a higher level of fault tolerance, use five ZooKeeper services. With five ZooKeepers, two can be lost and quorum maintained.
- For other services, it makes sense for them to be at least as reliable as ZooKeeper. Generally, this means at least two instances of the service for three ZooKeepers and three instances for five ZooKeepers.
- Include enough CLDBs to be as reliable as ZooKeeper. As CLDBs use a primary-secondary configuration, a MapR cluster can function with an odd or even number of CLDBs. The recommended minimum number of active CLDBs is two. To tolerate failures, more CLDBs are needed:
  - If you have three ZooKeepers, configure at least three CLDBs.
  - If you have five ZooKeepers, configure at least four CLDBs. With four CLDBs, the cluster can tolerate two CLDB failures and still provide optimal performance. Adding a fifth CLDB does not increase failure tolerance in this configuration.
- Include enough Resource Manager processes to be as reliable as ZooKeeper. Only one Resource Manager is active at a time:
  - If you have three ZooKeepers, you need at least two Resource Managers.
  - If you have five ZooKeepers, you need at least three Resource Managers. Three Resource Managers can survive the loss of two ZooKeepers.
- For most MapR clusters, the recommended configuration is:
  - Three ZooKeepers
  - Three CLDBs
  - Two or three Resource Managers
  - For larger clusters, increase the number of CLDBs or ZooKeepers for better performance or higher reliability. Table 1 shows the number of failures tolerated by various combinations of ZooKeeper, CLDB, and Resource Manager services.

Table

ZooKeepers	CLDBs	Resource Managers	ZK/CLDB/RM Failures Tolerated
3	2[1]	2	1
3	3	2	1

last-updated: Apr 11, 2022

Table (Continued)

ZooKeepers	CLDBs	Resource Managers	ZK/CLDB/RM Failures Tolerated
5	4	3	2
5	5[2]	3	2

[1]For optimal failure handling, the minimum number of CLDBs is three; hence, three or more CLDBs are recommended. With two CLDBs, the failure of one does not result in an outage, but recovery can take longer than with three.

[2]Using five CLDBs does not improve fault-tolerance significantly when compared with four CLDBs. However, it can be convenient to have the same number of CLDBs as ZooKeepers.

Priority 2 - Minimize Resource Contention

Every service on a node represents a tax on the resources provided by that node. Spreading services evenly across nodes maximizes performance and helps to keep failures isolated to failure domains. Due to power and networking considerations, a rack is usually the most common failure domain.

Follow these best practices to avoid performance bottlenecks:

- Spread like services across racks as much as possible. While not necessary, it is also convenient to put them in the same position, if possible.
- To maximize availability, use three or more racks even for small clusters. Using two racks is not recommended. If a cluster has three ZooKeepers, using two racks means one of the racks will host two ZooKeepers. In this scenario, a loss of a rack having two ZooKeepers can jeopardize the cluster.
  - For services that are replicated, make sure the replicas are in different racks.
  - Put the Resource Manager and CLDB services on separate nodes, if possible.
  - Put the ZooKeeper and CLDB services on separate nodes, if possible.
- Some administrators find it convenient to put web-oriented services together on nodes with lower IP addresses in a rack. This is not required.
- Avoid putting multiple resource-heavy services on the same node.
- Spread the following resources across all data nodes:
  - Clients
  - Drill
  - NFS

Priority 3 - Promote High Availability

Whenever possible, configure high availability (HA) for all services, not just for services that provide HA by default. CLDB, ZooKeeper, Resource Manager, and Drill provide HA by default. Some services are inherently stateless. If possible, configure multiple instances of these services:

- Kafka REST
- HBase Thrift
- HBase REST
- HTTPFS

- HiveServer 2 (HS2)
- Hue
- Kafka Connect
- MapR Data Access Gateway
- MapR Gateway
- Oozie
- OpenTSDB
- WebHCat
- WebServer

Priority 4 - Use Dedicated Nodes for Key Services for Large Clusters (50-100 Nodes)

Large clusters increase CLDB and Resource Manager workloads significantly. In clusters of 50 or more nodes:

- Use dedicated nodes for CLDB, ZooKeeper, and Resource Manager.

  Note: Dedicated nodes have the benefit of supporting fast fail-over for file-server operations.

- If fast fail-over is not critical and you need to minimize hardware costs, you may combine the CLDB and ZooKeeper nodes. For example, a large cluster might include 3 to 9 such combined nodes.
- If necessary, review and adjust the hardware composition of CLDB, ZooKeeper, and Resource Manager nodes. Once you have chosen to use dedicated nodes for these services, you might determine that they do not need to be identical to other cluster nodes. For example, dedicated CLDB and ZooKeeper nodes probably do not need as much storage as other cluster nodes.
- Avoid configuring Drill on CLDB or ZooKeeper nodes.

Example Clusters

The following examples are reasonable implementations of the design priorities introduced earlier in this section. Other designs are possible and may satisfy your unique environment and workloads.

- Example 1: 6-Node Cluster on page 121
- Example 2: 12-Node Cluster on page 122
- Example 3: 50-Node Cluster on page 123

Example 1: 6-Node Cluster

Example 1 shows a 6-node cluster contained in a single rack. When only a single rack is available, this example can work for small clusters. However, the recommended best practice for all clusters, regardless of size, is to use three or more racks, if possible.

Example 1a. Core and Hadoop for 6-Node Cluster

Physical Rack/ Failure Domain	Recommended Topology	Hostname	Core										Hadoop		
			Core (6)	Fileserver (6)	Client Components (6)	Zookeeper (3)	CLDB (3)	NFS (6)	Adminserver (2)	Gateway (2)	Metrics TSDB (2)	Metrics ES (2)	RM (2)	History (2)	Node Mgr (6)
Rack1	/data/rack1	h1	✓	✓	✓		✓	✓	✓					✓	✓
Rack1	/data/rack1	h2	✓	✓	✓		✓	✓	✓					✓	✓
Rack1	/data/rack1	h3	✓	✓	✓		✓	✓		✓		✓			✓
Rack1	/data/rack1	h4	✓	✓	✓	✓		✓		✓		✓			✓
Rack1	/data/rack1	h5	✓	✓	✓	✓		✓			✓		✓		✓
Rack1	/data/rack1	h6	✓	✓	✓	✓		✓			✓		✓		✓

Example 1b. Ecosystem Components for 6-Node Cluster

Physical Rack/ Failure Domain	Recommended Topology	Hostname	Ecosystem														
			HBase REST* (2)	HBase Thrift* (2)	Drill (6)	Spark (6)	Streams REST* (2)	HTTPFS* (2)	HS2 (2)	HS2 Metaserver (2)	Webhcat(2)	Spark HS(2)	Oozie (2)	Sqoop (2)	Hue (2)	MySQL (1)	Total[3]
Rack1	/data/rack1	h1	✓	✓	✓	✓						✓		✓			14
Rack1	/data/rack1	h2	✓	✓	✓	✓						✓		✓			14
Rack1	/data/rack1	h3			✓	✓	✓	✓			✓		✓				14
Rack1	/data/rack1	h4			✓	✓	✓	✓			✓		✓				14
Rack1	/data/rack1	h5			✓	✓			✓	✓					✓		13
Rack1	/data/rack1	h6			✓	✓			✓	✓					✓	✓	14

[3]*Total* cells show the total number of Core, Hadoop, and Ecosystem components installed on each host node for the example cluster.

*Denotes a service that is lightweight and stateless. For greater performance, consider running these services on all nodes and adding a load balancer to distribute network traffic.

Example 2: 12-Node Cluster

Example 2 shows a 12-node cluster contained in three racks:

Example 2a. Core and Hadoop for 12-Node Cluster

Physical Rack/ Failure Domain	Recommended Topology	Hostname	Core										Hadoop		
			Core (12)	Fileserver (12)	Client Components (12)	Zookeeper (3)	CLDB (3)	NFS (12)	Adminserver (3)	Gateway (3)	Metrics TSDB (3)	Metrics ES (3)	RM (3)	History (3)	Node Mgr (12)
Rack1	/data/rack1	h1	✓	✓	✓			✓	✓					✓	✓
Rack1	/data/rack1	h2	✓	✓	✓			✓		✓					✓
Rack1	/data/rack1	h3	✓	✓	✓		✓	✓							✓
Rack1	/data/rack1	h4	✓	✓	✓	✓		✓			✓	✓	✓		✓
Rack2	/data/rack2	h5	✓	✓	✓			✓	✓					✓	✓
Rack2	/data/rack2	h6	✓	✓	✓			✓		✓					✓
Rack2	/data/rack2	h7	✓	✓	✓		✓	✓							✓
Rack2	/data/rack2	h8	✓	✓	✓	✓		✓			✓	✓	✓		✓
Rack3	/dev/rack3	h9	✓	✓	✓			✓	✓					✓	✓
Rack3	/dev/rack3	h10	✓	✓	✓			✓		✓					✓
Rack3	/dev/rack3	h11	✓	✓	✓		✓	✓							✓
Rack3	/dev/rack3	h12	✓	✓	✓	✓		✓			✓	✓	✓		✓

Example 2b. Ecosystem Components for 12-Node Cluster

Physical Rack/ Failure Domain	Recommended Topology	Hostname	Ecosystem													
			HBase REST* (3)	HBase Thrift* (3)	Drill (12)	Spark (12)	Streams REST* (3)	HTTPFS* (3)	HS2 (3)	HS2 metaserver (3)	Webhcat(3)	Spark HS (3)	Oozie (3)	Sqoop (3)	Hue (3)	MySQL (3)	Total[3]
Rack1	/data/rack1	h1			✓	✓			✓			✓			✓		12
Rack1	/data/rack1	h2	✓	✓	✓	✓	✓	✓									12
Rack1	/data/rack1	h3			✓	✓							✓	✓		✓	11
Rack1	/data/rack1	h4			✓	✓				✓	✓						13
Rack2	/data/rack2	h5			✓	✓			✓			✓			✓		12
Rack2	/data/rack2	h6	✓	✓	✓	✓	✓	✓									12
Rack2	/data/rack2	h7			✓	✓							✓	✓		✓	11
Rack2	/data/rack2	h8			✓	✓				✓	✓						13
Rack3	/dev/rack3	h9			✓	✓			✓			✓			✓		12
Rack3	/dev/rack3	h10	✓	✓	✓	✓	✓	✓									12
Rack3	/dev/rack3	h11			✓	✓							✓	✓		✓	11
Rack3	/dev/rack3	h12			✓	✓				✓	✓						13

[3]*Total* cells show the total number of Core, Hadoop, and Ecosystem components installed on each host node for the example cluster.

*Denotes a service that is lightweight and stateless. For greater performance, consider running these services on all nodes and adding a load balancer to distribute network traffic.

Example 3: 50-Node Cluster

Examples 3 shows a 50-node cluster contained in five racks:

Example 3a. Core and Hadoop for 50-Node Cluster (Racks 1-3)

last-updated: Apr 11, 2022

Physical Rack/ Failure Domain	Recommended Topology	Hostname	Core										Hadoop		
			Core/Fluentd/Collectd (30)	Fileserver (30)	Client Components (27)	Zookeeper (3)	CLDB (3)	NFS (27)	Adminserver/Kibana/Grafana (3)	Gateway (3)	Metrics TSDB (3)	Metrics ES (3)	RM (3)	History (3)	Node Mgr (27)

Plan Initial Volumes

Describes why it is important to define volumes.

MapR manages the data in a cluster in a set of *volumes*. Volumes can be mounted in the Linux filesystem in a hierarchical directory structure, but volumes do not contain other volumes. Each volume has its own policies and other settings, so it is important to define a number of volumes in order to segregate and classify your data.

Plan to define volumes for each user, for each project, and so on. For streaming data, you might plan to create a new volume to store new data every day or week or month. The more volume granularity, the easier it is to specify backup or other policies for subsets of the data. For more information on volumes, see Managing Data with Volumes.

Security Considerations

Planning for security will help you identify security shortcomings and address them before you go into production.

MapR Data Platform releases provide security by default. If your cluster is not already secure, the MapR Converged Data Platform supports many different levels of security. For more information, see Getting Started with MapR Security on page 1405.

Before installing MapR software using the published packages, make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6569. If a vulnerability applies to your release, contact your MapR support representative for a fix, and apply the fix immediately, if applicable.

last-updated: Apr 11, 2022

If the cluster you are planning to install must communicate with other clusters, the clusters should have similar security attributes. Mixing secure and nonsecure clusters is not recommended. For more information, see Setting Up Cross-Cluster Security on page 1482.

User Accounts

This section identifies how to organize authorized users of the cluster.

Part of the cluster plan is a list of authorized users of the cluster. It is preferable to give each user an account, because account-sharing makes administration less secure. Any user of the cluster must be established with the **same Linux UID and GID on every node in the cluster**. Central directory services, such as LDAP, AD, and IPA are often used to simplify user maintenance.

Next Step

After you have a complete cluster plan, you are ready to prepare each node.

It is important to begin installation with a complete Cluster Plan, but plans should not be immutable. Cluster services often change over time, particularly as clusters scale up by adding nodes. Balancing resources to maximize utilization is the goal, and it will require flexibility.

The next step is to prepare each node. Most installation difficulties are traced back to nodes that are not qualified to contribute to the cluster, or which have not been properly prepared. For large clusters, it can save time and trouble to use a configuration management tool such as Puppet or Chef.

Proceed to Preparing Each Node and assess each node.

Installing MapR and MapR Ecosystem Components

Describes how to install MapR software and ecosystem components with or without the MapR Installer.

This *Installation Guide* has been designed as a set of sequential steps. The following topics are listed in the order which you would complete them. You must complete each step before proceeding to the next step.

This section assumes that you have already reviewed Planning the Cluster on page 107.

Within the Data Fabric (v6) Admin Series of training courses, HPE offers an installation training course. For more information, see the nearby Recommended Resources.

You can either use the installer script, or perform a manual installation. The installer script takes care of using the right repositories for your Linux version, and there is nothing that you have to worry about. HPE recommends that you use the installer script. The technically inclined can perform a manual installation.

MapR Repositories and Packages

Describes the repositories for MapR software and the ecosystem components.

Repositories for MapR Core Software

HPE hosts `rpm` and `deb` repositories for installing the MapR core software using Linux package-management tools. For every release of the core software, a repository is created for each supported platform.

Platform-specific installation repositories are hosted at: https://package.mapr.hpe.com/releases/v6.x.x/<platform>.

Repositories for MapR Ecosystem Packs

A MapR Ecosystem Pack (EEP) provides a set of ecosystem components that work together. HPE hosts `rpm` and `deb` repositories for easily installing the ecosystem components.

These platform-specific repositories are hosted at the following location:

- https://package.mapr.hpe.com/releases/MEP/MEP-<version>/<platform>

For more information about the MapR Ecosystem Packs (EEPs), see MapR Ecosystem Packs on page 3174.

GitHub Repositories for Source Code

HPE releases the source code for ecosystem components to GitHub, including all patches that HPE has applied to the components. Source code for all releases since March 2013 are available at https://github.com/mapr.

Maven Repositories for Application Developers

HPE hosts a Maven repository where application developers can download dependencies on MapR software or Hadoop ecosystem components. Maven artifacts for all releases since March 2013 are available at Maven Artifacts for MapR on page 4155.

Other Scripts and Tools

Other MapR scripts and tools can be found in the following locations:

- https://package.mapr.hpe.com/scripts/
- https://package.mapr.hpe.com/tools/

Preparing Each Node

Defines minimum requirements for each node in your cluster.

Every node contributes to the cluster, so each node must be able to run MapR and Hadoop software. Nodes must meet minimum requirements for operating system, memory and disk resources and installed software, such as Java. *Including unsuitable nodes in a cluster is a major source of installation difficulty.*

Table

Component	Requirements
CPU	64-bit x86
OS	RedHat, Oracle Linux, CentOS, SLES, or Ubuntu
Memory	16 GB minimum, more in production
Disk	Raw, unformatted drives and no partitions
DNS	Hostname, reaches all other nodes
Users	Common users across all nodes; passwordless ssh (optional)
Java	Must run Java 1.8
Other	NTP, Syslog, PAM

> **Tip:** For enhanced node performance and reliability, always set the MAPR_SUBNETS enivronment variable.

Use the subsequent sections as a checklist to make each candidate node suitable for its assigned roles. Install MapR software on each node that you identify as meeting the minimum requirements.

CPU and Operating System

Describes how to check whether your processor and operating system are supported by MapR software.

last-updated: Apr 11, 2022

Processor is 64-bit

To determine the processor type, run

```
$ uname -m
x86_64
```

If the output includes "x86_64," the processor is 64-bit. If it includes "i386," "i486," "i586," or "i686," it is a 32-bit processor, which is not supported by MapR software.

If the results are "unknown," or none of the above, use one of the following commands.

```
$ uname -a
Linux mach-name 2.6.35-22-server #33-Ubuntu SMP Sun Sep 19 20:48:58 UTC
2012 x86_64 GNU/Linux
```

In the `cpuinfo` file, the flag 'lm' (for "long-mode") indicates a 64-bit processor.

```
$ grep flags /proc/cpuinfo
flags               : fpu vme de pse tsc msr pae mce cx8 apic sep mtrr pge
mca cmov pat pse36 clflush dts acpi mmx fxsr sse sse2 ss syscall nx rdtscp
lm constant_tsc up arch_perfmon pebs bts rep_good xtopology tsc_reliable
nonstop_tsc aperfmperf pni pclmulqdq ssse3 cx16 sse4_1 sse4_2 popcnt aes
hypervisor lahf_lm ida arat
```

Supported Operating Systems

For the supported operating systems, see Operating System Support Matrix on page 5522.

To determine the name and version of the installed operating system, run the `lsb_release -a` command.

There is no problem if the `lsb_release` command reports "No LSB modules are available."

```
$ lsb_release -a
No LSB modules are available.
Distributor ID: Ubuntu
Description:    Ubuntu 10.10
Release:        10.10
Codename:       maverick
```

If the `lsb_release` command is not found, try one of the following alternatives:

```
$ cat /proc/version
Linux version 2.6.35-22-server (build@allspice) (gcc version 4.4.5 (Ubuntu/
Linaro 4.4.4-14ubuntu4) ) #33-Ubuntu SMP Sun Sep 19 20:48:58 UTC 2012
```

```
$ cat /etc/*-release
DISTRIB_ID=Ubuntu
DISTRIB_RELEASE=10.10
DISTRIB_CODENAME=maverick
DISTRIB_DESCRIPTION="Ubuntu 10.10"
```

If you determine that the node is running an older version of a supported OS, upgrade to at least a supported version, and test the upgrade before proceeding. If you find a different Linux distribution, such as Fedora or Gentoo, you must reformat and install a supported distribution on the node.

Memory and Disk Space

Describes required and recommended memory, storage, and disk capacities for each node.

Minimum Memory

A minimum of 16 GB memory is required on each node. MapR recommends at least 16 GB for a production environment. Typical MapR production nodes have 32 GB or more.

Run `free -g` to display total and available memory in gigabytes.

```
$ free -g
              total        used        free      shared      buffers
cached
Mem:              3           2           1           0
0           1
-/+ buffers/cache:            0           2
Swap:             2           0           2
```

If the `free` command is not found, you can use other options such as `grep MemTotal: /proc/meminfo`, `vmstat -s -SM`, `top`, or various GUI system-information tools.

MapR does not recommend using the `numad` service, since it has not been tested and validated with MapR software. Using the `numad` service can cause artificial memory constraints to be set, which can lead to performance degradation under load. To stop and disable the `numad` service:

1. Stop the service: `systemctl stop numad`.
2. Set the numad service *not* to start on reboot: `systemctl disable numad`

MapR does not recommend using *always overcommit* as it can lead to the kernel memory manager stopping processes to free memory, resulting in stopped MapR processes and system instability. Leave `vm.overcommit_memory` at its default value of 0, do not change the value to 1 or 2.

You can explore MapR on non-production equipment, but under the demands of a production environment, memory needs to be balanced against disks, network, and CPU.

Storage

For data disks, MapR Installer versions 1.12.0.0 and later require a minimum disk size that is equal to the physical memory on the node. If a data disk does not meet the minimum disk size requirement, a verification error is generated.

To display the currently available disks, use a command such as the following:

```
ls -l /dev/sd*
brw-rw---- 1 root 1000 8,  0 Sep 14 23:49 /dev/sda
brw-rw---- 1 root disk 8,  1 Sep 14 23:49 /dev/sda1
brw-rw---- 1 root disk 8,  2 Sep 14 23:49 /dev/sda2
brw-rw---- 1 root mapr 8, 16 Sep 20 11:44 /dev/sdb
brw-rw---- 1 root mapr 8, 32 Sep 20 11:44 /dev/sdc
brw-rw---- 1 root mapr 8, 48 Sep 20 11:44 /dev/sdd
```

To check the available disk space:

```
df /dev/sda
Filesystem     1K-blocks  Used Available Use% Mounted on
devtmpfs        12225720     0  12225720   0% /dev
```

MapR software works with raw unformatted devices and partitions. For optimized performance and high reliability, MapR recommends using raw unformatted devices. For data nodes, allocate at least three unmounted physical drives or partitions for MapR storage. MapR software uses disk spindles in parallel for faster read/write bandwidth and therefore groups disks into sets of three.

Minimum Disk Allocation: MapR software requires a minimum of one disk or partition for MapR data. However, file contention for a shared disk decreases performance. In a typical production environment,

multiple physical disks on each node are dedicated to the distributed MapR File System, which results in much better performance.

Maximum Disk Allocation: If you are planning to install multiple instances of MapR File System, the number of disks supported on a node can vary based on the number of instances you plan to install. For example, a single node with four instances of the MapR FileServer can support up to 360 disks.

Drive Configuration

Do not use RAID or Logical Volume Management with disks that are added to a MapR node. While MapR supports these technologies, using them incurs additional setup overhead and can affect your cluster's performance. Due to the possible formatting requirements that are associated with changes to the drive settings, configure the drive settings prior to installing MapR.

If you have a RAID controller, disable it, and let the system run in Host Bus Adapter (HBA) mode. For systems that do not support HBA, and have LSI MegaRAID controllers, configure the following drive-group settings for optimal performance:

Property (The actual name depends on the version)	Recommended Setting
RAID Level	RAID0
Stripe Size	>=256K
Cache Policy or I/O Policy	Cached IO or Cached
Read Policy	Always Read Ahead or Read Ahead
Write Policy	Write-Through
Disk Cache Policy or Drive Cache	Disabled

Enabling the Disk Cache policy can improve performance. However, enabling the Disk Cache policy is not recommended because it increases the risk of data loss if the node loses power before the disk cache is committed to disk.

Attention: Disable write caching on all MapR disks if the disks are not battery backed.

Minimum Disk Space

OS Partition. Provide at least 10 GB of free disk space on the operating system partition.

MapR File System. Provide the higher of 8 GB of free disk space or the memory allocated to the MapR MapR File System. Note that the disk space should be greater than the memory allocated to the MapR MapR File System.

Disk. Provide 10 GB of free disk space in the `/tmp` directory and 128 GB of free disk space in the `/opt` directory. Services, such as ResourceManager and NodeManager, use the `/tmp` directory. Files, such as logs and cores, use the `/opt` directory.

Swap space. For production systems, provide at least 4 GB of swap space. If you believe more swap space is needed, consult the swap-space recommendation of your OS vendor. The amount of swap space that a production system needs can vary greatly depending on the application, workload, and amount of RAM in the system. Note that the MapR Installer generates a warning if your swap space is either less than 10% of main memory, or less than 2 GB.

ZooKeeper. On ZooKeeper nodes, dedicate a partition, if practicable, for the `/opt/mapr/zkdata` directory to avoid other processes filling that partition with writes and to reduce the possibility of errors due to a full `/opt/mapr/zkdata` directory. This directory is used to store snapshots that are up to 64 MB. Since the four most recent snapshots are retained, reserve at least 500 MB for this partition. Do not share the physical disk where `/opt/mapr/zkdata` resides with any MapR MapR File System data partitions to avoid I/O conflicts that might lead to ZooKeeper service failures.

last-updated: Apr 11, 2022

Virtual Memory (swappiness)

Swappiness is a setting that controls how often the kernel copies the contents of RAM to swap. By setting `vm.swappiness` to the right value, you can prevent the system from swapping processes too frequently, but still allow for emergency swapping (instead of killing processes). For all Linux distributions, the MapR recommendation is to set `vm.swappiness` to 1.

To check the current value for `vm.swappiness` run:

```
cat /proc/sys/vm/swappiness
```

To change the value, run:

```
sudo sysctl vm.swappiness=1
```

The value of `vm.swappiness` can revert to a system default setting if you reboot the node. To make this setting permanent, enter `vm.swappiness=1` in `/etc/sysctl.conf` and save it.

Connectivity

This section describes and helps you troubleshoot connectivity requirements.

Fully Qualified Domain Names (FQDNs)

When you install a MapR cluster and you specify the host names using the MapR installer or the `configure.sh` script, use fully qualified domain names (FQDNs). **Do not use an alias or IP address to specify the host names.** Using an IP address can prevent services such as the timeline service from verifying security certificates. In addition, monitoring services can fail after installation because of connection requests that are rejected. These issues can be difficult to troubleshoot and can be prevented by using FQDNs.

It is important to use FQDNs when configuring a secure cluster. However, the practice also applies to non-secure clusters that might later be upgraded to be secure. The same connectivity issues can be encountered when a non-secure cluster is upgraded to a secure cluster. If your cluster is non-secure and will not be secured, or if you are not concerned about connection issues for the monitoring services, you may use IP addresses to specify the host names.

Unique Hostnames

Each node in the cluster must be accessible via DNS. More specifically, each node in the cluster must have a unique hostname, resolvable forward and backward with every other node with both normal and reverse DNS name lookup.

Run `hostname -f` to check the node's hostname. For example:

```
$ hostname -f
node125.corp.example.com
```

If `hostname -f` returns a name, run `getent hosts 'hostname'` to return the node's IP address and fully-qualified domain name (FQDN).

```
$ getent hosts 'hostname'
10.250.1.53     node125.corp.example.com
```

To troubleshoot hostname problems, edit the `/etc/hosts` file as `root`. A simple `/etc/hosts` might contain:

```
127.0.0.1     localhost
10.10.5.10    mapr-hadoopn.maprtech.prv mapr-hadoopn
```

last-updated: Apr 11, 2022

A common problem is an incorrect loopback entry (127.0.x.x) that prevents the IP address from being assigned to the hostname. For example, on Ubuntu, the default `/etc/hosts` file might contain:

```
127.0.0.1     localhost
127.0.1.1     node125.corp.example.com
```

A loopback (`127.0.x.x`) entry with the node's hostname will confuse the installer and other programs. Edit the `/etc/hosts` file and delete any entries that associate the hostname with a loopback IP. Only associate the hostname with the actual IP address.

Note: For more information about Ubuntu's default `/etc/hosts` file, see https://bugs.launchpad.net/ubuntu/+source/cloud-init/+bug/871966.

Use the `ping` command to verify that each node can reach the others using each node's hostname. For more information, see the hosts(5) man page.

Common Users

A user that accesses the cluster must have the same credentials and user ID (uid) on each node in the cluster. Every person or department that runs MapR jobs must have an account and must also belong to a common group ID (gid). The uid for each user, and the gid for each group, must be consistent across all nodes.

A `mapr` user must exist, and have the same UID across all the cluster nodes. The `mapr` user has full privileges to administer the cluster. If you create the `mapr` user before you install MapR , you can test for connectivity issues. If you do not create the `mapr` user, installing MapR automatically creates the user for you. The `mapr` user ID is automatically created on each node if you do not use a directory service, such as LDAP.

To create a group, add a user to the group, or create the `mapr` user, run the following command as root substituting a uid for *m* and a gid for *n*. (The error "cannot lock /etc/passwd" suggests that the command was not run as root.)

```
$ useradd mapr --gid n --uid m
```

Example: `$ groupadd -g 5000 mapr` `$ useradd -g 5000 -u 5000 mapr`

To verify that the users or groups were created, run `su mapr`. Verify that a home directory was created (usually `/home/mapr`) and that the users or groups have read-write access to it. The users or groups must have write access to the `/tmp` directory, or Warden will fail to start services.

Optional: Passwordless ssh

Setting up passwordless ssh is straightforward. On each webserver node, generate a key pair and append the key to an authorization file. Then copy this authorization file to each node, so that every node is available from the webserver node.

`su mapr` (if you are not already logged in as mapr) `ssh-keygen -t rsa -P '' -f ~/` *`filename`*

The `ssh-keygen` command creates *`filename`* , containing the private key, and *`filename`* `.pub`, containing the public key. For convenience, you may want to name the file for the hostname of the node. For example, on the node with hostname "node10.10.1.1,"

```
ssh-keygen -t rsa -P '' -f ~/node10.10.1.1
```

In this example, append the file `/home/mapr/node10.10.1.1.pub` to the `authorized_keys` file.

Append each webserver node's public key to a single file, using a command such as `cat` *`filename`* `.pub >> authorized_keys`. (The key file is simple text, so you can append the file in several ways, including a text editor.) When every webserver node's empty passphrase public key has been generated, and the

public key file has been appended to the primary "authorized_keys" file, copy this primary keys file to each node as `~/.ssh/authorized_keys`, where ~ refers to the mapr user's home directory (typically `/home/mapr`).

Recommended: Setting the MAPR_SUBNETS Variable
For enhanced performance and reliability, always set the MAPR_SUBNETS enivronment variable.

Java
To run MapR software and Hadoop, you must install a supported Java Development Kit (JDK) on your node.

Java

MapR Data Platform requires the Java Development Kit (JDK). Installing only the Java runtime environment (JRE) is not sufficient. Verify that one of the following JDK versions is installed on the node:

Java Requirements for MapR Core	• Sun Java JDK 1.8 • OpenJDK 1.8 **Note:** Make sure you have the development kit installed. Some JRE packages include jdk in the name, but do not provide the required JDK software.
Special Requirements for Using OpenJDK	If you use OpenJDK: • RedHat/CentOS must have `java-<version>-openjdk-devel` installed. • SLES nodes must have `java-<version>-openjdk-devel` installed. • Ubuntu nodes must have `openjdk-<version>-jdk` installed.

Note: The `openjdk-devel` and `openjdk-<version>-jdk` packages include the `jps` command that lists running Java processes and can show whether the CLDB has started. This command is not supported in the Sun Java JRE.

To install the Oracle/Sun Java JDK:	Obtain the Oracle/Sun Java Development Kit (JDK), available at Oracle's Java SE website. Find Java SE 8 in the archive of previous versions.

To install or update OpenJDK	Use a package manager, such as **yum** (RedHat, Oracle Linux, or CentOS), **apt-get** (Ubuntu) or **zypper** (SLES).
	• On RedHat, Oracle Linux, or CentOS:
	`# yum install java-1.8.0-openjdk-devel`
	• On Ubuntu:
	`# apt-get install openjdk-8-jdk`

last-updated: Apr 11, 2022

- SLES

```
# zypper install
java-1_8_0-openjdk-devel
```

JDK Support Matrix on page 5596
This matrix shows the Java Development Kit versions supported by different MapR Data Platform releases.

Infrastructure
Identifies certain software and settings that contribute to your node's infrastructure.

Network Time

To keep all cluster nodes time-synchronized, MapR requires software such as a Network Time Protocol (NTP) server (or chrony for RHEL 7) to be configured and running on every node. If server clocks in the cluster drift out of sync, serious problems will occur with certain MapR services. MapR raises a Time Skew alarm on any out-of-sync nodes. For more information about obtaining and installing NTP, see http://www.ntp.org/.

Advanced: It is recommended to install an internal time server with which the cluster nodes can sync directly. If internet connectivity is lost, the time on the cluster nodes stays in sync. For more details, refer to the preceding documentation link for NTP

System Locale

Ensure that your system locale is set to `en_us`. For more information about setting the system locale, see this website.

Syslog

`Syslog` should be enabled on each node to preserve logs for killed processes or failed jobs. Modern versions such as `syslog-ng` and `rsyslog` are possible, making it more difficult to be sure that a `syslog` daemon is present. One of the following commands should suffice:

```
syslogd -v
service syslog status

rsyslogd -v
service rsyslog status
```

Default umask

To prevent significant installation problems, ensure that the default umask for the root user is set to 0022 on all MapR nodes in the cluster. You can change the umask setting in the `/etc/profile` file, or in the `.cshrc` or `.login` file. The `root` user must have a 0022 umask because the MapR `admin` user requires access to all files and directories under the `/opt/mapr` directory, even those initially created by root services.

ulimit

`ulimit` is a command that sets limits on a user's access to system-wide resources. Specifically, it provides control over the resources available to the shell and to processes started by it.

The `mapr-warden` script uses the `ulimit` command to set the maximum number of file descriptors (`nofile`) and processes (`nproc`) to 64000. Higher values are unlikely to result in an appreciable performance gain. Lower values, such as the default value of 1024, are likely to result in task failures.

last-updated: Apr 11, 2022

Warning: The MapR recommended value is set automatically every time Warden is started.

Depending on your environment, you might want to set limits manually for service accounts used to run I/O-heavy operations rather than relying on Warden to set them automatically using `ulimit`.

PAM

Nodes that run the **Control System** can take advantage of Pluggable Authentication Modules (PAM) if found. Configuration files in the `/etc/pam.d/` directory are typically provided for each standard Linux command. MapR can use, but does not require, its own profile.

Security - SELinux, AppArmor

See SELinux Support on page 139.

TCP Retries

On each node, set TCP retries for `net.ipv4.tcp_retries2` to 5 so that MapR can detect unreachable nodes with less latency.

Note: The installation automatically sets TCP retries for `net.ipv4.tcp_syn_retries` to 4 on each node.

1. Edit the file `/etc/sysctl.conf` and add the following line:

   ```
   net.ipv4.tcp_retries2=5
   ```

2. Save the file and run:

   ```
   sysctl -p
   ```

NFS

Disable the stock Linux NFS server on nodes that will run the MapR NFS server.

iptables/firewalld

Enabling `iptables` on a node can close ports that are used by MapR. If you enable `iptables`, make sure that required ports remain open. Check your current `iptables` rules by using the following command:

```
$ service iptables status
```

In CentOS 7, `firewalld` replaces `iptables`. To check your current `iptables` rules, use this command:

```
systemctl status firewalld
```

To ensure that the required ports are available, disable `firewalld` by using this command:

```
systemctl disable firewalld
```

Transparent Huge Pages (THP)

For data-intensive workloads, MapR recommends disabling the Transparent Huge Pages (THP) feature in the Linux kernel.

RHEL Example

```
$ echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

last-updated: Apr 11, 2022

CentOS 7 Example

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

Ubuntu Example

```
$ echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

Automated Configuration

Some users find tools such as `Ansible`, `Puppet`, or `Chef` useful to configure each node in a cluster. Make sure, however, that any configuration tool does not reset changes made when MapR packages are later installed. Specifically, do not let automated configuration tools overwrite changes to the following files:

- `/etc/sudoers`
- `/etc/sysctl.conf`
- `/etc/sysctl.d/60-mapr_elasticsearch.conf`
- `/etc/sysctl.d/60-mapr_fluentd.conf` on page 1395
- `/etc/security/limits.conf`
- `/etc/udev/rules.d/99-mapr-disk.rules`

Setting Resource Limits on CentOS/RedHat/Oracle Linux
While you can use Warden to automatically set resource limits, you may want to set limits manually.

Rather than relying on Warden to set resource file-access limits automatically using `ulimit`, you can use the following procedure to set the limits manually.

1. Edit `/etc/security/limits.conf` and add a line to set the resource limits. For example, set the resource limits to 65536.

   ```
   <MAPR_USER> - nofile 65536
   ```

2. Edit `/etc/security/limits.d/90-nproc.conf` to add a similar line.

   ```
   <MAPR_USER> - nproc 64000
   ```

3. Check that the `/etc/pam.d/su` file contains the following settings:

   ```
   #%PAM-1.0
   auth            sufficient      pam_rootok.so
   # Uncomment the following line to implicitly trust users in the "wheel"
   group.
   #auth           sufficient      pam_wheel.so trust use_uid
   # Uncomment the following line to require a user to be in the "wheel"
   group.
   #auth           required        pam_wheel.so use_uid
   auth            include         system-auth
   account         sufficient      pam_succeed_if.so uid = 0 use_uid quiet
   account         include         system-auth
   password        include         system-auth
   session         include         system-auth
   session         required        pam_limits.so
   session         optional        pam_xauth.so
   ```

last-updated: Apr 11, 2022

4. Use `ulimit` to verify settings.
5. Reboot the system.
6. Run the following command as the `mapr` user (not root) at a command line: `ulimit -n`

Setting Resource Limits on Ubuntu

While you can use Warden to automatically set resource limits, you may want to set limits manually.

Rather than relying on Warden to set resource limits automatically using `ulimit`, you can use the following procedure to set the limits manually.

1. Edit `/etc/security/limits.conf` and add a line to set the resource limits. For example, set the resource limits:

```
<MAPR_USER> - nofile 65536
<MAPR_USER> - nproc 64000
```

2. Edit `/etc/pam.d/su` and uncomment the following line.

```
session required pam_limits.so
```

3. Edit the `/etc/pam.d/common-session*` files to make sure the following entry is present:

```
# end of pam-auth-update config
session       required       pam_limits.so
```

4. Use `ulimit` to verify settings.
5. Reboot the system.
6. Run the following command as the `mapr` user (not root) at a command line: `ulimit -n`

Setting Resource Limits on SLES

While you can use Warden to automatically set resource limits, you may want to set limits manually.

Rather than relying on Warden to set resource limits automatically using `ulimit`, you can use the following procedure to set the limits manually.

1. Edit the `/etc/pam.d/common-session*` files to make sure the following entry is present:

```
# end of pam-auth-update config
session       required       pam_limits.so
```

2. Use `ulimit` to verify settings.
3. Reboot the system.
4. Run the following command as the `mapr` user (not root) at a command line: `ulimit -n`

SELinux Support

MapR Data Platform supports SELinux for cluster administrators who observe specific installation and administrative procedures.

Before using the MapR Data Platform with SELinux, note the following considerations and best practices:

last-updated: Apr 11, 2022

- **Installation:** Hewlett Packard Enterprise recommends disabling SELinux before installing data-fabric software. If you install the cluster by using the Installer, the Installer disables SELinux automatically. If you require the extra security provided by SELinux, you can enable SELinux and place it in enforcing mode after installation. Also, rules can be defined by observing regular operations while the cluster is running.
- **Known Issues:** For a list of known issues that you should be aware of when using SELinux with the MapR Data Platform, see Known issues: Running HPE Ezmeral Data Fabric on nodes with SELinux in enforcing mode.
- **Warnings in the Audit Log:** While using the HPE Ezmeral Data Fabric, if you see warnings in the SELinux audit log (`/var/log/audit/`) related to data-fabric services, the cluster admin can fix them by using `chcon` or similar tools.
- **Cluster-Admin Use of systemctl:** The data-fabric cluster admin (typically the `mapr` user) must be allowed to use `systemctl`. Without access to `systemctl`, Warden can fail to start cluster services.
- **System Administration:** SELinux introduces significant complexity and should be managed by an experienced system administrator. Managing SELinux is outside the scope of data-fabric cluster-administration activities.
- **Utilities and Services That Must Not Be Blocked** The following inexhaustive list of utilities and services must remain unblocked at all times for the MapR Data Platform to run successfully in an SELinux environment:
  - `bash`
  - `dmidecode`
  - `glibc`
  - `hdparm`
  - `initscripts`
  - `iputils`
  - `irqbalance`
  - `libgcc`
  - `libstdc++`
  - `lsof`
  - `net-tools`
  - `nfs-utils`
  - `nss`
  - `perl`
  - `python`
  - `redhat-lsb-core`
  - `rpcbind`

- `shadow-utils`
- `syslinux`
- `userspace-rcu`

Installing with the MapR Installer

The MapR Installer automates the process of installing MapR software and offers you a variety of options to complete the installation.

Use this option . . .	When	See for more information
MapR Installer web interface	You need a wizard-like tool to install MapR software, and you want visual feedback about the installation process.	MapR Installer on page 5395
MapR Installer Stanzas	You need a script-based tool to install MapR software, and you do not want to click through the menus and options provided by the web-based MapR Installer.	MapR Installer Stanzas on page 5503
MapR Installer Containers	You want to use either the web-based MapR Installer or Stanzas from a Docker container.	MapR Installer Containers on page 5497
MapR Installer in the Cloud	You want to deploy or modify a MapR cluster in Amazon AWS or Microsoft Azure.	Installing MapR in the Cloud on page 249

Note: If you do not want to use one of the MapR Installer options, you still have the option to install the software manually. See Installing without the MapR Installer on page 141.

Installing without the MapR Installer

Describes how to install MapR software and ecosystem components manually.

These steps describe how to install a secure MapR cluster. If your cluster does not need to be secure, you can still use this procedure and skip over the steps indicated for security.

After you have planned the cluster and prepared each node, you can install the MapR distribution from the MapR repository or package files. Installing the software requires that you perform certain steps on each node. You can install data-fabric ecosystem components, such as Hive, after you bring up the cluster.

Warning: Before you install, make sure that all nodes meet the requirements for installation. See Preparing Each Node on page 129 for more information. Failure to prepare nodes is the primary cause of installation problems. **You must also make sure that the package dependencies are installed. See MapR Installer Prerequisites and Guidelines on page 5396. These packages are downloaded for you when you use the MapR Installer, but must be installed manually before you install without using the MapR Installer.**

You must also have the following information from your cluster plan when you install:

- A list of the hostnames and IP addresses for all nodes and the services that you want to run on each node.
- A list of all disks and/or partitions to use on each node.

Note: For information about repositories and packages for MapR software and Hadoop Ecosystem tools, see MapR Repositories and Packages on page 128.

To successfully install MapR software, complete each step described in subsequent sections. To learn how HPE uses, shares, transfers, and manages personal information, see the HPE Privacy Statement.

last-updated: Apr 11, 2022

Step 1: Install the Package Key
Before you install MapR packages, you must install the package key.

MapR packages are cryptographically signed. Before you can install the packages, you must install the package key: `maprgpg.key`. For SLES only, you do not have to install the key because `zypper` allows package installation with or without the key.

- To install the package key, issue the command appropriate for your Linux distribution:
  - CentOS/RedHat/Oracle Linux

    ```
    rpm --import https://package.mapr.hpe.com/releases/pub/maprgpg.key
    ```

  - Ubuntu

    ```
    wget -O - https://package.mapr.hpe.com/releases/pub/maprgpg.key | sudo
    apt-key add -
    ```

Step 2: Prepare Packages and Repositories
To install services correctly, each node must have access to the package files.

The MapR software distribution is separated into two repositories that contain the package files:

- **MapR packages.** These provide core functionality for MapR clusters, such as the MapR filesystem.
- **Ecosystem packages.** These packages are not specific to MapR. Examples include the packages for Hive and Spark.

Some MapR services have internal dependencies that require additional packages. For example, when you install the CLDB service on a node, the node must also have `mapr-core` and `mapr-fileserver` installed. You can install dependencies on each node before beginning the MapR installation process, or you can configure repositories and allow the package manager on each node to resolve the dependencies. For a list of package dependencies, see Packages and Dependencies for MapR Software.

You can make packages available to each node, as described in subsequent sections, using the MapR Internet repository, a local repository, or a local path with rpm or deb package files. For information about packages and repositories for MapR software and Hadoop Ecosystem tools, see MapR Repositories and Packages on page 128.

Using the MapR Internet Repository
This section describes how to make packages available through the MapR Internet repository.

The MapR repository on the Internet provides all of the packages required to install a MapR cluster using native tools such as:

- `yum` on RedHat, Oracle Linux, or CentOS
- `zypper` on SLES
- `apt-get` on Ubuntu

Installing from the Internet repository is generally the easiest installation method, but requires the greatest amount of bandwidth. With this method, each node is connected to the Internet to download the required packages.

Set up repositories by completing the steps for your RedHat/Oracle Linux/CentOS, SLES, or Ubuntu distribution.

Adding the MapR Repository on RHEL, CentOS, or Oracle Linux
This section describes how to install the MapR Internet repository.

1. Change to the `root` user or use `sudo`.
2. Create a text file called `maprtech.repo` in the `/etc/yum.repos.d/` directory with the following content, replacing `<version>` with the version of MapR that you want to install: (For the correct paths for all past releases, see the MapR Repositories and Packages on page 128.)

```
[maprtech]
name=Your Company Name
baseurl=https://package.mapr.com/releases/v<version>/redhat/
enabled=1
gpgcheck=1
protect=1

[maprecosystem]
name=Your Company Name
baseurl=https://package.mapr.com/releases/MEP/MEP-<version>/redhat
enabled=1
gpgcheck=1
protect=1
```

3. If your connection to the Internet is through a proxy server, you must set the `http_proxy` environment variable before installation: You should also set the value for the `http_proxy` environment variable by adding the following section to the `/etc/yum.conf` file:

```
http_proxy=http://<host>:<port>
export http_proxy
```

```
proxy=http://<host>:<port>
proxy_username=<username>
proxy_password=<password>
```

4. If you are installing release 6.1.0 on RHEL or CentOS 8.x, enable the EPEL repository as described in Enable the EPEL Repository on CentOS 8.x, RHEL 8.x, or Oracle Linux 8.x on page 144. Starting in RHEL 8.x, a `mapr-core-internal` package dependency (`sdparm`) is deprecated and moved to EPEL, and installation cannot complete without enabling it.

Enable the EPEL Repository on CentOS 6.x, RHEL 6.x, or Oracle Linux 6.4 or higher
This section describes how to download and install the EPEL repository.

1. Download the EPEL repository:

```
wget https://archives.fedoraproject.org/pub/archive/epel/6/x86_64/
epel-release-6-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-6*.rpm
```

Enable the EPEL Repository on CentOS 7.x, RHEL 7.x, or Oracle Linux 7.0/7.1

This section describes how to download and install the EPEL repository.

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-7.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-latest-7*.rpm
```

Enable the EPEL Repository on CentOS 8.x, RHEL 8.x, or Oracle Linux 8.x

This section describes how to download and install the EPEL repository.

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-latest-8*.rpm
```

Adding the MapR Repository on SUSE

This section describes how to install the MapR Internet repository.

To verify that a SUSE release is supported by the MapR Data Platform, see Operating System Support Matrix on page 5522.

1. Change to the `root` user or use `sudo`.
2. Use the following command to add the repository for MapR packages, replacing `<version>` with the version of MapR that you want to install:

```
zypper ar https://package.mapr.hpe.com/releases/v6.x.x/suse/ maprtech
```

3. Use the following command to add the repository for ecosystem packages: (For the correct paths for all past releases, see the MapR Repositories and Packages on page 128.)

```
zypper ar https://package.mapr.hpe.com/releases/MEP/MEP-<version>/suse/
maprecosystem
```

4. If your connection to the Internet is through a proxy server, you must set the `http_proxy` environment variable before installation:

```
http_proxy=http://<host>:<port>
             export http_proxy
```

5. Update the system package index by running the following command:

```
zypper refresh
```

6. MapR packages require a compatibility package in order to install and run on SUSE. Execute the following command to install the SUSE compatibility package:

```
zypper install mapr-compat-suse
```

Installing sshpass

Before installing a cluster on a SUSE image, you must run the following command to install sshpass:

```
zypper --non-interactive -q --no-gpg-checks -p http://download.opensuse.org/
distribution/leap/42.3/repo/oss/ install sshpass
```

Adding the MapR Repository on Ubuntu
This section describes how to install the MapR Internet repository.

1. Change to the `root` user or use `sudo`.
2. Add the following lines to `/etc/apt/sources.list`, replacing `<version>` with the version of MapR that you want to install. See the MapR Repositories and Packages on page 128 for the correct paths for all past releases.

   Release 5.2.1 through 6.2.0

```
deb https://package.mapr.hpe.com/releases/v<version>/ubuntu/ binary
trusty
deb https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu/
binary trusty
```

3. Update the package indexes:

```
apt-get update
```

4. If your connection to the Internet is through a proxy server, add the following lines to `/etc/apt/apt.conf`:

```
Acquire
{
  Retries "0";
  HTTP
  {
     Proxy "http://<user>:<password>@<host>:<port>";
  };
};
```

Using a Local Repository
This section describes how to make packages available through a local repository.

You can set up a local repository on each node to provide access to installation packages. With this method, nodes do not require internet connectivity. The package manager on each node installs from packages in the local repository. To set up a local repository, nodes need access to a running web server to download the packages.

Subsequent sections describe how to create a single repository that includes both MapR components and the Hadoop ecosystem components.

Creating a Local Repository on RHEL, CentOS, or Oracle Linux
This section describes how to create and use a local repository.

1. Log in as `root` on the node or use `sudo`.

2. Create the following directory if it does not exist: `/var/www/html/yum/base`
3. On a computer that is connected to the internet, download the following files, substituting the appropriate `<version>` number and `<datestamp>`: (See MapR Repositories and Packages on page 128 for the correct paths for all past releases.)

```
https://package.mapr.hpe.com/releases/v6.x.x/redhat/
mapr-<version>GA.rpm.tgz
https://package.mapr.hpe.com/releases/MEP/MEP-<version>/redhat/
mapr-mep-<version>-<datestamp>.rpm.tgz
```

4. Copy the files to `/var/www/html/yum/base` on the node, and extract them there.

```
tar -xvzf mapr-v<version>GA.rpm.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.rpm.tgz
```

5. Create the base repository headers: When finished, verify the content of the new `/var/www/html/yum/base/repodata` directory: `filelists.xml.gz, other.xml.gz, primary.xml.gz, repomd.xml`

```
createrepo /var/www/html/yum/base
```

Add the repository on each node

Each node must contain your local repository.

- Create a text file called `maprtech.repo` in the `/etc/yum.repos.d` directory with the following content:

```
[maprtech]
name=MapR Technologies, Inc.
baseurl=http://<host>/yum/base
enabled=1
gpgcheck=0
```

Warning: The EPEL (Extra Packages for Enterprise Linux) repository contains dependencies for the `mapr-metrics` package on RedHat/CentOS/Oracle Linux. If your RedHat/CentOS/Oracle Linux cluster does not use the `mapr-metrics` service, you can skip EPEL configuration.

Enable the EPEL repository on CentOS 6.x, RHEL 6.x, or Oracle Linux 6.4 or higher

This section describes how to download and install the EPEL repository.

1. On a computer that is connected to the internet, download the EPEL repository:

```
wget https://archives.fedoraproject.org/pub/archive/epel/6/x86_64/
epel-release-6-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-6*.rpm
```

Enable the EPEL repository on CentOS 7.x, RHEL 7.x, or Oracle Linux 7.0/7.1

This section describes how to download and install the EPEL repository.

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-7.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-7*.rpm
```

Enable the EPEL repository on CentOS 8.x, RHEL 8.x, or Oracle Linux 8.x

This section describes how to download and install the EPEL repository.

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-8*.rpm
```

Creating a Local Repository on SUSE

This section describes how to create and use a local repository.

1. Login as `root` on the node or use `sudo`.
2. Create the following directory if it does not exist: `/var/www/html/zypper/base`
3. On a computer that is connected to the Internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`: (See MapR Repositories and Packages on page 128 for the correct paths for all past releases.)

```
https://package.mapr.hpe.com/releases/v<version>/suse/
mapr-<version>GA.rpm.tgz
https://package.mapr.hpe.com/releases/MEP/MEP-<version>/suse/
mapr-mep-<version>-<datestamp>.rpm.tgz
```

4. Copy the files to `/var/www/html/zypper/base` on the node, and extract them there.

```
tar -xvzf mapr-<version>GA.rpm.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.rpm.tgz
```

5. Create the base repository headers: When finished, verify the content of the new `/var/www/html/zypper/base/repodata` directory: `filelists.xml.gz, other.xml.gz, primary.xml.gz, repomd.xml`

```
createrepo /var/www/html/zypper/base
```

Add the repository on each node

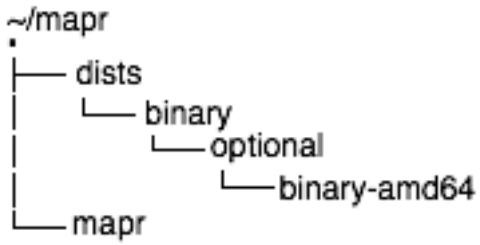
Each node must contain your local repository.

- Issue the following command to add the repository for MapR packages and the MapR ecosystem packages, substituting the appropriate `<host>`:

```
zypper ar http://<host>/zypper/base/ maprtech
```

Creating a Local Repository on Ubuntu
This section describes how to create and use a local repository.

1. Login as `root` on the machine where you will set up the repository.
2. Change to the directory `/root`, and create the following directories within it:



3. On a computer that is connected to the Internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`: (See Data Fabric Repositories and Package Archives for the correct paths for all past releases.)

```
https://package.mapr.hpe.com/releases/v7.x.x/ubuntu/
mapr-<version>GA.deb.tgz
https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu/
mapr-mep-<version>-<datestamp>.deb.tgz
```

4. Copy the files to `/root/mapr/mapr` on the node, and extract them there:

```
tar -xvzf mapr-<version>GA.deb.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.deb.tgz
```

5. Navigate to the `/root/mapr/` directory.
6. Use `dpkg-scanpackages` to create `Packages.gz` in the `binary-amd64` directory:

```
dpkg-scanpackages . /dev/null | gzip -9c > ./dists/binary/optional/
binary-amd64/Packages.gz
```

7. Move the entire `/root/mapr/mapr` directory to the default directory served by the HTTP server (for example, `/var/www`), and make sure the HTTP server is running.

Add the repository on each node
Each node must contain your local repository.

1. On each node, use *one* of the following methods to add the repository:
   - If you have installed the `software-properties-common` package, use the `add-apt-repository` utility to add the repository:

     Release 7.0.0 and later

EEP	`add-apt-repository 'deb https://package.mapr.hpe.com/releases/MEP/ MEP-<version>/ubuntu binary bionic'`

Core	`add-apt-repository 'deb https://package.mapr.hpe.com/releases/v<version>/ ubuntu binary bionic'`

Releases 5.2.1 through 6.2.0

EEP	`add-apt-repository 'deb https://package.mapr.hpe.com/releases/MEP/ MEP-<version>/ubuntu binary trusty'`
Core	`add-apt-repository 'deb https://package.mapr.hpe.com/releases/v<version>/ ubuntu binary trusty'`

- If the `software-properties-common` package is not installed, create a file in `/etc/apt/sources.list.d` whose content is a single line as follows:

  Release 7.0.0 and later

EEP	`deb https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu binary bionic`
Core	`deb https://package.mapr.hpe.com/releases/v<version>/ubuntu binary bionic`

  Releases 5.2.1 through 6.2.0

EEP	`deb https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu binary trusty`
Core	`deb https://package.mapr.hpe.com/releases/v<version>/ubuntu binary trusty`

  Note: File names must end with `.list` and may only contain letters (a-z and A-Z), digits (0-9), underscore (_), hyphen (-), and period (.) characters.

2. On each node, update the package indexes (as `root` or with `sudo`). After performing these steps, you can use `apt-get` to install MapR software and Hadoop ecosystem components on each node from the local repository:

```
apt-get update
```

Using a Local Path with rpm or deb Package Files

This section describes how to make packages available through a local path.

You can download package files, store them locally, and then install MapR from the files. This option is useful for clusters that are not connected to the Internet.

Warning: In order for the installation to succeed, this method requires that you pre-install the MapR package dependencies on each node.

For a list of the dependency packages required for the MapR services that you are installing, see Packages and Dependencies for MapR Software on page 68. Manually download the packages and install them.

To install MapR from downloaded package files, complete the following steps:

1. Using a machine connected to the internet, download the tarball for the core components and the ecosystem components, substituting the appropriate `<platform>`, `<version>`, and `<datestamp>`:
   - `https://package.mapr.hpe.com/releases/v6.x.x/<platform>/mapr-v<version>GA.rpm.tgz` (or `.deb.tgz`)

last-updated: Apr 11, 2022

- `https://package.mapr.hpe.com/releases/MEP/MEP-<version>/<platform>/mapr-mep-<version>-<datestamp>.rpm.tgz` (or `.deb.tgz`)

  For the correct paths for all past releases, see MapR Repositories and Packages on page 128.

2. Extract the tarball to a local directory, either on each node or on a local network accessible by all nodes:

```
tar -xvzf mapr-<version>GA.rpm.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.rpm.tgz
```

Step 3: Install Cluster Service Packages
The installation process varies based on the location of your packages and the configuration of your cluster.

Install services based on your cluster plan and service layout.

Before Installing Packages

Note these considerations:

- **Review security vulnerabilities:** Make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6569. If a vulnerability applies to your release, contact your support representative for a fix. Apply the fix immediately, if applicable.
- **Collectd Known Issue (MFS-10783):** After a manual installation of release 6.1.0 or 6.1.1 on RHEL or CentOS 8.x, Collectd can fail to start because of a known issue. Error messages indicate that `libcrypto.so.10` cannot open a shared object file. If you are installing release 6.1.0 or 6.1.1 on RHEL or CentOS 8.x, install the `compat-openssl10` package on all cluster nodes before installing the `mapr-*` packages:

```
yum install compat-openssl10
```

List of Packages by Node

The following table lists the core packages to install on cluster nodes:

On These Nodes	Install These Packages
On all [compute] cluster nodes	`mapr-fileserver`

On designated cluster nodes	`mapr-cldb`
	`mapr-zookeeper`
	`mapr-mastgateway`
	`mapr-nfs` or `mapr-loopbacknfs`[1]
	`mapr-webserver`[2]
	`mapr-apiserver`[2]
	`mapr-gateway`
	`mapr-resourcemanager`
	`mapr-nodemanager`
	`mapr-historyserver`
	`mapr-timelineserver`

On client machines that run Hadoop commands that are not already part of the cluster	`mapr-client`

[1]See NFS Considerations on page 151.

[2]For special considerations related to the installation of the `mapr-webserver` and `mapr-apiserver` packages, see API Server and Web Server Packages for EEP 8.1.0 on page 6507.

Warning: This table is a rough guide and does not include the additional non-MapR packages required for internal Packages and Dependencies for MapR Software or Hadoop ecosystem components.

Install the packages based on a thorough plan. For example cluster designs, see Example Cluster Designs on page 118.

To install MapR, select one of the installation methods in the subsequent topics, depending on your operating system.

NFS Considerations

When you install `mapr-nfs`, NFSv3 is installed. To install NFSv4, you must use the `mapr-nfs4server` package. NFS is not secure by default. If you wish to configure NFSv4 server to work with Kerberos servers, you must first install Active Directory and Kerberos servers. For more information, see Installing MapR NFS on page 386 and Configuring NFSv4 Server for Kerberos on page 1209.

Consider installing `mapr-loopbacknfs` if you need a secure POSIX client. Note that the Installer installs `mapr-loopbacknfs` on all nodes in the cluster when **Enable NFS** is not specified. For more information about `mapr-loopbacknfs`, see MapR POSIX Clients on page 399.

Installing from a Repository

Before installing from the repository, change to the `root` user or use `sudo`.

- On RedHat, CentOS, or Oracle Linux, use the `yum` command to install the services that you want to run on the node.

  Syntax and Example

  ```
  yum install <package_name> <package_name> <package_name>
  ```

  ```
  yum install mapr-fileserver mapr-webserver
  ```

- On SLES, use the `zypper` command to install the services that you want to run on the node.

  Syntax and Example

  ```
  zypper install <package_name> <package_name> <package_name>
  ```

  ```
  zypper install mapr-fileserver mapr-webserver
  ```

- On Ubuntu, use the `apt-get` commands to update the Ubuntu package cache and install the services that you want to run on the node.

  1. Update the Ubuntu package cache:

     ```
     apt-get update
     ```

2. Install the services:

   Syntax and Example

```
apt-get install <package_name> <package_name> <package_name>
```

```
apt-get install mapr-fileserver mapr-webserver
```

Installing from a Local Repository

Before installing from the repository, change to the `root` user or use `sudo`.

- On RedHat, CentOS, Oracle Linux, or SLES, use `rpm` command to install the appropriate packages for the node:

  1. Change the working directory to the location where the `rpm` package files are located.
  2. Install the services:

     Syntax and Example

```
yum install <package_file> <package_file> <package_file>
```

```
yum install /path/to/mapr-core-<version>.x86_64.rpm
mapr-cldb-<version>.x86_64.rpm \
             mapr-resourcemanager-<version>.x86_64.rpm
mapr-webserver-<version>.x86_64.rpm \
```

     Note: Replace `<version>` with the exact version string found in the package filename.

- On Ubuntu, use the `dpkg` command to install the appropriate packages for the node.

  1. Change the working directory to the location where the `deb` package files are located.
  2. Install the services:

     Syntax and Example

```
dpkg -i <package_file> <package_file> <package_file>
```

```
dpkg -i mapr-core-<version>.x86_64.rpm mapr-cldb-<version>.x86_64.rpm \
             mapr-resourcemanager-<version>.x86_64.rpm
mapr-webserver-<version>.x86_64.rpm \
```

     Note: Replace `<version>` with the exact version string found in the package filename.

Installing from Package Files

When you install from package files, you must manually pre-install any dependency packages in order for the installation to succeed. Most MapR packages depend on the package `mapr-core`. Similarly, many Hadoop ecosystem components have internal dependencies. See Packages and Dependencies for MapR Software for details.

Step 4: Verify Installation Success
To confirm success, check each node.

To verify that the software was installed successfully, check the `/opt/mapr/roles` directory on each node. The software is installed in the `/opt/mapr` directory and a file is created in `/opt/mapr/roles` for every service that installs successfully. The following example shows the `/roles` directory with services that installed successfully:

Example

```
# ls -l /opt/mapr/roles
total 0
-rw-r--r-- 1 root root 0 Jul 11 07:29 cldb
-rw-r--r-- 1 root root 0 Jul 11 07:29 fileserver
-rw-r--r-- 1 root root 0 Jul 11 07:01 nodemanager
-rw-r--r-- 1 root root 0 Jul 11 07:01 resourcemanager
-rw-r--r-- 1 root root 0 Jul 11 07:29 apiserver
-rw-r--r-- 1 root root 0 Jul 11 07:29 zookeeper
```

Step 5: Set Environment Variables
Before starting ZooKeeper or Warden, you must complete this step.

Set Environment Variables on page 2289 for the cluster. The `/opt/mapr/conf/env.sh` script looks for the directory where Java is installed and sets `JAVA_HOME` automatically. However, if you need to specify a different location for `JAVA_HOME`, edit `/opt/mapr/conf/env_override.sh`. This variable *must* be set before starting ZooKeeper or Warden. For more information, see About env_override.sh on page 2290.

Step 6: Configure Nodes
Connect nodes to the cluster, configure security, and arrange node storage.

You run the `configure.sh` script on a node to enable the node to communicate with the cluster. You must configure each node that is part of the cluster and each node that connects to the cluster as a client.

Perform the following operations to configure a node:

Operation	Description
Prepare to run configure.sh	This topic describes some information you will need to gather before running the `configure.sh` script.
Enabling Security on page 154	These steps configure your cluster for security, enabling security for authentication, authorization, and data. Data-at-rest (DARE) encryption can also be enabled during this task. If you do not want your cluster to be secure, do not perform the steps in this procedure. Go to Configuring Nodes without Security on page 157.
Configure nodes without security	These steps configure each node to be a part of the cluster but do not configure security. If you want your cluster to be secure, do not perform this procedure. Go to Enabling Security on page 154.
Configure storage	To configure storage on a node, you can manually run `disksetup`. You need to perform this step for nodes in the cluster that are installed with the `mapr-fileserver`. The steps you use to configure storage vary depending on whether or not DARE is enabled or disabled.

Preparing to Run configure.sh
Before you run `configure.sh`, collect the information that you need to run the script based on your requirements.

The `configure.sh` script can configure a node for the first time or update existing node configurations. Therefore, it has many configuration options that you can use.

- Note the hostnames of the CLDB and ZooKeeper nodes. Optionally, you can specify the ports for the CLDB and ZooKeeper nodes as well. The default CLDB port is 7222. The default ZooKeeper port is 5181.

last-updated: Apr 11, 2022

- If a node in the cluster runs the HistoryServer, note the hostname for the HistoryServer. The HistoryServer node must be specified by using the `-HS` parameter.
- If one or more nodes in the cluster runs the ResourceManager, note the hostname or IP address for each ResourceManager node. Based on the version you install and your ResourceManager high availability requirements, you may need to specify the ResourceManager nodes using the `-RM` parameter. High availability for the ResourceManager is configured by default and does not need to be specified.
- If `mapr-fileserver` is installed on a node, you can use `configure.sh` with the `-F` option to format the disks and set up partitions. The `-F` option allows you to create a text file that lists the disks and partitions for use by the filesystem on the node. `configure.sh` passes the file to the `disksetup` utility. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition with a space. For example:

  ```
  /dev/sdb
  /dev/sdc1 /dev/sdc2 /dev/sdc4
  /dev/sdd
  ```

  Or you can manually run `disksetup` after you run `configure.sh`. See Configuring Storage on page 158.
- For a cluster node that is on a VM, use the `--isvm` parameter when you run `configure.sh`, so that the script uses less memory.

Enabling Security
Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

The following steps enable:

- Security for the cluster nodes
- Wire-level encryption for the platform and ecosystem components
- Authentication for all network-based connections
- (Optional) Data-at-rest encryption on the cluster

When you set up a cluster, you must run the `configure.sh on page 2053` script on each node that you want to add to the cluster. After you enable security, review the System Behavior Changes After Enabling Security on page 1410.

Basic Procedure

To enable security for the cluster, follow these steps in order:

1. If the cluster is running, shut it down.

2. Delete the `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files on a machine where wire-level security is not enabled, as the `configure.sh` script fails if you already have these files in the directory.

   Note: The `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files are generated during installation of the Web server even if you did not enable security.

   For example, to delete the files, run the following commands:

   ```
   cd /opt/mapr/conf
   /bin/rm -f ssl_keystore ssl_keystore.p12 ssl_keystore.pem ssl_truststore
   ssl_truststore.p12 ssl_truststore.pem
   ```

   If you are re-running the script due to an invocation error from a previous run, the `cldb.key` and `maprserverticket` files may have already been created. Delete these files, as the script fails if you already have these files in the directory. For example, run the following command to delete these files:

   ```
   cd /opt/mapr/conf
   /bin/rm -f cldb.key maprserverticket ssl_keystore ssl_keystore.p12
   ssl_keystore.pem ssl_truststore ssl_truststore.p12 ssl_truststore.pem
   ```

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

   ```
   /opt/mapr/server/configure.sh -secure -dare -genkeys -Z
   <Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
   ```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify a fully-qualified domain name (FQDN) as described in Connectivity on page 133. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

   Important: You must run `configure.sh -dare -genkeys` only *once* on one CLDB node, since the resulting files must be copied to other nodes.

   This command generates the following files in the `/opt/mapr/conf` directory:

   - `cldb.key`
   - `dare.master.key`
   - `maprserverticket`
   - `ssl_keystore`
   - `ssl_keystore.p12`
   - `ssl_keystore.pem`
   - `ssl_truststore`
   - `ssl_truststore.p12`
   - `ssl_truststore.pem`

last-updated: Apr 11, 2022

Note: The `dare.master.key` file is generated only if data at rest encryption is enabled on the cluster.

Tip: A comprehensive listing of the Trust and Key Store files is at: Understanding the Key Store and Trust Store Files on page 1408.

4. Copy the `cldb.key` to any node with the CLDB or Zookeeper service installed, and copy the `dare.master.key` to any node with the CLDB service installed.

   Note: Copy the `dare.master.key` file only if you are enabling data at rest encryption on the cluster.

5. Verify that the files `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` are owned by the user that runs cluster services. This user is `mapr` by default. Also, the `maprserverticket`, `ssl_keystore`, `ssl_keystore.p12`, and `ssl_keystore.pem` files must have their UNIX permission-mode bits set to `400`, and the `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files must be readable to all users.

6. Copy the `maprserverticket`, `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files to the `/opt/mapr/conf` directory of *every* node in the cluster.

7. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

   ```
   /opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
   <CLDB_node_list> -N <cluster_name>
   ```

   The `-secure` option indicates that security must be enabled on the node where the command is run and the `-dare` option indicates that data at rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

   Important: You must also do this on any nodes that you add to the cluster in the future.

8. Copy the `ssl_truststore`, `ssl_truststore.p12`,and `ssl_truststore.pem` files to any client nodes outside the cluster.

   Important: If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

9. Optionally, enable encrypted quorum ZooKeeper communication. See zoo.cfg on page 2220 for more information.

10. Log in as the `mapr` superuser using the maprlogin command: `maprlogin password` (in this command, `password` is literal text).

11. If clients will connect to multiple secure clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. See Setting Up the Client for more information on MapR clients.

Advanced Procedure

In certain situations, you may opt for variant of the basic procedure. Such situations include, but are not limited to the following:

- You are running the script on a host that is configured without a domain name.
- You have a cluster where all the machines do not have the same domain name.
- You wish to import your own custom certificates instead of the self-signed certificates generated by the `configure.sh` utility.

Running on Hosts with no Configured Domain Name

When used without the `-certdomain` argument, the `configure.sh` script discovers the domain name of the node on which it is being executed using the `hostname -d` command and then creates a 100-year self-signed certificate using the PKCS#1 v1.5 with SHA-512 hash function (SHA512withRSA) with a wildcard certificate with the common name `(CN) *.<domain>`. For example, if `hostname -d` returns the domain name `mycompany.com`, then the CN of the certificate is `*.mycompany.com`. This certificate works for all machines within the `mycompany.com` domain and can therefore be copied to all cluster nodes as specified in Step 5 in the Basic Procedure.

Certificate generation fails if the host that you are running the script from is configured without a domain name. To fix this, modify your machine configuration so that `hostname -d` returns a non-empty string and then run the `configure.sh` script.

Alternatively, re-run the script with the `-certdomain` option as shown in Step 3 of the Basic Procedure:

```
/opt/mapr/server/configure.sh -secure -genkeys -certdomain <domain_name> -Z
<Zookeeper_node_list> -C <CLDB_node_list> [ -N <cluster_name> ]
```

Securing Clusters with Multiple Domain Names

Generally, all machines within a cluster should belong to the same domain. In the unusual case where you have a cluster with different machines belonging to different domains, applications that perform hostname verification can fail if you run the `configure.sh` script (as described in Step 3 of the Basic Procedure on page 1406) to generate a single-domain wildcard certificate. In this case, you must provide your own multi-domain wildcard certificate and import the custom certificate into the keystore as described in Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster.

Using Custom Certificates

To import your own custom certificates into the keystore instead of using the self-signed certificates, see Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster.

zoo.cfg on page 2220
Lists the ZooKeeper configuration file.

Configuring Nodes without Security
Describes how to configure all nodes without security during installation without the MapR Installer.

Note: This step does not configure your cluster for enhanced security. If you want your cluster to be secure, do not perform this step. Go to Enabling Security on page 154.

Run the `configure.sh` script with the following options on all nodes in the cluster:

```
/opt/mapr/server/configure.sh -Z <Zookeeper_node_list> -C <CLDB_node_list>
[-RM <host>] [-HS <host>] [-L <logfile>] [-N <cluster name>] [-F <disk
list>]
```

where:

- Both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]`.

last-updated: Apr 11, 2022

- For the hostname, specify a fully-qualified domain name (FQDN) as described in Connectivity on page 133. Do not specify an alias or IP address.
- Specify `-N <cluster_name>` if the cluster is not yet named.

Configuring Storage
This section describes how to format disks for cluster storage manually by using `disksetup`.

The disksetup utility formats disks for use by the MapR cluster. `disksetup` removes all data from the specified disks. Make sure you specify the disks correctly, and back up any data that you want to save. If you are re-using a node that was used previously in another cluster, it is important to format the disks to remove all data from the old cluster. For more information about the utility, see disksetup.

Note: The `disksetup` script assumes that you have free, unmounted physical partitions or hard disks for use by MapR software. To determine if a disk or partition is ready for use by MapR software, see Setting Up Disks for MapR.

disksetup and DARE

If data-at-rest-encryption (DARE) is enabled, you must use a different set of steps for configuring storage using `disksetup`. See the appropriate subtopic in this section.

Configuring Storage with DARE Disabled
This section describes how to format disks for cluster storage manually using `disksetup` with data-at-rest encryption (DARE) disabled.

Manually Running disksetup

You can create a text file that lists the disks and partitions for use by MapR software on a node. Each line should list either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition with a space. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

In the following example, `/tmp/disklist` is a text file that lists the disks and partitions:

Example

```
/opt/mapr/server/disksetup /tmp/disklist
```

Configuring Storage with DARE Enabled
This section describes how to format disks for cluster storage manually using `disksetup` with data-at-rest encryption (DARE) enabled.

Manually Running disksetup

You can create a text file that lists the disks and partitions for use by MapR software on a node. Each line should list either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition with a space. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

In the following example, `/tmp/disklist` is a text file that lists the disks and partitions:

Example

```
/opt/mapr/server/disksetup /tmp/disklist
```

Using disksetup with DARE-Enabled Nodes

In a DARE-enabled cluster, you must use a different set of steps to run `disksetup`. `disksetup` will fail on some nodes if the DARE master key is not available. CLDB nodes have a local copy of the DARE master key, so `disksetup` works on CLDB nodes. Other nodes require a connection with a running CLDB node in order to run `disksetup`.

Use these steps to run `disksetup` on the CLDB nodes and then start the CLDB nodes so that you can then run `disksetup` on the remaining nodes and start those nodes:

1. Format the disks on the CLDB nodes (the nodes that contain the `dare.master.key`):

   ```
   /opt/mapr/server/disksetup /tmp/disklist
   ```

2. Start ZooKeeper and Warden so that other nodes can access the DARE master key on the CLDB nodes:
   a. Start ZooKeeper on all the ZooKeeper nodes:

      ```
      service mapr-zookeeper start
      ```

   b. Start Warden on the CLDB nodes:

      ```
      service mapr-warden start
      ```

3. Format the remaining node disks:

   ```
   /opt/mapr/server/disksetup /tmp/disklist
   ```

4. Start Warden on the remaining nodes:

   ```
   service mapr-warden start
   ```

Step 7: Bring up the Cluster
Before you can install monitoring or ecosystem components, you must enable the cluster by starting ZooKeeper and Warden and verifying the cluster installation status.

Bringing up the cluster involves starting ZooKeeper and Warden, installing a MapR license, and viewing the cluster installation status. Once these initial steps are done, the cluster is functional, and you can use the Control System or the Command Line Interface (CLI) to examine nodes and activity on the cluster.

Starting ZooKeeper and Warden
Starting ZooKeeper and Warden brings up the cluster.

Depending on the options that you specified when running configure.sh on page 2053, Zookeeper and Warden might already be started.

Note: For a DARE-enabled cluster, you can skip this step because you already started the cluster in order to configure disk storage.

To check that Zookeeper is started, use this command on Zookeeper nodes:

```
systemctl status mapr-zookeeper
```

To check that Warden is started:

```
systemctl status mapr-warden
```

To start the cluster if Zookeeper and Warden are not started:

1. Start ZooKeeper on all nodes where it is installed, by issuing the following command:

   ```
   systemctl start mapr-zookeeper
   ```

2. Start Warden on all nodes:

   ```
   systemctl start mapr-warden
   ```

For clusters, ensure that Zookeeper has established a quorum. Use the nc command to check.

To install nc, use one of the following commands:

```
On RHEL: dnf install nmap-ncat
On SLES: zypper install netcat-openbsd
On Ubuntu: apt-get install netcat
```

To check for a quorum, run:

```
echo srvr | nc localhost 5181 | grep Mode
```

This command returns *leader* or *follower* if Zookeeper has established a quorum.

Note: For a single Zookeeper node (is not part of a cluster), the nc command always returns *standalone*.

Troubleshooting Installation
If you are having difficulty bringing up the cluster, you have a number of options.

Difficulty bringing up the cluster seems daunting, but most cluster problems are easily resolved. For the latest support tips, visit the Ezmeral Data Fabric Community.

- Can each node connect with the others? For a list of ports that must be open, see Ports Used by MapR Software on page 2290.
- Is the Warden service running on each node? On the node, run the following command as root:

  ```
  service mapr-warden status
     WARDEN running as process 18732
  ```

  If the Warden service is not running, check the Warden log file, `/opt/mapr/logs/warden.log`, for clues. To restart the Warden service:

  ```
  service mapr-warden start
  ```

- The ZooKeeper service is not running on one or more nodes:
  - Check the Warden log file for errors related to resources, such as low memory

    - Check the Warden log file for errors related to user permissions
    - Check for DNS and other connectivity issues between ZooKeeper nodes
- The `maprcli` program `/opt/mapr/bin/maprcli` won't run
    - Did you configure this node?
- Instance Mismatch Node Alarm is raised
    - Restart Warden to ensure that the number of MapR File System instances is as configured.
- Permission errors appear in the log
    - Check that MapR changes to the following files have not been overwritten by automated configuration management tools:

`/etc/sudoers`	Allows the `mapr` user to invoke commands as root
`/etc/security/limits.conf`	Allows MapR services to increase limits on resources such as memory, file handles, threads and processes, and maximum priority level
`/etc/udev/rules.d/99-mapr-disk.rules`	Covers permissions and ownership of raw disk devices

Before contacting your HPE support representative, collect your cluster logs by using the mapr-support-collect script.

Installing the Cluster License
You must have a valid license to unlock the enterprise features of the MapR Data Platform. You can obtain a trial license by contacting your HPE support representative.

For details, see Adding a License on page 777.

Verifying the Cluster Installation Status
You can use the command line or the Control System to verify the status of your installation.

Using the CLI to Check the Cluster Installation Status

1. Log in to a cluster node.

2. Use the following command to list the MapR services:

```
maprcli service list
  logpath                                displayname
name             state
  /opt/mapr/logs/mfs.log                 FileServer
fileserver       0
  /opt/mapr/hadoop/hadoop-2.7.0/logs     ResourceManager
resourcemanager  0
  /opt/mapr/hadoop/hadoop-2.7.0/logs     JobHistoryServer
historyserver    0
  /opt/mapr/logs/cldb.log                CLDB
cldb             0
  /opt/mapr/logs/nfsserver.log           NFS Gateway
nfs              0
  /opt/mapr/hadoop/hadoop-2.7.0/logs     NodeManager
nodemanager      0
  /opt/mapr/logs/gateway.log             GatewayService
gateway          0
  /opt/mapr/logs/hoststats.log           HostStats
hoststats        0
  /opt/mapr/apiserver/logs/apiserver.log APIServer
apiserver        0

maprcli license list
maprcli disk list -host <name or IP address>
```

3. Restart Warden on all remaining nodes using the following command:

```
service mapr-warden restart
```

Warden is then responsible for starting the rest of the services configured on each node.

Using the Control System to Check the Cluster Installation Status

1. Log in to the Control System using the host name of the node where you installed the `mapr-webserver`. For more information, see Setting Up the Control System on page 423.

   Note: Because MapR monitoring has not been installed yet and the Control System relies on MapR monitoring for metrics collection, some Control System functions will not be available. You can still use the Control System to check the cluster services.

2. Click the **Nodes** tab to verify that all nodes are present and healthy (no alarms are present).

3. Click the **Services** tab to check for any stopped or failed services.

Step 8: Install Metrics Monitoring

To enable metering and the display of certain metrics by the Control System, you must install collectd and OpenTSDB components. Metrics monitoring is part of MapR monitoring, which also includes log monitoring. MapR Monitoring components are available as part of the MapR Ecosystem Pack (EEP) that you selected for the cluster.

Complete these steps to install metrics monitoring as the `root` user or using `sudo`. Installing metrics monitoring components on a client node or edge node is not supported.

1. For metrics monitoring, install the following packages:

Component	Requirements
collectd	Install the `mapr-collectd` package on each node in the MapR cluster.

Component	Requirements
OpenTSDB and AsyncHBase	Install the `mapr-opentsdb` on one or more nodes. To allow failover of metrics storage when one OpenTSDB node is unavailable, install OpenTSDB on at least three nodes in the cluster. **Note:** `mapr-opentsdb` depends on `mapr-asynchbase`, and `mapr-asynchbase` is automatically installed on the node where you install `mapr-opentsdb`.
Grafana	Optional: Install the `mapr-grafana` package on at least one node in the MapR cluster. Grafana does not need to be installed for metering and is optional for metrics monitoring in general.

On a three-node cluster, you could run the following commands to install metrics packages:

- For CentOS/RedHat:
  - Node A: `yum install mapr-collectd mapr-grafana`
  - Node B: `yum install mapr-collectd mapr-opentsdb`
  - Node C: `yum install mapr-collectd`
- For Ubuntu:
  - Node A: `apt-get install mapr-collectd mapr-grafana`
  - Node B: `apt-get install mapr-collectd mapr-opentsdb`
  - Node C: `apt-get install mapr-collectd`
- For SLES:
  - Node A: `zypper install mapr-collectd mapr-grafana`
  - Node B: `zypper install mapr-collectd mapr-opentsdb`
  - Node C: `zypper install mapr-collectd`

2. **Release 6.0.1 and later:** Configure a password for Grafana:
   - For a **secured cluster**, ensure that the `/opt/mapr/conf/ssl_truststore.pem` file is present in `/opt/mapr/conf` on the Grafana nodes. If the `/opt/mapr/conf/ssl_truststore.pem` file is not present, you must copy it from the CLDB primary node to `/opt/mapr/conf` on the Grafana nodes.

     Note: In a secure cluster, Grafana uses PAM to authenticate using the cluster administrator login ID (typically the `mapr` user ID) and password, so no additional information is needed.

   - For a **nonsecured cluster**, you must configure a password for the Grafana `admin` user ID at the time of running `configure.sh`. If no password is provided, the password reverts to `admin`, which is the default pre-MEP 5.0.0 password. Use *one* of the following methods to pass the password to Grafana:

- On the nodes where Grafana is installed, export the password as an environment variable before calling `configure.sh`:

  ```
  export GRAFANA_ADMIN_PASSWORD="<newGrafanaPassword>"
  ```

  Then run `configure.sh` as you normally would run it (go to step 3).

- Add the following options to the `configure.sh` command in step 3. This method explicitly passes the password on the `configure.sh` command line:

  ```
  -EPgrafana '-password <newGrafanaPassword>'
  ```

- Add the following options to the `configure.sh` command in step 3. This method explicitly passes the password on the `configure.sh` command line by specifying a file:

  ```
  -EPgrafana '-password <name of local file containing new password>'
  ```

3. On **every cluster node**, run `configure.sh` with the `-R` and `-OT` parameters, and other parameters, as needed, for the Grafana password. A Warden service must be running when you use `configure.sh -R -OT`.

   ```
   /opt/mapr/server/configure.sh -R -OT <comma-separate list of OpenTSDB
   nodes>
   ```

Parameter	Description
`-R`	After initial node configuration, specifies that `configure.sh` should use the previously configured ZooKeeper and CLDB nodes.
`-OT`	Specifies a comma-separated list of host names or IP addresses that identify the OpenTSDB nodes. The OpenTSDB nodes can be part of the current MapR cluster or part of a different MapR cluster. The list is in the following format: • `hostname/IP address[:port_no] [,hostname/IP address[:port_no]...]` **Note:** The default OpenTSDB port is 4242. If you want to use a different port, specify the port number when you list the OpenTSDB nodes.

For example, to configure monitoring components you can run one of the following commands:

- In this example, default ports are used for the OpenTSDB nodes.

  ```
  /opt/mapr/server/configure.sh -R -OT NodeB
  ```

- In this example, non-default ports are specified for the OpenTSDB nodes:

  ```
  /opt/mapr/server/configure.sh -R -OT NodeB:4040
  ```

- If you are installing metrics monitoring only for use with the Metering utility, you can use the `-EPcollectd` option to collect only metering metrics and omit database metrics. See Installing Metering Using Manual Steps on page 284.

After you run `configure.sh -R`, if errors are displayed see Troubleshoot MapR Monitoring Installation Errors on page 172.

4. To start collecting metrics for the NodeManager and ResourceManager services, restart these services on each node where they are installed.

```
maprcli node services -name nodemanager -nodes <space separated list of
hostname/IPaddresses> -action restart
```

```
maprcli node services -name resourcemanager -nodes <space separated list
of hostname/IPaddresses> -action restart
```

Step 9: Install Log Monitoring

Installing the MapR monitoring logging components is optional. The logging components enable the collection, storage, and visualization of MapR core logs, system logs, and ecosystem component logs. MapR Monitoring components are available as part of the MapR Ecosystem Pack (EEP) that you selected for the cluster.

Note: As of release 6.0, if you install the logging components on a secure cluster, you must generate the Elasticsearch keys, certifications, and trust stores on an Elasticsearch node (designated as the primary) and then distribute them to the other Elasticsearch nodes in the cluster, as shown below in step 3.

Complete the steps to install the logging components as the `root` user or using `sudo`. Installing logging components on a client node or edge node is not supported.

1. For log monitoring, install the following packages:

Component	Requirements
fluentd	Install the `mapr-fluentd` package on each node in the cluster.
Elasticsearch	Install the `mapr-elasticsearch` package on at least three nodes in the cluster to allow failover of log storage if one Elasticsearch node is unavailable.
Kibana	Install the `mapr-kibana` package on at least one node in the cluster.

Note: On secure Ubuntu 14.04 or 16.04 clusters, Elasticsearch can fail to generate a keystore password if the `uuid-runtime` package is not installed. `uuid-runtime` is one of the package dependencies required for installing without the MapR Installer. See the entry for SPYG-934 and `uuid-runtime` in the Known Issues at Release (MapR 6.1.0) on page 47.

For example, on a three-node MapR cluster, you can run the following commands to install log packages:

- For CentOS/RedHat:
  - Node A: `yum install mapr-fluentd mapr-elasticsearch`
  - Node B: `yum install mapr-fluentd mapr-elasticsearch`
  - Node C: `yum install mapr-fluentd mapr-elasticsearch mapr-kibana`
- For Ubuntu:
  - Node A: `apt-get install mapr-fluentd mapr-elasticsearch`

last-updated: Apr 11, 2022

- Node B: `apt-get install mapr-fluentd mapr-elasticsearch`
- Node C: `apt-get install mapr-fluentd mapr-elasticsearch mapr-kibana`

- For SLES:
  - Node A: `zypper install mapr-fluentd mapr-elasticsearch`
  - Node B: `zypper install mapr-fluentd mapr-elasticsearch`
  - Node C: `zypper install mapr-fluentd mapr-elasticsearch mapr-kibana`

2. *For secure MapR clusters*, run `maprlogin print` to verify that you have a user ticket for the MapR user and the `root` user. These user tickets are required for a successful installation. If you need to generate a MapR user ticket, run `maprlogin password`. For more information, see Generating a MapR User Ticket on page 1426.

3. *For secure MapR clusters*, use the following steps to generate the Elasticsearch keys, certificates, and trust stores on the master Elasticsearch node, and then distribute them to other nodes:

   a. Select one Elasticsearch node as the master, and run `configure.sh -R` on that node.

   b. Run the following command on the master Elasticsearch node:

   ```
   /opt/mapr/server/configure.sh -OT <comma-separated list of
   OpenTSDB nodes> -ES <comma-separated list of Elasticsearch
   nodes> -R -EPelasticsearch -genESKeys
   ```

   For descriptions of the parameters used in this command, see the table in step 6.

   

   Important: If DNS resolution on the nodes is not completely configured, running the `configure.sh -genESKeys` step will fail. For example, key creation will fail if reverse lookups do not work. Suppose that the DNS lookup for a node with `hostname node1.qa.lab` returns 192.100.1.1. If the DNS lookup for 192.100.1.1 returns nothing (instead of `hostname node1.qa.lab`), key creation will fail.

   c. For Elasticsearch, copy the specified files to the locations indicated in the following table.

File	Permissions	Copy from location (on master)	Copy to location (all other ES nodes)
`es-root-ca.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/ca/es-root-ca.pem`	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/ca`
`admin-usr-private-key.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/admin-usr-private-key.pem`	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/certs`
`admin-usr-signed.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/admin-usr-signed.pem`	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/certs`

last-updated: Apr 11, 2022

File	Permissions	Copy from location (on master)	Copy to location (all other ES nodes)
admin-usr-clientCombo.pem	0600	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/admin-usr-clientCombo.pem	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/certs
truststore.jks	0640	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/truststore.jks	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/keystores
admin-usr-keystore.jks	0640	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/admin-usr-keystore.jks	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/keystores/admin-usr-keystore.jks

last-updated: Apr 11, 2022

Note: In the preceding table and the tables that follow, `<ver>` in a directory path represents the Elasticsearch, Kibana, or Fluentd version. These versions depend on the currently installed EEP. This table shows the versions for various EEPs:

EEP	Elasticsearch Version	Kibana Version	Fluentd Version
6.3.0	6.5.3	6.5.3	1.4.0
6.2.0	6.5.3	6.5.3	1.4.0
6.1.1	6.5.3	6.5.3	1.3.2.1
6.1.0	6.5.3	6.5.3	1.3.2.0
6.0.x	6.2.3	6.2.3	1.1.2
4.0.0 through 5.0.2	5.4.1	5.4.1	0.14.20

d. For Kibana, copy the specified files to the locations indicated in the following table:

Note: If the `/ca` and `/certs` copy-to directories do not exist for Kibana, you must create them. In addition, the directories and all files within them must be owned by `mapr:mapr`, or the services will not start.

File	Permissions	Copy from location (on master)	Copy to location (all other Kibana nodes)
`es-root-ca.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/ca/es-root-ca.pem`	`/opt/mapr/kibana/kibana-<ver>/config/ca`
`kibanaserver-usr-clientCombo.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/kibanaserver-usr-clientCombo.pem`	`/opt/mapr/kibana/kibana-<ver>/config/certs`
`kibanaserver-usr-signed.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/kibanaserver-usr-signed.pem`	`/opt/mapr/kibana/kibana-<ver>/config/certs`
`kibanaserver-usr-private-key.pem`	0600	`/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/kibanaserver-usr-private-key.pem`	`/opt/mapr/kibana/kibana-<ver>/config/certs`

e. For Fluentd, copy the specified files to the locations indicated in the following table:

Note: If the `/ca` and `/certs` copy-to directories do not exist for Fluentd, you must create them. In addition, the directories and all files within them must be owned by `mapr:mapr`, or the services will not start.

File	Permissions	Copy from location (on master)	Copy to location (all other Fluentd nodes)
es-root-ca.pem	0600	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/ca/es-root-ca.pem	/opt/mapr/fluentd/fluentd-<ver>/etc/fluentd/ca/
fluentd-usr-signed.pem	0600	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/fluentd-usr-signed.pem	/opt/mapr/fluentd/fluentd-<ver>/etc/fluentd/certs
fluentd-usr-private-key.pem	0600	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/fluentd-usr-private-key.pem	/opt/mapr/fluentd/fluentd-<ver>/etc/fluentd/certs
fluentd-usr-clientCombo.pem	0600	/opt/mapr/elasticsearch/elasticsearch-<ver>/etc/elasticsearch/sg/fluentd-usr-clientCombo.pem	/opt/mapr/fluentd/fluentd-<ver>/etc/fluentd/certs

4. **MapR 6.0.1 and later:** *For secure MapR clusters,* copy the `$ES_HOME/etc/elasticsearch/.keystore_password` file from the Elasticsearch master node to `$KIBANA_HOME/config/.keystore_password` on the nodes where you are running Kibana. The `.keystore_password` file contains a system-generated password that is used to authenticate Kibanaserver-to-Elasticsearch-server communication.

5. **Release 6.0.1 and later:** *For secure MapR clusters,* configure a password for the Elasticsearch `admin` user to enable authentication for the end user using Kibana to search the Elasticsearch log index. This password needs to be provided at the time of running `configure.sh`. If no password is specified, you will default to the pre-mep-5.0.0, default password of `admin`. Use *one* of the following methods to pass the password to Elasticsearch/Kibana:

   - On the nodes where Fluentd/Elasticsearch/Kibana is installed, export the password as an environment variable before calling `configure.sh`:

     ```
     export ES_ADMIN_PASSWORD="<newElasticsearchPassword>"
     ```

     Then run `configure.sh` as you normally would run it (go to step 6).

   - Add the following options to the `configure.sh` command in step 6. This method explicitly passes the password on the `configure.sh` command line:

     ```
     -EPelasticsearch '-password <newElasticsearchPassword>' -EPkibana
     '-password <newElasticsearchPassword>' -EPfluentd '-password
     <newElasticsearchPassword>'
     ```

     Example

     ```
     /opt/mapr/server/configure.sh -R -v -ES mfs74.qa.lab -ESDB /opt/
     mapr/es_db -OT mfs74.qa.lab -C mfs74.qa.lab -Z
     mfs74.qa.lab -EPelasticsearch '-password helloMapR' -EPkibana
     '-password helloMapR' -EPfluentd '-password helloMapR'
     ```

- Add the following options to the `configure.sh` command in step 6. This method explicitly passes the password on the `configure.sh` command line by specifying a file:

```
-EPelasticsearch '-password <name of local file containing new
password>'  -EPkibana '-password <name of local file containing new
password>' -EPfluentd '-password <name of local file containing new
password>'
```

Example

```
/opt/mapr/server/configure.sh -R -v -ES mfs74.qa.lab -ESDB /opt/
mapr/es_db -OT mfs74.qa.lab -C mfs74.qa.lab -Z
mfs74.qa.lab -EPelasticsearch '-password /tmp/es_password' -EPkibana
'-password /tmp/es_password' -EPfluentd '-password /tmp/es_password'
```

6. Run `configure.sh` on each node in the MapR cluster with the `-R` and `-ES` parameters, adding parameters to configure the Fluentd/Elasticsearch/Kibana password as needed. Optionally, you can include the `-ESDB` parameter to specify the location for writing index data. A Warden service must be running when you use `configure.sh -R`.

```
/opt/mapr/server/configure.sh -R -ES <comma-separate list of
Elasticsearch nodes> [-ESDB <filepath>]
```

Parameter	Description
`-ES`	Specifies a comma-separated list of host names or IP addresses that identify the Elasticsearch nodes. The Elasticsearch nodes can be part of the current MapR cluster or part of a different MapR cluster. The list is in the following format: • `hostname/IPaddress[:port_no] [,hostname/IPaddress[:port_no]...]` **Note:** The default Elasticsearch port is 9200. If you want to use a different port, specify the port number when you list the Elasticsearch nodes.
`-ESDB`	Specifies a non-default location for writing index data on Elasticsearch nodes. In order to configure an index location, you only need to include this parameter on Elasticsearch nodes. By default, the Elasticsearch index is written to `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/`. **Note:** Elasticsearch requires a lot of disk space. Therefore, a separate filesystem for the index is strongly recommended. It is not recommended to store index data under the `/` or the `/var` file system. Upgrading to a new version of MapR monitoring removes the `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/` directory. If you want to retain Elasticsearch index data through an upgrade, you must use the `-ESDB` parameter to specify a separate filesystem or back up the default directory before upgrading. The Pre-Upgrade Steps for MapR Monitoring on page 342 include this step.

last-updated: Apr 11, 2022

Parameter	Description
`-genESKeys`	Generates needed keys and certificates for the master Elasticsearch node in a secure cluster.
`-OT`	Specifies a comma-separated list of host names or IP addresses that identify the OpenTSDB nodes. The OpenTSDB nodes can be part of the current MapR cluster or part of a different MapR cluster. Do not use this option when you configure a node for the first time. Use this option along with the `-R` parameter. A Warden service must be running when you use `configure.sh -R -OT`. The hostname list should use the following format: `hostname/IP address[:port_no] [,hostname/IP address[:port_no]...]` **Note:** The default OpenTSDB port is 4242. If you want to use a different port, specify the port number when you list the OpenTSDB nodes.
`-R`	After initial node configuration, specifies that `configure.sh` should use the previously configured ZooKeeper and CLDB nodes.

For example, to configure MapR monitoring components you can run one of the following commands:

- In this example, a location is specified for the Elasticsearch index directory, and default ports are used for Elasticsearch nodes:

```
/opt/mapr/server/configure.sh -R -ES NodeA,NodeB,NodeC -ESDB /opt/mapr/myindexlocation
```

- In this example, non-default ports are specified for Elasticsearch, and the default location is used for the Elasticsearch index directory:

```
/opt/mapr/server/configure.sh -R -ES NodeA:9595,NodeB:9595,NodeC:9595
```

After you run `configure.sh -R`, if errors are displayed see Troubleshoot MapR Monitoring Installation Errors on page 172.

7. If you installed Kibana, perform the following steps:
   a) Use one of the following methods to load the Kibana URL:
      - From the Control System, select the **Kibana** view. After you select the **Kibana** view, you may also need to select the **Pop-out page into a tab** option.
      - From a web browser, launch the following URL: `https://<IPaddressOfKibanaNode>:5601`
   b) When the Kibana page loads, it displays a `Configure an index pattern` screen. Provide the following values:

      Note: The **Index contains time-based events** option is selected by default and should remain selected.

last-updated: Apr 11, 2022

Field	Value
Index name or pattern	`mapr_monitoring-*`
Time-field	`@timestamp`

c) Click **Create**.

Troubleshoot MapR Monitoring Installation Errors

Review the following solutions to errors that you may encounter when you run `configure.sh` to configure MapR monitoring.

Elasticsearch Errors

could not determine matching interface

Cause: The DNS is probably not setup correctly on this node.

Solution: Contact your DNS administrator or verify that `/etc/hosts` and `/etc/nssswitch.conf` are configured correctly. The `etc/hosts` file should list the host names and the hosts parameter in `/etc/nssswitch.conf` should be set to files dns.

Failed to create <esdb directory name>

Cause: There is not enough disk space, `configure.sh` was not run as the `root` user, or the index directory path is not valid.

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that there is enough disk space.
- Verify that the file system where the index directory will be created is not read-only. See Log Aggregation and Storage on page 1391 for more information on the index directory location.
- If you included the `-ESDB` parameter, verify that the index directory path uses a valid format: `/<existing_directory1>/<existing_directory2>/<new index directory>`.

Failed to resolve hostname

Cause: The DNS is probably not set up correctly on this node.

Solution: Contact your DNS administrator or verify that `/etc/hosts` and `/etc/nssswitch.conf` are configured correctly. `/etc/hosts` should list the host names if the DNS database is not updated, and the hosts parameter in `/etc/nssswitch.conf` should be set to `files dns`

OpenTSDB Errors

Incompatible asynchbase jar found

Cause: The version of asynchbase installed on this node is not compatible with OpenTSDB.

Solution: Install the correct asynchbase package on each OpenTSDB node. See the EEP release notes to determine the compatibility between package versions.

Failed to install asynchbase Jar file

Cause: There is not enough disk space, the file system is read-only, or `configure.sh` was not run as the root user.

last-updated: Apr 11, 2022

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that you are logged in as the root user or using sudo.
- Verify that there is enough disk space.
- Verify that the file system containing the `/opt/mapr/opentsdb` directory is mounted as read/write.

Failed to create TSDB tables - need to rerun `configure.sh -R` or run `create_table.sh` as `$MAPR_USER`

Cause: On a secure cluster, this issue usually occurs when you run `configure.sh` to configure the nodes to use MapR monitoring without first creating user tickets for the `root` user and the `$MAPR_USER`.

Solution: Complete one or all of the following steps:

- Verify that you have a user ticket for both root and the $MAPR_USER before running `configure.sh` or `create_table.sh`. Run `maprlogin print` to verify that you have a user ticket for the MapR user and the `root` user. If you need to generate a MapR user ticket, run `maprlogin password`.
- Re-run `configure.sh`. For example, `configure.sh -R -OT <comma-separate list of OpenTSDB nodes> -ES <comma-separate list of Elasticsearch nodes>`
- Run `${OTSDB_HOME}/share/opentsdb/tools/create_table.sh` to create OpenTSDB tables in the `mapr.monitoring` volume.

Fluentd Errors

fluentd service not enabled - missing clusterid

Cause: The MapR cluster was not up and running before `configure.sh` was run with the options to configure MapR monitoring.

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that the CLDB services is running. If not, start Warden with the following command: `service mapr-warden start`.
- Verify that the `$MAPR_HOME/conf/clusterid` file exists.

Collectd Errors

collectd service not enabled - missing clusterid

Cause: The cluster was not up and running before `configure.sh` was run with the options to configure MapR monitoring.

Solution: Complete one or all of the following steps and then re-run `configure.sh`:

	• Verify that the CLDB services is running. If not, start Warden with the following command: `service mapr-warden start`. • Verify that the `$MAPR_HOME/conf/clusterid` file exists.

Grafana Errors

Failed to pick default data source host	**Cause:** The OpenTSDB nodes list defined by the `-OT` parameter was incorrect. **Solution:** Check the syntax and the validity of those nodes.
Failed to create scratch config file	**Cause:** There is not enough disk space, `configure.sh` was not run as the `root` user, or the file system was mounted as read-only. **Solution:** Complete one or all of the following steps and then re-run `configure.sh`: • Verify that you are logged in as the `root` user or using sudo. • Verify that there is enough disk space. • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write.
Failed to change the port	**Cause:** The `sed` utility failed to edit a port value in the temporary configuration file. This may occur due to issues with file system permissions, disk space, or file corruption. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write. • Verify that there is enough disk space. • Re-install the MapR monitoring packages.
Failed to configure ssl for grafana	**Cause:** The `sed` utility failed to edit a port value in the temporary configuration file. This can occur due to issues with file system permissions, disk space, or file corruption. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write. • Verify that there is enough disk space. • Re-install the MapR monitoring packages.
ERROR: Failed to install grafana warden config file	**Cause:** There is not enough disk space, `configure.sh` was not run as the root user, or the file system containing `/opt/mapr/grafana` is mounted as read-only.

last-updated: Apr 11, 2022

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that you are logged in as the `root` user or using sudo.
- Verify that there is enough disk space.
- Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write.

Kibana Errors

Failed to configure elasticsearch server URL

Cause: There is not enough disk space, `configure.sh` was not run as the root user, or the file system containing `/opt/mapr/kibana` is mounted read-only.

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that you are logged in as the `root` user or using sudo.
- Verify that there is enough disk space.
- Verify that the file system containing `/opt/mapr/kibana` is mounted as read/write.

Failed to configure ssl for Kibana

Cause: There is not enough disk space or the root user does not have the required directory permissions to create the file in the `/opt/mapr/kibana/kibana-<version>/config` directory.

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that there is enough disk space.
- Verify that the file system containing `/opt/mapr/kibana` is mounted as read/write.

Kibana logon unsuccessful because Searchguard "Service Unavailable"

Cause: On a slower server, Kibana logons sometimes do not succeed because the Searchguard configuration containing the user names and passwords has not finished loading. You might notice an error like the following in the Elasticsearch `MapRMonitoring.log`:

```
[2018-06-30T07:47:15,062][ERROR]
[c.f.s.a.BackendRegistry  ] Not
yet initialized (you may
need to run sgadmin)
```

Solution: Try using the following command to restart Elasticsearch:

```
maprcli node services -name
elasticsearch -action restart -nodes $
(hostname -f)
```

Step 10: Install Ecosystem Components Manually

You can install one or more ecosystem components from any MapR Ecosystem Pack (EEP) that is supported by the MapR cluster version. An EEP consists of a group of ecosystem components that work together.

Prerequisite: Set up the EEP Repository

Complete the following steps on each node in the cluster:

1. Verify that each node can access the ecosystem packages associated with the EEP version that you want to install. For information about how to set up the ecosystem repositories or to manually download each package, see Step 2: Prepare Packages and Repositories on page 142.
2. Update the repository cache to get the latest list of available packages:
   - On RedHat/CentOS:

     ```
     yum clean all
     ```

   - On SLES:

     ```
     zypper refresh
     ```

   - On Ubuntu:

     ```
     apt-get update
     ```

Manually Install Ecosystem Components

Review the MapR Ecosystem Pack Release Notes to determine the list of ecosystem components available in the EEP that you have selected. Then, complete the installation steps for each component that you want to install.

Note:

- If you want to use the optional OJAI Distributed Query Service on page 505, you must install Drill. See Installing Drill on page 177.
- For special considerations related to the installation of the `mapr-apiserver` and `mapr-webserver` packages (for the control system) in releases 6.2.0 and later, see Setting Up the Control System on page 423.

Installing AsyncHBase Libraries

This topic includes instructions for using package managers to download and install AsyncHBase from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Execute the following commands as `root` or using `sudo`.

1. Based on your operating system, run one of the following commands to install the package:

On Red Hat /Centos	`yum install mapr-asynchbase`

On SLES	`zypper install mapr-asynchbase`
On Ubuntu	`apt-get install mapr-asynchbase`

2. Run the `configure.sh` script with the following command to configure the AsyncHBase role for the node:

```
/opt/mapr/server/configure.sh -R
```

After installing the `mapr-asynchbase` package, the AsyncHBase JAR file `asynchbase-<version>-mapr.jar` is in the `/opt/mapr/asynchbase/asynchbase-<version>` directory.

Installing Drill

This topic provides instructions for using package managers to download and install Drill.

You can install and run Drill on any number of nodes in your MapR cluster. You can install Drill to run under the Warden service or under YARN. Starting in MapR 6.0 and Drill 1.11, Drill is secured by default when you install Drill on a secure MapR 6.x cluster.

Note: See Component Versions for Released EEPs for version support in each EEP release.

MapR Default Security Configuration

Starting in Drill 1.11, Drill is automatically secured when you install Drill in a 6.x MapR cluster that was installed with the default MapR security configuration. The default security configuration uses MapR-SASL (mapr tickets) to provide authentication, authorization, and encryption for cluster security.

Note: The default security configuration does not support Drill-on-YARN.

The default MapR security configuration is not required. You can install Drill and configure custom security, or turn security off after installing with the default security configuration. See the *Drill Installation Security Scenarios* section below for more information. See Securing Drill.

Installing Drill Under Warden or YARN

You can install and run Drill under Warden or you can install and run Drill under YARN. If you are currently running Drill under Warden, you can upgrade Drill and continue to run Drill under Warden, or you can migrate Drill to run under YARN. See Migrate Drill to Run Under YARN for instructions.

When Warden manages the Drill cluster, you can use the MapR Control System for monitoring. YARN (Yet Another Resource Negotiator) is a cluster management tool that automates the resource sharing process in a cluster. When you launch Drill under YARN, YARN deploys (localizes) Drill onto each node. You can monitor the Drill cluster using the Drill-on-YARN Application Master web UI.

Drill Packages

You can use package managers to manually install the appropriate Drill package. The Drill packages provide the software needed to run Drill. MapR provides mapr-drill package and also a mapr-drill-yarn package.

Drill includes the Drill daemon, the core Drillbit service that runs on a node. Each node running the Drillbit service can receive, plan, and execute queries sent from a client. The software also includes the drill-shell command line interface, a pure-Java console-based utility, for connecting to a Drill cluster and executing SQL commands.

The following sections list the Drill packages and their descriptions:

last-updated: Apr 11, 2022

mapr-drill	The mapr-drill package is required to run Drill under the MapR Warden service. This package installs or upgrades the Drill software in `/opt/mapr/drill` and integrates Drill with the MapR Warden service. You install this package on all nodes designated to run Drill. **Note:** Verify that you get both the mapr-drill and mapr-drill-internal packages, especially if you install or upgrade through the URL or download through the MapR repositories. Also, verify that the packages have the same version. For example, if you install Drill 1.14, both packages should be version 1.14.
mapr-drill-yarn	The mapr-drill-yarn package is required to run Drill under YARN. This package installs the Drill software in `/opt/mapr/drill`. You install this package on the node that you designate as the Drill-on-YARN client. See Install Drill to Run Under YARN for details. YARN deploys Drill to every node included in the Drill cluster. Installing this package on every node is not required. **Note:** If any users need to access SQLLine, you must install the mapr-drill-yarn package on every node where users expect access to SQLLine.

Drill and Query Services

To use the optional OJAI Distributed Query Service on page 505, you must install Drill and configure and register the service. See Configure the OJAI Distributed Query Service on page 182.

Drill Installation Security Scenarios

The following sections describe some manual installation scenarios for Drill with information about security configuration:

Installing or Upgrading Drill

You can install Drill on a MapR cluster with or without default security. After you install the Drill package, you must run the configuration script, configure.sh -R, to configure the Drill service on the nodes. When you run the configuration script, the script recognizes whether your MapR cluster is using the default security or not, and configures Drill accordingly.

In a secure cluster, an internal Drill configuration script automatically adds the security configuration to the `drill-distrib.conf` and `distrib-env.sh` files. See Securing Drill.

Note: You can override these default security settings in the `drill-override.conf` file, but doing so is not recommended or supported.

If your cluster is not using the default security, the internal Drill configuration script does not configure any security for Drill. Instead, it copies warden.drill-bits.conf to the conf.d directory.

Installing Drill with MapR and Configuring Custom Security

If you install MapR and Drill, and you want to manually secure the cluster and Drill instead of using the default security option, you must add a .customSecure file to the /opt/mapr/conf/ directory before you run configure.sh, as shown:

1. Run `/usr/bin/touch /opt/mapr/conf/.customSecure` to add the .customSecure file.
2. Run `configure.sh -R`.

last-updated: Apr 11, 2022

The configuration script recognizes the .customSecure file which indicates not to configure the default security settings. At this point, you can manually configure security in drill-override.conf.

Turning Default Security On|Off After You Install Drill

If you installed Drill on a MapR cluster with the default security option enabled, you can disable it. Likewise, if you did not enable the default security option, you can enable it. When you enable or disable the default security option, security is applied or removed across the cluster.

For example, if your cluster is not secure and you enable the default security option, the entire MapR cluster is secured, as well as all supported ecosystem components, including Drill.

In such a scenario, you must run the configure.sh script with the `-secure` or `-unsecure` and `-forceSecurityDefaults` flags to update the configuration of the nodes and apply or remove security across the cluster, as shown:

```
/opt/mapr/server/configure.sh -forceSecurityDefaults [ -unsecure | -secure ]
 -C <CLDB_node> -Z <ZK_node>
```

The configuration script communicates with internal ecosystem scripts to automatically configure or remove security across the cluster.

Component and System Compatibility Matrix

See the Interoperability Matrix pages for information about the compatibility of Drill with operating systems and ecosystem projects.

Drill Storage and Format Plug-in Support Matrix

See the Drill Storage and Format Plugin Support Matrix page for a list of supported and unsupported data sources and formats in Drill on MapR.

Install Drill to Run Under Warden

Verify that your system meets the prerequisites listed below and then follow the instructions listed in Installing Drill to Run Under Warden to install the mapr-drill package on all nodes designated to run Drill under the MapR Warden service.

Note: See Component Versions for Released EEPs for version support in each EEP release.

Prerequisites

Before you install Drill, read Installing Drill, and verify that the system meets the following prerequisites:

- The MapR cluster is installed and running. Installing Drill first can result in configuration issues
- The EEP repository is configured. For instructions, see Step 9: Install Ecosystem Components Manually.

Refer to the Apache Drill Release Notes and Drill Release Notes for a list of known issues.

Hive and HBase Support

Installation of a supported version of Hive is optional. Support differs, depending on the MapR Ecosystem Pack version that you install. See Component Versions for Released EEPs for version support in each EEP release.

Note: As of MapR 6.0, HBase is not supported.

Installing Drill to Run Under Warden

last-updated: Apr 11, 2022

Explains how to manually install the latest version of Drill to run under the MapR Warden service on the MapR Converged Data Platform.

Note: Starting in Drill 1.11, Drill is automatically secured when installed on a 6.x MapR cluster with the default MapR security configuration. The default security configuration uses MapR security (mapr tickets) to provide authentication, authorization, and encryption for cluster security. See Securing Drill amd Component Versions for Released EEPs for more information.

Complete the following steps as `root` or using `sudo` to install Drill on a client or server node:

1. To install Drill, issue the command appropriate for your system:

RedHat/CentOS	`yum install mapr-drill`
Ubuntu	`apt-get install mapr-drill`
SLES	`zypper install mapr-drill`

   Note: SLES is supported as of Drill 1.9.0-1703 and Drill 1.10.0-1703.

2. Run the configuration script to update the node configuration, as shown:

```
/opt/mapr/server/configure.sh -R
```

   Note: See configure.sh for more information about the script.

3. Verify that Drill is configured and running on the node. You can use one of the following methods to verify that the Drillbit service is running on the node:
   - Issue the following command to verify the status of the Drillbit service from the command line:

```
jps
```

   - Log in to the Control System at `https://<host_name>:8443` to verify the status of the Drillbit service.

     Note: You should see the Drillbit listed as a service running on the node.

4. Optionally, modify the Drill configuration. For example, you can change the log file directory, increase heap space and direct memory, or configure the MapR File System as the persistent configuration storage. See Configuring Drill on page 3237.

   Note: You must restart the drillbit for the new configuration to take effect.

5. Repeat steps 1 through 3 on any other nodes designated to run Drill.

   Note:

   You can start|stop|restart the Drillbit service on one or more nodes using the Control System or the following command:

   ```
   $ maprcli node services -name drill-bits -action start|restart|
   stop -nodes <node host names separated by a space>
   ```

   Use the host name if possible. Using host names instead of IP addresses is a best practice.

   You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

Install Drill to Run Under YARN

You can install and configure Drill to run under YARN. See Drill-on-YARN Overview. If you are currently running Drill under Warden, back up the directory from your previous Drill installation, and migrate Drill to run under YARN. See Migrate Drill to Run Under YARN.

Note: Drill-on-YARN is an advanced feature used to manage a production Drill cluster. Only skilled Drill and MapR administrators, familiar with YARN, should configure Drill to run under YARN. If you are new to Drill, consider using Drill under Warden until you are familiar with Drill and the Drill cluster.

Note: The MapR default security feature introduced in MapR 6.0 is not supported with Drill-on-YARN.

Verify that your system meets the prerequisites below and then follow the instructions in Installing Drill to Run Under YARN to install the mapr-drill-yarn package on the node designated as the Drill-on-YARN client to run Drill under YARN.

Prerequisites

Verify that your system meets the following prerequisites before you install Drill to run under YARN:

- The MapR cluster is installed and running. Installing Drill first can result in configuration issues
- You have planned the YARN cluster. See YARN on page 738, Planning the Cluster on page 107, and Example Cluster Designs on page 118.
- - ResourceManager is installed on one node in the YARN cluster, and you have calculated disk requirements for the YARN ResourceManager.
  - NodeManager is installed on all nodes in the YARN cluster.
- You have designated one node to act as the Drill-on-YARN client. This is the node on which you install the mapr-drill-yarn package. The Drill-on-YARN client is a command-line program that starts, stops, and monitors the Drill cluster. The client provides the information that YARN needs to start the Application Master.
- Cluster resources can accommodate the Drill memory, CPU, and disk requirements.
- The EEP repository is configured. For instructions, see Step 8: Install Ecosystem Components Manually.

Hive and HBase Support

Installation of a supported version of Hive and HBase is optional. Support differs based on the EEP version that you install. See Component Versions for Released EEPs for version support in each EEP release.

last-updated: Apr 11, 2022

Installing Drill to Run Under YARN

This topic includes instructions for using package managers to download and install Drill.

Verify that the system meets the prerequisites. You must install the mapr-drill-yarn package on a node designated to run as the Drill-on-YARN client.

Note: The MapR default security feature introduced in MapR 6.0 is not supported with Drill-on-YARN.

Complete the following steps as `mapr` using `sudo` to install Drill on the node:

Note: If users need to access SQLLine, you must install the mapr-drill-yarn package on every node used to access SQLLine.

1. To install Drill, issue the command appropriate for your system:

RedHat/CentOS	`yum install mapr-drill-yarn`
Ubuntu	`apt-get install mapr-drill-yarn`
SLES	`zypper install mapr-drill-yarn`

   Note: SLES is supported as of Drill 1.9.0-1703 and Drill 1.10.0-1703.

   Note: Drill does not automatically start after you install the packages.

2. Configure Drill to run under YARN. See Configuring Drill to Run Under YARN.

Configure the OJAI Distributed Query Service

Use these steps to install and configure the OJAI Distributed Query Service on page 505:

1. Using the EEP 4.0 or later repository, install Drill to run under Warden on all data nodes. See Install Drill to Run Under Warden on page 179.
2. Configure the query service by running the following configure.sh script command on the Drill nodes:

```
/opt/mapr/server/configure.sh -R -QS
```

3. Register the query service:

   Note: In the following command `<clustername>` is the name of the cluster as specified in `/opt/mapr/conf/mapr-clusters.conf`.

```
maprcli cluster queryservice setconfig -enabled true -clusterid
<clustername>-drillbits -storageplugin dfs -znode /drill
```

Installing Flume

This topic includes instructions for using package managers to download and install Flume from the EEP repository.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

last-updated: Apr 11, 2022

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176

Execute the following commands as `root` or using `sudo`.

1. On each planned Flume node, install `mapr-flume`:
   - On Ubuntu: `apt-get install mapr-flume`
   - On CentOS/Redhat: `yum install mapr-flume`
   - On SLES: `zypper install mapr-flume`
2. If you want to integrate Flume with MapR Event Store For Apache Kafka, install the Streams Client on each Flume node.
   - On Ubuntu:

     ```
     apt-get install mapr-kafka
     ```

   - On RedHat/CentOS:

     ```
     yum install mapr-kafka
     ```

   - On SLES:

     ```
     zypper install mapr-kafka
     ```

Installing HBase

This topic includes instructions for using package managers to download and install HBase from the EEP repository.

Before installing HBase, you should plan which cluster nodes should run the HBase Master service, and which nodes should run the HBase RegionServer. At least one node (generally three nodes) should run the HBase Master. For example, install HBase Master on the ZooKeeper nodes. Only a few of the remaining nodes or all of the remaining nodes can run the HBase RegionServer.

The following procedures use the operating-system package managers to download and install from the EEP repository.

Install HBase on a Cluster Node

The following instructions use the package manager to download and install HBase from the EEP repository to a cluster node.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Run the following commands as `root` or using `sudo`.

1. On each planned HBase Master node, install `mapr-hbase-master`:
   - Ubuntu:

     ```
     apt-get install mapr-hbase-master
     ```

   - RedHat/CentOS:

     ```
     yum install mapr-hbase-master
     ```

- SLES:

```
zypper install mapr-hbase-master
```

2. On each planned HBase RegionServer node, install `mapr-hbase-regionserver`:
   - Ubuntu:

```
apt-get install mapr-hbase-regionserver
```

   - RedHat/CentOS:

```
yum install mapr-hbase-regionserver
```

   - SLES:

```
zypper install mapr-hbase-regionserver
```

3. On all HBase nodes, run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

Installing HBase Client and Tools

MapR 6.0.x does not support HBase as an ecosystem component. Beginning with EEP 6.3.0, MapR 6.1 reintroduced HBase as an ecosystem component. With EEP 6.3.0 and later you can install the HBase Client and tools even if you decide not to install HBase as an ecosystem component. This topic describes the HBase Client and other tools that are available for use with the MapR Database.

Service	Description
HBase Client	After installing the HBase Client, you can use the HBase Shell to manipulate MapR Database tables. MapR Database also supports a number of HBase APIs for use with MapR Database binary tables. For information on installation and configuration, see Installing HBase on a Client Node on page 185. For more information about MapR Database tables and HBase APIs, see Developing Applications for Binary Tables on page 2452.
HBase Thrift Gateway	HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to MapR Database tables. For information on installation and configuration, see Installing the HBase Thrift Gateway.
HBase REST Gateway	HBase REST Gateway includes an API and a service that accepts REST requests to connect to MapR Database tables. For information on installation and configuration, see Installing the HBase REST Gateway.
AsyncHBase Libraries	AsyncHBase library provides asynchronous Java APIs to access MapR Database tables. For information on installation and configuration, see Installing AsyncHBase Libraries on page 176.

last-updated: Apr 11, 2022

Installing HBase on a Client Node
The following instructions use the package manager to download and install HBase from the EEP repository to a client node. When you install HBase on a client node, you can use the HBase shell from a machine outside the cluster.

MapR 6.0.x does not support HBase as an ecosystem component. Beginning with EEP 6.3.0, MapR 6.1 reintroduced HBase as an ecosystem component. With EEP 6.3.0 and later you can install the HBase Client and tools even if you decide not to install HBase as an ecosystem component.

Before you being, verify the following prerequisites:

- The EEP repository is set up. For the steps to set up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176
- The MapR client must be installed on the node where you install the HBase client.

  For MapR client setup instructions, see Setting Up the Client.
- You must know the IP addresses or hostnames of the ZooKeeper nodes on the cluster.

Run the following commands as `root` or using `sudo`.

1. On the client computer, install `mapr-hbase`:

CentOS or Red Hat	`yum install mapr-hbase`
Ubuntu	`apt-get install mapr-hbase`
SLES	`zypper install mapr-hbase`

2. On all HBase nodes, run configure.sh with a list of the CLDB nodes and ZooKeeper nodes in the cluster.

Configuring HBase on a Client Node
You can use a script to configure client nodes for use with HBase 1.1.13 or later on a secure or nonsecure MapR cluster.

You configure client nodes as part of a new installation or when you need to upgrade `mapr-hbase` on the client node from a previous HBase version (for example, HBase 1.1.8) to 1.1.13 or later.

Configuration Using the configure_client.sh Script

The `configure.sh` utility does not support the configuration of client nodes for HBase. However, you can use the following script to configure a client by specifying the ZooKeeper host name and port. The script supports secure (MapR-SASL) and nonsecure clusters, but does not support Kerberos (see Manual Configuration on page 185):

```
/opt/mapr/hbase/hbase-1.1.13/bin/configure_client.sh -zkServer <host>:<port>
```

Manual Configuration

To configure a client node manually for use with HBase 1.1.13 or later on a secure or nonsecure MapR cluster, do the following:

last-updated: Apr 11, 2022

Desired Security	Do this . . .	Example

Nonsecure	**1.** Modify the `hbase.zookeeper.quorum` property to change the hostname and add the ZooKeeper port.	`<property>`
		`  <name>hbase.zookeeper.quorum</name>`
		`  <value><hostname>:5181</value>`
		`</property>`

Secure (MapR-SASL)	**1.** Modify the `hbase.zookeeper.quorum` property as shown in the nonsecure example.
	2. Add the properties shown in this example.
		`<property>`
		`  <name>hbase.security.authentication</name>`
		`  <value>maprsasl</value>`
		`</property>`
		`<property>`
		`  <name>hbase.rpc.protection</name>`
		`  <value>privacy</value>`
		`</property>`

Secure (Kerberos)	**1.** Modify the `hbase.zookeeper.quorum` property as shown in the nonsecure example.
	2. Add the properties shown in this example.
		`<property>`
		`  <name>hbase.security.authentication</name>`
		`  <value>kerberos</value>`
		`  </property>`
		`  <property>`
		`  <name>hbase.rpc.protection</name>`
		`  <value>privacy</value>`
		`  </property>`
		`<property>`
		`  <name>hbase.master.kerberos.principal</name>`
		`  <value><username>/<fqdn>@<realm></value>`
		`</property>`
		`<property>`
		`  <name>hbase.regionserver.kerberos.principal</name>`
		`  <value><username>/<fqdn>@<realm></value>`
		`</property>`

Installing the HBase Thrift Gateway

The HBase Thrift Gateway can be installed on any node where the `mapr-client` package or the `mapr-core` package is installed.

Complete the following steps to install the HBase Thrift Gateway:

1. Run the following command to install the HBase Thrift package:

On CentOS / Red Hat	`yum install mapr-hbasethrift`
Ubuntu	`apt-get install mapr-hbasethrift`
SLES	`zypper install mapr-hbasethrift`

2. Run configure.sh on the node where you installed the HBase Thrift package:

```
/opt/mapr/server/configure.sh -R
```

After you install the HBase Thrift package and run `configure.sh -R`, Warden starts and monitors the service. Warden also displays the status of the HBase Thrift service on the MapR Control System user interface.

Installing the HBase REST Gateway

The HBase REST Gateway can be installed on any node where the `mapr-client` package or the `mapr-core` package is installed.

Complete the following steps to install the HBase REST Gateway:

1. Run the following command to install the HBase REST Gateway package:

On CentOS / Red Hat	`yum install mapr-hbase-rest`
Ubuntu	`apt-get install mapr-hbase-rest`
SLES	`zypper install mapr-hbase-rest`

2. Run configure.sh on the node where you installed the HBase REST Gateway package:

```
/opt/mapr/server/configure.sh -R
```

After you install the HBase REST package and run `configure.sh -R`, Warden starts and monitors the service. Warden also displays the status of the HBase REST service on the MapR Control System user interface.

Installing Hive

This topic includes instructions for using package managers to download and install Hive from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176

You can install Hive on a node in the MapR cluster or on a MapR client node. Installation of HiveServer2 on a client node is not supported by MapR. If you wish to install HS2 on a client node, note that one or more required JAR files may **not** be installed during the installation of `mapr-client`. Copy the following JAR file from a resource manager node to the MapR client node:

```
/opt/mapr/hadoop/hadoop-<X.X.X>/share/hadoop/yarn/
hadoop-yarn-server-resourcemanager-<X.X.X>-mapr-<YYYY>.jar
```

Here:

X.X.X	Refers to the version (for example, hadoop-2.7.0)
YYYY	Refers to the release tag of ecosystem component (for example, 1602)

Note: Copying the JAR file may allow you to work with Hive in non-secure mode.

See the Hive Release Notes for a list of fixes and new features.

Hive is distributed as the following packages:

last-updated: Apr 11, 2022

Package	Description
`mapr-hive`	The core Hive package.
`mapr-hiveserver2`	The Hive package that enables HiveServer2 to be managed by the warden, allowing you to start and stop HiveServer2 using maprcli or the MapR Control System. The `mapr-hive` package is a dependency and will be installed if you install `mapr-hiveserver2`. At installation time, Hiveserver2 is started automatically.
`mapr-hivemetastore`	The Hive package that enables the Hive Metastore to be managed by the warden, allowing you to start and stop Hive Metastore using maprcli or the MapR Control System. The `mapr-hive` package is a dependency and will be installed if you install `mapr-hivemetastore`. At installation time, the Hive Metastore is started automatically.
`mapr-hivewebhcat`	The Hive package that enables WebHCat to be managed by the warden, allowing you to start and stop WebHCat using maprcli or the MapR Control System. The `mapr-hive` package is a dependency and will be installed if you install `mapr-hivewebhcat.` At installation time, the WebHCat is started automatically.

Make sure the environment variable `JAVA_HOME` is set correctly. For example:

```
# export JAVA_HOME=/usr/lib/jvm/java-7-sun
```

You can set these system variables by using the shell command line or by updating files such as `/etc/profile` or `~/.bash_profile`. See the Linux documentation for more details about setting system environment variables.

Note: The MapR cluster must be up and running before installing Hive.

On Ubuntu, while configuring the new version of Hive, you could have an issue caused by an incomplete removal of previously installed Hive packages. To avoid this issue, use the `purge` command for complete removal of all previously installed Hive packages.

Execute the following commands as `root` or using `sudo`.

1. On each planned Hive node, install Hive packages.
   - To install Hive:

On CentOS / RedHat	`yum install mapr-hive`
On SLES	`zypper install mapr-hive`
On Ubuntu	`apt-get install mapr-hive`

   - To install Hive and HiveServer2:

On CentOS / RedHat	`yum install mapr-hive mapr-hiveserver2`
On SLES	`zypper install mapr-hive mapr-hiveserver2`
On Ubuntu	`apt-get install mapr-hive mapr-hiveserver2`

last-updated: Apr 11, 2022

- To install Hive, HiveServer2, and HiveMetastore:

On CentOS / RedHat	`yum install mapr-hive mapr-hiveserver2 mapr-hivemetastore`
On SLES	`zypper install mapr-hive mapr-hiveserver2 mapr-hivemetastore`
On Ubuntu	`apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore`

- To install Hive, HiveServer2, HiveMetastore and WebHCat:

On CentOS / RedHat	`yum install mapr-hive mapr-hiveserver2 mapr-hivemetastore mapr-hivewebhcat`
On SLES	`zypper install mapr-hive mapr-hiveserver2 mapr-hivemetastore mapr-hivewebhcat`
On Ubuntu	`apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore mapr-hivewebhcat`

Note: Starting from EEP-5.0.2 and EEP-6.0.1+, you can use Apache Derby as the underlying database (only for test purposes). To configure Hive on Derby DB, install all Hive packages (`mapr-hive`, `mapr-hiveserver2` `mapr-hivemetastore`, and `mapr-hivewebhcat`), and run the `configure.sh` command, as described in Step 3 later in this procedure.

CAUTION: Do not use `datanucleus.schema.autoCreateAll` for populating underlying databases. For more details, see prohibited usage of `datanucleus.schema.autoCreateAll` property .

2. Configure the database for Hive Metastore.
   See Configuring Database for Hive Metastore on page 3411 for more information.
3. Run `configure.sh on page 2053` with the `-R` option.

```
/opt/mapr/server/configure.sh -R
```

After Hive is installed, the executable is located at: `/opt/mapr/hive/hive-<version>/bin/hive`.

See Hive User Impersonation for the steps to configure user impersonation for Hive and the MapR cluster.

To configure Hive on Tez, see Configuring Hive and Tez on page 3502.

Installing HttpFS
This topic includes instructions for using package managers to download and install HttpFS from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176

Execute the following commands as `root` or using `sudo`.

1. Install the `mapr-httpfs` package:
   - Ubuntu
     ```
     # apt-get install mapr-httpfs
     ```
   - RedHat/CentOS
     ```
     # yum install mapr-httpfs
     ```
   - SLES
     ```
     # zypper install mapr-httpfs
     ```
2. Run `configure.sh` on page 2053 with the `-R` option.
   ```
   /opt/mapr/server/configure.sh -R
   ```

Installing Hue

This topic includes instructions for using package managers to download and install Hue from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Note: The Hue package, `mapr-hue`, can be installed on either a MapR cluster node (recommended) or a MapR client node. If you choose to install on a client node, keep in mind that Hue directories are owned by the user who installed Hue.

Execute the following commands as `root` or using `sudo`.

1. Install the Hue packages.

   On Ubuntu:
   ```
   apt-get install mapr-hue
   ```
   On RedHat/ CentOS:
   ```
   yum install mapr-hue
   ```
   On SLES:
   ```
   zypper install mapr-hue
   ```
2. If the node is a MapR Client node, follow the additional instructions:

   a) To determine who the <INSTALL_USER> is, enter:
   ```
   logname
   ```

b) Set the following properties in `hue.ini` to that user.

```
server_user=<INSTALL_USER>
server_group=<INSTALL_USER>
default_user=<INSTALL_USER>
```

c) Change the `default_hdfs_superuser` property to the owner of `/var` on the cluster.

Warning: The `<INSTALL_USER>` must exist on the cluster on *all* nodes. It must also be set as the proxy user in *all* configuration files listed in Configure Hue, depending on the Hue version you are installing.

3. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

Installing Other Components

Based on your requirements, you may also want to install the following components on at least one node in the cluster.

Component	Description
MapR Database	Required for access to MapR Database tables
HttpFS	Required for viewing files in MapR File System through Hue file browser
Sqoop2	Required to create and submit jobs to transfer bulk data between structured datastores and the MapR File System.
Spark	Required to process data using the Notebook UI.
Hive	Required to run queries with HiveServer2.
Oozie	Required for Oozie workflows

When you finish installing Hue, go to Configure Hue to learn how to configure Hue.

Installing Impala

This section describes how to use package managers to download and install Impala from the MEP repository.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Impala is comprised of a set of components that you install and run on a single node or on multiple nodes in a cluster. To run Impala in your cluster, you install the required Impala packages on designated nodes. The Impala packages contain the following Impala components:

- Impala daemon
- Impala statestore
- Impala catalog
- Impala binaries

The following table lists the Impala packages and their descriptions:

last-updated: Apr 11, 2022

Package	Description
`mapr-impala`	A package that contains all of the Impala binaries, including the Impala server, impala-shell, statestore, and catalog.
`mapr-impala-server`	The role package that installs the Impala daemon role on the node. This package enables Warden to manage the service. It is recommended (not required) that you install the Impala daemon on a node with the MapR fileserver installed.
`mapr-impala-statestore`	The role package that installs the Impala statestore role on the node. This package enables Warden to manage the service.
`mapr-impala-catalog`	The role package that installs the Impala catalog role on the node. This package enables Warden to manage the service.

Verify that your system meets the prerequisites and then install Impala.

Impala Prerequisites
This section describes software prerequisites for Impala.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

To successfully install and run Impala, verify that the system meets the following hardware and software requirements. Note that Impala must be installed on a node that contains MapR Core. Because of tight coupling with Core, it is not possible to run Impala on a client node.

Prerequisite	Requirement
Operating System	The MapR repository provides packages for the 64-bit operating systems listed in Operating System Support Matrix on page 5522. For restrictions associated with a specific operating system or Impala version, see the support table for your EEP under EEP Components and OS Support on page 5536.
MapR Software	See Component Versions for Released EEPs on page 5586. Also see EEP Support and Lifecycle Status on page 5531.
EEP repository	Set up the EEP repository, if you have not already done so. For instructions on setting up the EEP repository, see Step 2: Prepare Packages and Repositories on page 142.

Hive Metastore	You must install and configure a Hive metastore. Configure the Hive metastore service and connect to a MySQL database through the service. For more information, see Installing Hive.
	Note: Verify that `hive-site.xml` contains the `hive.metastore.uris` setting, and substitute the appropriate host name for `metastore_server_host` on every Impala server node.
	Example
	`<property>`
	`  <name>hive.metastore.uris</name>`
	`  <value>thrift://<metastore_server_host>:9083</value>`
	`</property>`

Hive	Hive 2.3 is required to run Impala 2.12.x. Impala must have access to the same metastore database that Hive uses. For Hive configuration information, see the Hive documentation.
MapR Database	MapR Database binary tables (HBase 1.1.13 API) are required to run Impala. Install `mapr-hbase-1.1.13.0` from the EEP repository.
Java	JDK 1.8 is required. See JDK Support Matrix on page 5596.

OpenSSL	Version 1.0.2 (or newer)

Impala Installation Steps
This topic provides instructions for using package managers to download and install Impala from the EEP repository.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Install the Impala package on nodes in the cluster that you have designated to run Impala. Install the Impala server on every node designated to run impalad. Install the statestore and catalog packages on only one node in the cluster.

Note: It is recommended that you install statestore and catalog together on a separate machine from the Impala server.

Complete the following steps to install Impala, impala-server, statestore, and catalog:

1. Install the `mapr-impala` package on all the nodes designated to run Impala. To install the package, issue the following command:

   ```
   $ sudo yum install mapr-impala
   ```

2. In `/opt/mapr/impala/impala-<version>/conf/env.sh`, complete the following steps:
   a) Verify that the statestore address is set to the address where you plan to run the statestore service.

      ```
      IMPALA_STATE_STORE_HOST=<IP address hosting statestore>
      ```

   b) Change the catalog service address to the address where you plan to run the catalog service.

      ```
      CATALOG_SERVICE_HOST=<IP address hosting catalog service>
      ```

   c) Add the `mem_limit` and `num_threads_per_disk` parameters to `IMPALA_SERVER_ARGS` to allocate a specific amount of memory to Impala, and limit the number of threads that each disk processes per impala server daemon. The default Impala memory setting is high, which can result in conflict between Impala and other frameworks running in the cluster. Adding these parameters can alleviate any potential resource conflicts.

      ```
      export IMPALA_SERVER_ARGS=${IMPALA_SERVER_ARGS:- \
          -log_dir=${IMPALA_LOG_DIR} \
          -state_store_port=${IMPALA_STATE_STORE_PORT} \
          -use_statestore -state_store_host=${IMPALA_STATE_STORE_HOST} \
          -catalog_service_host=${CATALOG_SERVICE_HOST} \
          -be_port=${IMPALA_BACKEND_PORT} \
          -mem_limit=<absolute notation or percentage of physical memory> \
          -num_threads_per_disk=<n>}
      ```

   See Additional Impala Configuration Options for more information about these options and other options that you can modify in `env.sh`.

Warning:

The default maximum heap space allocated to the MapR File System file server should provide enough memory for the MapR File System file server to run concurrently with Impala, however you can modify it if needed. To modify the maximum heap space, navigate to `/opt/mapr/conf/warden.conf`, and change the `service.command.mfs.heapsize.maxpercent` parameter. Issue the following command to restart Warden after you modify the parameter:

```
service mapr-warden restart
```

Refer to warden.conf for more Warden configuration information.

3. Verify that the following property is configured in `hive-site.xml` on all the nodes:

```
<property>
        <name>hive.metastore.uris</name>
        <value>thrift://<metastore_server_host>:9083</value>
</property>
```

4. Install the Impala components.
   a) To install the statestore service, issue the following command:

```
$ sudo yum install mapr-impala-statestore
```

   b) To install the catalog service, issue the following command:

```
$ sudo yum install mapr-impala-catalog
```

   c) To install the Impala server, issue the following command:

```
$ sudo yum install mapr-impala-server
```

5. Run `configure.sh` to refresh the node configuration.

```
/opt/mapr/server/configure.sh -R
```

6. If the Hive metastore has MapR-SASL enabled, copy `$HIVE_HOME/conf/hive-site.xml` to `$IMPALA_HOME/conf/`. Repeat this step any time `hive-site.xml` is modified.

At this point, the Impala servers, catalog, and statestore should be running. For instructions on how to run a simple Impala query and how to query MapR Database tables, refer to Example: Running an Impala SQL Query and Query MapR Database and HBase Tables with Impala.

Installing Kafka Schema Registry (Developer Preview)
This topic includes instructions for using package managers to download and install the Kafka Schema Registry from a MapR repository.

Note: This feature is presented as a *developer preview*. Developer previews are not tested for production environments, and should be used with caution.

Because it is a *developer preview* feature, the Kafka Schema Registry is not provided in the EEP 6.1 repository. You must download the packages from https://package.mapr.com/labs/mapr-schema-registry. Using the MapR Installer to install the Kafka Schema Registry is not currently supported.

The Kafka Schema Registry is a service that provides a RESTful interface for storing and retrieving schemas. The Kafka Schema Registry can be installed on one or several nodes. To install the `schema registry` package on a node, run the following commands as `root` or using `sudo`:

1. Install the schema registry package:

   On Ubuntu:

   ```
   apt-get install mapr-schema-registry
   ```

   On RedHat/ CentOS:

   ```
   yum install mapr-schema-registry
   ```

   On SLES:

   ```
   zypper install mapr-schema-registry
   ```

2. Run `configure.sh -R`:

   ```
   /opt/mapr/server/configure.sh -R
   ```

   Note: Because the Kafka Schema Registry is managed by Warden, you don't have to restart Warden after installing the registry. Warden brings up the service after a few minutes.

To manage and administer the Kafka Schema Registry, see Kafka Schema Registry on page 3941.

Installing KSQL
This topic describes how to use package managers to download and install KSQL from the EEP repository.

Note: You cannot upgrade from KSQL 4.1.1. You must uninstall version 4.1.1 and then install the newer version of KSQL.

Preparing for Installation

KSQL is included in EEP repositories beginning with EEP 6.0.0. For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

The default KSQL configuration parameters are stored in `/opt/mapr/ksql/ksql-<version>/etc/ksql`.

KSQL Operational Modes

To install KSQL, you can use the MapR Installer or the manual steps on this page. KSQL can be used in one of two modes:

Mode	Description
Interactive Mode	This mode is non-secure and allows developers to write KSQL queries interactively using the KSQL CLI.
Non-interactive Mode	This mode is more secure than the Interactive mode and is designed for KSQL query production deployment. Since the queries are known ahead of time, you can run non-interactive queries with more restrictive permissions.

Installation steps are the same for both modes. Run the following commands as `root` or using `sudo`.

last-updated: Apr 11, 2022

Install KSQL in Interactive or Non-interactive Mode

You can install the `mapr-ksql` package on as many or as few nodes as you want. Installing on multiple nodes can increase availability of the service.

On Ubuntu:

```
apt-get install mapr-ksql
```

On RedHat/ CentOS:

```
yum install mapr-ksql
```

On SLES:

```
zypper install mapr-ksql
```

Verify KSQL Installation

To confirm successful installation, you can:

- Check for the presence of the KSQL home folder at `/opt/mapr/ksql/ksql-<version>`.
- Perform a test run:
  1. Start the KSQL server:

     ```
     /opt/mapr/ksql/ksql-[version]/bin/ksql-server-start /opt/mapr/ksql/
     ksql-<version>/etc/ksql/ksql-server.properties
     ```

  2. Verify that KSQL is running by making a call to `http://localhost:8084/info`. For example:

     ```
     curl http://localhost:8084/info
     ```

     The expected response is:

     ```
     {"KsqlServerInfo":{"version":"(version)"}}
     ```

Configure KSQL

To configure KSQL, see KSQL Configuration on page 3846.

Installing Kafka Streams

Kafka Streams is a Java library and is part of the `mapr-kafka` package. Kafka Streams does not require special installation steps; however, you must install the `mapr-core` and `mapr-kafka` packages to use Kafka Streams.

Maven Dependency

To compile a Kafka Streams application, you must add the appropriate Maven dependency. Add a mapr maven repository and the Kafka Streams dependency to your `pom.xml` file to pull in the Maven artifacts.

- For Maven repository information and Kafka Streams dependency versions, see Maven Artifacts for MapR on page 4155
- For more information about Maven artifacts and running a Kafka Streams Java application, see Running a Kafka Streams Java App on page 3856.

Example

The following `pom.xml` example may not correlate with the product versions you are installing.

```
<repository>
    <id>mapr-releases</id>
    <url>https://repository.mapr.com/maven/</url>
</repository>
<dependency>
    <groupId>org.apache.kafka</groupId>
    <artifactId>kafka-streams</artifactId>
    <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
    <groupId>org.apache.kafka</groupId>
    <artifactId>kafka-clients</artifactId>
    <version>2.1.1.200-mapr-710</version>
</dependency>
```

Configure Kafka Streams

To configure Kafka Streams, see Kafka Streams Configuration on page 3855.

Installing MapR Event Store For Apache Kafka Clients
This topic includes instructions for using package managers to download and install MapR Event Store For Apache Kafka Clients from the EEP repository.

Note: The MapR Event Store For Apache Kafka Java client is installed with the MapR Client on page 388.

Installing MapR Event Store For Apache Kafka C Client
The MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka.

- For instructions on installing the MapR Client, see Installing the MapR Client on page 389
- For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Installation

As of MapR 6.0.1, the MapR C client is installed as part of the MapR Core installation and the mapr-client package installation. The MapR C client is available on Linux, Mac, and Windows operating systems.

Note: Specific installation is *not* required as of MapR 6.0.1!

For MapR 5.2.1 through MapR 6.0.0, the MapR C client must be installed. The MapR C client is available on Linux and Mac operating systems. As `root` or using `sudo`, install the `mapr-librdkafka` package on nodes where you want to run or build applications.

- On Ubuntu:

  ```
  apt-get install mapr-librdkafka
  ```

- On RedHat/CentOS:

  ```
  yum install mapr-librdkafka
  ```

- On SLES:

```
zypper install mapr-librdkafka
```

- On Mac OS:

1. Download the following TAR file: `https://package.mapr.hpe.com/releases/MEP/<MEP version>/<operating system>/<package>.tar.gz`
2. Extract the TAR file under /opt/mapr:

```
tar -C /opt/mapr/ -zxf <librdkafka_tarFile_location>
```

Note: The `mapr-librdkafka` package pulls in the mapr-client as a dependency if the node does not have the `mapr-client` or `mapr-core` package installed.

Configuration

For MapR 6.0.1 and higher, use the following configuration instructions.

Linux	For Linux installations, add `/opt/mapr/lib` to the end of LD_LIBRARY_PATH. `export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib`
Mac	For Mac installations, add `/opt/mapr/lib` to the end of DYLD_LIBRARY_PATH. `export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib`
Windows	For Windows installations, no additional configuration is required. Link your application and run your programs against the MapR Data Platform Client dynampic link libraries (dll) located at: `C:\opt\mapr\lib`. The corresponding librdkafka header is `C:\opt\mapr\include\librdkafka`.

Attention: For MapR 6.0.0 and earlier, see Configuring the MapR Event Store For Apache Kafka C Client on page 2796 for instructions on configuring the client.

Installing MapR Event Store For Apache Kafka Python Client
The MapR Event Store For Apache Kafka Python Client is a binding for librdkafka that is dependent on the MapR Event Store For Apache Kafka C client (MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka).

Prerequisites

Note: As of MapR 5.2.1, you can create Python client applications for MapR Event Store For Apache Kafka.

Verify that the following components are installed on the node:

- MapR Event Store For Apache Kafka C Client (mapr-librdkafka)

last-updated: Apr 11, 2022

- GNU Compiler Collection (GCC) is installed on the node.
- Python version 2.7.1 and above, up to Python version 3.6.x.
- Python pip
- python-devel (This is required for nodes with the Linux operating system.)

Note: For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Important: Because the MapR Event Store For Apache Kafka Python Client is dependent on the MapR Event Store For Apache Kafka C Client, you must configure the MapR Event Store For Apache Kafka C Client before using the MapR Event Store For Apache Kafka Python Client. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.

Installation

Note: The Python client is available for Linux or Mac operating systems.

To install the MapR Event Store For Apache Kafka Python Client using the Python Software Foundation, run the following command as `root` or using `sudo`:

- On Linux:

```
pip
install --global-option=build_ext --global-option="--library-dirs=/opt/
mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

- On Mac:

```
pip
install --user --global-option=build_ext --global-option="--library-dirs=/
opt/mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

Note: The referenced package works on nodes with the Linux or the Mac operating system. The Python Client for MapR Event Store For Apache Kafka is *not* supported on Windows.

Alternatively, you can install the MapR Event Store For Apache Kafka Python Client via the MapR package repository:

```
https://package.mapr.hpe.com/releases/MEP/<MEP version>/mac/
mapr-streams-python-<version>.tar.gz
```

Troubleshooting Mac OS Installation

If you install the MapR Event Store For Apache Kafka Python Client on a Mac without the `--user` flag, you may encounter a "Not Permitted" error, signifying that you don't have permission to create a LICENSE file. The error will look similar to the following:

```
Copying LICENSE -> /System/Library/Frameworks/Python.framework/Versions/2.7/
                error: [Error 1] Operation not permitted:
                '/System/Library/Frameworks/Python.framework/Versions/2.7/
LICENSE'
```

To fix this issue, execute the following steps. These steps apply to users with a new Mac OS Sierra version 10.12.5.

1. Reboot your Mac while simultaneously holding the **Command** and **R** keys to go into Mac OS X Recovery mode.
2. Select **Utilities**, and then **Terminal**.
3. Type `csrutil disable`. A message will pop up, informing you that your System Integrity Protection (SIP) has been sucessfully disabled.
4. Reboot your Mac again.
5. Go into the Terminal and execute the following command as the `root` user:

```
pip
install --global-option=build_ext  --global-option="--library-dirs=/opt/
mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

6. Once the script runs successfully, reboot your Mac while holding the **Command** and **R** keys. You will go into Mac OS X Recovery mode.
7. Select **Utilities**, and then **Terminal**.
8. Type `csruntil enable` to enable your SIP.

Note: To avoid this error, consider using a virtual Python environment or the `--user` flag.

Installing MapR Event Store For Apache Kafka C#/.NET Client
The MapR Event Store For Apache Kafka C#/.NET client is a binding for librdkafka that is dependent on the MapR Event Store For Apache Kafka C client (MapR Event Store For Apache Kafka C Client is a distribution of librdkafka that works with MapR Event Store For Apache Kafka).

Note: As of MapR 6.0.1/ EEP 5.0, you can create C#/.NET client applications for MapR Event Store For Apache Kafka.

Requirements

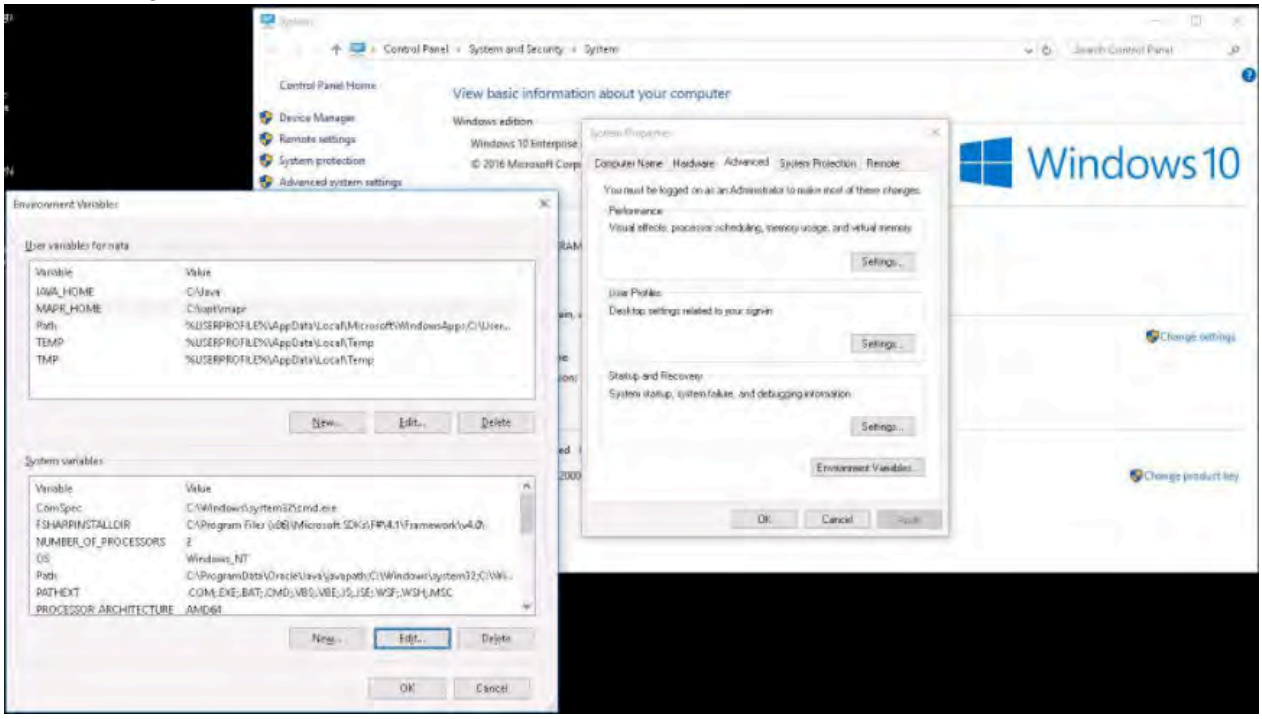
Verify that the following components are installed on the node:

- MapR Client on Windows 7 (or higher) x64 operating systems
- MapR cluster version 6.0.1 or greater
- Java 8 SDK and set Java HOME
- MapR Event Store For Apache Kafka C Client (mapr-librdkafka 0.11.3)
- MapR Event Store For Apache Kafka C#/.NET Client (mapr-streams-dotnet)
- .NET SDK 4.5.x or 4.6.x or .NET Core SDK 1.1
- nuget.exe

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

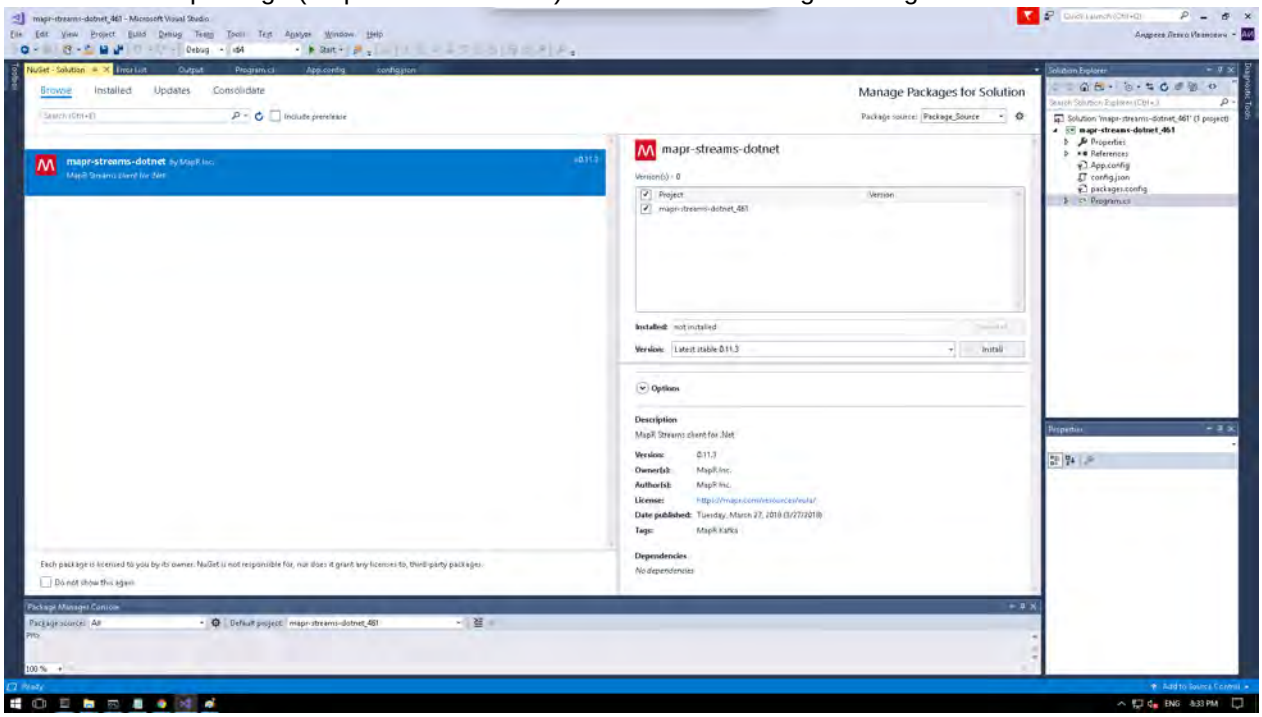
Important: Because the MapR Event Store For Apache Kafka C#/.NET Client is dependent on the MapR Event Store For Apache Kafka C Client, you must configure the MapR Event Store For Apache Kafka C Client before using the MapR Event Store For Apache Kafka C#/.NET Client. See Configuring the MapR Event Store For Apache Kafka C Client on page 2796.

The following screenshot shows the Environment Variables on Windows:



Installing on Windows

To install from the Visual Studio, search for the MapR Event Store For Apache Kafka C#/.NET package (mapr-streams-dotnet) in the NuGet Package Manager UI.



To install from PowerShell:

1. Run the following command in the Package Manager Console:

```
Install-Package mapr-streams-dotnet -<version>
```

To add the package initial in .NET Core:

1. Create the application, for example: `dotnet new console`
2. Add the C#/.NET Client package, for example: `dotnet add package mapr-streams-dotnet`
3. Add a dependency in your **.csproj** file:

```
<ItemGroup>
<PackageReference Include="mapr-streams-dotnet" Version="<version
number>" />
</ItemGroup>
```

Installing MapR Event Store For Apache Kafka Tools
This topic includes instructions for using package managers to download and install MapR Event Store For Apache Kafka Tools from the EEP repository.

Note: For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176

To install manually, first run the following commands as `root` or using `sudo`.

- On RedHat/Centos:

```
yum install <package_name>
```

- On Ubuntu:

```
apt-get install <package_name>
```

- On SLES:

```
zypper install <package_name>
```

After you install the Kafka tools, configure the Kafka components by running `configure.sh -R` on each node where you installed the Kafka tools:

```
/opt/mapr/server/configure.sh -R
```

Table

Package	Description
mapr-kafka	The core Kafka package. Required for MapR Event Store For Apache Kafka and other Kafka components for MapR Event Store For Apache Kafka.
mapr-ksql	The KSQL for MapR Event Store For Apache Kafka package.
mapr-schema-registry	The Schema Registry for MapR Event Store For Apache Kafka package.

last-updated: Apr 11, 2022

Table (Continued)

Package	Description
mapr-kafka-rest	The Kafka REST Proxy for MapR Event Store For Apache Kafka package.
mapr-kafka-connect-jdbc	The JDBC connect package for Kafka Connect for MapR Event Store For Apache Kafka.
mapr-kafka-connect-hdfs	The HDFS connect package for Kafka Connect for MapR Event Store For Apache Kafka.

Kafka REST Proxy for MapR Event Store For Apache Kafka

The following packages are required for Kafka REST Proxy for MapR Event Store For Apache Kafka:

- mapr-kafka
- mapr-kafka-rest
- mapr-client

Note: Before manually installing, verify that the **/opt/mapr/conf/daemon.conf** file exists and contains the mapr user and group.

Note: After installation, the Warden process automatically detects the configuration and starts the Kafka REST Proxy for MapR Event Store For Apache Kafka service on port 8082. This service is viewable on the Control System.

Note: The Kafka REST Proxy for MapR Event Store For Apache Kafka service can be run on multiple cluster nodes simultaneously.

Kafka Connect for MapR Event Store For Apache Kafka

The following packages are required for Kafka Connect for MapR Event Store For Apache Kafka:

- mapr-kafka
- mapr-kafka-connect-jdbc
- mapr-kafka-connect-hdfs

Note: The Kafka Connect for MapR Event Store For Apache Kafka service can be run on multiple cluster nodes simultaneously.

Installing MapR Data Access Gateway

This topic includes instructions for using package managers to download and install the MapR Data Access Gateway from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

The MapR Data Access Gateway is included in EEP repositories beginning with EEP 5.0.0. The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster. For EEP 6.0.0, the MapR Database JSON REST API and Python OJAI client use this service.

In the MapR Installer, the gateway is not visible as a unique service but is installed when the MapR DataBase service is selected and can also be installed manually using this procedure. The gateway should be installed on at least two nodes, if possible, but not on CLDB or Zookeeper nodes. It is recommended to install the service on the same node as the gateway server.

last-updated: Apr 11, 2022

Run the following commands as `root` or using `sudo`.

1. Install the MapR Data Access Gateway package:

   On Ubuntu:

   ```
   apt-get install mapr-data-access-gateway
   ```

   On RedHat/ CentOS:

   ```
   yum install mapr-data-access-gateway
   ```

   On SLES:

   ```
   zypper install mapr-data-access-gateway
   ```

2. Run `configure.sh -R`:

   ```
   /opt/mapr/server/configure.sh -R
   ```

   Note: As the MapR Data Access Gateway is managed by Warden, you don't have to restart Warden after installing the gateway. Warden brings up the service after a few minutes.

To manage and administer the gateway, see Administering the MapR Data Access Gateway on page 1492.

To learn more about the gateway, see Understanding the MapR Data Access Gateway on page 750.

Installing Livy

This topic includes instructions for using package managers to download and install Livy from the EEP repository.

For instructions to set up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Run the following commands as `root` or using `sudo`:

1. Install the mapr-livy package:

   RedHat/CentOS

   ```
   # yum install mapr-livy
   ```

   SLES

   ```
   # zypper install mapr-livy
   ```

   Ubuntu

   ```
   # apt-get install mapr-livy
   ```

2. Run the configure.sh script with the following command to configure the Livy role for the node:

   ```
   /opt/mapr/server/configure.sh -R
   ```

Installing S3 Gateway

The S3 Gateway is an object storage server that can be used with the Amazon S3 cloud storage service.

Notice: The S3 gateway is included in EEP 6.0.0 - EEP 8.0.0 repositories.

This topic provides instructions for manually installing the S3 gateway version 1.0.x on an Edge node or on a server node (for example, a MapR cluster node) that is running MapR software.

The S3 gateway has two packages:

Package Name	Description
`mapr-objectstore-client`	The binary package.
`mapr-objectstore-gateway`	The role package that includes Warden configuration information.

Note: You cannot install the S3 gateway with the MapR Installer.

Requirements

The S3 gateway has the following requirements:

- A working MapR cluster. Connecting to a MapR cluster requires either `mapr-core` or `mapr-client`, depending on the node type. A server node must have `mapr-core` installed. An Edge node must have `mapr-client` installed.
- For Ubuntu only, install the `syslinux-utils` package:

```
sudo apt install syslinux-utils
```

- For Zypper only, install the `libcap-progs` package:

```
sudo zypper install libcap-progs
```

- A POSIX client must be installed and configured on each node where the S3 gateway will be used.
- JDK version 8 or higher.

Installing and Configuring a POSIX client for the S3 gateway

Note: The following instructions install the POSIX client (for a basic license) and JDK 8. If JDK 8 is already installed, omit it when you run the installation command. For more information about POSIX, see Installing FUSE-based POSIX Client Packages on page 400.

1. To install the POSIX client and JDK 8, run the command appropriate for your system:
   - Ubuntu

     ```
     sudo apt install openjdk-8-jdk-headless mapr-posix-client-basic
     ```

   - RedHat/CentOS

     ```
     sudo yum install java-1.8.0-openjdk.x86_64 mapr-posix-client-basic
     ```

   - SLES

     ```
     sudo zypper install java-1.8.0-openjdk.x86_64 mapr-posix-client-basic
     ```

2. In the `/opt/mapr/conf/fuse.conf` file, set the mount directory and the path to the user ticket.

last-updated: Apr 11, 2022

- `fuse.mount.point` - Use this parameter to set the mount directory. The default setting is `/mapr`.
- `fuse.ticketfile.location` – Use this parameter to set the path to the user ticket.

3. Create a mount directory and set permissions, as shown:

```
mkdir -m 777 /mapr
```

4. Start the MapR Posix service:

```
sudo systemctl start
mapr-posix-client-basic.service
```

5. Verify that the MapR cluster is mounted to the `/mapr` directory:

```
ls -la /mapr
```

You should see a directory with the MapR cluster name and cluster data inside. By default, the directory is `'my.cluster.com'` unless you define a different name for the cluster, for example:

```
ls -la /mapr/
total 1
drwxr-xr-x 7 mapr mapr 6 Feb 16 18:06 example.mapr.cluster
```

Edge Node Installation
An Edge node must have the `mapr-client` installed before you install the S3 gateway.

Run commands as `root` or using `sudo`.

To install the S3 gateway on an Edge node, complete the following steps:

1. Configure the repositories for MapR core and EEP components:
   - Ubuntu

     ```
     sudo add-apt-repository 'deb
     <link-to-release-repository>
     binary trusty' -y
     sudo add-apt-repository 'deb
     <link-to-mep-repository> binary
     trusty' -y
     ```

   - RedHat/CentOS

     See Adding the MapR Repository on RHEL, CentOS, or Oracle Linux on page 143.

   - SLES

     See Adding the MapR Repository on SUSE on page 144.

2. Update the repositories on the Edge node:
   - Ubuntu

     ```
     sudo apt-get update
     ```

- RedHat/CentOS

```
sudo yum clean all
sudo yum makecache --refresh
```

- SLES

```
sudo zypper ref
```

3. To install the S3 gateway, run the command appropriate for your system:
   - Ubuntu

```
sudo apt install
mapr-objectstore-client
```

   - RedHat/CentOS

```
sudo yum install
mapr-objectstore-client
```

   - SLES

```
sudo zypper install
mapr-objectstore-client
```

4. Run the `/opt/mapr/objectstore-client/objectstore-client-x.x.x/bin/configure.sh` script to configure the S3 gateway:

```
sudo /opt/mapr/objectstore-client/
objectstore-client-<version>/bin/
configure.sh -c -u
<userName> -g <groupName> --path /
path/to/filesystem/

#In this command:
-c is the client node with the
objectstore-client.
-u(--user) is the user
admin for working with the
objectstore-client.
-g(--group) is the group.
-p(--path) is the path for
mounting the filesystem.
```

5. To start the S3 gateway, run the `objectstore.sh` script:

```
sudo /opt/mapr/objectstore-client/
objectstore-client-<version>/bin/
objectstore.sh start
```

6. Verify that the S3 gateway process is running:

```
sudo /opt/mapr/objectstore-client/
objectstore-client-<version>/bin/
objectstore.sh status
```

When the S3 gateway is running, the system returns: `Minio is running`

7. Configure the S3 gateway. See Configuring S3 Gateway on page 3961 for instructions.

To delete the S3 gateway on an Edge node, complete the following steps:

1. Stop the S3 gateway service:

```
sudo /opt/mapr/objectstore-client/
objectstore-client-<version>/bin/
objectstore.sh stop
```

2. Delete the packages from the system:
   - Ubuntu

```
sudo apt remove
mapr-objectstore-client --purge
```

   - RedHat/CentOS

```
sudo yum remove
mapr-objectstore-client
```

   - SLES

```
sudo zypper remove
mapr-objectstore-client
```

Server Node Installation

A server in this context refers to a node in a MapR cluster. A server node must have `mapr-core` installed before you can install the S3 gateway.

Run commands as a user with admin privileges on the cluster.

To install the S3 gateway on a server, complete the following steps:

1. Verify that the following requirements are met:
   - MapR software is installed on the server, and the EEP 6.x repositories are configured. For more information about configuring repositories, see Step 2: Prepare Packages and Repositories on page 142.
   - The MapR POSIX client is installed.
   - For Ubuntu clusters, you must install `syslinux-utils`:

```
sudo apt install syslinux-utils
```

- To support impersonation in SLES clusters, you must install the `libcap-progs` library:

```
sudo zypper install libcap-progs
```

2. Update the repositories:
   - Ubuntu

```
sudo apt-get update
```

   - RedHat/CentOS

```
sudo yum clean all
sudo yum makecache --refresh
```

   - SLES

```
sudo zypper ref
```

3. To install the S3 gateway, run the command appropriate for your system:
   - Ubuntu

```
sudo apt install
mapr-objectstore-gateway
mapr-objectstore-client
```

   - RedHat/CentOS

```
sudo yum install
mapr-objectstore-gateway
mapr-objectstore-client
```

   - SLES

```
sudo zypper install
mapr-objectstore-gateway
mapr-objectstore-client
```

4. To configure Warden, use `configure.sh` on the first run:

```
sudo /opt/mapr/server/
configure.sh -R
```

5. Verify that the S3 gateway process is running:

```
sudo /opt/mapr/objectstore-client/
objectstore-client-<version>/bin/
objectstore.sh status
```

When the S3 gateway is running, the system returns: `Minio is running`

6. Configure the S3 gateway. See Configuring S3 Gateway on page 3961 for instructions.

To delete the S3 gateway on a Server node, complete the following steps:

1. Stop the objectstore service:

```
/opt/mapr/bin/maprcli node
services -name objectstore -nodes
<node_name> -action stop
```

2. Delete the packages from the system:
   - Ubuntu

```
sudo apt remove
mapr-objectstore-gateway --purge

sudo apt remove
mapr-objectstore-client --purge
```

   - RedHat/CentOS

```
sudo yum remove
mapr-objectstore-gateway
sudo yum remove
mapr-objectstore-client
```

   - SLES

```
sudo zypper remove
mapr-objectstore-gateway
sudo zypper remove
mapr-objectstore-client
```

For More Information

To use the S3 gateway, see these topics:

- S3 Gateway on page 3959
- Configuring S3 Gateway on page 3961
- AWS CLI

For more information about S3 commands, see the Amazon S3 Documentation.

Uninstalling the S3 Gateway
Describes how to stop the Object Store service and remove the packages for an edge node or server node.

Uninstalling from an Edge Node

To uninstall the S3 gateway from an edge node, you must stop the service and then delete the package from the node:

1. Stop the S3 gateway service:

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
objectstore.sh stop
```

2. Delete the packages from the system:
   - Ubuntu

```
sudo apt remove mapr-objectstore-client --purge
```

   - RedHat/CentOS

```
sudo yum remove mapr-objectstore-client
```

   - SLES

```
sudo zypper remove mapr-objectstore-client
```

Uninstalling from a Server Node

To uninstall the S3 gateway from a server node, you must stop the service and then delete the packages from the node:

1. Stop the S3 gateway service:

```
/opt/mapr/bin/maprcli node services -name objectstore -nodes
node_name -action stop
```

2. Delete the packages from the system:
   - Ubuntu

```
sudo apt remove mapr-objectstore-gateway --purge
sudo apt remove mapr-objectstore-client --purge
```

   - RedHat/CentOS

```
sudo yum remove mapr-objectstore-gateway
sudo yum remove mapr-objectstore-client
```

   - SLES

```
sudo zypper remove mapr-objectstore-gateway
sudo zypper remove mapr-objectstore-client
```

Installing Myriad

Describes Myriad requirements and installation.

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

The following table specifies the Myriad installation requirements.

Table

Requirement	Description
Operating Systems	• RedHat/CentOS 6.2, 6.6, and 7.0 • Ubuntu 14.04
Myriad Requirements	• JDK 7 or 8
MapR Minimum Requirements	• MapR Core • MapR Zookeeper • MapR CLDB • MapR FileServer • MapR Webserver

The following table specifies the ports used by Myriad.

Table

Application	Port
Mesos Master UI	http://<hostname>:5050
Marathon UI	http://<hostname>:8080
Myriad UI	http://<hostname>:8192 **Note:** The Myriad UI is available once a Resource Manager is launched.

Note: If your environment has both Marathon and Spark installed on the same node, a conflict occurs because the default port for both is 8080. To resolve this conflict, change the port for one of the applications.

The Myriad installation is a manual installation where Apache Mesos is installed before MapR Myriad.

1. Download and build Mesos and (optionally) Marathon. See http://mesos.apache.org/getting-started/ for Mesos and https://mesosphere.github.io/marathon/docs/ for Marathon.

   Important: Install Apache Mesos on all node where resources will be shared. In addition, at least one (1) node should be running both Primary and Secondary installations and one (1) node running only Secondary installation.

2. Download and deploy MapR Myriad.
   a) Download the Myriad 0.2 tarball. See for more information.

   b) Myriad 0.2-1710 Release Notes on page 6265Extract Myriad from the tarball.

   ```
   tar -zxf mapr-myriad-0.2.tar.gz
   ```

last-updated: Apr 11, 2022

c) Deploy Myriad and configuration files.

```
mkdir -p /opt/mapr/hadoop/hadoop-{HADOOP_VERSION}/share/hadoop/
myriad/lib
ln -sf {PROJECT_HOME}/libs/* {HADOOP_HOME}/share/hadoop/myriad/lib
ln -sf {PROJECT_HOME}/conf/* {HADOOP_HOME}/etc/hadoop/
```

3. On the Mesos primary node, install (as a minimum) Apache Mesos and the following MapR packages:

```
mapr-core
mapr-fileserver
mapr-cldb
mapr-webserver
```

On RedHat / CentOS	`yum -nogpgcheck install <package> <package> ...`
On Ubuntu	`apt-get install <package> <package> ...`

4. Install MapR Zookeeper on its primary node:

   The MapR `mapr-zookeeper` package can be installed on any node that is designated as its primary node. For example, on the Mesos master node:

```
mapr-zookeeper
```

5. (optional) Install Mesos-DNS on its master node:

   Mesos-DNS can be installed on any node that is designated as its master. For example, on the Mesos master node. See https://github.com/mesosphere/mesos-dns/tree/master/docs.

6. On the Mesos secondary nodes, install (as a minimum) Apache Mesos and the following MapR packages.

```
mapr-core
mapr-fileserver
```

Small Cluster Installation

The following example shows an installation on a CentOS6 operating system, a three (3) node cluster where one node is the master node for Mesos, Mesos-DNS, MaprR CLDB, and MapR Zookeeper, and two nodes are Mesos secondary nodes.

Download and build Mesos on all nodes.

Unpack and install Myriad from the tarball.

On the master node, install (as a minimum) Apache Mesos and the following MapR packages:

```
yum -nogpgcheck install
mapr-core mapr-fileserver mapr-zookeeper mapr-cldb mapr-webserver
```

last-updated: Apr 11, 2022

On the two Mesos secondary nodes, install (as a minimum) Apache Mesos and the following MapR packages:

```
yum -nogpgcheck install
mapr-core mapr-fileserver
```

See Configure Myriad.

Installing Oozie
This topic includes instructions for using package managers to download and install Oozie from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

The Oozie client/server architecture requires you to install two packages, `mapr-oozie` and `mapr-oozie-internal`, on the client node and the server node. `mapr-oozie` is dependent on `mapr-oozie-internal. mapr-oozie-internal` is automatically installed by the package manager when you install `mapr-oozie`.

Execute the following commands as `root` or using `sudo` on a MapR cluster:

1. Install `mapr-oozie` and `mapr-oozie-internal`:

   RedHat/CentOS

   ```
   yum install mapr-oozie mapr-oozie-internal
   ```

   SLES

   ```
   zypper install mapr-oozie mapr-oozie-internal
   ```

   Ubuntu

   ```
   apt-get install mapr-oozie mapr-oozie-internal
   ```

2. For non-secure clusters, add the following two properties to `core-site.xml` located in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/core-site.xml`:

   ```
   <property>
     <name>hadoop.proxyuser.mapr.hosts</name>
     <value>*</value>
   </property>
   <property>
     <name>hadoop.proxyuser.mapr.groups</name>
     <value>*</value>
   </property>
   ```

3. Restart the YARN services. For YARN mode, restart NodeManager and ResourceManager:

   ```
   maprcli node services -name nodemanager -action restart -nodes <space
   delimited list of nodes>
   maprcli node services -name resourcemanager -action restart -nodes
   <space delimited list of nodes>
   ```

4. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

5. On client or edge nodes installed with EEP 6.3.1 or EEP 7.0.0 or later, run the following `configure.sh` command:

   For secure clusters, use:

```
/opt/mapr/oozie/oozie-5.1.0/bin/configure.sh -R -c --secure
```

   For non-secure clusters, use:

```
/opt/mapr/oozie/oozie-5.1.0/bin/configure.sh -R -c --unsecure
```

6. Export the Oozie URL to your environment:

   For secure clusters, use the following `export` command, and specify the `oozie_port_number` as `11443`:

```
export OOZIE_URL='<https://<Oozie_node>:<oozie_port_number>/oozie>'
```

   For non-secure clusters, use the following `export` command, and specify the `oozie_port_number` as `11000`:

```
export OOZIE_URL='<http://<Oozie_node>:<oozie_port_number>/oozie>'
```

7. Check the Oozie status with the following command:

```
/opt/mapr/oozie/oozie-<version>/bin/oozie admin -status
```

8. If high availability for the Resource Manager is configured, edit the `job.properties` file for each workflow and insert the following statement

```
JobTracker=maprfs:///
```

9. If high availability for the Resource Manager is not configured, provide the address of the node running the active ResourceManager and the port used for ResourceManager client RPCs (port 8032). For each workflow, edit the `job.properties` file and insert the following statement:

```
JobTracker=<ResourceManager_address>:8032
```

10. Restart Oozie:

```
maprcli node services -name oozie -action restart -nodes <space
delimited list of nodes>
```

Note: If high availability for the Resource Manager is not configured and the ResourceManager fails, you must update the `job.properties` with the active ResourceManager.

Installing Pig

This topic includes instructions for using package managers to download and install Pig from the EEP repository.

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

On a MapR cluster, execute the following commands as `root` or using `sudo`:

1. On each planned Pig node, install `mapr-pig`:

Ubuntu	`apt-get install mapr-pig`
RedHat/ CentOS	`yum install mapr-pig`
SLES	`zypper install mapr-pig`

2. Make sure the `JAVA_HOME` environment variable is set correctly. For example:

```
# export JAVA_HOME=/usr/lib/jvm/java-<version>-sun
```

Installing Sentry

This topic includes instructions for using package managers to download and install Sentry from the EEP repository.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Set up the EEP repository, if you have not done so. For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Install Sentry as `root` or using `sudo`.

On the nodes designated to run Sentry, install `mapr-sentry`:

- On Ubuntu:

```
apt-get install mapr-sentry
```

- On RedHat/CentOS:

```
yum install mapr-sentry
```

- On SLES:

```
zypper install mapr-sentry
```

Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

To set up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Spark is distributed as four separate packages:

Package	Description
`mapr-spark`	Install this package on any node where you want to install Spark. This package is dependent on the `mapr-client` package.
`mapr-spark-master`	Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the `mapr-spark` and the `mapr-core` packages.
`mapr-spark-historyserver`	Install this optional package on Spark History Server nodes. This package is dependent on the `mapr-spark` and `mapr-core` packages.
`mapr-spark-thriftserver`	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the `mapr-spark` and `mapr-core` packages.

Run the following commands as `root` or using `sudo`.

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

Note: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

On CentOS / Red Hat

```
yum install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

On Ubuntu

```
apt-get install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

On SLES

```
zypper install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

Note: The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

Spark is installed into the `/opt/mapr/spark` directory.

last-updated: Apr 11, 2022

3. For Spark 2.x:

   Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

   For example:

   ```
   localhost
   worker-node-1
   worker-node-2
   ```

4. Set up passwordless ssh for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x .

5. As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.

   For Spark 2.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
   ```

6. If you want to integrate Spark with MapR Event Store For Apache Kafka, install the Streams Client on each Spark node:

   - On Ubuntu:

     ```
     apt-get install mapr-kafka
     ```

   - On RedHat/CentOS:

     ```
     yum install mapr-kafka
     ```

7. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.11.jar` from the MapR Data Platform Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

8. After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at Configuring Spark Standalone on page 4030.

Installing Spark on YARN

This topic describes how to use package managers to download and install Spark on YARN from the EEP repository.

To set up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Spark is distributed as three separate packages:

Package	Description
`mapr-spark`	Install this package on each node where you want to install Spark. This package is dependent on the `mapr-client` package.
`mapr-spark-historyserver`	Install this optional package on Spark History Server nodes. This package is dependent on the `mapr-spark` and `mapr-core` packages.

Package	Description
`mapr-spark-thriftserver`	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the `mapr-spark` and `mapr-core` packages.

To install Spark on YARN (Hadoop 2), execute the following commands as `root` or using `sudo`:

1. Verify that JDK 1.7 or later is installed on the node where you want to install Spark.
2. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory:

   ```
   hadoop fs -mkdir /apps/spark
   hadoop fs -chmod 777 /apps/spark
   ```

   Note: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.
3. Install the packages:

   On Ubuntu

   ```
   apt-get install
   mapr-spark mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

   On CentOS / Red Hat

   ```
   yum install mapr-spark
   mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

   On SLES

   ```
   zypper install
   mapr-spark mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

   Note: The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.
4. If you want to integrate Spark with MapR Event Store For Apache Kafka, install the Streams Client on each Spark node:
   - **On Ubuntu:**

     ```
     apt-get install mapr-kafka
     ```

   - **On CentOS / Red Hat**:

     ```
     yum install mapr-kafka
     ```
5. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.11.jar` from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

   For repository-specific information, see Maven Artifacts for MapR on page 4155

6. After installing Spark on YARN but before running your Spark jobs, follow the steps outlined at Configuring Spark on YARN on page 4033.

Installing Spark on Mesos
This section includes instructions to download and install Apache Spark on Apache Mesos.

The MapR distribution of Spark on Mesos is only certified on CentOS.

Spark 2.1.0 runs with Apache Mesos 1.0.0 or later. You do not need to apply any special patches of Mesos. If you are already running a Mesos cluster, you can skip this topic.

Install Mesos following the instructions at Getting Started with Mesos.

Note: If you are building Mesos, execute the build steps as user 'mapr'. Also change the owner of the directory where you have unpacked the Mesos archive to user and group 'mapr'.

```
cd /path/to/mesos
sudo chown -R mapr:mapr /path/to/mesos
```

Installing Sqoop1
This topic includes instructions for using package managers to download and install Sqoop1 from the EEP repository.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Execute the following commands as `root` or using `sudo:`

On each planned Sqoop node, install `mapr-sqoop`:

On Ubuntu	`apt-get install mapr-sqoop`
On RedHat / CentOS	`yum install mapr-sqoop`
On SLES	`zypper install mapr-sqoop`

Installing Sqoop2
This topic includes instructions for using package managers to download and install Sqoop2 from the EEP repository.

For instructions on setting up the EEP repository, see Step 10: Install Ecosystem Components Manually on page 176.

Sqoop2 includes two packages:

- The client package, `mapr-sqoop2-client` (install on each node that will act as a client)
- The server package, `mapr-sqoop2-server` (install on at least one node in the cluster)

The Sqoop2 server also acts as a MapReduce client, so each node where you install the `mapr-sqoop2-server` package must also have Hadoop installed and configured. If you have a lot of client users, you can install multiple servers on multiple nodes, so as not to overload a single server.

Warning: Sqoop2 packages cannot be installed on the same nodes as Sqoop1 packages. However, you can use both versions in the same Hadoop cluster by installing Sqoop1 and Sqoop2 on different nodes.

Execute the following commands as `root` or using `sudo`:

1. On each Sqoop2 server node, install `mapr-sqoop2-server`:

On Ubuntu	`apt-get install mapr-sqoop2-server`
On RedHat and CentOS	`yum install mapr-sqoop2-server`
On SLES	`zypper install mapr-sqoop2-server`

2. On each Sqoop2 client node, install `mapr-sqoop2-client`:

On Ubuntu	`apt-get install mapr-sqoop2-client`
On RedHat and CentOS	`yum install mapr-sqoop2-client`
On SLES	`zypper install mapr-sqoop2-client`

3. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

4. Start each Sqoop server node.

```
maprcli node services -name sqoop2 -action start -nodes <space delimited
list of nodes>
```

Step 11: Run configure.sh
Run `configure.sh` with the `-R` option to complete the configuration of ecosystem components that were added manually.

After installing ecosystem components manually, you must run the `configure.sh` script with the `-R` option on each node in the cluster:

```
/opt/mapr/server/configure.sh -R
```

Configuring the Cluster

Describes post-installation configuration tasks for MapR clusters.

After installing MapR core and any desired ecosystem components, you might need to perform additional tasks to ready the cluster for production. To learn more about configuring clusters, see this course.

Configure the OJAI Distributed Query Service on page 182	If you want to use the optional OJAI Distributed Query Service on page 505, you must install Drill and configure and register the service.

last-updated: Apr 11, 2022

Setting up Topology	The locations of nodes and racks in a cluster determine the location of replicated copies of data. Optimally defined cluster topology results in data being replicated to separate racks, providing continued data availability in the event of rack or node failure.
Setting Up Volumes	Keeping volume hierarchy efficient to maximize data availability. Without a volume structure in place, performance will be negatively affected. Referring to the volume plan created in Planning the Cluster, use the Control System or the `maprcli` command to create and mount distinct volumes to allow more granularity in specifying policy for subsets of data. If you do not set up volumes, and instead store all data in the single volume mounted at /, it creates problems in administering data policy later as data size grows.
Setting Up Central Configuration	MapR services can be configured globally across the cluster, from primary configuration files stored in a MapR filesystem, eliminating the need to edit configuration files on all nodes individually.
Designating NICs for MapR on page 844	If multiple NICs are present on nodes, you can configure MapR to use one or more of them, depending on the cluster's need for bandwidth. See Cluster Design Objectives on page 110 for more information.
Setting up NFS	Access data on a licensed MapR cluster, mount the MapR cluster, and use standard shell scripting to read and write live data through NFS, which can be faster than using `hadoop fs` commands.
Configuring Authentication	If you use Kerberos, LDAP, or another authentication scheme, make sure PAM is configured correctly to grant MapR access.
Configuring Permissions	By default, users are able to log on to the Control System, but do not have permission to perform any actions. You can grant specific permissions to individual users and groups.
Setting Usage Quotas	You can set specific quotas for individual users and groups.
Configuring Alarm Notifications	If an alarm is raised on the cluster, MapR sends an email notification. For example, if a volume goes over its allotted quota, MapR raises an alarm and sends an email to the volume creator.
Setting Up the Client and MapR POSIX Client	You can access the cluster either by logging into a node on the cluster, or by installing MapR client software on a machine with access to the cluster's network.
Working with Mirror Volumes	To access multiple clusters or mirror data between clusters, work with mirror volumes.

Installing the File Migration Service on the Edge Cluster

Describes how to install the File Migration service on CentOS nodes.

To install the package on CentOS, run the following command:

```
yum install mapr-filemigrate
```

Note: The File Migration service is only supported on CentOS. There are no packages for Debian-based OS.

Since the File Migration service provides for high availability, you can install it on as many nodes as you wish. Warden will ensure that it is always active on exactly one node.

After installation, a sample properties file, `FileMigrate.properties.default`, with default values is placed in the `/opt/mapr/filemigrate/filemigrate-1.0.0/conf` directory. To manually edit the properties file, follow the steps for Configuring the File Migration Service Using the Properties File on page 1009. Using the UI to configure the service, automatically creates the necessary file in the `maprfs:///var/mapr/filemigrate` directory. For more information, see Configuring File Migration Service Using the UI on page 1007.

last-updated: Apr 11, 2022

Installing the MapR XD Distributed File and Object Store

Describes how to install MapR XD software with or without the MapR Installer.

The steps for installing the MapR XD Distributed File and Object Store are the same as the steps for installing MapR software, with some exceptions as follows.

For more information about the MapR XD, see MapR XD Distributed File and Object Store on page 451.

Before Installing the MapR XD Using the MapR Installer

Regardless of the method you use to install the MapR XD, before installing, you should review the information in these topics:

- MapR Repositories and Packages on page 128
- Preparing Each Node on page 129

Installing the MapR XD Using the MapR Installer

Use these steps to install the MapR XD using the web-based MapR Installer:

1. Download the MapR Installer. See MapR Installer on page 5395.
2. On the **Version & Services** page of the MapR Installer, specify these values:
   - **MapR Version:** 6.1.0 or later.
   - **Edition:** MapR Data Platform Enterprise Edition.
   - **Select Configuration Options:** Select security options as needed.
   - **License Option:** Apply the MapR XD license after the installation completes.
   - **EEP Version:** The EEP version is pre-selected.
   - **Auto-Provisioning Template:** MapR File System and Object Store (MapR XD). You do not need to select any services.
3. Click **Next** to advance through the menus.
4. On the **Monitoring** page, enable metrics collection with either the full or minimum configuration.
5. When the MapR Installer indicates that the installation is complete, go to After Installing a MapR XD Cluster on page 224.

Installing the MapR XD without Using the MapR Installer

Use the following information to install the MapR XD using manual steps.

You can use the manual installation steps described in Installing without the MapR Installer on page 141 to install the MapR 6.0.0 or later packages. Perform all steps unless otherwise indicated. Note the following considerations for some steps:

Step 1	Follow the documented steps.
Step 2	A repository needs to be configured for the Metrics Monitoring components. These components are available in the EEP repository.
Step 3	Install these MapR 6.0.0 or later packages at a minimum:

last-updated: Apr 11, 2022

	• `mapr-core` • `mapr-fileserver` • `mapr-cldb` • `mapr-nfs`[1] • `mapr-mastgateway` • `mapr-webserver` • `mapr-zookeeper` For information about packages and dependencies, see Packages and Dependencies for MapR Software on page 68.
Step 4	Follow the documented steps.
Step 5	Follow the documented steps.
Step 6	Follow the documented steps.
Step 7	Apply the MapR XD license.
Step 8	Complete the steps to install Metrics Monitoring.
Step 9	Installing Log Monitoring is optional.
Step 10	Skip this step. Except for the Metrics Monitoring components, you do not need to install any ecosystem components.
Step 11	Complete this step. Running `configure.sh` with the `-R` option is required.

[1]When you install `mapr-nfs`, NFSv3 is installed. To install NFSv4, you must use the `mapr-nfs4server` package. Neither NSFv3 nor NSFv4 provides security by default. You can configure NFSv4 server to work with Active Directory and Kerberos servers, but you must first install Active Directory and Kerberos servers. For more information, see Configuring NFSv4 Server for Kerberos on page 1209. NFSv3 does not support security. .

After Installing a MapR XD Cluster

After successfully installing the cluster, configure the cluster and set up clients using this information:

- Configuring the Cluster on page 221
- Setting Up Clients and Services on page 385

Installing MapR Data Fabric for Kubernetes

This section describes how to plan for and install the MapR Container Storage Interface (CSI) Storage Plugin and the MapR Data Fabric for Kubernetes FlexVolume Driver.

Getting Started with the MapR Container Storage Interface (CSI) Storage Plugin

This section describes how to plan for, install, and upgrade the MapR Container Storage Interface (CSI) Storage Plugin.

See MapR Container Storage Interface (CSI) Storage Plugin Overview on page 666 for more information.

Planning for the MapR Container Storage Interface (CSI) Storage Plugin
Includes information you should review before installing or using the MapR Container Storage Interface (CSI) Storage Plugin.

For release notes information, see MapR CSI Storage Plugin Release Notes on page 6550.

Downloads (CSI)
Lists the downloads for the MapR Container Storage Interface (CSI) Storage Plugin.

Downloads for the MapR Container Storage Interface (CSI) Storage Plugin are available at these locations:

Site	URL	Contents
Docker Hub	FUSE: • https://hub.docker.com/r/maprtech/csi-kdfplugin • https://hub.docker.com/r/maprtech/csi-kdfprovisioner • https://hub.docker.com/r/maprtech/csi-kdfdriver Loopback NFS: • https://hub.docker.com/r/maprtech/csi-nfsplugin • https://hub.docker.com/r/maprtech/csi-kdfprovisioner • https://hub.docker.com/r/maprtech/csi-nfsdriver	Docker containers for the MapR installation files
GitHub Repository	https://github.com/mapr/mapr-csi	MapR installation and example `.yaml` files: • A **deploy** folder that contains the latest CSI Plugin deployment `.yaml` files in `deploy/kubernetes/fuse` and `deploy/kubernetes/nfs` • An **examples** folder that contains example `.yaml` files • A **build** folder that contains the custom template to build CSI plugin container image

Prerequisites for Installing the MapR Container Storage Interface (CSI) Storage Plugin
Lists the prerequisites for installing and using the MapR Container Storage Interface (CSI) Storage Plugin.

Hardware and Software Requirements

To install and use the MapR Container Storage Interface (CSI) Storage Plugin, you must have the following:

Component	Supported Versions
MapR XD Distributed File and Object Store	6.1.0 or later. For additional version compatibility information, see CSI Version Compatibility on page 5596.
MapR Ecosystem Pack (EEP)	Any EEP supported by MapR 6.1.0 or later. See EEP Support by MapR Core Version.

last-updated: Apr 11, 2022

Component	Supported Versions
Kubernetes Software	1.17 and later*
OS (Kubernetes nodes)	All nodes in the Kubernetes cluster must use the same Linux OS. Configuration files are available to support: • CentOS • RHEL (use CentOS configuration file) • Ubuntu **Note:** Docker for Mac with Kubernetes is not supported as a development platform for containers that use MapR for Kubernetes.
CSI Driver	FUSE and Loopback NFS drivers (implementing the CSI spec with v1.3.0). The download location shows the latest version of the driver.
Sidecar Containers	The CSI plugin pod uses: • `csi-node-driver-registrar` — v1.3.0 • `livenessprobe` — v2.2.0 The CSI provisioner pod uses: • `csi-attacher` — v2.2.0 • `csi-provisioner` — v1.6.0 • `csi-snapshotter` — v3.0.2 • `snapshot-controller` — v3.0.2 • `livenessprobe` — v2.2.0 • `csi-resizer` — v0.5.0
POSIX License	The Basic POSIX client package is included by default when you install MapR for Kubernetes. The Platinum POSIX client can be enabled by specifying a parameter in the pod specification. To enable the Platinum POSIX client package, see Enabling the Platinum Posix Client for MapR Data Fabric for Kubernetes FlexVolume Driver on page 3166. For a comparison of the Basic and Platinum POSIX client packages, see Preparing for Installation (MapR POSIX Client) on page 400.

*Kubernetes alpha features are not supported.

Before You Install

Before installing the MapR Container Storage Interface (CSI) Storage Plugin, note that the installation procedure assumes that the Kubernetes cluster is already installed and functioning normally. In addition:

1. Ensure that all Kubernetes nodes use the same Linux distribution.

   For example, all nodes can be CentOS nodes, or all nodes can be Ubuntu nodes. A cluster with a mixture of CentOS and Ubuntu nodes is not supported.

2. Configure your Kubernetes cluster to allow privileged pods by running the following commands:

```
$ ./kube-apiserver ...  --allow-privileged=true …
```

```
$ ./kubelet ...  --allow-privileged=true ...
```

3. Enable mount propagation to share volumes mounted by one container with other containers in the same pod and other pods on the same node.

   See Mount Propagation for more information.

4. Apply CRDs to your Kubernetes cluster if they are not already present:

   Kubernetes 1.20 and Later

```
kubectl apply -f https://
raw.githubusercontent.com/kubernetes-csi/external-snapshotter/v4.2.1/
client/config/crd/snapshot.storage.k8s.io_volumesnapshotclasses.yaml
kubectl apply -f https://
raw.githubusercontent.com/kubernetes-csi/external-snapshotter/v4.2.1/
client/config/crd/snapshot.storage.k8s.io_volumesnapshotcontents.yaml
kubectl apply -f
https://raw.githubusercontent.com/kubernetes-csi/external-snapshotter/
v4.2.1/client/config/crd/snapshot.storage.k8s.io_volumesnapshots.yaml
```

   Kubernetes 1.19 and Earlier

```
kubectl apply -f https://raw.githubusercontent.com/
kubernetes-csi/external-snapshotter/release-3.0/client/config/crd/
snapshot.storage.k8s.io_volumesnapshotclasses.yaml
kubectl apply -f https://raw.githubusercontent.com/
kubernetes-csi/external-snapshotter/release-3.0/client/config/crd/
snapshot.storage.k8s.io_volumesnapshotcontents.yaml
kubectl apply -f https://raw.githubusercontent.com/
kubernetes-csi/external-snapshotter/release-3.0/client/config/crd/
snapshot.storage.k8s.io_volumesnapshots.yaml
```

   For more information see Snapshot Controller.

5. For OpenShift, install the SecurityContextConstraints by applying `deploy/openshift/csi-scc.yaml` in the `mapr-csi` GitHub repository:

```
oc apply -f deploy/openshift/csi-scc.yaml
```

last-updated: Apr 11, 2022

6. Create the state volume-mount path, and update the CSI driver `yaml`. In prior releases, the state of dynamically provisioned volumes and their snapshots was held in memory. The provisioner would lose this state if the controller pod was restarted or upgraded. After restarts, the provisioner would fail to take snapshots, restore snapshots, resize or clone previously created volumes.

   With the latest version of the CSI driver, the provisioner persists the encrypted state of the dynamically provisioned volumes and their snapshots in a volume on the data-fabric cluster. If the controller pod is restarted, the state is automatically recovered, and operations on previously created volumes work as intended.

   You can change the state volume-mount prefix by updating the `--statevolmountprefix=/path/to/dir` argument in the `mapr-kdfprovisioner` image of the CSI driver `yaml`.

   Note: The directory you specify needs to be read-writable for all users who provision volumes on the data-fabric cluster using CSI drivers:

   ```
   # Create state volume mount path
   hadoop fs -mkdir /apps/k8s
   hadoop fs -chmod 777 /apps/k8s

   # Update csi driver yaml
   --statevolmountprefix=/apps/k8s
   ```

7. Understand the number of volume mounts per node that your application requires. The CSI driver default is 20 volume mounts per node. You can modify the number of volume mounts per node by adjusting the value of the `maxvolumepernode` parameter in the `csi-maprkdf-<version>.yaml` or `csi-maprnfskdf-<version>.yaml` file.

Installing, Uninstalling, and Upgrading the MapR Container Storage Interface (CSI) Storage Plugin
This section describes the steps for installing, uninstalling, and upgrading the MapR Container Storage Interface (CSI) Storage Plugin.

By default, the CSI Driver includes CentOS 8 as the base image. If you want to customize the installation, you can build your own container with a FUSE-based POSIX supported OS. See Building Your Own Container on page 229 for more information.

Installing the CSI Driver

1. Download and install the CSI Driver custom resource definition on the Kubernetes cluster by running the following command:

   ```
   kubectl create -f csi-maprkdf-v<version>.yaml
   ```

   where `<version>` is the driver version being installed.

   FUSE

   ```
   kubectl create -f csi-maprkdf-v<version>.yaml
   ```

   Loopback NFS

   ```
   kubectl create -f csi-maprnfskdf-v<version>.yaml
   ```

   When you run the command to install the CSI Driver, the service accounts, rule-based access controls (RBAC), and the statefulset and daemonset are created on the pods on the Kubernetes cluster.

2. Verify the installation by running the following command.

   ```
   kubectl get pods --all-namespaces -o wide
   ```

After installing, you can use the CSI Driver to statically and dynamically provision and mount a MapR volume. See Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3104 for more information.

Uninstalling the CSI Driver

- To uninstall the CSI driver, run the following command:

  ```
  kubectl delete -f csi-maprkdf-v<version>.yaml
  ```

  where `<version>` is the driver version being installed.

  FUSE

  ```
  kubectl delete -f csi-maprkdf-v<version>.yaml
  ```

  Loopback NFS

  ```
  kubectl delete -f csi-maprnfskdf-v<version>.yaml
  ```

  When you run the command to uninstall, all the pods with the mount provisioned by CSI Driver are removed.

Upgrading the CSI Driver

Online upgrades for the CSI driver are not currently supported. To perform an offline upgrade, use the following steps:

1. Shut down all application pods that have a persistent volume mounted in the HPE Ezmeral Data Fabric.
2. Reapply the new CSI driver `.yaml`, and wait for Kubernetes to restart all the CSI pods:

   ```
   kubectl apply -f csi-maprkdf-<version>.yaml
   ```

3. Restart application pods.

Building Your Own Container

Describes how to build a container using the MapR Container Storage Interface (CSI) Storage Plugin template.

The MapR Container Storage Interface (CSI) Storage Plugin includes a template in the `build` directory to build your own container. The following template shows the MapR Container Storage Interface (CSI) Storage Plugin build for FUSE POSIX with CentOS 8 image. In the example, `<tag>` is the image version (available tags):

```
## FOR FUSE
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
# CentOS Package Build
FROM centos:centos8
LABEL mapr.os=centos8
ENV container docker
# Setup repos and dl prereqs + Mapr Core
COPY mapr.repo /etc/yum.repos.d/
RUN rpm --import http://dl.fedoraproject.org/pub/epel/RPM-GPG-KEY-EPEL-8; \
   rpm --import https://package.mapr.hpe.com/releases/pub/maprgpg.key; \
   rpm --import https://package.mapr.hpe.com/releases/pub/gnugpg.key; \
   yum -y update && yum -y clean all; \
   yum -y install epel-release; \
   sed -i 's/^mirror/#mirror/g' /etc/yum.repos.d/epel.repo; \
   yum install -y mapr-client mapr-posix-client-basic
```

```
mapr-posix-client-platinum && \
   yum -y update && yum clean all && rm -rf /var/cache/yum; \
   mkdir -p /opt/mapr/lib/fusebasic /opt/mapr/lib/fuseplatinum; \
   cp /opt/mapr/lib/libMapRClient_c.so.1 /opt/mapr/lib/fusebasic/
libMapRClient_c.so.0; \
   rm -rf /opt/mapr/lib/libMapRClient_c.so.1
# Add Tini
ENV TINI_VERSION v0.18.0
ADD https://github.com/krallin/tini/releases/download/${TINI_VERSION}/tini /
tini
RUN chmod +x /tini
# Copy utils, driver and set entrypoint
COPY --from=docker.io/maprtech/csi-kdfdriver:<tag> \
    /go/src/plugin/bin/* /opt/mapr/bin/
RUN chmod +x /opt/mapr/bin/csi-kdfplugin; \
   chmod +x /opt/mapr/bin/start-fuse;
WORKDIR /opt/mapr
ENTRYPOINT ["/tini", "--", "bin/csi-kdfplugin"]
```

The template contains the information on the image for setting up the repository, deploying the (Basic, Container, or Platinum) POSIX client, information on the entry point, and Tini for POSIX process management. You can customize the template and build it by running the `docker-custom-build.sh` utility in the `build` directory or by running the `docker build` command with the custom image tag.

The following template shows the MapR Container Storage Interface (CSI) Storage Plugin build for Loopsback NFS with CentOS 8 image. In the example, `<tag>` is the image version (available tags):

```
## FOR NFS

# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved

# CentOS Package Build
FROM centos:centos8
LABEL mapr.os=centos8
ENV container docker
# Setup repos and dl prereqs + Mapr Core
COPY mapr.repo /etc/yum.repos.d/
RUN rpm --import http://dl.fedoraproject.org/pub/epel/RPM-GPG-KEY-EPEL-8; \
    rpm --import https://package.mapr.hpe.com/releases/pub/maprgpg.key; \
    rpm --import https://package.mapr.hpe.com/releases/pub/gnugpg.key; \
    yum -y update && yum -y clean all; \
    yum -y install epel-release; \
    sed -i 's/^mirror/#mirror/g' /etc/yum.repos.d/epel.repo; \
    sed -i 's/^#base/base/g' /etc/yum.repos.d/epel.repo; \
    yum install -y mapr-loopbacknfs; \
    yum clean all && rm -rf /var/cache/yum

# Add Tini
ENV TINI_VERSION v0.18.0
ADD https://github.com/krallin/tini/releases/download/${TINI_VERSION}/tini /
tini
RUN chmod +x /tini

# Copy utils, driver and set entrypoint
COPY --from=docker.io/maprtech/csi-nfsdriver:<tag> \
     /go/src/plugin/bin/* /opt/mapr/bin/
RUN chmod +x /opt/mapr/bin/csi-nfsplugin; \
    chmod +x /opt/mapr/bin/start-loopbacknfs;
WORKDIR /opt/mapr
ENTRYPOINT ["/tini", "--", "bin/csi-nfsplugin"]
```

Installing the HPE Ezmeral CSI Operator
Describes how to download and install the HPE Ezmeral CSI Operator for Kubernetes for deployment in Kubernetes and OpenShift environments.

Overview

The HPE Ezmeral CSI Operator for Kubernetes packages, deploys, and manages HPE Ezmeral CSI Drivers on Kubernetes and OpenShift. After installing the operator and creating a CSI Driver object, you can enable static and dynamic provisioning of persistent volumes on the MapR Data Platform platform.

Installing the Operator in Kubernetes

To install the operator in a Kubernetes environment:

1. Install the Operator Lifecycle Manager (OLM) tool. The OLM allows you to manage the operators running on your cluster:

   ```
   $ curl -sL https://github.com/operator-framework/
   operator-lifecycle-manager/releases/download/v0.17.0/install.sh |
   bash -s v0.17.0
   ```

2. Install the HPE Ezmeral CSI Operator by running the following command:

   ```
   $ kubectl create -f https://operatorhub.io/install/
   hpe-ezmeral-csi-operator.yaml
   ```

   The operator is installed in the `my-hpe-ezmeral-csi-operator` namespace and is usable only from this namespace.

3. After installation, use the following command to watch the operator come up:

   ```
   $ kubectl get csv -n my-hpe-ezmeral-csi-operator
   ```

4. To instantiate the driver object, create a file named `hpe-csi-operator.yaml`, and populate it according to the CSI Driver that is being deployed.

5. Create a CSI Driver object. The operator supports FUSE and Loopback NFS drivers. In the following examples, `<tag>` is the image tag:

   - **HPE Ezmeral CSI Driver (FUSE)**

     ```
     apiVersion: ezmeral.hpe.com/v1
     kind: HPEEzmeralCSIDriver
     metadata:
       name: hpeezmeralcsidriver
       namespace: my-hpe-ezmeral-csi-operator
     spec:
       controllerImage: maprtech/csi-kdfprovisioner:<tag>
       nodeImage: maprtech/csi-kdfplugin:<tag>
       pullPolicy: IfNotPresent
     ```

- **HPE Ezmeral CSI Driver (Loopback NFS)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralNFSCSIDriver
metadata:
  name: hpeezmeralnfscsidriver
  namespace: my-hpe-ezmeral-csi-operator
spec:
  controllerImage: maprtech/csi-kdfprovisioner:<tag>
  nodeImage: maprtech/csi-nfsplugin:<tag>
  pullPolicy: IfNotPresent
```

6. Verify that the HPE Ezmeral CSI Operator and CSI Driver pods are running in the namespace:

```
$ oc get pods -n my-hpe-ezmeral-csi-operator
```

The CSI Driver is now ready to use. To use the CSI Driver to statically and dynamically provision and mount a data-fabric volume, see Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3104.

Installing the Operator in OpenShift

You can install the HPE Ezmeral CSI Operator in the OpenShift environment by using the OpenShift CLI or the web console.

Prerequisites for OpenShift Installation

The HPE Ezmeral CSI Driver needs to run in privileged mode and needs access to host ports in the host network and must be able to mount `hostPath` volumes. Hence, before deploying the HPE Ezmeral CSI Operator on OpenShift, you must create a set of security context constraints (SCCs) to allow the CSI Driver to run with these privileges:

```
curl -sL https://raw.githubusercontent.com/mapr/mapr-csi/master/deploy/
openshift/operator-scc.yaml > hpe-ezmeral-csi-scc.yaml
```

1. Change `my-hpe-ezmeral-csi-driver` to the name of the project (for example, `hpe-ezmeral-csi` below) where the CSI Operator is being deployed:

```
oc new-project hpe-ezmeral-csi --display-name="HPE Ezmeral CSI Drivers
for Kubernetes"
sed -i  's/my-hpe-ezmeral-csi-driver/hpe-ezmeral-csi/g'
hpe-ezmeral-csi-scc.yaml
```

2. Deploy the SCC:

```
oc create -f hpe-ezmeral-csi-scc.yaml
securitycontextconstraints.security.openshift.io/hpe-ezmeral-csi-scc
created
```

Installing the Operator Using the OpenShift CLI

The following steps show an example of operator deployment using `oc`. This example assumes that the SCC has been applied to the project and has `kube:admin` privileges. The example deploys to the `hpe-ezmeral-csi` project, as described in the previous steps.

1. Create an operator group:

```
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: hpe-ezmeral-csi-operator
  namespace: hpe-ezmeral-csi
spec:
  targetNamespaces:
  - hpe-ezmeral-csi
```

2. Create a subscription to the operator:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: hpe-ezmeral-csi-operator
  namespace: hpe-ezmeral-csi
spec:
  channel: stable
  installPlanApproval: Automatic
  name: hpe-ezmeral-csi-operator
  source: certified-operators
  sourceNamespace: openshift-marketplace
```

The operator is now installed on the OpenShift cluster. Creation of the subscription triggers the creation of the InstallPlan and CSV:

3. Display information about the InstallPlan and CSV:

```
oc get installplan -n hpe-ezmeral-csi
NAME            CSV                                  APPROVAL    APPROVED
install-5lmzg   hpe-ezmeral-csi-operator.v<ver>   Automatic   true

oc get csv -n hpe-ezmeral-csi
NAME
DISPLAY                                                  VERSION
REPLACES   PHASE
hpe-ezmeral-csi-operator.v<ver>   HPE Ezmeral Data Fabric CSI Operator
for Kubernetes   <ver>                Succeeded
```

4. Create a CSI Driver object. The operator supports FUSE and Loopback NFS drivers:

   - **HPE Ezmeral CSI Driver (FUSE)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralCSIDriver
metadata:
  name: hpeezmeralcsidriver
  namespace: hpe-ezmeral-csi
spec:
  controllerImage: registry.connect.redhat.com/maprtech/
csi-kdfprovisioner:latest
  nodeImage: registry.connect.redhat.com/maprtech/csi-kdfplugin:latest
  pullPolicy: IfNotPresent
```

- **HPE Ezmeral CSI Driver (LoopbackNFS)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralNFSCSIDriver
metadata:
  name: hpeezmeralnfscsidriver
  namespace: hpe-ezmeral-csi
spec:
  controllerImage: registry.connect.redhat.com/maprtech/
csi-kdfprovisioner:latest
  nodeImage: registry.connect.redhat.com/maprtech/csi-nfsplugin:latest
  pullPolicy: IfNotPresent
```

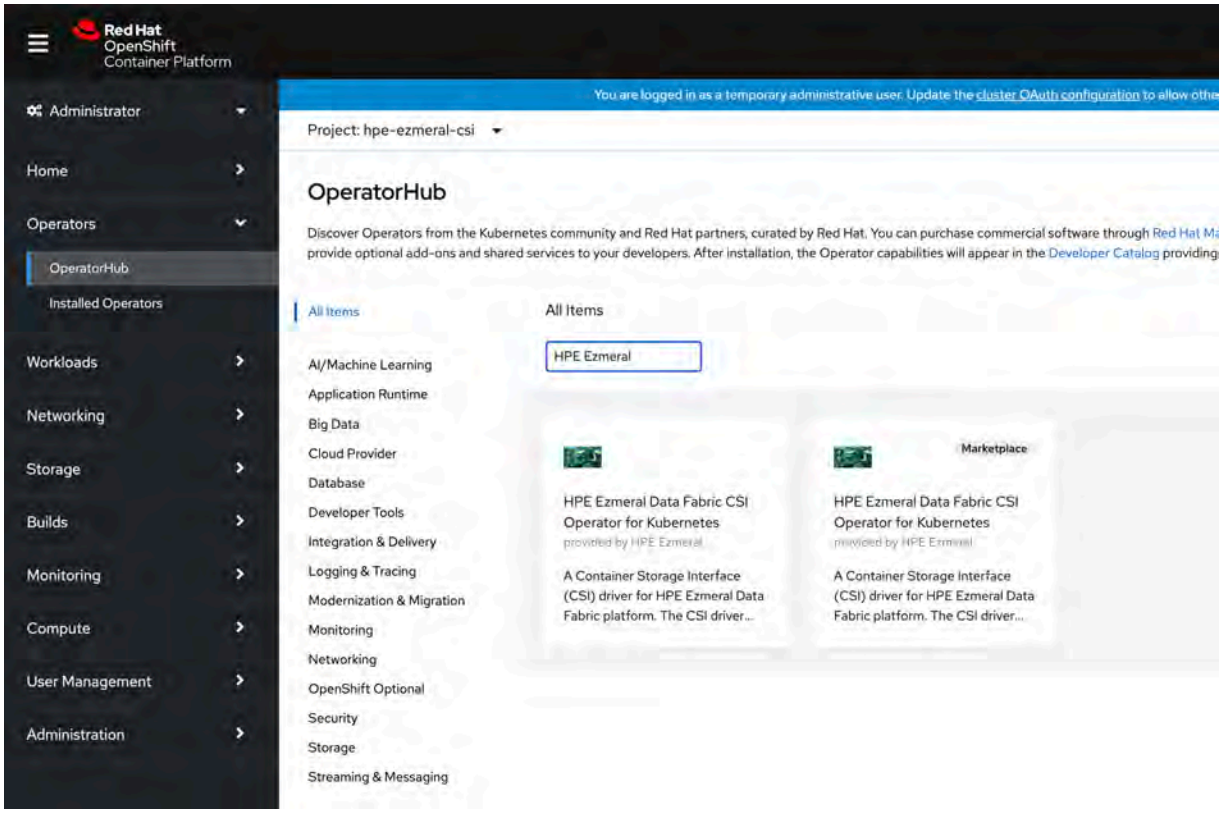
5. Verify that HPE Ezmeral CSI Operator and CSI Driver pods are running in the namespace:

```
# oc get pods -n hpe-ezmeral-csi
NAME                                              READY   STATUS
RESTARTS   AGE
hpe-ezmeral-csi-controller-0                      7/7     Running
0          62s
hpe-ezmeral-csi-driver-operator-9dd887bf7-hdxc9   1/1     Running
0          4m6s
hpe-ezmeral-csi-node-79xw5                        3/3     Running
0          61s
hpe-ezmeral-csi-node-m2gpv                        3/3     Running
0          61s
hpe-ezmeral-csi-node-x25dr                        3/3     Running
0          61s
hpe-ezmeral-nfscsi-controller-0                   7/7     Running
0          29s
hpe-ezmeral-nfscsi-node-hhrhv                     3/3     Running
0          28s
hpe-ezmeral-nfscsi-node-jz5cx                     3/3     Running
0          28s
hpe-ezmeral-nfscsi-node-tvtgm                     3/3     Running
0          28s
```

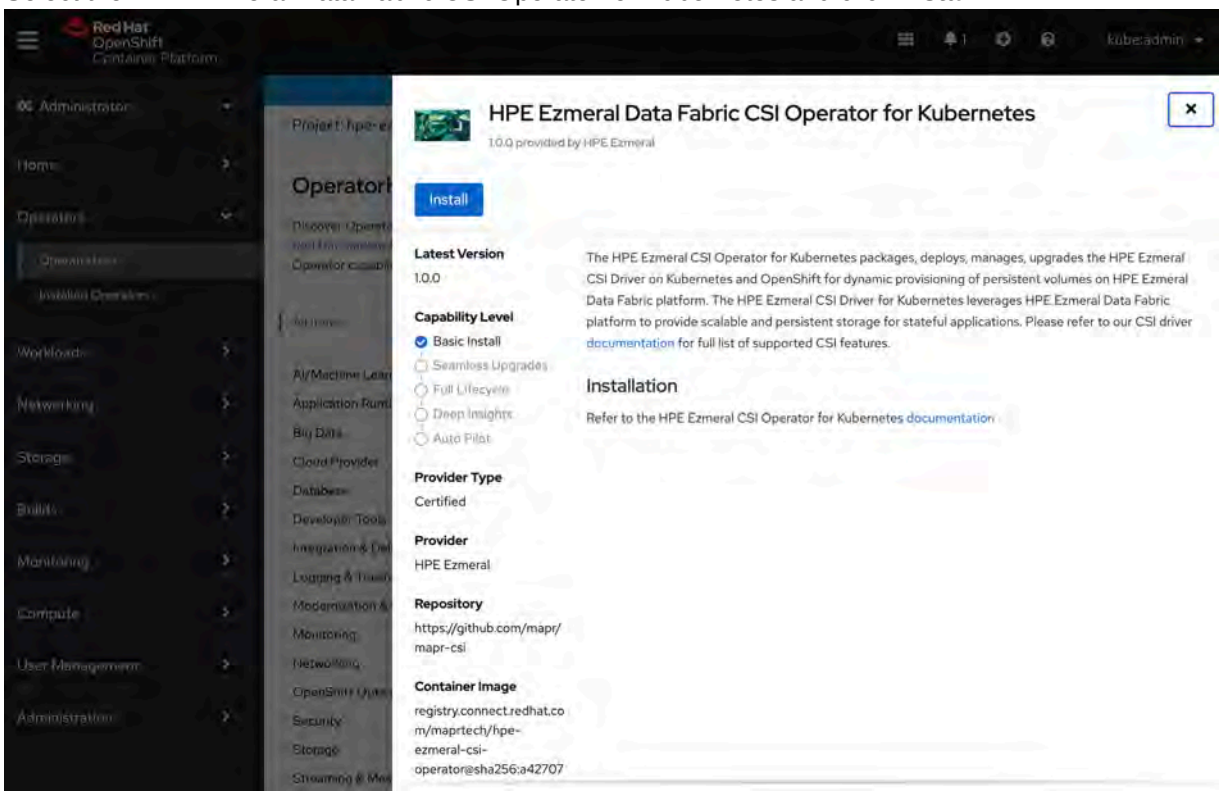
Installing the Operator Using the OpenShift Web Console

Use the following steps to install the operator using the web console:

1. Once the SCC has been applied to the project, log in to the OpenShift web console as `kube:admin`, and navigate to **Operators > OperatorHub**.
2. In the search field, type `HPE Ezmeral`, and press enter:

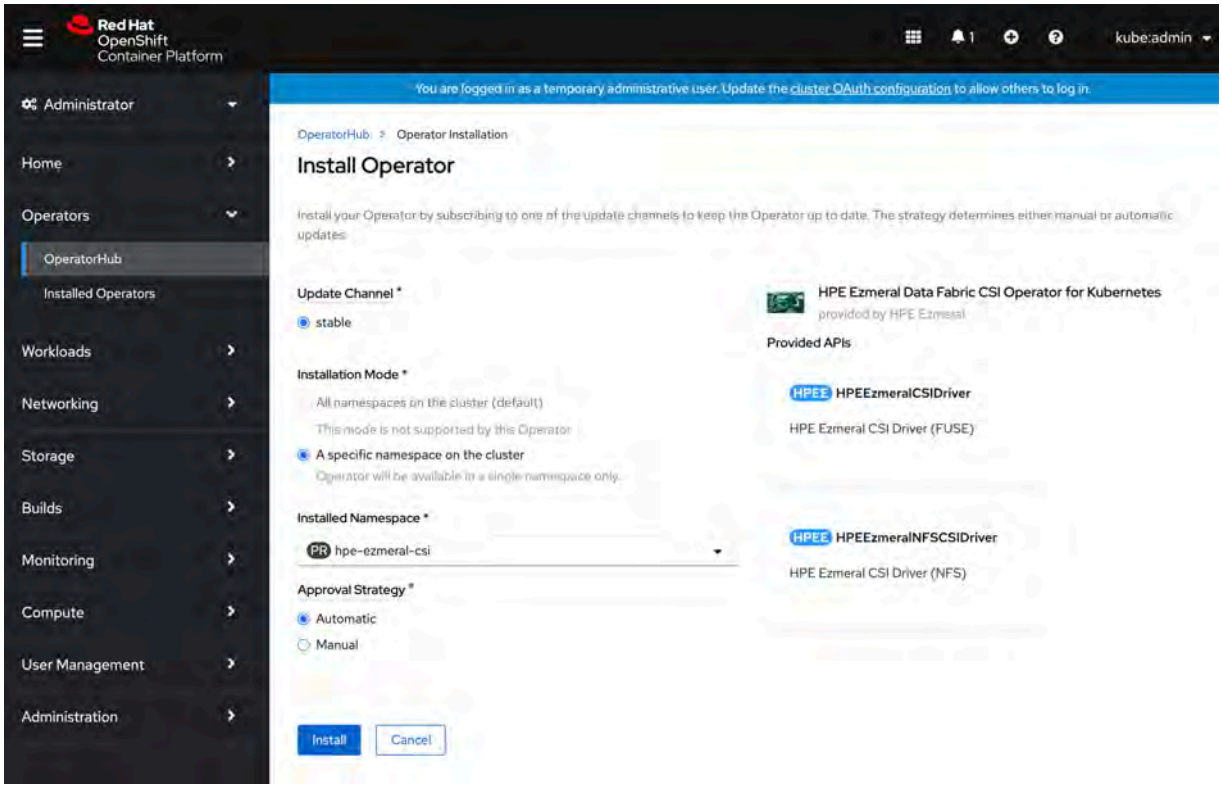


3. Select the HPE Ezmeral Data Fabric CSI Operator for Kubernetes and click **Install**:

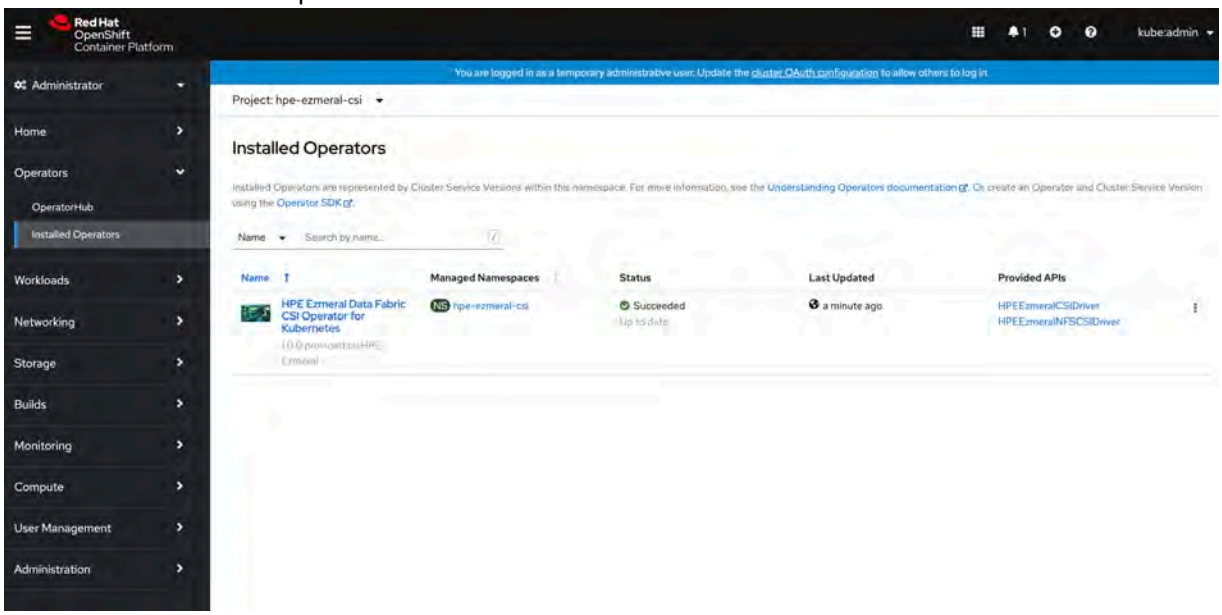


4. In the next pane, click **Install**:

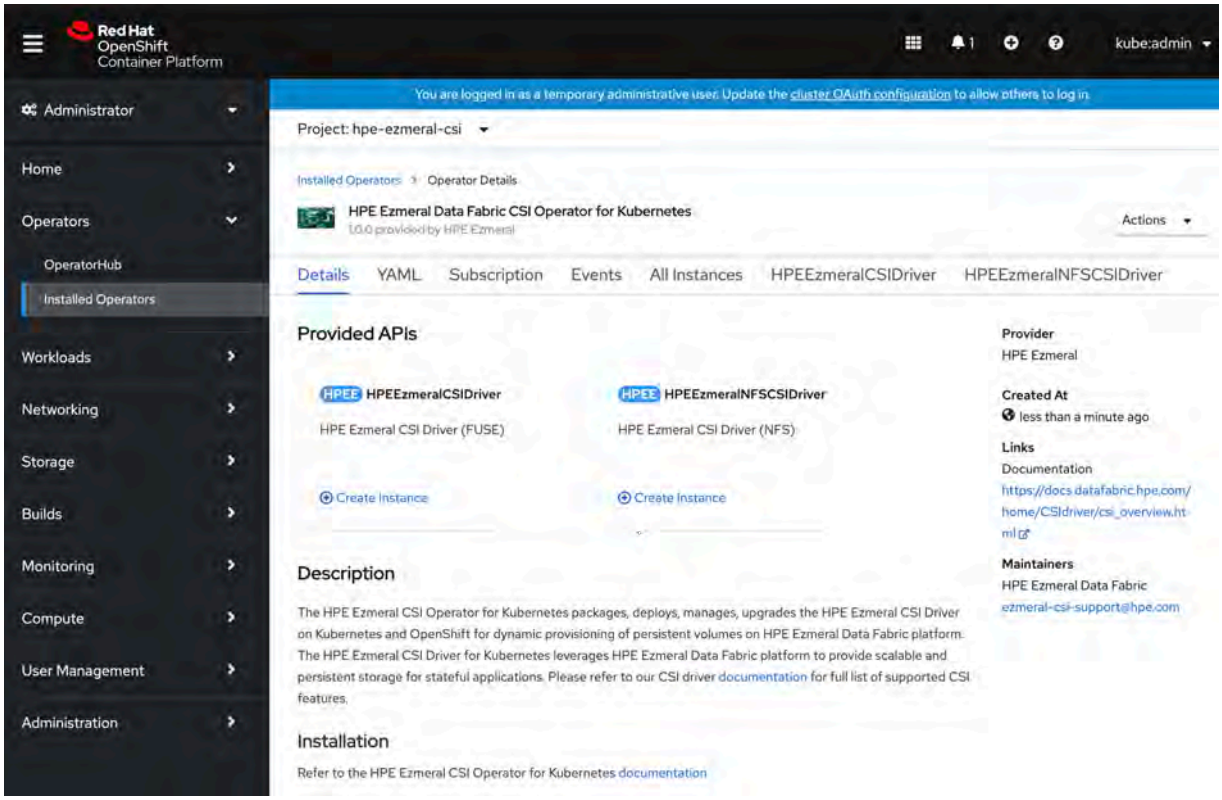
last-updated: Apr 11, 2022



5. The HPE Ezmeral CSI Operator is now installed:

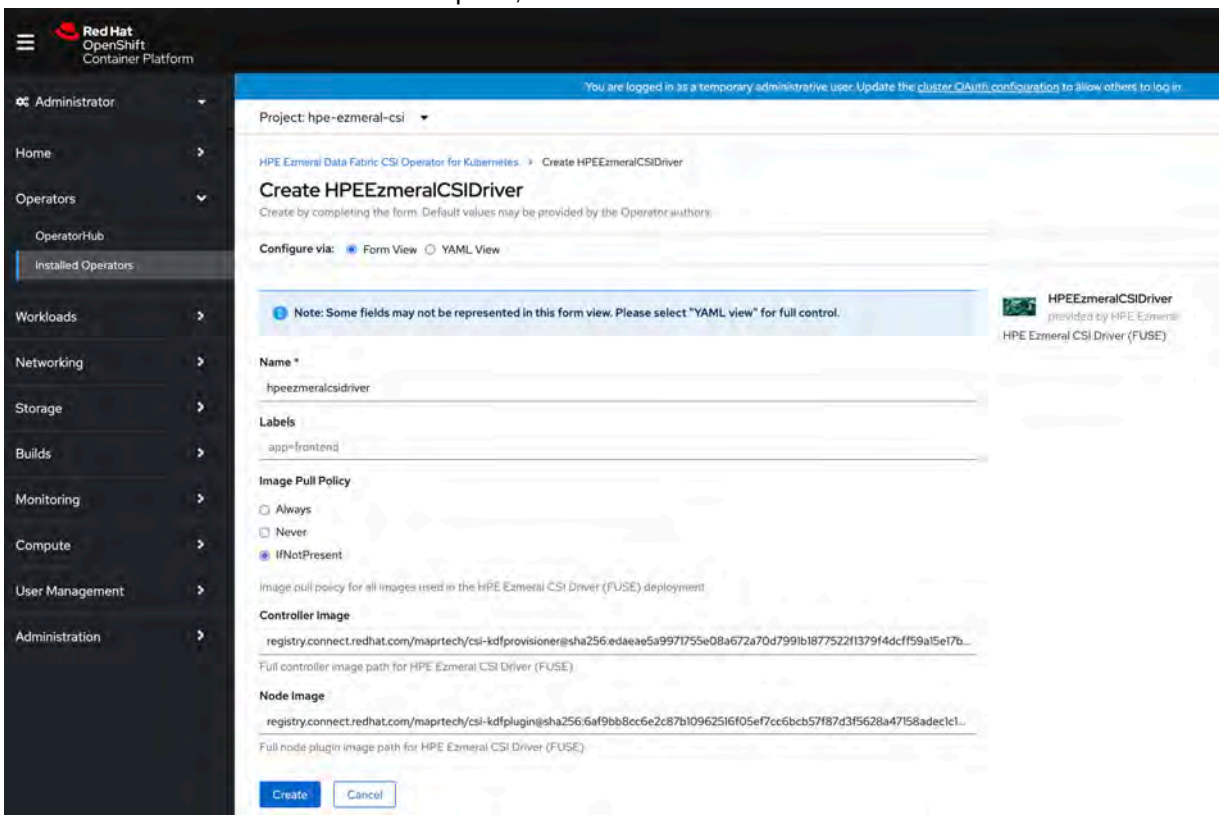


6. Click the HPE Ezmeral Data Fabric CSI Operator for Kubernetes to view the **Operator Details**:



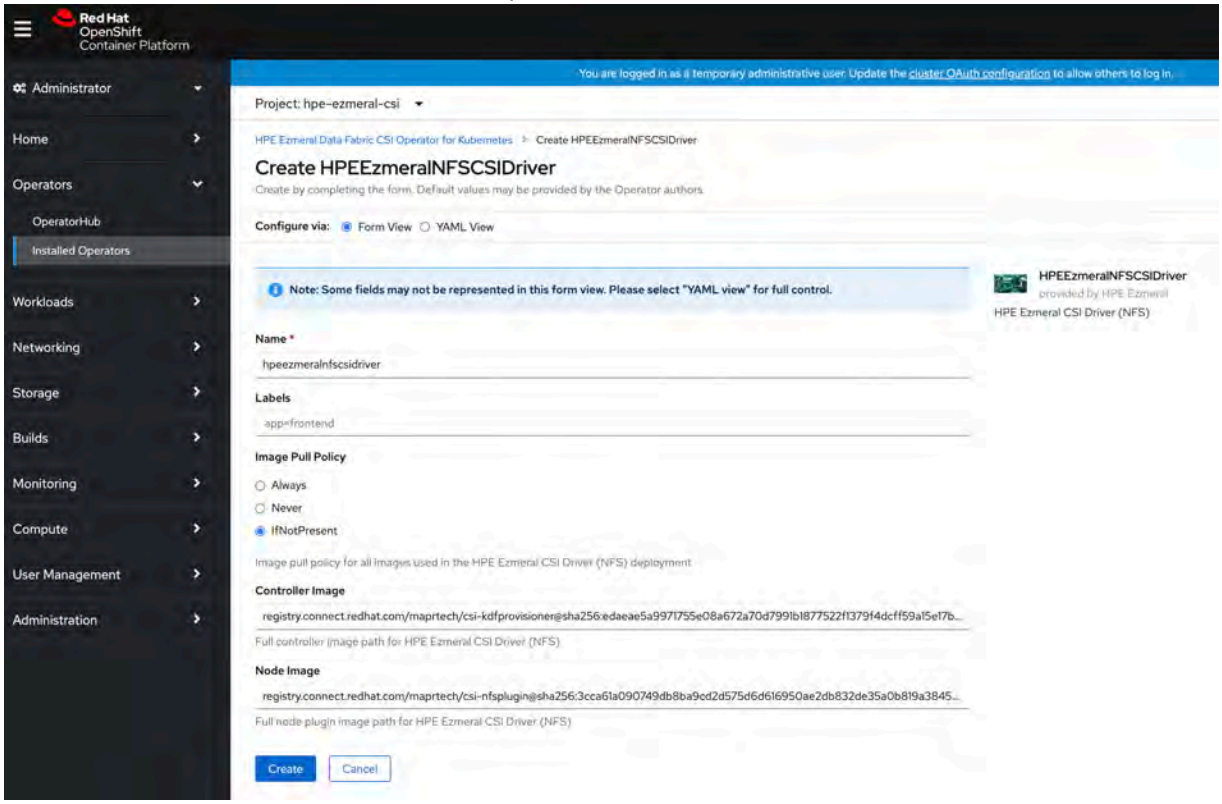
7. To create the HPE Ezmeral CSI Driver (FUSE), click **Create Instance** under **HPEEzmeralCSIDriver**.

8. In the **Create HPEEzmeralCSIDriver** pane, click **Create**:

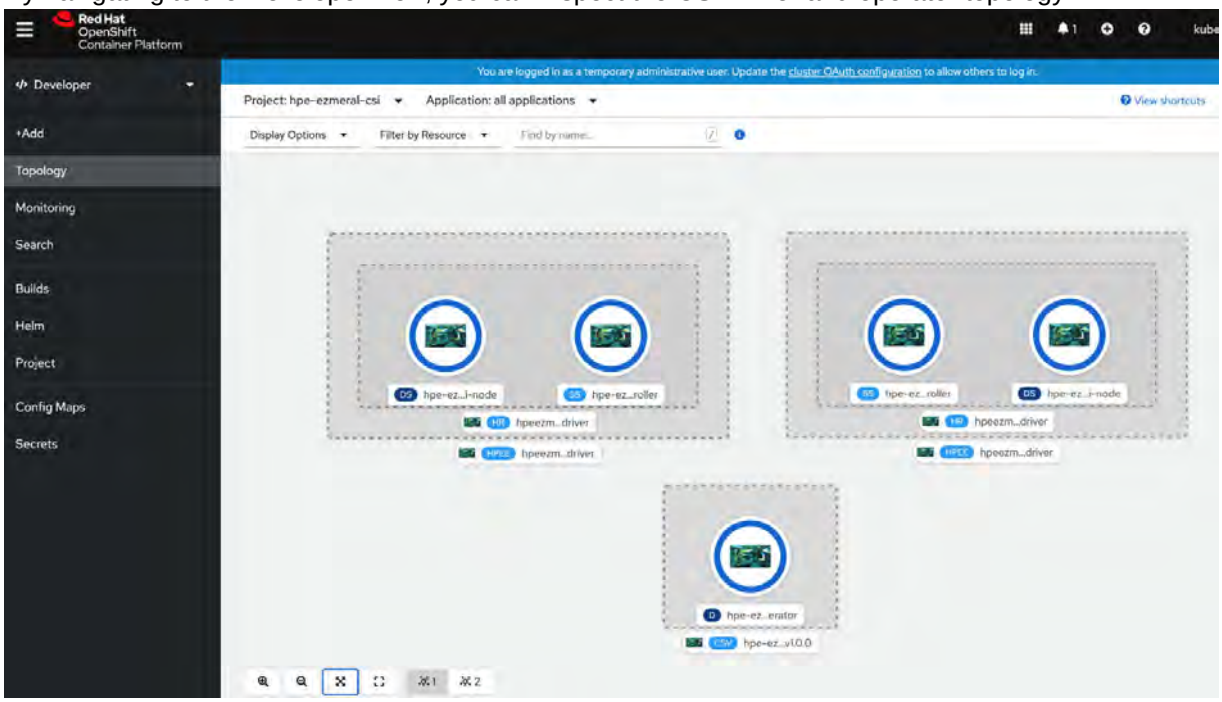


9. To create the HPE Ezmeral CSI Driver (NFS), click **Create Instance** under **HPEEzmeralNFSCSIDriver**.

10. In the **Create HPEEzmeralNFSCSIDriver** pane, click **Create**:



11. By navigating to the Developer view, you can inspect the CSI Driver and operator topology:



last-updated: Apr 11, 2022

The CSI Driver is now ready for use. To use the CSI Driver to statically and dynamically provision and mount a data-fabric volume, see Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3104.

Migrating from MapR Data Fabric for Kubernetes FlexVolume Driver to MapR Container Storage Interface (CSI) Storage Plugin
Describes how to migrate from the MapR Data Fabric for Kubernetes FlexVolume driver to the MapR Container Storage Interface (CSI) Storage Plugin.

Installing both the CSI Driver and FlexVolume Driver on the same Kubernetes cluster can lead to an unstable Kubernetes environment. To migrate from the FlexVolume Driver to CSI Driver:

1. Stop all the container workloads using the FlexVolume Driver and de-provision the FlexVolume Driver.
2. Uninstall the FlexVolume Driver.
3. Install the CSI Driver.
   For more information, see Installing, Uninstalling, and Upgrading the MapR Container Storage Interface (CSI) Storage Plugin on page 228.
4. Modify the existing storage classes, PersistentVolumeClaims, PersistentVolumes, and Pod specifications to refer to the CSI Driver as the default Driver.
5. Resume the workloads you stopped (in step 1 above).

Getting Started with the MapR Data Fabric for Kubernetes FlexVolume Driver

Serves as a pointer on how to plan for, install, and upgrade MapR for Kubernetes.

For more information about the MapR for Kubernetes, see MapR Data Fabric for Kubernetes FlexVolume Driver Overview on page 671.

Planning for the MapR Data Fabric for Kubernetes FlexVolume Driver
Points to information you should review before installing or using the MapR for Kubernetes FlexVolume driver.

For release note information, see MapR Data Fabric for Kubernetes Release Notes.

Prerequisites for Using the MapR Data Fabric for Kubernetes FlexVolume Driver

To use the *MapR Data Fabric for Kubernetes* FlexVolume driver, you must have the following software versions:

Component	Supported Versions
MapR XD Distributed File and Object Store	5.2.2 or later
MapR Ecosystem Pack (EEP)	Any EEP supported by MapR 5.2.2 or later. See EEP Support by MapR Core Version.
Kubernetes Software	1.9*
OS (Kubernetes nodes)	All nodes in the Kubernetes cluster must use the same Linux OS. Configuration files are available to support: • CentOS • Red Hat (use CentOS configuration file) • SLES (use CentOS configuration file) • Ubuntu

Component	Supported Versions
	Note: Docker for Mac with Kubernetes is not supported as a development platform for containers that use the MapR Data Fabric for Kubernetes.
Volume Plug-in	1.0 or later. The download location shows the available versions of the plug-in. Plug-ins are supported for: • CentOS • Ubuntu • Microsoft Azure AKS • Red Hat OpenShift** • Google Kubernetes Engine (GKE) **Note:** Amazon EKS is not currently supported.
Provisioner	1.0 or later. The download location shows the available versions of the provisioner.
POSIX License***	The Basic POSIX client package is included by default when you install the MapR Data Fabric for Kubernetes. The Platinum POSIX client can be enabled by specifying a parameter in the Pod spec. To enable the Platinum POSIX client package, see Enabling the Platinum Posix Client for MapR Data Fabric for Kubernetes FlexVolume Driver on page 3166. For a comparison of the Basic and Platinum POSIX client packages, see Preparing for Installation (MapR POSIX Client) on page 400.

*Kubernetes alpha features are not supported.

**OpenShift Origin is supported because it supports Kubernetes 1.9. The OpenShift Container Platform (formerly known as OpenShift Enterprise) can be used only if it supports Kubernetes 1.9.

***Only the POSIX client is supported. NFSv3 is not supported.

Downloads (FlexVolume)

Downloads for the MapR Data Fabric for Kubernetes FlexVolume driver are available at these locations:

Site	URL	Content
MapR Software Downloads Site	https://package.mapr.hpe.com/tools/KubernetesDataFabric	MapR installation (`.yaml`) files
Docker Hub	https://hub.docker.com/r/maprtech/kdf-provisioner/ https://hub.docker.com/r/maprtech/kdf-plugin/	Docker containers for the MapR installation files
GitHub Repository	https://github.com/mapr/KubernetesDataFabric	Three types of resources: • A **build** folder that contains the Docker images used to build the data fabric • A **deploy** folder that contains the same files provided on the MapR Software Download site

Site	URL	Content
		• An **examples** folder that contains example `.yaml` files

Installing the MapR Data Fabric for Kubernetes FlexVolume Driver

This section describes the steps you must take to prepare for installation and install the configuration files for the MapR Data Fabric for Kubernetes FlexVolume driver.

Installing MapR and Kubernetes Software on Separate Nodes

This section describes how to install the configuration files for the MapR Data Fabric for Kubernetes. In this configuration, MapR and Kubernetes software must be installed on separate nodes.

To install the MapR Data Fabric for Kubernetes, you must download the configuration files and use the Kubernetes `kubectl` interface to install the namespace, RBAC, plug-in, and provisioner `.yaml` files.

Before Installation

Before installing the MapR Data Fabric for Kubernetes, note these preinstallation best practices:

- You must install the configuration files in the order shown in the steps below. Using a different installation order can cause problems.
- Ensure that all Kubernetes nodes use the same Linux distribution. For example, all nodes can be CentOS nodes, or all nodes can be Ubuntu nodes. But a cluster with a mixture of CentOS and Ubuntu nodes is not supported.
- This procedure does not allow you to install the MapR Data Fabric for Kubernetes on a Kubernetes node that is also a node in a MapR cluster. If a Kubernetes node already has MapR software installed, installing the MapR Data Fabric for Kubernetes can cause issues with the running MapR cluster. See Installing MapR and Kubernetes Software on the Same Nodes on page 243.
- Do not install the MapR client on a node where the volume plug-in configuration file is installed. The MapR client can be installed on a node in the Kubernetes cluster, but it must be installed **before** the MapR Data Fabric for Kubernetes is installed on the same Kubernetes cluster.

Installation Steps

Use these steps to install the configuration files:

1. Download the following configuration (`.yaml`) files from `https://package.mapr.hpe.com/tools/KubernetesDataFabric/v<version>/` to a directory on a node in the Kubernetes cluster:

File	Description
`kdf-namespace.yaml`	Configuration file for the `mapr-system` namespace, under which all MapR components are installed.
`kdf-rbac.yaml`	RBAC configuration file. This file enables the provisioner to call the Kubernetes APIs that it needs to function.
• `kdf-plugin-centos.yaml` • `kdf-plugin-ubuntu.yaml` • `kdf-plugin-azure.yaml`[1] • `kdf-plugin-openshift.yaml`[2]	Configuration files used to install the plug-in. Download the plug-in file that matches your environment. You can use the CentOS configuration file for Red Hat, CentOS, or SLES Kubernetes hosts.

File	Description
• `kdf-plugin-gke.yaml`[3]	
`kdf-provisioner.yaml`	Configuration file used to install the provisioner inside the Kubernetes cluster.

[1]Before installing the `kdf-plugin-azure.yaml`, see Azure AKS Considerations on page 245.

[2]To install the `kdf-plugin-openshift.yaml`, see OpenShift Considerations on page 246.

[3]To install the `kdf-plugin-gke.yaml`, see Google Kubernetes Engine (GKE) Considerations on page 247.

2. In Kubernetes, use the `kubectl create` command with the `-f` option to create the namespace for the plug-in and provisioner:

   Note: The examples in this procedure assume that you are running each `kubectl create` command from the directory containing the downloaded configuration files.

   ```
   kubectl create -f kdf-namespace.yaml
   ```

3. In Kubernetes, use the `kubectl create` command with the `-f` option to install the RBAC file:

   Note: Do not apply the RBAC file in OpenShift environments. See OpenShift Considerations on page 246.

   ```
   kubectl create -f kdf-rbac.yaml
   ```

4. In the plug-in configuration file that you downloaded in step 1, set the Kubernetes service location and the FlexVolume plug-in path. To specify the Kubernetes service location, specify the external location and port of your API server. You can find the correct values by doing a `kubectl config view` and looking at the current context and then looking at the cluster selected for that context. This information is used to look up tickets:

   ```
   - name : KUBERNETES_SERVICE_LOCATION
     value: "changeme!:6443"
   ```

   If your Kubernetes environment has a nonstandard location for FlexVolume plug-ins (for example, Azure environments sometimes use a nonstandard location), specify the FLEXVOLUME_PLUGIN_PATH by changing the directory in the `value:` field:

   ```
   - name : FLEXVOLUME_PLUGIN_PATH
     value: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec"
   ```

5. Use the `kubectl create` command with the `-f` option to install the plug-in. The plug-in that you specify in the `create` command depends on your operating system environment:

   Note: When you issue the `kubectl create -f` command, a daemon set copies the plug-in to every node in the Kubernetes cluster.

   ```
   kubectl create -f kdf-plugin-centos.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-ubuntu.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-azure.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-openshift.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-gke.yaml
   ```

6. In Kubernetes, use the `kubectl create` command with the `-f` option to install the provisioner on a single node of the Kubernetes cluster. Kubernetes determines the node on which to install the provisioner.

   ```
   kubectl create -f kdf-provisioner.yaml
   ```

7. To begin using the MapR Data Fabric for Kubernetes, see Kubernetes FlexVolume Driver Configuration on page 3150.

Installing MapR and Kubernetes Software on the Same Nodes

Note: This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

This section describes how to install the configuration files for the MapR Data Fabric for Kubernetes. In this configuration, MapR and Kubernetes software can coexist on the same nodes if certain version requirements are met.

Important: Some versions of the MapR Data Fabric for Kubernetes do not support installing MapR and Kubernetes software on the same nodes. To ensure that you are using a version that supports this feature, see the MapR Data Fabric for Kubernetes release notes.

Before Installation

Before installing the MapR Data Fabric for Kubernetes, note these preinstallation requirements:

- This procedure assumes that the Kubernetes cluster is already installed and functioning normally.

last-updated: Apr 11, 2022

- Ensure that all Kubernetes nodes use the same Linux distribution. For example, all nodes can be CentOS nodes, or all nodes can be Ubuntu nodes. But a cluster with a mixture of CentOS and Ubuntu nodes is not supported.
- This procedure requires stopping Warden and Zookeeper on all nodes in the MapR cluster and then restarting Warden and Zookeeper on all nodes. The steps cannot be performed online one node at a time.
- Do not install the MapR client on a node where the volume plug-in configuration file is installed. The MapR client can be installed on a node in the Kubernetes cluster, but it must be installed **before** the MapR Data Fabric for Kubernetes is installed on the same Kubernetes cluster.

CAUTION: Do not try to install the volume plug-in without following the steps below. Doing so can cause MapR libraries to be overwritten.

Install the MapR 6.0.1 or Later Cluster on the Kubernetes Nodes

Use any of the methods described in Installing with the MapR Installer on page 141 to install a MapR 6.0.1 or later cluster on the existing Kubernetes nodes.

Install the MapR Data Fabric for Kubernetes

Use these steps to install the MapR Data Fabric for Kubernetes on the Kubernetes cluster:

1. Stop all running jobs on the MapR cluster.
2. Stop Warden on all MapR cluster nodes by running the following command on each node:

   ```
   service mapr-warden stop
   ```

3. Stop Zookeeper on all MapR Zookeeper nodes by running the following command on each node:

   ```
   service mapr-zookeeper stop
   ```

4. Deploy the MapR Data Fabric for Kubernetes components by using steps 1 through 6 of Installing MapR and Kubernetes Software on Separate Nodes on page 241.
5. Configure the `MAPR_SUBNETS` environment variable to ensure that MapR software does not use the `docker0` network interface on each node. See Designating NICs for MapR on page 844.

   If `MAPR_SUBNETS` is not set, the CLDB uses all NICs present on the node. When Docker is installed on a node, the`docker0` bridge is created as a virtual NIC for use by the Docker containers. You must configure the `MAPR_SUBNET` setting to include the physical NICs that you want the CLDB to use and *exclude* the `docker0` network interface. In this way, you can avoid issues with duplicate or non-routable IP addresses. For more information about `docker0`, see Docker container networking.
6. Start Zookeeper on all MapR Zookeepr nodes by running the following command on each node:

   ```
   service mapr-zookeeper start
   ```

7. Start Warden on all MapR cluster nodes by running the following command on each node:

   ```
   service mapr-warden start
   ```

Pod Security Policies and the MapR Data Fabric for Kubernetes

If your Kubernetes administrator has turned on Pod Security Policies, you must create a PSP for the MapR Data Fabric for Kubernetes. You should use your organization's best practices for writing a PSP, but you must enable several parameters in the PSP for your `maprkdf` service account:

```
volumes:
    - 'hostPath'
    - 'flexVolume'
allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
 allowedFlexVolumes:
    - driver: mapr.com/maprfs
```

Here is an example of a PSP that would work:

```
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  name: mapr-kdf-psp
spec:
  volumes:
    - 'configMap'
    - 'emptyDir'
    - 'projected'
    - 'secret'
    - 'downwardAPI'
    - 'persistentVolumeClaim'
    - 'hostPath'
    - 'flexVolume'
  allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
  allowedFlexVolumes:
    - driver: mapr.com/maprfs
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
```

You enable a PSP for a ServiceAccount as part of a ClusterRole that is bound to the ServiceAccount. See Using RBAC Authorization. For example, add the `mapr-kdf-psp` to a ClusterRole like this:

```
- apiGroups: ['extensions']
    resources: ['podsecuritypolicies']
    verbs:     ['use']
    resourceNames:
    - mapr-kdf-psp
```

Azure AKS Considerations

Microsoft Azure turns on PodSecurityPolicies by default. This means you must create RBAC and PodSecurityPolicies for both the plug-in and any containers that call the plug-in.

last-updated: Apr 11, 2022

Here is an example of a PSP. It is recommended that you adapt this PSP to the security best practices of your organization:

```
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  name: mapr-kdf-psp
spec:
  volumes:
    - 'configMap'
    - 'emptyDir'
    - 'projected'
    - 'secret'
    - 'downwardAPI'
    - 'persistentVolumeClaim'
    - 'hostPath'
    - 'flexVolume'
  allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
  allowedFlexVolumes:
    - driver: mapr.com/maprfs
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
```

Azure uses a non-standard FlexVolume path: `/etc/kubernetes/volumeplugins`. This path has already been changed in `kdf-plugin-azure.yaml`.

You must set the KUBERNETES_SERVICE_LOCATION for Azure. You can find the correct value by connecting to your Azure cluster using the `kubectl` interface. Use the `kubectl config view` command, and find the server name and port for the current context.

In Azure, the Kubelet process is running inside a *hypercube* container. The MapR plug-in must run inside that container. This means that the plug-in log is somewhat hidden. To view the plug-in log:

```
docker ps <to find the hyperkube container>
docker exec -it <hyperkube container ID> /bin/bash
cd /opt/mapr/logs
cat plugin plugin-k8s.log
```

OpenShift Considerations

For OpenShift environments, the installation steps are the same as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241. However, you must not apply the RBAC file. Instead run the following commands:

```
oc create -f kdf-openshift-sa.yaml
oc create -f kdf-openshift-scc.yaml
oc adm policy add-scc-to-user maprkdf-scc
system:serviceaccount:mapr-system:maprkdf
oc create -f kdf-openshift-cr.yaml
oc adm policy add-cluster-role-to-user mapr:kdf
system:serviceaccount:mapr-system:maprkdf
```

All other installation steps are the same.

Google Kubernetes Engine (GKE) Considerations

To create a Google Kubernetes Engine (GKE) cluster, you must use Ubuntu node images instead of CentOS.

The high-level installation steps are as follows:

1. Create a cluster with Ubuntu nodes.
2. Follow the steps later on this page to create a PodSecurityPolicy (PSP).
3. Install the namespace, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241.
4. Install the PSP.
5. Install the RBAC file, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241.
6. Modify the service location in the plug-in, as described later on this page.
7. Install the `kdf-plugin-gke.yaml`, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241
8. Install the provisioner, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241

Creating a PSP

GKE turns on PodSecurityPolicies by default. This means that you must create Role-Based Access Control (RBAC) and PodSecurityPolicies for both the plug-in and any containers that call the plug-in. Before you can edit RBAC and PSPs in GKE, you have to give your `kubectl id` sufficient permissions. Assuming you have already logged into Google Cloud and connected your cluster to `kubectl`, you need to execute the following command:

```
gcloud info | grep Account
```

The command returns an email address. Copy the email address into the following command:

```
kubectl create clusterrolebinding
yourname-cluster-admin-binding --clusterrole=cluster-admin --user=myname@exa
mple.org
```

If this command is successful, you will have permissions to create a Pod security policy. Here is an example of a PSP. It is recommended that you adapt this PSP to the security best practices of your organization:

```
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  name: mapr-kdf-psp
spec:
  volumes:
    - 'configMap'
    - 'emptyDir'
    - 'projected'
    - 'secret'
    - 'downwardAPI'
    - 'persistentVolumeClaim'
```

last-updated: Apr 11, 2022

```
    - 'hostPath'
    - 'flexVolume'
  allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
  allowedFlexVolumes:
    - driver: mapr.com/maprfs
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
```

Nonstandard FlexVolume Path and Service Location

GKE uses a non-standard FlexVolume path: `/home/kubernetes/flexvolume`. This path has already been changed in `kdf-plugin-gke.yaml`. However, you must set the KUBERNETES_SERVICE_LOCATION for GKE. To do this, you must edit the `kdf-plugin-gke.yaml` file to specify the service location. You can find the correct value by connecting to your GKE cluster using the `kubectl` interface. Use the `kubectl config view` command, and find the server name and port for the current context.

Upgrading the MapR Data Fabric for Kubernetes

This section describes how to upgrade the plug-in and dynamic provisioner, or upgrade Pods with attached volumes.

Upgrading the Plug-in and Provisioner

Before upgrading the plug-in, stop any Pods using the plug-in. You may want to quiesce any traffic hitting the Pod before shutdown. Failure to shut down the Pods before replacing the plug-in can lead to the Pod not being able to access its data until it is restarted.

Removing the plug-in does not kill existing Pods. The Pods should only lose their mounted storage when a new version of the plug-in is installed and the libraries used to communicate with MapR software are deleted.

Upgrading the provisioner does not require stopping Pods, but dynamic provisioning (creating MapR volumes for new PersistentVolumeClaims) will be unavailable during the provisioner upgrade.

Use these steps to upgrade the plug-in:

1. Stop any Pods using the the plug-in to be upgraded. Before shutting down the Pod, you might want to quiesce any traffic hitting the Pod.

   Note: If any Pods that use the MapR Data Fabric for Kubernetes are not shut down during the plug-in upgrade, those Pods will have mount access removed and will need to be deleted and re-created as new Pods. If existing Pods need to be removed or are stuck in the Terminating state, you can delete them forcefully by using the `kubectl delete pod` command:

   ```
   kubectl delete pod <pod-name> -n
   <pod-namespace> --force --grace-period=0
   ```

2. Download the new plug-in. See Downloads (FlexVolume) on page 240.

last-updated: Apr 11, 2022

3. Delete the old plug-in:

```
kubectl delete -f kdf-<old_plugin>.yaml
```

4. Deploy the new plugin:

```
kubectl create -f kdf-<new_plugin>.yaml
```

Upgrading Pods with Attached Volumes

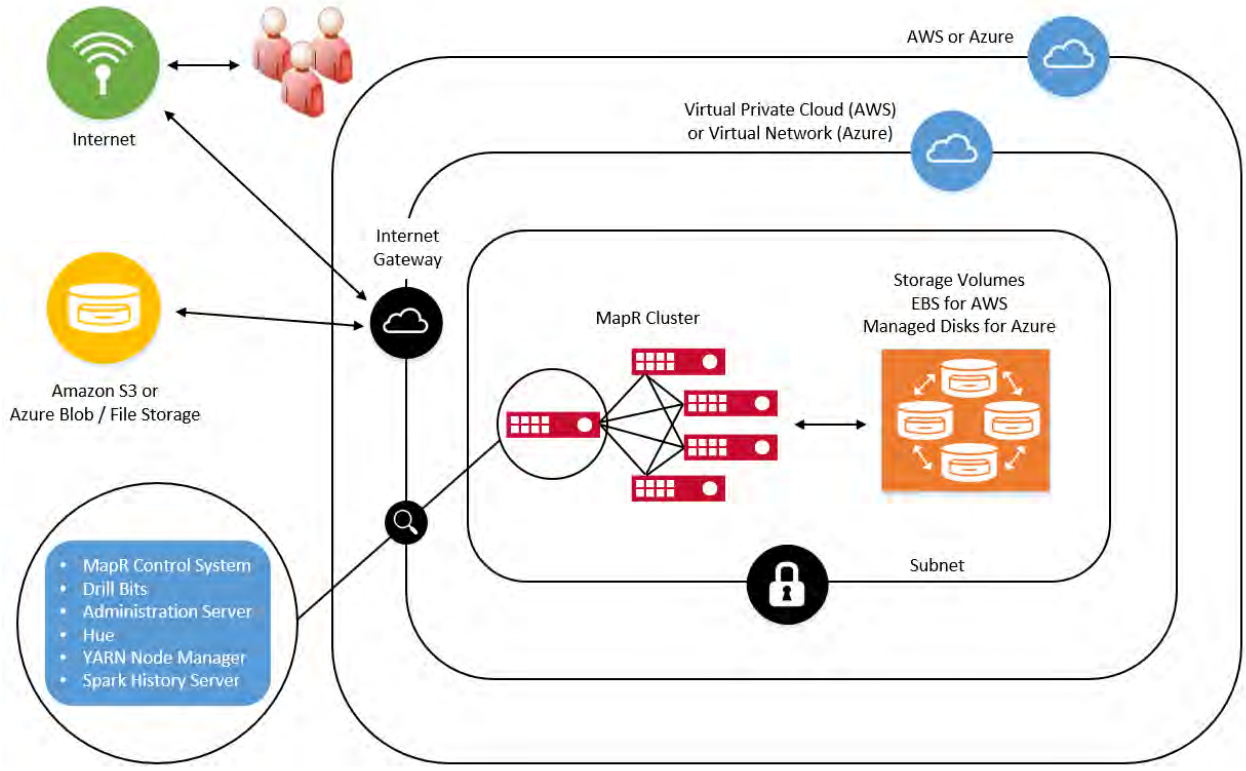
Pods with mounted volumes can be patched in place. See Update API Objects in Place Using kubectl patch. Volumes will disappear only when the Pod is deleted. Patching a Pod does not affect the mount. When a Pod is deleted, a volume disappears. However, if you delete a Pod using a PersistentVolume and you leave the PVC alive, you can remount the PersistentVolumeClaim and its PersistentVolume with a new Pod. In this scenario, there is no disruption or need to recreate the PersistentVolume.

Installing MapR in the Cloud

Provides an overview of MapR cloud installer capabilities.

With the latest MapR Installer, you can deploy a MapR cluster in the cloud quickly and customize your deployment using HPE-provided reference templates. You can provision a cluster in Amazon AWS or in Microsoft Azure and take advantage of the benefits of cloud computing.

The following diagram shows the high-level architecture for a cloud-based MapR cluster:



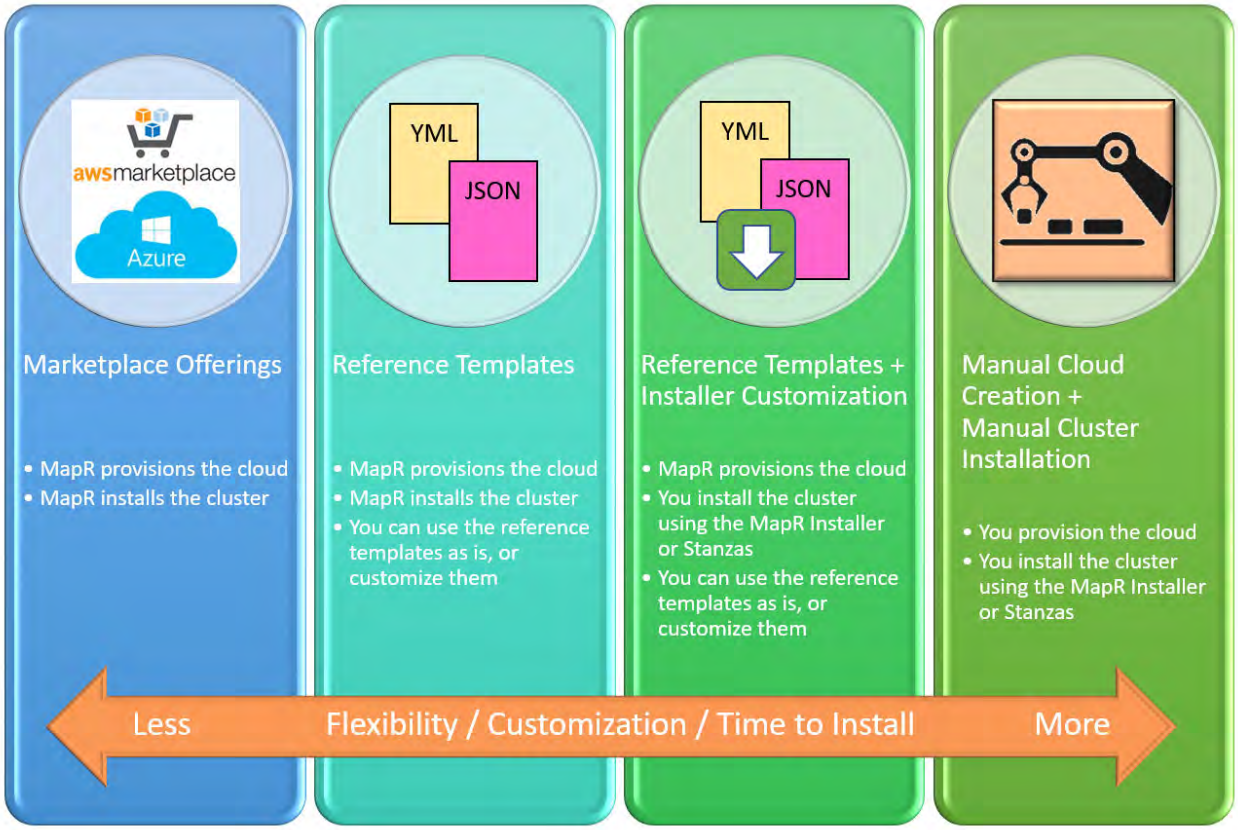
MapR Installer tools and templates provide several options for provisioning the cloud and installing the cluster. These options vary in:

- The time it takes to perform the installation

last-updated: Apr 11, 2022

- The level of customization each option supports
- The complexity of the installation

The following diagram shows the different options for provisioning to the cloud and installing the cluster. These options allow you to customize your MapR deployments to meet your business goals and make it easier for you to pay for only the MapR software that you use.



Marketplace Offerings

MapR offerings for Amazon AWS and Microsoft Azure allow you to deploy MapR clusters quickly to test new features and software versions:

- MapR Offerings in the AWS Marketplace on page 252
- MapR Offerings in the Azure Marketplace on page 267

MapR Reference Templates

MapR reference templates assist in provisioning. You can use the templates as is or modify them to control the way your installation is provisioned. The reference templates both provision your instance in the cloud and install a MapR cluster to your specifications. For more information, see:

- About the MapR Reference Templates for AWS on page 258
- About the MapR Reference Templates for Azure on page 272

MapR Installer Web Interface

The MapR Installer allows you to install, add services, upgrade, scale, and gather information about your MapR on-premise or cloud-based cluster. You can use the Installer after your cluster is deployed, or deploy just the MapR Installer and use the web interface or MapR Installer Stanzas to customize your installation.

MapR Installer Stanzas

MapR Installer Stanzas give you a programmatic interface to perform most of the functions available in the MapR Installer web insterface. See MapR Installer Stanzas on page 5503.

Custom Images

MapR tools allow you to build custom Amazon Machine Images (AMIs) or Azure VM images to meet additional security or software requirements for your environment. See Creating Custom Images on page 278.

Supported Operating Systems

Supported operating systems and MapR software for the cloud Installer are:

Operating systems	RHEL 7.4, Ubuntu 14.04, Ubuntu 16.04, CentOS 7.4, SLES 12 SP 2
MapR Core	5.2.2 or later
MapR Ecosystem Pack (EEP)	3.0.1 or later

Planning for Access to the Cluster

Before installing a MapR cluster in the cloud, be sure to review this information so that you can plan for access to the cluster.

Public and Private IP Addresses

Cloud-based MapR clusters are installed by default in a virtual private cloud (AWS) or virtual network (Azure) using private IP addresses. You must make sure you have a way to connect to the private IP addresses of each node in the cluster. For the Azure marketplace offering and the reference templates (AWS and Azure), OpenVPN can be configured to facilitate secure access.

For the AWS marketplace offering, if you don't use a public IP address, you need to ensure that you have a way to connect to the VPC and the private IP of the nodes.

Security Groups

The MapR reference templates for AWS and Azure support the use of security groups. Security groups allow you to control precisely the traffic that can access your instance. For AWS, you can use existing security groups or create new ones. For more information, see:

- AWS Security Group Information
- Azure Network Security Group Information

OpenVPN

Some MapR reference templates for AWS and Azure provide an option to install OpenVPN. OpenVPN is an open-source software application that creates a virtual private network (VPN) between your workstation and the cloud-based MapR cluster. If you do not want to use your network infrastructure or public IP addresses to connect to the cloud, OpenVPN can provide a secure connection. For more information, see Using OpenVPN on page 279.

last-updated: Apr 11, 2022

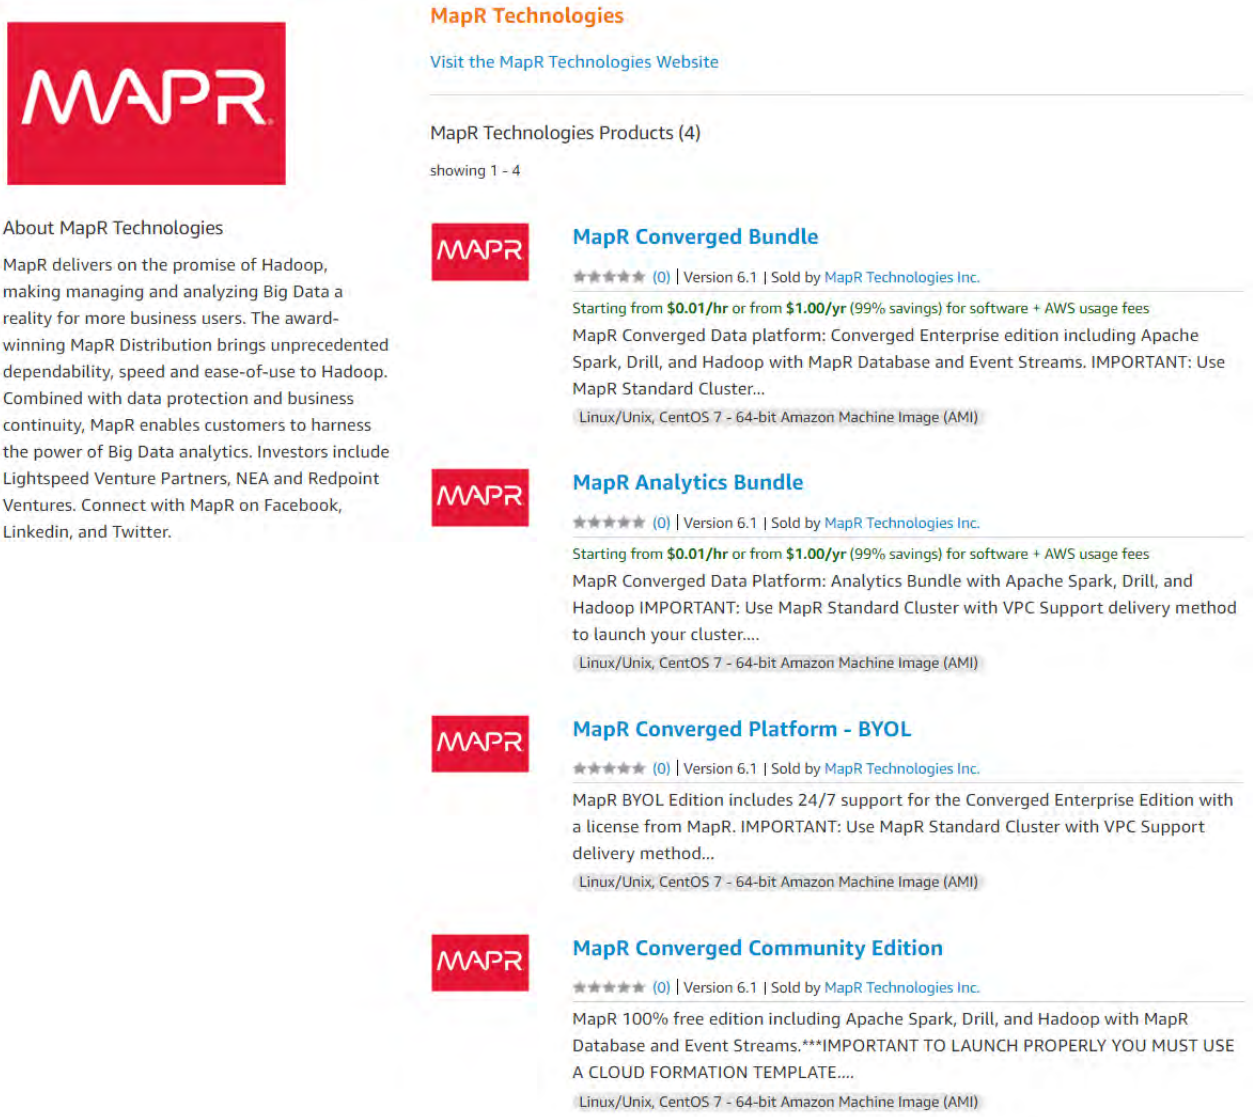
Deploying MapR Clusters on AWS

This section describes cloud-deployment procedures for Amazon AWS.

For similar procedures supporting Microsoft Azure, see Deploying MapR Clusters on Azure on page 267.

MapR Offerings in the AWS Marketplace

To view the MapR offerings in the AWS Marketplace, open a browser, and navigate to the MapR AWS Seller page:



MapR offerings include AMIs with hourly, bring-your-own (BYO), and community licenses:

MapR CDP Offering	Licensed Hourly?	Customizable?	Enterprise Features	MapR Support	Description
Analytics Bundle	Yes	No	Enabled	Included	MapR XD Distributed File and Object Store, Apache Spark, Apache Drill, Apache Hadoop
Converged Bundle	Yes	Yes	Enabled	Included	MapR XD, MapR Database, MapR Event Store For Apache Kafka, Apache Spark, Apache Drill, Apache Hadoop

MapR CDP Offering	Licensed Hourly?	Customizable?	Enterprise Features	MapR Support	Description
Community Edition	No	Yes	Disabled	Not included	MapR XD, MapR Database, MapR Event Store For Apache Kafka, Apache Spark, Apache Drill, Apache Hadoop
BYOL (Bring Your Own License)	No	Yes	Available Separately	Available Separately	MapR XD, MapR Database, MapR Event Store For Apache Kafka, Apache Spark, Apache Drill, Apache Hadoop

Deploying a Cluster in AWS Using a Marketplace Offering
Explains how to deploy a cluster using the AWS Marketplace Offering.
Prerequisites for Using a Marketplace Offering

MapR marketplace offerings leverage predefined provisioning templates that simplify the process of provisioning the instance and installing the cluster. To run the predefined provisioning templates, you need to have the following permissions to create roles and policies in AWS:

- `iam:GetRole`
- `iam:PassRole`
- `iam:PutRolePolicy`
- `iam:CreateRole`
- `iam:AddRoleToInstanceProfile`
- `iam:CreateInstanceProfile`

If you do not have these permissions, consider using the MapR reference templates to deploy your cluster. See About the MapR Reference Templates for AWS on page 258.

Steps for Deploying Using a Marketplace Offering

Use these steps to deploy a cluster using one of the MapR Marketplace offerings for AWS:

1. Navigate to the MapR page in the AWS Marketplace. For more information, see MapR Offerings in the AWS Marketplace on page 252.
2. Click the title of the MapR offering that you want to use. AWS displays product overview and pricing information for you to review.
3. Set the region and EC2 instance type.
4. Click **Continue to Subscribe**. The **Subscribe to this software** page appears.
5. Click **Continue to Configuration**. The **Configure this software** page appears.
6. In the **Fulfillment Option** field, select **MapR Standard Cluster with VPC Support**.
7. Click **Continue to launch**. The **Launch this software** page appears.
8. Under **Choose Action**, select **Launch CloudFormation**.
9. Click **Launch**. The **Create Stack** page is displayed. Note that the **Specify an Amazon S3 Template URL** option is selected, and the URL for the MapR template is prefilled in the **URL** field.
10. Click **Next**. The MapR CloudFormation template is displayed.

11. Fill in the template as follows.

Filling in the Template Values

The Community Edition and bring-your-own-license (BYOL) offerings contain some template parameters that are not present in the Converged and Analytics offerings. These parameters are marked accordingly in the following steps.

1. In the **Specify Details** section, enter a stack name in the **stack name** field. The stack name cannot contain spaces.
2. In the **Parameters** section, enter a cluster name for the **clusterName** field.
3. Enter a password for the **clusterAdminPassword** field. This is the password you will use to log into the Control System or the MapR Installer.

   Note: For cloud deployments, the installer uses the Cluster Admin Password as the MySQL root password when it creates a MySQL database for services that require a database.
4. Enter the MapR Ecosystem Pack version for the **EEP** field. Typically, the EEP value is pre-filled for the MapR release you selected. For more information about supported EEPs, see EEP Support by MapR Core Version.
5. In the **provisioningTemplate** list, select from the list of auto-provisioning templates. For more information about the templates, see Auto-Provisioning Templates on page 5448. This parameter is provided only for the BYOL / Community and Converged offerings.
6. In the **nodeCount** field, specify the number of nodes in the cluster.
7. In the **installerOnitsOwn** field, select **true** to configure the MapR Installer on a node that is not part of the cluster. If **true** is selected, the installer is started on a t2.small instance. Select **false** to configure the installer on a node in the cluster. If you select **true**, the cluster will consist of the **nodeCount** plus another node for the installer. This parameter is provided only for the BYOL / Community offerings.
8. In the **Node Configuration** section, select an instance type from the **InstanceType** list. The MapR-supported instance types in AWS are:
   - m4.xlarge, m4.2xlarge, m4.4xlarge, m4.10xlarge, m4.16xlarge
   - m3.xlarge, m3.2xlarge
   - c4.2xlarge, c4.4xlarge, c4.8xlarge
   - c3.2xlarge, c3.4xlarge, c3.8xlarge
   - r4.large, r4.xlarge, r4.2xlarge, r4.4xlarge, r4.8xlarge
   - r3.large, r3.xlarge, r3.2xlarge, r3.4xlarge, r3.8xlarge
   - p2.xlarge
   - g2.8xlarge
   - Local Storage Instances (Use only local disks, not EBS):
     - i3.large, i3.xlarge, i3.2xlarge, i3.4xlarge, i3.8xlarge
     - d2.xlarge, d2.2xlarge, d2.4xlarge, d2.8xlarge

   For more information about instance types, see Amazon EC2 Instance Types.

last-updated: Apr 11, 2022

9. In the **useinstanceStore** field, set the value to **true** if the machine type supports instance stores (ephemeral disks) and you want to use only those disks. No EBS volumes will be attached. This parameter is provided only for the BYOL / Community offerings.

   Note: This field is enabled for d2.* and i3.* instance types. i3.* uses NVMe disks, which are added by default in AWS. If you use i3.* images, the option is implicitly true.

10. In the **diskCount** field, specify the number of disks per node.

11. In the **diskType** field, specify the disk type. For more information, see Amazon EBS Volume Types.

12. In the **diskSize** field, specify the disk size.

13. In the **AWS Infrastructure Configuration** section, enter a key pair in the **keyName** field. Use the key pair that you configured in "Creating a Key Pair."

14. In the **useExistingSubnet** field, leave this field empty if you would like a new VPC and subnets created. Specify a subnet ID if you want to use existing subnets.

    If you choose to use your own subnet:

    - The subnet must have access to the Internet.
    - The subnet must be able to communicate to all hosts within the subnet on all ports.
    - You must have a mechanism to connect with the hosts on the subnet.

15. In the **securityGroups** field, specify the security group IDs for an existing subnet if you specified a subnet ID for **useSubnet**. Leave this field empty to create a new VPC and subnets.

16. In the **assignPublicIP** field, set the value to **true** if you want to assign a public IP address to each node. Otherwise, set the value to **false**.

    Note: It is recommended that you enable `assignPublicIP` if you are not using your own subnet, and you are letting the template create the VPC and subnet.

17. In the **publicAccessCIDR** field, specify an IP address range if you want to restrict the IP address from which the stack can be accessed. This field applies only when the template creates the VPC and subnets.

18. Click **Next**. The **Options** section is displayed.

19. Click the arrow to expand the **Advanced** subsection. MapR templates do not require any specific values in this section. However, in the **Advanced** subsection, for debugging purposes it can be useful to set **Rollback on failure** to **No** so that resources are not deleted in the event of failure.

20. Click **Next**. The Review page allows you to review your selections. Click **Previous** if you need to change a selection.

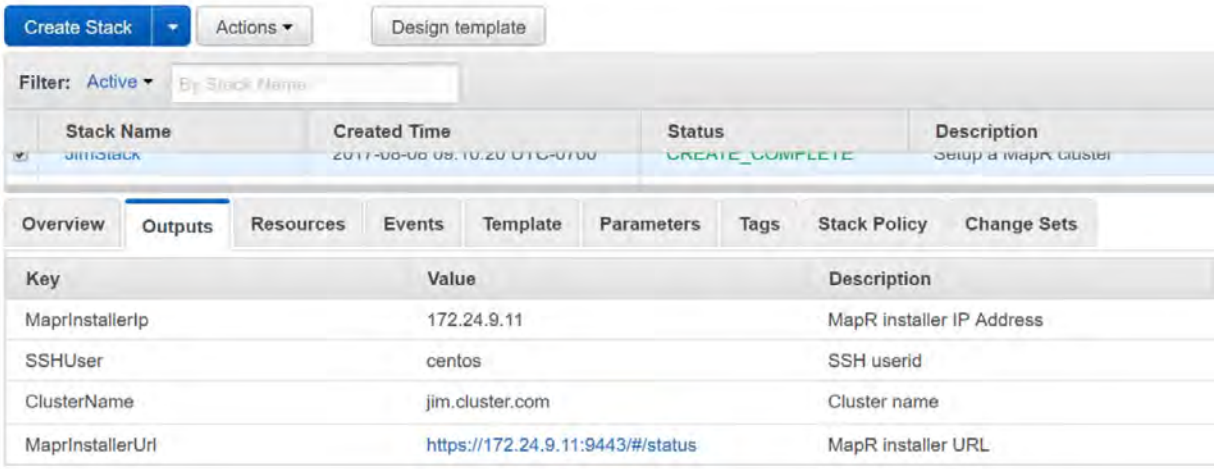
21. Otherwise, select **I acknowledge that AWS CloudFormation might create IAM resources**.

22. Click **Create** to start the process of stack creation. After a moment, the new stack is listed at the top of the CloudFormation console with a status of CREATE_IN_PROGRESS. To view the status of stack creation, select the stack, and click the **Events** tab.

    Note: Stack creation for a three-node cluster can take 15-20 minutes. Depending on the size of the cluster, stack creation can take longer in some cases.

last-updated: Apr 11, 2022

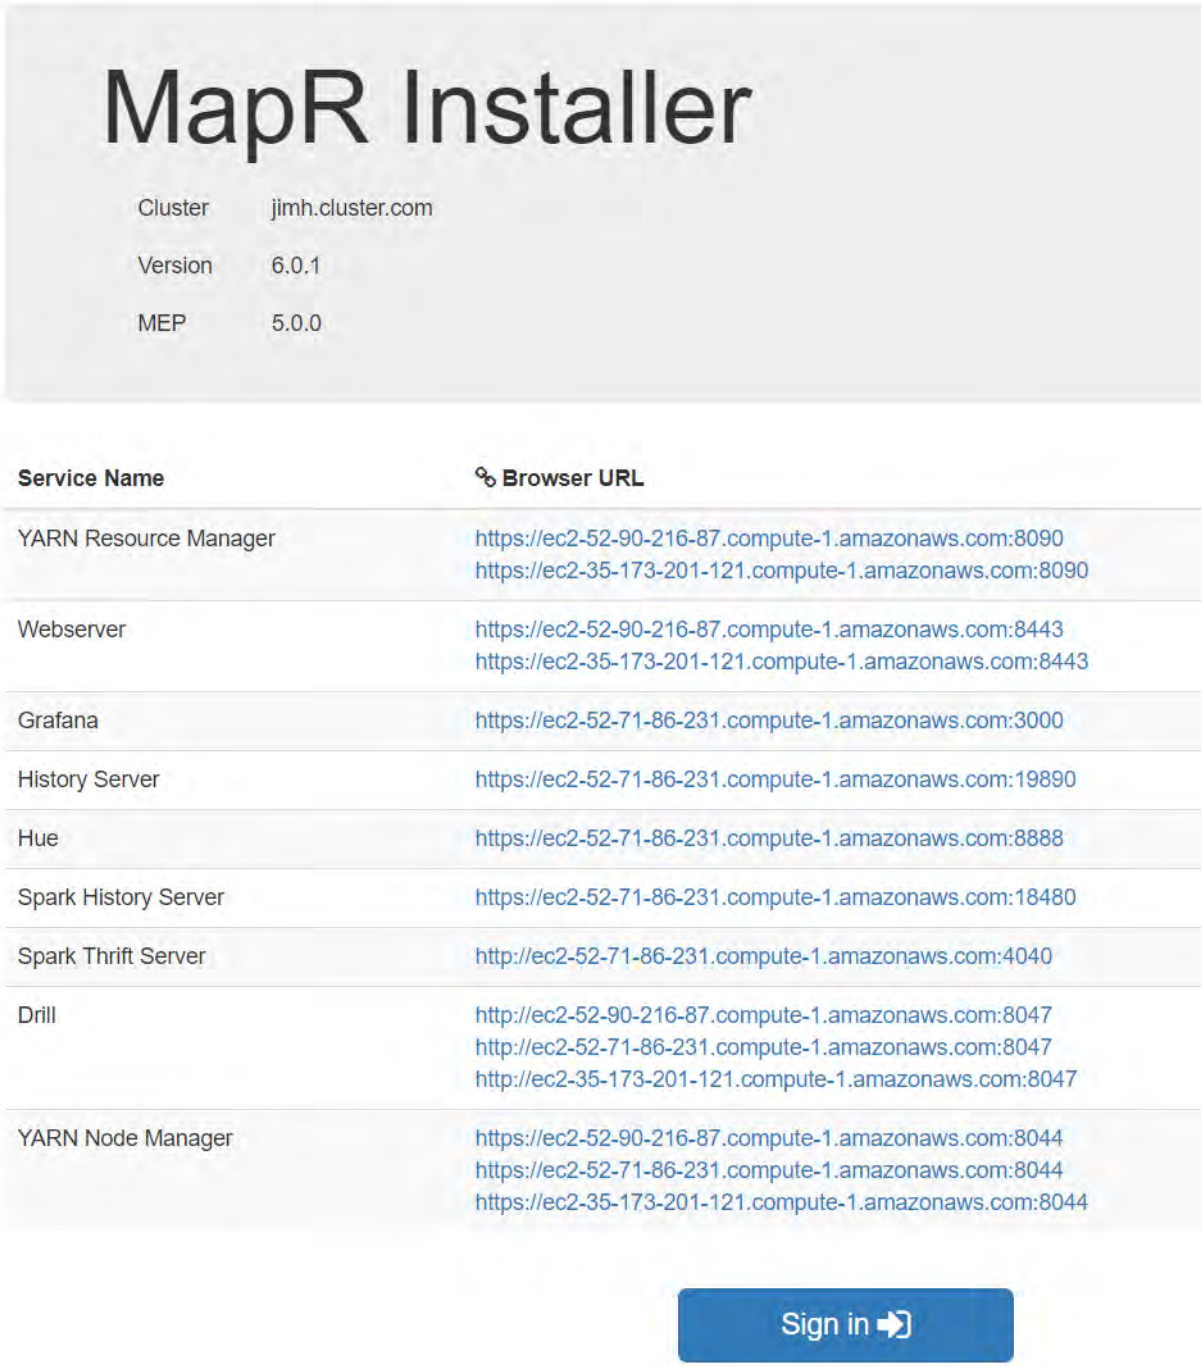
23. When the stack creation status shows CREATE_COMPLETE, the stack is created, and the cluster is installed. Click the **Outputs** tab to view the outputs. For example:



24. If stack creation generates an error, click the **Events** tab to get more information. You can expand the event message to see more information about the event.

25. If you are using an existing subnet, set up a secure connection to the subnet by using VPN or other means.

26. Once you are connected, you can click the **MaprInstallerUrl** link on the **Outputs** tab to start the web-based installer. The installer status page shows links to resources you can use to get more information about the cluster. To log on to the Control System, click one of the **Webserver** links.



Deploying a Cluster in AWS Using the MapR Reference Templates

If you need more flexibility than the marketplace offerings provide, you can use the MapR reference templates. The reference templates for AWS contain the CloudFormation parameters for deploying a MapR cluster. The reference templates allow you to:

- Create a customized CloudFormation template
- Limit the template choices
- Limit the machine types used

last-updated: Apr 11, 2022

- Customize AWS resources
- Use your own base image
- Use your own custom Stanza template

About the MapR Reference Templates for AWS

The MapR reference templates for AWS are sample CloudFormation templates that you can use to set up a MapR cluster. You can use the templates without modification, or you can customize them to suit your environment. Be sure to review the following information before using the reference templates. For more information about CloudFormation, see AWS CloudFormation.

The reference templates can be found on GitHub in folders organized by the MapR Installer version. To determine your MapR Installer version, see Checking the MapR Installer Version on page 5412.

This table describes the AWS reference templates:

Template Type	Template File Name	Function
Primary Template	`aws_cf_maprcluster_with_role.yml`	Creates a MapR cluster along with all the privileges and roles required by the MapR Installer. Use this template if you are privileged to create roles and policies in AWS.
Primary Template	`aws_cf_maprcluster.yml`	Creates a MapR cluster. This template requires the IAM role to be provided as an input. If you do not have the permission to create roles and privileges, ask your administrator to create the role for them. The `aws_cf_maprcluster_role.yml` template can be used for this purpose.
Primary Template	`aws_cf_maprcluster_ami.yml`	Creates a MapR cluster. For this template, you must provide an AMI ID and ssh user with SUDO privilege as inputs. The AMI can be any CentOS, Ubuntu, or SLES image on which the `mapr-setup.sh image prep` has not been run. The `root` disk (where `/opt/mapr` will be installed) must have a minimum of 128 GB, and swap space must be at least 10% of memory or less than 2 GB. Note that the CentOS, Ubuntu, or SLES version must be a version that is supported by MapR 5.2.2.
Primary Template	`aws_cf_maprcluster_with_cred.yml`	Creates a MapR Cluster. This template requires an AWS access key and an AWS secret key to be provided as an input. If you do not know the access key and secret key, contact your AWS administrator to obtain them.
Utility Template*	`aws_cf_maprcluster_role.yml`	Creates a role with the privileges necessary for the MapR Installer to create, modify, and release AWS instances. Once the role is created, you can pass the role name into the `aws_cf_maprcluster.yml` template.
Utility Template*	`aws_cf_maprcluster_nodes.yml`	Creates the launch configuration and auto-scaling group. If you are doing a custom deployment, you can customize this template to your needs.
Utility Template*	`aws_cf_vpc_openvpn.yml`	Deploys a VPC capable of supporting a MapR cluster. It can also, optionally, set up an OpenVPN Access Server. The OpenVPN Access Server supports two client connections for testing purposes. You can buy licenses for the Access Server from the OpenVPN website. Once the VPC is created, you can pass the subnet ID into any of the deployment templates.
Utility Template*	`aws_cf_maprcluster_vpc.yml`	Unused.
Utility Template*	`aws_cf_maprcluster_dsr.yml`	Unused

Template Type	Template File Name	Function
Sample Stanza Input File	`mapr-core.yml`	Provided as a convenience for users who need a script-based tool to install MapR software. See MapR Installer Stanzas on page 5503.

*Utility templates support the primary templates. You can modify them to suit your needs. Updated utility templates must be uploaded to s3 and referenced in your customized primary templates. The primary templates contain fully-qualified references to the utility templates.

Before Using the MapR AWS Templates

Before using the MapR AWS templates, make sure you have configured the following security prerequisites.

Configuring an AWS Account

Users who run MapR cloud formation templates must have certain minimum permissions. Contact your AWS administrator to ensure that the following AWS Policy is attached to your user account:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "autoscaling:*",
                "cloudformation:*",
                "ec2:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::*:role/*"
        },
        {
            "Effect": "Allow",
            "Action": "s3:*",
            "Resource": "arn:aws:s3:::*"
        }
    ]
}
```

To create a more secure user, you can restrict the user to a specific role using `iam:PassRole` when you create the role. For example, if your role name is `maprinstaller`, the resource entry for iam role would be:

```
"Resource": "arn:aws:iam::*:role/maprinstaller"
```

For more information about the role used for the MapR Installer, see Creating a Role for the MapR Installer on page 260.

Creating a Key Pair

Key pairs allow you to prove your identity electronically in AWS. Key pairs are region specific. You need a key pair for every region in which you intend to deploy. To create a key pair:

1. In AWS, navigate to **Services > EC2 > Key Pairs**.
2. Click **Create Key Pair**.

3. Give the key pair a name, and click **Create**.
4. Save the key-file. You will need the key-file if you need to ssh into any of the hosts.

Creating a Role for the MapR Installer

During the provisioning process, you must supply an IAM role name that can be passed on to the MapR Installer. IAM roles allow instances to delegate permissions in the absence of AWS credentials.

To create the role for the MapR Installer:

1. Log on to the AWS Management Console.
2. In the list of **Services**, under **Security, Identity, and Compliance**, click **IAM**.
3. Click the **Policies** link.
4. Click **Create policy**.
5. Give the policy a name and a description.
6. In the **Policy Document** field, paste the following policy statement:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "autoscaling:Describe*",
                "autoscaling:CreateLaunchConfiguration",
                "autoscaling:DeleteLaunchConfiguration",
                "autoscaling:SuspendProcesses",
                "autoscaling:UpdateAutoScalingGroup",
                "cloudformation:DescribeStack*",
                "cloudformation:GetTemplate",
                "cloudformation:UpdateStack",
                "ec2:CreateKeyPair",
                "ec2:DeleteKeyPair",
                "ec2:ImportKeyPair",
                "ec2:DescribeKeyPairs",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceAttribute",
                "ec2:ModifyInstanceAttribute",
                "ec2:DescribeSubnets",
                "ec2:RunInstances",
                "ec2:StartInstances",
                "ec2:StopInstances",
                "ec2:CreateVolume",
                "ec2:AttachVolume",
                "ec2:DescribeVolumes"
            ],
            "Resource": "*"
        }
    ]
}
```

7. Click **Create policy**.
8. Navigate to **Services > IAM > Roles**.
9. Click **Create new role**.

10. For the role type, select the **AWS Service Role > Amazon EC2**.
11. Filter by **Customer Managed**.
12. Select the policy created earlier.
13. Give the role a name and description.
14. Click **Create role**.

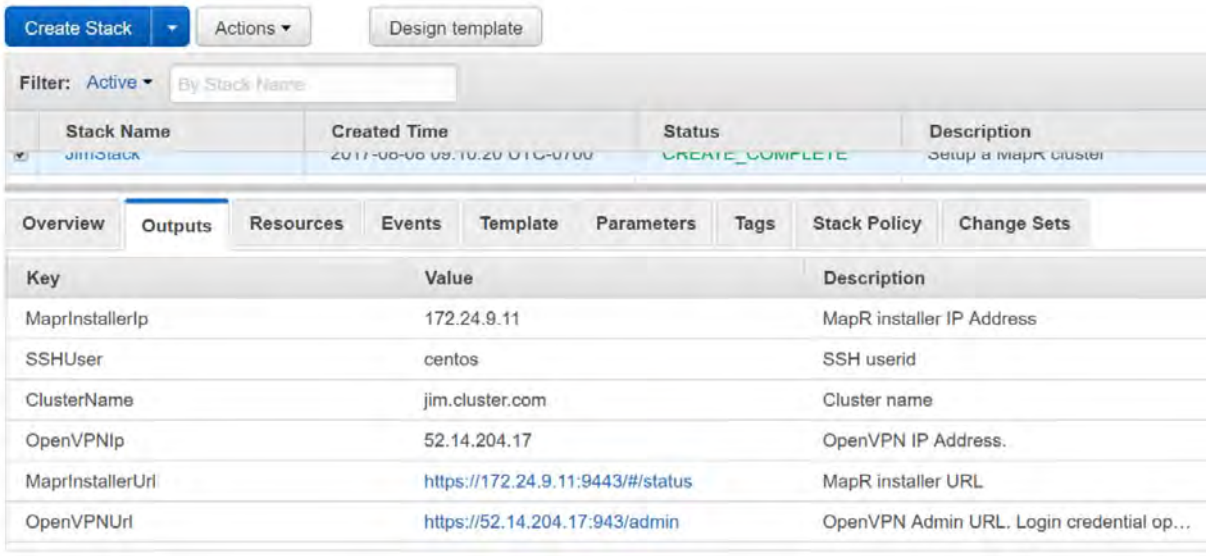
Later, during the provisioning process, you will provide the role name as an input to the reference template.

Running the MapR AWS Templates

You can use this procedure to install a MapR cluster in AWS using one of the MapR reference templates. You can run the templates as is or modify them and provide the modified template as an input to this procedure.

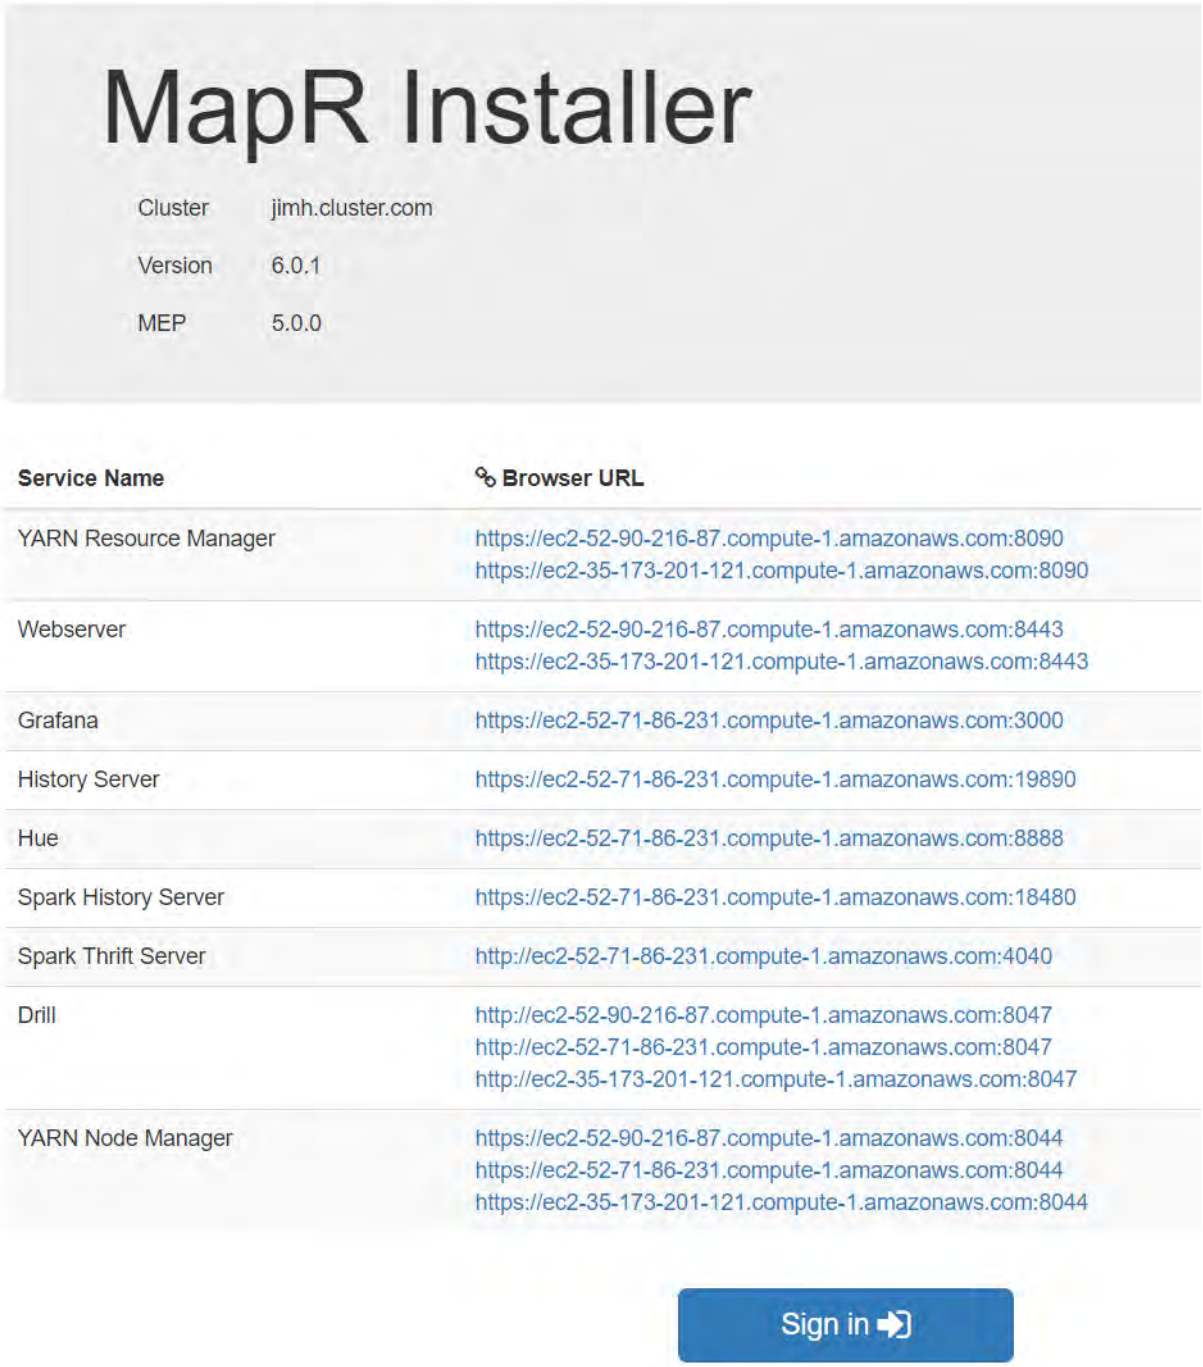
1. Sign in to the AWS Management Console.
2. Navigate to the **CloudFormation** console. The **Stacks** page is displayed.
3. Click **Create Stack**.
4. In the **Choose a template** section, select the option to upload a local template or specify the URL of a template on S3. For the locations of the MapR reference templates, see About the MapR Reference Templates for AWS on page 258.
5. Click **Next**. The MapR CloudFormation template is displayed.
6. Fill in the parameter values. See Parameter Information for AWS Reference Templates on page 263.
7. Click **Next**. The **Options** section is displayed. MapR templates don't require any specific values in this section. However, in the Advanced subsection, for debugging purposes it can be useful to set **Rollback on failure** to **No** so that resources are not deleted in the event of failure.
8. Click **Next**. The Review page allows you to review your selections. Click **Previous** if you need to change a selection.
9. Otherwise, select **I acknowledge that AWS CloudFormation might create IAM resources with custom names**.
10. Click **Create** to start the process of stack creation. The new stack is listed at the top of the CloudFormation console with a status of CREATE_IN_PROGRESS. Stack creation for a three-node cluster can take 15-20 minutes. Depending on the size of the cluster, stack creation can take longer in some cases. To view the status of stack creation, select the stack, and click the **Events** tab. You can expand the event message to see more information about an event.

    If there are errors during CloudFormation, see CloudFormation Troubleshooting on page 265.
11. When the stack creation status shows CREATE_COMPLETE, the stack is created. Click the **Outputs** tab to view the outputs. For example:



12. If you are using an existing subnet, set up a secure connection to the subnet by using OpenVPN or other means. See Using OpenVPN on page 279.

13. Once you are connected, you can click the **MaprInstallerUrl** to start the installer. The installer status page shows links to resources you can use to get more information about the cluster.



Parameter Information for AWS Reference Templates
Describes the parameters in the MapR reference templates for AWS.

Note that different templates can display different parameters and may present the parameters in a different order.

Parameter	Do this . . .
`Stack name`	Specify the stack name. MapR resources in AWS are grouped together as a stack that you create and delete as a single unit. The stack name cannot contain spaces.

last-updated: Apr 11, 2022

Parameter	Do this . . .
`keyName`	Enter the key pair that you configure in Creating a Key Pair on page 259.
`IAMInstanceProfile`	Enter the role you created in Creating a Role for the MapR Installer on page 260.
`clusterName`	Enter a name for the cluster.
`clusterAdminPassword`	Enter the password you will use to log into the Control System or the MapR Installer. This is the password for the UID `mapr`. **Note:** For cloud deployments, the installer uses the **Cluster Admin Password** as the MySQL root password when it creates a MySQL database for certain services that require a database.
`clusterAdminPasswordConfirm`	Enter the `clusterAdminPassword` again for verification.
`MEP`	Select the MapR Ecosystem Pack version.
`provisioningTemplate`	Select from the list of auto-provisioning templates. For more information about the templates, see Auto-Provisioning Templates on page 5448. Some offerings are preconfigured for provisioning and might not display this parameter.
`nodeCount`	Specify the number of nodes in the cluster.
`amiID`	Specify the Amazon Machine Image (AMI) ID. Leave this field empty to use a default AMI.
`sshUser`	Specify the ssh user with sudo privilege for the AMI you specified in `amiID`.
`instanceType`	Select from the list of AWS instance types. MapR CloudFormation templates support the following instance types: • m4.xlarge, m4.2xlarge, m4.4xlarge, m4.10xlarge, m4.16xlarge • m3.xlarge, m3.2xlarge • c4.2xlarge, c4.4xlarge, c4.8xlarge • c3.2xlarge, c3.4xlarge, c3.8xlarge • r4.large, r4.xlarge, r4.2xlarge, r4.4xlarge, r4.8xlarge • r3.large, r3.xlarge, r3.2xlarge, r3.4xlarge, r3.8xlarge • p2.xlarge • g2.8xlarge • Local Storage Instances (Use only local disks, not EBS) • i3.large, i3.xlarge, i3.2xlarge, i3.4xlarge, i3.8xlarge • d2.xlarge, d2.2xlarge, d2.4xlarge, d2.8xlarge For more information about instance types, see Amazon EC2 Instance Types.
`useInstanceStore`	Set this value to **true** if the machine type supports instance stores (ephemeral disks) and you want to use only those disks. No EBS volumes will be attached. **Note:** This field is enabled for d2.* and i3.* instance types. i3.* uses NVMe disks, which are added by default in AWS. If you use i3.* images, the option is implicitly true.
`diskCount`	Specify the disks per node.
`diskType`	Specify the disk type. For more information, see Amazon EBS Volume Types.

last-updated: Apr 11, 2022

Parameter	Do this . . .
`diskSize`	Specify the disk size.
`installerOnItsOwn`	Select **true** to configure the MapR Installer on a node that is not part of the cluster. When you select **true**, the installer is started on a t2.small instance. Select **false** to configure the installer on a node in the cluster. Note that if you select **true**, the cluster will consist of the **nodeCount** plus another node for the installer.
`useExistingSubnet`	Specify a subnet ID if you want to use an existing subnet. Leave this field empty if you would like a new BPC and subnets created. If you choose to use your own subnet: • The subnet must have access to the Internet. Hosts on that subnet must have transparent outbound access to the Internet with no additional configuration required. This means either an automatic VPN or public IP addresses. The system will connect to the Internet to update packages and software. • The subnet must be able to communicate to all hosts within the subnet on all ports. • You must have a mechanism to connect with the hosts on the subnet.
`securityGroups`	Specify the security group IDs for an existing subnet if you specified a subnet ID for **useExistingSubnet**. Leave this field empty to create a new VPC and subnets.
`installOpenVPN`	Select **True** if you want to install OpenVPN. For more information, see Using OpenVPN on page 279.
`openVPNuser`	Specify a user name for OpenVPN if you will use OpenVPN to connect to the cluster. For more information, see Using OpenVPN on page 279.
`openVPNpassword`	Specify a password for OpenVPN if you will use OpenVPN to connect to the cluster. For more information, see Using OpenVPN on page 279
`assignPublicIP`	If you want to assign a public IP address to each node, set this value to **true**. If you set the value to **false**, you must ensure that you have a way to connect to the private IP addresses. **Note:** It is recommended that you enable `assignPublicIP` if you are not using your own subnet, and you are letting the template create the VPC and subnet.
`publicAccess CIDR`	If you want to restrict the IP address from which the stack can be accessed, specify the IP address range in this field. This field applies only when the template creates the VPC and subnets.

CloudFormation Troubleshooting

If there are errors during CloudFormation:

- Check the stack creation events for more information. Click the **Events** tab to get more information. You can expand the event message to see more information about the event.
- Check the status of the auto scaling group. In EC2, click **Auto Scaling Groups**. Select a group. Then select the **Activity History** tab.
- Consult the AWS troubleshooting information.

Modifying the MapR AWS Templates

Suppose you want to customize the installation of a MapR cluster. You might want to predefine variables for your users or restrict the choices for some fields. You might want to define subnet information in a more detailed way. You can do this by modifying the MapR-provided reference templates.

last-updated: Apr 11, 2022

For more information about customizing a template, see About the MapR Reference Templates for AWS on page 258 and Working with AWS CloudFormation Templates

After customizing a template, you can run the template using the steps in Running the MapR AWS Templates on page 261.

Installing the AWS Instance and MapR Cluster Manually

For more information, see these MapR blogs:

- 9 Step to Deploying the MapR Converged Data Platform on AWS
- Manual AWS Deployment

Deleting an AWS Stack

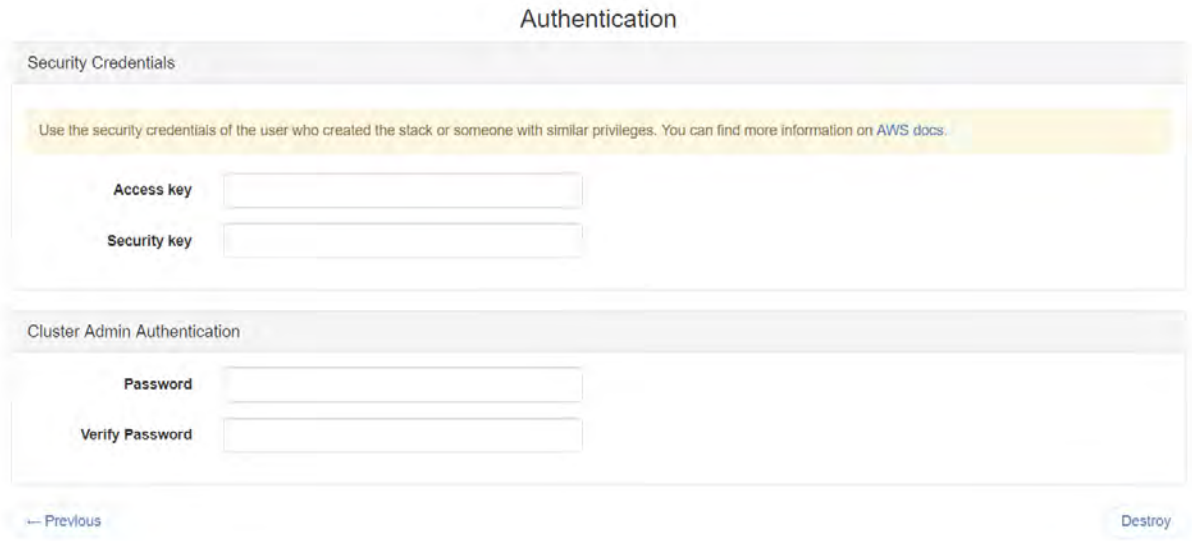
MapR resources in AWS are grouped together, making it easy for you to remove them. You can use the MapR Installer **Destroy** button to delete an AWS stack in one operation. The **Destroy** button appears when the MapR Installer detects cloud installations that were created using MapR scripts.

You can also use AWS menu commands to delete an AWS stack. Because the MapR stack is an Auto Scaling Group, deleting it using AWS menu commands requires some extra steps. First, you must disable certain AWS processes that protect against shutting down the stack. Then you must delete the stack.

Delete an AWS Stack Using the Destroy Button

To remove an AWS stack using the MapR Installer, you can use the **Destroy** button:

1. Log in to the MapR Installer.
2. On the status page, click the **Destroy** button. A confirmation box asks if you want to delete the MapR cluster.
3. Click **OK**. The **Authentication** page appears:



4. Enter your security credentials, and click **Destroy**. The Installer displays:

```
We will start to delete your cluster and all the resources associated
with it. Please check the AWS console to verify that all resources were
deleted successfully.
```

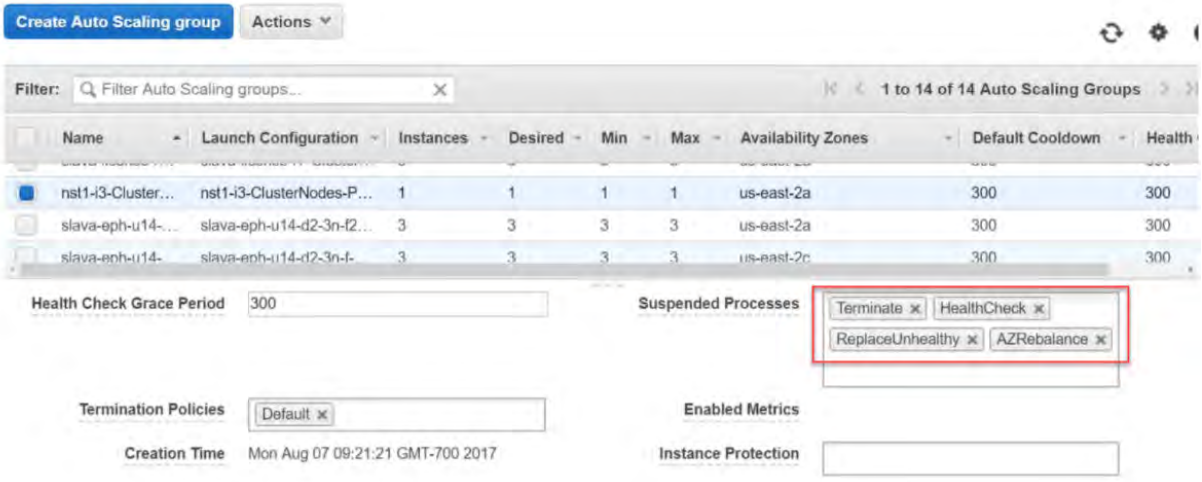
You can monitor the status of stack deletion in the AWS console.

Delete Suspended Processes

Use these steps if you want to delete your MapR stack using AWS menu commands. You do not need to use these steps if you use the MapR Installer **Destroy** button. To remove a MapR stack using AWS menu commands, you must delete suspended processes and then delete the stack.

1. Click **Services > EC2**.
2. In the left navigation pane, under **Auto Scaling**, click the link to **Auto Scaling Groups**.
3. In the list of Auto Scaling Groups, find and select the name of your stack.

   Tip: Type the first few letters of the stack name in the **Filter** field to find the stack.
4. Click the **Details** tab to select it.
5. Click **Edit**.
6. Scroll down to the **Suspended Processes** section:



7. Click the "x" in each of the suspended processes to delete it.
8. Click **Save**.

Delete the Stack

You do not need to use these steps if you use the MapR Installer **Destroy** button. To remove an AWS stack manually, you must delete suspended processes and then delete the stack.

1. Navigate to the CloudFormation section, and select your stack.
2. From the **Actions** menu, select **Delete Stack**.
3. To confirm the delete operation, click **Yes, Delete**.

Deploying MapR Clusters on Azure

This section describes cloud-deployment procedures for Microsoft Azure.

To view the MapR reference architecture for Azure, see the Reference Architecture For Azure Deployments.

For procedures supporting Amazon AWS, see Deploying MapR Clusters on AWS on page 252.

MapR Offerings in the Azure Marketplace

last-updated: Apr 11, 2022

To view the MapR offerings in Azure:

1. In a browser, navigate to the Azure portal.
2. Click **Marketplace**.
3. In the Search field, enter `MapR`, and press **Enter**.

The documentation in this section supports the following offering:

```
MapR Converged Data Platform v6
```

Prerequisites for Deploying a MapR Cluster in Azure

To deploy a MapR cluster in Azure, you must have an Azure subscription and sufficient subscription linits or quotas to deploy a cluster of the specified size. For more information, see:

- Azure Subscription
- Subscription Limits / Quotas

Deploying a Cluster in Azure Using the MapR Marketplace Offering

Explains how to deploy a cluster in Azure using the Marketplace Offering.

Before you can use a MapR marketplace offering to deploy a cluster in Microsoft Azure, you must select and configure certain parameters and gain access to the cluster.

Select the Offering

1. Navigate to the MapR page in the Azure Marketplace. For more information, see MapR Offerings in the Azure Marketplace on page 267.
2. Select **MapR Converged Data Platform v6**.
3. Click **Create**.

Configure Basic Settings

1. In the **Admin username** field, enter the user name for the cluster administrator (for example, `admin_mapr`). This is an operating-system account that will be created on all nodes in the cluster.
2. In the **Authentication type** field, select **Password** or **SSH public key**.
3. In the **Admin password** field, enter the password for the Admin user. The password must be between 12 and 72 characters long and must have three of the following:
   - One lower case character
   - One upper case character
   - One number
   - One special character that is not "\" or "-".

   Note: For cloud deployments, the installer uses the Cluster Admin Password as the MySQL root password when it creates a MySQL database for certain services that require a database.
4. Reenter the **Admin password**.
5. In the **Subscription** field, enter the subscription option that is appropriate for your installation.

6. In the **Resource group** field, either select the option to create a new resource group and give it a name, or select the option to use an existing group. The examples in this procedure use `myRG` as the resource group name.
7. In the **Location** field, select your region.
8. Click **OK**.

Configure the MapR Cluster Configuration

1. In the **MapR cluster name** field, enter a name for the cluster. Give your cluster a DNS-friendly name, such as `my.cluster.com`. The name should be unique across all of your clusters.
2. In the **Cluster admin password** field, enter the password for the UID `mapr`. The password must be between 6 and 30 characters, and must include at least one uppercase letter, one lowercase letter, and one numeric digit.

   Note: The UID `mapr` is not the same account as the Admin user account that you created in step 1 of Configure Basic Settings on page 268. The Admin user account is used for MapR software installation and can be used subsequently for SSH access and server administration. The UID `mapr` is the MapR administrator account, which is an additional OS account that is created on each node in the cluster and acts as the MapR system user.
3. Confirm the password.
4. In the **EEP version** field, ensure that the MapR Ecosystem Pack (EEP) version is selected.
5. In the **License type** field, select either the Enterprise or Community
6. In the **Provisioning template** field, select the auto-provisioning template. For more information, see Auto-Provisioning Templates on page 5448.
7. In the **Node count** field, enter the number of nodes.
8. Click **OK**.

Complete the Node Configuration

1. In the **Virtual Machine Size** menu, select a VM size, first clicking **View all** if you need to see the supported machines for the selected region.
2. In the **Disk count** field, enter the number of disks.
3. In the **Disk type** field, select between SSD and HDD disks.
4. In the **Disk size** field, enter the disk size in gigabytes.
5. Click **OK**.

Configure Global Access and Security

1. In the **Virtual network** field, create a new virtual network or choose an existing one.
2. Complete the **Subnets** values as needed:
   - Private subnet name
   - Private subnet address prefix
   - Public subnet name

last-updated: Apr 11, 2022

- Public subnet address prefix

3. In the **Public internet access CIDR** field, enter the public Internet access CIDR, or use * for all Internet traffic. This field enables you to set or restrict the outside Internet IP addresses that can access the cluster.
4. In the **Install OpenVPN** field, select **True** if you want to install OpenVPN. For more information about using OpenVPN to access this MapR cluster, see Using OpenVPN on page 279.
5. In the **OpenVPN login user** field, specify a user name for OpenVPN.
6. In the **OpenVPN login user password** field, specify a password for OpenVPN. The password must be at least 6 characters, no more than 30 characters, and must include at least one upper case letter, one lower case letter, and one numeric digit.
7. Confirm the password.
8. In the **Disk type** field, select **SSD** or **HDD** as the disk type.
9. Click **OK**.

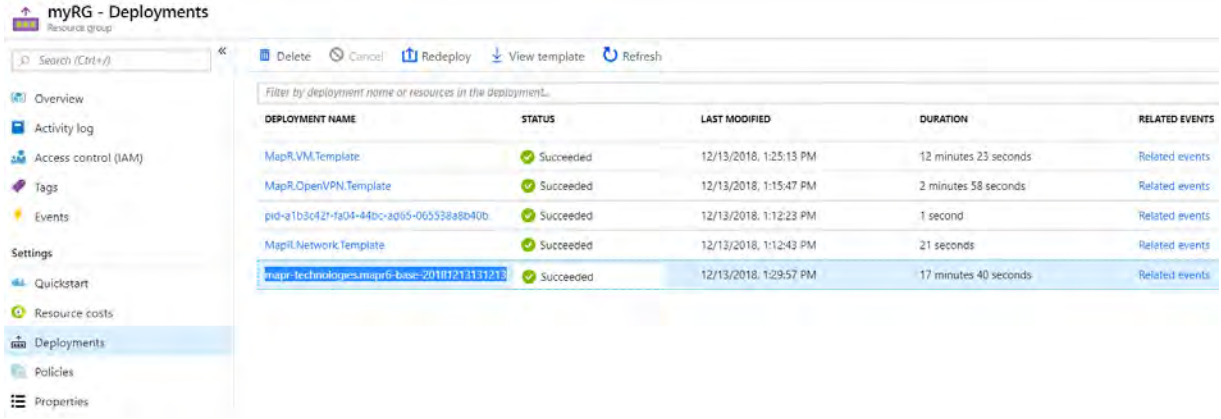
Complete the Summary Information and Purchase

1. Review the summary information and, if necessary, navigate back through the menus to make corrections or updates.
2. Click **OK**.
3. On the **Create** screen, review your contact information and then click **Create**.

Gain Access to the Cluster

1. Navigate to the **Resource groups** menu.
2. Click the link for your resource group (for example, `myRG`) to monitor the creation of resources.
3. Once the cluster is deployed, you can access it through a collection of URLs provided by the MapR Installer. These URLs may require a VPN connection, and you may need to use a tool such as OpenVPN to connect to the virtual machine. For more information, see Using OpenVPN on page 279.

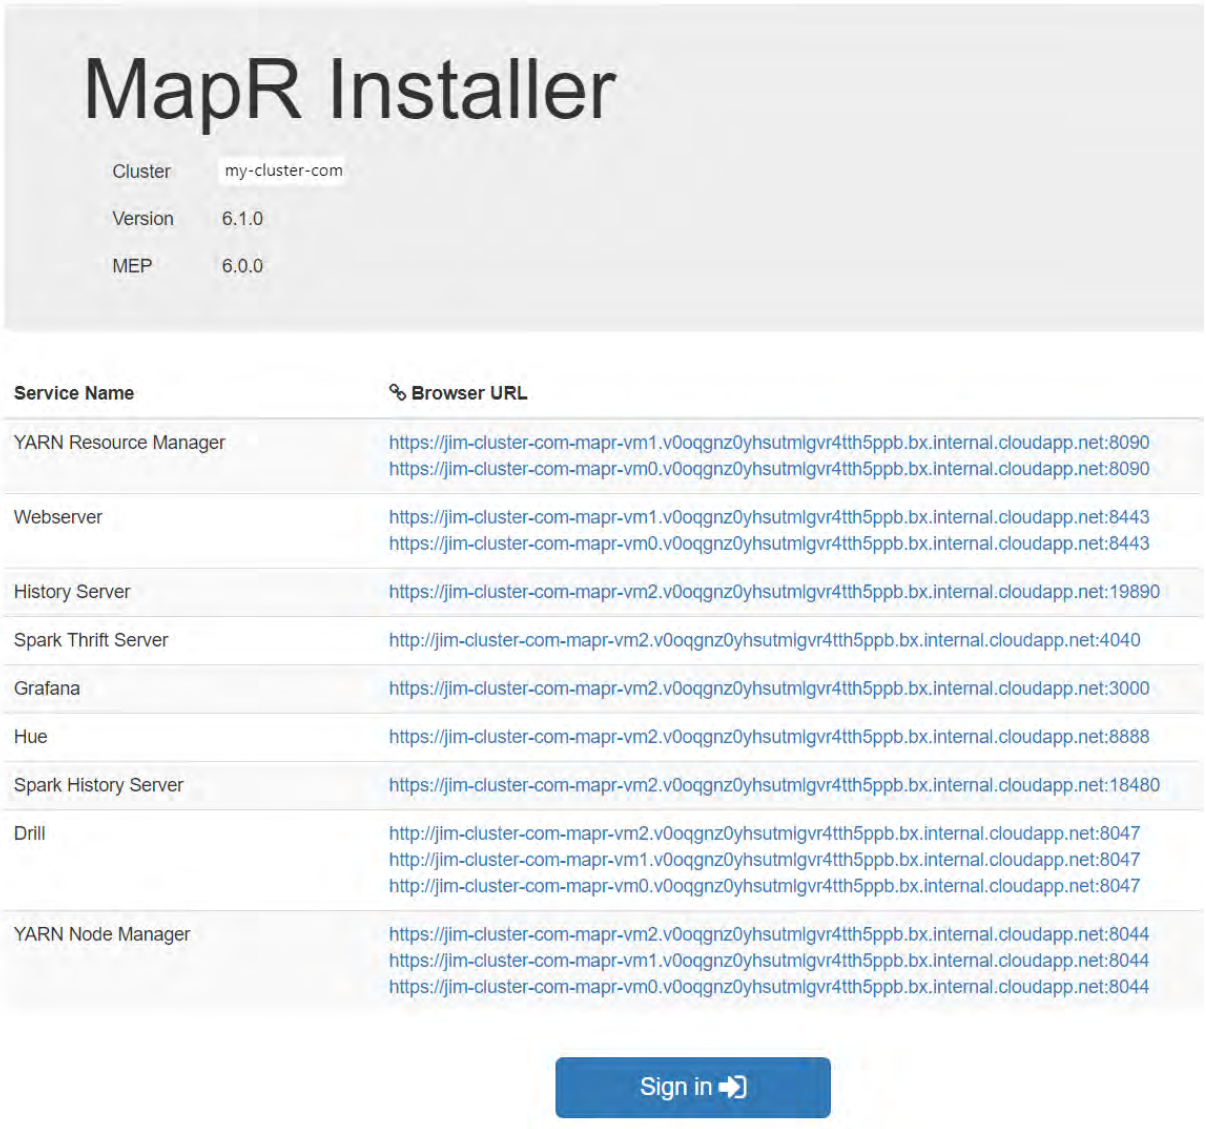
   If you did not choose to install OpenVPN in step 4 of Configure Global Access and Security on page 269, you must use another method or tool to connect to the virtual machine.
4. Once you are connected, use the **MAPRINSTALLERURL** to access the status page of the MapR Installer. To locate the **MAPRINSTALLERURL**, navigate to **Resource Groups > myRG > Deployments**, and click the cluster deployment name. For example:



The **Overview** page appears.

5. Click the **Outputs** tab to display the **MAPRINSTALLERURL** information.

6. Paste the **MAPRINSTALLERURL** into a browser to access the status page of the MapR Installer, which shows links to resources you can use to get more information about the cluster:



7. To log in to the Control System, click one of the **Webserver** links, using the password you specified for the UID `mapr` in Configure the MapR Cluster Configuration on page 269.

last-updated: Apr 11, 2022

About the MapR Reference Templates for Azure

The MapR reference templates for Azure contain the scripts and JSON templates for deploying a MapR cluster. You can use the reference templates without modification, or you can customize them to suit your environment.

The reference templates can be found on GitHub in folders organized by the MapR Installer version. To determine your MapR Installer version, see Checking the MapR Installer Version on page 5412.

This table describes the Azure reference templates:

Note: For a given JSON file name, the deployment name in Azure is similar, but does not necessarily match the file names below.

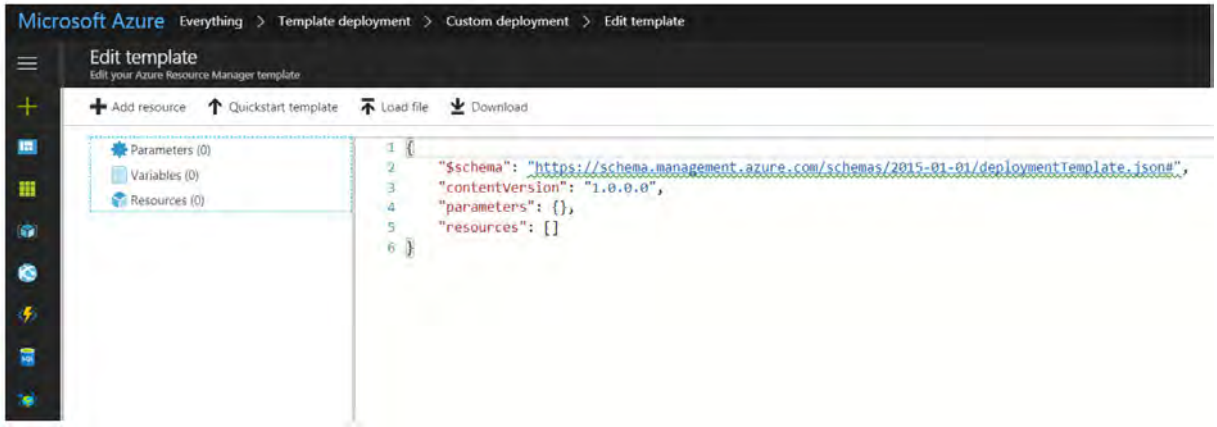
Template Type	Template File Name	Function
Primary Template	`mainTemplate.json`	References the child templates that do segregated work to create Azure resources and deploy MapR software. This is where most of the defaults can be changed to customize deployments.
Child Template	`createUiDefinition.json`	MapR marketplace GUI implementation. This is a standalone file and isn't used to deploy MapR software. This file generates JSON from user input and then sends the JSON to the `mainTemplate.json`.
Child Template	`network.json`	Child template to `mainTemplate.json`. Creates a Virtual Network and Subnet when the option to create a new is supplied.
Child Template	`openvpn.json`	Child template to `mainTemplate.json`. Creates all VM resources for the OpenVPN server then executes the `mapr-vpn.sh` script.
Child Template	`vm.json`	Child template to `mainTemplate.json`. Creates all VM resources in the cluster, including the installer node. For password-enabled and public-key-enabled OS users only.
Script	`install_openvpn_access_server.sh`	Installs OpenVPN core to an Ubuntu 17 image.
Script	`mapr-cloud-configure.sh`	Installs MapR to the newly created VMs. The `vm_xxx.json` files will send parameters to this file to initiate a Stanza MapR installation. This file is run only on the installer node.
Script	`mapr-init.sh`	Initialization script that is run on all nodes in the cluster (not just the install node). For example, this script sets passwords and sudo access.
Script	`mapr-vpn-configure.sh`	Alters the configuration of the core OpenVPN to match inputs from the user.
Script	`mapr-vpn.sh`	Decides if OpenVPN has been installed and configured already. Since the templates might be run several times by expanding the cluster, this file will not attempt to install or configure OpenVPN if it has been done already.
Sample Stanza Input File	`mapr-core.yml`	Basic Stanza file. This file has several placeholders that `mapr-cloud-configure.sh` changes. For example, changes to services that are global across all types of deployments can be changed here. Provided as a convenience for users who need a script-based tool to install MapR software. See MapR Installer Stanzas.

Running the MapR Azure Templates

last-updated: Apr 11, 2022

This procedure describes how to run the MapR reference template for Azure to deploy your MapR cluster.

1. Download the `mainTemplate.json` file from GitHub. For more information about the template, see About the MapR Reference Templates for Azure on page 272.
2. Navigate to the Azure portal, and click **New (+)**.
3. In the search field, type **Template deployment**.
4. Click **Create**.
5. Click **Build your own template in the editor**. In the **Edit template** screen, you can load a file or paste the contents of a template into the work area.



6. Paste the contents of the `mainTemplate.json` file into the **Edit template** working area.
7. Click **Save**. The template fields are displayed.
8. In the Basics section, enter your site-specific values for the following fields:
   - Subscription
   - Resource group (new or existing)
   - Location
9. In the **Settings** section, enter the username for the virtual machine in the **Admin Username** field. This is the username for the virtual machine.
10. In the **Admin Auth Type** field, enter the authentication type (password or SSH public key) for the virtual machine.
11. In the **Admin Password** field, enter the password for the virtual machine.
12. In the **Admin Public Key** field, enter the public key authentication for the virtual machine. If you entered an **Admin Password**, this field can be left blank.
13. In the **Cluster Name** field, enter your cluster name.
14. In the **Cluster Admin Password** field, enter the password corresponding to the MapR UID. For MapR images, the user defaults to `mapr`.

    Note: For cloud deployments, the installer uses the **Cluster Admin Password** as the MySQL root password when it creates a MySQL database for certain services that require a database.
15. In the **EEP Version** field, enter the MapR Ecosystem Pack (EEP) version.

last-updated: Apr 11, 2022

16. In the **Service Template** field, enter the auto-provisioning template corresponding to the services you need. For more information, see Auto-Provisioning Templates on page 5448.
17. In the **Node Count** field, enter the number of nodes.
18. In the **Instance Type** field, enter one of the following instances. MapR Azure templates support the following instance types. For more information about Azure instance types, see Sizes for Linux Virtual Machines in Azure.
    - Standard_D4s_v3
    - Standard_D8s_v3
    - Standard_D16s_v3
    - Standard_DS12_v2
    - Standard_DS13_v2
    - Standard_DS14_v2
    - Standard_DS15_v2
    - Standard_DS3_v2
    - Standard_DS4_v2
    - Standard_DS5_v2
    - Standard_E4s_v3
    - Standard_E8s_v3
    - Standard_E16s_v3
    - Standard_E32s_v3
    - Standard_F8s
    - Standard_F16s
    - Standard_GS2
    - Standard_GS3
    - Standard_GS4
    - Standard_L4s
    - Standard_L8s
    - Standard_L16s
    - Standard_L32s
19. In the **Disk Type** field, enter the disk type to use for managed disks (Premium_LRS, Standard_LRS).
20. In the **License Type** field, enter your license type.
21. In the **Disk Size** field, enter the size in gigabytes (GB) of each disk.

22. In the **Disk Count** field, enter the number of disks.
23. In the **Public Access CIDR** field, enter the public Internet access CIDR. (Use * for all Internet traffic.) This field allows you to set or restrict the outside Internet IP addresses that can access the cluster.
24. In the **Install Open VPN** field, enter `true` if you want to install OpenVPN to enable access to a private cluster. For more information about OpenVPN, see Using OpenVPN on page 279.
25. In the **Open Vpn User** field, enter the login user for OpenVPN.
26. In the **Open Vpn Password** field, enter the password for the OpenVPN login user. Use a strong password to protect your cluster.
27. In the **Vnet Name** field, enter the name of the virtual network.
28. In the **Vnet Resource Group** field, enter the resource group where the virtual network will be created.
29. In the **Vnet Address Prefix** field, enter the address prefix for the virtual network.
30. In the **Vnet New or Existing** field, enter `new` or `existing` to describe the virtual network.
31. In the **Vnet Private Subnet Name** field, enter the subnet name of the virtual network.
32. In the **Vnet Private Subnet Address Prefix** field, enter the private subnet address prefix of the virtual network.
33. In the **Vnet Public Subnet Name** field, enter the subnet name of the virtual network.
34. In the **Vnet Public Subnet Address Prefix** field, enter the public subnet address prefix of the virtual network.
35. In the **Vnet Public Subnet Start Address** field, enter the public subnet start address of the virtual network.
36. In the **Location** field, enter your region
37. Click the option to agree to the terms and conditions.
38. Click **Purchase**.
39. Navigate to the Azure resource groups page to monitor the creation of the cluster.

Note: Cluster creation for a three-node cluster can take 15-20 minutes. Depending on the size of the cluster, cluster creation can take hours in some cases.

Modifying the MapR Azure Templates

Suppose you want to customize the installation of a MapR cluster. You might want to predefine variables for your users or restrict the choices for some fields. You might want to define subnet information in a more detailed way. You can do this by modifying the MapR-provided reference templates.

For more information about customizing a template, see About the MapR Reference Templates for Azure on page 272 and Azure Resource Manager Template Deployment.

After customizing a template, you can run the template using the steps in Running the MapR Azure Templates on page 272.

What Happens During Azure Deployment

last-updated: Apr 11, 2022

The primary reference template for Azure (`mainTemplate.json`) is a starting point for all the child templates that create Azure resources. When the primary template is deployed, some resources are created in parallel. Here is what happens in a typical deployment:

1. The primary template is deployed.
2. If the option to create a new network was selected, the `MapR.Network.Template` is deployed.
3. `MapR.Network.Template` creates the virtual network and subnet(s).
4. `MapR.VM.Template` and, optionally, the `MapR.OpenVPN.Template` are started in parallel.
5. `MapR.VM.Template` creates all the resources needed to install and run MapR software. The number of resources varies depending on the Node Count you selected. This process creates:
   - Virtual machines
   - Network interfaces
   - Managed disks

   After these resources are completely created, the MapR installation starts via Stanza.
6. `MapR.OpenVPN.Template` creates one virtual machine, network interface, and managed disk. This Ubuntu machine has the OpenVPN server installed via script after these resources are completely created.

Azure Deployment Troubleshooting

If Azure reports a problem during deployment, follow these steps to determine where the problem occurred. Typically, the problem is either an Azure resource issue or a MapR installation issue.

1. Use these steps to learn more about the issue that needs troubleshooting:
   a. Log in to the Azure portal.
   b. In the left navigation pane, select **Resource groups**.
   c. Find the resource group to which the MapR installation was deployed.
   d. Click **Deployments**.
   e. Find the deployment that had a failure. Typically, an error on the Microsoft.Template will not be relevant, and there should be at least two deployments with a failure.
   f. If the error does not report an issue with `mapr-installer`, the issue is not MapR-related, and the error reported should indicate the Azure issue that caused the problem.
2. If the issue appears to be MapR-related:
   a. Use `ssh` to connect to the MapR installer node.

      Note: The MapR Installer is always created on the virtual machine that ends in the number 0. For example, `certtest1-cluster-com-mapr-vm0` would have the running installer, while `certtest1-cluster-com-mapr-vm3` (or any other number) would not.

   b. As `root`, go to `/var/lib/waagent/custom-script/download/0/`.
   c. Inspect the `stdout` and `stderr` files. These files contain the messages output from running the scripts that install the MapR software using Stanzas.

last-updated: Apr 11, 2022

d. If the problem cannot be identified, check the MapR Installer logs at `/opt/mapr/installer/logs`. For more information, see Logs for the MapR Installer on page 5453.

Installing the Azure Resource Group and MapR Cluster Manually

For more information, see the MapR blogs.

Deleting a MapR Cluster in Azure

You delete a MapR cluster in Azure by using the MapR Installer Destroy button or by deleting the resource group.

The **Destroy** button is present when the MapR Installer detects cloud installations that were created using MapR scripts. Note that any data contained in the cluster will be lost when you use the **Destroy** button or delete the resource group.

Delete an Azure Cluster Using the Destroy Button

To remove an Azure cluster by using the **Destroy** button:

1. Log in to the MapR Installer.
2. On the status page, click the **Destroy** button. The MapR Installer prompts you for security credentials and the cluster admin password.
3. Enter your security credentials and MapR cluster admin password, and click **OK**.

Deleting an Azure Cluster Using the Azure Console

You can also delete a MapR cluster in Azure by deleting the resource group.

1. In the Azure portal, navigate to the **Resource groups** page.
2. Select the resource group to be deleted.
3. Right-click the resource group, and select **Delete resource group**.
4. Confirm the resource to be deleted by typing the resource group name.
5. Click **Delete**.

Customizing Your Deployment by Using the MapR Installer Web Interface

If you use a MapR offering or reference template, the cluster is installed for you according to the parameters you specified. Another way to customize the resources and services provisioned to a MapR cluster on AWS or Azure is to create a stack or resource group with only the MapR Installer. Once the stack or resource group is created, you can use the MapR Installer web interface to finish configuring the cluster.

This procedure is the same for AWS and Azure:

1. Choose one of these procedures to create an AWS stack or an Azure resource group:
   - Running the MapR AWS Templates on page 261
   - Running the MapR Azure Templates on page 272
2. When you run the template, fill in the MapR template values as described in one of previous topics:

   Important: In the **provisioningTemplate** field (AWS) or **Service Template** field (Azure), select **Custom-Configuration** for the Auto-Provisioning Templates on page 5448. Selecting **Custom-Configuration** instructs the template to install only the MapR Installer and related software so that you can finish the cluster installation on your own.

last-updated: Apr 11, 2022

3. After stack creation (AWS) or resource group creation (Azure), log on to the MapR Installer, and use the web interface and on-screen user assistance to configure the resources and services you need in the cluster.

   Note: For cloud-based installations, the MapR Installer displays **Authentication** screens with cloud-specific parameters that are different from the **Authentication** screens for on-premise clusters. Use the tooltips on these screens to understand the authentication information that you need to provide for your cluster.

Creating Custom Images

The `mapr-setup.sh` script allows you to build custom Amazon Machine Images (AMIs) or Azure VM images. You can use these images to create more instances of the original image. With a couple of exceptions, the steps for creating custom images are the same for AWS and Azure.

To create a custom image:

1. Create the instance from which you want to build the image.
2. Download or copy `mapr-setup.sh` to the instance. For more information, see MapR Installer.
3. Prep the image. This step adds MapR software to the image. For example:

   ```
   ./mapr-setup.sh image prep --version 5.2.2
   ```

4. Respond to the questions in the script.
5. (Optional): Install other software as needed on the image.
6. (Azure only): Finalize the image:

   ```
   ./mapr-setup.sh image finalize azure
   ```

7. Create the image by using the `image create` command:

   Note: (Azure only): The image create command must be run off the VM that you want to make an image out of. The command can be run anywhere the Azure CLI is installed or anywhere the MapR Installer 1.6 setup script is installed.

   - **AWS example**

     ```
     ./mapr-setup.sh image create
     ```

   - **Azure example**

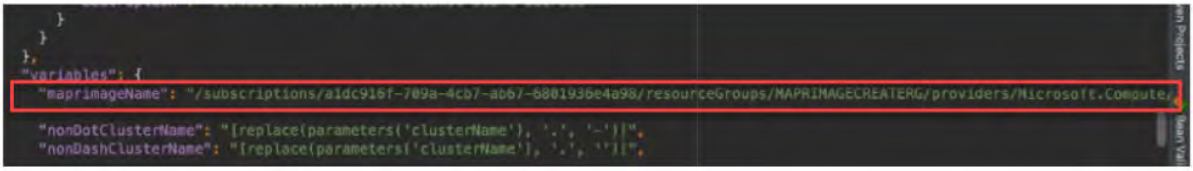
     In this example, the script looks in the `MapRImageCreateRG` resource group for a machine called `MyVirtualMachine` and creates an image called `MapRImage2`:

     ```
     ./mapr-setup.sh image create azure -u user@mapr.com -g
     MapRImageCreateRG -n MyVirtualMachine -i MapRImage2
     ```

8. (AWS only): Once the image is created, you can see the image ID in the EC2 console.
9. (Azure only): Once the image is created, you can see the image in the list of resource groups. You can copy the image ID from the script:

Note: Another way to obtain the Azure image ID is to navigate to the Azure console and check the resource ID for the new image:

10. (AWS only): Update the AMI ID in the `RegionMap` of your CloudFormation template.
11. (Azure only): Update the resource ID in the `maprimageName` field in the ARM template.



12. (AWS only): Run the CloudFormation template using the steps in Running the MapR AWS Templates on page 261.
13. (Azure only): Run the ARM template using the steps in Running the MapR Azure Templates on page 272.

Adding Nodes to a Cloud-Based Cluster

You can increase the capacity of a cloud-based MapR cluster by adding nodes using the MapR Installer or MapR Installer Stanzas. See Extending a Cluster by Adding Nodes.

Shutting Down and Restarting a Cloud-Based MapR Cluster

Shutting down and restarting a cloud-based MapR cluster is different from shutting down and restarting an on-premise cluster. For on-premise clusters, using the MapR Installer **Shutdown** button stops MapR services but leaves the nodes running. For cloud-based clusters, the shutdown operation halts all nodes in the cluster. Shutdown and restart are the same for AWS and Azure clusters.

For shutdown instructions, see one of these topics:

- Shutting Down a Cluster Using the MapR Installer Shutdown Button on page 5446
- Shutting Down a Cluster Using an Installer Stanza Command on page 5514

Restarting a Cloud-Based Cluster

In EC2 or the Azure portal, find the servers that are in the shutdown state, and restart them. Note that it takes a few minutes for the nodes to discover each other.

Using OpenVPN

You can use OpenVPN to create a secure tunnel between your workstation and the private subnet for the MapR cluster.

Using OpenVPN with AWS

To download the OpenVPN desktop client:

1. On the **Outputs** tab, copy the **OpenVPNUrl**. For example:

   ```
   https://52.14.236.170:943/admin
   ```

2. Paste the URL into a browser, but remove the `admin`. For example:

   ```
   https://52.14.236.170:943/
   ```

   OpenVPN displays download links for the OpenVPN Connect app.

3. Click the appropriate link to download the app for your workstation. You need to do this only once.

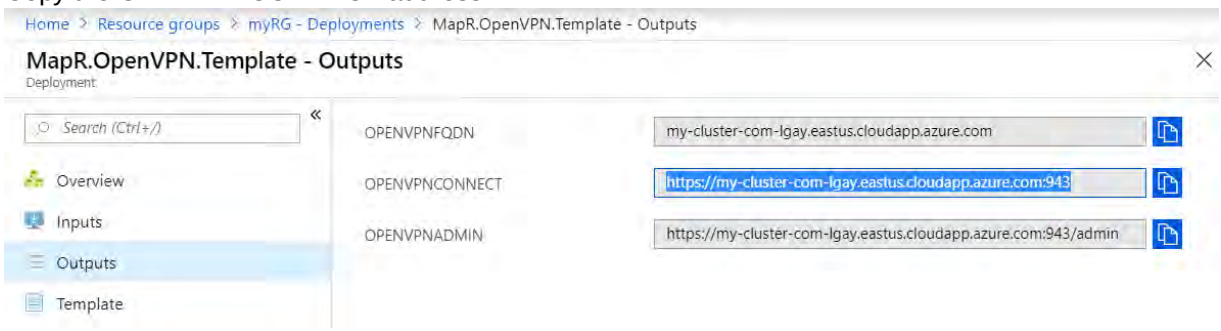
To connect to the cluster using OpenVPN:

1. Use the OpenVPN **Connect** command to display the **Login** screen.
2. In the **Server** field, paste the **OpenVPNIp** value from the **Outputs** tab.
3. In the **Username** and **Password** fields, enter the OpenVPN username and password you specified in the reference template.

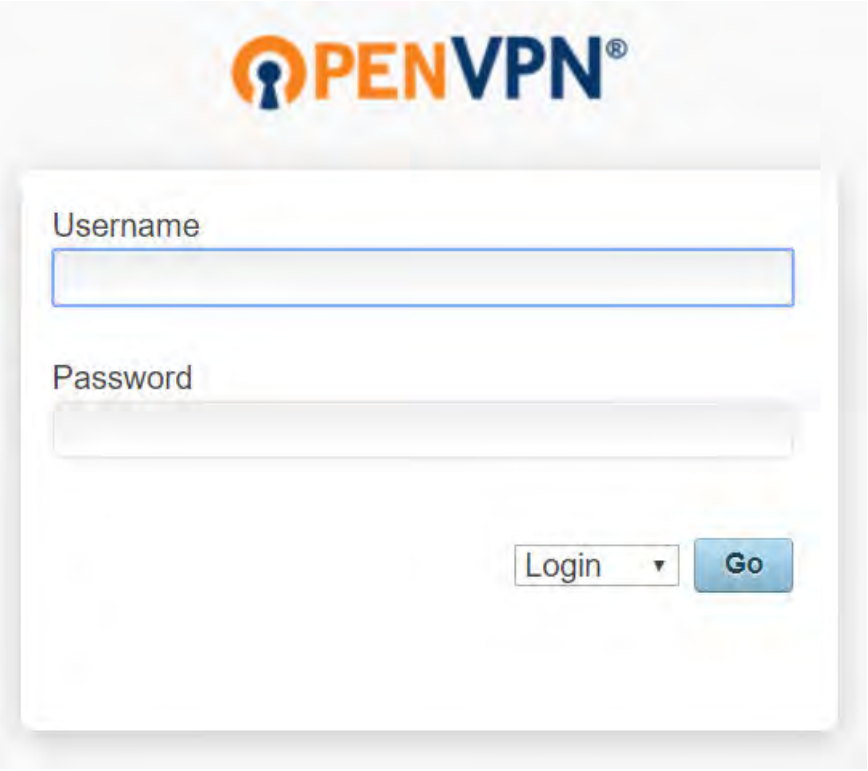
Using OpenVPN with Azure

For Azure clusters, you can use the OPENVPNCONNECT URL and your OpenVPN login user name and password to establish a secure connection to the OpenVPN server. Then you can download and install the OpenVPN client and use the client to connect to the cluster. To locate the Open VPN URL:

1. Navigate to the **Resource groups** menu, and click the link for your Resource group.
2. Click **Deployments > MapR.Open.VPN Template > Outputs**.
3. Copy the OPENVPNCONNECT address:



4. Paste the OPENVPNCONNECT address into a browser. The OpenVPN login dialog appears:



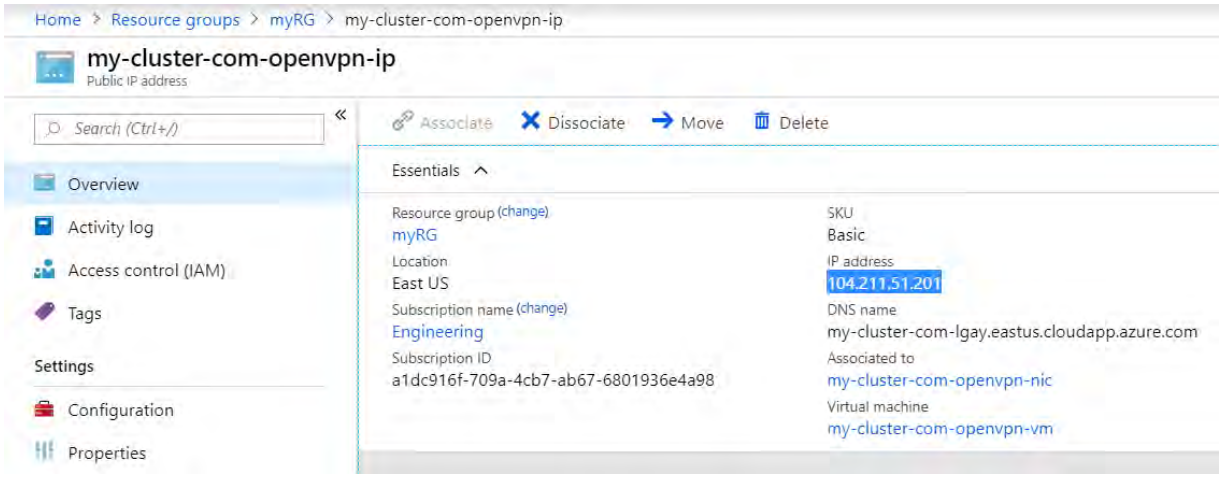
5. Log in using the OpenVPN login user name and password that you specified in Configure Global Access and Security on page 269. The OpenVPN download page appears:

last-updated: Apr 11, 2022

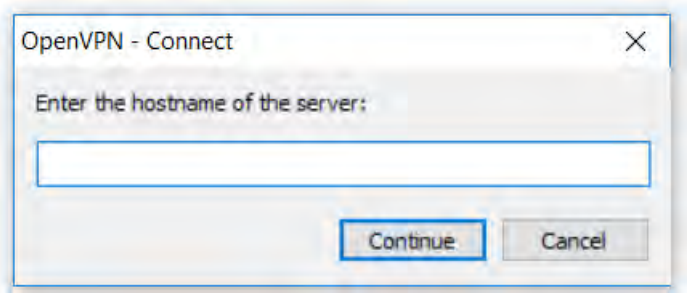
6. Click the appropriate link to download the OpenVPN installation file to your workstation.
7. Double-click the installation file to install the OpenVPN client.

To connect to the cluster using the OpenVPN public IP address:

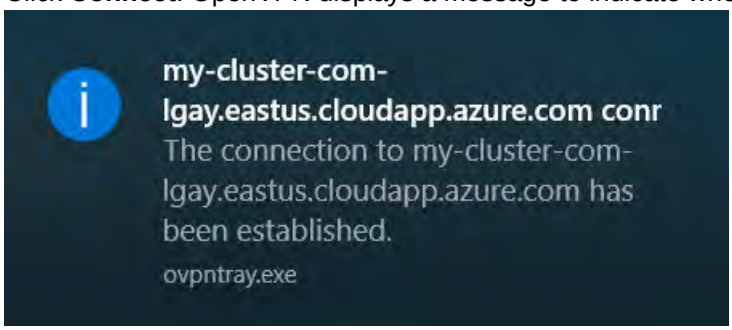
1. Locate the OpenVPN public IP address by navigating to **Resource Groups > myRG**.
2. In the list of resources, click the link for the public IP address. For example: `my-cluster-com-openvpn-ip`. IP address information is displayed:



3. In the system tray, open the OpenVPN Connection application, and select **Connect**. The OpenVPN Connect dialog appears:



4. Enter the OpenVPN IP address into the hostname field, and click **Continue**.
5. In the **Username** and **Password** fields, enter the OpenVPN username and password you specified in the reference template:Locate the OpenVPN public IP address by navigating to **Resource Groups > myRG**.
6. Click **Connect**. OpenVPN displays a message to indicate when you are connected:



Known Issues for Cloud-Based Clusters

Before installing a MapR cluster in the cloud, be sure to review these known issues:

Issue	Description
IN-2012	An issue in the Java version used by the MapR Installer prevents the Installer from supporting a domain suffix that starts with a number. Azure generates a random string for the domain suffix, so this problem can occur intermittently. **Workaround** The `mapr-setup.sh` script checks for the DNS Suffix during installation and fails with an error similar to the following when the suffix begins with a number. If you see this error message, create new nodes and retry the installation with a DNS Suffix that does not start with a number. `ERROR: The DNS Suffix 14x325z0ek4ezp1skptqsztkyg.dx.internal.cloudapp.net starts with a number which is incompatible with OpenJDK keytool application. This cluster is invalid. Recreate the cluster again; DNS Suffix is 14x325z0ek4ezp1skptqsztkyg.dx.internal.cloudapp.net; First character of DNS Suffix is: 1\n*.*`
IN-860	If you create a cluster using a MapR marketplace offering for Amazon AWS and use ephemeral drives, and you then shut down the cluster, most MapR services cannot be restarted. This happens because the disks are new, and the MapR cluster is not aware of the ephemeral drives. **Workaround:** Do not use clusters with ephemeral drives, or do not shut down the cluster. When the cluster is not in use, terminate it.
IN-974	If you request public IP addresses for the MapR Installer nodes in Amazon AWS, the IP addresses can change after a shutdown and restart of the cluster, and the MapR Installer status page continues to display the old public IP addresses. **Workaround:** None.

Links to AWS and Azure Documentation

Cloud-computing platforms add new features and capabilities almost daily.

For more information about using the Amazon or Microsoft cloud platforms:

- Amazon AWS Documentation
- Microsoft Azure Documentation

Installing Metering

This section describes how to install Metering by using the MapR Installer or manual steps.

Installing Metering Using the MapR Installer

This section describes how to install Metering by using the MapR Installer.

Metering is part of the `mapr-apiserver` package and is installed by default when you use the MapR Installer to install MapR 6.1 or later. Metering requires a minimal level of metrics collection to be enabled. On the **Monitoring** page of the MapR Installer web interface, you can choose between two configuration options for metrics collection:

- A "full collection configuration" installs collectd on all nodes in the cluster with a configuration suitable for monitoring all available node metrics. This configuration is the default setting.
- A "minimum collection configuration" installs collectd on all nodes in the cluster with a configuration suitable for supporting metering metrics collection (but not MapR Database table metrics). Note that when you choose this option, table metrics are not visible in the MapR Control System.

last-updated: Apr 11, 2022

For more information about Metering, see Metering on page 1320. To get started using the MapR Installer, see MapR Installer.

Installing Metering Using Manual Steps

This section describes how to install Metering by using manual steps.

For MapR 6.1 and later releases, no special steps are needed to install Metering. Following the manual installation steps in Installing without the MapR Installer on page 141 installs Metering. Note these considerations:

- Metering is included in the `mapr-apiserver` package and is installed when you install or upgrade to MapR 6.1.
- Metering requires a minimal level of metrics collection to be enabled. You must install collectd and OpenTSDB. See Step 8: Install Metrics Monitoring on page 162. Grafana does not need to be installed for metering and is optional for metrics monitoring in general.
- The manual steps for configuring metrics collection configure collectd to monitor all available node metrics. You can configure collectd to collect only metering metrics (and omit MapR Database table metrics) by using the `-EPcollectd -minimal` option with `configure.sh`. For example:

  ```
  /opt/mapr/server/configure.sh -C nodeA -Z nodeB -EPcollectd -minimal
  ```

  To change from the minimal collection configuration back to the full collection configuration, use the `-EPcollectd -all` option with `configure.sh`.

To use Metering, see Metering on page 1320.

Upgrading MapR Core or EEP Components

Depending on your current configuration, you may choose to upgrade the release version (core), ecosystem components, clients, or monitoring components.

Getting Started with Upgrades

Most upgrades involve moving from one version of core to another version and upgrading MapR Ecosystem Pack (EEP) components at the same time. To learn about the different methods you can use to execute this kind of upgrade, see Upgrade Workflows on page 285.

Upgrading an EEP

To upgrade an ecosystem component, you must upgrade the EEP to which it belongs. EEPs can be upgraded when you upgrade core or independently of a core upgrade. If your core release supports multiple EEP versions, you might be able to upgrade to a different EEP without upgrading core. See EEP Support and Lifecycle Status on page 5531.

If a component is supported by your current EEP, you can add the component at any time by using manual steps or the **Incremental Install** function of the MapR Installer. See Upgrading MapR Ecosystem Packs on page 335.

Upgrading MapR Clients

The MapR client is a part of core. You upgrade client nodes after you upgrade the cluster nodes but before enabling new features. See Planning Upgrades to MapR Clients on page 301.

last-updated: Apr 11, 2022

Upgrading MapR Monitoring

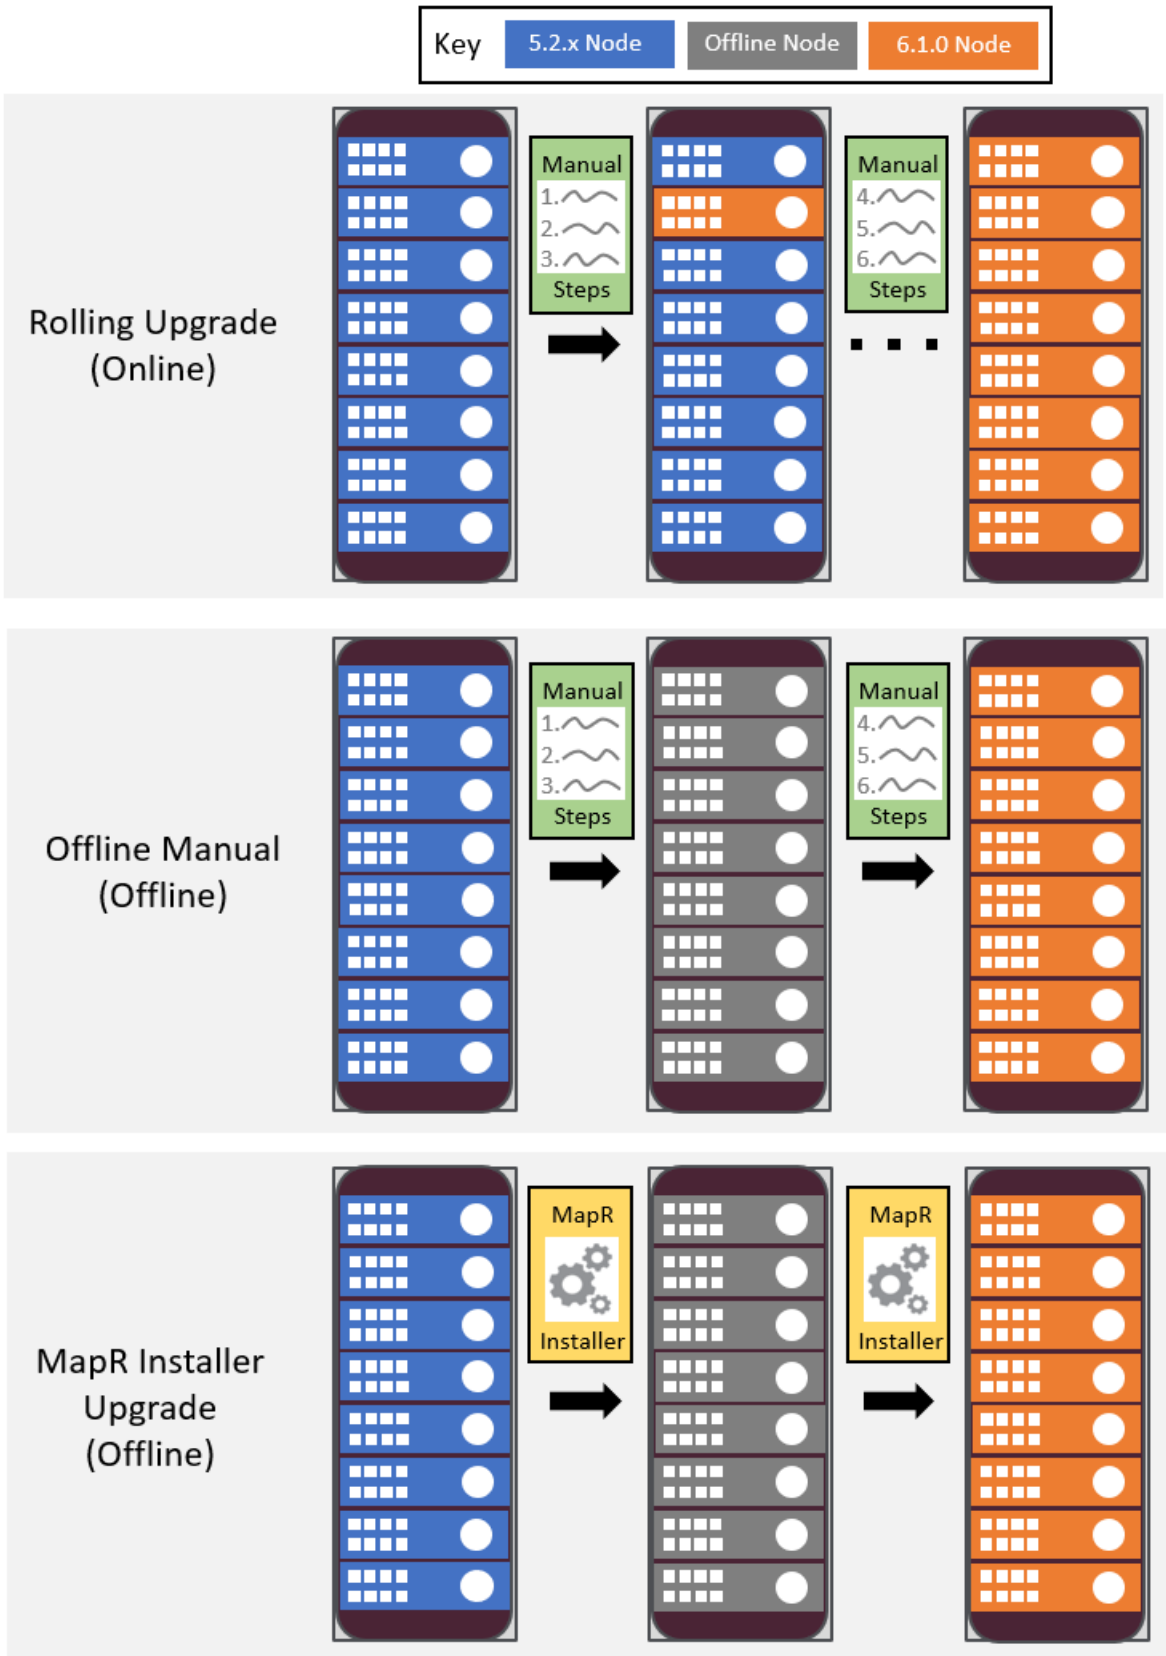
MapR Monitoring components are available as part of the MapR Ecosystem Pack (EEP) that you selected for the cluster. Once MapR Monitoring is installed, you can upgrade MapR Monitoring components as part of the EEP upgrade process. You can upgrade a EEP without having to upgrade core, provided the EEP you plan to upgrade to is supported by the current release. See Upgrading MapR Ecosystem Packs on page 335.

Upgrade Workflows

This section describes three common methods for upgrading from one MapR core release to another. The workflows in this section introduce you to the high-level steps for each method and provide links to pages showing more detail.

To view the basic steps for a specific workflow, click one of the workflows in the following illustration:

last-updated: Apr 11, 2022



1. Click here to view the workflow
2. Click here to view the workflow

last-updated: Apr 11, 2022

3. Click here to view the workflow

Workflow: Manual Rolling Upgrade
This page summarizes the steps for upgrading from MapR 5.2.x to MapR 6.1.x by using a manual rolling upgrade. In this workflow, the cluster to be upgraded is ; after the upgrade, the cluster will continue to be .

Manual Rolling Upgrade Summary

In a manual rolling upgrade, you upgrade the software one node at a time so that the cluster as a whole remains operational throughout the process. The manual rolling upgrade requires you to:

1. Perform pre-upgrade checks.
2. Perform a rolling upgrade of core.
3. Verify that all use cases are functional on the cluster.
4. Upgrade the EEP to 6.0.0.
5. Merge custom configuration settings.
6. Enable MapR 6.1.x features.
7. Perform post-upgrade checks.

The workflow later in this section provides more detail to help you get started with a manual rolling upgrade.

Considerations for Manual Rolling Upgrades

Before performing a manual rolling upgrade, note these considerations:

- Rolling upgrades only upgrade core packages, not ecosystem components. A rolling upgrade of ecosystem components is not supported.
- If you choose to do a rolling upgrade on a cluster with core and ecosystem components, the ecosystem components will continue to work during the rolling upgrade as long as the ecosystem components are not updated. If you choose to upgrade core and ecosystem components together, the ecosystem components might not function properly during the upgrade process.
- You can only perform a manual rolling upgrade from the following MapR versions:
  - MapR 5.2.x with EEP 3.0.1 or later
  - MapR 6.0.0 with EEP 4.0.x or 4.1.x
  - MapR 6.0.1 with EEP 5.0.x
  - MapR 6.1.0 with EEP 6.x.x
- If your cluster is running MapR 5.2.x but your EEP is not 3.0.1 or later (for example, you have EEP 2.0.3), you must upgrade to EEP 3.0.1 or later before you can do a rolling upgrade to MapR 6.1.x. See Upgrading MapR Ecosystem Packs on page 335.
- If you want to use a manual rolling upgrade from a pre-5.2 release to MapR 6.1.x, you must do multiple rolling upgrades, one of which upgrades your cluster to a MapR / EEP combination that can upgrade directly to MapR 6.1.x.
- After upgrading MapR Core to MapR 6.1.x, you must upgrade ecosystem components to EEP 6.0.0 or later, and this must be done before you enable MapR 6.1.x features.

Manual Rolling Upgrade Workflow

High-Level Steps	Detailed Information (review all items unless noted otherwise)
1. Understand MapR Core/MEP Dependencies 	• Operating System Support Matrix on page 5522 • Operating System Support Matrix (MapR 5.x) • EEP Support and Lifecycle Status on page 5531 • Component Versions for Released EEPs
2. Workflow: Offline Manual Upgrade

This page summarizes the steps for upgrading from MapR 5.2.x to MapR 6.1.x by using the offline manual upgrade. In this workflow, the cluster to be upgraded is nonsecure; after the upgrade, the cluster will continue to be nonsecure, but can be secured by using manual steps.

Offline Manual Upgrade Summary

In an offline manual upgrade, cluster processes and the jobs that depend on them are stopped on all nodes so that packages can be updated. The offline upgrade process is simpler than a rolling upgrade, and usually completes faster. The offline manual upgrade requires you to:

1. Perform pre-upgrade checks.
2. Shut down the cluster.
3. Upgrade core to 6.1.x.
4. Upgrade the EEP to 6.0.0.
5. Merge custom configuration settings.
6. Start the cluster and perform post-upgrade checks.
7. Enable core 6.1.x features.

last-updated: Apr 11, 2022

The workflow later on this page provides more detail to help you get started with an offline manual upgrade.

Considerations for Offline Manual Upgrades

Before performing an offline manual upgrade, note the following considerations:

Note: After upgrading core to release 6.1.x, you must upgrade ecosystem components to an EEP that is compatible with your MapR 6.1.x release. This must be done before you enable MapR 6.1.x features. To determine the compatible EEPs, see EEP Support and Lifecycle Status on page 5531.

- You can perform an offline upgrade to MapR 6.1.xfrom the following core versions: 3.x, 4.0.x, 4.1, 5.x, and 6.x.
- The offline upgrade procedure requires an outage of the entire cluster. During the maintenance window, the administrator:
  - Stops all jobs on the cluster.
  - Stops all cluster services.
  - Upgrades packages on all nodes (which can be done in parallel).
  - Brings the cluster back online at once.

Offline Manual Upgrade Workflow

Workflow: MapR Installer Upgrade
This page summarizes the steps for upgrading from MapR 5.2.x to MapR 6.1.x by using the MapR Installer.

In this workflow, the cluster to be upgraded is nonsecure; after the upgrade, the cluster will continue to be nonsecure, but can be secured by using the **Incremental Install** function of the MapR Installer.

Installer Upgrade Summary

In an upgrade using the MapR Installer, the Installer shuts down MapR core on the entire cluster, upgrades and configures MapR core, starts MapR core, upgrades EEP components, and then starts the EEP components. Like the offline manual upgrade, the MapR Installer upgrade is an *offline* upgrade. The MapR Installer upgrade requires you to:

1. Plan for the upgrade.
2. Update the MapR Installer to version 1.10.
3. Launch the Installer and select **Version Upgrade**.
4. Complete the upgrade through the Installer.
5. Merge custom configuration settings.
6. Perform post-upgrade checks.

The workflow later on this page provides more detail to help you get started with the MapR Installer upgrade.

Considerations for MapR Installer Upgrades

Before upgrading using the MapR Installer, note these considerations:

- Upgrades using the MapR Installer are supported only from release 5.2.x with EEP 3.0.1 or later.
- If security is enabled on the cluster – either MapR default security or custom security – you cannot upgrade from release 5.2.x using the MapR Installer; you must use one of the manual upgrade workflows. Note that upgrades from secure release 6.0.0 or 6.0.1 clusters can be done using the MapR Installer, as described in Planning Your MapR Core Upgrade on page 298.
- Security settings cannot be changed during a version upgrade using the MapR Installer.
- Before upgrading using the MapR Installer, you must update the installer to version 1.10 or later.
- This procedure assumes that the cluster was originally installed using the MapR Installer or a MapR Installer Stanza. If the cluster was installed manually, you must use the manual steps to upgrade or use probe and import to generate the installer database.
- When upgrading to release 6.1 using the MapR Installer, EEP 3.0.1 or later is upgraded automatically to EEP 6.0.0.

Upgrading MapR Core

Describes the process of upgrading MapR core.

Upgrading MapR core typically includes upgrading:

- MapR Core
- Ecosystem Components
- MapR Clients

Upgrading MapR core means you will need to upgrade to a MapR Ecosystem Pack (EEP). For example, upgrading to release 6.2 requires you to upgrade to EEP 7.0.0 or later before you can enable release 6.2 features.

The steps for upgrading a EEP are in another section of this guide because EEPs can be upgraded independently of the core version. The following procedures prompt you when it is necessary to plan for or upgrade a EEP.

Upgrading MapR core consists of the following steps:

last-updated: Apr 11, 2022

1. Planning the Upgrade – Determine the upgrade method, when to upgrade, and whether ecosystem components or MapR clients need to be upgraded along with core.
2. Preparing to Upgrade – Prepare the cluster for upgrade while it is still operational. This includes pre-upgrade steps for MapR core and ecosystem components.
3. Upgrading the Cluster
   - Upgrading with the MapR Installer - Use a web interface that automates the upgrade of MapR core and ecosystem components.
   - Upgrading without the MapR Installer - Perform steps to upgrade core and manually upgrade each ecosystem component.
4. Finishing the Upgrade -Complete the post-upgrade steps for MapR core and any ecosystem components that you upgraded.
5. Upgrading MapR clients – Perform steps to upgrade the MapR client.

Note: In this document, the *existing* version refers to the release version that you are upgrading *from* and the *new* version refers to the release version that you are upgrading to.

Instructions in the following sections guide you through each upgrade step:

Upgrading and Your License
If you are upgrading from MapR version 5.0 or earlier, the Base License file must be manually updated on all nodes in your cluster.

Important: As of MapR version 5.1, because of the new license categories, you must manually update the Base License file. This applies to all upgrade methods (MapR Installer, MapR Installer Stanzas, or manual rolling upgrade).

To update the Base License file, copy the new Base License file from the `/opt/mapr/conf.new/` directory to the `/opt/mapr/conf/` directory on *every node in your cluster*.

```
cp /opt/mapr/conf.new/BaseLicense.txt /opt/mapr/conf/
```

Note: The BaseLicense.txt file must be copied before starting Warden; otherwise, Warden must be restarted.

MapR Event Store For Apache Kafka Module

If you are upgrading from the Enterprise Database Edition (M7) to the Enterprise Edition and want to use the MapR Event Store For Apache Kafka module, you must purchase additional licensing. In this case, you will be issued a new license to apply. See Managing Licenses on page 777 for more information.

License Editions

As of MapR 5.1, MapR licenses are categorized by new editions and modules that further define the features supported by an edition. See the following table for descriptions of the new license options:

License Edition	Description
Community Edition	An unlimited, free, community-supported MapR edition with one free NFS Gateway. This edition includes Hadoop, MapR Database, and MapR Event Store For Apache Kafka. However, real-time global replication of MapR Database tables or MapR Event Store For Apache Kafka is not included.

License Edition	Description
Enterprise Edition	MapR Edition that enables enterprise class features such as high availability, multi-tenancy, and disaster recovery. Each of the following modules for the Enterprise Edition unlocks a portion of the total platform capabilities: **Analytics** — Enables enterprise class features for analytic use cases, such as highly-available NFS and support for services such as YARN and MapReduce. **Database** — Enables enterprise class features for operational NoSQL database, with MapR Database JSON and binary tables, and real-time global database replication. **Streams** — Enables enterprise class features for publish/subscribe event streaming, with MapR Event Store For Apache Kafka and real-time global stream replication.

For more information, see What's Included.

License Mapping

With the release of 5.1 and MapR Event Store For Apache Kafka, the licensing model has been simplified, allowing more choice in which specific features are licensed on a cluster. See the following table to understand how the new MapR licenses correspond to the legacy license editions with which you are familiar:

Legacy Edition	New Edition & Module(s)
M3 or Community Edition	Community Edition. Starting in 5.1, the Community Edition includes MapR Event Store For Apache Kafka.
M5 or Enterprise Edition	Enterprise Edition with Hadoop Module.
M7 or Enterprise Database Edition	Enterprise Edition with Hadoop and Database modules.

MapR Metering Feature

Beginning with the MapR 6.1 release, MapR software supports metering. Annual subscriptions will continue to be offered, but metering gives you the option of purchasing a variable consumption plan that is based on usage.

For more information, see MapR Software Licensing.

Checking Your Cluster License

To view license information on your cluster, see Viewing the Licenses on the Cluster on page 778.

For MapR Data Platform licensing information, see Product Licensing on page 6581.

MapR POSIX Licenses

Beginning with MapR 6.0.1, customers who purchase MapR XD Distributed File and Object Store Enterprise Premier automatically receive the following licenses for free:

- MapR FUSE POSIX Basic Client
- MapR POSIX Client for Containerized Apps (required for MapR PACC and DSR functionality)

For more information, see the MapR Editions web page.

Removes a license. Permissions required: `fc` or `a`.

license showid on page 1689
Displays the cluster ID for use when creating a new license. Permissions required: `login`.

MapR Core Upgrade Process

When you upgrade MapR core, you will also upgrade a number of cluster components.

The following cluster components are upgraded with MapR core:

- Storage Layer: MapR File System fileserver and Container Location Database (CLDB) services
- Cluster Management Services: ZooKeeper and Warden
- NFS server
- Web server, including the Control System user interface and REST API to cluster services
- The `maprcli` commands for managing cluster services
- Any new features and performance enhancements introduced with the new version.

When you upgrade MapR core, the following changes occur within the `/opt/mapr` directory:

- If required, additional folders are added.

- Product binaries are replaced by binaries associated with the new version.
- Existing configuration files remain in the active directory and default configuration files associated with the new version are installed in a new directory:

Default Configuration File Directories	Active Configuration File Directories
`/opt/mapr/conf.new`	`/opt/mapr/conf`
`/opt/mapr/conf/conf.d.new`	`/opt/mapr/conf/conf.d`

When MapR core includes an updated hadoop common version, a new hadoop directory is installed and the following changes also occur:

- The `/opt/mapr/conf/hadoop_version` file reflects the new hadoop version number.
- Paths in the `/opt/mapr/conf/conf.d/warden.<servicename>.conf` files reflect the new hadoop directory.
- The following symlinks in `/opt/mapr/lib` reflect the new hadoop version:
  - `hadoop-auth-2.x.x.jar`
  - `hadoop-yarn-api-2.x.x.jar`
  - `hadoop-yarn-client-2.x.x.jar`
  - `hadoop-yarn-common-2.x.x.jar`
  - `hadoop-common-2.x.x.jar`
- A new hadoop 2.x directory is created under `/opt/mapr/hadoop`.

  If a hadoop 2.x directory already exists, the configuration files from the existing hadoop 2.x directory will replace the default configuration files in the new 2.x hadoop directory thereby retaining the existing configuration. The existing hadoop 2.x directory is also moved into the following directory: `/opt/mapr/hadoop/OLD_HADOOP_VERSION`.

Shows the Hadoop RPC protocol version and compatible MapR client versions for each MapR release.

Planning Your MapR Core Upgrade

Describes how to develop a successful plan for your upgrade process.

The key to a successful upgrade process is to plan the process ahead of time. This page helps you develop an upgrade process that fits the needs of your cluster and users.

Choosing a Cluster Upgrade Method

Supported upgrade methods are:

- Manual rolling upgrade
- Offline manual upgrade
- Offline upgrade using MapR Installer

Upgrade Workflows on page 285 describe these methods in more detail. The method you choose affects the flow of events while upgrading packages on nodes and the duration of the maintenance window.

The following table summarizes the MapR core upgrade paths supported for each method:

Upgrade From	Upgrade To	Offline	Rolling
3.x	MapR 6.1.0	Yes	No
4.x	MapR 6.1.0	Yes	No*
5.x	MapR 6.1.0	Yes	Yes**
6.x	MapR 6.1.0	Yes	Yes

*Rolling upgrades from 4.x to 5.x are supported, after which you may perform another rolling upgrade from 5.x to 6.x.

**MapR core by itself supports rolling upgrades from release 5.x to later releases. If your cluster includes MapR core and MapR ecosystem components, rolling upgrades to release 6.x are supported only from release 5.2.x and EEP 3.0.1 or later. Ecosystem components will continue to work during a rolling upgrade of MapR core as long as the ecosystem components are not updated. But the rolling upgrade of ecosystem components is not supported. If you choose to upgrade MapR core and ecosystem components together, the ecosystem components might not function properly during the upgrade process.

The following table summarizes upgrade support for MapR Ecosystem Packs (EEPs):

Upgrade From	Upgrade To	Offline	Rolling
Pre-MEP	EEP 6.0.0	Yes	No
EEP 1.1.x	EEP 6.0.0	Yes	No
EEP 2.x	EEP 6.0.0	Yes	No
EEP 3.0.1+	EEP 6.0.0	Yes	Yes*
EEP 4.x	EEP 6.0.0	Yes	Yes*
EEP 5.x	EEP 6.0.0	Yes	Yes*

*A rolling upgrade of MapR core is supported, and ecosystem components will continue to work during the rolling upgrade, but a rolling upgrade of ecosystem components is not supported.

Transition EEPs

The following EEPs are considered *transition EEPs* because you can upgrade these EEPs directly to release 6.1.0 using a rolling upgrade (for components that support a rolling upgrade):

- EEP 3.0.1 and later 3.0.x
- EEP 4.x
- EEP 5.x

Transition EEPs can coexist with release 6.1.0 only during the course of an upgrade. You must not enable release 6.1.0 new features while a transition EEP is in use on release 6.1.0. You must upgrade to EEP 6.0.0 before enabling new features for release 6.1.0.

Offline Upgrade

The offline upgrade process is simpler than a rolling upgrade, and usually completes faster. In an offline upgrade, MapR software processes and the jobs that depend on them are stopped on all nodes so that packages can be updated. Offline upgrade is the default upgrade method when other methods cannot be used.

Offline Upgrade Paths without the MapR Installer

last-updated: Apr 11, 2022

You can perform an offline upgrade from the following core versions:

- MapR 3.x
- MapR 4.0.x
- MapR 4.1
- MapR 5.x
- MapR 6.x

Note: After upgrading MapR core to release 6.0 or later, you must upgrade ecosystem components to an EEP that is compatible with your core 6.0 or later release. To determine the compatible EEPs, see EEP Support and Lifecycle Status on page 5531. This must be done before you enable core features.

During the maintenance window, the administrator:

- Stops all jobs on the cluster.
- Stops all cluster services.
- Upgrades packages on all nodes (which can be done in parallel).
- Brings the cluster back online at once.

Rolling Upgrade

In a manual rolling upgrade, you upgrade the MapR software one node at a time so that the cluster as a whole remains operational throughout the process. The fileserver service on each node goes offline while packages are upgraded, but its absence is short enough that the cluster does not raise the data-under-replication alarm.

The following restrictions apply to rolling upgrades:

- In release 6.0 and later, only manual rolling upgrades are supported. Scripted rolling upgrades are not supported.
- Rolling upgrades only upgrade core packages, not ecosystem components. A rolling upgrade of ecosystem components is not supported.
- If you choose to do a rolling upgrade on a cluster with core and ecosystem components, the ecosystem components will continue to work during the rolling upgrade as long as the ecosystem components are not updated. If you choose to upgrade core and ecosystem components together, the ecosystem components might not function properly during the upgrade process.
- The administrator should block off a maintenance window, during which only critical jobs are allowed to run and users expect longer-than-average run times.

Rolling Upgrade Paths

You can perform a manual rolling upgrade from only the following core versions:

- Release 5.2.x with EEP 3.0.1 or later
- Release 6.x with EEP 4.0.0 or later

Note: After upgrading core, you must upgrade ecosystem components to EEP 4.0.0 or later, and this must be done before you enable release 6.x or later features. To determine the EEP required by your release, see EEP Support and Lifecycle Status on page 5531.

last-updated: Apr 11, 2022

Updating the JDK

Check the JDK Support Matrix to verify that your JDK version is supported by the core version to which you are upgrading. Releases 6.0 and 6.1 require JDK 8. For more information, see the JDK Support Matrix.

Planning for Security

Security is not enabled by default for upgrades. During an upgrade, the security attributes of your cluster are preserved unless you decide to change them. Note that if you have configured security on a release 5.2.x cluster, you cannot use the MapR Installer or Stanzas to upgrade. You must upgrade manually. For information about custom security, see Customizing Security in MapR on page 1474.

Before upgrading core software, make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6569. If a vulnerability applies to your release, contact your HPE support representative for a fix, and apply the fix immediately, if applicable.

Scheduling the Upgrade

Consider the following factors when scheduling the upgrade:

- When will preparation steps be performed? How much of the process can be performed before the maintenance window?
- What calendar time would minimize disruption in terms of workload, access to data, and other stakeholder needs?
- How many nodes need to be upgraded? How long will the upgrade process take for each node, and for the cluster as a whole?
- When should the cluster stop accepting new non-critical jobs?
- When (or will) existing jobs be terminated?
- How long will it take to clear the pipeline of current workload?
- Will other Hadoop ecosystem components (such as Hive) get upgraded during the same maintenance window?
- When and how will stakeholders be notified?

Planning Upgrades to MapR Clients

Determine if you need to upgrade MapR client nodes. You upgrade MapR client nodes after you upgrade the cluster nodes but before enabling new features.

MapR Client Nodes

On each MapR client node, upgrade to the client version that is compatible with the operations that you want to perform on the cluster. The following table shows which supported client operations are available based on the client version and the cluster version.

The following client operations are supported on 4.0.x and 5.x clusters and clients.

- File system access
- Submit MapReduce (MR) v1 job
- Submit MapReduce v2 applications

The following client operation is supported on 4.0.2 and higher clusters with 4.0.2 and higher clients. For example, this operation is not available on a 5.1 cluster with a 4.0.1 client.

last-updated: Apr 11, 2022

- Submit MapReduce version 2 applications with Resource Manager zero-configuration failover

MapR POSIX Client Nodes

On MapR POSIX client nodes, the only supported client operation is filesystem access. As of release 5.1, MapR FUSE-based POSIX clients are available in addition to MapR loopback NFS clients.

Note: Only releases 5.1 or higher support MapR FUSE-based POSIX clients.

MapR POSIX loopback NFS clients can be upgraded or a fresh install can be performed.

See Upgrading the MapR POSIX loopbacknfs Client on page 328 and Migrating to FUSE-based POSIX Clients for more information.

Note: Basic and Platinum POSIX client packages are recommended for fresh installation and for all new clusters.

Upgrade to the client version supported by your cluster, as shown in the following table. Upgrading to the 5.x client is recommended for 4.1 and 5.x clusters of MapR loopbacknfs POSIX nodes. If you plan on using FUSE-based POSIX clients, ensure that the cluster has been upgraded to release 5.1 or higher because the FUSE-based POSIX client can only connect to clusters running release v5.1 or higher.

The following table shows which MapR loopback NFS client versions are supported by which MapR data-fabric clusters. For example, the release 6.0 cluster supports 4.0.2, 4.1, 5.0, 5.1, and 5.2 loopback NFS clients.

Table

	6.x client	5.2 client	5.1 client	5.0 client	4.1 client	4.0.2 client	4.0.1 client
6.x cluster	Yes	Yes	Yes	Yes	Yes	Yes	N/A
5.2 cluster	Yes	Yes	Yes	Yes	Yes	Yes	N/A
5.1 cluster	Yes	Yes	Yes (recommended)	Yes	Yes	Yes	N/A
5.0 cluster	Yes	Yes	Yes (recommended)	Yes	Yes	Yes	N/A
4.1 cluster	Yes	Yes	Yes (recommended)	Yes	Yes	Yes	N/A
4.0.2 cluster	Yes	Yes	Yes	Yes	Yes	Yes	N/A

Determining Cross-Cluster Feature Support

MapR Data Platform supports features that operate on more than one cluster. Before you upgrade, consider the impact of the following cross-cluster features:

Volume Mirroring	Volume mirroring works from a lower MapR version to a higher MapR version irrespective of the features that you enable on the higher version. For example, you can mirror volumes from a release 6.1 cluster to a release 6.2 cluster irrespective of whether or not you have enabled the new features present in the release 6.2 version. However, volume mirroring from a higher release version to a lower release version works only when you enable identical set of features on both clusters. For example, you can mirror volumes from a release 6.2 cluster to a release 6.1 cluster only if you do not

last-updated: Apr 11, 2022

	enable new features that are present on the release 6.2 cluster.
Table Replication	Table replication works between clusters of different versions as long as both versions support MapR Database table replication. For example, you can replicate MapR Database binary tables from a release 6.2 cluster to a release 6.0 cluster. **Note:** As of release 5.2, MapR Database JSON table replication is also supported. You cannot replicate MapR Database JSON tables to a cluster that runs a version prior to release 5.2.

Planning for the MapR Ecosystem Pack

To plan for the MapR Ecosystem Pack (EEP), see Planning MapR Ecosystem Pack Upgrades.

What's Next

Go to Preparing to Upgrade MapR Core on page 303.

Preparing to Upgrade MapR Core

Complete these pre-upgrade steps for MapR core.

Upgrade a test cluster before upgrading your production cluster. After you have planned your upgrade process, prepare the cluster for upgrade while your existing cluster is fully operational. Prepare to upgrade as described in this section to minimize downtime and eliminate unnecessary risk. Design and run health tests and back up critical data. Performing these tasks during upgrading reduces the number of times you have to touch each node, but increases down-time during upgrade.

Complete the following pre-upgrade steps:

1. Verify System Requirements for All Nodes

Verify that all nodes meet the following minimum requirements for the new version of core software:

- **Software dependencies.** Package dependencies in the MapR distribution can change from version to version. If the new MapR version has dependencies that were not present in the older version, you must address them on all nodes before upgrading your software. Installing dependency packages can be done while the cluster is operational. See Packages and Dependencies for MapR Software. If you are using a package manager, you can specify a repository that contains the dependency package(s), and allow the package manager to automatically install them when you upgrade the MapR packages. If you are installing from package files, you must pre-install dependencies on all nodes manually.
- **Hardware requirements.** The newer version of packages might have greater hardware requirements. Hardware requirements must be met before upgrading.
- **OS requirements.** MapR OS requirements do not change frequently. If the OS on a node doesn't meet the requirements for the newer MapR version, plan to decommission the node and re-deploy it with an updated OS after the upgrade. See Operating System Support Matrix on page 5522 and Operating System Support Matrix (MapR 5.x).
- **Certificate requirements.** Recent versions of Safari and Chrome web browsers have removed support for older certificate cipher algorithms, including those used by some MapR versions. For more information about resolving this issue, see Unable to Establish a Secure Connection on page 6569.

2. Design Health Checks

Plan what kind of test jobs and scripts you will use to verify cluster health as part of the upgrade process. You will verify cluster health several times before, during, and after upgrade to ensure success at every step, and to isolate issues whenever they occur. Create both simple tests to verify that cluster services start and respond, as well as non-trivial tests that verify workload-specific aspects of your cluster.

Design Simple Tests

Here are a few examples of simple tests you can design to check node health:

- Use maprcli commands to see if any alerts exist and to verify that services are running as expected. For example:

```
# maprcli node list -columns svc
hostname
service                                                 ip
labnode55
nodemanager,cldb,fileserver,hoststats                   10.10.82.55
labnode56
nodemanager,fileserver,hoststats                        10.10.82.56
labnode57
fileserver,nodemanager,hoststats                        10.10.82.57
labnode58
fileserver,nodemanager,webserver,hoststats              10.10.82.58
                       ...lines deleted...
                       # maprcli alarm list
                       alarm state
description
                        entity    alarm name
alarm statechange time
                       1            One or more licenses is about to
expire within 25 days
CLUSTER   CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION   1366142919009
                       1            Can not determine if service: nfs is
running. Check logs at: /opt/mapr/logs/nfsserver.log         labnode58
NODE_ALARM_SERVICE_NFS_DOWN            1366194786905
```

  In this example, you can see that an alarm is raised indicating that MapR software expects an NFS server to be running on node `labnode58`, and the node list of running services confirms that the nfs service is not running on this node.

- Batch create a set of test files.
- Submit a MapReduce application.
- Run simple checks on installed Hadoop ecosystem components. For example, run a Hive query.

Design Non-trivial Tests

Appropriate non-trivial tests are specific to your particular cluster workload. You may have to work with users to define an appropriate set of tests. Run tests on the existing cluster to calibrate expectations for “healthy” task and job durations. On future iterations of the tests, inspect results for deviations. Some examples:

- Run performance benchmarks relevant to the cluster’s typical workload.
- Run a suite of common jobs. Inspect for correct results and deviation from expected completion times.
- Test correct inter-operation of all components in the Hadoop stack and third-party tools.
- Confirm the integrity of critical data stored on the cluster.

last-updated: Apr 11, 2022

3. Verify Cluster Health

Run the test you designed in step 2 to verify the cluster health prior to upgrade.

- Run the suite of simple tests to verify that basic features of the MapR core are functioning correctly, and that any alarms are known and accounted for.
- Run the suite of non-trivial tests to verify that the cluster is running as expected for a typical workload, including integration with Hadoop ecosystem components and third-party tools.

Proceed with the upgrade only if the cluster is in an expected, healthy state.

4. Back Up Critical Data

Data in the MapR cluster persists across upgrades from version to version. However, as a precaution, you might want to back up critical data before upgrading. If you deem it practical and necessary, you can do any of the following:

- Copy data out of the cluster using `distcp` to a separate, non-Hadoop datastore.
- Mirror critical volume(s) into a separate MapR cluster, creating a read-only copy of the data which can be accessed via the other cluster.

When services for the new version are activated, the MapR File System will update data on disk automatically. The migration is transparent to users and administrators. Once the cluster is active with the new version, you cannot roll back.

5. Run Your Upgrade Plan on a Test Cluster

Before executing your upgrade plan on the production cluster, perform a complete *dry run* on a test cluster. You can perform the dry run on a smaller cluster than the production cluster, but make the dry run as similar to the real-world circumstances as possible. For example, install all Hadoop ecosystem components that are in use in production, and replicate data and jobs from the production cluster on the test cluster. The goals for the dry run are:

- Eliminate surprises. Get familiar with all upgrade operations you will perform as you upgrade the production cluster.
- Uncover any upgrade-related issues as early as possible so you can accommodate them in your upgrade plan. Look for issues in the upgrade process itself, as well as operational and integration issues that could arise after the upgrade.

6. Pause Cross-Cluster Operations

Complete the steps for each cross-cluster feature used by this cluster:

- **Volume Mirroring.** If volumes from another cluster are mirrored on this cluster, use one of the following options to stop the mirroring of volumes on this cluster:

Using the Control System	See Stopping the Mirror on page 920.
Using a `maprcli` command	Run the `maprcli volume mirror stop` command on this cluster. See volume mirror stop on page 2004.

- **Table Replication.** If source tables on this cluster are replicated to tables on another cluster, pause the replication of tables on this cluster. Use one of the following options for each source table on this cluster:

Using the Control System	1. Log in to the Control System and go to the source table information page. 2. On the Replications tab associated with the source table, select each replica and then click **Actions** > **Pause Replication** > **.**
Using a `maprcli` command	Run the `maprcli table replica pause` command. See table replica pause on page 1866.

Note: Once you have completed the MapR core upgrade and the Post-Upgrade Steps for MapR Core on page 322, you can resume cross-cluster operations.

7. Back up Configuration Files

If you are upgrading the MapR FUSE-based POSIX client on Ubuntu, create a backup copy of your custom settings in the `fuse.conf` file in `/opt/mapr/conf` directory. If you do not create a backup copy, you might lose your custom settings for the POSIX client because the new `fuse.conf` file with default settings will overwrite your current `fuse.conf` file with custom settings.

If you are upgrading the MapR FUSE-based POSIX client on other supported operating systems, during upgrade the software automatically sets up the `fuse.conf.backup` file in addition to the new `fuse.conf` file in the `/opt/mapr/conf` directory.

Consider creating the `env_override.sh` file to store custom settings for environmental variables. Upgrading to a new MapR release causes the `env.sh` file to be replaced and removes any custom settings. Creating the `env_override.sh` file can simplify the management of environmental variables. For more information, see About env_override.sh on page 2290.

8. Migrate from MapReduce Version 1

MapReduce version 1 (MRv1) is deprecated for MapR 6.0 or later. If you were previously using MRv1, you must prepare your cluster to run MapReduce version 2 (MRv2) applications before upgrading to core 6.0 or later:

- Ensure that the MapReduce mode on your cluster is set to `yarn`. MRv2 is an application that runs on top of YARN.
- Uninstall all packages associated with MRv1.

For more information about how to prepare your cluster to run MRv2 applications, see Migrating from MapReduce Version 1 to MapReduce Version 2 on page 307.

9. Migrate from Mahout and Storm

Mahout and Storm are not supported on core 6.0 or later. Before the upgrade, disable applications that use these components, and remove the Mahout and Storm packages. To view the ecosystem components supported on MapR releases, see Component Versions for Released EEPs.

10. Prepare to Upgrade the MapR Ecosystem Pack

Complete the pre-upgrade steps in Preparing to Upgrade the MapR Ecosystem Pack. Then return to this section.

What's Next

Go to Upgrading MapR Core With the MapR Installer on page 308 or Upgrading MapR Core Without the MapR Installer on page 309.

Migrating from MapReduce Version 1 to MapReduce Version 2

If you previously ran MRv1 jobs on your cluster, prepare your cluster to run YARN applications in MapR 6.0 or later.

Configuring the MapReduce Mode

Client and cluster nodes submit MapReduce applications to the YARN framework (`yarn` mode) unless you configure them to use the classic framework (`classic` mode). Because MapReduce version 1 (MRv1) is deprecated for MapR 6.0 and later, you can no longer submit MRv1 jobs using `classic` mode. If you previously configured your client and cluster nodes to use `classic` mode, you must prepare your cluster to run YARN applications in MapR 6.0 or later. Before upgrading to MapR 6.0 or later, ensure that the MapReduce mode is set to `yarn` in the environment variable, on client nodes, and on the cluster.

Configure the MapReduce mode for the following components:

Component	How to Change the Mode to `yarn`:
Environment Variable	Set the MapReduce mode in an environment variable: **1.** Open a terminal on the client node. **2.** Enter the following command on the shell: `export MAPR_MAPREDUCE_MODE=yarn`
Client	In the hadoop_version file on a MapR client node, verify the MapReduce mode is set to `yarn`. **1.** Open the hadoop_version file in the following location: `/opt/mapr/conf/` **2.** If the default_mode parameter is set to `classic`, change it to `yarn`: `default_mode=yarn`.
Cluster	Run the following command to display the cluster-wide mode: `maprcli cluster mapreduce get`. If the cluster is set to `classic` mode, use the command line or the MapR Control System to set it back to the `yarn`default for all nodes in the cluster: • To set the cluster's MapReduce mode using maprcli: **1.** Run the following command: `maprcli cluster mapreduce set -mode yarn`. • To set the cluster's MapReduce mode in the MapR Control System: **1.** Log in to the MapR Control System. **2.** Perform one of the following operations: • In the header area, click the link that contains the current MapReduce version. • In the **System Settings** view of the Navigation Pane, click **MapReduce Version.** **3.** In the **Configure MapReduceMode** dialog, select the `yarn` option for the cluster. **4.** Click **OK**.

last-updated: Apr 11, 2022

Uninstalling MRv1 Packages

After verifying that the MapReduce mode is set to `yarn`, uninstall the packages associated with MRv1:

- `mapr-jobtracker`
- `mapr-tasktracker`
- `mapr-metrics`

The following table lists uninstall commands by operating system. Use these commands to uninstall the above packages:

Operating System	Uninstall Command
Ubuntu	`apt-get remove <package name>`
CentOS/RedHat:	`yum remove <package name>`
SLES	`zypper rm <package name>`

Upgrading MapR Core With the MapR Installer

If the cluster that you want to upgrade was installed using the MapR Installer, use the MapR Installer to upgrade MapR core.

Before you begin, review Planning Your MapR Core Upgrade on page 298, and verify that your cluster is prepared for an upgrade. In some cases, a maintenance update can be performed rather than a version upgrade. For more information, see Performing a Maintenance Update on page 5447

Warning: The **Version Upgrade** operation is an *offline* operation. Service failures, job failures, or the loss of customized configuration files can occur if you do not perform the steps to prepare the cluster for an upgrade.

Note: To upgrade to release 6.0 or later using the MapR Installer, release 5.2.x and EEP 3.0.1 or later must be installed on your cluster. If security is enabled on the cluster, you cannot use the MapR Installer or Stanzas to upgrade. You must perform the upgrade manually.

1. Update the MapR Installer. For more information, see Updating the MapR Installer on page 5409.
   This step ensures that the MapR Installer has access to the latest packages.
2. Halt jobs and applications. Stop accepting new jobs and applications, and stop YARN applications.

   ```
   # yarn application -list
   # yarn application -kill <ApplicationId>
   ```

   You might also need specific commands to terminate custom applications.
3. Launch the MapR Installer URL (`https://<hostname/IPaddress>:9443`)
4. Select the **Version Upgrade** option to complete the upgrade through the MapR Installer. The installer allows you to specify the core version, the MapR Ecosystem Pack (EEP) version, and the components and services you want to install.

last-updated: Apr 11, 2022

Note:

- Incorporate a brief delay when you use the **Version Upgrade** screen. After specifying the core version, the EEP version, and the services you need, wait a minute or two before clicking **Next** to advance to the next screen. This delay gives the Installer time to process the selections that you made.
- Do not refresh the browser page during the upgrade sequence. Doing so can cause errors. For more information, see IN-1915 in MapR Installer Known Issues.
- If you upgrade a non-secure cluster to release 6.0.1 or later and metrics monitoring is enabled, the MapR Installer asks you to specify a password for the Grafana administrator ID (`admin`). You must specify a password. For more information about Grafana password requirements, see Logging on to Grafana on page 1382.
- If the MapR Installer indicates that the version upgrade failed, or if the following error message is displayed, use the **Import State** command to revert the cluster to the last known state. See Importing or Exporting the Cluster State on page 5447.

```
Custom secure cluster < MapR core 6.0.0 cannot be upgraded
```

5. Once the upgrade through the MapR Installer is complete, perform the post-upgrade steps. See Finishing the MapR Core Upgrade on page 322.

Upgrading MapR Core Without the MapR Installer
You can upgrade MapR core without using the MapR Installer.

First, you perform an offline or rolling upgrade of the MapR core manually. Next, you configure the new version to enable support of MapR core features. Finally, you upgrade ecosystem components manually.

When upgrading, you can install packages from the following sources:

- The MapR Internet repository
- A local repository
- Individual package files

Go to the next topic to begin setting up repositories.

When you are finished upgrading MapR core, you will need to follow the steps to upgrade the ecosystem components, as described in Upgrading the MapR Ecosystem Pack Without the MapR Installer.

Note: MapR 6.0 and later releases are only compatible with EEP 4.0.0 and later EEPs (see EEP Support by MapR Core Version). If you upgrade MapR core to MapR 6.0 or later, you must install or upgrade to EEP 4.0.0 or later. Clusters with EEP 3.0.1 or later are allowed to upgrade to MapR 6.0 or later, but such clusters must not enable new features, add new services, add new nodes, or make configuration changes until EEP 3.0.1 or later is upgraded to EEP 4.0.0 or later.

Then proceed to Finishing the MapR Core Upgrade on page 322.

Setting Up Repositories
This section describes how to set up internet and local repositories for each operating system.

Both internet repositories and local repositories can be set up. In addition, package files can be downloaded, stored locally, and then the software can be installed from the files. The following sections describes how to do both for each operating system.

Platform-specific upgrade repositories are hosted at: https://package.mapr.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

See MapR Repositories and Packages on page 128 for more information about repositories and packages.

Using the MapR Internet Repository
It is usually easiest to install a MapR cluster from an Internet repository.

The MapR repository on the Internet provides all of the packages required to install a cluster using native tools such as `yum` on RedHat, Oracle Linux, or CentOS, or `apt-get` on Ubuntu, or `zypper` on SUSE. Installing from the MapR repository is generally the easiest installation method, but requires the greatest amount of bandwidth. With this method, each node is connected to the Internet to download the required packages.

When setting up a repository for the new version, leave in place the repository for the existing version because you might need to use it again.

Prepare packages and repositories on every node, or on a single node if keyless SSH is set up for the root user.

Set up repositories by completing the steps for your RedHat/Oracle Linux/CentOS, SUSE, or Ubuntu distribution.

For information on repositories and packages for MapR software and Hadoop Ecosystem tools, see MapR Repositories and Packages on page 128.

Repositories for Core Software

HPE hosts `rpm` and `deb` repositories for installing the core software using Linux package management tools. For every release of the core software, a repository is created for each supported platform.

Platform-specific upgrade repositories are hosted at: https://package.mapr.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

Repositories for Ecosystem Tools

HPE hosts `rpm` and `deb` repositories for installing ecosystem tools, such as Flume, Hive, Myriad, Oozie, Pig, and Sqoop. At any given time, the recommended versions of ecosystem tools that work with the latest version of core software are available here.

These platform-specific repositories are hosted at the following locations:

- https://package.mapr.hpe.com/releases/MEP/MEP-<version>/<platform>

  Note: The MEP-<version> directory can be represented by a 2-digit number or a 3-digit number (for example, MEP-2.0 or MEP-2.0.0). See Understanding Two-Digit and Three-Digit EEPs on page 5450.

Set Up the Internet Repository: RHEL/CentOS
This section describes how to set up a `maprtech.repo` file before adding an Internet repository.

Before upgrading your cluster software, you need to set up or update a `maprtech.repo` file. The `baseurl` properties of the `maprtech.repo` specify the URLs of the packages you want to install. To access the URLs for all release packages, see Packages and Dependencies for MapR Software.

1. Change to the `root` user or use `sudo`.

2. Create a text file called `maprtech.repo` in the `/etc/yum.repos.d/` directory with the following content, replacing `<version>` with the version of software that you want to install.

```
[maprtech]
name=MapR Technologies
baseurl=https://package.mapr.com/releases/v<version>/redhat/
     enabled=1
     gpgcheck=0
     protect=1

[maprecosystem]
name=MapR Technologies
baseurl=https://package.mapr.com/releases/MEP/MEP-<version>/redhat
    enabled=1
    gpgcheck=0
    protect=1
```

3. If your connection to the Internet is through a proxy server, set the `http_proxy` environment variable before installation.
   - Method 1:

     ```
     http_proxy=http://<host>:<port>
     export http_proxy
     ```

   - Method 2: Set the value for the `http_proxy` environment variable by adding settings to the `/etc/yum.conf` file.

     ```
     proxy=http://<host>:<port>
     proxy_username=<username>
     proxy_password=<password>
     ```

4. Download and install EPEL (Extra Packages for Enterprise Linux) if you use the `mapr-metrics` service; otherwise, skip this step.
   - RHEL/CentOS 6.x:

     ```
     wget http://download.fedoraproject.org/pub/epel/6/x86_64/
     epel-release-6-8.noarch.rpm
     rpm -Uvh epel-release-6*.rpm
     ```

   - RHEL/CentOS 7.0

     ```
     wget http://dl.fedoraproject.org/pub/epel/
     epel-release-latest-7.noarch.rpm
     ```

Set Up the Internet Repository: SUSE

This section describes how to add an internet repository using a zypper command.

As root or sudo, you add the repository for the latest packages using a zypper command to specify URLs to the packages. See the Packages and Dependencies for MapR Software for the URLs for all release packages.

1. Change to the root user or use `sudo`.

last-updated: Apr 11, 2022

2. Add the repository for MapR packages, replacing <version> with the software version that you want to install.
   ```
   zypper ar https://package.mapr.hpe.com/releases/v<version>/suse/ maprtech
   ```
3. Add the repository for ecosystem packages.
   ```
   zypper ar https://package.mapr.hpe.com/releases/MEP/MEP-<version>/suse/
   maprecosystem
   ```
4. If your connection to the Internet is through a proxy server, set the `http_proxy` environment variable before installation.
   ```
   http_proxy=http://<host>:<port>
   export http_proxy
   ```
5. Update the system package index.
   ```
   zypper refresh
   ```

Set Up the Internet Repository: Ubuntu

This section describes how to add repositories to the `sources.list`.

As `root` or using `sudo`, you add the repositories to the `sources.list`. The `sources.list` specifies the URLs to the packages that you want to install. See Packages and Dependencies for MapR Software on page 68 for the URLs for all release packages.

1. Change to the `root` user or use `sudo`.
2. Add the following lines to `/etc/apt/sources.list`, replacing `<version>` with the version that you want to install.

   Release 7.0.0 (with EEP 8.1.0) and later
   ```
   deb https://package.mapr.hpe.com/releases/v7.0.0/ubuntu/ binary bionic
   deb https://package.mapr.hpe.com/releases/MEP/MEP-8.1.0/ubuntu/ binary
   bionic
   ```

   Release 5.2.1 through 6.2.0
   ```
   deb https://package.mapr.hpe.com/releases/v<version>/ubuntu/ binary
   trusty
   deb https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu/
   binary trusty
   ```

   Release 5.2 and earlier
   ```
   deb https://package.mapr.hpe.com/releases/<version>/ubuntu/ mapr optional
   deb https://package.mapr.hpe.com/releases/MEP/MEP-<version>/ubuntu/
   binary trusty
   ```
3. Update the package indexes:
   ```
   apt-get update
   ```

4. If your connection to the Internet is through a proxy server, add the following lines to `/etc/apt/apt.conf`:

```
Acquire {
Retries "0";
HTTP {
Proxy "http://<user>:<password>@<host>:<port>";
};
};
```

Using a Local Repository
If you install a MapR cluster from a local repository, you do not need an internet connection.

You can set up a local repository on each node to provide access to installation packages. With this method, nodes do not require internet connectivity. The package manager on each node installs from packages in the local repository. To set up a local repository, nodes need access to a running web server to download the packages.

Set up repositories by completing the steps for your RedHat/Oracle Linux/CentOS, SUSE, or Ubuntu distribution.

Platform-specific upgrade repositories are hosted at: https://package.mapr.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

For more information about repositories and packages for MapR software and Hadoop Ecosystem tools, see MapR Repositories and Packages on page 128.

Set Up the Local Repository: RHEL/CentOS

To create a local repository, download your files from the Internet and then add the repositories to each node in the cluster.

You create a local repository from files that you download from the internet, and then add the repositories to each node in the cluster. The files that you download differ from version to version. Using a `maprtech.repo` file, you specify URLs of the RHEL/CentOS packages. See the Packages and Dependencies for MapR Software for the URLs for all release packages.

1. Log in as root on the node or use `sudo`.
2. Create the following directory if it does not exist: `/var/www/html/yum/base`
3. On a computer that is connected to the internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`:

   For example:

```
https://package.mapr.hpe.com/<product_package>.rpm.tgz
```

4. Copy the files to `/var/www/html/yum/base` on the node, and extract them there.

   For example:

```
tar -xvzf <product_package>.rpm.tgz
```

5. Create the base repository headers.

```
createrepo /var/www/html/yum/base
```

6. Verify that the content of the new `/var/www/html/yum/base/repodata` directory contains `filelists.xml.gz`, `other.xml.gz`, `primary.xml.gz`, and `repomd.xml`.

7. On each node, create a text file called `maprtech.repo` in `/etc/yum.repos.d`.

```
[maprtech]
name=MapR Technologies, Inc.
baseurl=http://<host>/yum/base
enabled=1
gpgcheck=0
```

Set Up the Local Repository: SUSE

To create a local repository, download your files from the internet and then add the repositories to each node in the cluster.

You create a local repository from files that you download from the internet, and then add the repositories to each node in the cluster. The files that you download differ from version to version. See the Packages and Dependencies for MapR Software for the URLs for all versions.

1. Login as root on the node or use `sudo`.
2. Create the following directory if it does not exist: `/var/www/html/zypper/base`
3. On a computer that is connected to the internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`.

   For example:

```
https://package.mapr.hpe.com/releases/<version>/suse/
mapr-<version>GA.rpm.tgz
```

4. Copy the files to `/var/www/html/zypper/base` on the node, and extract them there.

   For example:

```
tar -xvzf <product_package>.rpm.tgz
```

5. Create the base repository headers.

   `createrepo /var/www/html/zypper/base`
6. Verify that the new `/var/www/html/zypper/base/repodata` directory contains the following files.

   `filelists.xml.gz`, `other.xml.gz`, `primary.xml.gz`, `repomd.xml`
7. Add the repositories for core and the ecosystem packages to each node in the cluster.

   `zypper ar http://<host>/zypper/base/ maprtech`

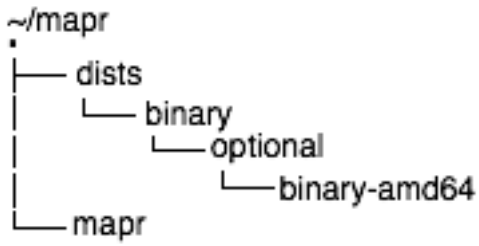
Set Up the Local Repository: Ubuntu

To create a local repository, download your files from the internet and then add the repositories to each node in the cluster.

You create a local repository from files that you download from the internet, and then add the repositories to each node in the cluster. The files that you download differ from version to version. See the Packages and Dependencies for MapR Software for the URLs for all versions.

1. Login as root on the machine where you will set up the repository.
2. Change to the directory `/root` and create the following directories within it:

last-updated: Apr 11, 2022



3. On a computer that is connected to the internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`.

   For example:

   ```
   https://package.mapr.hpe.com/releases/v<version>/ubuntu/
   mapr-v<version>GA-upgrade.deb.tgz
   ```

4. Copy the files to `/root/mapr/mapr` on the node, and extract them there.

   For example:

   ```
   tar -xvzf <product_package>.deb.tgz
   ```

5. Navigate to the `/root/mapr/` directory.

6. Use `dpkg-scanpackages` to create `Packages.gz` in the `binary-amd64` directory.

   ```
   dpkg-scanpackages . /dev/null | gzip -9c > ./dists/binary/optional/
   binary-amd64/Packages.gz
   ```

7. Move the entire `/root/mapr` directory to the default directory served by the HTTP server (for example, `/var/www`) and make sure the HTTP server is running.

8. Add the following line to `/etc/apt/sources.list` on each node, replacing <host> with the IP address or hostname of the node where you created the repository.

   ```
   deb http://<host</mapr binary optional
   ```

9. On each node update the package indexes (as root or with `sudo`).

   ```
   apt-get update
   ```

10. Use `apt-get` to install MapR software and Hadoop ecosystem components from the local repository on each node.

Set Up Individual Package Files

This section describes how to upgrade MapR software using individual package files.

You can download package files, store them locally, and then install MapR from the files. This option is typically used to upgrade clusters that are not connected to the internet.

Platform-specific upgrade repositories are hosted at: https://package.mapr.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

See MapR Repositories and Packages on page 128 for more information about repositories and packages.

To upgrade MapR using individual package files, you need to first pre-install the MapR package dependencies on each node. See the Packages and Dependencies for MapR Software for the dependency

last-updated: Apr 11, 2022

packages required for the cluster services that you are installing. Manually download the packages and install them.

1. Using a machine connected to the internet, download the tarball for the MapR components and the Hadoop ecosystem components, substituting the appropriate `<platform>`, `<version>`, and `<datestamp>`.

   For example: `https://package.mapr.hpe.com/releases/v<version>/ubunto/mapr-v<version>GA-upgrade.deb.tgz`

2. Extract the tarball to a local directory, either on each node or on a local network accessible by all nodes.

   ```
   tar -xvzf <product_package>.tgz
   ```

Upgrading MapR Core
The following topics describe offline and manual upgrades, and manual rolling upgrades.

Note: After completing your upgrade, see Post-Upgrade Steps for MapR Core on page 322

Offline and Manual Upgrade Procedure
The offline, manual upgrade procedure is suitable for upgrading small clusters. On large clusters, these steps are commonly performed on all nodes in parallel using scripts or remote management tools.

This procedure assumes that you have planned and prepared for the upgrade as described earlier. This procedure also assumes that the cluster meets prerequisites, including the correct JDK for the core version to which you are upgrading. For more information, see the JDK Support Matrix.

Note: An offline upgrade is performed as the `root` user or with sudo.

At the end of this procedure, you use `yum update` or `zypper update` on RHEL/CentOS or SLES to upgrade the packages. Ignore any warnings that certain packages are not installed. Packages will be upgraded correctly, and no additional packages will be installed.

1. Notify stakeholders of the impending upgrade, and then stop accepting new jobs and applications. Terminate running jobs and applications by running `maprcli` commands on appropriate nodes in the cluster.

   For YARN applications, use the following commands:

   ```
   # yarn application -list
            # yarn application -kill <ApplicationId>
   ```

2. Disconnect NFS mounts. Unmount the MapR NFS share from all clients connected to it, including other nodes in the cluster. This allows all processes accessing the cluster via NFS to disconnect gracefully.

   For example, if the cluster is mounted at `/mapr`: `# umount /mapr`

3. Display the services on each node in the cluster, and stop ecosystem component services on the nodes.

   ```
   # maprcli node list -columns hostname,csvc
   # maprcli node services -multi '[{ "name": "hue", "action": "stop"},
   { "name": "oozie", "action": "stop"}, { "name": "hs2", "action":
   "stop"}]' -nodes <hostnames>
   ```

4. If a MapR POSIX client service is running, stop the service:

last-updated: Apr 11, 2022

- For the mapr-loopbacknfs service:

```
service mapr-loopbacknfs stop
```

- For the FUSE-based POSIX basic service:

```
service mapr-posix-client-basic stop
```

- For the FUSE-based POSIX platinum service:

```
service mapr-posix-client-platinum stop
```

5. Determine where CLDB and ZooKeeper services are installed.
6. Stop Warden on CLDB nodes first, and then on all remaining nodes.
7. Stop ZooKeeper on all nodes where it is installed.
8. Ensure that no stale cluster processes are running. If so, stop the processes:

```
ps -ef | grep mapr
pkill -u mapr
```

9. Remove any existing patches:
   a. Run one of the following commands to determine if a patch is installed.
      - RHEL/CentOS and SLES: `rpm -qa mapr-patch`
      - Ubuntu: `dpkg -l | grep mapr-patch`

      If the command displays no output, no patch is installed.
   b. If one or more patches are installed, run one of the following commands to remove the patches:
      - RHEL/CentOS or SLES: `sudo rpm -e mapr-patch`
      - Ubuntu: `sudo apt-get -y remove mapr-patch`
10. Upgrade core packages by installing the appropriate package key.
    - RHEL/CentOS: `sudo rpm --import https://package.mapr.hpe.com/releases/pub/maprgpg.key`
    - SLES: No package key needed.
    - Ubuntu: `wget -O - https://package.mapr.hpe.com/releases/pub/maprgpg.key | sudo apt-key add -`
11. Upgrade these core component and MapR hadoop common packages on all nodes where packages exist.

    Components to upgrade are:
    - `mapr-cldb`
    - `mapr-core`
    - `mapr-core-internal`

- `mapr-fileserver`
- `mapr-gateway`
- `mapr-hadoop-core`
- `mapr-historyserver`
- `mapr-mapreduce2`
- `mapr-nfs`
- `mapr-nodemanager`
- `mapr-resourcemanager`
- `mapr-webserver`
- `mapr-zookeeper`
- `mapr-zk-internal`

When using `yum update` or `zypper update`, do not use a wildcard such as `mapr-*` to upgrade all MapR packages, which could erroneously include Hadoop ecosystem components such as `mapr-hive` and `mapr-pig`.

- RHEL/CentOS:

```
yum update mapr-cldb mapr-core mapr-core-internal mapr-gateway
mapr-fileserver mapr-hadoop-core mapr-historyserver mapr-mapreduce2
mapr-nfs mapr-nodemanager mapr-resourcemanager mapr-webserver
mapr-zookeeper mapr-zk-internal
```

- SLES:

```
zypper update mapr-cldb mapr-compat-suse mapr-core mapr-core-internal
mapr-gateway mapr-fileserver mapr-hadoop-core mapr-historyserver
mapr-mapreduce2 mapr-nfs mapr-nodemanager mapr-resourcemanager
mapr-webserver mapr-zookeeper mapr-zk-internal
```

- Ubuntu: First get a list of the MapR packages installed on the node, and then run `apt-get install` on the listed packages.

```
# dpkg --list | grep "mapr" | grep -P "^ii"| awk '{ print $2}'|tr "\n"
" "
# apt-get install <package-list>
```

12. Verify that packages were installed successfully on all nodes. Confirm that there were no errors during installation, and check that `/opt/mapr/MapRBuildVersion` contains the expected value.

For example:

```
# cat /opt/mapr/MapRBuildVersion
6.1.0.xxxxxxxxxxxxxx.GA
```

See Post-Upgrade Steps for MapR Core on page 322

Manual Rolling Upgrade Description
In a manual rolling upgrade, you upgrade the MapR software one node at a time so that the cluster as a whole remains operational throughout the process.

Note: Rolling upgrades to MapR 6.0 or later are supported only for clusters running MapR 5.2.x with EEP 3.0.1 or later. If you are upgrading from an earlier version, upgrade MapR core manually and offline. See Offline and Manual Upgrade Procedure on page 316.

Before you Upgrade

Before you begin a manual rolling upgrade, perform the following steps:

- Determine the upgrade groups. To see a list of services on each node, run the following command:

```
maprcli node list -columns hostname,csvc
```

- If the cluster is secure, the cluster admin user must have a security ticket created before running the upgrade. Otherwise, some upgrade commands will not run.

Group Upgrade Order

Upgrade cluster nodes in groups based on the services running on each node. Upgrade groups of nodes in the following order:

Group	Nodes in this Group
1	Each node only has ZooKeeper. This establishes a stable ZooKeeper quorum on the new version, which remains active through the rest of the upgrade process.
2	Each node only has a MapR gateway (`mapr-gateway-x.x.x`), or it has ZooKeeper. When upgrading from MapR 6.0 or 6.0.1 to MapR 6.1.x or later, you must upgrade the MapR gateway before fileserver.
3	Each node only has fileserver or it has fileserver, MapR gateway, and ZooKeeper.
4	Each node only has NodeManager or it has NodeManager, fileserver, MapR gateway, and ZooKeeper.
5	Each node only has ResourceManager or it has ResourceManager, NodeManager, fileserver, MapR gateway, and ZooKeeper. When you upgrade nodes in this group, upgrade nodes with the standby ResourceManagers before you upgrade the node with the active ResourceManager.
6	Each node has ResourceManager, NodeManager, fileserver, MapR gateway, and ZooKeeper.
7	Each node only has CLDB server or it has CLDB server, ResourceManager, NodeManager, fileserver, MapR gateway, and ZooKeeper. When you upgrade nodes in this group, upgrade nodes with the secondary CLDB before you upgrade the node with the primary CLDB.

Package Upgrade Order

When you upgrade each node, upgrade existing packages in the following order:

last-updated: Apr 11, 2022

- On all operating systems except SLES, upgrade the `mapr-core` package first. Subsequent packages can be done in any order.
- On SLES, upgrade the `mapr-compat-suse` package first and the `mapr-core` package second. Subsequent packages can be done in any order.

The following is a list of the primary packages:

- `mapr-cldb`
- `mapr-compat-suse` (if upgrading on SLES)
- `mapr-core-internal`
- `mapr-core`
- `mapr-fileserver`
- `mapr-gateway`
- `mapr-hadoop-core`
- `mapr-historyserver`
- `mapr-mapreduce2`
- `mapr-nfs`
- `mapr-nodemanager`
- `mapr-resourcemanager`
- `mapr-webserver`
- `mapr-zk-internal`
- `mapr-zookeeper`

What's Next

See Manual Rolling Upgrade Procedure on page 320

Manual Rolling Upgrade Procedure

Describes how to manually upgrade each node to the latest version of MapR packages.

Complete the following upgrade steps for each node in each upgrade group.

1. Download the archive file from https://package.mapr.hpe.com/releases/.
2. Extract the archive file. When you upgrade each package, be sure to specify the full path to the files in this local directory.

   ```
   tar -xzvf <archive file>
   ```

3. Run commands to determine if a patch is installed. If the commands display no output, no patch is installed.
   - RHEL/CentOS and SLES: `rpm -qa mapr-patch`
   - Ubuntu: `dpkg -l | grep mapr-patch`

4. Get the default MapReduce mode for the cluster.

   ```
   maprcli cluster mapreduce get
   ```

5. Stop CLDB if it is running on the node, before putting that node in maintenance mode. Else, the maintenance mode operation is not permitted

   ```
   maprcli node services -name cldb -action stop -nodes mapr-<node>
   ```

6. Set the node to maintenance mode.

   ```
   sudo maprcli node maintenance -nodes <hostname> -timeoutminutes 30
   ```

7. Notify the CLDB that the node is going to be upgraded.

   ```
   sudo maprcli notifyupgrade start -node <hostname>
   ```

8. Stop Warden.

   ```
   sudo service mapr-warden stop
   ```

9. If ZooKeeper is installed on the node, stop ZooKeeper.

   ```
   service mapr-zookeeper stop
   ```

10. Remove any patches installed on the node.
    - RHEL/CentOS or SLES: `sudo rpm -e mapr-patch`
    - Ubuntu: `sudo apt-get -y remove mapr-patch`

11. Upgrade each MapR package on the node based on the defined package upgrade order by running this command for each package:
    - RHEL/CentOS or SLES: `sudo rpm --quiet --force --nosignature -U </FullPathToPackage/PackageName.rpm>`
    - Ubuntu: `sudo dpkg --force-all -i </FullPathToPackage/PackageName.deb>`

      Note: During the upgrade process on Ubuntu, the system displays *dpkg* warnings about overwriting. You can ignore these warnings.

12. Configure the node.

    ```
    sudo /opt/mapr/server/configure.sh -R
    ```

13. If ZooKeeper is installed on the node, start ZooKeeper.

    ```
    service mapr-zookeeper start
    ```

14. Start Warden.

    ```
    sudo service mapr-warden start
    ```

15. Check that the CLDB is running. If output is displayed, the CLDB is running. If not, start CLDB.

    ```
    maprcli node list
    ```

last-updated: Apr 11, 2022

16. Unset maintenance mode on the node, notify the CLDB about the upgraded version, and about the finished status of the upgrade process.

```
sudo maprcli node maintenance -nodes <hostname> -timeoutminutes 0
sudo maprcli config save -values {mapr.targetversion:"`cat /opt/mapr/
MapRBuildVersion`"}
sudo maprcli notifyupgrade finish -node <hostname>
```

17. Wait for the containers to synchronize, run the following command, and check that there is no output.

```
/opt/mapr/server/mrconfig info containers resync local
```

    No output signifies that the containers are synchronized.

See Post-Upgrade Steps for MapR Core on page 322.

Finishing the MapR Core Upgrade
This section provides post-upgrade steps for MapR core.

Post-Upgrade Steps for MapR Core
After upgrading MapR core, several manual steps are required.
Considerations for Upgrades Using the MapR Installer
If you use the MapR Installer to upgrade the cluster, some post-upgrade steps for MapR core do not need to be performed. This page describes the post-upgrade steps that are performed by the MapR Installer and the steps that you must perform manually.

This information is relevant to the workflow for MapR Installer upgrades. The information on this page also applies to upgrades performed using MapR Installer Stanzas.

Post-Upgrade Step for MapR Core	Performed by MapR Installer?	Notes
Step 1: Restart and Check Cluster Services on page 323	Yes, with exceptions. See the notes.	Usually, you do not need to perform this step. When you use the MapR Installer to upgrade, the Installer runs `configure.sh` on each node, starts ZooKeeper and Warden, and sets the new cluster version. If the `env_override.sh` file is present, the Installer uses environment variables from the `env_override.sh` file. If you use the MapR Installer to upgrade, you need to perform this step manually only if you make significant changes to configuration files *after* the upgrade (see Step 2: Manually Update Configuration Files on page 325).
Step 2: Manually Update Configuration Files on page 325	No	You might need to perform this step. The MapR Installer uses default configuration-file settings and does NOT update configuration files. You must perform this step after upgrading using the MapR Installer only if you have made configuration-file customizations that you want to migrate to the upgraded cluster. Depending on the customization, you might also need to restart services or even the full cluster after updating configuration files.
Step 3: Upgrade Clients on page 326	No	You need to perform this step. Enabling some new features, such as `mfs.feature.name.container.size.control` can cause client failures if the features are enabled before the clients are upgraded.

Post-Upgrade Step for MapR Core	Performed by MapR Installer?	Notes
Step 4: Enable New Features on page 330	Yes	You do not need to perform this step. The MapR Installer enables new features as part of a version upgrade.
Step 5: Update Hadoop Configuration File on page 334	Yes	You do not need to perform this step. The MapR Installer updates the Hadoop configuration file, if necessary, as part of a version upgrade.

Step 1: Restart and Check Cluster Services
After upgrading core using either a manual offline or rolling upgrade method (not upgrading with the MapR Installer) and upgrading your ecosystem components, configure and restart the cluster and services.

Note: This task is applicable only to manual offline and rolling upgrade methods.

Important: Before restarting cluster services, upgrade any existing ecosystem packages to versions compatible with the upgraded MapR release. For more information, see EEP Components and OS Support.

This procedure configures and restarts the cluster and services, including ecosystem components, remounts the NFS share, and checks that all packages have been upgraded on all nodes.

After finishing this procedure, run non-trivial health checks, such as performance benchmarks relevant to the cluster's typical workload or a suite of common jobs. It is a good idea to run these types of checks when the cluster is idle. In this procedure, you configure each node in the cluster without changing the list of services that will run on the node. If you want to change the list of services, do so after completing the upgrade. After you have upgraded packages on all nodes, perform this procedure on all nodes to restart the cluster. Upon completion of this procedure, core services are running on all nodes.

1. Merge any custom edits that you made to your cluster environment variables into the new `/opt/mapr/conf/env_override.sh` file before restarting the cluster. This is because the upgrade process replaces your original `/opt/mapr/conf/env.sh` file with a new copy of `env.sh` that is appropriate for the data-fabric release to which you are upgrading. The new `env.sh` does not include any custom edits you might have made to the original `env.sh`. However, a backup of your original `env.sh` file is saved as `/opt/mapr/conf/env.sh<timestamp>`. Before restarting the cluster, you must add any custom entries from `/opt/mapr/conf/env.sh<timestamp>` into `/opt/mapr/conf/env_override.sh`, and copy the updated `env_override.sh` to all other nodes in the cluster. See About env_override.sh on page 2290.

2. On each node in the cluster, remove the `maprusertícket` file. For manual upgrades, the file must be removed to ensure that impersonation works properly. The `maprusertícket` file is re-created automatically when you restart Warden. For more information, see Installation and Upgrade Notes (MapR 6.1.0) on page 39.
   ```
   # rm /opt/mapr/conf/maprusertícket
   ```

3. If you are upgrading from core 6.0.x to 6.2.0, create the `ssl_truststore.pem` and `ssl_keystore.pem` files. These files are used by the Data Access Gateway, Grafana, and Hue components. This step is necessary only for manual upgrades because upgrades performed with the MapR Installer distribute the files automatically. Use these commands:
   a) Use the `manageSSLKeys.sh` utility to generate the files:
   ```
   /opt/mapr/server/manageSSLKeys.sh convert -N my.cluster.com /opt/mapr/conf/ssl_truststore /opt/mapr/conf/ssl_truststore.pem

   /opt/mapr/server/manageSSLKeys.sh convert -N my.cluster.com /opt/mapr/conf/ssl_keystore /opt/mapr/conf/ssl_keystore.pem
   ```

b) Copy the generated `ssl_keystore.pem` and `ssl_truststore.pem` files to the `/opt/mapr/conf/` directory on all the nodes in the cluster.

4. On each node in the cluster, run `configure.sh` with the `-R` option:
   ```
   # /opt/mapr/server/configure.sh -R -HS <hostname>
   ```

5. If ZooKeeper is installed on the node, start it:
   ```
   # service mapr-zookeeper start
   ```

6. Start Warden.
   ```
   # service mapr-warden start
   ```

7. Run a simple health-check targeting the filesystem and MapReduce services only. Address any issues or alerts that might have come up at this point.

8. Set the new cluster version in the `/opt/mapr/MapRBuildVersion` file by running the following command on any node in the cluster:
   ```
   # maprcli config save -values {mapr.targetversion:"`cat /opt/mapr/MapRBuildVersion`"}
   ```

9. Verify the new cluster version:
   For example:
   ```
   # maprcli config load -keys mapr.targetversion
   mapr.targetversion
   6.1.0.xxxxxxxxxx.GA
   ```

10. Remount the MapR NFS share:
    The following example assumes that the cluster is mounted at `/mapr`: `# mount -o hard,nolock <hostname>:/mapr /mapr`

11. Run commands, as shown in the example, to check that the packages have been upgraded successfully:
    Check the following:
    - All expected nodes show up in a cluster node list, and the expected services are configured on each node.
    - A master CLDB is active, and all nodes return the same result.
    - Only one ZooKeeper service claims to be the ZooKeeper leader, and all other ZooKeepers are followers.

    For example:
    ```
    # maprcli node list -columns hostname,csvc
    hostname configuredservice ip
    centos55 nodemanager,cldb,fileserver,hoststats 10.10.82.55
    centos56 nodemanager,cldb,fileserver,hoststats 10.10.82.56
    centos57 fileserver,nodemanager,hoststats,resourcemanager 10.10.82.57
    centos58 fileserver,nodemanager,webserver,nfs,hoststats,resourcemanager
    10.10.82.58
    ...more nodes...

    # maprcli node cldbmaster
    cldbmaster
    ServerID: 8851109109619685455 HostName: centos56
    ```

```
# service mapr-zookeeper status

MapR Technologies, Inc. zookeeper service.
```

Step 2: Manually Update Configuration Files
After upgrading MapR core using a manual offline or rolling upgrade method, update your configuration files.

Note: This task is applicable to all manual upgrade methods: offline and rolling upgrades.

Important: After upgrading MapR but before enabling new features, all nodes in your cluster must be upgraded, and all configuration files must be updated.

To manually update the configuration files:

1. On all nodes, manually merge new configuration settings from the `/opt/mapr/conf.new/warden.conf` file into the `/opt/mapr/conf/warden.conf` file.
2. For secure clusters: On all nodes, manually copy `/opt/mapr/conf.new/mapr.login.conf` to the `/opt/mapr/conf/` directory, and set the file permissions to 0644. This file contains Zookeeper security information.
3. On all nodes, manually merge new configuration settings from the files in the `/opt/mapr/conf/conf.d.new/` directory to the files in the `/opt/mapr/conf/conf.d/ directory`.

4. Manually merge the port and authentication configuration information in the `/opt/mapr/conf/web.conf` directory from the pre-6.0 release version to the `/opt/mapr/apiserver/conf/properties.cfg` file of the upgraded release version.

   For example, the following from the `/opt/mapr/conf/web.conf` file from the pre-6.0 version must be manually copied over to the `/opt/mapr/apiserver/conf/properties.cfg` file of the new version:

   ```
   # HTTPS Settings
   mapr.webui.https.port=8443
   mapr.rest.auth.methods=kerberos,basic // if kerberos auth
   ```

5. Manually merge new configuration settings in `/opt/mapr/conf/fuse.conf` file with custom settings in `/opt/mapr/conf/fuse.conf.backup` file and restart FUSE for the settings to take effect.

   After the upgrade, on all supported operating systems other than Ubuntu, the new `fuse.conf` file and a backup copy of the `fuse.conf` file from prior version named `fuse.conf.backup` are available in the `/opt/mapr/conf` directory. You can find the new parameters with default values in the new `fuse.conf` file and your custom settings from the prior version in the `fuse.conf.backup` file. On Ubuntu, you can find the new `fuse.conf` file in the `/opt/mapr/conf` directory and by default, there is no backup copy of the `fuse.conf` file from prior version unless you created one before upgrade.

Note: When hadoop common is updated along with MapR core, a new directory is created for the new hadoop common version and the configuration files in the existing `/opt/mapr/hadoop/hadoop-2.x.x` directory are automatically copied into the active directory associated with the new hadoop 2.x.x directory. For example, when you upgrade from 4.1 to 5.x, configuration files that were in the hadoop-2.5.1 directory are copied into the hadoop-2.7.1 directory.

Step 3: Upgrade Clients
After you upgrade your cluster, you may also need to upgrade your MapR client or MapR POSIX client.

When you upgrade the cluster, consider if your MapR client or your MapR POSIX client needs to be upgraded as well. See Planning Upgrades to MapR Clients on page 301.

Additionally, MapR POSIX loopbacknfs clients can be migrated to FUSE-based POSIX clients on Basic POSIX client packages. MapR POSIX loopbacknfs clients can *not* be migrated to Platinum POSIX client packages.

See Migrating to FUSE-based POSIX Clients for more information.

Note: Basic and Platinum POSIX client packages are recommended for fresh installation and for all new clusters.

Upgrading the MapR Client

Depending on which MapR client you want to update, you will either need to install and reconfigure or perform a package upgrade.

To get a newer version of the Windows or Mac OS X MapR client, install the newer MapR client and reconfigure it. To get a newer version of the Linux MapR client, perform a package upgrade.

Upgrading the MapR Client on a Linux Server

This section describes how to upgrade the MapR client on a Linux Server.

To upgrade the MapR client on an RHEL, SLES, or Ubuntu server, you must upgrade the `mapr-client` package. When you upgrade the MapR client packages on the server, the configuration files in the `/opt/mapr/hadoop/hadoop-2.x.x` directory are automatically copied into the active directory associated with the Hadoop 2.x.x directory.

1. Remove any currently installed client patches. For example:

- **On RedHat and CentOS**

```
yum remove mapr-patch-client-<version>
```

- **On Ubuntu**

```
apt-get remove mapr-patch-client-<version>
```

- **On SLES**

```
zypper remove mapr-patch-client-<version>
```

2. Configure the repository to point to the target release and operating system.
3. Run the following command to upgrade the client package:
   - On RedHat / CentOS: `yum update mapr-client`
   - On SLES: `zypper update mapr-client`
   - On Ubuntu: `apt-get install mapr-client`

Related tasks

Upgrading the MapR loopbacknfs POSIX Client on a Linux Server on page 328
This section describes how to upgrade the MapR loopbacknfs POSIX Client on a Linux server.

Upgrading the MapR Client on Windows

This section provides instructions on how to upgrade the MapR client on Windows.

When you upgrade the MapR client on Windows, you need to rename the existing client directory, install the new version, and then merge the configuration files.

1. Rename the existing client installation directory. For example, you can rename `\opt\mapr` to `\opt_old\mapr.`
2. Complete the installation steps in Installing the MapR Client on Windows on page 397.
3. To retain existing configurations and accepts new defaults, merge the contents of the following directories in the previous installation with the ones in the new installation:
   - `%MAPR_HOME%\hadoop\hadoop-2.x.x\etc\hadoop`
   - `%MAPR_HOME%\hadoop\hadoop-0.20.0\conf`

Upgrading the MapR Client in Mac OS X

This section describes how to upgrade the MapR client on Mac OS X.

When you upgrade the MapR client on Mac OS X, you need to rename the existing client directory, install the new version, and then merge the configuration files.

1. Rename the existing client installation directory. For example, you can rename `/opt/mapr` to `/opt_old/mapr.`
2. Complete the installation steps in Installing the MapR Data Platform Client on Mac OS X on page 395.
3. To retain existing configurations and accept the new defaults, merge the contents of the following directories in the previous installation with the ones in the new installation:
   - `opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`

- `opt/mapr/hadoop/hadoop-0.20.0/conf`

Upgrading the MapR POSIX loopbacknfs Client

Perform a package upgrade to get a newer version of the MapR POSIX loopbacknfs Client.

To get a newer version of the MapR POSIX loopback NFS client, perform a package upgrade. MapR POSIX loopback NFS client can be upgraded or a fresh install can be performed.

Additionally, MapR POSIX loopbacknfs client can be migrated to a FUSE-based POSIX Basic client. MapR POSIX loopback NFS clients can *not* be migrated to FUSE-based Platinum POSIX clients.

See Migrating to FUSE-based POSIX Clients for more information.

Note: Basic and Platinum POSIX client packages are recommended for fresh installation and for all new clusters.

Upgrading the MapR loopbacknfs POSIX Client on a Linux Server

This section describes how to upgrade the MapR loopbacknfs POSIX Client on a Linux server.

To upgrade the MapR loopbacknfs POSIX client on a RHEL, SLES, or Ubuntu server, you must upgrade the `mapr-loopbacknfs` package.

Note: To migrate the MapR POSIX Client to a FUSE-based POSIX client, see Migrating to FUSE-based POSIX Clients.

1. Stop the `mapr-loopbacknfs` service.

```
service mapr-loopbacknfs stop
```

2. Remove any currently installed client patches. For example:
   - On RedHat / CentOS: `yum remove mapr-patch-loopbacknfs`
   - On SLES: `zypper remove mapr-patch-loopbacknfs`
   - On Ubuntu: `apt-get remove mapr-patch-loopbacknfs`
3. Upgrade the `mapr-loopbacknfs` package.
   - On RedHat / CentOS: `yum update mapr-loopbacknfs`
   - On SLES: `zypper update mapr-loopbacknfs`
   - On Ubuntu: `apt-get install mapr-loopbacknfs`
4. Update the cluster configuration information in the `mapr-loopbacknfs.new` file.

```
vi /usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs.new
```

5. Copy `mapr-loopbacknfs.new` to the `mapr-loopbacknfs` script

```
cp
/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs.new
/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs
```

6. Start the loopbacknfs service.

```
service mapr-loopbacknfs start
```

7. Check the status of the loopbacknfs service.

```
service mapr-loopbacknfs status
```

Troubleshooting MapR loopbacknfs POSIX Client Upgrades

If you are having difficulty upgrading the MapR POSIX client, it might be due to a shared-memory-segment lock.

If the `mapr-loopbacknfs` service fails to start after an upgrade, use the following steps to determine if a shared-memory-segment lock was the cause of the failure:

1. Open the `loopbacknfs.log` file. The loopbacknfs.log file is in the following directory: `/usr/local/mapr-loopbacknfs/logs/`
2. Check for the following string: `Create/Attach to shm failed`
3. If the string is present, perform the following steps:
   a) Run the following command to identify the `shmid` of the lock: `ipcs -m | grep 0x0000161c`
   b) Run the following command to remove the lock:`ipcrm -m <shm id>`
   c) Start the `mapr-loopbacknfs` service.

Migrating to FUSE-Based POSIX Clients

This section describes how to migrate from the loopbacknfs POSIX client to the FUSE-based POSIX basic client.

The FUSE-based Basic or Platinum POSIX client package is recommended for fresh installation and for all new clusters. If you are currently running the loopbacknfs POSIX client, you can migrate to the FUSE-based POSIX basic client package. By default, the system will only allow migrating the existing loopbacknfs POSIX client to the FUSE-based POSIX basic client. If you choose to upgrade using the existing loopbacknfs POSIX client licenses, by default, the system upgrades the selected nodes to the (paid) FUSE-based POSIX basic client. You cannot use existing licenses to migrate to the Platinum POSIX client package.

Before upgrading, ensure that the cluster has been upgraded to release 5.1.0 or higher because the FUSE-based POSIX client can only connect to clusters running release 5.1.0 or higher.

To migrate to the FUSE-based POSIX Basic client:

1. Stop the existing loopbacknfs POSIX service, unmount the mountpoint, and uninstall the `mapr-loopbacknfs` POSIX client.
   For more information, see MapR loopbacknfs POSIX Client.
2. Run the following command to remove the loopbacknfs service node from the cluster:

```
/opt/mapr/bin/maprcli node remove -service nfsserver -nodes <node-name>
```

   If the host has multiple services, run the following command:

```
/opt/mapr/bin/maprcli node remove -hostids <service host id>
```

3. Install the FUSE-based POSIX basic client package.
   For more information, see Installing a POSIX FUSE Client Package on Your Machine. When you install the FUSE-based POSIX client package, the licenses for the loopbacknfs POSIX client are automatically applied to the new client package.

4. Verify the FUSE-based POSIX client license.
   For more information, see Configuring the MapR FUSE-Based POSIX Client on page 1240.

Upgrading the MapR FUSE POSIX Client on a Linux Server

This section describes how to upgrade the MapR FUSE POSIX client on a Linux server.

To upgrade the MapR FUSE POSIX client on a RHEL, SLES, or Ubuntu server, you must upgrade the `mapr-posix-client-basic` or `mapr-posix-client-platinum` package.

1. Stop the `mapr-posix-client-basic` or `mapr-posix-client-platinum` service. For example:

   ```
   service mapr-posix-client-basic stop
   ```

2. Remove any currently installed client patches. For example:
   - On RHEL / CentOS: `yum remove mapr-patch-posix-client-basic`
   - On SLES: `zypper remove mapr-patch-posix-client-basic`
   - On Ubuntu: `apt-get remove mapr-patch-posix-client-basic`
3. Upgrade the `mapr-posix-client-basic` or `mapr-posix-client-platinum` package:
   - On RHEL / CentOS: `yum update mapr-patch-posix-client-basic`
   - On SLES: `zypper update mapr-patch-posix-client-basic`
   - On Ubuntu: `apt-get install mapr-patch-posix-client-basic`
4. Update the cluster configuration information in the `/opt/mapr/conf/fuse.conf` file:

   ```
   vi /opt/mapr/conf/fuse.conf
   ```

5. Copy any new parameters from `fuse.conf.new` to the `/opt/mapr/conf/fuse.conf` file.
6. Start the FUSE POSIX service:

   ```
   service mapr-patch-posix-client-basic start
   ```

7. Check the status of the FUSE POSIX service:

   ```
   service mapr-patch-posix-client-basic status
   ```

Step 4: Enable New Features

Describes the new features to enable after upgrading MapR core without the MapR Installer using a manual offline or rolling upgrade method.

This task applies to all manual upgrade methods: offline, rolling, and manual rolling upgrades. After a successful manual upgrade, administrators have the option to enable new features that are not enabled by default. During a fresh install, these features are enabled automatically.

Before Enabling New Features

Before enabling new features, review these important notes:

- You can obtain a list of features for your currently installed software by using the following command:

```
maprcli cluster feature list
```

- Before enabling new features, you must upgrade all nodes in the cluster and all clients that access the cluster. Do NOT enable new features if your release 6.0 or later cluster is configured with EEP 3.0.x. For release 6.0 or later, upgrade all nodes to EEP 4.0 or later before you enable release 6.0 or later features. EEP 3.0.x is supported only for upgrade purposes. See EEP Support and Lifecycle Status on page 5531.
- The `maprcli config save` command is no longer available for enabling features.

How to Enable New Features

You enable new features by using the `maprcli cluster feature enable` command. For more information about this command, see maprcli cluster commands.

HPE recommends that you enable *all* new features. Use the following command:

```
maprcli cluster feature enable -all
```

Feature Summary

The following table describes considerations for enabling some features. The table does not represent a complete list of MapR features:

Feature	Feature Name	Available as of Release	Description
Data-at-Rest Encryption	`mfs.feature.dare`	6.1	Enables support for encrypting data at rest on the MapR cluster. See Enabling Encryption of Data at Rest on page 1413 for more information.
Data Tiering	`mfs.feature.storage.tiering.support`	6.1	Enables support for offloading data to different storage tiers. See Enabling Tiering on page 957 for more information.
Name Container Threshold	`mfs.feature.name.container.size.control`	6.0.1	Enables support for setting a limit on the size of data stored in the name container for a volume.
Directcopy for Autosetup Replication, Change Data Capture and Secondary Index	`mfs.feature.db.streams.v6.support`	6.0	Enables the following: • MapR Database tables and MapR Event Store For Apache Kafka to use the directcopy option with the autosetup replication feature. • MapR Database table Change Data Capture (CDC) feature. • MapR Database Secondary Index feature.

last-updated: Apr 11, 2022

Feature	Feature Name	Available as of Release	Description
Enforce Guaranteed Minimum Replication	`mfs.feature.enforce.min.replication`	6.0	Enables support for enforcing minimum number of replicas for (read-write) volumes during write operations. **Note:** Do not enable this feature before upgrading all the nodes in the cluster. If you enable this feature before upgrading all the nodes, MapR File System shuts down on the nodes that have not yet been upgraded.
CLDB Snapshot Improvements	`mfs.feature.snapshotdb.lite`	6.0	This feature stays disabled even after you enable it, till you perform a CLDB failover. The feature is enabled only after the CLDB failover is complete, after which you can experience significant performance improvements for snapshot create and delete operations.
External IPs for CLDB	`cldb.feature.external.ip`	6.0	Enables support for external IP addresses and port forwarding. Set the environment variables (as described here) before enabling this feature. After enabling this feature, perform a CLDB failover to allow MapR File System to re-register.
Container Identity Reuse	`cldb.feature.cid.reuse`	5.2.1	Support for container identity reuse.
Fast inode Scan for Mirroring	`mfs.feature.fastinodescan.support`	5.2.1	Enables fast mirroring when there are large numbers of files with few changes.
Streams Connect Support	`mfs.feature.streams.connect.support`	5.2.1	Enables support for Kafka Connect in the distributed mode.
Extended Attributes	`mfs.feature.fileace.support`	5.2	Enables support for adding, retrieving, and removing extended attributes on files and directories.
Hardlinks	`mfs.feature.hardlinks.support`	5.2	Enables support for retrieving hard links on files.
Access Control Expressions for MapR File System	`mfs.feature.fileace.support`	5.1	Enables the setting of Access Control Expressions on filesystem and whole volume data.
MapR Event Store For Apache Kafka and MapR Database as a document database	`mfs.feature.db.json.support`	5.1	Enables the use of MapR Streams and MapR Database as a Document Database on page 507.
MapR Auditing	`mfs.feature.audit.support`	5.0	Logs audit records of cluster-administration operations and operations on directories, files, and tables.

Feature	Feature Name	Available as of Release	Description
MapR Volume Upgrade	`mfs.feature.volume.upgrade` `mfs.feature.rwmirror.support`	5.0	Enables support for promotable mirrors on both old-format and new-format volumes.
MapR Database Table Replication	`mfs.feature.db.repl.support`	4.1	Enables support for MapR Database table replication.
Promotable Mirror Volumes	`mfs.feature.rwmirror.support`	4.0.2	Enables support for promotable mirror volumes.
Reduce On-Disk Container Size	`cldb.reduce.container.size`	4.0.2	Reduces the space required on-disk for each container. The reduction of the on-disk container size takes effect after the CLDB service restarts or fails over. **Note:** After enabling this feature on a cluster with more than a million containers, it may take some time for the initial failover to complete, as the CLDB rewrites container location tables and storage pool container map tables. However, this delay does not reoccur with any subsequent failovers.
Bulk Loading of Data to MapR Database Tables	`mfs.feature.db.bulkload.support`	3.1.1	Enables support for bulk loading of data to MapR Database tables. Used when upgrading from MapR version 3.1 or earlier.

last-updated: Apr 11, 2022

Feature	Feature Name	Available as of Release	Description

Access Control Expressions and Table Region Merges	`mfs.feature.db.ace.support`
	`mfs.feature.db.regionmerge.support`
	`mfs.feature.filecipherbit.support`
		3.1	The following features enable support for Managing Access Control Expressions on page 1448 (ACEs) and table region merge on page 1847. Used when upgrading from MapR version 3.0.x.
			`mfs.feature.db.ace.support`
			`mfs.feature.db.regionmerge.support`
			These features are automatically enabled with a fresh install or when you upgrade from a version earlier than 3.0.x.
			Important: After enabling ACEs for MapR tables, table access is enforced by table ACEs instead of the filesystem. As a result, all newly created tables are owned by root and have their mode bits set to 777.
			The following feature enables encryption of network traffic to or from a file, directory, or MapR Database table. This feature is enabled after you enable security features on your cluster.
			`mfs.feature.filecipherbit.support`
			Warning: Clusters with active security features experience job failures until this configuration value is set.

Step 5: Update Hadoop Configuration File
When manually upgrading (manual offline and manual rolling upgrade) from version 4.x to version 6.x and switching from classic mode to YARN mode, you must manually update the Hadoop configuration file.

This task is applicable only if you are upgrading from any version of 4.x to any version of 6.x and you did not convert from classic mode to YARN mode before the upgrade. In addition, this step is applicable for only the manual offline upgrade and the manual rolling upgrade. This step is not applicable when using the MapR Installer upgrade method.

1. Change directory to **/opt/mapr/conf** directory.

```
cd /opt/mapr/conf/
```

2. Edit the Hadoop configuration file

```
vim hadoop_version
```

last-updated: Apr 11, 2022

3. Change the `yarn_version` parameter to the actual version of Hadoop. For example:

```
yarn_version=2.7.0
```

Installing Additional MapR Core Features
Some features can require the installation of additional packages after an upgrade to a new release.

Installing Monitoring After an Upgrade

MapR Monitoring, also known as the Spyglass initiative, provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications. You can only install MapR Monitoring after you upgrade ecosystem components.

- To install MapR Monitoring without the MapR Installer, see Step 8: Install Metrics Monitoring on page 162 and Step 9: Install Log Monitoring on page 165.
- To install MapR Monitoring with the MapR Installer, launch the MapR Installer URL (`https://<hostname/IPaddress>:9443`) and select the Incremental Install option. With the incremental installation option, you can install new packages and also install MapR Monitoring.

Securing the Upgraded Cluster
Nonsecure clusters can be secured after the upgrade process.

If your cluster was nonsecure before you upgraded it, the cluster will remain nonsecure after the upgrade. If you used the manual-rolling or offline-manual workflows to upgrade and you want to add security, see Getting Started with MapR Security on page 1405.

If you used the MapR Installer workflow to upgrade, and you want to add security, see Using the Enable MapR Secure Cluster Option on page 5427.

Upgrading MapR Ecosystem Packs

Describes how to upgrade MapR Ecosystem Packs (EEPs), either as part of a MapR core upgrade or to take advantage of a new EEP for the current version of MapR core.

An MapR Ecosystem Pack (EEP) provides a set of ecosystem components that are fully tested by HPE to be interoperable except where noted. For more information about EEPs, see MapR Ecosystem Packs.

Planning MapR Ecosystem Pack (EEP) Upgrades
The set of ecosystem components that you run in the cluster must all belong to the same EEP.

As of release 5.2, you must install ecosystem components as part of an EEP. You will be offered packs to install that contain selected component versions. After upgrading, you may want to upgrade to a more recent EEP to get the latest patch releases or newer versions of ecosystem components.

Most MapR core versions support multiple EEPs, but the set of ecosystem components that you run in the cluster must all belong to the same EEP. You cannot selectively upgrade components. When you upgrade an EEP, all components are replaced with the versions contained in the newly selected EEP.

To compare ecosystem component versions across EEPs, see Component Versions for Released EEPs.

For EEP lifecycle information, see EEP Support and Lifecycle Status on page 5531.

For details about the ecosystem components available in each EEP and the list of EEPs supported by your MapR core version, see the EEP Release Notes on page 5658.

For API or behavioral changes associated with new ecosystem components, see the documentation for the individual component under Ecosystem Components.

Preparing to Upgrade the MapR Ecosystem Pack
Complete these pre-upgrade steps for each ecosystem component in the EEP that you want to upgrade.

For the components provided in each EEP, see the EEP Release Notes on page 5658.

These steps are intended primarily for ecosystem-component upgrades performed manually (without the MapR Installer). However, you need to perform some pre-upgrade steps even if you are upgrading using the MapR Installer.

Stopping each service is optional if you are using the MapR Installer because the Installer stops all services before upgrading. But the MapR Installer does NOT back up configuration files.

Important: Regardless of the upgrade method that you use, follow the pre-upgrade steps for backing up your configuration files before upgrading. The upgrade process replaces your current configuration files with new configuration files that contain default values for the release to which are upgrading. Any custom settings are lost and must be migrated manually as part of the post-upgrade steps.

Pre-Upgrade Steps for Drill
Complete the following steps before you upgrade Drill with or without the MapR Installer.

Starting in Drill 1.11, Drill is automatically secured when installed in a release 6.x cluster with the default MapR security configuration. The default security configuration uses MapR security (`mapr` tickets) to provide authentication, authorization, and encryption for cluster security. See Securing Drill for more information.

Note: The default security feature introduced in release 6.0 is not supported with Drill-on-YARN.

Note: See Component Versions for Released EEPs for version support in each EEP release.

Preserving Custom Security When Upgrading Core and Drill

You can perform a manual upgrade, for example from a secured release 5.2 cluster to 6.0, to preserve your security settings from 5.2. When you upgrade, a special file, /opt/mapr/conf/.upgrade_from, checks for security settings. If security is set, the same settings carry over to 6.x.

During a custom upgrade, Drill configurations are not carried over. You must either reconfigure all of your Drill settings, or save your previous settings and then override the default Drill settings. You can manually secure Drill either by copying over the old drill-override.conf file into /opt/mapr/drill/drill-<version>/conf or by updating the /opt/mapr/drill/drill-<version>/conf/drill-distrib.conf file with the security settings.

After you upgrade, you must run configure.sh -R to configure the cluster. When you run the configuration script, it adds a .customSecure file to the /opt/mapr/conf directory. This file calls the internal ecosystem scripts, but does not configure Drill.

If you decide you want to enable the default security option, you can do so by running configure.sh with the -secure and -forceSecurityDefaults flags, as shown:

```
/opt/mapr/server/configure.sh -forceSecurityDefaults [ -unsecure | -secure ]
 -C <CLDB_node> -Z <ZK_node>
```

Running configure.sh with these flags secures the cluster and supported ecosystem components. The internal Drill configuration script configures Drill security in the drill-distrib.conf and distrib-env.sh files. See Securing Drill.

Drill Management Service

Drill can run under the MapR Warden service or under YARN. You can upgrade Drill and continue to run Drill under the MapR Warden service. If you are currently running Drill under the MapR Warden service, you can migrate Drill to run under YARN. If you want to migrate Drill to run under YARN, see Migrate Drill to Run Under YARN.

If you are upgrading Drill to run under Warden, Drill should preserve your storage plugin and configuration files when you upgrade. However, you should backup and restore your configuration files and UDF JAR files.

Pre-Upgrade Steps

last-updated: Apr 11, 2022

Complete the following steps on Drill servers and clients before you upgrade Drill:

1. Optionally, back up storage plugin configurations:
   a. Open the Drill Web Console. The Drill node that you use to access the Web Console is a node that is currently running the Drillbit process.
   b. Click the **Storage** tab.
   c. Click **Update** next to a storage plugin.
   d. Copy the configuration to a text file, and save the file.
   e. Repeat steps **c** and **d** for each storage plugin configuration that you want to save.
2. To stop the Drillbit service on all nodes, issue the following command:

```
maprcli node services -name drill-bits -action stop -nodes <node
hostnames separated by a space>
```

Pre-Upgrade Steps for Flume
Complete the following steps before you upgrade Flume with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You need to back up configuration files for Flume if you made configuration changes that you want to carry over to the next version.

1. Locate configuration files in `/opt/mapr/flume/flume-<version>/conf/`.
2. Copy the configuration files to a location outside the MapR installation directory.
   After upgrading, you can reapply changes to the updated Flume using the backup.

Pre-Upgrade Steps for HBase
Complete the following steps before you upgrade HBase with or without the MapR Installer.

1. **Upgrade your HBase Java applications.**
   Check your HBase applications for Java APIs that are no longer supported in HBase 1.1. See HBase Java API Support. Then, update the applications to use APIs supported by HBase 1.1 and recompile your applications with HBase 1.1.
2. **Take a snapshot of the HBase volume.** This step is applicable if you are upgrading with the MapR Installer or upgrading manually.
   The snapshot creates a backup of the volume data that you can use to recover your data in the event that corruption occurs during the upgrade process. For more information, see Creating Volume Snapshots on page 947.
3. **Optional: Create a backup copy of any configuration files that contain customized values.** This step is applicable if you are upgrading with the MapR Installer or upgrading manually.
   The configuration files are located in `/opt/mapr/hbase/hbase-<version>/conf/`. Copy any that you want to back up to another location. If you plan to upgrade with the MapR installer, copy files to a location that is outside the MapR installation directory. After upgrading, you can reapply changes to the updated HBase installation using the backup.

Considerations for Upgrading to HBase 1.1.13
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

last-updated: Apr 11, 2022

Removing the Mappings Property

A release 6.0.x cluster installed using the MapR Installer contains an `hbase.table.namespace.mappings` property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file. For example:

```
<property>
   <name>hbase.table.namespace.mappings</name>
   <value>*:/</value>
</property>
```

Release 6.0.x clusters support MapR Database, but they do not support HBase. Therefore, if you upgrade the cluster manually from Release 6.0.x, you need to remove this property in order to support HBase connections to both HBase and MapR Database.

If you do not remove the property, you might see the following message:

```
This client is configured to use MapR tables only. HBase status is not
available. MapR cluster status
can be viewed using the 'maprcli dashboard info' command or the UI.
```

How HBase Configuration Files Are Preserved During an Upgrade

Starting with EEP 6.3.0, existing HBase configuration files are automatically saved during an upgrade. This table describes what happens to HBase configuration files during an upgrade.

When you upgrade from HBase Version	To Version	HBase Configuration Files
1.1.8	1.1.13	Are overwritten by new configuration files.
1.1.13	1.1.13 (with patches)[1]	Are saved (not overwritten).

[1]An upgrade from HBase 1.1.13 to HBase 1.1.13 is a valid upgrade path if patches have been added to HBase 1.1.13 and you want to apply the patches.

This example shows a listing of the configuration files that are saved after an upgrade from HBase 1.1.8 to HBase 1.1.13:

```
[mapr@node2 etc]$ ls /opt/mapr/hbase/
hbase-1.1.13 hbase-1.1.8.201904050941 hbaseversion

$ ls /opt/mapr/hbase/hbase-1.1.8.201904050941/conf/
hadoop-metrics2-hbase.properties hbase-env.sh hbase-policy.xml
hbase-site.xml log4j.properties regionservers
warden.hbaserest.conf warden.hbaserest.conf.template
warden.hbasethrift.conf warden.hbasethrift.conf.template
```

Applications and Security

Existing HBase applications might need to be modified to work properly with HBase 1.1.13 in a secure MapR cluster:

HBase API Client	No changes
HBase REST	No changes if the old client used PAM (can now be changed to mapr-sasl header)
HBase Thrift over HTTP	No change if the old client used PAM (can now be changed to mapr-sasl header)

HBase Thrift over Socket	No changes

Configuring the Default Database for HBase Clients

EEP 6.3.0 introduced some minor changes to default database configuration. For details, see Configure the Default Database for HBase Clients on page 3389.

Pre-Upgrade Steps for HBase Client
Complete the following steps before you upgrade HBase Client with or without the MapR Installer.

If you made configuration changes that you want to carry over to the next version of HBase Client, you need to back up configuration files.

1. Copy the configuration files in `/opt/mapr/hbase/hbase-<version>/conf/` to a location outside the MapR installation directory.
2. After upgrading, you can reapply changes to the updated HBase Client by merging the configuration files back into `/opt/mapr/hbase/hbase-<version>/conf/`. See Post-Upgrade Steps for HBase Client on page 373 for more information.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 337
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Pre-Upgrade Steps for Hive
Complete the following steps before you upgrade Hive with or without the MapR Installer.

You need to back up the metastore database in case an error occurs during the Hive upgrade. You also need to back up configuration files if you made configuration changes that you want to carry over to the next version.

1. Back up the metastore database.
   ```
   mysqldump -u<user> -p<passwd> <metastore_db_name> -r metastore-db-dump.sql
   ```
2. Copy the configuration files in `/opt/mapr/hive/hive-<version>/conf/` to a location outside the MapR installation directory.
   After upgrading, you can reapply changes to the updated Hive installation using the backup.
3. Stop Hive services.
   ```
   maprcli node services -name hivemeta -action stop -nodes <list of hive
   nodes>
   maprcli node services -name hs2 -action stop -nodes <list of hive nodes>
   maprcli node services -name  hcat -action stop -nodes <list of hive
   nodes>
   ```

Preserving the Hive Configuration
Starting from EEP-6.0.0, preserving of user configuration logic is built into Hive.

- For a minor version update (for example, `Hive-2.1-1803` to `Hive-2.1-1808`), user configuration from a previous version is copied to a folder with an old version timestamp and is also copied to a new version `conf` folder.
- For a major version update (for example, `Hive-2.1-1803` to `Hive-2.3-1808`), user configuration from a previous version is **only** copied to a folder with an old version timestamp.

Starting from EEP-5.0.2 and EEP-6.0.1, a logic of preserving user Warden files configuration for Hive Metastore, HiveServer2 and WebHCat are built into Hive.

- For a minor version update (for example, `Hive-2.1-1808` to `Hive-2.1-1901`), user configuration of Warden files from a previous version is copied to a folder with an old version timestamp and is also preserved in the `MAPR_HOME/conf/conf.d/` folder.
- For a major version update (for example, `Hive-2.1-1808` to `Hive-2.3-1901`), user configuration from a previous version is **only** copied to a folder with an old version timestamp.

Pre-Upgrade Steps for HttpFS
Complete the following steps before you upgrade HttpFS with or without the MapR Installer.

Stop the HttpFS service using the following command:

```
maprcli node services -name httpfs -action stop -nodes <ip_address>
```

For EEP 6.3.4 and earlier, back up existing configuration files if you made HttpFS configuration changes that you want to carry over to the next version. Typically, the following configuration files contain changes:

- `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/webapps/webhdfs/WEB-INF/web.xml`
- `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml`
- `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/tomcat-users.xml`
- `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`

To back up configuration files, copy the files to a location outside the MapR installation directory. After upgrading, you can reapply changes to the updated httpFS installation using the backup.

Note: To verify EEP and core version support, see EEP Support and Lifecycle Status on page 5531.

Preserving HttpFS Configuration
Preserving of user configuration logic is built into HttpFS.

- User configuration from a previous version is copied to a folder with an old version timestamp and is also copied to a new version `conf` folder.

Pre-Upgrade Steps for Hue
Complete the following steps before you upgrade Hue with or without the MapR Installer.

1. Stop the Hue service:
   ```
   maprcli node services -name hue -action stop -nodes <ip_address>
   ```
2. Create a Hue database dump as a JSON object:

   For MySQL, PostgreSQL, or Oracle

   ```
   source /opt/mapr/hue/hue-<version>/build/env/bin/activate
   hue dumpdata > ~/dump-hue-<version>.json
   deactivate
   ```

   For SQLite

   ```
   cd /opt/mapr/hue/hue-<version>/desktop
   sqlite3 desktop.db .dump > ~/dump-hue-<version>-sqlite.bak
   ```
3. Copy the configuration properties from `/opt/mapr/hue/hue-<version>/desktop/conf/` to a location outside your MapR installation directory.

   After upgrading, you can reapply changes to the updated Hue installation using the backup.

Preserving Hue Configuration
Starting from EEP-6.0.0, preserving of user configuration logic is built into Hue.

- For a major version update (for example, `Hue-3.2-1803` to `Hive-4.2-1808`), user configuration from a previous version is **only** copied to a folder with an old version timestamp (`/HUE_HOME/hue-3.12.0.201707281202`).

Pre-Upgrade Steps for Impala
Complete the following steps before you upgrade Impala with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Stop the Impala server, statestore, and catalog services on all Impala nodes.

1. Run the following command to stop the Impala server on each Impala node:

```
$ maprcli node services -name impalaserver -action stop -nodes <node IP
addresses separated by a space>
Example:$ maprcli node services -name impalaserver -action stop -nodes
10.10.30.166
```

2. Run the following command to stop the Impala statestore instances:

```
$ maprcli node services -name impalastore -action stop -nodes <node IP
addresses separated by a space>
Example:$ maprcli node services -name impalastore -action stop -nodes
10.10.30.166
```

3. Run the following command to stop the Impala catalog instances:

```
$ maprcli node services -name impalacatalog -action stop -nodes <node IP
addresses separated by a space>
Example:$ maprcli node services -name impalacatalog -action stop -nodes
10.10.30.166
```

Preserving Impala Configuration
Starting from EEP 6.0.0, preserving of user configuration logic is built into Impala.

- For a minor version update (for example, `Impala-2.10-1803` to `Impala-2.10-1808`), user configuration from a previous version is copied to a folder with an old version timestamp and is also copied to a new version `conf` folder.
- For a major version update (for example, `Impala 2.7.0-1710` to `Impala-2.10-1808`), user configuration from a previous version is **only** copied to a folder with an old version timestamp.

Pre-Upgrade Steps for MapR Data Access Gateway
Complete the following steps before you upgrade the MapR Data Access Gateway with or without the MapR Installer.

Stop the service:

```
maprcli node services -nodes <node name> -name data-access-gateway -action
stop
```

Pre-Upgrade Steps for Livy

Complete the following steps before you upgrade Livy with or without the MapR Installer.

1. Stop the Livy service if it is installed:

   ```
   maprcli node services -name livy -action stop -nodes <ip_address>
   ```

2. If necessary, back up configuration files:

   If you made configuration changes that you want to carry over to the next version, you need to back up the configuration files. Typically, the following configuration files contain changes:

   - `/opt/mapr/livy/livy-<version>/conf/livy.conf`
   - `/opt/mapr/livy/livy-<version>/conf/livy-env.sh`

   To back up configuration files, copy the files to a location outside the MapR installation directory. After upgrading, you can reapply changes to the updated Livy installation using the backup.

Livy is included in the MapR EEP repositories beginning with EEP 4.0.0. Before EEP 4.0.0, Livy was included as a package called `mapr-hue-livy`, and released only as a part of Hue. The configuration files for `mapr-hue-livy` have a different location:

- `/opt/mapr/hue-livy/hue-livy-<version>/conf/livy.conf`
- `/opt/mapr/hue-livy/hue-livy-<version>/conf/livy-env.sh`

Note:

- Starting from EEP-6.0, for Livy upgrades, from Livy 0.3 and above, user configuration files are saved during upgrade.
- For Livy upgrades from `mapr-hue-livy 3.12`, user configuration files are NOT saved during the upgrade.
- For manual Livy upgrades from `mapr-hue-livy 3.12` on Ubuntu, you need to remove the old `mapr-hue livy` package manually.

Pre-Upgrade Steps for MapR Monitoring

Complete the following steps before you upgrade MapR Monitoring Components with or without the MapR Installer.

During an upgrade using the MapR Installer, a script backs up many of the configuration files. However, whether or not you are upgrading manually or by using the MapR Installer, it is a best practice to back up the files manually. Manual backups can help in case an error occurs or the specific file you customized is not automatically backed up by the script.

Before performing the pre-upgrade steps, note these important considerations:

- The MapR Monitoring upgrade is an offline upgrade and *not* a rolling upgrade.
- This upgrade procedure is customized for the MapR implementation of the monitoring components. Because the MapR implementation has a narrow focus and there are numerous components, the upgrade steps are simplified. MapR upgrade documentation does *not* include all of the upgrade steps that are included in the vendor documentation for each component. Before starting the upgrade process, consider familiarizing yourself with the vendor-upgrade steps to determine if your environment requires extra measures to protect data and configurations.
  - Elasticsearch upgrade
  - Kibana upgrade
  - Search Guard upgrade

last-updated: Apr 11, 2022

- Grafana upgrade

- This upgrade sequence does not implement security in the MapR Monitoring components. If the cluster you are upgrading is secure and you are upgrading to a new version of Elasticsearch, the security keys will be deleted when you upgrade the monitoring packages. You must regenerate the keys and copy them to the appropriate nodes after upgrading. The Post-Upgrade Steps for MapR Monitoring on page 379 provide links to the installation procedures containing this information.

1. Before backing up configuration files, ensure that your Elasticsearch and Kibana indexes are not affected by the upgrade:

   Note: This step assumes that log monitoring is configured. You can skip this step if your cluster is not configured for log monitoring.

   a) If you are using Elasticsearch version 2.x, upgrade your Elasticsearch index to version 6. For upgrade information, see: https://www.elastic.co/guide/en/elasticsearch/reference/current/reindex-upgrade.html

   You need to upgrade your Elasticsearch index if your cluster is running a EEP in the range 1.1 through 3.0.x. See the following table. EEPs 1.1 through 3.0.x use Elasticsearch version 2.3.3. If your cluster is running a EEP in the range 4.0.0 through 5.0.x, you are using Elasticsearch 5.4.1, and you do NOT need to upgrade the index. For more information about Elasticsearch / Search Guard version information, see this website.

MapR Core	EEP	Elasticsearch Version	SearchGuard Version	Kibana Plugin Version
6.1.0	6.1.0	6.5.3.0	24.0	17
6.1.0	6.0.x	6.2.3	23.0	14
6.0.x	4.0.0 through 5.0.2	5.4.1	N/A	N/A
5.2.x	3.0.5 and earlier	2.3.3	N/A	N/A

   For more information about the MapR Monitoring component versions included in each EEP, see Component Versions for Released EEPs on page 5586.

   b) Create a snapshot of the Kibana index to capture index information before the upgrade. This information will be restored after the upgrade. For snapshot information, see https://www.elastic.co/guide/en/elasticsearch/reference/5.6/modules-snapshots.html.

2. Before you upgrade metric monitoring components, create a backup of the configuration files to a location outside your MapR installation directory. The following configuration file-lists include files that are commonly used for configuration and may not include every file that you may have customized.
   - Collectd configuration files:
     - /opt/mapr/conf/conf.d/warden.collectd.conf
     - /opt/mapr/collectd/collectd-<version>/etc/collectd.conf
     - /etc/logrotate.d/collectd
   - Grafana configuration files:
     - /opt/mapr/conf/conf.d/warden.grafana.conf
     - /opt/mapr/grafana/grafana-<version>/etc/grafana/grafana.ini
     - /opt/mapr/grafana/grafana- <version>/etc/grafana/ldap.toml

last-updated: Apr 11, 2022

- OpenTSDB configuration files:
  - /opt/mapr/conf/conf.d/warden.opentsdb.conf
  - /opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/opentsdb.conf
  - /opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/logback.xml
  - opt/mapr/opentsdb/opentsdb-<version>/bin/tsdb_cluster_mgmt.sh (This file is not automatically backed up.)

3. Before you upgrade log monitoring components, create a backup of the following files to a location outside your MapR installation directory. The following configuration file lists include files that are commonly used for configuration and may not include every file that you may have customized.
   - Kibana configuration files:
     - /opt/mapr/conf/conf.d/warden.kibana.conf
     - /opt/mapr/kibana/kibana-<version>/etc/conf/kibana.js
   - fluentd configuration files:
     - /opt/mapr/conf/conf.d/warden.fluentd.conf
     - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf
     - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/es_config.conf
     - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/maprfs_config.conf
     - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/grok-patterns
     - /etc/logrotate/fluentd
   - Elasticsearch configuration files:
     - /opt/mapr/conf/conf.d/warden.elasticsearch.conf
     - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/elasticsearch.yml
     - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/logging.yml
     - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator.yml
     - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator_actions/delete_indices.yml (This file is not automatically backed up.)
     - /opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/ (This directory is the default location for Elasticsearch index data. You must back up this directory unless you specified a non-default location using the `-ESDB` parameter with `configure.sh` during installation.)

4. Stop all MapR monitoring services on the cluster.
   a) To stop collectd, run the following command:

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action stop
```

b) To stop Grafana, run the following command:

```
maprcli node services -name grafana -nodes <space separated list of
hostname/IPaddresses> -action stop
```

c) To stop OpenTSDB, run the following command:

```
maprcli node services -name opentsdb -nodes <space separated list of
hostname/IPaddresses> -action stop
```

d) To stop Kibana, run the following command:

```
maprcli node services -name kibana -nodes <space separated list of
hostname/IPaddresses> -action stop
```

e) To stop fluentd, run the following command:

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action stop
```

f) To stop Elasticsearch, run the following command:

```
maprcli node services -name elasticsearch -nodes <space separated
list of hostname/IPaddresses> -action stop
```

Pre-Upgrade Steps for MapR Object Store with S3-Compatible API
Complete the following steps before you upgrade the MapR Object Store with S3-Compatible API with or without the MapR Installer.

Stop the service:

```
maprcli node services -nodes <node name> -name objectstore -action stop
```

Pre-Upgrade Steps for MapR Event Store For Apache Kafka Tools
Complete the following steps before you manually upgrade MapR Event Store For Apache Kafka Tools.

Kafka REST

Run the following command to stop the Kafka REST service on each node:

```
maprcli node services -name kafka-rest -action stop -nodes <list of Kafka
REST service nodes>
```

To see how configuration files are saved during an upgrade, see Saving Kafka REST Configurations on page 3872.

Kafka Connect

Run the following command to stop the Kafka Connect service on each node:

```
maprcli node services -name kafka-connect -action stop -nodes <list of
Kafka Connect service nodes>
```

To see how configuration files are saved during an upgrade, see Saving Kafka Connect Configurations on page 3941.

Pre-Upgrade Steps for Oozie
Complete the following steps before you upgrade Oozie with or without the MapR Installer.

1. Stop any jobs or coordinators that are in a RUNNING or SUSPENDED state.
2. **For upgrades without the MapR Installer:** Stop the Oozie service.

   ```
   # maprcli node services -name oozie -action stop -nodes <node names>
   ```

3. (OPTIONAL) Back up Oozie configuration files and save them to a location outside the MapR installation. Configuration properties are located in /opt/mapr/oozie/oozie-<version>/conf/. After upgrading, you can reapply changes to the updated Oozie installation using the backup.
4. **For upgrades without the MapR Installer:** Remove the old share libraries and examples from the following directories:

   ```
   maprfs:///oozie/share
   maprfs:///user/${user.name}/examples
   ```

5. **For upgrades from EEP 3.0.x to EEP 4.0 (or later):** If you are upgrading Oozie 4.3.0 on a secure cluster and you have not already configured SSL on your Oozie server and client, you must perform the following steps:
   a) Configuring Oozie on a Secure Cluster on page 3990
   b) Configuring Oozie Clients to Use SSL (Oozie 4.3.0) on page 3991

Preserving Oozie Configuration

Starting from 1808 release, EEP 4.1.2, EEP 5.0.1, EEP 6.0.0 and newer versions, in case of a version update, configuration from a previously installed version of Oozie is stored in a folder with an old version timestamp.

Pre-Upgrade Steps for Pig
Complete the following steps before you upgrade Pig with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You need to back up configuration properties files if you made configuration changes that you want to carry over to the next version.

1. Locate the files in `/opt/mapr/pig/pig-<version>/conf/` directory.
2. Copy the files to a location outside the MapR installation.
   After upgrading, you can reapply changes to the updated Pig installation using the backup.

Pre-Upgrade Steps for Sentry
Complete the following steps before you upgrade Sentry with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

You must stop the Sentry service before you upgrade. If you modified the configuration files in your current installation of Sentry, you can back up the configuration files to preserve the changes that you want to carry over to the next version.

To stop the Sentry service, issue one of the following commands:

- If the warden.sentry.conf exists in the /opt/mapr/conf/conf.d/ directory:

```
maprcli node services -name sentry -action stop -nodes <list of Sentry
service nodes>
```

- If the warden.sentry.conf does not exist in the /opt/mapr/conf/conf.d/ directory:

```
/opt/mapr/sentry/sentry-<SENTRY_VERSION>/bin/sentry-daemon.sh stop
```

To back up the configuration files, copy the files in `/opt/mapr/sentry/sentry-<version>/conf/` to a location outside of the MapR installation directory. After upgrading, you can reapply changes to the updated Sentry installation using the backup.

Preserving Sentry Configuration
Starting from EEP 6.0.0, preserving of user configuration logic is built into Sentry.

- For a minor version update (for example, `Sentry-1.7-1803` to `Sentry-1.7-1808`), user configuration from a previous version is copied to a folder with an old version timestamp and is also copied to a new version `conf` folder.
- For a major version update (for example, `Sentry-1.6-1707` to `Sentry-1.7-1808`), user configuration from a previous version is **only** copied to a folder with an old version timestamp.

Upgrading from EEP 6.3.1 and EEP 7.0.0
If you are upgrading from Sentry in EEP 6.3.1 or EEP 7.0.0 to Sentry in the latest EEP version, you must manually back up the `/conf` and `/logs` directories located in SENTRY_HOME. After the upgrade completes, add those directories back into the SENTRY_HOME directory.

You can locate the `/conf` and `/logs` directories in the Sentry installation directory, as shown:

```
ll /opt/mapr/sentry/sentry-1.7.0
total 76
drwxr-xr-x 2 mapr mapr  4096 Jan  5 13:34 bin
-rw-r--r-- 1 mapr mapr 15211 Jan  5 10:26 CHANGELOG.txt
drwxr-xr-x 2 mapr mapr  4096 Jan  5 13:34 conf
drwxr-xr-x 2 mapr mapr  4096 Jan  5 13:34 conf.d
drwxr-xr-x 2 mapr mapr  4096 Jan  5 13:34 conf.new
drwxr-xr-x 4 mapr mapr 12288 Jan  5 13:34 lib
-rw-r--r-- 1 mapr mapr 16000 Jan  5 10:26 LICENSE.txt
drwxr-xr-x 2 mapr mapr  4096 Jan  5 13:34 logs
-rw-r--r-- 1 mapr mapr   388 Jan  5 10:26 NOTICE.txt
-rw-r--r-- 1 mapr mapr  1580 Jan  5 10:26 README.md
drwxr-xr-x 3 mapr mapr  4096 Jan  5 13:34 scripts
```

For additional information, see Sentry on page 3817.

Pre-Upgrade Steps for Spark
Complete the following steps before you upgrade Spark with or without the MapR Installer.
Pre-Upgrade Steps for Spark Standalone

1. Copy configuration files from `/opt/mapr/spark/spark-<version>/conf` to a location outside of the MapR installation directory.

   For example, if Spark SQL is configured to work with Hive, copy the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file to a backup directory.

2. Shut down the spark-master, spark-historyserver services (if the spark-historyserver is running).

```
maprcli node services -nodes <node-ip> -name spark-master -action stop
maprcli node services -nodes <node-ip> -name spark-historyserver -action
stop
```

3. As the `mapr` user, stop the secondary instances:

   For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
```

   For Sparx 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-workers.sh
```

Pre-Upgrade Steps for Spark on YARN

1. Copy configuration files from `/opt/mapr/spark/spark-<version>/conf` to a location outside of the MapR installation directory.

   For example, if Spark SQL is configured to work with Hive, copy the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file to a backup directory.

2. Shut down the spark-historyserver services (if the spark-historyserver is running):

```
maprcli node services -nodes <node-ip> -name spark-historyserver -action
stop
```

Preserving Spark Configuration

Starting from EEP 6.0.0, in case of a version update, configuration from a previously installed version of Spark is stored in a folder with an old version timestamp.

Pre-Upgrade Steps for Sqoop1

Review the following information before you upgrade Sqoop1 with or without the MapR Installer.

Preserving the Sqoop1 Configuration

Starting from EEP 6.0.0, in case of a version update, the configuration from a previously installed version of Sqoop is stored in a folder with an old version timestamp.

After an upgrade from Sqoop 1.4.6 to 1.4.7, configuration files are saved and overwritten by new configuration files. After an update from Sqoop 1.4.7 to a newer package of 1.4.7, configuration files are saved (but not overwritten). The following example shows a listing of the configuration files that are saved after an update from Sqoop 1.4.7 (EEP 7.0.0) to newer package of Sqoop 1.4.7 (EEP 7.0.1):

```
ls /opt/mapr/sqoop/
sqoop-1.4.7  sqoop-1.4.7.202009100127
ls /opt/mapr/sqoop/sqoop-1.4.7.202009100127/conf/
oraoop-site-template.xml  sqoop-env-template.cmd  sqoop-env-template.sh
sqoop-site-template.xml  sqoop-site.xml
```

Pre-Upgrade Steps for Sqoop2

Complete the following steps before you upgrade Sqoop2 with or without the MapR Installer.

1. Back up configuration files. Copy configuration files from `/opt/mapr/sqoop/sqoop-<version>/conf/sqoop.properties` to a location outside the MapR installation.
   For example, you can copy the file to a `/tmp` directory:

```
cp /opt/mapr/sqoop/sqoop-<version>/conf/sqoop.properties /tmp/
```

2. Delete the Sqoop2 repository (`/opt/mapr/sqoop/repository`).

   Note: Because of SQOOP-1593, you also should not create a backup of the Sqoop2 repository before you upgrade.

3. **For upgrades to be performed without the MapR Installer:** Stop each Sqoop2 server node:

   ```
   maprcli node services -name sqoop2 -action stop -nodes <space delimited
   list of nodes>
   ```

Pre-Upgrade Steps for Tez

Complete the following steps before you upgrade Tez with or without the MapR Installer.

If you made any configuration changes that you want to carry over to the next version, you need to back up the configuration properties files:

1. Locate the files in the `/opt/mapr/tez/tez-<version>/conf/` and `/opt/mapr/tez/tez-<version>/tomcat/apache-tomcat-<version>/webapps/tez-ui/config/` directories.
2. Copy the files to a location outside the MapR installation directory.
3. Delete the old `/apps/tez` directory on the MapR File System layer.

   ```
   hadoop fs -rm -r /apps/tez
   ```

   After upgrading, you can reapply changes to the updated Tez installation using the backup.

Preserving the Tez Configuration

Starting from EEP 6.0.0, Tez assists you in preserving the user configuration.

- For a minor version update (for example, `Tez-0.8-1803` to `Tez-0.8-1808`), the user configuration from a previous version is copied to a folder with an old version timestamp and also copied to a new version `conf` folder.
- For a major version update (for example, `Tez-0.8-1803` to `Tez-0.9-1808`), the user configuration from a previous version is **only** copied to a folder with an old version timestamp.

CentOS and SLES OS	• For upgrades from EEP 3.x to EEP 6.0.0, no additional steps are needed to preserve the user configuration. • For upgrades from EEP 4.0.0/4.1.0 to EEP 6.0.0, preserving the user configuration works only for configuration files (such as `tez-site.xml` and `configs.js`), but the Tomcat service is still present from the previous Tez version. As a precondition for upgrade from EEP 4.0.0/4.1.0, manually stop the Tomcat service and remove the `tez-0.8/` directory. • For upgrades from EEP 4.1.1/5.0.0 to EEP 6.0.0, no additional steps are needed to preserve the user configuration.
Ubuntu	• For upgrades from EEP 3.x to EEP 6.0.0, no additional steps are needed to preserve the user configuration.

last-updated: Apr 11, 2022

- For upgrades from EEP 4.0.0/4.1.0 to EEP 6.0.0, preserving the user configuration works only for configuration files (such as `tez-site.xml` and `configs.js`), but the Tomcat service is still present from the previous Tez version. As a precondition for upgrade from EEP 4.0.0/4.1.0, manually stop the Tomcat service and remove the `tez-0.8/` directory.
- For upgrades from EEP 4.1.1/5.0.0 to EEP 6.0.0, you need to preserve the user configuration manually.

Upgrading the MapR Ecosystem Pack With the MapR Installer
If the cluster that you want to upgrade was installed using the MapR Installer, you can use the MapR Installer to upgrade the MapR Ecosystem Pack (EEP).

1. Verify that all ecosystem components are prepared for an upgrade.

   Warning: Service failures, job failures, or the loss of customized configuration files can occur if you do not perform the steps to prepare ecosystem components for an upgrade.

2. Update the MapR Installer. For more information, see Updating the MapR Installer on page 5409.
   This step ensures that the MapR Installer has access to the latest packages.

3. Halt jobs and applications. Stop accepting new jobs and applications, and stop YARN applications.

   ```
   # yarn application -list
   # yarn application -kill <ApplicationId>
   ```

   You might also need specific commands to terminate custom applications.

4. Launch the MapR Installer URL (`https://<hostname/IPaddress>:9443`).

5. Select the **Incremental Install** option.

6. Select the **EEP Version** to which you want to upgrade, and complete the upgrade through the MapR Installer.

7. Once the upgrade through the MapR Installer is complete, perform the post-upgrade steps. See Finishing the MapR Ecosystem Pack Upgrade.

Upgrading the MapR Ecosystem Pack Without the MapR Installer
After you upgrade MapR core without using the MapR Installer, you need to upgrade ecosystem components with manual steps. First, verify that your repository is configured to use an MapR Ecosystem Pack (EEP) that is supported by your cluster version. Then, upgrade each component manually.

Note: If you installed the cluster with the MapR Installer, do not use the following steps to upgrade your ecosystem components. Instead, see Upgrading MapR Core With the MapR Installer on page 308.

Prerequisite: Set up the EEP Repository

Complete the following steps on each node in the cluster when you upgrade without the MapR Installer:

1. Verify that each node can access the ecosystem packages associated with the EEP version that you want to use. For information on how to setup the ecosystem repositories or to manually download each package, see Setting Up Repositories on page 309.

2. Update the repository cache to get the latest list of available packages:
   - On RedHat/CentOS:
     ```
     # yum clean all
     ```
   - On SLES:
     ```
      # zypper refresh
     ```
   - On Ubuntu:
     ```
     # apt-get update
     ```

Manually Upgrade Ecosystem Components

Review the EEP Release Notes on page 5658 to determine the list of ecosystem components available in the EEP that you have selected. Then, complete the manual upgrade steps for each component that you want to upgrade.

Upgrading AsyncHBase Libraries

This section describes how to upgrade the AsyncHBase Libraries without the MapR Installer.

To upgrade to a more recent version of the AsyncHBase library, install the new version. See Installing AsyncHBase Libraries.

Note: AsyncHBase 1.7 is binary compatible with AsyncHBase 1.6.

Upgrading Drill

This section describes how to upgrade Drill without the MapR Installer.

Before you upgrade Drill, complete the pre-upgrade steps.

Complete the following steps on the Drill server and client nodes as root or using sudo to upgrade Drill without the MapR Installer:

1. To eliminate cached packages and files, issue the following command:
   ```
   yum clean all
   ```
2. To upgrade Drill, issue the command appropriate for your system on each Drill node:
   - RedHat/CentOS
     ```
     yum update mapr-drill
     ```
   - Ubuntu
     ```
     sudo apt-get install mapr-drill
     ```
   - SLES
     ```
     zypper update mapr-drill
     ```

     Note: SLES is supported as of Drill 1.9.0-1703 and Drill 1.10.0-1703.

3. Complete the post-upgrade steps for Drill.

Upgrading Flume
This section describes how to upgrade Flume without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Flume installs into separate directories named after the version, such as `/opt/mapr/flume/flume-<version>/`.

To upgrade with the package manager, run one of the following commands:

On RedHat and CentOS:	`yum update mapr-flume`
On Ubuntu:	`apt-get install mapr-flume`
On SLES:	`zypper update mapr-flume`

To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory (`/opt/mapr/flume/flume-<version>/conf/`). See Post-Upgrade Steps for Flume on page 372.

Upgrading HBase
This section describes how to upgrade HBase without the MapR Installer.

Upgrading an established deployment of HBase requires planning and consideration before beginning the upgrade process. Below are items to consider as you plan to upgrade:

- **Check for version interoperability and perform any required MapR cluster upgrade first.** To see which versions of HBase are supported in each MapR release, see the HBase Release Notes on page 5855 and Interoperability Matrices on page 5519. If you also plan to upgrade the core release as part of upgrading your HBase cluster, upgrade core first (see Upgrading MapR Core on page 294). After successfully upgrading core, upgrade the HBase component.
- **Perform health checks.** Perform health checks and address any concerns before upgrading HBase. As a start, run `hbck` to check for any inconsistencies in HBase data. For usage details, refer to the Apache HBase Reference Guide.

  ```
  hbase hbck
  ```

- **Review the cluster service layout.** While planning to upgrade, it is a good time to review your cluster service layout and determine if the right services are running on the right set of nodes. For example, as your cluster grows, you will tend to isolate cluster-management services from compute services on separate nodes. Review Planning the Cluster on page 107 and Installing HBase on page 183 for details on planning the service layout.
- **Consider migration of data, maintenance of HBase services, and any version-specific considerations that apply to you.** For details, refer to the Apache HBase Reference Guide.
- **Perform a test upgrade.** Because the upgrade process takes HBase services offline and requires careful planning, perform a test upgrade on a development cluster to make sure you understand the process. After you have experienced success on a dev cluster, proceed with your production cluster.

To upgrade, complete the upgrade steps for the version of HBase to which you want to upgrade.

Upgrade from HBase 1.1.8

Complete the following steps to upgrade HBase 1.1.8 to 1.1.13 or later:

1. Ensure that you have completed the pre-upgrade steps.
2. Use the following commands to upgrade the packages:

   After configuring repositories so that the version you want to install is available, you can use a package manager to install from the repository. The upgrade process removes all but the following directories in the current HBase directory: `conf` and `logs`.

To upgrade with a package manager:

On RedHat and CentOS

To upgrade an HBase region server node:

```
yum update
mapr-hbase
mapr-hbase-regio
nserver
```

To upgrade an HBase master node:

```
yum update
mapr-hbase
mapr-hbase-maste
r
```

To upgrade an HBase client node:

```
yum update
mapr-hbase
```

On Ubuntu

To upgrade an HBase region server node:

```
apt-get install
mapr-hbase
mapr-hbase-regio
nserver
```

To upgrade an HBase master node:

```
apt-get install
mapr-hbase
mapr-hbase-maste
r
```

To upgrade an HBase client node:

```
apt-get install
mapr-hbase
```

On SLES

To upgrade an HBase region server node:

```
zypper update
mapr-hbase
```

```
mapr-hbase-regio
nserver
```

To upgrade an HBase master node:

```
zypper update
mapr-hbase
mapr-hbase-maste
r
```

To upgrade an HBase client node:

```
zypper update
mapr-hbase
```

If you have additional HBase services or libraries installed, you should also upgrade those packages to match the HBase version you are upgrading to.

- Upgrade HBase Thrift Gateway.
- Upgrade the AsynchHbase Libraries.
- To upgrade the libhbase libraries, see Using the libhbase Library on page 3398.

3. Migrate any custom configuration settings to the configuration files within the `conf` directory:

```
/opt/mapr/hbase/hbase-<version>/conf/
```

4. Run `configure.sh -R` on all of the upgraded HBase nodes:

```
$ /opt/mapr/server/configure.sh -R
```

5. Complete the post-upgrade steps.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 337
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Upgrading HBase Client and Tools

This section describes how to upgrade HBase Client and other tools without the MapR Installer.

Note that release 6.0.x provides Apache HBase-compatible APIs and client interfaces but does not support HBase as an ecosystem component. MapR 6.1.0 supports HBase with EEP 6.3.0 and later.

Service	Description
HBase Client	Upgrading the HBase Client upgrades both the HBase Shell and the HBase APIs supported for use with MapR Database binary tables and MapR Database JSON tables.
HBase Thrift Gateway	HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to MapR Database tables. See Upgrading HBase Thrift Gateway on page 355 for upgrade information.

Service	Description
HBase REST Gateway	HBase REST Gateway includes an API and a service that accepts REST requests to connect to MapR Database tables. See Upgrading HBase REST Gateway on page 355 for upgrade information.
AsyncHBase Libraries	AsyncHBase library provides asynchronous Java APIs to access MapR Database tables. See Upgrading AsyncHBase Libraries on page 351 for upgrade information.

Upgrading HBase Thrift Gateway

Complete the following steps to upgrade the HBase Thrift Gateway:

1. Run the following command to upgrade the HBase Thrift package:

On CentOS / Red Hat	`yum update mapr-hbasethrift mapr-hbase`
Ubuntu	`apt-get update mapr-hbasethrift mapr-hbase`
SLES	`zypper update mapr-hbasethrift mapr-hbase`

2. Run the `configure.sh` script with the `-R` option on the node where you upgraded the HBase Thrift package:

```
/opt/mapr/server/configure.sh -R
```

Upgrading HBase REST Gateway

Complete the following steps to upgrade the HBase REST Gateway:

1. Run the following command to upgrade the HBase REST package:

On CentOS / Red Hat	`yum update mapr-hbase-rest mapr-hbase`
Ubuntu	`apt-get update mapr-hbase-rest mapr-hbase`
SLES	`zypper update mapr-hbase-rest mapr-hbase`

2. Run configure.sh on the node where you upgraded the HBase Thrift package:

```
/opt/mapr/server/configure.sh -R
```

Upgrading AsyncHBase Libraries

This section describes how to upgrade the AsyncHBase Libraries without the MapR Installer.

last-updated: Apr 11, 2022

To upgrade to a more recent version of the AsyncHBase library, install the new version. See Installing AsyncHBase Libraries.

Note: AsyncHBase 1.7 is binary compatible with AsyncHBase 1.6.

Upgrading Hive
This section describes how to upgrade Hive without the MapR Installer.

Use one of the following methods to upgrade the Hive components on all nodes where Hive is installed.

To:

- Upgrade with a package manager, install new packages from the repository:
  - On RedHat and CentOS:

```
yum update mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On Ubuntu:

```
apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On SLES:

```
zypper update mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

- Manually remove a prior version and manually install the latest version in the repository, run the package manager twice, first to remove the old version, and again to install the new version.

  Note: In this case, configurations are not preserved automatically.

  - On RedHat and CentOS:

```
yum remove mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
yum install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On Ubuntu:

```
apt-get remove mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On SLES:

```
zypper remove mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
zypper install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory. See Post-Upgrade Steps for Hive on page 373.

last-updated: Apr 11, 2022

Upgrading from Hive 2.1 to Hive 2.3 with Oracle DB used in Metastore
This section describes how the different upgrade scenarios from Hive 2.1 to Hive 2.3.

Column type verification

You need to first check your current Oracle DB schema and understand your upgrade scenario.

All the examples below use the Oracle SQL*Plus tool to execute SQL statements. Use the `DESCRIBE <Table name>;` to command to check the Oracle table information for following Hive metastore tables:

- `COLUMNS_V2`
- `SD_PARAMS`
- `TABLE_PARAMS`
- `SERDE_PARAMS`

Table

Table	Column	Possible value of column type	
		Scenario I	Scenario II
(1)	(2)	(3)	(4)
COLUMNS_V2	TYPE_NAME	CLOB	VARCHAR2(4000)
SD_PARAMS	PARAM_VALUE	CLOB	VARCHAR2(4000)
TABLE_PARAMS	PARAM_VALUE	CLOB	VARCHAR2(4000)
SERDE_PARAMS	PARAM_VALUE	CLOB	VARCHAR2(4000)

If column `TYPE_NAME` in the `COLUMNS_V2` table has `VARCHAR2(4000)` as the data type, then you have to perform upgrade scenario I. If column `TYPE_NAME` in the `COLUMNS_V2` table has a data type `CLOB`, then you have to perform upgrade scenario II.

All columns types must belong to the same upgrade scenarios, in other words all your columns types must be `VARCHAR2` or `CLOB`.

Use upgrade scenario I

Upgrading to Hive 2.3 (EEP 6.1.0 and above)

To upgrade from Hive-2.1 to Hive 2.3, first download Hive 2.3 from the EEP 6.1.0 package repository and perform the upgrade according to the common upgrade instructions.

Upgrading to Hive 2.3 (before EEP 6.1.0)

To upgrade Hive 2.1 to Hive 2.3 (before EEP 6.1.0), edit the `upgrade-2.1.0-to-2.2.0.oracle.sql` file:

```
nano $HIVE_HOME/scripts/metastore/upgrade/oracle/
upgrade-2.1.0-to-2.2.0.oracle.sql
```

Remove the `@039-HIVE-12274.oracle.sql;` line from the upgrade script and then perform the upgrade according to the common upgrade instructions.

Use upgrade scenario II

Upgrade to Hive 2.3 (EEP 6.1.0 and above)

last-updated: Apr 11, 2022

1. Replace the content of `@039-HIVE-12274.oracle.sql;` file to:

```
-- change PARAM_VALUE to CLOBs
ALTER TABLE COLUMNS_V2 ADD (TEMP CLOB);
UPDATE COLUMNS_V2 SET TEMP=TYPE_NAME;
ALTER TABLE COLUMNS_V2 DROP COLUMN TYPE_NAME;
ALTER TABLE COLUMNS_V2 RENAME COLUMN TEMP TO TYPE_NAME;

ALTER TABLE TABLE_PARAMS ADD (TEMP CLOB);
UPDATE TABLE_PARAMS SET TEMP=PARAM_VALUE, PARAM_VALUE=NULL;
ALTER TABLE TABLE_PARAMS DROP COLUMN PARAM_VALUE;
ALTER TABLE TABLE_PARAMS RENAME COLUMN TEMP TO PARAM_VALUE;

ALTER TABLE SERDE_PARAMS ADD (TEMP CLOB);
UPDATE SERDE_PARAMS SET TEMP=PARAM_VALUE, PARAM_VALUE=NULL;
ALTER TABLE SERDE_PARAMS DROP COLUMN PARAM_VALUE;
ALTER TABLE SERDE_PARAMS RENAME COLUMN TEMP TO PARAM_VALUE;

ALTER TABLE SD_PARAMS ADD (TEMP CLOB);
UPDATE SD_PARAMS SET TEMP=PARAM_VALUE, PARAM_VALUE=NULL;
ALTER TABLE SD_PARAMS DROP COLUMN PARAM_VALUE;
ALTER TABLE SD_PARAMS RENAME COLUMN TEMP TO PARAM_VALUE;

-- Expand the hive table name length to 256
ALTER TABLE TBLS MODIFY (TBL_NAME VARCHAR2(256));
ALTER TABLE NOTIFICATION_LOG MODIFY (TBL_NAME VARCHAR2(256));
ALTER TABLE PARTITION_EVENTS MODIFY (TBL_NAME VARCHAR2(256));
ALTER TABLE TAB_COL_STATS MODIFY (TABLE_NAME VARCHAR2(256));
ALTER TABLE PART_COL_STATS MODIFY (TABLE_NAME VARCHAR2(256));
ALTER TABLE COMPLETED_TXN_COMPONENTS MODIFY (CTC_TABLE VARCHAR2(256));

-- Expand the hive column name length to 767
ALTER TABLE COLUMNS_V2 MODIFY (COLUMN_NAME VARCHAR(767));
ALTER TABLE PART_COL_PRIVS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE TBL_COL_PRIVS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE SORT_COLS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE TAB_COL_STATS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE PART_COL_STATS MODIFY (COLUMN_NAME VARCHAR2(767));
```

2. Add the following line to the `$HIVE_HOME/scripts/metastore/upgrade/oracle/upgrade-2.1.0-to-2.2.0.oracle.sql` file after the `@038-HIVE-10562.oracle.sql;` line:

```
@039-HIVE-12274.oracle.sql;
```

3. Perform upgrade according to the common upgrade instructions.

Upgrade to Hive 2.3 (before EEP 6.1.0)

1. Replace the content of `@039-HIVE-12274.oracle.sql;` file to the same as in the previous scenario.

2. Make sure that the following line is present in the `$HIVE_HOME/scripts/metastore/upgrade/oracle/upgrade-2.1.0-to-2.2.0.oracle.sql` file:

```
@039-HIVE-12274.oracle.sql;
```

3. Perform upgrade according to the common upgrade instructions.

last-updated: Apr 11, 2022

Upgrading HttpFS
This section describes how to upgrade HttpFS without the MapR Installer.

For EEP 6.3.4 and later, run one of the following commands to upgrade the HttpFS using package manager and install the new packages from the repository:

- On RedHat/CentOS:

```
yum update mapr-httpfs
```

- On Ubuntu:

```
apt-get install mapr-httpfs
```

- On SLES:

```
zypper update mapr-httpfs
```

For EEP 6.3.3 and earlier, run the following set of commands as `root` or with `sudo` to upgrade the HttpFS packages:

- On RedHat/CentOS

```
yum remove mapr-httpfs
rm -rf /opt/mapr/httpfs/
yum install mapr-httpfs
```

- On Ubuntu

```
apt-get autoremove mapr-httpfs
rm -rf /opt/mapr/httpfs/
apt-get install mapr-httpfs
```

- On SLES

```
zypper remove mapr-httpfs
rm -rf /opt/mapr/httpfs/
zypper install mapr-httpfs
```

 **Note:** To verify EEP and core version support, see EEP Support and Lifecycle Status on page 5531.

Upgrading Hue
This section describes how to upgrade Hue without the MapR Installer.

Execute the following commands as a user with admin permissions:

1. Run one of the following commands to upgrade Hue using a package manager:
   - On Ubuntu:

```
apt-get install mapr-hue
```

   - On RedHat/CentOS:

```
yum update mapr-hue
```

- On SLES:

```
zypper update mapr-hue
```

2. For EEP 4.0.0 and later, update Livy using the steps in Upgrading Livy on page 361. For EEP releases earlier than EEP 4.0.0, run one of the following commands to upgrade Hue-livy using a package manager:
   - On Ubuntu:

```
apt-get install mapr-hue-livy
```

   - On RedHat/CentOS:

```
yum update mapr-hue-livy
```

   - On SLES:

```
zypper update mapr-hue-livy
```

Upgrading Impala

This section describes how to upgrade Impala without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

1. Upgrade the `mapr-impala` package on all Impala nodes in the cluster:

```
$ sudo yum update mapr-impala
```

2. In `/opt/mapr/impala/impala-<version>/conf/env.sh`, complete the following steps:
   a. Verify that the Statestore address is set to the address where you plan to run the statestore service.

```
IMPALA_STATE_STORE_HOST=<IP address hosting statestore>
```

   b. Change the Catalog service address to the address where you plan to run the catalog service.

```
CATALOG_SERVICE_HOST=<IP address hosting catalog service>
```

   Refer to Additional Impala Configuration Options for a list of other options that you can modify in `env.sh`.

3. Verify that `hive-site.xml` has the following property configured on all nodes:

```
<property>
    <name>hive.metastore.uris</name>
    <value>thrift://<metastore_server_host>:9083</value>
</property>
```

4. To upgrade the statestore service, issue the following command:

```
$ sudo yum update mapr-impala-statestore
```

5. To upgrade the catalog service, issue the following command:

```
$ sudo yum update mapr-impala-catalog
```

Note: It is recommended (not required) that you install the catalog service on the same node as the statestore service.

6. To upgrade the impala server, issue the following command:

```
$ sudo yum update mapr-impala-server
```

7. Run `configure.sh` to refresh the node configuration.

```
/opt/mapr/server/configure.sh -R
```

Upgrading the MapR Data Access Gateway

This section describes how to upgrade the MapR Data Access Gateway without the MapR Installer.

Complete the following steps to upgrade the MapR Data Access Gateway without the MapR Installer.

1. Install the new package using the command that is appropriate for your distribution:

RedHat/CentOS	`yum update mapr-data-access-gateway`
Ubuntu	`apt-get install mapr-data-access-gateway`
SLES	`zypper update mapr-data-access-gateway`

2. On the CLDB master node, use the `manageSSLKeys.sh` script to generate the p12 keystore file, which enables OpenSSL communication channel for the MapR gRPC service. For example:

```
/opt/mapr/server/manageSSLKeys.sh convert -k -N <cluster_name> /opt/mapr/
conf/ssl_keystore /opt/mapr/conf/ssl_keystore.pem
```

3. Copy the `/opt/mapr/conf/ssl_keystore.p12` and `/opt/mapr/conf/ssl_keystore.pem` files to all other nodes that contain the MapR Data Access Gateway.

Upgrading Livy

This section describes how to upgrade Livy without the MapR Installer.

Run the following command to upgrade Livy using a package manager:

- On RHEL/CentOS:

```
yum update mapr-livy
```

last-updated: Apr 11, 2022

- On Ubuntu:

```
apt-get install mapr-livy
```

- On SLES:

```
zypper update mapr-livy
```

Note: Livy is included in EEP repositories beginning with EEP 4.0.0. Before EEP 4.0.0, it was included as a package called mapr-hue-livy and released only as a part of Hue.

Upgrading MapR Monitoring
Complete the following steps to upgrade MapR Monitoring without the MapR Installer.

Note: Before performing the following steps, make sure that you have completed the Pre-Upgrade Steps for MapR Monitoring on page 342.

Execute the following commands as `root` or using `sudo`.

1. Upgrade the following metric monitoring packages wherever they are installed on the cluster: `mapr-collectd`, `mapr-grafana`, and `mapr-opentsdb`.

   For example, on a three node cluster, you could run the following commands to upgrade metrics monitoring packages:

   - For CentOS/RedHat:
     - Node A:

```
yum upgrade mapr-collectd mapr-grafana
```

     - Node B:

```
yum upgrade mapr-collectd mapr-opentsdb
```

     - Node C:

```
yum upgrade mapr-collectd
```

   - For Ubuntu:
     - Node A:

```
apt-get install mapr-collectd mapr-grafana
```

     - Node B:

```
apt-get install mapr-collectd mapr-opentsdb
```

     - Node C:

```
apt-get install mapr-collectd
```

   - For SLES:

- Node A:

```
zypper update mapr-collectd mapr-grafana
```

- Node B:

```
zypper update mapr-collectd mapr-opentsdb
```

- Node C:

```
zypper update mapr-collectd
```

2. Upgrade the following log monitoring packages wherever they are installed on the cluster: `mapr-fluentd`, `mapr-elasticsearch`, and `mapr-kibana`.

   For example, on a three node MapR cluster, you can run the following commands to upgrade log monitoring packages:

   - For CentOS/RedHat:
     - Node A:

```
yum upgrade mapr-fluentd mapr-elasticsearch
```

     - Node B:

```
yum upgrade mapr-fluentd mapr-elasticsearch
```

     - Node C:

```
yum upgrade mapr-fluentd mapr-elasticsearch mapr-kibana
```

   - For Ubuntu:
     - Node A:

```
apt-get install mapr-fluentd mapr-elasticsearch
```

     - Node B:

```
apt-get install mapr-fluentd mapr-elasticsearch
```

     - Node C:

```
apt-get install mapr-fluentd mapr-elasticsearch mapr-kibana
```

   - For SLES:
     - Node A:

```
zypper update mapr-fluentd mapr-elasticsearch
```

- Node B:

```
zypper update mapr-fluentd mapr-elasticsearch
```

- Node C:

```
zypper update mapr-fluentd mapr-elasticsearch mapr-kibana
```

Reinstalling Monitoring Components After an Upgrade
During an upgrade from EEP 6.x to EEP 7.0.0 or EEP 7.0.1, some monitoring components do not get updated because of an error in the fourth digit of the package version. This page provides a workaround for the issue.

The issue (known issue ES-77 or FLUD-55) is fixed in EEP 7.1.0 and later.

This issue can occur during manual upgrades or upgrades performed using the Installer. The affected components can include any or all of the following:

- Elasticsearch
- Fluentd
- Grafana
- Kibana

Follow these steps to identify, remove, and reinstall the packages that were not upgraded:

1. After upgrading, use one of the following commands to check the package versions of the installed monitoring components:

OS	Command
RHEL/CentOS	`yum list installed`
SLES	`zypper packages --installed-only`
Ubuntu	`apt list --installed`

2. Identify the packages that were not upgraded. The following table shows the desired versions for each package for EEPs 7.0.0 and 7.0.1. For more version information, see Component Versions for Released EEPs on page 5586.

Package	Desired Version	
	EEP 7.0.0	EEP 7.0.1
`mapr-elasticsearch`	6.8.8.0	6.8.8.0
`mapr-fluentd`	1.10.3.0	1.10.3.0
`mapr-grafana`	6.7.4.0	6.7.4.0
`mapr-kibana`	6.8.8.0	6.8.8.0

3. Before removing the packages that were not upgraded:

last-updated: Apr 11, 2022

a) Ensure that you have backed up any configuration files and indexes as described in Pre-Upgrade Steps for MapR Monitoring on page 342. For Elasticsearch in particular, you must back up the default location for Elasticsearch index data unless you specified a non-default location using the `-ESDB` parameter with `configure.sh` during installation.

b) Export or make backup copies of any custom dashboards you configured for Grafana or Kibana.

4. Manually uninstall the packages that were not upgraded by using one of the following commands. For example, to uninstall the Elasticsearch package:
   - RHEL/CentOS:
     - `yum remove mapr-elasticsearch`
   - SLES:
     - `zypper remove mapr-elasticsearch`
   - Ubuntu:
     - `apt remove mapr-elasticsearch --purge`
5. Install the desired packages for EEP 7.0.0 or EEP 7.0.1 using *one* of the following methods:
   - **Method 1 – Using the Installer**

     Using the Installer, perform an incremental installation. See Using the Incremental Install Function on page 5443.
   - **Method 2 – Manual Reinstall**

     For Grafana, reinstall the package and run `configure.sh` using the commands shown in Step 8: Install Metrics Monitoring on page 162.

     For Elasticsearch, Fluentd, and Kibana, reinstall the packages and run `configure.sh` using the commands shown in Step 9: Install Log Monitoring on page 165.

Upgrading the S3 Gateway
Upgrading from S3 gateway version 1.0.x to 2.0.0 is not supported.
Edge Node Upgrade

Complete the following steps to upgrade the S3 gateway on an Edge node:

1. Stop the MapR Object Store service:

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
objectstore.sh stop
```

2. Upgrade the S3 gateway:

```
# Ubuntu
sudo apt-get install mapr-objectstore-client

# RedHat/CentOS
sudo yum update mapr-objectstore-client

# SLES
sudo zypper update mapr-objectstore-client
```

3. Run `configure.sh`:

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
configure.sh
-c -u <userName> -g <groupName> --path /path/to/filesystem/
```

4. Restart the service:

```
sudo /opt/mapr/objectstore-client/objectstore-client-<version>/bin/
objectstore.sh start
```

Server Node Upgrade

Complete the following steps to upgrade the S3 gateway on a server node:

1. Stop the MapR Object Store service:

```
maprcli node services -nodes <nodename> -name objectstore -action stop
```

2. Upgrade the S3 gateway:

```
# Ubuntu
sudo apt install mapr-objectstore-client mapr-objectstore-gateway

# RedHat/CentOS
sudo yum install -f  mapr-objectstore-client mapr-objectstore-gateway

# SLES
sudo zypper update mapr-objectstore-client mapr-objectstore-gateway
```

3. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

4. Restart the service:

```
maprcli node services -nodes <node name> -name objectstore -action
          restart
```

Upgrading the MapR Event Store For Apache Kafka Python Client

This section describes how to upgrade the MapR Event Store For Apache Kafka Python Client without the MapR Installer.

To install the MapR Event Store For Apache Kafka Python Client using the Python Software Foundation, run the following command as `root` or using `sudo`:

```
pip
install -upgrade --global-option=build_ext --global-option="--library-dirs=/
opt/mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

OR:

```
pip
install -U --global-option=build_ext --global-option="--library-dirs=/opt/
```

```
mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

Alternatively, you can install the MapR Event Store For Apache Kafka Python Client via the MapR package repository:

```
https://package.mapr.hpe.com/releases/MEP/<MEP version>/mac/
mapr-streams-python-<version>.tar.gz
```

Upgrading MapR Event Store For Apache Kafka Tools
Complete the following steps to upgrade MapR Event Store For Apache Kafka Tools without the Installer.

If you are upgrading from Kafka 2.1.1 to 2.6.1, you may first want to review Changes in Kafka 2.6.1 on page 3863. To upgrade, run the following commands as `root` or using `sudo`:

1. Stop the service using `maprcli node services -name <name_service> - action stop - nodes <space delimited list of Kafka tools server nodes>`:
2. Run one of the following commands to upgrade the Kafka REST Proxy for MapR Streams:
   - On Ubuntu:

     ```
     apt-get install mapr-kafka-rest
     ```

   - On RedHat/CentOS:

     ```
     yum update mapr-kafka-rest
     ```

   - On SLES:

     ```
     zypper update mapr-kafka-rest
     ```

3. Run one of the following commands to upgrade the Kafka Connect for MapR Event Store For Apache Kafka - HDFS Connector:
   - On Ubuntu:

     ```
     apt-get install mapr-kafka-connect-hdfs
     ```

   - On RedHat/CentOS:

     ```
     yum update mapr-kafka-connect-hdfs
     ```

   - On SLES:

     ```
     zypper update mapr-kafka-connect-hdfs
     ```

4. Run one of the following commands to upgrade the Kafka Connect for MapR Event Store For Apache Kafka - JDBC Connector:
   - On Ubuntu:

     ```
     apt-get install mapr-kafka-connect-jdbc
     ```

- On RedHat/CentOS:

```
yum update mapr-kafka-connect-jdbc
```

- On SLES:

```
zypper update mapr-kafka-connect-jdbc
```

5. Run `configure.sh -R` on each node where you installed Kafka components to complete the configuration: `/opt/mapr/server/configure.sh -R`

Apply custom configurations to the new version by migrating any custom configuration settings into the new default files in the **conf** directory. See Post-Upgrade Steps for MapR Event Store For Apache Kafka Tools on page 379 for more information.

Upgrading Oozie

This section describes how to upgrade Oozie without the MapR Installer.

Run the following command to upgrade Oozie using a package manager:

- On RedHat/CentOS:

```
yum update mapr-oozie
```

- On Ubuntu:

```
apt-get install mapr-oozie
```

- On SLES:

```
zypper update mapr-oozie
```

Upgrading Pig

This section describes how to upgrade Pig without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Complete the following steps to upgrade Pig without the MapR Installer.

Run the following command to upgrade Pig using a package manager:

On RedHat and CentOS	`yum update mapr-pig`
On Ubuntu	`apt-get install mapr-pig`
On SLES	`zypper update mapr-pig`

To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory. See Post-Upgrade Steps for Pig on page 381.

Upgrading Sentry

This section describes how to upgrade Sentry without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Before you complete the following step to upgrade Sentry without the MapR Installer, verify that you have completed the pre-upgrade steps for Sentry.

To upgrade Sentry, issue the command appropriate for the system:

RedHat/CentOS	`yum update mapr-sentry`
Ubuntu	`apt-get install mapr-sentry`
SLES	`zypper update mapr-sentry`

Upgrading Spark Standalone

This section describes how to upgrade Spark Standalone without the MapR Installer.

1. Install the Spark packages.
   - On Ubuntu:
     ```
     apt-get install mapr-spark mapr-spark-master mapr-spark-historyserver
     ```
   - On RedHat/CentOS:
     ```
     yum update mapr-spark mapr-spark-master mapr-spark-historyserver
     ```
   - On SLES:
     ```
     zypper upgrade mapr-spark mapr-spark-master mapr-spark-historyserver
     ```
2. (Optional): Starting in the EEP 4.0 release, you can install the MapR Spark Thrift Server package.

On Ubuntu	`apt-get insall mapr-spark-thriftserver`
On RedHat / CentOS	`yum install mapr-spark-thriftserver`
On SLES	`zypper install mapr-spark-thriftserver`

Upgrading Spark on YARN

This section describes how to upgrade Spark on YARN without the MapR Installer.

The following instructions explain how to upgrade an existing installation of Spark. Spark will be installed in a new subdirectory under `/opt/mapr/spark`.

1. Install the Spark packages.

   Note: You only need to upgrade the mapr-spark-historyserver if your previous installation included this package.

last-updated: Apr 11, 2022

On Ubuntu	`apt-get install mapr-spark mapr-spark-historyserver`
On RedHat / CentOS	`yum update mapr-spark mapr-spark-historyserver`
On SLES	`zypper upgrade mapr-spark mapr-spark-historyserver`

2. (Optional): Starting in the EEP 4.0 release, you can install the MapR Spark Thrift Server package.

On Ubuntu	`apt-get insall mapr-spark-thriftserver`
On RedHat / CentOS	`yum install mapr-spark-thriftserver`
On SLES	`zypper install mapr-spark-thriftserver`

Upgrading Sqoop1

This section describes how to upgrade Sqoop1 without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Use one of the following methods to upgrade Sqoop1 without the MapR Installer.

To:

- Upgrade with a package manager and install new packages from the repository, run the following command:

On RedHat and CentOS	`yum update mapr-sqoop`
On Ubuntu	`apt-get install mapr-sqoop`
On SLES	`zypper update mapr-sqoop`

- Manually remove a prior version and then manually install the latest version in the repository, run the following commands:

On RedHat and CentOS	`yum remove mapr-sqoop` `yum install mapr-sqoop`
On Ubuntu	`apt-get remove mapr-sqoop` `apt-get install mapr-sqoop`

last-updated: Apr 11, 2022

On SLES	`zypper remove mapr-sqoop` `zypper install mapr-sqoop`

To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory (`/opt/mapr/sqoop/sqoop-<version>/conf/`). See Post-Upgrade Steps for Sqoop1 on page 383.

Upgrading Sqoop2

This section describes how to upgrade Sqoop2 without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Execute the following commands as `root` or using `sudo`:

1. On each Sqoop2 server node, upgrade the `mapr-sqoop2-server` packages.

On Ubuntu	`apt-get install mapr-sqoop2-server`
On RedHat and CentOS	`yum update mapr-sqoop2-server`
On SLES	`zypper update mapr-sqoop2-server`

2. On each Sqoop2 client node, install `mapr-sqoop2-client.`

On Ubuntu	`apt-get install mapr-sqoop2-client`
On RedHat / CentOS	`yum update mapr-sqoop2-client`
On SLES	`zypper update mapr-sqoop2-client`

Upgrading Tez

This section describes how to upgrade Tez without the MapR Installer.

Complete the following steps to upgrade Tez without the MapR Installer.

Use the following method to upgrade Tez on all the nodes where Tez is installed.

- Upgrade with a package manager, install new packages from the repository.

On RedHat and CentOS	`yum update mapr-tez`
On Ubuntu	`apt-get install mapr-tez`
On SLES	`zypper update mapr-tez`

To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory. See Post-Upgrade Steps for Tez on page 384.

last-updated: Apr 11, 2022

Finishing the MapR Ecosystem Pack Upgrade

Complete the post-upgrade steps for each ecosystem component that was upgraded.

Post-Upgrade Steps for Drill

Complete the following steps after you upgrade Drill with or without the MapR Installer.

1. Configuration files from the previous installation now reside in `/opt/mapr/drill/OLD_DRILL_VERSIONS`. If you have made any changes to configuration files in the previous version, compare and restore your previous configurations in the `/opt/mapr/drill/drill-<version>/conf` directory. Also, copy over any UDF or custom storage or format plugin JAR files that you added to the previous Drill directory.

   

   Note: The `drill-override.conf` contains your ZooKeeper configuration and any other options specified in the file. The `drill-env.sh` file contains any options that you modified, such as Drill memory allocation. The `logback.xml` file contains changes you may have made to use Lilith.

2. Run `configure.sh` to refresh the node configuration.

   ```
   $ /opt/mapr/server/configure.sh -R
   ```

   

   Note: Drill should be configured and running on the node. You can use one of the following methods to verify that the Drillbit service is running on the node:

   - Issue the following command to verify the status of the Drillbit service from the command line:

     ```
     jps
     ```

   - Log in to the Control System at `https://<host name>:8443` and click **Services** to verify the status of the Drillbit service.

   You should see the Drillbit listed as a service running on the node.

3. Enter the following URL in a web browser to access the Drill Web Console and verify that your storage plugin configurations were preserved during the upgrade:

   ```
   http://<IP address or host name>:8047/storage
   ```

   If your storage plugins were not preserved, use the back up that you took before the upgrade to restore them.

   

   Note: You can start/stop/restart the Drillbit service on one or more nodes using the Control System or the following command:

   ```
   $ maprcli node services -name drill-bits -action start|restart|
   stop -nodes <node host names separated by a space>
   ```

   Use the host name if possible. Using host names instead of IP addresses is a best practice.

   You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

Post-Upgrade Steps for Flume

Complete the following steps after you upgrade Flume with or without the MapR Installer.

last-updated: Apr 11, 2022

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Migrate Custom Configurations (optional).

Migrate any custom configuration settings into the new default files in the conf directory (`/opt/mapr/flume/flume-<version>/conf/`).

Post-Upgrade Steps for HBase

Complete the following steps after you upgrade HBase without the MapR Installer.

If you upgrade using the MapR Installer, running `configure.sh` is not necessary.

Run `configure.sh -R`.

```
/opt/mapr/server/configure.sh -R
```

After you run the `configure.sh -R` command, the HBase Thrift, HBase REST, HBase Master, and HBase RegionServer services are started automatically.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 337
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Post-Upgrade Steps for HBase Client

Complete the following steps after you upgrade HBase Client with or without the MapR Installer.

Merge custom configuration files with the new default files (optional).

1. If you backed up HBase Client configuration files into a location outside the installation directory before upgrading HBase Client, you must retrieve them if you want to save your custom configuration.
2. Merge HBase Client configuration files from with the new default files in `/opt/mapr/hbase/hbase-<version>/conf/`. Be sure not to simply copy over the configuration files: to avoid overwriting the default files, conduct a merge.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 337
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Post-Upgrade Steps for Hive

Complete the following steps after you upgrade Hive with or without the MapR Installer.

1. Migrate Hive Configuration.

   Migrate any custom configuration settings into the Hive 2.3 version in the `/opt/mapr/hive/hive-2.3/conf/` directory.

2. Update the Hive Metastore.

   For upgrades from the old version of Hive to the new version, run the `schematool` command with the `-upgradeSchema` option.

   Note: Review and, if necessary, perform the steps described in Troubleshooting Hive Upgrade Issues on page 374 before running this command.

   ```
   /opt/mapr/hive/hive-<version>/bin/schematool -dbType
   <metastore_database> -upgradeSchema
   ```

   For example, for upgrades from Hive 2.1 to 2.3 on MySQL, run the following command:

   ```
   /opt/mapr/hive/hive-2.3/bin/schematool -dbType mysql -upgradeSchema
   ```

3. Run `configure.sh -R`.

   ```
   /opt/mapr/server/configure.sh -R
   ```

   This step enables Warden to recognize the newly installed services.

4. Verify that the metastore database update completed successfully. You can use the following diagnostic tests:
   - Run the `show tables` command in Hive and make sure it returns a complete list of all your Hive tables.
   - Perform simple SELECT operations on Hive tables that existed before the upgrade.
   - Perform filtered SELECT operations on Hive tables that existed before the upgrade.

Troubleshooting Hive Upgrade Issues

This section describes how to troubleshoot inconsistencies in an underlying database after creating tables with the `datanucleus.schema.autoCreateAll` property.

The `datanucleus.schema.autoCreateAll` property creates tables gradually. After creating tables using this property, if you upgrade to Hive 2.3 using `schematool`, the `schematool` command will not be able to verify all the necessary tables because all the necessary tables were not created by the `datanucleus.schema.autoCreateAll` property.

1. Determine the version from which you are upgrading.
2. Start MySQL:

   ```
   mysql -u <user> -p <password>
   ```

3. Run the following commands in your MySQL command line.

Upgrade from Hive 1.2	`USE metastore;`
	`SOURCE /opt/mapr/hive/hive-2.1/scripts/metastore/upgrade/mysql/hive-schema -1.2.0.mysql.sql;`
	`SOURCE /opt/mapr/hive/hive-2.1/scripts/metastore/upgrade/mysql/hive-txn-schema`

```
        -0.13.0.mysql.sql;
```

Upgrade from Hive 1.0

```
USE metastore;
SOURCE /opt/mapr/hive/hive-2.1/
scripts/metastore/upgrade/mysql/
hive-schema-0.14.0.
mysql.sql;
```

Upgrade from Hive 0.13

```
USE metastore;
SOURCE /opt/mapr/hive/hive-2.1/
scripts/metastore/upgrade/mysql/
hive-schema-0.13.0.mysql.sql;
```

Running SOURCE for the version before the upgrade makes the underlying database consistent for running `schematool` command with the `-upgradeSchema` option.

Post-Upgrade Steps for HttpFS

Complete the following steps after you upgrade HttpFS with or without the MapR Installer.

1. Migrate any custom HttpFS configuration settings into the new default files.
   - The following examples show configuration file locations:
     - `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/webapps/webhdfs/WEB-INF/web.xml`
     - `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/server.xml`
     - `/opt/mapr/httpfs/httpfs-1.0/share/hadoop/httpfs/tomcat/conf/tomcat-users.xml`
     - `/opt/mapr/httpfs/httpfs-1.0/etc/hadoop/httpfs-site.xml`
2. Run the `configure.sh` script after making configuration changes:

```
sudo bash /opt/mapr/server/configure.sh -R
```

Post-Upgrade Steps for Hue

Complete the following steps after you upgrade Hue with or without the MapR Installer:

1. To configure the Hue-livy package after upgrading, see Integrate Hue 3.10+ With Spark 2 on page 3663.
2. After upgrading on Ubuntu, remove the `mapr-hue-base` package:

```
apt-get remove mapr-hue-base
```

3. Copy the changes that you made for required services in your existing `hue.ini` file into the latest version of the file:

```
/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini
```

Note: Hue 3.9 uses the old Query editor to work with Hive and Impala queries, and introduces new Spark Notebooks. Hue 3.10+ uses Notebooks as a replacement for the old Query editor for Hive and Impala. If you are upgrading to Hue 3.10+, and you want to have access to your saved queries in the old Hive or Impala Query editor, you need to configure Hue to use the old Query editor. To do this, set the `use_new_editor` property in the `hue.ini` file to `false`. For example:

```
[desktop]
...
  # Choose whether to show the new SQL editor.
  use_new_editor=false
```

4. If you use SQLite as the Hue database, load its backup:
   a) If the Hue node runs on Ubuntu, install sqlite3:

```
apt-get install sqlite3
```

   b) Run the following commands:

```
cd /opt/mapr/hue/hue-<new_version>/desktop
mv desktop.db desktop.db.old
sqlite3 desktop.db < ~/dump-hue-<old_version>-sqlite.bak
sqlite3 desktop.db
DELETE FROM django_content_type;
```

5. Update the old database schema so that it is compatible with the new upgraded version:
   a) For Hue 4.3+:

```
source /opt/mapr/hue/hue-<new_version>/bin/activate
hue migrate --run-syncdb --fake-initial
deactivate
```

   For example, run the following commands to update the database schema to make it compatible with Hue 4.3+:

```
source /opt/mapr/hue/hue-4.3.0/bin/activate
hue migrate --run-syncdb --fake-initial
deactivate
```

b) For Hue version up to Hue 4.2:

```
source /opt/mapr/hue/hue-<new_version>/bin/activate
hue syncdb --noinput
hue migrate --merge
deactivate
```

For example, run the following commands to update the database schema to make it compatible with Hue 4.2:

```
source /opt/mapr/hue/hue-4.2.0/bin/activate
hue syncdb --noinput
hue migrate --merge
deactivate
```

If you are using MySQL, PostgreSQL, or Oracle, and you have trouble with the database during the Hue upgrade, you can restore your data from the backup that you created during the Pre-Upgrade Steps for Hue:

```
source /opt/mapr/hue/hue-<new_version>/bin/activate
hue loaddata --ignorenonexistent ~/dump-hue-<old_version>.json
deactivate
```

6. **For upgrades performed without the MapR Installer:** If you are using Hadoop MRv1, complete the following steps to establish communication between Hue and the JobTracker processes:
   a) Remove existing Hue plugins from the MapReduce lib directory:

```
rm /opt/mapr/hadoop/hadoop-0.20*/lib/hue-plugins-*.jar
```

   b) Copy new Hue plugins to the MapReduce lib directory:

```
cp /opt/mapr/hue/hue-<version>/desktop/libs/hadoop/java-lib/
hue-plugins-*.jar /opt/mapr/hadoop/hadoop-0.20*/lib/
```

   For example, run the following commands to copy the Hue plugin for Hue 3.10+:

```
cp /opt/mapr/hue/hue-3.10.0/desktop/libs/hadoop/java-lib/
hue-plugins-*.jar /opt/mapr/hadoop/hadoop-0.20*/lib/
```

   c) Restart the JobTracker services:

```
maprcli node services -jobtracker restart -nodes <ip_addresses>
```

7. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

If you do not complete this step, Hue may fail to start and the Control System may still display references to the Hue version that you upgraded from.

8. Restart the Hue service:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

last-updated: Apr 11, 2022

Post-Upgrade Steps for Impala

Complete the following steps after you upgrade Impala with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Start the Impala, statestore, and catalog services. Always restart the Impala statestore service prior to restarting the Impala server on nodes in the cluster.

1. Issue the following command to start the Impala statestore service on the designated host in the cluster:

```
$ sudo maprcli node services -name impalastore -action start -nodes
<node IP addresses separated by a space>
Example:$ sudo maprcli node services -name impalastore -action
start -nodes 10.10.30.166
```

2. Issue the following command to start the catalog service on the designated host in the cluster:

```
$ sudo maprcli node services -name impalacatalog -action start -nodes
<node IP addresses separated by a space>
Example:$ sudo maprcli node services -name impalacatalog -action
start -nodes 10.10.30.166
```

3. Issue the following command to start the Impala server on each Impala node:

```
$ sudo maprcli node services -name impalaserver -action start -nodes
<node IP addresses separated by a space>
Example:$ sudo maprcli node services -name impalaserver -action
start -nodes 10.10.30.166
```

Note: Check the Impala log files for errors if the services do not start successfully. You can locate log files in the following Impala installation directory on each node:

```
/opt/mapr/impala/impala-<version>/logs
```

Post-Upgrade Steps for MapR Data Access Gateway

Complete the following steps after you upgrade the MapR Data Access Gateway with or without the MapR Installer.

1. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

2. Restart the service:

```
maprcli node services -nodes <node name> -name
data-access-gateway -action restart
```

Post-Upgrade Steps for Livy

Complete the following steps after you upgrade Livy with or without the MapR Installer.

Optional: Migrate Custom Configurations

Transfer any custom configuration settings into the new default files in the `conf` directory (`/opt/mapr/livy/livy-<version>/conf/`).

Post-Upgrade Steps for MapR Monitoring
Complete the following steps after you upgrade MapR Monitoring Components with or without the MapR Installer.

1. After you upgrade monitoring components, add customized properties from the configuration files that you backed up before the upgrade to the files in the new installation directories.

   Backups of many of the MapR Monitoring component configuration files are stored in the `/opt/mapr/<component>/<component>-<new_version>/etc` directory and its subdirectories. During the backup of a configuration file, the upgrade script appends the component version number to the filename. For example, the backup filename for `collectd.conf` is `collectd.conf-5.5.1`. Therefore, if you did not manually back up the configuration files before upgrading MapR Monitoring components, you may be able to retrieve the configuration.

2. On each node in the cluster, run `configure.sh` with the `-R` option.

   ```
   /opt/mapr/server/configure.sh -R
   ```

3. If you created a snapshot of the Kibana index as described in Pre-Upgrade Steps for MapR Monitoring on page 342, restore the snapshot to ensure that you have access to index information that was present before the upgrade. See https://www.elastic.co/guide/en/elasticsearch/reference/5.6/modules-snapshots.html.

4. If you need to configure the MapR Monitoring components for security, follow the steps in the installation procedures to generate the necessary files and distribute them across the cluster:
   - Step 8: Install Metrics Monitoring on page 162
   - Step 9: Install Log Monitoring on page 165

Post-Upgrade Steps for MapR Object Store with S3-Compatible API
Complete the following steps after you upgrade the MapR Object Store with S3-Compatible API with or without the MapR Installer.

1. Run `configure.sh -R`:

   ```
   /opt/mapr/server/configure.sh -R
   ```

2. Restart the service:

   ```
   maprcli node services -nodes <node name> -name objectstore -action
   restart
   ```

Post-Upgrade Steps for MapR Event Store For Apache Kafka Tools
Complete the following steps after manually upgrading MapR Event Store For Apache Kafka Tools.

Kafka REST Proxy

The following post-upgrade steps are applicable when upgrading Kafka REST Proxy.

1. Review your configuration files and modify as needed:

   ```
   /opt/mapr/kafka-rest-<version>/config
   ```

last-updated: Apr 11, 2022

2. Run the `configure.sh` file. For example:

```
/opt/mapr/server/configure.sh -R
```

3. Start the Kafka REST service

```
maprcli node services -name kafka-rest -action start -nodes < list of
Kafka REST service nodes >
```

To see how configuration files are saved during an upgrade, see Saving Kafka REST Configurations on page 3872.

Kafka Connect

The following post-upgrade steps are applicable when upgrading Kafka Connect.

1. Review your configuration files and modify as needed:

```
/opt/mapr/kafka-<version>/config
```

2. Run the `configure.sh` file. For example:

```
/opt/mapr/server/configure.sh -R
```

3. Start the Kafka Connect service

```
maprcli node services -name kafka-connect -action start -nodes <list of
Kafka Connect service nodes>
```

To see how configuration files are saved during an upgrade, see Saving Kafka Connect Configurations on page 3941.

Post-Upgrade Steps for Oozie

Complete the following steps after you upgrade Oozie with or without the MapR Installer.

1. Add customized properties from the configuration files that you saved before the upgrade to the files in the new Oozie `conf` directory: `/opt/mapr/oozie/oozie-<version>/conf/.`

2. If your Oozie installation is configured to use a MySQL or Oracle database and you are upgrading to a new Oozie version, copy the JDBC driver jar file for MySQL or Oracle to the following directory:

```
/opt/mapr/oozie/oozie-<oozie version>/libext
```

3. Run `configure.sh -R`:

```
# /opt/mapr/server/configure.sh -R
```

4. Verify that Oozie is in the 'Running' state and then run the following command to upgrade the database schema:

```
# /opt/mapr/oozie/oozie-<version>/bin/ooziedb.sh upgrade -run
```

5. Restart the Oozie server:

```
maprcli node services -name oozie -action restart -nodes <node names>
```

6. Start any Oozie coordinators that you stopped before the upgrade.

7. If needed, update the Oozie shared libraries, as described in Updating the Oozie Shared Libraries on page 4000.

Post-Upgrade Steps for Pig
Complete the following steps after you upgrade Pig with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Migrate Custom Configurations (optional).

Migrate any custom configuration settings into the new default files in the conf directory (`/opt/mapr/pig/pig-<version>/conf/`).

Post-Upgrade Steps for Sentry
Complete the following steps after you upgrade Sentry with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

If you saved the configuration files from the previous installation of Sentry, you can migrate the saved settings into the new default files. Use the schema tool to upgrade the database schema and then start the Sentry service.

1. (Optional) Migrate the settings in the saved configuration files from the previous version of Sentry into the new default files in `/opt/mapr/sentry/sentry-<version>/conf/`.

2. To upgrade the database schema using the schema tool, issue the following command:

```
/opt/mapr/sentry/sentry-<SENTRY_VERSION>/bin/sentry --command
schema-tool --conffile <sentry-site.xml> --dbType
<db-type> --upgradeSchema
```

3. To start the Sentry service, issue one of the following commands
   - If the warden.sentry.conf exists in the `/opt/mapr/conf/conf.d/` directory:

```
maprcli node services -name sentry  -action start -nodes <list of
Sentry service nodes>
```

   - If the warden.sentry.conf does not exist in the `/opt/mapr/conf/conf.d/` directory:

```
/opt/mapr/sentry/sentry-<SENTRY_VERSION>/bin/sentry-daemon.sh  start
<sentry-site.xml>
```

Post-Upgrade Steps for Spark
Complete the following steps after you upgrade Spark with or without the MapR Installer.

Post-Upgrade Steps for Spark Standalone Mode

1. (Optional) Migrate Custom Configurations.
   Migrate any custom configuration settings into the new default files in the conf directory (`/opt/mapr/spark/spark-<version>/conf`).
2. If Spark SQL is configured to work with Hive, copy the `hive-site.xml` file into the `conf` directory (`/opt/mapr/spark/spark-<version>/conf`).
3. Run the following commands to configure the secondary instances:
   a) For Spark 2.x:
      Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`.
      For Spark 3.x:
      Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`.
   b) Add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.
      For example:

      ```
      localhost
      worker-node-1
      worker-node-2
      ```

4. Run configure.sh -R.
5. Restart all the spark secondary instances as the `mapr` user:
   For Spark 2.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/start-slaves.sh spark://
   <comma-separated list of spark master hostname: port>
   ```

   For Spark 3.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/start-workers.sh spark://
   <comma-separated list of spark master hostname: port>
   ```

6. Delete the old Spark directory from `/opt/mapr/spark`. For example, if you upgraded from Spark 2.1.0 to 2.3.1, you need to delete `/opt/mapr/spark/spark-2.1.0`.
   Starting with the EEP 6.1.0 release, for Spark 2.2.1 and later versions, after an upgrade the old directory is automatically removed. Only the new directory and the directory with the timestamp is present.

Post-Upgrade Steps for Spark on YARN

1. (Optional) Migrate Custom Configurations.
   Migrate any custom configuration settings into the new default files in the conf directory (`/opt/mapr/spark/spark-<version>/conf`). Also, if you previously configured Spark to use the Spark JAR file from a location on the MapR File System, you need to copy the latest JAR file to the MapR File System and reconfigure the path to the JAR file in the `spark-defaults.conf` file. See Configure Spark JAR Location on page 4033.

2. If Spark SQL is configured to work with Hive, copy the `hive-site.xml` file into the conf directory (`/opt/mapr/spark/spark-<version>/conf`).
3. Run configure.sh -R.
4. Delete the old Spark directory from `/opt/mapr/spark`. For example, if you upgraded from Spark 2.1.0 to 2.3.1, you need to delete `/opt/mapr/spark/spark-2.1.0`.

   Starting with the EEP 6.1.0 release, for Spark 2.2.1 and later versions, after an upgrade the old directory is automatically removed. Only the new directory and the directory with the timestamp is present.

Post-Upgrade Steps for Sqoop1
Complete the following steps after you upgrade Sqoop1 with or without the MapR Installer.

Important: This component is deprecated. HPE recommends using an alternate product. For more information, see Discontinued Ecosystem Components on page 5584.

Migrate Custom Configurations.

Migrate any custom configuration settings into the new default files in the `conf` directory (`/opt/mapr/sqoop/sqoop-<version>/conf/`).

Post-Upgrade Steps for Sqoop2
Complete the following steps after you upgrade Sqoop2 with or without the MapR Installer.

1. Perform one of the following steps:
   a) Manually update the `sqoop.properties` file with new options. On each Sqoop2 server node, set the following property in `sqoop.properties` file:

   ```
   org.apache.sqoop.repository.schema.immutable=false
   org.apache.sqoop.connector.autoupgrade=true
   org.apache.sqoop.driver.autoupgrade=true
   ```

   b) Run `configure.sh -R`:

   ```
   /opt/mapr/server/configure.sh -R
   ```

   c) Stop Sqoop2:

   ```
   maprcli node services -name sqoop2 -action stop -nodes <space
   delimited list of Sqoop2 server nodes>
   ```

   d) Use the upgrade utility to update the sqoop.properties file. On each Sqoop2 server node, run the upgrade utility.

   ```
   /opt/mapr/sqoop/sqoop-<version>/bin/sqoop2-tool upgrade
   ```

   When the upgrade utility completes successfully, the following message displays: `Tool class org.apache.sqoop.tools.tool.UpgradeTool has finished correctly.`

   Note: In Sqoop 1.99.6, the sqoop.properties file is in the following directory: `/opt/mapr/sqoop/sqoop-<version>/server/conf/`. In Sqoop 1.99.7, the sqoop.properties file is in the following directory: `/opt/mapr/sqoop/sqoop-<version>/conf/`.
2. Optionally, add customized properties from the `sqoop.properties` file that you saved before the upgrade to the new `sqoop.properties` file.

last-updated: Apr 11, 2022

3. If Sqoop is not running, start the Sqoop Server.

```
maprcli node services -name sqoop2 -action start -nodes <space delimited
list of Sqoop2 server
      nodes>
```

Post-Upgrade Steps for Tez
Complete the following steps after you upgrade Tez with or without the MapR Installer.

After a minor version update, for example from `Tez-0.9-1808` to `Tez-0.9-1901`, no changes to the user configuration, `tez-site.xml` file, are applied. To apply the latest changes manually, see the Tez Release Notes on page 6481.

1. (Optional) Migrate any custom configuration settings into the new default files in the `/opt/mapr/tez/tez-<old version>/conf/` directory.
2. Reconfigure the Hive-on-Tez User Interface. This is necessary because the old tomcat folder gets removed from the cluster during the upgrade procedure. For details, see Hive-on-Tez User Interface on page 3506.
3. If you are using the MapR Installer, no additional steps are required. For manual installation, you need to configure Hive and Tez. See Configuring Hive and Tez on page 3502.

Preparing the Cluster for a Maintenance Update

This section identifies how to prepare for applying either a minor update or a patch.

Depending on the task you need to perform, see the following topics:

To prepare for a minor update of the core version:	Preparing to Upgrade MapR Core on page 303
To prepare to apply a patch:	Verify Cluster Readiness for a Patch

For more information about maintenance updates, see Performing a Maintenance Update on page 5447.

Performing a Maintenance Update

Perform a maintenance update when you want to upgrade to a new patch version of MapR core or apply a patch.

A maintenance update is an update to your installed MapR software that does not require configuration-file changes. Performing a maintenance update has no effect on the ecosystem packages (EEP components). You perform a maintenance update when you want to do either or both of the following:

- **Update to a new patch version of MapR core.** For example, you can perform a maintenance update to change your MapR core version from MapR 6.1.0 to MapR 6.1.1. You cannot use a maintenance update to change your MapR core version from a minor version, such as 6.1, to another minor version, such as 6.2. Use the **Version Upgrade** button for minor-version upgrades. The **Version Upgrade** button also permits an upgrade to a patch version of MapR core.
- **Apply a patch.** The **Maintenance Update** page is one of several installer screens that offer the **Patch file** option. See Applying a Patch Using the MapR Installer on page 438.

You cannot perform a maintenance update if your current EEP version is incompatible with the selected MapR core version. For example, you cannot do a maintenance update from MapR 6.1.0 and EEP 6.3.0 to MapR 6.1.1 because EEP 6.3.0 is not compatible with MapR 6.1.1. For EEP and core compatibility information, see EEP Support and Lifecycle Status on page 5531.

Note: The maintenance update is an offline update (not a rolling update).

You perform a maintenance update using the MapR Installer. To perform a maintenance update:

1. Verify that your installed EEP is supported by the core version you plan to select for the maintenance update. To check your EEP version, see Checking the EEP Version on page 5413. For EEP and core compatibility information, see EEP Support and Lifecycle Status on page 5531.
2. Update the MapR Installer to the latest supported version. See Updating the MapR Installer on page 5409.
3. Prepare the cluster for a maintenance update by referring to one or both of these topics:
   - Preparing to Upgrade MapR Core on page 303
   - Verify Cluster Readiness for a Patch
4. Start the MapR Installer. For more information, see MapR Installer on page 5395.
5. Click the **Maintenance Update** button.
6. Change the MapR core version, or install a MapR core patch, or both.

   Important: During patch-file installation, do not refresh the browser page while the patch file is being uploaded. Doing so can interrupt the upload process.
7. Click **Next** to complete the update.

Related concepts

Checking the EEP Version on page 5413
Some MapR Installer operations require you to know the version of the currently installed MapR Ecosystem Pack (EEP). You can check the EEP version easily from within the MapR Installer user interface or derive the EEP version from your repository information.

MapR Installer Updates on page 5481
MapR Installer updates provide new features or bug fixes.

Related reference

EEP Support and Lifecycle Status on page 5531
This page shows the EEPs that are supported for different core releases and the current lifecycle status for each EEP.

Setting Up Clients and Services

Describes how to set up and use interfaces to an cluster from a client computer.

MapR packages are contained in two different repositories:

- **Core packages**: Contains the API server, the webserver, CLDB, the core MapR package, file server, the NFS servers, the gateway, various POSIX and thin clients, and ZooKeeper. The latest versions of these packages are at https://package.mapr.com/releases/v6.2.0/.
- **EEP (previously *MEP*) packages**: These are the ecosystem packages and contain Drill, Hadoop, Hive, Livy, Pig, Spark, Tez, and Yarn. Available versions of these packages are at https://package.mapr.com/releases/MEP/.

MapR provides the following interfaces for working with a cluster from a client computer:

Direct Access NFS™

Describes how to configure Direct Access NFS to mount the MapR File System to a local directory.

Use Direct Access NFS™ to mount the MapR filesystem locally as a directory on a Mac, Linux, or Windows computer.

last-updated: Apr 11, 2022

See Managing the MapR NFS Service on page 1176 for more information.

Installing MapR NFS
Describes how to install the NFS service on a node.

The following sections describe how to install the NFSv3 server, NFSv4 server, and the NFS client.

Installing the NFSv3 Server

- Install the NFSv3 server package.
  To install, run the following command:

Red Hat or CentOS	`yum install mapr-nfs`
Ubuntu	`apt-get install mapr-nfs`
SLES	`zypper install mapr-nfs`

  If the NFS server is installed without fileserver on a node, the node will be placed in the `/nfsserver` topology. If the fileserver is installed at a later time, the node will be moved to the `/data` topology, which is the default for fileserver nodes.

Installing the NFSv4 Server

The NFSv4 server can only be installed on MapR 6.1 or later clusters. Both NFSv4 and NFSv3 servers cannot run on the same node. If you have the NFS client running on an edge node, you can use that client to connect to the MapR NFS server on clusters running either 5.2, where NFSv3 server can be installed, or 6.1, where NFSv4 or NFSv3 can be installed.

1. Download, if necessary, and install the `nfs-utils` package, if it is already not installed, on the host where you plan to install the NFSv4 server.
2. Modify the `/etc/yum.repos.d/mapr_ecosystem.repo` file on CentOS/SLES or `/etc/apt/sources.list` file on Ubuntu to add the following:
   - CentOS:

```
[mapr-dev-ecosystem]
name=mapr-dev-ecosystem
baseurl=http://artifactory.devops.lab/artifactory/eco-rpm/releases/
opensource/redhat
enabled=1
gpgcheck=0
```

   - Ubuntu:

```
deb http://artifactory.devops.lab/artifactory/eco-deb binary trusty
#opensource.repo
```

3. Ensure that `rpc.statd` is running on the node.
   To verify, run the following command:

```
ps -ef| grep rpc.st
    rpcuser 18889 1 0 01:04 ? 00:00:00 /sbin/rpc.statd
    root 27016 6933 0 01:25 pts/0 00:00:00 grep color=auto rpc.st
```

   If it is already not running, execute the following to start it:

```
/sbin/rpc.statd
```

4. Install NFSv4 server package.
   To install, run the following command:

Red Hat or CentOS	`yum install mapr-nfs4server`
Ubuntu	`apt-get install mapr-nfs4server`
SLES	`zypper install mapr-nfs4server`

   The `mapr-nfsganesha` package is also installed as a dependency package. If NFS server is installed without fileserver on a node, the node is in `/nfsserver` topology. If fileserver is installed at a later time, the node is moved to `/data` topology, which is the default for fileserver nodes.

5. Run `configure.sh` on page 2053 utility with the `-u` and `-g` options to configure the services to run under user `mapr` and the group of the `mapr` user.

   Important: This step is required only if you are configuring NFSv4 server to work with Kerberos.

Installing the NFS Client

- To install the NFS client, run the following command:

Red Hat or CentOS	`sudo yum install nfs-utils`
Ubuntu	`sudo apt-get install nfs-common`
SLES	`sudo zypper install nfs-client`

Note: NFSv3 clients cannot connect to the NFSv4 server because the NFSv4 server only supports v4 protocol.

Mounting NFS on the MapR Filesystem on a Cluster Node

Refer to Accessing Data with NFS v4 on page 1193 and Mounting NFS to MapR File System on a Cluster Node on page 1185 for steps to mount NFS to a MapR filesystem.

last-updated: Apr 11, 2022

Before You Start Using MapR NFS

Make sure the following conditions are met before using the MapR NFS gateway:

- The stock Linux NFS service must not be running. Linux NFS and MapR NFS cannot run concurrently.
- MapR NFSv3 and NFSv4 should not be installed on the same node.
- The lock manager (nlockmgr) must be disabled.
- On Red Hat and CentOS v6.0 and higher, the `rpcbind` service must be running.

  You can use the command `ps ax | grep rpcbind` to check.
- On Red Hat and CentOS v5.x and lower, and on Ubuntu and SLES, the `portmapper` service must be running.

  You can use the command `ps ax | grep portmap` to check.
- The `mapr-nfs` package for NFSv3 or `mapr-nfs4server` package for NFSv4 must be present and installed.

  You can list the contents in the `/opt/mapr/roles` directory to check for `nfs` in the list.
- Make sure you have applied a Community Edition (M3) license or an Enterprise Edition (M5) license (paid or trial) to the cluster.

  See Adding a License.
- Make sure the MapR NFS service is started.

  See Starting, Stopping, and Restarting MapR NFSv3 on page 1184 or Starting, Stopping, and Restarting MapR NFSv4 on page 1216.
- Verify that the primary group of the user listed for `mapr.daemon.user` in the `/opt/mapr/conf/daemon.conf` file is `mapr.daemon.group`.

  Restart Warden after any changes to `daemon.conf`.

For information about mounting the cluster using:

- NFSv3, see Accessing Data with NFS v3 on page 1183.
- NFSv4, see Accessing Data with NFS v4 on page 1193.

For information on upgrading your cluster, see Upgrading MapR Core on page 294.

Warning: To preserve compatibility with 32-bit applications and system calls, MapR-NFS uses 32-bit inode numbers by default. On 64-bit clients, this default forces the client's 64-bit inode numbers to be hashed down to 32 bits. Hashing 64-bit inodes down to 32 bits can potentially cause inum conflicts. To change the default behavior to 64-bit inode numbers, set the value of the `Use32BitFileId` property to 0 in the `nfsserver.conf` file, then restart the NFS server.

MapR Client

Describes how to install the MapR client to run Hadoop commands, jobs, and applications from a client machine.

You can use the client to:

- Submit MapReduce applications.
- Submit YARN applications.

- Run `hadoop fs` on page 5364, and `hadoop mfs` on page 5373 commands.

The method that you use to submit the Hadoop commands on Mac and Windows clients is different from the method that is used on Linux machines. For more information, see Running Hadoop Commands on a Mac and Windows Client.

Installing the MapR Client
This section describes how to prepare the client machine for the installation process.

CAUTION: Do not attempt to install MapR Ecosystem Pack (EEP) service components on client machines. Client machines do not have the service-management framework required to host the service components.

Before you install the MapR client, perform the following steps:

- **Verify that the operating system on the machine where you plan to install the client is supported.** For a list of operating systems that are compatible with the MapR clients, see MapR Client Support Matrix on page 5598.
- **Verify that the machine where you plan to install the client is not a cluster node.** The MapR client is intended for use on a computer that has no other MapR server software installed.
- **Ensure that the hostname of the machine is set to a fully qualified DNS name**. This is critical as else configure.sh will fail to generate SSL keys.
- **Obtain connectivity information and cluster setup requirements.** When you use `configure.sh` to configure the client, you will need to know the following details:
  - The cluster name. You will need the cluster name when you specify the `-N` parameter.
  - The IP addresses and ports of the CLDB nodes on the cluster. You will need this information when you specify the CLDB nodes with the `-C` parameter.
  - If one or more nodes in the cluster run the ResourceManager, you may need to specify the hostname or IP address for each ResourceManager nodes using the `-RM` parameter. If the cluster is configured to use zero-configuration failover, do not specify the ResourceManager nodes. If the cluster is not configured to use zero-configuration failover, specify each ResourceManager node.
  - Determine if the cluster is secure. If the cluster is secure, you will need to specify the `-secure` parameter when you run `configure.sh`.
  - If a node in the cluster runs the HistoryServer, note the hostname for the HistoryServer. You must specify each HistoryServer node using the `-HS` parameter.
- **Add the hostname mapping.** In the `/etc/hosts` file of the client machine, add a mapping between the CLDB nodes in the cluster and the IP addresses of those nodes.

  For example, add the IP address 10.10.82.22 and CLDB node name centos22 on the Mac OSX where you installed the client:

```
127.0.0.1       localhost
255.255.255.255 broadcasthost
::1             localhost
fe80::1%lo0     localhost
10.10.82.22     centos22
```

- **Configure repositories for the client.** The client nodes also need to have the MapR repositories configured in order to pull the client packages. See MapR Repositories and Packages on page 128.

last-updated: Apr 11, 2022

To install the client, obtain the MapR packages for your operating system at https://package.mapr.hpe.com/releases/ and complete the installation steps described in one of the subsequent topics.

Installing the MapR Client on CentOS, RedHat, Oracle Linux
This section describes how to install the MapR client on CentOS, RedHat, Oracle Linux.

1. Remove any previous MapR software. You can use `rpm -qa | grep mapr` to get a list of installed MapR packages, then type the packages separated by spaces after the `rpm -e` command:

   ```
   rpm -qa | grep mapr
   rpm -e mapr-fileserver mapr-core
   ```

2. Install the MapR package key. The package key must be installed before you can install MapR packages. For more information, see Step 1: Install the Package Key on page 142:

   ```
   rpm --import https://package.mapr.hpe.com/releases/pub/maprgpg.key
   ```

3. Install the MapR client for your target architecture:

   ```
   yum install mapr-client.x86_64
   ```

4. To use this client with a secure cluster or clusters, copy the `ssl_truststore` file from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. See Managing Secure Clusters on page 1482 for details on how to connect to a secure cluster.

5. Run `configure.sh` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Non-secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

   Secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -secure -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

Note:

If the cluster was configured with a cluster-admin `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

If the cluster-admin user ID is present on the client node, include these options:

- `-u`
- `-g`

If the cluster-admin user ID is not present on the client node, include these options:

- `-u`
- `-g`
- `--create-user | -a`
- `-U`
- `-G`

The following table describes each option:

Option	Description
`-u`	The user name under which MapR services run.
`-g`	The group name under which MapR services run.
`--create-user | -a`	Creates a local user to run MapR services, using the specified user either from the `-u` parameter, or from the environment variable `$MAPR_USER`.
`-U`	The user ID to use when creating `$MAPR_USER` with the `--create-user` or `-a` option; corresponds to the `-u` or `--uid` option of the `useradd` command in Linux.
`-G`	The group ID to use when creating `$MAPR_USER` with the `-create-user` or `-a` option; corresponds to the `-g` or `-gid` option of the `useradd` command in Linux.

6. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

Related concepts

Managing Secure Clusters on page 1482
Provides procedures that will enable you to use MapR clusters securely.

Related tasks

Step 1: Install the Package Key on page 142
Before you install MapR packages, you must install the package key.

Related reference

configure.sh on page 2053
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up MapR client nodes, and configuring services for a node.

Installing the MapR Client on SLES

This section describes how to install the MapR Client on SLES.

last-updated: Apr 11, 2022

1. Remove any previous MapR software. You can use `rpm -qa | grep mapr` to get a list of installed MapR packages:

   ```
   rpm -qa | grep mapr
   ```

   Then type the package names separated by spaces after the `zypper rm` command. For example:

   ```
   zypper rm mapr-fileserver mapr-core
   ```

2. Run the following command to install the MapR client:

   ```
   zypper install mapr-client
   ```

3. To use this client with a secure cluster or clusters, copy the `ssl_truststore` file from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool.

4. Run `configure.sh` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -secure -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

   Non-secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

last-updated: Apr 11, 2022

Note:

If the cluster was configured with a cluster-admin `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

If the cluster-admin user ID is present on the client node, include these options:

- `-u`
- `-g`

If the cluster-admin user ID is not present on the client node, include these options:

- `-u`
- `-g`
- `--create-user | -a`
- `-U`
- `-G`

The following table describes each option:

Option	Description
`-u`	The user name under which cluster services run.
`-g`	The group name under which cluster services run.
`--create-user | -a`	Creates a local user to run cluster services, using the specified user either from the `-u` parameter, or from the environment variable `$MAPR_USER`.
`-U`	The user ID to use when creating `$MAPR_USER` with the `--create-user` or `-a` option; corresponds to the `-u` or `--uid` option of the `useradd` command in Linux.
`-G`	The group ID to use when creating `$MAPR_USER` with the `-create-user` or `-a` option; corresponds to the `-g` or `-gid` option of the `useradd` command in Linux.

5. At the end of the client installation, run the `maprlogin password` command to create a valid ticket to connect to the cluster.

Installing the MapR Client on Ubuntu

This section describes how to install the MapR client on Ubuntu.

last-updated: Apr 11, 2022

1. Remove any previous MapR client software.

   You can use `dpkg --list | grep mapr` to get a list of installed MapR packages, then type the packages separated by spaces after the `dpkg -r` command. Example: `dpkg -l | grep mapr`.

   ```
   dpkg -r mapr-core mapr-fileserver
   ```

2. Update your Ubuntu repositories. For example:

   ```
   apt-get update
   ```

3. Run the following command to install the MapR client:

   ```
   apt-get install mapr-client
   ```

4. To use this client with a secure cluster or clusters, copy the `ssl_truststore` file from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool.

5. Run `configure.sh` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -secure -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

   Non-secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

Note:

If the cluster was configured with a cluster-admin `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

If the cluster-admin user ID is present on the client node, include these options:

- `-u`
- `-g`

If the cluster-admin user ID is not present on the client node, include these options:

- `-u`
- `-g`
- `--create-user | -a`
- `-U`
- `-G`

6. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

Related concepts

Installing the MapR Data Platform Client on Mac OS X

This section describes how to install the MapR Data Platform client on Mac OS X.

Limitation: Under OS X, the `getgroups` command returns a maximum of 16 groups for a user. If the Mac OS user for which you are installing the client attempts to read or write to a MapR Data Platform filesystem resource as a member of a group that was not included in the list of 16 groups returned by `getgroups`, file permission errors may result.

1. Create the `/opt` directory: `sudo mkdir -p /opt`
2. Download the file for the version that you want to install:

   ```
   https://package.mapr.hpe.com/releases/<version>/mac/<mapr-client package name>
   ```

3. Open the **Terminal** application.
4. Extract `mapr-client-<version>.tar.gz` into the `/opt` directory:

   ```
   sudo tar -C /opt -zxf mapr-client-<version>.tar.gz*
   ```

5. Before running `configure.sh`, make sure that `JAVA_HOME` is set correctly for the client in the following script: `/opt/mapr/conf/env.sh`

   For example:

   ```
   $ export JAVA_HOME=$(/usr/libexec/java_home)
   ```

6. To use this client with a secure cluster or clusters, copy the `ssl_truststore` file from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool.

7. Run `configure.sh` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Non-secure cluster example

   ```
   sudo /opt/mapr/server/
   configure.sh -N
   my.cluster.com -c -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS nodeA
   ```

   Secure cluster example

   ```
   sudo /opt/mapr/server/
   configure.sh -N
   my.cluster.com -c -secure -C
   mynode01:7222,mynode02:7222,mynode03
   :7222
   ```

   Note:

   If the cluster was configured with a cluster-admin `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

   If the cluster-admin user ID is present on the client node, include these options:

   - `-u`
   - `-g`

   If the cluster-admin user ID is not present on the client node, include these options:

   - `-u`
   - `-g`
   - `--create-user | -a`
   - `-U`
   - `-G`

last-updated: Apr 11, 2022

8. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

For information about running Hadoop commands on Mac OS X, see Running Hadoop Commands on a Mac and Windows Client on page 417.

Related concepts

Managing Secure Clusters on page 1482

Installing the MapR Client on Windows

Installing the MapR Data Platform client makes it possible to access the MapR filesystem from a Windows workstation.

Compatibility with Network Address Translation (NAT) Adapters

In VM environments, the MapR client on Windows works with a single NAT virtual adapter as long as it is the only virtual adapter configured for the VM. If you want to use more than one adapter, you must use other types of virtual adapters. If you use multiple NAT adapters in your VM environment, your jobs and file-system operations will fail.

Use these steps to install the client:

1. Make sure Java is installed on the computer and that the `JAVA_HOME` environment variable is set correctly.

   Note: The path that you set for the JAVA_HOME environment variable must not include spaces.

2. Create the directory `\opt\mapr` on your `c:` drive (or another hard drive of your choosing). You can use Windows Explorer, or type the following at the command prompt: `mkdir c:\opt\mapr`
3. Set the `MAPR_HOME` environment variable to `c:\opt\mapr`
4. Open the command line.
5. Use the following command to navigate to `MAPR_HOME`: `cd %MAPR_HOME%`
6. Download the file for the version that you want to install into `MAPR_HOME`:

   ```
   https://package.mapr.hpe.com/releases/<version>/windows/<package name>
   ```

7. Extract the archive by right-clicking on the file and selecting **Extract All...**
8. From the command line, run `configure.bat` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   For details about the syntax, parameters, and behavior of configure.bat, see configure.sh.

   Non-secure cluster example

   ```
   server\configure.bat -N
   my.cluster.com -c -C
   ```

last-updated: Apr 11, 2022

```
mynode01:7222,mynode02:7222,mynode03
:7222 -HS nodeA
```

Secure cluster example

```
server\configure.bat -N
my.cluster.com -c -secure -C
mynode01:7222,mynode02:7222,mynode03
:7222
```

9. To use this client with a secure cluster or clusters, copy the `ssl_truststore` file from the `/opt/mapr/conf` directory on the cluster to the `c:\opt\mapr\conf` directory on the client.

   If this client will connect to multiple clusters, you must merge the `ssl_truststore` files on the server by using the `/opt/mapr/server/manageSSLKeys.sh` tool, and then copy the merged file to `c:\opt\mapr\conf` on the client. For an example of merging the `ssl_truststore` files, see step 3 in Configuring Secure Clusters for Running Commands Remotely on page 1484.

   See Managing Secure Clusters on page 1482 for details on how to connect to a secure cluster.

10. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

For more information about running Hadoop commands on Windows, see Running Hadoop Commands on a Mac and Windows Client on page 417.

Related concepts

Managing Secure Clusters on page 1482
Provides procedures that will enable you to use MapR clusters securely.

Configuring the Windows Client

You can use the MapR client on Windows.

This section describes how to configure the MapR client on Windows:

Configuring MapR Client User on Windows

Before you use the Windows Client, configure it with information from your cluster.

Before running applications on the Windows Client, configure the `core-site.xml` file with the UID, GID, and user name of the cluster user that will be used to access the non-secure cluster.

Note: If you are on secure cluster, this configuration is not needed because on secure clusters, the username is available through the ticket.

Complete the following steps:

1. Obtain the UID and GID that has been set up for your user account. To determine the correct UID and GID values for your username, log into a cluster node and type the `id` command. In the following example, the UID is 1000 and the GID is 2000:

   ```
   $ id
   uid=1000(juser) gid=2000(juser)
   groups=4(adm),20(dialout),24(cdrom),46(plugdev),105(lpadmin),119(admin),1
   22(sambashare),2000(juser)
   ```

2. Add the following parameters to the `core-site.xml` files that correspond to the version of the hadoop commands that you plan to run:

```
<property>
  <name>hadoop.spoofed.user.uid</name>
  <value>{UID}</value>
</property>
<property>
  <name>hadoop.spoofed.user.gid</name>
  <value>{GID}</value>
</property>
<property>
  <name>hadoop.spoofed.user.username</name>
  <value>{id of user who has UID}</value>
</property>
```

Warning: You must use the *numeric* values for `UID` and `GID`, not the text names.

Note: When wire-level security is implemented on Windows, spoofing is not supported. This greatly increases the security of the cluster, but the `core-site.xml` file settings above then have no effect.

For MapReduce version 2 or other applications that run on YARN, the `core-site.xml` file(s) that you need to edit is located at: `%MAPR_HOME%\hadoop\hadoop-2.x.x\etc\hadoop\core-site.xml`.

Configure the Windows Client to Submit MapReduce Version 2 Applications
This section describes how to add a property that allows you to run MapReduce version 2 applications from a Windows Client.

- Before running any MapReduce version 2 (MRv2) applications from a Windows client, add the following property to the `mapred-site.xml` file:

```
<property>
<name>mapreduce.app-submission.cross-platform</name>
<value>true</value>
</property>
```

The `mapred-site.xml` file for MRv2 applications is located in the following directory:

```
%MAPR_HOME%\hadoop\hadoop-2.x.x\etc\hadoop\mapred-site.xml
```

MapR POSIX Clients

Describes how to install the POSIX loopback NFS, and the FUSE-based POSIX clients.

This section contains instructions for installing the MapR POSIX Clients. The MapR software provides a POSIX loopback NFS client package, and FUSE-based POSIX Basic and Platinum client packages. Each FUSE-based POSIX client package implies a specific MapR filesystem throughput optimization of n/G per second. These clients can be installed and used according to the same principles as the POSIX loopback NFS client.

Overview of loopback NFS and FUSE-based POSIX Clients

The NFS version 3.0 protocol does not have secure data transit, nor authentication capabilities to authenticate users who connect to the MapR NFS version 3.0 server. Any client and any user can connect to the MapR NFS server, remotely.

Loopback NFS tightens security and ensures that only authenticated users can access the NFS server. The loopback NFS client runs on the same node as the NFS server, and can connect to only that NFS server based on the ticket generated. Remote clients cannot access the server.

> **Tip:** For enhanced performance and reliability, use a FUSE-based POSIX client that works similar to the loopback NFS server in terms of security and authentication, and always set the MAPR_SUBNETS enivronment variable.

Note: NFS version 4.0 has in-built security and authentication. Remote clients and users can access MapR NFS version 4.0 servers securely.

Installing the mapr-loopbacknfs Package
MapR POSIX clients enable application servers, web servers, and other client nodes and applications to read and write directly and securely to a MapR cluster.

Consider installing `mapr-loopbacknfs` if you need a secure POSIX client. You can install the `mapr-loopbacknfs` client on any client node, even your laptop, if you have Linux installed. A client node must have a supported Linux OS distribution and must be outside the MapR cluster, not running `mapr-fileserver` or other Hadoop services. You cannot install the MapR POSIX client on a Windows or Mac OS X machine.

As a POSIX client, `mapr-loopbacknfs` can use any of the 10 POSIX connections provided by the Basic license. If you need more POSIX client connections, consider upgrading to a Platinum license, as described in Preparing for Installation (MapR POSIX Client) on page 400.

Attention: Note that the Installer installs `mapr-loopbacknfs` on all nodes in the cluster when **Enable NFS** is not specified.

To install `mapr-loopbacknfs` on your machine, perform the following steps for your version of Linux, as the `root` user or using `sudo`. The package is installed to the `/usr/local/mapr-loopbacknfs` directory.

- **For CentOS, RHEL, or Oracle Linux**

```
[root@ip-<ip_address> ~] # yum install mapr-loopbacknfs
```

- **For SLES**

```
# zypper install mapr-compat-suse
```

```
# zypper install mapr-loopbacknfs
```

- **For Ubuntu**

```
# sudo apt-get install mapr-loopbacknfs
```

Installing FUSE-based POSIX Client Packages
Describes how to install a FUSE-based Basic or Platinum POSIX client package.

FUSE-based POSIX clients allow app servers, web servers, and other client nodes and apps to read and write data directly and securely to a MapR cluster like a Linux filesystem.

Preparing for Installation (MapR POSIX Client)
To install the MapR POSIX Client on a node, you must meet certain requirements.

The MapR POSIX client can be installed on any node if you have Linux installed. You cannot install the MapR POSIX client on a Windows or Mac OS X machine. The client requires Java 1.7 or later to be installed on your system.

last-updated: Apr 11, 2022

POSIX Client Package Summary

Two separate POSIX client packages are provided, each with different performance tiers. Each package implies a specific MapR File System throughput optimization of n/GB (bytes) per second where n=1 for Basic, and n=5 for Platinum POSIX client. These clients can be installed and used according to the same principles as the POSIX loopback NFS client. The following table lists the packages.

	Basic POSIX Client	Platinum POSIX Client
Name	MapR POSIX Client Basic	MapR POSIX Client Platinum
Number of Clients	Up to 10 free	Free
Performance	Up to 1GB (Byte)/sec	Up to 5GB (Byte)/sec (with HT disabled)
MapR Package	`mapr-posix-client-basic`	`mapr-posix-client-platinum`

Client-Side Hardware Requirements

To accommodate the POSIX client, your hardware should meet the following requirements:

	Basic	Platinum
Hyper-threading*	Off	Off
Physical CPU(s) (with HT disabled)	1	2
Core(s) per socket	8	8
Socket(s)	1	2
Processor speed	2.2 GHz	2.60 GHz
Memory Click Speed	>=1333 MHz	>=1666 MHz
NICs	10 Gbps (2 GB/sec)	40 Gbps (5 GB/sec)

* Disabling hyper-threading (HT) improves performance.

Linux Kernel Tuning Recommendations

If the client connects to the servers over a 40GigE switch, you should set the following parameters in `/etc/sysctl.conf` to 16 MB on all the nodes to achieve maximum throughput.

Note: This setting is not required, but if the network has a large capacity, this setting allows the OS to buffer large chunks of data for transmission, which improves throughput.

- `net.core.rmem.max`
- `net.core.rmem_default`
- `net.core.wmem_max`
- `net.core.wmem_default`
- `net.ipv4.tcp_rmem`
- `net.ipv4.tcp_wmem`
- `net.ipv4.tcp_mem`

Installing the FUSE-Based POSIX Client

Describes how to install the FUSE-based POSIX client package on your system.

last-updated: Apr 11, 2022

FUSE-based POSIX clients require the FUSE kernel module. Run the following command to load the kernel module:

```
modprobe fuse
```

You can install the FUSE-based POSIX client on any node, including cluster nodes.

To install the mapr-posix-client-* package on your machine, where * refers to the basic or the platinum client package, perform the following steps for your version of Linux, as the `root` user, or using `sudo`. The package is installed to the `/opt/mapr/bin/` directory.

1. Run the following command to install the POSIX client package on your machine.
   - **For CentOS, RHEL, or Oracle Linux**

     ```
     # yum install mapr-posix-client-*, where * is either the basic or the
     platinum package
     For example: yum install mapr-posix-client-basic
     ```

     Troubleshooting: On Oracle Linux, you must also install the `compat-openssl10` package to get the POSIX client running:

     ```
     yum install compat-openssl10
     ```

   - **For SLES**

     ```
     # zypper install mapr-posix-client-*, where * is either the basic or
     the platinum package
     For example: zypper install mapr-posix-client-basic
     ```

   - **For Ubuntu**

     ```
     # sudo apt-get install mapr-posix-client-*, where * is either the
     basic or the platinum package
     For example: apt-get install mapr-posix-client-basic
     ```

2. To use this client with a secure cluster or clusters, copy the following files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.
   - `ssl_truststore`
   - `ssl-client.xml`

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. You must perform the merging on the cluster. See Managing Secure Clusters on page 1482 for details on how to connect to a secure cluster.

3. Run `configure.sh` to set this node as a client node.
   - For a fresh installation of the POSIX client, run `configure.sh` as follows:

     ```
     /opt/mapr/server/configure.sh -N <clustername> -C <CLDBhost> -Z
     <ZooKeeperhost> -c
     ```

- When reinstalling the POSIX client, run `configure.sh` with the -R option to reuse the existing configuration.

```
/opt/mapr/server/configure.sh -c -R
```

Note: To use the POSIX client with a secure cluster, add the `-secure` option when running `configure.sh`. However, do NOT add the `-secure` option when running `configure.sh` with the -R option.

4. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

To configure, start, and mount the client:

- Configure the POSIX client
- Start the POSIX client
- Mount the cluster

About the MapR Persistent Application Client Container (PACC)

This container gives you seamless access to MapR cluster services.

This topic introduces the MapR Persistent Application Client Container (PACC), including its function, benefits, components, and applications.

The MapR (PACC) is a Docker-based container image that includes a container-optimized MapR client. The PACC provides seamless access to MapR Converged Data Platform services, including MapR File System, MapR Database, and MapR Event Store For Apache Kafka. The PACC makes it fast and easy to run containerized applications that access data in MapR.

FUSE POSIX Client for File-Based Applications

To support persistent, file-based applications, the MapR PACC includes a FUSE-based MapR POSIX Client, optimized for containers, that allows app servers, web servers, and other applications to read and write data directly to the MapR filesystem. If your cluster has a MapR POSIX Client for Containers license, the PACC can connect with MapR 5.1 or later clusters.

Traditionally, all file data created by containers is lost when a container is terminated, which can happen during an application or hardware failure. By using the POSIX client within the PACC, applications can reliably persist file data directly to the MapR filesystem, where it can be re-attached to the container in the event of application or hardware failures.

Support for Microservice Applications

To support stateful microservice applications, the MapR PACC also contains a container-optimized version of the MapR client, which includes libraries for accessing MapR Database and MapR Event Store For Apache Kafka.

Secure Access

The MapR PACC is designed to provide access to a secure cluster for all MapR Converged Platform data services. Users can pass a MapR ticket file into the container at runtime. All data access, whether to MapR File System, MapR Database, or MapR Event Store For Apache Kafka, is authorized and audited according to the authenticated identity of the ticket file.

last-updated: Apr 11, 2022

PACC Contents

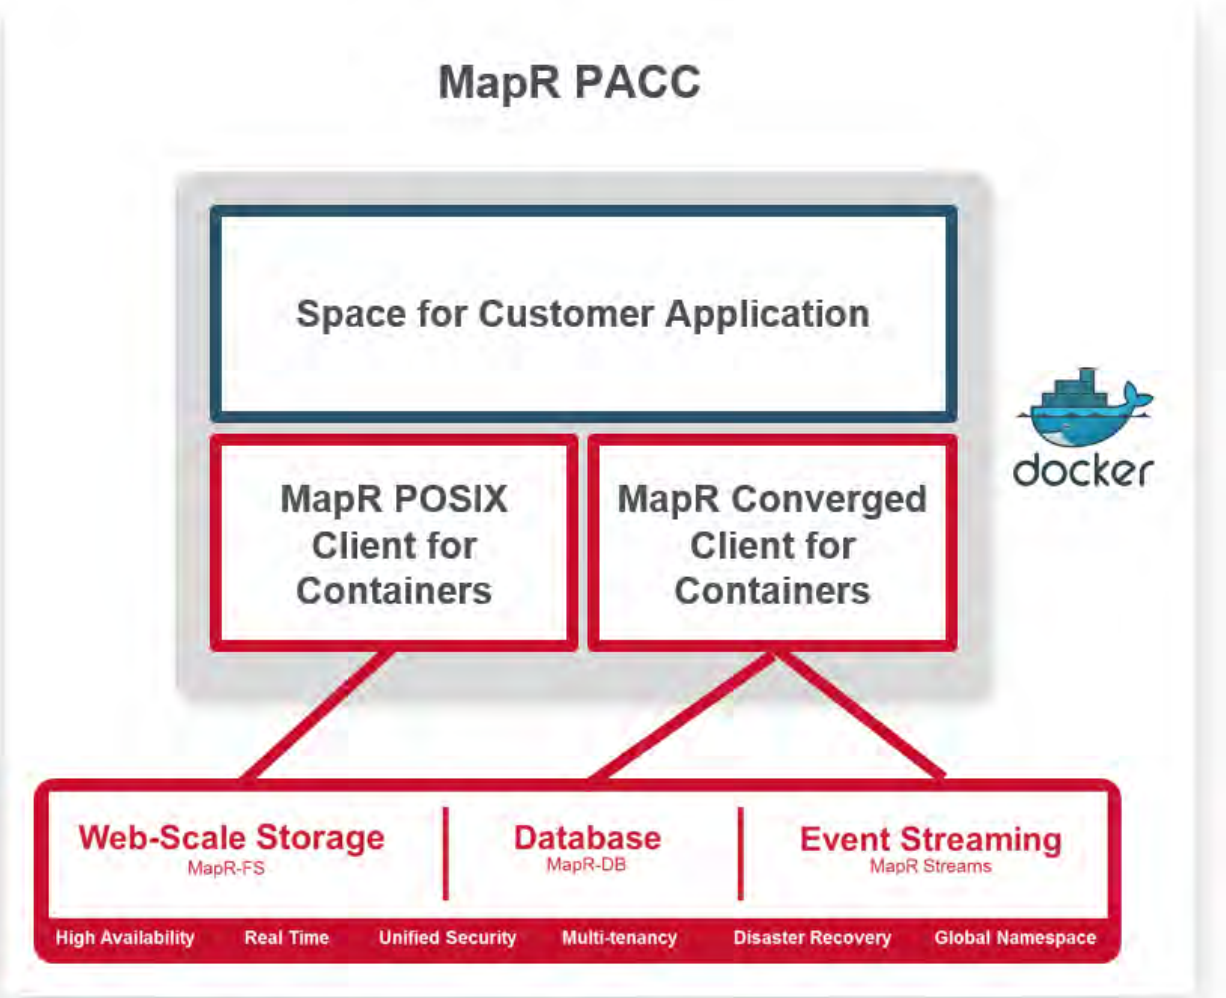
The PACC includes the following components:

- MapR Database Client[1]
- MapR Event Store For Apache Kafka Client
- POSIX Client for Containers
- Hadoop Client with YARN[2]
- HBase Client[2]
- Hive Client[2]
- Pig Client[2]
- Python
- Java
- Curl, Wget, Openssl, NFS-common, etc

[1]The MapR Database client includes support for MapR Database binary tables and MapR Database JSON tables.

[2]Included only if specified and only in MapR PACC images created using `mapr-setup.sh`.

The following diagram illustrates the contents of the PACC, and how it allows applications to access MapR Converged Data Platform services.



Pre-Built and User-Created Images

To get started with the MapR PACC, you can take advantage of pre-built Docker images or create your own images to include site-specific environmental parameters:

To . . .	See this topic
See a list of the MapR pre-built Docker images	Extending a MapR PACC on page 408
Create your own images containing MapR software	Creating a MapR PACC Image Using mapr-setup.sh on page 409

Before Deploying the MapR PACC

Perform a series of checks on the platform and MapR cluster before deploying the MapR PACC.

Before you deploy a MapR PACC, or an application container based on the PACC, perform the following checks on the platform and MapR cluster.

On the platform where you plan to deploy...	On the MapR cluster...

last-updated: Apr 11, 2022

• Verify that Docker 1.12.5 or later is installed and the Docker daemon is up and running. For download instructions, see this Docker website.
• Verify that you have sufficient disk space for use by the container.
  • 1 GB for the pre-built images
  • 1.5 GB for the user-created images
	• If you plan to connect to the MapR filesystem using the POSIX client, you *must* verify that you have a license for the MapR POSIX Client for Containers. No license is required to connect to MapR Database or MapR-Streams. To obtain the license, do one of the following:
	  • Clusters registered with the MapR Enterprise Trial license can connect unlimited POSIX Clients for Containers.
	  • For production use of the POSIX Client for Containers, contact your HPE sales representative.
	• Obtain the information that you will use to set up the container. You need to gather:
	  • The cluster name.
	  • The time zone of the container. If no time zone is specified, the container uses UTC as the default time zone.
	  • The IP addresses of the cluster nodes running the CLDB.
	  • A ticket if you need to connect to a secure cluster.

Leveraging MapR File System Storage for Application Persistence

The data associated with containers is typically not persistent. If you specify a MapR mount path using `MAPR_MOUNT_PATH`, any data written to the mounted directory will be persisted to the MapR filesystem. For example, you could create a symlink to the Apache log directory and persist all log files in the MapR filesystem.

If you specify a MapR mount path and if your hardware or application fails, re-launching the container in any location using the same Docker runtime environment variables will result in all pre-created data being available for use.

Security Considerations

You should be aware of security considerations for secure and non-secure clusters when using MapR PACCs. See Security Considerations for the MapR PACC.

Security Considerations for the MapR PACC

This section describes key considerations for using Docker containers with secure and non-secure MapR clusters.

Secure Clusters

Docker containers, like other virtualization technologies, allow client access from user identities that are not controlled by central IT. As a result, these technologies can be problematic when used with clusters that are not secure (where trust is based on trusting the client). Therefore, HPE suggests that you use secure clusters with MapR PACCs.

MapR PACCs, and applications built from them, are launched with a MapR ticket that contains the application's identity from the perspective of the cluster. On secure clusters, the user identity, user ID (`UID`), and group ID (`GID`) are specified in the MapR ticket and passed to the MapR filesystem for cluster communication. The ticket ensures that operations, such as authorization and auditing, are performed as the authenticated MapR user. A different ticket should be created for each container that is launched. The user's identity should be the identity of the user who accesses data.

last-updated: Apr 11, 2022

All access from Docker containers to the MapR cluster requires a MapR ticket be present inside the container. Users or administrators should generate a MapR ticket for each container prior to launch, and pass the ticket into the container at runtime. The MapR ticket *must* be generated for the user that your applications access the cluster as. You should create a container user with the same `MAPR_CONTAINER_USER`, `MAPR_CONTAINER_GROUP`, `MAPR_CONTAINER_GID`, and `MAPR_CONTAINER_UID` runtime environment variables.

Always use service or user tickets, not impersonation tickets. The ticket type and lifetime should consider the lifetime of the application being deployed. Use of impersonation tickets may allow rogue applications running in containers to impersonate arbitrary users (including `root` or `mapr`) and gain access to any data in the cluster.

The MapR ticket file location in the container is set with the `MAPR_TICKETFILE_LOCATION` environment variable, which is set at runtime for the user specified in `MAPR_CONTAINER_USER`. The ticket file must always be stored in `/tmp`. For example: `/tmp/mapr_ticket`.

In case of loss or breach, you can revoke tickets.

Non-Secure Clusters

On non-secure clusters, you can restrict access by running the application inside the container as a user with appropriate privileges on the MapR cluster. This is controlled using runtime environment variables.

Note: HPE recommends that you do not use either `mapr` or `root` users.

- **`MAPR_CONTAINER_USER`** and **`MAPR_CONTAINER_UID`** specify:
  - The default user invoked when starting the container
  - The user that the user application inside the container will run as
- **`MAPR_CONTAINER_GID`** represents the `GID` that the application inside the Docker container will run as
- **`MAPR_CONTAINER_GROUP`** represents the group that the application inside the Docker container will run as

Writing Applications to Use the MapR PACC

This section describes a number of resources for developing applications to use the MapR MapR Persistent Application Container Client.

Developing applications to use the MapR PACC is the same as developing applications on other MapR-supported platforms. To get started, see these topics:

last-updated: Apr 11, 2022

- MapR File System and Applications
- MapR Database and Applications
- MapR Event Store For Apache Kafka and Applications

To build a container for your application that can leverage MapR Data Platform services, you will create a Dockerfile referencing the MapR PACC which installs your application and its dependencies. You can then build and launch your application using the same runtime variables described later in this section.

Extending a MapR PACC
You can use a MapR PACC to create a new Docker image.

These pre-built Docker container base images – called MapR Persistent Application Client Containers (PACCs) – are available in the maprtech/pacc public repository:

Table

PACC Repository and Tag	Container OS			
	CentOS 6.8	CentOS 7.x	Ubuntu 14.04	Ubuntu 16.04
6.1.0	N/A	`maprtech/pacc:6.1.0_6.0.0_centos7` or `maprtech/pacc:latest` or `maprtech/pacc`	N/A	`maprtech/pacc:6.1.0_6.0.0_ubuntu16`
6.0.1	N/A	`maprtech/pacc:6.0.1_5.0.0_centos7`	N/A	`maprtech/pacc:6.0.1_5.0.0_ubuntu16`
6.0.0	N/A	`maprtech/pacc:6.0.0_4.0.0_centos7`	N/A	`maprtech/pacc:6.0.0_4.0.0_ubuntu16`
5.2.2	`maprtech/pacc:5.2.2_3.0.1_centos6`	`maprtech/pacc:5.2.2_3.0.1_centos7`	`maprtech/pacc:5.2.2_3.0.1_ubuntu14`	`maprtech/pacc:5.2.2_3.0.1_ubuntu16`
5.2.1	`maprtech/pacc:5.2.1_3.0_centos6`	`maprtech/pacc:5.2.1_3.0_centos7`	`maprtech/pacc:5.2.1_3.0_ubuntu14`	N/A
5.2.0	`maprtech/pacc:5.2.0_2.0_centos6`	`maprtech/pacc:5.2.0_2.0_centos7`	`maprtech/pacc:5.2.0_2.0_ubuntu14`	N/A

While you cannot modify a MapR-provided Docker image directly, you can build a custom image that is based on a MapR Persistent Application Client Container (PACC). The following example shows a custom Dockerfile that is used to create a new Docker image. In this example, an application has a JAR file that takes a producer as a parameter and runs a custom function.

The example has two parts. In Part 1, the custom Dockerfile uses the Docker `FROM` command to download a MapR PACC to a container on the user platform. A directory is created, and a JAR file is copied into the container so that it can be run in Java. The `CMD` command starts the application inside the container. In Part 2, the custom Dockerfile is built using the `docker build` command.

Part 1. Creating a Custom Dockerfile

```
FROM maprtech/pacc:5.2.0_2.0_centos6

# Copy jar to container
RUN mkdir -p /usr/share/mapr-apps/
COPY mapr-streams-examples-1.0-SNAPSHOT-jar-with-dependencies.jar /usr/
```

last-updated: Apr 11, 2022

```
share/mapr-apps/mapr-app-001.jar

# Run producer application in container
CMD [ "java", "-cp", "$MAPR_CLASSPATH:/usr/share/mapr-apps/
mapr-app-001.jar", "com.mapr.examples.Run", "producer" ]
```

Part 2. Building a Custom Docker Image From the Dockerfile

```
docker build -t <new docker image> .
  Note: Above needs to be run in the same directory as Dockerfile
  Make sure the image is created and no issue building Docker image.
docker images -a
```

Creating a MapR PACC Image Using `mapr-setup.sh`

This section describes how to download and run the `mapr-setup.sh` script to create a MapR Persistent Application Container Client (PACC) image.

To create a MapR PACC image using `mapr-setup.sh`:

1. Before using `mapr-setup.sh`, review these topics to understand important prerequisites and security considerations:
   - Before Deploying the MapR PACC on page 405
   - Security Considerations for the MapR PACC on page 406
2. Download the `mapr-setup.sh` script from mapr.com to a Linux or Mac OS X platform where Docker 1.12.5 or later is installed.

   Note: Running `mapr-setup.sh` on Windows is not supported.
3. Run the mapr-setup.sh script with the `docker client` command to create the Docker image:

   ```
   ./mapr-setup.sh docker client
   ```
4. Answer the command-line prompts to provide the information needed to configure the image. The following table describes each prompt. If you press **Enter** without specifying a value, `mapr-setup.sh` uses the default value shown in the square brackets ([]):

Parameter	Notes
`Build MapR client image? (y/n) [y]`	Press y to continue or n to exit the script.
`Image OS class (centos7, ubuntu16) [<local OS>]:`	Specify the base operating system on which to build the image. **Note:** SLES is not currently supported.
`Docker FROM base image name:tag [centos:centos7]:`	Specify the starting image used to create the new image. If necessary, you can enter your own tag and image name to choose a base image already created for your installation.
`MapR core version [6.x.x]:`	Specify the MapR core version that matches the version of the MapR cluster you want to access using the PACC. For the supported MapR core values, see Table 1 in Extending a MapR PACC on page 408. If you want to install the Hadoop Client with YARN, you must select `5.2.1` or later.

last-updated: Apr 11, 2022

`MapR MEP version [x.x.x]:`	Specify the EEP version that matches the EEP version of the MapR cluster you want to access using the PACC. Supported values are `2.0` or later. If you want to install the Hadoop Client with YARN, you must select EEP `3.0` or later. For more information about EEPs, see EEP Components and OS Support.
`Install Hadoop YARN client (y/n) [n]:`	Choose whether to install the Hadoop Client with YARN. Note that the Hadoop Client with YARN requires MapR core version 5.2.1 and EEP 3.0 or later. If you choose No, the script installs the POSIX (FUSE), MapR Database, and MapR Streams clients. The script does not install the Hadoop Client with YARN and does not ask if you want to install the Hive, Pig, and Streams clients.
`Add POSIX (FUSE) client to container? (y/n) [y]:`	Choose whether to install the POSIX (FUSE) client.
`Add HBase client to container? (y/n) [n]:`	Choose whether to install the HBase client.
`Add Hive client to container? (y/n) [n]:`	Choose whether to install the Hive client.
`Add Pig client to container? (y/n) [n]:`	Choose whether to install the Pig client.
`Add Spark client to container? (y/n) [n]:`	Choose whether to install the Spark client.
`Add MapR Streams clients to container? (y/n) [y]:`	Choose whether to install the MapR Streams clients.
`MapR client image tag name [<name>]:`	Accept the software-provided name for the image, or provide your own name. This is the name you will use to run the image to create the MapR PACC. The script automatically provides a name. For example: `maprtech/pacc:6.0.0_4.0.0_centos7_yarn_fuse_hbase_hive_pig_streams`
`Container network mode (bridge|host) [bridge]:`	Select the Docker network mode. For more information, see the Docker documentation.
`Container memory: specify host XX[kmg] or 0 for no limit [0]:`	Specify the maximum amount of memory (in kilobytes, megabytes, or gigabytes) that Docker allows the container to access. For example: • 2g • 4096m • 0 Accepting the default (0), means there is no restriction on memory, and the container can use as much memory as the platform makes available.

last-updated: Apr 11, 2022

5. Press **Enter** after the last prompt. The script creates the image and notifies you of successful creation. For example:

```
    Complete!

    ...Success

    Stopped service mapr-posix-client-container

    ...Success

     ---> 170362a5a82d
    Removing intermediate container 8f100b9d6d9b
    Step 7/8 : ENTRYPOINT /opt/mapr/installer/docker/mapr-setup.sh
container
     ---> Running in f98e5cde91ed
     ---> 7099a990a422
    Removing intermediate container f98e5cde91ed
    Step 8/8 : CMD start
     ---> Running in f6ae4139ab41
     ---> 01ca2ab6d0d3
    Removing intermediate container f6ae4139ab41
    Successfully built 01ca2ab6d0d3

    Edit '/root/thinclient/docker_images/client/mapr-docker-client.sh'
to set
       MAPR_CLUSTER and MAPR_CLDB_HOSTS and then execute it to start the
container
```

`mapr-setup.sh` creates the `mapr-docker-client.sh` sample-run file and displays the location of the file:

```
Edit '/root/thinclient/docker_images/client/mapr-docker-client.sh' to set
MAPR_CLUSTER and MAPR_CLDB_HOSTS and then execute it to start the
container
```

`mapr-docker-client.sh` contains environment variables for the image and makes it easy for you to start the container.

6. Edit the `mapr-docker-client.sh` script file. At a minimum, you must provide the `MAPR_CLUSTER` name and the `MAPR_CLDB_HOSTS` information. For example:

```
MAPR_CLUSTER=my.cluster.com
MAPR_CLDB_HOSTS=perfnode13[4-9].perf.lab
```

Note: To specify multiple entries, you can use a comma-separated list of CLDB hosts or an expression like the expressions described in "What expressions can I use to specify multiple nodes?" in the MapR Installer FAQ on page 5421.

You may wish to provide other values. You can:

- Start the FUSE client by specifying the `MAPR_MOUNT_PATH`.
- For a secure cluster, use a ticket by specifying a `MAPR_TICKETFILE_LOCATION`. For more information about security parameters, see Running the MapR PACC Using Docker on page 413.
- For secure and non-secure clusters, follow security best practices by specifying these parameters:
  - `MAPR_CONTAINER_USER`

last-updated: Apr 11, 2022

- MAPR_CONTAINER_GROUP
- MAPR_CONTAINER_UID
- MAPR_CONTAINER_GID

- Set environment variables, such as MAPR_CLASSPATH, MAPR_HOME, PATH, and others.
- Set the container time zone by specifying MAPR_TZ. The default is UTC.
- Add the POSIX mount by uncommenting the MAPR_MOUNT_PATH parameter and specifying a mount path value. The MAPR_MOUNT_PATH parameter is commented out for Mac builds but not for Linux builds. If you uncomment the parameter, you can ignore the following error message:

```
Started service mapr-posix-client-container [FAILED]
```

7. Run the mapr-docker-client.sh file to start the container:

```
./docker_images/client/mapr-docker-client.sh
```

The script uses the current user name to create a user for cluster access. This user is created so that you can run your application as a MapR client user:

```
Testing for cluster user account...

Enter MapR cluster user name: robertjones

User 'robertjones' does not exist. Creating new cluster user account...

Enter 'robertjones' uid: 502
 Enter 'robertjones' group name: users
 Enter 'robertjones' password: <password>
...Success

Configuring MapR client ( -c -C perfnode134.perf.lab -N
my.cluster.com)...

create /opt/mapr/conf/conf.old
Configuring Hadoop-2.7.0 at /opt/mapr/hadoop/hadoop-2.7.0
Done configuring Hadoop
CLDB node list: perfnode134.perf.lab:7222
Zookeeper node list:
Node setup configuration: hbinternal
Log can be found at: /opt/mapr/logs/configure.log

...Success
```

The successful completion of this step results in a user prompt that is inside the newly running container. Take care not to exit this prompt inadvertently, as doing so terminates the container.

8. Open a new session to the Docker host, and use the `docker ps` and `docker inspect` commands to inspect the container. Do not try to run the `docker ps` and `docker inspect` commands from the user prompt created in Step 7. You must open a new session to the Docker host to avoid terminating the container:

```
docker ps
docker inspect <container-run-ID>
```

Running the MapR PACC Using Docker

This section describes and provides examples for using the `docker run` command to run a pre-built MapR container image.

To run a pre-built MapR container image, you:

1. Select a PACC or an application built from the PACC.
2. Determine if your MapR cluster is secure by viewing the contents of the file `/opt/mapr/conf/mapr-clusters.conf`. For example, the following shows a non-secure cluster:

```
my.cluster.com secure=false ip-172-24-11-84
```

   If your cluster is secure, generate a MapR service ticket by following the instructions in Generating a Service Ticket on page 1428.

3. Use the `docker run` command to run the container. You can run the command from a Linux prompt, Windows command line, or a Mac terminal.
4. Verify that the container was created and is connected to the cluster.

Note: You run user-created MapR images from the `mapr-client.sh` script file. See Creating a MapR PACC Image Using mapr-setup.sh on page 409.

Using the `docker run` Command

Here is the general syntax for the `docker run` command:

```
docker run -it -e MAPR_CLUSTER=<cluster-name> -e
MAPR_TZ=<time-zone> -e MAPR_CLDB_HOSTS=<cldb-list> -e
MAPR_CONTAINER_USER=<user-name> -e MAPR_CONTAINER_PASSWORD=<password> -e
MAPR_CONTAINER_UID=<uid> -e MAPR_CONTAINER_GID=<gid> -e
MAPR_CONTAINER_GROUP=<group-name> -e MAPR_TICKETFILE_LOCATION=/tmp/
mapr_ticket -v <ticket-file-host-location>:/tmp/mapr_ticket:ro -e
MAPR_MOUNT_PATH=<path_to_fuse_mount_point> --cap-add SYS_ADMIN --cap-add
SYS_RESOURCE --device /dev/fuse --security-opt apparmor:unconfined
<image-name>
```

The following table describes the keys and variables used in the syntax:

Note: Pay special attention to the mandatory parameters. If you neglect to specify all mandatory parameters, the `docker run` command will fail.

Key	Variable	Mandatory/Optional	Description
`MAPR_CLUSTER`	`<cluster-name>`	Mandatory	The name of the MapR cluster to which the container will connect.

last-updated: Apr 11, 2022

Key	Variable	Mandatory/Optional	Description
MAPR_CLDB_HOSTS	<cldb-list>	Mandatory	CLDB host IP addresses separated by a comma. For example: `(hostname[:port_no] [,hostname[:port_no]...])`
MAPR_CONTAINER_USER	<user-name>	Mandatory	The user that the user application inside the Docker container will run as. This configuration is functionally equivalent to the Docker native `-u` or `--user`. Do not use Docker `-u` or `--user`, as the container needs to start as the `root` user to bring up FUSE before switching to the MAPR_CONTAINER_USER. The user specified here is the user that all storage operations on the MapR cluster will be performed as. Therefore, HPE recommends not using `root` or `mapr`. For secure clusters, this user must match the user in the MapR ticket passed via MAPR_TICKETFILE_LOCATION. This user also owns the `/opt/mapr` directory tree.
MAPR_CONTAINER_PASSWORD	<password>	Optional	The password of the user running inside the container. If not specified, it defaults to the <user-name>.
MAPR_TZ	<time-zone>	Optional	The time zone inside the container. For a list of time-zone settings, see this website. The default is UTC.
MAPR_CONTAINER_UID	<uid>	Optional	The UID that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a UID is not provided, the default is UID 1000. Providing a UID is strongly recommended. For secure clusters, this UID must match the UID specified in the MapR ticket file.
MAPR_CONTAINER_GID	<gid>	Optional	The GID that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a GID is not provided, the default is GID 1000. Providing a GID is strongly recommended. For secure clusters, this GID must match the GID specified in the MapR ticket file.
MAPR_CONTAINER_GROUP	<group-name>	Optional	The group that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a group name is not provided, the default is `users`. Providing a group name is strongly recommended.

last-updated: Apr 11, 2022

Key	Variable	Mandatory/Optional	Description
			For secure clusters, the group must match the group specified in the MapR ticket file.
`MAPR_TICKETFILE_LOCATION`	`/tmp/mapr_ticket`	Optional (required only for a secure cluster)	The location inside the container where the ticket file resides. For more information about MapR tickets, see Managing Tickets.
`MAPR_MOUNT_PATH`	`<path-to-fuse-mount-point>`	Optional (required only for FUSE client use)	The path to the FUSE mount point. If this parameter is not specified, the FUSE client is disabled.
`-v`	`<ticket-file-host-location>:/tmp/mapr_ticket:ro`	Optional (required only for a secure cluster)	The location of the ticket on the host where you are running the container, and the desired location of the ticket file in the Docker container. The `docker run` command maps the location on the host with the location inside the container. `ro` means read-only. `-v` refers to a volume mount. Make sure the owner and group on the host ticket file match the UID and GID specified in the MapR ticket file.
`--cap-add`	`SYS_ADMIN`	Optional (required only for FUSE use)	A parameter that is needed for the FUSE process to start inside the container, as `root` access to the FUSE device is required.
`--cap-add`	`SYS_RESOURCE`	Optional (required only for FUSE use)	A parameter that is required for the FUSE process to start.
`--device`	`/dev/fuse`	Optional (required only for FUSE use)	A parameter that is required to mount the FUSE device.
	`<image-name>`	Mandatory	The name of the container image to run. This is either the MapR Persistent Application Client Container (PACC) or a custom application container built from the PACC.
`--security-opt`	`apparmor:unconfined`	Optional (required only on Ubuntu hosts)	A parameter that is required for FUSE on Ubuntu hosts. For more information, see Docker-16429.

Example `docker run` Commands

Here are four examples for using the `docker run` command:

- Secure Cluster with FUSE-Based POSIX Client
- Secure Cluster without FUSE-Based POSIX Client
- Non-Secure Cluster with FUSE-Based POSIX Client
- Non-Secure Cluster without FUSE-Based POSIX Client

The following command generates a service ticket on the cluster or a client that is valid for 30 days. (For more `maprlogin` command examples, see maprlogin Command Examples).

```
maprlogin generateticket -type service -cluster cluster1 -duration
30:0:0 -out /tmp/bobs_ticket -user bob
```

last-updated: Apr 11, 2022

The ticket can be copied from `/tmp/bobs_ticket` to `/user/tickets/bobs_ticket` on the container host and used in the following `docker run` commands for secure clusters:

Secure Cluster with FUSE-Based POSIX Client

```
docker run -it -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_TICKETFILE_LOCATION=/tmp/mapr_ticket -v  /
user/tickets/bobs_ticket:/tmp/mapr_ticket:ro -e MAPR_MOUNT_PATH=/
mapr --cap-add SYS_ADMIN --cap-add SYS_RESOURCE --device /dev/fuse maprtech/
pacc:5.2.1_3.0_centos7
```

Secure Cluster without FUSE-Based POSIX Client

```
docker run -it -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_TICKETFILE_LOCATION=/tmp/mapr_ticket -v  /
user/tickets/bobs_ticket:/tmp/mapr_ticket:ro maprtech/pacc:5.2.1_3.0_centos7
```

Non-Secure Cluster with FUSE-Based POSIX Client

In a non-secure cluster, specifying the MAPR_CONTAINER_USER, MAPR_CONTAINER_GROUP, MAPR_CONTAINER_UID, and MAPR_CONTAINER_GID is strongly recommended, and these values must match the user credentials on the server:

```
docker run -it --cap-add SYS_ADMIN --cap-add SYS_RESOURCE --device /dev/
fuse -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_CONTAINER_GROUP=dev -e
MAPR_CONTAINER_UID=10000 -e MAPR_CONTAINER_GID=10000 -e MAPR_MOUNT_PATH=/
mapr maprtech/pacc:5.2.1_3.0_centos7
```

Non-Secure Cluster without FUSE-Based POSIX Client

In a non-secure cluster, specifying the MAPR_CONTAINER_USER, MAPR_CONTAINER_GROUP, MAPR_CONTAINER_UID, and MAPR_CONTAINER_GID is strongly recommended, and these values must match the user credentials on the server:

```
docker run -it -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_CONTAINER_GROUP=dev -e
MAPR_CONTAINER_UID=10000 -e MAPR_CONTAINER_GID=10000 maprtech/
pacc:5.2.1_3.0_centos7
```

Tip:

To re-launch a container, you can use these Docker commands:

```
# docker ps -a
# docker start <container-run-ID>
```

Use `docker start -i` if you need to start with an interactive shell.

Verifying the Launch of the MapR PACC

After running the `docker run` command, you should see the `Starting services` message. For example:

```
Starting services (mapr-posix-client-container)...
Started service mapr-posix-client-container
...Success
$
```

When the installation is successful, the client connects to the cluster, storage is mounted, and the FUSE POSIX client is started automatically. Use the `ls $MAPR_MOUNT_PATH` command to test the connection to the cluster. This command should return the cluster name. For example:

```
$ ls $MAPR_MOUNT_PATH
cluster1
```

To display some directories on the cluster, use this command:

```
$ ls $MAPR_MOUNT_PATH/cluster1
apps var user hbase opt tmp
```

MapR PACC Sample Application
These examples demonstrate how to deploy and run a MapR application into a container.

For an example of deploying and running a MapR application into a container, see:

Getting Started with a Client Container (blog)

MapR PACC Known Issues
This topic describes some known issues that you should be aware of while troubleshooting.

Issue	Description
DOC-148	On Mac OS X, using `mapr-setup.sh` to create a Docker image can generate the following error when the ping to a hostname fails: `ERROR: Hostname <hostname> cannot be resolved. Correct the problem and retry mapr-setup.sh` **Workaround:** To enable remote login on the Mac, select the **Remote Login** option in **System Preferences > Sharing**. Then retry the `mapr-setup.sh` command.

INFO-47	When running PACC or Zeppelin Docker images, starting or restarting the FUSE client incorrectly reports FAILED. Docker generates an error like the following:
	`mapr-posix-client-container [FAILED]`
	If you can access the MapR filesystem from your client, then ignore the error. You can also confirm a successful FUSE client start by checking `/opt/mapr/logs/posix-client-container.log`. The following shows a successful start:
	`Mon Oct 16 10:49:56 PDT 2017: Mounting posix-client-container / mapr --log_path /opt/mapr/logs --client_lib_path /tmp -o allow_other -o big_writes -o auto_unmount -o async_dio -o max_background=64 -o auto_inval_data at /mapr ...`
	`Starting fuse with 1 libraries`
	`Mon Oct 16 10:49:56 PDT 2017: Result:0`
	`Mon Oct 16 10:50:06 PDT 2017: Running /etc/init.d/ mapr-posix-client-container status`
	`Mon Oct 16 10:50:06 PDT 2017: posix-client-container is mounted at /mapr.`
	The error is due to incorrect handling of a MapR script's return exit code.

Running Hadoop Commands on a Mac and Windows Client

The location from which you run Hadoop commands depends on your machine.

When you run hadoop commands on the Mac and Windows client, use the Hadoop 2 version to run MapReduce version 2 applications.

last-updated: Apr 11, 2022

To run the..	Run the command from this location:
Hadoop 2 version of the command	On Windows: `%MAPR_HOME%\hadoop\hadoop-2.x.x\bin` On Mac: `/opt/mapr/hadoop/hadoop-2.x.x/bin`

On Linux installations, the installer creates symlinks to the hadoop directories by default. On Mac, you can create the symlinks. Once the symlinks are created, you can specify the version of the hadoop command as mentioned in the Hadoop command documentation.

Important: Notes Specific to Windows

- The user that runs hadoop commands from the hadoop 2 directory cannot have a space or a hyphen (-) in the username.
- The native Hadoop library is not present on Windows. Therefore, the `hadoop fs -getmerge` command is not available.

Create Symlinks to Hadoop Directories for the Mac Client
Run Hadoop commands using the hadoop2 keywords.

Perform the following steps to create hadoop2 symlinks in the `usr/local/bin` directory for a MapR client on Mac OS X:

1. Run the following commands as root to create the symlinks:

```
ln -s /opt/mapr/hadoop/hadoop-2.x.x/bin/hadoop /usr/local/bin/hadoop2
ln -s /opt/mapr/bin/hadoop /usr/local/bin/hadoop
```

Note: In the command above, replace hadoop-2.x.x with the actual hadoop 2 version number that you have installed.

2. Add the Hadoop binaries to the PATH environment variable. For example, add the following text to the user login shell script such as ~/.bashrc:

```
export PATH=/opt/mapr/bin:/opt/mapr/hadoop/hadoop-2.x.x/bin:/opt/mapr/
hadoop/hadoop-0.20.2/bin:${PATH}
```

Note: In the text above, replace hadoop-2.x.x with the actual hadoop 2 version number that you have installed.

Now, you can run hadoop commands using the `hadoop1` and `hadoop2` keywords.

Installing the MAST Gateway

Describes how to install the MapR Automated Storage Tiering (MAST) Gateway service.

The MAST Gateway acts as the centralized entry point for all the operations that need to be performed on the tiered storage. The MAST Gateway can be installed (with or without MapR File System) on specific hosts on the cluster with access to the 3rd party cloud storage (for cold tier operations) or on the edge node. Before you install the MAST Gateway, review the Pre-Installation Considerations on page 419.

See Configuring the MAST Gateway Service on page 1259 after installing the MAST Gateway.

Installing the MAST Gateway Using the MapR Installer

When you install release 6.1 or later using the MapR Installer on page 5395, select the **MapR-XD: Cloud Scale Data Platform auto-provisioning template** to install the MAST Gateway automatically on all the nodes.

Installing the MAST Gateway from the Command-line

- Run the following command on the node where you want to install the MAST Gateway:

CentOS	`yum install mapr-mastgateway`
Ubuntu	`apt-get install mapr-mastgateway`
SLES	`zypper install mapr-mastgateway`

Installing Additional MAST Gateways from the Command-line

If you install a new MAST Gateway on a cluster already performing tiering operations (using other installed MAST Gateways), perform the following steps to force CLDB to rebalance utilization of all the MAST Gateways including the newly added MAST Gateway:

1. Install the `mapr-mastgateway` package on the node.
2. Run `configure.sh` on page 2053 with the `-R` option to register the MAST Gateway with the CLDB.
   For example:

   ```
   /opt/mapr/server/configure.sh -R
   ```

   After this command runs, newly created volumes are assigned to this MAST Gateway.
3. Run the following command to force CLDB to reassign existing volumes to the least utilized MAST Gateways:

   ```
   /opt/mapr/server/mrconfig mastgateway refreshvolassignment <volume-name>
   ```

   You must run this command once for each volume to reassign. HPE recommends running this command for all volumes if MAST Gateway is either newly added to the cluster or permanently removed from the cluster. When this command runs, CLDB reassigns the volume tiering operation to the least utilized MAST Gateway, which might be the newly added MAST Gateway, to force rebalancing.

   For more information, see `mastgateway refreshvolassignment` on page 2167.

Pre-Installation Considerations

Lists the recommendations that you must follow before installing MAST Gateways.

By default, the MAST Gateway uses 16 threads for volume and file offload and recall operations and another 16 threads for handling internal operations and other operations such as reads (which triggers automatic recall requests), writes, etc. Each thread processes offload or recall of a container (associated with a volume). Each MAST Gateway can process one or more volumes (and associated containers) simultaneously depending on the number of threads available for processing the containers associated with the volumes. Each volume is assigned to a MAST Gateway for a tiering operation irrespective of the number of containers associated with the volume.

For example, suppose you have a volume with 5 containers. The MAST Gateway allocates 5 threads, one per container, to process the offload of that volume's data; the other 11 threads are available for other tiering-related operations on other tiering-enabled volumes. However, if you have a volume with 20 containers. The MAST Gateway allocates all 16 threads to process the offload of that volume's data and as threads are freed, other unprocessed containers associated with the volume are processed. Now, suppose

last-updated: Apr 11, 2022

that you have configured multiple MAST Gateways for the volume that has 20 containers. . Volume offload is then distributed among the multiple MAST gateways, leading to enhanced performance of the cluster. If you have multiple large volumes with multiple containers, MapR recommends more than one MAST Gateway to process all the containers associated with all the volumes.

If you have a limited number of nodes that can access the cold tier (because of controlled access to WAN, proxy setup, etc.), install and run MAST Gateway on only those nodes and set up proxy server parameters in the `mastgateway.conf` file. See step 5 in Configuring the MAST Gateway Service on page 1259 for more information on the configuration parameters to set for using a proxy server. On the other hand, if all the cluster nodes can access the tier, then consider the following before deploying the MAST Gateway:

1. A single MAST Gateway can offload at around 300 MB/sec at full throttle. So, compute the minimum number of MAST Gateways based on network capacity of the connection to the tier.
2. If you expect many volume offloads and recall operations to get triggered at the same time, consider installing MAST Gateways on a few more nodes or adding more MAST Gateways at a later time. See Installing the MAST Gateway on page 418 for information.

In general, you must allocate at least 2GB of memory for the MAST Gateway operations. The memory consumption can increase during heavy load. See settings for configuring memory for MAST Gateway in Step 7 for Configuring the MAST Gateway Service on page 1259.

Note: Before installing MAST Gateways, you must ensure that the system time on all the cluster nodes is the same. If the system time on CLDB and file server nodes are different, the mtime rule for migrating data might not work as intended. If you see a time skew alarm in the cluster, resolve the alarm immediately to prevent catastrophic failures.

Supported Clients

To manually perform tiering-related operations on a volume, you can use the following:

- The maprcli command
- The REST API

To manually perform tiering-related operations on a file, you can use the following:

- The FUSE-based POSIX client client
- The loopbacknfs POSIX client client
- The NFS client
- The hadoop command
- The maprcli command
- The REST API

You must use clients from MapR v6.1 for accessing tiered volumes and performing tiering operations. You cannot use mixed mode clients to access and run tiering jobs on tiered volumes.

Enabling Soft Mount and Setting the Timeout

Describes how to enable soft mount, and set the RPC timeout for MapR components.

By default, all MapR File System, MapR Database, and MapR-Streams operations never timeout as they wait (hard mount behavior) for the operation to succeed and/or the server to respond. You can configure a soft mount behavior by setting the values for the following parameters in the `core-site.xml` or `hbase-site.xml` file:

`fs.mapr.hardmount`	Specifies whether or not to enable hard mount. Value can be: • `true` - enable hard mount • `false` - disable hard mount The default value is `true`.
`fs.mapr.rpc.timeout`	This parameter is valid for MapR 6.0.0 and earlier. Specifies the RPC timeout value in seconds. The default value is 300 seconds. The value cannot be less than 30 seconds. If the value is greater than 300 seconds, TCP keepalive probes are sent to prevent the TCP socket from timing out. If value is below 300 seconds, the RPCs will timeout after the specified time.
`streams.rpc.timeout.ms`	This parameter is new as of MapR 6.0.1. Specifies the RPC timeout value in milliseconds. The default value is 300000 milliseconds. The value cannot be lower than 30000 milliseconds. If the value is greater than 300000 milliseconds, TCP keepalive probes are sent to prevent the TCP socket from timing out. If value is below 30000 milliseconds, the RPCs will timeout after the specified time.

These parameter settings affect all clients.

Note: For MapR-Streams, these parameters can be set as configuration properties when constructing the Consumer or Producer Java object. For more information, see MapR-Streams.

Enabling Soft Mount

1. Open the `core-site.xml` or `hbase-site.xml` file and add the parameter as follows:

```
<property>
  <name>fs.mapr.hardmount</name>
  <value>false</value>
  <description>enabling soft mount by setting value to false</
description>
</property>
```

2. Save and close the file.

last-updated: Apr 11, 2022

Setting RPC Timeout

1. Open the `core-site.xml` or `hbase-site.xml` file and add the parameter as follows:

   As of MapR 6.0.1:

   ```
   <property>
     <name>streams.rpc.timeout.ms</name>
     <value>300000</value>
     <description>RPC timeout value</description>
   </property>
   ```

   For MapR 6.0.0 and earlier:

   ```
   <property>
     <name>fs.mapr.rpc.timeout</name>
     <value>30</value>
     <description>RPC timeout value</description>
   </property>
   ```

2. Save and close the file.

Troubleshooting

Describes changes to `core-site.xml` file to troubleshoot issues.

fs.mapr.bind.retries Parameter

If there are issues related to unavailability of port, set the value for `fs.mapr.bind.retries` configuration parameter in `core-site.xml` file to `true`. If `true`, the client tries to bind during client initialization for 5 minutes before failing. By default, the `fs.mapr.bind.retries` configuration parameter is set to `false`.

For example, your entry in `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.bind.retries</name>
  <value>true</value>
  <description>Bind during client initialization for 5 minutes</description>
</property>
```

fs.mapr.bailout.on.library.mismatch Parameter

When running any application with older versions of the MapR JARs, the system could hang if the older JARs link to the native library installed on cluster nodes that have been updated to a newer MapR version. The `fs.mapr.bailout.on.library.mismatch` parameter detects mismatched libraries, fails the job, and logs an error message. The parameter is enabled by default. You can disable the parameter on all the YARN nodes and resubmit the job for the job to continue to run. To disable the parameter, you must set it to `false` in the `core-site.xml` file.

For example, to disable, your entry in the `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.bailout.on.library.mismatch</name>
  <value>false</value>
  <description>Disabling to continue running jobs</description>
</property>
```

libMapRClient.so Binary

The `libMapRClient.so` binary is in `/opt/mapr/lib` directory and also bundled in `maprfs-XXX.jar` file. All the applications that include the JAR also have `libMapRClient.so` binary. If there are multiple `libMapRClient.so` on a machine and if you know the location of all the JARs, you can run the following commands to check the mapr version of a binary:

```
# jar tvf mapr-<XXX>.jar | grep libMapRClient.so
# jar xvf mapr-<XXX>.jar com/mapr/fs/native/Linux/x86_64/libMapRClient.so
# cd com/mapr/fs/native/Linux/x86_64/
# strings libMapRClient.so | grep mapr-version
# cd /opt/mapr/lib
# strings libMapRClient.so | grep mapr-version
```

This is useful in determining if there are old binaries installed on the system.

Setting Up the Control System

Describes how to configure and access the Control System.

The Control System allows you to manage the cluster (including nodes, volumes, users, and alarms) through a comprehensive graphical user interface with all the functionality of the command line or REST APIs.

Installing the Web Server and API Server

In prior releases, the `mapr-webserver` package contained both the Control System UI static files and the server running the Java application. Starting from v6.0, the UI static files are in `mapr-webserver`. The `mapr-apiserver` runs the server that sends the queries. The apiserver allows you to perform cluster administration programmatically.

When you install `mapr-webserver`, the `mapr-apiserver` is automatically installed because of the dependency on the `mapr-apiserver` to perform the queries. If `mapr-webserver` is installed, you can use the graphical user interface to manage your cluster. You can also install the `mapr-apiserver` independently to run APIs or web clients that query or programmatically access MapR File System, MapR Database, and other components; however, without the webserver, the Control System will not be available on this node to perform administrative tasks using the UI.

To install the webserver and/or apiserver, see Installing MapR and MapR Ecosystem Components on page 128.

- If you install using the MapR Installer, by default, the installer selects one instance of the `mapr-webserver` and `mapr-apiserver` to install. You can specify additional webserver and/or apiserver instances to install in the *Configure Service Layout* page.
- If you install manually, run the appropriate command on the node to install the `mapr-webserver` and/or `mapr-apiserver` packages. For more information on the command to run, see Step 3: Install Cluster Service Packages on page 150. After you install the packages, run the following commands:
  - `/opt/mapr/server/configure.sh -R`
  - `maprcli node services -nodes <nodes> -name apiserver -action start`

For the purposes of high availability, the recommendation is to run at least 2 instances of the webserver and 2 instances of the apiserver.

Configuring Metrics and Logging to Enable Metrics Visualization

During installation using the MapR Installer, you can configure metrics and logging using settings on the **Monitoring** page of the MapR Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the panes on the Control System. If you did not install metrics collection or logging during your initial installation, you can add it later by selecting the feature during an Incremental Install.

Configuring SameSite Cookie Support

The SameSite attribute of the Set-Cookie HTTP response header allows you to declare if your cookie should be restricted to a first-party or same-site context.

Edit the following section in the `/opt/mapr/apiserver/conf/web.xml` file to set the SameSite cookie:

```
<session-config>
   <cookie-config>
     <http-only>true</http-only>
     <max-age>86400</max-age>
     <name>MAPR.APISERVER.JSESSIONID</name>
     <secure>true</secure>
     <comment>__SAME_SITE_LAX__</comment>
   </cookie-config>
   <session-timeout>30</session-timeout>
 </session-config>
```

Set it to one of the following values:

_SAME_SITE_STRICT_	Cookies will only be sent in a first-party context and not be sent along with requests initiated by third party websites.
_SAME_SITE_LAX_	Cookies are allowed to be sent with top-level navigations and will be sent along with GET request initiated by the third party website. This is the default value.
_SAME_SITE_NONE_	Cookies will be sent in all contexts, that is, sending cross-origin is allowed.

For more information, see SameSite cookies.

Browser Compatibility

The Control System is web-based, and works with the following browsers:

- Chrome 58 and later
- Safari 11.x for v6.0.1

  Safari 10.x for v6.0

  Note: Safari Private Window is not supported.
- Firefox 53 and later
- Microsoft Edge 15, 16, and 17

Note: If you encounter the following error on Firefox 79 and above:

```
Secure Connection Failed
Error code: SEC_ERROR_REUSED_ISSUER_AND_SERIAL
```

then delete the Control System certificates as described to resolve this error.

Launching the Control System

To use the Control System, navigate to the host that is running the WebServer in the cluster. Control System access to the cluster is typically using HTTP on port 8080 or using HTTPS on port 8443. You should disable pop-up blockers in your browser to allow MapR to open help links in new browser tabs.

The first time you open the Control System using HTTPS from a new browser, the browser alerts you that the security certificate is unrecognized. This is normal behavior for a new connection. Add an exception in your browser to allow the connection to continue.

Configuring the Control System

Describes the configuration of Control System properties.

The Control System properties can be configured in the `/opt/mapr/apiserver/conf/properties.cfg` file. For example:

```
ojai.cache.size=64
mapr.webui.https.port=8443
doc.url=https://docs.datafabric.hpe.com/
proxy.zkservices=elasticsearch,opentsdb
activity.metrics.thread.pool.size=10
```

The properties are as follows:

activity.metrics.thread.pool.size

Default Value: 10

Description: Denotes the number of threads used to query table metrics.

authentication.pam.service

Default Value: `mapr-admin`

Description: The file to use for PAM authentication.

doc.url

Default Value: https://docs.datafabric.hpe.com/

Description: The URL to the MapR documentation.

log.sensitive.keys

Default Value: Not Applicable

Description: The properties to exclude from the logs. For example, to hide SMTP or LDAP passwords in the logs, specify the properties for the passwords as follows:

```
log.sensitive.keys=<mapr.smtp.sender.password>;<mapr.ldap.binddnpasswd>
```

If you do not specify this property, passwords are not hidden in the logs.

mapr.rest.auth.methods

Default Value: `basic`

Description: The authentication methods to use for MapR REST calls. Add `kerberos` to this setting to enable SPNEGO.

mapr.webui.http.port

Default Value: 8081

last-updated: Apr 11, 2022

	Description: The port to use to connect to the Control System.
mapr.webui.https.port	*Default Value:* 8443 *Description:* The port to use to securely connect to the Control System.
ojai.cache.size	*Default Value:* 64 *Description:* The size of the cache in MB that the OJAI controller uses.
proxy.zkservices	*Default Value:* `elasticsearch,opentsdb` *Description:* The proxy to use for ZooKeeper services
requestHeaderSize	*Default Value:* 8KB *Description:* The size of the request header.
ssl.exclude-ciphers	*Default Value:* `TLS_DHE.,TLS_EDH` *Description:* The encryption ciphers that should *not* be used for communication.
ssl.exclude-protocols	*Default Value:* `SSLv3,TLSv1,TLSv1.1` *Description:* The security protocols that should *not* be used for communication.
ssl.keystore	*Default Value:* `/opt/mapr/conf/ssl_keystore` *Description:* The path to the SSL keystore.
ssl.truststore	*Default Value:* `/opt/mapr/conf/ssl_truststore` *Description:* The path to the SSL truststore.

Note: You must restart the apiserver for the changes to take effect. For example, run the following command to restart the apiserver:

```
maprcli node services -action restart -name apiserver -nodes `hostname`
```

Configuring Authentication

Lists the authentication methods supported by the Control System and the apiserver.

Both the Control System and apiserver (that processes REST API calls) require one of the following method of authentication:

- Basic authentication (with a username and password) on secure and non-secure clusters. Refer to documentation for information on setting up username, password, and permissions for accessing the Control System and REST API calls.
- Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO) on secure clusters to authenticate REST calls to the Control System and access the resources directly. Refer to documentation for information on configuring SPNEGO for the Control System and REST API calls.
- Pluggable Authentication Modules (PAM) for password verification. Refer to documentation for information on configuring PAM for the Control System and REST API calls.

For information on using the Control System, `maprcli` commands, and the REST APIs, refer to topics under 6.1 Administration on page 752.

Configuring Impersonation

Lists the process to permit the `mapr` user to impersonate other users.

last-updated: Apr 11, 2022

Impersonation, also known as identity assertion, is one user (the `mapr` super user) accessing data and submitting jobs on behalf of another user.

Note: Only the `mapr` user can impersonate other users.

For secure clusters, to have a request processed as an impersonated user:

1. The user submitting the request must be the `mapr` user and the request should have the HTTP header X-MAPR-IMPERSONATED-USER, passed in the request.

   The value of the header is the username of the impersonated user.

2. The header must also include `"Authorization: Basic <base64_encoding_of_userID:pwd>"` for the apiserver to authorize the request.

   Here userID is `mapr` and the password is the PAM Linux password for `mapr` user on the node on which the apiserver is running.

For example:

```
curl -XPOST -H "Accept: application/json" -H  "X-MAPR-IMPERSONATED-USER:
m7user1" -H "Authorization: Basic bWFwcjptYXBy" -k https://10.20.30.40:8443/
rest/table/create?path=%2Ftmp%2FsrcC -v
```

For a non-secure cluster, MapR requires a file for the user to impersonate in the `/opt/mapr/conf/proxy` directory. The logged-in user is allowed to impersonate only if the `/opt/mapr/conf/proxy/<user_to_impersonate>` file is present. By default, this file is created during installation for the `mapr` user and the `root` user. If the file is not present, HTTP 403 is returned to the client if the client attempts to impersonate a user who does not have the file.

Migrating to MapR

Provides instructions for migrating business-critical data and applications from an Apache Hadoop cluster to a MapR cluster.

This guide provides instructions for migrating business-critical data and applications from an Apache Hadoop cluster to a MapR cluster.

The MapR distribution is 100% API-compatible with Apache Hadoop, and migration is a relatively straightforward process. The additional features available in MapR provide new ways to interact with your data. In particular, MapR provides a fully read/write storage layer that can be mounted as a filesystem via NFS, allowing existing processes, legacy workflows, and desktop applications full access to the entire cluster.

Migration consists of planning, deployment, and migration of components, applications, data, and nodes.

See the https://docs.datafabric.hpe.com/home/ReleaseNotes/c_relnotes_intro.html for up-to-date information about migration issues.

Planning and Initial Deployment

There are a number of considerations to take into account before migrating from Apache Hadoop to MapR Hadoop.

The first phase of migration is planning. In this phase you will identify the requirements and goals of the migration, identify potential issues in the migration, and define a strategy.

The requirements and goals of the migration depend on a number of factors:

- Data migration: can you move your datasets individually, or must the data be moved all at once?

last-updated: Apr 11, 2022

- Downtime: can you tolerate downtime, or is it important to complete the migration with no interruption in service?
- Customization: what custom patches or applications are running on the cluster?
- Storage: is there enough space to store the data during the migration?

The MapR Hadoop distribution is 100% plug-and-play compatible with Apache Hadoop, so you do not need to make changes to your applications to run them on a MapR cluster. MapR Hadoop automatically configures compression and memory settings, task heap sizes, and local volumes for shuffle data.

Initial Deployment

The initial MapR deployment phase consists of installing, configuring, and testing the MapR cluster and any ecosystem components (such as Hive or Pig) on an initial set of nodes. Once you have the MapR cluster deployed, you will be able to begin migrating data and applications.

To deploy the MapR cluster on the selected nodes, see the Installing MapR and MapR Ecosystem Components on page 128

Component Migration

This section describes how to migrate customized components to MapR Hadoop.

MapR Hadoop features the complete Hadoop distribution including components such as Hive. There are a few things to know about migrating Hive, or about migrating custom components you have patched yourself.

Custom Components

If you have applied your own patches to a component and wish to continue to use that customized component with the MapR distribution, you should keep the following considerations in mind:

- **MapR libraries**: All Hadoop components must point to MapR for the Hadoop libraries. Change any absolute paths. Do not hardcode `hdfs://` or `maprfs://` into your applications. This is also true of Hadoop ecosystem components that are not included in the MapR Hadoop distribution (such as Cascading). For more information see Working with MapR File System.
- **Component compatibility**: Before you commit to the migration of a customized component (for example, customized HBase), check the MapR release notes to see if HPE has issued a patch that satisfies your business requirements. HPE publishes a list of Hadoop common patches and MapR patches with each release and makes those patches available for HPE customers to take, build, and deploy.
- **ZooKeeper coordination service**: Certain components depend on ZooKeeper. When you migrate your customized component from the HDFS cluster to the MapR cluster, make sure it points correctly to the MapR ZooKeeper service.

Hive Migration

You can continue to use Hive tables in a MapR cluster.

Hive facilitates the analysis of large datasets stored in the Hadoop filesystem by organizing that data into tables that can be queried and analyzed using a dialect of SQL called HiveQL. The schemas that define these tables and all other Hive metadata are stored in a centralized repository called the *metastore*.

If you would like to continue using Hive tables developed on an HDFS cluster in a MapR cluster, you can import Hive metadata from the metastore to recreate those tables in MapR. Depending on your needs, you can choose to import a subset of table schemas or the entire metastore in one go:

last-updated: Apr 11, 2022

- **Importing table schemas into a MapR cluster**: Use this procedure to import a subset of the Hive metastore from an HDFS cluster to a MapR cluster. This method is preferred when you want to test a subset of applications using a smaller subset of data.
- **Importing an entire Hive metastore into a MapR cluster**: Use the following procedure to import an entire Hive metastore from an HDFS cluster to a MapR cluster. This method is preferred when you want to test all applications using a complete dataset. You will need to redirect all of links that formerly pointed to the HDFS (`hdfs://<namenode>:<port number>/<path>`) to point to MapR File System (`maprfs:///<path>`).

  MySQL is a very popular choice for the Hive metastore and is used in the following example. If you are using another RDBMS, consult the relevant documentation.

1. Ensure that both Hive and your database are installed on one of the nodes in the MapR cluster. For step-by-step instructions on setting up a standalone MySQL metastore, see Using MySQL for the Hive Metastore.
2. On the HDFS cluster, back up the metastore to a file.

   ```
   mysqldump [options] \--databases db_name... > filename
   ```

3. Ensure that queries in the dumpfile point to the MapR File System rather than HDFS. Search the dumpfile and edit all of the URIs that point to `hdfs://` so that they point to `maprfs:///` instead.
4. Import the data from the dumpfile into the metastore running on the node in the MapR cluster:

   ```
   mysql [options] db_name < filename
   ```

Using Hive with MapR volumes

MapR File System does not allow moving or renaming across volume boundaries. Be sure to set the Hive Scratch Directory and Hive Warehouse Directory in the same volume where the data for the Hive job resides before running the job. For more information, see How Hive Handles Scratch Directories on MapR in Hive Directories.

HBase Migration

The MapR Hadoop distribution includes HBase, with a number of MapR-exclusive enhancements.

HBase is the Hadoop database, which provides random, real-time read/write access to very large datasets. The MapR Hadoop distribution includes HBase and is fully integrated with MapR enhancements for speed, usability, and dependability. MapR provides a volume (normally mounted at `/hbase`) to store HBase data.

- **HBase bulk load jobs**: If you are currently using HBase bulk load jobs to import data into the HDFS, make sure to load your data into a path under the `/hbase` volume.
- **Compression**: The HBase write-ahead log (WAL) writes many tiny records, and compressing it would cause massive CPU load. Before using HBase, turn off MapR compression for directories in the HBase volume.

Migrating between Apache HBase and MapR Database Binary Tables

You can use the CopyTable tool to migrate data from an Apache HBase table to a MapR Database binary table.

MapR Database tables can be parsed by the Apache CopyTable tool (`org.apache.hadoop.hbase.mapreduce.CopyTable`).

Before You Start

Before migrating your tables to another platform, consider the following points:

last-updated: Apr 11, 2022

- **Schema Changes**. Apache HBase and MapR Database binary tables have different limits on the number of column families. When you are migrating to MapR Database binary tables, you may be interested in changing your table's schema to take advantage of the increased availability of column families.
- **API Mappings**: When you are migrating from Apache HBase to MapR Database tables, examine your current HBase applications to verify the APIs and HBase Shell commands used are fully supported.
- **Namespace Mapping**: If the migration will take place over a period of time, be sure to plan your table namespace mappings in advance to ease the transition. See Mapping to HBase Table Namespaces on page 430 for more information.
- **Implementation Limitations**: MapR Database binary tables do not support HBase coprocessors. If your existing Apache HBase installation uses coprocessors, plan any necessary modifications in advance. MapR Database binary tables support a subset of the regular expressions supported in Apache HBase. Check your existing workflow and HBase applications to verify you are not using unsupported regular expressions.

When migrating to MapR Database binary tables, change your Apache HBase client to the MapR client by installing the version of the `mapr-hbase` package that matches the version of Apache HBase on your source cluster.

See Installing MapR Software for information about MapR installation procedures, including setting up the proper repositories.

Mapping to HBase Table Namespaces

This section describes mapping table namespaces between Apache HBase tables and MapR Database binary tables.

The MapR implementations of the HBase Java API and libhbase differentiate between Apache HBase tables and MapR Database tables according to table names. In certain cases, such as migrating code from Apache HBase tables to MapR Database tables, users need to force the API they are using to access a MapR Database table, even though the table name could map to an Apache HBase table. The `hbase.table.namespace.mappings` property allows you to map Apache HBase table names to MapR Database tables. This property is typically set in the configuration file `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml`.

In general, if a table name includes a slash (`/`), the name is assumed to be a path to a MapR Database table, because slash is not a valid character for Apache HBase table names. In the case of "flat" table names without a slash, namespace conflict is possible, and you might need to use table mappings.

Table Mapping Naming Conventions

A table mapping takes the form *`name`*`:`*`map`*, where *`name`* is the table name to redirect and *`map`* is the modification made to the name. The value in *`name`* can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

last-updated: Apr 11, 2022

Mappings and Table Listing Behaviors

When you use the `list` command without specifying a directory, the command's behavior depends on two factors:

- Whether a table mapping exists
- Whether Apache HBase is installed and running

Here are three different scenarios and the resulting `list` command behavior for each.

- There is a table mapping for *, as in `*:/tables`. In this case, the `list` command lists the tables in the mapped directory.
- There is no mapping for *, and Apache HBase is installed and running. In this case, the `list` command lists the HBase tables.
- There is no mapping for *, and Apache HBase is not installed or is not running.
  - For HBase 0.98.12, the shell will try to connect to an HBase cluster but it will return an error instead.
  - For HBase 1.1 or above, if the `mapr.hbase.default.db` property in the hbase-site.xml is set to `hbase`, the list command will return an error stating that HBase is not available. If the `mapr.hbase.default.db` property is set to `maprdb`, list command will list the MapR Database tables under the user's home directory.

Example 1: Map all HBase tables to MapR Database tables in a directory

In this example, any flat table name `foo` is treated as a MapR Database table in the directory `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>*:/tables_dir</value>
        </property>
```

Example 2: Map specific Apache HBase tables to specific MapR Database tables

In this example, the Apache HBase table name `mytable1` is treated as a MapR Database table at `/user/aaa/mytable1`. The Apache Hbase table name `mytable2` is treated as a MapR Database table at `/user/bbb/mytable2`. All other Apache HBase table names are treated as stock Apache HBase tables.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/</value>
        </property>
```

Example 3: Combination of specific table names and wildcards

Mappings are evaluated in order. In this example, the flat table name `mytable1` is treated as a MapR Database table at `/user/aaa/mytable1`. The flat table name `mytable2` is treated as a MapR Database table at `/user/bbb/mytable2`. Any other flat table name `foo` is treated as a MapR Database table at `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/,*:/tables_dir</value>
        </property>
```

Compression Mappings

MapR Database binary tables support the LZ4, LZF, and ZLIB compression algorithms.

When you create a MapR Database binary table with the Apache HBase API or the HBase shell and specify the LZ4, LZO, or SNAPPY compression algorithms, the table uses the LZ4 compression algorithm.

When you describe a MapR Database binary table's schema through the HBase API, the LZ4 and OLDLZF compression algorithms map to the LZ4 compression algorithm.

Copying Data

Note: The Apache CopyTable tool launches a MapReduce application. The nodes on your cluster must have the correct version of the `mapr-hbase` package installed. To ensure that your existing HBase applications and workflow work properly, install the `mapr-hbase` package that provides the same version number of HBase as your existing Apache HBase.

Launch the CopyTable tool with the following command, specifying the full destination path of the table with the `--new.name` parameter:

```
hbase org.apache.hadoop.hbase.mapreduce.CopyTable
-Dhbase.zookeeper.quorum=<ZooKeeper IP Address>
-Dhbase.zookeeper.property.clientPort=5181 --new.name=/user/john/foo/
mytable01
```

This example migrates the existing Apache HBase table `mytable01` to the MapR Database tables `/user/john/foo/mytable01`. On the node in the MapR cluster where you will launch the CopyTable tool, modify the value of the `hbase.zookeeper.quorum` property in the `hbase-site.xml` file to point at a ZooKeeper node in the source cluster. Alternately, you can specify the value for the `hbase.zookeeper.quorum` property from the command line. This example specifies the value in the command line.

1. Create the destination table. This example uses the HBase shell. The maprcli and the Control System are also viable methods.

   ```
   [user@host]$ hbase shell
   HBase Shell; enter 'help<RETURN>' for list of supported commands.
   Type "exit<RETURN>" to leave the HBase Shell

   hbase(main):001:0> create '/user/john/foo/mytable01', 'usernames',
   'userpath'
   0 row(s) in 0.2040 seconds
   ```

2. Exit the HBase shell.

   ```
   hbase(main):002:0> exit
   [user@host]
   ```

3. From the command line, use the CopyTable tool to migrate data.

   ```
   [user@host] hbase
   org.apache.hadoop.hbase.mapreduce.CopyTable -Dhbase.zookeeper.quorum=zkno
   de1,zknode2,zknode3 --new.name=/user/john/foo/mytable01 mytable01
   ```

Verifying Migration

After copying data to the new tables, verify that the migration is complete and successful. In increasing order of complexity:

1. Verify that the destination table exists. From the HBase shell, use the `list` command, or use the `hadoop fs -ls /user/john/foo` command from a Linux prompt:

```
hbase(main):006:0> list '/user/john/foo'
TABLE
/user/john/foo/mytable01
1 row(s) in 0.0770 seconds
```

2. Check the number of rows in the source table against the destination table with the `count` command:

```
hbase(main):005:0> count '/user/john/foo/mytable01'
30 row(s) in 0.1240 seconds
```

3. Hash each table, then compare the hashes.

Decommissioning Apache HBase Nodes

To decommission nodes running Apache HBase, follow these steps for each node:

1. From the HBase shell, disable the Region Load Balancer by setting the value of `balance_switch` to `false`:

```
hbase(main):001:0> balance_switch false
```

2. Leave the HBase shell by typing `exit`.

3. Run the *graceful stop* script to stop the HBase RegionServer:

Warning: The `graceful_stop.sh` script does not look up the hostname for an IP number. Do not pass an IP number to the script. Check the list of RegionServers in the Apache HBase Master UI to determine the hostname for the node being decommissioned.

```
[user@host] cd /opt/mapr/hbase/hbase-<hbase-version>
./bin/graceful_stop.sh <hostname>
```

Application Migration

Before you migrate your applications to the MapR Hadoop distribution, consider testing your applications using a small subset of data.

In this phase, you will migrate your applications to the MapR cluster test environment. The goal of this phase is to get your applications running smoothly on the MapR cluster using a subset of data. Once you have confirmed that all applications and components are running as expected you can begin migrating your data.

Migrating your applications from HDFS to MapR is relatively easy. MapR Hadoop is 100% plug-and-play compatible with Apache Hadoop, so you do not need to make changes to your applications to run them on a MapR cluster.

Application Migration Guidelines Keep the following considerations in mind when you migrate your applications:

last-updated: Apr 11, 2022

- **MapR Libraries**: Ensure that your applications can find the libraries/configs it is expecting. Make sure the java classpath includes the path to `maprfs.jar` and the `java.library.path` includes `libMapRClient.so`
- **MapR Storage**: Every application must point to MapR File System (`maprfs:///`) rather than the HDFS (`hdfs://`). If your application uses fs.default.name then it will work automatically. If you have hardcoded HDFS links into your applications, you must redirect those links so they point to MapR File System. Setting a default path of `maprfs:///` tells your applications to use the cluster specified in the first line of mapr-clusters.conf. You can also specify a specific cluster with `maprfs:///mapr/<cluster name>/`.
- **Permissions**: The distcp command does not copy permissions; permissions defined in HDFS do not transfer automatically to MapR File System. MapR uses a combination of access control lists (ACLs) to specify cluster or volume-level permissions and file permissions to manage directory and file access. You must define these permissions in MapR when you migrate your customized components, applications, and data. For more information, see Managing Permissions.
- **Memory**: Remove explicit memory settings defined in your applications. If memory is set explicitly in the application, the jobs may fail after migration to MapR.

Generally, the best approach to migrating your applications to MapR is to import a small subset of data and test and tune your application using that data in a test environment before you import your production data.

The following procedure offers a simple roadmap for migrating and running your applications in a MapR cluster test environment.

1. Copy over a small amount of data to the MapR cluster. Use the hadoop distcp hftp command to copy over a small number of files:

   ```
   $ hadoop distcp hftp://namenode1:50070/foo maprfs:///bar
   ```

   You must specify the namenode IP address, port number, and source directory on the HDFS cluster. For more information, see Copying Data from Apache Hadoop
2. Run the application.
3. Add more data and test again.
4. When the application is running to your satisfaction, use the same process to test and tune another application.

Data Migration

After you migrate your applications to the MapR cluster, you can copy your data from the Apache Hadoop HDFS to the MapR cluster.

Once you have installed and configured your MapR cluster in a test environment and migrated your applications to the MapR cluster you can begin to copy over your data from the Apache Hadoop HDFS to the MapR cluster.

Use any of the following methods to copy data from an HDFS cluster to a MapR cluster:

Method	Description
hdfs:// protocol	You can use the hadoop distcp command with the `hdfs://` protocol to copy data from an HDFS cluster into a MapR cluster. Use this method if the HDFS cluster and the MapR cluster use the same RPC protocol version. For all other scenarios, use the `webhdfs://` protocol or NFS gateway to copy data to a MapR cluster.

Method	Description
webhdfs:// protocol	You can use the hadoop distcp command with the `webhdfs://` protocol to copy data from an HDFS cluster into a MapR cluster.
NFS	You can mount a MapR cluster to an HDFS cluster via NFS mount and then use the hadoop distcp command to copy data between the two clusters.

Using the hdfs:// Protocol
This section describes how to copy data from an HDFS cluster to a MapR cluster using the hdfs:// protocol.

Before you can copy data from an HDFS cluster to a MapR cluster using the `hdfs://` protocol, you must configure the MapR cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a MapR Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and MapR clusters and then complete the steps listed under Verifying Access to an HDFS Cluster.

You also need the following information:

- `<NameNode>`: the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>`: the port for connecting to the NameNode in the HDFS cluster
- `<HDFS path>`: the path to the HDFS directory from which you plan to copy data
- `<MapR-FS path>`: the path in the MapR cluster to which you plan to copy HDFS data
- `<file>`: a file in the HDFS path

To copy data from HDFS to MapR File System using the `hdfs://` protocol, complete the following steps:

1. Run the following hadoop command to determine if the MapR cluster can read the contents of a file in a specified directory on the HDFS cluster:

   ```
   hadoop fs -cat <NameNode>:<NameNode port>/<HDFS path>/<file>
   ```

   For example:

   ```
   hadoop fs -cat hdfs://nn1:8020/user/sara/contents.xml
   ```

2. If the MapR cluster can read the contents of the file, run the distcp command to copy the data from the HDFS cluster to the MapR cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> maprfs://
   <MapR-FS path>
   ```

   For example:

   ```
   hadoop distcp hdfs://nn1:8020/user/sara maprfs:///user/sara
   ```

   Note the required triple slashes in `maprfs:///`

Using the webhdfs:// Protocol
This section describes how to copy data from an HDFS cluster to a MapR cluster using the webhdfs:// protocol.

Before you can copy data from an HDFS cluster to a MapR cluster using the `webhdfs://` protocol, you must configure the MapR cluster to access the HDFS cluster. To do this, complete the steps listed in

Configuring a MapR Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and MapR clusters and then complete the steps listed under Verifying Access to an HDFS Cluster.

To copy data from HDFS to MapR File System using the `webhdfs://` protocol, complete the following steps:

1. The HDFS cluster must have WebHDFS enabled. Verify that the following parameter exists in the `hdfs-site.xml` file and that the value is set to `true`.

   ```
   <property>
   <name>dfs.webhdfs.enabled</name>
   <value>true</value>
   </property>
   ```

   You also need the following information:

   - `<NameNode>`: the IP address or hostname of the NameNode in the HDFS cluster
   - `<NameNode HTTP Port>`: the HTTP port on the NameNode in the HDFS cluster
   - `<HDFS path>`: the path to the HDFS directory from which you plan to copy data
   - `<MapR-FS path>`: the path in the MapR cluster to which you plan to copy HDFS data

2. Run the following command from a node in the MapR cluster to copy data from HDFS to MapR File System using `webhdfs://`:

   ```
   hadoop distcp webhdfs://<NameNode>:<NameNode HTTP Port>/<HDFS path>
   maprfs:///<MapR-FS path>
   ```

   For example:

   ```
   hadoop distcp webhdfs://nn2:50070/user/sara maprfs:///user/sara
   ```

   Note the required triple slashes in `maprfs:///`.

Using NFS

This section describes how to copy data from an HDFS cluster to a MapR cluster using NFS.

If NFS is installed on the MapR cluster, you can mount the MapR cluster to the HDFS cluster and then copy files from one cluster to the other using `hadoop distcp`. If you do not have NFS installed and a mount point configured, see Accessing Data with NFS and Setting Up MapR NFS.

To perform a copy using `distcp` via NFS, you need the following information:

- `<MapR NFS Server>`: the IP address or hostname of the NFS server in the MapR cluster
- `<maprfs_nfs_mount>`: the NFS export mount point configured on the MapR cluster; default is /mapr
- `<hdfs_nfs_mount>`: the NFS mount point configured on the HDFS cluster
- `<NameNode>`: the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>`: the port on the NameNode in the HDFS cluster
- `<HDFS path>`: the path to the HDFS directory from which you plan to copy data
- `<MapR-FS path>`: the path in the MapR cluster to which you plan to copy HDFS data

To copy data from HDFS to MapR File System using NFS, complete the following steps:

1. Issue the following command to mount the MapR cluster to the HDFS NFS mount point:

   ```
   mount <MapR NFS Server>:/<maprfs_nfs_mount> /<hdfs_nfs_mount>
   ```

   For example:

   ```
   mount 10.10.100.175:/mapr /hdfsmount
   ```

2. Issue the following command to copy data from the HDFS cluster to the MapR cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> file:///
   <hdfs_nfs_mount>/<MapR-FS path>
   ```

   For example:

   ```
   hadoop distcp hdfs://nn1:8020/user/sara/file.txt file:///hdfsmount/user/
   sara
   ```

3. Issue the following command from the MapR cluster to verify that the file was copied to the MapR cluster:

   ```
   hadoop fs -ls /<MapR-FS path>
   ```

   For example:

   ```
   hadoop fs -ls /user/sara
   ```

Node Migration

You can add decommissioned HDFS data nodes to your MapR cluster.

Once you have loaded your data and tested and tuned your applications, you can add decommission HDFS data-nodes and add them to the MapR cluster.

This is a three-step process:

- **Decommissioning nodes on an Apache Hadoop cluster**: The Hadoop decommission feature enables you to gracefully remove a set of existing data-nodes from a cluster while it is running, without data loss. For more information, see the Hadoop Wiki FAQ.
- **Meeting minimum hardware and software requirements**: Ensure that every data-node you want to add to the MapR cluster meets the hardware, software, and configuration requirements.
- **Adding Nodes to a MapR cluster**: You can add those data-nodes to the MapR cluster. For more information, see Adding Nodes to a Cluster.

Applying a Patch

You can apply a patch by using the MapR Installer, by using the command line (a manual process), or by using an Installer Stanza.

Downloading a Patch

MapR patches can be downloaded from a secure FTP server.

To download the latest MapR patches for supported versions:

last-updated: Apr 11, 2022

1. Navigate to the secure FTP server at https://sftp.mapr.com.
2. Log in using `maprpatches` for your **Login ID**. Leave the **Password** field blank.
3. Click **Login**.

For patch information, visit the Support notices of known issues, some with patches or workarounds.

Applying a Patch Using the MapR Installer

The MapR Installer automates much of the work involved in applying MapR patches.

For clusters with many nodes, using the MapR Installer can save you time and reduce the likelihood of errors when compared with other methods of applying patches. With the MapR Installer, you can apply a patch during a:

- New installation of MapR software
- Maintenance update
- Version upgrade
- Incremental Install

Note: Applying a patch using the MapR Installer is an offline update (not a rolling update). Also, you cannot use the MapR Installer to apply a patch to an edge node or a client node.

To apply a patch using the MapR Installer:

1. Obtain the patch from MapR Support. See Applying a Patch on page 437.
2. Ensure that the cluster is ready for a patch update. For more information, see Verify Cluster Readiness for a Patch. Then return to this procedure.
3. Start the MapR Installer. For more information, see Installer.
4. Select the **Patch file** option:

If . . .	Then . . .
MapR software is not yet installed on the cluster (new installation)	Click the **Patch file** option under the **MapR Version** field on the **Version & Services** page.
MapR software is already installed (maintenance update or version upgrade)	Do one of the following: • Click the **Maintenance Update** button. If you are performing a maintenance update, the Patch file option appears on the **Maintenance Update** page. For more information, see Performing a Maintenance Update on page 5447. • Click the **Version Upgrade** button on the MapR Installer page. If you are performing a version upgrade, the **Patch file** option appears under the **MapR version** on the **Upgrade Version & Services** page. • Click the **Incremental Install** button. The Patch file option appears on the **Version & Services** page.

The installer prompts you to select the patch.

5. Select the patch file, and click **Choose**. The installer verifies that the core version of the installed core (or the core version you are upgrading to) matches the core version of the patch file name. The installer also ensures that the patch file starts with *mapr-patch*, ends with *rpm* or *deb*, and does not include text such as *client* or *nfs* (to ensure that it is a core patch file). The installer does not ensure that the patch you are applying is a patch number higher than the one that is already installed (if a patch is already installed).

6. Make other installer selections as needed. The patch is uploaded and will be installed in the background after the installer has applied any core packages.

   Note: The next time you run the MapR Installer on the cluster, the installer shows the updated patch version on the **Incremental Install** page or, if you enable patch installation, on the **Version Upgrade** or **Maintenance Update** page.

Applying a Patch Manually

MapR patches are version-specific and cumulative. Each patch contains the code fixes that were included in the previous patch for that release version.

Before applying a patch, note these considerations:

- For patch-download information, see Applying a Patch on page 437.
- The steps for patching the Control System are different from the steps for patching MapR core. See Special Considerations for the Control System Patches on page 444.
- You can also apply a patch using the MapR Installer. See Applying a Patch Using the MapR Installer on page 438.
- A patch for a given software version can be removed, and an older patch for the same MapR software version can be installed. However, rolling back a cluster from a newer release version to an older version is not supported.
- Different types of patches are available, and some patches can only be installed on specific nodes:

Patch Type	Install on These Nodes
`mapr-patch`	All control and data nodes
`mapr-patch-client`	MapR client nodes only
`mapr-patch-loopbacknfs`	Any node where POSIX is supported
`mapr-patch-nfs4server`	Any node where NFSv4 is supported
`mapr-patch-posix-client-basic`	Any node where FUSE POSIX is supported
`mapr-patch-posix-client-platinum`	Any node where FUSE POSIX is supported

Applying a patch is a three-step process:

1. Step 1: Verify Cluster Readiness for a Patch on page 440

last-updated: Apr 11, 2022

2. Step 2: Apply the Patch to Data Nodes on page 441
3. Step 3: Apply the Patch to CLDB Nodes on page 442

When you apply a patch to the cluster, the patched files along with original files (non-patched) are copied to the `/opt/mapr/.patch` folder. In the `/opt/mapr/.patch` folder, the file ending with `.0` is the original file (non-patched) and the file ending with `.<patch_number>` is the patched version. Therefore, if there is a file under `/opt/mapr/.patch/lib/`, you can compare that with the corresponding file under `/opt/mapr/lib/` by using the `md5sum` command to verify that the patch was successfully deployed.

If you need more information or if you encounter any problems with patch installation, contact HPE Support.

Step 1: Verify Cluster Readiness for a Patch
Before you apply a patch, check that the cluster is ready for a patch to be applied. In addition to the prerequisites, consider verifying that the cluster utilizes best practices which will facilitate a more optimal patch installation.

Patch Install Prerequisites

Before you apply a patch on the cluster, verify that all CLDB nodes are running and that container 1 is fully replicated on each CLDB node.

Run `maprcli dump containerinfo -ids 1 -json`. In the output, all CLDBs should be listed under `ActiveServers` and each node should report a VALID state.

For example:

```
...
      "data":[
             {
                "ContainerId":1,
                "Epoch":3,
                "Master":"<masterCLDB_IP>:5660--3-VALID",
                "ActiveServers":{
                  "IP:Port":[
                      "<masterCLDB_IP>:5660--3-VALID",
                      "<slaveCLDB_IP>:5660--3-VALID",
                      "<slaveCLDB_IP>:5660--3-VALID"
                   ]
              },
                  "InactiveServers":{
                   },
                  "UnusedServers":{
              },
...
```

Note: RESYNC state will display when container 1 is not fully replicated on that node. You must wait until each CLDB node has a VALID state for container 1 before proceeding with the patch installation.

For more information, see dump containerinfo on page 1616

Best Practices for Patch Installation

Failure to follow the best practices may, in some cases, impact the speed in which the patch installation completes. Check to see if your cluster abides by the following best practices:

The volume min replication setting should be greater than or equal to 2 for CLDB volume.	This ensures that container 1 always has at least two valid copies. Run the following command to list the current replication setting: `maprcli dump volumeinfo -volumename mapr.cldb.internal -json` In the output, the "VolumeMinReplication" parameter lists the current replication setting for the named volume. For more information, see maprcli dump volumeinfo.
No under replicated volumes should exist on the cluster.	Run the following command to check for under-replicated volumes: `maprcli alarm list` For more information, see maprcli alarm list.

Each CLDB node should be configured to have a minimum of 3 disks in its storage pool.	Run the following command on each CLDB node to get a list of the disks configured for each storage pool:
	`mrconfig sp list [-v]`
	In this example output, there are three disks associated with SP1:
	`ListSPs resp: status 0:2 No. of SPs (2), totalsize 4562260 MB, totalfree 4537550 MB`
	`SP 0: name SP1, Online, size 2736933 MB, free 2724749 MB, path /dev/sdb, log 200 MB, port 5660, guid a3055a6db41f285b005883bbd701c1e5, clusterUuid -5009075714600063565-100367519220387605, disks /dev/sdb /dev/sdd /dev/sde`
	For more information, see mrconfig sp list.

Step 2: Apply the Patch to Data Nodes

When applying a patch manually, apply the patch to nodes dedicated to storing and processing data prior to applying the patch on nodes that run the CLDB. This includes nodes that run the Fileserver for storage and processing components such as the NodeManager and the HBase client.

Note: For clusters with more than 100 data nodes, it is a best practice to apply the patch in batches. Also, wait a few minutes before proceeding to the next batch of nodes.

On each data node:

1. Stop the MapR Warden and ZooKeeper (if installed) services:
   a) To stop MapR Warden, run the following command:
   ```
   sudo service mapr-warden stop
   ```
   b) If Zookeeper is installed on the node, run this command:
   ```
   sudo service mapr-zookeeper stop
   ```

last-updated: Apr 11, 2022

2. If there is already a patch installed on the cluster, run one of the following commands to uninstall it:
   - On CentOS/Redhat: `sudo rpm -e mapr-patch`
   - On SLES: `sudo zypper remove mapr-patch`
   - On Ubuntu: `sudo apt-get -y remove mapr-patch`
3. Install the patch using one of the following commands:
   - On CentOS/RedHat: `sudo rpm -ivh mapr-patch-<new_patch_number>.rpm`
   - On SLES: `sudo zypper install mapr-patch-<new_patch_number>.rpm`
   - On Ubuntu: `sudo dpkg -i mapr-patch-<new_patch_number>.deb`
4. Start the MapR Warden and ZooKeeper (if installed) services:
   a) If ZooKeeper is installed on the node, run this command to start ZooKeeper:

   ```
   sudo service mapr-zookeeper start
   ```

   b) To start Warden, run this command:

   ```
   sudo service mapr-warden start
   ```

5. To verify that the patch was installed successfully, run one of the following commands:
   - On CentOS/Redhat or SLES: `sudo rpm -ql mapr-patch-<new_patch_number>`
   - On Ubuntu: `sudo dpkg -l | grep mapr-patch-<new_patch_number>`

Step 3: Apply the Patch to CLDB Nodes
When applying a patch manually, apply the patch to CLDB secondary nodes prior to applying the patch on the primary CLDB node. After you apply a patch to a CLDB node, you must verify that container 1 is fully replicated before proceeding to apply the patch to the next CLDB node.

For large clusters with many containers, when you do not patch CLDB nodes in the prescribed order, there may be a considerable delay before the cluster can process client operations. For smaller clusters, this is not critical as the cluster can generally start accepting client operations in about 5 minutes.

Complete the following steps on each CLDB secondary node and then on the CLDB primary node:

1. Stop the MapR Warden and ZooKeeper (if installed) services:
   a) To stop MapR Warden , run the following command:

   ```
   sudo service mapr-warden stop
   ```

   b) If ZooKeeper is installed on the node, run this command:

   ```
   sudo service mapr-zookeeper stop
   ```

2. If there is already a patch installed on the cluster, run one of the following commands to uninstall it:
   - On CentOS/RedHat: `sudo rpm -e mapr-patch`
   - On SLES: `sudo zypper remove mapr-patch`
   - On Ubuntu: `sudo apt-get -y remove mapr-patch`

3. Install the patch using one of the following commands:
   - On CentOS/RedHat: `sudo rpm -ivh mapr-patch-<new_patch_number>.rpm`
   - On SLES: `sudo zypper install mapr-patch-<new_patch_number>.rpm`
   - On Ubuntu: `sudo dpkg -i mapr-patch<new_patch_number>.deb`
4. Start the MapR Warden and ZooKeeper (if installed) services:
   a) If ZooKeeper is installed on the node, run this command to start ZooKeeper:

   ```
   sudo service mapr-zookeeper start
   ```

   b) To start Warden, run this command:

   ```
   sudo service mapr-warden start
   ```

5. To verify that the patch was installed successfully, run one of the following commands:
   - On CentOS/RedHat or SLES: `sudo rpm -ql mapr-patch-<new_patch_number>`
   - On Ubuntu: `sudo dpkg -l | grep mapr-patch-<new_patch_number>`
6. Verify that the CLDB node that you patched is running and that container 1 on that node is fully replicated.

   Run `maprcli dump containerinfo -ids 1 -json`.

   In the output, the CLDB node that you just patched should be listed under ActiveServers, and should report a VALID state for container 1.

   For example:

   ```
   ...
         "data":[
                {
                   "ContainerId":1,
                   "Epoch":3,
                   "Master":"<masterCLDB_IP>:5660--3-VALID",
                   "ActiveServers":{
                     "IP:Port":[
                         "<masterCLDB_IP>:5660--3-VALID",
                         "<slaveCLDB_IP>:5660--3-VALID",
                         "<slaveCLDB_IP>:5660--3-VALID"
                      ]
                },
                    "InactiveServers":{
                     },
                    "UnusedServers":{
                },
   ...
   ```

   Note: The RESYNC state will display when container 1 is not fully replicated on that node. You must wait until the CLDB node that you just patched has a VALID state for container 1.

   For more information, see dump containerinfo on page 1616

last-updated: Apr 11, 2022

Applying a Patch Using an Installer Stanza

Applying a patch using an Installer Stanza leverages the automation provided by the patch-install capability of the web-based MapR Installer.

To apply a patch using an Installer Stanza, you specify a file name and directory in the `environment.patch_location` parameter in the Stanza (YAML) file. Then you issue the `install` command to run the Stanza.

Note: Applying a patch using the MapR Installer is an offline update (not a rolling update).

For information about the `install` command, see Installing or Upgrading MapR Core Using an Installer Stanza on page 5509. For information about the Stanza parameters, see Working with MapR Installer Stanza Files on page 5504.

Rolling Back a Patch

Removing a previously installed patch is a manual process. You can revert to a previous version of the patch by first removing the current patch and then installing the previous version.

Always test patch installs in a test environment before applying patches to production environments. If a newly installed patch for a given software version delivers unexpected behavior, you can remove the patch or install an older patch for the same data-fabric software version. To roll back to a previous patch version, use the steps in Step 2: Apply the Patch to Data Nodes on page 441, but install the desired older version of the patch instead of the latest version.

The latest patch version (for example, version n) and the previous patch version (version `n-1`), are always available on sftp.mapr.com. To log in, specify `maprpatches` for the **Login ID**, and leave the **Password** field blank.

For technical assistance in removing a patch and restoring the functionality that existed before the patch was installed, open a case with HPE Support.

Note: Rolling back a cluster from a newer data-fabric software version to an older version is not supported. See Applying a Patch Manually on page 439.

Special Considerations for the Control System Patches

Patches for the Control System are handled differently from patches for cluster data nodes and CLDB nodes.

The Control System software is updated as a package rather than a patch file. While MapR core patches typically include a prefix such as `mapr-patch` or `mapr-patch-client`, or `mapr-patch-posix-client-basic`, Control System software is updated as a new package and does not use the MapR core patch mechanism.

To identify a Control System patch package, look for `mapr-apiserver` or `mapr-webserver` in the package name, and use these steps to update your currently installed packages:

1. Stop the `apiserver` service on all Control System nodes:

```
$ maprcli node services -filter [csvc==apiserver] -name
apiserver -action stop
```

2. Upgrade the existing `mapr-apiserver` and `mapr-webserver` packages. For example:
   - On CentOS/RedHat or SLES:

```
$ rpm -Uvh <path to new mapr-apiserver>
$ rpm -Uvh <path to new mapr-webserver>
```

last-updated: Apr 11, 2022

- On Ubuntu:

```
$ dpkg -i <path to new mapr-apiserver>
$ dpkg -i <path to new mapr-webserver>
```

3. Run `configure.sh` to update the configuration for the new packages:

```
$ /opt/mapr/server/configure.sh -R --noRecalcMem
```

4. Start the `apiserver` service on all Control System nodes:

```
$ maprcli node services -filter [csvc==apiserver] -name
apiserver -action start
```

Special Considerations for FUSE POSIX Patches

Patches for some features, such as the FUSE POSIX client, can require post-installation steps.

When you install a FUSE POSIX patch, a new and backup copy of the `fuse.conf` file are created in the `/opt/mapr/conf` directory. These files are called:

- `fuse.conf.new`
- `fuse.conf.old`

You can find the new parameters in the `fuse.conf.new` file. If needed, you can copy the new parameters to your existing `fuse.conf` file and restart FUSE for the settings to take effect.

For FUSE POSIX configuration information, see Configuring the MapR FUSE-Based POSIX Client on page 1240.

Applying a Patch to a MapR POSIX Client

This procedure enables you to apply a patch to any of the MapR POSIX clients, which include the MapR loopbacknfs POSIX client, the FUSE-based POSIX basic client, and the FUSE-based POSIX platinum client.

1. Before applying a patch to a FUSE-based POSIX client, review Special Considerations for FUSE POSIX Patches on page 445.
2. Use one of the following commands to stop the POSIX client service:
   - For the `mapr-loopbacknfs` service:

```
service mapr-loopbacknfs stop
```

   - For the FUSE-based POSIX basic service:

```
service mapr-posix-client-basic stop
```

   - For the FUSE-based POSIX platinum service:

```
service mapr-posix-client-platinum stop
```

3. Remove any currently installed client patches:

last-updated: Apr 11, 2022

For the `mapr-loopbacknfs` service:	• On Red Hat / CentOS:
	`yum remove mapr-patch-loopbacknfs-<old_patch_number>.rpm`
	• On SLES:
	`zypper remove mapr-patch-loopbacknfs-<old_patch_number>.rpm`
	• On Ubuntu:
	`apt-get remove mapr-patch-loopbacknfs-<old_patch_number>.deb`

For the FUSE-based POSIX basic service:	• On Red Hat / CentOS:
	`yum remove mapr-patch-posix-client-basic-<old_patch_number>.rpm`
	• On SLES:
	`zypper remove mapr-patch-posix-client-basic-<old_patch_number>.rpm`
	• On Ubuntu:
	`apt-get remove mapr-patch-posix-client-basic-<old_patch_number>.deb`

For the FUSE-based POSIX platinum service:	• On Red Hat / CentOS:
	`yum remove mapr-patch-posix-client-platinum-<old_patch_number>.rpm`
	• On SLES:
	`zypper remove mapr-patch-posix-client-platinum-<old_patch_number>.rpm`
	• On Ubuntu:
	`apt-get remove mapr-patch-posix-client-platinum-<old_patch_number>.deb`

last-updated: Apr 11, 2022

4. Apply the new patch:

For the `mapr-loopbacknfs` service:	• On Red Hat / CentOS:
	`sudo rpm -i mapr-patch-loopbacknfs-<new_patch_number>.rpm`
	• On SLES:
	`sudo zypper install mapr-patch-loopbacknfs-<new_patch_number>.rpm`
	• On Ubuntu:
	`sudo dpkg -i mapr-patch-loopbacknfs-<new_patch_number>.deb`

For the FUSE-based POSIX basic service:	• On Red Hat / CentOS:
	`sudo rpm -i mapr-patch-posix-client-basic-<new_patch_number>.rpm`
	• On SLES:
	`sudo zypper install mapr-patch-posix-client-basic-<new_patch_number>.rpm`
	• On Ubuntu:
	`sudo dpkg -i mapr-patch-posix-client-basic-<new_patch_number>.deb`

For the FUSE-based POSIX platinum service:	• On Red Hat / CentOS:
	`sudo rpm -i mapr-patch-posix-client-platinum-<new_patch_number>.rpm`
	• On SLES:
	`sudo zypper install mapr-patch-posix-client-platinum-<new_patch_number>.rpm`
	• On Ubuntu:
	`sudo dpkg -i mapr-patch-posix-client-platinum-<new_patch_number>.deb`

last-updated: Apr 11, 2022

5. Use one of the following commands to restart the POSIX client service:
   - For the `mapr-loopbacknfs` service:

     ```
     service mapr-loopbacknfs start
     ```

   - For the FUSE-based POSIX basic service:

     ```
     service mapr-posix-client-basic start
     ```

   - For the FUSE-based POSIX platinum service:

     ```
     service mapr-posix-client-platinum start
     ```

6.1 MapR Data Platform

MapR Data Platform is the industry-leading data platform for AI and analytics that solves enterprise business needs.

The MapR Data Platform enables you to master critical data challenges, specifically:

- Speed up AI and analytics initiatives for more impact at production scale
- Accelerate time-to-value for hybrid cloud and multi-cloud strategies
- Create highly reliable, scalable data fabric
- Use data streams for real-time edge analytics
- Implement Kubernetes containerization more effectively

The MapR Data Platform allows you to address your critical data needs while providing industry-leading performance, data security, easy application development, and true scalability.

The MapR Data Platform enables you to solve critical business needs:

last-updated: Apr 11, 2022

Business Need	MapR Data Platform Provides....	Typical Use Cases...
AI and Analytics	A data platform approach for full range of AI, ML, Analytics with no silos, faster response and mission critical reliability at scale	• Contextual experiences • Recommendations • Churn detection • Real-time analytics • DWH offload • Operational data hub • Fraud detection • Security analytic
IOT and Edge Analytic	Seamless edge to on-prem or cloud data movement with analytic	• IoT Analytic • Edge to edge fabric • Anomaly detection • Preventative maintenance • Multi-cloud • Streaming analytic • Real-time response
Journey to Cloud	Easy data and application movement between on-prem and multiple clouds delivers lower TCO, higher flexibility	• Scale-out storage • Global repository, persistent data containers • High-performance filesystem • Multi-cloud choice • GDPR
Containers	Enable stateful applications in containers to use system-of-record data in a high-reliability platform	• Improve agility • Greater flexibility • Higher elasticity • Better utilization

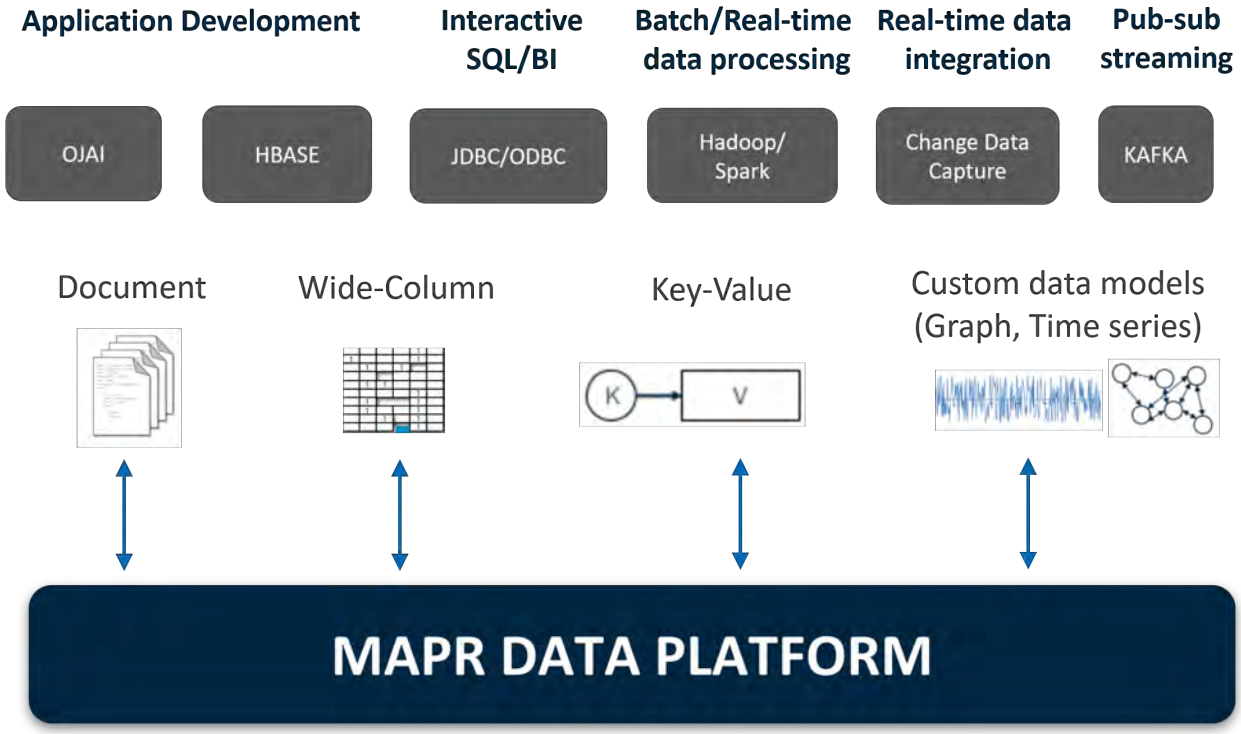
High-level View of the MapR Data Platform

The following diagram shows the basic components of the MapR Data Platform.



Get Started

To learn more about MapR Data Platform, see this course.

For planning information and the manual installation steps, see:

- Planning the Cluster on page 107
- Minimum Cluster Size on page 112
- Installing without the MapR Installer on page 141

You can jump right into using the MapR Data Platform:

- MapR Sandbox for Hadoop: Try out a single-node cluster that's ready to roll, right out of the box!
- MapR Installer: Use the MapR Installer to set up a production cluster, large or small. See MapR Installer on page 5395.

Learn More about the Architecture of the MapR Data Platform Components

This system overview contains architectural details about the components that run on the MapR Data Platform and the relationships between the components. See these topics to learn about each component.

Additional Resources

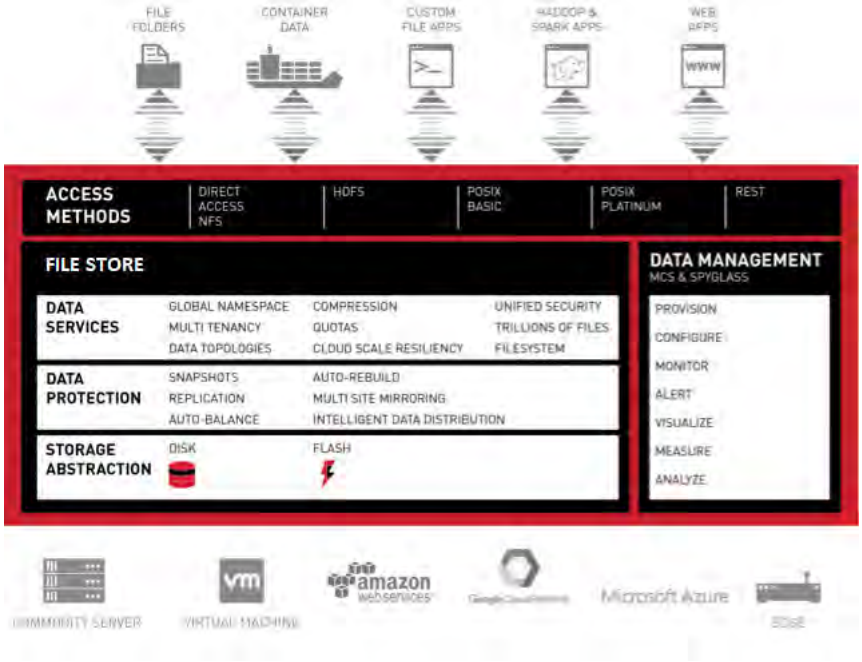
For an excellent introduction to how a data fabric can help enable a comprehensive data strategy, see this blog.

MapR XD Distributed File and Object Store

MapR XD Distributed File and Object Store is a distributed filesystem for data storage, data management, and data protection. MapR XD supports mounting and cluster access via NFS and FUSE-based POSIX clients (basic, platinum, or PACC) and also supports access and management via HDFS APIs.

MapR XD is the only cloud-scale data store that enables you to build a fabric of exabyte-scale. MapR XD supports trillions of files, 100s of 1000s of client nodes, and runs on edge clusters, on-prem data centers, and the public cloud.

You can manage your clusters from the Managed Control System (web console) and monitor them using HPE Ezmeral Data Fabric Monitoring (Spyglass initiative).



1. Direct Access NFS
2. HDFS
3. FUSE-based POSIX Clients
4. REST API
5. Storage Abstraction
6. Data Protection
7. MapR File System
8. MapR Control System
9. MapR Monitoring

How Do I Get Started?

Refer to the documentation specific to your role:

last-updated: Apr 11, 2022

Architect	Administrator/Dev Ops	Developer
Planning the Cluster	Installing the MapR XD	Managing data using maprcli
Planning for high availability	Setting up volumes, volume replication, snapshots, and mirroring schedules	Accessing MapR filesystem using HDFS APIs
Reviewing security capabilities and architecture	Configuring security with ACLs/ACEs and tickets	
	Mounting the cluster for access using NFS and POSIX clients	
	Managing the cluster using the Control System and monitoring the cluster using MapR Monitoring

- Administrator's Reference
- File Store APIs

File System

Discusses the features of the MapR distributed file system and compares it to the Hadoop Distributed File System (HDFS).

The MapR distributed file system provides a unified data solution for structured data (tables) and unstructured data (files).

The MapR file system is a random, read-write distributed file system that allows applications to concurrently read and write directly to disk. The Hadoop Distributed File System (HDFS), by contrast, has append-only writes and can only read from closed files. As HDFS is layered over the existing Linux file system, a large number of input/output (I/O) operations decrease the cluster's performance. The MapR distributed file system also eliminates the Namenode associated with cluster failure in other Hadoop distributions, and enables special features for data management, and high availability.

The storage system architecture used by the MapR distributed file system is written in C/C++ and prevents locking contention, eliminating performance impact from Java garbage collection.

The following table highlights some of the features of the :

Feature	Description
Storage pools	A group of disks to which the MapR file system writes data.
Containers	An abstract entity that stores files and directories in the MapR file system. A container always belongs to exactly one volume, and can hold namespace information, file chunks, or table chunks for that volume.
CLDB	A service that tracks the location of every container.
Volumes	A management entity that stores and organizes containers. Used to distribute metadata, set permissions on data in the cluster, and for data backup. A volume consists of a single name container, and a number of data containers.

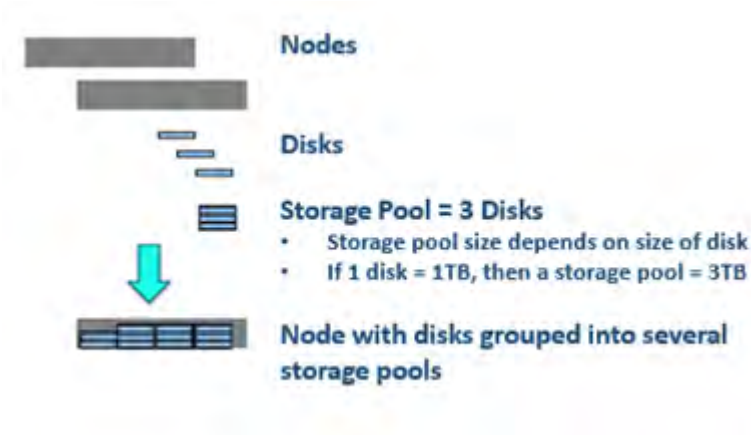
last-updated: Apr 11, 2022

Feature	Description
Direct Access NFS	Enables applications to read and write data directly on to the cluster.
POSIX Clients	The loopbacknfs, and FUSE-based POSIX clients connect to one or more MapR clusters, and allow app servers, web servers, and applications to write data directly, and securely to the MapR cluster.

Storage Pools
Describes what storage pools are.

The MapR File System storage architecture consists of multiple storage pools that reside on each node in a cluster. A storage pool is made up of one or more disks grouped by the MapR file system. The default number of disks in a storage pool is three. The containers that hold the MapR filesystem data are stored in, and replicated among the storage pools in the cluster.

The following image represents disks grouped together to create storage pools that reside on a node:



Write operations within a storage pool are striped across disks to improve write performance. Stripe width and depth are configurable with the disksetup script. As the MapR filesystem performs data replication, you do not need to configure RAID.

Containers and the CLDB
Describes what containers are, and the role of the Container Location Database (CLDB) in managing them.

The MapR filesystem stores data in abstract entities called containers that reside on storage pools. Each storage pool can store many containers. Blocks enable full read-write access to the MapR filesystem, with efficient snapshots.

An application can write, append, or update more than once in the MapR filesystem, and can also read a file as it is being written. In other Hadoop distributions, an application can only write once, and the application cannot read a file as it is written.

On average, a container size is 10-30 GB. The default container size is 32GB. Large number of containers allow for greater scaling and allocation of space in parallel, without bottlenecks.

Described from the physical layer:

- Files are divided into chunks.
- The chunks are assigned to containers.
- The containers are written to storage pools, which are made up of disks on the nodes in the cluster.

The following table compares the MapR filesystem storage architecture to the HDFS storage architecture:

last-updated: Apr 11, 2022

Storage Architecture	HDFS	MapR Filesystem
Management layers	Files, directories and blocks, managed by Namenode.	Volume, which holds files and directories, made up of containers, which manage disk blocks and replication.
Size of file shard	64MB block	256MB chunk
Unit of replication	64MB block	32GB container
Unit of file allocation	64MB block	8KB block

To preserve data, the MapR filesystem automatically replicates containers across various nodes on the cluster. Container replication creates multiple synchronized copies of the data across the cluster for failover. Container replication also helps localize operations, and ensures that read operations occur in parallel. When a disk or node failure brings a container's replication levels below a specified replication level, the MapR filesystem automatically re-replicates the container elsewhere in the cluster until the desired replication level is achieved. A container only occupies disk space when an application writes to it.

The CLDB (Container Location Database) maintains information about the location of every container in the cluster, defines the container precedence in the replication chain, and organizes container content updates across the replication chain. It runs as a system of independent servers, only one of which is a master at any time.

The MapR filesystem and other services (such as NFS Gateway and POSIX) send heartbeat (HB) messages to the master CLDB. The CLDB is registered with ZooKeeper, and the master CLDB to ZooKeeper connection is kept alive by sending a probe message every few seconds. The CLDB service tracks the location of every container, and uses these HB messages to determine the state of all containers on that node. The CLDB actively participates in the failover of a node in the event of a node failure.

Understanding Replication
Describes how replication works, and how to configure the replication factor.

Volumes are stored as pieces called containers that contain files, directories, and other data. By default, the maximum container size is 32 GB. The MapR administrator sets the maximum container size using the `cldb.container.sizemb` parameter (see the config commands). Containers are replicated to protect data. Normally, each container has three copies stored on separate nodes to provide uninterrupted access to all data, even if a node fails.

For each volume, you can specify a desired and minimum data replication factor, and a desired and minimum namespace (name container) replication factor.

When enabled, the CLDB manages the namespace container replication separate from the data container replication. Use this capability when you have low volume replication, but want to have higher namespace replication.

Note: The namespace container parameters, *nsreplication* or *nsminreplication*, must be the same or larger than the equivalent data replication parameter, *replication* or *minreplication*.

Data Replication

- The replication factor is the number of replicated copies that you need for normal operation and data protection. When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, the CLDB actively creates additional copies of the container while trying to minimize the impact of making an additional copy of the container. Re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter (configurable using the configuration API). The minimum replication factor is 1 and the maximum is 6 (default: 3).
- The minimum value of the minimum replication factor is the smallest number of copies you need in order to adequately protect against data loss. When the replication factor falls below this minimum value, re-replication occurs aggressively if data is being actively written to the container. If the `enforceminreplicationforio` property is set to `true`, writes succeed only when the minimum replication factor requirements are met. If the `enforceminreplicationforio` property is set to `true` and the minimum number of copies are not available, the client is asked to retry. In the case of a:
  - Hard mount, the client might try for up to 10 minutes and then return an error
  - Soft mount, the client might return an error

  The minimum value of the minimum replication factor is 1 and the maximum value is 6 (default:2). In all cases, the minimum replication factor cannot be greater than the replication factor. When you increase the minimum replication factor, if the `enforceminreplicationforio` property (configurable at the volume level) is set to `true`, the requirement to maintain a minimum number of copies is not enforced during writes until new copies of all containers associated with the volume are created.

Name Container Replication

- The namespace replication factor is the number of namespace container replicated copies that you need for normal operation and data protection. When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, the CLDB actively creates additional copies of the container while trying to minimize the impact of making an additional copy of the container. Re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter (configurable using the configuration API). The minimum replication factor is 1 and the maximum is 6 (default: 3).
- The minimum value of the minimum namespace replication factor is the minimum number of namespace container replicated copies you want in order to adequately protect against data

last-updated: Apr 11, 2022

loss. When the replication factor falls below this minimum value, re-replication occurs aggressively if data is being actively written to the container. If the `enforcemineplicationforio` property (configurable at the volume level) is set to `true`, writes succeed only when this minimum value of the minimum replication factor requirements are met. If this property is set to `true` and minimum number of copies are not available, the client is asked to retry. In the case of a:

- Hard mount, the client tries for up to 10 minutes and then return an error
- Soft mount, the client returns an error

The system does not wait for lost replicas to become available again. The minimum value of the muinimum replication factor is 1 and the maximum value is 6 (default: 2). In all cases, the minimum replication factor cannot be greater than the replication factor. When you increase the minimum replication factor, if the `enforceminreplicationforio` property is set to `true`, the presence of the minimum number of copies is not enforced during writes until new copies of all containers associated with the volume are created.

Note: The maximum replication setting of 6 does **not** apply for ***mapr.cldb.internal volume containers*** (CID-1). The number of CID-1 container replicas are always equivalent to the number of CLDB nodes in the cluster.

If any containers in the CLDB volume fall below the minimum value of the minimum replication factor, the cluster is inaccessible until aggressive re-replication restores the minimum level of replication. If a disk failure is detected, any data stored on the failed disk is re-replicated without regard to the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter.

If all copies of a container, which are neither under nor over replicated, are on the same rack, MapR automatically detects and distributes the copies, such that they are all not on the same rack, after 12 hours. If a container is under replicated and MapR is unable to find a different rack for the new copy, the creation of the copy is deferred. If another rack is unavailable for the new copy after 3 hours, MapR creates a copy of the container on the same rack and if this results in all copies of the container being on the same rack, MapR distributes the copies after 12 hours. Also, during replication, MapR tries to defer the scenarios where all copies end up on the same rack. As per deferring policy:

- If a container has copies less than the "minimum replication" but greater than 2 and if both copies end up on the same rack, then MapR tries to create the third copy on a different rack for up to 3 hours.
- If a container has copies more than the minimum but less than the desired and if all copies are on the same rack, then MapR tries to create the next copy on a different rack for up to 3 hours.

If you do not set the namespace (NS) replication and minimum namespace replication values explicitly, they assume the same values as (data) replication and minimum replication respectively. This means that all changes to (data) `replication` and `minreplication` parameters are also reflected in `nsreplication` and `nsminreplication`. If `nsreplication` or `nsminreplication` is modified or specified during creation, `nsreplication` and `nsminreplication` start assuming values different from `replication` and `minreplication`.

Table Replication vs Mirroring - Understanding the Differences

This section describes the advantages of both Table Replication and Mirroring, to let you determine the best option for your use case.

Advantages of Table Replication

1. Table replication replicates each table update instantaneously, in seconds (subject to compute and network resources). Mirroring has a much larger RTO (recovery time objective), in minutes.
2. Table replication also transmits lesser data because it just transmits the actual physical rows and nothing else.
3. In table replication, both the end points are READ-WRITE masters with the option of two-way multi-master replication.
4. Table replication proceeds from Source Table > Destination Gateway(s) > Destination Table, which provides reasonable isolation between the two end point clusters. The source table talks only to the Destination Gateway(s).

When using mirroring, avoid placing table replication sources in the mirror volume. Doing so, creates problems if the mirror is broken and promoted.

For tables and streams, table replication is usually the right choice. However, there are exemptions where mirroring is the best choice.

Advantages of Mirroring

1. Since a volume mirror represents a moment in time, there is a higher probability of recovering from a volume than from multiple tables.
2. You can retain old states of a mirror. If you have deleted a bunch of data in your tables and table replication has replicated those changes, then you can recover your data from a mirror.
3. Mirrors are helpful during development. Create a read-write mirror and use for development. Revert it to the last mirrored state and start over. The point is that you can revert the entire volume to a known state, as needed.
4. Use local mirror(s) to increase read throughput.
5. You can use mirrors to obtain traceability and reproducibility during data operations such as machine learning. You can have separate mirrors for different clusters, and operations on one mirror do not affect the other.

Understanding Topology

Provides an overview of how to define cluster topology.

The MapR software uses node topology to determine the location of replicated copies of data. Node topology describes the locations of nodes in a cluster. You can define the cluster topology by specifying a topology for each node in the cluster. Use topology to group nodes by rack or switch, to provide a hint as to how data should be replicated to protect against data loss or unavailability because of a switch or rack failure.

In a topology, MapR distributes container copies optimally among leaf nodes. For example, in a topology such as `europe/uk/london/DC2/room4/row22`, where `row22` contains multiple racks such as `row22/rack1`, `row22/rack2`, `row22/rack3`, and so on, MapR tries to ensure that all copies of the container do not end up on the same rack (for example, `rack1`). By setting each leaf value to correspond to a physical rack, you can ensure that replicated data is distributed across racks to improve fault tolerance.

Related concepts

Setting Up Node Topology on page 805
Define node topologies for every node in the cluster.

Setting Up Volume Topology on page 915
Specifies how to use volume topology to place volumes on specific racks, nodes, or groups of nodes.

Volumes, Snapshots, and Mirrors
Describes what Snapshots and Mirrors are, and the advantages of using them for replication.

Volumes are a management entity that logically organize a cluster's data. Since a container always belongs to exactly one volume, that container's replicas all belong to the same volume as well. Volumes do not have a fixed size and they do not occupy disk space until the MapR filesystem writes data to a container within the volume. A large volume may contain anywhere from 50-100 million containers.

The CLI and REST API provide functionality for volume management. Typical use cases include volumes for specific users, projects, development, and production environments. For example, if an administrator needs to organize data for a special project, the administrator can create a specific volume for the project. The MapR filesystem organizes all containers that store the project data within the project volume. A cluster can have many volumes.

The MapR filesystem creates a name container for each volume. The name container stores the volume's namespace and file chunk locations, along with inodes for the objects in the filesystem. The filesystem stores the metadata for files and directories in the name container, which is updated with each write operation.

The first 64KB of each file in a volume is written to the name container. Data beyond 64KB is written to data containers. Data containers are created only when the file or table data goes above 64KB. Each name or data container is associated with only one volume; volumes may have many associated data containers, but only one name container.

Local volumes are confined to one node, and are not replicated. Local volumes are part of the cluster's global namespace, and are accessible on the path `/var/mapr/local/<host>`.

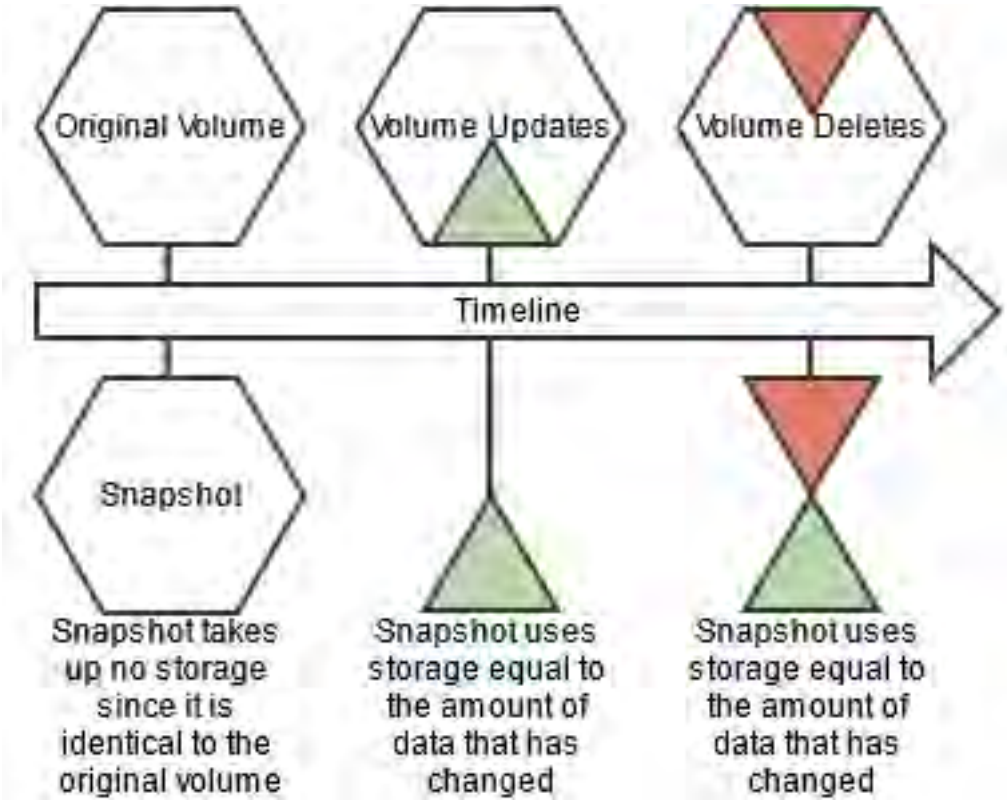
On a cluster with an Enterprise Edition or Enterprise Database Edition license, you can create a special type of volume called a mirror, a local or remote read-only copy of an entire volume. Mirrors are useful for load balancing or disaster recovery. You can also create a snapshot, an image of a volume at a specific point in time. Snapshots are useful for rollback to a known data set.

On a cluster, you can create a tenant share, or volume for tenant users. A tenant share is an isolated space where you can set different policies, quotas, and access privileges for specific users/hosts (referred to as tenants). This allows each tenant to own its own copy of storage space, users, data security, administration, and other such specifications. For more information, see Multitenancy on File System on page 488.

Snapshots

Snapshots enable you to roll back to a known good data set and recover data always in case of data corruption or accidental deletions, without the help of storage administrators. A snapshot is a read-only image of a volume that provides point-in-time recovery. Snapshots only store changes to the data present in the volume, and as a result make extremely efficient use of the cluster's disk resources. Snapshots preserve access to historical data, and protect the cluster from user and application errors. You can create a snapshot manually, or automate the process with a schedule. Snapshots are stored in the `.snapshots` directory. You can always view snapshots from this directory.

The following image represents a mirror volume, and a snapshot created from a source volume:



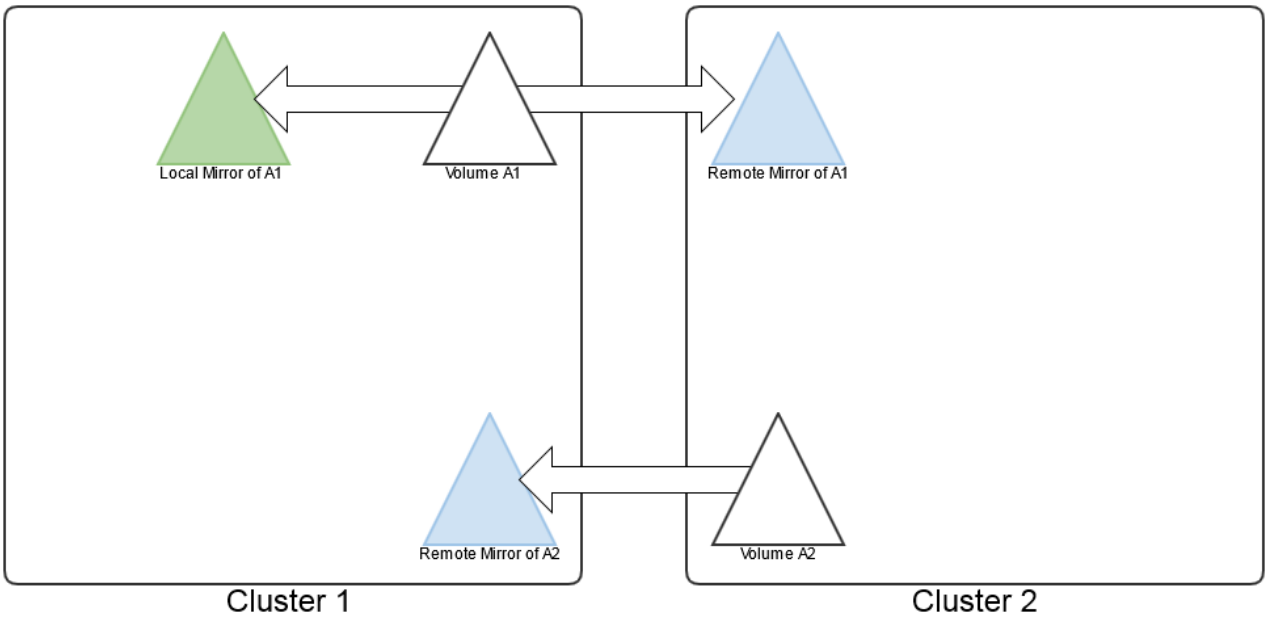
New write operations on a volume with a snapshot are redirected to preserve the original data. Snapshots only store the incremental changes in a volume’s data from the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota.

Mirror Volumes

MapR provides built-in mirroring to set recovery time objectives and to automatically mirror data for backup. You can create local or remote mirror volumes to mirror data between clusters, data centers, or between on-premise and public cloud infrastructures.

Mirror volumes are read-only copies of a source volume. You can control the schedule for mirror refreshes from the Control System or with the command-line tools. You can create local (on the same cluster) or remote (on a different cluster) mirror volumes from the Control System, or from the command line.

last-updated: Apr 11, 2022



When you create a mirror volume, the MapR filesystem creates a temporary snapshot of the source volume. The mirroring process reads content from the snapshot into the mirror volume. The source volume remains available for read and write operations during the mirroring process. The initial mirroring operation copies the entire source volume. Subsequent mirroring operations only update the differences between the source volume and the mirror volume.

Mirror volumes can be promoted to read-write volumes. The main use case for this feature is to support disaster-recovery scenarios in which a read-only mirror needs to be promoted to a read-write volume so that it can become the primary volume for data storage. In addition, read-write volumes that were mirrored to other volumes can be made into mirrors (to establish a mirroring relationship in the other direction). You can also convert read-write volumes back to read-only mirrors.

Related concepts

Understanding Replication on page 454
Describes how replication works, and how to configure the replication factor.

Types of Volumes

Lists the various types of volumes.

This glossary explains the different types of volumes.

Term	Definition

NC Standard Volume	A non-convertible (NC) standard volume is a volume with read-write capabilities, created *before* MapR version 4.0.2. These volumes cannot be converted to standard mirror volumes. If this volume type is designated as a source volume when a mirror volume is created, the mirror volume will be a NC mirror volume.
	A NC standard volume is designated as type 0 in the output of the `volume info` command. For example:
	`maprcli volume info -name oldrw`
	lists
	`"mirrortype":0`

last-updated: Apr 11, 2022

Term	Definition
Standard Volume	A standard volume is a read-write volume created as of MapR version 4.0.2. A standard volume can be converted from read-write to mirror (read-only). If a mirror is created from this type of volume, the mirror can be promoted to a read-write volume. A standard volume is designated as type `rw` on the command line. For example: `maprcli volume create -name volA -path /testvol -type rw`

NC Mirror Volume	A non-convertible read-only mirror volume is a volume created *before* MapR version 4.0.2. This volume type cannot be promoted to a read-write volume, and can only be created from a NC standard volume.
	A NC mirror volume is designated as type 1 in the output of the `volume info` command. For example:
	`maprcli volume info -name oldmirror`
	lists
	`"mirrortype":1`

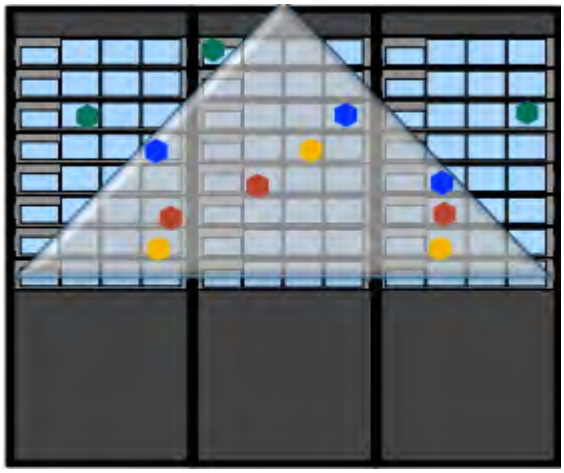
Standard Mirror	Standard mirror is a mirror volume that starts as a read-only volume, and can be promoted to a read-write volume. A standard mirror volume is designated as type `mirror` on the command line and can only use a standard volume as its source. For example: `maprcli volume create -name volB -path /mirvol -type mirror -source volA`

Volume Topology
Describes what volume topology is, and the topology of replicas and mirrors.

The topology describes the locations of nodes and racks in the cluster. Volume topology is based on node topology. You define volume topology after you define node topology. When you set up node topology, you can group nodes by rack or switch. MapR File System uses node topology to determine where to replicate data for continuous access to the data in the event of a rack or node failure.

A volume's topology defines which racks or nodes a volume includes.

The following image represents a volume that spans a cluster:



last-updated: Apr 11, 2022

Topology of Local Volume Replicas

The primary copies for containers of local volumes are placed on the local node. The nodes for the replica copies for containers of local volumes are chosen in the following order:

1. Use a topology that is explicitly specified for replicas during volume creation or modification.
2. Use the relative path for replicas of local volumes if the configuration parameter specifies such a path.
3. Use the default volume topology.

See Setting the Topology for Local Volume Replicas on page 916, Creating Replicas of Local Volumes in Custom Topology Using the CLI on page 917, and Setting Default Volume Topology Using the CLI on page 917.

Mirror Volume Topology

When the root volume on a cluster is mirrored, the source root volume contains a writable volume link, `.rw` that points to the read/write copies of all local volumes. In that case, the mount path `/` refers to one of the root volume's mirrors, and is read-only. The mount path `/.rw` refers to the source volume, and is read/write.

A mount path that consists entirely of mirrored volumes refers to a mirrored copy of the specified volume. When a mount path contains volumes that are not mirrored, the path refers to the target volume directly. In cases where a path refers to a mirrored copy, the `.rw` link is useful for navigating to the read/write source volume.

Sample Volume Topology with Mirrors

The following example shows a volume topology with mirrors:

For the four volumes `/`, `a`, `b`, and `c`, the following table indicates the volumes referred to by example mount paths for particular combinations of mirrored and not mirrored volumes in the path:

/	a	b	c	This Path	Refers To This Volume...	Which is...
Mirrored	Mirrored	Mirrored	Mirrored	`/a/b/c`	Mirror of c	Read-only
Mirrored	Mirrored	Mirrored	Mirrored	`/.rw/a/b/c`	c directly	Read/Write
Mirrored	Mirrored	*Not Mirrored*	Mirrored	`/a/b/c`	c directly	Read/Write
Mirrored	Mirrored	*Not Mirrored*	Mirrored	`/a`	Mirror of a	Read-only
Not Mirrored	Mirrored	Mirrored	Mirrored	`/a/b/c`	c directly	Read/Write

Authorization with Volumes: Intelligent Policy Management

Describes methods to manage volume permissions.

The MapR filesystem uses volumes as a unique management entity. A volume is a logical unit that you create to apply policies to a set of files, directories, tables, and sub-volumes. You can create volumes for each user, department, or project. Mirror volumes and volume snapshots provide data recovery and data protection functionality.

Volumes can enforce disk usage limits, set replication levels, establish ownership and control permissible actions, and measure the cost generated by different projects or departments. When you set policies on a volume, all files contained within the volume inherit the same policies set on the volume. Other Hadoop distributions require administrators to manage policies at the file level.

You can manage volume permissions through one of the following:

- Access Control Lists (ACLs) in the Control System or from the command line. ACLs can be used to control administrative access to volumes.
- Access Control Expressions (ACEs) in the Control System or from the command line. ACEs can be used to control data access using boolean expressions.

You can also set read, write, and execute permissions on a file or directory for users and groups with ACEs and standard UNIX commands, when that volume has been mounted through NFS, or using standard `hadoop fs` commands.

Mirror Volumes
Provides a synopsis of what mirror volumes are and the mirroring process.

Creating a mirror volume is similar to creating a normal read/write volume. However, when you create a mirror volume, you must specify a source volume from which the mirror retrieves content. This retrieval is called the mirroring operation. Like a normal volume, a mirror volume has a configurable replication factor. Only one copy of the data is transmitted from the source volume to the mirror volume. MapR volumes can only be mirrored and NOT replicated. However, the source and mirror volumes handle their own internal MapR filesystem replication (which is based on the replication factor) independently. MapR File System internally replicates source and mirror volumes independently of each other.

Note: Volume mirroring from a lower MapR version to higher MapR version is supported. For example, you can mirror volumes from a MapR 4.0.1 cluster to a MapR 5.2 cluster. However, you cannot mirror volumes from a MapR 5.2 cluster to a MapR 4.0.1 cluster.

Mirroring Process

The MapR system creates a temporary snapshot of the source volume at the start of a mirroring operation. The mirroring process reads content from the snapshot into the mirror volume. The source volume remains available for read and write operations during the mirroring process.

If the mirroring operation is schedule-based, the snapshot expires according to the value of the schedule's **Retain For** parameter. Snapshots created during manual mirroring persist until they are deleted manually.

The mirroring process transmits only the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations can be extremely fast. If the fastinodescan feature is enabled, mirroring will proceed significantly faster when there are large number of files and few changes since the last mirroring operation. The fastinodescan feature is enabled by default for all new installations, but must be manually enabled if you are upgrading from pre-5.2.x versions. See the Upgrade Guide for information on enabling this feature. To determine whether the fastinodescan feature is enabled, run the following command:

```
/opt/mapr/bin/maprcli config load -json | grep
mfs.feature.fastinodescan.support
```

To use the fastinodescan feature on converted or promoted volumes, mirroring must be restarted from the source volume after converting volume from mirror to read-write and vice versa.

The mirroring operation never consumes all available network bandwidth, and throttles back when other processes need more network bandwidth. The server sending mirror data continuously monitors the total round-trip time between the data transmission and arrival, and uses this information to restrict itself to 30% of the available bandwidth (continuously calculated). If the network or servers anywhere along the entire path need more bandwidth, the sending server throttles back automatically. If more bandwidth opens up, the sender automatically increases how fast it sends data. Mirror throttling can be disabled so that all available bandwidth is devoted to mirror operations. See Disabling Mirror Throttling for details.

During the copy process, the mirror is a fully-consistent image of the source volume. Mirrors are atomically updated at the mirror destination. The mirror does not change until all bits are transferred, at which point

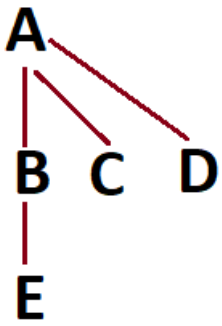
all the new files, directories, blocks, etc., are atomically moved into their new positions in the mirror-volume. The previous mirror is left behind as a snapshot, which can be accessed from the .snapshot directory. These old snapshots can be deleted on a schedule.

Mirroring is extremely resilient. In the case of a network partition, where some or all of the machines that host the source volume cannot communicate with the machines that host the mirror volume, the mirroring operation periodically retries the connection. Once the network is restored, the mirroring operation resumes.

Altering Mirror Relationships

You can use the volume modify on page 2005 command to change mirror relationships. You can change the mirror relationship to any of the volumes (either `rw` or `mirror`) that have the same mirror root, as the mirrored volume.

For example, consider the mirror tree:



Volume E mirrors volume B. However, if volume B becomes unavailable, you can set either volume A, or volume C, or volume D as the source of mirroring for volume E, since volume B, volume C, and volume D have the same mirror data source volume, which is volume A.

Mirror Types
Explains the available mirror types.

You can check the status of your volumes in terms of their mirror type. The `maprcli volume info` command returns the following `mirrortype` values:

mirrortype	Description	Volume upgrade required (to support promotability)
0	Old-format volume, created in an earlier release and present in the cluster after an upgrade to Version 5.0	Yes, if the volume is intended for use as a read-write mirror.
1	An old-format mirror volume whose source volume is a type 0 volume (in any MapR version). These mirror volumes cannot be upgraded.	No, not allowed. The `maprcli volume upgradeformat` command returns an error for these volumes.
2	New-format mirror volume that may be promoted to read-write (no upgrade command required).	No, not needed. These volumes are already in the new format and are promotable.
3	New-format standard volume: either created new in 5.0 or upgraded in 5.0 via the maprcli volume promote command.	No, not needed. These volumes are already in the new format and are promotable.

To check the mirror types for your volumes in Version 5.0, run the following command:

```
maprcli volume list -columns volumename,mirrortype -json
...
 {
   "volumename":"vol999",
   "mirrortype":0
  },
  {
   "volumename":"volume1",
   "mirrortype":3
  },
  {
   "volumename":"volume2",
   "mirrortype":3
  },
  {
   "volumename":"volume3",
   "mirrortype":2
  },
...
```

Local Mirroring
Describes the use of local mirror volumes. The local mirror volume and its source are present on the same cluster,

A *local mirror volume* is a mirror volume whose source is on the same cluster. Local mirror volumes are useful for load balancing or for providing a read-only copy of a data set.

You can locate your local mirror volumes in specific servers or on racks with particularly high bandwidth, mounted in a public directory separate from the source volume.

The most frequently accessed volumes in a cluster are likely to be the root volume and its immediate children. To load-balance read operations on these volumes, mirror the root volume (typically `mapr.cluster.root`, which is mounted at `/`). By mirroring these volumes, you can serve read requests from the mirrors, and distribute load across the nodes. Less-frequently accessed volumes that are lower in the hierarchy do not need mirror volumes. Since the mount paths for those volumes are not mirrored throughout, those volumes are writable.

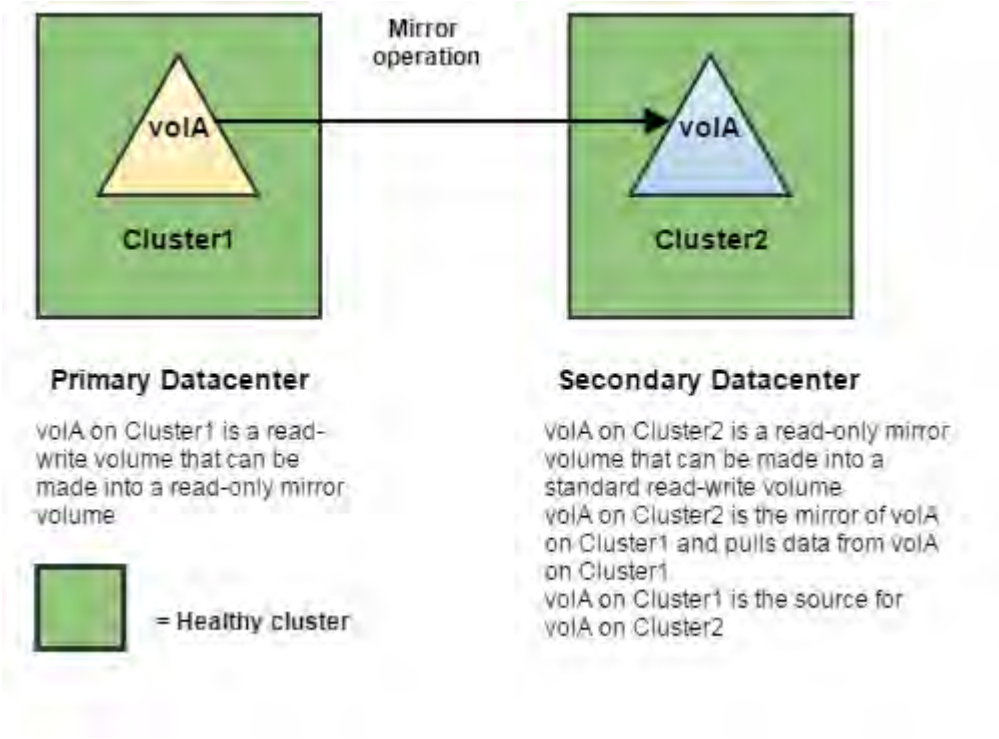
Remote Mirroring
Describes the concept and purpose of remote mirror volumes.

A remote mirror volume is a mirror volume with a source in another cluster. You can use remote mirrors for offsite backup, for data transfer to remote facilities, and for load and latency balancing for large websites. By mirroring the cluster's root volume and all other volumes in the cluster, you can create an entire mirrored cluster that keeps in sync with the source cluster.

Backup mirrors for disaster recovery can be located on physical media outside the cluster, or in a remote cluster. If disaster strikes the source cluster, you can check the time of last successful synchronization to determine the freshness of the backup (see Mirror Status).

Once data volumes are created in a primary data center, the MapR administrator creates mirror volumes in a remote secondary data center. The following diagram illustrates the mirror relationship between these two volumes:

last-updated: Apr 11, 2022



Note: When you use promotable mirrors, you must set up the volumes on the destination cluster in the same way as on the primary site. This means that volume names are the same and mount points are the same. If you use a hierarchical mounting structure (such as /A/B) on the primary site, you must recreate the same structure once you promote the mirror volumes at the secondary site.

Mirror Cascades
Describes what mirror cascades are, and their advantages.

In a cascade, one mirror synchronizes to the source volume, and each successive mirror uses a previous mirror as its source. Mirror cascades are useful for propagating data over a distance, then re-propagating the data locally instead of transferring the same data remotely again for each copy of the mirror. In the following example, the < character indicates a mirror's source:

```
/ < mirror1 < mirror2 < mirror3
```

A mirror cascade makes more efficient use of your cluster's network bandwidth, but synchronization can be slower to propagate through the chain. For cases where synchronization of mirrors is a higher priority than network bandwidth optimization, make each mirror read directly from the source volume:

```
mirror1 >   < mirror2
          /
mirror3 >   < mirror4
```

You can:

- Create a mirror cascade by setting the source volume of each mirror in the **Properties** tab of the Control System when creating a mirror volume.
- Break a mirror cascade made from existing mirror volumes by changing the source volume of each mirror in the **Properties** tab of the Control System when editing the mirror volume.

Promotable Mirrors
Explains the use of promotable mirrors for enhanced performance, data recovery, and business continuity.

In general, mirror volumes are created for the purpose of preventing or minimizing data loss. Data loss scenarios range from accidental overwrites to rack failures, to a disaster that destroys an entire data center. Mirror volumes are also used to improve performance or to make copies of data for use in other clusters without impacting production.

As of the 4.0.2 release, all new mirror volumes can be made into read-write volumes. In addition, read-write volumes that were mirrored to other volumes can be made into mirrors (to establish a mirroring relationship in the other direction). This functionality is useful in scenarios such as:

- Disaster recovery If a read-write volume with critical data goes down in a primary data center, a mirror volume in a remote data center can be made into a read-write volume in order to maintain business continuity. Later, if the primary data center comes back online, the original mirror relationship can be restored by making the new read-write volume back into a mirror volume.
- Running applications on a copy of production data
- Resynchronization (reestablishing a mirror relationship after it is broken)

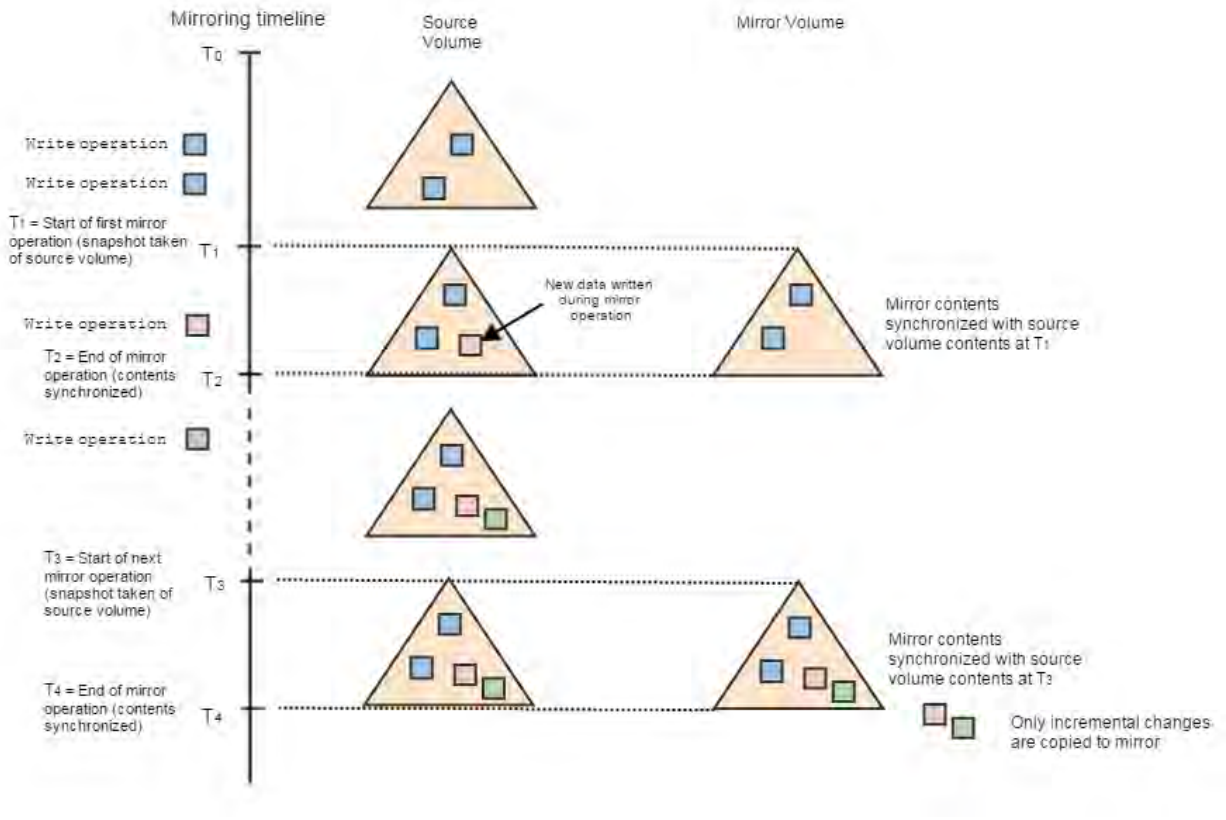
For a hands-on tutorial on promotable mirrors, check this blog.

Incorporating Mirror Volumes into a Disaster Recovery Plan
Lists the points to note when incorporating mirror volumes into a disaster recovery plan.

Mirroring critical data to a remote data center (with the ability to make mirror volumes into read-write volumes) addresses the following objectives:

- Recovery Point Objective (RPO) - the age of the files you need to recover (and how much data you can afford to lose)
- Recovery Time Objective (RTO) - how soon you need to have a working data center in order to maintain business continuity

In a typical scenario that employs remote mirrors, the contents of a source volume are mirrored to a mirror volume in a remote cluster at a frequency specified by the mirror schedule. At the start of each mirror operation, a snapshot is taken of the source volume's contents. The mirror operation takes some time to complete, and while the data is being copied from the snapshot to the mirror volume, more data is written to the source volume. This data will be captured during the next mirror operation. When each mirror operation completes, the contents of the mirror volume are identical to the contents of the source volume at the time of the snapshot. For subsequent mirror operations, only the incremental changes (additions and deletions) are copied to the mirror volume, which synchronizes its contents with the contents of the source volume at the time of the snapshot.



If the source cluster goes down, any data written to the source volume since the last successful mirror operation cannot be copied to the mirror. The amount of data lost depends on the number of write operations in the interval from the last successful mirror to the time the cluster goes down.

Factors that Affect RTO

Lists the factors that affect the Recovery Time Objective (RTO).

During a disaster, an administrator must first determine that the link between the primary data center and the secondary data center has failed. Next, the administrator begins the process of switching applications that were running on the primary data center over to the secondary data center. For write applications, the administrator begins converting mirror volumes to read-write volumes, starting with volumes that contain the most critical data. Note that read applications can run on read-only mirrors, but write applications can only run on read-write volumes.

To gauge how long it will take to switch applications from the primary data center to the secondary data center (and to set the RTO accordingly), consider these factors:

- Detection time (how long it takes to determine that the link is down between the two data centers)
- Switching time (how long it takes to switch applications from one data center to the other)
- Promotion time (how long it takes to change read-only mirror volumes to read-write volumes that can run write applications). Promotion time is based on the number of containers in a volume or across volumes.
- Whether mirror throttling is enabled (the default) or disabled (which speeds up the mirroring process)

Various factors affect the amount of data that can be recovered through the use of mirror volumes. To specify a realistic recovery point objective in your disaster recovery plan, take the following factors into account:

last-updated: Apr 11, 2022

- Mirror schedule (how often the mirror is synchronized with its source volume) - Note that the first mirror operation is a full synchronization between source and mirror volumes. Subsequent mirror operations are incremental - only the changes that occurred since the last mirror event need to be copied in order to synchronize the contents between the two volumes.
- Network link between the source volume and the mirror volume (consider the stability and quality of the link, as well as latency, throughput, and other activities across the link)

Data Tiering
Provides an overview of what tiering is, its various types, and its working.

MapR provides rule-based automated tiering functionality that allows you to seamlessly integrate with:

- Low-cost storage as an additional storage tier in the MapR cluster for storing file data that is less frequently accessed ("warm" data) in erasure-coded volume.
- 3rd party cloud object storage as an additional storage tier in the MapR cluster to store file data that is rarely accessed or archived ("cold" data).

In this way, valuable on-premise storage resources can be used for more active or "hot" file data and applications, while "warm" and/or "cold" file data can be retained at minimum cost for compliance, historical, or other business reasons. MapR provides consistent and simplified access to and management of the data.

See also: Working with Tiered Volumes on page 926

Where is data tiered?

For "warm" data, MapR allows you to offload data to specific nodes or low-cost hardware in a topology. MapR uses erasure coding to protect data on the low-cost hardware. Erasure coding also reduces the storage overhead in the range of 1.2x-1.5x. See Overview of Tiers on page 471 for more information on erasure coding.

For "cold" data, MapR allows you to easily offload your cluster data to public, private, and hybrid clouds. You can offload data to remote cloud from vendors such as Amazon AWS, Google Cloud Platform, Microsoft Azure, IBM Cleversafe, Hitachi HCP, and Minio. This allows you to tap into cloud-scale capacity.

Note: MapR supports tiering for only file and volume data; tiering of tables and streams is not supported.

MapR allows you to configure a volume at the time of volume creation for either warm or cold tier, but not both. If you do not know the type of tier to associate with the volume, you can still create a volume that is tiering-enabled and associate a specific tier later with the volume. However, volumes not enabled for tiering at the time of volume creation cannot be enabled for tiering after the volume is created. You cannot modify the type of tier associated with the volume after the volume is created.

When you create a volume and configure it for warm or cold tiering — associating a warm or cold tier, a storage policy (referred to as rule in the CLI), and an offload schedule — MapR automatically moves the data out of the volume and into the tier, and purges the data in the volume on the MapR cluster to release the disk space on the MapR cluster. However, for tiering-enabled volumes, the amount of hard quota you set is the total space allocated for the volume irrespective of the location (cluster or tier) of the volume data. Writes fail when volume disk space usage reaches the quota assigned for the volume whether or not volume data is local (on the cluster) or remote (on the tier). Also, if you want to recall volume data back to the MapR cluster, you must have the disk space in the volume equivalent to the amount of data being recalled from the tier. You can retrieve and view the disk space usage metric, including the amount of data offloaded to the tier, for a tiering-enabled volume using the Control System, the CLI, and REST API.

How frequently is data offloaded?

MapR automatically offloads data based on the criteria that you define in the storage policy for offloading data and at the frequency you specify in the schedule. MapR automatically offloads data in the volume at the frequency in the schedule only if data in the volume meets the criteria in the associated storage policy. If you do not specify a criteria, for volumes configured for:

- Erasure coding (warm tier), MapR applies a default criteria, which is a modification timestamp of 1 day, for offloading data.
- Remote archiving (cold tier), MapR does not associate a default criteria. You can use the Control System, CLI, and REST API to manually trigger an offload of volume data.

For more information, see Data Storage Policy on page 474. If you do not associate a schedule for offloading data, for volumes configured for:

- Erasure coding (warm tier), MapR automatically uses the default Automatic Tiering Scheduler, which uses internal policies to decide when to schedule the offload operation.
- Remote archiving (cold tier), MapR does not associate a default schedule. You can use the Control System, CLI, and REST API to manually trigger an offload of volume data.

Even when you manually trigger an offload, MapR offloads data only if the data meets the criteria defined in the storage policy. In addition, for warm-tier volumes, MapR offloads data only if the object (stripe) has data exceeding 90% of the object payload; if an object has data less than 90% of the object payload, the object is not offloaded and the metadata tables are not updated. For more information, see Data Offload and Purge on page 475.

What is the MAST Gateway?

The MapR automated storage tiering (MAST) Gateway acts as the centralized entry point for all the tiering operations. CLDB assigns tiering-enabled volumes to MAST Gateways for processing all tiering operations for the volume. For more information, see Overview of MAST Gateway on page 472.

How is compressed and encrypted data transferred and stored?

Data is encrypted during transfer to ensure security of data if the cluster is a secure cluster and if wire-level security is enabled for the volume. In addition, stored data is encrypted if:

- The warm-tier volume is enabled for data-at-rest encryption (`dare`).
- The cold-tier volume is enabled for tier encryption (`tierencryption`).

Data in the volume is transferred and stored as-is, compressed or uncompressed, on the tier. You can set up replication, snapshots, and mirror volumes for tiering-enabled volumes. See Data Replication, Snapshots, Mirroring, Auditing, and Metrics Collection on page 478 for more information.

How are reads, writes, and deletes handled?

When a client tries to read offloaded data, MapR processes the read request of the warm-tiered and cold-tiered standard and mirror volume data differently. Similarly, when a client writes to a tiered volume, MapR processes appends and overwrites differently. See Data Reads, Writes, and Recalls on page 481 for more information.

Data, once offloaded, is purged on the MapR cluster to release the disk space. When you delete an entire file, part of a file, or a snapshot, corresponding objects are removed from the tier also. See Data Compaction on page 485 for more information.

Enabling Tiering

To enable tiering, see Enabling Tiering on page 957

.

Overview of Tiers

Describes what warm and cold tiers are.

MapR considers data that is active and frequently accessed as "hot" data and data that is rarely accessed as “warm” or “cold” data. The mechanism used to store "hot" data is referred to as the hot-tier (or the MapR cluster), the mechanism used to store "warm" data is referred to as the EC-tier (or low-cost storage alternative on the MapR cluster), and the mechanism to store "cold" data is referred to as the cold tier (or low-cost storage alternative on the cloud). Hot, warm, and cold data is identified based on the rules and policies set by the administrator.

Data starts off as hot when it is first written to local storage (on the MapR cluster). It becomes warm or cold based on the rules and policies the administrator configures. Data can then be set up to be automatically offloaded using the MapR automated storage tiering (MAST) Gateway service to the erasure coded volume on the low-cost storage alternative on the MapR cluster (warm tier) or to the low-cost storage alternative on the 3rd party cloud object store (cold tier) like AWS S3.

Warm Tier	On the MapR cluster, every volume enabled for erasure coding (or warm tiering) acts as a "front-end" volume and has a corresponding hidden erasure coded (or EC) volume in the specified topology (of the low-cost storage alternative). Erasure coding (EC) is a data protection technique where data is broken into many fragments (or *m* pieces) and encoded with some extra redundant fragments (or *n* pieces) to guard against disk failures. That is, for volumes configured for erasure coding, file data in the volume is broken into many fragments (or *m* pieces) and encoded with pre-configured number of redundant fragments (or *n* pieces). In the event of disk failure, any *m* piece can be used to get back the original file. See Erasure Coding Scheme for Data Protection and Recovery on page 926 for more information. Although you write to and read from the front-end volumes, the front-end volume is akin to a staging area, where volume’s data is held on demand. Data written to a volume is periodically moved to the back end erasure coded volume, releasing the disk space for the front-end volume on the filesystem and providing the space savings of erasure coded volumes. Data in the front-end volume is moved to the corresponding erasure coded volume based on an offload schedule. The front-end volume holds only small amount of required data, and data is shuffled between the front-end volume and the corresponding erasure coded volume as required. See Data Reads, Writes, and Recalls on page 481 for more information. There is also a visible tier-volume on the MapR cluster for storing the metadata associated with the volume. When you create a warm tier, the tier volume named `mapr.internal.tier.<tiername>` is by default created in the `/var/mapr/tier` path. When you create a warm-tier volume using the `ecenable` parameter or the Control System, a warm tier is automatically created and the corresponding tier volume named `mapr.internal.tier.autoec.<volName>.<creationTime>` is, by default, created in the `/var/mapr/autoectier` path.

last-updated: Apr 11, 2022

	While three-way replicated regular volumes require 3 times the amount of disk space of the regular volume, erasure coded volumes reduce the storage overhead in the range of 1.2x-1.5x. On the MapR cluster, only the metadata of the volume in the namespace container is 3-way replicated. You can create one warm tier per volume using the Control System, the CLI, and REST API or create and associate multiple volumes with different erasure coding schemes with the same warm tier using the CLI and REST API (only). You cannot associate the same warm tier with multiple volumes using the Control System.
Cold Tier	On the MapR cluster, every cold tier (referred to as remote target in the Control System) has a bucket on the 3rd party cloud store where volume data is offloaded based on the policy configured by the administrator. Volume data in 64KB data chunks is packed into 8MB sized objects and offloaded to the bucket on the tier and the corresponding volume metadata is stored in a visible tier-volume as MapR Database tables on the MapR cluster. During writes and reads, volume data is recalled to the MapR cluster if necessary. Data written to the volume is periodically moved to the remote target, releasing the disk space on the filesystem. See Data Reads, Writes, and Recalls on page 481 for more information. Data stored on the MapR cluster requires 3 times the amount of disk space of the regular volume on premium hardware due to replication (default being 3). After offloading to the cloud, the space used by data (including data in the namespace container) in the volume on the MapR cluster is freed and only the metadata of the volume in the namespace container is 3-way replicated on the MapR cluster. There is also a visible tier-volume on the MapR cluster for storing the metadata associated with the volume. When you create a cold tier, the tier volume named `mapr.internal.tier.<tierName>` is by default created in the `/var/mapr/tier` path. A directory/folder for the volumes associated with the tier, identifiable by `volumeid`, is created under the path after the first offload of data from the volume to the tier. You can create one tier per volume or create and associate multiple volumes with the same tier using the Control System, the CLI, and REST API.

See also: Managing Tiers on page 957

Overview of MAST Gateway
Describes the role of the MAST Gateway for operations on tiered storage.

The MAST Gateway can be installed on specific hosts on the MapR cluster with access to the tier. The MAST Gateway acts as the centralized entry point for all the operations that need to be performed on the tiered storage including the following:

Warm Tier	For volumes configured for warm tiering, the MAST Gateway:

- Identifies files in the volume that are ready to be offloaded, fetches data corresponding to these files from MapR File System, and packs this data for offload. It:
  - Identifies and fetches the data to offload.

    It handles both compressed and uncompressed data. Compressed data from the file server is transferred and stored as-is on the warm tier.
  - Creates stripes based on the erasure coding scheme.

    For example, for an erasure coding scheme of 4+2, the stripe depth would be 6x4MB=24MB.
  - Manages statistics on the amount of data offloaded.
  - Prepares a corresponding metadata on the MapR cluster for the data.

    The MAST Gateway stores the metadata in MapR Database tables in a separate volume associated with the tier.
- Tracks invalid data and deletes stripelets that are completely invalid.
- Fetches data from the tier.
- Recalls whole volume from the tier to the MapR cluster.

Cold Tier

For volumes configured for cold tiering, the MAST Gateway:

- Identifies files in the volume that are ready to be offloaded, fetches data corresponding to these files from MapR File System, and packs this data for offload. It:
  - Identifies and fetches the data to offload and creates objects (including creating new buckets) in the storage tier for the data.
  - Manages statistics on the amount of data offloaded.
  - Updates metadata references for remote access.
- Tracks invalid data and deletes objects that are completely invalid.
- Fetches data from the tier. It:
  - Handles both compressed and uncompressed data. If data on file server is compressed, the compressed data is not uncompressed/re-compressed during offload or recall. Compressed data from the file server is transferred and stored as-is on the cold tier.

last-updated: Apr 11, 2022

    - Ensures that data is decrypted, if it is encrypted, before forwarding it to MapR File System.
- Recalls whole volume from the tier to the MapR cluster.

The MAST Gateway uses curl to transfer data to and from S3 cloud storage.

The MAST Gateway uses an exponential backoff retry mechanism. If curl fails to connect to the S3 destination even after a minute of trying, or if curl fails to fetch data from the S3 destination even after 5 minutes of being connected, the MAST Gateway declares a failure and reports it to the CLDB. The CLDB then reschedules the (vol) tasks after 30 minutes.

The MAST Gateway sends heartbeat messages to CLDB every 5 seconds. CLDB manages the discovery and a minimal global state of the MAST Gateway service. CLDB also manages the volumes and any policy configurations on the volumes. When a volume is assigned to a gateway, the volume remains assigned to the gateway across CLDB, Gateway, and cluster restarts. Volumes are assigned evenly to gateways and CLDB balances the gateway load. For more information, see Balancing Gateway Load on page 1264.

By default, the MAST Gateway uses 16 threads for volume and file offload and recall operations and another 16 threads for handling internal operations and other operations such as reads (which triggers automatic recall requests), writes, etc. Each thread processes uses the curl library to offload or recall a container (associated with a volume). Each MAST Gateway can process one or more volumes (and associated containers) simultaneously depending on the number of threads available for processing the containers associated with the volumes. Each volume is assigned to a MAST Gateway for a tiering operation irrespective of the number of containers associated with the volume.

When a MAST Gateway goes down during a volume-level offload, CLDB does not immediately reassign all the volumes assigned to that MAST Gateway to other gateways. CLDB waits for some time to allow the MAST Gateway to come back up and send heartbeat again; CLDB re-assigns volumes with pending tasks to other gateways if the MAST Gateway does not come back up again. All other volumes are redistributed when the gateway balancer runs again. On the other hand, if the MAST Gateway comes back up again, the volumes remain assigned to the MAST Gateway. The load on the MAST Gateways is rebalanced when the balancer runs again. See Balancing Gateway Load on page 1264 for more information. MAST Gateways use transactions to ensure that all the updates are consistent, and that any new gateway can pick up exactly from where the old gateway left.

If a MAST Gateway goes down during a file-level offload and if the offload was triggered using:

- The `hadoop` command, CLDB reassigns the volume to another MAST Gateway.
- The MapR CLI, REST API, or dot interface, CLDB does not reassign to another MAST Gateway.

See also: Managing the MAST Gateway on page 1259

Data Storage Policy
Provides an overview of creating storage policies and formulating rules to offload data.

You can configure a storage policy (or rules) for data at the volume level. The storage policy simplifies the lifecycle management of data in the volume including automated migration of files to low-cost storage alternatives. The policy can contain rules for files that have a well-defined lifecycle or for files you want to switch to different storage tiers during their lifecycle.

You can specify the rules, at the volume level, to selectively identify files to offload (such as file size, file owner, and file modification time), the schedule for offloading the data (for example, 2 months after file modification), and the settings for storing (such as the location and credentials for the tier) and recalling the offloaded data. You can configure one rule per volume using the CLI or REST API. You can also associate a schedule to automatically offload data at scheduled intervals based on the associated rules.

See Managing Storage Policies on page 970 for more information.

Data Offload and Purge
Describes the process of offloading data to warm and cold tiers, and purging data from storage pools.

The MAST Gateway service drives the offload process. On volumes configured for warm or cold tiering, the CLDB notifies the MAST Gateway service to start the offload based on either of the following:

- The schedule set at the volume level for offload.
- The request triggered by the client (through the Control System, the CLI, or REST API).

The MAST Gateway service then scans the files in the volume and starts the offload by picking the files that meet the criteria in the rule associated with the volume.

Offloading Data to the Warm Tier

On volumes configured for warm tiering, the MAST Gateway service detects the files that meet the criteria in the configured rules, collects data to offload from the read-write containers of the front-end volume on the MapR file system, and:

1. Creates objects based on the erasure coding scheme.

   For example, for an erasure coding scheme of 4 + 2 (6) and stripe depth of 4 MB, which is the default, the object size is 4 x 4 MB = 16 MB and the stripe length is 6 x 4 MB = 24 MB. When offloading a file, the file must contain data exceeding 90% of the object payload to qualify for offload. When offloading a volume, an object can contain multiple small files. Objects that fall below the threshold are not offloaded.

   Note: Data is broken into many fragments (or *m* pieces) and encoded with some extra redundant fragments (or *n* pieces) to guard against disk failures.

2. Prepares a corresponding metadata on the MapR cluster for the data.

   The MAST Gateway stores the metadata in MapR Database tables in a separate volume associated with the tier.

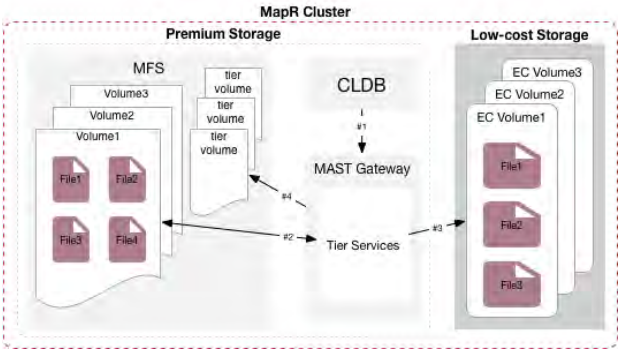
3. Offloads the objects to the tier.

   Note: If an object contains less than 90% of the object payload, the object is not offloaded and the metadata table is not updated; the volume might have local data. However, the MAST Gateway will report successful job completion.

   Data is offloaded to the tier in the same state, compressed or uncompressed, as was stored in the front-end volume. If data encryption is enabled on the front-end volume (using the `dare` parameter), data is encrypted during and after offload to the erasure-coded volume.

The following illustration shows the CLDB notifying the MAST Gateway service to start the offload (#1) and the MAST Gateway fetching data from the front-end volume (#2), offloading the data to the associated erasure-coded volume (#3), and then writing metadata to the tier volume associated with the front-end volume (#4).

last-updated: Apr 11, 2022



When offloading files, small files might not always qualify for offload because objects that contain less than 90% of the object payload do not qualify for an offload. For example, suppose the files in a volume enabled for warm-tier erasure coding scheme 4 + 2 are 2 MB each. If the object size for the volume is 16 MB (4 x 4 MB), an individual file of 2 MB is less than 90% of the object payload. In this case, a 2 MB file does not qualify for offload by itself. Similarly, portions of a large file might not qualify for offload. For example, suppose a file in the volume enabled for warm-tier erasure coding scheme 4 + 2 is 20 MB. The object size for the volume is 16 MB (4 x 4 MB), and the individual file of 20 MB exceeds the upper limit of the object payload. Portions of data in the file are offloaded, and up to 4 MB of file data might still be on the cluster.

Offloading Data to Cold Tier

On volumes configured for cold tiering, the MAST Gateway service detects the files that meet the criteria in the configured rules, collects data to offload from the read-write containers and snapshots for the volume on the MapR file system, and:

1. Packs 64 k data chunks into 8 MB-sized objects.
2. Creates the bucket on the tier (or remote target) if the specified bucket is already not present on the tier.
3. Prepares corresponding metadata on the MapR cluster for the data and creates the objects in the tier.

   The MAST Gateway stores the metadata in MapR Database tables in a separate volume associated with the tier.

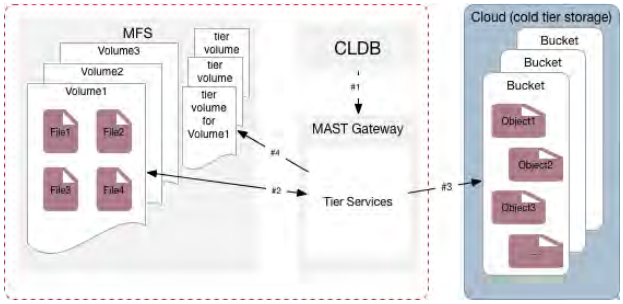
4. Offloads the data to the tier using libcurl.

   Note: Data is offloaded to the tier in the same state, compressed or uncompressed, it was stored on the MapR File System. If data encryption is enabled at the volume level (using the `tierencryption` parameter), data is encrypted during and after offload. See `volume create` or `volume modify` for more information about the parameter.

   For the offloaded data, the unique object IDs are generated using a combination of cluster ID, volume ID, and a unique sequence of numbers. For example, the names of the objects in S3 can look similar to the following:

   ```
   0.b258a07.86e.1
   0.b258a07.86a.1
   0.b258a07.86c.1
   ```

   The following illustration shows the CLDB notifying the MAST Gateway service to start the offload (#1) and the MAST Gateway fetching data from the volume (#2), offloading the data to the third-party storage alternative (#3), and then writing metadata to the tier volume associated with the volume (#4).



The MAST Gateway service notifies the CLDB when the offload operation completes successfully. Entire volumes can be moved from "hot" to "warm" tier or "hot" to "cold" tier and vice-versa on demand by using CLIs. For each offloaded volume, the MapR File System stores only the metadata for the offloaded data in a volume on the hot tier.

Note: If the offload fails, an alarm, VOLUME_ALARM_OFFLOAD_FAILURE, is raised. Check the log file for more information about the error. For log information, see Enabling Debug Logging for MAST Gateway on page 1266. For some errors, CLDB tries to offload the data again after a brief wait. For more information, see Retrying Failed Operation on page 939.

See also: Offloading a Volume to a Tier on page 933 and Offloading a File to a Tier Using the CLI and REST API on page 1012

Purging Data on MapR File System

While offloading, metadata is written to the MapR Database table in a separate volume associated with the tier, and the data blocks are removed from the storage pool in the hot-tier. An offload is considered successful only when data on all active replicas has been purged (or removed from the storage pool to release the disk space on the MapR file system) in the hot-tier. When you offload data at the file level, all data, including recalled data, is immediately purged from the hot-tier. For more information, see Data Compaction on page 485.

last-updated: Apr 11, 2022

Data Replication, Snapshots, Mirroring, Auditing, and Metrics Collection
Provides an overview of what Data Replication, Snapshots, Mirroring, Auditing, and Metrics Collection are.

Replication

Data from one of the replica containers is first offloaded and then the data in all the replica containers is purged. MapR File System only stores the metadata after data is offloaded. The offload is considered successful only when data on all active replicas have been purged (or removed from the storage pool to release the disk space on the MapR filesystem). If, during the offload, the node on which one of the replicas reside is down, the data on that container is purged once the node comes back up.

In the tiering architecture, although data is moved to the storage tier, the namespace of the volume continues to be 3-way replicated. So, the metadata related to namespace container has 3x cost.

The offloaded replica containers are recalled if/when the whole volume is recalled. When a replica is reinstituted to the cluster as a result of a recall operation, a re-synchronization happens to bring all the replicas up to date from the designated master container.

Note: The offload and recall settings on the master container are applicable to the replica containers as well.

Snapshots

You can associate a snapshot schedule with tiering-enabled volumes. When the data in the volume is offloaded, associated snapshots are also offloaded and MapR File System only stores the metadata. If the whole volume is recalled, the snapshots are also recalled to the MapR filesystem. When offloading recalled snapshots, the rules for data offload apply to snapshots as well.

Note: You may experience latencies when accessing snapshots associated with offloaded data.

Mirroring

You can create tiering-enabled source volumes and associate them with tiering-enabled mirror volumes. You cannot associate tiering-enabled mirror volumes with standard volumes that are not tiering-enabled and vice versa. Only homogeneous combination of mirror and standard volumes are supported; heterogeneous combination of mirror and standard volumes are **not** supported.

Note: Both mirror volume and source volume data can be set up to be offloaded to the same tier (that is the same cold tier) or different tiers (that is different cold tiers). MapR does not require the source and mirror volume to be configured to use the same tier or have the same tier settings. Warm tier enabled volumes can have the same tier settings; however, the volume's tier only stores the meta data and data in each volume is offloaded to an associated back-end volume.

When a synchronization of the tiering-enabled mirror volume with the (local or remote) tiering-enabled source volume is triggered (either manually or automatically based on a schedule), the mirror volume synchronizes with the source volume if source volume data is local (and not yet tiered). On the other hand, if the source volume data is tiered, the tiering-enabled mirror volume synchronizes with the tiered data fetched by the MAST Gateway that is assigned to the source volume. Incremental changes in the mirror volume are offloaded based on the offload rules associated with the tiering-enabled mirror volume.

Using Tiering-Enabled Mirror Volumes for Disaster Recovery	You can create a secondary, cost optimized disaster recovery cluster for a primary three-way replicated cluster. To do this, create two clusters — a primary tiering-enabled cluster with no active schedule to automatically offload data and an associated secondary cluster where primary cluster data is mirrored and then aggressively offloaded to the tier. While the primary or source cluster continues to be three-way replicated, if the the secondary, disaster recovery cluster data is:

last-updated: Apr 11, 2022

- Erasure coded (warm tier), it provides space savings in the range of 1.2x-1.5x.
- On a third-party cloud storage (cold tier), it can be three-way replicated on a low-cost storage alternative.

In case of a disaster, you can recall data from the tier to the MapR cluster.

Note: If you promote a tiering-enabled mirror volume during an offload or recall operation of the data associated with the mirror volume, the offload or recall operation is aborted and the mirror volume is converted to a read-write volume; the `tierjobstatus` command for the offload or recall job shows AbortedInternal status.

Auditing

The MapR audit feature lets you log audit records of cluster-administration operations and operations on the data in the volume. Scheduled (and automatically triggered) tiering operations such as offload and compaction are not audited. However, if auditing is enabled at the cluster level, the manually triggered volume-level tiering operations such as offload, recall, abort, etc. are audited in the CLDB audit logs. For example, you can see a record similar to the following in the `/opt/mapr/logs/cldbaudit.log.json` file for `volume offload` on page 2023 command:

```
{"timestamp":
{"$date":"2018-06-07T15:34:28.580Z"},"resource":"vol1","operation":"volumeOf
fload","uid":0,"clientip":"10.20.30.40","status":0}
```

If auditing is enabled for data in the tiering-enabled volume and files within, file-level tiering operations such as offload, recall, etc. triggered using the REST API, hadoop, and dot-interface are audited in the FS audit logs (`/var/mapr/local/<hostname>/audit/5661/FSAudit.log-<*>.json` file).See Auditing Data Access Operations on page 698 for the list of file-level tiering operations that are audited. You can selectively enable or disable auditing of these operations. See Selective Auditing of MapR File System, MapR Database Table, and MapR Event Store For Apache Kafka Operations Using the CLI on page 761 for more information. For example, you can see records similar to the following in the `/var/mapr/local/<hostname>/audit/5661/FSAudit.log-<*>.json` file for `file offload` on page 1659 command:

```
/mapr123/Cloudpool19//var/mapr/local/abc.sj.us/audit/5660/
FSAudit.log-2018-09-12-001.json:1:{"timestamp":
{"$date":"2018-09-12T05:47:04.199Z"},"operation":"FILE_OFFLOAD","uid":0,"ipA
ddress":"10.20.35.45","srcFid":"3184.32.131270","volumeId":16558233,"status"
:0}
```

Both the `tier rule list` on page 1892 and `tier list` on page 1880 commands are audited in the `/opt/mapr/logs/cldbaudit.log.json` file as well as the `/opt/mapr/mapr-cli-audit-log/audit.log.json` file. The record in the audit log might look something similar to the following:

```
{"timestamp":
{"$date":"2018-06-13T09:15:24.004Z"},"resource":"cluster","operation":"offlo
adRuleList","uid":0,"clientip":"10.10.81.14","status":0}
{"timestamp":
{"$date":"2018-06-13T09:14:42.304Z"},"resource":"cluster","operation":"tierL
ist","uid":0,"clientip":"10.10.81.14","status":0}
```

When auditing operations like `tierjobstatus` and `tierjobabort`, the coalesce interval set at the volume level is not honored. You may see multiple records of the same operation from the same client in the log.

Read requests processed using cache-volumes or erasure-coded volumes are not audited because when the file is accessed, the request first goes to the front-end volume and the operation is audited there. The audit record contains the ID of the front-end volume (volid) and primary file ID (fid). However, the write to the cache-volume for a volume-level recall of data is audited in the audit logs on the file server hosting the cache-volume with the primary file ID (fid). The write to the cache-volume for a file-level recall of data is not audited.

In addition, you can enable auditing of offload and/or recall events at both the volume and file levels by enabling auditing for `filetieroffloadevent` and `filetierrecallevent` at the volume level. By default, auditing is disabled for `filetieroffloadevent` and `filetierrecallevent`. If you enable auditing for `filetieroffloadevent` and `filetierrecallevent` using the `dataauditops` parameter with the `volume create` on page 1931 or `volume modify` on page 2005 command, the following are audited in the FS audit log:

- For `filetieroffloadevent`, files offloaded by running the `file offload` on page 1659 command or (only) files purged on MapR filesystem after running `volume offload` on page 2023 command.
- For `filetierrecallevent`, files recalled by running the `file recall` on page 1660 or `volume recall` on page 2025 command.

For example, you can see a record similar to the following in the `/var/mapr/local/<hostname>/audit/5661/FSAudit.log-<*>.json` file if auditing is enabled at the volume-level for `filetieroffloadevent`:

```
abc.sj.us/audit/5661/FSAudit.log-2018-06-07-001.json:{"timestamp":
{"$date":"2018-06-07T07:27:58.810Z"},"operation":"FILE_TIER_OFFLOAD_EVENT","
uid":2000,"ipAddress":"1}
```

For more information:

- Auditing in MapR on page 690
- Managing Auditing on page 757

Collecting Metrics

If volume metrics collection is enabled on the tiering-enabled volume, metrics for all read and write operations on the tiered volume are logged in the metrics log. For example, you can see a record similar to the following in the metrics log file:

```
{"ts":1534960230000,"vid":248672388,"RDT":0.0,"RDL":0.0,"RDO":0.0,"WRT":3636
22.7,"WRL":7209.0,"WRO":2580.0}
{"ts":1534960250000,"vid":248672388,"RDT":363686.7,"RDL":2856.0,"RDO":2847.0
,"WRT":0.0,"WRL":0.0,"WRO":0.0}
```

Tiering-related operations do not generate metrics records. That is, volume and file level offload, recall, and abort operations are not logged in the metrics log. However, the volumes created to support tiering (such as the cache-volume, the metadata volume, and the erasure-coded volume) have metrics collection enabled and the metrics records for these volumes are logged with the ID of the associated parent or front-end volume. That is, read operations on the the cache-volume are logged with the ID of the associated front-end volume. For example, you can see records similar to the following in the metrics log file for the volume:

```
{"ts":1534968850000,"vid":209801522,"RDT":6328.5,"RDL":161.0,"RDO":158.0,"WR
T":0.0,"WRL":0.0,"WRO":0.0}
{"ts":1534968860000,"vid":209801522,"RDT":234669.7,"RDL":5241.0,"RDO":5143.0
,"WRT":0.0,"WRL":0.0,"WRO":0.0}
```

See Enabling Volume Metric Collection on page 1301 and Collecting Volume Metrics on page 1300 for more information.

Data Reads, Writes, and Recalls
Provides a synopsis of how data is read and written to a warm or cold tier.

Once offloaded to the storage tier, data is considered to be warm or cold on the storage tier, but the data can still be accessed (read, written, and recalled).

Read of Tiered Data

Depending on whether the standard volume data is outside the MapR cluster and in the cloud (cold tiering) or on the MapR cluster (warm tiering), MapR processes the request to read standard volume data and mirror volume data.

Data Reads on Tiering-Enabled Standard Volumes

MapR processes client requests to read standard volume data on the warm tier and the cold tier differently.

Warm Tier

When a client attempts to read, the read request is first sent to the front-end volume and if the data exists in the front-end volume, the data is returned from the front-end volume. If data is not in the front-end volume, the data is returned from the erasure coded volume.

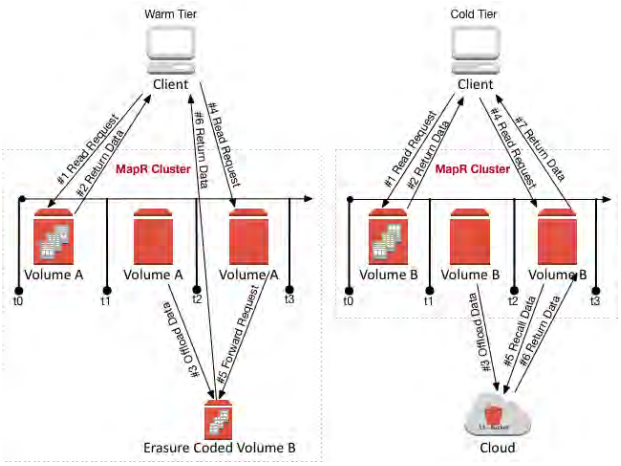
Cold Tier

When a client attempts to read, the read request is first sent to the volume on the MapR cluster and if the data exists in the volume on the cluster, the data is returned from the volume. On the other hand, if the data was offloaded, the MAST Gateway recalls the data from the cold-tier to process the read request. See Recall of Tiered Data on page 484 for more information on recalled data.

The following illustration shows a client sending the data read request first (#1) to the tiering-enabled volume and the response (#2) being served from the volume on the MapR cluster. Then (#3), data is offloaded to the back-end erasure coded volume (for Volume A) and to the cloud (for Volume B). When the client next sends a read request to the volume on the MapR cluster (#4), for:

- Volume A, the MAST Gateway forwards the request to the back-end erasure-coded volume (#5) from where data is returned (#6) to the client.

- Volume B, the MAST Gateway recalls the data (#5 and #6) from the cloud to the volume on the MapRcluster, from where data is returned (#7) to the client.



Data Reads on Tiering-Enabled Mirror Volumes

MapR processes client requests to read mirror volume data on the warm tier and the cold tier differently.

Warm Tier

When a client attempts to read, the read request is first sent to the front-end volume and if the data exists in the front-end mirror volume, the data is returned from the front-end volume. If data is not in the front-end volume, the data is returned from the erasure coded volume.

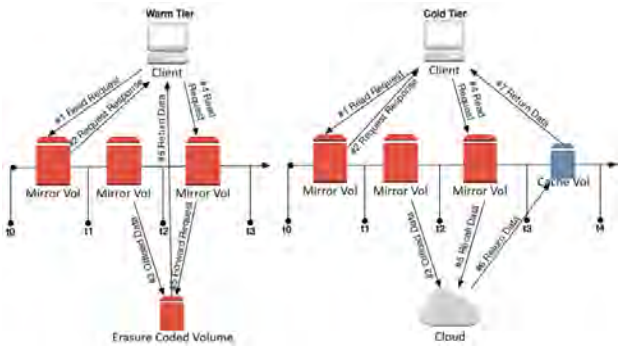
Cold Tier

When a client attempts to read, the read request is first sent to the volume on the MapR cluster and if the data exists in the volume on the cluster, the data is returned from the volume. On the other hand, if the data was offloaded, the MAST Gateway recalls or fetches a copy of the data (from the tier) into an associated cache-volume, from where data is returned to the client. See Recall of Tiered Data on page 484 for more information on recalled data.

The following illustration shows a client sending the read request first (#1) to the tiering-enabled mirror volume and the response (#2) being served from the volume on the MapR cluster. Then (#3), data is offloaded to the back-end erasure coded volume (for

warm tier) and to the cloud (for cold tier). When the client next sends a read request to the volume on the MapR cluster (#4), for:

- Warm tier, data is returned from the back end erasure-coded volume (#5).
- Cold tier, data is recalled in the associated cache-volume (#5 and #6), from where data is returned to the client (#7).



The cache-volume named `mapr.internal.cv.<volume-name>_<id>` is created when the tiering-enabled mirror volume is created. Although it may not hold any data initially, a copy of the tiered data is fetched into the cache-volume whenever there is a read of the cold-tiered mirror volume data or explicit recall of (cold or warm) tiered mirror volume data. You can use the `volume info` on page 1965 command on the tiering-enabled mirror volume to get the offload and recall statistics, which are from the cache-volume, for the mirror volume.

The cache-volume has the same replication factor as the mirror volume (at the time of volume creation); changes to the mirror volume replication factor do not trigger a change to the replication factor of the associated cache-volume.

If the tiering-enabled mirror volume is deleted, the cache-volume is also deleted. If the tiering-enabled mirror volume is promoted to a read-write volume, the associated cache-volume is deleted.

Write on Tiered Data

When writes happen, if the write is:

- An append, new data is offloaded when the data meets the criteria in the rule (associated with the volume) for offload.
- A change to existing data (overwrite), the data is recalled to the MapR filesystem to allow the write to succeed and then offloaded when the data meets the criteria in the rule (associated with the volume) for offload. See Recall of Tiered Data on page 484 for more information on recalled data.

Note: If cold data is accessed (read/written) frequently, I/O to that file may suffer large latencies. In such scenarios, recall the whole volume or the corresponding files.

Recall of Tiered Data

Offloaded data is automatically recalled when a client performs a read or overwrite on the data in the cold-tier, or when a client performs an overwrite on the data in the warm-tier. The MAST Gateway fetches a copy of the data to allow the operations to succeed. You can also manually trigger a recall of:

- All volume data using the `maprcli` command or REST API.

  See Recalling a Volume to MapR File System on page 936 for more information.

- File using the `hadoop` command, `maprcli` command, REST API, (loopbacknfs or FUSE-based) POSIX client, or the NFS client.

  See Recalling a File to MapR File System Using the CLI and REST API on page 1012 and Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1014 for more information.

Based on the expiration time period set at the volume level for recalled data, recalled data is:

- Offloaded again based on the rules if there are changes to the data.
- Purged when the compactor runs if there are no changes to the data.

For a cold tiering volume, explicitly recall the volume before running any analytics jobs.

For mirror volumes, when you recall tiered data, data from the tier is recalled into an associated cache-volume, which is created at the time of the creation of the tiering-enabled mirror volume. For all explicit recall of warm-tiered data and explicit and automatic recalls of cold-tiered data, the MAST Gateway recalls data into the associated cache-volume. The data in the cache-volume is "hot" in the cluster, or available for reads, for the duration of the expiry-period. The recalled data is purged by the compactor when the expiration time that is set at the volume level is reached or has passed.

If the recall fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 939 for more information.

Moving Data from Non-Tiered Volumes to Tier Enabled Volumes
Provides a synopsis of how to move data from non-tiered volumes to tier-enabled volumes.

Non-tiered volumes cannot be offloaded.

Use the following procedure to transfer data from a non-tiered volume to a fresh tiered volume, and then offload the data from the tiered volume.

If you are short on space, you can first break up large volumes into multiple small volumes.

You can then transfer one sub-volume at a time.

For example, assume that there are sub-volumes `/hugevolume/dir1`, `/hugevolume/dir2`, ..., `/hugevolume/dirN`. To transfer:

1. Create a new tiering enabled volume say `dir1`.
2. Mount it at `/tmp/dir1`.
3. Snapshot `/hugevolume/dir1`.
4. Use `distcp` to copy the snapshot to `/tmp/dir1`.
5. After the initial transfer, perhaps snapshot again and use rsync to sync the changes to `/tmp/dir1` to minimize downtime.
6. Delete `/hugevolume/dir1`.
7. Unmount the `dir1` volume and re-mount at `/hugevolume/dir1`.

8. Now `/hugevolume/dir1` will tier according to the schedule and rule specified when creating it in step 1.

9. Repeat the process for dir2 to dirN.

Data Compaction
Describes how data is purged from a cluster.

When you release the space allocated to a volume on the MapR cluster by deleting a file or snapshot, or by truncating a file, the MapR tier compactor can be set up to run automatically or manually to release the space on the tier associated with the volume by deleting the corresponding stripes or objects from the tier. In addition, when you recall data, the compactor automatically purges the recalled data on the MapR cluster if there are no changes to the data. By default, the compactor runs on an automatic internal schedule to determine if any deletion has happened on the MapR cluster since it last ran, and if necessary, remove the corresponding stripelets or objects from the tier.

MapR uses two settings (at the volume level) to determine when and how frequently to run the compactor:

- Overhead threshold — You can specify a percentage of offloaded data that must have been deleted to trigger the compaction operation. By default, the compactor performs the compaction operation only if at least 30% of the offloaded data is deleted.
- Compactor schedule — You can set up a custom schedule to run the compactor. By default, MapR uses the Internal Automatic Scheduler (ID is 4), which is based on internal parameters, to run the compactor.

The compactor runs only when there are no other tiering operations running for the volume. If there are other tiering operations, such as offload or recall, running for the volume, the compactor does not run until the tiering operation completes. If a tiering operation is triggered while the compactor is running, the tiering operation will fail. You cannot trigger a volume-level tiering job when another job is running for the volume. You can trigger a file-level offload or recall operation when a volume level job is running and vice-versa.

Purging Recalled Data

When you recall data to the MapR cluster explicitly (by running the `recall` command) or implicitly (by doing a read or an overwrite), the recalled data is purged by the compactor if there are no changes to the data and if the expiration time for recalled data has been reached or has passed. You can also manually run the compactor to force an immediate purge of recalled data. See Running the Compactor to Purge Recalled Data on the MapR Cluster on page 942 for more information.

Purging Stale Data

When you release space on the MapR cluster by deleting or modifying data, the compactor purges the data on the tier also. Depending on whether file data is completely deleted or partially deleted on the MapR cluster, the MapR compactor processes purging of data on the tier.

Warm Tier	For warm tiered volumes, the MapR compactor identifies corresponding objects (or stripes) on the tier and deletes entire objects first. After deleting entire objects, if there are partial objects to delete, the MapR compactor identifies the objects (with partially deleted data) that can be coalesced, fetches them, creates new objects with combined data, updates the metadata in the DB tables, deletes the old objects from the tier, and offloads the new objects to the tier. The compactor handles partial deletions only after deleting entire objects and only if the size of the remaining data to delete exceeds the compaction threshold.
Cold Tier	For cold tiered volumes in the S3 environment, while entire objects can be easily deleted, modifications and partial deletions are not supported. For example,

assume that data associated with a file is distributed across objects. When a file is deleted on the MapR cluster, corresponding data on the S3 tier can be easily removed if the object in the S3 tier only contains data associated with the deleted file. On the other hand, if the object also contains data from other files, the object cannot be deleted, and S3 does not support changes to the object or partial deletion of the object.

For partial deletions, the MapR compactor identifies the objects (with partially deleted data) that can be coalesced, fetches them, creates new objects with combined data, updates the metadata in the DB tables, deletes the old objects from the tier, and offloads the new objects to the S3 tier. The compactor handles partial deletions only after deleting entire objects and only if the size of the remaining data to delete exceeds the compaction threshold.

You can manually trigger the compactor to purge the stale data on the tier. See Running the Compactor to Purge Stale Data on the Tier on page 942 for more information.

Tuning Last Access Time
Provides an overview of the Last Access Time feature and its tuning.

What is Last Access Time?

Last Access Time (`atime`) is *file* metadata that is updated whenever a file is read. You can use `atime` for file management and governance decisions such as:

- Deleting files that have not been accessed for a while
- Tiering files (to warm or cold tier) that have not been accessed for a while
- Migrating files that have not been accessed frequently
- Purging files that have not been accessed for a time

Considerations When Enabling Last Access Time

- `atime` update can be enabled only on Standard/Erasure Coding/Object Tiering volumes. It cannot be enabled on mirrored volumes. If you convert the mirror volume to a Read/Write volume, `atime` is disabled by default. You can enable `atime` with the volume modify command.
- `atime` is applicable only for files. The `atime` of directories is NEVER updated.
- While the `read` operation is audited, the `atime` operation is not audited as it is an internal operation.
- The volume offload operation does not update `atime` but a file read from a backend/frontend volume updates `atime`.
- The file recall operation also updates `atime`.
- The file read operation on the EC/Tiered backend volume updates `atime` on the frontend volume.
- At the time of mirroring, the `atime` update frequency (`atimeUpdateInterval`) is propagated from the source volume to the mirror volume. However, any subsequent changes made to this frequency on the source volume, are not automatically propagated to the mirror volume.
- The time when you enabled `atime` updates (`atimeTrackingStartTime`) is updated to the current time in the following cases:

- Just started tracking `atime`, which means that the `atime` update frequency was previously zero
- If the value of `atime` update frequency is decreased
- If the value of `atime` update frequency is increased and `atime` has not been tracked for the duration of the new frequency value

Exceptions to Last Access Time Updates
`atime` is never updated when:

- Only the meta data of the file is being read
- The file is read from the client cache
- The file is read from a snapshot
- The `atimeUpdateInterval` has not been exceeded:

  For example, assume that for a volume the `atimeUpdateInterval` is set to 1 day. A file is created at 11AM and the file is read at 10:55AM the next day. If the read finishes at 10:58AM, `atime` will not be updated as the `atimeUpdateInterval` did not cross a day.

  For another example, assume that for a volume the `atimeUpdateInterval` is set to 1day. A file is created at 11AM and the file is read at 10:55AM the next day. If the read completes at 11:10AM, the `atime` will still not be updated though the read completed after 24 hours, because read was triggered at 10:55AM. `atime` will only be updated when the file is next read.

Upgrade Considerations

When a cluster is upgraded to MapR Data Platform 6.2, `atime` is not enabled on the old volumes. You need to enable `atime` manually using the volume modify command.

When a cluster along with a few clients are upgraded to MapR Data Platform 6.2, while the remaining clients are not upgraded, the older clients can not update `atime` on files. Only the upgraded clients can trigger an `atime` update. However, the older clients can see the updated `atime` value (updated by the upgraded clients).

Enabling the Last Access Time Feature

The Last Access Time feature is not automatically enabled irrespective of whether you perform a fresh installation or an upgrade. To enable and activate the Last Access Time feature, run:

```
maprcli cluster feature enable -name mfs.feature.update.atime
```

Enabling Last Access Time on Volumes

For performance reasons, the `atime` feature is disabled on volumes by default. You can enable `atime` updates at the volume level when creating or modifying volumes.

To set the frequency of `atime` updates, use the `atimeUpdateInterval` parameter when creating or modifying volumes. ***The value is in days***. The default value of `0` indicates that `atime` is never updated.

For example, a value of **2** indicates that the `atime` is updated *Once* every **2** days (48 hours) with the first read on the file. `atime` will not be updated on further reads on the file till the 48 hours have passed.

Viewing the Last Access Time Value

To view the `atime` value of a specific volume, use the volume info on page 1965 command.

last-updated: Apr 11, 2022

Last Access Time Example

The following command creates a volume and sets the `atime` to 2 days:

```
maprcli volume create -name stdvol1 -path /stdvol1 -atimeUpdateInterval 2d
```

To view the Last Access Time frequency, run:

```
maprcli volume info -name stdvol1 -json | grep atime
            "atimeUpdateInterval":"2",
            "atimeTrackingStartTime":"2021-03-14 22:45:25 GMT-0700",
```

Here, the frequency is set to 2 days. The time when `atime` was enabled on the volume is also displayed.

Creates a rule for offloading data to a tier.

Multitenancy on File System

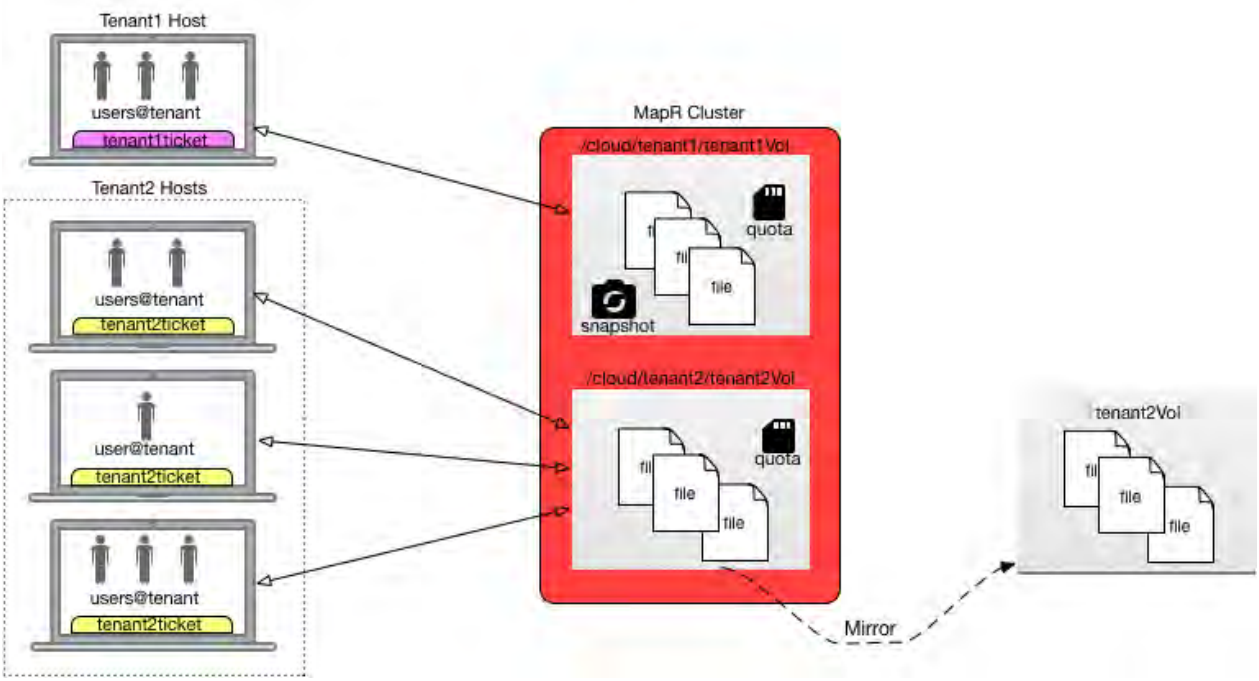
Describes what multitenancy is and how tenant data is kept private for each tenant.

Multitenancy architecture enables a single instance of a software to be provisioned for multiple customers or users, who are referred to as tenants. Each tenant, or group of users, has a specific share of the instance including access to its data, configuration, and access management. On the cloud, this enables a software-as-a-service (SaaS) provider to provision the software for multiple tenants.

The MapR File System multitenancy architecture enables you to create and restrict a MapR volume (referred to as a share) to a subset of client nodes. By doing this, you can isolate users or hosts (referred to as tenants). Isolation enables you to set policies, quotas, and access privileges for specific tenants. You can provision the MapR file system on the cloud to various tenants, with each tenant owning its own copy of storage space, users, data security, administration, and so on.

In a multitenant environment, tenants operate in their own provisioned spaces, unaware of other tenants on the cluster. Tenants have exclusive access to data in their environment only.

For example, the following diagram depicts a cluster provisioned on the cloud for two tenants, Tenant1 and Tenant2. The cluster has two separate volumes, mounted at directories `/cloud/tenant1`, and `/cloud/tenant2`. Each tenant volume contains file data created and managed by tenant users on the tenant host. Each tenant maps to a different volume and therefore, data in each volume can have different policies, disk-usage quotas, snapshot and mirroring schedules. By using appropriate tenant tickets, access to data in these volumes is restricted only to users on the appropriate tenant hosts, and eliminates the possibility of a user from Tenant2 accessing data on the Tenant1 volume, and vice versa.



You can access tenant shares using loopbacknfs and FUSE-based POSIX clients only. After you mount the tenant volume for access using (FUSE-based and loopbacknfs) POSIX clients, you can perform operations using standard Linux commands.

Setting Up a Tenant
Lists the process for setting up a tenant.

To set up a tenant:

1. On the server:
   a) Log in to the cluster as the administrator and create a user (for the tenant admin) on the cluster.
      The user (for the tenant) must exist on all the cluster nodes with the same UID and GID or all the cluster nodes must connect to the same LDAP server. See Managing Users and Groups on page 752 for more information.

      Note: The superuser for a tenant, referred to as tenant admin, must have a UID of `0` on the tenant host(s) to access the tenant volume (only) and all data in the tenant volume. Although the tenant admin has the same UID as the MapR superuser, the tenant admin does not have the same level of access and administration privileges as the MapR superuser because the tenant admin's access is based on the tenant ticket and is restricted to the tenant volume.

   b) Generate a tenant ticket for the user.
      For more information, see Generating a Ticket for a Tenant on page 1429.

   c) Copy the ticket to the tenant host and grant the tenant administrator read access to the ticket.

   d) Create a volume (or share) on the cluster for the tenant.
      For more information, see Creating a Volume for a Tenant on page 881.

2. On the tenant instance:
   a) Log in as tenant administrator (`root`).

last-updated: Apr 11, 2022

b) Mount the filesystem using loopbacknfs or the FUSE-based POSIX client.
For more information, see Mounting a Tenant Volume on page 904.

Note: While starting the POSIX client, use the tenant ticket configured in step 1.

c) As tenant admin, grant access to users by setting permissions to data using either file ACEs or mode bits.
For more information, see Enabling and Restricting Access to Tenant Volume and Data on page 925.

Provisioning File System for Multiple Tenants - Sample Workflow
Illustrates a sample workflow for provisioning the MapR file system to multiple clients.

For example, suppose there are two tenants Tenant1 and Tenant2. The following steps show the workflow for provisioning the two tenants:

1. The cluster administrator creates two users, Tenant1 and Tenant2, on the MapR cluster and creates volumes (or shares) on the cluster for the two tenants.
   For example, to create volumes on the cluster:

```
$ /opt/mapr/bin/maprcli volume create -name tenant1Vol -path /
tenant1Enoke -tenantuser Tenant1
$ /opt/mapr/bin/maprcli volume create -name tenant2Vol -path /
tenant2Enoke -tenantuser Tenant2
```

2. The cluster administrator generates tickets for the users, copies the tickets to the tenant servers (tenant1Host and tenant2Host), and grants the tenant admins (tenant1Admin and tenant2Admin) read access to the ticket.
   For example, to:
   - Generate ticket for the users:

```
$ maprlogin generateticket -type tenant -cluster myCluster -user
tenant1 -out /tmp/tenant_Tenant1_ticket.txt
$ maprlogin generateticket -type tenant -cluster myCluster -user
tenant2 -out /tmp/tenant_Tenant2_ticket.txt
```

   - Copy tickets to appropriate tenant hosts:

```
$ scp /tmp/tenant_Tenant1_ticket.txt
tenant1Admin@tenant1Host:~tenant1Admin/
$ scp /tmp/tenant_Tenant2_ticket.txt
tenant2Admin@tenant2Host:~tenant2Admin/
```

3. The tenant administrators log into their respective hosts and mount their shares by starting the client.
   For example, to start the:

FUSE-based POSIX client

a. Update the following parameters in the `fuse.conf` file:

`fuse.ticketfile.location`	For: • Tenant1, `tenant1Admi` `tenant_Tenant1_tic`

	• Tenant2, `tenant2Admi` `tenant_Tenant2_tic`
`fuse.mount.point`	For: • Tenant1, `/tenant1Eno` • Tenant2, `/tenant2Eno`
`fuse.export`	For: • Tenant1, `/tenant1Eno` `tenant1Vol` • Tenant2, `/tenant2Eno` `tenant2Vol`

b. Run the following command to start the service:

```
$ service mapr-posix-client-*
start
```

loopbacknfs POSIX client

a. Update the tenant ticket file location in `/etc/loopbacknfs/initscripts/mapr-loopbacknfs` file.

b. Run the following command to start the service:

```
$ service mapr-loopbacknfs start
```

4. The tenant administrators can grant access to users within their tenant namespace by modifying data access using *Access Control Expression (ACE)*s.

Direct Access NFS

Describes the MapR direct access file system.

The MapR direct access file system enables real-time read/write data flows using the Network File System (NFS) protocol. Standard applications and tools can directly access the MapR File System storage layer using NFS. Legacy systems can access data, and traditional file I/O operations work as expected on a conventional UNIX file system. A remote client can easily mount a MapR cluster over NFS to move data to and from the cluster. Application servers can write log files and other data directly to the MapR cluster's storage layer instead of caching the data on an external direct or network-attached storage.

You can mount a MapR cluster directly through a network file system (NFS) from a Linux or a Mac client. When you mount a MapR cluster, applications can read and write data directly into the cluster with standard tools, applications, and scripts. MapR enables direct file modification and multiple concurrent reads and writes with POSIX semantics. For example, you can run a MapReduce application that outputs to a CSV file, and then import the CSV file directly into SQL through NFS.

MapR exports each cluster as the directory `/mapr/<cluster name>`. If you create a mount point with the local path `/mapr`, Hadoop FS paths and NFS paths to the cluster will be the same. This makes it easy to work on the same files through NFS and Hadoop. In a multi-cluster setting, the clusters share a single namespace. You can see them all by mounting the top-level `/mapr` directory.

last-updated: Apr 11, 2022

POSIX Clients

Describes the usage of MapR POSIX clients.

The MapR filesystem supports direct and secure access to data using loopback NFS or FUSE-based POSIX clients.

The loopbacknfs POSIX client allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a MapR cluster, with transmitted data compressed in both directions. The MapR single-user mapr-loopbacknfs licenses gives secure access to one or more clusters, which allows native client applications to run securely on cluster data.

The FUSE-based POSIX basic and platinum clients run as a user space process to connect to one or more MapR clusters and allow app servers, web servers, and applications to read and write data directly and securely to the MapR clusters like a Linux filesystem. Each client implies a specific MapR filesystem throughput optimization of *n/G* per second.

Both loopbacknfs and FUSE-based POSIX clients can be installed on supported Linux and Ubuntu distributions and require direct network access to all MapR cluster nodes. They connect to the MapR cluster directly (no NFS gateway) to read and write data securely.

Copying Data from Apache Hadoop to a MapR Cluster

Describes the procedure to copy data from an Apache Hadoop to a MapR cluster.

You can use the hdfs protocol, webhdfs protocol, or NFS to copy data from Apache Hadoop to a MapR cluster.

The following table describes these methods:

Method	Description
hdfs:// protocol	You can use the `hadoop distcp` command with the `hdfs://` protocol to copy data from a HDFS cluster into a MapR cluster if the HDFS cluster and the MapR cluster use the same RPC protocol version. For all other scenarios, use the `webhdfs://` protocol or NFS gateway to copy data to a MapR cluster.
webhdfs:// protocol	You can use the `hadoop distcp` command with the `webhdfs://` protocol to copy data from a HDFS cluster into a MapR cluster.
NFS	You can mount a MapR cluster to a HDFS cluster using NFS mount and then use the `hadoop distcp` command to copy data between the two clusters.

Refer to the following sections for information about how to copy data from Hadoop to a MapR cluster:

About the MapR Persistent Application Client Container (PACC)

This container gives you seamless access to MapR cluster services.

This topic introduces the MapR Persistent Application Client Container (PACC), including its function, benefits, components, and applications.

The MapR (PACC) is a Docker-based container image that includes a container-optimized MapR client. The PACC provides seamless access to MapR Converged Data Platform services, including MapR File System, MapR Database, and MapR Event Store For Apache Kafka. The PACC makes it fast and easy to run containerized applications that access data in MapR.

FUSE POSIX Client for File-Based Applications

To support persistent, file-based applications, the MapR PACC includes a FUSE-based MapR POSIX Client, optimized for containers, that allows app servers, web servers, and other applications to read and write data directly to the MapR filesystem. If your cluster has a MapR POSIX Client for Containers license, the PACC can connect with MapR 5.1 or later clusters.

Traditionally, all file data created by containers is lost when a container is terminated, which can happen during an application or hardware failure. By using the POSIX client within the PACC, applications can reliably persist file data directly to the MapR filesystem, where it can be re-attached to the container in the event of application or hardware failures.

Support for Microservice Applications

To support stateful microservice applications, the MapR PACC also contains a container-optimized version of the MapR client, which includes libraries for accessing MapR Database and MapR Event Store For Apache Kafka.

Secure Access

The MapR PACC is designed to provide access to a secure cluster for all MapR Converged Platform data services. Users can pass a MapR ticket file into the container at runtime. All data access, whether to MapR File System, MapR Database, or MapR Event Store For Apache Kafka, is authorized and audited according to the authenticated identity of the ticket file.

PACC Contents

The PACC includes the following components:

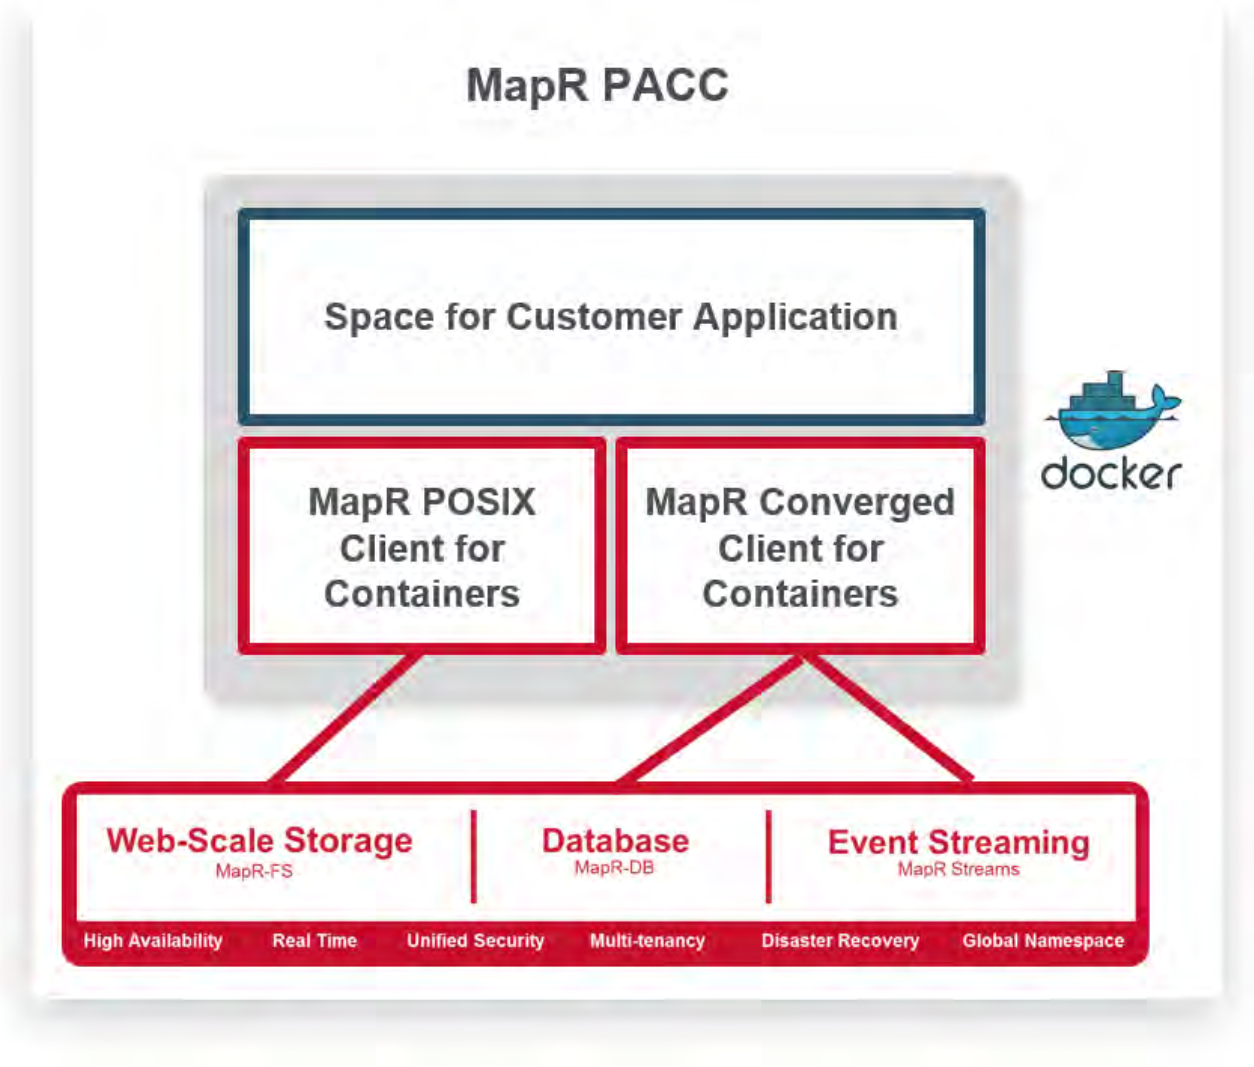
- MapR Database Client[1]
- MapR Event Store For Apache Kafka Client
- POSIX Client for Containers
- Hadoop Client with YARN[2]
- HBase Client[2]
- Hive Client[2]
- Pig Client[2]
- Python
- Java
- Curl, Wget, Openssl, NFS-common, etc

last-updated: Apr 11, 2022

[1]The MapR Database client includes support for MapR Database binary tables and MapR Database JSON tables.

[2]Included only if specified and only in MapR PACC images created using `mapr-setup.sh`.

The following diagram illustrates the contents of the PACC, and how it allows applications to access MapR Converged Data Platform services.



Pre-Built and User-Created Images

To get started with the MapR PACC, you can take advantage of pre-built Docker images or create your own images to include site-specific environmental parameters:

To . . .	See this topic
See a list of the MapR pre-built Docker images	Extending a MapR PACC on page 408
Create your own images containing MapR software	Creating a MapR PACC Image Using mapr-setup.sh on page 409

MapR Control System

Provides a brief description of the MapR Control System.

last-updated: Apr 11, 2022

The MapR Control System provides a graphical control panel for cluster administration with all the functionality of the command-line or REST APIs. The Control System provides job monitoring metrics and helps you troubleshoot issues, such as which jobs required the most memory in a given week, or which events caused job and task failures.

The Control System provides various views, which you can use to configure and monitor your cluster:

Overview	The Control System **Overview** page provides a summary of information about the cluster including a cluster heat map that displays the health of each node organized by service, an alarms summary, cluster utilization that shows the CPU, memory, and disk space usage, the number of available, unavailable, and under replicated volumes, and MapReduce applications.
Services	The Control System **Services** page provides a summary of the services running across the cluster.
Nodes	The Control System **Nodes** page provides a summary of information about the nodes on the cluster including a heat map that displays the health of each node, resource utilization that shows the CPU and memory usage, all active alarms, and a list of all the nodes on the cluster with links that provide shortcuts to more detailed information about the node.
Data	The Control System **Data** drop-down menu contains links to pages that provide summary of information about volumes, tables, and streams.
Admin	The Control System **Admin** drop-down menu contains links to pages for user and cluster management tasks such as setting up permissions, quotas, and email settings for users, enabling cluster-level and data auditing, configuring balancer settings, and adding licenses.

Note: During installation using the MapR Installer, you can configure metrics and logging using settings on the Monitoring page of the MapR Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the panes on the Control System.

Using MapR Data Platform Monitoring (Spyglass Initiative)

MapR Data Platform Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

Metric Monitoring

Administrators can monitor the current status of the cluster and anticipate future cluster requirements with dashboards. For example, you can use metrics dashboards to visualize the following:

Storage Utilization	Use metrics dashboards to monitor storage trends. For example, you can compare the volume of MapR File System usage at different times to the MapR File

last-updated: Apr 11, 2022

	System capacity and then allocate resources to the MapR File System accordingly.
Node Utilization	Use metrics dashboards to check for node overload. For example, if the CPU usage is high on a few nodes, you may want to distribute the load across more nodes for better performance and efficiency.
MapR Database Operational Trends	Use metrics dashboards to display historical trends for MapR Database operations. For example, if a user reports MapR Database slowness, the historical trends associated with row scans, get, and put operations can be used to identify the node(s) on which the performance degradation occurs.

Log Monitoring

Administrators can use dashboards to visualize, search, and review logs when troubleshooting issues. For example, you can use log dashboards to troubleshoot the following issues:

Service Failures	When metrics indicate that one or more services are down, use log dashboards to check the logs for each failed service and drill-down to each associated node.
Application Failures	When an application or job fails, use log dashboard to identify possible bottlenecks. For example, you can search the logs for a given application ID across all the nodes in the cluster.
MapR File System Performance	When users experience MapR File System or NFS slowness, use log dashboards to search the MapR filesystem logs for service errors or application issues.

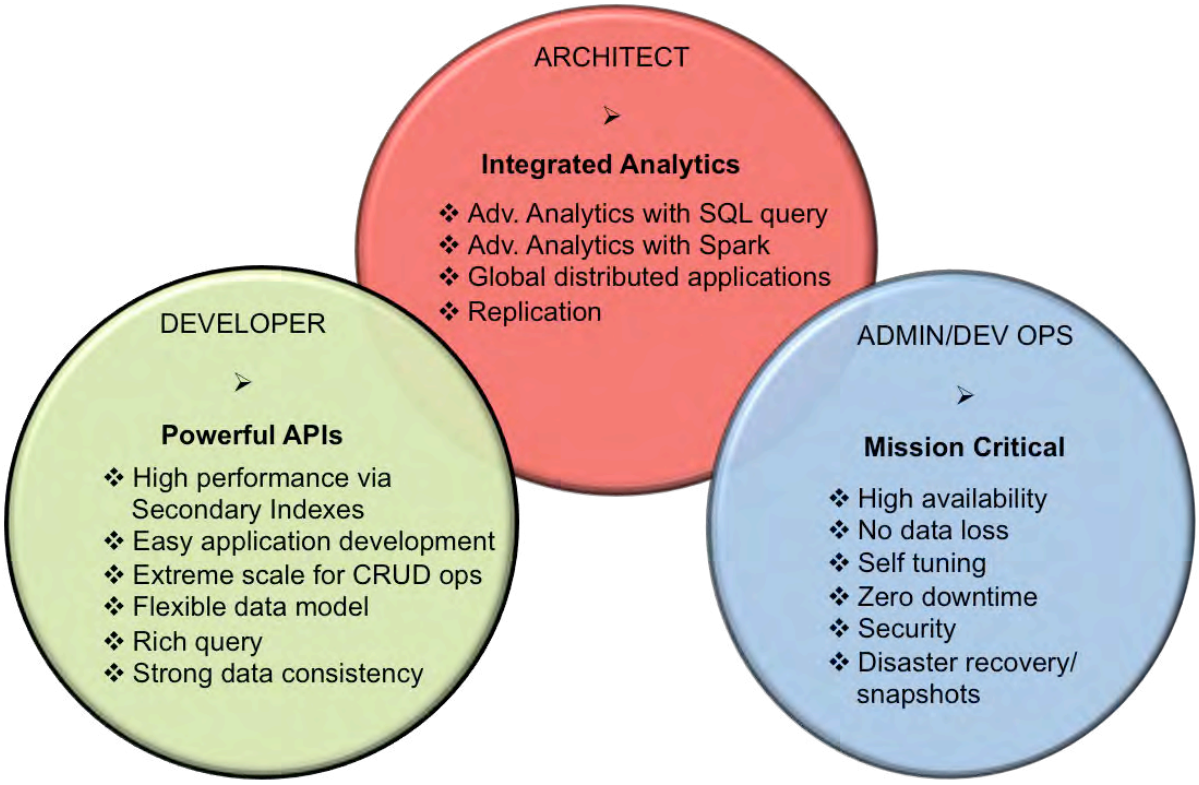
MapR Database

MapR Database is an enterprise-grade, high-performance, NoSQL database management system that you can use for real-time, operational analytics.

Why MapR Database?

MapR Database is built into the MapR Data Platform platform. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



1. The MapR Database and Apps section provides information and examples on developing applications for MapR Database binary and JSON tables.
2. This section provides information on how to adminster tables, table regions, and column families. The tools for performing administration are the MCS (MapR Control System) user interface and the maprcli.
3. The MapR Database architecture covers topics associated with database design issues.

What databases does the MapR Database include?

The MapR Database includes two NoSQL databases:

- **Key-value database with HBase API**
  - Supports Apache HBase tables and databases.
  - Provides a native implementation of the HBase API for optimized performance on the MapR platform.
- **JSON document database based on the OJAI API**
  - Supports JSON documents as a native data store.
  - Stores JSON documents in MapR Database JSON tables.

How do I get started?

The following table provides links to useful resources for developers, architects, and administrators.

- Blog: Provisioning Secure Access Controls in MapR Database

Architecture

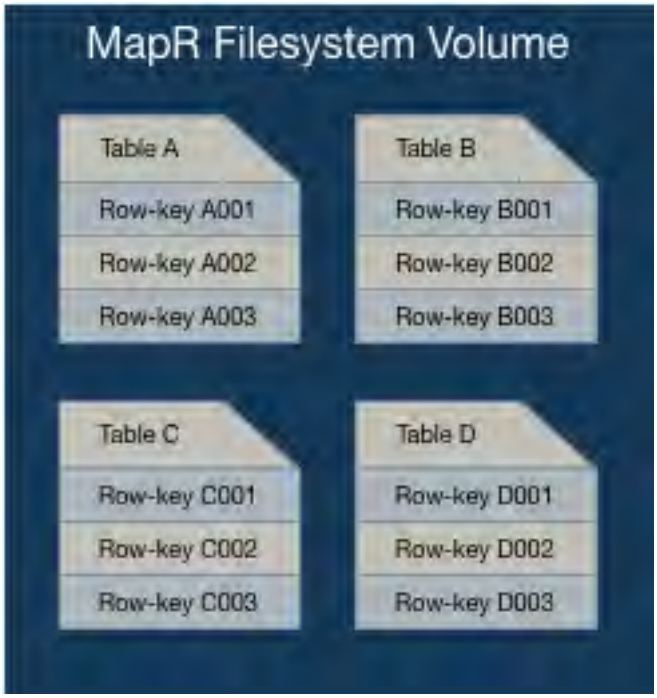
MapR Database is an enterprise-grade, high performance, NoSQL (“Not Only SQL”) database management system. You can use it to add realtime, operational analytics capabilities to big data applications. As a multi-model NoSQL database, it supports both JSON document models and key-value data models.

Why use MapR Database?

- **Integrated analytics with SQL**: MapR Database's integration with Drill for MapR provides a low latency, distributed, SQL query engine for large-scale datasets, including structured and semi-structured, nested data.
- **Operational analytics**: MapR Database can run in the same cluster as Apache™ Hadoop® and Apache Spark, letting you immediately analyze or process live, interactive data. This also enables you to eliminate data silos to speed the data-to-action cycle, providing a more efficient data architecture.
- **Global distribution of applications**: Application access to MapR Database tables is distributable on a global scale.
- **Flexible data model**: You can use MapR Database as both a document database and a column-oriented database. As a document database, MapR Database stores JSON documents in JSON tables. As a column-oriented database, it stores binary files in binary tables.

How is MapR Database Related to MapR XD Distributed File and Object Store?

MapR Database implements tables within the framework of the MapR filesystem. MapR Database creates tables (both binary and JSON tables) in logical units called *volumes*.



What are MapR Database's Architectural Advantages?

MapR Database's architecture has the following advantages:

- It reduces process overhead because it has no extra layers to pass through when performing operations on data.

  MapR Database, like several other NoSQL databases, is a log-based database. MapR Database runs inside of the MapR filesystem process, which enables it to read from and write to disks directly. In contrast, other NoSQL databases must communicate with a separate process to performs disk reads and writes. The approach taken by MapR Database eliminates extra process hops, duplicate caching, and needless abstractions, with the consequence of optimizing I/O operations on your data.

- It minimizes compaction delays because it avoids I/O storms when it merges logged operations with structures on disk.

  As a log-based database, MapR Database must write logged operations to disk. MapR Database stores table *regions* (also called *tablets*) and smaller structures within them partially as b-trees. Together with write-ahead logs (WAL), these b-trees comprise log-structured-merge trees. Write-ahead logs for the smaller structures within regions are periodically restructured by rolling merge operations on the b-trees. As MapR Database performs these merges at small scales, applications running against MapR Database see no significant effects on latency while the merges are taking place.

  Note: Apache HBase also uses the term *regions*.

What Design Factors are Important when Using MapR Database?

- **Rowkey Optimization**: The design of a table's rowkeys affects the speed at which client applications can access data. It also impacts database performance if hotspotting occurs. The better the design, the faster the data access. See Table Rowkey Design on page 542 for more information.

- **Column Family Optimization**: Column families enable you to group related sets of data and restrict queries to a defined subset, leading to better performance. When you design a column family, think about what kinds of queries you are going to use most often, and group your columns accordingly. See Column Families in JSON Tables on page 527 and Column Families in Binary Tables on page 541 for more information.
- **Replication Implementation**: The design of table replication (in addition to the automatic replication that occurs with table regions within a volume) depends on your desired outcome and the complexity of your environment. See Table Replication on page 610 for more information.
- **Security Implementation**: You can implement security at various levels including for table replication, JSON documents, and general access. Determining what level and where is part of the architectural design. See Security on JSON Tables on page 529, and Security on page 683.

MapR Database and MapR XD
Describes how MapR Database tables are implemented directly in the MapR filesystem, which allows MapR Database to leverage the same architecture as the rest of the platform and results in minimal additional management.

- MapR Database tables are created in logical units called *volumes*.
- MapR Database tables are sharded by implementing *table regions* (also called *tablets*)
- Table regions are stored in abstract entities called *data containers*.
- Data containers belong to MapR File System volumes.

Tables and Volumes

As volumes are a management entity that logically organize a cluster's data, they can be used to enforce disk usage limits, set replication levels, define snapshots and mirrors, and establish ownership and accountability.

Volumes do not have a fixed size and they do not occupy disk space until the filesystem writes data to a container within the volume. A large volume may contain anywhere from 50-100 million containers.

Tables are stored in containers and implemented in volumes, and provide the following capabilities:

- Multi-Tenancy
- Snapshots
- Mirroring and Replication

Table Regions and Containers

Each region of a table, along with its corresponding write-ahead log (WAL) files, b-trees, and other associated structures, is stored in one container. Each container (which can be from 16 to 32 GB in size) can store more than one region (which by default is 4096MB in size). The recommended practice is to use the default size for a region and allow it to be split automatically. Massive regions can affect synchronization of containers and load balancing across a cluster. Smaller regions spread data better across more nodes.

Note: Since a container always belongs to exactly one volume, that container's replicas all belong to the same volume as well.

The following are the key advantages to storing table regions in containers:

- Cluster Scalability
- High Data Availability

last-updated: Apr 11, 2022

For more information about containers, see Containers and the CLDB on page 453.

Cluster Scalability
Information about and location of tables (and files) is not tracked directly, but through MapR File System containers by the CLDB. As this architecture keeps the CLDB size small, it becomes practical to store 10s of exabytes in a MapR cluster, regardless of the number of tables and files.

The location of containers in a cluster is tracked by that cluster's container location database (CLDB). CLDBs are updated only when a container is moved, a node fails, or as a result of periodic block change reports. The update rate, even for very large clusters, is therefore relatively low. The MapR filesystem does not have to query the CLDB often, so it can cache container locations for very long times.

Moreover, CLDBs are very small in comparison to Apache Hadoop namenodes. Namenodes track metadata and block information for all files, and the locations for all blocks in every file as well. As blocks are typically 200 MB in size on an average, the total number of objects that a namenode tracks is very large. CLDBs, however, track containers, which are much larger objects, so the size of the location information can be 100 to 1000 times smaller than the location information in a namenode. CLDBs do not track information about tables and files.

High Availability
Due to the way updates to table regions (also called tablets) are applied and replicated, data in table regions are instantly available. Tables and table regions are part of abstract entities called *containers* that provide the automatic replication of table regions (with a default of three) across the nodes of a cluster.

Containers are replicated to a configurable number of copies. These copies are distributed to different nodes in the same cluster as the original or primary container. The cluster CLDB determines the order in which the replicas are updated. Together, the replicas form a replication chain that is updated transactionally. When an update is applied to a region (also called tablets) in the primary container (which is at the head of a replication chain), the update is applied serially to the replicas of that container in the chain. The update is complete only when all replicas in the chain are updated.

As a result of this architecture, when a hardware failure brings down a node, the regions served by that node are available instantly from one of the other nodes that have the replicated data.

MapR software can detect the exact point at which replicas diverge, even at a 2-GB-per-second update rate. The software randomly picks any one of the three copies as the new master, rolls back the other surviving replicas to the divergence point, and then rolls forward to converge with the chosen master. MapR software can do this on the fly with very little impact on normal operations.

Note: Since containers are contained in volumes, the automatic replication factor is set at the volume level.

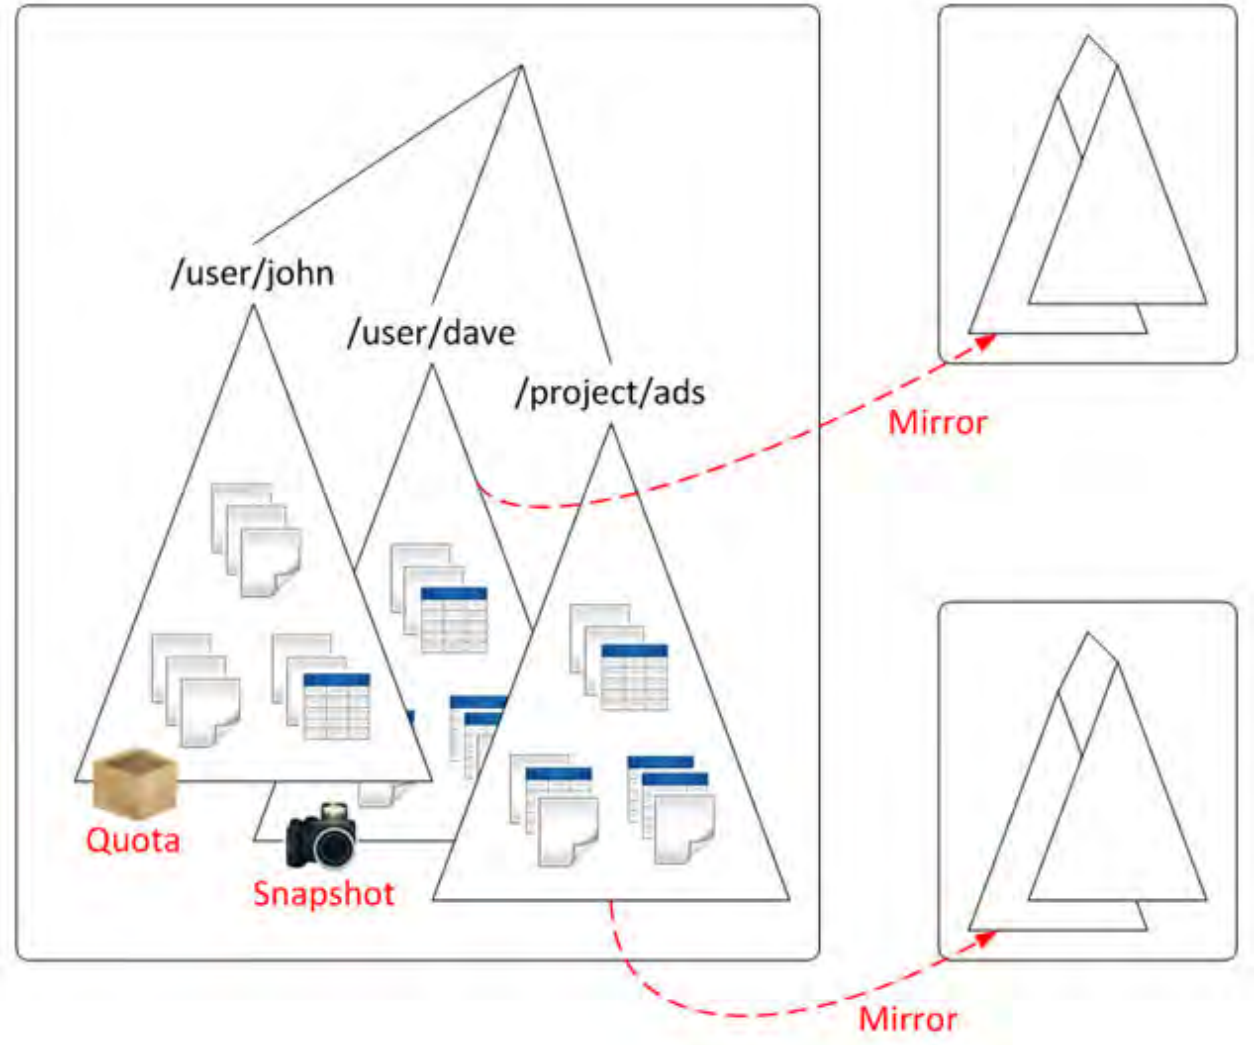
Multi-Tenancy
Since MapR Database tables are created in volumes, when you restrict the volume, you also restrict the table data. If a volume is restricted to a subset of a cluster's nodes, then it allows you to isolate sensitive data or applications, and even use heterogeneous hardware in the cluster for specific workloads.

For example, you can use data placement to keep personally identifiable information on nodes that have encrypted drives, or to keep MapR Database tables on nodes that have SSDs. You can also isolate work environments for different database users or applications and place MapR Database tables on specific hardware for better performance or load isolation.

Isolation of work environments for different database users or applications lets you set policies, quotas, and access privileges for specific users and volumes. You can run multiple jobs with different requirements without conflict.

As an example, the following diagram depicts a MapR cluster storing table and file data. The cluster has three separate volumes mounted at directories `/user/john`, `/user/dave`, and `/project/ads`. As shown, each directory contains both file data and table data, grouped together logically. Since each directory maps to a different volume, data in each directory can have a different policy. For example, `/`

`user/john` has a disk-usage quota, while `/user/dave` is on a snapshot schedule. Furthermore, two directories, `/user/john` and `/project/ads` are mirrored to locations outside the cluster, providing read-only access to high-traffic data, including the tables in those volumes.



Example: Restricting table storage with quotas and physical topology

This example creates a table with disk usage quota of 100GB restricted to certain data nodes in the cluster. First, create a volume named `project-tables-vol`, specifying the quota and restricting storage to nodes in the `/data/rack1` topology, and mounting it in the local namespace. Next, use the HBase shell to create a new table named `datastore`, specifying a path inside the `project-tables-vol` volume.

```
$ pwd
/mapr/cluster1/user/project

$ls
bin   src

$ maprcli volume create -name project-tables-vol -path /user/project/tables
\
    -quota 100G -topology /data/rack1

$ ls
bin   src   tables
```

last-updated: Apr 11, 2022

```
$ hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
hbase(main):001:0> create '/user/project/tables/datastore', 'colfamily1'
0 row(s) in 0.5180 seconds
hbase(main):002:0> exit

$ ls -l tables
total 1
lrwxr-xr-x 1 mapr mapr 2 Oct 25 15:20 datastore ->
mapr::table::2252.32.16498
```

Snapshots

Since MapR Database tables are created in volumes, you can use a volume snapshot to capture the state of a volume's directories, MapR Database tables, and files at an exact point in time.

Use volume snapshots for rollbacks, hot backups, model training, and real-time data analysis management.

Rollback from errors	Application errors or inadvertent user errors can mistakenly delete data or modify data in an unexpected way. With volume snapshots, you can rollback your MapR Database tables to a known, well-defined state.
Hot backups	You can create backups of table data on the fly for auditing or governance compliance.
Model training	Machine-learning frameworks can use snapshots to enable a reproducible and auditable model training process. Snapshots allow the training process to work against a preserved image of the training data from a precise moment in time. In most cases, the use of snapshots requires no additional storage and snapshots are taken in less than one second.
Managing real-time data analysis	By using snapshots, query engines such as Apache Drill can produce precise synchronic summaries of data sources subject to constant updates, such as sensor data or social media streams. Using a snapshot of your MapR Database data for such analyses allows very precise comparisons to be done across multiple ever-changing data sources without the need to stop real-time data ingestion. See MapR Snapshots for more details.

Mirroring and Replication

Since MapR Database tables are created in volumes, mirroring of volumes lets you automatically replicate differential data in real-time across clusters. You might want mirror volumes to create disaster recovery solutions for databases or to provide read-only access to data from multiple locations.

As MapR Database does not require RegionServers to be reconstructed, databases can be brought up instantly on the mirrored site if the active site goes down.

Mirroring is a parallel operation, copying data directly from the nodes of one MapR cluster to the nodes in a remote MapR cluster. The contents of the volume are mirrored consistently, even if the files in the volume are being written to or deleted.

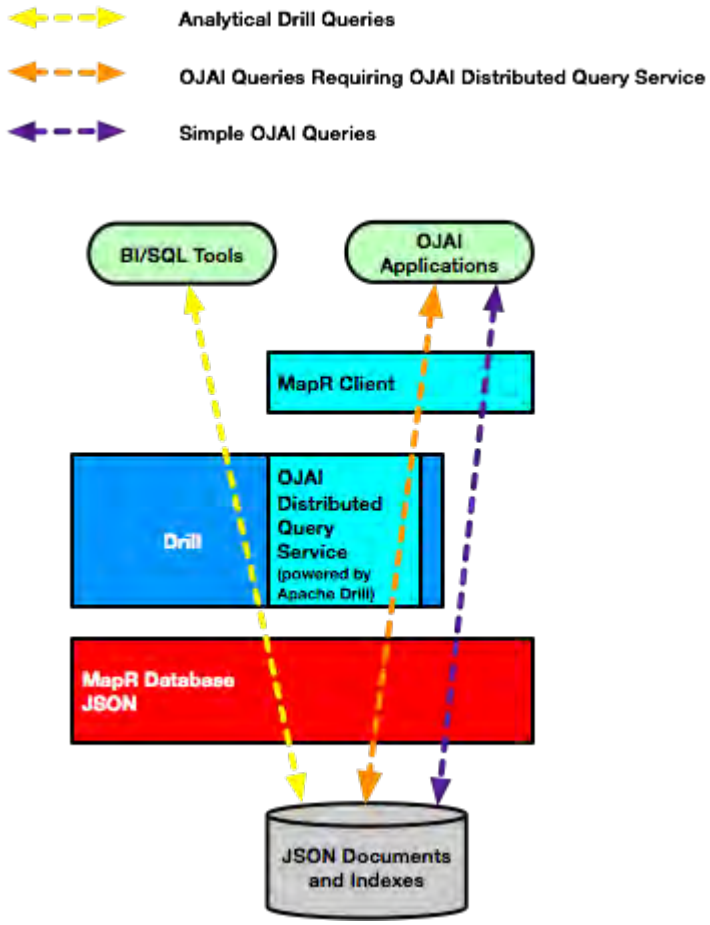
MapR captures only data that has changed at the file-block level since the last data transfer. After the data differential is identified, it is then compressed and transferred over the WAN to the recovery site, using very low network bandwidth. Finally, checksums are used to ensure data integrity across the two clusters. There is no performance penalty on the cluster because of mirroring.

See Mirror Volumes on page 463 for more details.

OJAI Distributed Query Service

OJAI queries either directly access MapR Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for MapR Database JSON, powered by Apache Drill. The MapR client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of MapR Drill.

The following diagram summarizes the different code paths and the components involved for processing MapR Database JSON queries.



MapR automatically chooses which code path to use.

The following table summarizes the functionality that each code path supports:

Simple OJAI Queries	OJAI Queries Requiring OJAI Distributed Query Service	Analytical Drill Queries
• Can use single secondary index • Configurable limit on sorts • Serial query execution	• Can use multiple secondary indexes • No imposed limit on sort size • Parallel query execution • Query optimization for operational queries	• Can use multiple secondary indexes • No imposed limit on sort size • Parallel query execution • Query optimization for analytical queries

last-updated: Apr 11, 2022

Simple OJAI Queries	The right path in the preceding image represents simple queries issued through an OJAI application. These queries can leverage a single index and operate on smaller data sets that do not benefit from parallel query execution. Queries in this code path do not use the OJAI Distributed Query Service. If the OJAI Distributed Query Service is not installed, all OJAI queries use this code path. When queries run through this code path, sorts on large data sets may fail if the result size exceeds the size of a configurable parameter. See Querying in OJAI Applications on page 2579 for more details.
OJAI Queries Requiring OJAI Distributed Query Service	The middle path represents more complex queries issued through an OJAI application. These queries use the enhanced functionality available in the OJAI Distributed Query Service. This includes sorting large data sets and distributed, parallel query execution. When the Distributed Query Service is installed, the MapR client decides whether a query benefits from the service and automatically redirects the query to the service. The OJAI Distributed Query Service is a lightweight subset of the full Drill query engine that is well suited for the typical queries issued by OJAI. It excludes the more advanced functionality needed by analytical queries. The OJAI Distributed Query Service also provides more sophisticated index selection, including leveraging multiple indexes in a single query. It uses a cost based optimizer to select the indexes that provide the best performance.
Analytical Drill Queries	The left path represents SQL queries issued by BI and SQL tools to Drill. This path leverages Drill's analytical capabilities. It can optimize and process complex queries on large data sets in parallel and provide interactive query response times. The optimizer used by Drill is a superset of the optimizer used by the OJAI Distributed Query Service. It is also a cost based optimizer, but includes more comprehensive optimization techniques needed by complex analytical queries.

For more information about how secondary index selection and execution works in MapR Database JSON, see Selection and Execution of Secondary Indexes on page 582.

Note: Prior to MapR version 6.0.1, the OJAI Distributed Query Service was named the OJAI Query Service.

Data Models

MapR Database can be used as both a document database and a column-oriented database. As a document database, JSON documents are stored in HPE Ezmeral Data Fabric Database JSON table. As a column-oriented database, binary files are in stored HPE Ezmeral Data Fabric Database binary tables.

MapR Database as a Document Database

JSON documents are stored in MapR Database JSON tables. When you create a table in a volume, the table type is specified as JSON. Only JSON-like documents can be stored in JSON tables. Typically, tables of the same type (in this case, JSON) are created in their own volume.

last-updated: Apr 11, 2022

Each document is stored in a table row and indexed by the "_id" field.

JSON Table
{“_id … }
{“_id … }
{“_id … }

MapR Database as a Column-Oriented Database

Data is stored as a collection of key-value pairs where the key serves as a unique identifier. Typically, tables of the same type (in this case, binary) are created in their own volume.

Binary Table			
Row Key	**Column A**	**Column B**	**Column C**
Key 001	Value for A	Value for B	Value for C
Key 002	Value for A	Value for B	Value for C
Key 003	Value for A	Value for B	Value for C

MapR Database as a Document Database

MapR Database supports JSON documents as a native data store. A JSON document is a tree of fields. These JSON documents are stored in MapR Database tables.

MapR Database as a document database, implements JSON documents in MapR Database JSON tables.

- MapR Database JSON tables use the OJAI data model and support the OJAI API.
- Documents are in JSON format; MapR Database stores them in an efficient binary encoding, rather than plain ASCII text.
- With JSON tables, each value has a unique key (`_id`). You identify fields in the document using field paths. For example, `address.street`:

```
{
    "_id": "ID001",
    "name" : "Bob",
    "address": {
        "house" : 123,
        "street": "Main",
        "phones": [
            { "mobile": "555-1234" },
            { "work": "+1-123-456-7890" }]},
    "hobbies": ["badminton", "chess", "beaches"]
}
```

Note: Each JSON document can have different fields.

last-updated: Apr 11, 2022

With JSON document support, you can:

- Store data that is hierarchical and nested, and evolves over time.
- Read and write individual document fields, subsets of fields, or whole documents from and to disk. To update individual fields or subsets of fields, there is no need to read entire documents, modify them, and then write the modified documents to disk.
- Build applications with the MapR Database JSON API library, which is an implementation of the Open JSON Application Interface (OJAI). This is an API library for easily managing complex, evolving, hierarchical data. You can use more data types than the standard types that JSON supports, create complex queries, and access JSON table documents without connection or configuration objects. This allows large-scale applications to manage JSON documents.
- Filter query results within MapR Database before results are returned to client applications.
- Run client applications on Linux, OS X, and Windows systems.
- Perform complex data analysis on your JSON data with Apache Drill or other analytical tools in real time without having to copy data to another cluster.
- Scale your data to span thousands of nodes.
- Control read and write access to single fields and subsets of fields within a JSON table by using access-control expressions (ACEs).
- Control the disk layout of single fields and subdocuments within JSON tables.
- Use Secondary Indexes on page 544 to improve query performance.

JSON Documents
A JSON document is a tree of fields. Each field has a name, type, and value. In the case of an array type, the array field name and array index identify individual elements in the array. Field names are strings. The root of each document is a map. The advantages of JSON documents include the data types it supports and its schema flexibility. MapR Database provides tools that enable you to operate on JSON documents.

An online retailer of sports equipment might have this JSON document for storing data about a set of bicycle pedals:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    }
}
```

last-updated: Apr 11, 2022

Data Types

MapR Database JSON documents support a richer set of data types beyond what JSON supports. JSON documents can have scalar data, nested documents, and arrays. MapR Database JSON stores the data in a format that maintains the types. To access JSON documents, you can use the OJAI API. The API exposes data types in a manner specific to the programming language of the API. JSON Document Data Types on page 511 describes each category of types in relation to the sample JSON document shown earlier.

Comparing and Sorting Data Types

Comparisons and sorts of data types differ depending on whether the types are comparable or not. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 513 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 514 to learn which types fall into each category and to understand their behavior.

Schema Flexibility

The structure of each document, called the document's *schema*, is easy to change. Simply add new fields. For example, if the online retailer wants to allow customers to review products, it is simple to add the reviews to any document for a product.

In this example, highlighted in bold, the `comments` are added as an array with two nested documents:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

Identifying Document Fields

To learn about how to access JSON document fields, see JSON Document Field Paths on page 515. The material includes examples that use the JSON document shown earlier.

Querying Document Fields

MapR Database allows you to specify query conditions in a JSON format using syntax supported by the OJAI API. See OJAI Query Condition Syntax on page 2606 for details.

last-updated: Apr 11, 2022

JSON Document Size

The default maximum size of a JSON document is 32 MB. This size includes the field values in the document, as well as the names, types, and other field metadata. You can configure this size by running the command described at Configuring Maximum Row Sizes Using the CLI on page 1025.

Tools for Working with JSON Documents

These are the tools you can use to create, read, update, and delete JSON documents in MapR Database:

MapR Database Shell

This shell is a light-weight tool for administering, manipulating, and querying JSON tables and documents. Learn more about it at MapR Database Shell (JSON Tables) on page 5286.

OJAI API

The OJAI API provides an interface for creating, reading, updating, and deleting JSON documents.

MapR Database JSON supports the OJAI API in the following languages:

- Java
- Node.js
- Python
- C#
- Go

To learn about how to create, update, and delete JSON documents, see Managing JSON Documents on page 2542. To learn about how to query JSON documents, see Querying in OJAI Applications on page 2579.

For information that is specific to each language, see the following:

Java

See Java OJAI Client API for the complete API.

Node.js

See Using the Node.js OJAI Client on page 2673 for an introduction to this client.

See Node.js OJAI Client API for the complete API.

Python

See Using the Python OJAI Client on page 2678 for an introduction to this client.

See Python OJAI Client API for the complete API.

C#

See Using the C# OJAI Client on page 2688 for an introduction to this client.

See C# OJAI Client API for the complete API.

Go	See Using the Go OJAI Client on page 2692 for an introduction to this client. See Go OJAI Client API for the complete API.
MapR Database JSON REST API	The REST API enables you to use HTTP calls to perform basic operations on MapR Database JSON tables. Learn more about it at Using the MapR Database JSON REST API on page 2696.

JSON Document Data Types

MapR Database JSON documents support a richer set of data types beyond what JSON supports. JSON documents can have scalar data, nested documents, and arrays.

Scalar Data

Scalar data fields can contain strings or numbers. The scalar fields in the sample document are highlighted in bold as follows:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

Scalar fields can contain the following data types:

Data Type	Description
Binary	An uninterpreted sequence of bytes
Boolean	A data type of two possible values that are typically denoted by `true` and `false`
Byte	A 8-bit signed integer that ranges in value from -128 to 127
Date	A 32-bit integer that represents the number of DAYS since epoch, that is. January 1, 1970 00:00:00 UTC. The value is absolute and is time-zone independent.

last-updated: Apr 11, 2022

Data Type	Description
Double	A double-precision 64-bit floating-point number
Float	A single-precision 32-bit floating-point number
Int	A 32-bit signed integer that ranges in value from −2,147,483,648 to 2,147,483,647
Long	A 64-bit signed integer that ranges in value from -(2^{63}) to 2^{63} - 1
Short	A 16-bit signed integer that ranges in value from −32,768 to 32,767
String	A sequence of characters
Time	A 32-bit integer that represents time of the day in milliseconds. The value is absolute and is time-zone independent.
Timestamp	A 64-bit integer that represents the number of milliseconds since epoch, that is, January 1, 1970 00:00:00 UTC. Negative values represent dates before epoch.

Nested Documents

Nested document fields can contain documents that themselves contain scalar data, nested documents, arrays, or a combination of any of these types. The nested documents in the sample document are highlighted in bold as follows:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

Note: Nested documents can also be referred to as *maps*.

A nested document can include subfields that are themselves nested documents. In the following example, `location` is a nested document that has two nested document subfields, `address` and `geoCoordinates`:

```
{
   "_id": "001",
   "location": {
      "address": {
```

```
         "number": 100,
         "street": "Main St.",
         "city": "San Francisco",
         "state": "CA",
         "zipCode": "90210"
      },
      "geoCoordinates": {
         "latitude": 37.7817529521,
         "longitude": -122.39612197
      }
   }
}
```

There is no limit on the number of nestings in a nested document. However, you should consider the extra complexity that additional nestings may add to your applications.

Arrays

Array fields contain lists of values that are accessible by means of index numbers. The values can be scalar, nested documents, arrays, or a combination of any of these types. For example, the following document has two arrays, both highlighted in bold:

- `features`: An array with two scalar strings
- `comments`: An array with two nested documents

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

Note: Arrays can also be referred to as *lists*.

Using Comparable JSON Document Data Types in Comparisons and Sorts
: Defines comparable data types and their usage.

  Data types that have a well defined order amongst the types are comparable data types. In a filter condition, if a document's field value and the comparison value are of comparable types, the document

last-updated: Apr 11, 2022

qualifies if the condition returns true. This applies regardless of whether you have created secondary indexes on the comparison fields.

Based on the preceding definition, numeric types are comparable. This includes the following types:

- INT
- SHORT
- LONG
- FLOAT
- DOUBLE

Note: FLOAT and DOUBLE are approximate representations of decimal values. They may not return `true` in equality comparisons against their equivalent decimal values.

Example

Consider the following example where you have four documents, each with a field, `AccountBalance`. The types of the field differ, as noted in the table, but they are all comparable numeric types:

Document Name	`AccountBalance` Field Value	`AccountBalance` Field Type
DOCUMENT1	1900.12	FLOAT
DOCUMENT2	10000	INT
DOCUMENT3	10	LONG
DOCUMENT4	27.88	DOUBLE

If you specify a sort on the field `AccountBalance`, MapR Database sorts the field in the following order:

Document Name	`AccountBalance` Field Value
DOCUMENT3	10
DOCUMENT4	27.88
DOCUMENT1	1900.12
DOCUMENT2	10000

Secondary indexes sort and store data based on the values of the indexed fields. When reading through the index, MapR Database returns the documents in the order of index.

For example, suppose you have an index where `AccountBalance` is the indexed field. A query with the condition, `"AccountBalance > 20"`, returns the documents in the following order if MapR Database processes the query using the index:

- DOCUMENT4
- DOCUMENT1
- DOCUMENT2

Using Non-comparable JSON Document Data Types in Comparisons and Sorts

Defines non-comparable data types and their usage.

Non-comparable data types are data types that do not follow a well-defined order. In contrast to comparisons between comparable types, comparisons between fields and values of non-comparable types

last-updated: Apr 11, 2022

do not qualify even if you perceive a match in values. This is true whether you have indexed the field you are comparing or not.

Arrays and nested documents also fall into the non-comparable category. Since these entities do not have a defined ordering, only equality comparisons on these types are meaningful. For arrays, the order of the array elements must match; for nested documents, all fields in the nested document must match, but the order of the fields is not relevant.

You cannot order on Container Field Paths on page 518. For example, you cannot order on the field `a[].b`, even if the subfield `b` has scalar data.

Example

Consider the following example. If your field, `docField`, has string values and you compare it against a numeric value, none of the string values in the field match the numeric. Likewise, if your field has numeric values and you compare it against a string value, none of the numeric values in the field match the string. Both field and comparison values must be strings or integers to match:

Document Name	Value of Field `docField`	Type of Field `docField`	Filter Condition	Field Value Qualifies Filter Condition?
DOCUMENT1a	23	STRING	`docField = 23`	No
DOCUMENT1b	23	INT	`docField = 23`	Yes
DOCUMENT2a	45	INT	`docField = '45'`	No
DOCUMENT2b	45	STRING	`docField = '45'`	Yes
DOCUMENT3		No type due to missing value	`docField = 23`	No
DOCUMENT4	NULL	No type due to NULL value	`docField = '45'`	No

MapR Database does not define a fixed ordering across non-comparable types. It sorts the values within comparable types and within each non-comparable type, but not across both.

In the previous example, when sorting on `docField`, you could obtain the following for a sort in ascending order:

Document Name	Value of Field `docField`	Type of Field `docField`
DOCUMENT1b	23	INT
DOCUMENT2a	45	INT
DOCUMENT1a	23	STRING
DOCUMENT2b	45	STRING
DOCUMENT4	NULL	No type due to NULL value
DOCUMENT3		No type due to missing value

Note the independent ordering of the integer and string values. Also note that for the rows with NULL and missing field values, the row with NULL appears before the row with a missing value.

JSON Document Field Paths

To access fields in a JSON document, you use a *field path*. The syntax for a field path can vary, depending on the data type you are accessing: nested documents, arrays, nested documents within arrays, and multidimensional arrays.

last-updated: Apr 11, 2022

The examples in this topic reference the following sample JSON document:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

In the simplest case, the field path is the name of the field and refers to the entire field.

Nested Documents

If a field is a nested document, specifying the nested document identifies the entire nested document.

To identify individual fields in a nested document, you use a *dot notation* to specify their paths. A field path is a sequence of field names that leads to the particular field that you are interested in. The names are separated by dots.

The following shows a document with multiple levels of nested documents:

```
{
   "a" : {
       "b" : {
            "c" : {
                "d" : "value_for_d"
            }
        }
    }
}
```

The field path for field d using dot notation is `a.b.c.d`.

The following table shows examples of field paths using dot notation for the sample JSON document:

Field Path	Value Returned
`specifications`	`{ "specifications": {"color":"black","weight_per_pair":"260g"} }` The entire nested document field `specifications`
`specifications.weight_per_pair`	`{"specifications":{"weight_per_pair":"260g"}}` The `weight_per_pair` subfield in `specifications`
`specifications.color`	`{"specifications":{"color":"black"}}` The `color` subfield in `specifications`

Arrays

If the field is an array, specifying the array's field name identifies the entire array.

To access an element in an array, specify the position of the element in the array, starting at offset zero.

The following table shows examples of field paths that reference arrays for the sample JSON document:

Field Path	Value Returned
`features`	`{ "features":[ "Low-profile design", "Floating SH11 cleats included" ] }` The entire `features` array
`features[0]`	`{"features":["Low-profile design"]}` The first element of the `features` array
`features[1]`	`{ "features": [null,"Floating SH11 cleats included"] }` The second element of the `features` array **Note:** `null` is shown in the first element of the array to signify that the element returned is the second entry from the array.
`comments[0]`	`{ "comments": [{"comment":"Best money I ever spent!","username":"hlmencken"}] }` The first element of the `comments` array, which is a nested document

last-updated: Apr 11, 2022

Container Field Paths

Starting in MapR 6.1, MapR Database introduces the notion of a *container field path*. Using a container field path, you can access a field that is either a single value or an arbitrary array element.

If you have a field that has a single value (rather than an array of values), when using a container field path, MapR Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values. The array elements and scalar values can be of any type.

To specify a container field path, place square brackets after the field name:

```
fieldName[]
```

A container field path is useful if you want to perform one of the following scenarios:

- Perform comparisons on a field path that is either a single value or an arbitrary array element
- Access subfields in a nested document, where the nested document is either an arbitrary array element or a single nested document
- Access arbitrary elements in an array

See OJAI Query Conditions Using Container Field Paths on page 2615 for more details about the first scenario. The next two sections describes the second and third scenarios.

Nested Documents Within Arrays

Array elements can be nested documents. You can reference individual subfields within these nested documents with container field paths, starting in MapR 6.1. If you have a field that has a single value (rather than an array of values), if you use a container field path, MapR Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values.

For example, suppose you have the following two JSON documents in a MapR Database table, and `addresses` has an array of nested documents in the first document and a nested document in the second document:

```
{
  "_id":"1",
  "addresses":[
    {"state":"CA","city":"SJ"},
    {"state":"CA","city":"SC"},
    {"state":"WA","street":"NE 39th"}
  ]
}
{
  "_id":"2",
  "addresses":{"state":"CA","city":"SJ"}
}
```

You can use `addresses[].state` to reference the `state` subfield across all nested documents in both documents.

The following table describes the field paths supported and what each field path returns:

Field Path	Value Returned *(Number in Description Corresponds to Document ID)*

`addresses`	`{`
	`  "addresses": [`
	`  {"city":"SJ","state":"CA"},`
	`  {"city":"SC","state":"CA"},`
	`  {"state":"WA","street":"NE 39th"}]`
	`}`
	`{`
	`  "addresses":{"city":"SJ","state":"CA"}`
	`}`
	1. The array containing three nested documents
	2. The single nested document

`addresses.city`	`{}`
	`{"addresses":{"city":"SJ"}}`
	1. Empty because `addresses` is not a nested document
	2. The `city` subfield in the nested document

`addresses[0]`	`{`
	`  "addresses":`
	`  [{"city":"SJ","state":"CA"}]`
	`}`
	`{}`
	1. The first element in the `addresses` array
	2. Empty because `addresses` is not an array

`addresses[2].state`	`{`
	`  "addresses":`
	`  [null,null,{"state":"WA"}]`
	`}`
	`{}`
	1. The `state` subfield from the nested document in the third element of the `addresses` array
	Note: `null` is shown in the first two elements of the array to signify that the element returned is the third entry from the array
	2. Empty because `addresses` is not an array

`addresses[0].state, addresses[0].city`	`{"addresses":[{"city":"SJ","state":"CA"}]}`
	`{}`
	1. The `city` and `state` subfields from the nested document
	2. Empty because `addresses` is not an array

last-updated: Apr 11, 2022

Field Path	Value Returned *(Number in Description Corresponds to Document ID)*
`addresses[].city` **Note:** Supported starting in MapR 6.1	`{ "addresses": [ {"city":"SJ"}, {"city":"SC"}, {} ] } { "addresses": {"city":"SJ"} }` **1.** An array of nested documents with a `city` subfield; the third array element is empty because the third nested document does not have a `city` subfield **2.** A single nested document with a `city` subfield
`addresses[].state, addresses[].city` **Note:** Supported starting in MapR 6.1	`{ "addresses": [ {"city":"SJ","state":"CA"}, {"city":"SC","state":"CA"}, {"state":"WA"} ] } { "addresses": {"city":"SJ","state":"CA"} }` **1.** An array of nested documents with `city` and `state` subfields; the third array element has only a `state` subfield because the third nested document does not have a `city` subfield **2.** A single nested document with `city` and `state` subfields

Container Field Paths Across Multiple Levels of Nested Documents

You can use container field paths at any level of a nested document.

For example, suppose you have the following document:

```
{
   "_id": "account001",
   "projects": [
      {
         "id": "proj001",
         "manager": { "name": "Guy Bones", "email": "gbones@pro.com" },
         "customer": {
            "name": "My Company",
            "contacts": [
               {
               "id": "user_jdoe",
               "emails": [
                  { "type": "work", "value": "jdoe@comp.com" },
```

```
                  { "type": "personal", "value": "jdoe@gmail.com" }
               ],
               "addresses": [
                  {
                     "type": "work",
                     "value": {"street":"21 King Av","city": "Redwood",
"zip": 94065, "state": "CA" }
                  }
               ],
               "phones": [
                  { "type": "cell", "value": "+16505556764" },
                  { "type": "office", "value": "+14075556764" }],
               "role": "CEO"
               },
               {
               "id": "user_simsom",
               "emails": [
                  { "type": "work", "value": "simson@comp.com" },
                  { "type": "personal", "value": "simson@gmail.com" }
               ],
               "addresses": [
                  {
                  "type": "work",
                  "value": {"street":"21 King Av.","city":"Redwood","zip":
94065,"state": "CA" }
                  }
               ],
               "phones": [
                  { "type": "cell", "value": "+16505556777" },
                  { "type": "office", "value": "+1407555444" }],
               "role": "PM"
               }
            ]
         }
      },
      {
         "id": "proj002",
         // ...
      }
   ]
}
```

The following table shows field paths that use the container field paths across multiple nested documents and the values returned:

Field Path	Value Returned

`projects[].customer.contacts[].emails[].value`	<pre>{
	  "projects":[
	    {
	    "customer":{
	      "contacts":[
	        {
	          "emails":[
	            {"value":"jdoe@comp.com"},
	            {"value":"jdoe@gmail.com"}
	          ]
	        },
	        {
	          "emails":[
	
	{"value":"simson@comp.com"},
	
	{"value":"simson@gmail.com"}
	          ]
	        }
	      ]
	    },
	    { // data for proj002 }
	  ]
	}</pre>

`projects[].customer.contacts[].role`	<pre>{
	  "projects":[
	    {
	      "customer":
	        {
	          "contacts":[
	            {"role":"CEO"},
	            {"role":"PM"}
	          ]
	        }
	    },
	    { // data for proj002 }
	  ]
	}</pre>

Multidimensional Arrays

Arrays can have more than one dimension.

For example, suppose you want to store the high and low temperatures by week. The following document contains the high and low temperatures in Fahrenheit for the seven days beginning on April 29th, 2018. The document uses a two-dimensional array to store the high and low temperatures for each day. The first element of each nested array element is the high temperature for a day, and the second element is the low:

```
{
   "_id" : "001",
   "temps" : [[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]],
   "weekOf" : "4/29/2018"
}
```

To access individual high or low temperatures by day, you specify a two-dimensional array element with the desired array indexes. To access a pair of high and low temperatures, you specify a single array index.

last-updated: Apr 11, 2022

Field Path	Value Returned
`temps[0]`	`{"temps":[[61,49]]}`
`temps[5][1]`	`{"temps":[null,null,null,null,null,[null,53]]}` **Note:** `null` is shown for all array elements preceding the desired element

There is no limit on the number of dimensions in an array.

Container Field Paths with Multidimensional Arrays

Starting in MapR 6.1, a container field path can refer to arbitrary array elements across multiple array dimensions. To reference arbitrary elements in the two-dimensional `temps` array shown earlier, you specify:

```
temps[][]
```

Extending the convention by which a container field path with one set of square brackets treats a scalar value as an array with one element, a container field path with two square brackets treats a one-dimensional array as a two-dimensional array with a single element, where the element is that one-dimensional array.

For example, in the following document, although `temps` has only a single array, you can use `temps[][]` to refer to either the high or low temperature in the array:

```
{
   "_id" : "002",
   "temps" : [81,60],
   "weekOf" : "5/12/2018"
}
```

The same convention applies across *N* dimensions. A container field path with *N* square brackets treats an *(N-1)*-dimensional array as the only element in an *N*-dimensional array.

You can also use the container field paths for a subset of dimensions, provided a dimension that specifies container field path does not precede a dimension that specifies an explicit element. The following table illustrates this:

Field Path	Value Returned

`temps[0][]`	`{"temps":[[61,49]]}`
	`{"temps":[81,60]}`
	The temperatures on the first day of the week

`temps[2][]`	`{"temps":[null,null,[75,51]]}`
	`{"temps":[]}`
	The temperatures on the third day of the week

`temps[]`	`{"temps":[[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]]}`
	`{"temps":[81,60]}`
	The temperature pairs across all days

last-updated: Apr 11, 2022

Field Path	Value Returned
`temps[][0]`	Disallowed because the container field path in the first dimension precedes element 0 in the second dimension

MapR Database JSON Tables

JSON documents are stored in MapR Database JSON tables. MapR Database supports schema flexibility in the documents and provides the tools to efficiently access them. It optimizes the storage of the JSON documents, providing high performance.

When a JSON document is added to a JSON table, it is put in a table row. The table row is part of one column family (although you can create more, as described in Column Families in JSON Tables on page 527). The value in the row is a single JSON document that is stored in a binary format. The binary format allows MapR Database to make a number of optimizations to the document's layout to make data access fast and efficient. MapR Database also maintains the data types associated with fields in a JSON document.

The JSON documents in a table need not have identical structures. It is possible to include in a table any number of JSON documents that have no common fields or share only a subset of fields.

For example, an online retailer might have the following three documents in a single JSON table. Only a subset of fields is common to all three documents. These are key differences:

- Each document has a different nested document in a field named `specifications`.
- Only two of the documents have arrays in the field `features`.
- The `retailers` field has different types in the first and third documents.

Document 1

```
{
    "_id" : "ID1",
    "product_ID" : "4GGC859",
    "name" : "Thresher 1000",
    "brand" : "Careen",
    "category" : "Bicycle",
    "type" : "Road bicycle",
    "price" : 2949.99,

    "specifications" : {
        "size" : "55cm",
        "wheel_size" : "700c",
        "frameset" : {
            "frame" : "Carbon Enduro",
            "fork" : "Gabel 2"
        },
        "groupset" : {
            "chainset" : "Kette 230",
            "brake" : "Bremse
FullStop"
      },
        "wheelset" : {
            "wheels" : "Rad Schnell
10",
            "tyres" : "Reifen Pro"
        }
    },

    "retailers": {
        "name" : "Eden Bicycles",
        "location" : {
```

last-updated: Apr 11, 2022

```
            "city" : "Castro Valley",
            "state" : "CA"
        }
    }
}
```

Document 2

```
{
    "_id" : "ID2",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,

    "features" : [
        "Low-profile design",
        "Floating SH11 cleats
included"
    ],

    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    }
}
```

Document 3

```
{
    "_id" : "ID3",
    "product_ID" : "3ML6758",

    "brand" : "Careen",
    "category" : "Jersey",
    "type" : "Clothing",
    "price" : 76.99,

    "features" : [
        "Wicks away moisture.",
        "SPF-30",
        "Reflects light at night."
    ],

    "specifications" : {
        "sizes" :
["S","M","L","XL","XXL"],
        "colors" : [
            "white",
            "navy",
            "green"
        ]
    },

    "retailers" : [
        {
            "name" : "Bespoke Cycles",
            "city": "San Francisco",
            "state" : "CA"
        },
        {
            "name" : "Trek Bicycle",
```

```
            "city" : "New York",
            "state" : "NY"
        }
    ]
}
```

Container Syntax

Starting in MapR Database 6.1, even though the `retailers` field is an array of nested documents in document 1 and a nested document in document 3, you can reference subfields of the nested documents in both documents using the following container syntax:

```
retailers[].name
```

Specifying that field reference returns the following for the three documents:

```
{
    "retailers":{"name":"Eden Bicycles"}
}
{}
{
    "retailers":[
        {"name":"Bespoke Cycles"},
        {"name":"Trek Bicycle"}]
}
```

Note: An empty document is returned for the second document because that document does not have a `retailers` field.

See Container Field Paths on page 518 for more information.

Table Paths

Tables are stored in the MapR filesystem. When providing the path to a table in MapR tools and APIs, use these conventions:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` in `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Tools for Creating and Administering JSON Tables

These are the tools available for creating and administering JSON tables in MapR Database:

MapR Database Shell	This shell is a light-weight tool for manipulating JSON tables and documents. Learn more about it at MapR Database Shell (JSON Tables) on page 5286.
MapR Database JSON Client API	This API allows you to manage MapR Database JSON tables. The API includes methods to create, alter, and drop tables and column families. Learn more about these APIs at Managing JSON Tables on page 2522.
Python OJAI Client	This API allows you to create and drop MapR Database JSON tables in Python. Learn more about it at Using the Python OJAI Client on page 2678.

MapR Database JSON REST API	The REST API allows you to create and drop MapR Database JSON tables using HTTP calls. Learn more about it at Using the MapR Database JSON REST API on page 2696.
MapR Database JSON utilities	MapR Database JSON supports several utilities for loading tables. Learn more about these utilities at Loading Documents into JSON Tables on page 1036.
maprcli commands	The `maprcli table` commands fully support JSON tables. See table.

Note: For a list of tools available to query and manage documents in MapR Database JSON tables, see Tools for Working with JSON Documents on page 510.

Column Families in JSON Tables

JSON tables store data in column families. A column family is a collection of fields that are stored together on disk. You can use column families to improve the performance of your queries.

Each table has a default column family, which is default storage for all fields in the documents of a table. You can create additional column families to store data for a collection of fields in a separate location on disk. Queries and other operations that only run on the data stored in a column family are more efficient and better performing than queries on the same data when that data is stored with other data in a table. You can also cache values from a column family in memory.

Default Column Families

Suppose you have three JSON documents in a table and all three documents have the field a.

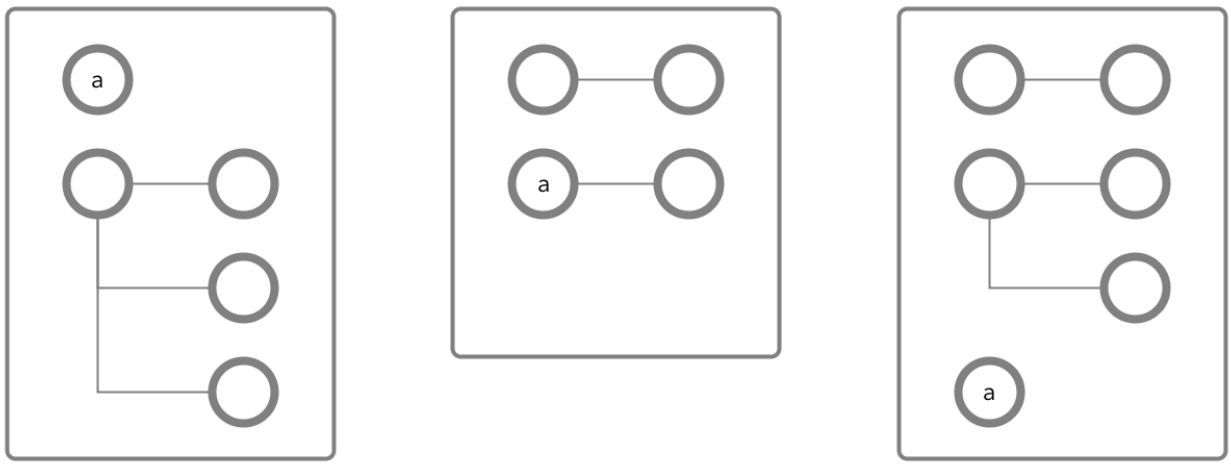

Figure 1: Schematic diagrams of three JSON documents, showing fields but not values, each document with a field named a

At this point, you have not created any non-default column families. So, all of the data in the table resides in the *default* column family. Each JSON table is created with a *default* column family.

Using Column Families to Optimize Data Access

To optimize data access for your applications, you plan to place some data that will be heavily queried in a new column family at path `a.b`, where `b` is a field that does not exist yet. Fields do not have to exist before you create column families on them.

last-updated: Apr 11, 2022

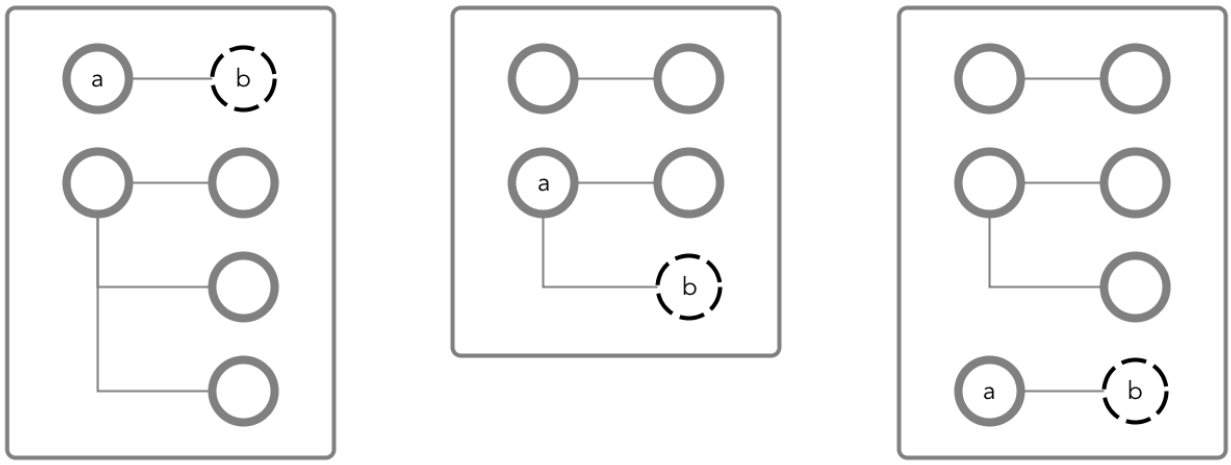

Figure 2: The same three JSON documents, showing where the new column family will be created

You create a column family at the path `a.b` with the name `CF1`.

When you create field `b`, it will belong to the column family `CF1`. All values of `b`, as well as the values of all fields that might be created after `b`, will be stored together on disk. Applications can read data directly from this column family and avoid reading the rest of the document at the same time, making queries faster and more efficient.

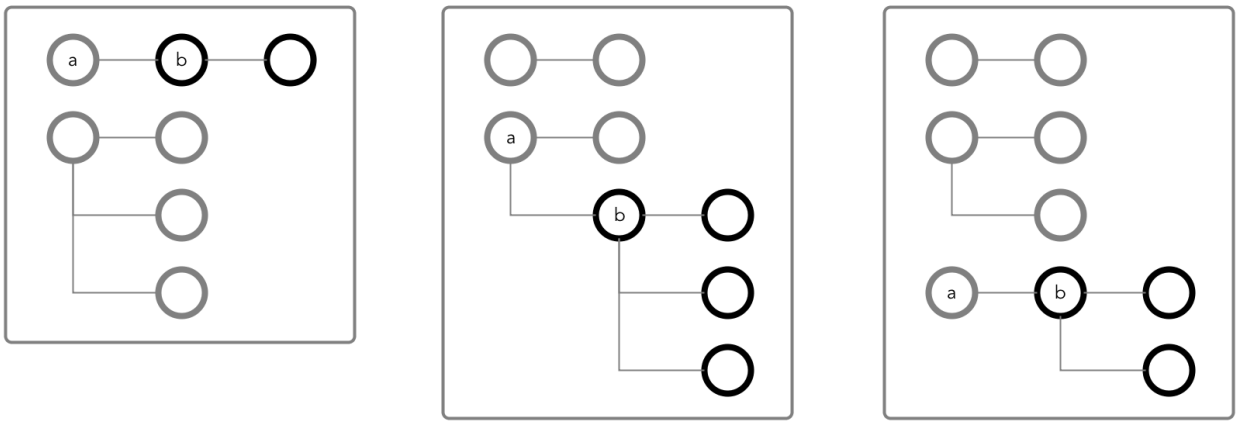

Figure 3: The three JSON documents with column family `CF1` in black

Creating Multiple Column Families

You can create up to 64 column families in a JSON table. The column families can be at any location in your documents. For example, these two documents both use the same non-default column families at the paths `a.b`, `a.b.c`, and `d`.

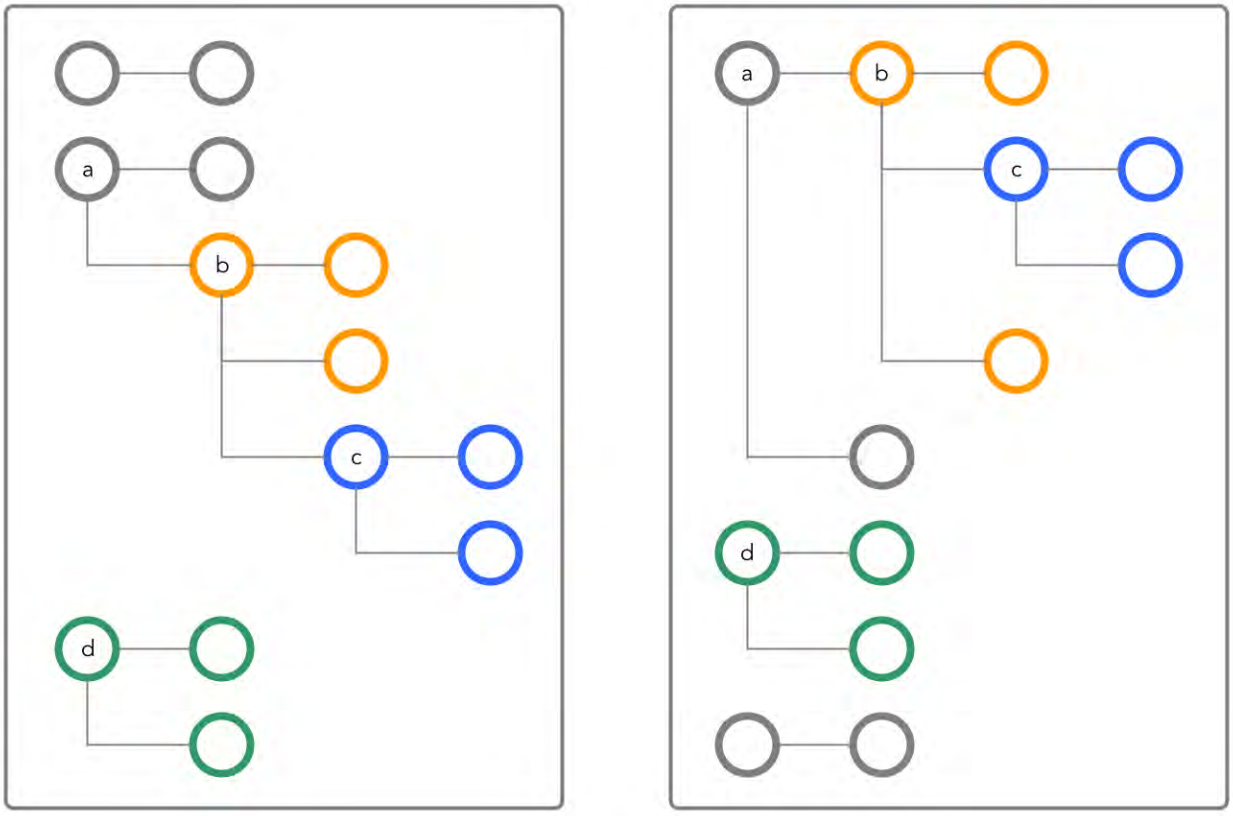

Figure 4: Two JSON documents that use the same non-default column families are highlighted in orange, blue, and green

Column Family Best Practices

If the path at which you want to create a column family already exists, it is recommended that the path and any fields under it contain no data. After the conversion of the path to a column family, it is possible that data existing in the path before the conversion could become inaccessible.

Applications and Column Families

Applications do not need to be aware of the existence of column families. They perform CRUD operations using the paths of fields in a document. For example, to update any of the fields under `a.c`, an application does not need to be aware that the field is in the column family at the path `a.c`. The application simply moves through the document along the path to the field.

Column Family Limitation

You cannot define column families across array type fields, for example:

```
maprcli table cf create -path /tbl-mcf -cfname abc -force true -jsonpath
a.b[0]
ERROR (22) -  Malformed path "a.b[0]", valid format is like "a.b.c".
```

For information about array fields, see JSON Document Field Paths.

Security on JSON Tables

By using access control expressions (ACEs), you can grant or deny access to fields and column families that are in JSON tables.

For an explanation of the syntax of ACEs, see ACE Syntax on page 1448.

last-updated: Apr 11, 2022

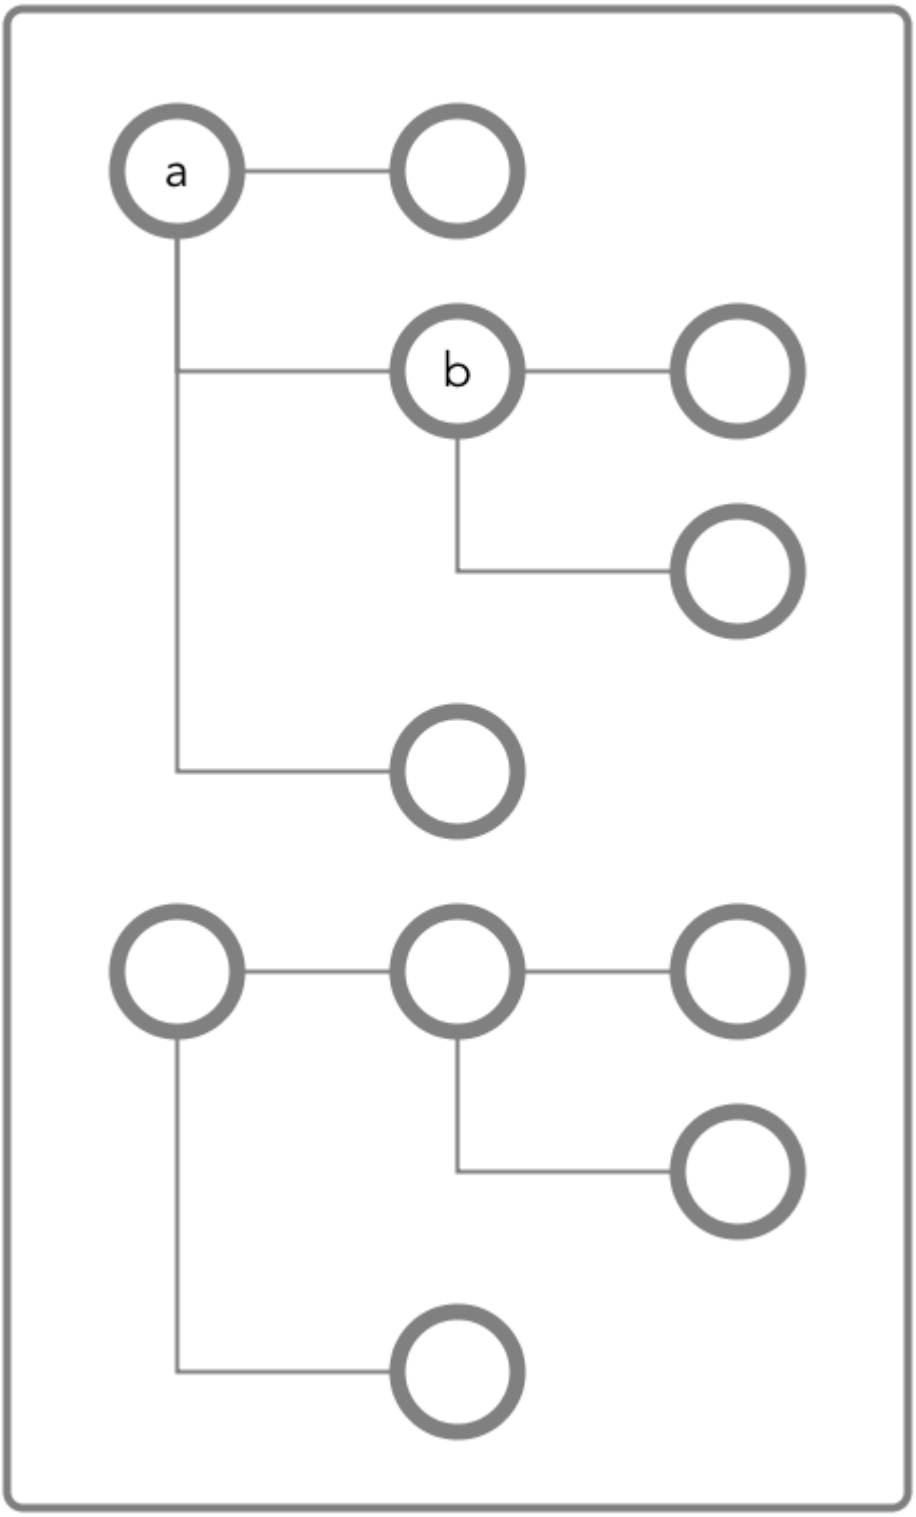
There are three types of permission:

- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access the fields to which the grantee has write or read permission.

For example, suppose that a user has read and write access only on field b in this document.

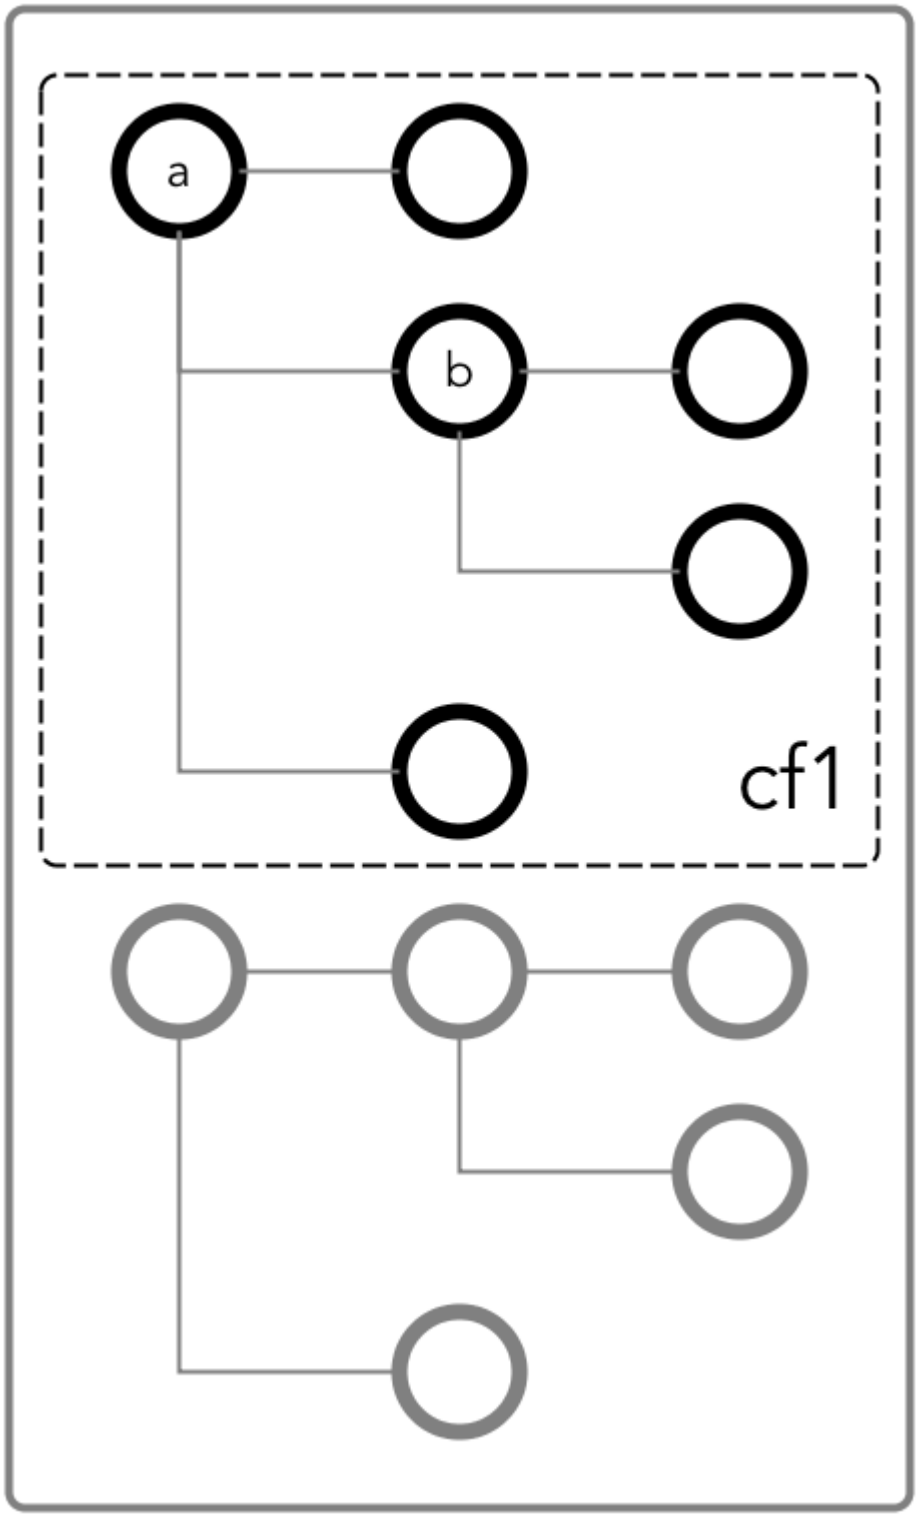


To access field b, the user would need to be able to traverse (pass through) field a. In this case, as the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If the user is denied the traverse permission on the default column family, the user cannot access field b. Granting traverse permission on field a in this case has no effect.

last-updated: Apr 11, 2022

In the next example, field a is a column family named `cf1`.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

Read (`readperm`)

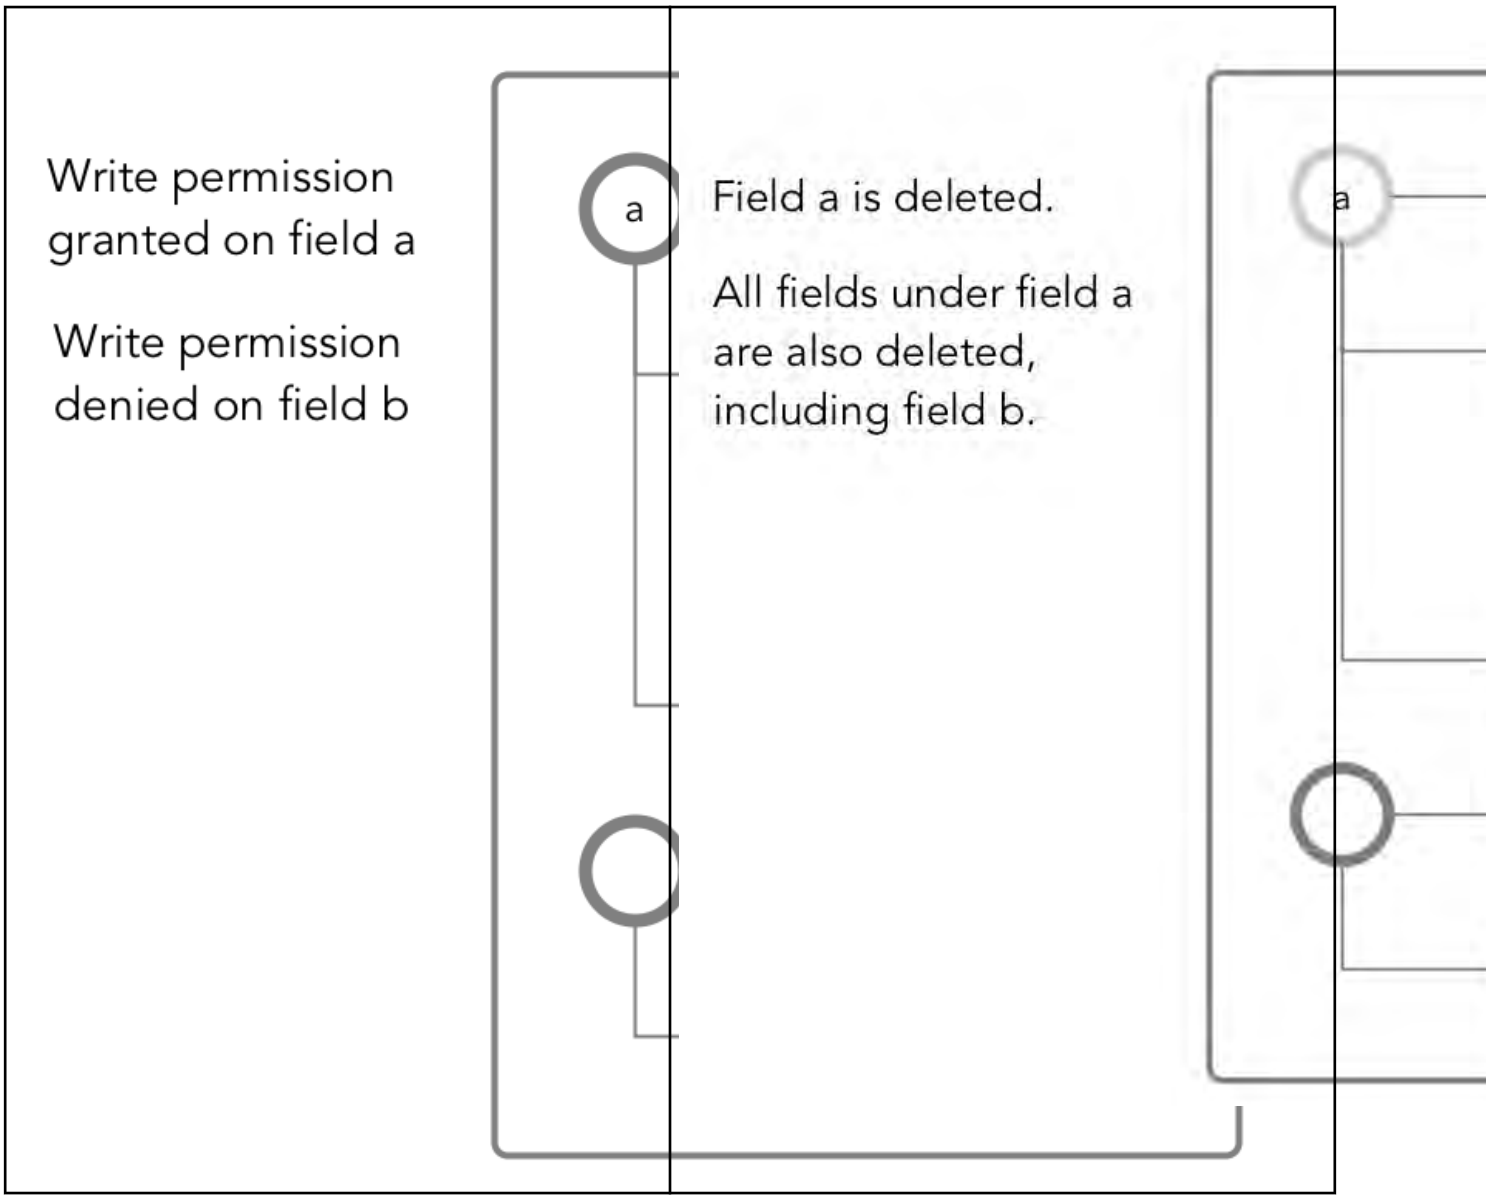
This permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field that was granted permission. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite a field's value.

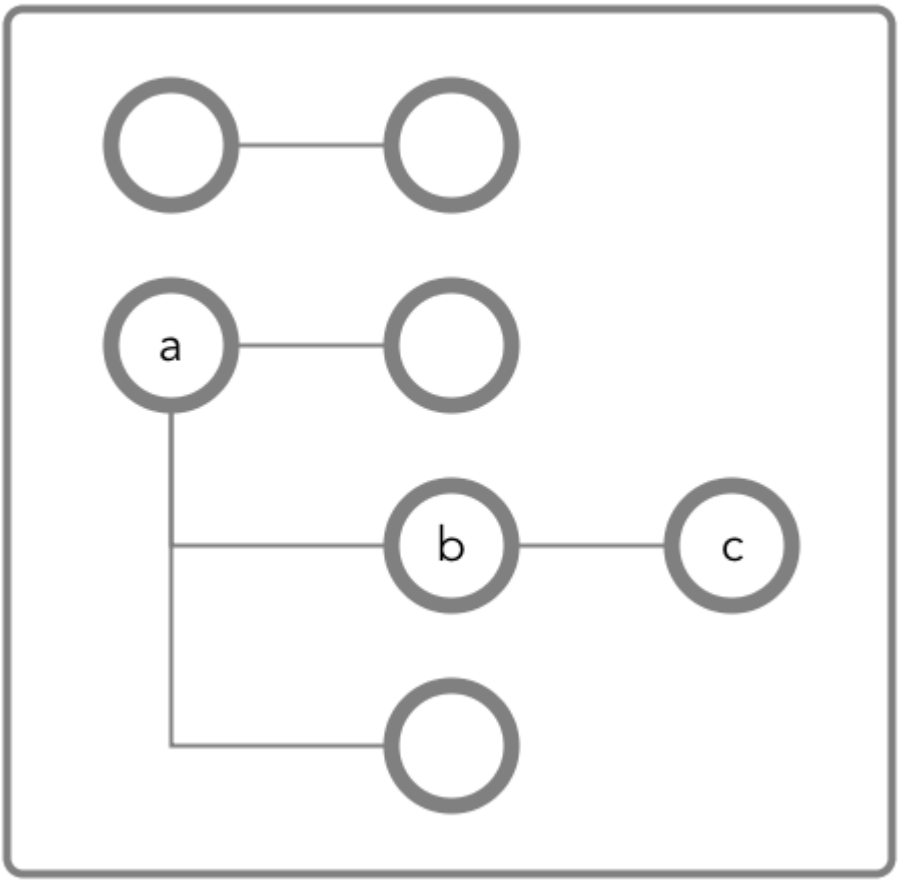
As illustrated in the following two diagrams, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Permissions on the Default Column Family
If a JSON document field is in the MapR Database JSON default column family, you must have `readperm` and `writeperm` permissions to perform read and write operations on the field. You either receive the permissions from the default column family, inherit them from the field's parent field, or have the permissions from an explicit grant on the field.

The following diagram shows a JSON document where all fields are in the default column family.

last-updated: Apr 11, 2022



Granting Read and Write Permissions on Field c

To perform both read and write operations on field c, when it is in the default column family, you must have both `readperm` and `writeperm` access on field c:

- If you have `readperm` and `writeperm` permissions on the default column family, then you have access to field c.
- If you have `readperm` and `writeperm` permissions on field b, then you have access to field c. You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.
- If you have `readperm` and `writeperm` permissions on the default column family *but* either field a or b denied you permissions:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field a or b).
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field c.
- If you do *not* have `readperm` and `writeperm` permissions on the default column family:
  - You must have `traverseperm` permission granted to you on either the default column family or field b.
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field c.

The following are examples of commands that grant these permissions:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname default
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname default
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf edit
  -path <path to JSON table >
  -cfname default
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname default
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

Granting Read or Write Permission on Field c

To perform either read or write operations on field c, when it is in the default column family, you must have either `readperm` or `writeperm` access on field c:

- If you have the same permission (`readperm` or `writeperm`) on the default column family, then you have access to field c.
- If you have the same permission (`readperm` or `writeperm`) on field b, then you have access to field c. You do not need any further permissions. Field c inherits your `readperm` or `writeperm` permission from field b.
- If you have the same permission (`readperm` or `writeperm`) on the default column family *but* either field a or b denied you permission:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field a or b).
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field c.
- If you do *not* have the same permission (`readperm` or `writeperm`) on the default column family:
  - You must have the `traverseperm` permission granted to you on either the default column family or field b.
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field c.

The following example grants `traverseperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
```

last-updated: Apr 11, 2022

```
   -cfname default
   -name a.b
   -traverseperm u:<user ID> | <existing ACE for this field>
```

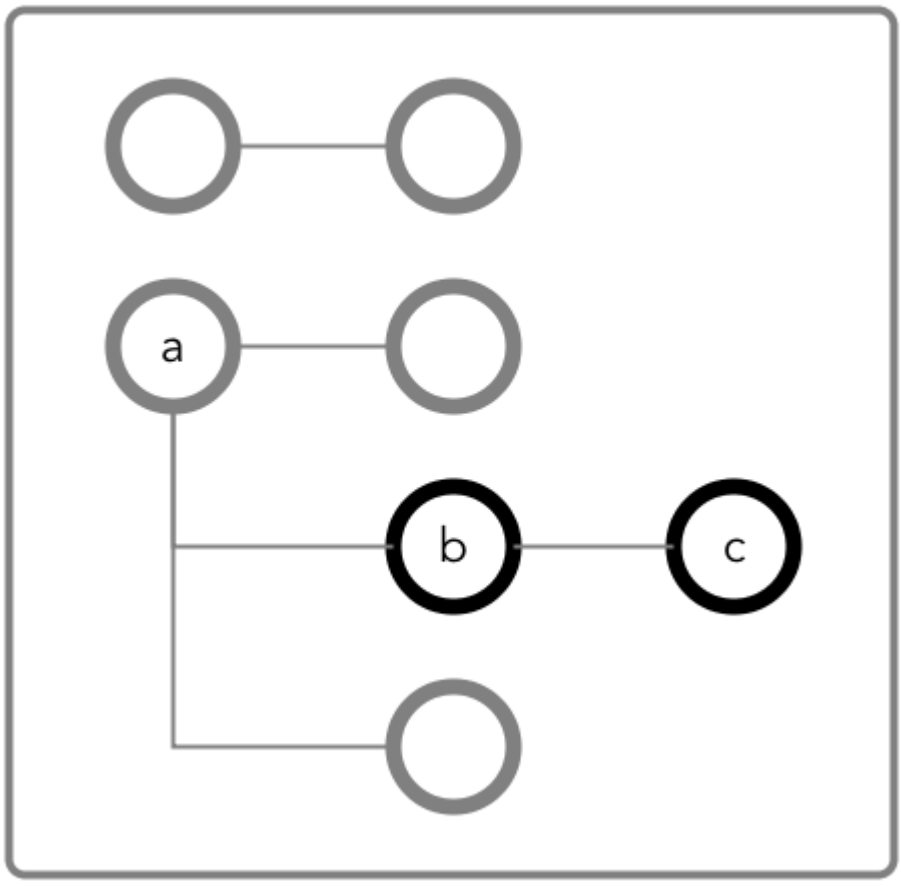
The following example grants `readperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
   -path <path to JSON table>
   -cfname default
   -name a.b.c
   -readperm u:<user ID> | <existing ACE for this field>
```

Permissions on Non-default Column Families
If a JSON document field is not in the MapR Database JSON default column family, you must have `readperm` and `writeperm` permissions to perform read and write operations on the field. You either receive the permissions from the column family, inherit them from the field's parent field, or have the permissions from an explicit grant on the field.

Note: Non-default column families are an advanced feature of MapR Database's native JSON support. For more information, see Managing Column Families on page 2538.

The following diagram shows a JSON document where fields b and c are in a column family `cf1` that is defined at field b with the path `a.b`.



Granting Read and Write Permissions on Field c

To perform both read and write operations on field c, when it is in column family `cf1`, you must have both `readperm` and `writeperm` access on field c:

- If you have `readperm` and `writeperm` permissions on `cf1`, then you have access to field c.
- If you have `readperm` and `writeperm` permissions on field b, then you have access to field c. You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.
- If you have `readperm` and `writeperm` permissions on `cf1` *but* either field a or b denied you permissions:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field a or b).
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field c.
- If you do *not* have `readperm` and `writeperm` permissions on `cf1`:
  - You must have `traverseperm` permission granted to you on either `cf1` or field b.
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field c.

The following are examples of commands that grant these permissions:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname cf1
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname cf1
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf edit
  -path <path to JSON table >
  -cfname cf1
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname cf1
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

Granting Read or Write Permission on Field c

To perform either read or write operations on field c, when it is in column family `cf1`, you must have either `readperm` or `writeperm` access on field c:

- If you have the same permission (`readperm` or `writeperm`) on `cf1`, then you have access to field c.

- If you have the same permission (`readperm` or `writeperm`) on field `b`, then you have access to field `c`. You do not need any further permissions. Field `c` inherits your `readperm` or `writeperm` permission from field `b`.
- If you have the same permission (`readperm` or `writeperm`) on `cf1` *but* either field `a` or `b` denied you permission:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field `a` or `b`).
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field `c`.
- If you do *not* have the same permission (`readperm` or `writeperm`) on `cf1`:
  - You must have the `traverseperm` permission granted to you on either `cf1` or field `b`.
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field `c`.

The following example grants `traverseperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
  -cfname cf1
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

The following example grants `readperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
  -cfname cf1
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
```

Permissions on Arrays
When granting permissions on a field, if the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

Note: This topic describes the behavior of permissions in MapR Database version 6.1 and later, regardless of the MapR version you used to grant the permissions. To understand how permissions on arrays behave in earlier releases, see Operational Changes (MapR 6.1.0) - Permissions on Arrays in MapR Database JSON.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
```

```
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person`, to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents, for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

MapR Database as a Column-Oriented Database

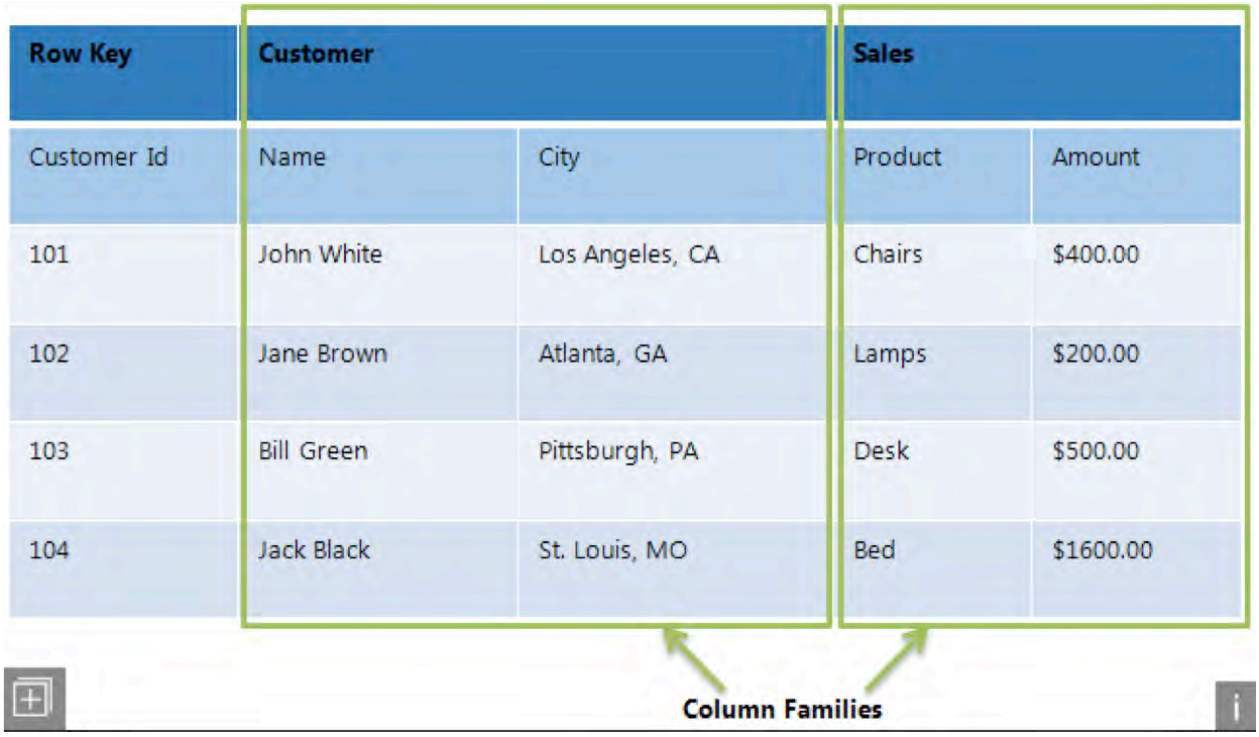
MapR Database supports column-oriented databases as a native data store. Column-oriented database tables in MapR Database are conceptually identical to tables in Apache HBase.

As a column-oriented database, MapR Database stores data in binary format. MapR Database supports the Apache HBase API and provides a native implementation of the HBase API. HBase applications can use MapR Database tables without modifying any code.

- MapR Database tables use the HBase data model.
- Allows for large-scale applications managing columnar data.

last-updated: Apr 11, 2022

- Binary compatibility with applications using standard HBase application APIs.
- With the binary tables, rows are indexed by key, columns identify data elements in each row, and column families are made up of columns.



MapR Database Binary Tables
MapR Database stores data as a nested series of maps. Each map consists of a set of key-value pairs, where the value can be the key in another map.

MapR Database stores structured data as a nested series of maps. Each map consists of a set of key-value pairs, where the value can be the key in another map. Keys are kept in strict lexicographical order: 1, 10, and 113 come before 2, 20, and 213.

In descending order of granularity, the elements of a binary table are:

- **Key**: Keys identify the rows in a table. In MapR Database, the maximum supported size of a row key is 64 KB. However, the recommended practice is to keep it lower than a few hundred bytes.
- **Row:** Rows span one or more column families and columns. In MapR Database, the maximum supported size of a row is 2 GB. However, the recommended practice is to keep the size under 2 MB. In general, MapR Database performs better with many small rows, rather than with fewer very large rows.
- **Column family**: A column family is a key associated with a set of columns. Specify this association according to your individual use case, creating sets of columns. A column family can contain an arbitrary number of columns. MapR Database binary tables support up to 64 column families.
- **Column**: Columns are keys that are associated with a series of timestamps that define when the value in that column was updated.
- **Timestamp**: The timestamp in a column specifies specifies when the data was written to that column.
- **Value**: The data written to that column at the specific timestamp.

This structure results in values with versions that you can access flexibly and quickly. Since MapR Database binary tables are *sparse*, any of the column values for a given key can be null.

last-updated: Apr 11, 2022

Example Table

This example uses JSON notation for representational clarity. In this example, timestamps are arbitrarily assigned.

Queries return the most recent timestamp, by default. For example, a query for the value in "arbitrarySecondKey"/"secondColumnFamily:firstColumn" returns `valueThree`. Specifying a timestamp with a query for "arbitrarySecondKey"/"secondColumnFamily:firstColumn"/11 returns `valueSeven`.

```
{
 "arbitraryFirstKey" : {
     "firstColumnFamily" : {
          "firstColumn" : {
               10 : "valueFive",
               7 : "valueThree",
               4 : "valueOne",
               }
          "secondColumn" : {
               16 : "valueEight",
               1 : "valueSeven",
               }
          }
     "secondColumnFamily" : {
          "firstColumn" : {
               37 : "valueFive",
               23 : "valueThree",
               11 : "valueSeven",
               4 : "valueOne",
               }
          "secondColumn" : {
               15 : "valueEight",
               }
          }
     }
 "arbitrarySecondKey" : {
     "firstColumnFamily" : {
          "firstColumn" : {
               10 : "valueFive",
               4 : "valueOne",
               }
          "secondColumn" : {
               16 : "valueEight",
               7 : "valueThree",
               1 : "valueSeven",
               }
          }
     "secondColumnFamily" : {
          "firstColumn" : {
               23 : "valueThree",
               11 : "valueSeven",
               }
          }
     }
}
```

Column Families in Binary Tables

Scanning an entire table for matches can be very performance-intensive. *Column families* enable you to group related sets of data and restrict queries to a defined subset, leading to better performance. When you design a column family, think about what kinds of queries are going to be used the most often, and group your columns accordingly.

You can specify compression settings for individual column families, which lets you choose the settings that prioritize speed of access or efficient use of disk space, according to your needs.

Be aware of the approximate number of rows in your column families. This property is called the column family's *cardinality*. When column families in the same table have very disparate cardinalities, the sparser table's data can be spread out across multiple nodes, due to the denser table requiring more splits. Scans on the sparser column family can take longer due to this effect. For example, consider a table that lists products across a small range of *model* numbers, but with a row for the unique serial numbers for each individual product manufactured within a given model. Such a table will have a very large difference in cardinality between a column family that relates to the model number compared to a column family that relates to the serial number. Scans on the model-number column family will have to range across the cluster, since the frequent splits required by the comparatively large numbers of serial-number rows will spread the model-number rows out across many regions on many nodes.

For a list of the properties that you can set when you create a column family, see the documentation for the `maprcli` command `table cf create` .

Note: When replicating a specific column family or column from a binary source table and a row is deleted, the destination table will show only a deletion for the specific column family or column. When replicating a specific column from a binary source table and its column family is deleted, the destination table will show only a deletion for the specific column.

Column Design

MapR Database tables split at the row level, not the column level. For this reason, extremely wide tables with very large numbers of columns can sometimes reach the recommended size for a table split at a comparatively small number of rows.

Warning: In general, design your schema to prioritize more rows and fewer columns.

As the MapR Database tables are *sparse*, you can add columns to a table at any time. Null columns for a given row do not take up any storage space.

Table Rowkey Design

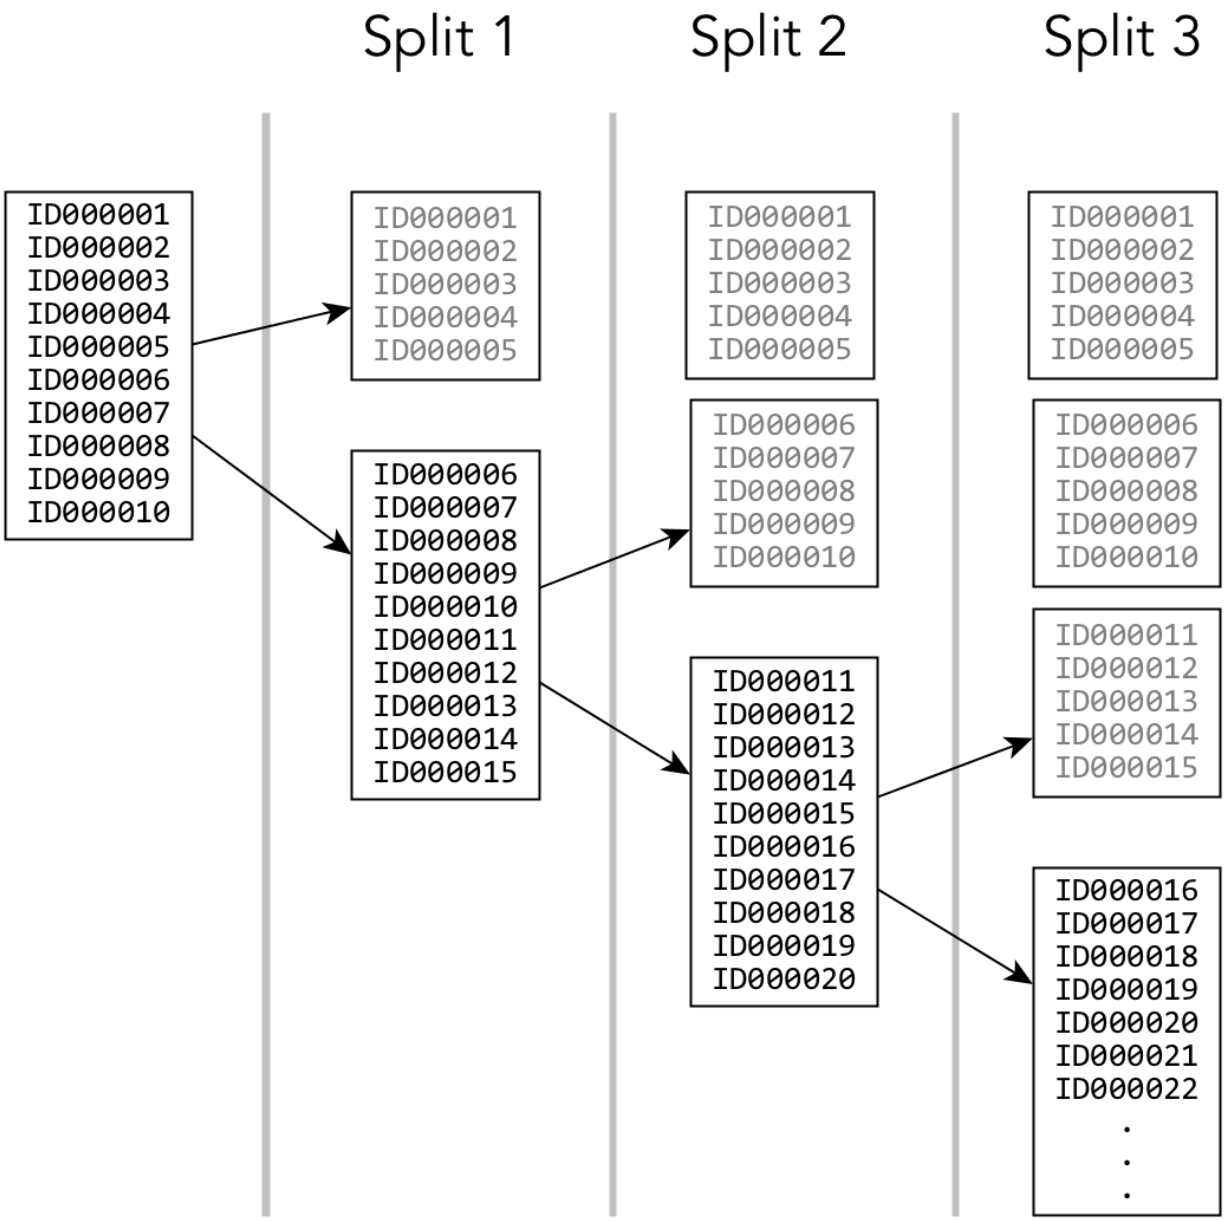
The design of a table's rowkeys affects the speed at which client applications can access data and the database performance if hotspotting occurs. The better the design, the faster the data access.

What is a Row Key?

For binary tables:	A row key identifies a row in a MapR Database binary table.
For JSON tables:	A row key identifies a row in a MapR Database JSON table. You specify row keys in the _id field in JSON documents. For example, if the value of the _id field in a JSON document is user000001, that value is also the rowkey for the row in which the JSON document is stored in a JSON table.

Avoiding Hotspotting

Because records in tables are stored in lexicographical order of their rowkeys, using a sequential generation method for rowkeys can lead to a hot-spot problem, as illustrated in this diagram.



A table region reaches a predetermined size and then splits into two regions. Because the rowkeys for new records are being created sequentially, new rows are added to only one of the new regions. The other region is not written to and remains at half of its maximum size. The problem is repeated with each subsequent split.

With MapR Database tables, the cluster handles sequential keys and table splits to keep potential hotspots moving across nodes, decreasing the intensity and performance impact of hot spots. However, hotspotting can still hamper database performance.

There are two strategies that you can use to avoid hotspotting:

Hashing keys	To spread write and insert activity across the cluster, you can randomize sequentially generated keys by hashing the keys, inverting the byte order. Note that these strategies come with trade-offs. Hashing keys, for example, makes table scans for key subranges inefficient, since the subrange is spread across the cluster.

last-updated: Apr 11, 2022

Salting keys	Instead of hashing the key, you can salt the key by prepending a few bytes of the hash of the key to the actual key. For a key based on a timestamp, for instance, a timestamp value of `1364248490` has an MD5 hash that ends with `ffe5`. By making the key for that row `ffe51364248490`, you avoid hotspotting. Because you know that the first four digits are a hash salt, you can derive the original timestamp by dropping those digits.

Composite Keys

Each row in a table can have only a single key. You can create composite keys to approximate multiple keys in a table. A composite key contains several individual IDs joined together, for example userID and applicationID. You can then scan for the specific segments of the composite row key that represent the original, individual ID.

Because rows are stored in sorted order, you can affect the results of the sort by changing the ordering of the fields that make up the composite row key. For example, if your application IDs are generated sequentially but your user IDs are not, using a composite key of userID+applicationID will store all rows with the same user ID closely together. If you know the userID for which you want to retrieve rows, you can specify the first userID row and the first userID+1 row as the start and stop rows for your scan, then retrieve the rows you're interested in without scanning the entire table.

When designing a composite key, consider how the data will be queried during production use. Place the fields that will be queried the most often towards the front of the composite key, bearing in mind that sequential keys will generate hotspotting.

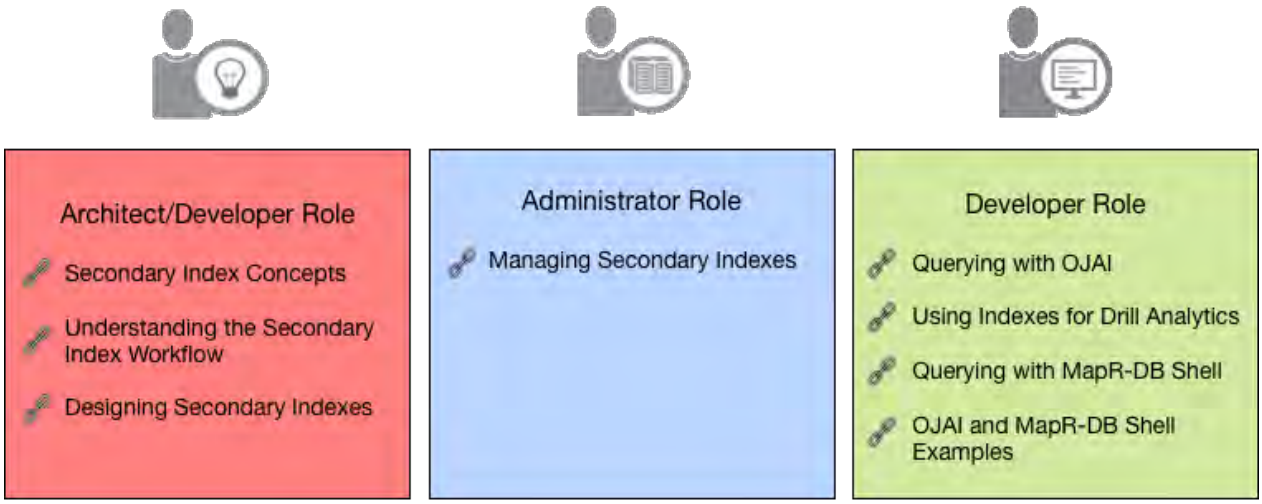
For binary tables:	You must create your own custom logic for working with composite keys in applications that use the HBase Java API. This API does not have built-in support for composite keys.
For JSON tables:	You must create your own custom logic for working with composite keys in applications that use the MapR Database OJAI Java API library. This API library does not have built-in support for composite keys.

Secondary Indexes

Beginning with MapR 6.0, MapR Database JSON natively supports secondary indexes on fields in JSON tables. Indexes provide you with flexible, high performance access to data stored in MapR Database.

How Do I Get Started?

The following diagram provides links to topics that you need to understand and use Secondary Indexes. Topics include conceptual information about indexes, how to decide what indexes to create, how to set up and use indexes, the `maprcli` commands used to create and maintain indexes, and how to query your data to leverage indexes. The information is organized based on roles.



1. Describes secondary index concepts, including use cases, types of indexes, types of queries that benefit from indexes, and how indexes are implemented
2. Describes the overall workflow for using secondary indexes. This includes the roles of different users and the workflow steps involved.
3. Describes how to design secondary indexes to provide the most benefit to MapR Database JSON queries
4. Describes how to manage secondary indexes including creating, deleting, and listing indexes, setting up your cluster for querying, and troubleshooting
5. Describes how to use the OJAI API library to query JSON tables, including special considerations related to secondary indexes
6. Describes how to leverage indexes when issuing SQL queries with Drill
7. Describes how to use the MapR Database Shell to query JSON tables
8. Contains samples of OJAI programs and MapR Database Shell commands that query JSON tables

What are Secondary Indexes?

A *secondary index* (also sometimes referred to in this documentation as an *index*) is a special table that stores a subset of document fields from a JSON table. The index orders its data on a set of fields, defined as the *indexed fields*. This is in contrast to the JSON table that orders its data on the table primary key (rowId or rowKey). If you have administrator privileges, you can create one or more indexes on each JSON table. After the indexes are created, applications can leverage them to accelerate query response times. Secondary indexes can also contain additional fields known as *included fields* (or sometimes *covered fields*) beyond those being indexed, so that many queries can be satisfied with a single read.

Secondary indexes provide efficient access to a wider range of queries on data in MapR Database. They allow queries to efficiently query data through fields other than the primary key. This capability results in MapR Database supporting a broader set of use cases. Applications that benefit include rich, interactive business applications and user-facing analytic applications. Secondary indexes also enable Business Intelligence tools and ad-hoc queries on operational datasets. See Uses for Secondary Indexes on page 548 for more information.

Important: Secondary indexes can be created only on MapR Database JSON tables.

last-updated: Apr 11, 2022

Why Use Secondary Indexes?

With the ever increasing amount of data stored in MapR Database JSON, indexing that data becomes critical. Without indexes, queries unnecessarily scan large amounts of data from the underlying JSON table. Queries could potentially scan every document in the table, even if they contain conditions that limit the documents to select. Query performance suffers and resource bottlenecks are inevitable when you use this data model.

Without indexes, applications and query layers resort to limited interactivity to avoid performance concerns. Using indexes solves this limitation in application scale, by reducing the number of documents client applications read, even when querying large data sets. This reduces I/O and CPU costs, resulting in improved performance.

The functionality and benefits of indexing available in MapR Database are similar to that of indexes in relational databases. The difference is that MapR Database indexes provide performance benefits at high scale, in combination with JSON flexibility on the query side and simplicity on the management side.

How Can I Use Secondary Indexes?

You can leverage MapR Database secondary indexes by using either the OJAI API, the MapR Database JSON REST API, or MapR Drill.

OJAI is the business application development interface on MapR Database. Typically, business applications are characterized by ultra low latency and extremely high throughput. When you build an application using OJAI, filtering and sorting through the API can leverage secondary indexes to accelerate query response times.

The MapR Database JSON REST API enables you to use HTTP calls to perform basic operations on MapR Database JSON tables, including querying.

Drill is the analytics SQL interface on MapR Database. Drill is a distributed SQL query engine that provides interactive response time for operational analytics, Business Intelligence (BI) tools such as Tableau, and ad-hoc queries on MapR Database. With MapR Drill, SQL queries can also leverage secondary indexes to accelerate query response times.

Regardless of whether queries originate from OJAI or Drill SQL, each interface seamlessly selects the optimal indexes to use. You do not need to write explicit code or provide directives on which indexes to use. If an appropriate index exists for a query, MapR Database leverages the index.

For more information about the OJAI API, see the following API links:

- Java OJAI Client API
- Node.js OJAI Client API
- Python OJAI Client API
- C# OJAI Client API
- Go OJAI Client API

For information about the MapR Database JSON REST API, see Using the MapR Database JSON REST API on page 2696.

For information about MapR Drill, see Apache Drill on MapR.

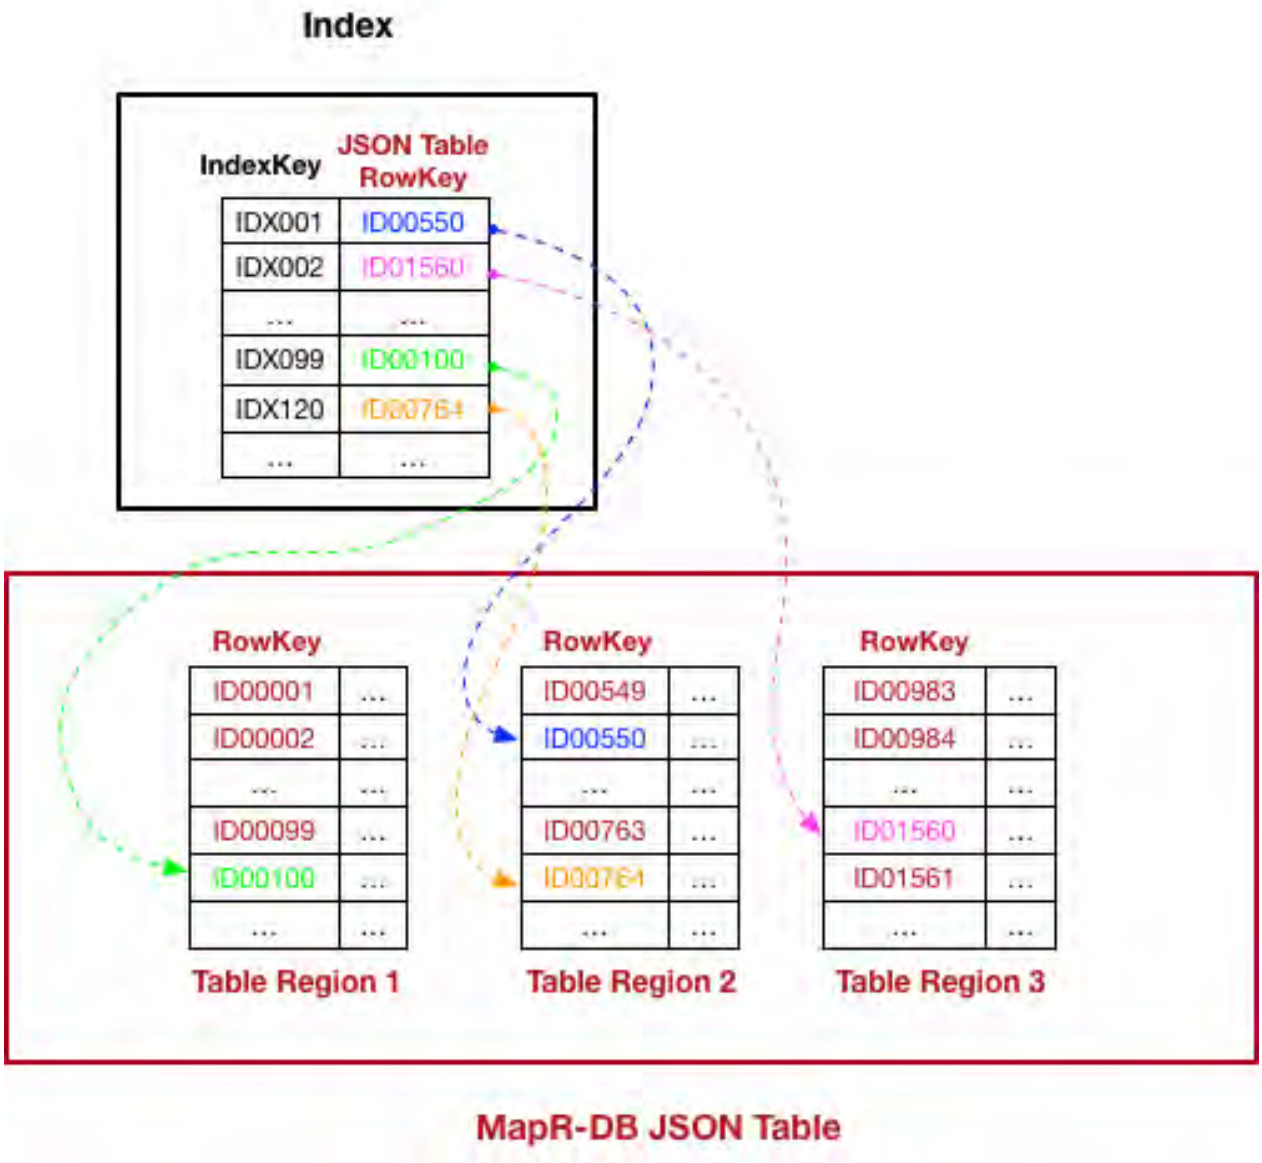
Secondary Index Concepts
Describes secondary index concepts, including use cases, types of indexes, types of queries that benefit from indexes, and how indexes are implemented.

Indexes created on regularly queried JSON table fields provide MapR Database quick access to data. Indexes primarily benefit queries with filters in the WHERE clause, queries with an ORDER BY clause for sorting, and queries where all fields projected in the query are included in the index. They provide the most benefit when an index contains all fields referenced in a query. For filters, indexes reduce the amount of data read. MapR Database implements indexes using JSON tables. Like JSON tables, an index stores data in sort order. Reading data through the index eliminates the need to sort the data if the index and query sort orders match.

Each JSON table in MapR Database has a unique field that serves as the rowkey. A secondary index contains indexed and included fields. The indexed fields, also referred to as *index keys*, define the sort order of the index. The index stores the values of the index keys along with the rowkey corresponding to each key value. The rowkey links the index to the JSON table. MapR Database can perform a range scan on the index and then use the corresponding rowkeys to quickly locate data in the JSON table. Additional fields can be included in the index so that queries that only need these included (or covered) fields can get all the data they need from the index and therefore will not require access to the base table.

The following diagram illustrates the mapping. Each index entry consists of the index key value followed by the rowkey of the corresponding JSON document. The color coding highlights the matching index and JSON table entries.

last-updated: Apr 11, 2022



Important: Secondary indexes can only be created on MapR Database JSON tables.

Uses for Secondary Indexes

Describes typical use cases that can benefit from secondary indexes.

Operational Analytics	Operational analytics require highly scalable, highly responsive, interactive, user-facing applications. Application developers can use OJAI API to build richer and more interactive applications. This enables users to retrieve data on a variety of columns in MapR Database JSON tables in a flexible way. In addition to processing queries, OJAI also enables them to sort on columns and paginate or restrict the results. The applications can be operational applications or operational analytical applications. For both categories, the level of user interactivity and query complexity is high. Sample applications include Customer 360, expense reporting systems, game management, product catalogs, and a variety of domain-specific analytics as service applications.

last-updated: Apr 11, 2022

Operational BI and Dashboards	Typical analytical workloads query snapshots of read-only data. Querying against MapR Database using Drill SQL enables these applications to get insights into the latest, changing data. Moreover, operational analytical queries usually access only a subset of fields from a table, often aggregating the data on a variety of dimensions and time ranges. Secondary indexes are extremely useful in these use cases. They improve the performance of well known query patterns.
Self-service Data Exploration	Users want to use their favorite BI reporting tool to issue ad-hoc queries against MapR Database JSON tables. They can achieve a simple, high performing data exploration experience using MapR Database and Drill SQL, while leveraging the capabilities of both. Using the MapR Database document model provides end to end JSON flexibility at the data storage level. Using Drill SQL provides dynamic schema discovery.

Types of Secondary Indexes

MapR Database JSON supports several index types, including simple indexes, composite indexes, hashed indexes, and indexes with casting. This section describes the properties of these indexes and the situations where each provides value.

The following diagram illustrates the different properties of indexes and index fields. Lines connecting properties represent properties that can be used in combination with one another. Click on the text in the diagram for a description of each property.

Indexed vs Included Fields

An index consists of indexed and included fields. Indexed fields are also referred to as *index keys*. The following lists describe the characteristics of each type of field:

Indexed Fields	• Determine the sort order of the index and the order of the query result when used • Allow filter conditions and ORDER BY conditions defined on these fields to be optimized
Included Fields (sometimes referred to as *covered fields*)	• Do not affect the sort order of the index or the order of the query result • Can avoid the need to read the base table if all required fields are included in the index

In general, you should define indexed fields on fields you filter and order on, and included fields on fields you reference but do not filter and order.

The following example illustrates when you would define an indexed vs an included field in your index. Assume you have a MapR Database JSON table with the following sample data that contains customer information.

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
        {"Type": "Home", "Number": "555-555-1234"},
        {"Type": "Mobile", "Number": "555-555-5678"},
        {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

Your query does the following:

1. Filters on `Address.Zipcode`
2. Selects `FullName.FirstName` and `FullName.LastName`

Since your query filters on `Address.Zipcode`, you should include that field as an indexed field. Also, because this query only needs the fields `FullName.FirstName` and `FullName.LastName`, you can set `FullName` as an included field. The result is that this query will only need to read from the index and will

not need to look at the original table. Other queries that, for example, need to read the phone numbers or address would still need to go back to the base table.

```
maprcli table index add -path /customerInfo -index zipCodeIdx \
   -indexedfields Address.Zipcode \
   -includedfields FullName
```

There are additional differences in how indexed and included fields behave. The following table summarizes these differences:

Indexed Field	Included Field
There are some restrictions in the data types of indexed fields. See Data Types and Secondary Index Fields on page 561 for the complete list of types.	Data types of included fields can be any type. There is no data type restriction.
The collective size of all indexed fields is a maximum of 32KB.	Included fields do not affect the size limit of an index.
Adding indexed fields increases the cost of key comparisons when scanning the index, due to the increase in the index key size.	Adding included fields does not impact the index scan cost.

Included fields influence whether an index is a *covering index* for a query. See Covering Indexes on page 560 for more information about this concept.

Indexed Field Sort Order

You can define each field in your index key to sort in either ascending or descending order. The default is ascending. Typically, you define the sort order to match the ORDER BY clause in your query. This allows the MapR Database to avoid performing an explicit sort. For example, if you issue queries where you return `AccountBalance` in descending order, create the following index.

```
maprcli table index add -path /customerInfo -index BalanceIdx \
   -indexedfields AccountBalance:-1
```

Simple vs Composite Indexes

Simple indexes are indexes with a single indexed field (or key). Composite indexes have more than one key. In both cases, you can define zero or more included fields. See Simple Indexes on page 552 and Composite Indexes on page 553 for additional details.

Hashed vs Non-Hashed Indexes

By default, indexes are stored in sort order across the index key values. This can lead to hotspots if the sort order of the index keys match the order data that is inserted into the JSON table. For example, if the indexed field has monotonically increasing timestamp values, such as the date a document is created, the tail end of the index becomes a hotspot. Hashed indexes avoid hotspotting by evenly distributing index writes across a number of logical partitions.

The following example creates a hashed index named `idx` on table, `tab`, with a single key, `idxKeyCol`.

```
maprcli table index add -path /tab -index idx -indexedfields idxKeyCol \
    -hashed true
```

See Hashed Indexes on page 555 for further details.

last-updated: Apr 11, 2022

Casting

You can CAST individual indexed fields to a specific data type. This is applicable when Drill SQL queries contain CAST expressions. The following example creates an index that casts the `age` field to an INT type and the `height` field to a FLOAT type.

```
maprcli table index add -path /castTable -index castIdx \
   -indexedfields '$CAST(age@INT)','$CAST(height@FLOAT)'
```

See Using Casts in Secondary Indexes on page 557 for further details.

Note: This feature only applies for queries issued through the Drill SQL interface. The OJAI API does not have CAST support.

Simple Indexes
A *simple index* is a secondary index that has only one indexed field and zero or more included fields. Simple indexes enable you to optimize queries that filter and sort on a single field. If all fields referenced in a query are either indexed or included fields in a simple index, then you can process the query by reading only the index.

Sort Order

MapR Database sorts simple indexes on the single indexed field. MapR Database sorts the indexed field values in ascending order by default, although you can specify a descending order when you create the index. Sorting indexes benefits your ORDER BY queries because the index eliminates the need for a SORT operator in the query plan.

Simple Index Examples

The following CLI commands demonstrate how you can create various types of simple indexes. For these examples, assume that you have a MapR Database JSON table with the following sample data:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
       {"Type": "Home", "Number": "555-555-1234"},
       {"Type": "Mobile", "Number": "555-555-5678"},
       {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

CLI Command	Description

`maprcli table index add -path /people \`
`-index emailIdx \`
`-indexedfields Email`
	• Creates a simple index on the `Email` field, with no included fields
	• Enables you to filter on the `Email` field

`maprcli table index add -path /people \`
`-index dobIdx \`
`-indexedfields DateOfBirth \`
`-includedfields FullName`
	• Creates a simple index, with an included field
	• Enables you to filter on `DateOfBirth` and project on `FullName`

`maprcli table index add -path /people \`
`-index LastNameIdx \`
`-indexedfields FullName.LastName:-1`
	• Creates a simple index on the `FullName.LastName` subfield, as a descending sort key
	• Allows you to filter on `FullName.LastName` and sort on the subfield in descending order

`maprcli table index add -path /people \`
`-index fullNameIdx \`
`-indexedfields FullName`
	• Creates a simple index on the nested document field `FullName`
	• Allows you to perform equality lookups on both the `LastName` and `FirstName` subfields of `FullName`

`maprcli table index add -path /people \`
`-index hobbiesIdx \`
`-indexedfields Hobbies`
	• Creates a simple index on the `Hobbies` array field
	• Allows you to filter for a specific list of hobbies

`maprcli table index add -path /people \`
`-index hobbyIdx \`
`-indexedfields Hobbies[]`
	• Creates a simple index using the container field path `Hobbies[]`
	• Allows you to filter for a specific hobby

`maprcli table index add -path /people \`
`-index phoneNumberIdx \`
`-indexedfields Phones[].Number`
	• Creates a simple index on the container field path `Phones[].Number`
	• Allows you to filter for a phone number, regardless of whether it is a home, work, or cell phone

Composite Indexes
A *composite index* is an index that has more than one indexed field and zero or more included fields. Composite indexes enable you to optimize queries that filter and sort on multiple fields. If all fields referenced in a query are either indexed or included fields in a composite index, then you can process the query by reading only the index.

Sort Order

MapR Database sorts the composite index in the order in which you have defined the indexed fields. For example, if you have an index on `Field1` and `Field2`, MapR Database sorts on `Field1` as the primary sort key and `Field2` as the secondary.

Each component in a composite index can have its own ordering. For example, you can specify an ascending sort order for one field and a descending sort order for another.

Composite Indexes and Container Field Paths

The indexed fields in a composite index can be Container Field Paths on page 518. However, if you specify more than one container field path in your indexed fields, the prefixes of the container field paths must be the same. This allows MapR Database to store index values that originate from the same array element in a single index row.

Examples of Supported Composite Indexes

Indexed Fields Allowed for Composite Index	Why Allowed?
`a[].b, x.z`	The indexed fields have only one container field path.
`a[].b, a[].c`	The indexed fields have a common container prefix, `a[]`.
`a[].b, a[].c[]`	The indexed fields have a common container prefix, `a[]`.
`a[].b[].c, a[].b[].d`	The indexed fields have a common container prefix, `a[].b[]`.

Examples of Unsupported Composite Indexes

If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must also be consistent. The third and fourth rows in the following table show examples of this restriction:

Indexed Fields Disallowed for Composite Index	Why Disallowed?
`a[].b, x[].y`	`a[]` and `x[]` are different container prefixes.
`a[].b[], a[].c[]`	Although both indexed fields have a common container prefix of `a[]`, `b[]` and `c[]` are different container field paths.
`a.b[].c, a.b.d`	In the first indexed field, subfield `b` is an array of nested documents. In the second, `b` is a single nested document. This results in a type conflict.
`a, a[]`	The first indexed field `a` is a scalar type while the second is an array. This also results in a type conflict.

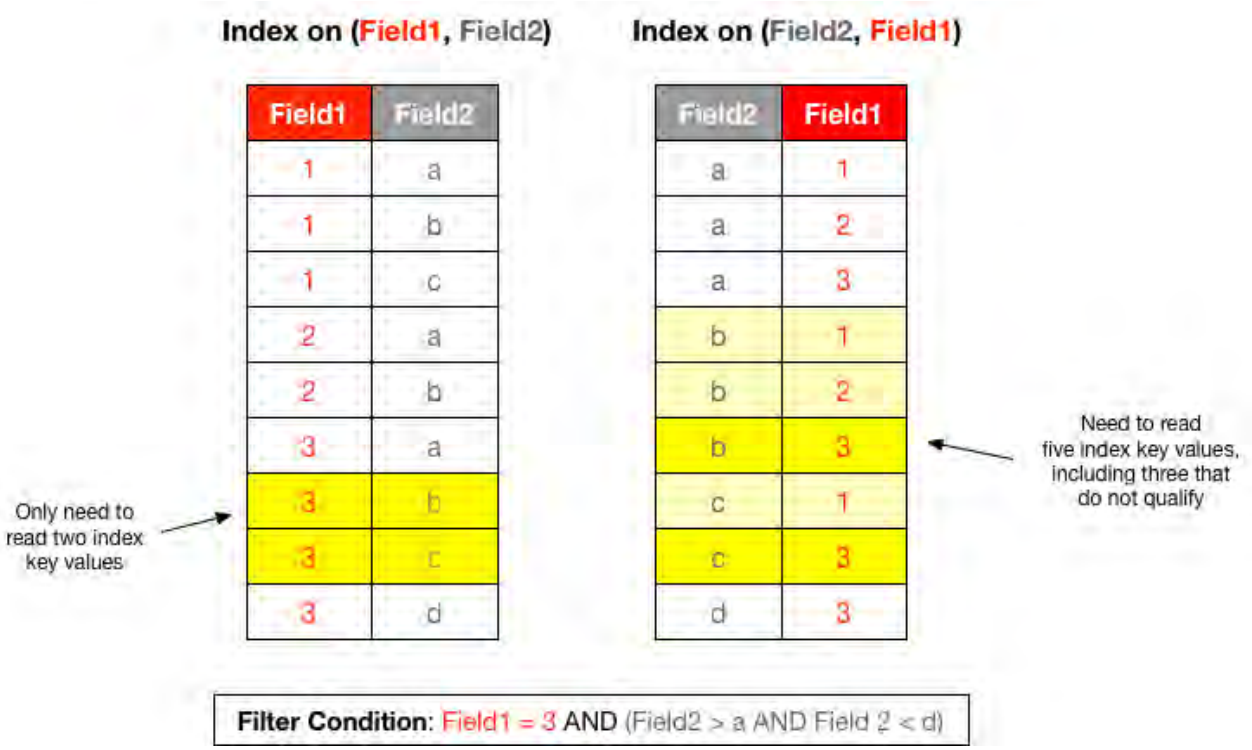
Query Conditions Using Composite Indexes and Container Field Paths

When you have a composite index defined on container field paths, your query condition must use the elementAnd operator to use all keys of the index. With the `and` operator, the conditions do not have to match the same array element; as a result, the matching indexed field values might span different index rows, preventing use of the composite index. See OJAI Query Conditions Using elementAnd on page 2619 for more details.

Composite Index Example

Consider the following example, which illustrates the impact of key order in a composite index:

last-updated: Apr 11, 2022



In the index on the left, the prefix key is `Field1`. MapR Database sorts the index first on `Field1`, and then on `Field2`. This aligns with the equality condition, `Field1 = 3`. MapR Database reads the least number of entries from the index on the left, due to this equality condition and the range condition on `Field2`.

In the index on the right, MapR Database sorts the index on `Field2`, followed by `Field1`. In this case, the matching key values are not contiguous in the index, as highlighted by the entries in a lighter shade of yellow. MapR Database uses the filter conditions on `Field2` to start the search in the index. It applies the filter condition on `Field1` while reading the index. This is less efficient because MapR Database must read those extra non-matching key values.

Related concepts

Restrictions on Secondary Indexes on page 565
This topic lists and describes the restrictions on secondary indexes. It is important for you to understand the type, size, field definition, option, and index use restrictions when defining and using secondary indexes.

Hashed Indexes

A *hashed index* is a secondary index that distributes keys across logical partitions to avoid creating hot spots when MapR Database updates the index with new keys from the JSON table.

Hot spots occur when data inserted into an indexed field has monotonically increasing values, or when a burst of write activity occurs. The former occurs with timestamp values. The latter occurs when you have a burst of updates on an indexed field over a small range of values. Hashed indexes enable MapR Database to evenly distribute new writes on an index and avoid hot spots.

Note: Hashed indexes do not resolve hot spots on the JSON table. For information about how to design rowkeys and avoid hot spots in the JSON table, see Table Rowkey Design.

Hashed indexes support the same conditional queries as non-hashed indexes, except that hashed indexes do not have a guaranteed sort order. Hashed indexes do not support ORDER BY queries due to the distribution of data across logical partitions. Consequently, sorting is performed by the query layer, which can increase the CPU costs and negatively impact performance.

By default, MapR Database creates ten partitions for a hashed index. You can modify this value when you create a hashed index using the maprcli table index add command or through the Control System. When a hashed index exists, MapR Database distributes table updates to the index across the logical partitions, which reside on different nodes. MapR Database orders the keys within each partition instead of ordering them across the entire index.

Note: Once you create an index with hashing enabled, you cannot disable hashing. You can remove the hashed index and then create a non-hashed (default) index on the field. See Removing Indexes and Adding Indexes.

Guidelines on Creating Hashed Indexes

- Create a hashed index on fields with monotonically increasing values, such as timestamp values.
- Create a hashed index on fields that MapR Database updates in bursts of write activity, for example when MapR Database updates a small range of possible values for the indexed field.
- Do not create hashed indexes for ORDER BY queries.
- Use the `maprcli table index list` command or the Control System to determine if an index is hashed. See maprcli table index list or Listing Indexes.
- After you create an index with hashing enabled, you cannot disable hashing.

Example Comparison of a Non-Hashed Index and Hashed Index

The following images depict a non-hashed (default) index and a hashed index. For the purpose of this example, assume that an index was created on the `DateCreated` field of a JSON table in MapR Database. Yellow highlighted areas indicate updates to the index.

Non-Hashed (Default) Index

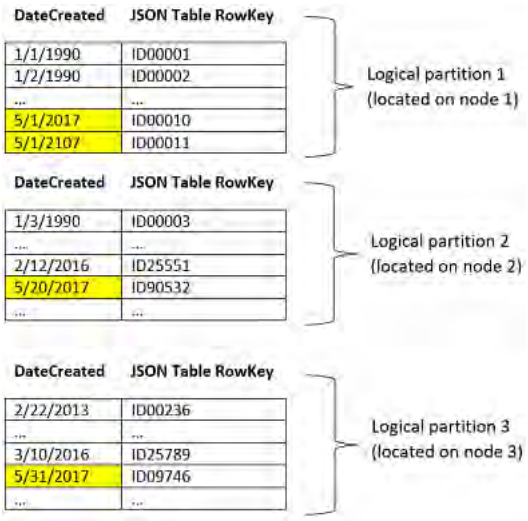
The non-hashed index propagates `DateCreated` field updates from the JSON table to the index. Notice that the dates are sorted within the index and no partitions exist. Depending on the size of the index, the index may exist on one or multiple nodes

DateCreated	JSON Table RowKey
1/1/1990	ID00001
1/2/1990	ID00002
...	...
...	...
5/1/2017	ID00010
5/1/2017	ID00011
...	...
5/20/2017	ID90532
...	...
5/31/2017	ID09746

.

Hashed Index

The hashed index propagates `DateCreated` field updates across the index partitions which reside on different nodes. Notice that dates are sorted within each partition and each partition resides on a different node.



Using Casts in Secondary Indexes
Defining an index that specifies index keys with CAST functions provides fast access for queries that contain CAST functions. The index converts the indexed field to the type specified by the CAST function and stores the result.

Create indexes using CAST functions if you want to CAST fields to specific data types in your queries. To define an index with the CAST function applied to a field, specify a CAST when defining the index key. The following example creates an index that casts the `age` field to an INT type and the `height` field to a FLOAT type.

```
maprcli table index add -path /castTable -index castIdx \
   -indexedfields '$CAST(age@INT)','$CAST(height@FLOAT)'
```

When issuing Drill queries through Business Intelligence (BI) tools, you can include CAST functions in your queries to create Drill views. Including CAST functions provides the metadata needed to optimally process the queries. For more information about using the CAST function with Drill, see Data Type Conversion.

Casting from NULL in Drill

You can cast from null to any data type supported by the indexes with the CAST function. However, null can be a valid JSON value for the string data type, for example:

```
{ "name": null }
```

Null can also represent the absence of an actual value, for example:

```
{ "_id":1,"name":"Annie" }
{ "_id":2 }  (name does not exist)
```

When you cast on columns with missing values, Drill does not return null for the missing values. Drill only returns null in cases where an actual value of null exists.

For example, if you have the following data stored in a JSON table named t1:

a1	b1
1	'abc'
2	null
3	'null'

And you issue the following query against the table:

```
SELECT a1, b1(cast b1 as varchar(20))) from t1;
```

Drill returns the following data:

a1	b1
1	abc
2	
3	null

Drill does not return null where null represents a missing value. Drill only returns null in the instance where null is stored as a string value.

Guidelines for Using Casts in Indexes

The following rules apply to CAST functions used in secondary indexes:

- You can include the CAST function only on indexed fields.
- You do not have to cast between comparable data types.
- Indexes support casting to the following data types:
  - Boolean
  - String
  - Int
  - Long
  - Float
  - Double
  - Date
  - Time
  - Timestamp

  Note: MapR Database does not support casting from any data type to `byte`, `short`, `decimal`, `binary`, or `interval`.

  Note: Queries that use the CAST function on fields with `timestamp` and `binary` data types are not supported.

- When casting to a `string` type, you can optionally specify a length. If you do not specify a length, it defaults to the maximum length of 255.
- When casting a `float` or `double` type to a `string` type, you cannot control the precision of the digits in the resulting string value. `Float` and `double` are approximate representations of decimal values.
- When casting from a `binary` type, MapR Database assumes that the binary value is a UTF-8 formatted string representation of the resulting data type.

- If MapR Database cannot cast a value, MapR Database indexes the row with an encoding error that specifies a CAST issue.
- You cannot cast all data types to the supported data types. See the Casting Matrix below for supported and unsupported combinations.

Casting Matrix

The following matrix displays supported and unsupported casting, from the data type shown in the column to the data type shown in the row. **Y** indicates a supported casting; **N** indicates an unsupported casting. Hyphen (**-**) indicates that casting is unnecessary, because the data types are comparable.

	int	**long**	**float**	**double**	**string**	**boolean**	**date**	**time**	**timestamp**
byte	Y	Y	Y	Y	Y	Y	N	N	N
short	Y	Y	Y	Y	Y	Y	N	N	N
int	-	Y	Y	Y	Y	Y	Y[1]	Y[2]	Y
long	Y	-	Y	Y	Y	Y	Y	Y	Y
float	Y	Y	-	Y	Y	Y	N	N	N
double	Y	Y	Y	-	Y	Y	N	N	N
string	Y	Y	Y	Y	-	Y[3]	Y	Y	Y
boolean	Y	Y	N	N	Y	-	N	N	N
date	N	N	N	N	Y	N	-	Y	Y
time	N	N	N	N	Y	N	N	-	N
timestamp	N	N	N	N	Y[4]	N	Y	Y	-
binary	Y	Y	Y	Y	Y	N	N	N	N
array	N	N	N	N	N	N	N	N	N
nested document	N	N	N	N	N	N	N	N	N

[1] When casting int/long to a date type, the date value is constructed based on the int/long value being the number of milliseconds since epoch.

[2] When casting int/long to a time type, the time value is constructed based on the int/long value being the time of day in milliseconds.

[3] MapR Database casts the strings `true`, `yes`, `on`, `y`, `t`, and `1` to boolean `true`. MapR Database casts the strings `false`, `no`, `off`, `n`, `f`, and `0` to boolean `false`.

[4] The string represents the time in UTC timezone.

Example Using Cast Function in an Index

This example shows you how to create an index with the CAST function.

The following statement queries a table named `lineitem` and casts the `L_LINENUMBER` and `L_ORDERKEY` fields to the `int` data type:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE CAST(L_LINENUMBER as
int) = 1 AND CAST(L_ORDERKEY as int) = 550;
```

You can create an index on the `L_LINENUMBER` and `L_ORDERKEY` fields and indicate the use of the CAST function and data type for each field, as follows:

```
maprcli table index add -path /drill/testdata/qa/sf1/maprdb/json/
lineitem -index l_cast_comp_1 \
   -indexedfields '$CAST(L_LINENUMBER@INT)','$CAST(L_ORDERKEY@INT)' \
   -includedfields L_LINESTATUS,L_QUANTITY
```

The index stores the values of the `L_LINENUMBER` and `L_ORDERKEY` fields as the `int` data type. MapR Database can use the index for any subsequent queries that use the CAST function to retrieve these fields as the `int` type, instead of accessing data in the primary table and converting the values to `int`.

Note: If you created an index on the `L_LINENUMBER` and `L_ORDERKEY` fields without the CAST function, the query used in this example would not benefit from the index.

Covering Indexes
A *covering index* is an index that allows MapR Database to process a query using secondary indexes without reading the JSON table. Using a *covering index* makes a query more efficient by avoiding the I/O overhead of fetching data from the JSON table.

If all fields referenced in a query are either indexed or included fields in a secondary index, then the secondary index is a covering index for that query. MapR Database determines whether an index is covering for a query.

A query that uses a covering index can reference only indexed fields from the index or a combination of indexed and included fields. While adding included fields to an index enables it to become a covering index, note that each field you add to an index increases its storage requirement. As the storage size increases, the cost of reading the index also increases; likewise, for the cost of adding and updating documents. Consider the impact on storage and updates when adding included fields to an index.

In contrast to a covering index, a noncovering index is an index that does not store all fields referenced by a query. In this case, lookups occur on the JSON table to retrieve the referenced fields that are not available in the index itself.

Whether an index is covering or noncovering depends on the query that uses the index. In the example at Types of Secondary Indexes on page 549, `zipCodeIdx` is a covering index for the noted query. If the query also selects the `Gender` field, `zipCodeIdx` is no longer a covering index for the query, but it still optimizes the filter condition.

Covering Indexes and Container Field Paths

When a query uses an index in which the indexed fields are container field paths, MapR Database cannot rely on only the indexed fields to treat the index as covering. This is due to the way MapR Database stores data in an index for container field paths. As described in Using Container Field Paths as Indexed Fields on page 562, MapR Database stores one row in the index for each array element. Thus, reading only the rows corresponding to matching array elements might not retrieve the other elements of the array.

To allow an index to be covering in this scenario, the referenced field must be an included field in the index.

For example, using the example at Types of Secondary Indexes on page 549, suppose you want to run the following query:

- Filter where `Hobbies[]` contains "Baseball"
- Select the `FullName` and all `Hobbies`

For an index to be covering for this query, you must define the index with following fields:

- Indexed Fields: `Hobbies[]`
- Included Fields: `Hobbies`, `FullName`

Note: MapR Database does not permit you to specify the same field as both an indexed and included field, unless the indexed field is a container field path.

Data Types and Secondary Index Fields

Secondary indexes support a specific set of data types. This section describes how indexed and included fields in secondary indexes behave for various categories of data types.

Data Types of Indexed Fields

Prior to MapR 6.1, the indexed fields in a secondary index had to contain scalar data. For each scalar data value, MapR Database stored a row in the index. See the table in the **Scalar Data** section of JSON Document Data Types for a list of scalar types.

Beginning with MapR 6.1, indexed fields can also be nested documents or arrays, but not array elements. As with scalar data values, MapR Database stores a row in the index for each nested document and array. The index improves equality filters on the entire nested document or array.

MapR 6.1 also supports using container field paths as indexed fields.

The following table summarizes what MapR Database supports, depending on the characteristics of the indexed field:

Characteristics of Indexed Field	Pre-6.1 Behavior	6.1 Behavior
Field contains scalar data	Supported	Supported
Field contains nested document data	Not supported	Supported
Field contains array data	Not supported	Supported
Field path is a nested document subfield	Supported only if the subfield contains scalar data	Supported for any data type
Field is an individual array element	Not supported	Not supported
Field uses a container field path	Not applicable	Supported

To understand what MapR Database stores for an indexed field defined on different data types, consider an example in which you have the following documents:

```
{"_id":"0", "field":0}
{"_id":"1", "field":[0,1,2]}
{"_id":"2", "field":{"subField":1}}
{"_id":"3", "field":{"subField":[1,2,3]}}
{"_id":"4", "field":[{"subField":1},{"subField":2}]}
{"_id":"5", "field":[{"subField":[1,2,3]},{"subField":[4, 5]}]}
```

The following table shows what an index defined on `field` stores and an OJAI query condition that matches the value stored in the index:

Document ID	Value Stored in Index Defined on `field`	Matching OJAI Query Condition
0	`0`	`{"$lt":{"field":1}}`
1	`[0,1,2]`	`{"$eq":{"field":[0,1,2]}}`
2	`{"subField":1}`	`{"$eq":{"field":{"subField":1}}}`

last-updated: Apr 11, 2022

Document ID	Value Stored in Index Defined on `field`	Matching OJAI Query Condition
3	`{"subField":[1,2,3]}`	`{"$eq":{"field":{"subField":[1,2,3]}}}`
4	`[{"subField":1},{"subField":2}]`	`{"$eq":{"field":[{"subField":1},{"subField":2}]}}`
5	`[{"subField":[1,2,3]},{"subField":[4, 5]}]`	`{"$eq":{"field":[{"subField":[1,2,3]},{"subField":[4,5]}]}}`

The following table shows what an index defined on `field.subField` stores and an OJAI query condition that matches the value stored in the index:

Document ID	Value Stored in Index Defined on `field.subField`	Matching OJAI Query Condition
0	*Missing* [1]	N/A
1	*Missing* [1]	N/A
2	`1`	`{"$lt":{"field.subField":5}}`
3	`[1,2,3]`	`{"$eq":{"field.subField":[1,2,3]}}`
4	*Missing* [2]	N/A
5	*Missing* [2]	N/A

Note:

[1] The index entry for documents 0 and 1 are missing because `field` is not a nested document in these documents.

[2] The index entries for documents 3 and 4 are missing because `field` is an array in those documents.

These indexes enable MapR Database to quickly look up values stored in the index. As shown in the table, these values can be scalars, arrays, or nested documents. In the case of the latter two types, MapR Database can only use the index for equality conditions.

Data Types of Included Fields

There are no type restrictions on the included fields in an index.

Using Container Field Paths as Indexed Fields

Starting in MapR 6.1, indexed fields in an index can be Container Field Paths on page 518. When you use a container field path as your indexed field and the field contains an array, then the index contains one row per array element. Therefore, the size of your index is proportional to the number of elements in the array.

Important: Consider the storage implications of your index if you decide to use a container field path as an indexed field. Also consider the performance impact from index updates. Updating an indexed array field in a single JSON document may require updating multiple index rows.

last-updated: Apr 11, 2022

When an indexed field is not a container field path, the index contains one row per field value.

For example, suppose you have the same set of documents shown earlier:

```
{"_id":"0", "field":0}
{"_id":"1", "field":[0,1,2]}
{"_id":"2", "field":{"subField":1}}
{"_id":"3", "field":{"subField":[1,2,3]}}
{"_id":"4", "field":[{"subField":1},{"subField":2}]}
{"_id":"5", "field":[{"subField":[1,2,3]},{"subField":[4, 5]}]}
```

The following table shows what each index stores if you define the index on the following container field paths:

- `field[]`
- `field[].subField`
- `field.subField[]`
- `field[].subField[]`

Each entry in the table represents a row in the index.

Document ID	Indexed Field Path			
	field[]	**field[].subField**	**field.subField[]**	**field[].subField[]**
0	`0`	*Missing* [1]	*Missing* [1]	*Missing* [1]
1	`0`	*Missing* [1]	*Missing* [1]	*Missing* [1]
	`1`			
	`2`			
2	`{"subField":1}`	`1`	`1`	`1`
3	`{"subField": [1,2,3]}`	`[1,2,3]`	`1`	`1`
			`2`	`2`
			`3`	`3`
4	`{"subField":1}`	`1`	*Missing* [2]	`1`
	`{"subField":2}`	`2`		`2`

last-updated: Apr 11, 2022

Document ID	Indexed Field Path			
	`field[]`	`field[].subField`	`field.subField[]`	`field[].subField[]`
5	`{"subField": [1,2,3]}`	`[1,2,3]`	*Missing* [2]	`1`
				`2`
	`{"subField":[4, 5]}`	`[4, 5]`		`3`
				`4`
				`5`

Note:

[1] The index entries for documents 0 and 1 are missing in all indexes except the index on `field[]` because `field` is not a nested document.

[2] The index entries for documents 3 and 4 are missing in the index on `field.subField[]` because `field` is an array in those documents.

To use these indexes, your query condition must use container field paths that correspond to the indexed fields. The following are sample OJAI query conditions that you might use with each index:

Indexed Field Path	Sample OJAI Query Condition	Matching Document(s)
`field[]`	`{"$eq":{"field[]":0}`	0, 1
	`{"$eq":{"field[]":{"subField": [1,2,3]}}}`	3, 5
`field[].subField`	`{"$eq":{"field[].subField":1}}`	2, 4
`field.subField[]`	`{"$gt":{"field.subField[]":2}}`	3
`field[].subField[]`	`{"$eq":{"field[].subField[]":2}}`	3, 4, 5

See OJAI Query Conditions Using Container Field Paths on page 2615 for further details about how these types of conditions behave.

Defining an Index With and Without a Container Field Path

As shown in these examples, defining an index on a container field path is different from defining an index on an entire array field. For example, an index on `field[]` can filter on individual array elements, whereas the index on `field` can filter only the entire value. Similarly, defining an index on `field[].subField[]`

last-updated: Apr 11, 2022

provides the most generality. It allows you to filter on any elements in `subField`, regardless of the data types in *both* `field` and `subField`. However, you also incur the overhead of storing more data in your index and the performance impact of updating the index.

Using Container Field Paths in Covering and Composite Indexes

With a container field path, you may need to add included fields in your index to make the index covering. See Covering Indexes and Container Field Paths on page 560 for details.

There are also limitations in the composite indexes you can define. See Composite Indexes and Container Field Paths on page 554 for details.

Comparisons and Sorts on Indexed Fields

Comparisons and sorts across data types differ depending on whether the types are comparable or noncomparable. This is not specific to secondary indexes. However, it impacts comparisons when using secondary indexes and the order MapR Database stores data in an index. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 513 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 514 to learn which types fall into each category and to understand their behavior.

Restrictions on Secondary Indexes on page 565
This topic lists and describes the restrictions on secondary indexes. It is important for you to understand the type, size, field definition, option, and index use restrictions when defining and using secondary indexes.

Restrictions on Secondary Indexes

This topic lists and describes the restrictions on secondary indexes. It is important for you to understand the type, size, field definition, option, and index use restrictions when defining and using secondary indexes.

Name Restrictions

You cannot use the following characters in the index name and in the indexed fields:

```
< > ? % \
```

To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  "♥,"♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  '♦,'♦=#;{}&()/'
```

To use either the **'** or the **"** character in the index name and in the indexed fields, enclose:

last-updated: Apr 11, 2022

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"'MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"♦●
♥,"LOTNo" -includedfields \
  "♦","♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'"MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "'●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  '♥',"♦=#;{}&()/"
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

  For example, you cannot create an index with the following indexed fields:

  ```
  a.b[].c, a.b.d
  ```

  Although subfield b appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

  See Composite Indexes and Container Field Paths on page 554 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

  If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (`INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG`).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.
- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:

- The indexed field is a container field path:

```
maprcli table index add -path /
people \
   -index phoneNumberIdx \
   -indexedfields
Phones[].Number \
   -includedfields
Phones[].Number
```

- The field specifies a cast to another type.

  You can create an index in which the `score` field is an indexed field cast as a `double` type, and `score` is also an included field. The included field retains the original data type of the `score` field:

```
maprcli table index add -path /
castTable \
   -index castIdx1 \
   -indexedfields
'$CAST(score@DOUBLE)' \
   -includedFields score
```

  You can create an index in which the `score` field is an indexed field, cast as a `double` type, and the `score` field is also another indexed field, cast as a `long` type:

```
maprcli table index add -path /
castTable \
   -index castIdx2 \
   -indexedfields
'$CAST(score@DOUBLE)','$CAST(scor
e@LONG)'
```

- You cannot use casts with included fields.

- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

  For example, suppose you have the following JSON table:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" :
"value",
                         "d" :
"value"
                    },
               "e" : "value"
          }
}
```

  If you create a column family at field `c` in the JSON path `a.b.c`, you cannot define field `a.b.c` as either an indexed or included field. You can define the fields `a`, `a.b`, and `a.b.d` as either indexed or included fields.

- You cannot specify an included field in which the data in the field spans more than one column family.

  In the following example, the included field `sl1.sl2` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm  readperm
traverseperm  jsonfamilypath
writeperm  minversions
maxversions  compression
ttl         inmemory  cfname
memoryperm
u:root           u:root
u:root
u:root     0
1            lz4
2147483647  false     default
u:root
u:root           u:root
u:root         sl1
u:root     0
1            lz4
2147483647  false     cf1
u:root
u:root           u:root
u:root         sl1.sl2.sl3
u:root     0
1            lz4
2147483647  false     cf2
u:root
u:root           u:root
u:root         sl1.sl2.sl3.sl4
u:root     0
1            lz4
2147483647  false     cf3
u:root

maprcli table index add -path /
cftab -index i1 -indexedfields
sl1.sl2.sl3.sl4.l4a,
sl1.l1a -includedfields
sl1.sl2,sl1.sl2.sl3.sl4.sl5.l5b -js
on
{
        "timestamp":1507419777919,
        "timeofday":"2017-10-07
04:42:57.919 GMT-0700 PM",
        "status":"ERROR",
        "errors":[
                {
                        "id":22,

"desc":"Data for included field
sl1.sl2 may not span more than one
column family."
                }
         ]
}
```

	• You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same. See Composite Indexes and Container Field Paths on page 554 for more details. • You cannot specify a composite index with an indexed field that is a subfield of another indexed field. For example, you cannot create an index with the following indexed fields: `a, a.b` The indexed field `a.b` is a subfield of the indexed field `a`.
Option Restrictions	• As indexes are automatically split, you cannot disable splits when you create your index.
Index Use Restrictions	• Indexes do not optimize non-existence filter conditions.

Queries that Benefit from Secondary Indexes

Secondary indexes benefit queries with filter conditions, ORDER BY clause, and projections.

They benefit these query elements in the following ways:

Filter Conditions	Eliminates full table scans, reducing the number of documents that MapR Database reads, if the filtering fields are keys in an index.
ORDER BY Clause	Eliminates the need to sort the data after scanning the index, if the index's sort order matches the query's sort order.
Projections	Eliminates the need to read the MapR Database JSON table, if all fields referenced in the query are fields in an index.

Note: The projections optimization is not supported for OJAI queries that execute through the OJAI Distributed Query Service, and SQL queries issued to MapR Drill. See OJAI Distributed Query Service on page 505 for details about the types of OJAI queries that use the service.

The following topics describe the specific query types and provide examples.

Using Indexes to Optimize Equality Conditions

Using indexes can help you improve the performance of queries that have equality conditions. You can define indexes that optimize equality conditions on scalar data fields, nested document and array fields, and container field paths.

If the index has a single key, the condition limits the index search to only the keys matching the scalar value. If the index has more than one key and there are equality conditions on all keys, the conditions limit the search to the combined matching values. If there are conditions on a subset of fields and the most significant keys have equality conditions, MapR Database limits the search to those scalar values.

last-updated: Apr 11, 2022

Assume that you have a MapR Database JSON table with documents in the following format:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
        {"Type": "Home", "Number": "555-555-1234"},
        {"Type": "Mobile", "Number": "555-555-5678"},
        {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

The examples in the following sections reference this sample JSON document.

Indexes on Scalar Data Fields in Equality Conditions

The following table provides examples where MapR Database can and cannot use the index with equality conditions on scalar data. The last entry in the table illustrates the case where you can use index to optimize an equality condition in combination with a range condition.

Note: This example assumes that a composite index exists on fields `Address.State` and `Address.City`.

Query Condition	How MapR Database Uses the Index
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$eq":{"Address.City":"Oakland"}} ] }`	Performs a lookup on the specified state and city values, and reads the index until the conditions no longer match.
`{"$eq":{"Address.State":"CA"}}`	Performs a prefix lookup to find matching state values. The value of the `Address.City` field is not relevant. Continues reading from the index until the state field no longer matches `"CA"`.
`{ "$and":[ {"$in":{"Address.State": ["CA","NY","MA"]}}, {"$eq":{"Address.City":"Springfield"}} ] }`	Performs the following three lookups in the index: • `Address.State = "CA" and Address.City = "Springfield"` • `Address.State = "NY" and Address.City = "Springfield"` • `Address.State = "MA" and Address.City = "Springfield"`

last-updated: Apr 11, 2022

Query Condition	How MapR Database Uses the Index
`{"$eq":{"Address.City":"Oakland"}}`	Even if the query references the field `Address.State`, MapR Database cannot use the index unless there is also an equality condition on the leading key of the index, `Address.State`.
`{"$in":{"Address.State":["CA","NY","MA"]}}`	Performs three prefix lookups, one for each of the values in the `IN` clause.
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge":{"Address.City":"Oak"}} ] }`	Reads from the index starting at the condition `Address.State = "CA"` and `Address.City = "Oak"`. Continues reading the index until the condition `Address.State = "CA"` no longer qualifies.

Indexes on Nested Document Fields in Equality Conditions

Starting in MapR 6.1, you can define an index on fields that contain nested documents. These indexes benefit only equality conditions. The query condition must specify all subfields from the nested document. They must match the subfields of nested documents stored in your MapR Database JSON table. The order of the subfields is not relevant.

For example, if you define an index on the `Addresses` field, and specify the following query condition:

```
{
  "$eq":{
    "Addresses":{
      "Street":"123 SE 22nd St.",
      "City":"Oakland",
      "State":"CA",
      "Zipcode":"94601-1001"
    }
  }
}
```

MapR Database can use the index to locate the sample document shown earlier.

On the other hand, if you specify the following condition instead:

```
{
  "$eq":{
    "Addresses":{
      "City": "Oakland",
      "State": "CA"
    }
  }
}
```

When MapR Database reads using the index and applies this query condition, it does not match the sample document. The condition is missing the `Street` and `Zipcode` subfields. If you want to match on only the `City` and `State` subfields, you can define a composite index on those subfields as described in the previous section.

Indexes on Array Fields in Equality Conditions

Starting in MapR 6.1, you can define an index on fields that contain array data. These indexes benefit only equality conditions. The array elements and their order specified in your query condition must match the content and order stored in your MapR Database JSON table.

For example, if you define an index on the `Hobbies` field, and specify the following query condition:

```
{"$eq":{"Hobbies":["Baseball", "Cooking", "Reading"]}}
```

MapR Database can use the index to locate the sample document shown earlier.

On the other hand, if you specify the following condition instead:

```
{"$eq":{"Hobbies":["Cooking", "Baseball", "Reading"]}}
```

When MapR Database reads using the index and applies this query condition, it does not match the sample document. Although the individual array elements match, the order does not.

If `Hobbies` also has scalar data, MapR Database can use the index to locate documents with the following condition:

```
{"$eq":{"Hobbies":"Baseball"}}
```

If your MapR Database JSON table has a document where the `Hobbies` field has a single value "Baseball", MapR Database can use the index to locate the matching document.

Indexes on Container Field Paths in Equality Conditions

Starting in MapR 6.1, you can define an index using a container field path as the indexed field.

For example, suppose you want to search for individual hobbies within the `Hobbies` array field, rather than matching the entire array field. You can define an index on the following field:

```
Hobbies[]
```

The following examples show equality conditions that benefit from this index:

Query Condition	Description
`{"$eq":{"Hobbies[]":"Baseball"}}`	Finds documents that contain Baseball as a hobby
`{"$in":{"Hobbies[]":["Baseball","Cooking"]}}`	Finds documents that contain either Baseball or Cooking as a hobby

<pre>{
  "$and":[
  {"$eq":{"Hobbies[]":"Baseball"}},
  {"$eq":{"Hobbies[]":"Cooking"}}
  ]
}</pre>
	Finds documents that contain both Baseball and Cooking as hobbies

When using the `Hobbies[]` container field path in the query condition, the condition matches both array elements and individual scalar values.

last-updated: Apr 11, 2022

For another example, suppose you want to filter on phone types. You can define an index on the following field:

```
Phones[].Type
```

The following examples show equality conditions that benefit from this index:

Query Condition	Description
`{"$eq":{"Phones[].Type":"Mobile"}}`	Finds documents that have a mobile phone number
`{"$in":{"Phones[].Type":["Mobile","Work"]}}`	Finds documents that contain either a mobile or work phone number
`{ "$and":[ {"$eq":{"Phones[].Type":"Mobile"}}, {"$eq":{"Phones[].Type":"Work"}} ] }`	Finds documents that contain both mobile and work phone numbers

When using the `Phones[].Type` container field path in the query condition, the condition matches instances where `Phones` is an array of nested documents as well as a single nested document.

Important: To use an index defined on a container field path, the container field paths in the query condition and indexed fields must match.

The following table shows examples of conditions that **do not** benefit from the index shown:

Indexed Field	Query Conditions that *do not* Benefit
`Hobbies`	`{"$eq":{"Hobbies[]":"Baseball"}}` This condition requires an index defined on `Hobbies[]`.
`Hobbies[]`	`{"$eq":{"Hobbies":["Baseball", "Cooking"]}}` This condition requires an index defined on `Hobbies`.
`Phones[].Type`	`{"$eq":{"Phones[0].Type":"Mobile"}}` This condition cannot be used with indexes because you cannot define an index on array elements.
`temps[][]`	`{"$ge":{"temps[][1]":60}}` This condition cannot be used with indexes because you cannot define an index on array elements..
	`{"$eq":{"temps[]":[78,54]}}` This condition requires an index defined on `temps[]`.

last-updated: Apr 11, 2022

Indexed Field	Query Conditions that *do not* Benefit
`temps[]`	`{"$ge":{"temps[][]":60}}` This condition requires an index defined on `temps[][]`.

OJAI Query Condition Syntax on page 2606
OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

Using Indexes to Optimize Range Conditions
Indexes can improve the performance of queries that have range conditions. The range conditions can appear in combination with equality conditions when the most significant index keys have equality conditions. You can define indexes that optimize range conditions on scalar data fields and container field paths.

The following range condition operators benefit from indexes:

- Less than (or equal to)
- Greater than (or equal to)
- Pattern matching operator LIKE, provided the pattern in the condition does not start with a wildcard character

Assume you have a MapR Database JSON table with documents in the following format:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
        {"Type": "Home", "Number": "555-555-1234"},
        {"Type": "Mobile", "Number": "555-555-5678"},
        {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

The examples in the following sections reference this sample JSON document.

Indexes on Scalar Data Fields in Range Conditions

The following table provides examples of when MapR Database can and cannot use the index with range conditions on scalar data. Assume that a composite index exists on the `Address.State` and

last-updated: Apr 11, 2022

`Address.City` fields. To use both indexed fields in the composite index, you must have an equality condition on `Address.State`.

Filter Condition	How MapR Database Uses the Index
`{"$le":{"Address.State":"CA"}}`	Reads from the beginning of the index up to and including the condition `Address.State <= "CA"`.
`{"$gt":{"Address.State":"CA"}}`	Reads from the index starting at the condition `Address.State > "CA"` through the end of the index.
`{"$like":{"Address.State":"C%"}}`	Performs a simple prefix match starting at the condition `Address.State >= "C"`. Continues reading the index until the filter no longer qualifies.
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge":{"Address.City":"Oak"}} ] }`	Reads from the index starting at the condition `Address.State = "CA" and Address.City >= "Oak"`. Continues reading from the index until the condition `Address.State = "CA"` no longer qualifies.
`{ "$and":[ {"$in":{"Address.State": ["CA","NY","MA"]}}, {"$gt":{"Address.City":"Spring"}} ] }`	Performs these three lookups and reads through the index: • `Address.State = "CA" and Address.City > "Spring"` • `Address.State = "NY" and Address.City > "Spring"` • `Address.State = "MA" and Address.City > "Spring"`
`{ "$and":[ {"$gt":{"Address.State":"C"}}, {"$gt":{"Address.City":"Oak"}} ] }`	Reads from the index starting at the condition `Address.State > "C"` through the end of the index. Although `Address.City` is part of the index key, MapR Database does not use `Address.City > "Oak"` when initiating the index search. Applies that filter while reading the index.
`{"$le":{"Address.City":"Oak"}}`	Even if the query references the field `Address.State`, MapR Database cannot use the index unless there is also an equality condition on the prefix key of the index, `Address.State`.

Indexes on Container Field Paths in Range Conditions

Starting in MapR 6.1, you can define an index using a container field path as the indexed field.

For example, suppose you want to apply range conditions on individual hobbies within the `Hobbies` array field. You can define an index on the following field:

```
Hobbies[]
```

The following examples show range conditions that benefit from this index:

last-updated: Apr 11, 2022

Query Condition	Description
`{"$like":{"Hobbies[]":"B%"}}`	Finds documents that contain hobbies that start with the letter "B"
`{"$gt":{"Hobbies[]":"Read"}}`	Finds documents that contain hobbies with a value greater than "Read"
`{ "$elementAnd":{ "Hobbies[]":[ {"$ge":{"$":"D"}}, {"$lt":{"$":"J"}} ] } }`	Finds documents that contain hobbies that start with letters between "D" and "I", inclusive

When using the `Hobbies[]` container field path in the query condition, the condition matches both array elements and individual scalar values.

For another example, suppose you want to apply range filters on phone numbers. You can define an index on the following field:

```
Phones[].Number
```

The following examples show range conditions that benefit from this index:

Query Condition	Description
`{"$like":{"Phones[].Number":"555%"}}`	Finds documents with phone numbers that have a 555 prefix
`{ "$elementAnd":{ "Phones[]":[ {"$gt": {"Number":"408-555-1234"}}, {"$lt":{"Number":"408-555-9999"} ] } }`	Finds documents that contain phone numbers in the specified range

When using the `Phones[].Number` container field path in the query condition, the condition matches instances where `Phones` is an array of nested documents as well as a single document.

Related concepts

OJAI Query Condition Syntax on page 2606
OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

Using Indexes to Optimize ORDER BY Queries
Using indexes can help you improve the performance of queries that have an ORDER BY clause. This includes ORDER BY clauses with either ascending or descending sorts, as well as more than one ordering field. The same index can optimize both filter conditions and the ORDER BY clause.

last-updated: Apr 11, 2022

To use the index for an ORDER BY query, the index's key list order and sort order must match the orderings specified in the query. If the index's keys also match filter conditions in the query, using the index also reduces the amount of data read from the index.

Index Key List Order and Sort Order Examples

The following table provides examples of when MapR Database can and cannot use an index for ordering, based on the index key list ordering and sort ordering specified. Assume that you have a table that has a composite index on fields `Address.State` and `FullName.LastName`. You have defined both keys in ascending order. Further assume that the query has an ORDER BY on the fields `Address.State` and `FullName.LastName`, both in ascending order:

Ordering in Query	Use of Index for Ordering
`Address.State:ASC`	Yes
`Address.State:DESC`	No Sort direction does not match.
`Address.State:ASC,` `FullName.LastName ASC`	Yes
`FullName.LastName:ASC`	No `Address.State` must be included as a prefix in the ordering.
`FullName.LastName:ASC,` `Address.State:ASC`	No Sort directions match, but the order of fields does not match.

Filtering and ORDER BY Query Examples

Assume that you have a composite index defined with the following two indexed fields:

- `Address.State:ASC`
- `FullName.LastName:ASC`

The following table shows examples for different filtering and ORDER BY scenarios using this composite index:

Query Condition	Ordering in Query	Index Use
`{"$eq":{"Address.State":"CA"}}`	`FullName.LastName:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`Address.State:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`Address.State:DESC`	Only filtering, because the sort direction does not match

last-updated: Apr 11, 2022

Query Condition	Ordering in Query	Index Use
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge": {"FullName.LastName":"Smith"}} ] }`	`FullName.LastName:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`Address.State:ASC, FullName.LastName:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`FullName.LastName:ASC`	Only filtering
`{"$in":{"Address.State":["CA","TX"]}}`	`FullName.LastName:ASC`	Only filtering
`{"$ge":{"FullName.LastName":"Smith"}}`	`Address.State:ASC, FullName.LastName:ASC`	Only ordering, because `FullName.LastName` is not a prefix in the filter lookup

Index Sort Order for Complex Types

Although you can define indexes on complex data types, there are limitations in the behavior.

Arrays and Nested Documents	Indexes defined on arrays and nested documents do not have a meaningful ordering because these types do not have a defined ordering.
Container Field Paths	You cannot order on a container field path. For example, you can define an index on the field `a[].b`, but you cannot order on it.

Partial Sorts with Non-Covering Indexes

MapR Database updates secondary indexes asynchronously, which can result in updates to the index lagging the parent JSON table. You can avoid this behavior in your OJAI application by setting a query option in your application. See Avoiding Partial Sorts with Secondary Indexes in OJAI on page 2589 for details about how to do this.

One consequence of this index update lag is the impact on queries that use non-covering indexes to provide the ordering of a query. Since the index is not fully synchronized with its parent JSON data, data read through the index might be out of date.

The following example illustrates this behavior.

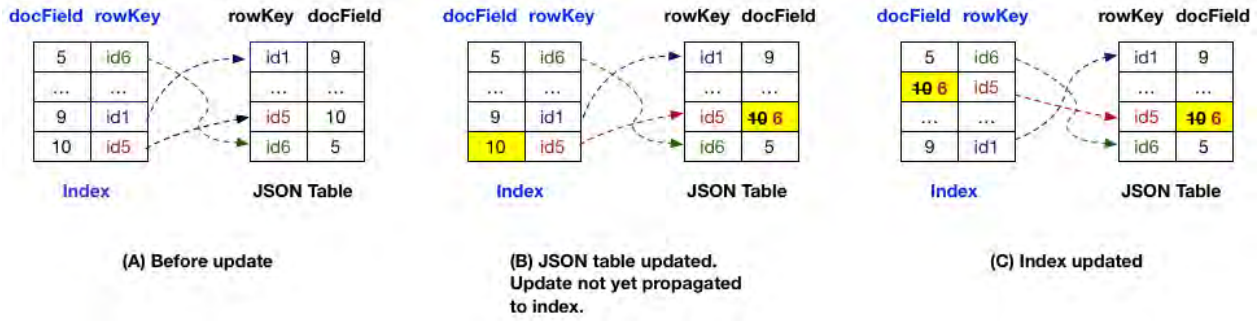
- Suppose you have a query with the following criteria:
  - Selects `docField`
  - Filter condition where `docField >= 5`
  - Order by on `docField`

last-updated: Apr 11, 2022

- You have an index where `docField` is an indexed field. The index optimizes both the filter condition and order by clause. The query also selects other fields, so the index is a non-covering index for the query.
- When reading through the index, MapR Database reads a document in which the `docField` value is 9. The data for that field in the JSON table is also 9. The data is consistent.
- The next entry in the index has `docField` set to 10. This value is in the proper sort order relative to the previous value of 9, but the data in the JSON table has changed from 10 to 6. The update is not yet reflected in the index.
- MapR Database returns the value 6 (not 10), which is out of order, relative to data previously read from the index.

The following table and diagram illustrates this example:

Update State	Query Result in docField Sort Order
Before update	5, …, 9, 10
JSON table updated, but not index	5, …, 9, 6
Index updated	5, 6, …, 9



Note: This behavior does not occur with covering indexes. MapR Database only reads from a single data source, the index, when using covering indexes.

See Asynchronous Secondary Index Updates on page 587 for a more detailed discussion of asynchronous index updates.

Using Indexes to Optimize Projections in Queries

OJAI queries that do not use the OJAI Distributed Query Service can use indexes even when there are no filter conditions referencing the fields of an index. This requires a full scan of the index. However, in cases where all fields referenced in the query are fields in an index, the need to read the MapR Database JSON table is eliminated. The referenced fields can be either indexed fields or included fields

The following table provides examples where MapR Database can and cannot use the index for projections. Assume you have an index with the following fields:

- Indexed fields - `IdxField1`, `IdxField2`
- Included fields - `Field3`, `Field4`, `Field5`

Further assume that the fields referenced in the index are a small subset of the total fields in the MapR Database JSON table. With these assumptions, avoiding reads on the JSON table is beneficial.

OJAI Query Elements	Use of Index for Projections
• SELECT `IdxField1`, `Field4`	Yes All fields referenced are fields in index.
• SELECT `Field3`, `Field4`	Yes All fields referenced are fields in index.
• SELECT `IdxField1`, `Field6`	No `Field6` not included in index.
• SELECT `IdxField1`, `Field3` • WHERE condition on `IdxField2`	No All fields referenced are fields in the index, but the index cannot be used with the WHERE condition.
• SELECT `IdxField1`, `Field3` • WHERE condition on `Field4`	No All fields referenced are fields in the index, but the index cannot be used with the WHERE condition.
• SELECT `IdxField1`, `Field4` • ORDER BY on `IdxField2`	No All fields referenced are fields in the index, but the index cannot optimize the ORDER BY. The query needs the OJAI Distributed Query Service to sort large data sets.

Projections on Container Field Paths

When your query projects a container field path and the container field path is an included field in an index, then MapR Database can use the index for the projection. It is not enough for the container field path to be an indexed field. See Covering Indexes and Container Field Paths on page 560 for details.

Using Multiple Indexes to Optimize Query Conditions
Indexes benefit queries that have multiple filter conditions. The OJAI Distributed Query Service can optimize these queries by creating query plans that scan multiple indexes and take the intersection of the matching documents.

Scanning multiple indexes is an alternative to using Composite Indexes on page 553. The following example illustrates how the OJAI Distributed Query Service does this.

Suppose you have a JSON table with an index on the `Address.State` field, another index on the `Address.City` field, and the query has the condition:

```
{
  "$and":[
    {"$lt":{"Address.State":"D"}},
    {"$gt":{"Address.City":"Oak"}}
  ]
}
```

The OJAI Distributed Query Service creates a query plan that uses the indexes as follows:

- Performs a scan on the first index using the `Address.State < "D"` condition.
- Performs a scan on the second index using the `Address.City > "Oak"` condition.
- Takes the intersection of the document IDs that match both conditions.

If you do not apply conditions on both `Address.State` and `Address.City` in most of your queries, defining separate indexes instead of a single composite field index may be more desirable. With a

last-updated: Apr 11, 2022

composite index on fields `Address.State` and `Address.City`, the query service does not choose the index unless there is a condition on field `Address.State`. If there is a condition on `Address.State`, the query service can choose the composite index. However, in order to restrict the search on both fields, there must be an equality condition on `Address.State`. See Using Indexes to Optimize Equality Conditions on page 570 for further details.

You can define separate single key indexes as well as a composite index, but this requires more storage and impacts performance throughput. See the sections on storage and throughput considerations in Designing Secondary Indexes on page 591 for further guidance.

The following table illustrates the differences between using a composite index versus multiple indexes. The second column shows the behavior when you have a composite index defined on `(Address.State, Address.City)`. The third column shows the behavior when you have separate simple indexes defined on each field.

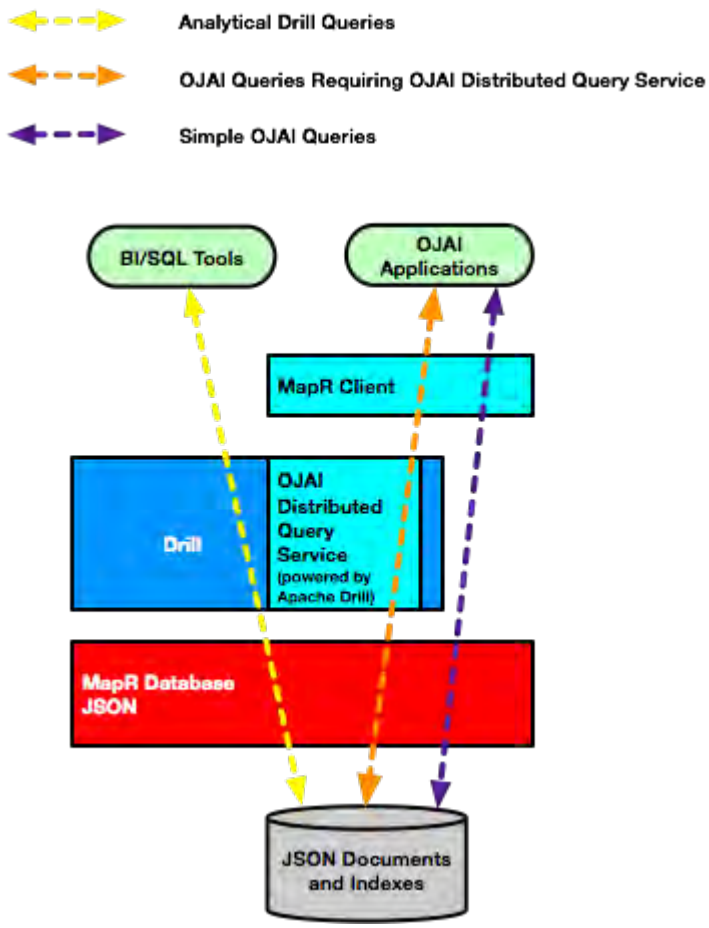
Filter Condition	Composite Index	Two Simple Indexes
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$eq": {"Address.City":"Oakland"}} ] }`	Index searched using both conditions	Separate index searches using each filter condition. Results intersected.
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge":{"Address.City":"Oak"}} ] }`	Index searched using both conditions	Separate index searches using each filter condition. Results intersected.
`{"$eq":{"Address.State":"CA"}}`	Index searched using single filter condition	Same as composite index case. However, since the simple index has only a single indexed field, it is smaller and more efficient to read.
`{ "$and":[ {"$ge":{"Address.State":"CA"}}, {"$eq": {"Address.City":"Oakland"}} ] }`	Index search initiated using only the `Address.State` condition. `Address.City` filter applied while reading the index.	Separate index searches using each filter condition. Results intersected.
`{"$eq":{"Address.City":"Oakland"}}`	Cannot use index	Index searched using single filter condition

Selection and Execution of Secondary Indexes

This section provides an overview of secondary index selection and execution in MapR Database JSON. It describes the variations in functionality, depending on the components you are using.

The following diagram summarizes the code paths and the components involved when using secondary indexes in MapR Database JSON. See OJAI Distributed Query Service on page 505 for more information about the components and code paths.

last-updated: Apr 11, 2022



Index Selection

All three code paths use a cost-based approach to select an optimal query plan. Cost based optimization chooses between alternatives where it may not be obvious which is the better index to use. Assume that you have the following two indexing options:

- Index 1 can be used to filter condition A in a query but cannot satisfy the sort criteria.
- Index 2 can be used to filter condition B in a query and also satisfy the sort criteria.

If filter condition A is more selective than filter condition B, although using index 1 requires reading less data, it requires a sort of the data. In contrast, using index 2 requires reading more data but does not incur the cost of sorting the data. A cost based optimizer estimates the cost of both options and chooses the one with the lower cost. It also estimates the cost of a full table scan. It may choose the full table scan if the index-based plans do not use selective filters.

The Simple OJAI Query code path can use indexes even when a query does not have filter or ORDER BY conditions that match the fields of an index. See Using Indexes to Optimize Projections in Queries on page 580 for details.

The Drill query optimizer and the optimizer used by the OJAI Distributed Query Service can select multiple indexes to process a query. The OJAI Distributed Query Service scans the indexes and takes the intersection of the matching documents from each index. The MapR client invokes scans of only a single index.

The rest of this section generally discusses the optimizer flow. Except where noted, the discussion applies to the optimizer used in all three code paths.

MapR Database gives the optimizer a list of indexes associated with the JSON table referenced in the query. The optimizer enumerates through the possible index choices using the following steps:

1. Identifies the set of indexes whose keys match filter conditions and possibly also the ORDER BY specification.
2. Estimates the cost of using each index.
3. Considers combinations of indexes and estimates the cost of these combinations. (Applies to the Drill and OJAI Distributed Query Service optimizers only.)

Using the cost estimates, the optimizer selects the index (or indexes) with the lowest cost, or if appropriate, a full table scan. The cost is a function of the index properties, table size, and selectivity of the filter conditions applied. Each of these factors contribute to the estimated cost in the following ways:

Index Properties

MapR Database provides the Drill optimizer with index properties. Index properties include the fields that comprise the index, whether the field is an indexed or included field, and the sort direction of each indexed field.

Table Size

MapR Database maintains information about table regions, including table size. The optimizer uses table size when calculating the cost of the query plan.

If JSON tables are small and fit into a single region, the overhead of using indexes on the table may not provide enough performance benefits to justify an index-based plan. In such a scenario, the optimizer could calculate a full table scan as cheaper to perform than an index scan, rendering any index on the table unnecessary. Even if you apply selective filters on small tables, the overhead of using indexes may not provide performance benefits.

Filter Selectivity

Filter Selectivity is the estimated number of rows based on the selectivity of each conditional expression in the WHERE clause. Filter selectivity is calculated as:

```
(output row count)/(total table row count)
```

For example, if you have 100 documents and 25 documents qualify the filter condition, the selectivity is .25.

Filter selectivity ranges between 0 and 1. The closer to 0, the more selective the filter. The more selective a filter, the lower the cost. High filter selectivity results in better query performance. If filter conditions are not selective enough for the optimizer to choose the index, remove the index to free up storage.

For example, defining an index on a field like `gender`, which has only two possible values, does not result in selective filtering. Consider adding other fields to define a composite index to make filtering with that index more selective. In general, define indexes on high cardinality fields unless your queries also sort on those fields.

For covering queries, Drill selects an index plan if the number of rows selected is less than or equal to .75 of the total number of rows in the JSON table. If the number of rows selected is greater than .75 of the total

last-updated: Apr 11, 2022

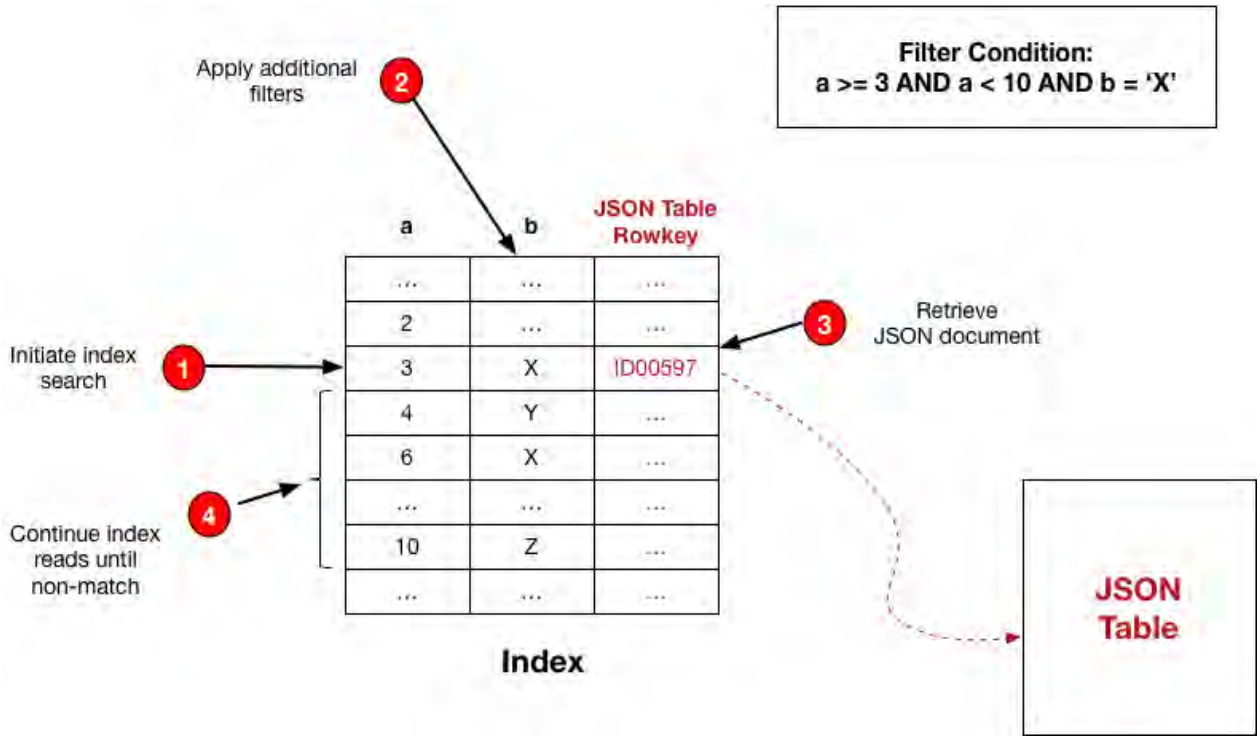
number of rows in the JSON table, Drill performs a full table scan.

For non-covering queries, the threshold is .025.

Note: In the **Simple OJAI Queries** code path, if you are using the OJAI API, you can force the MapR client to use a particular index, regardless of cost considerations. See Forcing Secondary Index Usage in OJAI on page 2589 for details.

Index Execution

After either the MapR client or Drill select an optimal query plan, MapR Database has the index (or list of indexes, in the case of a plan generated by Drill) from which to read. It reads the index to retrieve the corresponding documents from the JSON table. The following diagram and table illustrate the flow for a read from a composite index created on fields a and b.



Step #	Description	Details
1	Initiates index search	MapR Database searches the index, starting at the condition a >= 3.
2	Applies additional filters	MapR Database applies the filter condition on field b. It either moves to step 3 or 4, depending on whether the condition b = 'X' matches. For example, when b contains the value 'X', it proceeds to step 3. When b contains the value 'Y', it skips to step 4.
3	Retrieves JSON document	Using the rowkey in the entry, MapR Database reads the corresponding JSON document.

last-updated: Apr 11, 2022

Step #	Description	Details
4	Continues index reads until non-match	MapR Database reads the subsequent index keys provided they match the filter condition a `< 10`. If the condition matches, it goes back to step 2. Otherwise, MapR Database stops the search. For example, the reads stop when MapR Database reads the value 10 from field a.

Note: When a covering index satisfies the query, MapR Database skips reading the JSON table. TThis read is not required because the index provides all selected fields. In the preceding example, the MapR Database skips step 3.

Implementation of Secondary Indexes
This topic describes how MapR Database implements secondary indexes. It provides an overview of basic architectural concepts and the rationale behind design choices.

Global Indexes

MapR Database implements secondary indexes as *global indexes* rather than *local indexes*. With local indexes, each JSON table's regions (also called tablets) has a corresponding index tablet. The JSON table's and index's tablets are co-located. In contrast, with a global index, the index is a single, separate table with its own tablets and split points. Unlike JSON tables, indexes are always auto-split. There is no option to disable auto-splitting. When splitting index tablets, indexes are range partitioned by default. An alternative to range partitioning is to use hash partitioning to avoid creating hot spots.

Global indexes have the following advantages:

- They provide an ordering across all values in the indexed fields. A scan through the index can generate the sort required by ORDER BY clauses.
- They avoid having to read all partitions. When the data is range partitioned, MapR Database can direct index scans to the subset of partitions that qualify the desired key range.
- They require less data processing by minimizing the partitions that need to be read.

In summary, global indexes are well suited for scalable, read intensive use cases.

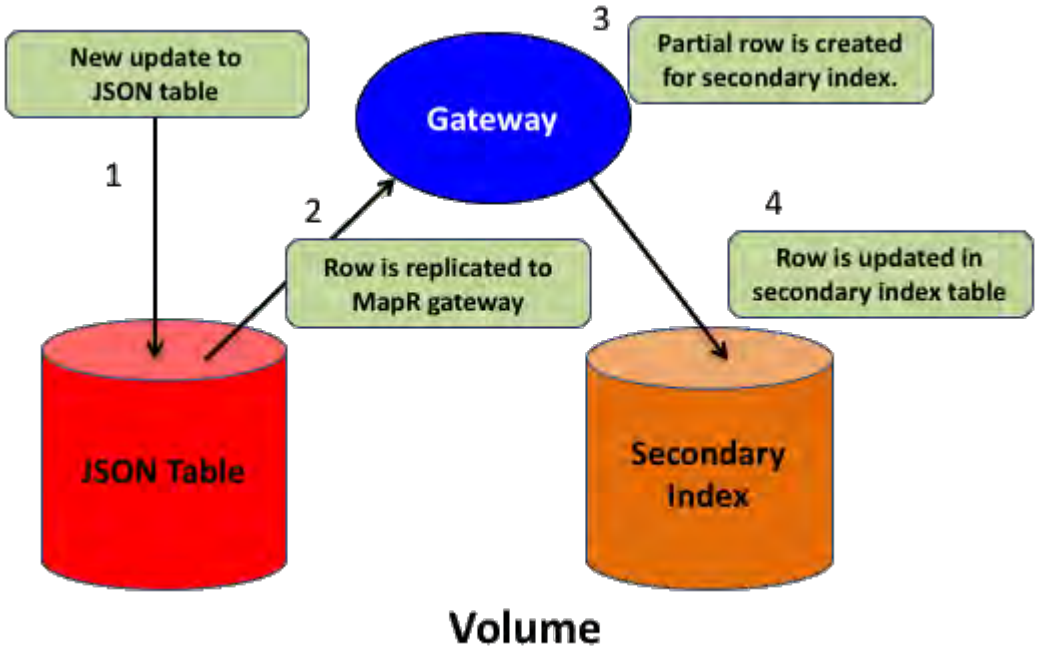
While global indexes are optimized for read intensive use cases, maintaining a global index incurs more overhead. Updates are more expensive if the JSON table and its indexes are on different nodes in the cluster.

Index Placement

Each secondary index shares the same volume and topology as its JSON table. Users cannot specify the path of an index. This simplifies the behavior of snapshot and mirroring.

Data Flow

After a secondary index has been created on a JSON table, the following occurs when an update (put operation) is made to the table:



1. A document in the JSON table is updated.
2. The row with the change is replicated to an internal MapR gateway.
3. The MapR gateway determines whether a secondary index is impacted and, if so, creates a partial row that contains the secondary index's indexed and included fields.
4. The secondary index row is updated.

When a secondary index is added, data that is already present in the JSON table is propagated to the index using a scan of the JSON table that retrieves indexed and included fields. This replaces step 2. Steps 3 and 4 are executed to populate the index.

Asynchronous Secondary Index Updates
Secondary indexes are updated asynchronously. The asynchronous approach favors performance and scalability over synchronous, transactional updates. However, this also means that indexed data can be stale compared to data in the JSON table, even though the data eventually becomes consistent with the JSON table data.

Impact of Asynchronous Indexes

By updating the index asynchronously, this avoids delaying updates to the JSON table.

From a user point of view, secondary indexes updates are complete when the MapR Database table data appears in the index. This occurs without application developers having to write any explicit code. Because indexes are asynchronously updated relative to the JSON table, there is a lag in updates appearing in the index. For a reasonably sized cluster, secondary index updates will typically occur within a few seconds of the update on the JSON table. When the JSON table and its secondary indexes are on separate nodes, the updates to the index are more expensive. The lag is potentially higher.

The following example illustrates how the lag in updates impacts queries that use indexes.

Suppose you have a JSON table that has a document with `_id=DOC1`. An update occurs on the indexed field, `a.b.c`, changing the value from v1 to v2. For queries that use a covering index, any of the following values might be returned for the `(_id, a.b.c)` pair:

- Only (DOC1,v1) - This occurs if the new value v2 has not yet been indexed.

- Only (DOC1,v2) - This occurs if the new value v2 is indexed and the old value v1 is deleted.
- Both (DOC1,v1) and (DOC1,v2) - This occurs if the new value v2 is indexed and the old value v1 is not yet deleted.
- Neither (DOC1,v1) nor (DOC1,v2) - This occurs if the value v1 is not indexed. The newer value v2 is not yet indexed, because value v1 is always indexed first.

For queries that use non-covering indexes, MapR Database re-reads the indexed and included fields when reading additional fields from the JSON table. This ensures that the query results are consistent in spite of update lags.

In the case where a non-covering index provides the ordering for the ORDER BY specification of a query, index lag can result in a partial sort of the result. See Partial Sorts with Non-Covering Indexes on page 579 for further details.

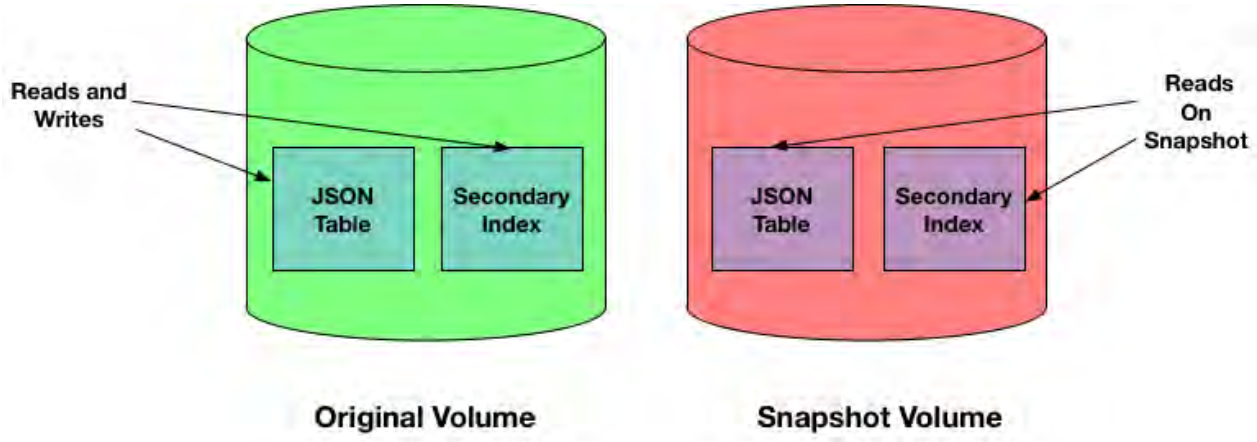
See Troubleshooting Secondary Indexes on page 1092 for information about how to determine if an index is lagging its JSON table.

Snapshots

Queries against snapshots containing tables with secondary indexes can return inconsistent results. This occurs if the data queried is actively changing at the time of snapshot creation. When creating a snapshot, if a secondary index on a JSON table does not have current data due to asynchronous updates of the index, the snapshot retains the lag in updates. The lag leads to the following behavior, which is similar to the behavior discussed in the previous section.

- For a query using a covering index, if the indexed data is out of sync, the query could return data that is current, old, or both.
- For a query using a non-covering index, if the indexed data is out of sync, the query returns the most recent data records.

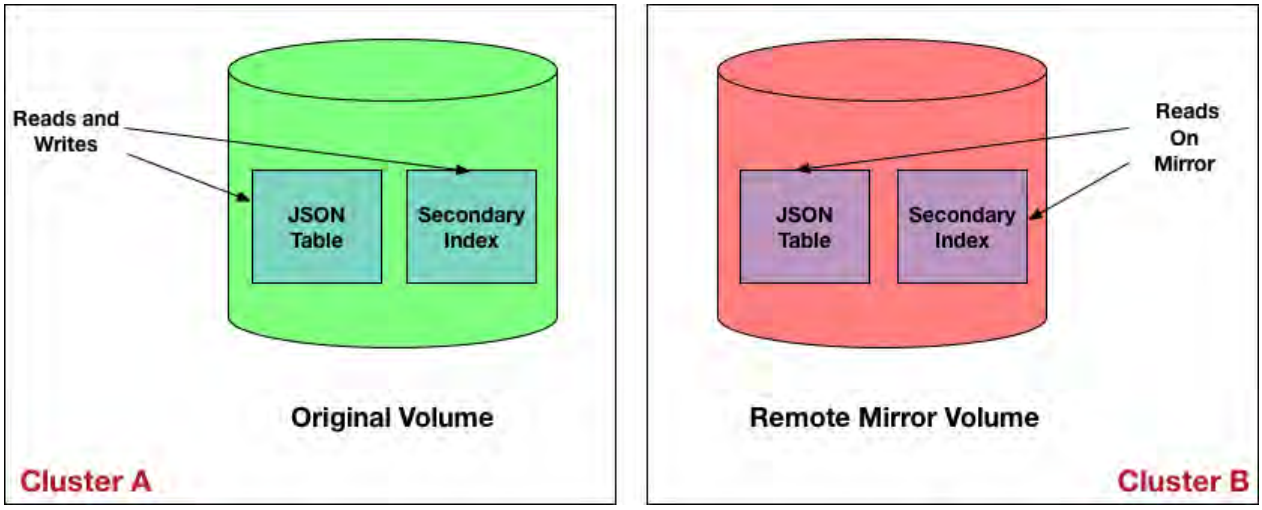
Important: Unlike data in the original volume, with snapshots, any lag between a JSON table and its secondary index will never get resolved. The snapshot data is read-only and never updated..



Mirroring

Queries against mirror volumes behave like queries against snapshots. Lags in the source volume carry over into the mirror volume. Upon refreshing a mirror volume, the lag can resolve itself.

last-updated: Apr 11, 2022



Reading Your Own Write Operations

Certain classes of applications require users to immediately see the data they have written. In these cases, getting stale data can confuse users. Think about an expense report application example where the user enters his expenses and wants to immediately see the entries. The asynchronous nature of indexes could be an issue in such a case. To avoid the possibility of reading stale data due to asynchronous indexes, the Java OJAI API Library provides functionality that enables you to read the result of your own write operation. See Reading Your Own Writes in Java OJAI on page 2668 to learn about how to use this feature in your application.

Replication and Security
Describes how secondary indexes are impacted by replication and security.

Replication

Secondary indexes are not replicated when tables are replicated by table replication (using the replication gateway). Only the JSON table data is replicated.

If you intend to query destination tables and use indexes, you must explicitly add an index to the replica table. Replicating tables and adding indexes are independent of each other.

Security

Secondary indexes reflect the access permissions of the underlying JSON table. *ACE* permissions are required on all indexed and included fields of an index before a query can use an index.

To add a secondary index on a JSON table, you need the `indexperm` permission. The table owner automatically has permission, but any other user must be assigned `indexperm` permission.

See table create on page 1788 for information about *ACE*, and table edit on page 1822 for information about table permissions.

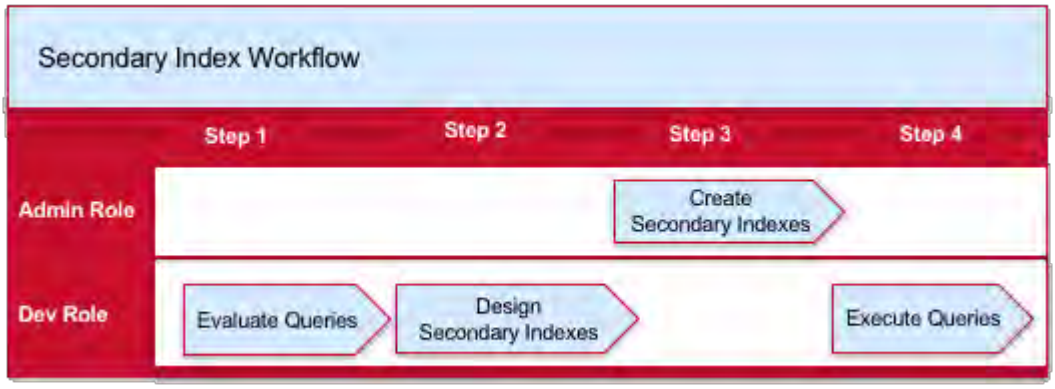
Understanding the Secondary Index Workflow

Describes the overall workflow for using secondary indexes. This includes the roles of different users and the workflow steps involved.

Before deploying secondary indexes, it is assumed that you have installed and configured MapR Database and MapR-Drill to use secondary indexes, and have created and populated your MapR Database JSON tables. Implementing secondary indexes on JSON tables in MapR Database requires that you understand indexing concepts, know which administrative tasks to perform, and design your indexes to provide the most benefits for your queries.

last-updated: Apr 11, 2022

The following diagram depicts the workflow and identifies the roles and order of tasks. Each step contains a link to a section in this page with further details.



1. How to Evaluate Queries that Benefit from Secondary Indexes
2. How to Design Secondary Indexes
3. How to Create Secondary Indexes
4. How to Query MapR Database JSON Tables

The following is a brief summary of each step:

1. Evaluate your queries to identify those that can benefit from indexes.
2. Design your indexes by determining which fields need to be indexed.
3. Create your indexes using either the Control System or `maprcli`.
4. Execute your queries.

How to Evaluate Queries that Benefit from Indexes

MapR Database JSON supports indexes with various properties. Each property benefits a certain class of queries. As part of deciding which of your queries will benefit from indexes, it is important to have a general understanding of these concepts. See Types of Secondary Indexes on page 549 and Queries that Benefit from Secondary Indexes on page 570 for more information.

How to Design Secondary Indexes

After you decide which queries can benefit from indexes, determine the set of indexes that provide the maximum benefits. See Designing Secondary Indexes on page 591 for more information.

How to Create Secondary Indexes

You can create secondary indexes using either the Control System or the maprcli table index command.

For example, to create a secondary index on the `name` field, use the following `maprcli` command:

```
maprcli table index add -path /Data/business -index newIndex -indexedfields
name
```

See Managing Secondary Indexes on page 1089 for other commands to manage secondary indexes.

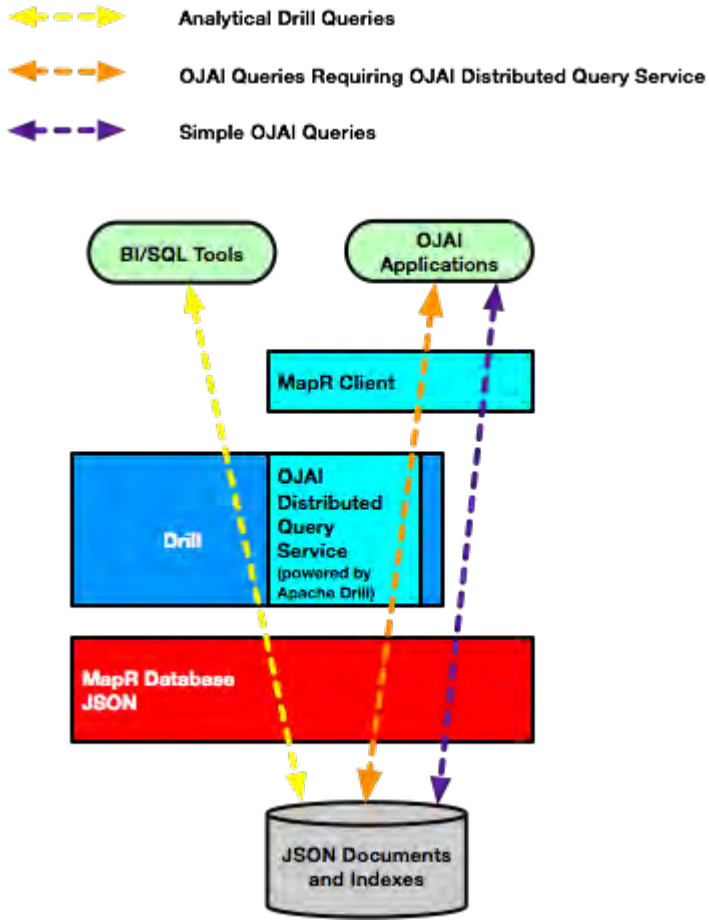
How to Query MapR Database JSON Tables

Depending on your use case, applications can access data in MapR Database through the following client interfaces:

OJAI Client API	Use for user-facing applications that need very high concurrency and ultra-low latency. The API is available in Java, Node.js, and Python.
MapR Database JSON REST API	Use for applications in which you want to access MapR Database JSON with HTTP calls.
MapR Drill SQL	Use for performing operational analytics or Business Intelligence (BI) for medium-to-high complexity queries that require low-to-medium concurrency and interactive response times.

These APIs seamlessly select the optimal indexes to use. You do not need to write explicit code or provide directives on which indexes to use.

The following diagram summarizes the components involved in the different scenarios.



For OJAI applications, the MapR client chooses the more appropriate of two possible execution paths, without user interaction. One of the paths leverages the OJAI Distributed Query Service on page 505, which supports more advanced index selection and parallel query execution. It also supports sorting large data sets. For example, if the sort order specified in your OJAI query does not match the sort order of an index, the MapR client automatically invokes the OJAI Distributed Query Service to perform the sort.

Designing Secondary Indexes

It is important that you create secondary indexes that provide the most benefit to your MapR Database JSON queries. This topic describes a general design approach that includes identifying query patterns,

last-updated: Apr 11, 2022

using common query patterns involving filters and ordering to determine which indexes to create, weighing the benefits of indexes against their update and storage costs, and taking into consideration index limitations.

The following diagram summarizes the general approach to designing your indexes:

1. Identify common query patterns
2. Determine potential indexes to create based on your query patterns
3. Evaluate the impact of index synchronization
4. Evaluate the storage requirements of indexes
5. Consider index restrictions
6. Evaluate tradeoffs and limitations

Before designing your secondary indexes in relationship to your queries, make sure you understand the index feature, how to set up and use indexing, the commands used to perform tasks, and how to query the data through your application. The following cover these topics:

- Secondary Index Concepts on page 547
- Understanding the Secondary Index Workflow on page 589

Identify Query Patterns

Query patterns, such as queries with filter conditions and ORDER BY clauses, indicate where indexes can improve performance. If a query does not contain selective filters, the overhead of using an index may cost more than a full table scan. You should also define your indexes so a single index benefits either multiple queries or individual queries that you run most often.

See Selection and Execution of Secondary Indexes on page 582 to understand how MapR Database chooses which secondary indexes to use and how they improve performance.

Determine Potential Indexes Based on Query Patterns

Based on your query patterns, the following table describes the types and characteristics of indexes you might want to create:

Identified Query Pattern	Potential Indexes to Create
Compares individual fields with selective filter conditions	Define single field indexes on the fields that you compare against. Verify that the fields contain supported data types.

last-updated: Apr 11, 2022

Filters against specific combinations of fields	Define composite field indexes instead of single field indexes. Specify the sequence of the index keys so fields that appear in equality conditions are the prefixes in the keys. See Using Multiple Indexes to Optimize Query Conditions on page 581 for additional guidance on defining composite vs single field indexes.
Accesses a subset of fields in a document, but does not filter or sort on these fields	Add those fields as included fields in indexes.
Filters on a subfield in a nested document	Define the index key on the subfield.
Filters on subfields in nested documents that are array elements	Define the index key using a container field path: for example, `arrayField[].subField`.
Filters and projects using a container field path	Define the container field path as both an indexed field and included field. See Covering Indexes and Container Field Paths on page 560 for more details.
Filters on individual elements of an array, which can appear in any position in the array	Define an index using a container field path: for example, `arrayField[]`.
Issues Drill SQL queries with filter conditions that contain CAST expressions	Specify the CAST function when defining the index key.
Sorts on fields	Define the sequence and order direction of the index keys to match the sequence and order direction of the fields your query sorts. If the sort order of the index keys matches the insertion order of documents, define hashed indexes.
Sorts on one set of fields and filters on another set using equality conditions	Define a composite index so that fields using equality conditions are the prefixes in the index keys, followed by the sort fields.

Evaluate Tradeoffs and Limitations

Synchronizing Indexes

When you design your indexes, remember that MapR Database must synchronize each index when you insert and update documents in the corresponding JSON table. This impacts the throughput performance of inserts and updates because MapR Database must perform additional writes. The impact increases with each additional index.

MapR Database performs the synchronization operation asynchronously, which minimizes throughput overhead. The consequence is that an index may be inconsistent relative to its JSON table. If your application cannot tolerate lag time between the update to the JSON table and the update to the index, you should take that into consideration when deciding whether to index specific fields.

See Asynchronous Secondary Index Updates on page 587 for more details about this feature.

Index Storage Requirements

Indexes increase your storage requirements. The storage size depends on the number of indexed and included fields in the index and the size of values stored in those fields. As the size of the index increases, the cost of reading the index also increases.

Consider the storage costs when creating indexes and deciding on the fields to add to the index.

Index Restrictions

When designing your indexes, make sure MapR Database indexes support the functionality you need. For example, it may not be possible to create an index on a particular field path.

See Restrictions on Secondary Indexes on page 565 for a complete list.

last-updated: Apr 11, 2022

Related concepts

Types of Secondary Indexes on page 549
MapR Database JSON supports several index types, including simple indexes, composite indexes, hashed indexes, and indexes with casting. This section describes the properties of these indexes and the situations where each provides value.

Queries that Benefit from Secondary Indexes on page 570
Secondary indexes benefit queries with filter conditions, ORDER BY clause, and projections.

Examples of Designing Secondary Indexes

These examples illustrate the concepts behind designing your secondary indexes. Although the examples focus on query patterns and do not account for sizing, storage, and updates, you should always weigh the benefits of indexes against these other requirements.

Assume that you have a MapR Database JSON table with the following customer data:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
      {"Type": "Home", "Number": "555-555-1234"},
      {"Type": "Mobile", "Number": "555-555-5678"},
      {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

The following table contains fields in the document that are candidates for indexing based on the sample queries:

Query #	Query	Candidate Fields for Indexing
1	Find all customers who were born in the 1970s.	• `DateOfBirth`
2	Find all customers who have an account balance greater than $10K. Order the information in descending order of balance.	• `AccountBalance`
3	List customers who live in California, ordering the list by `LastName`, `FirstName`.	• `Address.State` • `FullName.LastName` • `FullName.FirstName`
4	Find the ids and emails of customers who live in a specific zip code.	• `Address.Zip`

last-updated: Apr 11, 2022

Query #	Query	Candidate Fields for Indexing
5	Find customers who live in a specific set of states and have an account balance less than a specific value.	• `Address.State` • `AccountBalance`
6	Find male customers having a last name starting with the letter "S."	• `Gender` • `FullName.LastName`
7	Find all customers who have "Reading" as a hobby.	• `Hobbies[]`
8	Find all customers who have a mobile phone number with a prefix of "650".	• `Phones[].Type` • `Phones[].Number`

The following table contains indexes you can create to optimize the queries listed in the previous table and the rationale for doing so:

Index	Rationale
Simple index on `DateOfBirth`	Optimizes the range condition on `DateOfBirth` in Query 1. You need not create a hashed index, because it is unlikely that the order of `DateOfBirth` correlates with the insert order of new data.
Simple index on `AccountBalance`, specified as a descending key	• Optimizes the range condition on `AccountBalance` in Query 2. • Descending order of key meets the ordering criteria in Query 2. • Also optimizes the range condition on `AccountBalance` in Query 5 in combination with the index on `Address.State`.
Composite index on: • `Address.State` • `FullName.LastName` • `FullName.FirstName`	• Optimizes both the equality condition on `Address.State` and ordering in Query 3. • Inclusion of the name fields in the index meets Query 3 ordering. • Also optimizes the IN condition in Query 5 when used in combination with the index on `AccountBalance`.

Simple index with:
• Indexed field on `Address.Zip`
• Included fields on:
  • `Id`
  • `Email`
	• Optimizes the equality condition on `Address.Zip` in Query 4.
	• Adding the included fields avoids reading the JSON table in Query 4.

Composite index on: • `Gender` • `FullName.LastName`	• Optimizes equality condition on `Gender` and pattern matching condition on `FullName.LastName` for Query 6. • Specifying `Gender` as the leading key in combination with `FullName.LastName` results in more selective index lookups for Query 6.

last-updated: Apr 11, 2022

Index	Rationale
Simple index on `Hobbies[]`	Optimizes the equality condition on array elements of `Hobbies` in Query 7: `{"$eq":{"Hobbies[]":"Reading"}}`
Composite index on: • `Phones[].Type` • `Phones[].Number`	Optimizes the following two conditions in Query 8: • Equality condition on the `Type` subfield in nested documents in the `Phones` array. • Pattern matching condition on the `Number` subfield in nested documents in the `Phones` array.

Example with Multiple Container Field Paths

The following example references documents that store the high and low temperatures for each day in a week. They use an array to store the data, where each element in the array corresponds to a day of the week. For each day of the week, there is a two-element array of nested documents. The nested documents indicate whether the temperature corresponds to the high or low for that day. Typically, the outermost array has seven elements, one for each day of the week. But in cases where data is unavailable, the document has only the available days.

```
{
   "_id": "001",
   "temps": [{"hiLo": [{"type": "hi", "temp": 61}, {"type": "lo", "temp":
49}], "dow": "Sun"},
            {"hiLo": [{"type": "hi", "temp": 74}, {"type": "lo", "temp":
51}], "dow": "Mon"},
            {"hiLo": [{"type": "hi", "temp": 75}, {"type": "lo", "temp":
51}], "dow": "Tue"},
            {"hiLo": [{"type": "hi", "temp": 74}, {"type": "lo", "temp":
52}], "dow": "Wed"},
            {"hiLo": [{"type": "hi", "temp": 78}, {"type": "lo", "temp":
54}], "dow": "Thu"},
            {"hiLo": [{"type": "hi", "temp": 75}, {"type": "lo", "temp":
53}], "dow": "Fri"},
            {"hiLo": [{"type": "hi", "temp": 75}, {"type": "lo", "temp":
54}], "dow": "Sat"}],
   "weekOf": "4/29/2018"
}
{
   "_id": "002",
   "temps": {"hiLo": [{"type": "hi","temp": 81}, {"type": "lo", "temp":
60}], "dow":"Sat"},
   "weekOf": "5/12/2018"
}
{
   "_id": "003",
   "temps": [{"hiLo": [{"type": "hi", "temp": 80}, {"type": "lo", "temp":
55}], "dow": "Sun"},
            {"hiLo": [{"type": "hi", "temp": 78}, {"type": "lo", "temp":
54}], "dow": "Mon"},
            {"hiLo": [{"type": "hi", "temp": 79}, {"type": "lo", "temp":
54}], "dow": "Tue"},
            {"hiLo": [{"type": "hi", "temp": 77}, {"type": "lo", "temp":
53}], "dow": "Wed"},
            {"hiLo": [{"type": "hi", "temp": 79}, {"type": "lo", "temp":
54}], "dow": "Thu"},
            {"hiLo": [{"type": "hi", "temp": 77}, {"type": "lo", "temp":
```

```
54}], "dow": "Fri"},
             {"hiLo": [{"type": "hi", "temp": 78}, {"type": "lo", "temp":
54}], "dow": "Sat"}],
   "weekOf": "5/13/2018"
}
```

Suppose you frequently run the following queries:

Query	Description	Documents Returned
`find /apps/hiLoTemps --f weekOf --c '{"$eq": {"temps[].hiLo[].temp":60}}'`	Find weeks where any day has either a high or low temperature of 60.	002
`find /apps/hiLoTemps --f weekOf,temps[].hiLo[].type,temps[].hiLo[].temp --c '{ "$elementAnd":{ "temps[].hiLo[]":[ {"$eq": {"type":"hi"}}, {"$ge":{"temp":80}} ] } }'`	Find weeks and the high/low temperatures for all days on those weeks where any day of the week has a high temperature of at least 80.	002, 003

To optimize these queries, you should define an index with the following fields:

- Indexed fields: `temps[].hiLo[].temp`, `temps[].hiLo[].type`
- Included fields: `weekOf`, `temps[].hiLo`

By defining the composite index with `temps[].hiLo[].temp` as the first indexed field, the index can optimize both queries.

By adding `weekOf` as an included field, the index is a covering index for the first query. By adding `temps[].hiLo`, the index becomes a covering index for the second query as well. Note that you must add this included field even though the sub-fields are also indexed fields. This is due to how indexes with container field paths store data. For more details, see Covering Indexes and Container Field Paths on page 560.

Change Data Capture

The Change Data Capture (CDC) system allows you to capture changes made to data records in MapR Database tables (JSON or binary) and propagate them to a MapR Event Store For Apache Kafka topic.

These data changes are the result of inserts, updates, and deletions and are called change data records. Once the change data records are propagated to a topic, a MapR Event Store For Apache Kafka/Kafka consumer application is used to read and process them.

Note: The order of the records in the topic-partition is the same as the order of the changes made to the table. The order is retained because change data records for the same key are propagated to the same topic-partition.

last-updated: Apr 11, 2022

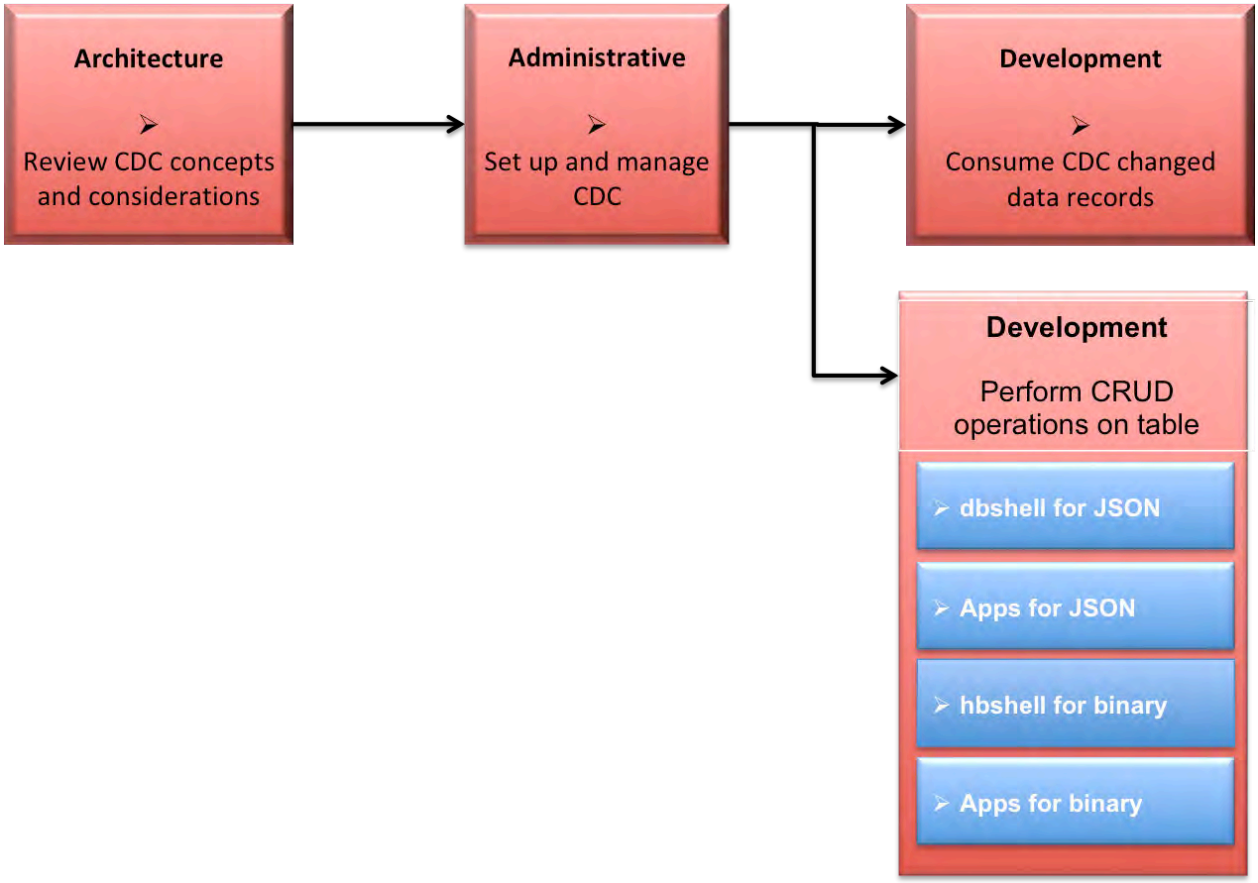
Why Use Change Data Capture?

CDC can be used in many ways, including the following:

- To track changes occurring in a MapR Database table and perform real-time processing on the data.
- To keep caches for search indexes (such as Elastic Search, Solr), materialized views, synchronization between data warehouses or data marts with data stored in MapR Database in real time.
- To manage separate MapR Database instances for transactional and reporting purposes and to keep them in sync in real time for real time analytics.
- To provide arbitrary external systems the ability to globally consume MapR Database table changes.

How Do I Get Started?

The following topics provide information you need to understand the CDC feature, to setup and use CDC, the maprcli commands used to perform tasks, and to consume the data via your application.



1. Learning about CDC
2. Administering Change Data Capture
3. Consuming CDC changed data records
4. Using dbshell to perform CRUD operations on MapR Database JSON tables
5. Developing client applications for MapR Database JSON tables.
6. Using hbshell to perform CRUD operations on MapR Database binary tables.

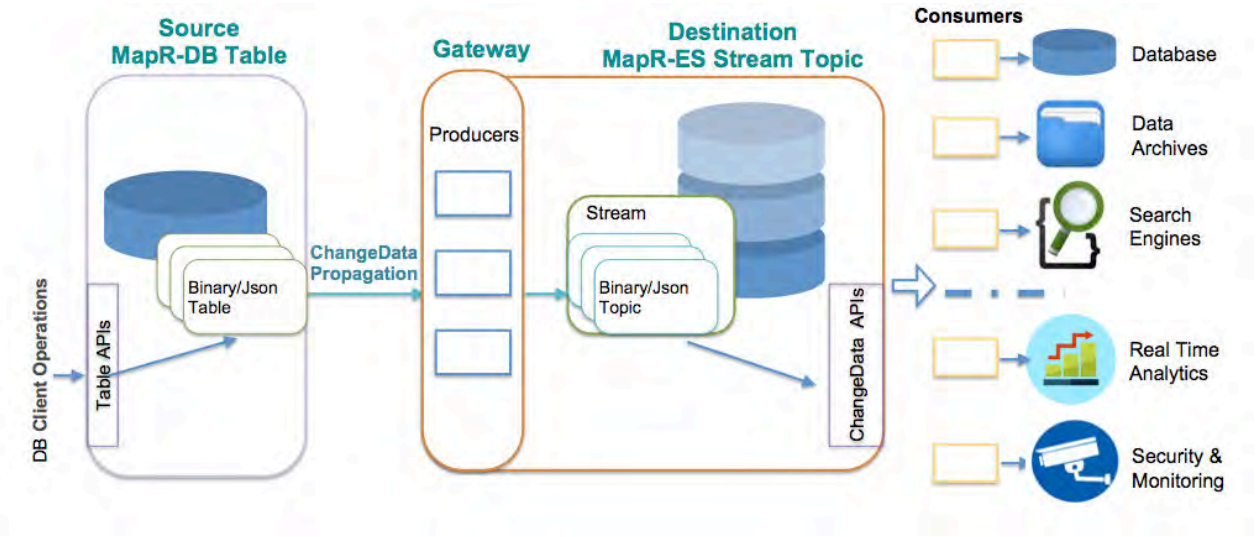
last-updated: Apr 11, 2022

7. Developing client applications for MapR Database binary tables.

Architecture and CDC

This section provides an overview of how CDC works.

CDC uses a log-based data capture for the changed data records, propagates the data (from the source table) using replication remote procedural calls (RPCs) through an internal MapR gateway and produces the data to a MapR Event Store For Apache Kafka destination stream topic(s). Once data is received by the topic, the changed data records can be consumed by external applications. The consumer application registers the CDC Deserializer as its record value deserializer and pulls the topic data by using a Kafka API. The data changes can be read from the ChangeDataRecord through the OJAI ChangeData APIs. Consumers could be databases, data archives, search engines, or applications that perform real-time analytics, security, or monitoring.



How are the Change Data Records Propagated?

The propagation is accomplished by setting up a change log that establishes a relationship between the source table and the destination stream. The change log can be setup by using the Control System, maprcli, or REST. Each change log can be paused, resumed, and removed. See Administering Change Data Capture on page 1106 and the `maprcli` table changelog on page 1813 command for more information.

As data is changed on the source table (through CRUD operations), each changed data record is propagated (replicated) to an internal MapR gateway. The order of when the data is produced to the stream topic is the same order of when the changed data records are replicated to the gateway. The data flow is one way, meaning, the flow is from a MapR Database source table to a MapR Event Store For Apache Kafka destination stream topic(s).

Note: When an array value is updated, the changed data record is the full array record rather the specific data change.

What is the Impact of using Columns/Column Families?

When propagating a specific column family or column from a binary source table and a row is deleted, the destination stream topic shows only a deletion event for the specific column family or column. When propagating a specific column from a binary source table with its entire column family deleted, the destination stream topic shows only a deletion event for the specific column.

In the scenario where you have a binary source table with fam0, fam1, and fam2 and you set up the change log *without* columns or column families:

last-updated: Apr 11, 2022

- If you delete fam0, fam1, and fam2, the change data event will be "delete fam0", "delete fam1" and "delete fam2".
- If you delete the row, the change data event will be "delete row".

In the scenario where you have a binary source table with fam0, fam1, and fam2 and you set up the change log *with* a column setup as fam1:col1, fam2.

- If you delete fam0, fam1, and fam2, the change data event will be "delete fam1:col1", "delete fam2".
- If you delete the row, the change data event will be "delete fam1:col1", "delete fam2".

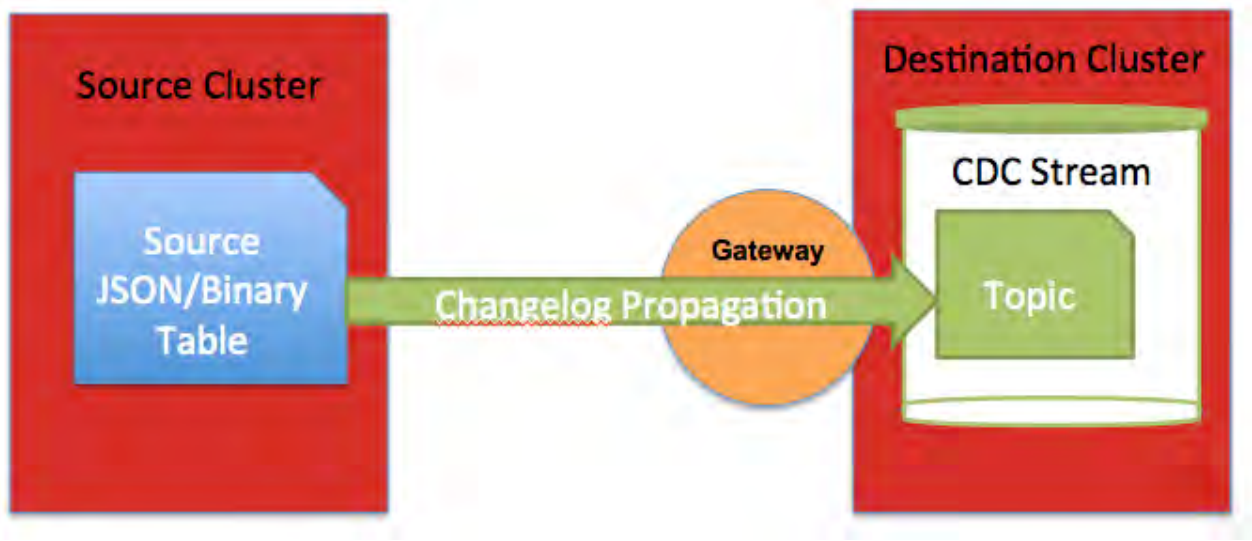
Where is the Destination Stream Setup?

The destination MapR Event Store For Apache Kafka stream can either be on the same cluster as the MapR Database source table or on a remote MapR cluster. Where and how destination streams are setup depends on the purpose for using CDC.

If you are propagating changed data from a source table on a source cluster to a destination stream topic on a remote destination cluster, you must setup a gateway. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering MapR Gateways on page 1150 and Configuring Gateways for Table and Stream Replication on page 1152.

The following diagram shows a simple CDC data model, with one source table to one destination topic on one stream. Since this scenario has the destination stream topic on a remote destination cluster, you must setup and configure a gateway.

Note: More complex CDC scenarios can be implemented and multiple gateways can be setup.



Important: If you have a secure cluster, you must setup secure configuration. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.

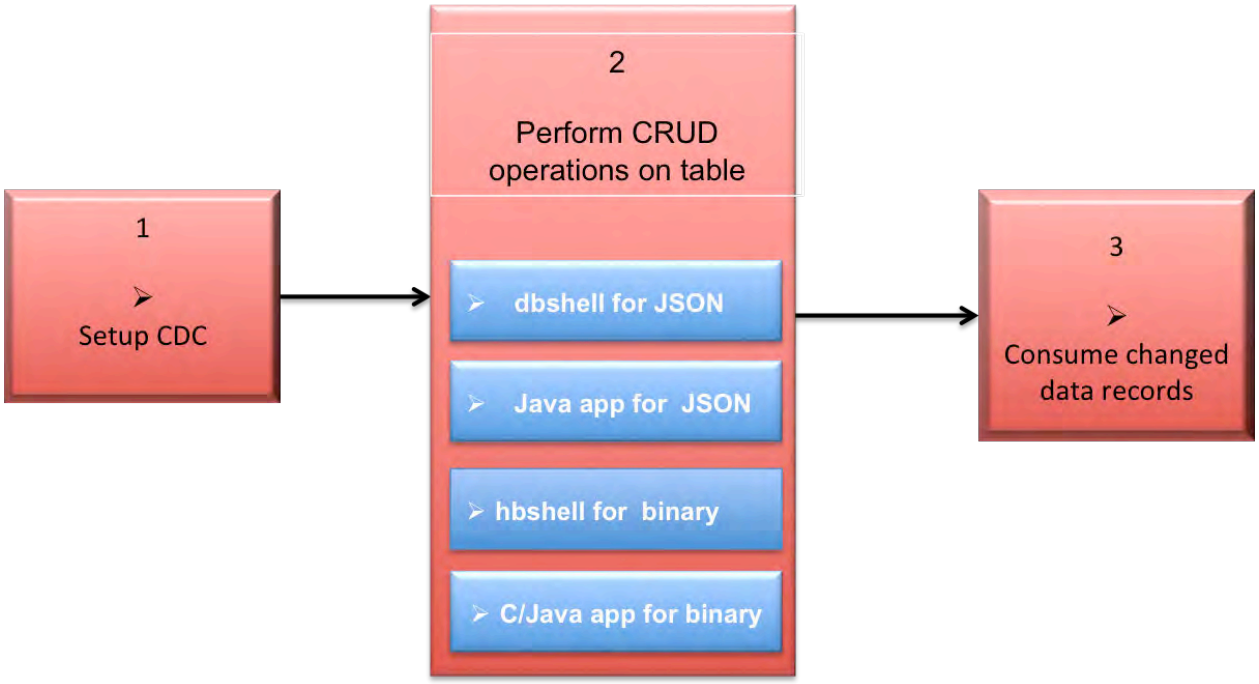
Getting Started with CDC

Describes an end-to-end flow of how to establish and use Change Data Capture (CDC). It assumes that a new table and dataset will be created, although an existing table with data can also be used.

End-to-End Workflow

The following diagram shows an end-to-end workflow of the Change Data Capture (CDC) feature.

Note: Steps 2 and 3 are interchangable. You may decide to start the consumer application for CDC changed data records *before* performing CRUD operations on the table.



1. Setup the CDC Environment
2. Using dbshell to perform CRUD operations on MapR Database JSON tables
3. Developing client applications for MapR Database JSON tables.
4. Using HBase to perform CRUD operations on MapR Database binary tables.
5. Developing client applications for MapR Database binary tables.
6. Consuming CDC changed data records

1. Setup the CDC environment.
   a. If you are propagating changed data from a source table on a source cluster to a destination stream topic on a *remote* destination cluster, you must setup a gateway. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering MapR Gateways on page 1150 and Configuring Gateways for Table and Stream Replication on page 1152.

   b. If you have a secure cluster, you must set up secure configuration. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.

   c. Establish a MapR Database table (JSON or binary) with data. You can create a new table and add data, or use an existing table with data. See maprcli table create for creating a new table or use the Control System. If you are using an existing table with data, skip to the next step.

   d. Create a MapR Event Store For Apache Kafka stream for the propagated changed data records using the `maprcli stream create -ischangelog` parameter. See maprcli stream create or use the Control System.

last-updated: Apr 11, 2022

e. Create a MapR Event Store For Apache Kafka stream topic for the changed data records. You can use the maprcli stream topic create command, the maprcli table changelog add command (this command creates a changelog relationsip between the source table and the destination stream topic), or the Control System when creating either a stream topic or a table changelog.

f. Create a changelog relationship between the source table and the destination stream topic with the maprcli table changelog add command or use the Control System. By creating a changelog relationship, you are creating an environment that propagates changed data records from a source table to a MapR Event Store For Apache Kafka topic.

Note: Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is `true`.

Note: Propagation is enabled as soon as you add the table changelog relationship. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See table changelog resume on page 1820 for more information.

g. Verify that the changelog exists. See table changelog list on page 1816 for information about your changelogs.

2. Perform CRUD operations (inserts, updates, and deletes) on the source table. The following utility and application can be used:

- mapr dbshell for MapR Database JSON documents
- hbshell for MapR Database binary data
- Java applications for MapR Database JSON
- C or Java applications for MapR Database binary data

3. Write a consumer with the Apache Kafka and OJAI API libraries that subscribes to the topic and consumes the change data records. There are multiple interfaces that are used for writing a CDC consumer. See Consuming CDC Records on page 2723 for a list of interfaces. See Building Consumers for CDC on page 2726 for an example.

Use Cases

Scenario	Setup Task	Notes
You want a CDC stream topic to contain all of the table data as changed data records.	You would setup CDC in the following manner before performing operations on the source table and consuming the change data records. **1.** Create an **empty** source table. **2.** Create the changelog stream. **3.** Create the changelog stream topic. **4.** Add the table changelog relationship. In this case, it does not matter if the `-propagateexistingdata` is set to true or false because you are starting with an empty source table. **5.** Verify that the changelog exists and that `replicaState` is REPLICA_STATE_REPLICATING. See table changelog list on page 1816 for more information.	In this case, all table data is propagated to the stream topic as change data records and the operation type is identified on each individual data record.
You want a CDC stream topic to contain all of the existing table data and changed data records.	You would setup CDC in the following manner before performing operations on the source table and consuming the change data records. **1.** Create a source table and add **data**, or alternatively, use an existing table that contains data. **2.** Create the changelog stream. **3.** Create the changelog stream topic. **4.** Add the table changelog relationship. Be sure that the `-propagateexistingdata` parameter is set to **true**. If you are using the command line to add the changelog, then you do not need to specify this parameter because the default is `true`. **5.** Verify that the changelog exists and no error is reported in the changelog list. When all the existing data in the table is delivered to the changelog, the replicaState becomes REPLICA_STATE_REPLICATING. See table changelog list on page 1816 for more information.	In this case, the existing table data is propagated to the stream topic and that data's operation type is identified as a SET operation. Subsequently, operations on the source table are propagated as changed data records and the operation type is identified on each individual data record. You can consume data at any time, however, there may be a delay before all of the existing table data is completely propagated, expecially if you have a large dataset. Be sure to check the `copyTableCompletionPercentage` field.

Scenario	Setup Task	Notes
You want a CDC stream topic to *not* contain any original table data and to capture only subsequent changed data records	You would setup CDC in the following manner before performing operations on the source table and consuming the change data records. **1.** Create a source table and **add** data, or alternatively, use an existing table that contains data. **2.** Create the changelog stream. **3.** Create the changelog stream topic. **4.** Add the table changelog relationship. Be sure that the `-propagateexistingdata` parameter is set to **false**. **5.** All new data operations applied to a source table after the replicaState becomes REPLICA_STATE_REPLICATING is *not* treated as original data and is delivered to the changelog. See table changelog list on page 1816 for more information.	In this case, the existing table data is not propagated to the stream topic and the operation type is identified on each individual data record.

Data Modeling and CDC

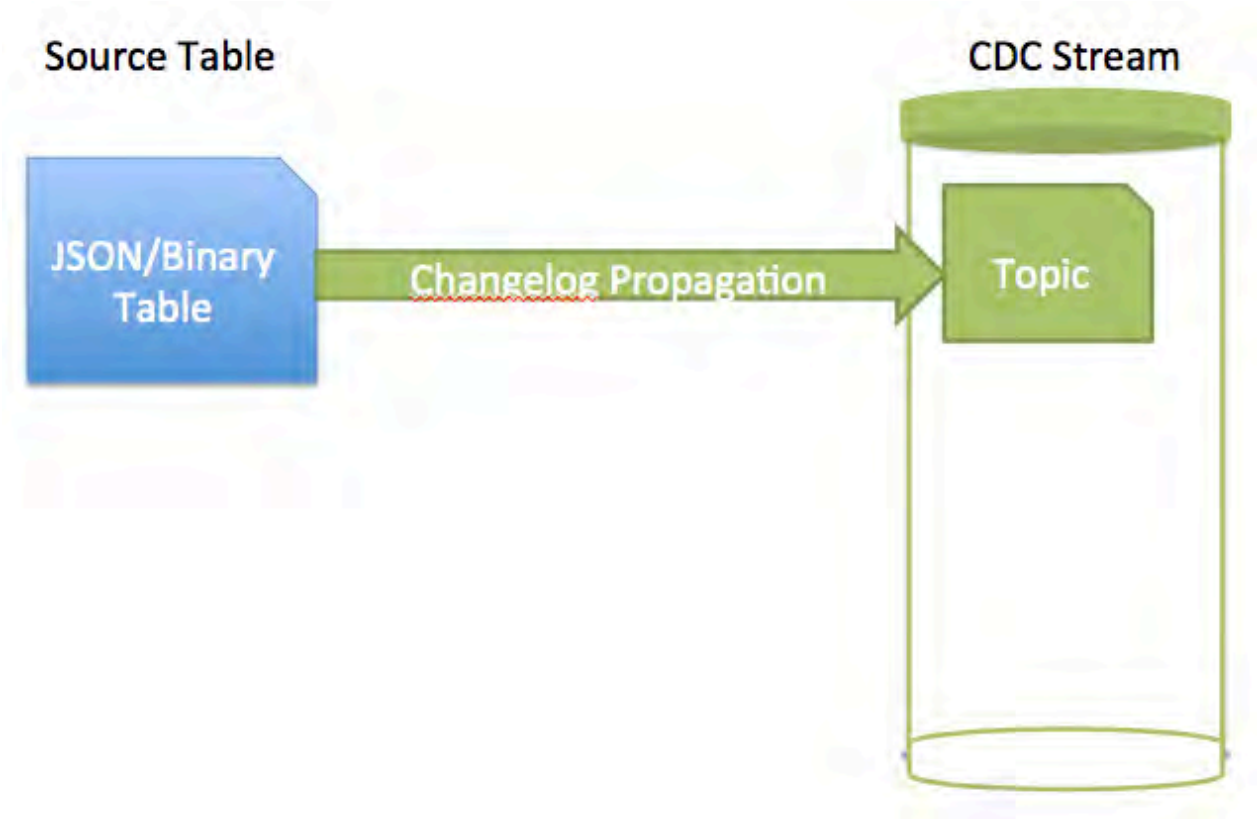
Change Data Capture (CDC) changed data records propagate in one direction - from a source table to a topic in a changelog stream. One stream with one topic can be created for the changed data records or multiple streams with multiple topics can be created.

Note: Propagation from multiple source tables to one stream topic is not supported.

One source to one destination topic on one stream

You might use this scenario if there are a large number of changed data records being propagated, and you want the topic on a separate or isolated volume, so that resources are dedicated to these particular changed data records.

The following graphic shows a source table's change data records being propagated to one topic on one stream.



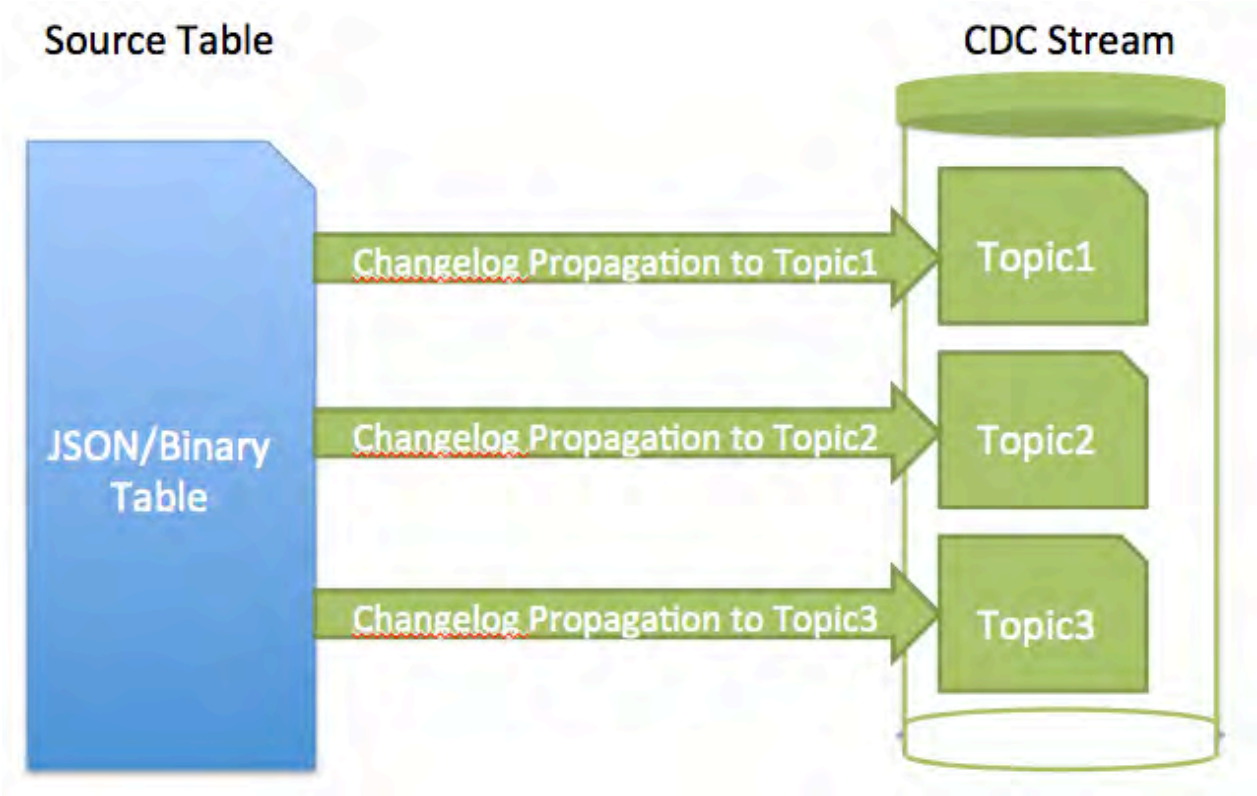
One source to multiple destination topics on one stream

You might use this scenario if you want to propagate specific changed data records from one source table to different topics.

When you set up a table changelog for data propagation, you can specify the column parameter to propagate a specific field or column family. Default: All fields are propagated. See table changelog add on page 1813 for information about adding a table changelog.

The following graphic shows a source table's change data records being propagated to multiple topics on a stream.

last-updated: Apr 11, 2022

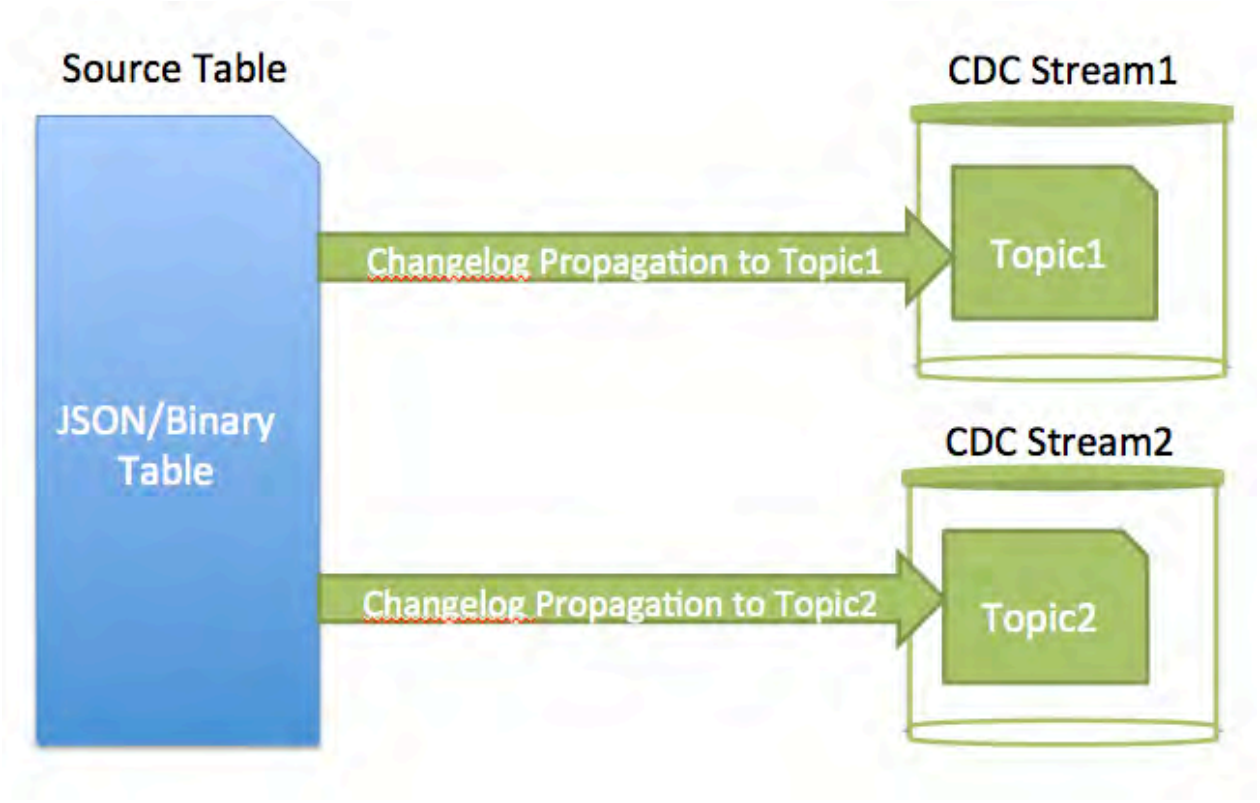


One source to multiple destination topics on multiple streams

You might use this scenario if the change data records are important and you want to have an extra copy for backup purposes.

The following graphic shows a source table's change data records being propagated to topics on multiple streams.

last-updated: Apr 11, 2022

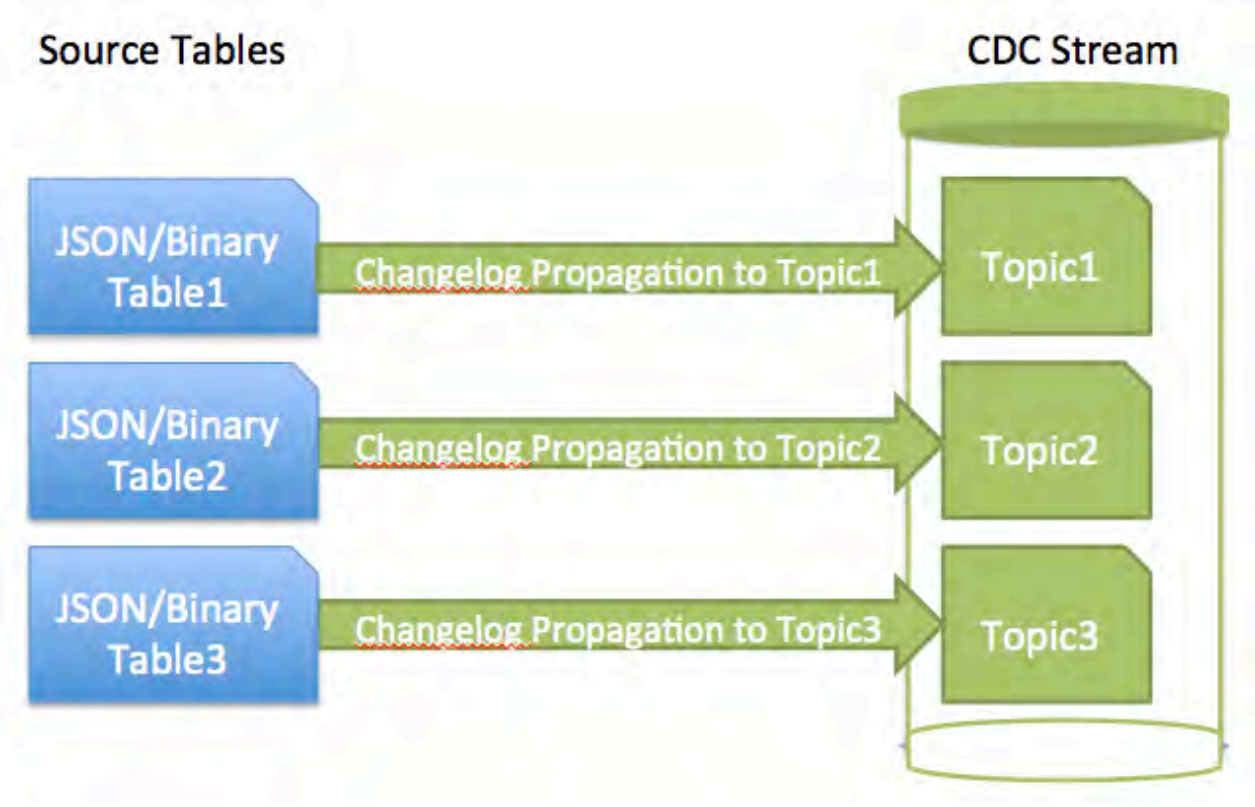


Multiple sources to multiple destination topics on one stream

You might use this scenario if you want to set up permissions to one stream so that a team has access to all the topics that they want to access. For example, if table1 and table2 has change data records that a team wants to monitor, then on the stream, you would grant permission to the monitoring team.

The following graphic shows three source tables' change data records being propagated to three topics on the same stream.

last-updated: Apr 11, 2022

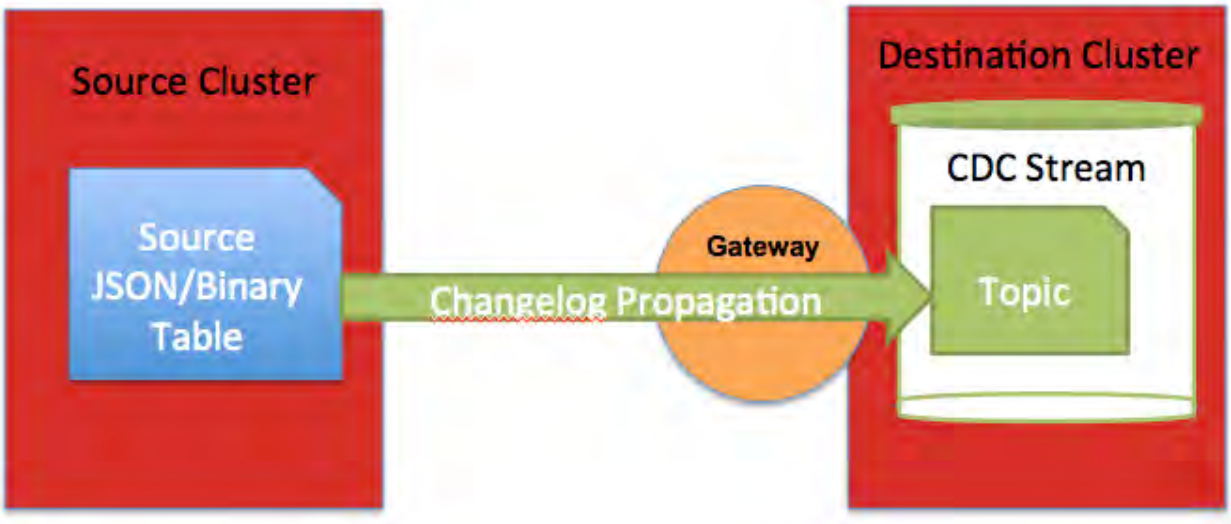


Source Cluster to Destination Cluster

If you are propagating changed data from a source table on a source cluster to a destination stream topic on a remote destination cluster, you must setup a gateway. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering MapR Gateways on page 1150 and Configuring Gateways for Table and Stream Replication on page 1152.

The following diagram shows a simple CDC data model, with one source table to one destination topic on one stream. Since this scenario has the destination stream topic on a remote destination cluster, you must setup and configure a gateway.

Note: More complex CDC scenarios can be implemented, and multiple gateways can be setup.



last-updated: Apr 11, 2022

Important: If you have a secure cluster, you must setup secure configuration. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.

Security and CDC
Security for CDC is applied through Access Control Expressions (ACEs). In addition, if a secure cluster configuration is implemented, then additional setup may be needed depending on the configuration.

Access Control Expressions (ACEs)

Since Change Data Capture (CDC) changed data records are propagated from a MapR Database source table to a MapR Event Store For Apache Kafka stream topic, use the access control expressions (ACEs) on the source table and destination stream for establishing permissions.

Once a MapR Event Store For Apache Kafka stream is created for purposes of receiving change data records, it is dedicated for that sole purpose. For example, a producer application should not perform CRUD operations on the topics in the stream.

The following permissions are applicable depending on the scenario:

- If you are a normal user and you want to create a changelog from a source table and to a destination stream topic, the following permissions are required:
  - `replperm` on the source table in the source cluster
  - `topicperm` on the destination stream in the destination cluster
- If you are a normal user and want to create a changelog between your own MapR Database table and someone else's stream topic, you must be granted `topicperm` permissions on the destination stream.
- If you are a normal user and want to receive or read the data in a stream topic, you must be granted `consumeperm` permission on the destination topic.

For more information about ACEs, see Managing Access Control Expressions on page 1448

Secure Clusters

The destination MapR Event Store For Apache Kafka stream could be in same cluster as the MapR Database source table or it could be on a remote MapR cluster. The configuration setup depends on the purpose for using CDC.

- If your destination stream is on the same cluster as the source table and the cluster is secure, then additional configurations are *not* required.
- If your destination stream is on a remote secure cluster, then a gateway and secure configuration must be setup. See Table Replication on page 610, Administering MapR Gateways on page 1150, and Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486

Restrictions for CDC
Lists the limitations for Change Data Capture.

The limitations for Change Data Capture are as follows:

- Non-CDC data cannot be propagated to changelog stream topics.
- Metadata or policy-driven operations are not propagated to changelog stream topics; only the changed data is propagated. For example, since column family and time-to-live (TTL) is metadata, they are not propagated to changelog stream topics. If metadata is changed in the source table, that information is unknown in relation to the destination stream topic data.
- Propagation of MapR Database JSON arrays is expensive because the full array is propagated to the changelog stream topic.

last-updated: Apr 11, 2022

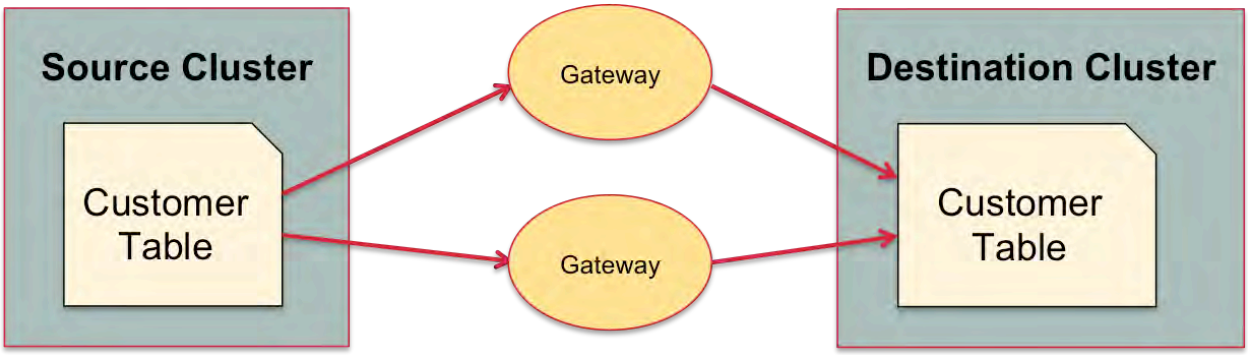
Table Replication

You can replicate data in one table to another table that is in the same cluster or in a separate cluster. This type of replication is in addition to the automatic replication that occurs with table regions within a volume.

You can replicate changes (puts and deletes), entire tables, specific column families, and specific columns.

MapR binary tables can only be replicated to binary tables; MapR JSON tables can only be replicated to JSON tables.

- Tables from which data is replicated are called source tables. Tables to which the data is replicated are called replicas.
- Clusters from which data is replicated are called source clusters. Clusters to which data is replicated are called destination clusters. A single cluster can be both a source cluster and a destination cluster, depending on the replication configuration in which the cluster participates.
- Replication takes place between source and destination clusters. However, source clusters do not send data to nodes in the destination cluster directly. The replication stream (the data being pushed to the replicas) is consumed by one or more MapR gateways in the destination cluster. The gateways receive the updates from the source cluster, batch them, and apply them to the replica tables. Multiple gateways serve the purpose of both load balancing and failover.



For more information about gateways, see Administering MapR Gateways on page 1150.

The maximum number of replicas that a source table can replicate to is 64. The maximum number of source tables from which a replica can accept updates is 64.

Modes of replication

Describes the asynchronous and synchronous modes of table replication.

You can replicate table data in one of two replication modes. You specify the mode per source-replica pair.

Asynchronous replication

In this replication mode, MapR Database confirms to client applications that operations are complete after the operations are performed on source tables. Updates are replicated in the background. Therefore, the latency of updates from client applications is not affected by the time required for the network round trip between the source cluster and the destination cluster.

This type of replication is well-suited for clusters that are geographically separated in wide-area networks.

MapR Database can throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. Throttling distributes disk reads and CPU usage more evenly over time, so that incoming operations on a source table can be completed faster. Throttling is disabled by default.

Asynchronous replication is the default replication mode.

Synchronous replication

In this replication mode, MapR Database confirms to client applications that changes have been applied to a source table only when these two conditions are true:

- The change was sent to all of the container copies in the local cluster.
- The change was sent to a gateway in the destination cluster. This operation takes place only after the first. Puts are not sent to gateways until after they are sent to all container copies in the cluster where the source table is located.

If a gateway fails, the source detects this and resends operations to the gateway when it is restarted or a new gateway is brought online.

Due to the confirmations that MapR Database receives on source clusters, synchronous replication is especially well-suited for creating a backup of your data for disaster recovery.

When the latency of a replication stream is high, MapR Database switches to asynchronous replication temporarily so that client applications are not blocked indefinitely. After the latency is sufficiently reduced, MapR Database switches back to synchronous replication. The same switching occurs when a gateway fails, and MapR Database does not resume synchronous replication until a new gateway is established or the failed gateway is restarted.

Supported replication topologies
Lists the `primary-secondary` and `multi-master` replication technologies.

There are two types of basic topologies that you can use for your replication scenarios: `primary-secondary` replication, with which you can construct several different types of more complicated topologies, and `multi-master` replication.

Primary-Secondary Replication
In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.

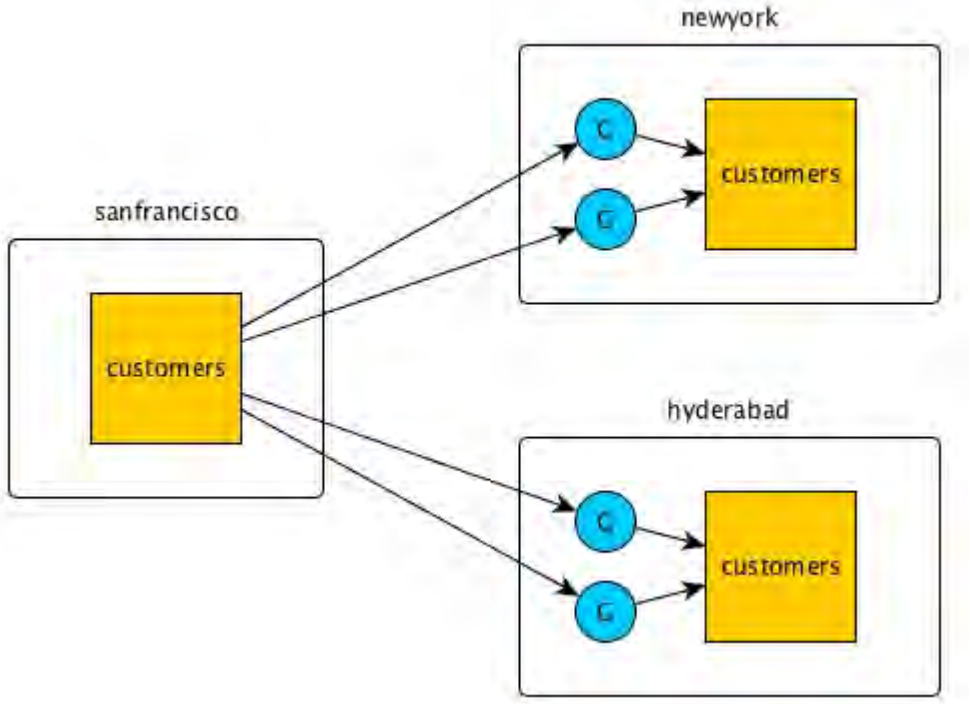
Several topologies are possible for primary-secondary replication:

Replication from one source table to one or more replica tables

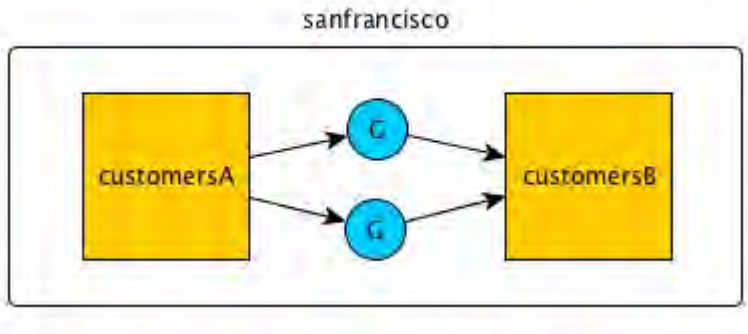
In this topology, updates on a source table are replicated to one or more replicas, but updates to the replicas are not replicated back to the source table.

For example, in this diagram, updates to the `customers` table in the cluster `sanfrancisco` are being replicated to the `newyork` and `hyderabad` clusters. The circles marked G each represent a MapR gateway.

However, changes to the table in the `newyork` and `hyderabad` clusters are not replicated back to the table in the `sanfrancisco` cluster.

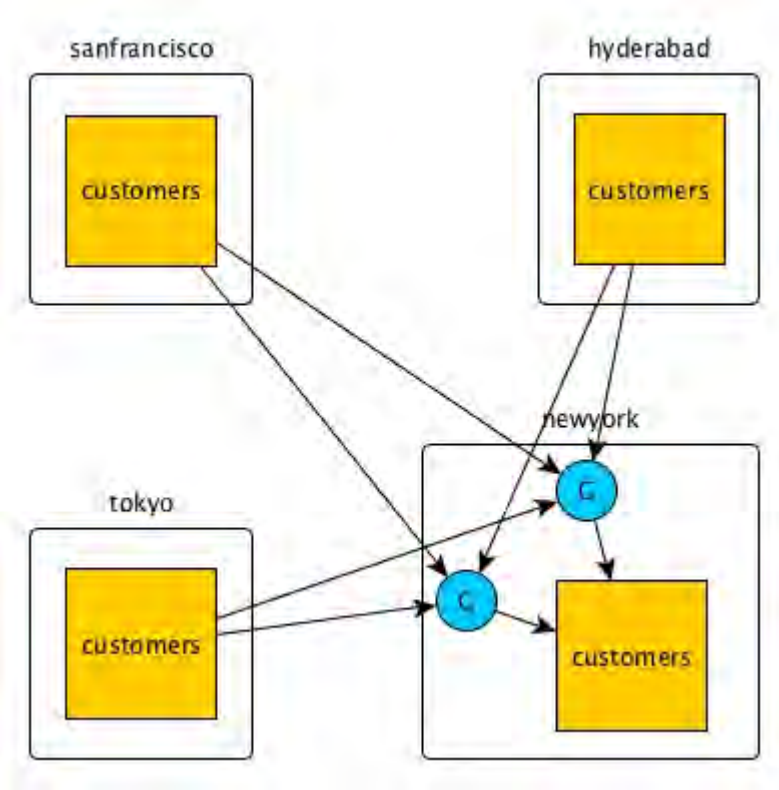


You can also replicate within a single cluster. In this example, the cluster `sanfrancisco` contains both the source table and the replica.



Many-to-one replication

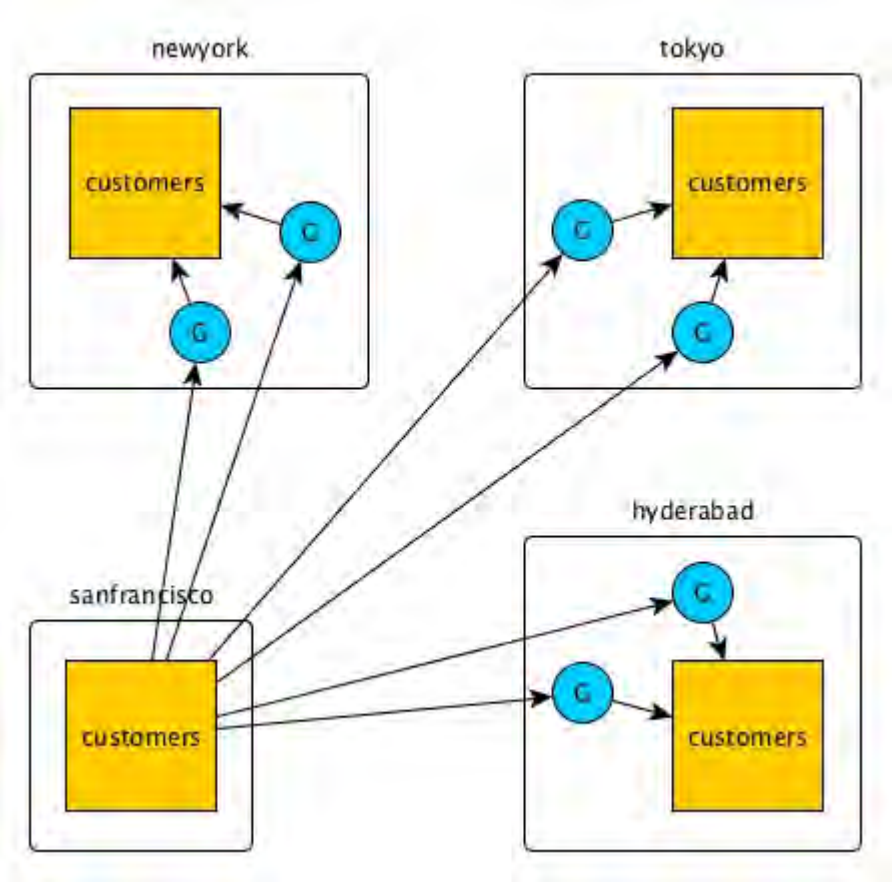
Multiple source tables can replicate to a single replica. In this diagram, operations on `customers` tables in three different clusters are replicated via gateways to the `customers` table in the `newyork` cluster.



One-to-many replication

A single source table can replicate to multiple replicas. In this diagram, operations on the `customers` table in the `sanfrancisco` cluster are replicated via gateways to replicas in three other clusters.

last-updated: Apr 11, 2022

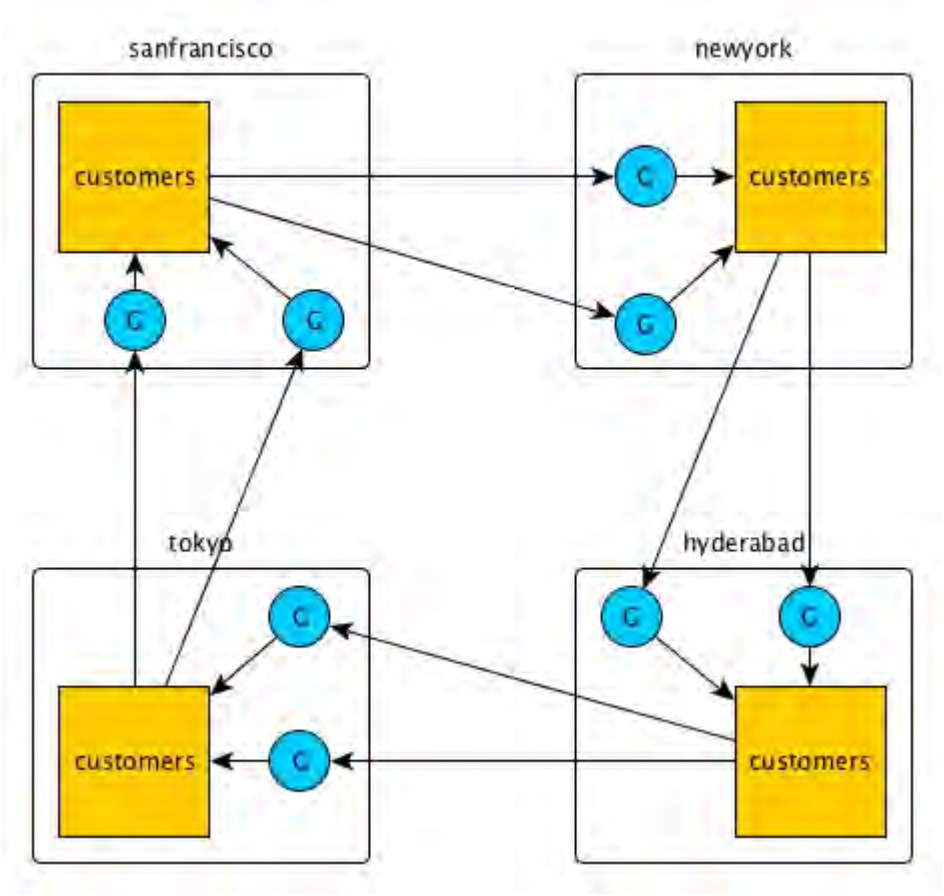


Replication loops

When three or more tables need to be kept in sync, you can set up primary-secondary replication between pairs of them to form a replication loop. Operations on a table are propagated to the other clusters in the loop, but there is no attempt to reapply the operations at the originating table. This is because the operations are tagged with a universally unique identifier (UUID) that identifies the table where the operations originated.

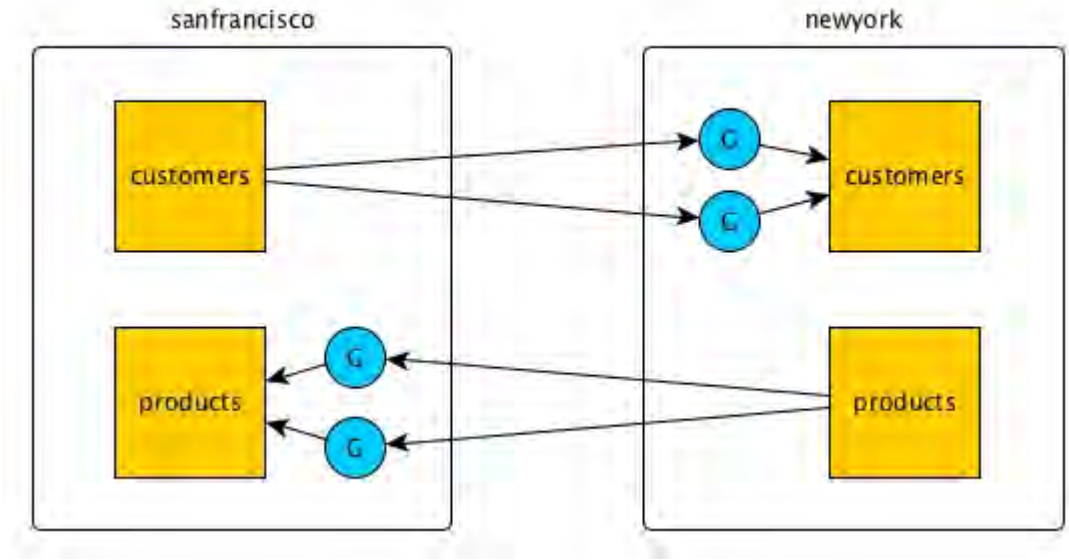
In this diagram, for example, operations on the `customers` table in the `hyderabad` cluster are replicated first to the `customers` table in the `tokyo` cluster. The operations are then replicated from the `tokyo` cluster to the `customers` table in the `sanfrancisco` cluster. Finally, the operations are replicated from the `sanfrancisco` cluster to the `customers` table in the `newyork` cluster. The `newyork` cluster does not replicate the operations to the `customers` table in the `hyderabad` cluster.

last-updated: Apr 11, 2022



Primary-Secondary replication in two directions

You can combine primary-secondary replication configurations to replicate data between clusters. Two clusters engaged in replication can each act as a source cluster and a destination cluster.

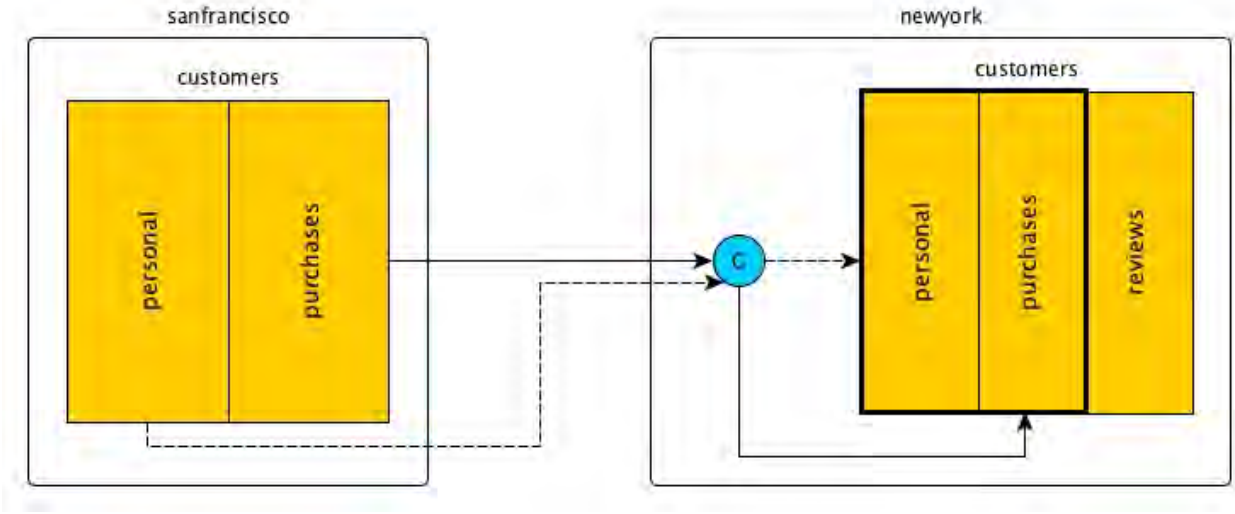


In this example, the data in the `customers` table in the cluster `sanfrancisco` is replicated to the `customers` table in the cluster `newyork`. At the same time, the data in the `products` table in the `newyork` cluster is replicated to the `products` table in the cluster `sanfrancisco`.

last-updated: Apr 11, 2022

In all primary-secondary configurations, changes made to replica tables are not replicated back to source tables. Therefore, if the replicated data is modified at the replica by client applications, the replica will become out of sync with the source table.

For example, you might replicate the two column families `personal` and `purchases` from the `customer` table in the `sanfrancisco` cluster to the `customers` table in the `newyork` cluster, as in this diagram. (For simplicity, the blue circle labeled G represents two or more gateways, rather than one as in the other diagrams in this topic.)



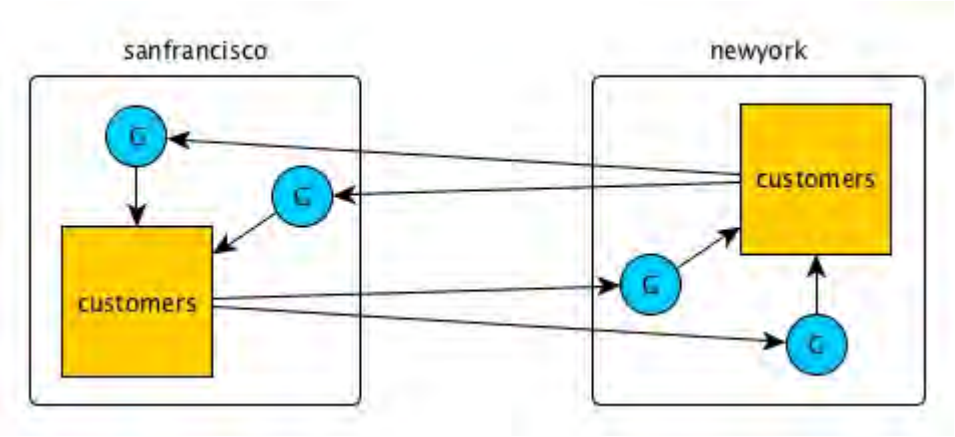
In primary-secondary replication, no updates to a replica are replicated back to the source. Any updates that applications might make to those two column families in the `customers` table in the `newyork` cluster will not be replicated to the `customers` table in the `sanfrancisco` cluster.

However, you do not have to protect a replica from all updates that are not due to replication. For example, the `customers` table in the `newyork` cluster might have an additional column family that is not populated with replicated data: `reviews`.

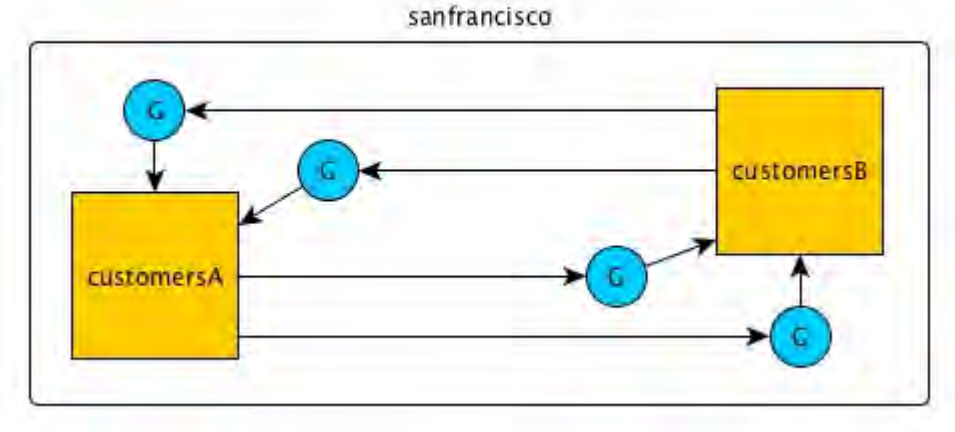
Multi-Master Replication
In this replication topology, there are two primary-secondary relationships, with each table playing both the primary and secondary roles. Client applications update both tables and each table replicates updates to the other.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permissions for updates to column families and columns are irrelevant; gateways have the implicit authority to update replicas.

In this diagram, the `customers` table on the cluster `sanfrancisco` replicates updates to the `customers` table in the cluster `newyork`. The latter table in turn replicates updates to the former table. MapR Database tags each table operation with the universally unique ID (UUID) that it has assigned the table at which the operation originated. Therefore, operations are replicated only once and are not replicated back to the originating table.



In this diagram, both tables are in a single cluster. Operations on table `customersA` are replicated to table `customersB` and vice versa.

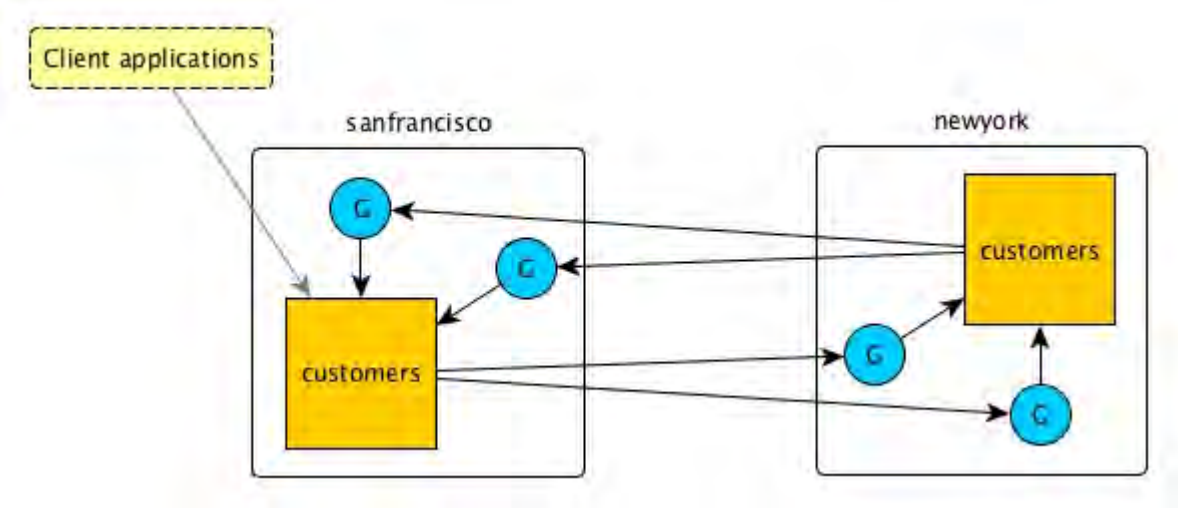


Offline Tables

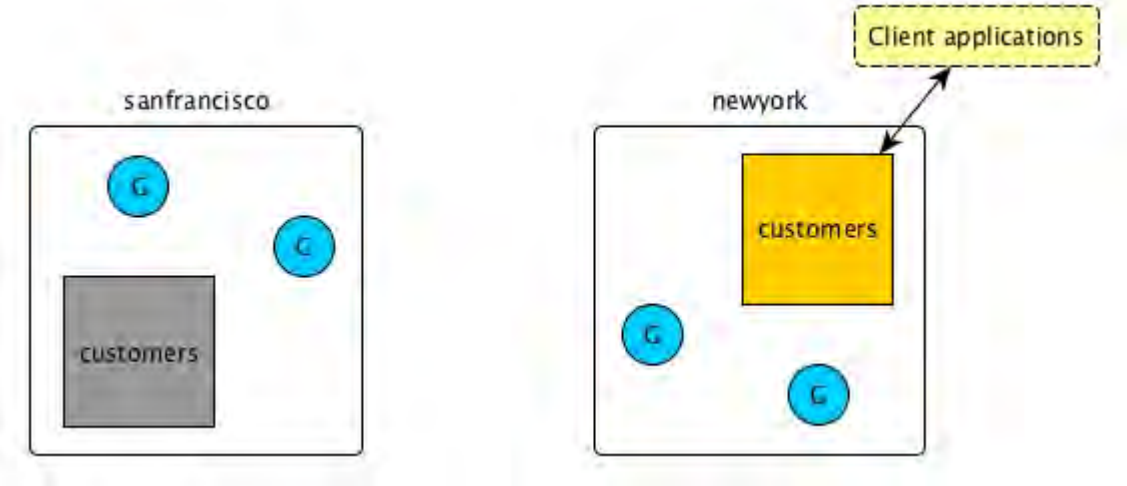
If one of the tables goes offline, you can direct client applications to the other table. When the offline table comes back online, replication between the two tables resumes automatically. When both tables are in synch again, you can redirect client applications back to the original table.

For example, assume that client applications are using the `customers` table that is in the cluster `sanfrancisco`.

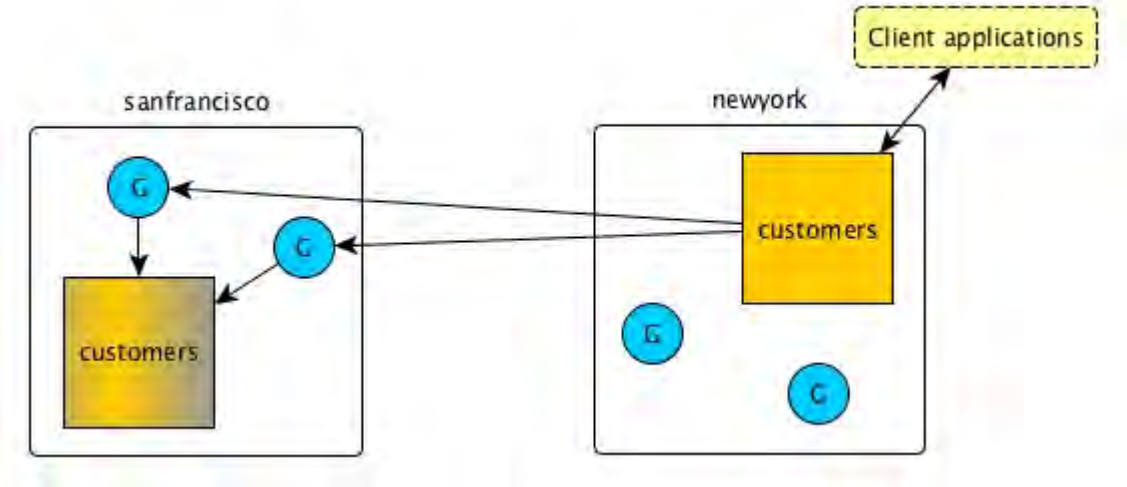
last-updated: Apr 11, 2022



The `customers` table in the `sanfrancisco` cluster becomes unavailable, so you redirect those client applications to the `customers` table in the `newyork` cluster.

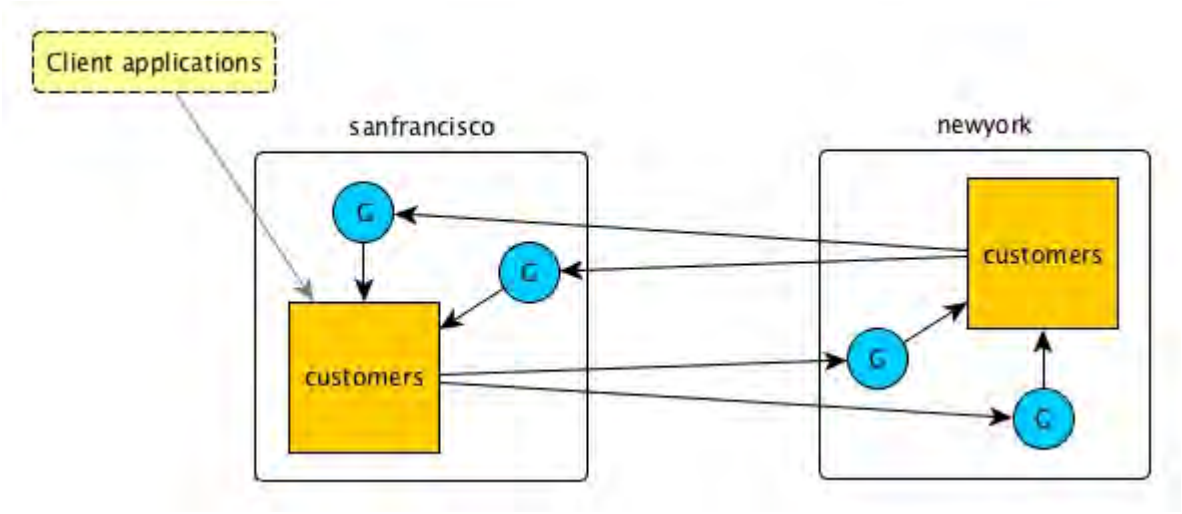


After the `customers` table in the `sanfrancisco` cluster comes back online, replication back to it starts immediately. As client applications are not yet using this table, there are no updates to replicate to the table in the `newyork` cluster.



last-updated: Apr 11, 2022

When the `customers` table in the `sanfrancisco` cluster is in sync with the other table, you can redirect your client applications back to it.



Conflict Resolution

The method that MapR Database uses to resolve conflicts depends on the type of table involved in a multi-master replication scenario.

Conflict resolution for binary tables	In the case of conflicting changes, MapR Database compares the cell timestamps of the two changes. In the rare event that the cell timestamps are identical, MapR Database compares the timestamps for when the changes arrived at their respective source tables. In the even rarer event that these latter timestamps are identical, MapR Database uses the C library function `memcmp` to compare the data that is being modified by the conflicting changes, favoring the greater value.
Conflict resolution for JSON tables	If two values conflict, MapR Database compares their types. The value of the type with the higher precedence is retained. Here is a list of the supported types in descending order of precedence: • Array • Document • Binary • Interval • Timestamp • Time • Date • Decimal • Double • Float • 64-bit integer

last-updated: Apr 11, 2022

- 32-bit integer
- 16-bit integer
- 8-bit integer
- UTF-8
- Boolean
- NULL

If both the conflicting values are of the same type, MapR Database compares the values themselves. All values are comparable except for values that are arrays or NULL.

Type	How Values Are Compared
Binary	The greater value is retained.
Interval	The later interval is retained.
Timestamp	The later timestamp is retained.
Time	The later time is retained.
Date	The later date is retained.
Decimal	The greater value is retained.
Double	The greater value is retained.
Float	The greater value is retained.
64-bit integer	The greater value is retained.
32-bit integer	The greater value is retained.
16-bit integer	The greater value is retained.
8-bit integer	The greater value is retained.
UTF-8	The greater lexicographic value is retained.
Boolean	TRUE is retained.

Time-to-Live for Deletes

Normally, delete operations are purged after the affected table cells are updated. Whereas the result of an update is saved in a table until another change overwrites or deletes it, the result of a delete is not saved. In multi-master replication, this difference can lead to tables being unsynchronized.

Example Scenario to Illustrate Time-to-Live for Deletes

1. On `/mapr/sanfrancisco/customers`, put row A at 10:00:00 AM.
2. On `/mapr/newyork/customers`, delete row A at 10:00:01 AM.

On `/mapr/sanfrancisco/customers`, the order of operations is:

- Put row A with a timestamp of 10:00:00 AM
- Delete row A with a timestamp of 10:00:01 AM (This operation is replicated from `/mapr/newyork/customers`.)

On `/mapr/newyork/customers`, the order of operations is:

- Delete row A with a timestamp of 10:00:01 AM
- Put row A with a timestamp of 10:00:00 AM (This operation is replicated from `/mapr/sanfrancisco/customers`.)

Now, though the put happened on `/mapr/sanfrancisco/customers` at 10:00:00 AM, the put reaches `/mapr/newyork/customers` several seconds after that. Assume that the actual time the put arrives at `/mapr/newyork/customers` is 10:00:03 AM.

To ensure that both tables stay synchronized, `/mapr/newyork/customers` should preserve the delete until after the put is replicated. Then, the delete can be applied after the put. Therefore, the time-to-live for the delete should be at least long enough for the put to arrive at `/mapr/newyork/customers`. In this case, the time-to-live should be at least 3 seconds.

In general, the time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours. Configure the value with the `-deletettl` parameter in the `maprcli table edit` command.

For example, suppose (to extend the scenario above) that you pause replication during weekdays and resume it on weekends. The put takes place on Monday morning `/mapr/sanfrancisco/customers` at 10:00:00 AM and the delete takes place at `/mapr/newyork/customers` at 10:00:01 AM. Replication does not resume until 12:00:00 AM Saturday morning. Given the volume of operations to be replicated and the potential for network problems, it is possible that these operations will not be replicated until Sunday. In this scenario, a value of 7 days for `-deletettl` (7 multiplied by 24 hours) should provide sufficient margin.

Gateways for Replicating MapR Database Tables

In MapR Database table replication, MapR Database replicates updates to tables (binary and JSON) on source MapR clusters to replicas of those tables on destination MapR clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

To set up gateways for replicating MapR Database tables:

- On the nodes of destination clusters, install the gateways.

  You must install gateways in the destination clusters.

  - If the destination cluster is remote from the source cluster, then the gateways must be in the remote cluster.
  - If the destination cluster is the source cluster, meaning that a source table and its replica are located in a single cluster, then the gateways must be in the local cluster.
  - If you have secondary indexes on your MapR Database JSON tables, then the gateways must be in the local cluster.

last-updated: Apr 11, 2022

- On the source clusters, configure the gateways by listing the destination cluster and the gateways that are running on them.

For information on configuring, and managing gateways, see:

- Configuring Gateways for Table and Stream Replication on page 1152
- Managing Gateways on page 1154

How Replication Works

During replication, MapR Database sends source table updates to the gateways on the destination clusters where the replicas of those source tables are located. Gateways batch the updates and then apply them to replicas.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, *ACE* on the replica that control permissions for updates to column families and columns are irrelevant; gateways have the implicit authority to update replicas.

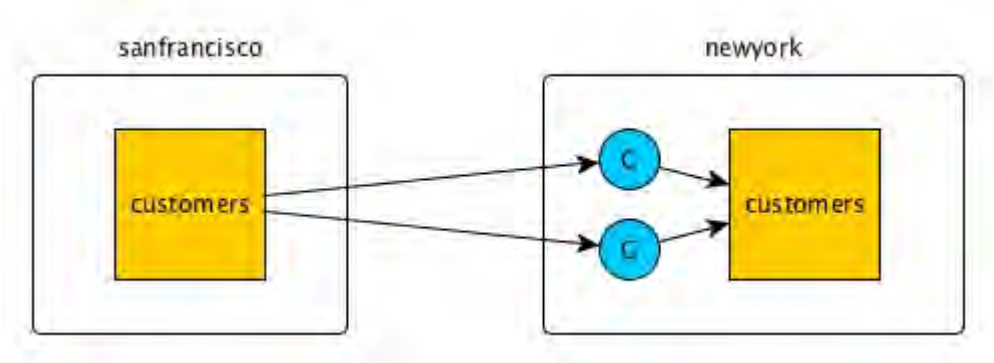
MapR Database distributes updates to a destination cluster's gateways in round-robin fashion. If a gateway is down or unreachable, MapR Database chooses another gateway or retries the operation on the same gateway.

Note: If a table is replicated to another table using the replication gateway, and you run a truncate operation on the source table, this operation is not replicated.

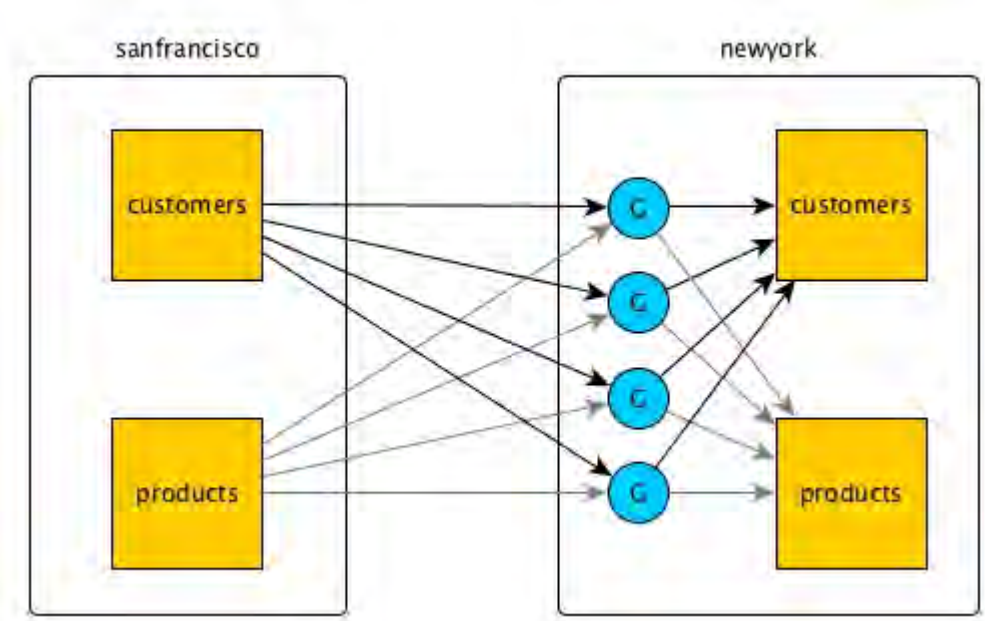
Gateways on nodes in remote destination MapR clusters

In this type of topology, gateways receive updates that are made to source tables, authenticate with the destination cluster on behalf of the source cluster, and apply the updates to the corresponding replicas.

This schematic diagram of basic inter-cluster primary-secondary replication shows updates to the customers table in the cluster `sanfrancisco` being sent to gateways. The gateways then apply the updates to the replica that is in the cluster `newyork`.



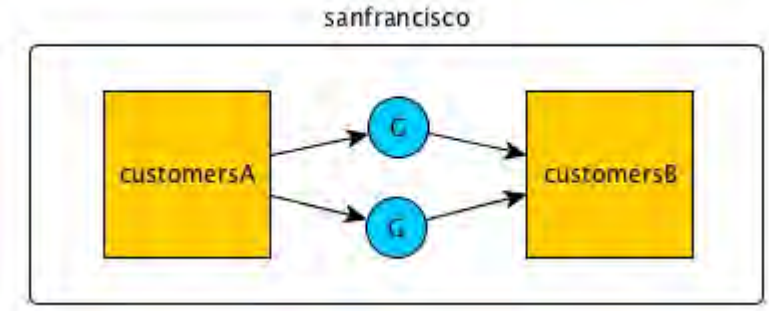
The gateways on a destination cluster are not assigned to particular replicas. They apply updates to all replicas on the destination cluster. For example, in this diagram, updates to two source tables in the cluster `sanfrancisco` are being replicated to two replicas in the cluster `newyork`. There are four gateways. Each gateway receives updates to both source tables, and each gateway applies those updates to both replicas.



Gateways on nodes within a MapR cluster serving as source and destination

In this type of topology, gateways again receive updates that are made to source tables and apply the updates to the replicas. However, all of this activity takes place within a single MapR cluster.

This schematic diagram of basic inter-cluster primary-secondary replication shows updates to the `customersA` table in the cluster `sanfrancisco` being sent to gateways. The gateways then apply the updates to the table `customersB`.



Related concepts

Administering MapR Gateways on page 1150
A MapR gateway mediates one-way communication between a source MapR cluster and a destination cluster. You can replicate MapR Database tables (binary and JSON) and MapR Event Store For Apache Kafka streams. MapR gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1152
Configuring gateways involves installing the `mapr-gateway` package on nodes on a MapR destination cluster and then configuring the MapR source cluster to communicate with the destination cluster. The MapR source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

Replica Autosetup for MapR Database Tables

The option to automatically set up table replication, also known as replica autosetup, performs the steps to set up and start the replication of MapR Database binary table and MapR Database JSON tables. The replica autosetup option is available through the Control System and maprcli commands.

In general, replica autosetup performs the following steps to set up replication:

1. Creates a new table with metadata from the source table in the destination cluster. The primary table attributes are copied initially if an auto setup is used, because auto setup creates the destination table and any subsequent changes to the primary table's metadata are not propagated to the destination table. In the manual table replication setup, no metadata is propagated, even during the setup.
2. Declares the new table to be a replica of the source table and sets a paused replication state to ensure that replication does not begin immediately after the next step.
3. Declares the source table as an upstream source for the replica.
4. Loads a copy of the source data into the replica.
5. For multi-master replication, replica autosetup declares the source table to be a replica of the new table and then declares the new table to be an upstream source for the source table.
6. Clears the paused replication state to start the replication stream.

By default, replica autosetup uses the directcopy option. However, based on how you run replica autosetup, you also have the choice not to use directcopy.

Replica Autosetup with Directcopy (default)

The directcopy option uses gateways to perform all setup operations including the initial population of data into the replica table. Directcopy is the default option when you setup table replication using the Control System or with the `maprcli table replica autosetup` command.

When a client submits a request to automatically setup table replication to the cluster, the source cluster acknowledges the request and begins to track the replica autosetup request from start to finish.

If a failure occurs when replica autosetup operations are in progress, the source cluster resumes operations from the point of failure.

Note: To check the replication status of a table, run the `maprcli table replica list` command. To stop the automatic setup of table replication, run `maprcli table replica remove`, or delete the source or replica table.

Replica autosetup with directcopy provides the following benefits:

- **Replica autosetup operations do not block the client from submitting additional requests.** When setting up table replication, the process to copy source data to the replica can be time consuming. The client does not need to wait for the replica autosetup request to complete before submitting another request.
- **Source cluster retries replica autosetup operations in case of failure.** The source cluster keeps track of the replica autosetup progress. This allows the source cluster to resume autosetup operations in the event of an intermittent failure. If you choose to not use directcopy, user intervention is required if a failure occurs.
- **Throttling of copy table operations is done by default.** Throttling prevents the initial copy of data from the source to the replica table from consuming all cluster resources.

Replica Autosetup without Directcopy (not default)

Without the directcopy option, replica autosetup submits a majority of the replication setup requests through the client and then runs a copy table utility to populate the initial table data. To use replica autosetup without the directcopy option, run `maprcli table replica autosetup` command with the `-directcopy` parameter set to `false`.

Without the directcopy option, once a client submits a replica autosetup request to the cluster, it must wait until the source cluster sends a notification that the autosetup request is complete before it can submit another request to the cluster. In this case, replica autosetup uses the client connection to submit autosetup operation requests such as create replica, add replica, and add upstream source. To populate the initial table data, the client runs `mapr copytable` for JSON tables and the `CopyTable` utility for binary tables.

If a failure occurs when replica autosetup operations are in progress, the client hangs and any replica tables that were created during the failed autosetup operations must be manually deleted before trying to setup replication again.

Table Replication States

The replication state indicates when table replication is in progress and displays the status of operations related to replica autosetup.

The `maprcli table replica list` command displays the following replication states.

State	Description
REPLICA_STATE_WAIT_TILL_BULKLOAD	Replica autosetup with directcopy has not started because bulkload is in progress on the source table.
REPLICA_STATE_CREATE_SCHEDULE	Replica autosetup with directcopy had scheduled the creation of the replica table.
REPLICA_STATE_COPY_SCHEDULE	Replica autosetup with directcopy has not started the initial copying of source data to the replica because it is waiting for other in-progress copy operations to complete.
REPLICA_STATE_COPY_IN_RECOVER	Replica autosetup with directcopy is resuming the copy of source data to the replica after a connection failure.

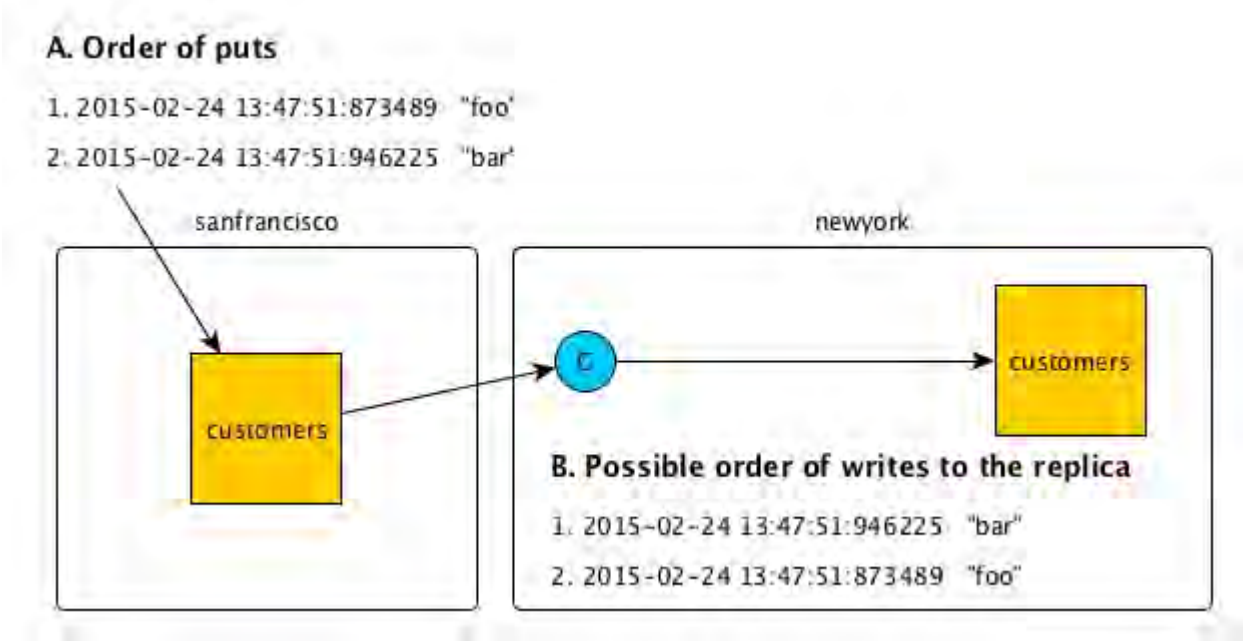
last-updated: Apr 11, 2022

State	Description
REPLICA_STATE_COPY_IN_PROGRESS	Replica autosetup with directcopy is copying the source data to the replica.
REPLICA_STATE_DELETING_CURSORS	Replica autosetup with directcopy is deleting progress cursors since the initial copy of source data to the replica is complete.
REPLICA_STATE_REPLICATING	Replication is in progress.
REPLICA_STATE_UNEXPECTED	Replica is in an unexpected state. See the `error` field in the output from `maprcli table replica list` for more information.

Order of Writes at Replicas

It is possible for replicated operations to arrive at and be written to a replica in an order different from the order they were written to a source table.

In this diagram, the values “foo” and then “bar” are written to the source table. However, due to network issues, the values are written to the replica in the reverse order: “bar”, “foo”



Client applications on the destination cluster should not depend on updates being written to the replica in the same order in which they were written to the source table.

Security and Replication

Describes how to replicate data between secure clusters.

Security is configured at all locations in the replication stream.

On clusters

You can replicate between clusters that are secure. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486 for more information about replication between secure clusters.

At source tables

The `-replperm` parameter lets you specify an *ACE* to declare who has permission to replicate data from a table. This parameter is available in the `maprcli table create` and `maprcli table edit` commands.

Across a network

You can send data encrypted or unencrypted when replicating between secure clusters by using the `-networkencryption` parameter when adding a replica to a source table.

At gateways

Gateways ensure that replicas receive updates only from source tables that are designated as upstream sources.

Moreover, gateways handle authentication with secure destination clusters.

At replicas

Due to several upstream security checks, no parameters are needed for setting *ACE* to declare who has permission to update a replica through a replication stream. However, before replication begins, replicas can be loaded with a snapshot of the data in corresponding source tables. Permission to perform such a load is controlled by the *ACE* that you set in the `-bulkloadperm` parameter for a replica. You can set the *ACE* with either the `maprcli table create` or the `maprcli table edit` command.

All other *ACE* defined for a replica still apply for local updates and reads.

Licensing

Describes the licensing requirements for MapR.

Table replication requires a license for MapR Enterprise Database Edition (M7) on source and destination clusters.

Gateways for Indexing MapR Database Data in Elasticsearch

As of MapR 6.0, MapR Database Elastic Search integration capability is deprecated and no longer available in the MapR Database product.

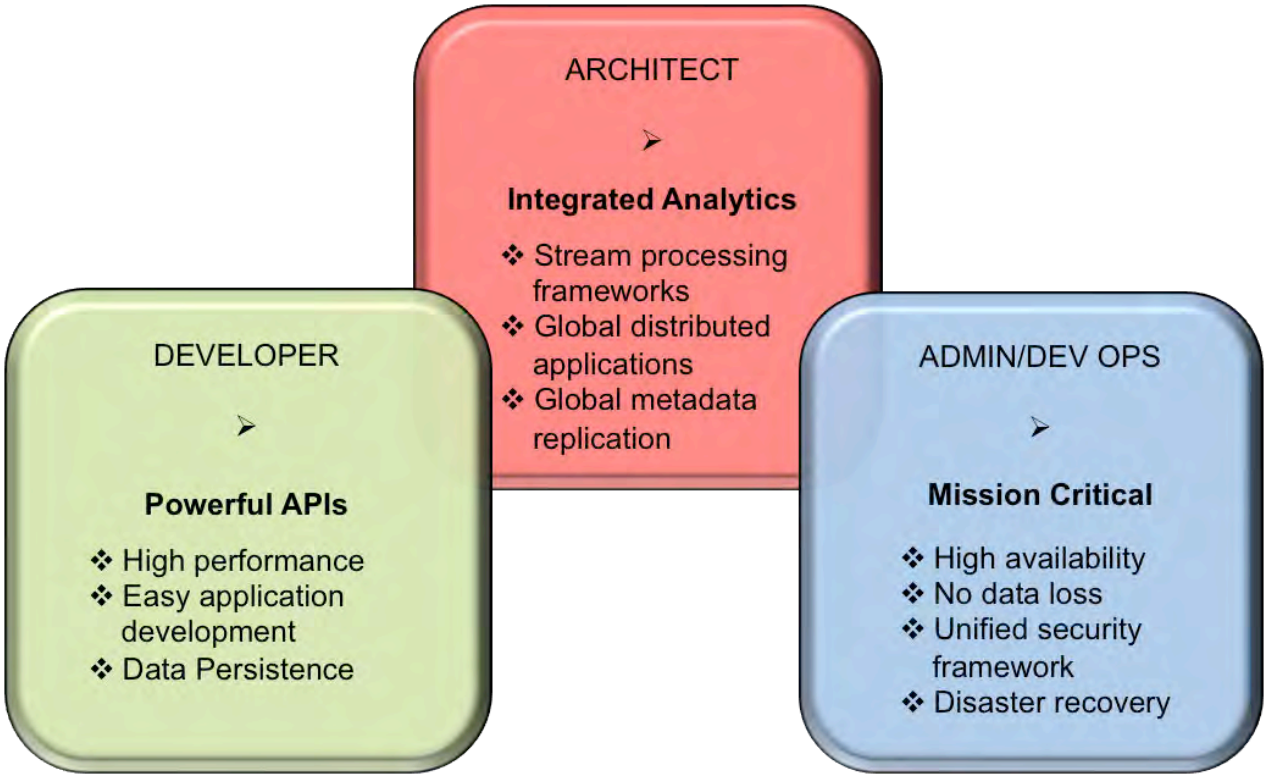
Attention: MapR Database Change Data Capture (CDC) framework can be used to integrate with latest versions of Elasticsearch. See Change Data Capture on page 597 for more information.

MapR Event Store For Apache Kafka

MapR Event Store For Apache Kafka brings integrated publish and subscribe messaging to the MapR Converged Data Platform.

Why MapR Event Store For Apache Kafka?

MapR Event Store For Apache Kafka is built into the MapR platform. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



1. The MapR Event Store For Apache Kafka and Apps section information and examples for developing Producer and Consumer applications.
2. The MapR Event Store For Apache Kafka concepts section covers information associated with streams, topics, and messages.
3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

How Do I Get Started?

Based on your role, review the MapR Event Store For Apache Kafka documentation. The following table identifies useful resources based on your role.

Developer	Architect	Administrator/Dev Ops
➢ MapR-ES and Applications	➢ MapR-ES Architecture	➢ Installing MapR
➢ MapR-ES Java Applications	➢ Stream Design	➢ Administering MapR-ES
➢ MapR-ES C Applications	➢ Life of a Message	➢ maprcli and REST API Syntax
➢ MapR-ES Python Applications	➢ Stream Replication	➢ Utilities for MapR-ES Streams

1. MapR Event Store For Apache Kafka and Apps
2. MapR Event Store For Apache Kafka Java Applications
3. MapR Event Store For Apache Kafka C Applications
4. MapR Event Store For Apache Kafka Python Applications
5. MapR Event Store For Apache Kafka architecture and concepts.
6. Determining stream design.
7. Describes the flow of a message from a producer to a consumer.
8. Describes the factors associated with stream replication.

- Blog: How to Persist Kafka Data as JSON in NoSQL Storage Using MapR Streams and MapR Database

Architecture

Streams contain topics that have logical collections of messages.

In MapR Event Store For Apache Kafka, topics are grouped into *streams*. Administrators can apply security, retention, and replication policies on streams. Combined with MapR File System and MapR Database in the MapR Data Platform, using these streams enables organizations to create a centralized, secure data lake that unifies files, database tables, and message topics.

Messages (topic data) are published to *topics* by Producer applications and are read by Consumer applications. All messages published to MapR Event Store For Apache Kafka are persisted, allowing future consumers to “catch-up” on processing and analytics applications to process historical data. Additionally, messages are specifically written to *topic partitions*.

Note: Topic partitions are stored in containers within volumes. Containers are written to storage pools, which are made up of disks on the nodes in the cluster. See Containers and the CLDB on page 453 for more information about containers.

Why Use MapR Event Store For Apache Kafka?

MapR Event Store For Apache Kafka is ideal for a variety of use cases, including the following:

Application event pipelines	Many types of applications generate event or log data that must be centrally stored and analyzed to gain insights about user activity or application performance. MapR Event Store For Apache Kafka simplifies these pipelines by transporting events to a central location, from which they can undergo event-by-event transformation and analysis.
Database change capture	Most modern databases enable users to generate an event each time an entry is added or modified. These events can be published to MapR Event Store For Apache Kafka to keep systems like search indexes and caches synchronized, as well as to feed security or notification applications.
Internet of Things	The explosion in the number of smart devices and sensors has created many situations in which billions of data points are created by millions of geographically dispersed sensors. MapR Event Store For Apache Kafka provides a reliable, global transport for these messages, enabling you to perform analytics both at the source and at a central location.

Replication

In addition to reliably delivering messages to applications within a single data center, MapR Event Store For Apache Kafka can continuously replicate data between multiple clusters, delivering messages globally. Like other MapR services, MapR Event Store For Apache Kafka has a distributed, scale-out design, allowing it to scale to billions of messages per second, millions of topics, and millions of producer and consumer applications.

Server and Client Libraries

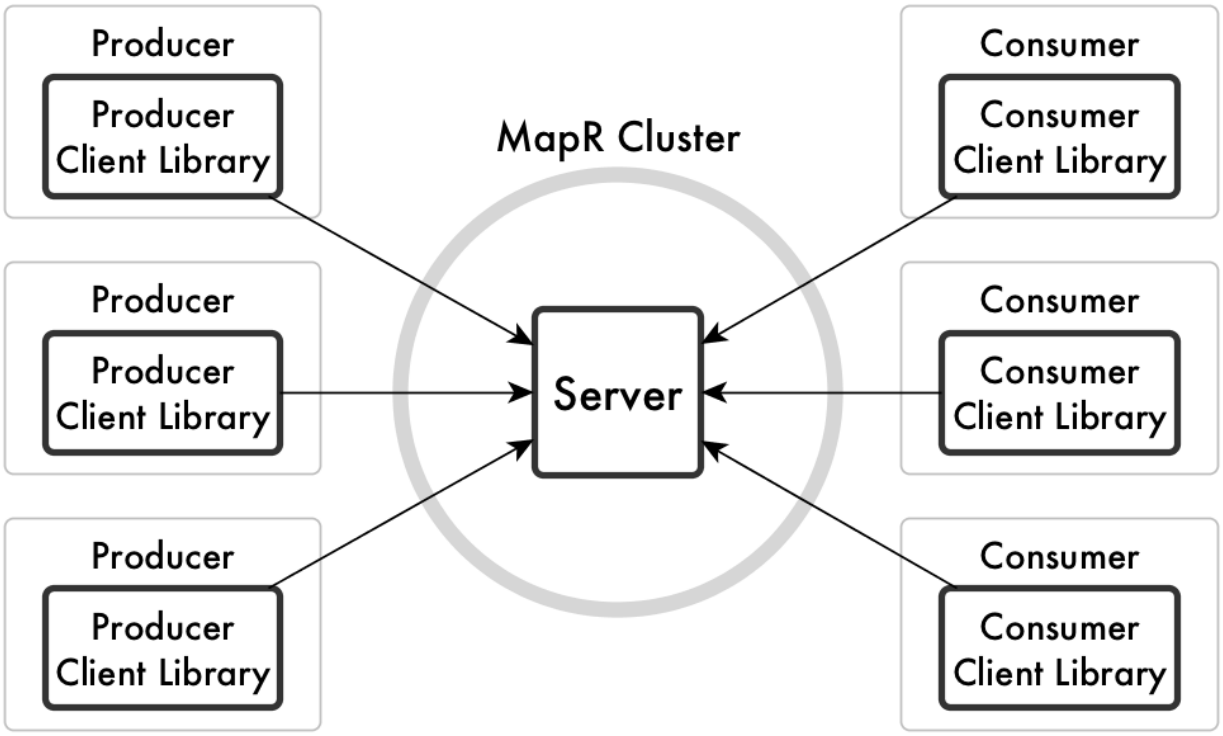

Figure 5: The relationship of the MapR Event Store For Apache Kafka server to producers, consumers, and client libraries

Server	The server manages streams, topics, and partitions and handles requests from the producer client library and the consumer client library.
Producer client library	This client side library which is part of the producer process receives the messages that are sent by producers, buffers the messages, and sends them to the server, which then publishes the messages and sends the client acknowledgements.
Consumer client library	This client side library which is part of the consumer process receives requests from consumers to poll subscriptions for unread messages, reads messages from topic partitions, and sends messages to consumers.

Stream Design

Streams are created in volumes and contain topics, which in turn, contain messages. Security, replication, retention, and compression policies are applied at the stream-level.

When designing the architecture, take in account the following factors:

- Security Permissions (using access-control expressions)

  Security permissions are set at the stream-level and, subsequently, topics inherit the stream permissions. See Stream Security on page 664 for more information.

- Data Replication

  MapR Event Store For Apache Kafka streams can be replicated to other streams in the same or different MapR clusters. For example, you can create a backup copy of a stream so that producers and consumers fail over to the backup if the original stream goes offline. See Stream Replication on page 656

- Data Retention

  The time-to-live of a message is the elapse time (in seconds) between the publication of a message in a topic in this stream and the expiration of that message. See Time-to-Live for Messages on page 637 for more information.

- Data Compression

  Topic messages can be sent to the server compressed. When compression is implemented, the messages are stored compressed, replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. See Managing Compression on page 988 for more information.

Pollution Monitor Example

Suppose that you plan to create the stream `pollution_monitors` to collect various measurements about pollution levels in European cities. However, during a planning session, the representative from Amsterdam says that her country wants to analyze the data for its cities and would like your company to replicate the data to its own MapR cluster, where its own consumers can read the replicated messages.

In this scenario, you might do the following:

- Create a stream dedicated to the Netherland's pollution data or even for every country you are monitoring. For example, create streams named `pollution_monitors_netherlands`, `pollution_monitors_sweden`, `pollution_monitors_france`, and so on.
- Within each stream, create topics for each city in that county. For example, create a topic named `amsterdam` that contains data from Amsterdam's pollution sensors.
- Since, in this scenario, the Amsterdam representative also requested stream replication to their own MapR cluster, you would set up stream replication from your MapR cluster to Amsterdam's MapR cluster. See Managing Stream Replication on page 1130 for information about setting up and managing replication.

Alternatively, consider that the Netherlands did not request replication to their own MapR cluster. However, you want to restrict access to the pollution data where consumers could read only pollution data for their respective country.

In this scenario, you might do the following:

- Create streams for each country.
- Create topics for each city in that country.
- Set each stream's `consumeperm` permission for consumers associated with that country. See Stream Security on page 664 for more information about security permissions used with MapR Event Store For Apache Kafka streams. For general information about access-control expressions, see ACE Syntax on page 1448.

Stream Topics

Topics are created in streams and contain logical collections of messages. These collections of messages are published to partitions in the topic.

Using MapR Event Store For Apache Kafka with MapR File System and MapR Database in the MapR, enables organizations to create a centralized, secure data lake that unifies files, database tables, and message topics.

Note: Topics inherit security permissions, time-to-live data retention, and data compression policies at the stream-level.

You can design topic usage in a variety of ways. For example, you might have an application that monitors the logs for mission-critical software. Your monitoring application could send informational messages to a topic named `info`, warning messages to a topic named `warnings`, and error messages to a topic named `errors`. Different downstream applications might monitor each topic.

You can manage topics for different scenarios:

- Set security policies that apply all of the topics in that stream. Security policies are set at the stream-level. See Stream Security on page 664 for more information.
- Set a default number of partitions for each new topic that is created in the stream. The default number partitions is set at the stream-level, however, individual topics can override the default. See Topic Partitions on page 634 for more information.
- Set a time-to-live for messages in every topic in the stream. Every message in every topic in a stream expires after a duration of time, unless you set the time-to-live to 0, meaning messages never expire. Time-to-live is set at the stream-level. See Time-to-Live for Messages on page 637 for more information.

Restrictions

- After a topic is created in a stream, it is not possible to move that topic to a different stream.

  For example, suppose you create the topic `structural_integrity_sensors_us_western_region`, one of a number of topics that collect data from sensors that keep watch over various measurements for bridges, buildings, and other structures. However, you have mistakenly created the topic in the stream `ventilation_systems` instead of the stream `structural_integrity_sensors`.

  Note: There is no command that will move a topic from its current stream to a different stream.

  To rectify this mistake:

  - You must delete the topic and recreate it in the other stream.
  - Any producers that published messages to the topic and any consumers that read messages from the topic must be modified to point to the new location of the topic. This is because producers and consumers refer to topics with a combination of stream name and topic name.
- Only the following characters are allowed for stream topic names:
  - Alphanumeric characters
  - Period, underscore, and dash
- When producing or consuming stream topic messages, you must specify the stream's path and name along with the topic name in the following manner:

  ```
  /<stream name>:<topic name>
  ```

  Note: If a topic is specified but the stream's path and name is not, depending on the application's programming language, you might get an error or nothing. If nothing happens and you are using Java, the assumption is that you are publishing to Apache Kafka.

last-updated: Apr 11, 2022

Topic Partitions

Partitions, which exist within topics, are parallel, ordered, immutable sequences of messages that are continually appended to.

Topics can contain multiple partitions, which make topics scalable by spreading the load for a topic across multiple servers.

Downstream applications that read messages can read from multiple partitions within a topic for faster performance than would be possible if they read from a single partition per topic. Downstream applications can also scale by having separate instances read from separate partitions.

When creating or editing a stream, a default number of partitions can be specified for that stream's topics. Topics inherit the stream's partition default. However, topics can also override the stream's partition default by setting the number of partitions to be used.

Performance

The default number of partitions for MapR streams and topics can impact performance. Depending on the volume of messages being published to a topic, the default number of partitions might be increased for efficient consumption.

When there is a high volume of messages being published to a topic:

- Multiple consumers, in consumer groups, reading from multiple partitions are handled more efficiently.
- Individual consumers each reading from a single partition are handled less efficiently.

Reference

The following lists topics that have more detailed information.

- See the maprcli stream create on page 1758 for information about creating streams with the `-defaultpartitions` parameter.
- See the maprcli stream edit on page 1765 for information about editing streams with the `-defaultpartitions` parameter.
- See the maprcli stream topic create on page 1781 for information about creating topics with the `-partitions` parameter.
- See the maprcli stream topic edit on page 1784 for information about modifying topics with the `-partitions` parameter.
- See the maprcli stream topic info on page 1785 for information about topic data including the `-partitions` parameter.
- See the MapR Event Store For Apache Kafka Java API Library on page 2756 for the methods used to create and edit streams and to create and edit topics.

Topic Creation

Topics are created in streams and contain logical collections of messages. They can be created either automatically through your producer application or manually through the Control System or the `maprcli` commands.

Automatic Creation

If the topic does not already exist, a topic is created automatically when a producer first publishes a message to it. This is the default behavior.

For example, you created the stream **anonymous_usage** that you intend to use to collect data about the usage of a software application that is soon to be released. However, you did not create any stream topics because the topics were not known at the time. After the software is released to the public, at some point, a

producer application starts publishing messages to a topic that is created based on the range within which the producer's IP address falls. At another point in time, another producer application starts publishing messages to a topic based on a different range of IP addresses. Eventually, the stream contains a number of topics for different IP address ranges.

Note: Automatic creation of topics can be turned off by setting the `autocreate` parameter to **false** either when creating the stream or by editing the stream. See the `maprcli` stream create on page 1758 or stream edit on page 1765 command for more information. If you turn off automatic creation, you must manually create the stream topic, otherwise, the publishing of a message fails.

Manual Creation
To create topics manually, use either the Control System or the `maprcli` commands. See Administering Streams on page 1119 for information about managing MapR Event Store For Apache Kafka streams, topics and replication. See the stream topic create on page 1781 command for specific information about creating stream topics with the `maprcli` command.

For example, you created a stream called **systemMetrics** that you intend to use to collect operational metrics from systems in your enterprise. You did create several topics based on system, location, company department, project, or some other criterion. In this case, you could create topics in advance because they were pre-planned.

Note: When you manually create a topic, you can have the option of customizing the number of topic partitions used, otherwise, the default number of partitions is inherited from the stream.

Topic Messages
Messages are key/value pairs, where keys are optional. The values contain the data payload, which can be text, images, video files, or any other types of data.

Messages are published into *topic partitions* by Producer applications and are read by Consumer applications. All messages published to MapR Event Store For Apache Kafka are persisted, allowing future consumers to “catch-up” on processing and analytics applications to process historical data. See Producers on page 643 and Consumers on page 647 for more information.

Offsets

Messages are assigned offsets when published to partitions. Offsets are monotonically increasing and are local to partitions. The order of messages is preserved within individual partitions, but not across partitions.

Note: As of MapR 6.0, the message offset in a partition starts from zero (0). If you are upgrading and did not enable the MapR Database/MapR Event Store For Apache Kafka feature **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).

Logical Schema of Messages
Each message has the same logical schema: _id, topic, partition, offset, timestamp, producer, key, and value.

As the logical schema of each message is the same, analytics applications can run queries on these fields. See MapR Event Store For Apache Kafka Java API Library on page 2756 for information about querying messages and mapr streamanalyzer on page 5348 for a sample application used to query and count messages in topics.

```
{
          "_id":<STRING>,
          "topic":<STRING>,
          "partition":<SHORT>,
          "offset":<LONG>,
          "timestamp":<LONG>,
          "producer":<VARCHAR>,
          "key":<BINARY>,
```

```
            "value":<VARBINARY>
            }
```

Field	Description
`_id`	A STRING value that represents the ID of the topic in which the message is located.
`topic`	A STRING value that represents the name of the topic in which the message is located.
`partition`	A SHORT value that represents the index of the partition in the topic.
`offset`	A LONG value that represents the position of the message within a partition.
`timestamp`	A LONG value that represents the date and time of the message. As of MapR 6.0.1, MapR Event Store For Apache Kafka supports an event-time timestamp. The timestamp type can be either `createtime` (default) or `logappendtime`. A `createtime` value (default) is the time defined by the user or application (when creating the message). If user or application does not define this value (or passes null), the client uses the current system timestamp. A `logappendtime` value is the time when the message (log) was appended to the server. **Tip:** Because each message is automatically produced into a topic-partition with an event-time timestamp as part of the message record, this allows the Consumer to seek based on the timestamp.
`producer`	A VARCHAR value that represents the value of the `client.id` configuration parameter for the producer that published the message. MapR Event Store For Apache Kafka does not require a value for this configuration parameter, so the value for this field could be empty.
`key`	A BINARY value that represents the key of the message. MapR Event Store For Apache Kafka does not require each message to have a key, so this value could be empty. The configuration parameter `key.serializer` for the producer that published the message specifies the means by which the key was serialized. Your application can deserialize the key by using the appropriate deserialization class in the `org.apache.kafka.common.serialization` package or a class that implements the `Deserializer` interface.
`value`	A VARBINARY value that represents the value of the message. The configuration parameter `value.serializer` for the producer that published the message specifies the means by which the value was serialized. Your application can deserialize the value by using the appropriate deserialization class in the `org.apache.kafka.common.serialization` package or a class that implements the `Deserializer` interface.

Resources

For more information about creating and editing streams or topics:

  - See the MapR Event Store For Apache Kafka Java API Library on page 2756 for the methods used to create and edit streams and to create and edit topics.

Time-to-Live for Messages
The time-to-live (TTL) for messages means that messages persist in the partitions of a stream topic for a specific time period. During that time, messages can be read or re-read by consumers. Once the TTL for a message expires, the message is marked for deletion.

Setting TTL for Message

Set the TTL for topic messages when you create or edit a stream. Since the TTL setting is specified at the stream-level, all messages in all topics associated with the stream will have the same TTL. The default TTL is 604,800 seconds (7 days).

Deleting Expired Messages

Expired messages are deleted by an automatic process that runs at periodic intervals of TTL/10 and no later than 24 hours. For example:

- If the TTL is set to 24 hours, expired messages are deleted once every 24 hours.
- If the TTL is set to 7 days (168 hours, which is the default), expired messages are deleted once every 24 hours because 24 is greater than 168/10.
- If the TTL is set to 20 days (480 hours), expired messages are deleted once every 48 hours because 48 is greater than 24.

Attention: The automatic process deletes messages from *active* streams that have an expired TTL. The automatic process does not purge deleted messages with an expired TTL from *idle* streams until producer or consumer operations are performed on the streams.

Monitor disk space utilization and manually delete messages from streams, as needed, to reclaim disk space.

To manually delete expired messages, run the `maprcli` command stream purge on page 1769.

Life of a Message
To show how the MapR Event Store For Apache Kafka concepts fit together, here is an example of the flow of one message from a producer to a consumer.

The Setup

Suppose that you are using MapR Event Store For Apache Kafka as part of a system to monitor traffic in San Francisco. Your producers are sensors in streets, freeways, bridges, overpasses, and other

infrastructure, as well as sensors reporting the weather in many different locations. Your consumers are various analytical and reporting tools.

In a volume in a MapR cluster, you create the stream `/somepath/traffic_monitoring`. In that stream, you create the topics `traffic`, `infrastructure`, and `weather_conditions`.

Of all of the sensors (producers) that your system uses to monitor traffic, let us choose a sensor that is under the pavement of Market Street and follow a message that it generates. We will follow a message that is generated by this sensor and published in the `traffic` topic.

Suppose that, when you created this topic, you created several partitions within it to help spread the load among the different nodes in your MapR cluster and to help improve the performance of your consumers. For simplicity, we will assume that the `traffic` topic has only one partition.

A Message Enters the System

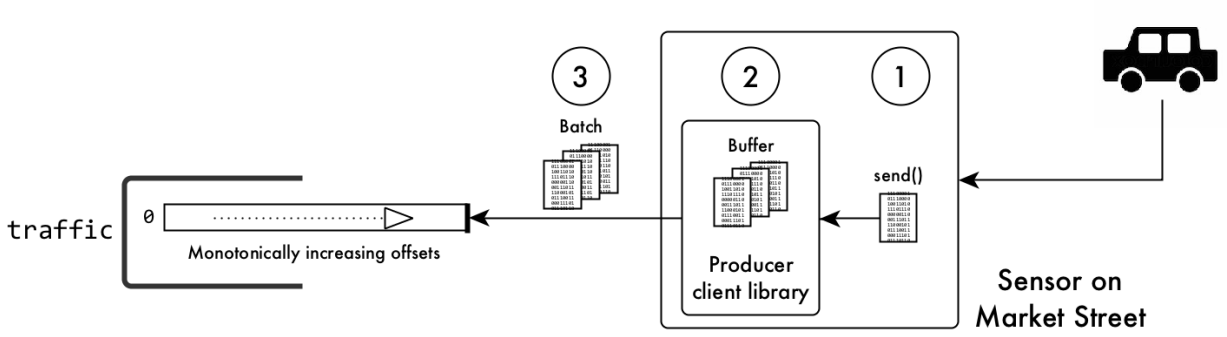

Figure 6: A car runs over a sensor, triggering the sending of a message

1. A car, one of hundreds on Market Street in morning rush-hour traffic, runs over the sensor. This action triggers the sensor to send a message to a MapR Event Store For Apache Kafka producer client library.

   Note: This message might list geospatial coordinates, time, date, direction, weight, distance between front and rear wheels, and more. MapR Event Store For Apache Kafka does not help you decide which data to collect.

2. The client buffers the message.

3. When the client has a large number of messages buffered (because other cars have subsequently triggered the sensor) or after an interval of time has expired, the client batches and sends the messages in the buffer. The message that we are following is published in the partition along with the rest of the messages in the batch. When the message is published, the MapR Event Store For Apache Kafka server assigns it the offset 001030 (which is only an example offset; real offsets are more sophisticated). These messages being the most recent to be published, are written to the head of the partition.

   For a moment, suppose that this example used more than one partition. In that case, the sensor could influence how the MapR Event Store For Apache Kafka server determines which messages go to which partition. In the example that we are following, the sensor could include a key with each message. The MapR Event Store For Apache Kafka server would hash the key to determine the partition to place the messages received from the sensor. More information about how partitions are selected if there are more than one in a topic is explained later in this documentation.

4. Each partition and all of its messages are replicated. The server owning the primary partition for the `traffic` topic assigns the offset 001030 to the message that we are following, and replicates the message to replica containers (replication rules are controlled at the volume level) within the MapR cluster.

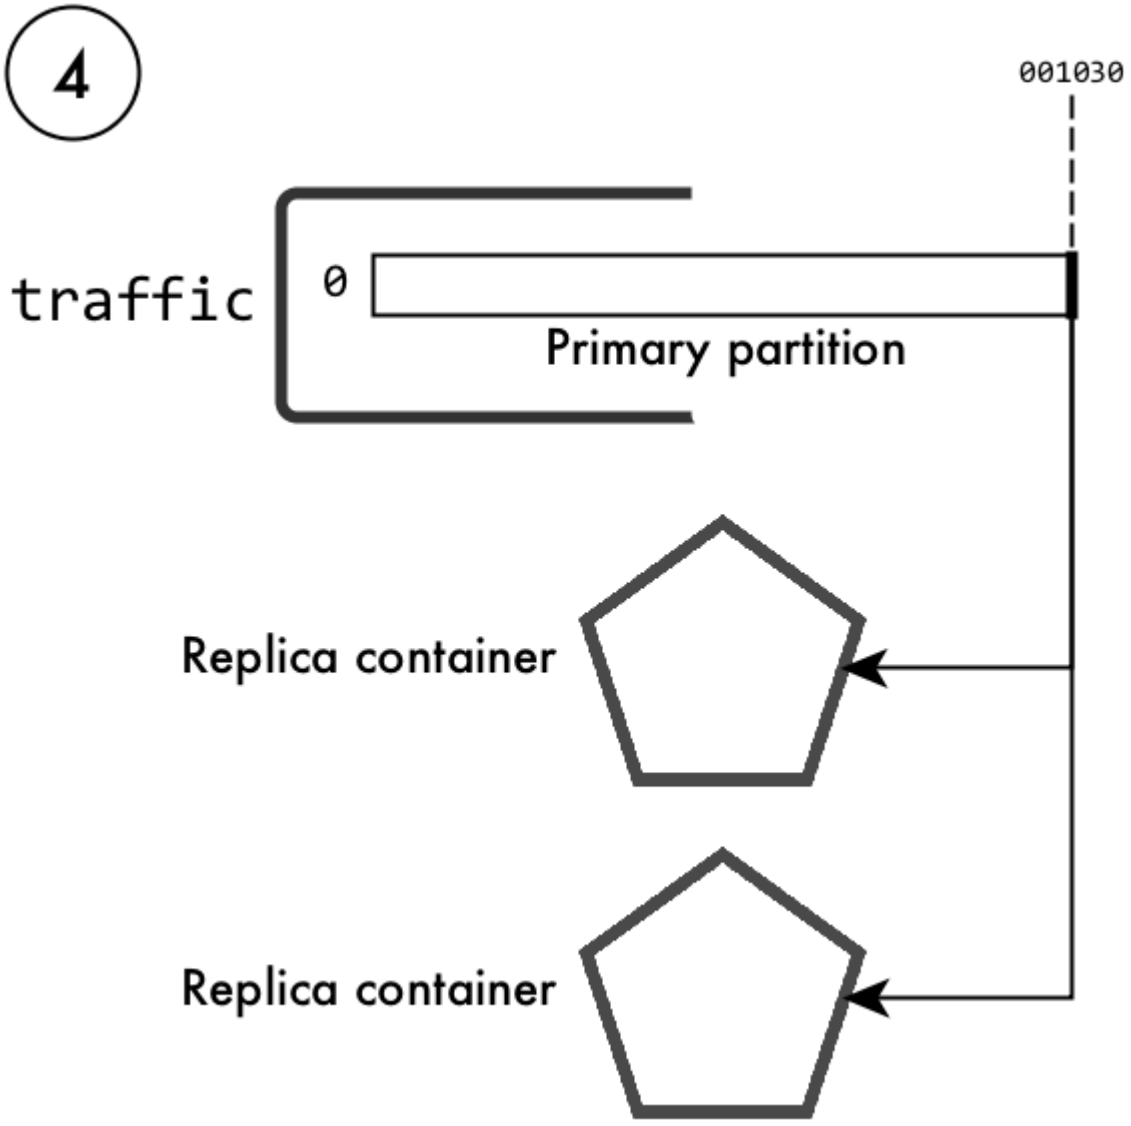

Figure 7: Replication of the partition in the topic `traffic`

5. The server acknowledges receiving the batch of messages and sends the offsets that it assigned to them.

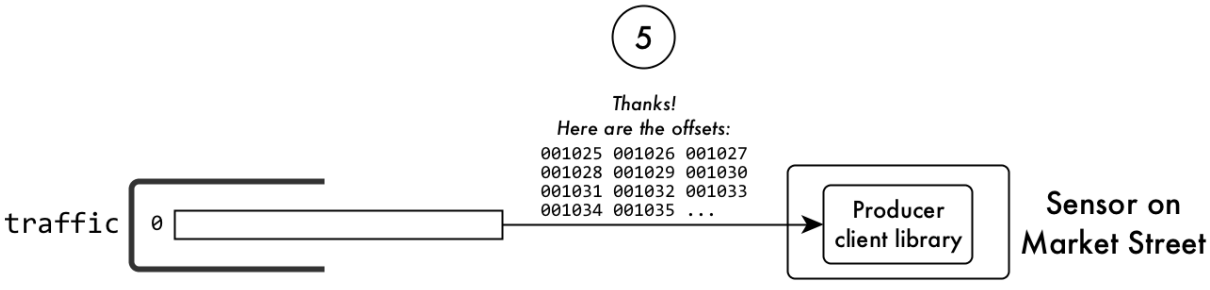

Figure 8: The server acknowledges receiving the messages

last-updated: Apr 11, 2022

The Message is Read from the System

An analytics application (consumer) that correlates traffic volume with weather conditions is subscribed to the `traffic` topic. Many more consumers could subscribe to it, too.

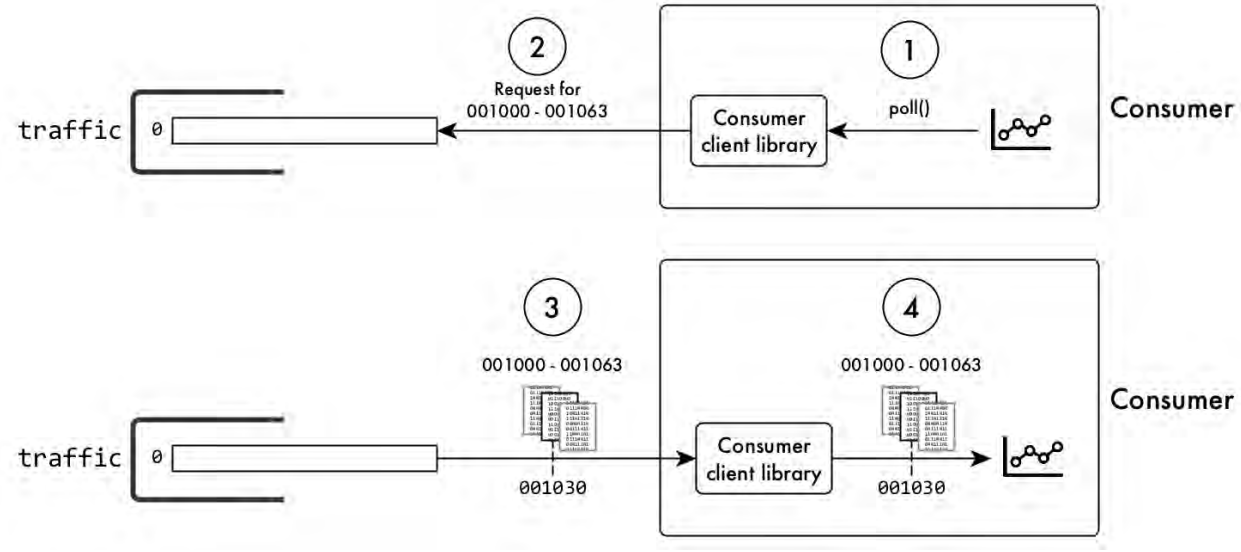

Figure 9: How messages are read

1. The application issues a request to the consumer client library to poll the topic for messages that the application has not yet read.
2. The client requests messages that are more recent than the consumer has yet read.
3. The primary partition returns multiple messages to the client. The originals of the messages remain on the partition and are available to other consumers.
4. The client passes the messages to the application, which extracts the data from them and processes it.
5. If more unread messages remain in the partition, the process repeats from step 2.

The Original Message is Deleted

Back in the cluster in San Francisco, messages are being continuously published to the partition in the `traffic` topic. Message 001030 is much further in the partition. More recent messages have filled the partition ahead of it.

When you created the stream, you set the time-to-live for messages to be six months. Message 001030 and messages around it have now been in the partition for that period, and are now expired. An automatic process eventually reclaims the disk space that message 001030 and the other expired messages are using.

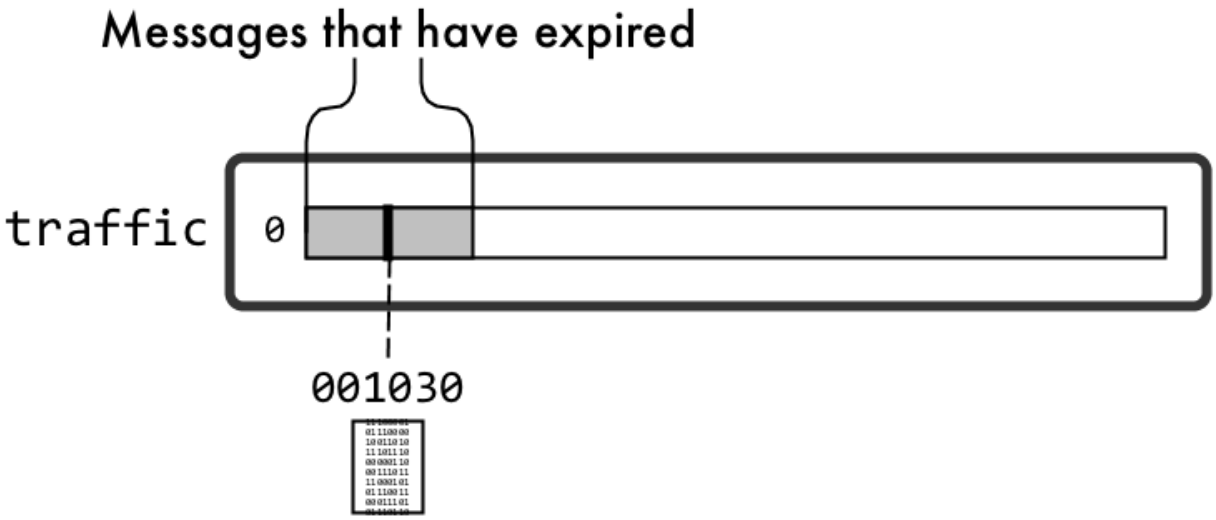

Figure 10: Messages to be deleted automatically

Log Compaction

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

Log compaction reduces the size of a topic-partition by deleting older messages and retaining the last known value for each message key in a topic-partition. The `mincompactionlag` parameter provides a lower bound on how long each message remains prior to compaction and the `deleteretention` parameter provides a lower bound on how long a tombstone (a message with a null value) is retained. See the maprcli stream create on page 1758 and stream edit on page 1765 commands and Enabling Log Compaction on page 2765 for more information about these retention parameters.

Note: Log refers to the topic-partition pair. So when you are performing log compaction on the stream, you are compacting the stream and all the topic-partitions.

Log compaction is used for the following purposes:

- Application recovery time - Since log compaction retains the last known value, it is a full snapshot of the latest records. It is useful for restoring state after a crash or system failure.
- Storage space - This becomes noticeable when there is a high volume of messages.

Compaction Process

Log compaction is implemented by running a compaction process in the background that identifies duplicates, determines whether older messages exist, and purges older messages from the topic-partition.

The following diagram shows an initial message (published to a topic-partition) that is identified by the key-value pair, K1V1. When a subsequent message (K1V2) is published to the topic-partition, based on it's key-value pair, it is identified as a duplicate. The compactor then deletes the older message (K1V1) from the topic-partition.

Log compaction never re-orders messages, just deletes them. Any consumer reading from the start of the log sees at least the final state of all records in the order they were written. In addition, the offset for a message never changes.

Compaction and Gateways

The log compaction process uses a gateway that has an internal index and a compactor. The internal index tracks message key-value pairs. this allows duplicate messages in the topic-partition to be identified. Based on the identification of duplicate messages, the compactor runs the compaction process which purges the older message from the topic-partition. This process results in stream data being compacted.

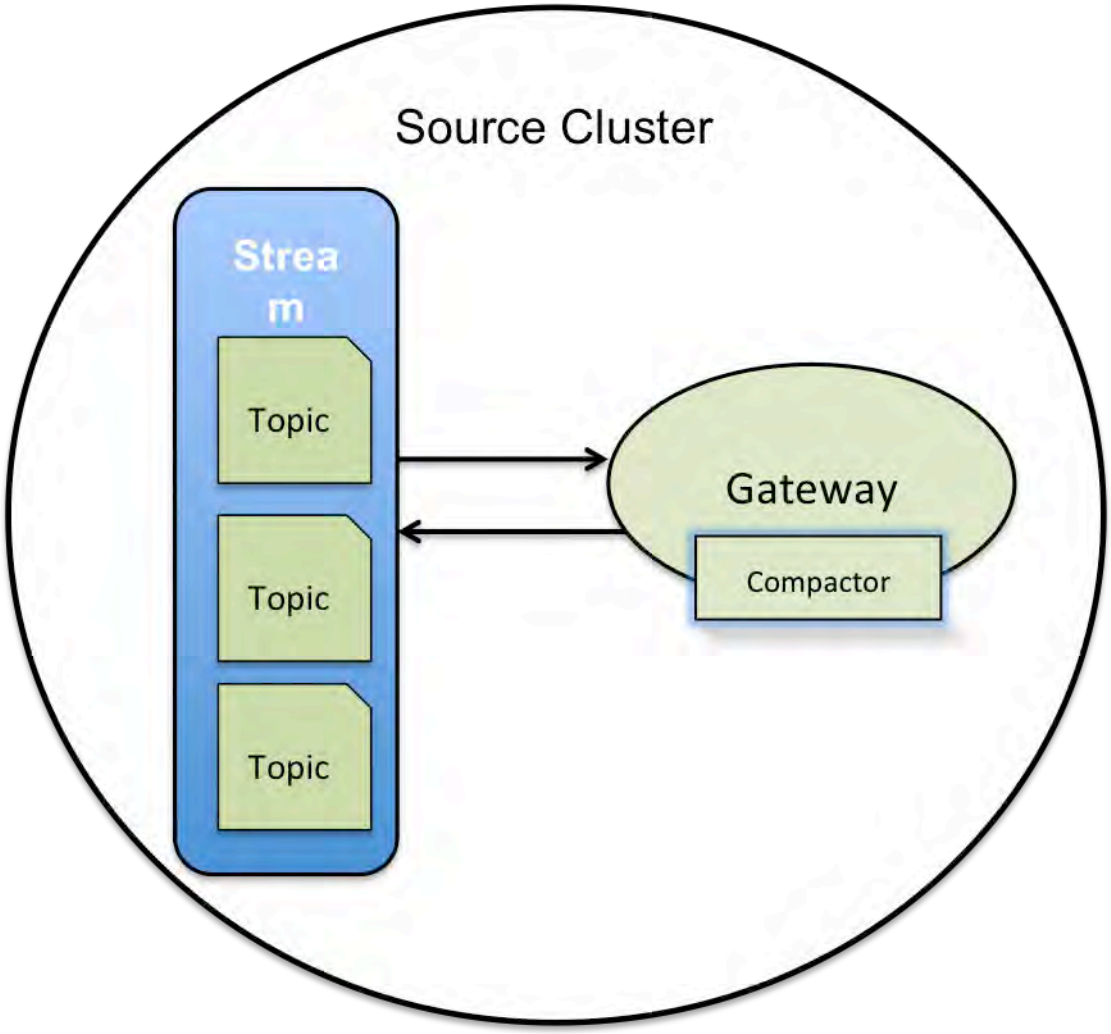

Figure 11: Log compaction with one gateway

The number of gateways impacts the compaction process, in that, increasing the number of gateways on the cluster improves the load distribution of the log compaction activity.

Important: Log compaction requires a gateway to be installed on the same cluster as the MapR stream. See Preparing Clusters for Log Compaction on page 1141 for more information about implementing gateways for this purpose. For example, if you are manually installing or upgrading, you must install a MapR gateway locally.

last-updated: Apr 11, 2022

Stream Replication

When a stream on a source cluster has both log compaction and replication enabled, the replica cluster does not automatically have log compaction enabled. You must explicitly enable log compaction on the replica cluster.

If a replica cluster has been upgraded and the stream data for a source cluster is compacted (that is, one or more messages have been deleted), then the source cluster replicates the compacted data to the replica cluster.

If a replica cluster has ***not*** been upgraded, the source cluster:

- Fails the replication.
- Automatically retries replication with an exponential backoff.
- Resumes replication when the replica cluster has been upgraded.

Note: The error message associated with the failed replication is displayed via the `maprcli stream replica status` command. This error requests that you upgrade the replica cluster.

Performance

Log compaction has a performance impact on other MapR Database and MapR Event Store For Apache Kafka applications running on the system. If log compaction is enabled on a very active stream (with more than 100K messages per second), all MapR Database and MapR Event Store For Apache Kafka applications running on the same cluster could see a drop in their performance (close to 2x).

Note: It is possible that the NODE_ALARM_TINY_BUCKET_FLUSH alarm may occur during high ingestion rates on source clusters with high topic-partition count. Under these circumstances, consider increasing the memory for MapR File System.

For More Information

See the following topics for more information:

- maprcli stream create on page 1758 and stream edit on page 1765
- Preparing Clusters for Log Compaction on page 1141
- MapR Event Store For Apache Kafka Java Applications on page 2754, MapR Event Store For Apache Kafka Java API Library on page 2756, and Enabling Log Compaction on page 2765

Producers

Producers are data-generating applications, such as sensors in automobiles or activity loggers in servers. Producers create messages with the collected data and publish the messages to MapR Event Store For Apache Kafka topics, specifically, to MapR Event Store For Apache Kafka topic-partitions.

Permissions

Before a producer can publish to topics, the user ID running the producer needs these permissions:

- The `writeAce` permission on the volume where the streams are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.
- The `produceperm` permission on the streams where the topics are located. Users with the `adminperm` permission on those streams can grant the `produceperm` permission.

Producing Messages

Producers create messages about the collected data and send the collected data to a MapR Event Store For Apache Kafka producer client library. In addition to the actual message, the producer specifies the topic that the message is intended for and an optional partition ID. The producer client buffers incoming messages and sends them (in batches) to the MapR Event Store For Apache Kafka server.

Note: In case of server failure, the producer client automatically continues to retry sending messages.

Attention: As of MapR 6.1, the MapR Event Store For Apache Kafka API enforces a maximum of 4096 partitions for a topic. That is, when you create an application with the API, the maximum number of partitions is 4096. If you previously created an application with MapR Event Store For Apache Kafka 6.0.1 API (or older) and you have upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in MapR 6.0.1 or earlier, you will be able to continue with the same number of partitions after upgrading.

Event-time Timestamp

As of MapR 6.0.1, MapR Event Store For Apache Kafka supports an event-time timestamp. The timestamp type can be either `createtime` (default) or `logappendtime`. See the `maprcli` stream create on page 1758 and stream edit on page 1765 for more information about these parameters.

Tip: Since each message is automatically published into a topic-partition with an event-time timestamp as part of the message record, this allows the Consumer application to seek records based on the timestamp.

Idempotent (exactly once) Producers

An "exactly-once" message delivery semantic produces messages without duplication. Each message is delivered once and only once. Exactly-once is insured by uniquely identifying a group of messages that are atomically persisted. Exactly-once message delivery is set with the producer idempotence option. See Modes of Publishing on page 645 for more information.

The following failure scenarios are addressed with idempotence:

- The stream processor might take input from multiple source topics and the ordering across these source topics is not deterministic across multiple runs. So if you re-run your stream processor that takes input from multiple source topics, it might produce different results.
- The stream processor might produce output to multiple destination topics. If the producer cannot do an atomic write across multiple topics, then the producer output can be incorrect if writes to some (but not all) partitions fail.
- The stream processor might aggregate or join data across multiple inputs. If one of the instances of the stream processor fails, then you need to be able to rollback the state materialized by that instance of the stream processor. On restarting the instance, you also need to be able to resume processing and recreate its state.
- The stream processor might look up enriching information in an external database or by calling out to a service that is updated out of band. By depending on an external service, the stream processor can be fundamentally non-deterministic. For example, if the external service changes its internal state between two runs of the stream processor, it can lead to incorrect results downstream.

For More Information

For more information about creating and editing streams or topics:

- See maprcli stream edit on page 1765 for information about editing streams.
- See maprcli stream info on page 1768 for information about streams.
- See maprcli stream topic create on page 1781 for information about creating topics.
- See maprcli stream topic edit on page 1784 for information about modifying topics.
- See maprcli stream topic info on page 1785 for information about topic data.

- MapR Event Store For Apache Kafka Java API
  - See the MapR Event Store For Apache Kafka Java API Library on page 2756 for the methods used to create and edit streams and to create and edit topics.

How Messages are Published
To publish a message, a producer sends a record to the producer client library, which batches the records before sending them to the server.

The producer client library sends the records to the server when any of the following conditions are met:

- The producer client library has batched enough messages to make an efficient remote procedure call (RPC) to the server.
- A message has been queued for the amount of time that is specified for the `streams.buffer.max.time.ms` configuration parameter.

  For the Java client, the default interval for flushes is 3000 milliseconds. For clients based on librdkafka (for example, C, Python, and C#), the default interval for flushes is 0 (zero) milliseconds.
- The producer client library has batched messages beyond the value of the `buffer.memory` configuration parameter.
- The application explicitly flushes messages.

> **Tip:** The default number of threads used for flushing messages is 64. In most cases, this number provides excellent performance. However, you can adjust this number by setting a value for the `fs.mapr.threads` parameter in the `core-site.xml` file on your client node.

Modes of Publishing
Describes different modes of publishing.

When publishing a message, a producer sends a record to the producer client library. The producer client library batches messages into multiple publish requests which are sent to the MapR Event Store For Apache Kafka server.

At Least Once

The default message delivery semantics is "at-least-one". At-least-once means that the message delivery guarantees that a message is published at least once to the MapR Event Store For Apache Kafka server. Messages are never lost but may be re-delivered.

Exactly Once

An "exactly once" message delivery semantics produces messages without duplication. Each message is delivered once and only once. Exactly once is insured by uniquely identifying a group of messages that are atomically persisted. Exactly once message delivery is set with the producer `idempotence` option.

Note: Exactly-once message deliver semantics is enabled by setting the producer configurable option, `enable.idempotence` to **true**. By supporting an idempotent producer, retries no longer introduce duplicates. See Enabling an Idempotent Producer on page 2766 for more information.

The following unique identifiers are associated with each message:

- Producer ID - A unique identifier is generated internally for each client and group of messages that are atomically persisted.

  As a minimum, the ID is a unique ID for a given stream-topic-partition. Producer IDs expire if a producer ID is inactive for a period of time. The default Producer ID expiration is 7 days. At that point, a new Producer ID is requested once the Producer ID is expired. To change the expiration date, see the `pidexpirysecs` parameter in `maprcli` stream create on page 1758 and stream edit on page 1765 for more information.

- Sequence Number - A number that is monotonically incremented on every produced group of messages for the given Producer ID, assigned when received, and generated internally.

Note: If the producer `idempotence` option, is not set to **true**, then "at least once" message delivery semantics applies.

If the client resends a message after the producer ID has expired, then `UnknownProducerIdException` is thrown.

For example:

- If message1 from clientA is sent to a stream-topic-partition0 and 7 days go by, the Producer ID expires.
- Then, if clientA sends another message that has the same data to the same stream-topic-partition (stream-topic-partition0), then `UnknownProducerIdException` is thrown because the Producer ID has expired..

Note: With the alternative "at least once" message delivery, in some failure scenarios, a message can be produced more than once for a single send call. Common reasons for message duplication include network error or server failure. For example, if a network error occurs and the message has been processed and persisted by the server, if the client re-tries sending a message to a server node, then the result could be duplicate messages in the system.

Server Acknowledgements

By default, publishing requests for messages are sent without waiting for acknowledgement (ack) from the MapR Event Store For Apache Kafka server.

The acknowledgement behavior is determined by the producer configuration parameter `streams.parallel.flushers.per.partition`, which defaults to **true**.

With an "at-least-once" message delivery, in some failure scenarios, a message can be produced more than once for a single send call. A common reason for message duplication is when a network error occurs, a client may retry sending a message to a server node. If the network error occurs after the message is processed and persisted by the server, it can lead to duplicate messages in the system.

Publishing without Ack	When publishing without ack (default), it is possible for messages to be published to the partitions out of order due to the presence of multiple network interface controllers, network errors, or retries. For example, suppose a producer is sending messages that are specifically for Partition 1. The producer client library buffers the messages and sends a batch to Partition 1. Meanwhile, the producer keeps sending messages for Partition 1 and the client

	continues to buffer them. The next time the producer client library has enough messages for Partition 1, the client sends another batch, irresepctive of whether or notMapR Event Store For Apache Kafka server has acknowledged the previous batch.
Publishing with Ack	If you always want messages to arrive to partitions in the order in which they were sent, set the configuration parameter `streams.parallel.flushers.per.partition` to **false**. This causes the producer client library to wait for ack (acknowledgements) from the MapR Event Store For Apache Kafka server before sending subsequent publish requests.

How Partitions are Chosen for Messages

Since the number of partitions in a topic can change over time, producers regularly refresh the information that they have about the topics that they know. This refresh interval is controlled by the `metadata.max.age.ms` configuration parameter.

Partitions of a topic are identified by their index number. For example, if a topic has four partitions, their IDs are 0, 1, 2, and 3.

Partitions are chosen for a message in the following ways:

- If the producer specifies a partition ID or if the StreamsPartitioner interface specifies one, the MapR Event Store For Apache Kafka server publishes the message to the partition specified.
- If the producer does not specify a partition ID but provides a key, the MapR Event Store For Apache Kafka server hashes the key and sends the message to the partition that corresponds to the hash.
- If neither a partition ID nor a key is specified, the MapR Event Store For Apache Kafka server randomly chooses an initial partition and sends messages in a sticky round robin fashion. .

  For example, suppose that for topic `traffic_sensors`, the server chooses Partition 1. The server then accumulates enough messages for an RPC of optimal size and sends the batch of messages to Partition 1. The server then does the same with Partition 2, and so on, eventually returning to Partition 1.

Consumers

Consumers are applications that you create such as analytics applications, reporting tools, or enterprise dashboards.

Consumers use the MapR Event Store For Apache Kafka APIs to request messages from the topics in which they are interested. If the server fails, consumer clients automatically retry requests continuously. A consumer client library sends unread messages, from which consumers extract data.

Consumers can run as separate processes on a single machine and as processes on different machines.

Before a consumer can read messages from topics, the user ID running the consumer needs these permissions:

- The `readAce` permission on the volume where the streams are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1459.
- The `consumeperm` permission on the streams where the topics are located. Users with the `adminperm` permission on those streams can grant the `consumeperm` permission.

Subscriptions

Consumers subscribe to topics. When a consumer subscribes to a topic or partition, it means that the consumer wants to receive messages from that topic or partition. For example, an analytics application might subscribe to the topics `rfids_productA`, `rfids_productB`, and more to track movement of products from factories to distribution centers. A reporting tool might subscribe to the topics `meters_NW`, `meters_SW`, and more to get a report of electricity usage in different geographic regions that a power company services.

A subscription is the list of the topics to which a consumer is subscribed.

Consumer Subscriptions

Consumers subscribe to topics. When a consumer subscribes to a topic or partition, it means that the consumer wants to receive messages from that topic or partition. A subscription is the list of the topics, specific partitions, or both to which a consumer is subscribed.

For example, an analytics application might subscribe to the topics `rfids_productA`, `rfids_productB`, and more to track movement of products from factories to distribution centers. A reporting tool might subscribe to the topics `meters_NW`, `meters_SW`, and more to get a report of electricity usage in different geographic regions that a power company services.

Consumers can subscribe to:

Topics

When a consumer subscribes to a topic, it reads messages from all of the partitions that are in the topic. The exception is when a consumer is part of a consumer group. Consumer groups and this exception are explained in Consumer Groups.

Consumers can subscribe to topics in two ways:

By name

Consumers specify the names of the topics to which they subscribe.

By regular expression

Consumers specify a regular expression and subscribe to all topics with names that match the regular expression.

The ability to use regular expressions is helpful when the `-autocreate` parameter for a stream is set to `true` and producers are allowed to create topics automatically at runtime.

To unsubscribe from topics to which you are subscribed with regular expressions, you must use the same regular expressions.

For example, suppose that you use this regular expression to subscribe to `topic0` and `topic1`:

```
topic[0-1]
```

last-updated: Apr 11, 2022

Next, you add `topic2`, `topic3`, and `topic4` to the subscription, as follows:

```
topic[0-4]
```

Trying subsequently to unsubscribe from, say, `topic0` has no effect. The consumer remains subscribed to it because `topic0` was subscribed to as part of a regular expression.

Trying to unsubscribe from `topic[0-1]` also has no effect because the regular expression `topic[0-4]` was used after `topic[0-1]`, and the latter is a superset of the former.

To unsubscribe from `topic0`, you have to follow these steps:

1. Unsubscribe from `topic[0-4]`. This step unsubscribes you from `topic2`, `topic3`, and `topic4`. You must follow this step because a) this regular expression was used last, and b) because it is a superset of `topic[0-1]`. The order in which regular expressions are used in subscriptions matters. If you were to unsubscribe from `topic[0-1]` first, you would still be subscribed to `topic[0-4]`.
2. Unsubscribe from `topic[0-1]`. This step unsubscribes you from `topic0` and `topic1`.

Partitions

Consumers can subscribe to individual partitions within topics. This is helpful when you want a consumer to read the messages published to a specific partition. For example, a producer might

publish messages for high-priority data to a specific partition for processing by a dedicated consumer.

When a consumer subscribes to individual partitions within a topic, the consumer does not receive messages from any of the other partitions in the topic.

Subscriptions to individual partitions can cause problems in consumer groups, as explained in the section Consumer Groups.

Consuming Messages
Describes the process by which consumers consume messages.

Consumers request the MapR Event Store For Apache Kafka consumer client library to check whether any new messages have been published in the topics or partitions to which they are subscribed, or the partitions that they are assigned. Consumers can do this at any time.

If a minimum number of bytes worth of messages is waiting across a consumer's subscription, MapR Event Store For Apache Kafka sends those messages to the consumer, up to a maximum number of bytes. You can configure this minimum and maximum in the configuration parameters for each consumer.

The MapR Event Store For Apache Kafka consumer client library sends the consumer messages that have been published by producers but not yet flushed to disk. If a consumer is able to consume data at the rate at which a producer publishes messages, the consumer client library continuously sends messages to consumers from its memory, increasing the speed of throughput from producer to consumer.

Time-based Consumption

As of MapR 6.0.1, MapR Event Store For Apache Kafka supports the consumption of messages based on the message's timestamp. When a consumer wants to search for messages based on a timestamp, the consumer provides the topic-partition and the timestamp, and then, MapR Event Store For Apache Kafka locates the message and returns the offset for that message. The returned message offset corresponds to the *earliest* message in a topic-partition whose timestamp is *equal to* or *greater than* (>=) the consumer-provided timestamp.

For example, with the following topic-partition, if your consumer-provided timestamp is 1522195205, then **offset 1** would be returned because it is the *earliest* message with a timestamp that is greater than or equal to the consumer-provided timestamp. In this case, greater than (>).

```
topic:partition0
        offset 0: 152219500
        offset 1: 152219510
        offset 2: 152219505
        offset 3: 152219515
```

> **Tip:** The consumer-provided timestamp and the returned message offset is in seconds since a Epoch Unix timestamp is used. In this example, the consumer-provided timestamp is March 26th, 2018 @ 12:00:05am and the message offsets are timestamped March 28th @ 12:00:00, 12:00:010, 12:00:05, and 12:00:15 in that order.

Resources

For information about MapR Event Store For Apache Kafka streams or topics, see:

- maprcli stream info on page 1768 for information about stream data.
- maprcli stream topic info on page 1785 for information about topic data.

Consumer Groups
Group consumers together by setting the same value for the `group.id` configuration parameter when you start each consumer.

For example, if you create three consumers and give each of them the group ID `clickstream_consumers`, together these consumers form the consumer group `clickstream_consumers`. MapR Event Store For Apache Kafka does not generate IDs for consumer groups. You can create IDs that make sense for your purposes. You specify the group ID by using the `group.id` configuration parameter when you create a consumer. IDs are strings that can be up to 2457 bytes long.

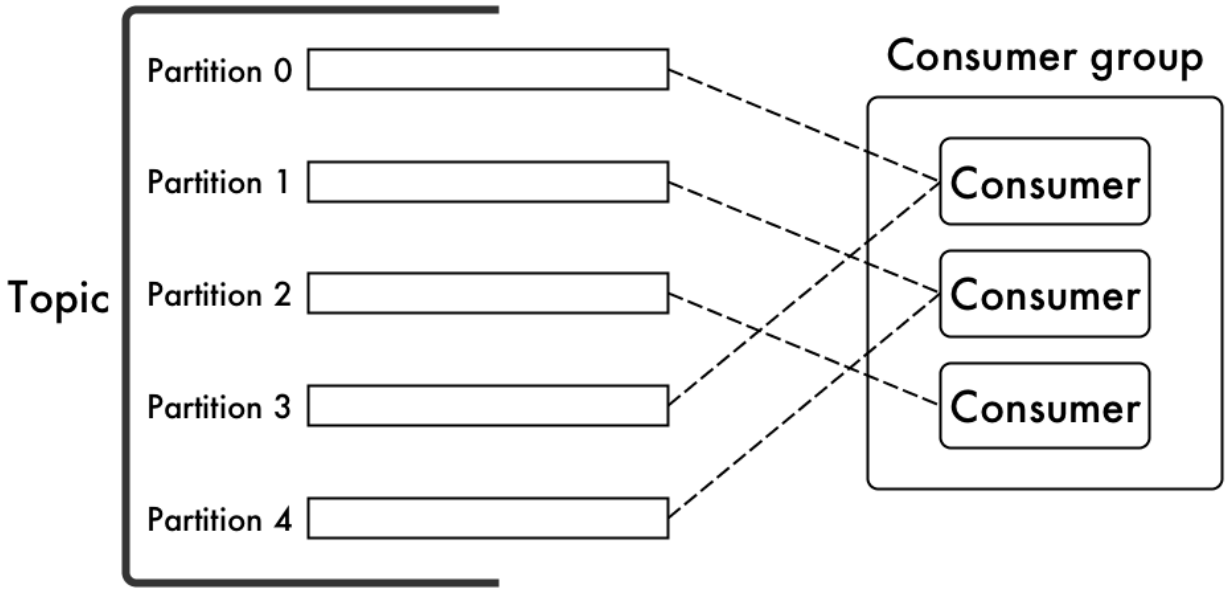
You can even create a consumer group that consists of only one consumer. In such a case, the unique ID that identifies the group would be shared with no other consumers.

The following are the benefits to creating consumer groups:

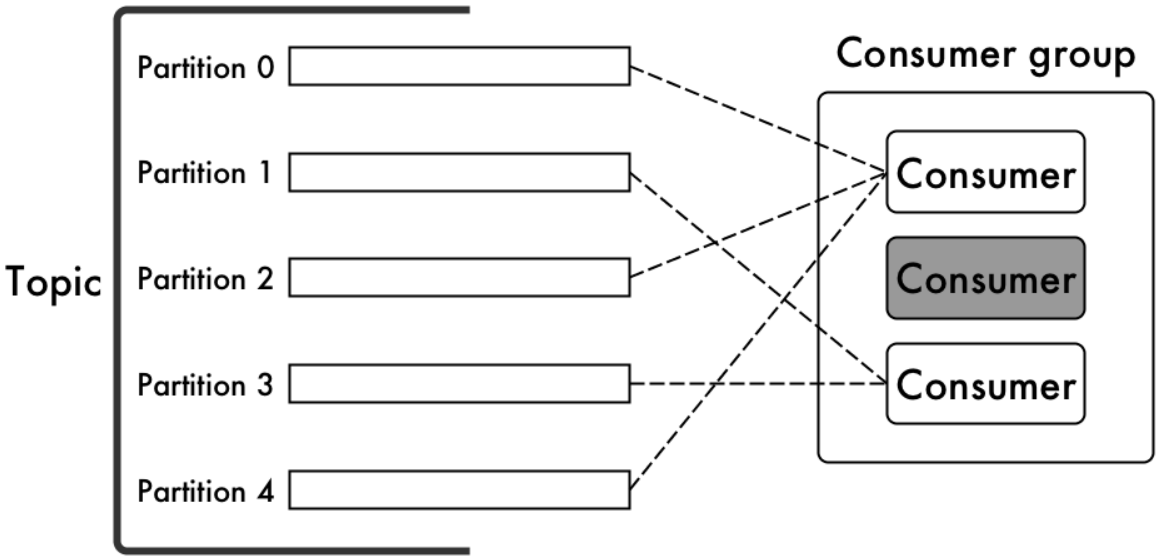
Parallelism when Consuming Messages
For parallelism when reading messages from topics, you can create consumer groups. These groups consist of consumers that are associated with an ID that you set for each of the participating consumers with the `group.id` configuration parameter. The partitions in each topic to which all of the consumers are subscribed, are assigned dynamically to the consumers in round-robin fashion.

These groups consist of consumers that are associated with an ID that you set for each of the participating consumers with the `group.id` configuration parameter. The partitions in each topic to which all of the consumers are subscribed, are assigned dynamically to the consumers in round-robin fashion.

For example, suppose that there are three consumers in a group and each consumer is subscribed to the same topic. There are five partitions in the topic. MapR Event Store For Apache Kafka assigns each partition to a consumer, with two consumers both being assigned two partitions.



If one of the consumers goes offline, the partitions are reassigned dynamically among the remaining consumers in the group.



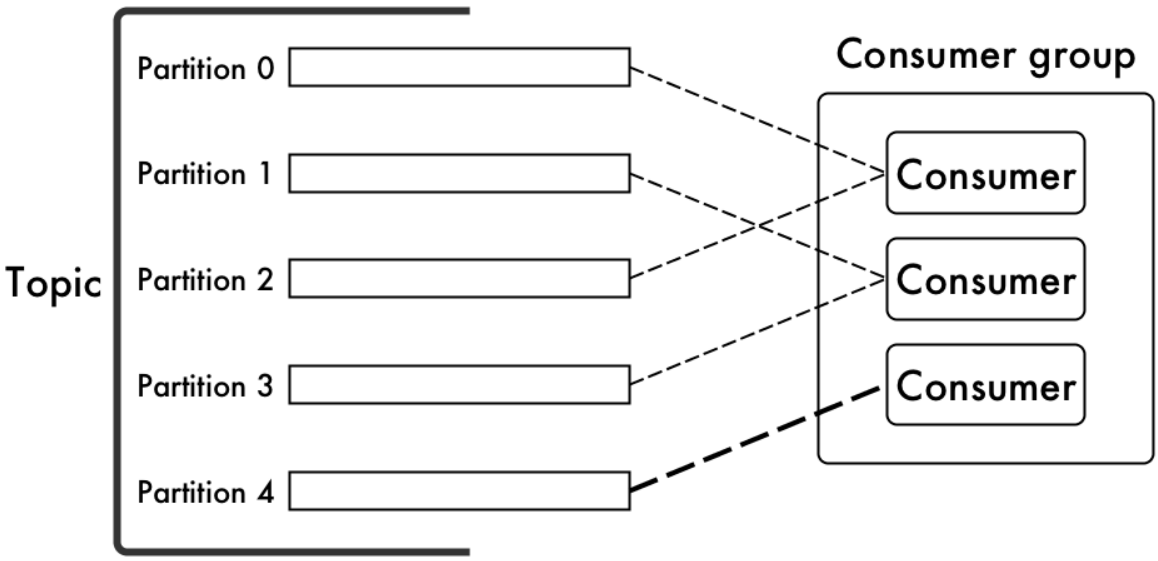
If the offline consumer comes back online or a different consumer is added to the group, again the partitions are redistributed among the consumers in the group.

This parallelism and dynamic reassignment is possible only when none of the consumers in a consumer group subscribe to individual partitions.

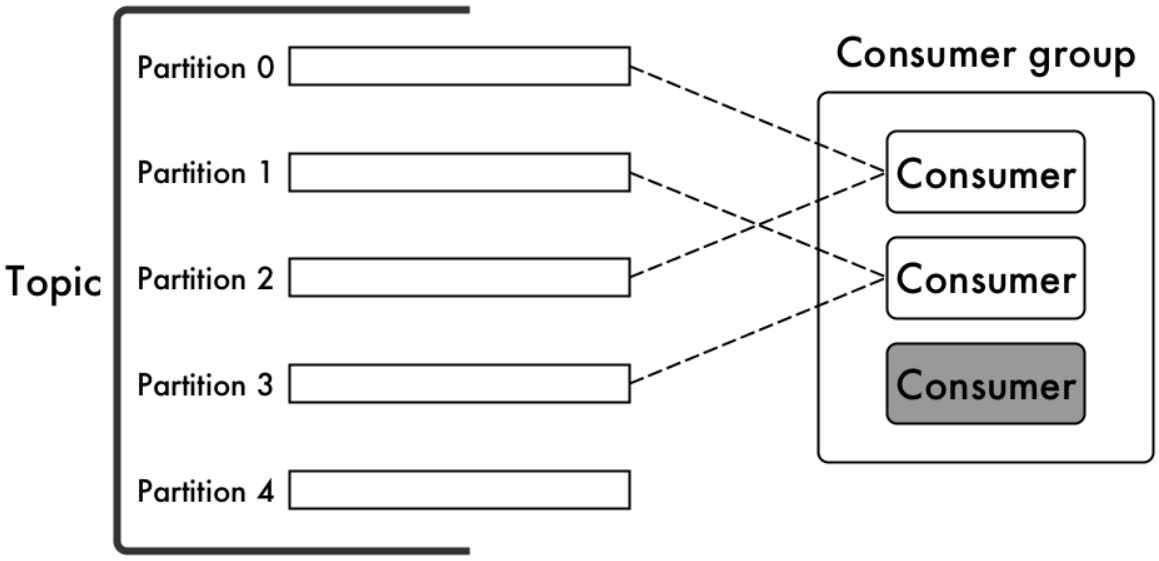
For example, suppose that from three consumers in a consumer group:

- Two subscribe to the same topic.
- One subscribes to a single partition within that topic.

If the topic has five partitions, MapR Event Store For Apache Kafka assigns four of them via round robin to two of the consumers. Only the remaining partition is read from the third consumer.



If that third consumer fails, MapR Event Store For Apache Kafka does not reassign its partition to either of the other consumers.

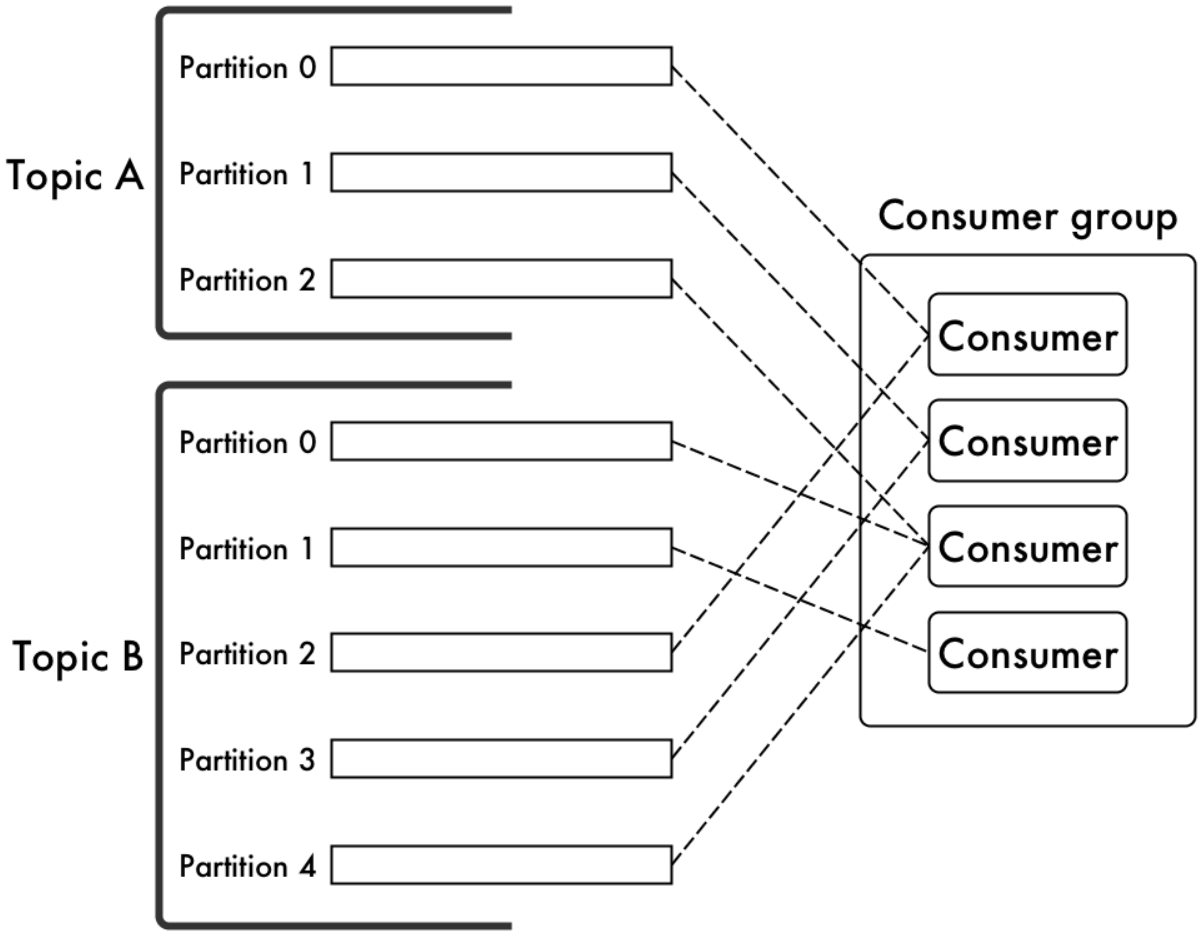


Now that you understand how partitions are assigned when the number of partitions is equal to or greater than the number of consumers in a consumer group, you might be wondering what happens if the number of partitions in a topic is less than the number of consumers in a consumer group. The answer is simply that one or more consumers in the consumer group will not be assigned any partitions from the topic.

That does not necessarily mean those consumers will be idle. There could be other topics to which the consumer group is subscribed, and those consumers could be assigned partitions from those other topics.

For example, in this diagram there is a consumer group with four consumers. Topic A has only three partitions, and those are assigned to the first three consumers shown in the group. However, the fourth consumer is not idle. The consumer group also subscribes to Topic B, which has more partitions than there are consumers. Each of the consumers in the group is assigned at least one partition from Topic B.

last-updated: Apr 11, 2022



Moreover, if a consumer that is assigned a partition from Topic A happens to fail, its partition will be reassigned to the fourth consumer.

Saving Cursor Position
The MapR Event Store For Apache Kafka server uses cursors to keep track of the messages that consumers in consumer groups have read.

There is one cursor per partition per consumer group. There are two kinds of cursors: read cursors and committed cursors.

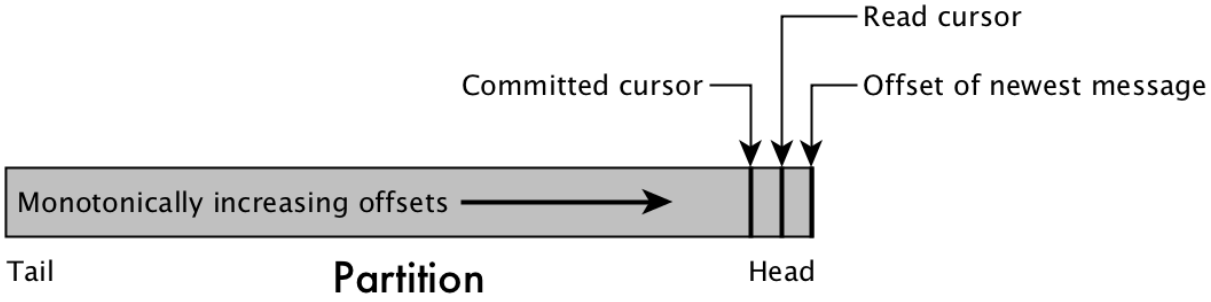


Figure 12: A topic partition and the cursors of a consumer group

A consumer's read cursor is the offset of the most recent message that MapR Event Store For Apache Kafka has sent to a consumer from a partition.

Consumers that are part of a consumer group can save the current position of their read cursor. Consumers can do this either automatically or manually. The saved cursor is called a committed cursor because it indicates that the consumer has processed all messages in a partition up to and including the one with this offset.

There are two benefits to committing cursors:

Failover on consumer failure	One benefit is that if a consumer fails and MapR Event Store For Apache Kafka reassigns the consumer's partitions to other consumers in a group, those consumers can start reading from the next offset after the committed cursor in each of those partitions.
Failover on cluster failure	When you backup a stream by replicating it to another cluster, committed cursors are also replicated. If the main cluster fails, consumers that are redirected to the standby copy of a stream can start reading from the next offset after committed cursors.
Read cursors	A consumer's read cursor is the offset of the most recent message that MapR Event Store For Apache Kafka has sent to a consumer from a partition.
Committed cursors	Consumers that are part of a consumer group can save the current position of their read cursor. Consumers can do this either automatically or manually. The saved cursor is called a committed cursor because it indicates that the consumer has processed all messages in a partition up to and including the one with this offset.

How often a consumer should commit depends on how much read duplication you are willing to tolerate. The more often a consumer commits, the less read duplication with which the consumer must contend.

The length of time since the failed consumer last committed determines (together with the rate at which messages are published to its partitions) how many messages are read a second time. For example, suppose that the auto-commit interval is five seconds. A consumer saves its commit cursor and then fails after three seconds. During those three seconds, the consumer's read cursor has continued to move through the messages. When its partitions are reassigned to other consumers in the group, those consumers will read three seconds of messages that the failed consumer already read.

There are two ways of committing cursors:

Automatic commits	The MapR Event Store For Apache Kafka server commits the cursors for a consumer that is in a consumer group based on the value of the `enable.auto.commit` configuration parameter. Set this parameter to `true` to enable auto-commit. The default value is `true`. The `auto.commit.interval.ms` configuration parameter determines the frequency of the commits in milliseconds. The default is value is 1000.
Manual commits	The Java API provides a method of committing cursors manually.

Consumer Failure and Recovery

When a consumer that is not associated with a consumer-group ID recovers from failure and comes back online, it can either start reading its partitions from the earliest offsets or from the latest offset. This choice is determined by the `auto.offset.reset` configuration parameter.

last-updated: Apr 11, 2022

If the consumer reads from the earliest offset in a partition, which is the offset of the message that has been in the partition longest without being deleted because of the expiration of the time-to-live interval for the stream, it might re-read a large number of messages before reading messages that were published after it failed.

If the consumer reads from the latest offset in a partition, which is the offset of the most current message at the time the consumer requests new messages from MapR Event Store For Apache Kafka, the consumer starts off up-to-date, but skips over the messages between its time of failure and the current time.

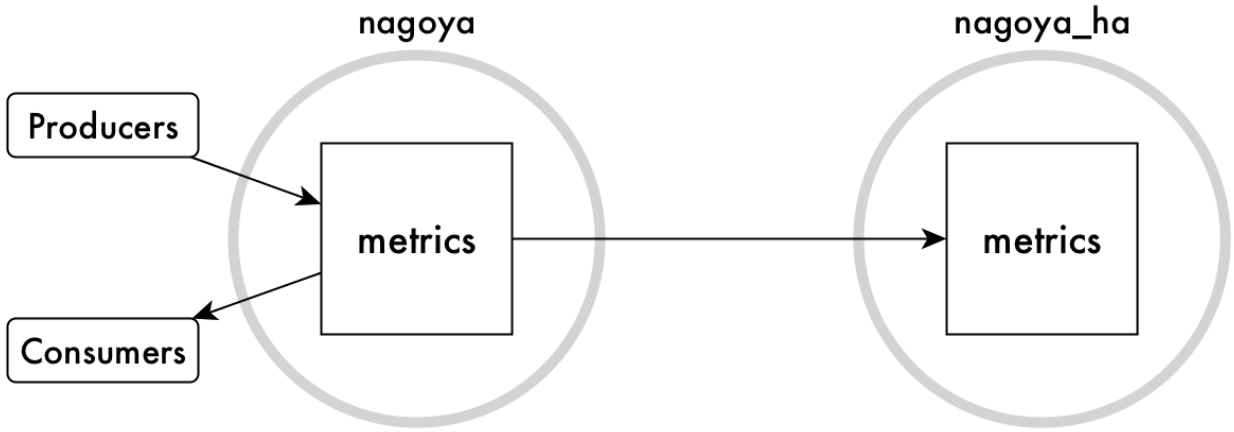
Stream Replication

You can replicate streams to other MapR clusters worldwide, or to other streams within a MapR cluster.

There are many scenarios in which replicating MapR Event Store For Apache Kafka streams can be useful.

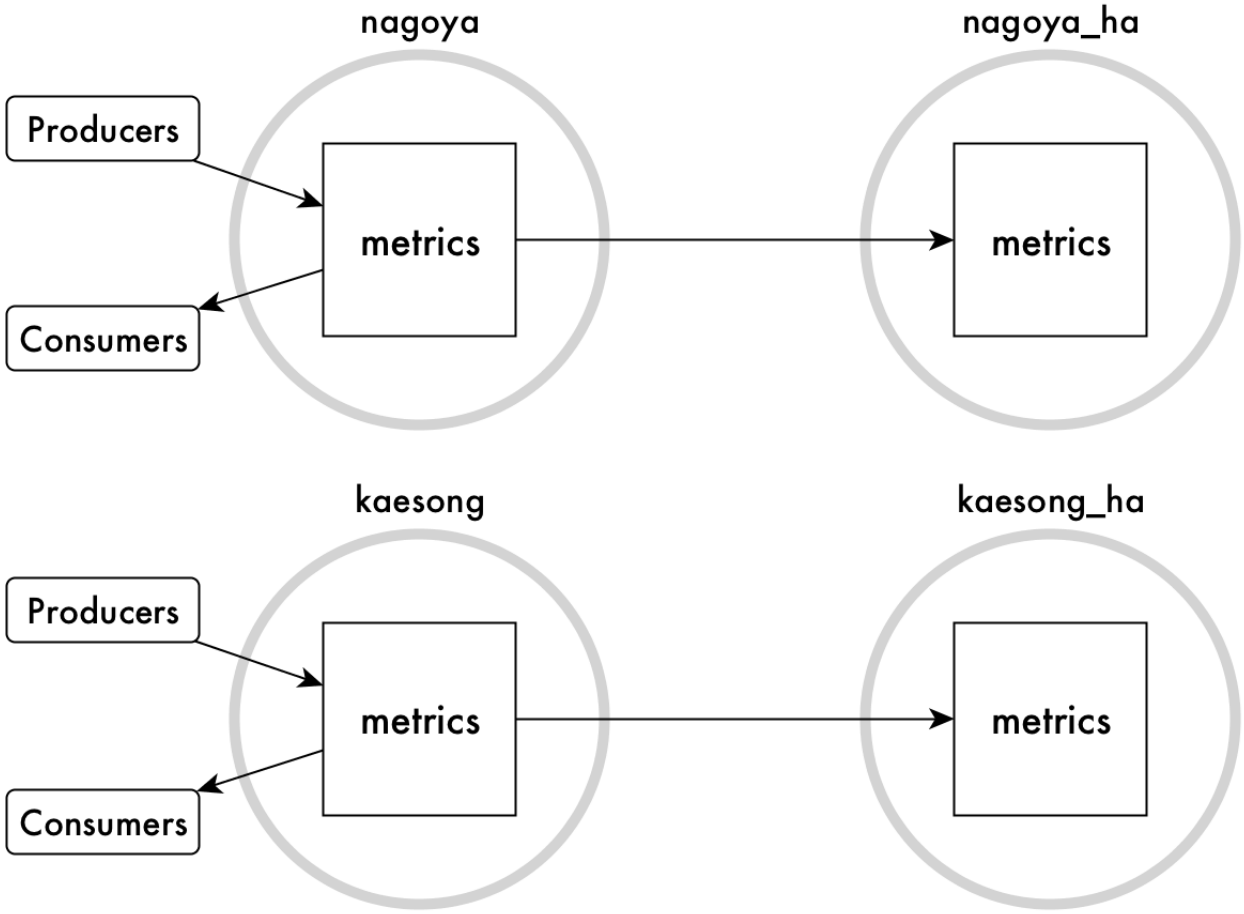
Basic Primary-Secondary Replication

For example, suppose that your company has a factory in Nagoya, and sensors in the equipment track different metrics. The sensors are producers publishing messages to a stream named `metrics`. The applications that use the collected metrics would read the messages from the stream, playing the role of consumers. With replication, the factory could create a stream in the `nagoya` cluster and maintain a backup of the stream in the `nagoya_ha` cluster.



This type of replication is called *basic primary-secondary replication* because replication is in one direction only. The metrics stream in the `nagoya_ha` cluster is considered to be a *replica*. The original metrics stream is considered to be the *upstream source* for the replica. This type of replication is simple to set up with the command `maprcli stream replica autosetup`.

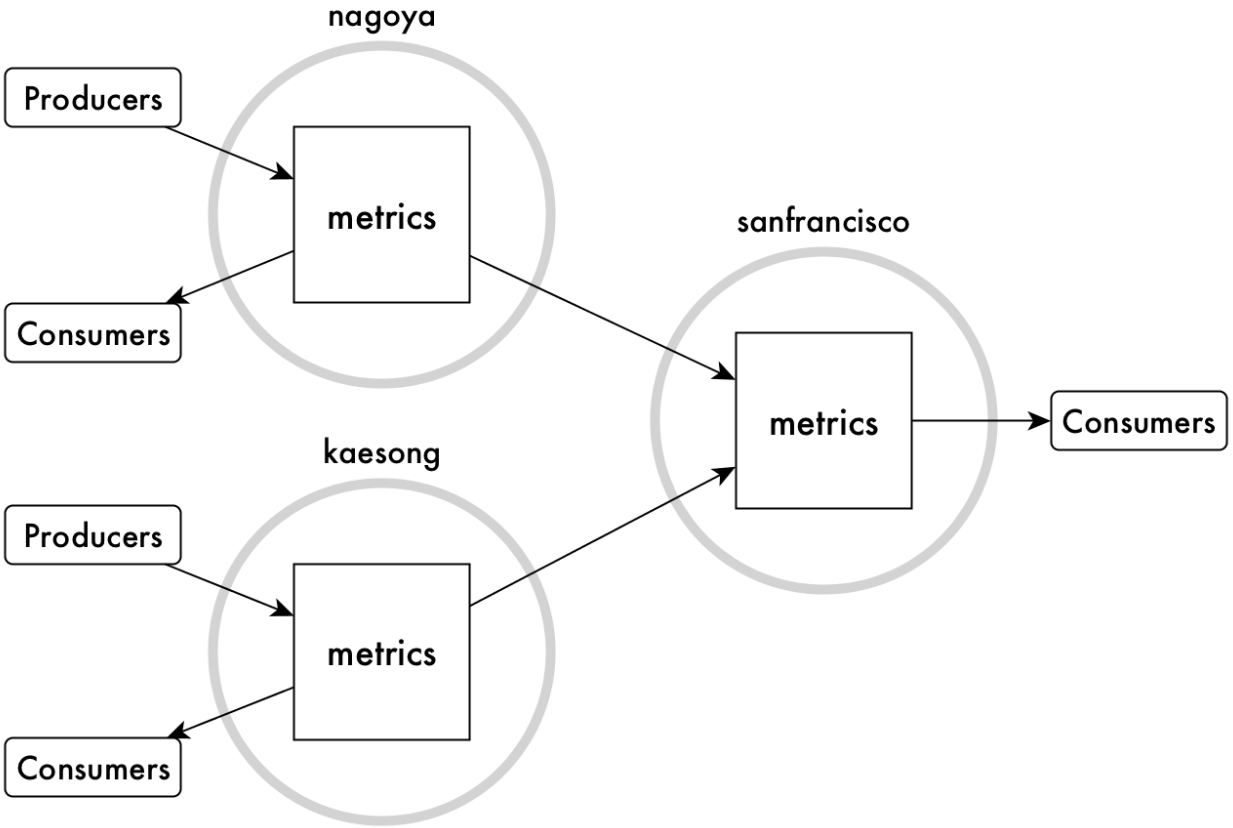
Suppose further that your company also has a factory in Kaesong that collects metrics from its equipment, analyzes the data, and replicates its own `metrics` streams to a backup.



Many-to-One Replication

Your company's headquarters are in San Francisco and you want data analysts there to analyze all data company-wide. You can replicate the two `metrics` streams that are in the your factories to the `metrics` stream in the `sanfrancisco` cluster. In this scenario, the replica is the `metrics` stream in the `sanfrancisco` cluster. This replica has two upstream sources: the `metrics` streams that are replicated from the two factories.

last-updated: Apr 11, 2022

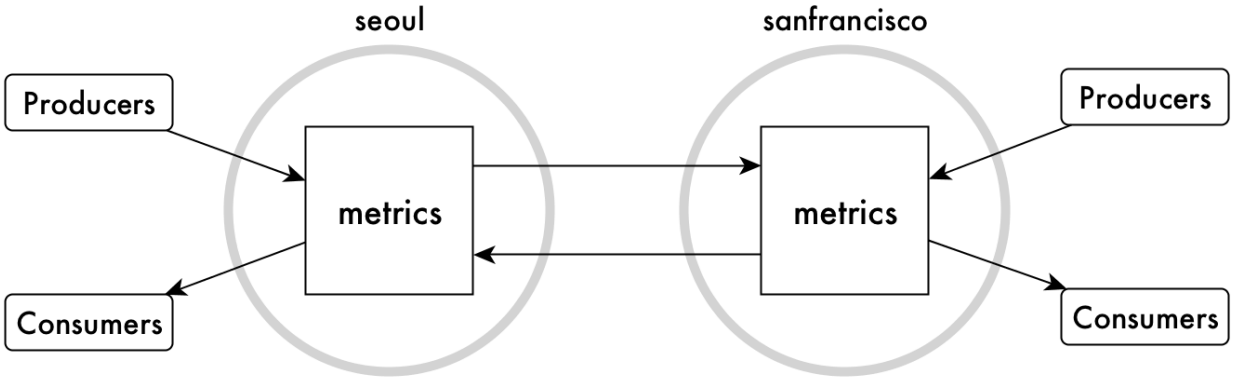


This type of replication, called *many-to-one replication*, requires that the topics in each stream have unique names, so that message offsets do not conflict. For example, suppose both factories have an assembly line named Line 2 and the topic in each factory's stream for collecting metrics from this line is named `line_2`. At some point, the Nagoya factory and the Kaesong factory both replicate messages that use the same offsets. Since offsets are replicated together with messages, messages can be overwritten in this case.

To avoid this type of problem, the sensors for Line 2 in the Nagoya factory might publish to a topic named `line_2_nagoya`, the sensors for Line 2 in the Kaesong factory might publish to a topic named `line_2_kaesong`, and so on. The consolidated stream in San Francisco would contain the topics `line_2_nagoya` and `line_2_kaesong`.

Multi-Master Replication

Another kind of of replication that can be useful is *multi-master replication*. You can use it when you need two streams, both to send updates to and receive updates from the other stream. Each stream is a replica and an upstream source. MapR Event Store For Apache Kafka keeps both streams synchronized with each other. This type of replication is also simple to set up with the command `maprcli stream replica autosetup`.



As with many-to-one replication, the names of the topics in each stream must be unique across both streams, so that offsets for messages do not conflict.

Updates are applied to replica streams by MapR gateways. See Gateways and Stream Replication on page 662 for more information.

Modes of Stream Replication
You can replicate streams in one of two replication modes. You specify the mode per source-replica pair.

Asynchronous replication

In this replication mode, MapR Event Store For Apache Kafka confirms to producers that messages are published after the messages are placed in partitions. Messages are replicated in the background. Therefore, the latency of message publishing is not affected by the time required for the network round trip between the source cluster and the destination cluster.

This type of replication is well-suited for clusters that are geographically separated in wide-area networks.

Asynchronous replication is the default replication mode.

Synchronous replication

In this replication mode, MapR Event Store For Apache Kafka confirms to producers that messages have been placed in partitions only after the messages are sent to a gateway in the destination cluster.

Due to the confirmations that MapR Event Store For Apache Kafka receives on source clusters, synchronous replication is especially well-suited for creating a backup of your data for disaster recovery.

When the latency of a replication stream is high, MapR Event Store For Apache Kafka switches to asynchronous replication temporarily so that producers are not blocked indefinitely. After the latency is sufficiently reduced, MapR Event Store For Apache Kafka switches back to synchronous replication.

The same switching from synchronous to asynchronous replication occurs if all gateways fail. MapR Event Store For Apache Kafka does not resume synchronous replication until a new gateway is established or at least one of the failed gateways is restarted.

Replica Autosetup for Streams
The option to automatically set up stream replication, also known as replica autosetup, performs the steps to set up and start the replication of streams. The replica autosetup option is available through the Control System and the CLI.

In general, replica autosetup performs the following steps to set up replication:

1. Creates a stream in the destination cluster.
2. Declares the new stream to be a replica of the source stream and ensures that replication does not begin immediately after the next step.

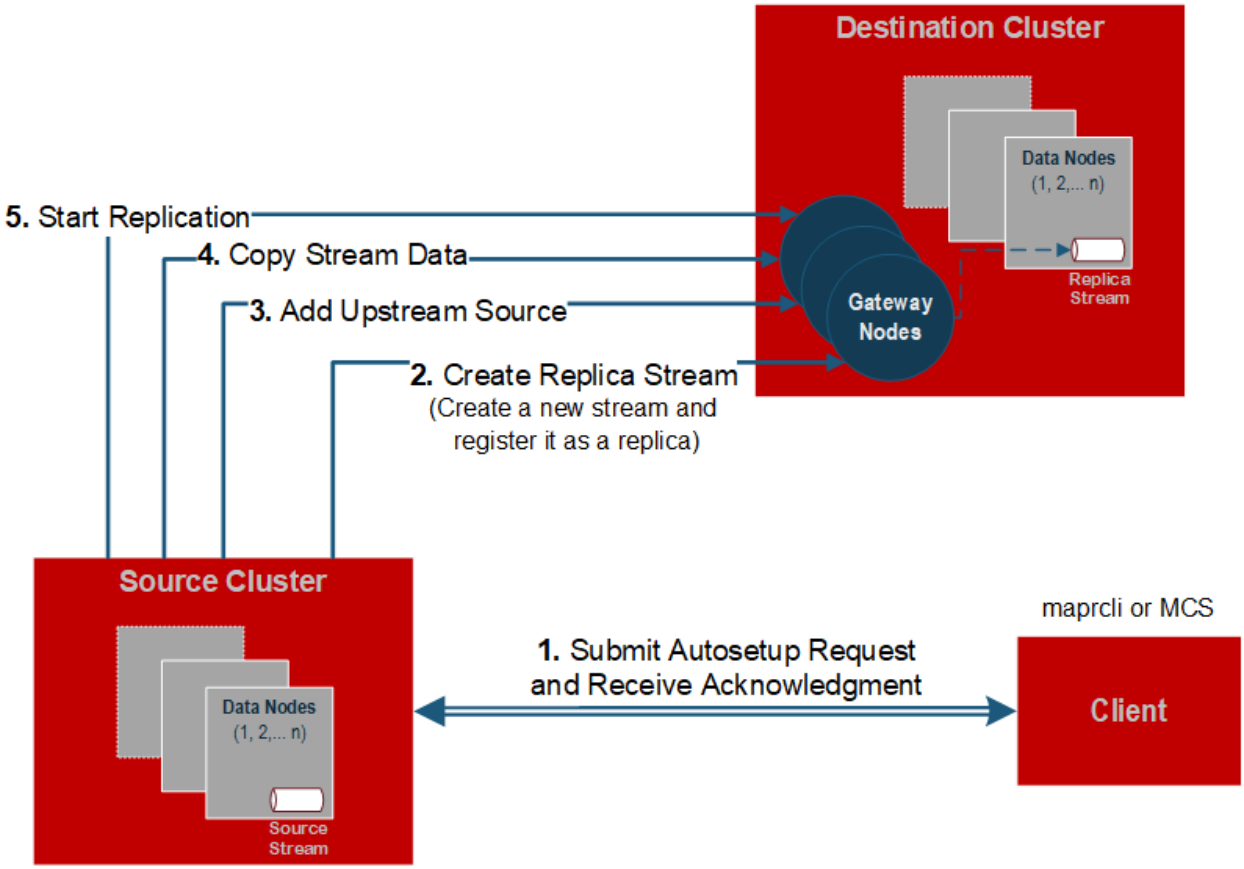
3. Declares the source stream as the original of the replica stream.
4. Loads a copy of the source stream into the replica.
5. For multi-master replication, replica autosetup declares the source stream to be a replica of the new stream and then declares the new stream to be an upstream source for the source stream.
6. Clears the paused replication state to start replication.

By default, replica autosetup uses the directcopy option. However, based on how you run replica autosetup, you also have the option not to use directcopy.

Replica Autosetup with Directcopy (default)

The directcopy option uses gateways to perform all setup operations including the initial population of data into the replica stream. Directcopy is the default option when you setup stream replication using the Control System or with the `maprcli stream replica autosetup` command.

When a client submits a request to automatically setup stream replication to the cluster, the source cluster acknowledges the request and begins to track the replica autosetup request from start to finish.



If a failure occurs when replica autosetup operations are in progress, the source cluster resumes operations from the point of failure.

Note: To check the replication status of a stream, run the `stream replica list` on page 1775 command. To stop the automatic setup of stream replication, run `stream replica remove` on page 1778, or delete the source or replica stream.

Replica autosetup with directcopy provides the following benefits:

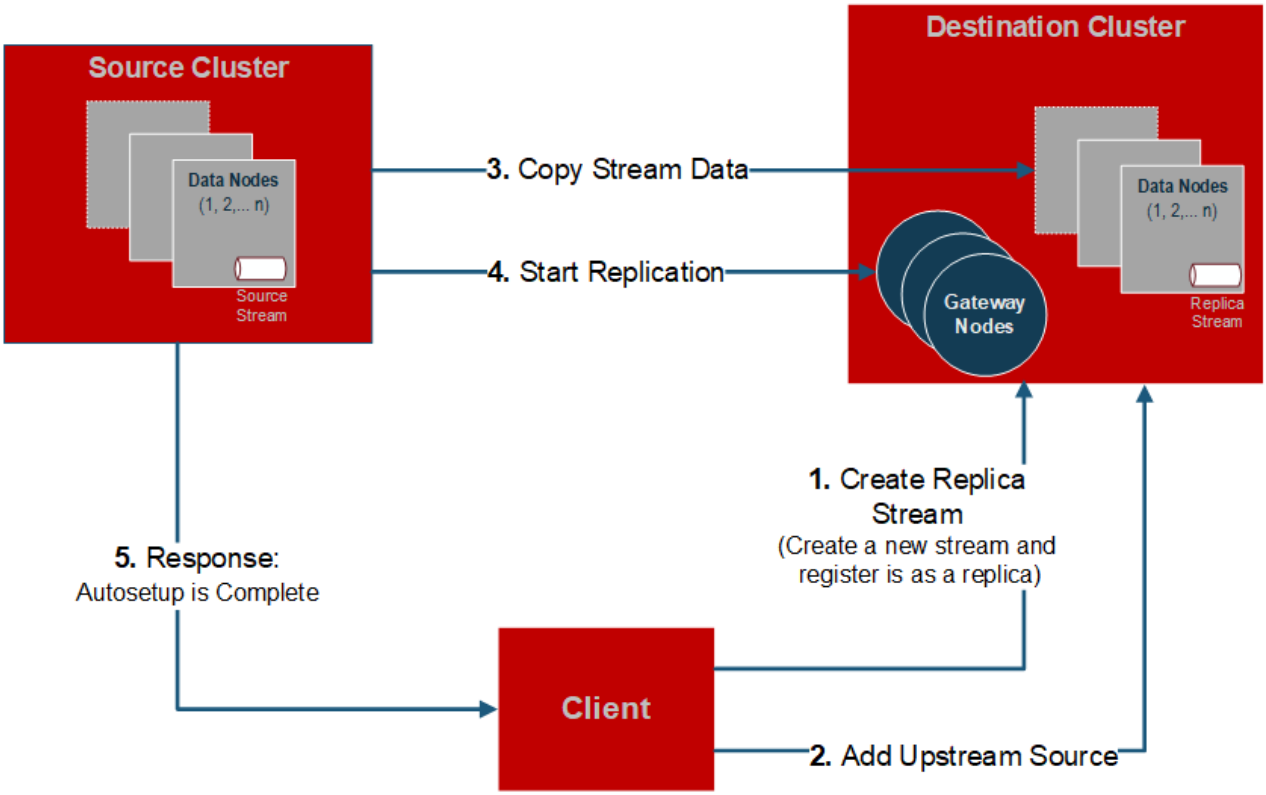
last-updated: Apr 11, 2022

- **Replica autosetup operations do not block the client from submitting additional requests.** When setting up stream replication, the process to copy source data to the replica can be time consuming. The client does not need to wait for the replica autosetup request to complete before submitting another request.
- **Source cluster retries replica autosetup operations in case of failure.** The source cluster keeps track of the replica autosetup progress. This allows the source cluster to resume autosetup operations in the event of an intermittent failure. If you choose to not use directcopy, user intervention is required if a failure occurs.
- **Throttling of copy table operations is done by default.** Throttling prevents the initial copy of data from the source to the replica stream from consuming all cluster resources.

Replica Autosetup without Directcopy (not default)

Without the directcopy option, replica autosetup submits a majority of the replication setup requests through the client and then runs the `mapr copystream` utility to populate the initial table data. To use replica autosetup without the directcopy option, run `maprcli stream replica autosetup` command with the `-directcopy` parameter set to `false`.

Without the directcopy option, once a client submits a replica autosetup request to the cluster, it must wait until the source cluster sends a notification that the autosetup request is complete, before it can submit another request to the cluster. In this case, replica autosetup uses the client connection to submit autosetup operation requests such as create replica, add replica, and add upstream source. Then, to populate the initial table data, it runs `mapr copystream`.



If a failure occurs when replica autosetup operations are in progress, the client hangs and any replica streams that were created during the failed autosetup operations must be manually deleted before you can try to setup replication again.

last-updated: Apr 11, 2022

States of Stream Replication

The replication state indicates when stream replication is in progress and it also displays the status of operations related to replica autosetup with directcopy. The `maprcli stream replica list` command displays the following replication states.

State	Description
REPLICA_STATE_WAIT_TILL_BULKLOAD	Replica autosetup with directcopy has not started because bulkload is in progress on the source table.
REPLICA_STATE_CREATE_SCHEDULE	Replica autosetup with directcopy had scheduled the creation of the replica table.
REPLICA_STATE_COPY_SCHEDULE	Replica autosetup with directcopy has not started the initial copying of source data to the replica because it is waiting for other in-progress copy operations to complete.
REPLICA_STATE_COPY_IN_RECOVER	Replica autosetup with directcopy is resuming the copy of source data to the replica after a connection failure.
REPLICA_STATE_COPY_IN_PROGRESS	Replica autosetup with directcopy is copying the source data to the replica.
REPLICA_STATE_DELETING_CURSORS	Replica autosetup with directcopy is deleting progress cursors since the initial copy of source data to the replica is complete.
REPLICA_STATE_REPLICATING	Replication is in progress.

Security for Stream Replication

Describes where security can be implemented for stream replication.

On clusters	You can replicate between streams that are in secure clusters.
At source streams	The `-adminperm` parameter in the commands `maprcli stream create` and `maprcli stream edit` lets you specify an *ACE* to declare who has administrative permissions on a stream, including permission to replicate the stream. The *ACE*s themselves are copied the first time during auto setup but are not replicated continuously. You need to manage the replicated and source *ACE*s separately after the initial setup.
Across a network	You can send data encrypted or unencrypted when replicating streams by using the `-networkencryption` parameter when you create or edit a replica.
At gateways	Gateways ensure that replicas receive data only from approved source streams.

Gateways and Stream Replication

When replicating streams, MapR Event Store For Apache Kafka replicates messages that are published to a source stream. Gateways are services that receive messages from source streams and publish them in replica streams.

You configure gateways on nodes that are in destination clusters. On source clusters, you list the destination clusters and the gateways that are running on them.

For information on configuring and managing gateways, see:

- Configuring Gateways for Table and Stream Replication on page 1152
- Managing Gateways on page 1154

last-updated: Apr 11, 2022

During replication, MapR Event Store For Apache Kafka sends messages from source streams to the gateways on the destination clusters, where the replicas of those source streams are located. Gateways batch the messages and then apply them to replicas. All messages from a source stream arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permission to publish messages are irrelevant; gateways have the implicit authority to publish messages to replicas.

MapR Event Store For Apache Kafka distributes messages to a destination cluster's gateways in round-robin fashion. If a gateway is down or unreachable, MapR Event Store For Apache Kafka chooses another gateway. If all of the gateways are down, MapR Event Store For Apache Kafka retries the operation periodically until a gateway comes online.

You must configure gateways in destination clusters. If the destination cluster is remote from the cluster in which a source stream is located, then the gateways must be in the remote cluster. If the destination cluster is the source cluster, meaning that a source stream and its replica are located in a single cluster, then the gateways must be in the local cluster.

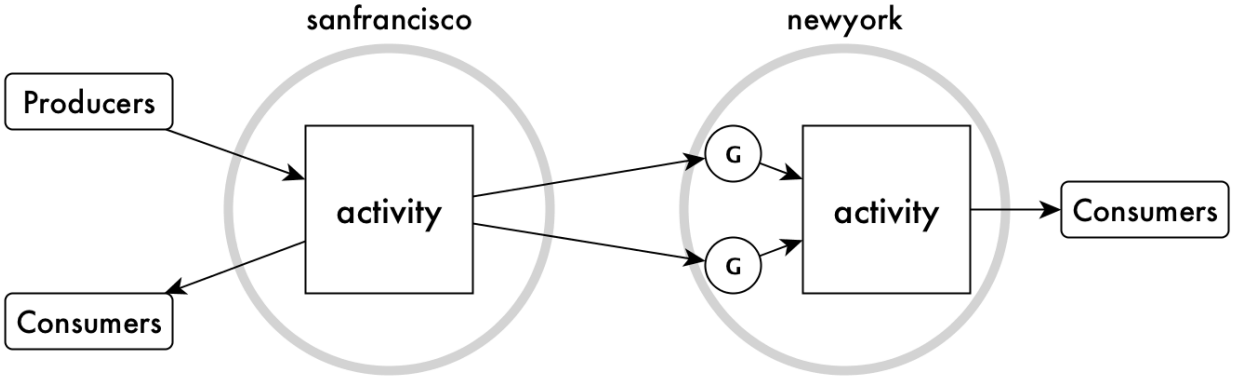
In a Primary-Secondary setup, you cannot have two primary instances with the same topic name replicating to the same secondary instance. It creates a conflict for that topic name. This is similar to Multi-Master replication where you must have separate topic names for Master1 (Cluster1) and Master2 (Cluster2).

For more information about replicating streams, see Stream Replication on page 656.

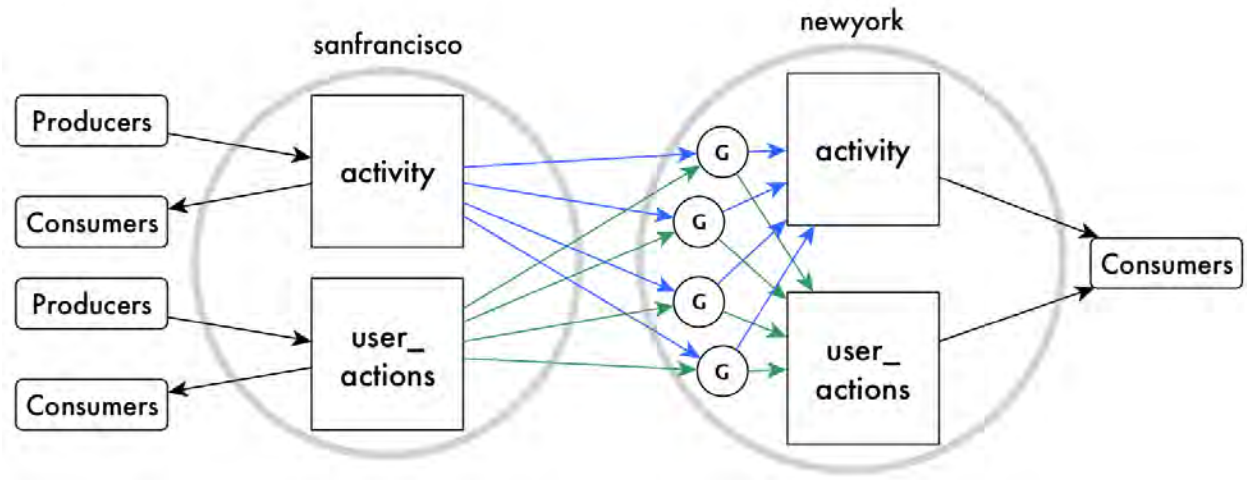
Gateways on nodes in remote destination MapR clusters

In this type of topology, gateways receive messages that are published to source streams, authenticate with the destination cluster on behalf of the source cluster, and publish the messages to the corresponding streams.

This diagram of basic intercluster primary-secondary replication shows messages from the `activity` stream in the cluster `sanfrancisco` being sent to gateways. The gateways then publish the messages to the replica stream that is in the cluster `newyork`.



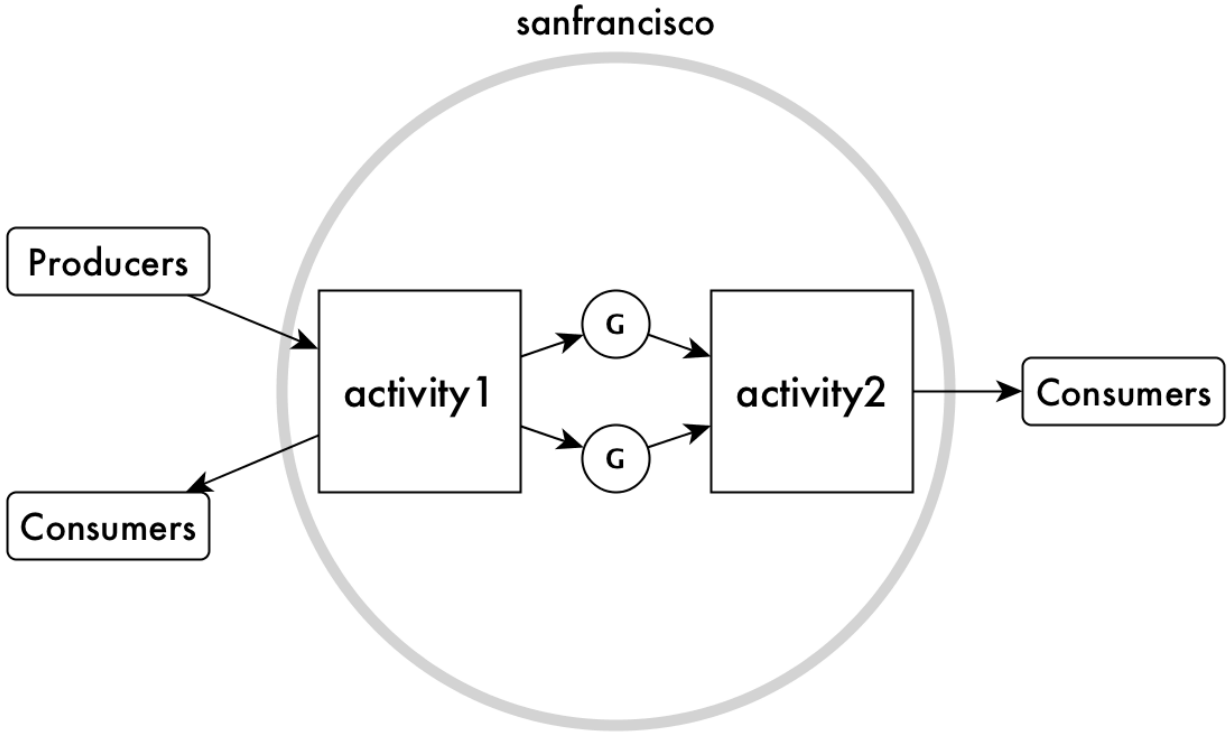
The gateways on a destination cluster are not assigned to particular replicas. They publish messages to all replicas on the destination cluster. For example, in the following diagram, messages from two source streams in the cluster `sanfrancisco` are replicated to two replicas in the cluster `newyork`. There are four gateways. Each gateway receives messages from both source streams, and each gateway applies those messages to the corresponding replicas.



Gateways on nodes within a MapR cluster serving as source and destination

In this type of topology, gateways also receive messages that are published to source streams and publish the streams to the replicas. However, all of this activity takes place within a single MapR cluster.

The following schematic diagram of basic intracluster primary-secondary replication shows messages from the `activity1` stream in the cluster `sanfrancisco` being sent to gateways. The gateways then publish the messages to the stream `activity2`.



Stream Security

The adminperm, copyperm, comsumeperm, produceperm, and topicperm security permissions protect topics in a stream from unauthorized access. In addition, MapR supports user impersonation.

ACE Permissions

The following *ACE*s are used to protect topics in a stream from unauthorized access. *ACE*s are set when you create or edit a stream.

`adminperm`	Determines which users can modify *ACE*s for a stream, set up replication of a stream, and modify other attributes of a stream. **Important:** By default, only the stream owner can modify this setting; however, a patch is available that changes this behavior. After applying the patch, both the stream owner and the MAPR user can modify this setting. The patch works with MapR Core-6.1.0. To install patches, see Applying a Patch.
`copyperm`	Determines the users who can run the `mapr copystream` and `mapr diffstreams` utilities on the stream. Users with this permission can publish messages to topics in a stream, read messages in topics from a stream, and create or remove topics in a stream. This permission is a combination of the `consumeperm`, `produceperm`, and `topicperm` permissions.
`consumeperm`	Determines the users who can read messages in topics from a stream.
`produceperm`	Determines the users who can publish messages to topics in a stream.
`topicperm`	Determines the users who can create topics in a stream or remove them.

The following example shows the `adminperm`, `consumeperm`, `produceperm`, and `topicperm` permissions on a stream named `traffic_sensors`, which includes the topics `traffic_sensors_sf` and `traffic_sensors_ny`.

Figure 13: How permissions grant or deny access to a stream

For general information about *ACE*s, see ACE Syntax on page 1448.

User Impersonation

MapR Event Store For Apache Kafka supports user impersonation through the Java API. See MapR Event Store For Apache Kafka Java API Library on page 2756 for more information. MapR Event Store For Apache Kafka does not support user impersonation through the C API or Python API.

Kafka REST supports outbound user impersonation. See User Impersonation on page 3871 for more information.

MapR Data Fabric for Kubernetes

This section describes the MapR Data Fabric for Kubernetes, which include the Container Storage Interface (CSI) driver for multiple container-orchestration systems, and the FlexVolume driver for Kubernetes.

The following table describes these features:

MapR CSI Storage Plugin	The CSI Storage Plugin is a volume driver that uses the industry-standard container-storage interface to expose the MapR Platform to workloads on container-orchestration systems.
MapR Data Fabric for Kubernetes FlexVolume Driver	The FlexVolume Driver is a set of Docker containers that provide persistent storage for Kubernetes objects through the MapR File System.

MapR Container Storage Interface (CSI) Storage Plugin Overview

This page describes how the MapR Container Storage Interface (CSI) Storage Plugin can be used to expose the MapR Data Platform to the containerized workload on Kubernetes.

To install or use the MapR Container Storage Interface (CSI) Storage Plugin, see:

last-updated: Apr 11, 2022

- Installing, Uninstalling, and Upgrading the MapR Container Storage Interface (CSI) Storage Plugin on page 228
- Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3104

About the MapR Container Storage Interface (CSI) Storage Plugin

The MapR Container Storage Interface (CSI) Storage Plugin is an industry-standard interface that Container Orchestration systems can use to expose MapR Data Platform to their containerized workloads. Traditionally, storage vendors had either to write and support multiple volume drivers for different Container Orchestration systems or choose not to support Container Orchestration systems. Using CSI, you can use the same volume driver with different Container Orchestration systems. Also, CSI enables the volume plug-ins to be containerized to make it agnostic to the host underneath, which might run other software such as MapR, allowing both Kubernetes and MapR to co-exist on the same node with CSI support.

The MapR CSI driver:

- Allows other software to run on the same node.
- Does not require volume plug-ins to be built into the Kubernetes binaries.
- Does not require direct access to the machine to deploy the volume plug-in.

The CSI Driver for MapR consists of `.yaml` configuration files for installation into Kubernetes. Once installed, a Kubernetes Container Storage Interface (CSI) driver for the file system and a Kubernetes Dynamic Volume Provisioner are available for both static and dynamic provisioning of MapR storage.

The CSI driver uses sidecar containers, which are containers included with the driver for handling Kubernetes events and for communicating with CSI drivers for storage provisioning. Specifically:

- The `csi-provisioner` provisions and creates volumes for the MapR Data Platform.
- The `csi-driver-registrar` registers the driver to the kubelet.
- The `csi-attacher` attaches volumes to the node and mounts the volumes.
- The `livenessprobe` probes the driver for health and readiness.
- The `csi-snapshotter` and `snapshot-controller` provision and create snapshots on the MapR Data Platform.

When you install the CSI driver, it creates a DaemonSet Pod for the CSI node service and StatefulSet Pod for CSI controller service.

Additional Resources

For more information about application containers and Kubernetes, see the following MapR references:

Static and Dynamic Volume Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin

Explains static and dynamic volume provisioning using the CSI plugin.

Kubernetes makes a distinction between static and dynamic provisioning of storage.

last-updated: Apr 11, 2022

Static Provisioning

In static provisioning, a MapR administrator first creates MapR volumes (mount points) and then ensures that they are mounted, and a Kubernetes administrator exposes those MapR mount points in Kubernetes through Kubernetes PersistentVolumes. In a typical static-provisioning scenario, a Pod author requests that a Kubernetes admin create a PersistentVolume that references an existing MapR mount point with a dataset that the Pod author is interested in. This PersistentVolume references the CSI driver. The CSI Driver mounts and unmounts MapR mount points for the requesting Pod. In addition, CSI supports the creation of a PersistentVolume directly by creating a PersistentVolumeClaim. The Pod author requests that a Kubernetes admin to create a PersistentVolume that points to the CSI driver and references an existing MapR mount point.

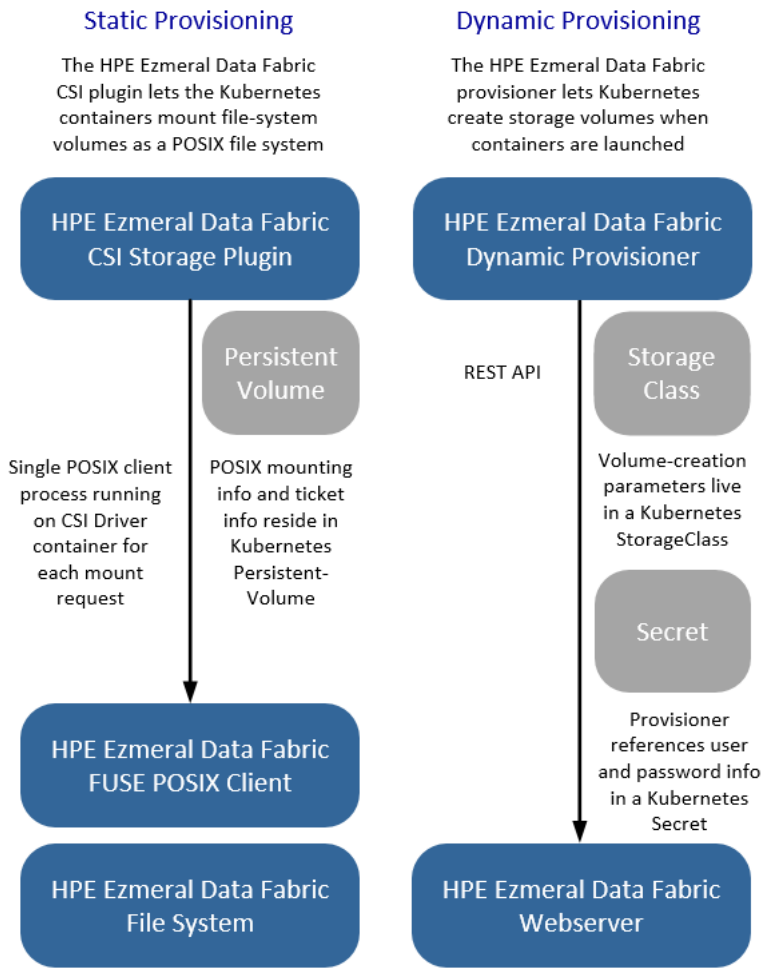
Dynamic Provisioning

In dynamic provisioning, a Kubernetes administrator creates a set of StorageClasses pointing to the CSI provisioner for MapR Data Fabric. Each StorageClass has a predefined set of storage characteristics. Examples of these characteristics include the CLDB hosts, REST server hosts, provisioner secret name and namespace, MapR volume name prefix, MapR volume mount path, and volume advisory quota size. The Pod creator searches the predefined Storage Classes for the one that best matches the creator's requirements. When the Pod references this StorageClass through a PersistentVolumeClaim, the StorageClass calls the CSI Provisioner for MapR Data Fabric to allocate storage for the requesting Pod dynamically and creates the volume.

To leverage the MapR file system with a Kubernetes cluster, you can create a PersistentVolume in Kubernetes.

The following diagram shows the two ways in which the PersistentVolume can be provisioned for the POSIX client. In the case of the Loopback NFS plugin, the Loopback NFS server performs the functions of the POSIX client shown in the diagram:

last-updated: Apr 11, 2022



Static Provisioning Implementation

To accomplish static provisioning, the CSI Driver for MapR Data Fabric for Kubernetes is deployed to all nodes in the Kubernetes cluster via a Kubernetes DaemonSet. The CSI Driver uses the Basic, which is the default, or the optional Platinum POSIX client to mount the MapR filesystem. The information that the POSIX client uses to connect to MapR is contained in a Kubernetes Volume or PersistentVolume. A MapR ticket inside a Secret, referenced by the Kubernetes Volume or PersistentVolume specification, is used by the POSIX client to pass secure data to the filesystem.

Dynamic Provisioning Implementation

To accomplish dynamic provisioning, the CSI provisioner is deployed as a StatefulSet in the Kubernetes cluster.

A Kubernetes Administrator must configure at least one storage class with MapR parameters (for example, mirroring, snapshots, quotas, and other parameters) for use during creation of the MapR volume. The storage class passes MapR administrative credentials to the provisioner through a Kubernetes Secret. Security for the provisioner is handled through role-based access control (RBAC) in Kubernetes.

Related tasks

Example: Statically Provisioning a Volume Using the MapR Container Storage Interface (CSI) Storage Plugin on page 3111

Example: Mounting a PersistentVolume for Static Provisioning on page 3113

Example: Mounting a PersistentVolume for Dynamic Provisioning Using MapR Container Storage Interface (CSI) Storage Plugin on page 3120

Raw Block Volumes
This page describes support for raw block volumes by the MapR Container Storage Interface (CSI) Storage Plugin.

The HPE implementation of CSI supports raw block volumes. Inside a container, this feature enables a persistent volume to appear as a block device instead of as a mounted file system. This feature can be useful for applications that do not work with NFS or FUSE or perform better on a standard Linux file system, such as EXT4 or XFS.

The following (or later) releases of the storage plugin support raw block volumes:

- MapR Container Storage Interface (CSI) Storage Plugin Release 1.2.x (FUSE POSIX) on page 6550
- MapR Container Storage Interface (CSI) Storage Plugin Release 1.0 (Loopback NFS) on page 6552

For more information, see Raw Block Volume Support in the Kubernetes documentation.

Comparing the FUSE POSIX and Loopback NFS Plugins
This page compares the two types of MapR Container Storage Interface (CSI) Storage Plugins and describes when to use them.

Features Common to Both Plugins

The FUSE POSIX and Loopback NFS plugins both support the following features:

- Create a volume
- Delete a volume
- Expand a volume
- Clone a volume
- Create a snapshot
- Delete a snapshot
- Restore a snapshot

Current versions of both plugins include the release 6.2 binaries and can be used with releases 6.1 or 6.2. In addition, both plugins can exist on the same Kubernetes cluster at the same time. Both plugins can also be used without a license; however, the FUSE POSIX plugin provides a `license` parameter that allows you to control the number of resources used, as described in Example: Mounting a PersistentVolume for Static Provisioning on page 3113.

How the Loopback NFS Plugin is Different

The Loopback NFS plugin leverages the MapR loopbacknfs POSIX Client. For more information about this client, see MapR loopbacknfs POSIX Client on page 1230.

The plugins differ in how they handle I/O. The Loopback NFS plugin uses asynchronous I/O, allowing more I/O operations. The Loopback NFS plugin also uses less memory and provides better performance for small-file writes and raw block storage.

How the FUSE POSIX Plugin is Different

The FUSE POSIX plugin leverages the MapR FUSE-Based POSIX Client. For more information about this client, see MapR FUSE-Based POSIX Client on page 1238.

The FUSE POSIX plugin uses synchronous I/O. FUSE POSIX runs with at most five clients (platinum license) and incurs resource overhead because of the high number of client threads, but works better for use cases that require high throughput.

MapR Data Fabric for Kubernetes FlexVolume Driver Overview

Describes how the FlexVolume driver for MapR Data Fabric for Kubernetes integrates with Kubernetes to provide persistent data for containers.

Important: The MapR Data Fabric FlexVolume Driver for Kubernetes is officially deprecated and becomes an unsupported product on October 31, 2022. Users of the FlexVolume Driver are encouraged to migrate to one of the available CSI drivers. See CSI Version Compatibility on page 5596.

To review the FlexVolume Driver end-of-life announcement, see support advisory 4822. For a comparison of the CSI and FlexVolume technologies, see FlexVolume.

To install or use the MapR Data Fabric for Kubernetes, see:

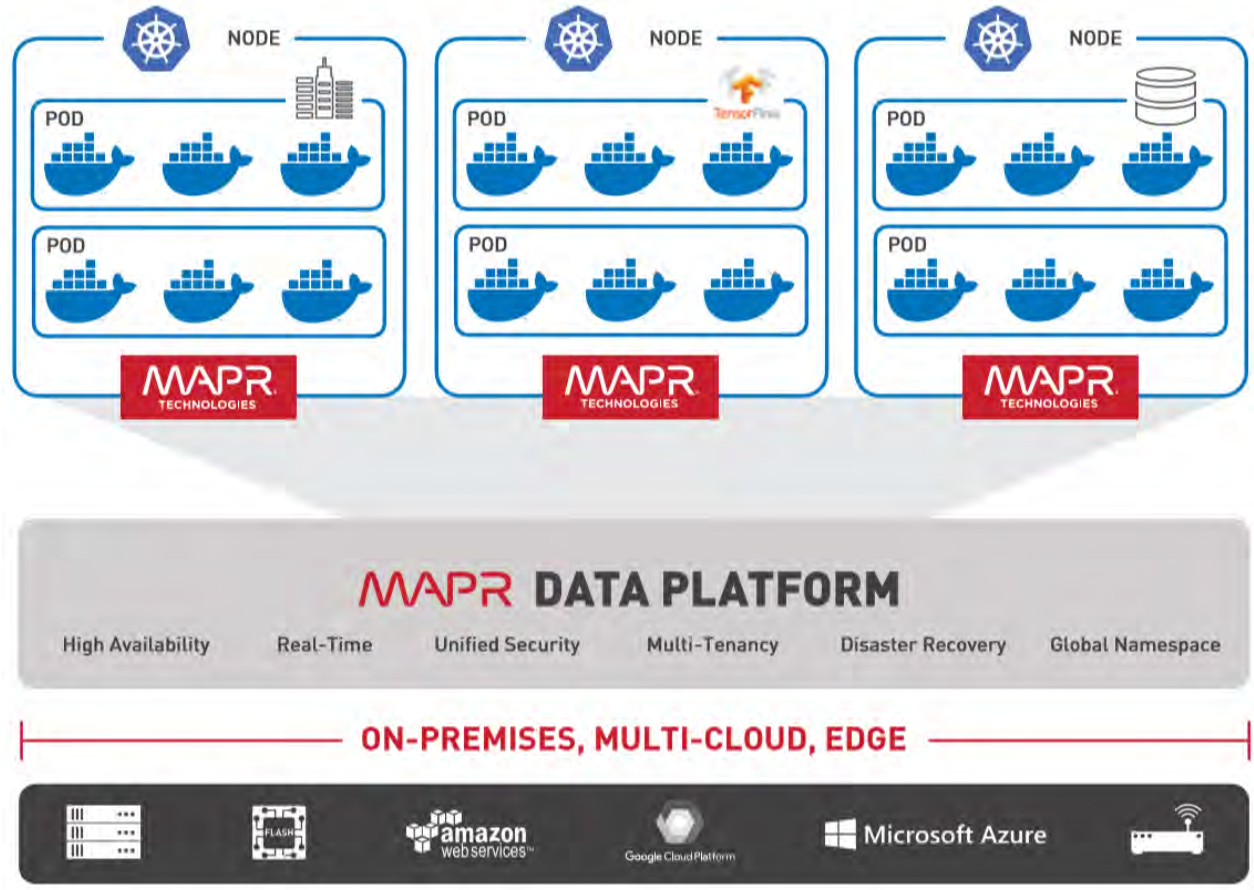
- Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 241
- Using the MapR Data Fabric for Kubernetes FlexVolume Driver on page 3151

About the MapR Data Fabric for Kubernetes

Most Pods in a Kubernetes environment should be portable, short-lived, and stateless. Traditionally, when a Pod is stopped or moved, the state of its containers could be lost. The MapR Data Fabric for Kubernetes:

- Provides long-lived, persistent storage for Pods and their containers.
- Allows containers running in Kubernetes to use the MapR filesystem for all of their storage needs.
- Allows secure storage of all container states in MapR XD Distributed File and Object Store.

last-updated: Apr 11, 2022



The MapR Data Fabric for Kubernetes consists of a set of Docker containers and their respective `.yaml` configuration files for installation into Kubernetes. Once installed, both a Kubernetes FlexVolume Driver for MaprFS and a Kubernetes Dynamic Volume Provisioner are available for both static and dynamic provisioning of MapR storage.

Containers

Containers are stand-alone, executable images of applications. They freeze all code needed to run an application, including an OS. Unlike VMs, containers run directly on an operating system without the need for a HyperVisor. Both Linux- and Windows-based applications can be packaged as containers. Containers represent an easy way to deploy applications in development and test environments. Using containers, developers can quickly create a development platform to test their code.

Containers are ephemeral by nature and light-weight. They enable setting up compute clusters quickly. They also allow a cluster to be dismantled quickly. To accomplish this task, containers are designed to be ephemeral. That is, they are designed to be somewhat stateless. However, truly stateless containers would eliminate many classes of applications. It is therefore important to provide containers with persistent data independent of the container lifecycle. A natural solution is to have persistent storage (data) presented to the containers, just as persistent storage is presented today for VMs and in bare-metal environments.

Container Management

Simple container solutions are somewhat limited when orchestrating multiple containers to solve complex business challenges. Managing containers for production is challenging. With many workloads transitioning to fully production-grade containers, cluster admins need something beyond a container engine like Docker. Several container-orchestration engines are now available to manage containers in production. Kubernetes is the most prominent example of these container-orchestration solutions.

last-updated: Apr 11, 2022

Kubernetes Volume Drivers

Kubernetes introduced the concept of FlexVolume drivers. FlexVolume drivers are intended to allow storage vendors to provide storage to containers managed by Kubernetes. The MapR Data Fabric for Kubernetes leverages Kubernetes FlexVolume drivers. There are additional Kubernetes components and concepts you should also be aware of:

- Kubernetes Volumes: A Kubernetes volume is a Kubernetes-managed resource concept. Kubernetes Volumes are associated with Kubernetes Pods. Kubernetes Volumes are different from MapR volumes. The lifecycle of a Kubernetes volume is tied to the lifecycle of a Kubernetes Pod, and the Kubernetes Volume is destroyed when the Pod is deleted.
- Kubernetes Persistent Volumes: As the name indicates, a Kubernetes Persistent Volume (PV) lifecycle is separate from the Pod that uses it. Persistent Volumes are referenced by Persistent Volume Claims (PVC), which are in turn referenced by Pods. Multiple Pods can claim a single PVC, but only a single PVC can bind with a PV.
- Storage Classes: A Storage Class is a way for administrators to advertise the different classes of storage they offer. For example, the admin can provide parameters in the storage class that define the frequency of snapshots or the number of mirrors associated with the storage. Storage Classes are used to dynamically provision a new storage volume for use by containers.
- MapR Volumes: The MapR Glossary defines a MapR volume as a tree of files and directories grouped for the purpose of applying a policy or set of policies to all of them at once. To avoid confusion, this document uses the terms *Kubernetes volume* and *MapR volume* to distinguish between the different types of volumes.

Kubernetes and MapR Volumes

In general, Kubernetes is not aware of MapR volumes. When static provisioning a MapR path, Kubernetes simply uses a MapR POSIX client to obtain a specific mount point within the MapR file system. When dynamically provisioning a new MapR volume for a container to use, the dynamic provisioner issues REST calls to the MapR REST server to create actual MapR volumes.

Static and Dynamic Provisioning Using FlexVolume Driver

Describes static and dynamic storage provisioning using the FlexVolume driver on a Kubernetes cluster.

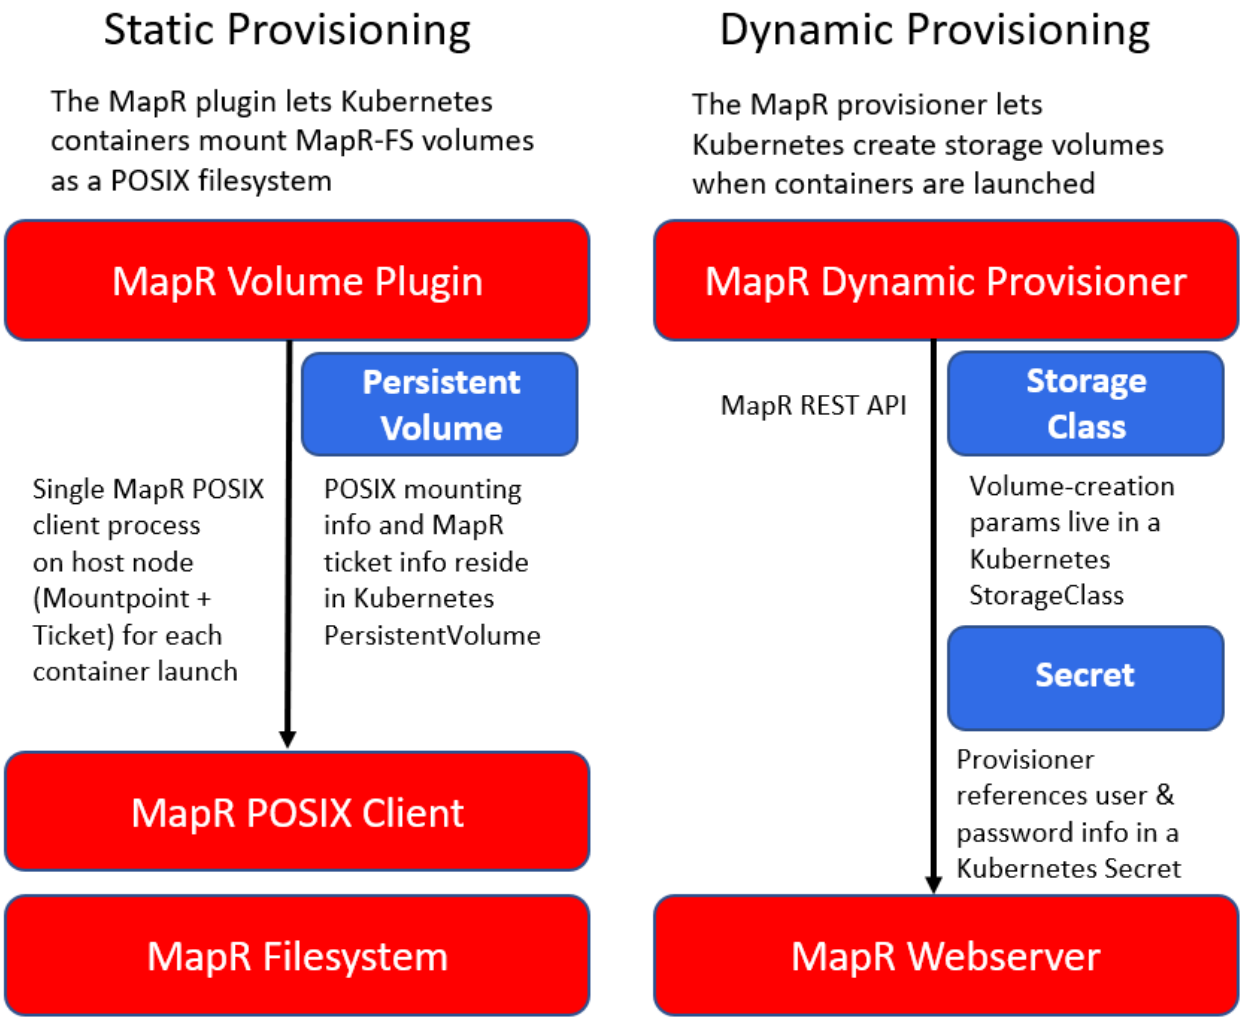
Kubernetes makes a distinction between static and dynamic provisioning of storage.

In static provisioning, a MapR administrator first creates MapR volumes (mount points) and then ensures that they are mounted. A Kubernetes administrator exposes these MapR mount points in Kubernetes through Kubernetes PersistentVolumes. In a typical static-provisioning scenario, a Pod author requests that a Kubernetes administrator create a PersistentVolume that references an existing MapR mount point with a dataset that the Pod author is interested in. This PersistentVolume references the MapR FlexVolume plug-in. The FlexVolume plug-in mounts and unmounts MapR mount points for the requesting Pod.

last-updated: Apr 11, 2022

In dynamic provisioning, a Kubernetes administrator creates a set of StorageClasses for Pods to invoke. Each StorageClass has a predefined set of storage characteristics. Examples of these characteristics include the MapR volume advisory quota size and snapshot rules. The Pod creator searches the predefined Storage Classes for the one that best matches the creator's requirements. When the Pod references this StorageClass through a PersistentVolumeClaim, the StorageClass calls the MapR Dynamic Provisioner to allocate storage for the requesting Pod dynamically.

To leverage MapR File System with a Kubernetes cluster, you can create a PersistentVolume in Kubernetes. This diagram shows the two ways in which the PersistentVolume can be provisioned:



Static Provisioning Implementation

To accomplish static provisioning, the MapR KDF FlexVolume plug-in is deployed to all nodes in the Kubernetes cluster via a Kubernetes DaemonSet. The volume plug-in uses the Basic or Platinum POSIX client to mount the MapR filesystem The information that the POSIX client uses to connect to MapR is contained in a Kubernetes Volume or PersistentVolume. A MapR ticket inside a Secret, referenced by the Kubernetes Volume or PersistentVolume specification, is used to pass secure data to the file system.

Dynamic Provisioning Implementation

To accomplish dynamic provisioning, the MapR KDF provisioner is deployed as a Kubernetes Deployment to a single node in the Kubernetes cluster. The provisioner requests the creation of MapR volumes when a container is launched. You can scale your provisioner deployment to multiple nodes for high availability. If a provisioner Pod is deleted, a new provisioner is started on another worker node in the cluster.

last-updated: Apr 11, 2022

A Kubernetes Administrator must configure at least one storage class with MapR parameters (for example, mirroring, snapshots, quotas, and other parameters) for use during creation of the MapR volume. The storage class passes MapR administrative credentials to the provisioner through a Kubernetes Secret. Security for the provisioner is handled through role-based access control (RBAC) in Kubernetes.

POSIX Integration and Licensing
Explains how the basic and platinum POSIX clients are supported on a Kubernetes cluster,

The MapR POSIX client provides fast-data access between the container and the MapR filesystem. For FlexVolume plug-in, the POSIX client is installed onto all Kubernetes worker nodes when you install the volume plug-in through its `.yaml` configuration file. For CSI Driver, the POSIX client is installed onto the CSI Driver container only.

For static provisioning, the volume plug-in uses the POSIX client to mount the MapR filesystem. The provisioner does not use the POSIX client to provision volumes, but a provisioned volume is mounted through POSIX when the plug-in is called after PV creation.

Support for Basic and Platinum Licenses

By default, the product includes the Basic POSIX client package, but you can enable the Platinum license, if needed. See Enabling the Platinum Posix Client for FlexVolume Driver and CSI Driver. Only the POSIX client is supported. NFSv3 and NFSv4 are currently not supported.

While the Platinum POSIX client offers up to five times better performance than the Basic POSIX client, resource utilization is significantly higher for the Platinum client. For a comparison of the Basic and Platinum packages, see Preparing for Installation.

Mounting Multiple MapR Paths

It is inefficient in both host resources and licenses to mount multiple MapR paths in the same Pod. In FlexVolume Driver, multiple mount points will consume additional resources on the Kubernetes host node. A more resource-efficient strategy is to use subpaths. See Using subpaths in the Kubernetes documentation.

Cluster Management

Provides a synopsis of the various cluster components and their management.

MapR provides high availability management and data processing services for automatic continuity throughout the cluster. You can use the Control System, command-line interface, or REST API to start, stop, and monitor services at the node or cluster level. MapReduce services such as the ResourceManager, management services such as the ZooKeeper, and data access services such as NFS provide continuous service during any system failure.

MapR Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

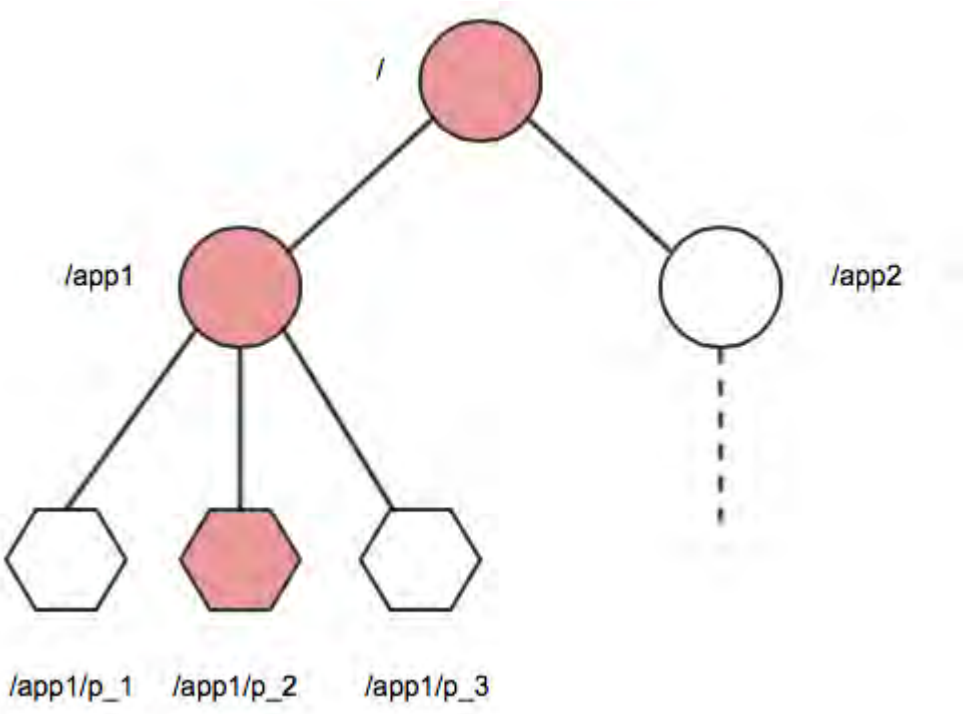
This section describes the following components and services, and also describes their roles in managing a MapR cluster:

ZooKeeper

Provides an overview of the ZooKeeper service.

ZooKeeper is a coordination service for distributed applications. It provides a shared hierarchical namespace that is organized like a standard filesystem. The namespace consists of data registers called znodes, for ZooKeeper data nodes, which are similar to files and directories. A name in the namespace is a sequence of path elements where each element is separated by a / character, such as the path `/app1/p_2` shown here:

last-updated: Apr 11, 2022



Namespace

The znode hierarchy is kept in-memory within each ZooKeeper server in order to minimize latency and to provide high throughput of workloads.

The ZooKeeper Ensemble

The ZooKeeper service is replicated across a set of hosts called an ensemble. One of the hosts is designated as the leader, while the other hosts are followers. ZooKeeper uses a leader election process to determine which ZooKeeper server acts as the leader, or master. If the ZooKeeper leader fails, a new leader is automatically chosen to take its place.

Establishing a ZooKeeper Quorum

As long as a majority (a quorum) of the ZooKeeper servers are available, the Zookeeper service is available. For example, if the ZooKeeper service is configured to run on five nodes, three of them form a quorum. If two nodes fail (or one is taken off-line for maintenance and another one fails), a quorum can still be maintained by the remaining three nodes. An ensemble of five ZooKeeper nodes can tolerate two failures. An ensemble of three ZooKeeper nodes can tolerate only one failure. As a quorum requires a majority, an ensemble of four ZooKeeper nodes can only tolerate one failure, and therefore offers no advantages over an ensemble of three ZooKeeper nodes. In most cases, you should run three or five ZooKeeper nodes on a cluster. Larger quorum sizes result in slower write operations.

Ensuring Node State Consistency

Each ZooKeeper server maintains a record of all znode write requests in a transaction log on the disk. The ZooKeeper leader issues timestamps to order the write requests, which when executed, updates elements in the shared data store. Each ZooKeeper server must sync transactions to disk and wait for a majority of ZooKeeper servers (a quorum) to acknowledge an update. Once an update is held by a quorum of nodes, a successful response can be returned to clients. By ordering the write requests with timestamps and waiting for a quorum to be established to validate updates, ZooKeeper avoids race conditions and ensures that the node state is consistent.

last-updated: Apr 11, 2022

Warden

Describes the Warden daemon that monitors and restarts services if they terminate.

Warden is a light Java application that runs on all the nodes in a cluster and coordinates cluster services. Warden's job on each node is to start, stop, or restart the appropriate services, and allocate the correct amount of memory to them. Warden makes extensive use of the znode abstraction discussed in the ZooKeeper section of this document to monitor the state of cluster services.

Each service running in a cluster has a corresponding znode in the ZooKeeper namespace, named in the pattern `/services/<servicename>/<hostname>`. Warden's Watcher interface monitors znodes for changes and acts when a znode is created or deleted, or when child znodes of a monitored znode are created or deleted.

Warden configuration is contained in the `warden.conf` file, which lists service triplets in the form `<servicename>:<number of nodes>:<dependencies>`. The `number of nodes` element of this triplet controls the number of concurrent instances of the service that can run on the cluster. Some services are restricted to one running instance per cluster, while others, such as the File Server, can run on every node. The Warden monitors changes to its configuration file in real time.

When a configuration triplet lists another service as a dependency, the Warden only starts that service after the dependency service is running.

Note: When Warden is started/restarted, the irqbalancer is enabled on nodes running MapR File System because it balances IRQ SMP affinities, which provide better performance.

Memory Management with the Warden

System administrators can configure how the cluster's memory is allocated to running the operating system, MapR File System, and Hadoop services. The configuration files `/opt/mapr/conf/warden.conf` and `/opt/mapr/conf/conf.d/warden.<servicename>.conf` include parameters that define how much of the memory on a node is allocated to the operating system, MapR File System, and Hadoop services.

You can edit the following memory parameters to reserve memory:

- The `service.<servicename>.heapsize.percent` parameter controls the percentage of system memory allocated to the named service.
- The `service.<servicename>.heapsize.max` parameter defines the maximum heapsize used when invoking the service.
- The `service.<servicename>.heapsize.min` parameter defines the minimum heapsize used when invoking the service.

For example, the `service.command.os.heapsize.percent`, `service.command.os.heapsize.max`, and `service.command.os.heapsize.min` parameters in the `warden.conf` file control the amount of memory that Warden allocates to the host operating system before allocating memory to other services.

The actual heap size used when invoking a service is a combination of the three parameters according to the formula:

```
max(heapsize.min, min(heapsize.max, total-memory * heapsize.percent / 100))
```

For more information, see Memory Allocation for Nodes.

last-updated: Apr 11, 2022

The Warden and Failover

The Warden on each node watches appropriate znodes to determine whether to start or stop services during failover. The following paragraphs provide failover examples for the CLDB and ResourceManager. Note that not all failover involves the Warden; NFS failover is accomplished using VIPs.

CLDB Failover	The ZooKeeper contains a znode corresponding to the active primary CLDB. This znode is monitored by the secondary CLDBs. When the primary CLDB znode is deleted, the secondary CLDBs recognize that the primary CLDB is no longer running. The secondary CLDBs contact ZooKeeper in an attempt to become the new primary CLDB. The first CLDB to get a lock on the znode in ZooKeeper becomes the new primary instance.
ResourceManager Failover	Starting in version 4.0.2, if the node running the ResourceManager fails and the Warden on the ResourceManager node is unable to restart it, Warden starts a new instance of the ResourceManager on another node. The Warden on every ResourceManager node watches the ResourceManager's znode for changes. When the active ResourceManager's znode is deleted, the Wardens on other ResourceManager nodes attempt to launch the ResourceManager. The Warden on each ResourceManager node works with the ZooKeeper to ensure that only one ResourceManager is running in the cluster. In order for failover to occur in this manner, at least two nodes in the cluster should include the ResourceManager role and your cluster must be use the zero configuration failover implementation.

The Warden and Pluggable Services

Services can be plugged into the Warden's monitoring infrastructure by setting up an individual configuration file for each supported service in the `/opt/mapr/conf/conf.d` directory, named in the pattern `warden.<servicename>.conf`. The `<servicename>:<number of nodes>:<dependencies>` triplets for a pluggable service are stored in the individual `warden.<servicename>.conf` files, not in the main `warden.conf` file.

The following services/packages have configuration files pre-configured at installation:

- Hue
- HTTP-FS
- The Hive metastore
- HiveServer2
- Oozie
- Spark-Master
- mapr-apiserver
- mapr-collectd
- mapr-drill
- mapr-elasticsearch

- mapr-resourcemanager
- mapr-schema
- mapr-sentry
- mapr-spark
- mapr-sqoop2
- mapr-storm
- mapr-tez
- mapr-timelineserver

last-updated: Apr 11, 2022

- mapr-webserver

A package can contain multiple services. For example, `mapr-spark` contains all of Spark services including Spark Thrift Server and Spark Master.

After you install a package and run the configure.sh on page 2053 utility, the associated Warden files are present in `/opt/mapr/conf/conf.d`.

The Warden daemon monitors the znodes for a configured component's service and restarts the service as specified by the configuration triplet. The configuration file also specifies resource limits for the service, ports used by the service (if any), and a location for log files.

In the triplet `<servicename>:<number of nodes>:<dependencies>`, the `<number of nodes>` can be set to `all`. The value `all` specifies that the service is to be started on every node on which the service is installed.

For example, consider the entry `services=kvstore:all;cldb:all:kvstore;hoststats:all:kvstore`. This entry specifies the following:

1. Start `kvstore` on all the nodes on which it is installed.
2. Start `cldb` on all the nodes on which it is installed, but wait until `kvstore` is up on all nodes. In other words, `cldb` depends on `kvstore` to be up.
3. Start `hoststats` on all nodes on which it is installed but wait until `kvstore` is up on all nodes. In other words, `hoststats` depends on `kvstore` to be up.

As another example, consider the entry: `resourcemanager:1:cldb`. Here, only one instance of `resourcemanager` is started, after `cldb` is up.

If this instance of `resourcemanager` goes down, Warden notices that the number of running instances is below the specified count, and automatically handles the failover. If multiple instances of `resourcemanager` get started, Warden terminates all the extra instances.

Dependencies are usually handled internally. Some non-core components do have dependencies among themselves, such as for example:

```
services=nodemanager:all:resourcemanager
hbmaster:all:cldb
hbregionserver:all:hbmaster
```

Here:

1. `nodemanager` depends on `resourcemanager`
2. `hbmaster` depends on `cldb`
3. `hbregionserver` depends on `hbmaster`

CLDB

Describes the Container Location Database (CLDB).

CLDB

The Container Location Database (CLDB) service tracks the following information about every container in the MapR file system:

- The node where the container is located.
- The container's size.

- The volume to which the container belongs.
- The policies, quotas, and usage for that volume.

For more information on containers, see File System on page 452.

The CLDB also tracks fileservers in the cluster and node activity. Running the CLDB service on multiple nodes distributes lookup operations across those nodes for load balancing, and also provides high availability.

When a cluster runs the CLDB service on multiple nodes, one node acts as the primary CLDB and the others act as secondary instances. The primary node has read and write access to the filesystem, while secondary nodes only have read access. The kvstore (key-value store) container has the container ID 1, and holds cluster-related information. The ZooKeeper tracks container information for the kvstore container. The CLDB assigns a container ID to each new container it creates. The CLDB service tracks the location of containers in the cluster by the container ID.

When a client application opens a file, the application queries the CLDB for the container ID of the root volume's name container. The CLDB returns the container ID and the IP addresses of the nodes in the cluster where the replicas of that container are stored. The client application looks up the volume associated with the file in the root volume's name container, then queries the CLDB for the container ID and IP addresses of the nodes in the cluster with the name container for the target volume. The target volume's name container has the file ID and inode for the target file. The client application uses this information to open the file for a read or write operation.

Each fileserver heartbeats to the CLDB periodically, at a frequency ranging anywhere from 1-3 seconds depending on the cluster size, to report its status and container information. The CLDB may raise alarms based on the status communicated by the FileServer.

Central Configuration

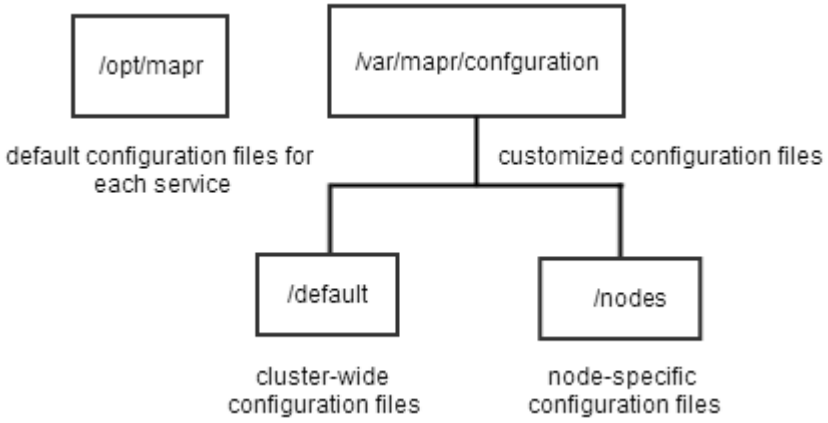
Describes the location where you can store customized configuration files, and the `pullcentralconfig` utility that is used to detect such files.

Each service on a node has one or more configuration files associated with it. The default version of each configuration file is stored locally under `/opt/mapr/`.

Customized versions of the configuration files are placed in the `mapr.configuration` volume, which is mounted at:

```
/var/mapr/configuration
```

The following diagram illustrates where each configuration file is stored:



MapR uses the `pullcentralconfig` script to detect customized configuration files in:

```
/var/mapr/configuration
```

This script is launched every five minutes by default. When the script finds a customized file, it overwrites the local files in `/opt/mapr`. First, the script looks for node-specific custom configuration files under:

```
/var/mapr/configuration/nodes/<hostname>
```

If the script does not find any configuration files at that location, the script searches for cluster-wide configuration files under:

```
/var/mapr/configuration/default
```

The `/default` directory stores cluster-wide configuration files that apply to all nodes in the cluster by default.

MapR Control System

Provides a brief description of the MapR Control System.

The MapR Control System provides a graphical control panel for cluster administration with all the functionality of the command-line or REST APIs. The Control System provides job monitoring metrics and helps you troubleshoot issues, such as which jobs required the most memory in a given week, or which events caused job and task failures.

The Control System provides various views, which you can use to configure and monitor your cluster:

Overview	The Control System **Overview** page provides a summary of information about the cluster including a cluster heat map that displays the health of each node organized by service, an alarms summary, cluster utilization that shows the CPU, memory, and disk space usage, the number of available, unavailable, and under replicated volumes, and MapReduce applications.
Services	The Control System **Services** page provides a summary of the services running across the cluster.
Nodes	The Control System **Nodes** page provides a summary of information about the nodes on the cluster including a heat map that displays the health of each node, resource utilization that shows the CPU and memory usage, all active alarms, and a list of all the nodes on the cluster with links that provide shortcuts to more detailed information about the node.
Data	The Control System **Data** drop-down menu contains links to pages that provide summary of information about volumes, tables, and streams.
Admin	The Control System **Admin** drop-down menu contains links to pages for user and cluster management tasks such as setting up permissions, quotas, and email settings for users, enabling cluster-level and data auditing, configuring balancer settings, and adding licenses.

Note: During installation using the MapR Installer, you can configure metrics and logging using settings on the Monitoring page of the MapR Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the panes on the Control System.

Related concepts

Setting Up the Control System on page 423
Describes how to configure and access the Control System.

Security

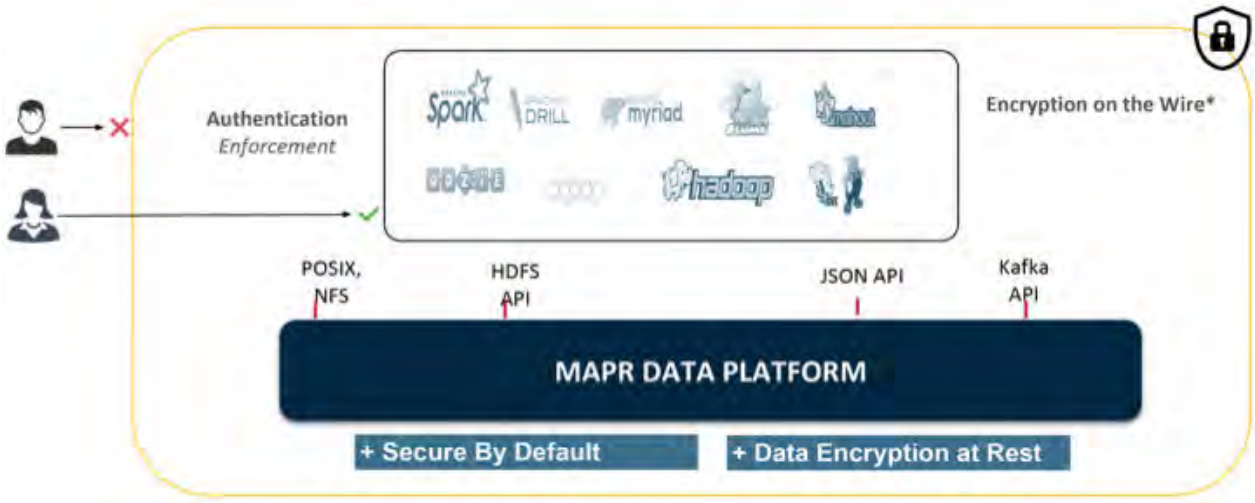
Provides an overview of the MapR security features.

Securing enterprise data is critical. To make securing data in clusters easy, the MapR Data Platform has a data protection scheme built directly into the platform that is enabled by default, simplifying the process of protecting critical data. You can take advantage of the default security settings, or you can implement data security manually. Either way, it is important to identify which data to secure.

Since data must be shared between nodes on the cluster, data transmissions between nodes, and from the cluster to the client are vulnerable to interception. Networked computers are also vulnerable to attacks where an intruder successfully pretends to be another authorized user and then acts improperly as that user. Additionally, networked machines share the security vulnerabilities of a single node. The MapR Data Platform supports the ability to apply protection directly as data enters and exits the platform. You do not need to apply an external management server or particular security plug-in.

Secure by Default	MapR, which includes the MapR Data Platform and EEP components, is secure out-of-the-box on all new installations, ensuring all network connections require authentication and all data in motion is protected with wire-level encryption. MapR provides the ability to apply security protection directly for data as it comes into and out of the platform without requiring an external security manager server or a particular security plug-in for each ecosystem component. The security semantics are applied automatically on data being retrieved or stored by any ecosystem component, application, or users.
Platform-Based Security	The MapR Data Platform applies security semantics automatically as data is being stored and retrieved from the platform. It supports all four pillars of security (authentication, authorization, auditing, and encryption), using platform-level capabilities that do not require external security tools or plugins.
Encryption	On the MapR Data Platform, data is protected by encrypting all data being transmitted over the wire and encrypting all data that is stored in the platform.

last-updated: Apr 11, 2022



The following sections describe the MapR security capabilities and security architecture.

Security Capabilities

A secure MapR environment is predicated on authentication, authorization, auditing, and encryption capabilities. You can use policy-based security to classify and manage these capabilities.

Authentication	Restricting access to a specified set of users. Robust authentication prevents third parties from representing themselves as legitimate users. MapR supports a wide range of authentication mechanisms depending on the network transport that includes MapR tickets, kerberos, Pluggable Access Module (PAM), Basic Authentication, MapRSASL, and SPNEGO. See Configuring Authentication on page 1424 for more information.
Authorization	Restricting an authenticated user's capabilities on the system. MapR provides sophisticated authorization controls to ensure that users can perform only the activities for which they have permissions, such as data access, job submission, cluster administration, and more. These permissions can be granted by an administrator through the browser-based Control System management and monitoring interface, or by using the command-line utilities. See Managing Access Controls on page 1445 for more information.
Auditing	Logging audit records of operations. MapR allows you to log audit records of cluster-administration operations and operations on directories, files, and tables. See Managing Auditing on page 757 for more information.
Encryption	Restricting an external party's ability to read data. Encryption is used to avoid exposure to breaches, such as packet sniffing and theft of storage devices.

last-updated: Apr 11, 2022

	In a secure MapR cluster, data transmission between nodes, and between a MapR cluster and ecosystem application is encrypted, preventing an attacker with access to that communication from gaining information about the contents of the transmission. Optionally, you can enable encryption for data at rest to prevent unauthorized users from accessing sensitive data, and protect against data theft through sector-level disk access. Data is protected by encrypting all data being transmitted over the wire and optionally encrypting all that is stored on the MapR platform. The MapR data encryption scheme is built directly into the platform and is enabled by default. See Managing Encryption for MapR Core on page 1410 for more information.

Security Architecture

MapR provides the following authentication and authorization functionality:

Filesystem permissions	For files and directories on the MapR cluster, you can leverage standard Unix-style permissions to grant access to authorized users. Since MapR File System is a POSIX-like filesystem, you can set user permissions as you would on any other Linux system. See Setting MapR File System Permissions on page 981 for more information.
Cluster, volume, and job queue Access Control Lists (ACLs)	You can specify the actions that a given user can perform on each of these cluster elements. You can use access control lists (ACLs) to grant permissions for performing administrative tasks at both the cluster and the volume level. See Managing Access Control Lists on page 1445 for more information.
Access Control Expressions for filesystem and natively stored MapR Database tables	ACEs control which files, directories, volumes, streams, and tables users or groups can access. ACEs are a powerful and flexible mechanism to grant permissions on structured and unstructured data. See Managing Access Control Expressions on page 1448 for more information.
Impersonation for centralized control of access to resources	Impersonation, also known as identity assertion, is one user accessing data and submitting jobs on behalf of another user. See Managing Impersonation on page 1476 for more information.

What to do Next

The MapR secure-by-default data platform provides security through a single option in the MapR Installer on page 5395 or by running the `configure.sh on page 2053` script with the `-secure` option after a manual installation. You can enable security on your cluster using the procedure described in the following topics:

- Using the Enable MapR Secure Cluster Option on page 5427 if you are installing with the MapR Installer on page 5395.
- Enabling Security on page 1405 if you are Installing without the MapR Installer on page 141.

After enabling security, optionally, you can perform the following tasks:

- Understand the security exceptions and take corrective action, where applicable.

last-updated: Apr 11, 2022

- Configure authorization on the resources.
- Configure auditing on administration and resources.
- Configure encryption for data at rest.
- If you have Hive installed, enable storage-based authorization for the Hive Metastore server.

Authentication in MapR

Describes types of authentication available with the MapR Data Platform and how to manage user authentication with the `maprlogin` utility.

Authentication ensures that who you really are and who you claim to be, match when identifying the end user to the system. MapR authentication supports standard Basic Authentication and SPNEGO authentication for web-based interfaces, and supports MapR tickets for many of the core system component non-web-based interfaces. A ticket is an object that contains specific information about a user, an expiration time, and a key. Tickets uniquely identify a user and are encrypted to protect their contents. You can use tickets to establish sessions between a user and the cluster.

Types of Authentication in MapR

MapR supports two methods of authenticating a user and generating a ticket: a username-password pair and Kerberos. Both of these methods are mediated by the maprlogin on page 2130 utility. When you authenticate with a username-password pair, the system verifies your credentials using Pluggable Authentication Modules (PAM). You can configure the cluster to use any registry that has a PAM module.

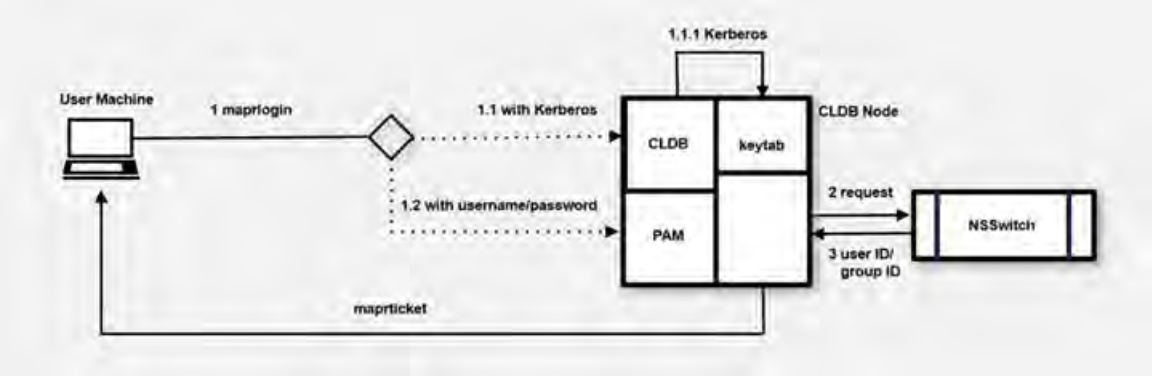
MapR tickets contain the following information:

- UID (generated from the UNIX user ID)
- GIDs (group IDs for each group the user belongs to)
- Ticket creation time
- Ticket expiration time (by default, 14 days)
- Renewal expiration time (by default, 30 days from the date of ticket creation)

A MapR ticket determines the user's identity. The system uses the ticket as the basis for authorization. A MapR cluster with security features enabled does not rely on the client-side operating system identity.

The maprlogin Utility for Generating Tickets

The `maprlogin on page 2130` utility supports user authentication with either username and password, or Kerberos to generate a unique session token called a *ticket*. The following diagram outlines the process flow:



MapR tickets are either implicitly or explicitly generated. On clusters that use Kerberos for authentication, a user that runs a MapR command without first using the `maprlogin` utility implicitly obtains a MapR ticket. During usage, the client runtime process first checks for a valid user ticket, and uses that ticket if it exists. If a ticket does not exist, the runtime process checks if Kerberos is enabled for the cluster and then checks for an existing valid Kerberos identity. When a valid Kerberos identity is found, the client implicitly generates a ticket for that Kerberos identity.

When you explicitly generate a ticket, you can authenticate either with your username and password, or with Kerberos:

1. The user on the client machine invokes the `maprlogin` utility, which connects to a CLDB node in the cluster using HTTPS. The host name for the CLDB node is specified in the `mapr-clusters.conf` file.
   - For username-password authentication, the node authenticates using PAM modules with the Java Authentication and Authorization Service (JAAS).

     The JAAS configuration is specified in the `mapr.login.conf` file. The system can use any registry that has a PAM module available.
   - For Kerberos authentication, the CLDB node verifies the Kerberos principal with the `keytab` file.
2. After authenticating, the CLDB node uses the standard UNIX APIs `getpwnam_r` and `getgrouplist`, which are controlled by the `/etc/nsswitch.conf` file, to determine the user IDs and group IDs.
3. The CLDB node generates a ticket and returns it to the client machine, completing the login communication between the client and the CLDB.
4. After login, the MapR server validates that the ticket is properly encrypted, to verify that the ticket was issued by the cluster's CLDB.
5. The server also verifies that the ticket has not expired or been blacklisted.
6. The server checks the ticket for a privileged identity such as the `mapr` user.

   Privileged identities have impersonation functionality enabled.
7. The ticket's user and group information are used for authorization to the cluster, unless impersonation is in effect.

Authorization in MapR

Describes the basics of authorization including Access Control Lists and Access Control Expressions.

Authorization restricts what an authenticated user can do with data. MapR enables you to create flexible authorization systems that grant a user capabilities to perform desired tasks, but prevents the user from performing tasks outside of that scope. Use a combination of Access Control Lists and Access Control Expressions to set up a flexible authorization system.

Access Control Lists	MapR supports Access Control Lists (ACLs) in several areas, including for regulating user privileges to the job queue and cluster. MapR also uses ACLs to control administrative access to volumes (administrative access is distinct from data access). An Access Control List (ACL) is a list of users or groups. Each user or group in the list is paired with a defined set of permissions that limit the actions that the user or group can perform on the object secured by the ACL. In MapR, the objects secured by ACLs are the job queue, volumes, and the cluster itself.

last-updated: Apr 11, 2022

	A job queue ACL controls who can submit jobs to a queue, kill jobs, or modify their priority. A volume-level ACL controls which users and groups have administrative access to that volume, and what actions they may perform, such as mirroring the volume, altering the volume properties, dumping or backing up the volume, or deleting the volume.
Access Control Expressions	MapR also provides a more powerful authorization known as Access Control Expressions. *ACE*s allow you to control access using powerful boolean logic expressions. You can use *ACE*s to control data access to MapR tables, files, directories, volumes, and streams. The MapR File System also supports standard POSIX filesystem permission levels. An *ACE* is a combination of user, group, and role definitions. A *role* is a custom defined name that is determined and implemented by your custom authorization code. It can be a property of a user or group that defines a set of behaviors that the user or group performs regularly. You can use ACEs to secure files, directories, volumes, tables, and streams that use native storage.

See the Configuring Data-Fabric Security on page 1402 section for information about the procedures for setting up and modifying ACLs and ACEs for the cluster, the volumes on the cluster, the job queue, the MapR filesystem, and the natively stored MapR tables and streams.

Encryption in MapR

Describes encryption types available on the MapR Data Platform.

MapR encryption restricts an external party's ability to read or modify data.

MapR supports encryption of data on wire and data at rest for preventing unauthorized access to sensitive data. These encryption methods are in addition to authentication and authorization protections. Encryption can be used to avoid exposure to breaches such as packet sniffing and theft of storage devices.

Data transmission between nodes on a secure MapR cluster is encrypted, preventing an attacker with access to that communication from gaining information about the contents of the transmission. Encryption of data-at-rest prevents unauthorized users from accessing sensitive data and protects against data theft through sector-level disk access.

On-Wire Encryption

Data transmission between nodes on a secure MapR cluster over any network connection supported by MapR is encrypted. When you run the `configure.sh` on page 2053 utility with the `-secure` option, you are enabling the cluster for security, authentication, and wire-level encryption for the platform and all ecosystem components. In secure mode, MapR automatically encrypts all data traffic. Enabling encryption ensures that data to and from the locations you specify is encrypted as it travels over the network.

MapR uses the following technologies to protect network traffic:

- The Secure Sockets Layer/Transport Layer Security (SSL/TLS) protocol secures several channels of HTTP traffic supporting TLS 1.0, 1.1(default), and 1.2.
- In compliance with the NIST standard, the 256-bit Advanced Encryption Standard in Galois/Counter Mode (AES256/GCM) secures several communication channels between cluster components.

The information in Security Protocols Used by MapR on page 689 includes details on the specific technologies used by particular elements of a cluster.

last-updated: Apr 11, 2022

Nodes with CPUs that support AES encryption at the hardware level provide superior performance on encryption tasks. You can determine if the CPU of a node supports the AES instruction set, by running the following command:

```
$ cat /proc/cpuinfo | grep flags | grep aes
```

Data-at-Rest Encryption

Data on disk (or data-at-rest) on a secure MapR cluster can be encrypted, enabling you to protect the data if a disk is compromised. Encryption of data-at-rest not only prevents unauthorized users from accessing sensitive data, but it also protects against data theft via sector-level disk access. When you run the `configure.sh` on page 2053 utility with the `-dare` option, you are enabling data at rest encryption feature at the cluster level. If encryption of data at rest is enabled, new volumes are encrypted by default with the option to create a volume without encryption. For example, if you have a volume that contains data that is not at all sensitive, you might not want to encrypt it. For encrypted volumes, MapR automatically encrypts data at rest and manages the keys used to encrypt data seamlessly; you do not need special utilities to encrypt or decrypt the data. MapR uses AES256/XTS to protect data on the disk.

SSL Certificates
Describes how certificates are used to perform authentication and encryption for websites that use the HTTPS protocol.

The TLS (Transport Layer Security formally SSL Secure Sockets Layer) certificate performs authentication and encryption for websites that use the HTTPS protocol. A certificate contains information about an entity and contains a public key. The public key is related to a private key which is NOT part of the certificate, but it is used by one entity when it communicates with another entity.

MapR stores the private key and certificate in a key store file called `ssl_keystore`. A certificate is also digitally signed so that it cannot be altered. The signer is known as the signing certificate.

In order for a HTTPS connection to be established, the following criteria must be met:

- The *server* must have a key file that contains a certificate and a private key
- The *client* must provide a trust file that contains a signer who signed the certificate used by the server
- The server certificate must be valid and not expired
- The client must determine that the SubjectDN in the certificate is acceptable

The process of enabling MapR security generates the common `ssl_keystore` and `ssl_truststore` files on the first CLDB server that are used by all clients and servers.

- The `ssl_keystore` contains a single self-signed certificate with a wildcard SubjectDN (for example, if the hostname of the CLDB is `a.b.com` the SubjectDN would be `CN=*.b.com`).
- The `ssl_truststore` contains the signer for the certificate in the `ssl_keystore`.

By default, MapR uses a unique self-signed certificate. You can use your own signing certificate by following the steps for Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster.

The REST API calls in a MapR cluster communicate over the HTTPS protocol on port 8443. These calls are secured with SSL certificates that identify a node to the cluster.

Security Protocols Used by MapR
Lists the various security protocols that MapR uses for encryption and authentication.

last-updated: Apr 11, 2022

Protocol	Encryption	Authentication
MapR RPC	AES/GCM	maprticket
Hadoop RPC and MAPRSASL	AES/GCM	maprticket
Hadoop RPC and Kerberos	Kerberos	Kerberos ticket
Generic HTTP Handler	HTTPS using SSL/TLS	maprticket, username and password, or Kerberos SPNEGO

For detailed information about component-level support for authentication, impersonation, and wire-level encryption, see MapR Security Support Matrix on page 5602.

HTTPS Excluded Ciphers
Lists the weak ciphers that are excluded from the MapR HTTPS implementation.

By default, the following weak TLS/SSL ciphers are excluded from the MapR HTTPS implementation:

- `SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_DES40_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_RC4_40_MD5`

You can modify this list of excluded ciphers by editing the `hadoop.ssl.exclude.cipher.suites` property in the `core-site.xml` file. Restart the web servers that use the HTTPS protocol after changing the list of excluded ciphers. The following web servers use HTTPS:

- Control System
- NodeManager
- ResourceManager
- HistoryServer
- CLDB
- HBase

Impersonation in MapR

Describes impersonation in MapR, which allows centralized control of access to resources in the MapR File System, MapR Database, and MapR Event Store For Apache Kafka.

Also known as identity assertion, impersonation is one user (authorized to impersonate another) or the `mapr` super user accessing data and submitting jobs on behalf of another user. Implementing impersonation provides authoritative, end-to-end security for your MapR installation, independent of remote authentication and security mechanisms that control user access to application features.

To implement impersonation in MapR, there are both MapR core and ecosystem component requirements that must be met as well as requirements at the application development level. These requirements are described in Access Control and Impersonation in MapR.

When all other requirements are met, enabling impersonation for the mapr superuser or for any other user is a simple task.

Auditing in MapR

MapR allows you to log audit records of cluster-administration operations, and operations on directories, files, streams and tables.

last-updated: Apr 11, 2022

The auditing capabilities in MapR are critical for regulatory compliance as well as for understanding user behavior. Regulations often require the ability to prove which user accessed which data. Logging user behavior helps to identify suspicious activities on sensitive data.

What Information is Collected?

If you enable auditing, MapR records information about data access, operations on data objects, and execution of `maprcli` commands, including the following:

- All administrator activities that use `maprcli` commands, REST API calls, and actions performed on a cluster through the Control System
- Authentication to the Control System
- Operations on directories and files
- Operations on MapR Database objects
- Operations on MapR Event Store For Apache Kafka

How is Auditing Typically Used?

By analyzing audit records, security analysts can answer questions such as these:

- Who accessed customer records outside of business hours?
- What actions did users take in the days before leaving the company?
- What operations were performed without following change control?
- Are users accessing sensitive files from protected or secured IP addresses?
- Why do my reports sourced from the same underlying data look different?

Data scientists can analyze audit records to answers these questions:

- Which data is used most frequently, is therefore of high value, and should be shared more broadly?
- Which data is least commonly used, is therefore of low value, and could be purged?
- Which data should be used more, is therefore underused, and needs better advertising?
- Which administrative actions are most commonly performed and are therefore candidates for automation?

How does Auditing Work?

For a comprehensive explanation on how auditing works, see How Does Auditing Work? on page 760.

What are the Levels of Auditing?

Levels of Auditing on page 693 explains the two levels of auditing.

What are the Prerequisites to Enable Auditing?

Ensure that you perform the prerequisites mentioned in Managing Auditing on page 757 before enabling auditing.

How to Enable or Disable Auditing of Data Access Operations?

To enable or disable auditing of data access operations, see Enabling and Disabling Auditing of Data Access Operations on page 758.

What is Audited for Data Access Operations?

Auditing Data Access Operations on page 698 describes the data access operations that are audited.

How to Enable or Disable Auditing of Cluster Administration Operations?

To enable or disable auditing of cluster administration operations, see Enabling and Disabling Auditing of Cluster Administration on page 758.

What is Audited for Cluster Administration Operations?

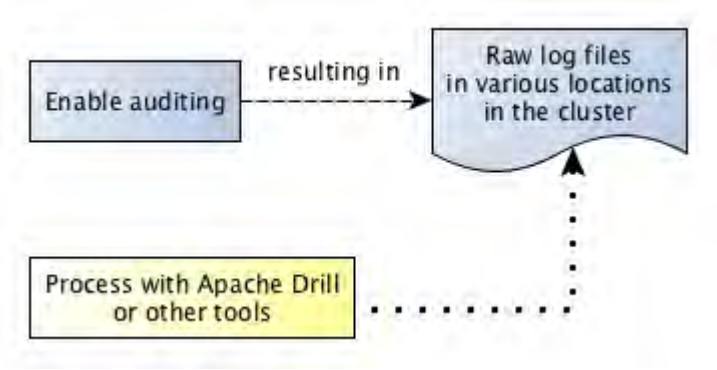
Auditing Cluster Operations on page 696 describes the operations that are audited on a cluster.

How to Selectively Audit MapR Objects?

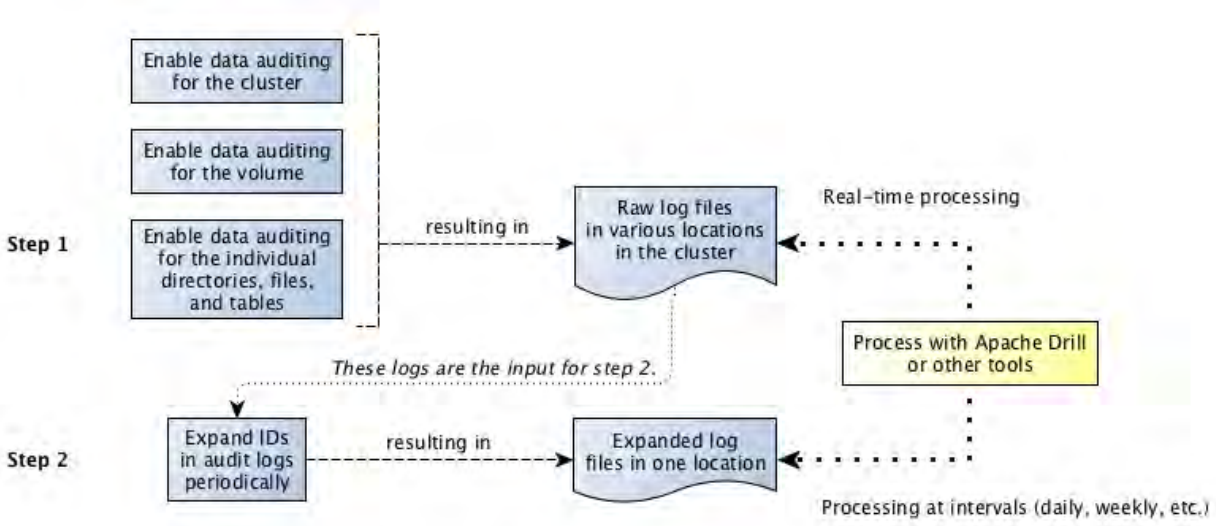
To selectively audit MapR Objects, see Selective Auditing of MapR File System, MapR Database Table, and MapR Event Store For Apache Kafka Operations Using the CLI on page 761.

How to use Audit Logs?

After you enable auditing, audit records immediately start to be recorded in audit logs. You can use Apache Drill or other tools to process these logs. The following diagram shows the workflow for processing audit logs of cluster-administration operations:



The next diagram shows the workflow for processing audit logs of filesystem and table operations.



The step "Expand IDs in log files periodically" refers to the use of the `expandaudit` utility. Raw audit logs contain file identifiers, volume identifiers, and user identifiers. The `expandaudit` utility looks up the names that are associated with those identifiers and puts them in new copies of the audit logs. In addition, the MapR audit streaming feature uses an API to convert file and volume IDs. The information on audit log files can be used to interpret auditing messages.

How to Stream Audit Logs?

To stream audit logs, see Streaming Audit Logs on page 701.

How to Enable or Disable Audit Streaming

To enable or disable audit streaming, see Enabling and Disabling Audit Streaming Using the CLI on page 764.

Levels of Auditing

Describes the two levels of auditing and the requirements to enable each level.

There are two levels of auditing:

- Auditing for cluster level operations
- Auditing of filesystem, table, and stream operations

In contrast to auditing cluster-level operations, auditing of filesystem, table, and stream operations needs to be enabled at multiple levels. For auditing file, table, and stream operations, you must first enable auditing at the cluster level and then enable auditing at the volume level. If you want:

- Granular or selective auditing of content in the volume, you must also enable auditing on each individual directory, file, table, and/or stream in the volume, recursively from the root directory, using the `hadoop` command. If auditing is enabled at the root directory, all new files inherit the property.
- To audit all content (files, tables, and/or streams) in the volume, you can set the `forceaudit` parameter at the volume level, irrespective of what is set (or whether or not auditing is enabled) at the individual file, table, and/or stream level.

The following table summarizes the requirements:

For this type of auditing...	You must enable...	Using...
Cluster-level operations	Auditing at the cluster level	`audit cluster` on page 1553 command
Granular or selective auditing of content (files, tables, and streams) in the volume	1. Auditing at the cluster level 2. Auditing at the volume level 3. Auditing on each individual file, table, and/or stream in the volume, recursively from the root directory	1. `audit cluster` on page 1553 command 2. `audit data` on page 1553, `volume create` on page 1931, or `volume modify` on page 2005 command 3. `hadoop mfs` on page 5373 command
Auditing all content (files, tables, and streams) in the volume (whether or not auditing is selectively enabled or disabled on the individual file, table, or stream)	1. Auditing at the cluster level 2. Auditing at the volume level	1. `audit cluster` on page 1553 command 2. `audit data` on page 1553, `volume create` on page 1931, or `volume modify` on page 2005 command

In the following diagram, the illustration on the left shows data auditing enabled at three levels: the cluster level, through the `maprcli audit data` command; the volume level, through any of the three volume commands shown in the diagram; and the level of the individual directory, file, table, or stream, recursively from the root directory, using the `hadoop` command. This allows you to include and/or exclude specific directories, files, tables, and streams for auditing. If auditing is not enabled at any one of these levels, operations on an object are not logged.

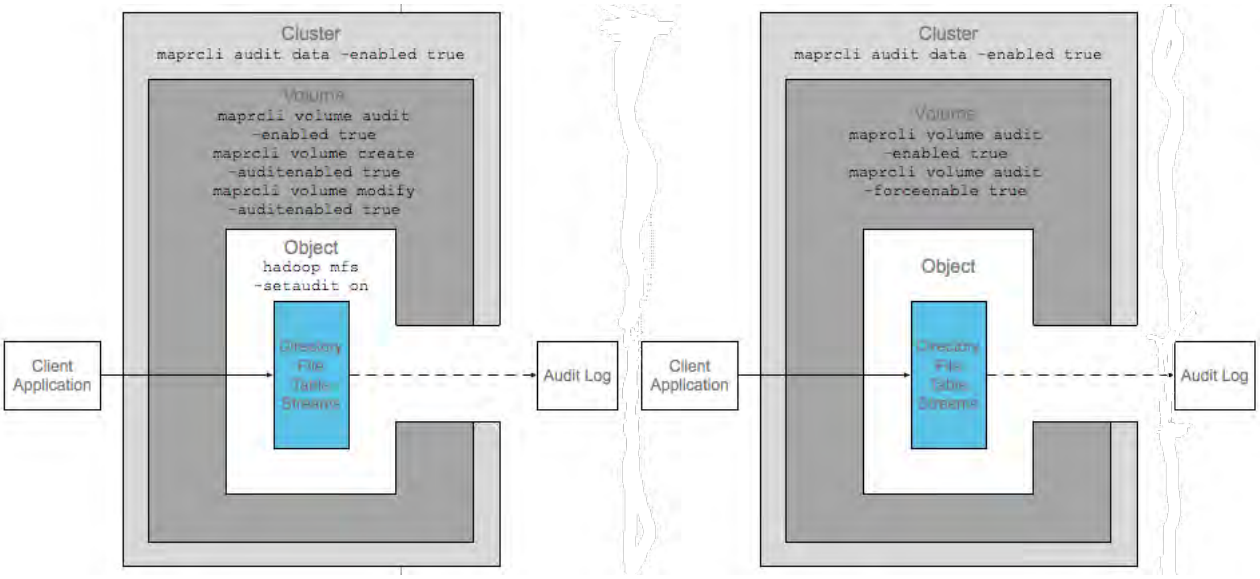
Alternatively, after enabling auditing at the cluster level, you can enforce auditing for all directories, files, tables, and streams at the volume level itself, irrespective of audit setting at the individual file, table, and/or stream level, using:

- `auditenabled` and `forceauditenable` parameters with the `volume create` on page 1931 or `volume modify` on page 2005 command.
- `enabled` and `forceenable` parameters with the `volume audit` on page 1922 command.

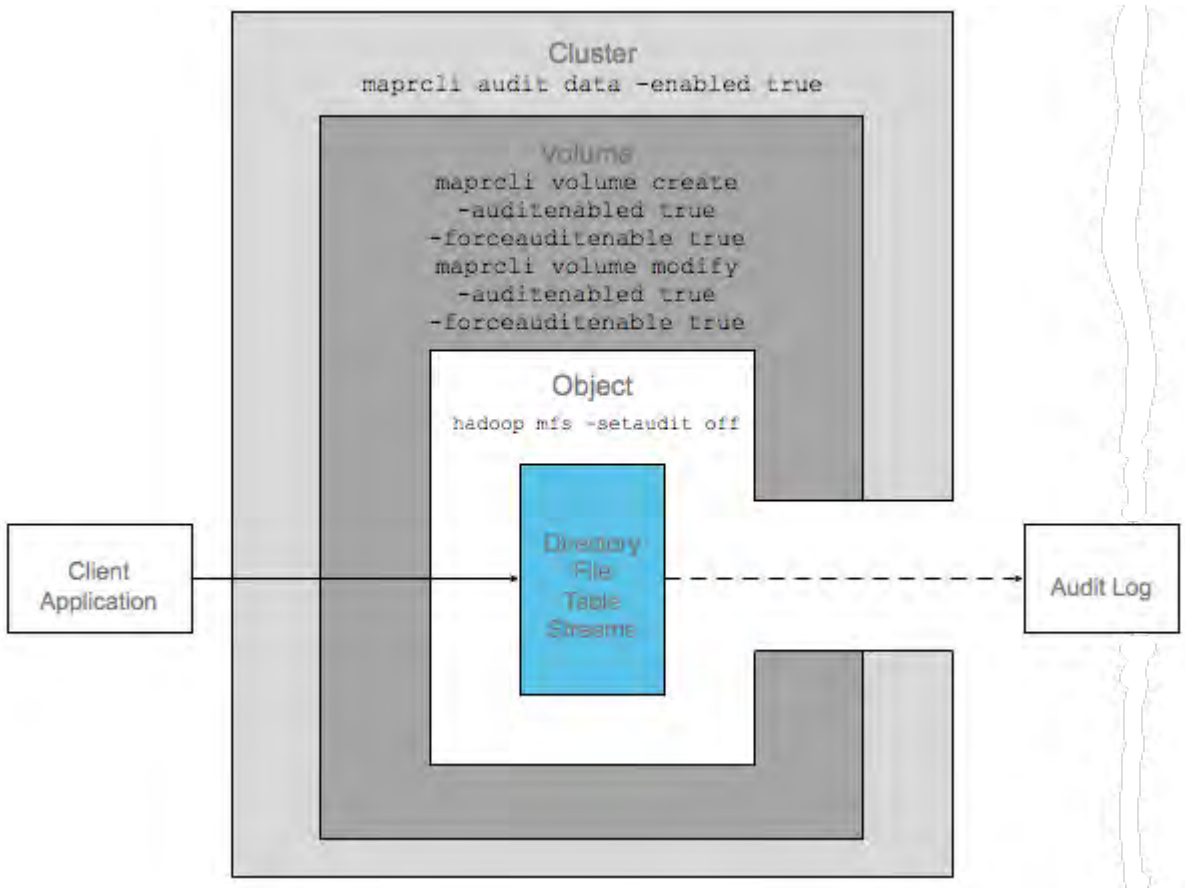
The illustration on the right shows auditing enabled at two levels: the cluster level, through the `audit data` on page 1553 command and the volume level through `volume audit` on page 1922 command (`enabled` and `forceenable` parameters).

Note: You can enable auditing at the volume level using the `volume create` on page 1931 and `volume modify` on page 2005 commands also.

As all levels are enabled, operations that, for example, a client application makes on a directory, file, table, or stream are recorded in an audit log.

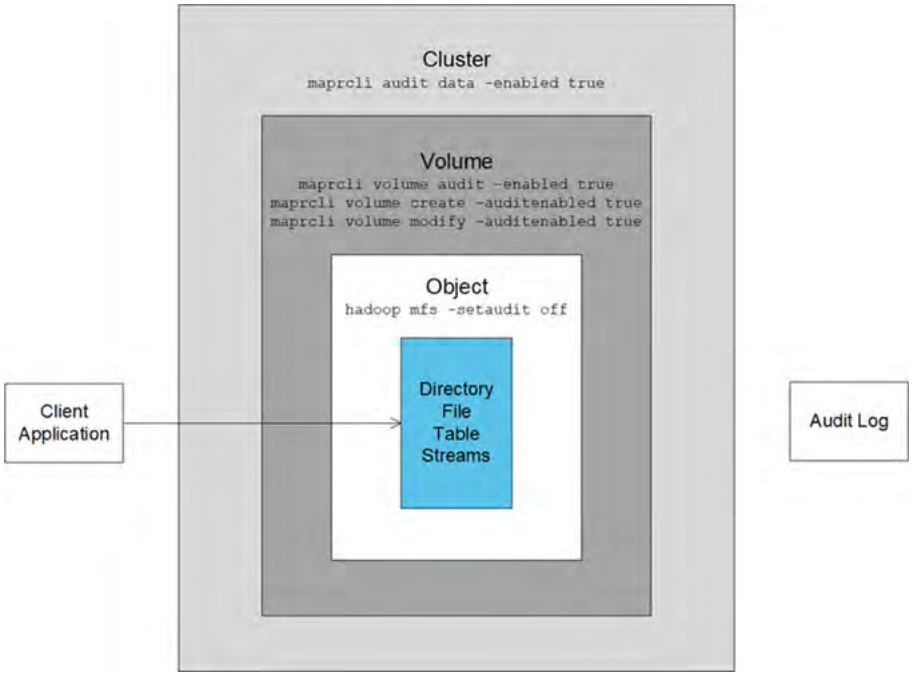


To state another example, in the following diagram, auditing is enabled at the cluster level using the `audit data` on page 1553 command and at the volume level through the `auditenabled` and `forceauditenable` parameters set using any one of the volume commands. Also note that although auditing is explicitly disabled at the directory, file, table, and/or stream level, operations on all directories, files, tables, and streams in the volume are audited because `forceauditenable` is set to `true` at the volume level.

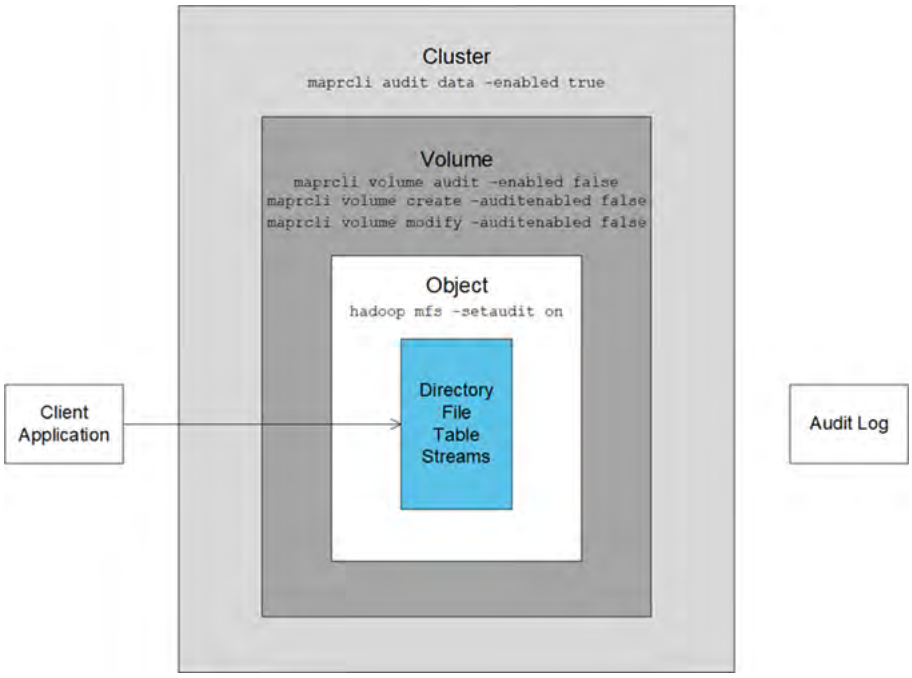


For granular or selective auditing, the following diagram shows auditing enabled at the cluster level and the volume level (with just the `auditenabled` parameter), but not on the directory, file, table, or stream on

which an operation is performed. Although the two higher levels are enabled for auditing, the operation is not logged in an audit log because the objects on which auditing has to be performed is not enabled for auditing.



For granular or selective auditing, as a final example, in the next diagram auditing is enabled on the individual directory, file, table, or stream, and at the cluster level. However, auditing is not enabled at the volume level. Therefore, the operation that the client application performs on the object is not recorded in an audit log.



Auditing Cluster Operations
Explains the operations that are audited for a cluster.

The following types of operations are audited when you run the `maprcli audit cluster` command on a cluster:

last-updated: Apr 11, 2022

- All `maprcli` commands, REST calls, and actions in the Control System that have effects at the cluster level, including those that enable auditing, are audited.
- All authentications to the Control System and authentications to MapR clusters via `maprlogin` are audited.
- All volume level tiering operations are audited.

Audit records for these operations are recorded in the following audit logs:

Audit logs for operations related to cluster management and authentications to clusters via maprlogin

Every CLDB operation is logged in the local filesystem of the CLDB node that responded to the operation. The log file is `/opt/mapr/logs/cldbaudit.log.json`.

Audit logs for maprcli commands, REST API calls, and actions in the Control System

Executions of `maprcli` commands, REST API calls, and actions in the Control System are logged in the local filesystem on the nodes where they are executed. Log files are located at `/opt/mapr/mapr-cli-audit-log/audit.log.json`. To see what information is recorded in typical log entries, see Example Log Entries for Audited maprcli Command Executions, REST API Calls, and Actions in the Control System.

The following `maprcli` commands, as well as their equivalent REST API calls and actions in the Control System, are also logged in audit logs on the servers where they are processed.

Command Family	Commands
acl	`acl edit, acl set, acl show`
audit	`audit cluster, audit data, audit info`
blacklist	`blacklist listusers, blacklist user`
cluster	`cluster mapreduce get, cluster mapreduce set`
config	`config load, config save`
entity	`entity info, entity list, entity modify`
license	`license add, license addcrl, license apps, license list, license listcrl, license remove, license showid`
nagios	`nagios generate`
rlimit	`rlimit get, rlimit set`
schedule	`schedule create, schedule list, schedule modify, schedule remove`
virtualip	`virtualip add, virtualip edit, virtualip list, virtualip move, virtualip remove`

last-updated: Apr 11, 2022

volume	`volume compact, volume container move, volume container switchmaster, volume create, volume fixmountpath, volume info, volume list, volume mirror push, volume mirror start, volume mirror stop, volume modify, volume mount, volume move, volume offload, volume recall, volume remove, volume rename, volume showmounts, volume snapshot list, volume snapshot preserve, volume snapshot remove, volume tierstats, volume tierjobabort, volume tierjobstatus, volume unmount`  **Note:** These commands are not audited: `volume dump create, volume dump restore, volume link create, volume link remove, volume snapshot create`

Audit logs for authentications to the Control System

Every attempt at authentication to the Control System, whether successful or unsuccessful, is logged to the local filesystem in `/opt/mapr/logs/authaudit.log.json` on the webserver node where an attempt was made.

Audit logs for volume level tiering operations

All volume level tiering operations, whether successful or unsuccessful, are logged in the `/opt/mapr/logs/cldbaudit.log.json` file.

Auditing Data Access Operations

Describes MapR File System, MapR Database, and MapR Event Store For Apache Kafka operations that are audited by default, and operations that can be selectively enabled or disabled for auditing.

This type of auditing is for operations that are managed by the MapR File System, MapR Database, and MapR Event Store For Apache Kafka. These operations take place within volumes and have effects at the level of the MapR filesystem.

Auditing of Operations on Directories and Files

The following table shows whether (`Y`) or not (`N`) the following operations on files and directories are audited. In the table, the operations with `Y` in the **Selective Auditing Support** column can be included and/or excluded from auditing. Operations with `N` in the **Selective Auditing Support** column are audited by default and cannot be excluded from auditing. Use the name specified in the **Operation Name to use for Selective Auditing** column when you run the maprcli command to enable or disable auditing for that operation.

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Directories	Files	Selective Auditing Support
Change group owner	CHGRP	chgrp	Y	Y	Y
Change owner	CHOWN	chown	Y	Y	Y
Change permissions	CHPERM	chperm	Y	Y	Y
Create	CREATE	create	N/A	Y	Y
Create symbolic link	CREATESYM	createsym	Y	Y	Y
Delete file	DELETE	delete	N/A	Y	Y
Disable auditing	DISABLEAUDIT	N/A	Y	Y	N

last-updated: Apr 11, 2022

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Directories	Files	Selective Auditing Support
Enable auditing	ENABLEAUDIT	N/A	Y	Y	N
Offload file to tiered storage	FILE_OFFLOAD	fileoffload or filetieroffloadevent	N/A	Y	Y
Recall file from tiered storage	FILE_RECALL	filerecall or filetierrecallevent	N/A	Y	Y
Scan offset ranges owned by given FID. Used in tiered operations to get owned offsets during offload and recall operations.	FILE_SCAN	filescan	N/A	Y	Y
Abort ongoing offload or recall of file	FILE_TIER_JOBABORT	filetierjobabort	N/A	Y	Y
Retrieve status for an existing file level tier job (offload/recall)	FILE_TIER_JOBSTATUS	filetierjobstatus	N/A	Y	Y
Audit event generated on file server while purging data during offload operation	FILE_TIER_OFFLOAD_EVENT	filetieroffloadevent	N/A	N	Y
Audit event generated on file server while recalling data during recall operation	FILE_TIER_RECALL_EVENT	filetierrecallevent	N/A	N	Y
Get attributes	GETATTR	geattr	N	N	Y
Get extended attributes	GETXATTR	getxattr	Y	Y	Y
Get the mode bits for files/directories accessed over NFS	GETPERM	getperm	Y	Y	Y
List extended attributes	LISTXATTR	listxattr	Y	Y	Y
Lookup	LOOKUP	lookup	Y	Y	Y
Create directory	MKDIR	mkdir	Y	N/A	Y
Read a file	READ	read	N/A	Y	Y
Read a directory	READDIR	readdir	Y	N/A	Y
Remove extended attributes	REMOVEXATTR	removexattr	Y	Y	Y
Rename	RENAME	rename	Y	Y	Y
Delete a directory	RMDIR	rmdir	Y	N/A	Y
Set attributes	SETATTR	setattr	Y	Y	Y
Set extended attributes	SETXATTR	setxattr	Y	Y	Y
Truncate a file	TRUNCATE	truncate	N/A	Y	Y
Write to a file	WRITE	write	N/A	Y	Y

last-updated: Apr 11, 2022

Auditing of Operations on MapR Database Binary Tables and JSON Tables

The following operations on both types of MapR Database tables are audited by default. Operations with `Y` in the **Selective Auditing Support** column can be included or excluded from auditing. Operations with `N` in the **Selective Auditing Support** column are audited by default and cannot be excluded from auditing. Use the name specified in the **Operation Name to use for Selective Auditing** column when you run the maprcli command to enable or disable auditing for that operation.

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Selective Auditing Support
Create a column family	DB_CFCREATE	tablecfcreate	Y
Modify a column family	DB_CFMODIFY	tablecfmodify	Y
Delete a column family	DB_CFREMOVE	tablecfdelete	Y
Scan a column	DB_CFSCAN	tablecfscan	Y
Get data	DB_GET	tableget	Y
Perform incremental bulk load	DB_IMPORTBUCKET	N/A	N
Perform full bulk load	DB_IMPORTSEGMENT	N/A	N
Put data	DB_PUT	tableput	Y
Compact a table region	DB_REGIONCOMPACT	N/A	N
Look up a region on the current node	DB_REGIONLOOKUP	N/A	N
Merge two consecutive regions	DB_REGIONMERGE	N/A	N
Split a region into two	DB_REGIONSPLIT	N/A	N
Configure a replica for a table	DB_REPLICAADD	N/A	N
Edit the replica for a table	DB_REPLICAEDIT	N/A	N
List the replicas for a table	DB_REPLICALIST	N/A	N
Remove a replica for a table	DB_REPLICAREMOVE	N/A	N
Scan a table	DB_SCAN	tablescan	Y
Create a table	DB_TABLECREATE	tablecreate	Y
View information about a table	DB_TABLEINFO	tableinfo	Y
Modify a table	DB_TABLEMODIFY	tablemodify	Y
Add an upstream source to a replica	DB_UPSTREAMADD	N/A	N
List all upstream sources for a replica	DB_UPSTREAMLIST	N/A	N
Remove an upstream source for a replica	DB_UPSTREAMREMOVE	N/A	N

Auditing of Operations on MapR Event Store For Apache Kafka

The following operations on MapR Event Store For Apache Kafka are audited by default. Operations with `Y` in the **Selective Auditing Support** column can be included or excluded from auditing. Operations with `N` in the **Selective Auditing Support** column are audited by default and cannot be excluded from auditing. Use the name specified in the **Operation Name to use for Selective Auditing** column when you run the maprcli command to enable or disable auditing for that operation.

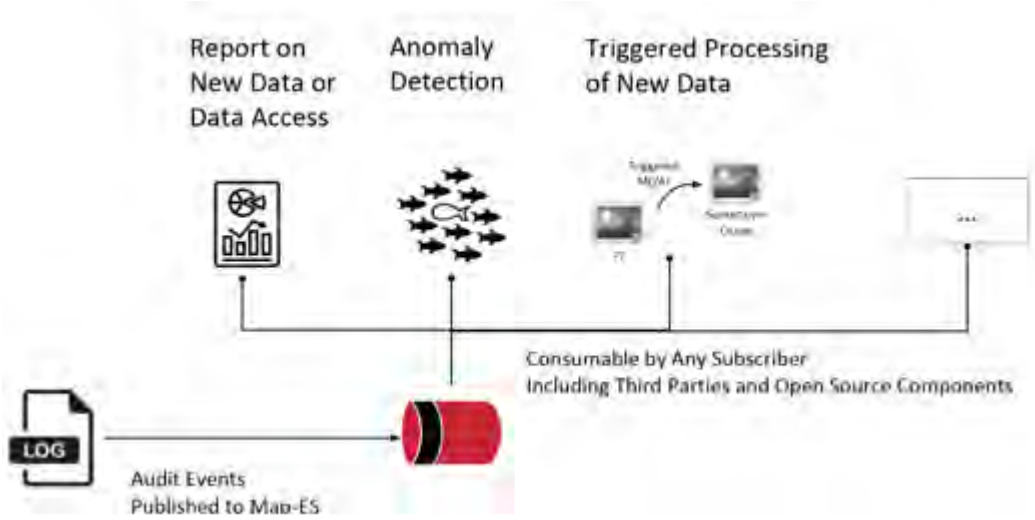
last-updated: Apr 11, 2022

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Selective Auditing Support
Modify attributes or permissions of a stream	DB_CFMODIFY	tablecfmodify	Y
Produce messages to topics of a stream	DB_PUT	tableput	Y
Add a replica	DB_REPLICAADD	N/A	N
Edit a replica	DB_REPLICAEDIT	N/A	N
List the replicas for a stream	DB_REPLICALIST	N/A	N
Remove a replica	DB_REPLICAREMOVE	N/A	N
Consume messages from topics of a stream	DB_SCAN	tablescan	Y
Add an upstream source to a replica	DB_UPSTREAMADD	N/A	N
List all upstream sources for a replica	DB_UPSTREAMLIST	N/A	N
Remove an upstream source from a replica	DB_UPSTREAMREMOVE	N/A	N

Streaming Audit Logs
Describes the audit streaming feature and how to consume the audit stream messages.

Audit-streaming (available from v6.0.1) eliminates the need to process the logs nightly using the `expandaudit on page 2096` utility and provides a way to process the audit data in real-time. The audit data is sent as a audit stream as the audit data is generated, opening the possibility for real-time processing of the audit data. You can use it to monitor data access such as:

- Who accessed certain files, tables, and/or streams at certain times
- What type of action is/was performed on the files, tables, and/or streams
- How many failed attempts were made on the files, tables, and/or streams in a certain period
- When did a particular property or configuration change and who changed it



Audit Stream Creation, Location, and Topic

Audit streaming is not enabled by default; you can enable audit streaming using the CLI. If the feature is enabled, MapR File System, MapR Database, and MapR Event Store For Apache Kafka operation-related audit logs and CLDB and auth audit logs are available as MapR Event Store For Apache Kafka topics. The audit-streaming consumer can view all audited operations on a node in the cluster in near real-time by subscribing to one or more topics associated with a node.

The audit stream is created when the hoststats process starts. If the hoststats process is restarted, the audit stream starts publishing to topics from where it left off processing audit logs; some audit log entries might be republished.

The audit log stream topic is available at the following location:

```
/var/mapr/auditstream/
```

Topics named `<clusterName>_<logType>_<nodeName>` are published to the stream (`/var/mapr/auditstream/auditlogstream:<clustername>_<logType>_<nodename>`). Here:

- `<clustername>` is the name of the cluster.
- `<logType>` is the type of the log. Valid types are `cldb`, `auth`, `fs`, and `db` (for both MapR Database and MapR Event Store For Apache Kafka logs).
- `<nodeName>` is the hostname of the node on which the operation was logged.

The message is in JSON format and is identical to the audit log content, as in the following example:

```
{"timestamp":
{"$date":"2017-04-27T10:53:37.239Z"},"operation":"CREATE","uid":0,"ipAddress
":"10.20.30.140","nfsServer":"10.20.30.140","parentFid":"2066.32.131358","ch
ildFid":"2066.33.262630","childName":"abc.txt","volumeId":106738640,"status"
:0}
```

Duration of Audit Stream Topics

Messages in the topics are stored by default for 7 days.

Consuming Audit Stream Messages

Only the `mapr` user can consume the stream. Refer to Sample Cached Consumer Application for Audit Stream on page 2741 and Sample Uncached Consumer Application for Audit Stream on page 2747 for information on consuming the messages using the sample consumers.

Security for Ecosystem Components

Whether you install MapR software by using the MapR Installer or by using manual steps, the platform and its ecosystem components are installed with security ON by default.

MapR Installer: Security with a Single Click

A single option in the MapR Installer controls security for the platform and ecosystem components. The **Enable MapR Secure Cluster** option is checked by default for new installations.

Before starting a new installation, if you want to disable security for the platform and ecosystem components, you can deselect the **Enable MapR Secure Cluster** option. Later, after the cluster is installed, if you want to add or remove security, you can select or deselect the option during an **Incremental Install** operation. For more information, see Enable MapR Secure Cluster.

last-updated: Apr 11, 2022

Note: Note that some exceptions to secure by default can require manual intervention. Also, before enabling security using the Incremental Install function, be sure to review the known issue (IN-1084) related to custom certificates. See MapR Installer Known Issues.

Manual Installation: Security with configure.sh

When you install a MapR cluster by using the manual steps, you configure security on all nodes by using the `configure.sh` script with the `-secure -genkeys` options, as described in Enabling Security on page 154.

Manual installation also creates a cluster that is *secure by default*. For individual ecosystem components, additional security measures are supported, depending on the component. See the notes in the following table.

Security and Ecosystem Components

The MapR platform and the majority of ecosystem components are installed to be secure by default (with some exceptions). The following table lists the EEP 6.0.0 ecosystem components that are secure by default when installed using the MapR Installer or manual installation steps.

Component	Supports Secure by Default	Notes
AsynchHBase	N/A	Security is not applicable. This component acts as a library.
Data Access Gateway 2.0	Yes	For more information, see Understanding the MapR Data Access Gateway on page 750.
Drill	Yes	For more information about Drill security, see Securing Drill on page 3275.
Flume	No	Flume is installed as a library but works like a service after the agents are started. To configure security for Flume, see Configuring Flume on page 3368. Security Exceptions on page 737 notes a security exception for Avro clients.
HBase	Yes	For more information, see HBase Configuration Properties on page 3390.
HBase REST / Thrift Gateway	Yes	For more information, see HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL on page 3404.
Hive	Yes	For more information, see Hive Security on page 3427.
Httpfs	Yes	For more information, see Configuring HttpFS on page 3610.
Hue	Yes	For more information, see Configure Hue with Security on page 3636.
Impala	No	This component can be configured to run on a secure MapRdata-fabric cluster. Security must be configured manually. See Impala Security on page 3811.

last-updated: Apr 11, 2022

Component	Supports Secure by Default	Notes
Kafka-Connect	Yes	For more information, see Worker Configuration on page 3908.
Kafka-REST	Yes	For more information, see User Impersonation on page 3871 and SSL Security Configuration on page 3870.
KSQL	No	For more information, see KSQL Security on page 3845.
Kafka Streams	No	For more information, see Kafka Streams Security on page 3862.
Livy	Yes	For more information, see Configure Livy on page 3839.
MapR Installer	Yes	For more information, see Using the Enable MapR Secure Cluster Option and Using the Enable MapR DARE Option.
MapR Object Store with S3-Compatible API	Yes	For more information, see S3 Gateway on page 3959.
Myriad	N/A	This component can be configured to run on a secure MapR cluster.
Oozie	Yes	For more information, see Configuring Oozie on a Secure Cluster on page 3990.
Pig	N/A	Security is not applicable. This component acts as a library.
Sentry	No	This component can be configured to run on a secure MapR cluster. Security must be configured manually.
Spark	Yes	For more information, see Spark configure.sh on page 4038.
Sqoop 1	N/A	Security is not applicable. This component acts as a library.
Sqoop2	Yes	For more information, see Configuring Sqoop2 on page 3680.
Timeline Server	Yes	For more information, see Configuring the Timeline Server to Use the Hive-on-Tez User Interface on page 3507.
MapR Monitoring Components		
collectd	Yes	Communicates over MapR streams. See Spyglass on Streams on page 1332.
ElasticSearch	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 737.
FluentD	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 737.

Component	Supports Secure by Default	Notes
Grafana	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 737.
Kibana	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 737.
OpenTSDB	Yes	Communicates over MapR streams. See Spyglass on Streams on page 1332.

Security Settings for Ecosystem Components

Lists the security settings for all MapR ecosystem components.

The security settings for the various MapR ecosystem components are as follows:

Security Settings for Hadoop/Yarn

File or command: `core-default.xml`	*Description*: Authentication used for the HTTP web-consoles *Default Secure Setting*: `hadoop.http.authentication.type:org.apache.hadoop.security.authentication.server.MultiMechsAuthenticationHandler` *Alternate Value or Change Command*: simple | kerberos | #AUTHENTICATION_HANDLER_CLASSNAME# *Notes*: None
File or command: `core-default.xml`	*Description*: Custom principal of the service *Default Secure Setting*: `hadoop.security.custom.auth.principal.class:com.mapr.security.MapRPrincipal` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: LDAP Configuration *Default Secure Setting*: `hadoop.security.group.mapping.ldap.search.filter.user:(&(objectClass=user)(sAMAccountName={0}))` *Alternate Value or Change Command*: None *Notes*: An additional filter to use when searching for LDAP users. The default filter is usually appropriate for Active Directory installations. If connecting to an LDAP server with a non-AD schema, replace the default filter with `(&(objectClass=inetOrgPerson)(uid={0})`. {0} is a special string used to denote where the username fits into the filter. If the LDAP server supports posixGroups, Hadoop can enable the feature by setting the value of this property to *posixAccount* and the value of the `hadoop.security.group.mapping.ldap.search.filter.group` property to *posixGroup*.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Client authentication types

	Default Secure Setting: `hadoop.security.authentication: CUSTOM` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Java class that handles HTTP auth secret *Default Secure Setting*: `hadoop.http.authentication.signature.secret:com.mapr.security.maprauth.MaprSignatureSecretFactory` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Group authentication cache duration *Default Secure Setting*: `hadoop.security.groups.cache.secs:300` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Name of the SignerSecretProvider class to use *Default Secure Setting*: `hadoop.http.authentication.signer.secret.provider:org.apache.hadoop.security.authentication.util.MapRSignerSecretProvider` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Service that manages the MapR ticket *Default Secure Setting*: `yarn.external.token.manager:com.mapr.hadoop.yarn.security.MapRTicketManager` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: OS security random device file path *Default Secure Setting*: `hadoop.security.random.device.file.path:/dev/urandom` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Key to set if the registry is secure *Default Secure Setting*: hadoop.registry.secure:false *Alternate Value or Change Command*: true *Notes*: Turning it on, changes the permissions policy from `open access` to restrictions on kerberos with the option of a user adding one or more auth key pairs down their own tree.
File or command: `core-default.xml & core-site.xml`	*Description*: Authentication class name *Default Secure Setting*: `hadoop.log.level.authenticator.class:com`

	`.mapr.security.maprauth.MaprAuthenticator` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*:Indicates if administrator ACLs are required to access instrumentation servlets (JMX, METRICS, CONF, STACKS) *Default Secure Setting*: hadoop.security.instrumentation.requires.admin:false *Alternate Value or Change Command*: true *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*:The keystores factory to use for retrieving certificates *Default Secure Setting*: hadoop.ssl.keystores.factory.class:org.apache.hadoop.security.ssl.FileBasedKeyStoresFactory *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Comma-separated list of crypto codec implementations for AES/CTR/NoPadding *Default Secure Setting*: hadoop.security.crypto.codec.classes.aes.ctr.nopadding:org.apache.hadoop.crypto.OpensslAesCtrCryptoCodec,org.apache.hadoop.crypto.JceAesCtrCryptoCodec *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: The attribute of the group object that identifies the users that are members of the group. *Default Secure Setting*: hadoop.security.group.mapping.ldap.search.attr.member:member *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Logs a warning message, if looking up a single user to group takes longer than the specified number of milliseconds *Default Secure Setting*: hadoop.security.groups.cache.warn.after.ms:5000 *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: The attribute applied to the LDAP Search Control properties to set a maximum time limit when searching and waiting for a result *Default Secure Setting*: `hadoop.security.group.mapping.ldap.directory.search.timeout:10000` *Alternate Value or Change Command*: The unit is in milliseconds. Set to `0` if an infinite wait period is desired. Default is `10` seconds.

	Notes: None
File or command: `core-site.xml`	*Description*: MapR service account ("mapr") impersonation *Default Secure Setting*: • `hadoop.proxyuser.mapr.hosts:*` • `hadoop.proxyuser.mapr.groups:*` *Alternate Value or Change Command*: None *Notes*: Set by default in version 6.1 secure install.
File or command: `yarn-site.xml`	*Description*: Defines the authentication used for the timeline server HTTP endpoint. *Default Secure Setting*: `yarn.timeline-service.http-authentication.type:com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHandler` *Alternate Value or Change Command*: Supported values are: `simple / kerberos / #AUTHENTICATION_HANDLER_CLASSNAME # Defaults to simple.` *Notes*: None.
File or command: `yarn-default.xml`	*Description*: The allowed pattern for UNIX user names enforced by the Linux-container-executor when used in Nonsecure mode (use case for this is using cgroups). *Default Secure Setting*: `yarn.nodemanager.linux-container-executor.nonsecure-mode.user-pattern:^[_.A-Za-z0-9][-@_.A-Za-z0-9]{0,255}?[$]?$` *Alternate Value or Change Command*: None *Notes*: The default value is taken from `/usr/sbin/adduser`.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Indicates whether or not to use SSL when connecting to the LDAP server. *Default Secure Setting*: `hadoop.security.group.mapping.ldap.ssl:false` *Alternate Value or Change Command*: true *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: An additional filter to use when searching for LDAP groups *Default Secure Setting*: `hadoop.security.group.mapping.ldap.search.filter.group:(objectClass=group)` *Alternate Value or Change Command*: None *Notes*: Change this filter when resolving groups against a non-Active Directory installation. See the description of `hadoop.security.group.mapping.ldap.search.filter.user` to enable `posixGroups` support.

last-updated: Apr 11, 2022

File or command: `core-default.xml & core-site.xml`	*Description*: This setting is the configuration controlling the validity of the entries in the cache containing the `userId` to `userName` and `groupId` to `groupName` mappings that are used by `NativeIO getFstat()`. *Default Secure Setting*: `hadoop.security.uid.cache.secs:14400` *Alternate Value or Change Command*: None *Notes*:None
File or command: `yarn-default.xml`	*Description*: Determines which of the two modes LCE should use on a nonsecure cluster. *Default Secure Setting*: `yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users:true` *Alternate Value or Change Command*: false *Notes*:Set this value to `true`, to launch all containers as the user specified in `yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user`. Set this value to `false` to run containers as the user who submitted the application.
File or command: `yarn-default.xml`	*Description*: Disable insecure protocols *Default Secure Setting*: `hadoop.ssl.exclude.insecure.protocols:SSLv3,TLSv1` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Class for user to group mapping (get groups for a given user) for ACL. *Default Secure Setting*: `hadoop.security.group.mapping:org.apache.hadoop.security.JniBasedUnixGroupsMappingWithFallback` *Alternate Value or Change Command*: None *Notes*: The default implementation `org.apache.hadoop.security.JniBasedUnixGroupsMappingWithFallback` determines if the Java Native Interface (JNI) is available. If JNI is available, the implementation uses the API within Hadoop to resolve a list of groups for a user. If JNI is not available, then the shell implementation `ShellBasedUnixGroupsMapping`, is used. This implementation shells out to the Linux/Unix environment with the `bash -c groups` command to resolve a list of groups for a user.
File or command: `core-default.xml & core-site.xml`	*Description*: Class for the 'custom type of authentication' method *Default Secure Setting*: `hadoop.security.custom.rpc.auth.method.class:org.apache.hadoop.security.rpcauth.MaprAuthMethod` *Alternate Value or Change Command*: None *Notes*: None

last-updated: Apr 11, 2022

File or command: `core-default.xml & core-site.xm`	*Description*: The attribute of the group object that identifies the group name *Default Secure Setting*: `hadoop.security.group.mapping.ldap.search.attr.group.name:cn` *Alternate Value or Change Command*: None *Notes*: The default setting is usually appropriate for all LDAP systems.
File or command: `core-default.xml & core-site.xm`	*Description*: The Java secure random algorithm. *Default Secure Setting*: `hadoop.security.java.secure.random.algorithm:SHA1PRNG` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xm`	*Description*: Indicates whether service-level authorization is enabled *Default Secure Setting*: `hadoop.security.authorization:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `core-default.xml & core-site.xm`	*Description*: Expiration time for entries in the the negative user-to-group mapping caching, in seconds *Default Secure Setting*: `hadoop.security.groups.negative-cache.secs:30` *Alternate Value or Change Command*: None *Notes*: This setting is useful when invalid users retry frequently. Set a low value for this expiration, since a transient error in group lookup could temporarily lock out a legitimate user. Set this parameter to zero or a negative value, to disable negative user-to-group caching.
File or command: `yarn-default.xml`	*Description*: Linux-container-executor setting *Default Secure Setting*: `yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user:nobody` *Alternate Value or Change Command*: None *Notes*: The UNIX user that containers run as when Linux-container-executor is used in Nonsecure mode (a use case for this is using cgroups) if the `yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users` is set to `true`.
File or command: `core-default.xml & core-site.xml`	*Description*: Cipher suite for crypto codec. *Default Secure Setting*: `hadoop.security.crypto.cipher.suite:AES/CTR/NoPadding` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Denotes the buffer size used by `CryptoInputStream` and `CryptoOutputStream`.

last-updated: Apr 11, 2022

	Default Secure Setting: `hadoop.security.crypto.buffer.size:8192` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Path to the JAAS configuration file *Default Secure Setting*: `hadoop.security.java.security.login.config.jar.path:/mapr.login.conf` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Indicates if anonymous requests are allowed when using `simple` authentication. *Default Secure Setting*: `hadoop.http.authentication.simple.anonymous.allowed:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `yarn-default.xml`	*Description*: Indicates if anonymous requests are allowed by the timeline server when using `simple` authentication. *Default Secure Setting*: `yarn.timeline-service.http-authentication.simple.anonymous.allowed:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Indicates how long (in seconds) an authentication token is valid before it has to be renewed. *Default Secure Setting*: `hadoop.http.authentication.token.validity:36000` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: IPC client fallback. *Default Secure Setting*: `ipc.client.fallback-to-simple-auth-allowed:false` *Alternate Value or Change Command*: true *Notes*: When a client is configured to attempt a secure connection, but attempts to connect to an insecure server, that server may instruct the client to switch to SASL SIMPLE (unsecure) authentication. This setting controls whether or not the client accepts this instruction from the server. When false (the default), the client does not allow the fallback to SIMPLE authentication, but aborts the connection.
File or command: `yarn-default.xml`	*Description*: Initial duration of the MapR ticket *Default Secure Setting*: `yarn.mapr.ticket.expiration:604800000` *Alternate Value or Change Command*: None

	Notes: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Protocols supported by SSL. *Default Secure Setting*: `hadoop.ssl.enabled.protocols:TLSv1` *Alternate Value or Change Command*: true *Notes*: When a client is configured to attempt a secure connection, but attempts to connect to an insecure server, that server may instruct the client to switch to SASL SIMPLE (unsecure) authentication. This setting controls whether or not the client accepts this instruction from the server. When false (the default), the client does not allow the fallback to SIMPLE authentication, but aborts the connection.
File or command: `core-default.xml` & `core-site.xml`	*Description*: List of excluded ciphers *Default Secure Setting*: `hadoop.ssl.exclude.cipher.suites:SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA,SSL_RSA_EXPORT_WITH_DES40_CBC_SHA, SSL_RSA_EXPORT_WITH_RC4_40_MD5,TLS_DHE_RSA_WITH_AES_128_CBC_SHA,TLS_DHE_RSA_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_256_CBC_SHA256,TLS_DHE_DSS_WITH_AES_256_CBC_SHA256,TLS_DHE_DSS_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_128_CBC_SHA256,TLS_DHE_DSS_WITH_AES_128_CBC_SHA256, TLS_DHE_DSS_WITH_AES_128_CBC_SHA` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Indicates whether client certificates are required *Default Secure Setting*: `hadoop.ssl.require.client.cert:false` *Alternate Value or Change Command*: true *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: The hostname verifier to provide for `HttpsURLConnections` *Default Secure Setting*: `hadoop.ssl.hostname.verifier:DEFAULT` *Alternate Value or Change Command*: Valid values are: `DEFAULT`, `STRICT`, `STRICT_I6`, `DEFAULT_AND_LOCALHOST`, and `ALLOW_ALL` *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Resource file from which SSL client keystore information is extracted *Default Secure Setting*: `hadoop.ssl.client.conf:ssl-client.xml` *Alternate Value or Change Command*: None *Notes*: This file is looked up in the classpath, and is usually present in the Hadoop `conf/` directory.
File or command: `mapred-default.xml`	*Description*: Buffer size for reading spills from file when using SSL.

	Default Secure Setting: `mapreduce.shuffle.ssl.file.buffer.size:65536` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: The keystores factory to use for retrieving certificates. *Default Secure Setting*: `hadoop.ssl.keystores.factory.class:org.apache.hadoop.security.ssl.FileBasedKeyStoresFactory` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Comma-separated list of crypto codec implementations for AES/CTR/NoPadding. *Default Secure Setting*: `hadoop.security.crypto.codec.classes.aes.ctr.nopadding:` `org.apache.hadoop.crypto.OpensslAesCtrCryptoCodec,org.apache.hadoop.crypto.JceAesCtrCryptoCodec` *Alternate Value or Change Command*: None *Notes*: The first implementation is used, if available. Other implementations are fallbacks.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Resource file from which SSL server keystore information is extracted. *Default Secure Setting*: `hadoop.ssl.server.conf:ssl-server.xml` *Alternate Value or Change Command*: None *Notes*: This file is looked up in the classpath, and is usually present in the Hadoop `conf/` directory.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Configures the HTTP endpoint for Yarn daemons. *Default Secure Setting*: `yarn.http.policy:HTTP_ONLY` *Alternate Value or Change Command*: The following values are supported: • HTTP_ONLY: Service is provided only on HTTP • HTTPS_ONLY: Service is provided only on HTTPS *Notes*: None.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Indicates whether or not to use SSL when connecting to the LDAP server. *Default Secure Setting*: `hadoop.security.group.mapping.ldap.ssl:false` *Alternate Value or Change Command*: None *Notes*: None.

File or command: `core-default.xml & core-site.xml`	*Description*: Enables or disables SSL connections to S3. *Default Secure Setting*: `fs.s3a.connection.ssl.enabled:true` *Alternate Value or Change Command*: false *Notes*: None.
File or command: `mapred-default.xml`	*Description*: Indicates whether to use SSL for for the Shuffle HTTP endpoints. *Default Secure Setting*: `mapreduce.shuffle.ssl.enabled:false` *Alternate Value or Change Command*: true *Notes*: None.

Security Settings for Hive

File or command: `hive-site.xml`	*Description*: Hive client authenticator manager class name *Default Secure Setting*: `hive.security.authenticator.manager:org.apache.hadoop.hive.ql.security.HadoopDefaultAuthenticator` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `hive-site.xml`	*Description*: Enables or disables Hive client authorization *Default Secure Setting*: `hive.security.authorization.enabled:true` *Alternate Value or Change Command*: false *Notes*: None.
File or command: `hive-site.xml`	*Description*: The Hive client authorization manager class name *Default Secure Setting*: `hive.security.authorization.manager:org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `hive-site.xml`	*Description*: List of comma separated Java regexes *Default Secure Setting*: `hive.security.authorization.sqlstd.confwhitelist:hive\.exec\.pre\.hooks` *Alternate Value or Change Command*: None *Notes*: You can modify configurations parameters that match these regexes when you enable SQL standard authorization.
File or command: `hive-site.xml`	*Description*: Authorization DDL task factory implementation *Default Secure Setting*: `hive.security.authorization.task.factory`

	`:org.apache.hadoop.hive.ql.parse.authorization.HiveAuthorizationTaskFactoryImpl` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Comma-separated list of non-SQL Hive commands that users are authorized to execute *Default Secure Setting*: `hive.security.command.whitelist:set,reset,dfs,add,list,delete,reload,compile` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Authenticator manager class name to be used in the metastore for authentication. *Default Secure Setting*: `hive.security.metastore.authenticator.manager:org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: When set to true, the metastore authorizer authorizes read actions on the database and table *Default Secure Setting*: `hive.security.metastore.authorization.auth.reads:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: Names of authorization manager classes (comma-separated) to be used in the metastore for authorization. *Default Secure Setting*: `hive.security.metastore.authorization.manager:org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider` *Alternate Value or Change Command*: None *Notes*: The user defined authorization class should implement interface `org.apache.hadoop.hive.ql.security.authorization.HiveMetastoreAuthorizationProvider`. All authorization manager classes have to successfully authorize the metastore API call for the command execution to be allowed.
File or command: `hive-site.xml`	*Description*: If true, the HiveServer2 WebUI is secured with PAM *Default Secure Setting*: `hive.server2.webui.use.pam=true` *Alternate Value or Change Command*: false *Notes*: None

File or command: `hive-site.xml`

Description: Class for PAM authentication

Default Secure Setting:
`hive.server2.webui.pam.authenticator:org.apache.hive.http.security.PamAuthenticator`

Alternate Value or Change Command: None

Notes: None

File or command: `hive-site.xml`

Description: Determines whether the metastore performs authorization checks against the underlying storage for operations such as drop-partition

Default Secure Setting:
`hive.metastore.authorization.storage.check.externaltable.drop:true`

Alternate Value or Change Command: false

Notes: Disallow the drop-partition if the user in question does not have permissions to delete the corresponding directory on the storage

File or command: `hive-site.xml`

Description: Determines whether the metastore performs authorization checks against the underlying storage for operations such as drop-partition

Default Secure Setting:
`hive.metastore.authorization.storage.checks:false`

Alternate Value or Change Command: true

Notes: Disallow the drop-partition if the user in question does not have permissions to delete the corresponding directory on the storage

File or command: `hive-site.xml`

Description: Client authentication types.

Default Secure Setting:
`hive.server2.authentication:PAM`

Alternate Value or Change Command:

- NONE: no authentication check – plain SASL transport
- LDAP: LDAP/AD based authentication
- KERBEROS: Kerberos/GSSAPI authentication
- CUSTOM: Custom authentication provider (use with property `hive.server2.custom.authentication.class`)
- PAM: Pluggable authentication module (added in Hive 0.13.0 with HIVE-6466)
- NOSASL: Raw transport (added in Hive 0.13.0)

Notes: None

File or command: `hive-site.xml`

Description: Use this property in LDAP search queries for finding LDAP group names to which a user belongs

Default Secure Setting:
`hive.server2.authentication.ldap.groupClassKey:groupOfNames`

Alternate Value or Change Command: None

Notes: Use this property to construct a LDAP group search query, and to indicate the `objectClass` of a group. Every LDAP group has a certain `objectClass`. For example: `group`, `groupOfNames`, and `groupOfUniqueNames`.

File or command: `hive-site.xml`

Description: LDAP attribute name on the group object that contains the list of distinguished names for the user, group, and contact objects that are members of the group.

Default Secure Setting: `hive.server2.authentication.ldap.groupMembershipKey:member`

Alternate Value or Change Command: None

Notes: For example: `member`, `uniqueMember`, or `memberUid`. Use this property in LDAP search queries when finding LDAP group names to which a particular user belongs. The value of the LDAP attribute as indicated by this property, should be a full DN for the user or the short username or userid.

For example, a group entry for `fooGroup` containing `member : uid=fooUser,ou=Users,dc=domain,dc=com` helps determine that `fooUser` belongs to LDAP group `fooGroup`.

See Group Membership for a detailed example. You can use this property to find the users, if a custom-configured LDAP query returns a group instead of a user (as of Hive 2.1.1). For details, see Support for Groups in Custom LDAP Query.

File or command: `hive-site.xml`

Description: This property indicates the prefix to use when building the `bindDN` for LDAP connection (when using only `baseDN`).

Default Secure Setting: `hive.server2.authentication.ldap.guidKey:uid`

Alternate Value or Change Command: None

Notes: `bindDN` is `<guidKey>=<user/group>,<baseDN>`. If the configuration uses `userDNPattern` and/or `groupDNPattern`, the `guidKey` is not required. The `guidKey` is required when only the `baseDN` is being used.

File or command: `hive-site.xml`

Description: When `true`, HiveServer2 in HTTP transport mode uses a cookie-based authentication mechanism.

Default Secure Setting: `hive.server2.thrift.http.cookie.auth.enabled:true`

Alternate Value or Change Command: None

Notes: None

File or command: `hive-site.xml`

Description: Sasl QOP value; set it to one of the following values to enable higher levels of protection for HiveServer2 communication with clients.

Default Secure Setting: `hive.server2.thrift.sasl.qop:auth-conf`

	Alternate Value or Change Command: One of: • auth – authentication only (default) • auth-int – authentication plus • integrity protection auth-conf – authentication plus integrity and confidentiality protection *Notes*: Note that setting `hadoop.rpc.protection` to a higher level than HiveServer2 does not make sense in most situations. HiveServer2 ignores `hadoop.rpc.protection` in favor of `hive.server2.thrift.sasl.qop`. This setting is applicable only if HiveServer2 is configured to use Kerberos authentication.
File or command: `hive-site.xml`	*Description*: Applies test settings for HS2 (for example for standard base authorization verification in `FallbackHiveAuthorizer` or in `SQLAuthorizationUtils`). *Default Secure Setting*: `hive.test.authz.sstd.hs2.mode:false` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Setting this property to `true` enables HiveServer2 to execute Hive operations as the user making the calls. *Default Secure Setting*: `hive.server2.enable.doAs=true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: Indicates whether metastore should use SSL *Default Secure Setting*: `hive.metastore.use.SSL:false` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: SSL certificate keystore location. *Default Secure Setting*: `hive.server2.keystore.path:/opt/mapr/conf/ssl_keystore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Set this to `true` to use SSL encryption in HiveServer2. *Default Secure Setting*: `hive.server2.use.SSL:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: SSL certificate keystore location for HiveServer2 WebUI.

	Default Secure Setting: `hive.server2.webui.keystore.path:/opt/mapr/conf/ssl_keystore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Set this to `true` to use SSL encryption for HiveServer2 WebUI. *Default Secure Setting*: `hive.server2.webui.use.ssl:true` *Alternate Value or Change Command*: true *Notes*: None
File or command: `hive-site.xml`	*Description*: SSL protocols that need to be disabled *Default Secure Setting*: `hive.ssl.protocol.blacklist:SSLv2,SSLv3` *Alternate Value or Change Command*: None *Notes*: None

Security Settings for Oozie

File or command: `oozie-default.xml` & `oozie-site.xml`	*Description*: Authentication used for Oozie HTTP endpoint *Default Secure Setting*: `oozie.authentication.type=simple` *Alternate Value or Change Command*: The supported values are: • simple • keberos • #AUTHENTICATION_HANDLER_CLASSNAME# *Notes*: None
File or command: `oozie-default.xml` & `oozie-site.xml`	*Description*: Denotes how long (in seconds) an authentication token is valid before it has to be renewed *Default Secure Setting*: `oozie.authentication.token.validity=36000` *Alternate Value or Change Command*: None *Notes*: None
File or command: `oozie-default.xml` & `oozie-site.xml`	*Description*: If not set, a random secret is generated at startup time *Default Secure Setting*: `oozie.authentication.signature.secret=` *Alternate Value or Change Command*: The signature secret for signing the authentication tokens *Notes*: None
File or command: `oozie-default.xml` & `oozie-site.xml`	*Description*: The domain to use for the HTTP cookie that stores the authentication token *Default Secure Setting*: `oozie.authentication.cookie.domain=`

	Alternate Value or Change Command: Set the domain appropriately to enable authentication to work correctly across all Hadoop node web-consoles. *Notes*: None
File or command: `oozie-default.xml & oozie-site.xml`	*Description*: Indicates whether anonymous requests are allowed *Default Secure Setting*: `oozie.authentication.simple.anonymous.allowed=true` *Alternate Value or Change Command*: false *Notes*: This setting is applicable only when using `simple` authentication
File or command: `oozie-site.xml`	*Description*: Controls whether SSL encryption is enabled *Default Secure Setting*: `oozie.https.enabled:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `oozie-site.xml`	*Description*: Path to a TrustStore file *Default Secure Setting*: `oozie.https.truststore.file:/opt/mapr/conf/ssl_truststore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `oozie-site.xml`	*Description*: Path to a KeyStore file *Default Secure Setting*: `oozie.https.keystore.file:/opt/mapr/conf/ssl_keystore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `oozie-site.xml`	*Description*: Password to the KeyStore *Default Secure Setting*: `oozie.https.keystore.pass:<password>` *Alternate Value or Change Command*: None *Notes*: None
File or command: `oozie-client-env.sh`	*Description*: Configuration for Oozie clients to use SSL *Default Secure Setting*: `export OOZIE_CLIENT_OPTS="${OOZIE_CLIENT_OPTS} -Djavax.net.ssl.trustStore=/opt/mapr/conf/ssl_truststore"` *Alternate Value or Change Command*: None *Notes*: None
File or command: `oozie-site.xml`	*Description*: User impersonation for Oozie *Default Secure Setting*: • `oozie.service.ProxyUserService.proxyuser.mapr.hosts:*`

last-updated: Apr 11, 2022

- `oozie.service.ProxyUserService.proxyuser.mapr.groups:*`

Alternate Value or Change Command: None

Notes: None

Security Settings for HTTPFS

File or command: `httpfs-site.xml`

Description: PAM authentication for `HttpFS`

Default Secure Setting:

- `httpfs.hadoop.authentication.type:multiauth`
- `httpfs.authentication.type:multiauth`

Alternate Value or Change Command: None

Notes: None

File or command: `httpfs-site.xml`

Description: User impersonation for `HttpFS`

Default Secure Setting:

- `httpfs.proxyuser.mapr.hosts:*`
- `httpfs.proxyuser.mapr.groups:*`

Alternate Value or Change Command: None

Notes: None

Security Settings for Hue

File or command: `hue.ini`

Description: Configure HTTPS for Hue UI

Default Secure Setting:

```
[desktop]
  ssl_certificate=${ssl_certificate}
  ssl_private_key=${ssl_private_key}
  ssl_password=${ssl_password}
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.2.0/desktop/
conf/.isSecure true

cat /opt/mapr/hue/hue-4.2.0/bin/env.d/
20secure

#!/bin/sh HUE_SECURE_FILE="$
{HUE_HOME}/desktop/conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ]
      && [ $(cat "$HUE_SECURE_FILE")
= "true" ] ; then export
      mechanism=$
{mechanism:-"MAPR-SECURITY"} export
      security_enabled=$
{security_enabled:-"true"} export
      ssl_cacerts=${ssl_cacerts:-"$
{MAPR_HOME}/conf/ssl_truststore.pem"}
```

```
export
      ssl_validate=$
{ssl_validate:-"true"} export
      ssl_certificate=$
{ssl_certificate:-"${MAPR_HOME}/conf/
ssl_keystore.pem"} export
      ssl_private_key=$
{ssl_private_key:-"${MAPR_HOME}/conf/
ssl_keystore.pem"} export
      ssl_password=$
{ssl_password:-"mapr123"}
fi
```

File or command: `hue.ini`

Description: Path to PEM truststore, and option to enable/disable certificate verification for SSL-encrypted connections to other services (RM, HS, NM, Spark HS, Oozie, Livy, Sqoop2, HBase, Hive, Impala)

Default Secure Setting:

```
[desktop]
  ssl_cacerts=${ssl_cacerts}
  ssl_validate=${ssl_validate}
```

Alternate Value or Change Command: true

Notes: Values are picked in the same way, as values for the previous parameter. Also, the installer overrides this property with value `false` by creating the following file:

```
cat /opt/mapr/hue/hue-4.2.0/bin/env.d/
30installer
# Do not edit this file. It
was generated automatically by MapR
Installer.
# Disable cetificate verification,
as Installer allows to use node IPs
instead of proper
# hostnames:
export ssl_cacerts=""
export ssl_validate="false"
```

File or command: `hue.ini`

Description: Configure Hue to use MapR-SASL for YARN (RM, NM, HS, Spark HS)

Default Secure Setting:

```
[hadoop]
  [[yarn_clusters]]
    [[[default]]]
      # ...
      # Change this if your YARN
cluster is secured
      # security_enabled=$
{security_enabled}
      # Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY
      # mechanism=${mechanism}
      # In secure mode(HTTPS), if SSL
```

```
certificates from Resource Manager's
      # Rest Server have to be
verified against certificate authority
      # ssl_cert_ca_verify=false
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.2.0/desktop/
conf/.isSecure true

cat /opt/mapr/hue/hue-4.2.0/bin/env.d/
20secure

#!/bin/sh
HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ] && [ $
(cat "$HUE_SECURE_FILE") = "true" ] ;
then export
   mechanism=$
{mechanism:-"MAPR-SECURITY"} export
   security_enabled=$
{security_enabled:-"true"} export
   ssl_cacerts=${ssl_cacerts:-"$
{MAPR_HOME}/conf/ssl_truststore.pem"}
export
   ssl_validate=$
{ssl_validate:-"true"} export
   ssl_certificate=$
{ssl_certificate:-"${MAPR_HOME}/conf/
ssl_keystore.pem"} export
   ssl_private_key=$
{ssl_private_key:-"${MAPR_HOME}/conf/
ssl_keystore.pem"} export
   ssl_password=$
{ssl_password:-"mapr123"}
fi
```

File or command: `hue.ini`

Description: Configure Hue to use MapR-SASL for `HttpFS`

Default Secure Setting:

```
[hadoop]
  [[hdfs_clusters]]
    [[[default]]]
      ...
      # Change this if your HDFS
cluster is secured
      security_enabled=$
{security_enabled}
      # Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY
      mechanism=${mechanism}
      # Enable mutual SSL
authentication
      # mutual_ssl_auth=False
      # Certificate for SSL connection
      # ssl_cert=keys/cert.pem
```

```
      # Private key for SSL connection
      # ssl_key=keys/
hue_private_keystore.pem
      # In secure mode (HTTPS), if
SSL certificates from YARN Rest APIs
      # have to be verified against
certificate authority
      ## ssl_cert_ca_verify=True
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.2.0/desktop/
conf/.isSecure true

cat /opt/mapr/hue/hue-4.2.0/bin/env.d/
20secure
#!/bin/sh

File or command: `hue.ini`

Description: Configure Hue to use MapR-SASL for Drill

Default Secure Setting:

```
[librdbms]
  [[databases]]
    # ...
    [[[drill]]]
      # ...
      # Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY.
      mechanism=${mechanism}
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.2.0/desktop/
conf/.isSecure true
cat /opt/mapr/hue/hue-4.2.0/bin/env.d/
20secure
#!/bin/sh
HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ]
     && [ $(cat "$HUE_SECURE_FILE")
= "true" ] ; then export
     mechanism=$
{mechanism:-"MAPR-SECURITY"} export
     security_enabled=$

     ssl_password=$
{ssl_password:-"mapr123"}
fi
```

File or command: `hue.ini`

Description: PAM/LDAP authentication between Hue and Hive

Default Secure Setting:

```
[desktop]
  # ...
  # Default LDAP/PAM/.. username and
password of the Hue user used for
authentication with other services.
  # Inactive if password is empty.
  # e.g. LDAP pass-through
authentication for HiveServer2 or
Impala.
  # Apps can override them
individually.
  auth_username=${MAPR_USER}
  auth_password=<user_password>
 ...

[beeswax]
  # ...
  # Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY
  mechanism=none
```

Alternate Value or Change Command: true

Notes: None

File or command: `hue.ini`

Description: PAM/LDAP authentication between Hue and Drill

Default Secure Setting:

```
[librdbms]
  [[databases]]
    # ...
    [[[drill]]]
      # ...
      # Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY.
      mechanism=none
      # Username to authenticate with
when connecting to the database.
      # Used with plain
authentication (mechanism set to
"none").
      user=<username>
      # Password matching the
username to authenticate with when
      # connecting to the database.
      # Used with plain
authentication (mechanism set to
"none").
      password=<password>
      # Execute this script to
produce the database password.
      # This will be used when
password is required and `password`
```

```
is not set.
      # password_script=
```

Alternate Value or Change Command: true

Notes: None

File or command: `hue.ini`

Description: User impersonation between Hue and YARN services (RM, NM, HS) + Spark HS

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to RM, NM, HS and SparkHS with the `doAs=<impersonation_target>` parameter

File or command: `hue.ini`

Description: User impersonation between Hue and HttpFS

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to HttpFS with the `doAs=<impersonation_target>` parameter

File or command: `hue.ini`

Description: User impersonation between Hue and Oozie

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to Oozie with the `doAs=<impersonation_target>` parameter

File or command: `hue.ini`

Description: User impersonation between Hue and Livy

Default Secure Setting: Enabled by default

Alternate Value or Change Command: false

Notes: Hue always send requests to Livy with the the `proxyUser=<impersonation_target>` option

File or command: `hue.ini`

Description: User impersonation between Hue and Hive

Default Secure Setting: `true` (enabled)

Alternate Value or Change Command: false

Notes: Hue automatically detects impersonation settings of Hive from `hive-site.xml`

File or command: `hue.ini`

Description: User impersonation between Hue and HBase Thrift (MapR-DB)

Default Secure Setting: `false` (disabled)

Alternate Value or Change Command: false

Notes: Hue automatically detects impersonation settings of Hive from `hbase-site.xml`

File or command: `hue.ini`

Description: User impersonation between Hue and Drill

Default Secure Setting:

```
[librdbms]
  [[databases]]
    # ...
    [[[drill]]]
      # ...
      # Available options:
      # "impersonation" to enable or
disable outbound impersonation.
      # "principal" of Drill service.
Used when Kerberos authentication is
enabled.
      options='{"impersonation":true}
```

Alternate Value or Change Command: true

Notes: None

File or command: `hue.ini`

Description: Authenticating Hue users with LDAP credentials

Default Secure Setting: TDB

Alternate Value or Change Command: None

Notes: None

File or command: `hue.ini`

Description: Determines which authentication method to use: `search and bind`, or `direct bind`

Default Secure Setting: `search_bind_authentication`

Alternate Value or Change Command: None

Notes: When set to `true`, Hue performs an LDAP search using `bind_dn` and `bind_password` as provided in `hue.ini`. The search can be further limited by the search filter `user_filter`. When set to `false`, Hue performs a direct bind to LDAP using the credentials provided from one of these sources:

- The UPN, formed by concatenating <shortname> (the user name provided on the Hue login page) and nt_domain (if nt_domain is specified)
- The ldap_username_pattern (if nt_domain is not specified)

File or command: `hue.ini`

Description: The NT domain to connect. This parameter is only used with Active Directory.

Default Secure Setting: `nt_domain`

Alternate Value or Change Command: None

Notes: Used with the `direct bind` method of authentication. If `nt_domain` is specified, then `ldap_username_pattern` is ignored.

File or command: `hue.ini`

Description: Used to connect to directory services other than Active Directory.

Default Secure Setting: `ldap_username_pattern`

Alternate Value or Change Command: None

	Notes: Used with the `direct bind` method of authentication. Usually takes the form `cn=<username>,dc=example,dc=com`
File or command: `hue.ini`	*Description*: The backend to use for authenticating users. *Default Secure Setting*: `backend` *Alternate Value or Change Command*: None *Notes*: Set it to `desktop.auth.backend.LdapBackend` for Hue authentication.

Security Settings for Drill

File or command: `drill-override.conf`	*Description*: Determines if encryption on the server is enabled for negotiating privacy with the Drill client. *Default Secure Setting*: `drill.exec.security.user.encryption.sasl.enabled=false` *Alternate Value or Change Command*: true *Notes*: None.
File or command: `drill-override.conf`	*Description*: Determines if the server is enabled for negotiating privacy with another Drillbit. *Default Secure Setting*: `drill.exec.security.bit.encryption.ssl.enabled=true` *Alternate Value or Change Command*: false *Notes*: None.
File or command: `drill-override.conf`	*Description*: TLS/SSL versions allowed *Default Secure Setting*: `drill.exec.impersonation.ssl.protocol: TLSv1.2` *Alternate Value or Change Command*: Other versions are possible *Notes*: None.
File or command: `drill-override.conf`	*Description*: Format of the keystore file *Default Secure Setting*: `javax.net.ssl.keyStoreType: JKS` *Alternate Value or Change Command*: jks, jceks, pkcs12 *Notes*: None.
File or command: `drill-override.conf`	*Description*: Location of the Java keystore file *Default Secure Setting*: `drill.exec.ssl.keyStorePath` *Alternate Value or Change Command*: ssl.server.keystore.location: /opt/mapr/conf/ssl_keystore *Notes*: Using it from MapR Hadoop properties, leveraging it from `drill-distrib.conf` property `drill.exec.ssl.useHadoopConfig: true`

File or command: `drill-override.conf`	*Description*: Password to access the private key from the keystore file. *Default Secure Setting*: `drill.exec.ssl.keyStorePassword` *Alternate Value or Change Command*: ssl.server.keystore.password *Notes*: Using it from MapR Hadoop properties, leveraging it from `drill-distrib.conf` property `drill.exec.ssl.useHadoopConfig: true`
File or command: `drill-override.conf`	*Description*: Format of the truststore file *Default Secure Setting*: `drill.exec.ssl.trustStoreType: JKS` *Alternate Value or Change Command*: jks, jceks, pkcs12 *Notes*: None
File or command: `drill-override.conf`	*Description*: Location of the Java keystore file containing the collection of CA certificates trusted by the Drill client. *Default Secure Setting*: `drill.exec.ssl.trustStorePath` *Alternate Value or Change Command*: ssl.server.truststore.location: /opt/mapr/conf/ssl_truststore *Notes*: None
File or command: `drill-override.conf`	*Description*: Password to access the private key from the keystore file specified as the truststore *Default Secure Setting*: `drill.exec.ssl.trustStorePassword` *Alternate Value or Change Command*: ssl.server.truststore.password *Notes*: None
File or command: `drill-distrib.conf`	*Description*: Changes the underlying implementation to the chosen value *Default Secure Setting*: `drill.exec.ssl.provider: JDK` *Alternate Value or Change Command*: OpenSSL/JDK *Notes*: None
File or command: `drill-distrib.conf`	*Description*: Use MapR SSL trust and key store *Default Secure Setting*: `drill.exec.ssl.useHadoopConfig` *Alternate Value or Change Command*: true *Notes*: None
File or command: `drill-distrib.conf`	*Description*: Drill Web UI HTTPS protocol for encryption *Default Secure Setting*: `drill.exec: { http.ssl_enabled: true, ssl.useHadoopConfig: true }` *Alternate Value or Change Command*: Default from Drill 1.13

	Notes: None
File or command: `drill-distrib.conf`	*Description*: Zookeeper znode ACL for Drill cluster info and query info *Default Secure Setting*: `zk.apply_secure_acl: true` *Alternate Value or Change Command*: false *Notes*: Set by default on MapR Secure cluster with installer in `drill-distrib.conf`. `drill.exec.zk.apply_secure_acl: true`
File or command: `drill-distrib.conf`	*Description*: Drill user impersonation, needed for MapR-DB to work properly with CF access *Default Secure Setting*: `drill.exec.impersonation.enabled: true` *Alternate Value or Change Command*: false *Notes*: Set by default on MapR Secure cluster with installer in `drill-distrib.conf`. `drill.exec.impersonation.enabled: true`, also see impersonation inbound policies for information on setting which users can impersonate others.
File or command: `drill-override.conf`	*Description*: Drill user impersonation, maximum number of hops - when one user creates a view on data and shares with other, how many hops are allowed *Default Secure Setting*: `drill.exec.impersonation.max_chained_user_hops: 3` *Alternate Value or Change Command*: Other numeric values *Notes*: Set by default on MapR Secure cluster with installer in `drill-distrib.conf`.
File or command: `drill-override.conf`	*Description*: Authentication mechanisms *Default Secure Setting*: `drill.exec.security.auth.mechanisms: ["MAPRSASL", "PLAIN"]` *Alternate Value or Change Command*: KERBEROS *Notes*: Set by default on MapR Secure cluster with installer in `drill-distrib.conf`.
File or command: `drill-override.conf`	*Description*: End user encryption mechanism *Default Secure Setting*: `drill.exec.security.user.encryption.sasl.enabled: true` *Alternate Value or Change Command*: Can set `drill.exec.security.user.encryption.ssl.enabled: true` *Notes*: Set by default on MapR Secure cluster with installer in `drill-distrib.conf`. To use SSL, set `drill.exec.security.user.encryption.ssl.enabled: true`.

	To use PLAIN (user/pass) authentication, SASL encryption cannot be set to `true`. You have to set SSL encryption to use PLAIN authentication. You can also use MapR tickets (SASL) with SSL encryption, but only with SSL encryption for both.

Security Settings for Spark

File or command: `spark-defaults.conf`	*Description*: SSL option for file download client (used to download jars and files from HTTPS-enabled servers). *Default Secure Setting*: `spark.ssl.fs.enabled true` *Alternate Value or Change Command*: https://spark.apache.org/docs/2.3.1/security.html *Notes*: None
File or command: `spark-defaults.conf`	*Description*: The password to the private key in the key store. *Default Secure Setting*: `spark.ssl.keyPassword <ssl-keystore-password>` *Alternate Value or Change Command*: None *Notes*: None
File or command: `spark-defaults.conf`	*Description*: Path to the key store file. The path can be absolute or relative to the directory in which the process is started. *Default Secure Setting*: · `spark.ssl.keyStore /opt/mapr/conf/ssl_keystore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `spark-defaults.conf`	*Description*: Password to the key store. *Default Secure Setting*: · `spark.ssl.keyStorePassword <ssl-keystore-password>` *Alternate Value or Change Command*: None *Notes*: None
File or command: `spark-defaults.conf`	*Description*: Path to the trust store file. The path can be absolute or relative to the directory in which the process is started. *Default Secure Setting*: · `spark.ssl.trustStore /opt/mapr/conf/ssl_truststore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `spark-defaults.conf`	*Description*: Password for the trust store. *Default Secure Setting*: · `spark.ssl.trustStorePassword <ssl-truststore-password>` *Alternate Value or Change Command*: None *Notes*: None

File or command: `spark-defaults.conf`	*Description*: The TLS protocol to use. The protocol must be supported by the JVM. *Default Secure Setting*: `· spark.ssl.protocol TLSv1.2` *Alternate Value or Change Command*: None *Notes*: None
File or command: `spark-defaults.conf`	*Description*: Configure encryption for the Spark HTTP file and broadcast servers *Default Secure Setting*: `spark.ssl.enabledAlgorithms TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA` *Alternate Value or Change Command*: None *Notes*: None

Security Settings for Livy

File or command: `livy.conf`	*Description*: MapR-SASL authentication *Default Secure Setting*: `livy.server.auth.type = multiauth` *Alternate Value or Change Command*: true *Notes*: None

File or command: `livy.conf`	*Description*: User impersonation with Livy
	Default Secure Setting:
	`livy.impersonation.enabled = true`
	`livy.superusers = <MAPR_USER>`
	Alternate Value or Change Command: true
	Notes: None

File or command: `livy.conf`	*Description*: HTTPS
	Default Secure Setting:
	`livy.keystore`
	`livy.keystore.password`
	`livy.key-password`
	Alternate Value or Change Command: true
	Notes: Values automatically filled on runtime using `com.mapr.web.security.WebSecurityManager`

Security Settings for Tez

File or command: `/opt/mapr/tez/tez-0.8/tomcat/apache-tomcat-9.0.1/conf/server.xml`	*Description*: SSL Config for Tez *Default Secure Setting*: `<Connector port="9444" protocol="org.apache.coyote.http11.Http11NioProtocol" maxThreads="150" SSLEnabled="true" scheme="https" secure="true" keyAlias="edl-dev-r01-tezui" keystoreFile="/opt/mapr/tez/tez-0.8/tomcat/apache-tomcat-9.0.1/conf/bdx1xxx0125.xxxxx.com.jks" keystorePass="xxxxxxxxxx"`

last-updated: Apr 11, 2022

	`keystoreType="JKS" clientAuth="false" sslProtocol="TLS" /> <!-- Define an AJP 1.3 Connector on port 8009 --> <Connector port="8009" protocol="AJP/1.3" redirectPort="9444" />` *Alternate Value or Change Command*: None *Notes*: Tez UI redirectPort value changed to 9444 (default value 8443 conflicts with the Control System)
File or command: `/opt/mapr/elasticsearch/elasticsearch-5.4.1/usr/share/elasticsearch/plugins/search-guard-5/sgconfig/sg_internal_users.yml`	*Description*: Kibana and ElasticSearch login account and password file *Default Secure Setting*: `admin:hash: <$2a$12$6ASxMQEBKYPyGUc10RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq>` *Alternate Value or Change Command*: https://docs.datafabric.hpe.com/home/AdministratorGuide/Changing_Password_for_ES_Kibana.html *Notes*: None
File or command: `/opt/mapr/conf/ssl_truststore*` and `/opt/mapr/conf/ssl_keystore*`	*Description*: SSL Keys *Default Secure Setting*: `Created at install, should rarely change, used by all web and REST HTTPS interfaces.` *Alternate Value or Change Command*: Add site specific certificates with keytool utiliity *Notes*: None

Security Settings for Grafana

File or command: /opt/mapr/grafana/grafana-version/etc/grafana/grafana.ini	*Description*: Certificate File *Default Secure Setting*: `/opt/mapr/grafana/grafana-4.6.1/etc/grafana/cert.pem` *Alternate Value or Change Command*: None *Notes*: None
File or command: /opt/mapr/grafana/grafana-version/etc/grafana/grafana.ini	*Description*: Certificate Key *Default Secure Setting*: `/opt/mapr/grafana/grafana-4.6.1/etc/grafana/key.pem` *Alternate Value or Change Command*: None *Notes*: None

Security Exceptions

"Secure by default" means network-safe authentication and encryption. This page describes areas in which secure-by-default capabilities are not yet implemented for the MapR platform or ecosystem components. Included where applicable, are links to more information to help you work around those issues.

Flume

Flume does not support any authentication mechanism for an Avro client. See Configuring Flume on page 3368.

Hive

MapR-SASL is not supported for Hive in HTTP mode.

last-updated: Apr 11, 2022

Hue

Certificate verification is disabled on Hue.

Impala

Impala is not secure by default, but encryption and authentication can be enabled. See Impala Security on page 3811.

KSQL

KSQL does not support encryption between a KSQL client and KSQL server.

NFSv3

NFSv3 is not secure by default, and there are no provisions for authentication or network encryption.

NFSv4

NFSv4 is not secure by default, but it can be secured using Kerberos to enable both encryption and authentication. See Configuring NFSv4 Server for Kerberos on page 1209.

OpenTSDB

There is no authentication or network encryption by default for read access over REST, and authentication and encryption cannot be enabled. However, note that no updates are allowed over REST; therefore, intruders cannot alter cluster metric data.

ZooKeeper

ZooKeeper supports server-to-server authentication by default, but ZooKeeper does not support encryption and cannot be configured to do so.

YARN

YARN is a resource-management and scheduling framework that distributes resource-management and job-management duties. YARN assigns the resource-management and job-management duties as follows:

- ResourceManager: manages cluster resources and tracks resource usage and node health.
- ApplicationMaster: a framework-specific process that negotiates resources for a single application (a single job or a directed acyclic graph of jobs), which runs in the first *container* allocated for the application.
- A YARN component called the HistoryServer archives job metrics and metadata. Status on completed applications is available via REST APIs.

The ResourceManager allocates resources among all the applications running the cluster. The ResourceManager includes a pluggable scheduler, which is responsible for allocating resources according to the resource requirements of the running applications. Current MapReduce schedulers, including the Capacity Scheduler and the Fair Scheduler, can be plugged into the YARN scheduler directly.

Label-based scheduling provides job placement control on a multi-tenant Hadoop cluster. Administrators can control exactly which nodes are chosen to run jobs submitted by different users and groups. An administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When users run jobs, they can place them on specified nodes on a per-job basis (using a job label) or on a per-queue level (using a queue label).

last-updated: Apr 11, 2022

The ResourceManager caches the mapping file, and checks every two minutes (the default monitoring period) for updates. If the file has been modified, the ResourceManager updates the labels for all active ApplicationMasters immediately.

Each application runs an ApplicationMaster to negotiate resources from the ResourceManager. The ApplicationMaster works with the NodeManagers to execute and monitor tasks. The duties of the ApplicationMaster are divided as follows:

- NodeManager: One instance runs on each node, to manage that node's resources.
- Container: An abstraction representing a unit of resources on a node.

The NodeManager provides containers to an application. The ResourceManager and the NodeManager provide the system for distributed management of applications and resources.

ResourceManager

Describes the role of the ResourceManager.

The ResourceManager is mainly concerned with arbitrating available resources in the cluster among competing applications, with the goal of maximum cluster utilization. The ResourceManager includes a pluggable scheduler called the YarnScheduler, which allows different policies for managing constraints such as capacity, fairness, and service level agreements.

The ResourceManager manages resources as follows:

- Each NodeManager takes instructions from the ResourceManager, reporting and handling containers on a single node
- Each ApplicationMaster requests resources from the ResourceManager, then works with containers provided by NodeManagers

The ResourceManager communicates with application clients via an interface called the ClientService. A client can submit or terminate an application and gain information about the scheduling queue or cluster statistics through the ClientService.

Administrative requests are served by a separate interface called the AdminService, through which operators can get updated information about cluster operation.

Behind the scenes, the ResourceTrackerService receives node heartbeats from the NodeManager to track new or decommissioned nodes. The NMLivelinessMonitor and NodesListManager keep an updated status of which nodes are healthy so that the scheduler and the ResourceTrackerService can allocate work appropriately.

A component called the ApplicationMasterService manages ApplicationMasters on all nodes, keeping the scheduler informed. A component called the AMLivelinessMonitor keeps a list of ApplicationMasters and their last heartbeat times, in order to let the ResourceManager know what applications are healthy on the cluster. Any ApplicationMaster that does not heartbeat within a certain interval is marked as dead and re-scheduled to run on a new container.

At the core of the ResourceManager is an interface called the ApplicationsManager, which maintains a list of applications that have been submitted, are running, or are completed. The ApplicationsManager accepts job submissions, negotiates the first container for an application (in which the ApplicationMaster will run) and restarts the ApplicationMaster if it fails.

The ResourceManager and NodeManagers communicate via heartbeats.

Configure the ResourceManager for high availability so that the failure of the ResourceManager service is a not single point of failure for the cluster. High availability of the ResourceManager is configured by default when you run `configure.sh` without specifying the `-RM` parameter.

last-updated: Apr 11, 2022

ApplicationMaster

Describes the role of the ApplicationMaster.

The ApplicationMaster is an instance of a framework-specific library that negotiates resources from the ResourceManager and works with the NodeManager to execute and monitor the granted resources (bundled as containers) for a given application. An application can be a process or set of processes, a service, or a description of work.

The ApplicationMaster is run in a container like any other application. The ApplicationsManager, part of the ResourceManager, negotiates for the container in which an application's ApplicationMaster runs when the application is scheduled by the YarnScheduler.

While an application is running, the ApplicationMaster manages the following:

- Application life cycle
- Dynamic adjustments to resource consumption
- Execution flow
- Faults
- Providing status and metrics

The ApplicationMaster is designed to support a specific framework, and can be written in any language since its communication with the NodeManagers and the ResourceManager is accomplished using extensible communication protocols. The ApplicationMaster can be customized to extend the framework or run any other code. For this reason, the ApplicationMaster is not considered trustworthy, and is not run as a trusted service.

An ApplicationMaster typically requests resources on multiple nodes to complete a job by sending the ResourceManager requests that include locality preferences and attributes of the containers. When the ResourceManager is able to allocate a resource to the ApplicationMaster, it generates a lease that the ApplicationMaster pulls on a subsequent heartbeat. A security token associated with the lease guarantees its authenticity when the ApplicationManager presents the lease to the NodeManager to gain access to the container.

The Application Master heartbeats to the ResourceManager to communicate its changing resource needs, and to let the ResourceManager know it is still alive. In response, the ResourceManager can return a lease on additional containers on other nodes, or cancel the lease on some containers. The ApplicationMaster can then adjust its execution strategy to fit the increase or decrease in available resources. When cluster resources become scarce, the ResourceManager can also request that the ApplicationMaster relinquish some resources. The ApplicationMaster can move work to other running containers in order to give up resources gracefully.

Containers

A YARN container is a result of a successful resource allocation, meaning that the ResourceManager has granted an application a lease to use a specific set of resources in certain amounts on a specific node. The ApplicationMaster presents the lease to the NodeManager on the node where the container has been allocated, thereby gaining access to the resources.

To launch the container, the ApplicationMaster must provide a container launch context (CLC) that includes the following information:

- Environment variables
- Dependencies (local resources such as data files or shared objects needed prior to launch)
- Security tokens

- The command necessary to create the process the application plans to launch

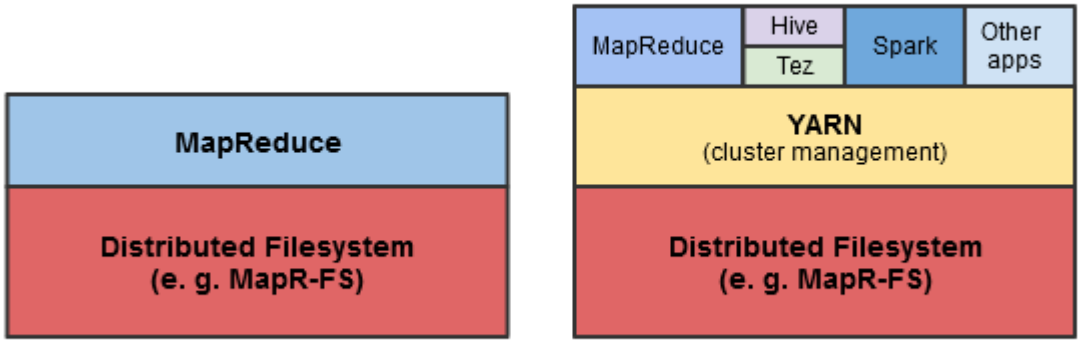
The CLC makes it possible for the ApplicationMaster to use containers to run a variety of different kinds of work, from simple shell scripts to applications to virtual machines.

MapReduce Version 2

Provides an overview of how MapReduce works.

YARN dynamically allocates resources for applications as they execute. The MapReduce version 1 (MRv1) has been rewritten to run as an application on top of YARN; this new version is called MapReduce version 2.0 (MRv2).

Figure 2. A comparison between MapReduce 1.0 and MapReduce 2.0



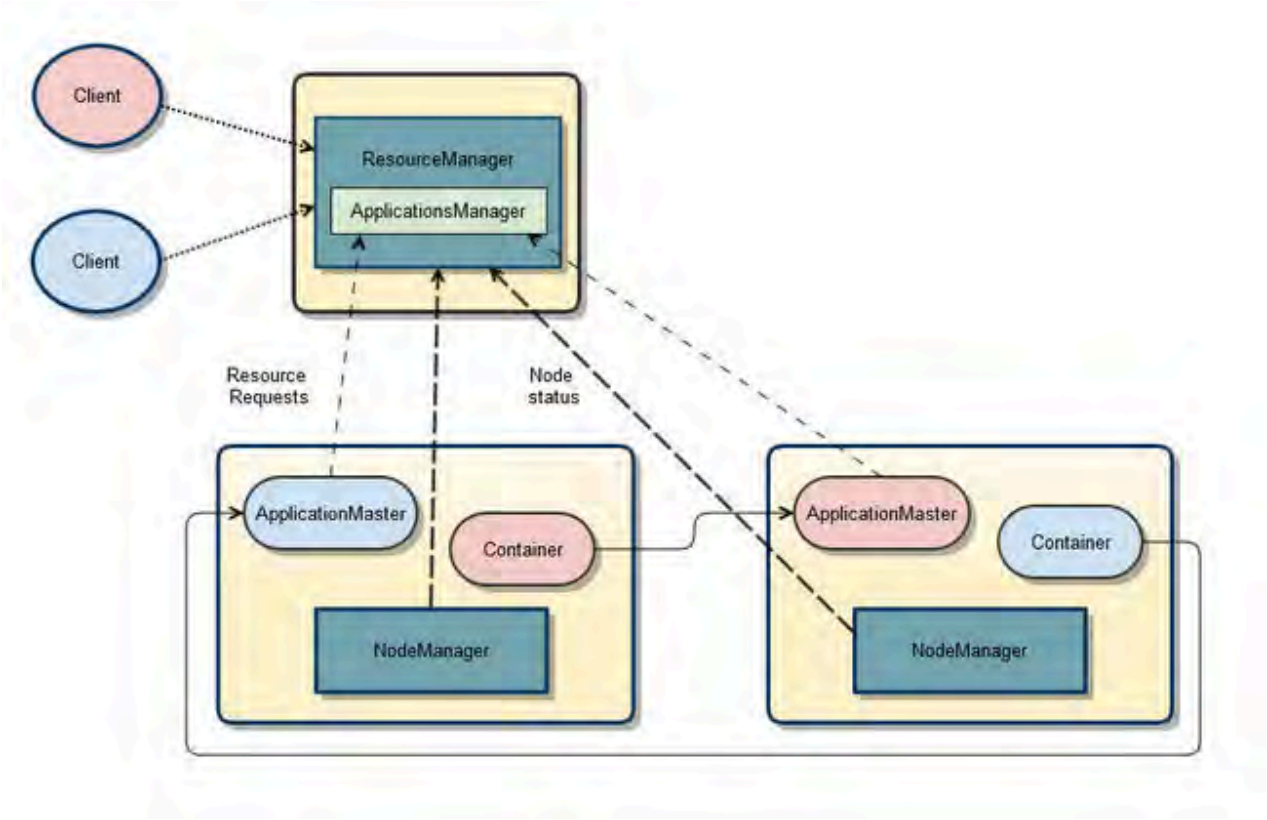
The main advancement in YARN architecture is the separation of resource management and job management, which were both handled by the same process (the JobTracker) in Hadoop 1.x. Cluster resources and job scheduling are managed by the ResourceManager, while resource negotiation and job monitoring are managed by an ApplicationMaster for each application running on the cluster. In MapReduce, each node advertises a relatively fixed number of map slots and reduce slots. This can lead to resource under-utilization, for example, when there is a heavy reduce load and map slots are available, because the map slots cannot accept reduce tasks (and vice versa).

YARN generalizes resource management for use by new engines and frameworks, allowing resources to be allocated and reallocated for different concurrent applications sharing a cluster. Existing MapReduce applications can run on YARN without any changes. At the same time, because MapReduce is now merely another application on YARN, MapReduce is free to evolve independently of the resource management infrastructure.

How Applications Work in YARN

Describes the data flow during application execution in YARN.

The following diagram and steps describe how data flows during application execution in YARN.



The following steps summarize execution of the application:

1. A client submits an application to the YARN ResourceManager, including the information required for the Container Life Cycle (CLC).
2. The ApplicationsManager (in the ResourceManager) negotiates a container and bootstraps the ApplicationMaster instance for the application.
3. The ApplicationMaster registers with the ResourceManager and requests containers.
4. The ApplicationMaster communicates with NodeManagers to launch the containers it has been granted, specifying the CLC for each container.
5. The ApplicationMaster manages application execution. During execution, the application provides progress and status information to the ApplicationMaster. The client can monitor the application's status by querying the ResourceManager or by communicating directly with the ApplicationMaster.
6. The ApplicationMaster reports completion of the application to the ResourceManager.
7. The ApplicationMaster deregisters with the ResourceManager, which then cleans up the ApplicationMaster container.

Direct Shuffle on YARN

Explains the shuffle phase of a MapReduce application.

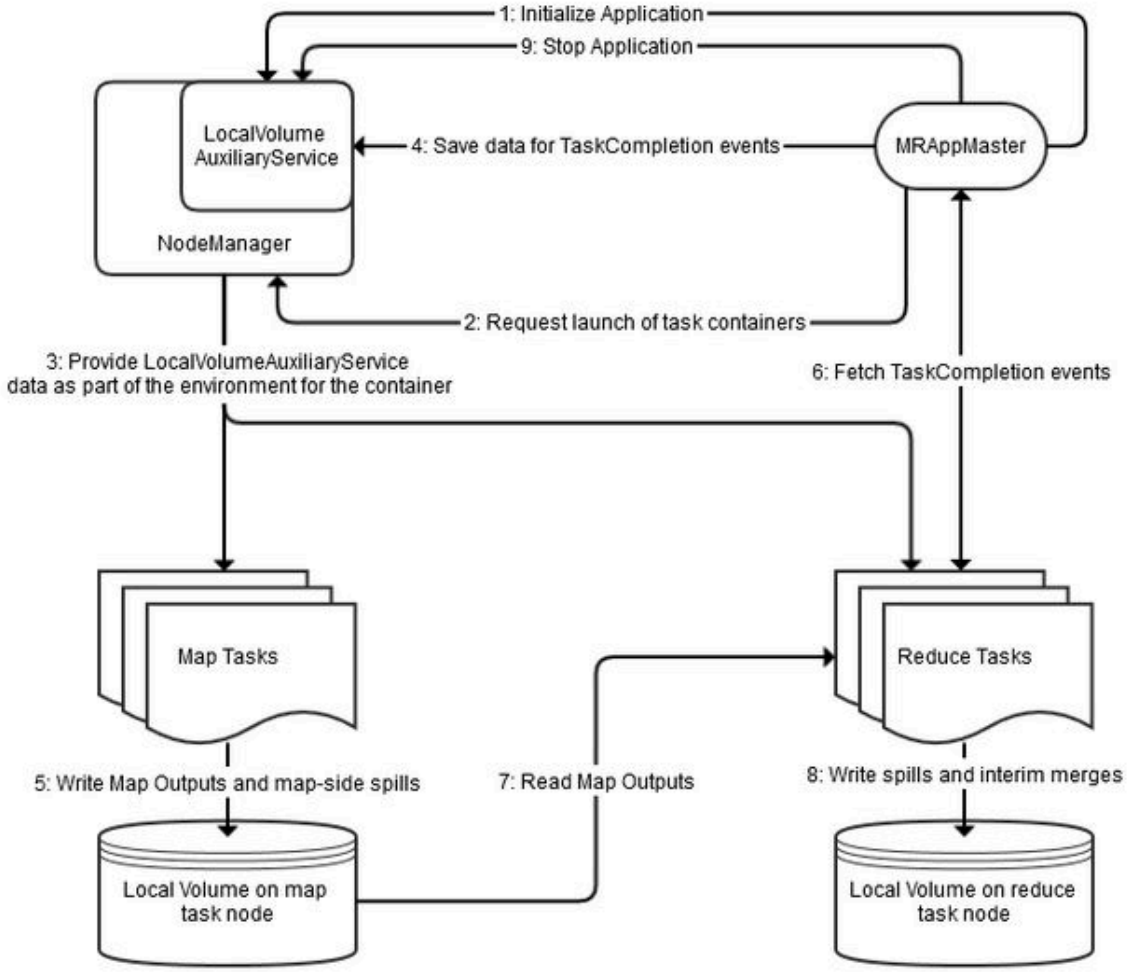
Overview of Direct Shuffle

During the shuffle phase of a MapReduce application, MapR writes to a MapR File System volume limited by its topology to the local node instead of writing intermediate data to local disks controlled by the operating system. This improves performance and reduces demand on local disk space while making the output available cluster-wide.

last-updated: Apr 11, 2022

Direct Shuffle is the default shuffle mechanism for MapR Data Platform. However, you can modify the `yarn-site.xml` and `mapred-site.xml` configuration files to enable Apache Shuffle for MapReduce applications. See Apache Shuffle on YARN.

The LocalVolumeAuxiliaryService runs in the NodeManager process. The LocalVolumeAuxiliaryService manages the local volume on each node and cleans up shuffle data after a MapReduce application has finished executing.



1. The MRAppMaster service initializes the application by calling `initializeApplication()` on the LocalVolumeAuxiliaryService.
2. The MRAppMaster service requests task containers from the ResourceManager. The ResourceManager sends the MRAppMaster information that MRAppMaster uses to request containers from the NodeManager.
3. The NodeManager on each node launches containers using information about the node's local volume from the LocalVolumeAuxiliaryService.
4. Data from map tasks is saved in MRAppMaster for later use in TaskCompletion events, which are requested by reduce tasks.
5. As map tasks complete, map outputs and map-side spills are written to the local volumes on the map task nodes, generating Task Completion events.

last-updated: Apr 11, 2022

6. ReduceTasks fetch Task Completion events from the Application Manager. The task Completion events include information on the location of map output data, enabling reduce tasks to copy data from MapOutput locations.
7. Reduce tasks read the map output information.
8. Spills and interim merges are written to local volumes on the reduce task nodes.
9. MRAppMaster calls `stopApplication()` on the LocalVolumeAuxiliaryService to clean up data on the local volume.

Configuration for Direct Shuffle

The deafult YARN parameters for Direct Shuffle are as follows:

```
<property>
    <name>yarn.nodemanager.aux-services</name>
    <value>mapreduce_shuffle,mapr_direct_shuffle</value>
    <description>shuffle service that needs to be set for Map Reduce to
run</description>
</property>
<property>
    <name>yarn.nodemanager.aux-services.mapr_direct_shuffle.class</name>
    <value>org.apache.hadoop.mapred.LocalVolumeAuxService</value>
</property>
```

The default mapred parameters for Direct Shuffle are as follows:

```
<property>
    <name>mapreduce.job.shuffle.provider.services</name>
    <value>mapr_direct_shuffle</value>
</property>
<property>
    <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
    <value>org.apache.hadoop.mapreduce.task.reduce.DirectShuffle</value>
</property>
<property>
    <name>mapreduce.job.map.output.collector.class</name>
    <value>org.apache.hadoop.mapred.MapRFsOutputBuffer</value>
</property>
<property>
    <name>mapred.ifile.outputstream</name>
    <value>org.apache.hadoop.mapred.MapRIFileOutputStream</value>
</property>
<property>
    <name>mapred.ifile.inputstream</name>
    <value>org.apache.hadoop.mapred.MapRIFileInputStream</value>
</property>
<property>
    <name>mapred.local.mapoutput</name>
    <value>false</value>
</property>
<property>
    <name>mapreduce.task.local.output.class</name>
    <value>org.apache.hadoop.mapred.MapRFsOutputFile</value>
</property>
```

last-updated: Apr 11, 2022

Apache Shuffle on YARN

You can disable Direct Shuffle and enable Apache Shuffle by modifying the configuration options in the `yarn-site.xml` and `mapred-site.xml` files. This page describes how to configure Apache Shuffle for MapReduce applications.

The shuffling phase in Hadoop is the process of transferring mappers intermediate output to the reducers. Direct shuffle increases the load on MapR File System disks. You can enable the Apache Shuffle to reduce the load on MapR File System disks.

Configuration for Apache Shuffle

Add the following property to `yarn-site.xml` file:

```
<property>
    <name>yarn.nodemanager.aux-services</name>
    <value>mapreduce_shuffle</value>
</property>
```

Add the following properties to `mapred-site.xml` file:

```
 <property>
    <name>mapreduce.job.shuffle.provider.services</name>
    <value>mapreduce_shuffle</value>
</property>
<property>
    <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
    <value>org.apache.hadoop.mapreduce.task.reduce.Shuffle</value>
</property>
<property>
    <name>mapreduce.job.map.output.collector.class</name>
    <value>org.apache.hadoop.mapred.MapTask$MapOutputBuffer</value>
</property>
<property>
    <name>mapred.ifile.outputstream</name>
    <value>org.apache.hadoop.mapred.IFileOutputStream</value>
</property>
<property>
    <name>mapred.ifile.inputstream</name>
    <value>org.apache.hadoop.mapred.IFileInputStream</value>
</property>
<property>
    <name>mapred.local.mapoutput</name>
    <value>true</value>
</property>
<property>
    <name>mapreduce.task.local.output.class</name>
    <value>org.apache.hadoop.mapred.YarnOutputFiles</value>
</property>
```

Logging Options on YARN

Describes the logging options that are available on YARN.

For YARN applications, there are various logging options to choose from based on the MapR version and the types of applications that you run. In 4.0.2 and later versions, you have the following logging options:

- For MapReduce version 2 (MRv2) applications, the default logging option is to log files on the local filesystem. However, central logging and YARN log aggregation are also available.

last-updated: Apr 11, 2022

- For non-MapReduce applications, the default logging option is to log files on the local filesystem. However,YARN log aggregation is also available.

Centralized Logging for MRv2	Centralized logging provides an application-centric view of all the log files generated by NodeManager nodes throughout the cluster. It enables users to gain a complete picture of application execution by having all the logs available in a single directory, without having to navigate from node to node. The MapReduce program generates three types of log output: • Standard output stream: captured in the `stdout` file • Standard error stream: captured in the `stderr` file • Log4j logs: captured in the `syslog` file Centralized logs are available cluster-wide as they are written to the following local volume on the MapR filesystem: / `var/mapr/local/<NodeManager node>/logs/yarn/userlogs` Since the log files are stored in a local volume directory that is associated with each NodeManager node, you run the `maprcli job linklogs` command to create symbolic links for all the logs in a single directory. You can then use tools such as `grep` and `awk` to analyze them from an NFS mount point. You can also view the entire set of logs for a particular application using the HistoryServer UI.
YARN Log Aggregation	The YARN log aggregation option aggregates logs from the local filesystem and moves log files for completed applications from the local filesystem to the MapR filesystem. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

Client Connections

The following sections describe how a client connects to local and remote MapR clusters.

How MapR clients Connect to the cluster

Explains how clients connect to a MapR cluster.

The MapR client connects to the cluster via CLDB nodes. When a connection attempt fails, the MapR client returns an error. When an existing connection is no longer available, the MapR client attempts to reconnect to a CLDB node.

For information about installing the MapR client, see MapR Client on page 388.

How the MapR Client Establishes connections to the Cluster

Client applications connect to a cluster via CLDB nodes. To identify the CLDB nodes, check the connection request or the `mapr-clusters.conf` file on the node that submits the connection request. When a client application attempts to connect to the cluster for the first time, the following scenarios can occur:

last-updated: Apr 11, 2022

- At least one of the CLDB nodes is online, in which case the connection is successful.
- None of the CLDB nodes is online, in which case the connection attempt fails.
- The CLDB nodes are listed incorrectly (for example, the IP addresses are incorrect), in which case the connection attempt fails.

When a connection attempt fails, the MapR client returns one of the following errors based on the application type:

Application Type	Error
C Application using HBase API	`ErrorCode = 1`.
C Applications using HDFS API	`NULL handle`
Java Application using HBase, OJAI, or MapR File System API	`java.io.IOException: Could not create FileClient`
Java Application using Kafka API for MapR Event Store For Apache Kafka	`org.apache.kafka.common.errors.NetworkException.`

How the MapR Client Re-establishes Failed Connections to the Cluster

If the CLDB goes down after a client application establishes its first connection to MapR, the client behavior depends on the setting for the `fs.mapr.hardmount` property in the `core-site.xml` file. The `core-site.xml` file is located in the client installation directory.

- If `fs.mapr.hardmount` is set to `true`, the MapR client is nonresponsive as it continuously attempts to reconnect to the CLDB. The MapR client responds when the CLDB comes back online. This is the default behavior.
- If `fs.mapr.hardmount` is set to `false`, the MapR client attempts to connect to each CLDB node that is listed in the `mapr-clusters.conf` file on the node that submitted the connection request. If all of the CLDB nodes are down, the MapR client returns the error EAGAIN/-EAGAIN to the client application. This error indicates that a connection could not be established because the CLDB nodes were not available or because the request timed out for specific reasons. For example, heavy traffic might have caused the network to be slow, or other nodes were unavailable.

Configuring Timeout for Inactive Connections

Configure `fs.mapr.binding.inactive.threshold` in `core-site.xml`. This parameter accepts a value in seconds, and refreshes existing bindings before performing the next I/O, if the time from the previous I/O crosses the given threshold. For example:

```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, which is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLDB to use for communication.

How Clients Connect to the Replica

Provides an overview of what Replicas are, and how MapR clients connect to them.

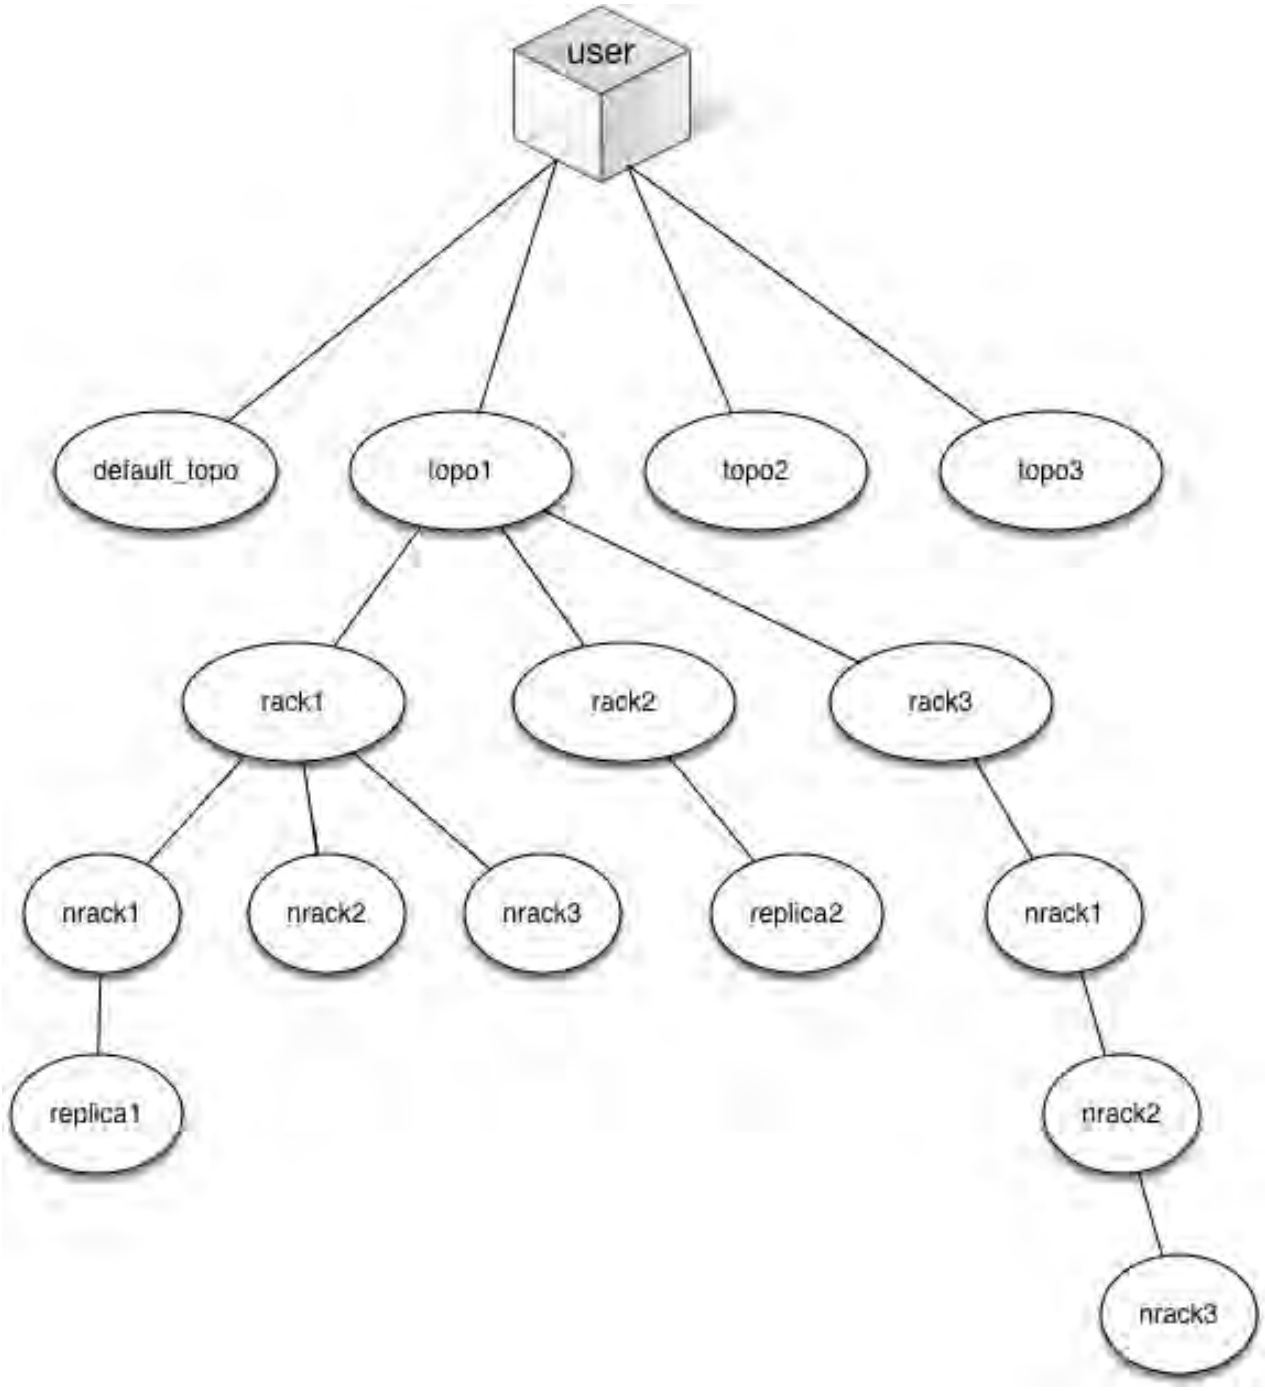
When a client connects to the MapR cluster for I/Os, the client is directed to the replica with the shortest distance. To calculate the distance, every client is given a specific path based on whether the client is connecting from within the cluster or from outside the cluster.

last-updated: Apr 11, 2022

For clients connecting from outside the cluster, because the topology is unknown, and MapR defines the path based on the topology configured in the CLDB configuration property (`cldb.default.node.topology`), the default rack (which is hard-coded as default-rack), and the client IP address. For example, suppose the client IP address is 10.10.10.1 and the value for the CLDB configuration property is `default_topo`. The client topology (or path) is: `/default_topo/default_rack/10.10.10.1`.

For clients on the cluster, the client node has a known topology and the path is built based on that topology, rack, and the client IP address. For example, suppose the client IP address is 10.10.10.1 and the client node topology is `/topo1/rack1`, the client path is: `/topo1/rack1/10.10.10.1`.

Assume the following node topology:



For the client connecting from outside or within the cluster, the replica that the client connects to is calculated based on the client's node topology (or path) and the distance between the nodes on the cluster. When trying to find the nearest replica, the system does a distance calculation based upon how far away the replica is from the MapR client looking for the replica and chooses the replica with the shortest topology or least number of hops from the client node. In the above example, the client connecting from:

- Outside the cluster with the path `/default_topo/default_rack/10.10.10.1` will connect to replica2
- Within the cluster with the path:
  - `/topo1/rack1/10.10.10.1` will connect to replica1
  - `/topo1/rack2/10.10.10.2` will connect to replica2
  - `/topo1/rack3/10.10.10.3` will connect to replica2

Locking Support in MapR

Provides a synopsis of how MapR supports locking for clients.

The MapRMapR File System does not support server-side locking. This means that locks are held by components outside of the filesystem layer and are therefore not shared or enforced globally. As a result, when locking is available, you will need to carefully understand exactly where this enforcement occurs and ensure that all programs using the same locks access them through the same enforcement point. Also, locks, when supported in MapR, are always whole file locks and advisory, not mandatory. The following table describes the locking support in MapR for the clients.

Client Type	Locking Support	Default Value	Notes
Hadoop	No	N/A	Hadoop does not support locking APIs.
FUSE-based POSIX	Yes	Lock	MapR supports advisory locking using kernel locking. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all users accessing the file are using FUSE and are on the same host.
Loopback NFS POSIX	No	N/A	No support in MapR for locking. However, you can use Network Lock Manager to lock with the `nolock` option on the `mount` command. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all lock users are using loopbacknfs and are on the same host.

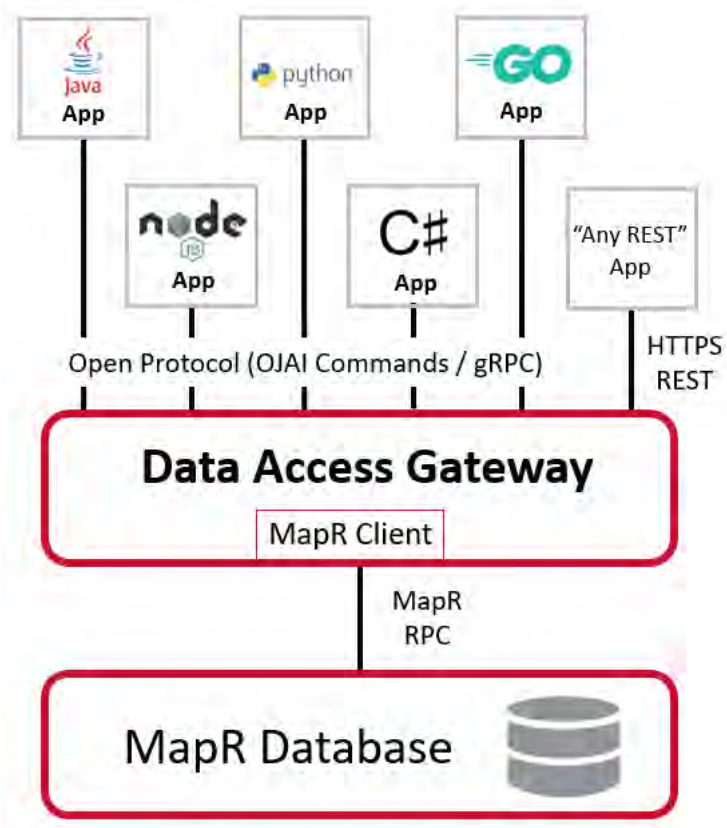
Client Type	Locking Support	Default Value	Notes
NFS v3	No	N/A	No support for locking in MapR. However, you can use Network Lock Manager to lock with the `nolock` option on the `mount` command. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all lock users are using NFS v3 and are on the same host.
NFS v4	Yes	NoLock	MapR supports advisory locking for NFS v4 server. The lock is enforced locally on the NFS v4 server, which means the lock is only meaningful if all lock users are using the same NFS v4 server. See Advisory Locking in NFS v4 on page 1218 for more information.

Understanding the MapR Data Access Gateway

The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster.

For the EEP 5.0 release, the service is used by the MapR Database JSON REST API. Starting with the EEP 6.0 release, the service can be used by the Node.js, Python, C#, and Go OJAI clients. Beginning with the EEP 6.3.0 release, the service can be used by the Java OJAI thin client.

The OJAI clients that connect to the Data Access Gateway use gRPC, an open-source RPC framework, to expose the MapR Database OJAI API to the client. RPC message headers for individual messages are encoded using Protocol Buffers. The message payload is encoded using OJAI JSON encoding. Depending on whether your MapR cluster has security enabled, TLS is either enabled or disabled, by default, for the gRPC service. When TLS is enabled, the SSL provider is OpenSSL.



The service runs on nodes in your MapR cluster. You can install the service manually or by using the MapR Installer on page 5395. Both installation methods support upgrades of existing MapR clusters. When installing the service, you can decide the number of nodes on which to install the service. The number of nodes you need depends on your scalability requirements.

Regardless of your scalability requirements, you should install the service on at least two nodes to provide high availability. To load balance requests and to achieve high availability and failover, you must use an external load balancer. For recommendations and best practices when using an external load balancer with gRPC, see gRPC Load Balancing.

The service runs as user `mapr`. However, the service issues all data access calls on behalf of the user requesting the data. For example, if user `john` is running the client application, the service reads data using the authorization of `john`, not `mapr`.

All traffic between the Data Access Gateway and other MapR services is encrypted. This is done regardless of whether the underlying MapR file system volume has encryption enabled.

Warden on page 677 manages the MapR Data Access Gateway. It handles stopping and starting of the service during node failovers and also controls the amount of memory assigned to the service.

Related concepts

Using the MapR Database JSON REST API on page 2696
Starting in the EEP 5.0 release, you can use a REST API to access MapR Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on MapR Database JSON tables.

Using the Node.js OJAI Client on page 2673
Starting with EEP 6.0, you can use the Node.js OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON from middleware components, and add, update, and query documents in a MapR Database JSON table.

Using the Python OJAI Client on page 2678

last-updated: Apr 11, 2022

Starting with EEP 6.0, you can use the Python OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Using the C# OJAI Client on page 2688
Starting with EEP 6.1.0, you can use the C# OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Using the Go OJAI Client on page 2692
Starting with EEP 6.0.0, you can use the Go OJAI client to write MapR Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Using the Java OJAI Thin Client on page 2670
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write MapR Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You can connect to MapR Database JSON, and add, update, and query documents in a MapR Database JSON table.

Administering the MapR Data Access Gateway on page 1492
The MapR Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the MapR cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Related tasks

Installing MapR Data Access Gateway on page 203
This topic includes instructions for using package managers to download and install the MapR Data Access Gateway from the EEP repository.

6.1 Administration

This section describes how to manage the nodes and services that make up a cluster.

This section is for system administrators tasked with managing MapR clusters. Topics include how to manage data by using volumes, how to monitor the cluster for performance, how to manage users and groups, how to add and remove nodes from the cluster, and more. The focus of this section is managing the nodes and services that make up a cluster using the Control System and the CLI or REST API.

Administering Users and Clusters

Lists topics that help manage a MapR cluster.

This section describes processes involved in managing a MapR cluster. Topics include setting up users and groups, adding licenses to the cluster, enabling/disabling auditing of cluster administration, configuring disk and role balancers, and allocating quotas for users and groups and setting cluster reserve limit.

Managing Users and Groups

Provides a brief introduction to user management on a MapR cluster.

The following two users are important when installing and setting up MapR software:

- `root` is used to install MapR software on each node.

last-updated: Apr 11, 2022

- The “MapR user” is the user that MapR services run as (typically named **mapr** or **hadoop**) on each node. The MapR user has full privileges to administer the cluster. Administrative privilege with varying levels of control can be assigned to other users as well.

Before installing MapR, decide on the name, user ID (UID) and group ID (GID) for the MapR user. The MapR user must exist on each node, and the user name, UID and primary GID must match on all nodes.

- When adding a *user* to a cluster node, specify the `--uid` option with the `useradd` command to guarantee that the user has the same UID on all machines.
- When adding a *group* to a cluster node, specify the `--gid` option with the `groupadd` command to guarantee that the group has the same GID on all machines.

MapR uses the native operating system configuration of each node to authenticate users and groups for access to the cluster. If you are deploying a large cluster, you should consider configuring all nodes to use LDAP or another user management system. You can use the Control System to grant specific permissions to particular users and groups. For more information, see Setting User Permissions. Each user can be restricted to a specific amount of disk usage. For more information, see Setting Quotas for Users and Groups.

By default, MapR grants the user `root` full administrative permissions. If the nodes do not have an explicit `root` login, grant full permissions to another user after deployment. See Adding Cluster Permissions on page 755.

On the node where you plan to run the `mapr-apiserver` (the Control System), install Pluggable Authentication Modules (PAM). See PAM Configuration for more information.

You can perform the following procedures to manage users and groups in a MapR cluster using the Control System (click **Admin** > **User Settings**) and the CLI:

Setting Up Email Addresses
Describes how to set up email addresses using the Control System and the CLI.
Setting Up Email Addresses Using the Control System

To set up email addresses for cluster users, in the Control System under **Admin** > **User Settings** > **Email Address**:

1. Choose one of the following to configure the cluster to use an SMTP server to send email:
   - **Use Company Domain** to specify a domain to append after each user name to complete each user's email address
   - **Use LDAP** to obtain each user's email address from an LDAP server.
2. Specify, for:

Use Company Domain

Domain to append after each user name to complete each user's email address in the **user** @ field.

Use LDAP

LDAP Server	The LDAP server address.
LDAP Port	The LDAP server port number. You can select the **Use Secured Port** checkbox to use port 636.
Bind Domain	The bind domain for the users.

Bind Domain Password	The bind password for the users.
Base Domain	The base domain.
UID Attribute	The user ID.
Mail Attribute	The mail attribute.

3. Click **Save Changes**.

Setting Up Email Addresses Using the CLI or the REST API

The basic command to set up email address for a user is:

```
maprcli entity modify -name <entityname> -type 0 -email <email>
```

For complete reference information, see `entity modify` on page 1649.

Setting Up SMTP
Describes how to set up SMTP information using the Control System and the CLI.

You can specify SMTP server information for the cluster using the Control System and the CLI.

Setting Up SMTP Using the Control System

Use the following procedure to configure the cluster to use an SMTP server to send email:

1. Log in to the Control System and click **Admin** > **User Settings** > **SMTP**.
2. Set up the email account the MapR cluster must use to send alerts and other notifications.

Provider	Select **Gmail**, **Office 365**, or **SMTP** from the drop-down menu. If you select **Gmail** or **Office 365**, the SMTP server and port information will be pre-filled for you.
SMTP Server	The SMTP server to use for sending mail.
This server requires an encrypted connection (SSL)	Specifies an SSL connection to SMTP.
SMTP Port	The SMTP port to use for sending mail.
Sender's Full Name	The name that MapR should use when sending email. Example: `MapR Cluster`
Sender's Email Address	The email address that MapR should use when sending email.
Sender's Username	The user name that MapR should use when logging on to the SMTP server.
Sender's SMTP Password	The password that MapR should use when logging on to the SMTP server.

3. Click **Save Changes**.
   An email request is sent to the specified email address. You can check the `/opt/mapr/logs/cldb.log` file if there is a problem sending the email. If there is a problem, also check the fields to make sure that the SMTP information is correct. Click **Revert** if you wish to cancel the changes.

Setting Up SMTP Using the CLI

Use the `maprcli config save` command to set the SMTP server. For example:

```
maprcli config save -values '{"mapr.smtp.provider":"gmail",
               "mapr.smtp.server":"smtp.gmail.com",
               "mapr.smtp.sslrequired":"true",
               "mapr.smtp.port":"465",
               "mapr.smtp.sender.fullname":"Ab  Cd",
               "mapr.smtp.sender.email":"xxx@gmail.com",
               "mapr.smtp.sender.username":"xxx@gmail.com",
               "mapr.smtp.sender.password":"abc"}'
```

For complete reference, see `config save` on page 1586.

Managing Permissions

Provides an overview of managing user permissions at the cluster, volume and file system levels.

You can manage user permissions at the cluster, volume, and filesystem levels. Cluster and volume permissions use access control lists (ACLs) to specify which actions a user can perform on a cluster or volume. File system permissions and *ACE*s control user access to volumes, directories, and files, similar to Linux file permissions. Users get the permissions that are directly assigned to them as well as the permissions assigned to the groups they are in. You must have `fc` permissions to manage permissions.

Adding Cluster Permissions

Describes how to set cluster permissions for users and groups through the Control System and the CLI.

The following table lists the actions that a user can perform on a cluster with the corresponding UI columns and codes used in the cluster *Access Control List (ACL)*:

UI	ACL	Allowed Action
Login	login	Log in to the Control System, use the API and command-line interface, read access on cluster and volumes
Start/Stop Service	ss	Start and stop services
Create Volumes	cv	Create volumes
Create Security Policy	cp	Required to create security policies. Users with Administrator (a) access can assign this permission to other administrators.
Administrator	a	Administrative access (can edit and view *ACL*s, but cannot perform cluster operations)
Full Control	fc	Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster *ACL*s.

Setting Permissions Using the Control System

Complete the following steps to add cluster permissions in the Control System:

1. Log in to the Control System and click **Admin** > **User Settings** > **Permissions**.
2. Under **USER PERMISSIONS**, select the type and specify the name of the user or group in the **Name** field.

last-updated: Apr 11, 2022

3. Select the checkbox associated with the permissions you want to grant to the user or group.
4. Click **Add Another** to add permissions for another user or group.
   Each row lets you assign permissions to a single user or group.

   Note: A user gets the permissions directly granted to the user as well as permissions granted to any group to which the user belongs.
5. Click **Save Changes** to save the changes.

Setting Permissions Using the CLI or the REST API

To set permissions using the CLI, run the following command:

```
/opt/mapr/bin/maprcli acl set
    [ -cluster <cluster name> ]
    [ -group <group> ]
    [ -name <name> ]
    -type cluster|volume
    [ -user <user> ]
```

See `acl set` on page 1531 for complete reference information.

Granting a User Full Control from the Command-Line

The user who has full control over the cluster can manage all aspects of the cluster operation except assign permissions for other users.

Complete the following steps to give full administrative control to a user:

1. Log on to any cluster node as `root` (or use `sudo`).
2. Execute the following command, replacing `<user>` with the username of the account that gets administrative control: `sudo /opt/mapr/bin/maprcli acl edit -type cluster -user <user>:fc`

   For general information about users and groups in the cluster, see Managing Users and Groups.

Removing Cluster Permissions
Describes how to remove cluster permissions using the Control System or the CLI.
Removing Cluster Permissions Using the Control System

Complete the following steps to remove cluster permissions in the Control System:

1. Log in to the Control System and click **Admin** > **User Settings** > **Permissions**.
2. Remove the desired permissions:
   - To remove all permissions for a user or group, click ⛔ associated with the row.
   - To change the permissions for a user or group, deselect the checkbox associated with the permissions you wish to revoke from the user or group.
3. Click **Save Changes** to save the changes.

Removing Cluster Permissions Using the CLI or REST API

The `acl set` command specifies the entire *ACL* for a cluster or volume. Any previous permissions are overwritten by the new values, and any permissions omitted are removed. To remove cluster permissions, run the `acl set` command and omit the permissions to remove. See `acl set` on page 1531 for complete reference information.

last-updated: Apr 11, 2022

Blocking Users Using the CLI

Explains how to block users using the CLI.

You can block users using the CLI. When a user is blocked, all existing tickets for the user are canceled and any request sent by the user that has a ticket older than the blocked timestamp is rejected. For more information, see How Tickets Work on page 1426.

Blocking Users Using the CLI or REST API

The basic command to blacklist a user is:

```
maprcli blacklistuser -user <user name>
```

For complete reference information, see `blacklist user` on page 1555.

Managing the Cluster

Lists the settings for managing the MapR cluster.

You can add licenses, set up auditing of cluster administration, configure disk space balancer tool settings and Role Balancer settings, configure how MapReduce programs run, allocate quotas for users and groups and set the cluster reserve limit, and generate the DNS Gateway record for table replication using both the Control System (click **Admin** > **Cluster Settings**) and the CLI.

Managing Auditing

Provides instructions for using MapR auditing features.

You can enable auditing of cluster administration and data-access operations using the Control System and the CLI. Enabling auditing of the filesystem, table, and streams operations requires running a command on a cluster, a command on individual volumes in the cluster, and a command on individual directories, files, and MapR Database tables and streams within those volumes.

These steps are summarized in the following table:

	Steps to enable auditing			
	Enable auditing of cluster administration	Enable data auditing on the cluster	Enable auditing of individual volumes	Enable auditing of individual directories, files, and MapR Database tables
Auditing of cluster administration		Not applicable	Not applicable	Not applicable

last-updated: Apr 11, 2022

Auditing of directories, files, and MapR Database tables	Not applicable			

Prerequisites for enabling auditing

- If you upgraded your MapR cluster from version 4.1 or earlier, you must enable the auditing feature.
  - Run `maprcli config save -values {"mfs.feature.audit.support":"1"}`
  - To verify that the feature is enabled, run `maprcli config load -json | grep "mfs.feature.audit.support"`
- Only the `root` user or `mapr` user can enable or disable auditing.

Enabling and Disabling Auditing of Cluster Administration
Describes how to enable and disable cluster administration auditing using the Control System and the CLI.

You can enable or disable auditing of cluster-management operations on a MapR cluster using the Control System and the CLI. See Auditing Cluster Operations on page 696 for the complete list of cluster management commands that are audited.

Enabling and Disabling Auditing of Cluster Administration Using the Control System

1. Log in to the Control System and go to the **Auditing** tab in the **Admin** > **Cluster Settings** page.
2. Move the **Enabled** slider to **Yes** to enable and **No** to disable cluster auditing.
3. Click **Save Changes** for the changes to take effect.

Enabling and Disabling Auditing of Cluster Administration Using the CLI or REST API

To enable or disable auditing of cluster-management operations on a MapR cluster, run the `maprcli audit cluster` command.

```
maprcli audit cluster -enabled <true | false>
```

For complete reference information, see `audit cluster` on page 1553.

Enabling and Disabling Auditing of Data Access Operations
Describes how to enable or disable auditing of data-access operations using the Control System and the CLI.

See Auditing Data Access Operations on page 698 for the complete list of data-access operations that can be audited.

Enabling and Disabling Auditing of Data Access Operations Using the Control System

To enable or disable auditing of data-access operations on a cluster:

1. Log in to the Control System and go to the **Auditing** tab in the **Admin** > **Cluster Settings** page.
2. Set the following:

Enabled	Move the slider to **Yes** to enable or to**No** to disable data auditing.
Maximum Size	Set the size in GB, which when reached causes an alarm to be sent to the dashboard on the Control System. The alarm is to notify the cluster administrator that the audit log size is large enough to need administrator intervention. The audit log continues to grow until the administrator takes action or until the retention period ends.
Retain Logs for	Set the period of time in days to keep the data in the audit log. After this period elapses, the content of the file is deleted and new entries are added to the file until the retention period elapses.

3. Click **Save Changes** for the changes to take effect.

Note: This action does not cause auditing to start for operations within the volumes. It only sets a flag that indicates that you allow auditing of individual volumes to be enabled when volume is created or modified.

Enabling and Disabling Auditing of Data Access Operations Using the CLI or REST API

1. To enable or disable auditing of the filesystem, table, and streams operations on a cluster, run the `maprcli audit data` command.

   This command does not cause auditing to start for operations within those volumes. It only sets a flag that indicates you allow auditing of individual volumes to be enabled with the `maprcli volume audit` command. The audit logs for file operations, table operations, and stream operations are affected by the value that you set for the `-retention` parameter.

2. To enable or disable auditing for a particular volume, run the `maprcli volume audit` command. To verify that auditing is enabled for a volume, run the `maprcli volume info` command.
   You can grep with the search term `'audited\|coalesce'`.

   ```
   maprcli volume info -name <volume_name> -json | grep -i 'audited\|
   coalesce'
   ```

   The output of the command should be as follows, with a 1 for the `audited` key and the value for the `coalesceinterval` key: `"audited":1, "coalesceInterval":2`

3. To enable or disable auditing for a particular directory, file, MapR Database table, or streams that existed in a volume at the time that you ran the `maprcli volume audit` command, run the `hadoop mfs` command with the `-setaudit` parameter.

   ```
   hadoop mfs -setaudit <on|off> <directory|file|table>
   ```

   Note: Wildcards are not supported for the names of filesystem objects in this command.

   Enabling auditing on a directory does not enable auditing on the files that already exist in the directory, though new files and directories created in the directory will have auditing enabled. For example, if you run this command on the root directory of a volume, all new files, directories, and tables that are subsequently created in the volume are audited. The creation of those objects is also audited.

After enabling auditing, if you create a:

- Snapshot of a volume, the snapshot inherits the audit settings of the original volume.

last-updated: Apr 11, 2022

- Local mirror or remote mirror of a volume, you must run the `maprcli volume audit` command to enable auditing on the mirror volume. Auditing for particular directories, files, and MapR Database tables in a mirror volume is automatically enabled if auditing is enabled for them in the source volume.

How Does Auditing Work?
Explains how auditing works on MapR objects.

When you enable the auditing of a particular directory, file, table, or stream, you set the *audit bit* to "on" for that object. You can tell whether auditing is enabled for a directory, file, or table by checking the status of the object's audit bit.

For example, the volume as shown in the following tree diagram, consists of the root directory, the two directories `dir1` and `dir2`, and two files in directory `dir1`. Every directory, file, table, and stream in a volume has an “audit bit” associated with it. You can tell whether, say, `dir1` has its audit bit on and is therefore enabled for auditing by running the `hadoop mfs -ls` command. The output of the command might look like as follows:

```
drwxrwxrwx Z U U 3 root root 100 2015-05-20 21:09 192473738 /dir1
```

The second `U` indicates that auditing is not enabled on the directory.

However, an `A` in place of that `U` indicates that auditing is enabled on the directory:

```
drwxrwxrwx Z U A 3 root root 100 2015-05-20 23:41 192473738 /dir1
```

In the first diagram, as well as in the next two diagrams, `U` indicates that the audit bit is turned off for a filesystem object and `A` indicates that the audit bit is on for that object. After you run `maprcli volume audit` on the volume, none of the audit bits are on:

```
/              U
-/dir1          U
 -file1         U
 -file2         U
-/dir2          U
```

Suppose you enable auditing on the root directory by running this command:

```
hadoop mfs -setaudit on /
```

Then, you create the file `file3` in `dir2` and you create the directory `dir3` and the file `file4` in it. The tree diagram now looks as follows :

```
/           A
-/dir1          U
 -file1         U
 -file2         U
-/dir2          U
 -file3         U
-/dir3          A
 -file4         A
```

The audit bit is still `U` on `dir1`, and the files are in `dir1`, and `dir2`. The new file `file3` in `dir2` inherits the audit bit from `dir2`.

`dir3` inherits the audit bit from the root folder, so the audit bit for `dir3` is `A`. Moreover, `file4` inherits the audit bit from `dir3`, so its audit bit is `A`, as well.

last-updated: Apr 11, 2022

Next, you run the following command to enable auditing in `dir1`:

```
hadoop mfs -setaudit on /dir1
```

Then, you create the file `file5`. The new file inherits the audit bit from its parent folder, so it is enabled for auditing immediately after it is created. However, `file1` and `file2` still have the audit bit turned off.

```
/         A
-/dir1           A
 -file1          U
 -file2          U
 -file5          A
-/dir2           U
 -file3          U
-/dir3           A
 -file4          A
```

As file1 and file2 existed before you turned on the audit bit for their parent folder, you need to enable auditing for them as follows:

```
hadoop mfs -setaudit on /dir1/file1
```

```
hadoop mfs -setaudit on /dir1/file2
```

Selective Auditing of MapR File System, MapR Database Table, and MapR Event Store For Apache Kafka Operations Using the CLI
Explains how to selectively audit MapR objects.

Administrators can specify filesystem, table, or stream operations to include or exclude from auditing. The operations that can be included or excluded from auditing are listed here.

Including or excluding specific operations from auditing requires running the `maprcli` command. You can specify the list of operations to include or exclude from auditing during volume creation using the `maprcli volume create` command, and afterwards using the `maprcli volume modify` or `maprcli volume audit` command.

To:

- Include operations for auditing, use the plus sign (+) before the operation.
- Exclude operations from auditing, use the minus sign (-) before the operation.

  Note: If the first operation in the list is to be excluded from auditing, it must be preceded by two minus (--) signs. Subsequent operations to exclude from auditing must be preceded by only a single minus (-) sign, whether or not the first operation was included (using a plus (+) sign) or excluded (using two minus (--) signs).

Note: If neither (plus (+) or minus (-)) sign is specified before an operation, the given operation is included for auditing.

Including and/or Excluding Operations

Including or excluding specific operations from auditing requires running the `maprcli` command.

Include or Exclude Operations During Volume Creation

During volume creation, the specified list of operations must either be included for auditing or excluded from auditing. You cannot specify a mixed list of included and excluded operations.

By default, all other operations other than the specified operations are:

last-updated: Apr 11, 2022

- Included for auditing if the specified list is a list of excluded operations.
- Excluded from auditing if the specified list is a list of included operations.

Examples

The following example shows how to enable auditing and exclude specific operations (such as `lookup`, `read`, and `write`) from auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -auditenabled true -dataauditops --lookup,-read,-write
```

In the above example, operations other than the ones specified are included for auditing.

The following example shows how to include all operations except `lookup` for auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -dataauditops --lookup
```

The following example shows how to include only `chown` operation for auditing and exclude all other operations from auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -dataauditops +chown
```

Include and Exclude Operations After Volume Creation

After volume creation, you can include and exclude certain operations from auditing using the `volume modify` or `volume audit` command. When you modify a volume (by running the `volume modify` command) or when you enable volume auditing (by running the `volume audit` command), you can specify a mixed list of included and excluded operations. There are no changes to operations that are not specified with the command.

For the list of operations that can be included and/or excluded from auditing, see Auditing of Filesystem Operations and Table Operations.

Examples

The following example shows how to include `create` operation for auditing and exclude `lookup` operation from auditing:

```
maprcli volume modify -name test-volume -dataauditops +create,-lookup
```

The following example shows how to include all operations except `lookup` for auditing:

```
maprcli volume audit -name test-volume -dataauditops +all,-lookup
```

Grouping of Operations

You can group all filesystem and table operations using the keyword `all`. If the operations to:

- Include for auditing are specified using the keyword `all`, you cannot specify other individual operations to include as well.

  For example, the following is *not* allowed:

  ```
  maprcli volume modify -name v1 -dataauditops +all,+mkdir
  ```

last-updated: Apr 11, 2022

- Exclude from auditing are specified using the keyword `all`, you cannot specify other individual operations to exclude as well.

  For example, the following is *not* allowed:

  ```
  maprcli volume modify -name v1 -dataauditops --all,-mkdir
  ```

If operations are specified using the keyword `all`, ensure that the individual operations specified with the same command are used to:

- Include, if `all` is used to exclude from auditing.
- Exclude, if `all` is used to include for auditing.

For example, the following is a valid combination of operations to audit:

```
maprcli volume modify -name v1 -dataauditops +all,-mkdir,-lookup
```

Verifying Selective Auditing of Operations

After you set up the list of operations to include and/or exclude from auditing, you can retrieve and verify the list of included and/or excluded operations using the `maprcli volume info` command. When you run the `volume info` command, the output will show the list of operations:

- Excluded (`disableddataauditoperations`) from auditing.
- Included (`enableddataauditoperations`) for auditing.

Example

The following example shows how to retrieve and verify the list of operations that are:

- Excluded from auditing
- Included for auditing

```
maprcli volume info -name test-volume -path /test/test-volume -json
```

Output

```
{
    "timestamp":1435182867317,
    "timeofday":"2016-01-10 02:54:27.317 GMT-0700",
    "status":"OK",
    "total":1,
    "data":[

```

Enabling and Disabling Audit Streaming Using the CLI
Explains how to enable or disable audit streaming using the CLI.

Audit streaming is not enabled by default. You can enable or disable audit streaming using the CLI.

Run the following command to:

- Enable audit streaming:

  ```
  maprcli config save -values '{"mfs.enable.audit.as.stream":"1"}'
  ```

  Note: If you are re-enabling audit streaming after disabling it, the audit stream starts publishing to topics from where it left off processing audit logs.

- Disable audit streaming:

  ```
  maprcli config save -values '{"mfs.enable.audit.as.stream":"0"}'
  ```

Configuring Balancer Settings
Provides an overview of the MapR disk space and replication role balancers.

You can use the disk space balancer and the replication role balancer to redistribute data and containers in the MapR storage layer to ensure maximum performance and efficient use of space. The disk space balancer works to ensure that the percentage of space utilized on all storage pools in the cluster is similar and prevent nodes from being overloaded. The replication role balancer changes the replication roles of containers so that the replication process uses network bandwidth evenly.

You can pipe the `maprcli config load` command through `grep` to view the balancer configuration values.

Example:

```
maprcli config load -json | grep balancer
         "cldb.balancer.disk.deltaToRepopulateStoragePoolsBins":"5",
         "cldb.balancer.disk.deltatorepopulatestoragepoolsbins":"5",
         "cldb.balancer.disk.max.switches.in.nodes.percentage":"10",
         "cldb.balancer.disk.overused.threshold":"90",
         "cldb.balancer.disk.sleep.interval.sec":"120",
         "cldb.balancer.disk.threshold.percentage":"70",
         "cldb.balancer.logging":"0",
         "cldb.balancer.role.max.switches.in.nodes.percentage":"10",
         "cldb.balancer.role.paused":"1",
         "cldb.balancer.role.skip.container.active.sec":"600",
         "cldb.balancer.role.sleep.interval.sec":"900",
         "cldb.balancer.startup.interval.sec":"1800",
         "cldb.disk.balancer.enable":"0",
         "cldb.role.balancer.replicascount.tolerance":"1",
         "cldb.role.balancer.replicassize.tolerance":"5",
```

```
          "cldb.role.balancer.strategy":"BySize",
```

You can use the `config save` command to set the appropriate balancer configuration values.

Example:

```
maprcli config save -values
{"cldb.balancer.disk.max.switches.in.nodes.percentage":"20"}
```

Note: By default, the balancers are turned off.

- To turn on the disk space balancer, use `config save` to set `cldb.disk.balancer.enable` to `1`.
- To turn on the replication role balancer, use `config save` to set `cldb.balancer.role.paused` to `0`.

Disk Space Balancer
Describes the role of the disk space balancer.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between nodes (subject to the constraints of the topology of the volume to which a container belongs). This movement of containers ensures that the percentage of space used on all the disks in the cluster is similar. The disk space balancer balances at the level of storage pools (SPs), keeping them at the same utilization level as the cluster average.

Note:

- Utilization Level of a SP = (Used space of the SP / Storage capacity of the SP)
- Cluster Average = (Used space across all SPs / Capacity of all SPs)

The disk space balancer distributes containers from highly utilized storage pools on one node in a cluster to less utilized storage pools on other nodes in the same cluster. It accomplishes this by first classifying storage pools into different bins (based on their utilization level). It checks every storage pool on a regular basis (every 2 minutes by default) and then classifies storage pools into bins based on their percentage utilization.

After classifying the storage pools into bins, the disk space balancer then moves containers (in two phases) out of the storage pools with more containers to storage pools with fewer containers. That is, it moves containers out of storage pools in higher bins to storage pools in lower bins in two phases:

- Phase 1 — storage pools in ‘Overused’ and ‘Above Average’ bins are balanced.
- Phase 2 — storage pools in ‘Average’ and ‘Below Average’ bins are balanced.

  Note: Movement of containers in phase 2 happens only when there are not many containers scheduled to be moved in phase 1, because movement of container at any point in time is throttled.

In both phases, the disk balancer attempts to move containers from storage pools in the highest utilized bin (the source SP) to suitable storage pools in the lowest utilized bin (the destination SP). If a suitable SP could not be found as the destination, the balancer attempts to move a container to the next least utilized bin. An SP is not deemed suitable as the destination if:

- Moving a container to that SP would cause the SP to move to the next bin.
- Data movement into the file server to which the SP belongs is blocked.

last-updated: Apr 11, 2022

- SP is not in the same topology as specified by the volume.
- Certain number of containers are currently being moved into the SP.

  Note: The number of simultaneous moves to a SP is capped at 2.
- SP is in the same bin as the source SP.
- Many containers of a container group associated with the same tiering-enabled volume reside on the SP.

  This feature ensures that containers of a container group associated with a tiering-enabled volume are distributed evenly across SPs and do not gather in a few SPs. The balancer accomplishes this by determining whether the destination SP has containers from the container group for the volume associated with the container that is identified for being moved to the destination SP.

An SP or its containers are not considered for balancing if:

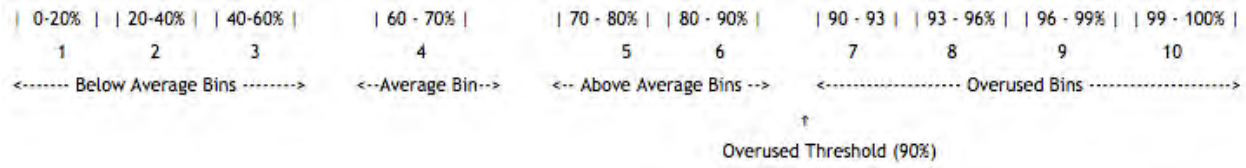
- Data movement from the file server to which the SP belongs is blocked.
- Container was active (that is, written to) in the previous 5 minutes.
- Containers were deleted in the previous minute.

  This is to allow space reclamation. If necessary, the bin will be balanced during the next iteration of the disk balancer.
- Percentage of data that is being transferred out of an SP is greater than or equal to 2% of the SP's storage capacity.
- Certain number of containers are currently being moved out of the SP.

  Note: The number of simultaneous moves out of an SP is capped at 2.

Sample Disk Balancer Settings for Organization of Bins

The following example illustrates disk balancer settings and the corresponding organization of bins to represent storage pool utilization:



In the preceding example, the:

1. Average cluster space utilization is 65%.
2. Average bin size is 10%. Hence, the average bin spans 5% on each side of the average space utilization.
3. Overused threshold is 90%.
4. Below average bin size is 20%.

   Below average bin utilization is partitioned into required number of bins (3). During division, the bin that is immediately to the left of the average bin might not span the default value. In other words, if the average bin spans from 50% to 60%, the below average bins will be cast as 0-20%, 20-40%, 40-50%.

last-updated: Apr 11, 2022

5. Above average bin size is 10%.

   Since the overused threshold is 90%, the above average bins span the utilization from the right boundary of the average bin up to the overused threshold. As with below average bins, as many possible bins are cast with the size of the above average bin, leaving the remaining utilization to be covered by the last (right-most) above average bin.

Enabling and Configuring Disk Balancer
Describes how to enable or disable the disk space balancer and other settings using the Control Panel and the CLI.

Enabling and Configuring Disk Balancer Using the Control System

To enable and configure disk space balancer using the Control System:

1. Log in to the Control System and click **Admin** > **Clusters Settings** > **Balancer**.
2. In the Disk Balancer section, move the **Enabled** slider to **Yes**.
   To enable disk space balancer from the command-line, see Configuring Disk Balancer Execution on page 768.
3. Select one of the presets or specify a custom percentage for **Threshold** and **Concurrent Disk Rebalancer** settings. You can :
   - **Disk Balancer Preset**:

     Moderate (Default)
     - **Threshold** — 70%
     - **Concurrent Disk Rebalancer** — 10%

     Rapid
     - **Threshold** — 50%
     - **Concurrent Disk Rebalancer** — 5%

     Relaxed
     - **Threshold** — 90%
     - **Concurrent Disk Rebalancer** — 25%

   - **Custom**, use the slider to set the threshold and concurrent disk rebalancer percentages.

   Here:

Threshold	Specifies the minimum utilization threshold for a storage pool to become eligible for rebalancing. Default value is 70%.
Concurrent Disk Rebalancer	Specifies the maximum percentage of data that can be rebalanced. The cluster will wait until the number of rebalancing operations affects less than this percentage of total data eligible for rebalancing. The default value is 10%.

4. Click **Save Changes** for the changes to take effect.

Enabling and Configuring Disk Balancer Using the CLI

The disk space balancer checks every storage pool on a regular basis and moves containers from a storage pool when that pool's utilization meets the following conditions:

- The storage pool is over 70% full.
- The storage pool's utilization exceeds the average utilization on the cluster by a specified threshold:
  - When the average cluster storage utilization is below 80%, the threshold is 10%.

last-updated: Apr 11, 2022

- When the average cluster storage utilization is below 90% but over 80%, the threshold is 3%.
- When the average cluster storage utilization is below 94% but over 90%, the threshold is 2%.

You can use the `config save` command to modify disk space balancer parameter values.

Example: `# maprcli config save -values {"cldb.balancer.disk.max.switches.in.nodes.percentage":"20"}`

The following list specifies the disk space balancer configuration parameters with their default values and descriptions:

cldb.disk.balancer.enable

Default Value: 1

Description: Specifies whether the disk space balancer runs:

- 0 - Disabled (does not perform any container moves)
- 1 - Enabled (normal operation)

By default, the disk balancer is disabled.

cldb.balancer.disk.threshold.percentage

Default Value: 70

Description: Threshold for moving containers out of a given storage pool, expressed as utilization percentage.

See also: Balancing Overused and Above Average Bins on page 769.

cldb.balancer.disk.max.switches.in.nodes.percentage

Default Value: 10

Description: This can be used to throttle the disk balancer. If it is set to 10, the balancer will throttle the number of concurrent container moves (minimum 1) to 10% of the total nodes in the cluster rounded up.

See Configuring Throttling on page 770.

Configuring Disk Balancer Execution
Explains how to tune the disk balancer execution parameters.

Even when the disk balancer is enabled, the disk balancer waits during cluster startup to give enough time for the cluster to settle down. The default wait time (specified in seconds) is 30 minutes and can be changed using the parameter `cldb.balancer.startup.interval.sec`. After every run, the disk balancer pauses for 2 minutes by default. The pause time (specified in seconds) can be increased through the parameter `cldb.balancer.disk.sleep.interval.sec`.

Run the `maprcli config save` command and set the following parameters to configure disk balancer:

Parameter	Default Value	Description
`cldb.balancer.startup.interval.sec`	1800 seconds	Wait time, in seconds, for cluster startup.
`cldb.balancer.disk.sleep.interval.sec`	120 seconds	Interval, in seconds, between disk balancer runs.

For example, to:

- Increase the wait time to an hour, change the default value of 1800 seconds to 3600 seconds:

```
maprcli config save -values {"cldb.balancer.startup.interval.sec":"3600"}
```

- Increase the pause time between disk balancer runs from 2 minutes to 5 minutes, change the default value of 120 seconds to 300 seconds:

```
maprcli config save -values
{"cldb.balancer.disk.sleep.interval.sec":"300"}
```

Preventing Volume Skew

By default, the disk balancer does not consider volume skew while moving containers out of a Storage Pool (SP). In the process, all containers of a volume may end up on only a few SPs. Such a volume skew is undesirable, specifically, for DB volumes. In such a skew, few servers handle all requests, resulting in reduced performance.

To prevent volume skew, set the `prevent.volume.skew.by.diskbalancer` parameter to `true` as follows:

```
maprcli config save -values {"prevent.volume.skew.by.diskbalancer":"true"}
```

This parameter checks whether moving a container out of a SP causes a volume skew elsewhere.

Note: Enabling this parameter may result in containers failing the volume underweight check and failing to be moved from a full SP. Consider this limitation and enable as per your need.

Configuring Bin Size
Explains how to configure the sizes of the various bins used by the disk balancer.

The number of bins used by the disk balancer is not constant and is determined by the sizes of different bins. You can configure the size of each of the bins (Below Average, Average, Above Average, and Overused) individually at run time. The larger the size of the bins, the greater the chance that two SPs that are in the vicinity of each other with respect to utilization fall in the same bin.

The default size of overused bins is only 3%, because SPs in this bin must be balanced at a finer granularity. The default size of above average, average, and below average bins is 20%. You can aggressively balance the storage pools across bins by reducing the size of each bin, forcing the SPs to fall into different bins. To reduce the size of each bin, specify the value for the following parameters using the `maprcli config save` command:

Parameter	Description
`dbal.above.avg.bin.size`	Specifies the bin size (%) of SPs whose usage is above the cluster average. The default is 20%.
`dbal.avg.bin.size`	Specifies the bin size (%) of SPs whose usage is in the average range. The default is 20%.
`dbal.below.avg.bin.size`	Specifies the bin size (%) of SPs whose usage is below the cluster average. The default is 20%.
`dbal.overused.bin.size`	Specifies the bin size (%) of SPs whose usage is in the overused range. The default is 3%.

For example, to reduce the size of the Below Average bin to 10%, run the following command:

```
maprcli config save -values {"dbal.below.avg.bin.size":"10"}
```

Balancing Overused and Above Average Bins
Describes how to balance highly utilized Overused and Above Average bins.

Storage pools in the Overused and Above Average bins are highly utilized. The default threshold of “overused” is 90%, which means that the first overused bin’s lower bound is 90%. You should in normal circumstances, never reset this threshold, but you can, if necessary, by setting the value for the parameter

last-updated: Apr 11, 2022

`cldb.balancer.disk.overused.threshold` using the `maprcli config save` command. For example:

```
maprcli config save -values {"cldb.balancer.disk.overused.threshold":"95"}
```

In scenarios where the cluster average is low, storage pools in Above Average bins too might not be highly utilized. In this case, to prevent unnecessary balancing activity, disk balancer uses an additional criterion to prevent wasted moves: only those storage pools whose utilization equals to or is greater than a certain threshold are considered for balancing. This threshold is controlled by the configurable parameter `cldb.balancer.disk.threshold.percentage`, whose default value is 70%.

Note: If the threshold of the Overused bin is set below the default value of 90%, the balancing threshold specified in the `cldb.balancer.disk.threshold.percentage` parameter is also applicable to Overused bins also.

Balancing Average and Below Average Bins
Provides an overview of how the disk balancer balances the Average and Below Average storage pool bins.

The primary task of the disk balancer is to balance highly utilized storage pools in Overused and Above Average bins. However, the disk balancer can also balance storage pools that are less utilized, for example, to distribute workload evenly across the nodes, or if a new node is added to the topology to add more storage. By default, the disk balancer performs this kind of balancing less frequently than the balancing of disk space utilization.

By default, the disk balancer balances storage pools in Average and Below Average bins every 6 hours. You can configure the interval by the setting the value (in minutes) for the parameter `dbal.below.avg.bins.balancing.frequency` using the `marpcli config save` command. For example:

```
maprcli config save -values
{"dbal.below.avg.bins.balancing.frequency":"360"}
```

Note: The disk balancer considers storage pools in these two bins only under the following conditions:

1. When there is not already too much SP balancing activity in the highly utilized bins.
2. If container movement out of SPs in the highly utilized bins is not possible.

Configuring Throttling
Explains how to throttle the number of container moves.

Although balancing storage pool disk space use is important, it requires network, computation, and disk bandwidth that must be shared with other functions. Hence, the number of container moves at any point of time is throttled.

The throttling factor controls the number of active container moves. If there are 100 nodes, and the throttling factor is 10, there can be 10 active moves. If however, the value is 12 (%), there can be 12 active moves.

Note: If you set the throttling factor to 0, the number of active moves is 1.

Therefore, effectively, the number of active moves is:

```
Max(1, throttling_factor x number_of_cluster_nodes)
```

By default, the maximum number of container moves is 10% of the number of nodes in the cluster. However, you can configure the throttling factor (percentage) by setting the parameter `cldb.balancer.disk.max.switches.in.nodes.percentage` using the `maprcli` command.

For example, to set the throttling factor to 12% of the number of nodes in the cluster, run the following command:

```
maprcli config save -values
{"cldb.balancer.disk.max.switches.in.nodes.percentage":"12"}
```

Retrieving Status of Storage Pools
Describes the CLI command to retrieve the status of Storage Pools.

You can use the `maprcli dump balancerinfo` command to view detailed information about the Storage Pools on a cluster.

Example:

```
# maprcli dump balancerinfo
usedMB  fsid                spid                                percentage
outTransitMB  inTransitMB  capacityMB
209     5567847133641152120  01f8625ba1d15db7004e52b9570a8ff3  1
0             0            15200
209     1009596296559861611  816709672a690c96004e52b95f09b58d  1
0             0            15200
```

If there are any active container moves when you run the command, `maprcli dump balancerinfo` returns information about the source and destination storage pools:

```
# maprcli dump balancerinfo -json
        ....
        {
        "containerid":7840,
        "sizeMB":15634,
        "From fsid":8081858704500413174,
        "From IP:Port":"10.50.60.64:5660-",
        "From SP":"9e649bf0ac6fb9f7004fa19d200abcde",
        "To fsid":3770844641152008527,
        "To IP:Port":"10.50.60.73:5660-",
        "To SP":"fefcc342475f0286004fad963f0fghij"
        }
```

Retrieving Balancer Status
Describes how to view the active container movement information from the Control Panel and the CLI.

You can view the active container moves information from the CLDB page on the Control Panel or use the `maprcli dump balancermetrics` command to see a cumulative count of container moves and MB of data moved between storage pools since the current CLDB became the primary CLDB.

Example:

```
# maprcli dump balancermetrics -json
{
  "timestamp":1337770325979,
  "status":"OK",
  "total":1,
  "data":[
    {
      "numContainersMoved":10090,
      "numMBMoved":3147147,
      "timeOfLastMove": "Wed May 23 03:51:44 PDT 2012"
    }
```

```
  ]
}
```

Viewing the List of Active Container Moves
Explains how to view the list of containers being moved, from the CLDB page.

- Log in to the Control System and go to the service information page for CLDB.
  The **Active Container Moves** section displays the following fields:

Container ID	The ID of the container being moved.
SizeMB	The size (in MB) of the container being moved.
From Location	The location from where the container is being moved.
From SP	The Storage Pool (SP) out of which the container is being moved.
To Location	The location to which the container is being moved.
To SP	The SP to which the container is being moved.

Volume Balancer
Describes the role of the volume balancer.

Volume balancer is used to distribute containers of a volume on all the storage pools that belong to the volume's topology. Although the disk balancer balances containers across storage pools, sometimes containers of a volume may accumulate on a few storage pools. For example:

- When the storage pools hosting a volume's containers are not highly utilized, the disk balancer might not spread the volume's containers across storage pools.
- When new storage pools are added to a topology and the storage pools on which the current containers reside are not highly utilized, although the disk balancer moves containers to new storage pools, it is not guaranteed that a specific volume's containers are evenly spread out.

In such cases, you can trigger the balancing of a volume using a `maprcli` command. Every time a volume gets out of balance, you can trigger the volume balancer (using the `maprcli` command) to balance the containers associated with the volume. The container moves triggered by disk and volume balancers do not cause other volumes to be imbalanced.

Note: If both disk balancer and volume balancer are triggered at the same time, volume balancer activity takes precedence.

Managing Volume Balancer
Explains the CLI commands that you can use to balance the containers of a volume.
Enabling and Disabling the Volume Balancer

The volume balancer is disabled by default. To enable or disable the volume balancer:

- Set the value for the `cldb.volume.balancing.enable` parameter using the `config save` on `page 1586` command. To:
  - Enable volume balancer, run the following command:

    ```
    maprcli config save -values {cldb.volume.balancing.enable:1}
    ```

  - Disable volume balancer, run the following command:

    ```
    maprcli config save -values {cldb.volume.balancing.enable:0}
    ```

After enabling the volume balancer feature, you must run the `volume balancecontainers` on `page 1925` command to balance the containers associated with a volume.

Balancing the Containers of a Volume

- Run the `maprcli volume balancecontainers` command to balance a volume.
  The basic command to balance a volume is:

```
/opt/mapr/bin/maprcli volume balancecontainers -name <vol_name>
```

  For more information, see `volume balancecontainers` on `page 1925`.

Stopping the Volume Balancer

- Run the `maprcli volume balancecontainers` command to stop or cancel a balancing activity.
  The command to cancel a volume balancer is:

```
/opt/mapr/bin/maprcli volume balancecontainers -name <vol_name> -cancel
true
```

  For more information, see `volume balancecontainers` on `page 1925`.

config save on page 1586
Saves configuration information, specified as key/value pairs. Permissions required: `fc` or `a`.

volume balancecontainers on page 1925
Balances the containers, or stops the balancing of containers associated with the volume.

Retrieving Balancer Status
Retrieve the status of a balancer activity using the CLI.

Run the `maprcli volume balancinginfo` command to retrieve the status of a currently running or scheduled balancer activity.

The basic command to retrieve the status of volume balancer is:

```
/opt/mapr/bin/maprcli volume balancinginfo -name <vol_name>
```

For more information, see `volume balancinginfo` on `page 1926`. For example:

```
# /opt/mapr/bin/maprcli volume balancinginfo -name Volume1 -json
{
  "timestamp":1502529117881,
  "timeofday":"2017-08-12 09:11:57.881 GMT+0000",
  "status":"OK",
  "total":5,
  "data":[
    {
      "volumeName":"Volume1"
    },
    {
      "isBalancingInProgress":false
    },
    {
      "numContainers":15
    },
    {
      "volumeSize":384
    },
```

```
    {
      "spInfo":[
        {
          "spId":"f891ae9e6663fa2000598ec48808155c",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"bed92c0ecfaefc8b00598ec48b01cdfe",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"b61aa1b814fd8bbc00598ec48d0af1d2",
          "capacity":157065,
          "usedSize":96,
          "desiredSize":97,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"7af11d5b9d223baa00598ec4850efb57",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        }
      ]
    }
  ]
}
```

Replication Role Balancer

Describes the features of the replication role balancer.

The replication role balancer manages containers to optimize the following:

- Network bandwidth during the replication process
- Disk I/O and CPU when serving read requests

The replication role balancer switches the replication roles of name and data containers to balance them across each storage pool in a volume. You can modify the `cldb.role.balancer.strategy` parameter from the `maprcli` to change how the role balancer manages the containers, either by size or count. You can also run the `dump rolebalancerinfo` command to see the status of active role switches or how container roles are balanced across each storage pool for a particular volume.

Replicated Containers

The name container is the first container created in every volume. Name containers can have either a *primary* or a *replica* role. Data containers can have a *primary*, *intermediate*, or *tail* role. By default, each

name and data container is replicated across the cluster three times, with the primary being the first container written. The primary is sequentially replicated two more times, into a container with either an intermediate or a tail container role. If too many primary or intermediate containers exist on a storage pool or if the primary and intermediate containers are too large, the role balancer switches some of these containers to tail containers.

By default, the role balancer compares the size of the primary and tail containers to determine if containers within a storage pool are balanced. For the best performance, the size of the primary containers in a volume should be evenly distributed across storage pools. The role balancer maintains this balance by ensuring that each type of container (primary, intermediate, and tail) accounts for `1/ReplicationFactor` of the total container size in a volume.

If the role balancer is configured to manage containers by count, it compares the number of primary and tail containers and balances the roles such that each type of container accounts for `1/ReplicationFactor` of the total number of containers in a volume. For example, if the replication factor is set to 3, the role balancer maintains a balance of ⅓ primary, ⅓ intermediate, and ⅓ tail containers in each volume.

MapR Database Considerations

To optimize MapR Database performance, you should configure the role balancer to manage containers by size. As described at MapR Database and MapR XD on page 501, MapR Database shards tables into *tablets* and stores the tablets in data containers. Only primary data containers serve reads. Therefore, configuring the role balancer by size spreads read requests evenly across the storage pools for a volume. To ensure the most optimal balancing for your MapR Database tables, you should consider storing them on dedicated volumes.

Assign Cache

The assign cache is a list of reserved containers on a particular file server node that are allocated by the CLDB (container location database). The replication role balancer does not balance the containers in the assign cache and does not include them when balancing the roles. See the maprcli dump rolebalancerinfo command for assign cache values and details.

Enabling and Configuring Replication Role Balancer
Describes how to use the Control System or the CLI to enable and configure the Replication Role Balancer.

Enabling and Configuring the Replication Role Balancer Using the Control System

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Balancer**.
2. From the Role Balancer section, set the **Enabled** slider to **Yes** .
3. Select one of the presets or specify a custom value for the **Concurrent Role Rebalancer** and **Delay for Active Data in Seconds** settings. You can choose:
   - Presets:

Default	• **Concurrent Role Rebalancer** — 20% • **Delay for Active Data in Seconds** — 600 sec
Rapid	• **Concurrent Role Rebalancer** — 5% • **Delay for Active Data in Seconds** — 300 sec
Moderate	• **Concurrent Role Rebalancer** — 10% • **Delay for Active Data in Seconds** — 600 sec

last-updated: Apr 11, 2022

Relaxed	• **Concurrent Role Rebalancer** — 25% • **Delay for Active Data in Seconds** — 1800 sec

- **Custom**, use the slider to set the concurrent role rebalancer percentage and delay for active data in seconds.

Here:

Concurrent Role Rebalancer	Specifies the maximum percentage of data affected by concurrent role rebalancer operations. The cluster will wait until the number of rebalancing operations affects less than this percentage of total data eligible for rebalancing.
Delay for Active Data in Seconds	At the time of calculation, the role rebalancer will skip any data that is active within this time interval. This prevents unnecessary tampering with data used in recent or ongoing computations.

4. Click **Save Changes** for the changes to take effect.

Enabling and Configuring Replication Role Balancer Using the CLI

You can use the `config save` command to modify the replication role balancer parameter values.

Example: `# maprcli config save -values {"cldb.role.balancer.strategy":"BySize"}`

The following table lists the replication role balancer configuration parameters with their default values and descriptions:

Parameter	Value	Description
cldb.balancer.role.paused	1	Specifies whether the role balancer runs: • 0 - Not paused (normal operation) • 1 - Paused (does not perform any container replication role switches)
cldb.role.balancer.strategy	"BySize"	Specifies how the replication role balancer balances containers, either by size or count. Use `"BySize"` or `"ByCount"` to indicate how role balancer balances containers.
cldb.balancer.role.max.switches.in.nodes.percentage	10	This can be used to throttle the role balancer. If it is set to 10, the balancer will throttle the number of concurrent role switches to 10% of the total nodes in the cluster (minimum 2).

Retrieving Role Balancer Status Using the CLI
Lists the CLI command to view the number of active replication role switches.

You can use the `maprcli dump rolebalancerinfo` command to view the number of active replication role switches. During a replication role switch, the replication role balancer selects a primary or intermediate data container and switches its replication role to that of a tail data container.

last-updated: Apr 11, 2022

Example:

```
# maprcli dump rolebalancerinfo -json
{
    "timestamp":1335835436698,
    "status":"OK",
    "total":1,
    "data":[
            {
               "containerid": 36659,
               "Tail IP:Port":"10.50.60.123:5660-",
               "Updates blocked Since":"Wed May 23 05:48:15 PDT 2012"
            }

    ]
}
```

Managing Licenses
Provides a synopsis of adding licenses using the Control System and the CLI.

You can add and remove licenses on your cluster using the Control System or the CLI:

- In the Control System, go to **Admin** > **Cluster Settings** > **Licenses**.
- On the command line, use the `maprcli license` commands.

Warning: Remove old licenses from the cluster when you add a new license. If multiple licenses exist, the cluster activates only the license with the lowest node count.

Adding a License
Add a license through the Control System or the CLI.
Adding a License Using the Control System

Complete the following steps to add a license using the Control System:

1. On a machine that is connected to the cluster and to the Internet, perform the following steps to open the Control System:
   a) In a browser, view the Control System by navigating to the node that is running the Control System: `https:/<webserver>/:8443`.

      Your computer will not have a HTTPS certificate yet, so the browser will warn you that the connection is not trustworthy. You can ignore the warning this time.

   b) Log in to the Control System as the administrative user you designated earlier.

      Until a license is applied, the Control System dashboard might show some nodes in the amber "degraded" state. Do not worry if not all nodes are green and "healthy" at this stage.
2. In the Control System, go to **Admin** > **Cluster Settings** > **Licenses**.
3. Add a license using the following options:

Import License	Allows you to import a license from the server. You must enter your credentials in the **Import License** window to retrieve your license information.
Upload License	Allows you to upload your license file through a browser.
Copy/Paste License	Allows you to copy and paste a license key in the **Copy and Paste License** window.
Get a Free Trial License	Navigates to the MapR licensing form online to get a trial license.

last-updated: Apr 11, 2022

4. Click **Submit**.

   If the cluster is already registered, the license is applied automatically. Otherwise, go to hpe.com and follow the instructions there to register the cluster.

Adding a License Using the CLI or the REST API

To add a license from the CLI:

1. Obtain a valid license file from MapR.
2. Copy the license file to a cluster node.
3. Run the following command to add the license:

   ```
   maprcli license add [ -cluster <name> ] -license <filename> -is_file true
   ```

   See `license add` on page 1680 for complete reference information.

Viewing the Licenses Using the Control System

To view licenses:

1. Log in to the Control System.
2. Click **Admin** > **Cluster Settings** > **Licenses**.

Under **LICENSES**, the pane displays the following information for each license:

Column Name	Column Description
Active	Indicates whether (✓) the license is active.
Grace	Denotes the remaining grace period (in days) before which you must renew the expired license.
Name	The name of the license.
Module/Type	The type of license.
Issued	The date the license was issued.
Expires	The license expiration date.
Nodes	The number of nodes to which the license applies.
Delete	The option to remove the license.

You can:

- Add a license
- Remove a license

Viewing the Licenses Using the CLI or REST API

The basic command to get a list of licenses on the cluster is:

```
maprcli license list -cluster <cluster>
```

Removing a License
Describes how to remove a license using the Control System and the CLI.
Removing a License Using the Control System

To remove a license:

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Licenses**.
2. Click the **Delete** link associated with the license to display the **Remove License** confirmation dialog.
3. Click **Submit** to remove the license.

Removing a License Using the CLI or REST API

To remove a license on a cluster:

1. From the command line, issue the `maprcli license list on page 1684` command. Example:
   ```
   maprcli license list
   ```
2. Look for the `id` parameter in the output from the license list command.
   This is the license ID. Example:
   ```
   grace id                          description       deletable license
   maxnodes
   true  5CTFWAeQQUIOc5Wm/onoOJqcCls MapR Base Edition false
        version: "1.0"
        customerid: "BaseLicenseUser"
        issuer: "MapR Technologies, Inc."
        licType: Base
        description: "MapR Base Edition"
        ...
   ```
3. Use the `maprcli license remove on page 1687` command to remove the license.
   Example:
   ```
   maprcli license remove -license_id 5CTFWAeQQUIOc5Wm/onoOJqcCls
   ```

Setting Quota Defaults for Users and Groups
Explains how to set disk space quotas for users and groups.

Quotas limit the disk space used by a volume or an *entity* (user or group) on an Enterprise Edition-licensed cluster, by specifying the amount of disk space the volume or entity is allowed to use. A volume quota limits the space used by a volume. A user/group quota limits the space used by all volumes owned by a user or group. These quotas work on tenant volumes as well.

You can set hard quota and advisory quota defaults for users and groups. When a user or group is created, the default quota and advisory quota apply unless overridden by specific quotas. You can set an entity quota that differs from the default using the entity modify on page 1649 command or through the Control System.

The size of a disk space quota is expressed in terms of the actual data stored from the user's point of view. Only post-compression data blocks are counted, and snapshot and replica space do not count against quotas. For example, a 10G file that is compressed to 8G and has a replication factor of 3 consumes 24G (3*8G), but charges only 8G to the user or volume's quota.

You can set an entity quota through the Control System and using the CLI.

Setting Quotas Using the Control System

Complete the following steps to set the entity quota in the Control System:

1. Go to **Admin** > **Cluster Settings** > **Quotas**.
2. Set the advisory and hard quotas for the:
   - User under **USER QUOTA**.
   - Group under **GROUP QUOTA**.

   Hard quota prevents writes above the specified threshold. Advisory quota does not enforce disk usage limit, but raises an alarm when the specified threshold is exceeded:
   - AE_ALARM_AEADVISORY_QUOTA_EXCEEDED - an entity exceeded its advisory quota
   - VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED - a volume exceeded its advisory quota

   In most cases, it is useful to set the advisory quota a little lower than the hard quota, to give advance warning that disk usage is approaching the allowed limit.

3. Set the cluster reserve limit, which is the amount of disk space that you wish to allocate for all volumes on the cluster.

   When you set a reserve limit, you provision a certain amount of space to the volumes as a percentage of the cluster capacity. This allows you to free up space that could potentially be unused, or allocate more space for replication.

   As data is written to the volume, available space is automatically allocated. The volume reserve increases up to the reserve limit you set here.

4. After setting the quota, click **Save** to save the settings.

Setting Entity Quotas Using the CLI or the REST API

To set an entity (user or group) quota, run the following command:

```
maprcli entity modify -name <entityname> -advisoryquota <advisory
quota> -quota <quota>
```

To manage quotas, you must have a or `fc` permissions.

Quotas are expressed as an integer value plus a single letter to represent the unit:

- B - bytes
- K - kilobytes
- M - megabytes
- G - gigabytes
- T - terabytes
- P - petabytes

Example: 500G specifies a 500-gigabyte quota. Do not use two-letter abbreviations for units, such as MB or GB.

For complete reference information, see the `entity modify` on page 1649 command.

Setting the Cluster Reserve Limit Using the CLI or REST API

To set the resource usage limit for the cluster's disk resource, run the following command:

```
maprcli rlimit set -resource disk -cluster <cluster name> -value <limit>
```

For complete reference information, see the `rlimit set` on page 1736 command.

Related reference

entity modify on page 1649
Modifies a user or group quota or email address. Permissions required: `fc` or `a`.

rlimit set on page 1736
Sets the resource usage limit for the cluster's disk resource.

Specifying the Location of Gateways
Describes how to set the location of the MapR gateways using either the Control System or the CLI.

On every source MapR cluster, you can specify the location of the gateways by adding a DNS record to your DNS server's zone file for your domain. In your DNS server's zone file for your domain, add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you can copy into a DNS configuration file, run a `maprcli` command

to generate the record, or create a record manually. For more information on gateways, see Managing Gateways on page 1154.

Specifying the Location of Gateways Using the Control System

To create a record using the Control System, follow these steps:

1. Log in to the Control System on the cluster where the gateways are located.
2. Click **Admin** > **Cluster Settings** > **Gateway**.
3. Click **Copy to Clipboard** to copy the generated DNS entry.
4. Paste the record into your zone file.

Specifying the Location of Gateways Using the CLI

To generate a record by using the `maprcli` command, follow these steps:

1. On the cluster where the gateways are located, run the following command.

   ```
   maprcli cluster gateway local -format dns
   ```

   If you want to run the command from a different cluster and point to the cluster that hosts the gateways, use the `-cluster` parameter to provide the name of the latter cluster.

2. Copy and paste the output of this command into your zone file.

Creating a Record Manually

If you want to create a record manually, use this format:

```
gateway.<clustername> IN TXT "<space-delimited list of hostnames>"
```

You can also specify IP addresses, though using hostnames is recommended so that it is easier to locate gateways if their IP addresses change. Combinations of hostnames and IP addresses are also supported. The default port is `7660`. If a gateway is using a different port, append a colon to the address and then specify the port number. Here is an example entry:

```
gateway.newyork.bigcompany.com gw1ny.bigcompany.com gw2ny.bigcompany.com
```

Multi-homing is also supported. Simply separate the entries for a single node with semicolons, as in this example that uses IP addresses:

```
gateway.newyork.bigcompany.com 10.10.34.20 10.10.34.22
10.10.34.24;173.194.79.121
```

Related concepts

Administering MapR Gateways on page 1150
A MapR gateway mediates one-way communication between a source MapR cluster and a destination cluster. You can replicate MapR Database tables (binary and JSON) and MapR Event Store For Apache Kafka streams. MapR gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1152
Configuring gateways involves installing the `mapr-gateway` package on nodes on a MapR destination cluster and then configuring the MapR source cluster to communicate with the destination cluster. The MapR source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

gateway.conf on page 2197
Gateways for Replicating MapR Database Tables on page 621

last-updated: Apr 11, 2022

In MapR Database table replication, MapR Database replicates updates to tables (binary and JSON) on source MapR clusters to replicas of those tables on destination MapR clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

Managing Alarms

You can view all the alarms and configure settings, including severity and notifications, on the Control System and using the CLI.

Viewing the List of Alarms

Specifies how to view the list of alarms raised, using either the Control System or the CLI.

You can view all the alarms on the Control System and using the CLI.

Viewing the List of Alarms in the Control System

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Alarms**.
   The **ALL ALARMS** pane displays all the alarms on the cluster.
2. Select:
   - **Cluster Alarms** — indicate problems that affect the cluster as a whole
   - **Node Alarms** — indicate problems on individual nodes
   - **Table Alarms** — indicate table replication-related problems
   - **User/Group Alarms** — indicate problems with user or group quotas
   - **Volume Alarms** — indicate problems in individual volumes

   For the selected view, the pane displays the following for each alarm:

Column Name	Column Description
Alarm Name	The name of the alarm.
Severity	The user-defined severity for the alarm.

Column Name	Column Description
Description	A one-line description of the alarm.
Info	Information on the alarm including alarm name, description, and recommended action to address the alarm.

You can click the alarm name to configure alarm settings.

Retrieving the List of Alarms Using the CLI or REST API

The basic command to list all alarms by type (Cluster, Node, User, or Volume) is:

```
maprcli alarm list -type (cluster|node|volume|AE)
```

For complete reference information, see `alarm list` on page 1545.

Configuring Alarm Settings

Set the severity and notifications for each alarm using either the Control System or the CLI.

Configuring Alarm Settings Using the Control System

To configure alarm setting from the Control System:

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Alarms**.
2. Select:
   - **Cluster Alarms** to configure settings for the alarms that affect the cluster as a whole
   - **Node Alarms** to configure settings for the alarms that indicate problems on individual nodes
   - **Table Alarms** to configure settings for the alarms that indicate table replication-related problems
   - **User Alarms** to configure settings for the alarms that indicate problems with user or group quotas
   - **Volume Alarms** to configure settings for the alarms that indicate problems in individual volumes
3. Click the name of the alarm to display the **Alarm Settings** window.
4. Specify a description of the alarm under **GENERAL** settings.
5. Configure alarm notifications (under **NOTIFICATIONS**) to allow MapR to send an email notification when the alarm is raised.
   a) Select (to enable) or deselect (to disable) the **Email Notifications** checkbox.
   b) If notifications are enabled, enter the user name or group name to which to send email when the alarm is raised, and click **Add**.
   See Setting Up SMTP on page 754 for additional information.
6. Click **Save Changes** to save your settings.

Configuring Alarm Settings Using the CLI or REST API

To set up alarm notifications, run the `alarm config save` command from the command line.

Warning: You must have `fc` (full control) or a (admin) permissions to run this command.

last-updated: Apr 11, 2022

The format of the command is:

```
maprcli alarm config save -cluster <cluster_name> -values
"<alarm>,<enableEmail>,<email>"
```

Assign values as follows:

Value	Description	Example
`alarm`	Name of the alarm	`DISK_FAILURE_ALARM`
`enableEmail`	Specifies whether individual alarm notifications are sent to any email address (including the default email address) for the alarm type. • 0 - do not send notifications to any email address for the alarm type • 1 - send notifications to all email addresses for the alarm type	`1`
`email`	One or more email addresses other than the default email address. If specified, alarm notifications are sent to these addresses as well, if *enableEmail* is set to *1*. Multiple email addresses must be separated by spaces only. You cannot use commas or other delimiters. For example, `user1@mycorp.com user2@mycorp.com` is valid.	`user1@mycorp.com`

Configuring the Alarm Threshold Using the CLI
You can configure the alarm threshold for certain alarms. For the alarms that support threshold configuration, this topic describes the command to run to set the threshold.

VOLUME_ALARM_INODES_EXCEEDED

Threshold is configurable at both the cluster and the volume level.

If configured at both the cluster and volume levels, the volume level threshold overrides cluster-level threshold.

To configure at the cluster-level, run the following commands:

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.max.inodes.volume.alarm.thresh
":"<value>"}'
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.default.max.namespace.size.mb.
alarm.thresh":"<value>"}'
```

To configure at the volume-level, run the following commands:

```
# /opt/mapr/bin/maprcli
volume modify -name
<volname> -maxinodesalarmthreshold
<threshold>
# /opt/mapr/bin/maprcli
```

last-updated: Apr 11, 2022

	`volume modify -name <volname> -maxnssizembalarmthreshold <threshold>`
VOLUME_ALARM_TOPOLOGY_ALMOST_FULL	Threshold is configurable at cluster level. To configure, run the following command: `# /opt/mapr/bin/maprcli config save -values '{"cldb.topology.almost.full.percentage":"<value>"}'`
VOLUME_ALARM_QUOTA_EXCEEDED	Threshold is configurable in volume properties. To configure, run the following command: `# /opt/mapr/bin/maprcli volume modify -name <volname> -quota <value>`
VOLUME_ALARM_TABLE_INDEX_LAG_HIGH	Threshold is configurable in volume properties. To configure, run the following command: `# /opt/mapr/bin/maprcli volume create -name <volname> -dbindexlagsecalarmthresh <value in seconds>`
VOLUME_ALARM_TABLE_REPL_LAG_HIGH	Threshold is configurable in volume properties. To configure, run the following command: `# /opt/mapr/bin/maprcli volume create -name <volname> -dbrepllagsecalarmthresh <value in seconds>`
VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED	Threshold is configurable in volume properties. To configure, run the following command: `# /opt/mapr/bin/maprcli volume modify -name <volname> -advisoryquota <value>`
AE_ALARM_AEQUOTA_EXCEEDED	Threshold is configurable in ae properties. `# /opt/mapr/bin/maprcli entity modify -name <entityname> -type <type> -quota <value>`
AE_ALARM_AEADVISORY_QUOTA_EXCEEDED	Threshold is configurable in ae properties. `# /opt/mapr/bin/maprcli entity modify -name <entityname> -type <type> -advisoryquota <value>`
NODE_ALARM_TOO_MANY_CONTAINERS	Threshold is configurable at cluster level.

last-updated: Apr 11, 2022

	This alarm is also raised when total number of containers (including snap containers) exceed 10 times the value of `pernode.numcntrs.alarm.thr`. `# /opt/mapr/bin/maprcli config save -values '{"pernode.numcntrs.alarm.thr":"<value>"}'`
NODE_ALARM_NO_HEARTBEAT	Threshold is configurable at cluster level. `# /opt/mapr/bin/maprcli config save -values '{"cldb.fs.mark.inactive.sec":"<value>"}'`
NODE_ALARM_HIGH_MFS_MEMORY	Threshold is configurable at cluster level. This alarm is raised when MapR File System memory consumption exceeds the threshold. `# /opt/mapr/bin/maprcli config save -values '{"mfs.high.memory.alarm.threshold":"<value>"}'`
CLUSTER_ALARM_CLUSTER_ALMOST_FULL	Threshold is configurable at cluster level. `# /opt/mapr/bin/maprcli config save -values '{"cldb.cluster.almost.full.percentage":"<value>"}'`
CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION	Threshold is configurable at cluster level. `# /opt/mapr/bin/maprcli config save -values '{"mapr.license.exipry.notificationdays":"<value>"}'`
CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS	Threshold is configurable at the cluster level by setting the value for the `cldb.snap.cntr.count.alarm.threshold` property in the `cldb.conf` file. See `cldb.conf` on page 2182 for more information. **Note:** The default value is `100000000`.

Viewing Alarm Information

Describes how to view alarm information using the Control System.

You can view notes for an alarm in the Control System.

Viewing Alarm Information in the Alarms Page

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Alarms**.
2. Select:
   - **Cluster Alarms** to view notes for the alarms that affect the cluster as a whole

last-updated: Apr 11, 2022

- **Node Alarms** to view notes for the alarms that indicate problems on individual nodes
- **Table Alarms** to view notes for the alarms that indicate table replication-related problems
- **User Alarms** to view notes for the alarms that indicate problems with user or group quotas
- **Volume Alarms** to view notes for the alarms that indicate problems in individual volumes

3. Click  associated with the alarm in the **Info** column.
   The **Alarm Information** window displays a description of the alarm and the recommended action to address the alarm.

Viewing Alarm Information in the Active Alarms Pane

- Click  associated with the alarm in the **Active Alarms** pane to view information on the alarm.
  The **Alarm Information** window displays a description of the alarm, type of alarm, information on the alarm, and recommended action to address the alarm.

Dismissing an Alarm
Describes how to dismiss an alarm, either manually or automatically, using either the Control System or the CLI.

You can dismiss an alarm using the Control System or the CLI. When you dismiss an alarm, it will be cleared. You can raise the alarm again:

- Manually using the CLI
- Automatically when the conditions for raising the alarm again are met

Dismissing Alarm(s) Using the Control System

The **Dismiss** action is available in all the **Active Alarms** pane and in the **Alarms Summary** page. To dismiss alarm(s):

1. Click **Dismiss**.
   The **Dismiss Alarms** dialog displays.
2. Verify the alarm(s) to dismiss and click **Dismiss** to dismiss the alarm(s).

Dismissing Alarm(s) Using the CLI

The basic command to dismiss an alarm is:

```
maprcli alarm clear -alarm <alarm>
```

For complete reference, see `alarm clear` on page 1536.

Muting and Unmuting Alarms
Describes how to mute and unmute alarms using either the Control System or the CLI.

You can mute (silence) one or more (non-critical) alarms for a specific period of time using either the Control System or the CLI. The alarm will be silenced for the duration of the mute period and CLDB will raise the alarm again after the mute period **only** if the conditions for raising the alarm instance again are met.

Muting Alarm(s) Using the Control System

The **Mute** action is available in all the **Active Alarms** pane and in the **Alarms Summary** page. To mute alarm(s):

1. Click **Mute** to display the **Mute Alarms** dialog.

last-updated: Apr 11, 2022

2. Verify the alarm(s) to mute.
3. Select the period of time (1 hour, 6 hours, or 24 hours) to mute the alarm for from the **Mute Alarms for** drop-down list.
4. Click **Mute Alarms** to mute the alarm(s).
   The alarm will be raised again if the associated issue is not resolved within the specified period of time.

Muting Alarm(s) Using the CLI

The basic command to mute an alarm is:

```
maprcli alarm mute -alarm <alarm name>[:<entity>]:<mute_period>
```

For complete reference, see alarm mute on page 1548.

Unmuting Alarm(s) Using the CLI

The basic command to mute an alarm is:

```
maprcli alarm unmute
```

For complete reference, see alarm unmute on page 1552.

Working with Multiple Instances of the File System
The Multi-MapR File System feature allows multiple instances of the file server to run on a single node in a single process.

Multiple instances of the MapR file server can run on a single node in a single process with the installation of the MapR XD Distributed File and Object Store, or the MapR Database software. On servers with SSDs with at least 2 storage pools (SP), two instances (per node) are configured by default. On servers without SSDs, a single instance is configured by default. Each instance runs as a separate library that is dynamically loaded into a single process. In this mode, each instance has a separate host ID; however, all the instances share the same hostname.

The maximum number of supported instances is 32. Instances should be configured based on the available CPU, memory, disks, and SPs. Each instance needs a minimum of 2GB, and instances should not exceed:

- Number of CPUs / 2
- Number of SPs (enforced)

File Server Instances

On MapR XD and MapR Database installations, nodes with SSDs can run multiple file server instances. To determine whether a node has SSDs, MapR uses the value of `mfs.disk.is.ssd` in the mfs.conf on page 2204 file, which must be set to `1`. Add this parameter to mfs.conf on page 2204, on a node that has SSDs.

For clusters with MapR XD or MapR Database license, if you set the `mfs.disk.is.ssd` in the mfs.conf on page 2204 file to 1, CLDB configures nodes with SSDs to have 2 file server instances by default. On homogeneous clusters, you can modify the number of instances by changing the value of the `multimfs.numsps.perinstance` parameter.

Ports for Multiple Instances of the MapR File System

Each instance listens on its own set of ports. Ensure that the appropriate ports are open for this feature. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756

(5660+96), instance 1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. The topology of all instances is the same.

The total number of instances depends on the number of MFS threads, as indicated by the parameter `mfs.numrpcthreads` in mfs.conf on page 2204.

To verify that these ports are open, run the following command from a remote machine:

```
mrconfig -i -h <ip> -p <port number> info threads
```

An error indicates that the port is not open. If a port (for example, port 5661) is blocked, this command prints something similar to the following:

```
------------------
|From Instance 5661::|
------------------
<...> rpc failed <...>
```

Host IDs for Multiple Instances of the MapR File System

For multiple instances of the MapR File System, do NOT add IDs manually, but let the system handle the host ID numbering.

Log Files

Each instance has its own set of log files in `$MAPR_HOME/logs`. When multiple instances are configured, the log files have the same name with a different instance ID; for example, `mfs.log.<N>-3` where `N` is the instance number.

Note: For the primary instance, the log file name does not include the instance number.

The RPC and security trace information are in a separate file per instance, `mfs-<N>.err`, where `N` is the instance number. For the primary instance, the file name does not include the instance number.

For example, suppose there are 2 instances running on ports 5660 and 5661. There are 2 sets of log files, one for each instance:

- `mfs.log-3` for the primary instance
- `mfs.log.1-3` for the second instance

The RPC and security trace information are present in the following files :

- `mfs.err` for the primary instance
- `mfs-1.err` for the second instance

Configuring the Number of Storage Pools per Instance

Describes how to set the number of storage pools for each filesystem instance, from the CLI.

As you add MapR File System instances, MapR assigns SPs to them. If MapR File System instances are removed, the SPs assigned to those instances are re-allocated among the remaining live MapR File System instances. By default, the value is 1, which implies that there is only 1 SP for all instances. You can re-configure the number of SPs per instance globally or at the node-level.

last-updated: Apr 11, 2022

Note: If the number of MapR File System instances is not as configured, the Instance Mismatch Alarm will be raised. If the alarm is raised on a:

- CLDB node, restart warden by running the following command:

```
service mapr-warden restart
```

- Non-CLDB node, restart file server by running the following command:

```
maprcli node services -nodes <node-ip> -fileserver restart
```

Global Configuration

If you configure globally, the configuration will be applied to all the nodes in the cluster. Make the following changes only on homogeneous clusters (that is, when all nodes in the cluster have the same type of disks and the stripe width of the disks is the same):

1. Run the following commands:

```
maprcli config save -values {multimfs.numsps.perinstance:3}
maprcli config save -values {multimfs.numinstances.pernode:2}
```

   The default value of the `multimfs.numsps.perinstance` parameter is 0. Suppose a node reports 9 SPs:

   - For a value of 3, the node would need to start 3 instances.
   - For a value of 5, the node would need to start 2 instances.

   For clusters with fast SSDs, this can be set to 1.

   Note: On AWS nodes with HDD, set the `multimfs.numsps.perinstance` parameter value to 50 to use a single instance.

2. Restart Warden in every node for the configuration change to take effect.

Node-level Configuration

At the node level, you can configure different number of instances for each node in the cluster. To change the number of SPs per instance:

1. Run the following command:

```
maprcli node modify -nodes <nodename> -numSpsPerInstance <n>
```

   The number of instances changes automatically when new SPs are created.

2. Restart Warden on the nodes where the configuration has changed.

Monitoring Multiple Instances of MapR File System
Describes how to monitor the health and performance of your cluster.
Determining the Number of Running Instances

- Run the following command to determine the number of instances actually running:

```
/opt/mapr/server/mrconfig info instances
```

Your output will look similar to the following. This output shows that two File Server instances are running on ports `5660` and `5661`.

```
/opt/mapr/server/mrconfig info instances
    2
    5660 5661
```

Alternatively, on large clusters, run the following command to:

- Determine the number of configured instances:

```
maprcli node list -columns numInstances
    hostname           numInstances  ip
    atsqa4-161.qa.lab  1             10.10.88.161
    atsqa4-162.qa.lab  1             10.10.88.162
    atsqa4-163.qa.lab  1             10.10.88.163
    atsqa4-164.qa.lab  1             10.10.88.164
```

- Determine the number of running instances reported by MapR File System to CLDB:

```
maprcli node list -columns numReportedInstances
    numReportedInstances  hostname           ip
    2                     atsqa4-161.qa.lab  10.10.88.161
    1                     atsqa4-162.qa.lab  10.10.88.162
    1                     atsqa4-163.qa.lab  10.10.88.163
    2                     atsqa4-164.qa.lab  10.10.88.164
```

Determining the Number of MapR File System Threads

You can run the mrconfig info threads on page 2163 command to view MapR File System threads from all the instances. The output is tagged to identify the instance.

Converting a Cluster from Root to Non-Root User from the Command-Line
Provides a synopsis of changing the running user from `root` to a non-root user on a cluster.

You can change a MapR cluster that runs as `root` to a non-root user. In addition to converting the MapR user to a non-root user, you can also disable superuser privileges to the cluster for the `root` user for additional security.

Warning: You must perform these steps on all nodes on a stable cluster. Do not perform this procedure concurrently while upgrading packages.

Converting a MapR Cluster from Root to Non-Root User from the Command-Line
Lists the process to change the running user from `root` to a non-root user on a cluster.

1. Create a user with the same UID/GID across the cluster. Assign that user to the `MAPR_USER` environment variable.
2. On each node:
   a) Stop the warden and the ZooKeeper (if present).

```
service mapr-warden stop
service mapr-zookeeper stop
```

   b) Run the `config-mapr-user.sh` script to configure the cluster to start as the non-root user.

```
/opt/mapr/server/config-mapr-user.sh -u <MapR user> [-g <MapR group>]
```

last-updated: Apr 11, 2022

c) Start the ZooKeeper (if present) and the warden.

```
service mapr-zookeeper start
service mapr-warden start
```

3. After the previous step is complete on all nodes in the cluster, run the `upgrade2mapruser.sh` script on all nodes.

```
/opt/mapr/server/upgrade2mapruser.sh
```

This command may take several minutes to return. The script waits ten minutes for the process to complete across the entire cluster. If the cluster-wide operation takes longer than ten minutes, the script fails. Re-run the script on all nodes where the script failed.

Warning: The `MAPR_UID_MISMATCH` alarm may be raised during this process. The alarm will be cleared when this process is complete on all nodes.

Disabling Superuser Access for the Root User from the Command-Line
Describes how to disable superuser access for the `root` user.

Note: Enabling the `cldb.squash.root` **OR** `cldb.reject.root` configuration values can cause instability with ecosystem open source components if they are running as `root`. [On MapR clusters, services are running as the admin cluster user, which is `mapr` (by default).] Root squash applies only to files, not tables or streams. Ensure that `root` is not running any services before performing this procedure.

Important: You can enable either of the following parameters, but NOT both.

1. To disable root user (UID 0) access to the MapR filesystem on a cluster that is running as a non-root user, use either of the following commands:
   - The *squash root* configuration value treats all requests from UID 0 as coming from UID -2 (nobody):

```
/opt/mapr/bin/maprcli config save -values {"cldb.squash.root":"1"}
```

   - The *reject root* configuration value automatically fails all filesystem requests from UID 0.

```
/opt/mapr/bin/maprcli config save -values {"cldb.reject.root":"1"}
```

2. You can verify that these commands worked, as shown in the following example.

```
/opt/mapr/bin/maprcli config load -keys cldb.squash.root,cldb.reject.root
cldb.reject.root cldb.squash.root
0 1
```

Starting Up a Cluster
Lists the steps to start a cluster that was previously shut down.

1. If the cluster nodes are not running, start them.
2. Change to the `root` user (or use `sudo` for the following commands).
3. Start ZooKeeper on the nodes where it is installed:

```
service mapr-zookeeper start
```

4. On all nodes, start Warden:

```
service mapr-warden start
```

5. Over a period of time (depending on the cluster size and other factors), the cluster comes up automatically. After the CLDB restarts, there is a 15-minute delay before replication resumes. This delay allows all nodes to register and begin heartbeat processing. You can configure this delay by using the `config save` command to set the `cldb.replication.manager.start.mins` parameter.

Shutting Down a Cluster

Lists the considerations to note and the procedure to shutdown a cluster.

Verify that MapReduce processes are not active, and that no data is being loaded to the cluster or being persisted within the cluster.

When you shut down a cluster, follow this sequence to preserve your data and replication:

1. Verify that recent data has finished processing.
2. Shut down any NFS servers.
3. Shut down any ecosystem components that are running.
4. Shut down ResourceManager and NodeManager services if you are using YARN
5. Shut down Warden on all nodes that are not running CLDB.
6. Shut down Warden on the CLDB nodes.
7. Shut down ZooKeeper on the ZooKeeper nodes.

Complete the following steps to shut down the cluster:

1. Change to the `root` user (or use `sudo` for the following commands).
2. Before shutting down the cluster, you will need a list of NFS nodes, CLDB nodes, and all remaining nodes. Once the CLDB is shut down, you cannot retrieve a list of nodes; it is important to obtain this information at the beginning of the process. Use the node list on page 1705 command as follows:
   - Determine which nodes are running the NFS gateway. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/
*]and[svc==nfs]" -columns id,h,hn,svc,rp
id
service
hostname             health  ip
6475182753920016590
fileserver,nodemanager,nfs,hoststats
node-252.cluster.us 0       10.10.50.252
8077173244974255917
nodemanager,cldb,fileserver,nfs,hoststats
node-253.cluster.us 0       10.10.50.253
5323478955232132984
webserver,cldb,fileserver,nfs,hoststats,resourcemanager
node-254.cluster.us 0  10.10.50.254
```

- Determine which nodes are running the CLDB. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/
*]and[svc==cldb]" -columns id,h,hn,svc, rp
```

- List all non-CLDB nodes. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/*]and[svc!
=cldb]" -columns id,h,hn,svc, rp
```

3. Shut down all NFS instances. Example:

```
/opt/mapr/bin/maprcli node services -nfs stop -filter [svc=="nfs"]
```

4. If your cluster is running any ecosystem components, shut down those components on all nodes.
5. Shut down all ResourceManager and NodeManager services on all nodes. To shut down ResourceManager and NodeManager services specify the maprcli node services command with the `name` parameter and either the `filter` or the `node` parameter . Example:

```
maprcli node services -name resourcemanager -filter <filter> -action stop
maprcli node services -name nodemanager -nodes <node> -action stop
```

6. SSH into each node that is not running CLDB and stop Warden with the command:

```
service mapr-warden stop
```

7. SSH into each CLDB node and stop Warden with the command:

```
service mapr-warden stop
```

8. SSH into each Zookeeper node and stop Zookeeper with the command:

```
service mapr-zookeeper stop
```

9. (Optional) Shut down the nodes using the Linux `halt` command.

Managing Another Unsecure Cluster Using the Control System
When logged into the Control System of one cluster, you can navigate to the Control System of another unsecure cluster.

To navigate to the Control System of another unsecure cluster:

- Select the name of the cluster to go to from the drop-down list associated with the name of the cluster into which you are currently logged.

  After a few minutes, the Control System login page for the other cluster displays.

Allocating Cluster Resource from the Command-Line
Provides a general overview on allocating cluster resources for a MapR Hadoop cluster.

In a MapR Hadoop cluster, the warden sets the default resource allocation for the operating system, MapR File System, MapR Hadoop services, and YARN applications. Warden allocates resources to MapR Hadoop services and applications based on the roles installed on a node. For example, warden allocates resources for YARN applications on nodes with NodeManager role installed.

In general, you should not need to override the values set in the default configuration files and by warden. However, you can provide updated values by adding or updating parameters in the Hadoop site configuration files or warden files. To override parameter values for a single job, the option can be overridden in the command line when submitting a YARN application to the cluster.

To determine the current value of a hadoop parameter, run `hadoop conf | grep <ParameterName>`. In the following example, the `hadoop conf` command was used to get the value of `mapreduce.map.memory.md`:

```
hadoop conf | grep mapreduce.map.memory.mb
<property><name>mapreduce.map.memory.mb</name><value>1024</
value><source>mapred-site.xml</source></property>
```

Alternatively, run `hadoop conf` without the `grep` command to get a full list of the current parameter values. To determine the current value of a warden parameter, open the warden files located in the following directories: `/opt/mapr/conf/conf.d` and `/opt/mapr/conf`.

Note: In some cases, the current value of the parameter can only be seen in the Control System or in ResourceManager.

Refer to Allocating Memory for Nodes on page 818 to allocate memory and resources in a MapR cluster.

Administering Nodes

Provides a synopsis of managing nodes in a cluster.

This section provides information about managing nodes in a MapR cluster. Topics include how to add nodes to the cluster and/or remove nodes from the cluster, manage the services installed on the nodes, and manage disks. You can manage nodes, disks, and services in the MapR cluster using the Control System and the CLI.

Managing Nodes

Describes the Nodes page on the Control System.

The **Nodes** page contains panes that display:

- Node Health — the health of the nodes organized by topology (by default) or service.
- Current Resource Utilization — the nodes that utilize the most (in percentage) CPU and memory.
- Active Node Alarms — the list of active node alarms on the cluster.
- List of nodes — the list of nodes on the cluster.

Note: The **Nodes** page is not available in the Kubernetes version of the Control System.

You can perform the following procedures to manage and monitor nodes using the Control System and the CLI:

Viewing the list of Nodes
Explains how to view the list of Nodes using either the Control System or the CLI.
Viewing the list of Nodes on the Control System

- Log in to the Control System and click **Nodes**.

  Note: The **Nodes** page is not available in the Kubernetes version of the Control System.

  The page contains the following panes:

Node Health	Displays each node's health.
Active Alarms	Displays active alerts for nodes in the cluster.
Current Resource Utilization	Plots the current CPU and memory utilization for each node as a graph. This helps visualize the nodes that utilize the most CPU and memory.
Nodes	Displays all the nodes in the cluster.

For each node in the cluster, the **Nodes** pane displays the following:

Column Name	Column Description
Health	The health of the node. Value can be: • — Healthy • — Degraded • — Critical • — Maintenance
Hostname	The hostname of the node.
Physical IPs	The physical IP address or addresses associated with the node.
Last FS Heartbeat	The time since the node's last heartbeat to the CLDB.
Memory Utilized	The amount of memory used by the node.
CPU Utilized	The CPU usage metric for the node.
Disk Utilized	The amount of disk space utilized on the node.
Physical Topology	The rack path to the node.
Running Services	The number of services running on the node.

Selecting the checkbox beside a node makes the following buttons available:

- Change Topology
- Remove Nodes
- Manage Services

Retrieving the list of Nodes Using the CLI or REST API

The basic command to view all the nodes on a cluster is:

```
maprcli node list -cluster <cluster>
```

For complete reference information, see node list on page 1705.

Customizing the List of Columns/Fields
Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.
Customizing the Columns in the Control System

1. Log in to the Control System and go to:

last-updated: Apr 11, 2022

- **Data** > **Volumes** page to customize columns displayed in the **Volumes** pane.

  Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- **Nodes** page to customize columns displayed in the **Nodes** pane.

  Note: The **Nodes** page is not available on the Kubernetes version of the Control Panel.

2. Click the **Customize Columns** icon ( ).
   In the **Customize Columns** dialog, the:
   - **Available** list displays the columns that are available for display.
   - **Selected** list displays the columns currently displayed in the pane.
3. Select the columns from the:
   a) Available list of columns and click to move selection to **Selected** columns (for display).
   b) Selected list of columns and click to remove selected columns from displaying.
4. (Optional) Click and/or down arrows to sort the order of columns.
5. Click **Save Changes** for the customization to take effect.

   Tip: To reset the display to its default columns, click **Reset to default columns**.

Customizing the Fields Using the CLI or REST API

Use the `-column` parameter with the `maprcli` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

  ```
  maprcli node list -columns service,health
  ```

  For complete reference information, see the `node list` on page 1705 command.

- To view the volume name for the list of volumes being retrieved, run the following command:

  ```
  maprcli volume list -columns volumename
  ```

  For complete reference information, see `volume list` on page 1979 command.

Reverting to Default List of Columns
Describes how to revert to the default list of columns on the Control System

1. Log in to the Control System and click:
   - **Data** > **Volumes** to revert to the default list of columns in the **Volumes** pane.

     Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** to revert to the default list of columns in the **Nodes** pane.

     Note: The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Click the **Customize Columns** icon ( ) .

last-updated: Apr 11, 2022

3. Click **Reset to default columns**,
4. Click **Save Changes**.
   The pane displays the default list of columns.

Filtering the List of Nodes
Describes how to setup search expressions and filter nodes based on specific criteria.

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of nodes. Expressions are implicitly connected by the AND operator.

Filtering the Node List in the Control System

1. Log in to the Control System and click **Nodes** to filter the list of nodes in the **Nodes** pane.

   Note: The **Nodes** menu is not available on the Kubernetes version of the Control System.

2. Click and select one of the following from the **Add Filter** drop down menu.
   - Health — to filter the list by node health
   - Hostname — to filter the list by hostname of node
   - Physical IP — to filter the list by IP address of node
   - Last FS Heartbeat — to filter the list by number of heartbeats sent to FS
   - CPU Utilized — to filter the list by number of cores utilized
   - Physical Topology — to filter the list by rack path
   - Configured Services — to filter the list by configured services
   - Memory Used — to filter the list by amount of memory used
   - Running Services — to filter the list by installed services
   - Used Disk Space — to filter the list by amount of disk space used
   - Virtual IP — to filter the list by virtual IP address
3. Specify the value in the drop-down field for the selected filter (to filter the list of nodes by) and click **Filter**.

   As you make selections and specify the filtering criteria, the pane displays only the nodes that match the specified filtering criteria.
4. Click:
   - **Add Filter** to add another filtering criteria.
   - to remove a filtering criteria.
   - to clear all filter settings.

Filtering the List Using the CLI

Use the `node list on page 1705` command with the `-filter` option, to specify large numbers of nodes by matching specified values in specified fields rather than by typing the name of each node explicitly. For example, you can retrieve all nodes on a specific subnet as follows:

```
maprcli node list -filter [ip==20.30.40.*]
```

For more information, see Filters on page 1526.

Monitoring Nodes
Explains how to monitor nodes using either the Control System or the CLI.

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

Note: The metrics collection infrastructure must be installed during installation to visualize the graphs and charts. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

To monitor the health of nodes:

1. Log in to the Control System and click:
   - **Overview** to view the health of the nodes in the **Node Health** pane.
   - **Nodes** to view the health of the nodes in the **Node Health** pane.
2. Select one of the following from the drop-down menu in the **Node Health** pane.
   - **By Service** to organize the display of nodes by services.

     This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running ( ) and is down ( ).

     Note: The color of the node (which reflects the status of the service) is even when a service is stopped (not running) on the node.
   - **By Topology** to view the display of nodes by topology.

     This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

	Indicates the node is healthy.
	Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: • There is no heartbeat from the MapR filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node.
	Indicates the node is in maintenance mode.
	Indicates critical issue(s) on the node. A node is considered to be in critical state if: • There is no heartbeat from the node for more than 5 minutes.

last-updated: Apr 11, 2022

- All MapR files system disks on the node are dead or are offline.
- All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour.
- File server is dead/inactive because there is no heartbeat for a long time.
- NFS server on node is dead.
- MapR install directory is full.
- Node reported high MapR filesystem memory usage.

Monitoring Node Resource Utilization from the Control System

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

Monitoring Active Node Alarms from the Control System

See Viewing Active Node Alarms on page 1317 for more information.

Monitoring Node Health Using the CLI or REST API

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see `node heatmap` on page 1702.

Viewing Node Details

Describes how to view node details using either the Control System or the CLI.

Viewing Node Details Using the Control System

1. Log in to the Control System and click **Nodes**.

   Note: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Click the hostname of the node.

   The information page for the node displays.

   - Summary tab (default view)
   - Metrics tab

   You can:

   - Change the topology of the node
   - Remove the node

Viewing Node Details Using the CLI or REST API

The basic command to retrieve information on a node is:

```
maprcli node metrics -nodes <hostname> -columns <column names>
```

For complete reference information, see `node metrics` on page 1723.

Viewing Node Summary
View a summary of the alarms, services, and disks on a node using either the Control System or the CLI.
Viewing Node Summary Using the Control System

- Log in to the Control System and go to the node information page.

  The page with information on the node displays and the **Summary** tab displays by default. The **Summary** tab contains panes for node-specific:

  - **Alarms** — displays active and recent alarms on the node. See Viewing Active Node Alarms on page 1317 for more information.
  - **Services** — displays services running on the node. See Viewing the Services Running on a Node Using the Control System on page 828 for more information.
  - **Disks** — displays information on the disks on the node. See Viewing the List of Disks on page 834 for more information.

Viewing Node Summary Using the CLI

The basic command to retrieve a summary of the disks on a node is:

```
maprcli node metrics -nodes <hostname> -columns DISKS
```

For complete reference information, see `node metrics` on page 1723.

Viewing Node Metrics
Explains how to view node metrics using the Control System.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to visualize the metrics that are desribed in the following section.

Monitoring Node Metrics Using the Control System

- Log in to the Control System and go to the **Metrics** tab in the node information page.

  By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

  You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

  - › to shift time window forwards.
  - ‹ to shift time window backwards.

  Click ⓘ associated with the chart to view information about the graph. Click ✎ to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

last-updated: Apr 11, 2022

Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

Metric	Charts
CPU Usage	• Node Active CPU Usage • Node CPU Usage** • Node CPU Usage IDLE • Node CPU Usage NICE • Node CPU Usage SYSTEM • Node CPU Usage USER • Node CPU Usage WAIT • MFS CPU Usage • Allocated vs Available CPU Cores • MapR Process CPU Usage • MAST Gateway CPU Usage • DB Gateway CPU Usage • Data Access Gateway CPU Usage
Memory Usage	• Node Free Memory • Node Utilized Memory*** • Node Memory Free vs Used* • MFS Process Memory Usage • MapR Process Memory Usage
SWAP Space	• Node Swap Free • Node Swap Used • Node Swap Space Available vs Used* • Node Swap IO
Node IOs	• Node Network IO* • Node Network Interface Input • Node Network Interface Output • Node Network Interface Error Input • Node Network Interface Error Output

last-updated: Apr 11, 2022

Metric	Charts
System Disk Throughput	• Disk Read Ops • Disk Write Ops • Disk Reads and Writes*
System Disk Latency	• Disk Avg Read Latency • Disk Avg Write Latency • Disk Read and Write Times
MFS Throughput	• MFS Read Throughput • MFS Write Throughput • MFS Read and Write Throughput • MFS System Disk Activity in Bytes*

* This metric is diplayed in the default chart view for a node.

** This metric is diplayed in the default chart view for a node and in the default list view for a table.

*** This metric is diplayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see Viewing Per Node Metrics for Table Activities on page 1297.
- All stream activities on a node, see Monitoring Streams Operations Using the Control System on page 1313.

Setting Up Node Topology
Define node topologies for every node in the cluster.

Define your cluster's topology by specifying a topology for each node in the cluster. You can use topology to group nodes by rack or switch, depending on how the physical cluster is arranged and how you want MapR to place replicated data.

Topology paths can be as simple or complex as needed to correspond to your cluster layout. In a simple cluster, each topology path might consist of the rack only (for example, `/rack-1`). In a deployment consisting of multiple large datacenters, each topology path can be much longer (for example, `/europe/uk/london/datacenter2/room4/row22/rack5/`). MapR uses topology paths to spread out replicated copies of data, placing each copy on a separate path. By setting each path to correspond to a physical rack, you can ensure that replicated data is distributed across racks to improve fault tolerance.

Changing the Topology of one or more Nodes
Describes how to move nodes from one topology to the other using either the Control System or the CLI.
Changing the Topology of Multiple Nodes Using the Control System

To change the rack or switch path for one or more nodes, under **Nodes**:

Note: The **Nodes** menu is not available on the Kubernetes version of the Control System.

1. Select the nodes from the list of nodes in the **Nodes** pane and click **Change Topology**.
   The **Change Node Topology** dialog displays.
2. Choose one of the following:

last-updated: Apr 11, 2022

- **Select Existing Topology** to select a topology from the list of existing topologies.
- **Create New Topology** to specify a new topology for the selected nodes.

3. Click **Change Topology** for the changes to take effect.

Changing the Topology of a Node Using the Control System

To change the rack or switch path for a node:

1. Go to the node information page and click **Change Topology**.
   The **Change Node Topology** dialog displays.
2. Choose one of the following:
   - **Select Existing Topology** to select a topology from the list of existing topologies.
   - **Create New Topology** to specify a new topology for the node.
3. Click **Change Topology** for the changes to take effect.

Changing the Topology Using the CLI or REST API

The basic command to move nodes to a different topology is:

```
/opt/mapr/bin/maprcli node move -serverids <server IDs> -topology <topology>
```

For complete reference information, see `node move` on page 1728.

The move will fail if the server ID is negative. To fix this issue, perform one of the following:

- If you are moving only a single server ID that is negative, or a bunch of server IDs that are all negative, prefix 0 as an additional server ID. For example:

```
/opt/mapr/bin/maprcli node move -serverids
0,-6151492882499457449,-2668056288676628812 -topology /data/mytopo -json
```

- If you are moving a bunch of server IDs with a mix of positive and negative server IDs, place a positive ID as the first ID. For example:

```
/opt/mapr/bin/maprcli node move -serverids
1507661865183706279,-6151492882499457449,-2668056288676628812 -topology /
data/mytopo -json
```

Setting Node Topology with a Script
Provides an overview of how to script setting up node topology.

For large clusters, you can specify complex topologies in a text file or by using a script. Each line in the text file or script output specifies a single node and the full topology path for that node in the following format:

```
<ip or hostname> <topology>
```

The text file or script must be specified and available on the local filesystem on all CLDB nodes:

- To set topology with a text file, set `net.topology.table.file.name` in `/opt/mapr/conf/cldb.conf` to the text file name
- To set topology with a script, set `net.topology.script.file.name` in `/opt/mapr/conf/cldb.conf` to the script file name

If you specify a script and a text file, the MapR system uses the topology specified by the script.

Adding Nodes to a Cluster
Describes how to add nodes to a cluster.

You can add nodes to a cluster using the web-based MapR Installer (version 1.6 or later), the MapR Installer Stanzas, or manually. To add nodes to your cluster using the MapR Installer or MapR Installer Stanzas, see Extending a Cluster by Adding Nodes on page 5437. Complete the following steps to add nodes manually to a cluster:

1. Prepare all nodes.

   If you do not use the Domain Name System (DNS), ping the new node from an existing node and vice versa. Use the host name instead of an IP address. If you do not get a response, and if you rule out a network problem, a possible fix is to edit the `/etc/hosts` files of all nodes in the cluster. All nodes need to be listed in all `/etc/hosts` files.

2. Plan which packages to install based on services you want to run on the new nodes.

   See Select Services on page 107 and MapR Repositories and Packages on page 128 for more information.

3. Install MapR Software.

   - On all new nodes, add the MapR Repository.
   - On each new node, install the planned packages.

   See Step 2: Prepare Packages and Repositories on page 142 and Step 3: Install Cluster Service Packages on page 150 for more information.

4. Configure all new nodes by running `configure.sh`.

   If you added a ZooKeeper role to a node, run the following command on all nodes with the new ZooKeeper list: `configure.sh -no-autostart`. See `configure.sh` on page 2053 for more information.

5. On all new nodes, format disks for use by MapR if you plan to re-use a node from another cluster.

   Format the disks from a re-used node to remove data from the old cluster.

   Note: All the disks (for use by MapR) on a node must be of the same type. That is, all the disks on a node must either be rotational or SSDs; node with disks of both types is not supported.

   See Formatting Disks on a Node From the Command-line on page 840 for more information.

6. If you manually modified configuration files on the existing nodes and those changes apply to the new nodes, copy only those changes to the respective files on the new nodes.

7. Perform the following steps if you added the node(s) to any secure cluster that is configured for cross-cluster operations.

   a) Copy the `/opt/mapr/conf/mapr-clusters.conf` file and `/opt/mapr/conf/ssl_truststore` file from another node to the new node(s).

   b) Copy the `/opt/mapr/conf/maprserverticket` file from:

      - A CLDB node if the new node is a CLDB node.
      - A non-CLDB node if the new node is not a CLDB node.

      The `/opt/mapr/conf/maprserverticket` file contains additional entry for cross-cluster tickets. See Configuring Secure Clusters for Cross-Cluster NFS Access on page 1490 for more information.

last-updated: Apr 11, 2022

8. Start ZooKeeper on all new nodes that have ZooKeeper installed:
   `service mapr-zookeeper start`
9. Start Warden on all new nodes:
   `service mapr-warden start`
10. Restart services that you reconfigured.
    Running `configure.sh` alone does not reconfigure services, such as ZooKeeper. Reconfigured services also require a restart. For example, restart ZooKeeper on each node, one at a time after running `configure.sh`. Restart the lead ZooKeeper last. Restarting ZooKeeper adds the new nodes into the existing ZooKeeper quorum. Services that need to connect to CLDB do not always discover a newly added CLDB node without restarting warden.
11. Set up node topology for the new nodes.
12. On any new nodes running NFS, set up NFS for HA.

Isolating CLDB Nodes
Lists the pros of creating CLDB-only nodes.

In a large cluster (100 nodes or more) create CLDB-only nodes to ensure high performance. This configuration also provides additional control over the placement of the CLDB data, for load balancing, fault tolerance, or high availability (HA). Setting up CLDB-only nodes involves restricting the CLDB volume to its own topology and making sure that all other volumes are on a separate topology. As both the CLDB-only path and the non-CLDB path are children of the root topology path, new non-CLDB volumes are not guaranteed to keep off the CLDB-only nodes. To avoid this problem, set a default volume topology. See Setting Default Volume Topology Using the CLI on page 917.

Setting Up a CLDB-Only Node
Describes how to setup a node for CLDB alone.

1. SET UP the node as usual:
   a) PREPARE the node, making sure it meets the requirements.
   b) ADD the MapR repository.
2. INSTALL the following packages to the node.
   - `mapr-cldb`
   - `mapr-webserver`
   - `mapr-core`
   - `mapr-fileserver`

Setting Up Volume Topology to Restrict the CLDB Volume to Specific Nodes
Explains how to permit access to CLDB volumes only from specific nodes.

1. Move all CLDB nodes to a CLDB-only topology (e. g. `/cldbonly`) using the MapR Control System or the following command:
   ```
   maprcli node move -serverids <CLDB nodes> -topology /cldbonly
   ```
2. Restrict the CLDB volume to the CLDB-only topology using the MapR Control System or the following command:
   ```
   maprcli volume move -name mapr.cldb.internal -topology /cldbonly
   ```

Moving Volumes to a Separate Topology from the CLDB-Only Nodes
Explains how to move non-CLDB volumes to a separate topology.

1. Move all non-CLDB nodes to a non-CLDB topology (e. g. `/defaultRack`) using the MapR Control System or the following command: `maprcli node move -serverids <all non-CLDB nodes> -topology /defaultRack`
2. Restrict all existing volumes to the topology `/defaultRack` using the MapR Control System or the following command: `maprcli volume move -name <volume> -topology /defaultRack`

   All volumes except `mapr.cluster.root` are re-replicated to the changed topology automatically.

   Warning: To prevent subsequently created volumes from encroaching on the CLDB-only nodes, set a default topology that excludes the CLDB-only topology.

Isolating ZooKeeper Nodes
Provides an overview on how to install a ZooKeeper-only node.

For large clusters (100 nodes or more), isolate the ZooKeeper on nodes that do not perform any other function. Isolating the ZooKeeper node enables the node to perform its functions without competing for resources with other processes. Installing a ZooKeeper-only node is similar to any typical node installation, but with a specific subset of packages.

Warning: Do not install the FileServer package on an isolated ZooKeeper node in order to prevent MapR from using this node for data storage.

Setting Up a ZooKeeper-Only Node
Explains how to install a ZooKeeper-only node.

1. SET UP the node as usual:
   a) PREPARE the node, making sure it meets the requirements.
   b) ADD the MapR Repository.
2. INSTALL the following packages to the node.
   - `mapr-zookeeper`
   - `mapr-zk-internal`
   - `mapr-core`

Configuration Example
This example assumes you are adding a new node to a cluster that is running the CLDB and ZooKeeper on three other nodes: `node_a`, `node_b`, and `node_c`. To configure a `new node_d`, which is not a CLDB or ZooKeeper node, run the following command:

```
$ /opt/mapr/server/configure.sh -N my.cluster.com -C
node_a,node_b,node_c -Z node_a,node_b,node_c
```

To configure a ZooKeeper node, use the `-no-autostart` option and the `-Z` option followed by the list of ZooKeeper nodes.

Removing Nodes from a Cluster
Provides an overview of how to remove nodes from a cluster.

You can remove a node using the `node remove` command, or using the Control System. Removing a node detaches the node from the cluster, but does not remove the MapR software from the cluster.

The following sections provide information about removing nodes from a cluster:

last-updated: Apr 11, 2022

Removing One or More Nodes
Describes how to decommission a node from service.

Perform the following prerequisite steps before removing a node using the Control System or CLI or REST API:

1. Drain the node of data by moving the node to the `/decommissioned` physical topology. All the data on a node in the `/decommissioned` topology is migrated to other volumes and nodes in the appropriate topologies.

2. Run the following command to check if a given volume is present on the node:

   ```
   maprcli dump volumenodes -volumename <volume> -json | grep IP:Port
   ```

   As an example, consider the volume `rocky` that is present on a node with IP `10.163.167.212`. To check whether this volume exists on this node, run the command:

   ```
    maprcli dump volumenodes -volumename rocky -json
   {
           "timestamp":1606879372378,
           "timeofday":"2020-12-01 07:22:52.378 GMT-0800 PM",
           "status":"OK",
           "total":1,
           "data":[
                   {
                           "Servers":{

   "IP:Port":"10.163.167.212:5660-192.168.122.1:5660--3-VALID"
                           }
                   }
           ]
   }
   ```

   The output shows that the volume `rocky` exists on node `10.163.167.212` that is accessible on port `5660`.

   To return just the IP and the Port alone, pipe the output through the `grep` command as follows:

   ```
    maprcli dump volumenodes -volumename test -json | grep IP:Port
    "IP:Port":"10.163.167.212:5660-192.168.122.1:5660--3-VALID"
   ```

   Run this command for each non-local volume in your cluster to verify that the node being removed is not storing any volume data.

3. Install CLDB or ZooKeeper on another node (only) if the node you are removing is a CLDB or ZooKeeper node and run `configure.sh` with `-C` and `-Z` options.

   This is to ensure that ZooKeeper quorum is maintained and that an optimal number of CLDB is available for high availability.

You can remove one or more nodes using the Control System and the CLI.

Removing Multiple Nodes Using the Control System

To remove one or more nodes:

1. Log in to the Control System and click **Nodes**.

   Note: The **Nodes** menu is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Remove Node(s)**.
   The **Remove Node(s)** dialog displays.
3. Verify the list of nodes to remove and click **Remove Nodes**.

Removing a Node Using the Control System

To remove a node:

1. Go to the Viewing Node Details on page 802 page and click **Remove Node**.
   The **Remove Node(s)** confirmation dialog displays.
2. Click **Remove Node**.

Removing one or more Nodes Using the CLI or REST API

Use the node remove on page 1729 command to remove one or more server nodes from the cluster. To run this command, you must have full control (`fc`) or administrator (a) permission. The syntax is:

```
maprcli node remove -nodes <node names> ]
```

If the following error is generated, you must wait for the state duration of the CLDB master node to reach 15 minutes or more. Otherwise, the node remove fails:

```
node remove failed for node <node_name>, Error: Resource temporarily
unavailable; CLDB just became master, node removed not allowed until
sometime
```

To check the state duration value, use this command:

```
maprcli dump cldbstate -json
```

After you issue the node remove on page 1729 command, wait several minutes to ensure that the nodes have been completely removed.

> **Tip:** To ensure that a node that is removed does not rejoin the cluster on reboot, either remove all MapR packages from the node, or remove the cluster configuration that is present in the `/opt/mapr/conf/mapr-clusters.conf` file on the node.

Related concepts

Migrating a Volume off a Node Using the CLI on page 915

Decommissioning a Node and Uninstalling MapR Software from the Command-line

Use the following procedure to remove a node and uninstall MapR software. This procedure detaches the node from the cluster and removes the MapR packages, log files, and configuration files, but does not format the disks.

Note: Before decommissioning a node, make sure any data on the node is replicated and any needed services are running elsewhere. If the node you are decommissioning runs a critical service, such as CLDB or ZooKeeper, verify that enough instances of that service are running on other nodes in the cluster. See Planning the Cluster for recommendations about service assignment to nodes.

Complete the following steps to permanently decommission a node:

1. Drain the node of data by moving the node to the `/decommissioned` physical topology. All data on a node in the `/decommissioned` topology is migrated to volumes and nodes in the `data` topology.

last-updated: Apr 11, 2022

2. Run the following command to check if a given volume is present on the node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

Note: Run this command for each non-local volume in your cluster to verify that the node being decommissioned is not storing any volume data.

3. Change to the `root` user (or use `sudo` for the following commands).
4. Stop Warden on the node by running the following command:

```
service mapr-warden stop
```

5. If ZooKeeper is installed on the node, stop it: `service mapr-zookeeper stop`
6. Determine which MapR packages are installed on the node:
   - `dpkg --list | grep mapr` (Ubuntu)
   - `rpm -qa | grep mapr` (Red Hat or CentOS)
7. Remove the packages by issuing the appropriate command for the operating system, followed by the list of services. Examples:
   - `apt-get purge mapr-core mapr-cldb mapr-fileserver` (Ubuntu)
   - `yum erase mapr-core mapr-cldb mapr-fileserver` (Red Hat or CentOS)
8. Remove the `/opt/mapr` directory to remove any instances of `hostid`, `hostname`, `zkdata`, and `zookeeper` left behind by the package manager.
9. Remove the `/mapr` directory to delete any NFS/POSIX client mount points.
10. Remove any MapR cores in the `/opt/cores` directory.
11. If the node you have decommissioned is a CLDB node or a ZooKeeper node, then run `configure.sh` on all other nodes in the cluster. See Configuring the Node.
12. Remove the node by running the following command:

```
maprcli node remove -nodes <node-name>
```

Reconfiguring a Node from the Command-Line
Provides an overview of the procedure to reconfigure a node using the CLI.

This procedure is designed to make changes to existing MapR software on a machine that has already been set up as a MapR cluster node. If you need to install software for the first time on a machine to create a new node, see Adding Nodes to a Cluster.

Complete the following steps to reconfigure a node:

1. Stopping the Node
Describes how to stop a node.

1. Change to the `root` user (or use `sudo` for the following commands).
2. Stop Warden: `service mapr-warden stop`

last-updated: Apr 11, 2022

3. Stop ZooKeeper, if installed on the node: `service mapr-zookeeper stop`

2. Formatting the Disks (Optional)
Provides an overview of how to format the disks.

If you are re-using a node that was used previously in another cluster, be sure to format the disks by using the `disksetup` script to remove any traces of data from the old cluster. Refer to the previous section, Formatting Disks on a Node, for instructions.

3. Installing or Removing Software or Hardware
Lists the considerations to install or remove software or hardware.

When the node is stopped, you can add, upgrade or remove software or hardware. At some point after adding or removing services, you should restart Warden, to re-optimize memory allocation among all the services on the node. It is not crucial to perform this step immediately; you can restart Warden any time when the cluster is not busy.

To add or remove individual MapR packages, use the standard package management commands for your Linux distribution:

- `apt-get` (Ubuntu)
- `yum` (Red Hat or CentOS)

For information about the packages to install, see Planning the Cluster.

The following sections provide information about adding or removing services from a node after it has been deployed in a cluster:

Adding a Service to an Existing Node
Explains how to add a service to a node.

The process of adding a service to a node is similar to the initial installation process for nodes. For further detail see Installing MapR Software.

1. Install the package(s) corresponding to the new role(s) using `apt-get` or `yum`.
2. Run `configure.sh` with a list of the CLDB nodes and ZooKeeper nodes in the cluster.
3. If you added the CLDB or ZooKeeper role, you must run `configure.sh` on all other nodes in the cluster.
4. If you added the fileserver role, run `disksetup` to format and prepare disks for use as storage.
5. Restart Warden.

```
service mapr-warden restart
```

When Warden restarts, it picks up the new configuration and starts the new services, making them active in the cluster.
Removing a Service from an Existing Node
Explains how to remove a service from a node.

1. Stop the service you want to remove by using the Control System or the `maprcli` command-line tool. The following example stops the Fileserver service:

```
maprcli node services -fileserver stop -nodes mapr-node1
```

2. Purge the service packages with the `apt-get`, `yum`, or `zypper` commands, as suitable for your operating system.

last-updated: Apr 11, 2022

3. Run the `configure.sh` script with the `-R` option.
4. When you remove the CLDB or ZooKeeper role from a node, run `configure.sh -R` on all nodes in the cluster.

4. Configuring the Node
Provides an overview of the `configure.sh` script to use to configure a node.

The script `configure.sh` configures a node to be part of a MapR cluster, or modifies services running on an existing node in the cluster. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run `configure.sh`, make sure you have a list of the hostnames of the CLDB and ZooKeeper nodes. You can optionally specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222
ZooKeeper	5181

The script `configure.sh` takes an optional cluster name and log file, and comma-separated lists of CLDB and ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>[:<port>]...] -Z
<host>[:<port>][,<host>[:<port>]...] [-L <logfile>][-N <cluster name>]
```

Note:

Each time you specify the `-Z <host>[:<port>]` option, you must use the *same order* for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example:

```
/opt/mapr/server/configure.sh -C
r1n1.sj.us:7222,r3n1.sj.us:7222,r5n1.sj.us:7222 -Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5
181 -N MyCluster
```

5. Starting the Node
Explains how to start a node.

1. If ZooKeeper is installed on the node, start it: `service mapr-zookeeper start`
2. Start Warden: `service mapr-warden start`

Renaming a Node from the Command-Line
Provides distribution-specific instructions for renaming a node.

Attention: Ensure that the host name you set is resolvable. Add the host name to the `/etc/hosts` file. For example: `10.10.19.22 host.qa.net`. MapR installation and commands fail if the host name is not resolvable.

To rename a node:

1. Stop Warden on the node. Example:

```
service mapr-warden stop
```

last-updated: Apr 11, 2022

2. If the node is a ZooKeeper node, stop ZooKeeper on the node. Example:

```
service mapr-zookeeper stop
```

3. Rename the host:
   - Red Hat 6.x and CentOS 6.x: To preserve the new host name after reboot, edit the `HOSTNAME` parameter in the `/etc/sysconfig/network` file and restart the `xinetd` service or reboot the node. To change the host name temporarily without a reboot, run:

     ```
     hostname desired-host-name
     ```

   - Red Hat 7.x and CentOS 7.x: Run the command:

     ```
     hostnamectl set-hostname desired-host-name --static
     ```

     Alternatively, enter the host name in the `/etc/hostname` file, and run:

     ```
     hostname -F /etc/hostname
     ```

     Both these methods preserve the host name across reboots.

   - On Ubuntu, first install *dbus* if it is not installed.

     ```
     apt-get install dbus
     ```

     Next, run the command:

     ```
     hostnamectl set-hostname desired-host-name --static
     ```

     Alternatively, edit the host name in the `/etc/hostname` file, and run:

     ```
     hostname -F /etc/hostname
     ```

     Both these methods preserve the host name across reboots.

4. If the node is a ZooKeeper node or a CLDB node, run `configure.sh` on page 2053 with a list of CLDB and ZooKeeper nodes.
5. If the node is a ZooKeeper node, start ZooKeeper on the node. Run:

```
service mapr-zookeeper start
```

6. Start Warden on the node. Run:

```
service mapr-warden start
```

After you rename a:

- CLDB or ZooKeeper node, run `configure.sh` on page 2053 on all the nodes with the new host name, to update the `mapr-clusters.conf` file with the new host name. Ensure that there are no duplicate entries in the file. Also, verify that the new host is accessible from all the nodes.

last-updated: Apr 11, 2022

- Node, some local volumes (such as for audit, and metrics) may exist with both the old and new host names. If you want, you can remove the local volumes with the old host name, use the existing local volume path, or remount to the new path.

Changing the IP Address of a Node
Describes how to change the IP address of any node in the cluster using the CLI.
Changing the IP Address of a Data Node

Complete the following steps to change the IP address of a data node:

1. Shut down Warden and ZooKeeper on the node to be changed.

   ```
   service mapr-zookeeper stop
   service mapr-warden stop
   ```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address.
   For example, run `ifconfig`.
7. If the `MAPR_SUBNETS` environment variable is set, edit the value for the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env.sh` file and make sure that the new IP address is part of it.
   See Setting Environment Variables for NIC Segregation on page 850 for more information.
8. Restart Warden on the node(s) where the IP address has changed.
9. Check that all nodes appear in the output of the node list command.

   ```
   /opt/mapr/bin/maprcli node list -columns ip
   ```

   You might have to wait a few minutes until all nodes are registered before you get the output from this command.

Changing the IP Address of CLDB Node

Complete the following steps to change an IP address of a CLDB node:

1. Shut down Warden and ZooKeeper on the node to be changed.

   ```
   service mapr-zookeeper stop
   service mapr-warden stop
   ```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.

5. Log into the node using the new IP address.
6. Check the IP address. For example, run `ifconfig`.
7. Run `configure.sh`.
   Use the `-C` option to provide a list of CLDB nodes.

   Note:

   If the initial setting was based on the IP address, run `configure.sh` on all nodes in the cluster.

   If the initial setting was based on the hostname, there is no need to run `configure.sh` on any nodes when you change the IP address.

8. Perform a rolling restart of Warden on all the nodes.
9. Check that all nodes appear in the output of the node list command. You might have to wait a few minutes until all nodes are registered before you get output from this command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

Changing the IP Address of ZooKeeper Node

Complete the following steps to change an IP address of a ZooKeeper node:

1. Shut down Warden and ZooKeeper on the node to be changed.

```
service mapr-zookeeper stop
service mapr-warden stop
```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address.
   For example, run `ifconfig`.
7. Run `configure.sh`.
   Use the `-Z` option to provide the list of ZooKeeper nodes.

   Note:

   If the initial setting was based on the IP address, run `configure.sh` on all the ZooKeeper, CLDB, and Data nodes in the cluster.

   If the initial setting was based on the hostname, there is no need to run `configure.sh` on any nodes when you change the IP address.

8. If you run the Drillbit service on any nodes in the cluster:
   a) Change the ZooKeeper address in the `conf/drill-override.conf` file on the Drill nodes.

last-updated: Apr 11, 2022

b) Start ZooKeeper on the ZooKeeper node, and then perform a rolling restart of ZooKeeper on all other ZooKeeper nodes.

A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.

9. Verify that the new node joined the ZooKeeper quorum.

```
service mapr-zookeeper status
```

10. Perform a rolling restart of Warden on all the nodes.

11. Check that all nodes appear in the output of the node list on page 1705 command. You might have to wait a few minutes until all nodes are registered before you get output from this command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

Viewing Active Node Alarms
Describes how to view active node alarms using the Control System and the CLI.
Viewing Active Node Alarms in the Control System

- **Note:** The **Nodes** page is not available in the Kubernetes version of the Control System.

Log in to the Control System and:

- Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
- Go to the node information page to view alarms in the **Alarms** pane for the selected node.
- Click (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
- Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

You can:

- View alarm notes
- Mute an alarm
- Dismiss an alarm

Retrieving Active Node Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

For complete reference information, see `alarm list` on page 1545.

Allocating Memory for Nodes
Describes how the Warden allocates memory for nodes.

When you run `configure.sh` on a node, Warden allocates memory for the operating system, `mfs service`, MapRHadoop services, and applications using the settings in the `warden.conf` and the `warden.<servicename>.conf` file.

Warden allocates memory to the following components in the following order:

1. Operating system
2. `mfs service`
3. MapR Hadoop services
4. Applications, such as YARN applications
5. If the node only runs MapR File System, NFS, and gateway, then 85% of all memory is allocated to MapR File System.

Note: In general, modify the settings in the warden files only under certain circumstances. If you modify the values in `warden.conf` or `warden.<servicename>.conf` file, you must restart Warden. Otherwise, updated parameters will not be used to allocate resources.

Allocating Memory for the OS, MapR File System, and Hadoop Services
Lists the parameters that control how Warden allocates memory for the OS, filesystem and the MapR Hadoop services.

Warden allocates memory to the operating system, MapR File System, and MapR Hadoop services based on the following parameters:

Parameter	Default OS	MapR File System	Hadoop Service(s)	Description
`service.command.<os|mfs|servicename>.heapsize.percent`	10	varies	varies	Defines the heap size percentage.
`service.command.<os|mfs|servicename>.heapsize.maxpercent`	Not Applicable	85	Not Applicable	Defines the heap size maximum percentage
`service.command.<os|mfs|servicename>.heapsize.max`	4000	Not Applicable	5000	Defines the maximum heap size in MB.
`service.command.<os|mfs|servicename>.heapsize.min`	256	512	256	Defines the minimum heap size in MB.

Memory settings for the operating system and the MapR File System are configured in the `warden.conf` file. The `warden.conf` file is located in `/opt/mapr/conf`. Other services, such as NodeManager and ResourceManager, have their own `warden.<servicename>.conf` file within `/opt/mapr/conf/conf.d`. For more information about the Warden files, see `warden.conf` and `warden.<servicename>.conf`.

Note: Warden allocates resources only for the MapR Hadoop services associated with roles that are installed on the node.

Allocating Memory for the MapR File System Service
Describes how Warden allocates memory for the filesystem service.

By default, Warden adds up the total memory consumed by all services and the OS, and then allocates 85% of the remainder to the MapR File System. If you do not intend to use MapR Database, you can set the `-noDB` option in `configure.sh` to specify that 20% of the memory available should be allocated to the MapR File System service. Allocating more memory to the MapR File System improves performance due to greater data caching. Data caching is especially vital when your main constraint is disk I/O. For the

last-updated: Apr 11, 2022

parameters that you can configure to give Warden more memory, see Allocating Memory for the OS, MapR File System, and Hadoop Services on page 819.

Performing Maintenance on a Node from the Command-Line
Describes how to maintain the performance of a node using the CLI.

You can place a node into a maintenance mode for a specified timeout duration. For the duration of the timeout, the cluster CLDBs do not consider this node's data as lost and do not trigger a resync of the data on the node.

The following sections describe how to perform maintenance on a node.

Putting a Node into Maintenance Mode
Describes how to put a node into maintenance mode.

When you put a node in maintenance mode, the node is marked unserviceable, but is still attached to the cluster.

Before putting a node into maintenance mode, ensure that:

- All copies of the CLDB volume exist if the node is a CLDB node. You can shut down the CLDB service on a node only if the CLDB is a secondary CLDB, or if you have enabled high availability for CLDB.

  You *cannot* put a node that is running both the CLDB and MapR File System services into maintenance mode.

- All running processing tasks (such as NodeManager, Spark, for example) that depend on the MapR File System have been stopped.

Warning: Do not put a node under maintenance if there are any volume under-replicated alarms because doing so may make some data completely offline.

To put a node into maintenance mode, perform the following actions:

1. From a terminal, issue the `node maintenance on page 1722` command:

   ```
   /opt/mapr/bin/maprcli node maintenance -nodes <IP|
   hostname> -timeoutminutes <minutes>
   ```

   When you run this command, specify a timeout (in minutes) long enough for you to perform necessary maintenance on the node.

   

   Note: For the duration of the timeout, the cluster's CLDB considers this node as available which implies CLDB does not trigger replication of data of this node until it is in maintenance mode. However, if a node is put under maintenance for more than 5 minutes, the MapR File System is shut down on that node so that clients who access containers on this node receive the appropriate error and retry other container copies. This value of 5 minutes is hard coded and cannot be changed. Even if you reboot the node, the maintenance mode persists till the timeout is reached.

2. Stop warden on the node.

   To bring the node back online, do one of the following::

   - Run the `node maintenance on page 1722` command with a timeout of `0`
   - Wait till the timeout is over. The node is automatically brought back online after the specified timeout is complete.

Taking a Node Out of Maintenance Mode
Describes how to bring a node back online from maintenance mode.

To take a node out of maintenance mode before the timeout expires, follow this process:

1. From a terminal, issue the following command:

```
maprcli node maintenance -nodes <IP address> -timeoutminutes 0
```

2. Restart Warden:

```
service mapr-warden restart
```

Managing Roles

Describes how to manage roles on a node.

You must install *role*s on nodes in a cluster before their corresponding *services* can be launched. For information on how to install roles on nodes, see Adding Roles to a Node. Refer to the following topics for managing the roles using the CLI.

Adding Roles to a Node

Lists the process to add a role.

You can add *role*s on a node after you deploy the node in a cluster. The process of adding a *role* to a node involves installing a package on the node and updating the cluster to recognize the new *role*. The process of adding a *role* depends on the *role* type.

Once you have added a *role* to a node, you must restart Warden. Observe the following best practices when restarting Warden on ZooKeeper and CLDB nodes:

- Perform a rolling restart of Warden to ensure that all services are up. A rolling restart of Warden means restart Warden on each node, one at a time, pausing until the previous restart finishes, before beginning the next.
- To avoid a failover from occurring, identify nodes running critical services, such as ResourceManager, and restart Warden last on those nodes.
- Restart Warden on nodes that run critical cluster services, such as ResourceManager, during periods of low activity.

Adding a Role

Describes how to add various roles to a MapR node.

Do not use these steps to add the CLDB or ZooKeeper role.

Note: When collectd is installed on a node with YARN ResourceManager or NodeManager, running configure.sh –R, to add or remove roles on the node, triggers these services to restart. During a restart, the NodeManager and ResourceManager are temporarily unavailable for new application submission. A patch is available to resolve this behavior. See Applying Patches.

The following steps describe how to add a role to a node:

1. Install the package corresponding to the new role using `apt-get, yum,` or `zypper,` depending on your platform.
2. Run `configure.sh -R` on the node where you added the role.

   If Warden is running, the new service starts automatically.
3. If you added the File server role, run `disksetup` to format and prepare disks for use as storage.

last-updated: Apr 11, 2022

4. Issue the following command to restart Warden on the node where you installed the role:

```
% service mapr-warden restart
```

Adding a CLDB Role Using the CLI
Describes how to add a CLDB role to a MapR node using the CLI.

Complete the following steps to add the CLDB role to a node in the cluster:
Adding a CLDB Role to a Node on an Unsecure Cluster

1. Install the CLDB package, `mapr-cldb`, on the node with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
2. Run `configure.sh` on page 2053 with the `-C` and `-R` options on the node where you added the new CLDB role.
   Use the `-C` option to provide the list of CLDB nodes. If Warden is running, the CLDB service starts automatically.
3. Run `configure.sh` on page 2053 with the `-R` options on all other nodes in the cluster.
   Use the `-C` option and provide the list of CLDB nodes, including the new node.
4. Verify that the node has a CLDB role by running the following command:

```
maprcli node listcldbs
```

   The output should show all the CLDB nodes including the node where the role was added.

Adding a CLDB Role to a Node on a Secure Cluster

1. Install the CLDB package, `mapr-cldb`, on the node with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
2. Copy the following files from the `/opt/mapr/conf` directory on any existing CLDB node on the cluster to the `/opt/mapr/conf` directory on this node.
   - `cldb.key`
   - `dare.master.key`
   - `maprserverticket`
   - `ssl_keystore`
   - `ssl_keystore.p12`
   - `ssl_keystore.pem`
   - `ssl_truststore`
   - `ssl_truststore.p12`
   - `ssl_truststore.pem`

   Note: This `dare.master.key` will be present only if the cluster is enabled for encryption of data at rest.

3. Run `configure.sh` on page 2053 with the following options on the node where you added the new CLDB role.
   - `-secure`: Use this option to enable the node for security.
   - `-C`: Use this option to include this node in the list of CLDB nodes. If Warden is running, the CLDB service starts automatically.
   - `-dare`: Use this option only if the cluster is enabled for data at rest encryption. Do not specify this if the cluster is not enabled for data at rest encryption.
   - Use one of the following to configure the list of ZooKeeper nodes:
     - `-R`: Use this option if the node is an existing cluster node. This option uses the previously configured list of ZooKeeper nodes. When `-R` is specified, the ZooKeeper credentials are read from `warden.conf` file.
     - `-Z`: Use this option if the node is a new node on the cluster. This option specifies the list of ZooKeeper nodes.
4. Run `configure.sh` on page 2053 with the following options on all other nodes in the cluster.
   - `-C`: Use this option to include the new CLDB node in the list of CLDB nodes.
   - `-R`: Use this option to use the previously configured list of ZooKeeper nodes.
5. Verify that the node has a CLDB role by running the following command:

   ```
   maprcli node listcldbs
   ```

   The output should show all the CLDB nodes including the node where the role was added.

Adding a ZooKeeper Role
Describes how to add a ZooKeeper role to a MapR node using the CLI.

If you are increasing the number of ZooKeeper roles in the cluster, for example from one to three, shut down the cluster before you add the role to the nodes to prevent any problems and then start the cluster upon completion.

Complete the following steps to add the ZooKeeper role to a node:

1. Install the ZooKeeper package corresponding to the new role.
2. Run `configure.sh -Z` on the node where you added the new ZooKeeper role.
   Using the `-Z` option provides the list of ZooKeeper nodes that includes the new node.
3. Run `configure.sh -Z` on all other nodes in the cluster.
   Using the `-Z` option to provide the list of ZooKeeper nodes that includes the new node.
4. Issue the following command to start or restart ZooKeeper on the node where you added the ZooKeeper role:

   ```
   % service mapr-zookeeper restart
   ```

5. Perform a rolling restart of ZooKeeper on all other ZooKeeper nodes.
   A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.

6. Issue the following command to verify that the new node joined the ZooKeeper quorum:

```
% service mapr-zookeeper qstatus
```

7. Perform a rolling restart of Warden on all other nodes.

   Warden picks up the new ZooKeeper node. Issue the following command to restart Warden on the node where you installed the role:

```
% service mapr-warden restart
```

Removing Roles from a Node
Describes how to remove a role from a node.

You can remove *role*s from nodes in the MapR cluster. The process of removing a *role* from a node depends on the *role* type.

Once you remove a *role* from a node, you must restart Warden. Observe the following best practices when restarting Warden on nodes that were ZooKeeper or CLDB nodes:

- Perform a rolling restart of Warden to ensure that all services are up. A rolling restart of Warden means restart Warden on each node, one at a time, pausing until the previous restart finishes, before beginning the next.
- To avoid a failover from occurring, identify nodes running critical services, such as ResourceManager, and restart Warden last on those nodes.
- Restart Warden on nodes that run critical cluster services, such as ResourceManager, during periods of low activity.

Removing a Role
Describes how to remove a role from a node, using the CLI.

Do not use these steps to remove the CLDB, ZooKeeper, or Fileserver role from a node.

Note: When collectd is installed on a node with YARN ResourceManager or NodeManager, running configure.sh –R, to add or remove roles on the node, triggers these services to restart. During a restart, the NodeManager and ResourceManager are temporarily unavailable for new application submission. A patch is available to resolve this behavior. See Applying Patches.

The following steps describe how to remove a role from a node:

1. If you are removing the NFS role, unmount any existing client mounts.

   Removing the NFS role from a node affects any Virtual IP (VIP) pools that include this node.

2. If the cluster has only one CLDB, run `configure.sh` with the `-C` option on all the nodes.

3. Stop the service for the role you want to remove, either through the Control System or by issuing a `maprcli` command:

```
% maprcli node services -name <service_name> -action stop -nodes
<node-name>
```

   The following example stops the webserver role on node "my-node":

```
% maprcli node services -name webserver -action stop -nodes my-node
```

4. Purge the role packages with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
5. Run `configure.sh -R` on the node where you removed the role.

   Warden picks up the new configuration automatically.
6. Issue the following command to restart Warden on the node where you removed the role:

```
% service mapr-warden restart
```

Removing a CLDB Role
Describes how to remove the CLDB role from a node.

1. If you have only one CLDB node in the cluster, add the CLDB role to another node.

   When failover occurs after removal of the CLDB node, the new CLDB node becomes the primary CLDB.
2. Issue the following command to stop the CLDB service on the node:

```
/opt/mapr/bin/maprcli node services -name cldb -action stop -nodes
mapr-<node>
```

3. Purge the CLDB package, `mapr-cldb`, with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
4. Run `configure.sh` on page 2053 with the `-C`, `-N` and `-Z` options on the node where you removed the role.

   Use the `-C` option to provide the list of CLDB nodes, excluding the node where you removed the role, `-N` to pass the name of the cluster, and `-Z` to specfy the list of ZooKeeper nodes.
5. Run `configure.sh` on page 2053 with the `-C`, `-N` and `-Z` options on all other nodes in the cluster.

   Use the `-C` option to provide the list of CLDB nodes, excluding the node where you removed the role, `-N` to pass the name of the cluster, and `-Z` to specify the list of ZooKeeper nodes.

Removing a ZooKeeper Role
Describes how to remove the ZooKeeper role from a node.

The following steps describe how to remove the ZooKeeper role from a node:

1. Issue the following command to stop ZooKeeper on the node:

```
% service mapr-zookeeper stop
```

2. Purge the ZooKeeper package `mapr-zookeeper`.
3. Run `configure.sh`.

   Use the `-Z` option and provide the list of ZooKeeper nodes that excludes the node where you removed the role.
4. Perform a rolling restart of ZooKeeper on all other ZooKeeper nodes.

   A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.

5. Issue the following command to verify that ZooKeeper is healthy and that the expected nodes adopted the ZooKeeper node:

```
% service mapr-zookeeper qstatus
```

6. Perform a rolling restart of Warden on all other nodes.

   Warden picks up the revised quorum.

Removing a Fileserver Role
Describes how to remove the Fileserver role from a node.

Removing the fileserver role from a node is more complex than removing other roles. The CLDB tracks data precisely on all fileserver nodes, and therefore you should direct the cluster CLDB to stop tracking the node before removing the fileserver role. For a planned decommissioning of a node, use node topologies to migrate data off the node before removing the fileserver role. For example, you could move the node out of a live `/data` topology into a `/decommissioned` topology that has no volumes assigned to it, in order to force data off the node. Otherwise, some data will be under-replicated as soon as the node is removed. Refer to Node Topology.

Note: The following procedure involves halting all MapR services on the node temporarily. If this might disrupt critical services on your cluster, such as CLDB, migrate those services to a different node first, and then proceed.

The following steps describe how to remove the fileserver role from a node:

1. Stop the warden, which will halt all MapR services on the node. Wait 5 minutes, after which the CLDB will mark the node as critical.
2. Remove the node from the cluster, to direct the CLDB to stop tracking this node.

   You can do this in the Control System GUI or with the `maprcli node remove` command.
3. Remove the fileserver role by deleting the file `/opt/mapr/roles/fileserver` on the node.
4. Run `configure.sh` on the node to reconfigure the node without the fileserver role.
5. Issue the following command to restart Warden on the node:

```
% service mapr-warden restart
```

6. Remove any volumes that were stored locally on the node.

   You can do this in the Control System or with the `maprcli volume remove` command.

Assigning Roles to Nodes for Best Performance
Guidelines to optimise the cluster's service layout for best performance.

The architecture of MapR software allows virtually any service to run on any node, or nodes, to provide a high-availability, high-performance cluster. The following guidelines help plan your cluster's service layout.

Do not Overload ZooKeeper

High latency on a ZooKeeper node can lead to an increased incidence of ZooKeeper quorum failures. A ZooKeeper quorum failure occurs when the cluster finds too few copies of the ZooKeeper service running. If the ZooKeeper node is also running other services, competition for computing resources can lead to increased latency for that node. If your cluster experiences issues relating to ZooKeeper quorum failures, consider reducing or eliminating the number of other services running on the ZooKeeper node.

last-updated: Apr 11, 2022

Separate High-Demand Services

The following guideline states the services to separate on large clusters:

- **ResourceManager on ZooKeeper nodes**: Avoid running the ResourceManager service on nodes that are running the ZooKeeper service. On large clusters, the ResourceManager service can consume significant resources.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, MapR recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services

Explains how to view the list of services using either the Control System or the CLI.

Viewing the Services Installed on the Cluster Using the Control System

- Log in to the Control System and click **Services**.

  The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

Column Name	Column Description
Service	The name of the installed service.
Running Nodes	The number of nodes on which the associated service is running. The service can be stopped ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is running.
Standby Nodes	The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is in standby state.
Failed Nodes	The number of nodes on which the service has failed. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has failed.
Stopped Nodes	The number of nodes on which the associated service is stopped (and not running). The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has been stopped.
Config Path	The path to the configuration file for the service.
Log Viewer	(Displays only if Kibana is installed on a node) The link ( ) to the Kibana UI.

  You can filter the list of services displayed by:

  - **EEP**, which includes services such as Hive, Drill, etc.
  - **Core**, which includes services such as CLDB, Hoststats, File server, etc.
  - **Monitoring**, which includes services such as Grafana, Kibana, etc.

last-updated: Apr 11, 2022

Viewing the Services Running on a Node Using the Control System

1. Log in to the Control System and click **Nodes**.

   Note: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:
   - Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.
   - Go to the **Summary** tab in the node information page to view detailed information on the services installed on a node.

   In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

Column Name	Column Description
Service	The name of the service.
State	The current state of the service. Value can be: • Running • Stopped
Memory Allocated	The amount of system memory allocated to the service.
System Memory Utilized	The percentage of memory utilized by the service.
CPU Usage	The CPU used by the service.
Log Path	The path to the service log file.
Log Viewer	The link to the Kibana UI (only if Kibana is installed).

   You can select the checkbox beside one or more services to take the following actions:
   - Start Services
   - Stop Services
   - Restart Services

   Note: If Kibana is installed, you can click to view the logs. See Kibana User Guide for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see service list on page 1746.

Enabling and Disabling a Service Using the CLI and REST API

Describes how to enable or disable a service using either the REST API or the CLI.

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

last-updated: Apr 11, 2022

Disabling a Service Using the CLI or REST API

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action disable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=disable' --user mapr:mapr`

Note: When you disable a service, the service is stopped and the service is not automatically starrted/restarted when Warden is started/restarted.

See `node services` on page 1730 for more information.

Enabling a Service Using the CLI or REST API

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action enable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=enable' --user mapr:mapr`

Note: When you enable a service, the service is started/restarted when Warden is started/restarted.

See `node services` on page 1730 for more information.

Related tasks

Restarting the Services on page 831
Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services
Explains how to start services using either the Control System, the CLI or the REST API.

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See Enabling and Disabling a Service Using the CLI and REST API on page 828 for more information.

Starting the Services Running on the Nodes Using the Control System

To start the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.

last-updated: Apr 11, 2022

3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

To start one or more services running on a node:

1. Go to the **Summary** tab in the node information page.
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
   The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click  for the service to start.
   The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see `node services` on page 1730.

Stopping the Services
Describes how to stop services using either the Control System, the CLI or the REST API.
Stopping the Services Running on the Nodes Using the Control System

To stop the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   Note: The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

To stop one or more services running on a node:

1. Go to the **Summary** tab in the node information page.
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
   The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop.
   The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see `node services` on page 1730.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

When a MapR system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

Note: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that MapR currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See Enabling and Disabling a Service Using the CLI and REST API on page 1159 for more information.

Restarting the Services Running on the Nodes Using the Control System

To restart the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   

   Note: The **Nodes** page is not available on the Kubernetes version of the Control System.
2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

last-updated: Apr 11, 2022

Restarting one or more Services on a Node Using the Control System

1. Go to the **Summary** tab in the node information page.
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
   The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click  associated with the service to restart.
   The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see `node services` on page 1730.

Enabling and Disabling a Service Using the CLI and REST API on page 1159
Describes how to enable or disable a service using either the REST API or the CLI.

Changing the User for MapR Services from the Command-Line

Explains how use the CLI to change the user that MapR services run as.

All services should run with the same uid/gid on all nodes in the cluster.

Running MapR Services as the Root User

1. Stop Warden.

   ```
   service mapr-warden stop
   ```

2. If ZooKeeper is installed on the node, stop it.

   ```
   service mapr-zookeeper stop
   ```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`
4. If Zookeeper is installed, start it.

   ```
   service mapr-zookeeper start
   ```

5. Start Warden.

   ```
   service mapr-warden start
   ```

last-updated: Apr 11, 2022

Running MapR Services as a Non-Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.
4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.
6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing NODE_ALARM_MAPRUSER_MISMATCH alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Running Data-Fabric Services as the Root User

1. Stop Warden:

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it:

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`
4. If ZooKeeper is installed, start it:

```
service mapr-zookeeper start
```

5. Start Warden:

```
service mapr-warden start
```

Running Data-Fabric Services as a Non-Root User

1. Stop Warden:

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it:

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.
4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`
6. If Zookeeper is installed, start it:

```
service mapr-zookeeper start
```

7. Start Warden:

```
service mapr-warden start
```

8. After clearing NODE_ALARM_MAPRUSER_MISMATCH alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Managing Disks

Provides a brief overview of adding and removing disks from the MapR filesystem.

You can add and remove disks in the MapR File System from the MapR Control System or using the `diskadd` and `diskremove` commands. MapR File System groups disks into *storage pools*, usually made up of two or three disks. When adding disks to the MapR File System, it is a good idea to add at least two or three at a time so that MapR can create properly-sized storage pools. Each node in a MapR cluster can support up to 36 storage pools.

To see which disks are used by MapR File System, check the `disktab` file that MapR maintains on each node.

Warning: For instructions on performing disk maintenance on a node, see Performing Maintenance on a Node. If a disk failure alarm is raised (`NODE_ALARM_DISK_FAILURE`), see Handling Disk Failures for instructions.

Refer to the following procedures to manage disks using the Control System and the CLI.

Viewing the List of Disks
Explains how to view the disks on a node using either the Control System or the CLI.
Viewing the List of Disks Using the Control System

To view both the system and filesystem disks:

1. Log in to the Control System and go to the node information page.
2. Go to the **Summary** tab.
   On this page, the **Disks** and **System Disks** panes display the following for each disk:

last-updated: Apr 11, 2022

Column Name	Column Description
Status	The status of the disk. Value can be one of the following: • — indicates disk is active or good. • — indicates disk is on standby. • — indicates disk is offline.
Device	The disk partition(s).
Mnt	Indicates whether (✓) or not the disk is mounted.
MapR File System	(Displayed in the **Disks** pane only) The disks available for MapR File System. A ✓ indicates that the disk was added to MapR File System.
File System	(Displayed in the **System Disks** pane only) The disks for system use.
Allocated	The amount of space allocated, in gigabytes.
Used	The percentage of disk space used.
Model#	The disk model number.
Firmware Version	The disk firmware version.
Storage Label	The label assigned to the disk.
Storage Pool	The ID of the storage pool associated with the disk.

Select the checkbox beside a disk in the **Disks** pane to:

- Add Disk(s) to MapR File System
- Remove Disk(s) from MapR File System

Note: Disks in the **System Disks** pane cannot be selected.

Retrieving the List of Disks Using the CLI or REST API

The basic command to list the disks on a node is:

```
maprcli disk list -host <host>
```

For complete reference information, see `disk list on page 1604`.

Setting Up Disks for MapR

This section describes how to set up disks during the normal installation process. Go to the `disksetup on page 2092` command page for information about other uses of this command.

MapR formats and uses disks for the Lockless Storage Services layer (MapR File System), and records these disks in the `disktab on page 2189` file. In a production environment, or when testing performance, MapR should be configured to use physical hard drives and partitions. In some cases, it is necessary to reinstall the operating system on a node so that the physical hard drives are available for direct use by MapR. Reinstalling the operating system provides an unrestricted opportunity to configure the hard drives. If the installation procedure assigns hard drives to be managed by the Linux Logical Volume Manager(LVM) by default, you should explicitly remove the drives you plan to use with MapRMapR Data Platform from the LVM configuration. It is common to let LVM manage one physical drive containing the operating system partition(s) and to leave the rest unmanaged by LVM for use with MapRMapR Data Platform.

last-updated: Apr 11, 2022

Note: It is not necessary to set up RAID (Redundant Array of Independent Disks) on disks used by MapR File System. MapRMapR Data Platform uses the disksetup script to set up storage pools. In most cases, you should let MapRMapR Data Platform calculate storage pools using the default stripe width of two or three disks. If you anticipate a high volume of random-access I/O, you can use the `-W` option with disksetup to specify larger storage pools of up to 8 disks each.

Notice: For more information on setting up disks, see Drive Configuration.

The following procedures are intended for use on physical clusters or Amazon EC2 instances. On EC2 instances, EBS volumes can be used as MapRMapR Data Platform storage, although performance will be slow.

Note: If you are using MapR on Amazon EMR, you do not have to use this procedure; the disks are set up for you automatically.

Determine if a disk or partition is ready for use by MapR
Explains the procedure to determine whether a disk or partition is ready for use by MapR.

Any disk or partition that passes the following testing procedure can be added to the list of disks and partitions passed to the `disksetup` command.

1. Run the command `sudo lsof <partition>` to determine whether any processes are already using the disk or partition.

   There should be no output when running `sudo fuser <partition>`, indicating there is no process accessing the specific disk or partition.

2. The disk or partition should not be mounted, as checked via the output of the `mount` command. If the disk or partition is mounted, unmount it using the `umount` command.

3. The disk or partition should not have an entry in the `/etc/fstab file`; comment out or delete any such entries.

4. The disk or partition should be accessible to standard Linux tools such as `mkfs`. You should be able to successfully format the partition using a command like `sudo mkfs.ext3 <partition>` as this is similar to the operations that MapR performs during installation. If `mkfs` fails to access and format the partition, then it is highly likely that MapR will encounter the same problem.

Specify disks or partitions for use by MapR
Describes the use of the `disksetup` script to format disks.

The disksetup script is used to format disks for use by the MapR cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by MapR on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run the disksetup script to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Note: The disksetup script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

Note: Run the disksetup script only after running the configure.sh script.

Evaluate MapR using a flat storage file instead of formatting disks
For evaluation, you can use a flat storage file instead of formatting disks.

When setting up a small cluster for evaluation purposes, if a particular node does not have physical disks or partitions available to dedicate to the cluster, you can use a flat file on an existing disk partition as the node's storage. Create at least a 16GB file, and include a path to the file in the disk list file for the `disksetup` script.

The following example creates a 20 GB flat file (`bs=1G` specifies 1 gigabyte blocks, multiplied by `count=20`) at `/root/storagefile`:

```
dd if=/dev/zero of=/root/storagefile bs=1G count=20
```

Add the created flat file to the disk list file `/tmp/disks.txt` to be used by `disksetup`:

```
/root/storagefile
```

Adding Disks to MapR File System
Describes how to add disks using either the Control System or the CLI.

You can add disks to MapR File System using the Control System and the CLI. Before adding the disks to MapR File System, add the physical disks to the node or nodes according to the correct hardware procedure.

- If you are removing and replacing failed disks, you must install the replacements, then re-add the replacement disks to MapR File System, along with the other disks that were in the same storage pool(s) as the failed disks. See Handling Disk Failures for more details.
- If you are removing disks but not replacing them, you can just re-add the other disks that were in the same storage pool(s) as the failed disks.

Note: Disks must be added on CLDB nodes one node at a time when Warden and MapR services are running.

Attention: Disable write caching on all MapR disks if the disks are not battery backed.

Adding Disks Using the Control System

Complete the following steps to add disks of type MapR File System using the Control System:

1. Log in to the Control System and go to the **Summary** tab in the node information page.

   Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the disks not yet added to MapR File System in the **Disks** pane and click **Add Disks to File System**.

   The **Add Disks to File System** confirmation dialog displays.

   Note: You cannot select disks of type *System* to add.

3. Review the list and click **Add Disk**.

   The disks are automatically formatted and properly-sized storage pools are automatically allocated.

last-updated: Apr 11, 2022

Adding Disks Using the CLI or REST API

The basic command to add disks to a node is:

```
maprcli disk add -disks <disk names> -host <host>
```

Note: This step reformats the disks. Any data on these disks will be lost.

For complete reference information, see `disk add` on page 1602.

Removing Disks from the File System

Explains how to remove disks using either the Control System or the CLI.

When you remove a disk from the MapR File System, other disks in the storage pool are also removed automatically from the MapR File System and are no longer in use (they are available but off-line). Their disk storage goes to 0%, and they are eligible to be added again to the MapR File System to build a new storage pool. You can either replace the disk and re-add it along with the other disks that were in the storage pool, or just re-add the other disks if you do not plan to replace the disk you removed. See Adding Disks to MapR File System on page 837 for more information.

Warning: Removing a disk in the storage pool that contains Container ID 1 shuts down CLDB, triggering a CLDB failover. Container ID 1 contains CLDB data for the primary CLDB. From the command-line, run the `maprcli disk remove` command without the `-force 1` option first and examine the warning messages to make sure you are not removing the disk with Container ID 1. To safely remove such a disk, perform a CLDB Failover on page 1500 to make one of the other CLDB nodes the primary CLDB, then remove the disk as normal with addition of the `-force 1` option.

Before removing or replacing disks, make sure the Replication Alarm (VOLUME_ALARM_DATA_UNDER_REPLICATED), Data Alarm (VOLUME_ALARM_DATA_UNAVAILABLE), Warm-Tier Data Node Down (VOLUME_ALARM_DEGRADED_EC_STRIPES), and EC Degraded Alarm (VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES) are not raised. These alarms can indicate potential or actual data loss. If either alarm is raised, you might be able to repair the problem using the `/opt/mapr/server/fsck` utility before removing or replacing disks.

Note: Using the `/opt/mapr/server/fsck` utility with the `-r` flag to repair a MapR File System risks data loss. Call MapR support before using `/opt/mapr/server/fsck -r`.

Removing Disks from MapR File System Using the Control System

Complete the following steps to remove disks using the Control System:

1. Log in to the Control System and go to the **Summary** tab in the node information page.
2. Select the disks to remove in the **Disks** pane and click **Remove Disk(s) from File System**.
   The **Remove Disk(s) from File System** confirmation dialog displays.

   Warning: One or more disks you selected may have unreplicated data on it and this action will forcefully remove the disks.
3. Review the list and click **Remove Disk**.
   Wait several minutes while the removal process completes. After you remove the disks, any other disks in the same storage pools are taken offline and marked as *available* (not in use by MapR).
4. Remove the physical disks from the node or nodes according to the correct hardware procedure.

last-updated: Apr 11, 2022

5. From a command line terminal, remove the failed disk log file from the `/opt/mapr/logs` directory.
   These log files are typically named like this:

   ```
   diskname.failed.info
   ```

Removing Disks from MapR File System Using the CLI or REST API

1. On the node, determine which disk to remove/replace by examining **Disk** entries in the `/opt/mapr/logs/faileddisk.log` file.
2. Run the following command, substituting the hostname or IP address for `<host>` and a list of disks for `<disks>`

   ```
   maprcli disk remove -disks <disk names> -host <host>
   ```

   Note: This command does not remove a disk containing unreplicated data unless forced.

   For complete reference information, see `disk remove` on page 1608.
3. Examine the screen output in response to the command you ran in step 2.
   For example:

   ```
   maprcli disk remove -host `hostname -f` -disks /dev/sdd
   message   host   disk
   removed.  host1  /dev/sdd
   removed.  host1  /dev/sde
   removed.  host1  /dev/sdf
   ```

   Make a note of the *additional* disks removed when the disk is removed. For example, the disks `/dev/sde` and `/dev/sdf` are part of the same storage pool and therefore removed along with the disk (`/dev/sdd`).
4. Confirm that the removed disks do not appear in the `disktab` file.
5. Remove the disk log file from the `/opt/mapr/logs` directory.
   For failed disks, these log files are typically named in the pattern *`diskname`*`.failed.info`.

When you replace a failed disk, add it back to the MapR File System along with the other disks from the same storage pool that were previously removed. Adding only the replacement disk to the MapR File System, results in a non-optimal storage pool layout, which can lead to degraded performance.

Once you add the disks to the MapR File System, the cluster automatically allocates properly-sized storage pools. For example, if you add ten disks, MapR allocates two storage pools of three disks each and two storage pools of two disks each.

Determining the Amount of Free Disk From the Command-Line
Lists the command to display the amount of free disk space.

To determine the amount of used and available disk space on the filesystem, run `df -h`. When running this command, if:

last-updated: Apr 11, 2022

- The given path points to the mount point, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/
Filesystem            Size  Used  Avail  Use%  Mounted on
posix-client-basic    4.4T  9.7G  4.4T   1%    /mapr
```

- The given path points to a volume with no (hard) quota, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol3
Filesystem          Size  Used  Avail  Use%  Mounted on
posix-client-basic  4.4T  9.7G  4.4T   1%    /mapr
```

- The given path points to a volume with (hard) quota set, the output will display the used and available disk space for the specific volume based on the allocated quota. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol2/
Filesystem          Size  Used  Avail  Use%  Mounted on
posix-client-basic  5.0G  2.5G  2.6G   49%   /mapr
```

Tolerating Slow Disks
Explains how to tune disk response timeouts.

The parameter `mfs.io.disk.timeout` in `mfs.conf` determines how long MapR waits for a disk to respond before assuming it has failed. If healthy disks are too slow, and are erroneously marked as failed, you can increase the value of this parameter.

Formatting Disks on a Node From the Command-line
Provides an overview of the disksetup script to format disks from the command line.

The disksetup script is used to format disks for use by the MapR cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by MapR on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run disksetup to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Note: The disksetup script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

Warning: Run disksetup only after running configure.sh.

Handling Disk Failures
Explains how to handle disk failures.

When a disk fails, MapR raises the node-level alarm `NODE_ALARM_DISK_FAILURE` on the node with the failed disk (or disks). At the same time, other disks in the same storage pool as the failed disk are taken

last-updated: Apr 11, 2022

offline. You can look at the Control System **Overview** page to view the health of the nodes and a list of alarms.

When you see a disk failure alarm, examine the log file at `/opt/mapr/logs/faileddisk.log` and check the **Failure Reason** field.

Examining the Cause of Failure
Names the log file that contains the cause of disk failures.

In the `faileddisk.log` file, you will see information on the cause of failure. In the following sample log output, the failure reason is *I/O error*. Notice that the log file also provides instructions for removing disks and adding them back to the MapR File System.

```
############################ Disk Failure Report
############################
Disk                :    /dev/sdd
Vendor              :    [vendor]
Model Number        :    [model]
Serial Number       :    [serial]
Firmware Revision   :    [firmware]
Size                :    [total]
Failure Reason      :    I/O error
Time of Failure     :    Fri Jan 31 12:48:00 GMT 2014
Resolution          :   Please refer to MapR's online documentation at
https://docs.datafabric.hpe.com on how to handle
        disk failures.
In summary, run the following steps:
a. If this appears to be a software failure, go to step
b. Otherwise, physically remove the disk /dev/sdd. Optionally, replace it
with a new disk.
b. Run the command "maprcli disk remove -host 127.0.0.1 -disks /dev/sdd" to
remove
        /dev/sdd from MapR-FS.
c. In addition to /dev/sdd, the above command removes all the disks that
belong to the same
        storage pool, from MapR-FS.      Note down the names of all removed
disks.
d. Add all the above removed disks (exclude /dev/sdd) and the new disk to
MapR-FS by
   running the command:
   "maprcli disk add -host 127.0.0.1 -disks <comma separated list of
      disks>"
   For example, If /dev/sdx is the new replaced disk, and /dev/
sdy, /dev/sdz were removed in
        step c), the command would be:
   "maprcli disk add -host 127.0.0.1 -disks /dev/sdx,/dev/sdy,/dev/
sdz"      If there is no new disk, the command would just
be:                   "maprcli disk add -host 127.0.0.1 -disks
    /dev/sdy,/dev/sdz"
```

Recovering from Disk Failure
Lists the disk errors and their resolution.

Most software failures can be remedied by running the fsck utility, which scans the storage pool to which the disk belongs and reports errors. For hardware failures, remove the failed disk and replace it according to the procedure in Removing and Replacing Disks.

The following are the types of failures and the recommended courses of action:

I/OTimeOut Error	*Failure Reason*: The default value for `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as stuck is 3 times the value of this parameter (3 x `mfs.disk.io.timeout`). The

	disk will be taken offline even if a single IO has not completed. *Action*: **1.** Check if the disks are good and still reliable. **2.** If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.
No Such Device	*Failure Reason*: The `$INSTALL_DIR/conf/disktab` file contains `"/MissingDisk"` or references a disk path not found in `/proc/partitions` file. *Action*: Run `mrdisk <device path>` to determine whether a disk is formatted for MapR File System. Also, check the device paths in `$INSTALL_DIR/conf/disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the MapR File System. If the disk paths have been renamed, fix them or run `disksetup -X` command to regenerate the disktab from `/proc/partitions`. Alternatively, restart the MapR File System to resolve disk name changes. If the problem still persists, contact MapR support.
ENODEV: MissingDisk# Error: disktab file contains a /MissingDisk# entry	*Failure Reason*: A disk corresponding to a GUID is missing and the corresponding disk path in the `disktab` file belongs to another disk. When an attempt is made to automatically fix the `disktab` file, this entry is replaced with `/MissingDisk# path`. *Action*: If a disk corresponding to a GUID is permanently lost, remove the line corresponding to it in the `disktab` file. Alternatively, run `maprcli disk remove _MissingDisk#` command, where # corresponds to the disk number, and restart the MapR File System.
EIO Error	*Failure Reason*: I/O error. This could be due to a bad block or disk. The system will offline the SP after one final attempt to complete the IO. *Action*: Check `/var/log/messages` for errors from the disk drivers.

CRC Error	*Failure Reason*: This could be due to a bad block or bit flip on the disk. The SP will be taken offline immediately.
	Action: Run `fsck -n <sp> -d` to perform a CRC (Cyclic Redundancy Check) on the data blocks in the storage pool, then bring it back online.
	To load all the SPs to the list of SPs, run:
	`mrconfig disk load or mrconfig sp load`
	To bring back all SPs online, run:
	`mrconfig sp refresh`

last-updated: Apr 11, 2022

To bring specific SPs back online, run:

```
mrconfig sp online <sp path>
```

SlowDisk Error

Failure Reason: The default value for the `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as slow is equal to the value of this parameter (1 x `mfs.disk.io.timeout`). Thirty or more slow IO completions in a short span of time (5 seconds) on the same disk is recorded as a slow event. The SP will be taken offline if 3 such events are recorded within an hour.

Note: After an hour, MapR filesystem will reset tracking (to 0).

Action:

1. Check if the disks are good and still reliable.
2. If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.

GUID of disk mismatches with the one in `$INSTALL_DIR/conf/disktab`

Failure Reason: Possible that disk names have changed.

Action: After a node restart, the operating system can reassign the drive labels (for example, `/sda`), resulting in drive labels no longer matching the entries in the `disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the MapR File System. Run `$INSTALL_DIR/server/disksetup -X` to update the `disktab` file by looking up the disks in `/proc/partitions` and make the disk paths match the GUIDs.

Unknown Error

Failure Reason: Any reason

Action: Contact MapR support.

Addressing Data Alarms

Lists all the data alarms and their mitigation.

When a disk fails, data on that disk becomes unavailable. As a result, you will probably see one of these two data alarms along with a **Disk Failure** alarm:

- **Data Unavailable** (`VOLUME_ALARM_DATA_UNAVAILABLE`) - if there was only one copy of data and it was on the failed disk; or if data was replicated more than once, but all disks with that data failed
- **Data Under Replicated** (`VOLUME_ALARM_DATA_UNDER_REPLICATED`) - if data on the failed disk is replicated elsewhere, but the minimum replication factor is not met as a result of the failed disk

If you see a **Data Unavailable** volume alarm in the cluster, follow these steps to run the /opt/mapr/server/fsck utility on all the offline storage pools. On each node in the cluster that has raised a disk failure alarm:

1. Run the following command to identify which storage pools are offline:

   ```
   [user@host] /opt/mapr/server/mrconfig sp list | grep Offline
   ```

last-updated: Apr 11, 2022

2. For each storage pool reported by the previous command, run the following command, where <sp> specifies the name of an offline storage pool:

   ```
   [user@host] /opt/mapr/server/fsck -n <sp> -r
   ```

   When you run fsck with the `-r` option, it identifies corrupt blocks and removes them. If there are no corrupt blocks, fsck clears the error condition so you can bring the storage pool back online.

   Note: Using the /opt/mapr/server/fsck utility with the `-r` flag to repair a filesystem risks data loss. Call MapR support before using `/opt/mapr/server/fsck -r`.

3. Verify that all **Data Unavailable** volume alarms are cleared. If **Data Unavailable** volume alarms persist, contact MapR support or post on answers.mapr.com.

If there are any **Data Under Replicated** volume alarms in the cluster, MapR can repair the problem by automatically replicating data and putting it on another disk. After you allow a reasonable amount of time for re-replication, verify that the under-replication alarms are cleared.

Using the /opt/mapr/server/fsck utility with the `-r` option produces different results depending on the scenario. The fsck utility does not interpret the scenario nor does it have a safe mode.

- If a disk is offline because of an imbalanced b-tree, using `fsck -r` may result in data loss from bad containers and data loss if additional replicas are unavailable.
- If a disk is offline because of an I/O error, using `fsck -r` produces indeterminate results. A disk that is throwing I/O errors is questionable in terms of data content and reliability. For example, an operation that completed on the disk but was never returned may have partial data remaining on the disk. Using `fsck -r` retains any partial data.
- If a disk is offline because of a slow I/O, using `fsck -r` does not produce data loss.

The most conservative usage of `fsck -r` is to run `fsck` without the `-r` option (verification mode) and check the output. If the output is ok, then run `fsck` with the `-r` option.

Note: Disk Failure node alarms that persist require disk replacement. If **Data Under Replicated** volume alarms persist, contact MapR support or post on answers.mapr.com.

Removing and Replacing Disks

If a disk fails due to a hardware problem, you will need to remove the disk. You can replace it, and then add that disk back to MapR File System along with the other disks that were automatically removed at the same time.

Refer to the following for information on how to remove and replace disks using the MapR command-line interface and the MapR Control System:

- Removing Disks from the File System on page 838
- Adding Disks to MapR File System on page 837

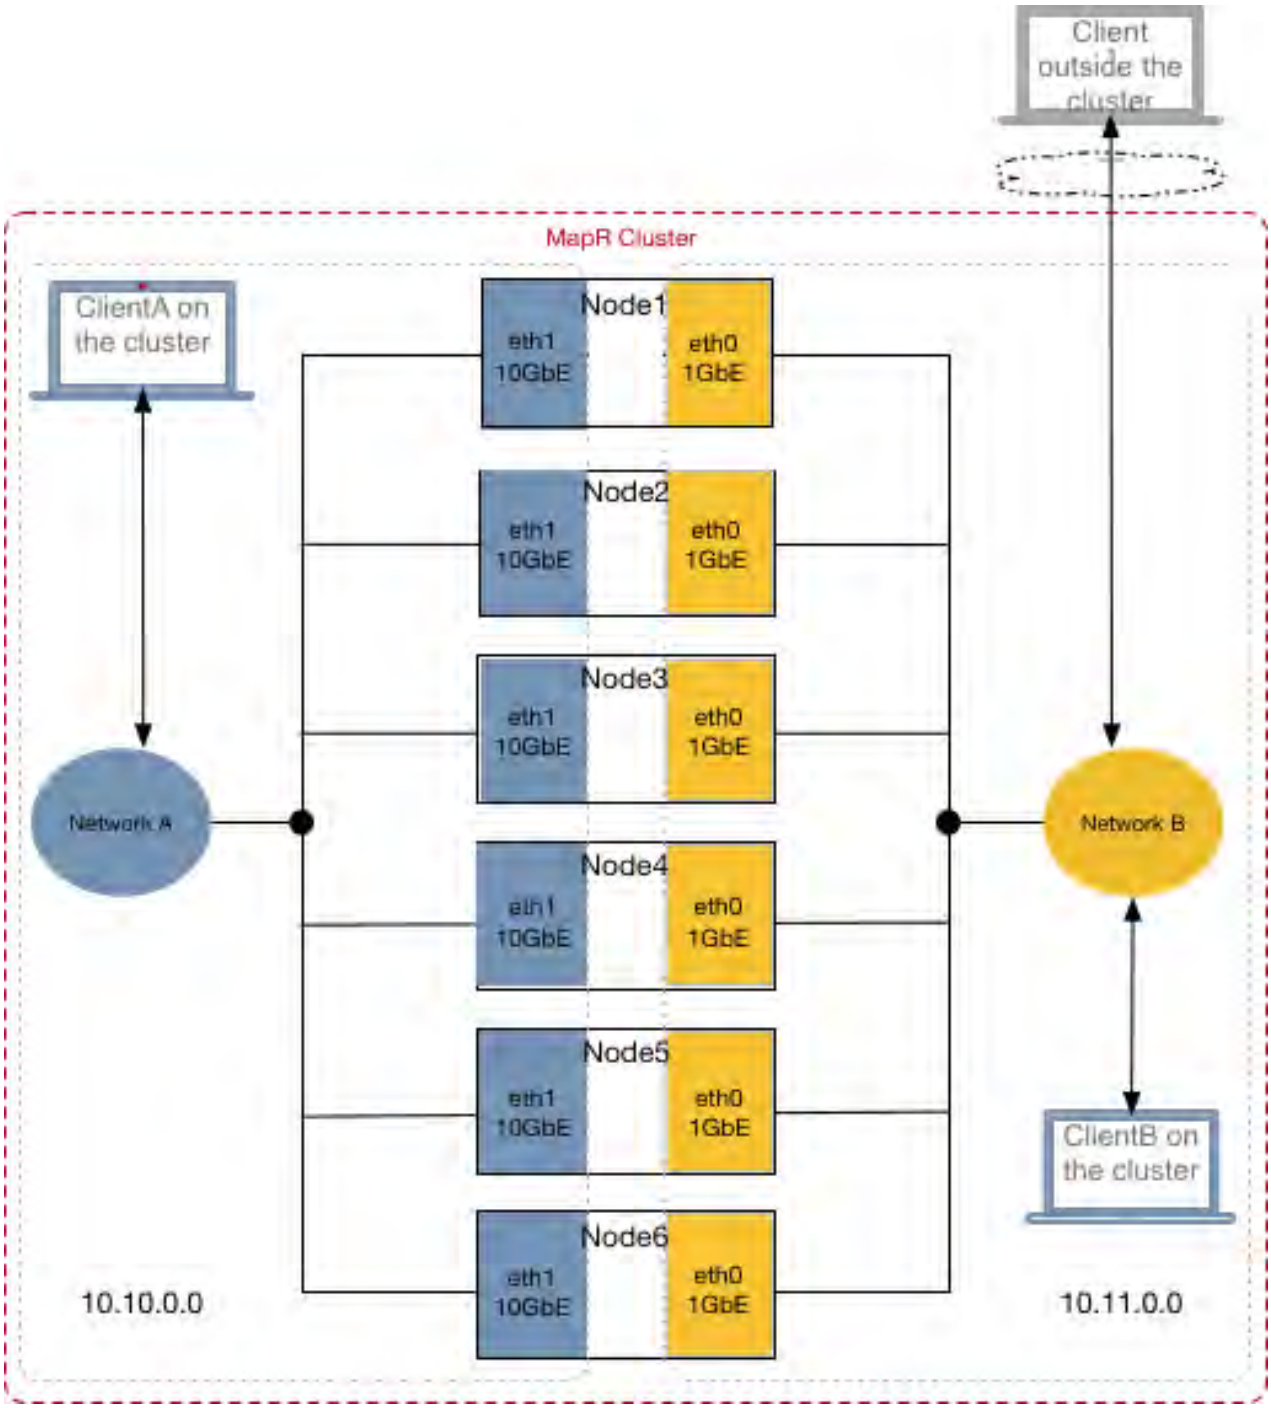
Designating NICs for MapR
Explains how to assign IP address blocks for MapR.

By default, MapR File System instances and the CLDB nodes advertise all the available IP addresses, and MapR automatically uses all available network interface cards (NICs) on each node for all communication. For nodes that have multiple NICs, MapR supports segregation of NICs such that certain IPs can be used for clients/communication within the cluster and certain IPs can be used for clients/communication from/to outside the cluster. Also, NICs can be segregated for specific (high-performance and/or low-performance) clients within the cluster.

For example, if you use multiple NICs of mixed speeds (such as 1GbE and 10GbE) on each node, you might want to separate them to two different networks depending on the Ethernet card speeds. You can

assign IP addresses in the same network to the NICs of 1GbE and assign IP addresses in another network to the NICs of 10GbE. That way, you can use the faster NICs for communication within the cluster or for certain high-performance clients (for example, FUSE-based POSIX client) and the slower NICs for external communication or for low-performance clients/jobs.

To illustrate this arrangement, the following diagram shows six nodes on a MapR cluster, each with a 1GbE NIC (eth0) and a 10GbE NIC (eth1). All the 1GbE NICs are networked together and connected to Network B. Likewise, all the 10GbE NICs are networked together (as part of a subnet written as 10.10.10.0/24 in CIDR notation) and connected to Network A, where peak performance is required. ClientA, which is within the cluster, communicates with cluster nodes over Network A and clients outside the cluster communicate with cluster nodes over Network B. The illustration also shows ClientB, which is a low-performance client inside the cluster, communicating with cluster nodes over Network B.



last-updated: Apr 11, 2022

MapR provides two environment variables, MAPR_SUBNETS and MAPR_EXTERNAL, which can be used to segregate NICs for internal and external clients or to segregate NICs for high-performance and low-performance clients.

About MAPR_SUBNETS Environment Variable

The MAPR_SUBNETS environment variable can be used to restrict MapR to a subset of NICs. If MAPR_SUBNETS is not set, all IPs are available for all communication. When MAPR_SUBNETS is set on:

- MapR File System nodes, MapR File System registers these IP addresses with CLDB as internal IP addresses on which MapR File System nodes can be reached.
- CLDB nodes, CLDB advertises the IP address to clients on the cluster.

You can set the MAPR_SUBNETS environment variable in the /opt/mapr/conf/env_override.sh file on all the nodes. On the cluster nodes, the value for this environment variable is a comma-separated list of subnet masks. For example:

```
export MAPR_SUBNETS=10.10.15.0/24,10.10.16.0/24
```

You can specify up to four NICs in the MAPR_SUBNETS environment variable. If your system has more than four NICs, MapR advertises the first four it finds or if MAPR_SUBNETS environment variable is set, MapR restricts the networks/IPs that are advertised based on the subnets specified therein.

The MAPR_SUBNETS environment variable can be set on the client if there is a NAT between the server and client. On the client, the value for this environment variable is an IP address of the client. For example:

```
export MAPR_SUBNETS=10.11.12.13/32
```

When specifying the IP address in the MAPR_SUBNETS environment variable on the client, use /32 to specify a single IP address.

For more information on the MAPR_SUBNETS environment variable, see Environment Variables on page 2289.

About MAPR_EXTERNAL Environment Variable

If all the IP addresses on the servers are public and can be accessed from an external system, the MAPR_EXTERNAL environment variable need not be set. However, if your cluster nodes have private IP addresses, to allow clients outside the cluster to reach the cluster nodes (such as when MapR is installed on the cloud or Docker container), specify the public IP addresses in the MAPR_EXTERNAL environment variable.

On the cluster nodes, you can set this variable in the /opt/mapr/conf/env_override.sh file. When MAPR_EXTERNAL is set on:

- MapR File System nodes, MapR File System registers these IP addresses with CLDB as the IP addresses on which external clients can reach MapR File System nodes. Communication between MapR File System nodes on the cluster still occurs over the internal IP addresses.
- CLDB nodes, CLDB advertises these IPs addresses to clients outside the cluster or data center.
- MAST Gateway nodes, the gateway registers these IP addresses with CLDB as the IP addresses on which external clients can reach the MAST Gateway.

Note: Do not set the MAPR_EXTERNAL environment variable on the client(s).

last-updated: Apr 11, 2022

The value for this environment variable is a comma-separated list of IP addresses; you cannot specify the hostname as value. For example:

```
ip1,ip2,ip3;
```

For example, you can specify the IP addresses of the 1GbE NICs (shown in the previous illustration) as the value for this environment variable, to allow external or low-performance clients to communicate with the cluster nodes.

```
export MAPR_EXTERNAL=10.11.0.0
```

For more information on the MAPR_EXTERNAL environment variable, see Environment Variables on page 2289.

About IP Addresses for ZooKeeper Nodes

You can specify the IP addresses of ZooKeeper nodes by running the `configure.sh` utility with both the `-Z` and `-EZ` options during cluster configuration and list the:

- Internal IP addresses with the `-Z` option
- External IP addresses with the `-EZ` option

When you specify the IP addresses using the `-Z` and `-EZ` options, these IP addresses are registered with CLDB and included in the `cldb.conf` file. In the `cldb.conf` file, the internal IP addresses set using the `-Z` option are the values for the `cldb.zookeeper.servers` parameter. The external IP addresses set using the `-EZ` option are the values for the `cldb.external.zookeeper.servers` parameter.

Note: You do not need to run the `configure.sh` command with the `-EZ` option during client configuration.

For more information, see `configure.sh` on page 2053.

If all the ZooKeepers have different IP addresses, port forwarding is not required and, optionally, you can specify the same port with all the IP addresses. However, in some cases, such as when there is a single external IP address being used by multiple ZooKeepers (as in a Docker container), you can specify ports for ZooKeepers when you run the `configure.sh` utility with the `-Z` and `-EZ` options. For more information, see Specifying Ports on page 852.

About Internal and External Clients

Clients communicating with CLDB using internal IP address (of CLDB) are considered internal clients (or clients within the cluster) and clients communicating with CLDB using external IP address (of CLDB) are considered external clients (or clients outside the cluster).

To configure a client as an internal or high-performance client, include CLDB's internal IP address in the `mapr-clusters.conf` file on the client host. Similarly, to configure a client as an external or low-performance client, include CLDB's external IP address in the `mapr-clusters.conf` file on the client host.

The `mapr-clusters.conf` file on the client host should not contain both internal and external IP addresses of the server on a cluster. The `mapr-clusters.conf` file can contain internal and external IP addresses only when the entries in the file on the client host are for multiple clusters. For example, suppose a client, which is an internal client on one cluster and external client on another cluster. The `mapr-clusters.conf` file on the client host can contain CLDB's internal IP address for the cluster on which the client is considered an internal client and CLDB's external IP address for the cluster on which the client is considered an external client.

Note: The `mapr-clusters.conf` file on the cluster nodes should not contain any external IP address.

Limitations

If:

- Both `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables are set, segregation of NICs for internal and external communication is possible. Internal communication happens over the IP addresses listed in the `MAPR_SUBNETS` environment variable and external communication happens over the IP addresses listed in the `MAPR_EXTERNAL` environment variable.
- Only `MAPR_SUBNETS` environment variable is set, MapR File System registers the IP addresses (in the `MAPR_SUBNETS` environment variable) with CLDB as internal IPs.

Note: Set both the environment variables in the `/opt/mapr/conf/env_override.sh` file to segregate internal or high performance clients, and external or low-performance clients.

You can specify up to 4 IP addresses in the `MAPR_SUBNETS` environment variable, and 4 IP addresses in the `MAPR_EXTERNAL` environment variable.

Note: You must configure ZooKeeper with an IP address that is reachable by both internal and external clients.

Summary

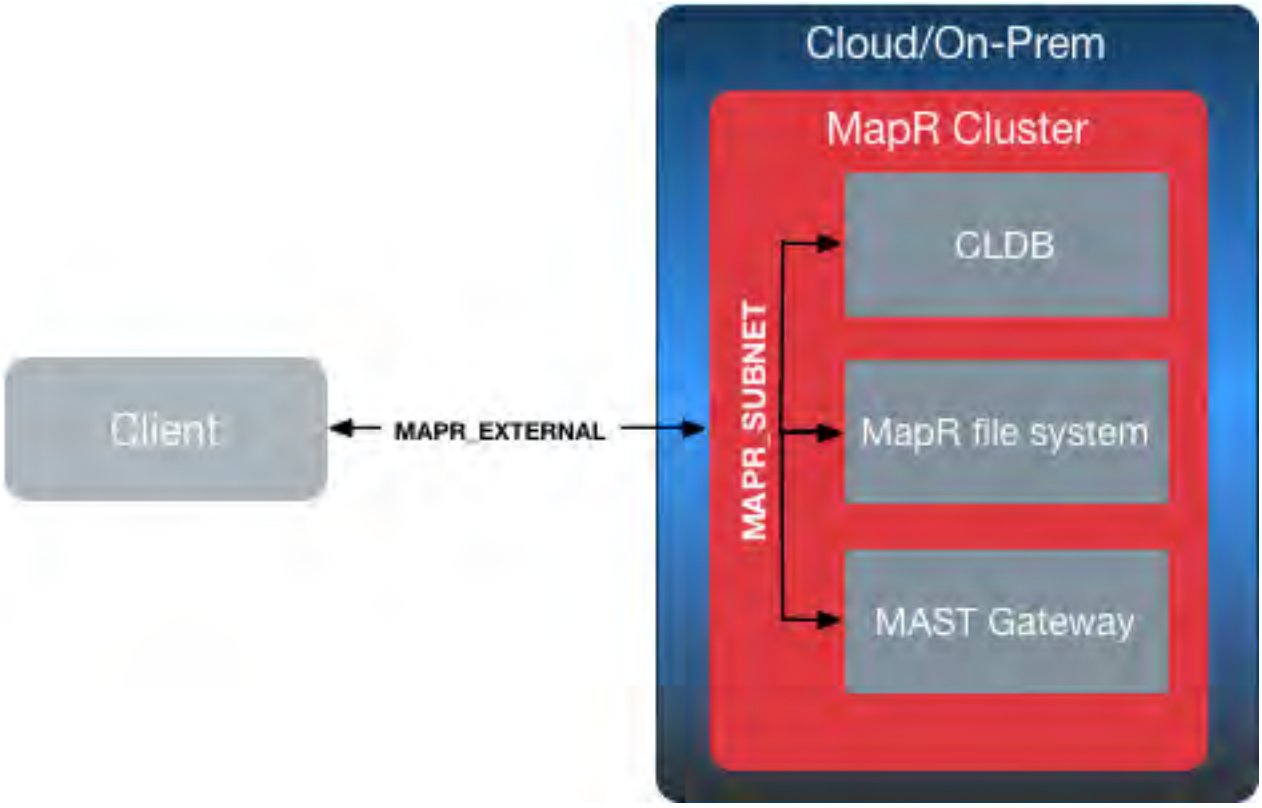
The following table describes the environment variables to set for the various services that use non-default ports and that support public IP address(es) for communication with external clients and remote clusters:

Service	Environment variable to set...	
	Public IP Address for External Clients/ Remote Clusters	**Non-default Port**
CLDB	`MAPR_EXTERNAL`	`CLDB_EXTERNAL_RPC_PORT`
MapR File System	`MAPR_EXTERNAL`	`MAPR_EXTERNAL`
MAST Gateway	`MAPR_EXTERNAL`	`MASTGATEWAY_EXTERNAL_RPC_PORT`

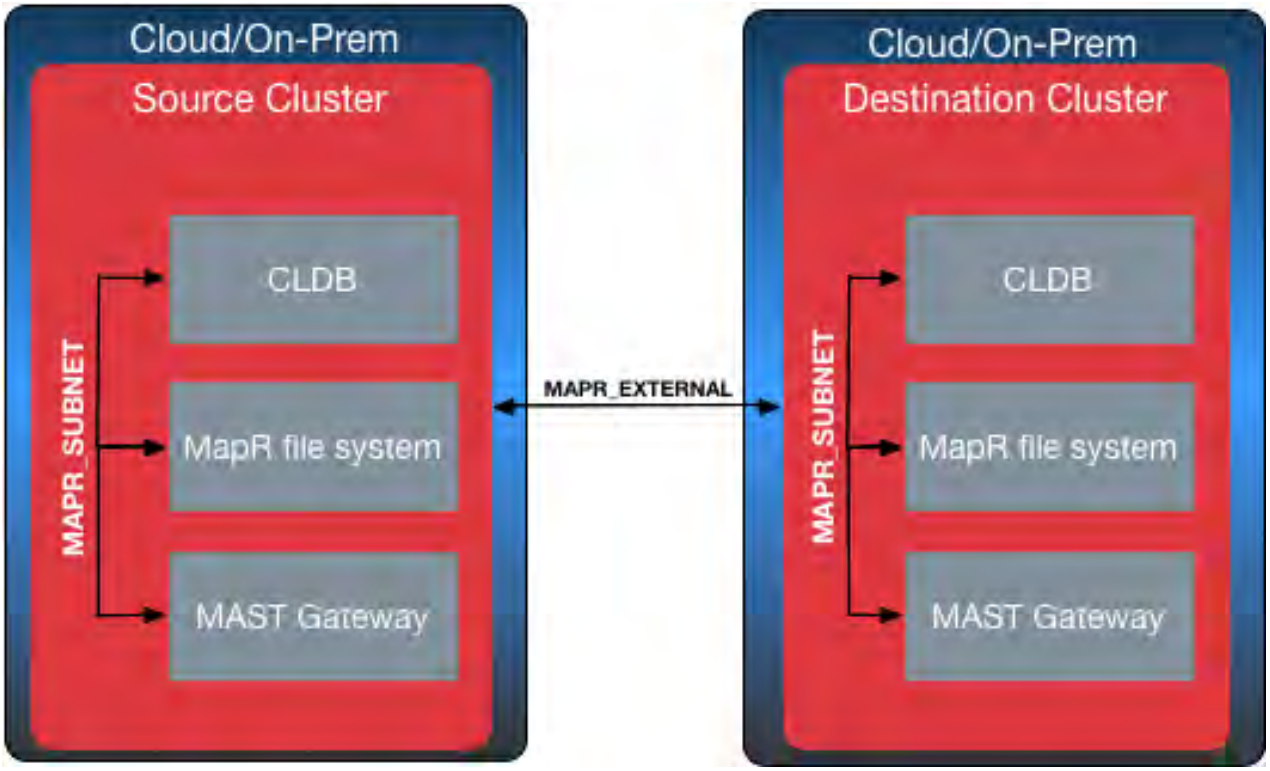
The following illustration shows the client communicating with CLDB, MapR filesystem, and MAST Gateway using the IP address(es) defined in the `MAPR_EXTERNAL` environment variable because all the IP addresses on the servers are not public and accessible outside the cluster. All communication between CLDB, MapR File System, and MAST Gateway on the same cluster happen over the IP address specified in the `MAPR_SUBNETS` environment variable because communication between the services and clients on the cluster is restricted to a subset of the available NICs.

When the client connects to the MapR filesystem from outside the cluster, the client uses either the default port (5660) or the port specified for the MapR filesystem in the `MAPR_EXTERNAL` environment variable. When communicating with CLDB, if the `CLDB_EXTERNAL_RPC_PORT` environment variable is set, the client communicates with CLDB over the port specified in this environment variable. Similarly for MAST Gateway, if the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable is set, the client communicates with MAST Gateway over the port specified in this environment variable. For both CLDB and MAST Gateway, if the ports are not set in the `CLDB_EXTERNAL_RPC_PORT` and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variables respectively, the client communicates over the default port.

last-updated: Apr 11, 2022



The following illustration shows that during mirroring and other cross-cluster activities, the services on the destination cluster communicate with the services on the source cluster using the IP address defined in the `MAPR_EXTERNAL` environment variable. Similar to the external client, the services and clients in the remote destination cluster communicate with the services in the source cluster over the default ports or the port specified in the environment variable for the service.



last-updated: Apr 11, 2022

Setting Environment Variables for NIC Segregation
Describes how to set environment variables to segregate NICs.

Use the `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables to segregate NICs for internal and external clients, or to segregate NICs for high-performance and low-performance clients.

Setting the MAPR_SUBNETS Environment Variable

To specify the internal IP addresses of CLDB and MapR File System nodes:

1. Stop warden on all the nodes on the cluster.
2. Set the IP address range to use in the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see About env_override.sh on page 2290.

   For example:

   ```
   export MAPR_SUBNETS=10.10.0.0/24
   ```

   To specify multiple subnets for MapRMapR Data Platform, use comma to separate the IP addresses.

   Before specifying the IP address, make sure the client and cluster nodes can communicate using that IP address. That is, ensure that the client can send packets and that they can be routed to all the interfaces of the cluster nodes, and the cluster nodes all have a route that reaches back to the client IP address.

   Note: For standalone programs (not using the `mapr` classpath), which do not pick up the settings in the `/opt/mapr/conf/env.sh` file, set `MAPR_SUBNETS` explicitly before the start of program.
3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add CLDB's internal IP address (or IP address specified in the `MAPR_SUBNETS` environment variable on the CLDB host) to the `mapr-clusters.conf` file on the (internal or high-performance) client host(s).

   The `mapr-clusters.conf` file specifies IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see mapr-clusters.conf on page 2200.

When you restrict MapRMapR Data Platform to certain subnets, MapRMapR Data Platform clients have full access to the MapRMapR Data Platform cluster on the designated subnets.
Setting the MAPR_EXTERNAL Environment Variable

To specify the external IP addresses of CLDB, MapR File System, and/or MAST Gateway nodes:

1. Stop warden on all the nodes on the cluster.
2. Set the IP addresses to use for external communication or for low-performance clients in the `MAPR_EXTERNAL` environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see About env_override.sh on page 2290.

   For example:

   ```
   export MAPR_EXTERNAL=10.11.0.0;
   ```

   To specify multiple subnets for MapRMapR Data Platform, use a comma to separate the IP addresses.
3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add the following in the mapr-clusters.conf file on the (external or low-performance) client host(s):

- CLDB's external IP addresses, which is the IP addresses specified in the `MAPR_EXTERNAL` environment variable on the CLDB hosts.
- CLDB's external port, which is the value of the `CLDB_EXTERNAL_RPC_PORT` environment variable if this is set on the CLDB hosts. See Specifying Ports for CLDB for more information.

The mapr-clusters.conf file contains the IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see mapr-clusters.conf on page 2200.

Examples

Suppose the value for the `MAPR_EXTERNAL` environment variable on MapR File System node is the following:

```
10.10.103.80,10.10.30.205
```

External clients can connect to MapR File System on IPs 10.10.103.80, 10.10.30.205 and the ports on which the MapR File System is reachable are the default ports. If MapR File System is running 2 instances, then:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>

If MapR File System is running 3 instances:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>
- Instance 3 is reachable on 10.10.103.80:<5662>, 10.10.30.205:<5662>

Suppose the value for the `MAPR_EXTERNAL` environment variable on a MAST Gateway node is the following:

```
10.20.30.100
```

External clients can connect to MAST Gateway on IP 10.20.30.100 and the port on which MAST Gateway is reachable is the default port (8660). If MapR File System is also running on this node, then both MapR File System and MAST Gateway are reachable on the IP 10.20.30.100 and the ports on which they are reachable are the default ports.

Specifying External IP Address of ZooKeeper Nodes

To specify the external IP addresses of ZooKeeper nodes, during cluster configuration:

- Run the configure.sh utility as follows:

```
/opt/mapr/server/configure.sh -C <hostname|IP>[,<hostname|IP>,..] -Z
<IP>[,<IP>..] \
-EZ <IP>[:<port>][,<IP>[:<port>]..] [-F <disk_list_file>] [-N
<cluster_name>]
```

In the preceding command:

- When each ZooKeeper node has a different external IP address, use the `-EZ` option to specify the IP address of each ZooKeeper node, and optionally the port as well (separated by a colon); the IP address can be different while the port number must be the same for every node.

last-updated: Apr 11, 2022

- When there are multiple ZooKeeper nodes listening on the same external IP (such as in a Docker container), use the `-EZ` option to specify IP address and port (separated by a colon); the port can be different while the IP address is the same for every node.

For more information, see Specifying Ports on page 852.

Specifying Ports

On installations where the MapR File System instances, CLDB, and/or MAST Gateway must be reached on non-standard ports, you can specify the ports to advertise in the `MAPR_EXTERNAL`, `CLDB_EXTERNAL_RPC_PORT`, and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variables respectively. This setting does not change the ports used by the servers, but changes the ports advertised to clients (to support port forwarding).

If the cluster nodes are no longer reachable on the standard ports, you can specify ports for MapR File System using the `MAPR_EXTERNAL` environment variable. `MAPR_EXTERNAL` allows the specification of the advertised ports for the MapR File System instances only; this environment variable cannot be used to specify ports for CLDB or the MAST Gateway. Instead, use `CLDB_EXTERNAL_RPC_PORT` environment variable to specify port for CLDB and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable to specify port for MAST Gateway. If ZooKeeper is not available on the default port or if there are multiple ZooKeepers listening on the same external IP address, you can specify ports for each ZooKeeper using the configure.sh utility.

See the following sections for more information on setting the ports.

Specifying Ports for MapR File System

If the port forwarding table is set up, ports must be configured for every MapR File System node on every MapR File System instance. For more information on the number of ports used by MapR File System instance(s), see Ports Used by MapR Software on page 2290. To specify the ports for MapR File System:

1. Open the `$MAPR_HOME/conf/env_override.sh` file. If the `env_override.sh` file is not present, you might have to create it. See About env_override.sh on page 2290.
2. Set the value for the `MAPR_EXTERNAL` environment variable.

   The value for the `MAPR_EXTERNAL` environment variable is a comma-separated list of IP addresses and colon-separated list of ports (to use for port forwarding).

   For example:

   ```
   export MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003
   ```

   The following example shows 3 MapR File System instances with 4 ports:

   ```
   export
   MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003:10000,10001,10002,10003:11000
   ,11001,11002,11003
   ```

   To specify:

   - Multiple IP addresses, use comma to separate the IP addresses.
   - Ports for multiple instances, use:
     - comma (`,`) to separate the ports for an instance
     - colon (`:`) to separate the set of ports for each instance

   If ports are not specified, MapR File System is assumed to be reachable on the default ports.
3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

last-updated: Apr 11, 2022

Specifying Ports for CLDB

The default port for CLDB is 7222. If you want to use another port:

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the CLDB host(s). If the env_override.sh file is not present, you might have to create it. See About env_override.sh on page 2290.
2. Set the value for the `CLDB_EXTERNAL_RPC_PORT` environment variable in the file.

   The value for this environment variable is the port to use for CLDB.

   For example:

   ```
   export CLDB_EXTERNAL_RPC_PORT=5000
   ```

   This is especially useful if MapRMapR Data Platform is installed in a Docker container or other guest hosts. If this is not set, CLDB must be reachable on the default port 7222.
3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.
4. Ensure that the mapr-clusters.conf file on the client host(s) contains the correct port number for CLDB.

Note: After setting this environment variable, make sure that `cldb.feature.external.ip` is enabled if you upgraded from a prior version of MapR to v6.0. For more information on enabling this feature, see Step 4: Enable New Features on page 330.

Specifying Port for MAST Gateway

The default port for MAST Gateway is *8660*. If you want to use another port:

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the MAST Gateway host(s). If the env_override.sh file is not present, you might have to create it. See About env_override.sh on page 2290.
2. Set the value for the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable in the file.

   The value for this environment variable is the port to use for MAST Gateway.

   For example:

   ```
   export MASTGATEWAY_EXTERNAL_RPC_PORT=15000
   ```

   If this is not set, MAST Gateway must be reachable on the default port *8660*.
3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

Specifying Ports for ZooKeeper

If ZooKeeper is not available on the default port or if all the ZooKeepers are listening on the same external IP address (such as in a Docker container), you can specify the port on which to reach each ZooKeeper. To specify the port on which to reach each ZooKeeper, during cluster configuration:

- Run the configure.sh utility with the `-EZ` option.

  The value for the `-EZ` option is a comma-separated list of external IP addresses of the ZooKeeper nodes and the port (for each IP address), separated by a colon, on which ZooKeeper can be reached. For example:

  ```
  /opt/mapr/server/configure.sh -C <IP|Hostname>[,<IP|Hostname>,...] -Z <IP|
  Hostname>[,<IP|Hostname>,...] \
  -EZ <IP|Hostname>:<Port>[,<IP|Hostname>:<Port>,...]
  ```

For example, you can specify:

- Different ports when the same external IP address is used for all ZooKeeper nodes as shown below:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172,17.0.3,172.17.0.4 -Z
172.17.0.2,172,17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.10.104.34:5182,10.10.104.34:5183 -N
my.cluster.com
```

- Same ports when different IP addresses are specified for ZooKeeper nodes:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172,17.0.3,172.17.0.4 -Z
172.17.0.2,172,17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.20.105.34:5181,10.30.106.34:5181 -N
my.cluster.com
```

Configuring MR AppMaster Port Mapping

1. Set the `yarn.app.mapreduce.am.job.client.port-range` parameter in the yarn-site.xml file to specific range of free ports in all the NodeManager nodes.

   Specify the range of ports that the MapReduce AppMaster can use when binding. Do not specify a value for this parameter if you want all possible ports. For example:

   ```
   50000-50050,50100-50200
   ```

   Note: Each Docker instance where NodeManager is running should have different range and the range should be different across all NodeManager nodes.

   For example:

   ```
   The yarn-site.xml file in docker container 1:
   <property>
           <name>yarn.app.mapreduce.am.job.client.port-range</name>
           <value>50000-50050</value>
   </property>
   The yarn-site.xml file in docker container 2:
   <property>
           <name>yarn.app.mapreduce.am.job.client.port-range</name>
           <value>50100-50150</value>
   </property>
   The yarn-site.xml file in docker container 3:
   <property>
           <name>yarn.app.mapreduce.am.job.client.port-range</name>
           <value>50151-50200,50250-50300</value>
   </property>
   ```

2. Set the port forwarding rules in host machine for these specific ranges.

   For example, if NM1 contains ranges from 50000 to 50050, then set the IP table rules such that when requests come on these ports, it is forwarded to NM1.

3. Specify the AWS or Docker host name for the IP address in the `/etc/hosts` file on the client system so that external clients can resolve Docker or AWS hostname properly when running the jobs.

   For example, your entry in the `/etc/hosts` file should look similar to the following:

   ```
   54.208.145.112 ip-10-10-0-103.ec2.internal
   ```

Working with a Logical Volume Manager
Explains the role and usage of a Logical Volume Manager.

The Logical Volume Manager creates symbolic links to each logical volume's block device, from a directory path in the form:

```
/dev/<volume group>/<volume name>
```

MapR needs the actual block location, which you can find by using the `ls -l` command to list the symbolic links.

1. Make sure you have free, unmounted logical volumes for use by MapR:
   - Unmount any mounted logical volumes that can be erased and used for MapR.
   - Allocate any free space in an existing logical volume group to new logical volumes.
2. Make a note of the volume group and volume name of each logical volume.
3. Use `ls -l` with the volume group and volume name to determine the path of each logical volume's block device. Each logical volume is a symbolic link to a logical block device from a directory path that uses the volume group and volume name:

   ```
   /dev/<volume group>/<volume name>
   ```

   The following example shows output that represents a volume group named `mapr` containing logical volumes named `mapr1, mapr2, mapr3,` and `mapr4`:

   ```
   ls -l /dev/mapr/mapr*
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr1 -> /dev/mapper/
   mapr-mapr1
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr2 -> /dev/mapper/
   mapr-mapr2
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr3 -> /dev/mapper/
   mapr-mapr3
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr4 -> /dev/mapper/
   mapr-mapr4
   ```

4. Create a text file `/tmp/disks.txt` containing the paths to the block devices for the logical volumes (one path on each line). Example:

   ```
   cat /tmp/disks.txt
    /dev/mapper/mapr-mapr1
    /dev/mapper/mapr-mapr2
    /dev/mapper/mapr-mapr3
    /dev/mapper/mapr-mapr4
   ```

5. Pass `disks.txt` to disksetup.

Tuning for SSDs
Lists the parameters to tune for optimal SSD performance.

On servers with SSDs:

1. Enable TRIM operation in the `mfs.conf` file, if recommended by the SSD vendor.

   By default, TRIM is disabled. To enable, set the value for `mfs.ssd.trim.enabled` to 1 in the `mfs.conf` file. For example:

   ```
   mfs.ssd.trim.enabled=1
   ```

2. Disable IO throttling in the `mfs.conf` file.

   To disable, set the value for `mfs.disk.iothrottle.count` to 50000. The default value for `mfs.disk.iothrottle.count` is 100. For example:

   ```
   mfs.disk.iothrottle.count=50000
   ```

3. Create storage pool with multiple SSDs (so that the throughput is less than 2GB/sec).

   Note: Create one storage pool per SSD only if the device is high-end.

   To create, run `disksetup`:

   ```
   /opt/mapr/server/disksetup -W <n> disks.txt
   ```

   For example, to create a storage pool with 2 SSDs, run the following command:

   ```
   /opt/mapr/server/disksetup -W 2 disks.txt
   ```

   For more information, see `disksetup` on page 2092.

Administering Volumes

This section provide information about how to organize and manage data using volumes, a unique feature of MapR clusters.

MapR provides volumes as a way to organize data and manage cluster performance. A volume is a logical unit that allows you to apply policies to a set of files, directories, and sub-volumes. You can use volumes to enforce disk usage limits, set replication levels, establish ownership and accountability, and measure the cost generated by different projects or departments. Create a volume for each user, department, or project.

You can mount volumes under other volumes to build a structure that reflects the needs of your organization. Sub-volumes are created by mounting a volume in a sub-directory of an already mounted volume. This establishes a parent-child relationship between the volumes whereas the parent volume is mounted in top-level directory and the child volume is mounted in the sub-directory. The volume structure defines how data is distributed across the nodes in your cluster. Create multiple small volumes with shallow paths at the top of your cluster's volume hierarchy to spread the load of access requests across the nodes.

A well-structured volume hierarchy is an essential aspect of your cluster's performance. As your cluster grows, keeping your volume hierarchy efficient maximizes data availability. Cluster performance is negatively affected when a volume structure is not in place.

The Control System **Volumes** page under **Data** contains the following tabs:

- Summary
- Snapshots
- User Disk Usage

last-updated: Apr 11, 2022

- Schedules
- Storage Policies
- Remote Targets

Managing Data with Volumes

Provides an overview of how to manage volume data.

The **Summary** tab in the **Volumes** page displays the following panes:

- Top Volume Utilization — Volumes that use the most amount of disk space.
- Active Alarms — List of active volume alarms on the cluster.
- Local and Remote Tier Storage utilization.
- Volumes — List of volumes.

The page includes the **Create Volume** button to create standard or (local and/or remote) mirror volumes. You can perform the following procedures to manage volumes on the MapR cluster using the Control System and the CLI.

Viewing the List of Volumes
Explains how to view the list of volumes either through the Control Panel or the CLI.
Viewing All the Volumes Using the Control System

- Log in to the Control Panel and click **Data** > **Volumes** > **Summary.**.

  Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

  The **Volumes** pane in the **Summary** tab (under **Data** > **Volumes**) displays the volumes in the cluster.

  Note: By default, system volumes are not displayed. If you wish to view system volumes also, select the **Include System Volumes** checkbox.

  If you are in another view, select **All Volumes** from the drop-down menu in the **Volumes** pane. Up to 10 volumes, sorted by name, are displayed in each page. For each volume, the pane displays the following information, by default:

Column Name	Column Description
Volumes	The name of the volume (used for default sorting).
Data Tiering	Whether volume is enabled or disabled for data tiering.
Alarms	The number of alarms associated with the volume. Hover the cursor over the number for information on the alarm including alarm name, severity, and time when the alarm was raised.
Mnt	Specifies whether (✓) volume is mounted.
Type	The type of volume. Both standard and mirror volumes are displayed.
Mount Path	The path where the volume is mounted.
Creator	The user or group that owns the volume.

last-updated: Apr 11, 2022

Column Name	Column Description
Quota	The amount of disk space allocated and utilized by the volume and associated snapshots and the cluster reserve limit (in red). If quota is not set, displays option to **Set Quota**.
Total Size	The total physical size of the volume and associated snapshots. When you move the cursor over the value, the popover shows the total logical size (**Data Size**), the logical size of the volume (**Volume Size**), and the logical size of the snapshots (**Snapshot Size**).
RF	The replication factor that specifies the number of copies for the volume.
Physical Topology	The rack path to the volume.

You can sort the list by volume name, mount, mount path, or creator.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- Edit the selected volume(s)
- Remove the selected volume(s)
- Create snapshot(s) of the selected volume
- Change the selected mirror volume(s) to standard volume(s)
- Start the mirroring operation(s) for the selected mirror volume(s)
- Stop the mirroring operation(s) for the selected mirror volume(s)
- Mount the selected volume(s)
- Unmount the selected volume(s)
- Offload selected volume(s)
- Recall selected volume(s)
- Abort currently running tiering job for selected volume(s)

Viewing the List of Standard Volumes Using the Control System

The **Volumes** pane in the **Summary** tab under **Data** > **Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays all the volumes in the cluster by default. To view a list of only the standard volumes:

- Select **Standard Volumes** from the drop-down menu in the **Volumes** pane.

  The list of standard volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the page displays the following information by default:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Alarms	The number of alarms associated with the volume. You can view the **Active Alarms** pane for more information on the alarms associated with a volume.
Mnt	Specifies whether the volume is mounted.

last-updated: Apr 11, 2022

Column Name	Description
Type	The type of volume. Only standard volumes are displayed.
Mount Path	The path where the volume is mounted.
Data Tiering	Whether volume is enabled or disabled for data tiering.
Creator	The user or group that owns the volume.
Quota	The amount of disk space allocated and utilized by the volume and associated snapshots and the reserve limit (in red). If quota is not set, displays option to **Set Quota**.
Total Size	The size of the volume and associated snapshots.
RF	The replication factor that specifies the number of copies for the volume.
Physical Topology	The rack path to the volume.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- Edit the selected volume(s)
- Remove the selected volume(s)
- Create snapshot(s) of the selected volume
- Mount the selected volume(s)
- Unmount the selected volume(s)

Viewing the List of Mirror Volumes Using the Control System

The **Volumes** pane in the **Summary** tab under **Data** > **Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of only the mirror volumes:

- Select **Mirror Volumes** from the drop-down menu in the **Volumes** pane.

  The list of mirror volumes in the cluster displays. By default, the list is sorted by volume name and the following columns are displayed:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Alarms	The number of alarms associated with the volume. You can view the **Active Alarms** pane (above) for more information on the alarms associated with a volume.
Mnt	Specifies whether the volume is mounted.
Source Volume	The source volume name for the mirror volume.
Source Cluster	The source cluster name for the mirror volume.
Originating Cluster	The originating cluster for the data being mirrored.
Originating Volume	The originating volume for the data being mirrored.
Mirror Status	The status of the last mirroring operation.
Percentage Complete	The percentage of the in-progress mirroring operation that has been completed.

last-updated: Apr 11, 2022

Column Name	Description
Data Tiering	Whether or not the volume is enabled or disabled for data tiering.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- Edit the selected volume(s)
- Remove the selected volume(s)
- Create snapshot(s) of the selected volume
- Change the mirror volume to a standard volume
- Start the mirroring operation(s) for the selected mirror volume(s)
- Stop the mirroring operation(s) for the selected mirror volume(s)
- Mount the selected volume(s)
- Unmount the selected volume(s)

Viewing the List of Tiered Volumes Using the Control System

The **Volumes** pane in the **Summary** tab of the **Data** > **Volumes** page (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of tiered standard and mirror volumes:

- Select **Tiered Volumes** from the drop-down menu in the **Volumes** pane.

  The list of tiered standard and mirror volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the pane displays the following information, by default:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Offload Tier	The name of the tier where the volume data is stored.
Job	The tiering operation that is currently running or was last performed on the volume. Value can be one of the following: • Offload — if volume data was offloaded or is currently being offloaded • Abort — if volume data offload or recall operation was aborted or is being aborted • Recall — if volume data was recalled or is being recalled from the tier
State	The status of the job.
Progress	The job completion percentage.
Start Date/Time	The date and time when the job was started.
End Date/Time	The date and time when the job completed.
Offload Speed	The amount of data (in MB) offloaded or being offloaded per second.

last-updated: Apr 11, 2022

Column Name	Description
Recall Speed	The amount of data (in MB) recalled or being recalled per second.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- Edit selected volume(s)
- Remove selected volume(s)
- Create snapshot(s) of selected volume(s)
- Change the mirror volume to a standard volume
- Start the mirroring operation(s) for the selected mirror volume(s)
- Stop the mirroring operation(s) for the selected mirror volume(s)
- Mount selected volume(s), if they are not already mounted
- Unmount selected volume(s), if they are currently mounted
- Offload selected volume(s)
- Recall selected volume(s)
- Abort currently running tiering job for selected volume(s)

Retrieving the List of Volumes Using the CLI and REST API

The basic command to retrieve the list of volumes is:

```
maprcli volume list
```

For complete reference information, see `volume list` on page 1979.

Customizing the List of Columns/Fields
Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.
Customizing the Columns in the Control System

1. Log in to the Control System and go to:
   - **Data** > **Volumes** page to customize columns displayed in the **Volumes** pane.

     Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** page to customize columns displayed in the **Nodes** pane.

     Note: The **Nodes** page is not available on the Kubernetes version of the Control Panel.

2. Click the **Customize Columns** icon ( ).
   In the **Customize Columns** dialog, the:
   - **Available** list displays the columns that are available for display.
   - **Selected** list displays the columns currently displayed in the pane.

last-updated: Apr 11, 2022

3. Select the columns from the:
   a) Available list of columns and click ▶ to move selection to **Selected** columns (for display).
   b) Selected list of columns and click ◀ to remove selected columns from displaying.
4. (Optional) Click ^ and/or down ⌄ arrows to sort the order of columns.
5. Click **Save Changes** for the customization to take effect.

   Tip: To reset the display to its default columns, click **Reset to default columns**.

Customizing the Fields Using the CLI or REST API

Use the `-column` parameter with the `maprcli` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

  ```
  maprcli node list -columns service,health
  ```

  For complete reference information, see the `node list` `on page 1705` command.

- To view the volume name for the list of volumes being retrieved, run the following command:

  ```
  maprcli volume list -columns volumename
  ```

  For complete reference information, see `volume list on page 1979` command.

Reverting to Default List of Columns
Describes how to revert to the default list of columns on the Control System

1. Log in to the Control System and click:
   - **Data** > **Volumes** to revert to the default list of columns in the **Volumes** pane.

     Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** to revert to the default list of columns in the **Nodes** pane.

     Note: The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Click the **Customize Columns** icon ( ) .
3. Click **Reset to default columns**,
4. Click **Save Changes**.
   The pane displays the default list of columns.

Filtering the List of Volumes
Explains how to filter the list of volumes using either the Control System or the CLI.

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

Filtering on the Control System

1. Log in to the Control System and click **Data** > **Volumes** to filter volumes in the **Volumes** pane.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select one of the following options from the **Add Filter** drop-down menu:
   - Volume — to filter the list by volume name
   - Usage — to filter the list by amount of disk used
   - Mount Path — to filter the list by mount path
   - Creator — to filter the list by entity or volume owner
   - Total Size — to filter the list by size of volume
   - Replication Factor — to filter the list by replication factor
   - Physical Topology — to filter by the rack path
   - Tier Type - to filter by a type of tier
   - Quota — to filter by hard quota
   - Data on Wire Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for on-wire encryption
   - Data at Rest Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for data-at-rest encryption (DARE)
   - Last Access Time - to filter by the Last Access Time
   - Coalesce Interval - to filter on the coalesce interval
3. Specify the value in the drop-down field for the selected filter (by which to filter the list of volumes) and click **Filter**.

   As you make selections and specify the filtering criteria, the pane displays only the volumes that match the specified filtering criteria.
4. Click:
   - **Add Filter** to add another filtering criteria.
   - ✕ to remove a filtering criteria.
   - 🗑 to clear all filter settings.

Filtering Using the CLI

The `volume list on page 1979` command can be used with the `-filter` option, which let you specify large numbers of volumes by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all volumes whose owner is *root* and whose name begins with *test* as follows:

```
maprcli volume list -filter [n=="test*"]and[on=="root"]
```

For more information, see Filters on page 1526.

last-updated: Apr 11, 2022

Creating a Volume
Describes volume types, and illustrates how to create volumes using either the Control System, CLI, or the REST API.

You can create a new (Standard or Mirror) volume using the Control System, the CLI or the REST API.

Creating a Volume Using the Control System

To create a new (Standard or Mirror) volume using the Control System:

1. Go to **Data** > **Volumes** and click **Create Volume**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   The **Create New Volume** page displays.

2. Select the **Volume Type** under **SETTINGS** in the **Properties** tab. Choose:
   - **Standard Volume** to create a read-write volume.
   - **Mirror Volume** to create a volume that is a read-only copy of a source volume.

     Tip: See also: Mirror Types on page 464.

3. Specify the following required settings in the **Properties** tab:

Standard Volume

Volume Name	Enter a name for the volume. The name should contain only the following characters: `A-Z a-z 0-9 _ - .` **Note:** • The volume name should not begin with `mapr.` because `mapr.` is used for system volumes. If you use `mapr.` at the start of the volume name, the volume may not display in the default view of the list of volumes on the Control System; you must select the **Include System Volumes** checkbox in the **Volumes** pane to view volumes with names beginning with `mapr`. • For tiering-enabled volumes, volume name should not exceed ninety-eight characters.
Accountable Entity	Select the type of *accountable entity (AE)* and enter the name of the entity in the associated text field.

Steps 4 to 8 are optional and allow you to define optional volume properties (for auditing, replication, and data tiering), volume access, and volume quota.

last-updated: Apr 11, 2022

If these are not defined, default values, where available, are used. You can skip to:

- (Optional) Step 9 to associate a snapshot schedule and/or an offload schedule with the volume.
- Step 10 to create the volume with basic settings.

Mirror Volume

Volume Name	Enter a name for the volume. The name should contain only the following characters: `A-Z a-z 0-9 _ - .`  **Note:** Do not begin the volume name with `mapr.` as `mapr.` is used for system volumes. If you use `mapr.` at the start of the volume name, the volume may not display in the default view of the list of volumes on the Control System; you must select the **Include System Volumes** checkbox in the **Volumes** pane to view volumes with names beginning with `mapr.`.

Source Volume Cluster	Enter the name of the cluster on which the source volume exists. The name should contain only the following characters: `A-Z a-z 0-9 _ - .` Mirroring only works between two secure clusters or between two non-secure clusters. Mirroring does not work when one cluster is secure and the other is non-secure.  **Note:** When setting up mirror volumes for mirroring between clusters, for the mirroring operation to run successfully, servers in one cluster cannot use the same IP addresses as servers in the other cluster. For example, if node A in cluster A has a private IP address of 10.10.20.29, no server in cluster B can have the same private IP address. Also, all the servers in destination cluster must be able to reach all the servers in the source cluster and vice versa. For example, suppose 10.10.20.29 is the only IP address used by node A in cluster A; then all servers in cluster B should be able to reach the IP address 10.10.20.29.

last-updated: Apr 11, 2022

Source Volume Name	Enter the name of the source volume, from which the mirror volume pulls data, (after selecting the source volume cluster). The name should contain only the following characters: `A-Z a-z 0-9 _ - .` If the source volume is on: • The same cluster, you must create a local mirror volume, which is useful for load balancing or for providing a read-only copy of a data set. See Local Mirroring on page 465 for more information. • Another cluster, you must create a remote mirror volume, which is useful for offsite backup, for data transfer to remote facilities, and for load and latency balancing. See Creating Remote Mirrors on page 880 for more information. **Note:** If you plan to enable tiering for the mirror volume, ensure that the selected source volume is also tiering-enabled. You cannot create tiering-enabled mirror volumes to mirror data in standard volumes that are not tiering-enabled. For information on setting up mirror cascades, see Mirror Cascades on page 466.

last-updated: Apr 11, 2022

Accountable Entity	Select the type of *accountable entity (AE)* and enter the name of the entity in the associated text field.

Steps 4 to 8 are optional and allow you to define optional volume properties (for auditing and replication), volume access, and volume quota. If these are not defined, default values, where available, are used. You can skip to:

- (Optional) Step 9 to associate a mirroring schedule, a snapshot schedule, and/or an offload schedule with the mirror volume.

  The mirroring schedule specifies how often to run the mirroring operation, which copies data (that has changed at the file-block level since the last data transfer) directly from the source, even if the files in the source volume are being written to or deleted.

  The snapshot schedule specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirroring operation.

  The offload schedule specified how often to offload data in the volume to the configured tier based on the criteria in the storage policy.

- Step 10 to create the mirror volume with basic settings.

4. (Optional) Specify the following general and auditing settings under **Properties**:

Mount	Specifies whether to automatically mount (**Yes**) or not mount (**No**) the volume after creation. By default, volumes are mounted immediately after creation. If this is set to **Yes**, you must also specify the mount path.
Mount Path	The path to mount the volume. This is required if the value for **Mount** is **Yes**. **Note:** The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).
Data Tier	Specifies whether (**Yes**) or not (**No**) to enable data tiering for volume.
Collect Metrics	Specifies whether (**Yes**) or not (**No**) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1300 and Enabling Volume Metric Collection on page 1301.
Volume Access	Specifies whether the volume is read-only or read/write volume. Data on a read-only volume can only be read and data can both be read from and written to a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.

last-updated: Apr 11, 2022

Enable Auditing	Select one of the following: • Disable auditing • Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume • Enable auditing of operations on all files, tables, and streams in the volume whether or not auditing is enabled for files, tables, and streams in the volume.
Coalesce Interval	The interval of time (in minutes) to use when logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled. The default value is 60 minutes.
Data on Wire Encryption	Specifies whether (**Yes**) or not (**No**) to encrypt data in the volume during transmission. By default, the value is **Yes** for all new volumes on a secure cluster. This parameter is not supported on unsecure clusters.
Data at Rest Encryption	Specifies whether (**Yes**) or not (**No**) to encrypt data-at-rest. This is not supported on unsecure clusters.

5. (Optional) Specify the following under **Properties** for volume (hot) data replication.

Topology	The rack path to the volume. The default topology is `/data`.
Optimize Replication for	The basis for the replication factor: • High throughput, or cascading replication, where volumes are replicated sequentially on intermediate and tail containers. • Low latency, or star replication, where volumes are replicated on multiple containers in parallel. The default value is high throughput. See Selecting a Replication Type for High Availability on page 909.
Replication	The minimum (**Minimum Replication**) and desired (**Target Replication**) number of copies for the volume data. The default minimum is 2, and the default target is 3.
Name Container Replication	The (**Minimum Replication**) and desired (**Target Replication**) number of copies for the name container associated with the volume. The default minimum is 2, and the default target is 3.
Guarantee Min Replication	Specifies whether (**Yes**) or not (**No**) to enforce minimum number of copies. If this is enabled (**Yes**), writes succeed only when the minimum number of copies exist. If this is enabled (**Yes**) and minimum number of copies are not available, the client is asked to retry. For more information, see Understanding Replication on page 454.

6. (Optional) If data tier is enabled (**Yes**), select one of the following, and set values for associated properties.

Erasure Coding (Warm)	For offloading data to an erasure coded volume, specify values for the following properties. If values are not specified, default values are applied.

Topology	The topology of the erasure coded volume from the drop-down list.
Storage Policy	The rule for offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See steps 3 - 5 in the Creating a Storage Tier Policy on page 972 topic for more information. If you do not select a storage policy, the default policy named `default.ectier.rule`, which is all files (p), is associated with the volume.

Erasure Coding	The erasure coding scheme, which is the number of data chunks and number of parity chunks. You can select one of the following from the **Scheme** drop-down menu: • 3,2 — for 3 data chunks and 2 parity chunks. You must have 5 or more nodes on the cluster for this option. If selected, this has 60% storage overhead and can tolerate failure of up to 2 nodes. • 4,2 — for 4 data chunks and 2 parity chunks. You must have 6 or more nodes on the cluster for this option. If selected, this has 50% storage overhead and can tolerate failure of up to 2 nodes. • 5,2 — for 5 data chunks and 2 parity chunks. You must have 7 or more nodes on the cluster for this option. If selected, this has 40% storage overhead and can tolerate failure of up to 2 nodes. • 6,3 — for 6 data chunks and 3 parity chunks. You must have 9 or more nodes on the cluster for this option. If selected, this has 50% storage overhead and can tolerate failure of up to 3 nodes.  **Note:** Although you can create a volume even if the required number of nodes are not present, offload operation fails if the required number of nodes are not present. See Erasure Coding Scheme for Data Protection and Recovery on page 926 for more information.

last-updated: Apr 11, 2022

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, specify values for the following properties.

Remote Target	The location to offload data to. You can click: • **Browse** to select an existing tier. • **Create** to create a new tier. See Creating a Storage Tier on page 958 for more information.
Storage Policy	The rule for offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See Creating a Storage Tier Policy on page 972 for more information.
Retention Duration after Recall	The number of days to retain data recalled from the tier to the MapR cluster. Once the number of days is reached, recalled data on the MapR cluster is purged (if there are no changes), or offloaded (if there are changes).
Tier Encryption	Specifies whether (**Yes**) or not (**No**) to enable encryption of data on the tier. This cannot be modified once it is set. The default value is **No** (disabled).

7. (Optional) Specify the following volume (administrative and user) access control settings in the **Authorization** tab:

<table>
<tr>
<td>ADMINISTRATIVE CONTROLS</td>
<td>
The users and/or groups that have one or more of the following permissions:
<table>
<tr><td>Dump & Backup</td><td>Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.</td></tr>
<tr><td>Restore & Mirror</td><td>Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.</td></tr>
<tr><td>Edit</td><td>Edit volume properties, create and delete snapshots.</td></tr>
<tr><td>Delete</td><td>Delete the volume.</td></tr>
<tr><td>Admin</td><td>View and edit access control settings (but cannot perform volume operations).</td></tr>
<tr><td>Full Control</td><td>Perform all volume-related administrative operations except changing access control settings.</td></tr>
</table>
To define administrative access control settings for another user or group, click Add Another.
Note: To perform this action from the command line, refer to acl set on page 1531.
By default, the root user and the volume creator have full control permissions on the volume.
<table>
<tr><td>Root Directory Permission</td><td>Set read, write, and/or execute permissions on the root directory for users, groups and others.</td></tr>
</table>
</td>
</tr>
</table>

USER ACCESS CONTROLS	The users, groups, and/or roles that have and/or do not have access to read and/or write to the volume. To grant or block access to users, groups, and/or roles, from the: • Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions. **Tip:** Click to create a copy of the associated access control setting. Click to remove the associated access control expression. To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step. • Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions: • ! — Negation operator. • & — AND operation. • | — OR operation. Use ( ), parentheses, for subexpressions. **Note:** You *cannot* specify user, group, or role individually if access is granted to all users (public). Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information. **Note:** If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings. By default, access is granted to all users (public). If access is granted to all users (public), access *cannot* also be granted individually to users, groups, and/or roles.

8. Define the amount of disk space (optional) in megabytes (MB), gigabytes (GB), or terabytes (TB) to allocate to the volume in the **Usage** tab:

   By default, there is no limit on the disk space.

   Warning: If the quota set for the mirror volume is less than the quota set for its source volume, the CLDB raises an alarm. The mirroring operation does not fail, but you must decide whether to add space and increase the mirror volume quota, or remove unwanted space from the source volume and decrease its quota.

Advisory Quota	An alarm is raised when this limit is reached.

last-updated: Apr 11, 2022

Hard Quota	Writes are not allowed when this limit is reached. When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes fail after you write 1GB of data whether or not the volume data is local (on the cluster), or offloaded (to the tier).

Note: The value for advisory quota cannot be greater than the value for hard quota.

The graph shows the currently used (across volumes), reserve limit (which is 90% of the total disk space on the cluster), and total amount of disk space at the cluster level.

9. (Optional) From the **Schedule** tab, select the schedule(s) to associate with the volume.

Standard Volume

You can click **Browse** to select an existing schedule, or click **Create** to create a schedule, for the following:

Snapshot Schedule	The snapshot schedule specifies when snapshots should be automatically created. If you do not define this schedule, snapshots are not created for this volume. Each snapshot created by a schedule has an expiration date that determines how long the snapshot is retained.
Tier Offload	The tier offload schedule specifies the frequency for automatically offloading data in the volume to the configured tier. This is only available for tiering enabled volumes.

Mirror Volume

You can click **Browse** to select an existing schedule, or click **Create** to create a schedule for the following:

last-updated: Apr 11, 2022

Snapshot Schedule	The snapshot schedule specifies how often to take a snapshot of the mirror volume to preserve the state of the mirror before a subsequent mirror operation. If corrupt data is copied from the source volume's snapshot into the mirror volume, you can roll back the mirror contents to the snapshot. Each snapshot created by a schedule has an expiration date that determines how long the snapshot is retained.
Mirror Schedule	The mirror schedule specifies how frequently the mirror volume must be synchronized with the source volume. If a disaster (or any type of data loss on a read-write source volume) occurs, the data can be recovered from the mirror volume, but any data written to the source volume since the last successful mirror operation is not on the mirror volume. Therefore, you should set the mirror schedule such that it meets your Recovery Point Objective (RPO). **Tip:** For best performance, select a mirroring schedule according to the anticipated rate of data changes and the available bandwidth for mirroring. See also: Guidelines for Setting Mirror Schedules on page 955.

last-updated: Apr 11, 2022

Tier Offload	The tier offload schedule specifies the frequency for automatically offloading data in the volume to the configured tier. This schedule is available only for tiering enabled volumes.

When selecting a schedule, you can choose your custom schedule if it exists, or one of the (following) defaults:

- Critical data
- Important data
- Normal data
- Automatic Tiering Scheduler (available only for tiering-enabled volumes)

10. Click **Create Volume** to create the volume.

- If you created a remote mirror, edit the `mapr-clusters.conf` file so that each cluster can resolve the nodes in the other cluster. For more information, see Setting Up Cross-Mirroring Between Unsecure Clusters on page 880.
- If the source volume at the primary datacenter is in a secure cluster, the destination cluster needs authorization to pull data from the source cluster in order to create a mirror volume. Authorization can be granted by means of a cross-cluster ticket generated by the source cluster administrator. For more information, see Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486.

Creating a Volume Using the CLI or the REST API

The basic command to create a volume is:

```
/opt/mapr/bin/maprcli volume create -name <name>
```

You can create a standard read-write volume, a (local or remote) mirror volume, and/or a tiering enabled standard read-write, and/or a (local or remote) mirror volume.

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

Standard Volume

The basic command to create a standard volume is:

```
/opt/mapr/bin/maprcli volume
create -name <volume name> -path
<volume path> -type rw
```

When creating and mounting a volume, the location of the mount point can be specified using the `path` parameter. The volume that is last in the `path` parameter is referred to as the parent volume. (The parent volume is the volume on which the volume link is created.)

For complete reference information, see `volume create` on page 1931.

Local Mirror Volume

1. Log in to the node on the cluster where you want to create the mirror.
2. Use the `volume create` command to create the mirror volume.

   Specify the `source` volume name, provide a `name` for the mirror volume, and specify the `type` as `mirror`. Optionally, associate a schedule with the volume. For example:

   ```
   /opt/mapr/bin/maprcli volume
   create -name volume-a -source
   volume-a -type mirror -schedule 2
   ```

   For complete reference information, see `volume create` on page 1931.

Remote Mirror Volume

1. Log in to the node on the cluster where you wish to create the mirror.
2. Use the `volume create` command to create the mirror volume.

   Specify the source volume and cluster in the format `<volume>@<cluster>`, provide a `name` for the mirror volume, and specify the `type` as `mirror`. Optionally, associate a schedule with the volume. For example:

   ```
   /opt/mapr/bin/maprcli volume
   create -name volume-a -source
   volume-a@cluster-1 -type
   mirror -schedule 2
   ```

   When creating and mounting a volume, the location of the mount point can be specified using the `path` parameter. The volume that is last in the `path` parameter is referred to as the parent volume. (The parent volume is the volume on which the volume link is created.)

   For complete reference information, see `volume create` on page 1931.
3. Ensure that each cluster can resolve the nodes in the other cluster.

   See:

   - Setting Up Cross-Mirroring Between Unsecure Clusters on page 880 for more information, if both the clusters are non-secure.
   - Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486 for more information, if both clusters are secure.

Tiering Enabled Volume	The basic command to create a tiering-enabled volume is the following: `/opt/mapr/bin/maprcli volume create -name <volName> -path <volmountpath> -tieringenable true`

For the complete list of supported parameters, see `volume create` on page 1931.

Creating Remote Mirrors
Describes the use of remote mirror volumes. The remote mirror volume is present on a different cluster from the source volume.

Creating remote mirrors is similar to creating local mirrors, except that the mirror volume resides in a different cluster from the source volume. To properly identify the source volume, you must specify the source cluster name when the mirror volume is created. In addition, you must edit the `mapr-clusters.conf` file so that each cluster can resolve the nodes in the other cluster.

To create a mirror on a remote cluster, you must have the same UID for the `MAPR_USER` (the cluster owner) for both the primary cluster (where the source volume resides) and the remote clusters (where the mirror volumes reside; also known as the destination clusters). You also need to have the following volume permissions:

- `dump` permission on the source volumes
- `restore` permission on the mirror volumes at the destination clusters

When a mirror volume is created on a remote cluster (according to the entries in the `mapr-clusters.conf` file), the CLDB checks that the local volume exists in the local cluster. If both clusters are not set up and running, the remote mirror volume cannot be created.

To summarize:

- Each cluster must be already set up and running.
- Each cluster must have a unique name.
- Every node in each cluster must be able to resolve all nodes in remote clusters, either through DNS or entries in `/etc/hosts`.
- The UID for the `MAPR_USER` (cluster owner) must be the same for the source and destination clusters, irrespective of which user account triggers the mirror operation.
- Volume permission must be set to `dump` on the source volumes.
- Volume permission must be set to `restore` on the mirror volumes.

See also: Remote Mirroring on page 465.

Setting Up Cross-Mirroring Between Unsecure Clusters
Describes how to edit the `mapr-clusters.conf` file to mirror volumes between unsecure clusters.

To mirror volumes between unsecure clusters, start by editing the `mapr-clusters.conf` on page 2200 file on the cluster of the source volume and create an entry for each additional cluster that hosts a mirror of the volume. The entry must list the name of the cluster, followed by a space-separated list of hostnames and ports for the CLDB nodes of the cluster. In addition, use the `secure` parameter to specify whether the clusters are secure or non-secure. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486 for more information about generating tickets for secure clusters.

Note: When mirroring between clusters, servers in one cluster cannot use the same IP addresses as servers in the other cluster. For example, if node A in cluster A has a private IP address 10.10.20.29, no server in cluster B can have the same private IP address. Also, all the servers in one cluster must be able to reach all the servers in the other cluster and vice versa. For example, suppose 10.10.20.29 is the only IP address used by node A in cluster A; then all servers in cluster B should be able to reach the IP address 10.10.20.29.

To set up cross-mirroring between unsecure clusters:

1. Review the requirements for Creating Remote Mirrors on page 880 before you begin.
2. On each cluster, make a note of the cluster name and CLDB nodes (the first line in `mapr-clusters.conf` on page 2200)
3. On each webserver and CLDB node, add the CLDB nodes of the remote cluster to `/opt/mapr/conf/mapr-clusters.conf`, using the following format:

   ```
   clustername1  <CLDB> <CLDB> <CLDB>
   [ clustername2  <CLDB> <CLDB> <CLDB> ]
   [ ... ]
   ```

   For example, suppose you have a cluster, `clusterA`, with two CLDB nodes, `nodeA` and `nodeB`. Now you want to add a second cluster called `clusterB` with CLDB nodes `nodeC` and `nodeD`. Edit the `mapr-clusters.conf` file and add the line for `clusterB` as shown:

   ```
   clusterA nodeA:7222 nodeB:7222
   clusterB nodeC:7222 nodeD:7222
   ```

   Warning: You must include the port number in the CLDB hostname notation.

   Here:

   a. First line contains cluster name and CLDB nodes of cluster A (the local cluster)

   b. Second line contains cluster name and CLDB nodes of cluster B (the remote cluster)

   The `mapr-clusters.conf` file for cluster B with 2 CLDB nodes (`nodeC` and `nodeD`) looks as follows:

   ```
   clusterB nodeC:7222 nodeD:7222
   clusterA nodeA:7222 nodeB:7222
   ```

   By creating additional entries in the `mapr-clusters.conf` file, you can mirror from one cluster to several others.
4. Set `secure=false` if both clusters are not secure. If both the clusters are secure, see Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486 for more information.

   Warning: Mirroring only works between two secure clusters or between two non-secure clusters. Mirroring does not work when one cluster is secure and the other is non-secure.
5. On each cluster, restart the `mapr-apiserver` service on all nodes where it is running.

Creating a Volume for a Tenant
Provides an overview of how to create a volume for a tenant using the CLI.

last-updated: Apr 11, 2022

To create a volume for a tenant (when you have Multitenancy on File System on page 488), do the following:

1. Log in to the cluster as administrator and ensure that the ticket for the tenant has already been generated and copied on to the tenant host.
   If necessary, follow steps in Generating a Ticket for a Tenant on page 1429 to set up the ticket for the tenant.
2. Create a volume for the tenant by running the following command:

```
$ maprcli volume create -name <volumeName> -path
<path_to_volume> -tenantuser <tenant_user>
```

Note: For more information, see the `maprcli volume create` command.

Viewing Volume Information
Describes how to view volume information using either the Control System or the CLI.

You can retrieve and view volume information using either the Control System or the CLI.

1. Log in to the Control System and go to the **Summary** tab in the **Data** > **Volumes** page.

   Note: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.
2. Click the volume name in the **Volumes** pane.
   The volume information page displays. On this page, you can perform the following actions based on the type of the volume.

Standard Volume	Click the **Select Action** drop-down menu to: • Edit the volume • Remove the volume • Snapshot a volume • Change the mount path and mount or unmount the volume • Convert the volume to a mirror volume • Rename the volume
Mirror Volume	Click the **Select Action** drop-down menu to: • Edit the Volume • Remove the volume • Snapshot a volume • Start/stop mirroring • Promote the volume to a standard (read/write) volume • Change volume mount information • Rename the volume
Tiering Volume	Click the **Select Action** drop-down menu to:

- Edit the Volume
- Remove the volume
- Snapshot a volume
- Change volume mount information
- Rename the volume
- Offload a volume to a tier
- Recall a volume from a tier
- Abort a volume tiering job

The page displays tabs for viewing:

- Summary of the volume including:
  - All recent and active volume alarms
  - Metrics (such as disk usage) for the volume
  - Volume details such as the general, auditing, and tiering settings for the volume, ACLs and ACEs on the volume, and volume quotas and schedules
- Snapshots associated with the volume

Viewing Volume Details

Describes how to retrieve and view volume information using either the Control System or the CLI.

Viewing Volume Details in the Control System

- Log in to the Control System and go to the **Summary** tab in the volume information page for the volume.

  You can view the following in the **Detail** pane:

Properties

Table

Created By	Indicates the user who created the volume.
Volume Type	Indicates the type of volume. Value can be one of the following: • Standard • Mirror
Volume Name	Indicates the name of the volume.
Accountable Entity	Indicates the name of the accountable entity.
Volume Access	Indicates the type of access allowed on the volume. Value can be one of the following: • Read/Write • Read-only

last-updated: Apr 11, 2022

Table (Continued)

Mounted	Indicates whether or not volume is mounted.
Mount Path	Indicates the mount path of the volume.
Data on Wire Encryption	Indicates whether (**Yes**) or not (**No**) on-wire encryption is enabled for the volume.
Data at Rest Encryption	Indicates whether (**Yes**) or not (**No**) data-at-rest encryption (DARE) is enabled for the volume.
Topology	Indicates the rack path to the volume.
Partially out of Topology	Indicates whether containers associated with the volume are outside the volume's main topology.
Last accessed	Indicates the date when the volume was last accessed.
Enable Auditing	Indicates whether auditing is enabled at the volume level.
Coalesce Interval	Indicates the interval of time (in minutes) used for logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled.

Table

Replication	Indicates the minimum (Min Target) and desired (Max Target) number of copies for the volume data.
Name Container Replication	Indicates the minimum (Min Target) and desired (Max Target) number of copies for the name container.
Optimize Replication	Indicates the basis for replication. Value can be one of the following: • High throughput, or cascading replication • Low latency, or star replication

Table (Continued)

Guarantee Min Replication	Indicates whether or not to enforce minimum number of copies.

Note: The following is visible only if warm tiering is enabled for the volume.

Table

Topology	Indicates the topology of the erasure-coded volume.
Remote Target	Indicates the name of the tier.
Storage Policy Name	Indicates the name of the storage policy.
Policy Detail	Indicates the rules in the policy for offloading data.
Retention Duration after Recall	Indicates the period of time to keep recalled data in the hot tier.
Erasure Coding Scheme	Indicates the number of data and parity chunks.
Tier Purged	Indicates the amount of offloaded data.

Note: The following is visible only if cold tiering is enabled for the volume.

Table

Remote Target	Indicates the name of the remote storage.
Storage Policy Name	Indicates the name of the storage policy.
Policy Detail	Indicates the rules in the policy for offloading data.
Retention Duration after Recall	Indicates the number of days to keep recalled data in the MapR cluster (hot tier).
Tier Purged	Indicates the amount of offloaded data.

last-updated: Apr 11, 2022

Authorization

ADMINISTRATIVE CONTROLS	Indicates the users and/or groups who: • Have admin access and/or full control on the volume. • Can perform one or more administrative operations such as create a dump file and backup the volume, restore and mirror the volume, edit the volume properties, and delete the volume.
USER ACCESS CONTROLS	Indicates the type of users — public, user, group, and/or role — that have and do not have access to volume data.

Usage

Quota	Indicates the amount of (advisory and hard) disk space allocated to the volume.
Graph	The graphs show: • **DISKUSAGE**: The total amount of disk space allocated for the volume and the amount of disk space used by the volume and associated snapshots. • **CLUSTER DISKSPACE**: The total amount of disk space on the cluster, the amount of disk space allocated and utilized by the volumes in the cluster, and the reserve limit.

Schedule

Snapshot Schedule	Indicates the schedule for automatically creating a snapshot of the volume for the purpose of preserving the state of the volume.

last-updated: Apr 11, 2022

Mirror Schedule	(Available only for mirror volumes) Indicates the schedule for automatically copying data (that has changed at the file-block level since the last data transfer) directly from the source volume to the mirror volume.
Offload Schedule	Indicates the schedule for automatically offloading data to the tier.

Viewing Volume Information Using the CLI or the REST API

The basic command to retrieve volume information is:

```
maprcli volume info (-name <volume_name> | -path <volume_path>)
```

You must specify either `name` or `path`, but not both. For complete reference for this command, see `volume info` on page 1965.

Viewing the list of Snapshots
Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

- The **Snapshots** tab under the **Data** > **Volumes** page displays all the snapshots on the cluster.

  For each snapshot, you can view the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	TBD

  You can select one or more snapshots to:

  - Preserve
  - Remove

Viewing the Snapshots Associated with a Volume Using the Control System

- Log in to the Control System and go to the **Snapshots** tab in the volume information page.

  The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.

last-updated: Apr 11, 2022

Column Name	Column Description
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	TBD

You can create a snapshot of the volume or select one or more snapshots to:

- Preserve
- Remove

Viewing Snapshots Using the CLI or REST API

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see `volume snapshot list` on page 2030.

Removing Volumes
Explains how to remove a volume using either the Control System or the CLI.

Note: When you remove a volume enabled for:

- Cold tiering, the directory/folder for the volume in the metadata volume associated with the tier is also removed asynchronously.
- Warm tiering, the directory/folder for the volume in the metadata volume associated with the tier and the erasure-coded volume are also removed asynchronously.

Removing Volumes Using the Control System

To remove one or more volumes, in the **Summary** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the volumes to remove from the list of volumes in the **Volumes** pane.

   Note: Alternatively, you can click the name of the volume to traverse to the volume details page.

2. Click **Remove Volume(s)** from the **Actions** drop-down menu.
   The **Remove Volume(s)** confirmation dialog displays.

3. Choose one of the following:

   - **Remove only if there are no dependent artifacts** — Specifies whether to check for dependencies before removing the volume. If the volume has dependencies, such as associated snapshots, the volume will not be deleted, but an alarm will be raised.

     Note: Volume will not be deleted if mirroring is in progress as the mirror volume is synchronized from a hidden internal snapshot of the source volume.

   - **Force remove even if there are dependent artifacts** — Indicates that volume must be removed forcefully, even if the volume has dependencies.

last-updated: Apr 11, 2022

4. Click **Remove Volume**.
   The selected volumes are removed.

Removing Volumes Using the CLI or REST API

The basic command to remove a volume is:

```
maprcli volume remove -name <volume name>
```

For complete reference information, see `volume remove` on page 2026.

Note: When a volume is removed, the data present in that volume is not purged from the filesystem immediately. The following parameters control when the deleted volumes are purged.

- `cldb.purge.delay.hours` — Time to wait (in hours) to trigger purge of any volume after CLDB becomes primary. The default value is 1 hour.
- `cldb.volumes.purge.frequency` — The frequency (in minutes) for purging the data of deleted volumes. The default value is 60 minutes.

  Use the `maprcli` command to set these parameters. For example:

  ```
  maprcli config save -values {"cldb.purge.delay.hours":"2"}
  maprcli config save -values {"cldb.volumes.purge.frequency":"120"}
  ```

Modifying Multiple Volumes

Explains how to modify volumes using either the Control System or the CLI.

Modifying Volumes Using the Control System

To edit multiple volumes, in the **Summary** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the volumes to edit in the **Volumes** pane and click **Edit Volume(s)** from the **Actions** drop-down menu.
   The **Edit Volumes** page displays. You can edit certain volume properties, authorization settings, usage settings, and schedule settings for the selected volumes.
2. Modify one or more of the following settings.

   Note: If the selected volumes share the same settings, the fields are pre-populated with the current value. If the selected volumes contain different settings, only the fields that have been set in all the selected volumes display.

last-updated: Apr 11, 2022

Properties

SETTINGS AND AUDITING	**Accountable Entity**	The *entity* accountable for this volume's usage.
	Collect Metrics	Specifies whether (**Yes**) or not (**No**) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1300 and Enabling Volume Metric Collection on page 1301.
	Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
	Enable Auditing	Select one of the following: • Disable auditing • Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume • Enable auditing of operations on all files, tables, streams in the volume whether or not auditing is enabled for files, tables, and streams in the volume.

REPLICATION (HOT)	**Replication**	Toggle Minimum Replication and set the desired and minimum number of copies of the volumes.
	Name Container Replication	Set the desired and minimum number of copies of the name container associated with the volumes.

Authorization

ADMINISTRATIVE CONTROLS	Users and groups that have permissions to perform administrative operations on this volume.

Usage

Volume Advisory Quota	Allocated disk space, which when exceeded raises an alarm but does not prevent writes.
Volume Hard Quota	Allocated disk space, which when exceeded prevents further writes.

Schedule

Snapshot Schedule	Schedule for creating snapshots of this volume.
Mirror Schedule	Schedule for running mirroring operation for the volumes.  **Note:** This is available only if all the selected volumes are mirror volumes.

 **Note:** To undo a change to a specific setting, click the associated . This action will revert the value to the current setting.

3. Click **Save Changes** for the changes to take effect.

Modifying Volumes Using the CLI or REST API

The basic command to modify a volume is:

```
maprcli volume modify -name <volume name>
```

For complete reference information including supported options, see `volume modify` on page 2005.

last-updated: Apr 11, 2022

Modifying a Volume
Describes how to edit a volume using either the Control System or the CLI.
Modifying a Volume Using the Control System

To modify a volume:

1. Log in to the Control System and go to the volume information page.
2. Click **Edit Volume** to display the **Edit Volume** page.
3. Modify one or more of the following general, auditing, and replication settings:

Standard Volume

SETTINGS AND AUDITING	**Accountable Entity**	The *entity* accountable for the volume's usage.
	Collect Metrics	Whether (**Yes**) or not (**No**) to enable metrics collection for the volume.
	Volume Access	Whether volume is a read-only or read/write volume.
	Enable Auditing	Select one of the following: • Disable auditing • Enable auditing for volume so that auditing can be enabled by directories, files, tables, and streams in the volume • Enable auditing of operations on all files, tables, streams in the volume whether or not auditing is enabled by files, tables, and streams in the volume.
	Coalesce Interval	Interval of time used when logging multiple instance of an operation on a node from a client IP, if auditing is enabled.
	Data on Wire Encryption	Whether (**Yes**) or not (**No**) to encrypt data in the volume during transmission. This is not supported on insecure clusters.

last-updated: Apr 11, 2022

HOT (REPLICATION)	**Topology**	The location of the volume in the cluster rack topology.
	Replication	Desired and minimum number of copies of the volumes.
	Name Container Replication	Desired and minimum number of copies of the name container associated with the volumes.

Mirror Volume

SETTINGS AND AUDITING	**Source Cluster Name**	The name of the cluster on which the source volume exists.
	Source Volume Name	The name of the source volume to mirror.
	Accountable Entity	The *entity* accountable for the volume's usage.
	Collect Metrics	Whether (**Yes**) or not (**No**) to enable metrics collection for the volume.
	Enable Auditing	Select one of the following: • Disable auditing • Enable auditing for volume so that auditing can be enabled by directories, files, tables, and streams in the volume • Enable auditing of operations on all files, tables, streams in the volume whether or not auditing is enabled by files, tables, and streams in the volume.
	Coalesce Interval	The interval of time to use when logging multiple instance of an operation on a node from a client IP, if auditing is enabled.
	Data on Wire Encryption	Whether (**Yes**) or not (**No**) to encrypt data in the volume during transmission. This is not

last-updated: Apr 11, 2022

REPLICATION (HOT)	**Topology**	The location of this volume in the cluster rack topology.
	Replication	Desired and minimum number of copies of the volume.
	Name Container Replication	Desired and minimum number of copies of the name container associated with the volume.

4. Set new (if **Data Tier** was enabled (**On**) during volume creation) or modify existing **DATA TIERING** settings.

Erasure Coding (Warm)

For offloading data to a warm tier, set new or modify existing values for the following properties.

Topology	The topology of the erasure coded volume from the drop-down list only if it is already not set.
Storage Policy	The rule (or criteria) for automatically offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See Creating a Storage Tier Policy Using the Control System on page 972 for more information.
Erasure Coding	The erasure coding scheme, which is the number of data chunks and number of parity chunks, only if it is already not set; you cannot modify existing scheme. See Erasure Coding Scheme for Data Protection and Recovery on page 926 for more information.

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, set new or modify existing values for the following properties.

Remote Target	The location to offload data to only if it is already not set; you cannot modify if it is already set. You can click: • **Browse** to select an existing tier. • **Create** to create a new tier. See Creating a Cold Tier Using the Control System on page 959 for more information.
Storage Policy	The rule (or criteria) for offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See Creating a Storage Tier Policy Using the Control System on page 972 for more information.
Retention Duration after Recall	The number of days to retain data recalled from the tier to the MapR cluster. Once the number of days is reached, recalled data on the MapR cluster is purged (if there are no changes) or offloaded (if there are changes).
Tier Encryption	The setting to enable (**Yes**) or disable (**No**) encryption of data on the tier only if it is already not set.

5. Make changes as needed to volume access.

ADMINISTRATIVE CONTROLS	Users and groups that have permissions to perform administrative operations on this volume. To: • Modify access to existing users, select or deselect permissions. • Grant access to another user, click **Add Another**, enter the user name, and select permissions to grant to the user.

last-updated: Apr 11, 2022

USER ACCESS CONTROLS	Specifies public or the users, groups, and/or roles that have and/or do not have access to read from and/or write to this volume. To grant or block access to users, groups, and/or roles, from the: • Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions. **Tip:** Click to create a copy of the associated access control setting. Click to remove the associated access control expression. To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step. • Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions: • ! — Negation operator. • & — AND operation. • | — OR operation. Use ( ), parentheses, for subexpressions. **Note:** You *cannot* specify user, group, or role individually if access is granted to all users (public). Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs on page 1473 for more information. **Note:** If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

6. (Optional) Modify volume quota as needed.

Volume Advisory Quota	Allocated disk space, which when exceeded raises an alarm but does not prevent writes.
Volume Hard Quota	Allocated disk space, which when exceeded prevents further writes.

7. (Optional) Add or modify schedule(s) as needed.

Standard Volume

Snapshot Schedule	Schedule for creating snapshots of the volume.

last-updated: Apr 11, 2022

Tier Offload Schedule	Schedule for offloading data to the storage tier. This is available only if volume is enabled for storage tiering.

Mirror Volume

Snapshot Schedule	Schedule for creating snapshots of this volume.
Mirror Schedule	Schedule for automatically synchronizing (mirroring) this volume with the source volume.
Tier Offload Schedule	Schedule for offloading data to the storage tier. This is available only if volume is enabled for storage tiering.

8. Click **Save Changes** for the changes to take effect.

Modifying a Volume Using the CLI or REST API

CLI

The basic command to modify a volume is:

```
maprcli volume modify -name <volume
name>
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<hostname>:8443/
rest/volume/modify?name=<volume
name>' --user mapr:mapr
```

For the complete list of editable parameters, see `volume modify` on page 2005.

Renaming a Volume

Describes how to rename a volume using the Control System, CLI or the REST API.

If you rename a volume, you must unmount and re-mount the volume to allow applications and/or users to continue accessing the volume.

Renaming a Volume Using the Control System

1. Log in to the Control System and go the volume information page.
2. Click **Rename Volume** from the **Select Action** drop-down menu to display the **Rename Volume** window.
3. Enter the new name for the volume in the **New Volume Name** field and click **Save Changes** for the changes to take effect.

   Note: For tiering-enabled volumes, volume name cannot exceed ninety-eight characters.

last-updated: Apr 11, 2022

Renaming a Volume Using the CLI and REST API

CLI

The basic command to rename a volume is:

```
maprcli volume rename -name
<oldName> -newname <newName>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/volume/rename?
name=<oldName>&newname=<newName>' --us
er mapr:mapr
```

See `volume rename` on page 2026 for more information.

Specifying Volume Inheritance Using the CLI

Lists volume properties that can be inherited from other volumes.

Volumes can be mounted using the web console, the `maprcli` commands (volume create or volume mount), or the REST commands. If the mount point is specified while creating a volume, new volumes can inherit properties from the parent volume. Mirror volumes can also inherit properties from the source volume of the mirror.

Volume inheritance is a convenience that can only be used during volume creation.

The maprcli volume modify command can be used to change the volume inheritance settings of a volume. That is, you can toggle the flag (associated with `allowgrant`) that indicates whether a volume, as a parent volume, wants its properties to be inherited by default or not. When creating and mounting a volume, the location of the mount point can be specified using the `path` parameter. The volume that is last in the `path` parameter is referred to as the parent volume. (The parent volume is the volume on which the volume link is created.)

Inheritance applies during volume creation only. If the settings in the parent volume is modified after the child volumes are created, these modified properties do not propagate to the child volumes.

Inheritance

The following table shows the list of inheritable parameters that are (Yes) and are not (No) inherited by a:

- Mirror volume from the source volume on the same cluster
- Mirror volume from the source volume on a different cluster

Note: All (non-mirror) volumes inherit all the inheritable properties from the parent volume. For more information on the properties, refer to `volume create` parameters.

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
`advisoryquota`	Yes	Yes
`ae`	Yes	No
`aetype`	Yes	No
`allowgrant`	Yes	Yes
`allowinherit`	Yes	Yes
`auditenabled`	Yes	Yes

last-updated: Apr 11, 2022

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
coalesce	Yes	Yes
dare	Yes	Yes[1], No[2]
dataauditops	Yes	Yes
dbindexlagsecalarmthresh	Yes	Yes
dbrepllagsecalarmthresh	Yes	Yes
ecscheme	Yes	No

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
`wiresecurityenabled`	Yes	Yes

- [1] If destination cluster is also enabled for data-at-rest encryption, `dare` setting is inherited by the mirror volume on the destination cluster.
- [2] If destination cluster is not enabled for data-at-rest encryption, `dare` setting is not inherited by the mirror volume on the destination cluster.
- [3] If `schedule` keyword is specified with the `skipinherit` parameter, schedule(s) are not inherited while inheriting volume properties from the source volume.
- [4] If `tiername` keyword is specified with the `skipinherit` parameter:
  - The tiering properties are not inherited by the mirror volume while inheriting volume properties from the tiering-enabled source volume.
  - For volumes enabled for warm-tier, the backend erasure-coded volume is not created.

Setting Data ACEs
Describes how to set ACE expressions using both the GUI and the CLI.

To set data *ACE* using the **Add Access Permission** window in the MapR Control System:

1. Specify the entities to set permissions for by doing one of the following:
   - Move the slider associated with **Public** to **Yes** to grant access to all users or to **No** to set permissions for individual users, groups, and/or roles.
   - Specify the users, groups, and/or roles to set permissions for in the associated fields.
   - Select the **Custom ACE** checkbox and enter the access control expression in the field.
2. Click **Add** to set permissions for all or for the specified users, groups, and/or roles.
3. Select the permissions to grant the specified users, groups, and/or roles from the **Permissions** column associated with the entities.
4. Click **Save Changes** to save the *ACE* settings.

Setting Whole Volume ACEs Using the CLI

See Setting Whole Volume ACEs on page 1459.
Setting Table ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.
Setting Stream ACEs Using the CLI

See Enabling Table and Stream Authorizations with ACEs on page 1461.

Changing or Setting Mount Information for a Volume
Describes how to set the mount path for a volume using either the Control System, the CLI, or the REST API.

You can set or change volume mount settings using the Control System, the CLI (`volume create` or `volume mount`), or the REST commands. To mount or unmount volumes under a directory, the user must have read/write permissions on the directory.

Changing or Setting Mount Information for a Volume Using the Control System

1. Log in to the Control System and go to the volume information page.
2. Select **Change Mount Information** from the **Select Action** drop-down menu.
   The **Change Mount Information** dialog displays.
3. Make the necessary changes.
   a) Specify whether (**Yes**) or not (**No**) to mount the volume.
   b) Enter the path in the **Mount Path** field.
   The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).

   Restriction:

   The path should contain only the following characters:

   ```
   A-Z a-z 0-9 _ - .
   ```
4. Click **Save Changes** for the changes to take effect.

Note: After changing the mount point, run `maprcli volume fixmountpath` command to notify CLDB of the change in the volume mount path.

Changing or Setting Mount Information Using the CLI or REST API

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

Restriction: The volume name and the path should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

For complete reference information including all available options, see `volume mount` on page 2020.

Mounting one or more Volumes

Explains how to set or change mount settings for volumes using the Control System or the CLI.

To mount volumes under a directory, you must have read/write permissions on the directory.

Changing or Setting Mount Information Using the Control System

To mount one or more volumes, in the **Summary** tab under **Data** > **Volumes**:

1. Select the volumes to mount from the list of volumes in the **Volumes** pane.
2. Select **Mount Volume(s)** from the **Actions** drop-down menu.
   The **Mount Volume(s)** confirmation dialog displays.

   Note: Only unmounted volumes with mount paths can be mounted. Volumes with no mount paths and volumes that are currently mounted, if selected, cannot be mounted.
3. Verify list of selected volumes.
   If necessary, click ✕ to remove a volume from the list of volumes to mount.
4. Click **Mount Volumes** to mount the selected volumes.

last-updated: Apr 11, 2022

Changing or Setting Mount Information Using the CLI or REST API

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

For complete reference information including all available options, see `volume mount` on page 2020.

Unmounting one or more Volumes
Describes how to unmount a volume using either the Control System or the CLI.

You can unmount multiple volumes using the Control System or the CLI. To unmount volumes under a directory, you must have read/write permissions on the directory.

Unmounting one or more Volumes Using the Control System

To unmount one or more volumes, in the **Summary** tab under **Data** > **Volumes**:

Note: When running on a Kubernetes cluster, the **Summary** tab is in the **Volumes** page under the **Volumes** menu.

1. Select the volumes to unmount from the list of volumes in the **Volumes** pane.
2. Select **Unmount Volume** from the **Actions** drop-down menu.
   The **Unmount Volume** confirmation dialog displays.

   Note: Only mounted volumes can be unmounted. Volumes that are currently not mounted, if selected, cannot be unmounted.
3. Verify list of selected volumes.
4. Click **Unmount Volumes** to unmount the selected volumes.

Unmounting one or more Volumes Using the CLI or REST API

The basic command to unmount the volume is:

```
maprcli volume unmount -name <volume name>
```

For complete reference information including all available options, see `volume unmount` on page 2050.

Mounting a Tenant Volume
Describes the steps to mount and access a tenant volume.

After the tenant volume is created on the cluster (for a multi-tenant environment), access the tenant volume on the tenant host with the following steps:

1. Log in to the tenant host as the tenant admin (`root`) and verify that a valid tenant ticket is available on the tenant host.
   For example, run the following command:

   ```
   ~tenantAdmin@tenantHost: maprlogin print -ticketfile /user/tenantAdmin/
   tenant_sample_ticket.txt
   Opening keyfile /user/tenantAdmin/tenant_sample_ticket.txt
   cHost: user = sampleTenant, created = 'Mon Jul 11 07:14:53 UTC 2016',
   expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11
   07:14:53 UTC 12016',
   uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
   ```
2. Perform one of the following:

- Set up the FUSE-based POSIX client configuration parameters (see Configuring MapR FUSE-based POSIX Client for Tenant Environment on page 1253) and mount the volume (see Mounting the MapR File System on page 1257).
- Set up an alias for NFS exports to export the tenant volume path (see Setting Up Aliases for NFS Exports on page 1184) and mount the volume for loopbacknfs service (see Starting the mapr-loopbacknfs Service to Access a Cluster).

3. Create accessible directories within the provisioned space for the tenant users.

Unmounting a Tenant Volume
Explains how unmount a tenant volume using the CLI.

To unmount a tenant volume and:

- Kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

When you run the command, replace * with basic or platinum, which corresponds with the POSIX client package that is installed on the system.

Note: For more information, see Unmounting the FUSE Mount.

- Stop the loopbacknfs service, run the following command:

```
service mapr-loopbacknfs stop
```

Note: For more information, see Managing the mapr-loopbacknfs Service on page 1236

Changing Volume Type

You can convert a standard volume to a mirror volume and promote a mirror volume to a standard volume.

A standard volume with one or more associated mirror volumes can be converted to a mirror volume that mirrors one of the its associated mirror volumes. The mirror volume that the converted standard volume is set to mirror must then be promoted to a standard volume. The converted standard volume then becomes a read-only copy of the promoted mirror volume.

Note: Standard volumes that do not have one or more associated mirror volumes cannot be converted to mirror volumes.

A mirror volume is a read-only physical copy of a standard volume. In general, mirror volumes are created for the purpose of preventing or minimizing data loss. Mirror volumes are also used to improve performance or to make copies of data for use in other clusters without impacting production. Mirror volumes can be changed to read-write volumes by converting the mirror volumes to standard volumes.

The following topics include procedures for converting a standard volume to a mirror volume and vice versa.

Changing a Standard Volume to a Mirror Volume
Describes how to convert a standard volume to a mirror volume.

You can convert a standard volume to a mirror volume and set it up to mirror one of its associated mirror volumes using the Control System, the CLI, or the REST API.

Changing a Standard Volume to a Mirror Volume Using the Control System

1. Log in to the Control System and go to the Viewing Volume Details on page 883 page for the standard volume.

2. Select **Make Mirror Volumes** from the **Select Action** drop-down menu.
   The **Mirror Volume** confirmation dialog displays.
3. Select the:
   - Name of the source cluster where the associated mirror volume that the converted volume will mirror, exists.
   - Name of the source volume that the converted volume will mirror, from the list of associated mirror volumes.

   The standard volume, when converted, can only be a mirror of one of its associated mirror volumes.
4. Click **Save Changes** for the changes to take effect.

   Note: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing a Standard Volume to a Mirror Volume Using the CLI or the REST API

CLI

To convert a standard volume to a mirror volume from the CLI, run the `maprcli volume modify` command with the `-type` option value set to `mirror`.

```
maprcli volume modify -name <volume
name> -type mirror
```

REST

To convert a standard volume to a mirror volume, send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&type=mirror' --user
mapr:mapr
```

For more information, see `volume modify` on page 2005.

Note: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing Mirror Volumes to Standard Volumes
Describes how to convert a mirror volume to a standard volume.

To change read-only mirror volumes to read-write (standard) volumes, you must promote the mirror volumes to standard volumes. After the mirror volume is promoted, the snapshot schedule specified for the mirror is used for the promoted read-write volume and the mirror schedule is disabled. You can promote a mirror volume to a standard volume using the Control System or the CLI.

Note: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror promotion time is typically negligible, but is dependent on the number of containers in the volume being promoted. For a volume with thousands of containers and a few terabytes of data, it may take a few seconds. For enormous volumes with tens of thousands of containers and hundreds of terabytes of data, promotion could take a few minutes.

After the promotion is complete, a status message is logged in the `cldb.log` file with the time taken. For example:

```
2021-06-27 22:47:00,563 INFO  VolumeMirrorInfo [VolumeMirrorThread0]:
    Volume conversion successfully completed for volume
v100k.m@c.228toMirror false.
    Time taken : 142395ms
```

Changing Multiple Mirror Volumes to Standard Volumes Using the Control System

To change one or more mirror volumes to standard volumes, in the **Summary** tab under **Data** > **Volumes**:

Note: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the mirror volumes to promote from the list of volumes in **Volumes** pane.
2. Select **Change to Standard Volume(s)** from the **Actions** drop-down menu.
   The **Change to Standard Volume(s)** confirmation dialog displays.
3. Review the list of mirror volumes to promote and click **Change Volume(s)** to change the mirror volumes to standard volumes.

Note: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see Handling Mount Points in Promoted Mirror Volumes on page 908.

Changing a Mirror Volume to a Standard Volume Using the Control System

1. Log in to the Control System and go to the volume information page for the mirror volume.
2. Select **Change to Standard Volume(s)** from the **Select Action** drop-down menu.
   The **Change to Standard Volume(s)** confirmation dialog displays.
3. Click **Change Volume(s)** to change the mirror volume to a standard volume.

Note: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see Handling Mount Points in Promoted Mirror Volumes on page 908.

Changing a Mirror Volume to a Standard Volume Using the CLI or REST API

For changing a mirror volume to a standard (read/write) volume using the CLI, run the `maprcli volume modify` command with the `-type` option value set to `rw` on the cluster where the mirror volume resides

last-updated: Apr 11, 2022

and specify the name of the mirror volume that is being promoted. In the following example, the mirror volume is named volA:

```
Cluster2> maprcli volume modify -name volA -type rw
```

For more information, see `volume modify` on page 2005.

Note: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see Handling Mount Points in Promoted Mirror Volumes on page 908.

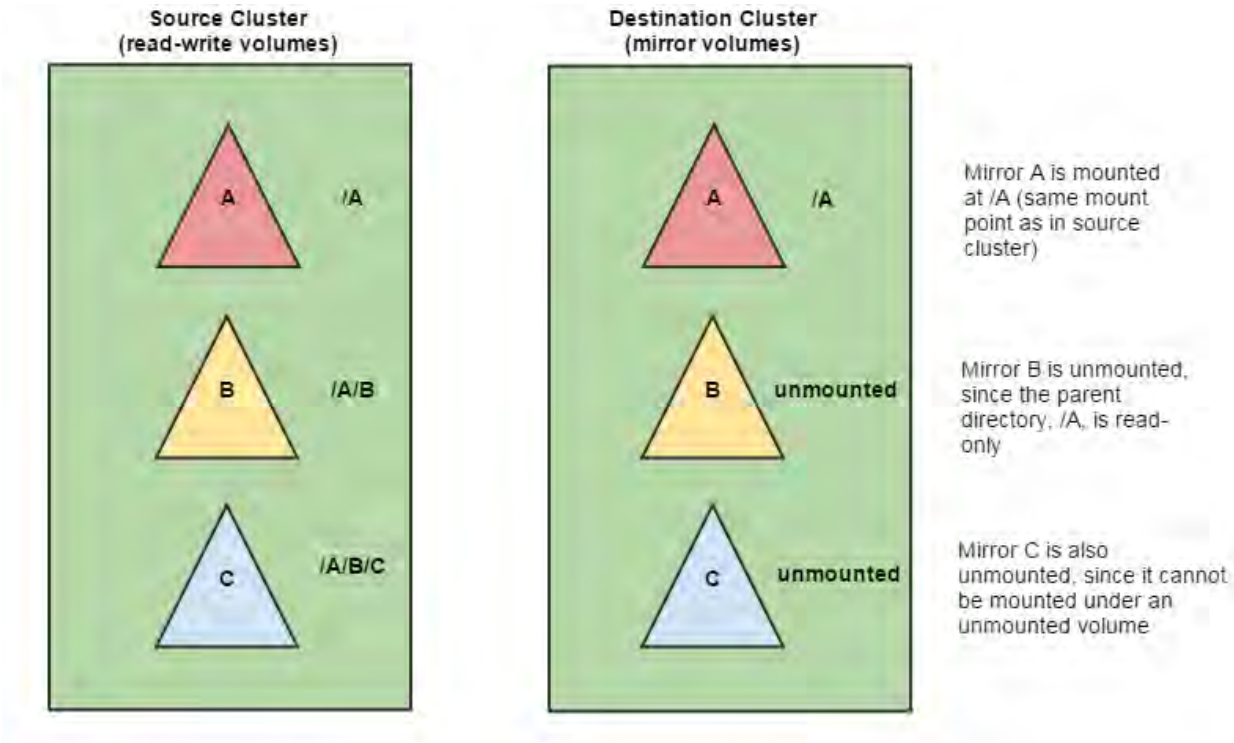
Handling Mount Points in Promoted Mirror Volumes
Explains how to use mount points in promoted mirror volumes.

After you promote read-only mirror volumes to read-write standard volumes, you must re-establish the mount points that were set up in the source cluster. To understand the steps in this process, consider the following scenario:

A source cluster has volumes A, B, and C, which are mounted at /A, /A/B, and /A/B/C respectively. Each source volume is mirrored to a volume in another cluster (the destination cluster). The names of the corresponding mirror volumes are also A, B, and C.

Note: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror volume A is mounted at /A, but since the mirror is read-only, no mount point can be created beneath it for mirror B or mirror C.



Warning: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly.

last-updated: Apr 11, 2022

Now suppose that all three mirror volumes are promoted to read-write volumes. Before any data can be written to these volumes, the volume links must be removed and the volumes must be remounted. The commands for each step are as follows:

1. Promote A, B, and C to read-write volumes.

```
Cluster2> maprcli volume modify -name A -type rw
Cluster2> maprcli volume modify -name B -type rw
Cluster2> maprcli volume modify -name C -type rw
```

   To promote using the Control System, see Changing Mirror Volumes to Standard Volumes on page 906.

2. Remove the volume links located at /A/B and /A/B/C. Since mirror A was already mounted, its volume links do not need to be removed.

```
maprcli volume link remove -path /A/B
maprcli volume link remove -path /A/B/C
```

3. Mount the promoted read-write volumes B and C at the same mount points used in the primary (source) cluster, in order to maintain an exact replica in the destination cluster.

```
Cluster2> maprcli volume mount -name B -path /A/B
Cluster2> maprcli volume mount -name C -path /A/B/C
```

   To mount using the Control System, see Mounting one or more Volumes on page 903.

Now the promoted volumes are accessible for write operations.

Selecting a Replication Type for High Availability
Describes replication types for high-availability clusters, and the tradeoffs of using them.

MapR volumes, stored as pieces called containers, are replicated, typically three times, on separate nodes to protect data and provide uninterrupted access to data in the event of a node failure. Since all form of data is replicated, in the event of a node failure, after a brief delay while the failure is being detected, clients are simply directed to a replica, which serves as an alternative location for a data object, to continue normally. The latency as a result of the failure being detected can be reduced by adjusting the number of TCP retries. Furthermore, selecting a container replication type that is appropriate for your cluster layout allows for faster replication of container state, which in turn allows for retrieval of the most current data in the event of a node failure.

MapR supports two types of container replication -- high-throughput or cascading replication, where volumes are replicated sequentially on intermediate and tail containers and low-latency or star replication, where volumes are replicated on multiple containers in parallel.

Note: For more information, see How MapR File System and Associated Services Work.

The tradeoffs between the replication types is one of latency and throughput. While the low-latency replication delivers relatively lower throughput than the high-throughput replication, the high-throughput replication suffers from relatively higher latencies than the low-latency replication. Another advantage of low-latency replication is that since the primary container is connected to all other replica containers, there is no need to failover a replica container in the event of a failure thus reducing the duration of recovery. However, with high-throughput replication, in the event of a failure of an intermediate container, clients may experience increased latency while CLDB, after detecting the failure, attempts to update the replication chain by making the next or tail container (whichever comes immediately after the failed container) as the next container in the chain.

last-updated: Apr 11, 2022

Converting Volume Replication Type (Low Latency to High Throughput) Using the CLI
Lists the process to convert a volume's replication type using the CLI.

A high throughput replication type allows for volumes to be replicated sequentially on intermediate and tail containers from a primary container.

To convert from a low-latency to a high throughput-replication type:

1. Change the permissions on the volume from read-write to read only.
   For example:

   ```
   maprcli volume modify -name mvol1,mvol2 -readonly true
   ```

   Wait for the running operations to complete before proceeding to the next step.

2. Convert the volume from `low_latency` replication type to `high_throughput` replication type using the `maprcli` command.
   For example:

   ```
   maprcli volume modify -name mvol1,mvol2 -replicationtype high_throughput
   ```

   Wait till replication type conversion is complete and the first container of the volume acquires a primary container. If necessary, run the following command to see if replication type has been converted:

   ```
   maprcli volume list -columns ReplTypeConversionInProgress,volumename
   ```

   If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (`0`). For example, the `0` in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the volumename column:

   ```
   maprcli volume list -columns ReplTypeConversionInProgress,volumename
   ReplTypeConversionInProgress
   volumename

3. Reset the permissions on the volume to read-write.
   For example, to reset, run the following command:

```
maprcli volume modify -name vol1,vol2 -readonly false
```

Converting Volume Replication Type (High Throughput to Low Latency) Using the CLI
Lists the process to convert the replication type of a volume using the CLI.

A low latency replication type allows for volumes to be replicated on multiple containers (in parallel) from the primary container.

Note: Contact MapR support before converting volumes to the `low_latency` replication type.

To convert from a high-throughput to a low-latency replication type:

1. Change the permissions on the volume from read-write to read only.
   For example:

```
maprcli volume modify -name mvol1,mvol2 -readonly true
```

   Wait for the running operations to complete before proceeding to the next step.

2. Convert the volume from `high_throughput` replication type to `low_latency` replication type using the `maprcli` command.
   For example:

```
maprcli volume modify -name mvol1,mvol2 -replicationtype low_latency
```

   Wait till replication type conversion is complete and all the containers of the volume acquire a primary container. If necessary, run the following command to see if replication type has been converted:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
```

   If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (`0`). For example, the `0` in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the volumename column:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
                        volumename
ReplTypeConversionInProgress
                        mapr.apps                     0
                        mapr.cldb.internal            0
                        mapr.cluster.root             0
                        mapr.configuration            0
                        mapr.doc22.lab.local.audit    0
                        mapr.doc22.lab.local.logs     0
                        mapr.doc22.lab.local.mapred   0
                        mapr.doc22.lab.local.metrics  0
                        mapr.doc23.lab.local.audit    0
                        mapr.doc23.lab.local.logs     0
                        mapr.doc23.lab.local.mapred   0
                        mapr.doc23.lab.local.metrics  0
                        mapr.hbase                    0
                        mapr.metrics                  0
                        mapr.opt                      0
                        mapr.resourcemanager.volume   0
                        mapr.tmp                      0
                        mapr.var                      0
                        users                         0
```

3. Reset the permissions on the volume to read-write.
   For example, to reset, run the following command:

```
maprcli volume modify -name vol1,vol2 -readonly false
```

Setting Quota for a Volume
Describes how to set disk quotas for a volume using either the Control System, the CLI or the REST API.
Setting Quota for a Volume Using the Control System

To set volume quotas, in the **Summary** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Ensure that the **Quota** column is displayed in the **Volumes** pane.
   If necessary, customize the columns to see the **Quota** column.
2. Click the **Set Quota** link associated with the volume for which you want to set quotas to display the **Set Quota** window.
3. Specify the following in the **Set Quota** window:
   a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

      Note: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

   b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

   Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), which is the default, or terabytes (TB).
4. Click **Save Changes** for the changes to take effect.

Setting Quota for a Volume Using the CLI or the REST API

You can set quotas for a volume when creating a new or modifying an existing volume.

CLI

The basic command to set quota for a volume is:

```
maprcli volume
create -name <volName> -path
<mountPath> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

```
maprcli volume
modify -name <volName> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&adviso
```

```
ryquota=<advisoryQuota>&quota=<hardQuo
ta>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&advisoryquota=<advisory
Quota>&quota=<hardQuota>' --user
mapr:mapr
```

For the complete list of required and optional parameters, see `volume create` on page 1931 and `volume modify` on page 2005.

Migrating a Volume off a Node Using the CLI

When you need to migrate a data volume off a particular node, move that node from the `/data` path to the `/decommissioned` path to avoid data under-replication.

- Establish a `/data` topology path to serve as the default topology path for the volumes in that cluster.
- Establish a `/decommissioned` topology path that is not assigned to any volumes.

> **Tip:** It is recommended that CLDB and ZooKeeper nodes are not in the same topology as the data nodes to ensure fast failover of the failed data node in the event of a data node failure.

Since no data volumes are assigned to the `/decommissioned` topology path , standard data replication will migrate the data off that node to other nodes that are still in the `/data` topology path.

You can run the following command to check if a given volume is present on a specified node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

Run this command for each non-local volume in your cluster. Once all the data has migrated off the node, you can decommission the node or place it in maintenance mode.

If you need to segregate CLDB data, create a `/cldb` topology node and move the CLDB nodes under `/cldb`. Point the topology for the CLDB volume (`mapr.cldb.internal`) to `/cldb`. See Isolating CLDB Nodes for details.

Note: To move an existing volume to another topology, you must have the Converged Enterprise Edition. Without the Converged Enterprise Edition, when you run the `maprcli volume move` command to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology

Specifies how to use volume topology to place volumes on specific racks, nodes, or groups of nodes.

After you define the node topology for the nodes in your cluster, you can use volume topology to place volumes on specific racks, nodes, or groups of nodes.

This section describes the process of setting up:

- Default volume topology
- Local volume topology
- Custom topology for local volume replicas

last-updated: Apr 11, 2022

Setting Up Volume Topology
Explains how to setup Volume Topology using either the Control System or the CLI.

MapRMapR Data Platform supports data placement control, in which you can place a volume on specific racks, nodes, or groups of nodes by setting its topology to an existing node topology. You can set volume topology using the Control System or with the volume move on page 2021 command.

To move an existing volume to another topology, you must have the Converged Enterprise Edition installed on your system. Without the Converged Enterprise Edition, when you try to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology Using the Control System

You can set up volume topology at the time of volume creation or change the volume topology after volume creation. To:

- Set up volume topology at the time of volume creation, see Creating a Volume on page 864.
- Modify volume topology, see Modifying a Volume on page 892.

Setting Up Volume Topology Using the CLI or REST API

To move a volume to a different topology, run the following command:

```
maprcli volume move -name <volume name> -topology <path>
```

For complete reference information, see volume move on page 2021.

Setting the Topology for Local Volume Replicas
Explains how to set the topology for local volume replicas using the CLI.

The primary copies for containers of local volumes are placed on the local node (specified with parameter `-localhost` in the `volume create` command). The nodes for the replica copies for containers of local volumes are chosen as follows:

1. If a topology is explicitly specified for replicas during `volume create` or `volume edit`, that topology will be used.

   ```
   maprcli volume create -name egLocalVol -path /test/local/volumes/
   examples/sample1 \
   -localvolumehost 10.20.30.40 -topology /rack1/test
   ```

   In the above example, the primaries for the volume are placed on node 10.20.30.40, and replicas will be placed on nodes in the topology /rack1/test.

   The `-topology` parameter is optional, and if it is not specified, CLDB will fall back to 2 or 3 below.

2. If the configuration parameter that specifies a relative path for replicas of local volumes is set, that will be used.

   ```
   maprcli config save -values
   {"cldb.local.volume.topology.trim.index":"-1"}
   ```

   This will trim the topology of the node specified by the localhost parameter and restrict the replicas to the resultant topology.

   By default, this configuration parameter is not set. To set this configuration parameter, see Creating Replicas of Local Volumes in Custom Topology Using the CLI on page 917. If the configuration parameter is not set, CLDB will fall back to 3 below.

3. The default volume topology will be used.

   The default volume topology is the value specified by the configuration parameter `cldb.default.volume.topology`. The default value for this parameter is `/data`. See Setting Default Volume Topology Using the CLI on page 917.

Creating Replicas of Local Volumes in Custom Topology Using the CLI

To set the configuration parameter for placing replicas of volumes in a topology relative to the local node, run the `maprcli config save` command. The value can be a:

- Positive number to indicate the number of paths to keep from the initial root (of the topology path). For example:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"1"}
```

- Negative number to indicate the number of paths to skip from the end of the topology path. For example:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
```

For example, suppose the local volume is created on a node that is under the topology `/data-center1/lab2/rack3/shelf4/10.10.20.30`. To create a local volume where the replicas are restricted to `/data-center1/lab2/rack3` topology, run the following command:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"3"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.10.20.30
```

Alternatively, you can run the following command to specify the path for the volume from the end of the topology path:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.20.30.40
```

The replicas for containers of the volume, egLocalVol, will be created on nodes under `/data-center1/lab2/rack3`.

Setting Default Volume Topology Using the CLI

Use the `config save` command to set the default topology for volumes.

By default, new volumes are created with a topology of `/data`. To change the default topology, use the `config save` on page 1586 command to change the `cldb.default.volume.topology` configuration parameter. Example:

```
maprcli config save -values "{\"cldb.default.volume.topology\":\"/data/
rack02\"}"
```

After this command is run, new volumes have the volume topology `/data/rack02` by default, which could be useful to restrict new volume data to a subset of the cluster.

Viewing Active Volume Alarms

Describes how to view volume alarms using the Control System and the CLI.

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

- Log in to the Control System and:

last-updated: Apr 11, 2022

- Click **Data** > **Volumes** to view all active volume alarms in the **Active Alarms** pane.

  Note: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

- Go to the **Summary** tab in the volume information page to view the recent and active alarms for the selected volume in the **Alarms** pane.

- Click (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.

- Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

You can:

- View information related to the alarm.
- Dismiss an alarm.
- Mute an alarm.

See Volume Alarms on page 2240 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 1545.

Working with Mirror Volumes

The mirroring process transmits the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations are generally very fast. The following sections describe how to manage the mirroring operation.

Changing the Limit for Concurrent Mirror Operations Using the CLI

The system allows a maximum of 50 concurrent mirroring operations by default. Mirroring operations include both mirroring and promoting from read-only mirrors to read-write standard volumes. The system parameter that controls this limit is `mapr.mirror.concurrent.ops`.

For large-scale mirror operations involving many volumes, a script automates the process. For example, if a script queues 100 volumes for mirroring operations, and the `mapr.mirror.concurrent.ops` limit is set to 50, the mirroring operations start on the first 50 volumes in the queue. As soon as one volume completes, another volume is processed from the queue until all 100 are completed. Since volumes are processed from the queue in first-in first-out (FIFO) order, the script should specify the most critical volumes first.

If you want to process more volumes at a time, you can raise the limit of the `mapr.mirror.concurrent.ops` parameter. To tune this parameter for maximum efficiency, consider the number of containers per volume. A higher number of containers per volume requires a lower limit than a lower number of containers per volume. To raise the limit to 500 for example, run the following command:

```
maprcli config save -values {"mapr.mirror.concurrent.ops":"500"}
```

last-updated: Apr 11, 2022

Pushing Changes to Mirrors Using the CLI

To *push* a mirror means to start pushing data from the source volume to all of its local mirrors. You can push source volume changes out to all mirrors using the `volume mirror push` command, which returns after the data has been pushed.

Moving Large Amounts of Data to a Remote Cluster Using the CLI

You can use the `volume dump create` command to create volume copies for transport on physical media. The `volume dump create` command creates backup files containing the volumes, which can be reconstituted into mirrors at the remote cluster with the volume dump restore command. Associate these mirrors with their source volumes with the `volume modify` command to re-establish synchronization.

Another way to transfer large amounts of data to a remote cluster is to create a small cluster locally and mirror to that local cluster. Then move that cluster to a remote location and enlarge it by adding more nodes.

Disabling Mirror Throttling Using the CLI

By default, mirror throttling is enabled, which means that the server that sends mirror data, restricts itself to about 30% of the available bandwidth, as measured in MapR's internal environment, with the default settings of the following parameters. Mirror throttling is based on the number of outstanding requests on the network, and outstanding I/O requests on disk, and can be tuned using the parameters, `mfs.disk.iothrottle.count`, `mfs.disk.resynciothrottle.factor`, and `mfs.network.resynciothrottle.factor`, in the `mfs.conf` file. When other processes need more network bandwidth, the server throttles back to slow down the rate of data transfer.

By disabling throttling, the mirror operation completes faster. To disable mirror throttling from the command line, run the `volume modify` command on the *source* volume and set the `-mirrorthrottle` option to `false`, as shown in this example:

```
/opt/mapr/bin/maprcli volume modify -name volA -mirrorthrottle false
```

This command disables throttling for all mirror volumes whose source is volA. Note that the `-mirrorthrottle` option only applies to volumes that have mirrors.

Recovering Volumes from Mirrors Using the CLI

Lists the process to recover mirror volumes, using the CLI.

1. Use the `volume dump create` command to create a full volume dump for each mirror volume you want to restore. Example: `maprcli volume create -e statefile1 -dumpfile fulldump1 -name volume@cluster`
2. Transport the volume dump to the rebuilt cluster.
3. For each volume on the mirror cluster, set up a corresponding volume on the rebuilt cluster.
   a. Restore the volume using the `volume dump restore` command. Example: `maprcli volume dump restore -name volume@cluster -dumpfile fulldump1`
   b. Copy the files to a standard (non-mirror) volume.

Starting the Mirror

Explains how to start a mirror operation using either the Control System or the CLI.

When a mirror starts, all the data in the source volume is copied into the mirror volume. Starting a mirroring operation requires the mirror volume to exist and be associated with a source. After you start a mirror, synchronize it with the source volume regularly to keep the mirror current.

Note: The `getIPTypeForCluster` method in `CLDBRpcCommonUtils` is unable to determine whether the IP type is internal or external, if `mapr-clusters.conf` contains both internal and external IPs. The fix is to only put in the internal IP in `mapr-clusters.conf` and keep the external IP in the `env.sh` file, before starting the mirror.

Starting the Mirror for Multiple Mirror Volumes Using the Control System

To start mirroring, in the **Summary** tab under **Data** > **Volumes**:

Note: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

1. Select the mirror volume(s) to synchronize.
   You *cannot* start mirror for:
   - Standard volumes
   - Mirror volumes currently mirroring
2. Select **Start Mirroring** from the **Actions** drop-down menu.
   The **Start Mirroring Volume(s)** confirmation dialog displays.
3. Verify the list of volumes to synchronize and click **Start Mirroring**.
   When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror for a Mirror Volume Using the Control System

To start mirroring:

1. Go to the volume information page for the mirror volume to synchronize.
2. Select **Start Mirroring** from the **Select Action** drop-down menu.
   The **Start Mirroring Volume** confirmation dialog displays.
3. Click **Start Mirroring**.
   When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror Using the CLI or REST API

The basic command to start a mirror is:

```
maprcli volume mirror start -name <volume name>
```

For complete reference information, see `volume mirror start` on page 1990.

Stopping the Mirror
Explains how to stop a mirror operation using either the Control System or the CLI.

Stopping a mirror halts any replication or synchronization process currently in progress. Stopping a mirror does not delete or remove the mirror volume.

Stopping the Mirror for Multiple Mirror Volumes Using the Control System

To stop mirroring, in the **Summary** tab under **Data** > **Volumes**:

Note: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

1. Select the mirror volume(s) to stop.
   You *cannot* stop the mirror operation for:
   - Standard volumes
   - Mirror volumes that are currently not mirroring
2. Select **Stop Mirroring** from the **Actions** drop-down menu.
   The **Stop Mirroring Volume(s)** confirmation dialog displays.
3. Verify the list of volumes to stop and click **Stop Mirroring**.
   When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror for a Mirror Volume Using the Control System

To stop mirroring:

1. Go to the volume information page for the mirror volume to stop.
2. Select **Stop Mirroring** from the **Select Action** drop-down menu.
   The **Stop Mirroring Volume** confirmation dialog displays.
3. Click **Stop Mirroring**.
   When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror Using the CLI or REST API

The basic command to stop a mirror is:

```
maprcli volume mirror stop -name <volume name>
```

For complete reference information, see `volume mirror stop` on page 2004.

Viewing Mirror Status
List mirror volumes and their status using the Control System and the CLI.

You can see a list of all mirror volumes and their current status in the **Mirror Volumes** view (in the Control System, select **Mirror Volumes** from the drop-down menu in the **Volumes** page under **Data** > **Volumes**) or using the `volume list` on page 1979 command. Use the volume mirror status on page 1991 command to view the details of the mirroring operation that is in progress. The volume mirror status on page 1991 command helps in troubleshooting the mirroring operation. For more information on trouble shooting mirroring, see the support article titled Monitor and Understand Volume Mirroring in MapR.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

To use the volume list command to explicitly list mirror volumes, you must define a filter. For example:

```
maprcli volume list -filter [n==<mirror name>] -columns \
         n,p,mirror-percent-complete,mrt -cluster <target cluster>
```

Mirrors and Performance

Completion time for a mirroring operation is affected by the available network bandwidth, and the amount of data to transmit. For best performance, set the mirroring schedule according to the anticipated rate of data changes, and the available bandwidth for mirroring.

Using Promotable Mirrors for Disaster Recovery

The concept of promoting a mirror refers to the ability to make a read-only mirror volume into a read-write volume. The main use case for this feature is to support disaster-recovery scenarios in which a read-only mirror needs to be promoted to a read-write volume so that it can become the primary volume for data storage.

A MapR administrator can perform the following tasks from a remote datacenter before, during, and after a disaster:

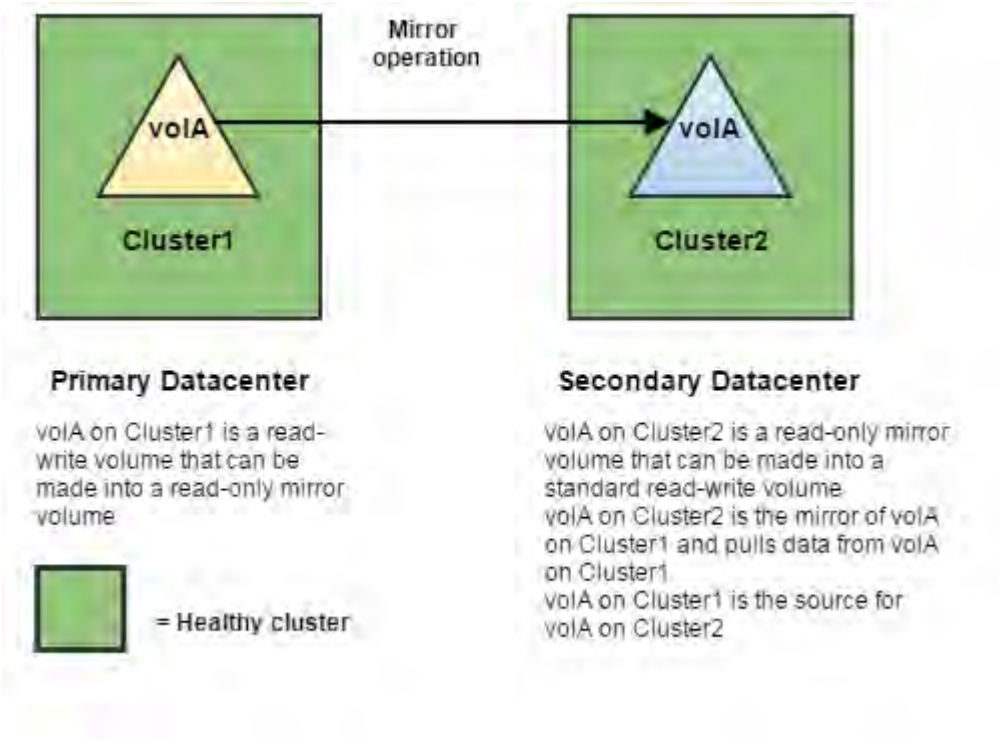
- Set up mirroring to a remote cluster
- Fail over to a mirror volume
- Restore the mirror relationship

For a brief overview of the terminology used to describe volume types, along with some basic commands, see the Types of Volumes on page 460.

The following sections provide information about how to use promotable mirrors for disaster recovery:

Setting up Mirroring to a Remote Cluster

Once data volumes are created in a primary datacenter, the MapR administrator creates mirror volumes in a remote secondary datacenter. The following diagram illustrates the mirror relationship between these two volumes:



Note: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

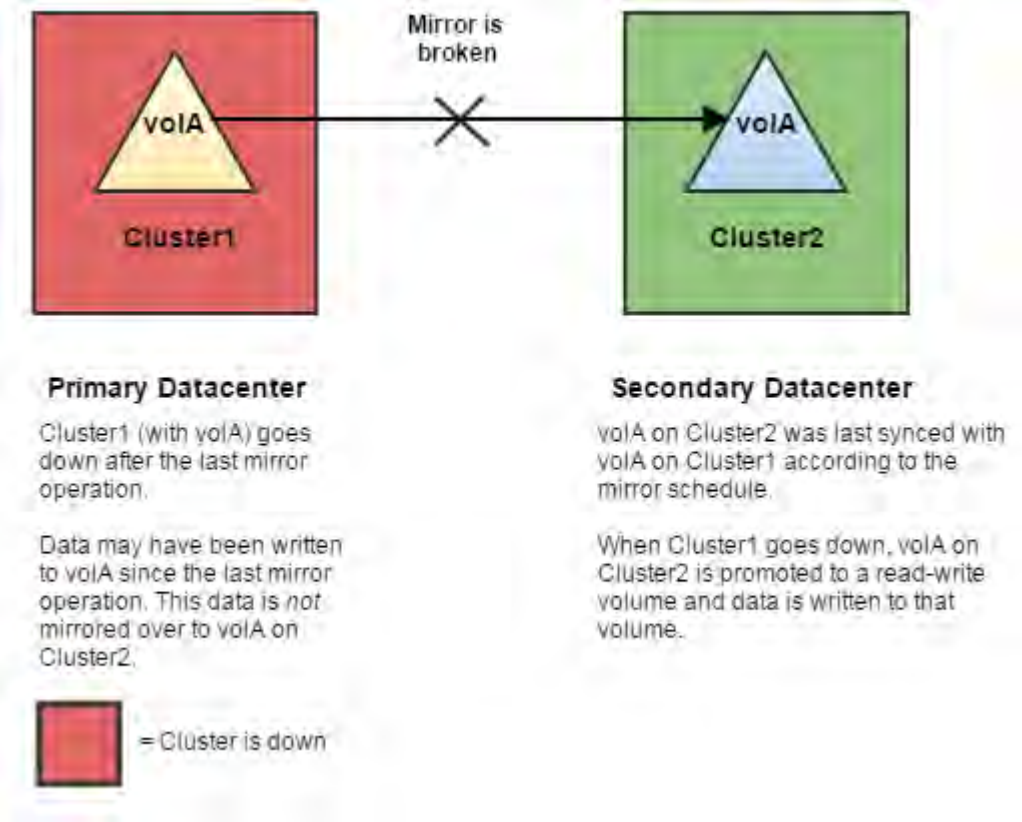
last-updated: Apr 11, 2022

The following sections provides information about how to set up mirroring to a remote cluster:

1. Creating Remote Mirrors on page 880
2. Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1486
3. Creating a Mirror Volume
4. Creating a Mirroring Schedule

Failing Over to a Mirror Volume

When a disaster occurs at a primary datacenter, data can no longer be written to the volumes in that location, and the mirror operation cannot be performed. In order to maintain business continuity, the administrator at the secondary datacenter promotes the read-only mirror volume to a read-write volume, which breaks the mirror relationship. At this point, the promoted mirror volume contains all the data that was on the source volume at the time of the most recent successful mirror operation.



The following sections provide information about how to fail over to a mirror volume:

- Changing Mirror Volumes to Standard Volumes on page 906
- Handling Mount Points in Promoted Mirror Volumes on page 908
- Changing the Limit for Concurrent Mirror Operations Using the CLI on page 918

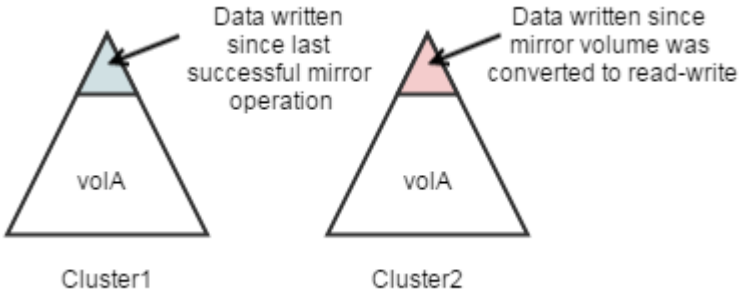
Restoring the Mirror Relationship

Explains how to restore the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

If the primary datacenter comes back online, the administrator can re-establish the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

last-updated: Apr 11, 2022

Note that the two read-write volumes will have different data, since data was written to the promoted mirror while the original source volume was down. The original source volume might also have different data that was written after the last mirror operation, but before the cluster went down. The administrator must decide which data to keep and use as the source.



Warning: Some data loss is inevitable in a disaster recovery scenario. To minimize potential data loss, use mirrors to provide a synchronized copy of each volume with critical data, and in the event of discrepancies, decide which data to preserve based on your company's policies.

The following sections provide information about how to restore the mirror relationship:

Preserving volA/Cluster1's Data

Suppose that volA in the primary datacenter contains crucial data that must be preserved, and you want to mirror its data to volA in the secondary datacenter (the same mirror relationship that was established originally). To recreate the original mirror relationship, convert the promoted volume, volA/Cluster2, from a read-write volume to a mirror of volA/Cluster1 by running the following command:

```
Cluster2> maprcli volume modify -name
volA -type mirror -source
volA@Cluster1
```

To use the Control System to convert volA/Cluster2 from a read-write volume to a mirror of volA/Cluster1, follow steps for Changing a Standard Volume to a Mirror Volume on page 905.

Preserving volA/Cluster2's Data on volA/Cluster1

Now suppose you want to preserve the data on volA/Cluster2 (in the remote datacenter) but you still want volA/Cluster1 to be the primary volume with volA/Cluster2 as its mirror. From the command line or the Control System, you can save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

You can use either of the following methods to preserve the data:

From the Control System

Complete the following steps from the Control System to save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

1. Stop writing new data to volA/Cluster2 by making this volume read-only:
   For detailed steps, see Modifying a Volume on page 892.
2. Make volA/Cluster1 a mirror of volA/Cluster2.
   For detailed steps, see Changing a Standard Volume to a Mirror Volume on page 905.

last-updated: Apr 11, 2022

3. Start mirroring.
   For detailed steps, see Starting the Mirror on page 919.
4. Promote volA/Cluster1 to a read-write volume.
   For detailed steps, see Changing Mirror Volumes to Standard Volumes on page 906.
5. Make volA/Cluster2 a mirror of volA/Cluster1.
   For detailed steps, see Changing a Standard Volume to a Mirror Volume on page 905.

From the Command Line

1. Stop writing new data to volA/Cluster2. To be sure no data is written to this volume, make it read-only by running this command:

```
Cluster2> maprcli volume modify -name volA -readonly true
```

2. Pull the data from volA/Cluster2 to volA/Cluster1 by making volA/Cluster1 a mirror of volA/Cluster2.

```
Cluster1> maprcli volume modify -name volA -type mirror -source
volA@Cluster2
```

3. Start the mirror operation.

```
Cluster1> maprcli volume mirror start -name volA
```

4. Once mirroring is done, promote volA/Cluster1 to a read-write volume. Note that the mirror relationship breaks at this point.

```
Cluster1> maprcli volume modify -name volA -type rw
```

5. Make volA/Cluster2 a mirror of volA/Cluster1.

```
Cluster2> maprcli volume modify -name volA -type mirror -source
volA@Cluster1
```

Enabling and Restricting Access to Tenant Volume and Data
Describes how to restrict access to tenant volumes in a multi-tenant environment.

In a multi-tenant environment, the tenant volume (share) can be accessed by all users on the tenant instance by default. To restrict access to specific users and/or groups:

1. Log in to the cluster as the cluster administrator and set *ACE*s on the volume using the volume commands.
   For example:

```
/opt/mapr/bin/maprcli volume modify -name <volumename> -readAce
"u:<user>|g:<group>" -writeAce "u:<user>|g:<group>"
```

   Here, value for <user> must be the UID of the user and value of <group> must be GID of the group on the tenant host.

   Tip: For more information, see `maprcli volume modify` command.

2. Log in as the tenant admin and set permissions for data access.

last-updated: Apr 11, 2022

You can set permissions using:

- Linux commands such as `chmod`, `chown`, and so on.
- *ACE*s, which can be set on files and directories in the volume. For more information, see Enabling Volume, Directory, and File Authorizations with ACEs on page 1452.

Working with Tiered Volumes

This section describes how to create tiered volumes and manage automatic and manual tiering jobs on the tiered volume.

Erasure Coding Scheme for Data Protection and Recovery

Describes the erasure coding (EC) schemes for data protection and recovery.

Erasure coding (EC) is a data protection method in which data is broken into fragments, expanded and encoded with redundant data pieces, and stored across a set of different nodes or storage media.

EC ensures that if data becomes corrupted, it can be reconstructed using other data and parity fragments.

The time required to reconstruct data depends on the number of data fragments in the chosen EC scheme, and the number of failures that have occurred. For example, reconstruction of EC scheme *10+2* takes longer compared to the reconstruction of EC scheme *3+2*, as a larger number of data and parity fragments must be read.

Considerations When Selecting an EC scheme

As an administrator, consider the following points when selecting an EC scheme:

- How many nodes can you afford to have?
- How many failures might occur? Do you anticipate a single failure, or multiple failures?
- Consider the following when determining how long you are willing to wait for a node to be rebuilt:
  - Rebuilds overhead - For 4+2, need to read data from 4 nodes to rebuild, for 6+3, need to read from 6 nodes to rebuild.
  - Reads overhead - For 4+2, need to read data from 4 nodes , for 6+3, need to read from 6 nodes. For degraded states, parity calculation overhead is an add-on.
  - Data classification - High ecschemes 10+2 , 12+4, are ideal for archived data, since data mostly remains untouched.

EC Schemes

In an erasure coded volume, an erasure coding scheme has the stripe layout *m+n*. The stripe is an array of *m* data fragments and *n* parity fragments.

Each fragment is called a stripelet. Each stripelet is present on a container and one stripe is across different containers on different nodes. The default stripelet size is 4MB. For an EC scheme *4+2* for example, the stripe size is 24MB.

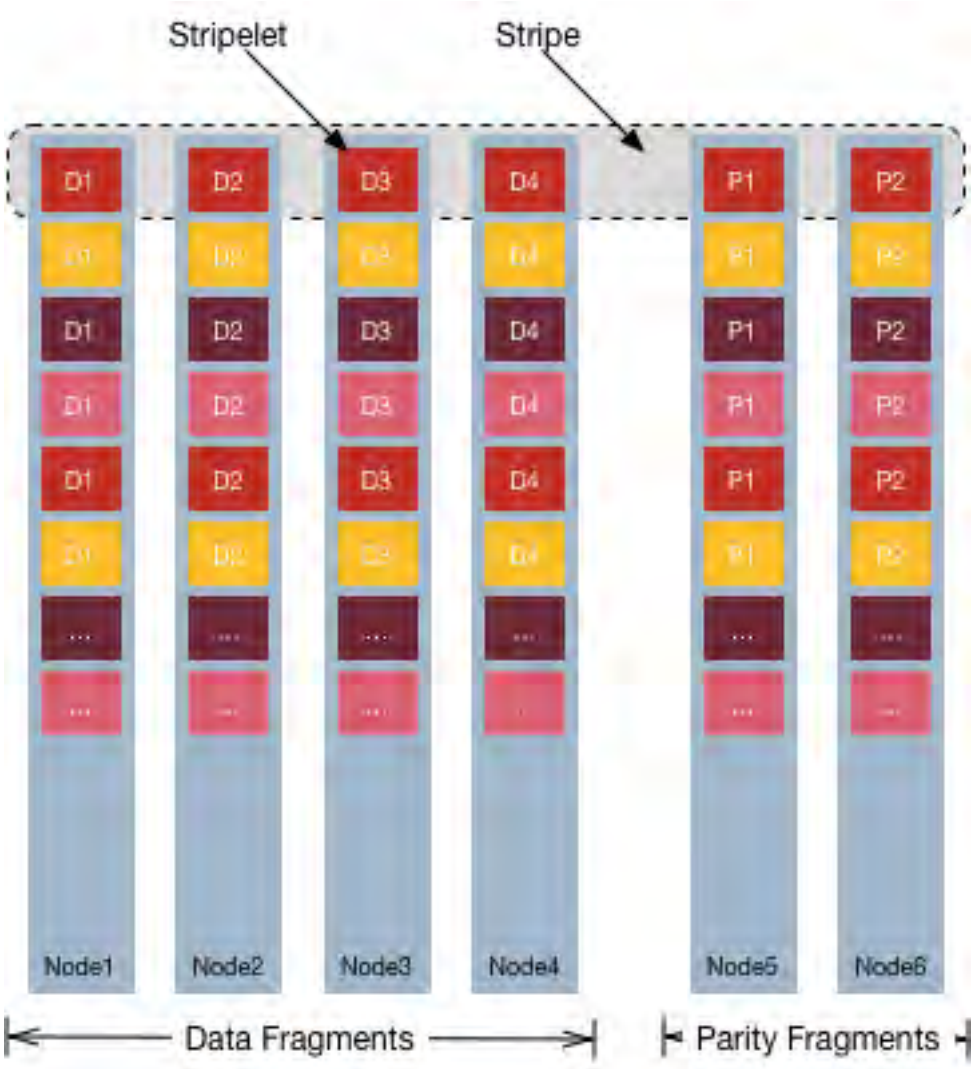
A Container Group (CG) is collection of such stripes. Based on the maximum size of a container (32 GB), the maximum number of stripes in a CG is 8K.

Each stripe is created by the same number of data fragments from all containers in the group of EC containers. Each container is placed on a different physical node.

- *m* is the number of data fragments.
- *n* is the number of redundant fragments (referred to as parity fragments).
- The parity is calculated using data from all data fragments.

- *m/(m+n)* is the encoding rate.
- *m+n* is the number of encoded fragments.
- You need to read a minimum of *m* blocks to recover data.
- You can recover data from a maximum of *n* failures.

For example, assume m=4, n=2, and stripe depth=4 MB.



- The number of data fragments is four (4), and while the number of parity fragments is two (2).
- The number of encoded fragments is six (6).
- The stripe size is 16 MB (4x4 MB) of user data, and 8 MB (2x4 MB) of parity fragments.
- The system can handle two (2) failures, and any fragment can be recovered from four (4) other fragments.

Requirements for using an erasure coding scheme

Requirements when using the Control System

- The number of data fragments must be 3 to 10.

last-updated: Apr 11, 2022

- The number of parity fragments must be greater than 1 and less than the number of data fragments.
- The number of data fragments must be greater than the number of parity fragments.
- The number of nodes must be greater than or equal to the sum of data and parity fragments.

Requirements when using the CLI

- The number of data fragments must be 2 to 10.
- The number of parity fragments must be greater than or equal to 1 and less than or equal to the number of data fragments.
- The number of data fragments must be greater than or equal to the number of parity fragments.

Select from the following schemes for erasure-coded volumes:

EC Scheme		Number of Data Nodes	Number of Parity Nodes	Total Number of Nodes Needed	Number of Failures Recoverable	Number of Nodes to Read to Recover Data
CLI	Control System					
3+2	3, 2	3	2	5	2	3
4+2	4, 2	4	2	6	2	4
5+2	5, 2	5	2	7	2	5
6+3	6, 3	6	3	9	3	6
10+<x> where x is a value from 1 to 9	N.A	10	x	10+x	x	10

Although you can create a volume without the required number of nodes for a specific scheme, volume offload fails if the required number of nodes are not present.

When choosing the scheme, note that more nodes leads to longer recovery time, resulting in degraded performance, network expense, and lengthy time to rebuild.

For example, consider a *12 + 4* EC scheme represented as `D0 + D1 + D2 +....+D10 + D11 + P0 +…+P3`

Suppose node D4 goes down, now to rebuild, a total of 12 stripelets must be read. This leads to huge performance degradation in network bandwidth, CPU cycles, and Disk IO .

To reduce the reconstruction cost, use EC Local Parity, where the number of stripelets to be read reduces to 6 for a single failure in the *12+2+2* scheme.

Important: The recommended number of nodes required for erasure coding is M+2N (rather than M+N) to ensure MapR self-healing and proper operation after N failures. N failures with only M+N nodes allows you to continue reading the data, but with significantly reduced performance because each read requires rebuilding data fragments. Also, manual intervention is required to protect the data from further failures. Currently, data will not be erasure coded if only M nodes are available. With M+2N nodes, N failures will self-heal with no operator intervention.

Specifying a Schedule for Offloading Data
Explains how to create a schedule for automatic offloading of data, using the Control System, the CLI and the REST API.

You can create a schedule using the Control System, the CLI, and REST API. After creating a schedule, you can associate it with the tiering-enabled volume when you create or modify the volume. If a schedule

for offloading data is associated with the volume, data is offloaded automatically as scheduled based on the rules associated with the volume for offloading data. You can also manually trigger the `maprcli` command to offload data.

The following schedules are available out-of-the-box for offloading data:

Schedule Name	Schedule ID
Critical data	1
Important data	2
Normal data	3
Automatic Tiering Scheduler	4*

* The Automatic Tiering Scheduler ID might be different on different clusters. To retrieve the correct ID, run the `schedule list` on page 1740 command.

For volumes enabled for warm tiering, the Automatic Tiering Scheduler is used by default for offloading data if you do not explicitly assign a schedule. The frequency of the Automatic Tiering Scheduler run is based on two the following:

time	The frequency. The `cldb.auto.offload.frequency.minutes` property stores the default value of 24 * 60 minutes. This can be configured using the `config save` on page 1586 command. The value for this property must be in minutes.
size	The amount of data (that has not yet been offloaded) in the volume. The `cldb.auto.offload.threshold.gb` property stores the global value for the size threshold. The default value for this property is 1024GB, which cannot be modified. However, you can override the global value at the volume-level using the `autooffloadthresholdgb` parameter with the `Creating a Volume` on page 864 and `volume modify` on page 2005 commands.

The Automatic Tiering Scheduler run is based on the time setting. However, it runs sooner if the size of the volume in the hot tier reaches or exceeds the size threshold.

For volumes enabled for cold tiering, you must assign a schedule to automatically offload data; if you do not assign a schedule, data is not offloaded automatically and you must manually run the offload command to offload data. You can associate the Automatic Tiering Scheduler with the cold-tier enabled volume or create a custom schedule and associate it with the volume to automatically offload data.

To:

- Create a schedule before creating the volume, see Creating a Schedule on page 954.
- Create a schedule when you are creating the volume, see step 9 in Creating a Volume on page 864.

Specifying a Schedule Using the Control System

You can associate a schedule with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** button in the **Data** > **Volumes** page.
- Editing the tiering-enabled volume by clicking **Edit Volume** button in the volume information page.

To associate an offload schedule with the volume, in the **Schedule** tab of the **Create Volume** or **Edit Volume** page:

1. Click the **Browse** link associated with the **Offload Schedule** field to display the **Browse Schedules** window.
2. Review the name and detail of each schedule and choose a schedule from the list.
3. Click **Save** to associate the schedule with the volume.
4. Complete the steps for creating or editing the volume.

Specifying a Schedule Using the CLI and REST API

You can associate a schedule with a tiering-enabled volume by specifying the `offloadschedule` parameter with the `volume create` on page 1931 or `volume modify` on page 2005 command.

CLI

Run a command similar to the following to associate a schedule when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -offloadschedule
<scheduleID> -json
```

  For the list of all other required and optional parameters, see `volume create` on page 1931.

- Editing the volume:

```
maprcli volume modify -name
<volName> -offloadschedule
<scheduleID> -json
```

  For the list of all other required and optional parameters, see `volume modify` on page 2005.

REST

Send a request of type POST. For example, to associate a schedule when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&offloadschedule=<scheduleID>' --us
er mapr:mapr
```

  For the list of all other required and optional parameters, see `volume create` on page 1931.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&offloadschedule=<sch
eduleID>' --user mapr:mapr
```

For the list of all other required and optional parameters, see `volume modify` on page 2005.

To disable automatic schedule-based offload of data, set the value for the `offloadschedule` parameter to `0`.

Creating a Tiering-Enabled Volume

You can create a tiering-enabled volume using the Control System, the CLI, and the REST API.

Creating a Tiering-Enabled Volume Using the Control System

1. Go to **Data** > **Volumes** and click **Create Volume**.
   The **Create New Volume** page displays.
2. Select the **Volume Type**, specify values for required/optional settings and auditing, and move the slider to **Yes** for **Data Tier** in the **Properties** tab.
   For information on all other properties and settings, see Creating a Volume on page 864.

   Note: The source volume for a tiering-enabled mirror volume must also be tiering-enabled. You cannot set up a tiering-enabled mirror volume to mirror a volume that is not tiering-enabled.
3. Click **Create Volume** to create the tiering-enabled volume.

You can proceed to associate a tier, tiering rule, and/or schedule with the volume.

Creating a Tiering-Enabled Volume Using the CLI and REST API

CLI

Run the following command to create a tiering-enabled volume:

```
$maprcli volume
create -name <volName> -path
<volmountpath> -tieringenable true
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volmountpath>&tie
ringenable=true' --user mapr:mapr
```

For more information, see `volume create` on page 1931.

Associating a Tier, Tiering Rule, and/or Schedule with a Volume

You can associate a tier, tiering rule, and/or schedule with a new volume or with an already tiering-enabled volume using the Control System, CLI, and the REST API.

Associating a Tier, Tiering Rule, and/or Schedule with a Volume Using the Control System

- Perform the steps in the following topics to associate a tier, tiering rule, and/or schedule with:
  - A new volume

- A tiering-enabled volume

Associating a Tier, Tiering Rule, and/or Schedule with a Volume Using the CLI

- Run the following command to associate a tier, tiering rule, and/or schedule with:
  - A new volume:

    ```
    $maprcli volume create -name <vol_name> -path
    <vol_mount_path> -tieringenable true -tiername <tier_name> -tieringrule
    <rule_name> -offloadschedule <schedule_ID>
    ```

    For more information, see volume create on page 1931.

  - An already tiering-enabled volume:

    ```
    $maprcli volume modify -name <vol_name> -tiername
    <tier_name> -tieringrule <rule_name> -offloadschedule <schedule_ID>
    ```

    For more information, see volume modify on page 2005.

Note: You cannot change the tier type or the tier for a volume after it is set.

Associating a Tier, Tiering Rule, and/or Schedule with a Volume Using the REST API

- Send a request of type POST to associate a tier, tiering rule, and/or schedule with:
  - A new volume. For example:

    ```
    curl -k -X POST 'https://<host>:8443/rest/volume/create?
    name=<vol_name>&path=<vol_mount_path>&tieringenable=true&tiername=<tier_
    name>&tieringrule=<rule_name>&offloadschedule=<schedule_ID>' --user
    mapr:mapr
    ```

    For more information, see volume create on page 1931.

  - An already tiering-enabled volume. For example:

    ```
    curl -k -X POST 'https://<host>:8443/rest/volume/modify?
    name=<vol_name>&tiername=<tier_name>&tieringrule=<rule_name>&offloadsche
    dule=<schedule_ID>' --user mapr:mapr
    ```

    For more information, see volume modify on page 2005.

Note: Volume's data tiering properties like tiername, ectopology, ecscheme, etc. cannot be modified after they are set.

Determining if a Volume is Enabled for Tiering

You can determine if a volume is enabled for tiering and if rules, schedules, and/or settings for recalled data are associated with the volume using the Control System and the CLI.

Determining if a Volume is Enabled for Tiering Using the Control System

- Log in to the Control System and click **Data** > **Volumes**.

  In the list of volumes displayed in the **Volumes** pane, the **Data Tiering** column contains the value **Enabled** for a volume if the volume is enabled for tiering. If you do not see the column, you can see the column by selecting the columns to display in the Control System.

last-updated: Apr 11, 2022

Determining if a Volume is Enabled for Tiering Using the CLI

- Run one of the following commands to determine if a volume is enabled for tiering:
  - `maprcli volume list -json`
  - `maprcli volume info -name <volName> -json`

  The output, if the volume is tiering-enabled (and has associated settings), should look similar to the following:

```
{
        "timestamp":1533959507772,
        "timeofday":"2018-08-10 08:51:47.772 GMT-0700 PM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "acl":{
                                "Principal":"User root",
                                "Allowed actions":"[dump, restore, m, a,
d, fc]"
                        },
                        ...
                        ...
                        "tierenable":"true",
                        "tierid":"169211273",
                        "tierruleid":"2",
                        "tieroffloadscheduleid":"6",
                        "tierencryption":"false",
                        "tierrecallexpirytime":"1",
                        "tiercompactionscheduleid":"4",
                        "tiercompactionoverheadthresh":"30",
                        "gateway":"10.10.108.120:8660",
                        "cvtotalused":0
                }
        ]
}
```

Offloading a Volume to a Tier

Explains how to offload a volume to a tier using either the Control System, the CLI, or the REST API.

At the volume level, data can be offloaded automatically by creating and associating a schedule with the tiering enabled volume or manually by triggering the offload operation. See Data Offload and Purge on page 475 for more information. The following sections describe how to set up an automatic offload of data and how to trigger a one-time manual offload data at the volume level using either the Control System, the CLI, or the REST API.

Note: For a tiered volume, there can be only one running job at any given time. For example, suppose another job is running on the tiered volume, if you trigger an offload operation, the offload operation will fail.

To offload volume data, you must have one of the following permissions:

- Cluster level fc permissions
- Volume level fc permissions
- Volume modify permissions

last-updated: Apr 11, 2022

Note: You can also offload individual files in a tiering-enabled volume to the associated tier. See Offloading a File to a Tier Using the CLI and REST API on page 1012 for more information.

Important: EC volumes are automatically offloaded once they crossed the size of `autooffloadthresholdgb` even if they are not using the Automatic scheduler. The default size is 1024 GB (1 TB). You can modify this size as specified in Offloading a Volume to a Tier on page 933.

Setting up Automatic Offload of Data Using the Control System

1. Create a tier.

   See Creating a Cold Tier Using the Control System on page 959 or Creating a Warm Tier Using the Control System on page 959 for more information.

2. Create a storage policy to associate with the volume.

   See Creating a Storage Tier Policy Using the Control System on page 972 for more information.

3. Create an offload schedule.

   See Specifying a Schedule for Offloading Data on page 928 for more information.

4. Create a tiering enabled volume and associate the tier, the storage policy, and schedule with the volume.

   See Creating a Tiering-Enabled Volume Using the Control System on page 931 for more information.

Triggering an Offload of all Data in a Volume to a Tier Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane.

   Selecting a volume makes the **Actions** drop-down menu available.

3. Click **Offload Data** from the **Actions** drop-down menu to display the **Offload Volume Data** confirmation window.

4. Review the list of volumes to offload and click **Offload**.

If the offload fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 939 for more information.

Setting up Automatic Offload of Data Using the CLI and REST API

To automatically offload data:

1. Create a tier, a rule that contains the criteria for offloading data to the tier, and a schedule to automatically offload data to the tier.

   For example:

CLI

```
/opt/mapr/bin/maprcli tier
create -name <tier_name> -type
ectier
/opt/mapr/bin/maprcli tier
create -name <tier_name> -type
cold -url <tier_url> -credential
<credentials>.txt -json
/opt/mapr/bin/maprcli tier rule
create -name <rule_name> -expr
```

```
<expressions>
/opt/mapr/bin/maprcli schedule
create -schedule <JSON>
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=ectier' --user
 mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=cold&url=<tier
_url>&credential=<credential_str>'
 --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/
create?
name=<rule_name>&expr=<expressions>'
 --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/schedule/create?
schedule=<JSON>' --user mapr:mapr
```

For more information, see Managing Tiers on page 957 and Managing Storage Policies on page 970.

2. Create a tiering-enabled volume and associate the tier, rule, and schedule (that you created in step 1) with the volume.

   For example, to create a volume and enable it for:

   - Warm tier:

     CLI

     ```
     /opt/mapr/bin/maprcli volume
     create -name <vol_name> -path
     <vol_mount_path> -tieringenable
     true -tiername
     <tier_name> -ecscheme
     <coding_scheme> -ectopology
     <ec_vol_topo> -tieringrule
     <rule_name> -offloadschedule
     <schedule_ID>
     ```

     REST

     ```
     curl -k -X POST 'https://
     abc.sj.us:8443/rest/volume/create?
     name=<vol_name>&path=<vol_mount_pat
     h>&tieringenable=true&tiername=<tie
     r_name>&ecscheme=<coding_scheme>&ec
     topology=<ec_vol_topo>&tieringrule=
     <rule_name>&offloadschedule=<schedu
     le_ID>' --user mapr:mapr
     ```

   - Cold tier:

     CLI

     ```
     /opt/mapr/bin/maprcli volume
     create -name <vol_name> -path
     <vol_mount_path> -tieringenable
     true -tiername
     ```

last-updated: Apr 11, 2022

```
<tier_name> -tieringrule
<rule_name> -offloadschedule
<schedule_ID> -recallexpirytime
2 -json
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_pat
h>&tieringenable=true&tiername=<tie
r_name>&tieringrule=<rule_name>&off
loadschedule=<schedule_ID>&recallex
pirytime=2' --user mapr:mapr
```

You can also specify the maximum amount of data (in GB) to offload automatically for warm-tier volumes using the `autooffloadthresholdgb` parameter. For more information, see Working with Tiered Volumes on page 926.

Triggering an Offload of all Data in a Volume to a Tier Using the CLI and REST API

CLI

Run the following command to manually trigger an offload of all data in the volume:

```
maprcli volume offload -name
<volume-name>
```

If you run the command with the `ignorerule` option value set to `true`, rules for the volume where the data resides is ignored and data is offloaded immediately. If the `ignorerule` option value is not specified or is set to `false` (default), data is offloaded based on the rules associated with the volume where the data resides.

REST

Submit a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/offload?
name=sampleVol' --user mapr:mapr
{"timestamp":1519947659597,"timeofday"
:"2018-03-01 03:40:59.597 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully started
offload."]}
```

For more information, see `volume offload` on page 2023.

If the offload fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 939 for more information.

Recalling a Volume to MapR File System

Explains how to recall offloaded data to the filesystem.

When you:

- Read data offloaded to a remote target (or cold tier), data is automatically recalled to the MapR File System to allow the read to succeed.
- Modify data offloaded to an erasure coded volume (or warm tier) or a remote target (or cold tier), data is automatically recalled to the MapR File System to allow the write to succeed.

The recalled data is automatically:

- Purged based on the expiration time period set at the volume level for recalled data if there are no changes (for example, read operation).
- Offloaded based on the rule and the expiration time period set at the volume level for recalled data if there are changes (for example, overwrite operation).

See Data Reads, Writes, and Recalls on page 481 for more information. If the recall fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 939 for more information.

You can manually recall all data in a volume using the Control System, CLI, or the REST API.

Note: For a tiered volume, there can be only one running job at any given time. If you trigger a recall operation when another job is running on the tiered volume, the recall operation will fail.

You can also recall individual files from the tier. See Recalling a File to MapR File System Using the CLI and REST API on page 1012 for more information.

Recalling Offloaded Volume Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to recall from the list of volumes in the **Volumes** pane.
   Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Recall Data** from the **Actions** drop-down menu to display the **Recall Tiered Data** confirmation window.
4. Review the list of volumes to recall and click **Recall Volumes**.
   For more information, see Recall of Tiered Data on page 484.

Recalling Offloaded Volume Using the CLI and REST API

CLI	Run the following command to recall volume data: `/opt/mapr/bin/maprcli volume recall -name <volName>`
REST API	Send a request of type POST to URL. For example: `curl -k -X POST 'https://abc.sj.us:8443/rest/volume/recall?name=volName' --user mapr:mapr`

For more information, see `volume recall` on page 2025.

Viewing the List of Running Jobs

You can view the tiering jobs currently running for a volume using the CLI and REST API. For a tiered volume, at any given time, there can be only one running job.

- Run the following command or send a request of type GET to retrieve the list of currently running tiering operations for a volume:

CLI	`maprcli volume tierjobstatus -name <volName>`
REST	`curl -k -X GET 'https://<host>:8443/rest/volume/tierjobstatus?name=<volName>' --user mapr:mapr`

For more information, see `volume tierjobstatus` on page 2038.

Terminating a Running Volume-Level Tiering Job
Describes how to terminate a volume-level tiering job using either the Control System or the CLI.

You can terminate an ongoing offload or recall of a volume using the Control System or the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the `volume offload` on page 2023 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See Recalling a Volume to MapR File System on page 936 for more information.

You can check the status of an abort operation using the `volume tierjobstatus` on page 2038 command.

Note: If you terminate a job that CLDB was retrying after a prior failed attempt (FailureRetriable job), CLDB will stop trying to run the job again. For more information on FailureRetriable job, see Retrying Failed Operation on page 939.

For information on terminating a file-level job, see Terminating a Running File-Level Tiering Job on page 1013 and Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1014.

Terminating a Volume Offload or Recall Operation Using the Control System

1. Log in to the Control System and click **Data** > **Volumes**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane.

   Selecting a volume makes the **Actions** drop-down menu available.

3. Click **Abort Tiering Job** from the **Actions** drop-down menu to display the **Abort Tiering Job** confirmation window.

4. Review the list of volumes and click **Abort Job**.

Aborting Volume Offload or Recall Operation Using the CLI and REST API

CLI

Run the following command to abort a running offload or recall operation:

```
maprcli volume tierjobabort -name
<volName>
```

For more information, see volume tierjobabort on page 2037.

REST API

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<host>:8443/rest/volume/
tierjobabort?name=<volName>' --user
mapr:mapr
```

Retrying Failed Operation

Volume-level

If an offload, recall, or abort operation for a volume fails, the volume tierjobstatus on page 2038 command shows one of the following statuses:

FailureFatal	Indicates failure is fatal and CLDB cannot retry the operation again.
FailureRetriable	Indicates failure to offload; however, CLDB will try again if the job is not manually restarted again or aborted.

CLDB tries the operation again (up to 5 times by default) after a specific wait time (of 30 minutes by default) for the following errors:

- EAGAIN
- ETIMEDOUT
- ENETUNREACH
- ENETDOWN
- ECONNRESET

The `RetryCount` field value in the volume tierjobstatus on page 2038 command output shows the number of times CLDB has retried so far. For example:

```
# maprcli volume tierjobstatus -name
testvol -json
{
 "timestamp":1503308792266,
 "timeofday":"2017-08-21 09:46:32.266
GMT+0000",
 "status":"OK",
 "total":1,
 "data":[
  {
   "offload":{
    "state":"FailureRetriable,
```

last-updated: Apr 11, 2022

```
RetryCount: 5",
    "startTime":"2017-08-21
09:07:17.506 GMT+0000",
    "endTime":"2017-08-21
09:08:49.799 GMT+0000",
    "gateway":"10.10.102.68:8660"
   }
  }
 ]

```

File-level

If the offload or recall operation for an individual file fails, the `file tierstatus` on page 1676 or `hadoop mfs` on page 5373 command returns one of the following:

Code	Message	Description
0	HAS_LOCAL_DATA	Indicates that the file is not yet fully offloaded.
1	NO_LOCAL_DATA	Indicates that the file was completely offloaded.
2	OP_FAIL	Indicates that the operation to retrieve the status failed.
3	INVALID_FILE	Indicates that the file does not exist.
4	FILE_NOT_TIERED	Indicates that the file is not in a tiered volume.
5	FILE_EMPTY	Indicates that the file specified for offload is an empty file.
6	NO_GATEWAY	Indicates that no MAST Gateways are available for offload operation.
7	OP_TIMEOUT	Indicates that there was no response from the MAST Gateway (maybe as a result of an error) during the offload or recall operation.
8	FTOS_SUCCESS	Indicates that the file was successfully offloaded or recalled.

last-updated: Apr 11, 2022

Code	Message	Description
9	FTOS_ABORTED	Indicates that the file offload or recall operation was aborted.
10	FTOS_ABORT_IN_PROGRESS	Indicates that the file offload or recall job is being aborted.
11	FTOS_TRANSFER_IN_PROGRESS	Indicates that the file offload is in progress.
12	FTOS_REQ_QUEUED	Indicates that the file offload is scheduled, but has not yet started.
13	FTOS_JOB_NOT_AVAILABLE	Indicates that the job ID specified with the tierjobstatus command is not available.

When a file-level offload or recall operation fails, CLDB **does not** retry the operation. For failed file-level:

- Offload operation, you can run the command to retry the operation. For more information, see Offloading a File to a Tier Using the CLI and REST API on page 1012. Alternatively, if the volume that the file is associated with has a data offload schedule, the file data is automatically offloaded based on the rules associated with the volume.
- Recall or abort operation, you can run the command again to retry the operation if the error returned is not EIO.

You can configure the number of times CLDB retries and the interval between retries using the CLI.

Configuring the Number of Retries

- Set the value for the `cldb.gateway.retry.count` parameter, whose default value is 5, to configure the number of times that CLDB tries again. For example, to configure CLDB to retry to offload, recall, or abort at least 10 times, run the following command:

```
# maprcli config save -values {"cldb.gateway.retry.count":"10"}
```

Configuring the Interval Between Retries

- Set the value for the `cldb.gateway.retry.waittime.seconds` parameter, whose default value is 1800 seconds (30 minutes), to configure the amount of time CLDB waits between retries. For example, to configure CLDB to wait for up to 4 hours (14400 seconds), run the following command:

```
# maprcli config save -values
{"cldb.gateway.retry.waittime.seconds":"14400"}
```

last-updated: Apr 11, 2022

Running the Compactor Using the CLI and REST API

You can trigger the compactor using the CLI and REST API to purge recalled data on the MapR cluster or to purge stale data on the tier. See Data Compaction on page 485 for more information.

Running the Compactor to Purge Recalled Data on the MapR Cluster

CLI	Run the following command to trigger the compactor and purge data whether or not the expiry time for recalled data has been reached: `maprcli volume compact -name <volName> -forcerecallexpiry true`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/volume/compact?name=<volName>&forcerecallexpiry=true' --user mapr:mapr`

For more information, see `volume compact` on page 1927.

Running the Compactor to Purge Stale Data on the Tier

CLI	Run the following command to trigger the compactor: `maprcli volume compact -name <volName>`
REST	Send a request of type POST. `curl -k -X POST 'https://<host>:8443/rest/volume/compact?name=<volName>' --user mapr:mapr`

When you trigger the compactor, the compactor purges stale data from the tier and also recalled data on the MapR cluster if the expiry time for recalled data has been reached. For more information, see `volume compact` on page 1927.

Retrieving the Status of a Volume-level Tiering Operation

You can check the status of an active volume offload, completed offload, aborted offload, and recall operations using the Control System, the CLI, and the REST API. For information on file level tiering job, see Retrieving Status of File-level Tiering Operation and File Data on page 1015.

Retrieving Status of Volume-level Operation Using the Control System

- Log in to the Control System and click **Data** > **Volumes**.
  The **Volumes** pane in the page displays the following for tiered volumes:
  - **Job** — The currently running or last completed tiering job for the volume.
  - **State** — The status of the tiering job.
  - **Progress** — The completion percentage of the tiering job.

Retrieving Status of Volume-level Operation Using the CLI and REST API

CLI

Run the following command to check the status of an active or completed offload, abort, and/or recall operation:

```
maprcli volume tierjobstatus -name
<volume_name> -json
```

Note: You must have full control (fc) permissions either at the cluster or at the volume level to run this command. To determine the status of a compaction operation, specify the `verbose` option with the `tierjobstatus` command. For example:

```
maprcli volume
tierjobstatus -name
<volume_name> -verbose true -json
```

REST

Send a request of type GET.

```
curl -k -X GET 'https://
<host>:8443/rest/volume/tierjobstatus?
name=<volume_name>' --user mapr:mapr
```

See Statuses on page 2040 for more information.

Retrieving Tiering Statistics Using guts

Explains how to use the `guts` utility to retrieve tiering statistics.

You can run the `/opt/mapr/bin/guts` utility to get granular information on ongoing offloads and recalls including:

- The number of objects that are offloaded to and recalled from the tier
- The number of reads and writes on MapR Database
- The number of reads and writes on MapR File System

Syntax

```
/opt/mapr/bin/guts <argument>:<options>
```

Arguments

Argument	Description
`mastgateway`	Refers to operations on the MAST Gateway node. See Usage on page 944 for information on the syntax for running the guts command with this argument.
`fstier`	Refers to operations on MapR File System node. See Usage on page 944 for information on the syntax for running the guts command with this argument.

last-updated: Apr 11, 2022

Options

Option	Description
`all`	Statistics for all operations.
`db`	Statistics for MAST Gateway operations currently running on MapR Database.
`mfsops`	Statistics for MAST Gateway operations on MapR File System.
`none`	Specifies the column(s) to exclude from the output.
`tier`	Statistics for MAST Gateway operations on the storage tier.

Usage

MAST Gateway Node

```
/opt/mapr/bin/guts mastgateway:all
/opt/mapr/bin/guts mastgateway:db
/opt/mapr/bin/guts mastgateway:tier
/opt/mapr/bin/guts mastgateway:mfsops
/opt/mapr/bin/guts mastgateway:none
```

MapR File System Node

```
/opt/mapr/bin/guts fstier:all
/opt/mapr/bin/guts fstier:none
```

Note: These commands might show statistics for several other fields. To skip, use `none` with the components whose fields you do not wish to retrieve. For example, to retrieve statistics for only the mastgateway tier, run the following command:

```
/opt/mapr/bin/guts allocator:none btree:none cache:none cleaner:none
client:none cpu:none db:none dbrepl:none disk:none fs:none fstier:none
gateway:none io:none kv:none log:none mastgateway:tier net:none
nfs:none rpc:none ssd:none streams:none time:none vcd:none
```

Output

`mastgateway:tier`

`objP`	Number of objects (whose maximum size is 8MB for cold-tier or whose size is computed based on the erasure coding scheme for warm-tier) that were offloaded to the storage tier.
`objG`	Number of objects (whose size is up to 1 MB for cold-tier and whose size is computed based on the erasure coding scheme for warm-tier) that were recalled from the storage tier.
`objD`	Number of deletions on the tier.

last-updated: Apr 11, 2022

`objPM`	Amount of data (in MB) offloaded per second to the storage tier.
`objGM`	Amount of data (in MB) recalled per second from the storage tier.

`mastgateway:db`

`tdbP`	Number of *puts* on MapR Database tables.
`tdbG`	Number of *gets* on MapR Database tables.
`tdbD`	Number of *deletes* on MapR Database tables.

`mastgateway:mfsops`

`moR`	Number of *read* requests from client to the MAST Gateway service to read from cache volumes.
`mp`	Number of MapR File System *purge* requests sent by the MAST Gateway service.
`mrw`	Number of MapR File System *reads* from the MAST Gateway service to perform modify/write operation.
`moRM`	Amount of MapR File System *reads* (in MB) sent by the MAST Gateway service to read offloaded data.
`mrwM`	Amount of *recall writes* (in MB) sent by the MAST Gateway service.

`fstier:all`

`tp`	Number of blocks (of 64KB) *purged* during an offload operation.
`trw`	Number of blocks (of 64KB) *written* during recall of offloaded data.
`trr`	Number of blocks (of 64KB) *read* during read of offloaded data.
`twr`	Number of blocks (of 64KB) *recalled* for partial overwrites.

last-updated: Apr 11, 2022

`guts` is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. `guts` is an internal utility, and is subject to change without notice.

cldbguts on page 2080
Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

Moving back end Volume from the Command Line

This section contains information on migrating the following volumes to a different topology:

- Metadata volume, which stores the DB tables for the metadata associated with the tier.
- Erasure-coded volume, which stores the erasure-coded data.

Moving Metadata Volume to Another Topology

By default, the volume, which stores the DB tables for the metadata associated with the tier, is created in `/var/mapr/tier/mapr.internal.tier.<volName>` and is in the `/data` topology. However, you can move the metadata volume to another topology using the `volume move` on page 2021 command. For example:

CLI

```
/opt/mapr/bin/maprcli
volume move -name
<metadataVolName> -topology <newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<metadataVolName>&topology=<newTo
po>' --user mapr:mapr
```

Moving Erasure-Coded Volume to Another Topology

The erasure-coded volume is by default created in the same topology as the front-end volume. You can specify a different topology for the erasure-coded volume when creating a front-end volume. You can also move the erasure coded volume to a different topology using the `volume move` on page 2021 command. For example:

CLI

```
/opt/mapr/bin/maprcli volume
move -name <volName> -ectopology
<newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<volName>&ectopology=<newTopo>'
 --user mapr:mapr
```

Here, the `name` parameter takes the name of the front-end volume and the `ectopology` parameter takes the topology to which to move the erasure-coded volume associated with the front-end volume. For more information, see `volume move` on page 2021.

last-updated: Apr 11, 2022

Using Volume Links for Read and Write Operations

When you mirror a volume, read requests to the source volume can be served by any of its mirrors on the same cluster via a volume link of type `mirror`. A volume link is similar to a normal volume mount point, except that you can specify whether it points to the source volume or its mirrors.

- To write to (and read from) the source volume, mount the source volume normally.

  As long as the source volume is mounted below a non-mirrored volume, you can read and write to the volume normally via its direct mount path. You can also use a volume link of type `writeable` to write directly to the source volume regardless of its mount point.

- To read from the mirrors, use the `volume link create` command to make a volume link (of type `mirror`) to the source volume.

  Any read requests from the volume link are distributed among the volume's mirrors. Since the volume link provides access to the mirror volumes, you do not need to mount the mirror volumes.

Managing Snapshots

This section provide information about managing snapshots.

A snapshot is a read-only image of a volume at a specific point in time. On clusters with an Enterprise Edition or higher license, you can create a snapshot manually or automate the process with a schedule. Snapshots are useful any time you need to be able to roll back to a known good data set at a specific point in time. For example, before performing a risky operation on a volume, you can create a snapshot to enable rollback capability for the entire volume.

A snapshot takes no time to create, and initially uses no disk space, because it stores only the incremental changes needed to roll the volume back to the state at the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota. When you view the list of volumes on your cluster in the MapR Control System, the value of the Snap Size column is the disk space used by all of the snapshots for that volume.

Note: Snapshot volumes inherit the auditing configurations of their original read-write volumes. For details about auditing, see Auditing.

You can perform the following tasks using the MapR Control System and the CLI.

Creating Volume Snapshots

Describes how to create snapshots of volumes using the Control System and the CLI.

You can create a snapshot manually using the Control System and the CLI, or use a schedule to automate snapshot creation.

Creating Snapshots of Multiple Volumes Using the Control System

To create snapshots of multiple (standard and/or mirror) volumes manually:

1. Log in to the Control System and go to the **Summary** tab in the **Data** > **Volumes** page.
2. Select the volume(s) for which you need to create the snapshots.
3. Click **Snapshot Volume** from the **Actions** drop-down menu.
   The **Snapshot Volume(s)** confirmation dialog displays.
4. Verify the list of volumes and enter a unique name for the snapshot in the **New Snapshot Name** field.
5. Click **Snapshot Volumes**.

last-updated: Apr 11, 2022

Creating a Snapshot of a Volume Using the Control System

You can create a snapshot manually or use a schedule to automate snapshot creation. To create a snapshot of a volume manually:

1. Log in to the Control System and go to the **Snapshots** tab in the volume information page.
2. Click **Create Snapshot** to display the **Create Snapshot** window.
3. Enter a unique name for the snapshot in the **New Snapshot Name** field.
4. Click **Create Snapshot** to create a snapshot of the volume.
   By default, manually created snapshots do not have an expiration date.

Creating Volume Snapshots Using the CLI or REST API

The basic command to create a snapshot is:

```
maprcli volume snapshot create -snapshotname <snapshot> -volume <volume>
```

For complete reference information, see `volume snapshot create` on page 2028.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

- The **Snapshots** tab under the **Data** > **Volumes** page displays all the snapshots on the cluster.
  For each snapshot, you can view the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	TBD

  You can select one or more snapshots to:

  - Preserve
  - Remove

Viewing the Snapshots Associated with a Volume Using the Control System

- Log in to the Control System and go to the **Snapshots** tab in the volume information page.
  The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.

last-updated: Apr 11, 2022

Column Name	Column Description
Expires On	The date when the snapshot expires.
Reclaim Size	TBD

You can create a snapshot of the volume or select one or more snapshots to:

- Preserve
- Remove

Viewing Snapshots Using the CLI or REST API

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see `volume snapshot list` on page 2030.

Viewing the Contents of a Snapshot from the Command Line
Describes how to view the contents of the `.snapshot` directory from the CLI.

At the top level of each volume is a directory named `.snapshot` containing all the snapshots for the volume. You can view the directory with `hadoop fs` commands or by mounting the cluster with NFS. To prevent recursion problems, `ls` and `hadoop fs -ls` do not show the `.snapshot` directory when you list the contents of the top-level volume directory. You must navigate explicitly to the `.snapshot` directory to view and list the snapshots for the volume.

Example:

```
hadoop fs -ls /myvol/.snapshot
   Found 1 items
   drwxrwxrwx   - root root          1 2011-06-01 09:57 /myvol/.snapshot/
2011-06-01.09-57-49
```

In the preceding example, `/myvol` is the mount point of the volume for which the snapshot named `2011-06-01.09-57-49` was created and stored in the `.snapshot` directory.

Preserving one or more Snapshots
Describes how to preserve a snapshot using the `volume snapshot preserve` command, or using the Control System.
Preserving Snapshots Using the Control System

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots, in the **Snapshots** tab (under **Data** > **Volumes**):

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the snapshot(s) you want to preserve.
2. Click **Preserve Snapshot** to preserve the snapshot(s).
   The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
   The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

last-updated: Apr 11, 2022

Preserving Snapshots Associated with a Volume Using the Control System

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots (and prevent them from expiring) associated with a volume:

1. Log in to the Control System and go to the **Snapshots** tab in the volume information page.
   The list of snapshots associated with the volume displays.
2. Select the snapshots to preserve and click **Preserve Snapshot**.
   The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
   The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Using the CLI or the REST API

The basic command to preserve the snapshots is:

```
maprcli volume snapshot preserve
```

For complete reference information, see `volume snapshot preserve` on page 2034.

Removing one or more Snapshots

Explains how to remove a snapshot using the `volume snapshot remove` command or using the Control System.

Each snapshot has a date and time at which it expires. You can remove a snapshot manually before its expiration, or you can preserve a snapshot to prevent it from expiring.

Removing Snapshots Using the Control System

To remove one or more snapshots, in the **Snapshots** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** in the Kubernetes version of the Control System.

1. Select the snapshots to remove.
2. Click **Remove Snapshot**.
   The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
   When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

Removing Snapshots Associated with a Volume Using the Control System

To remove one or more snapshots associated with a volume:

1. Log in to the Control System and go to the **Snapshots** tab in the volume information page.
   The list of snapshots associated with the volume displays.
2. Select the snapshots to remove and click **Remove Snapshot**.
   The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
   When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

last-updated: Apr 11, 2022

Removing Snapshots Using the CLI or REST API

The basic command to remove a snapshot is:

```
maprcli volume snapshot remove
```

For complete reference information, see `volume snapshot remove` on page 2036.

Copying From a Snapshot Using the CLI

Describes how to create a volume by copying data from a snapshot

Copying data from a snapshot involves a simple copy operation from the `.snapshot` directory to the destination, as in the following example. User input is marked in **bold**:

Note: This example assumes that the file system is mounted on /mapr using FUSE as explained in Mounting the Filesystem.

```
[user@host]$ maprcli volume snapshot create -snapshotname
uservolsnap -volume users
[user@host]$ maprcli volume snapshot list
snapshotid  sharedSize  volumename  ownername  cumulativeReclaimSizeMB
numSizeUpdates  snapshotname  enforcementMode      ownedsize
sizeUpdateRequestedAt         ownertype  numSizeUpdatesDesired  volumeid
creationtime                  volumepath  volumeSnapshotAces
256000049   0           users       mapr       0
0               uservolsnap   PolicyAceAndDataAce  0          Mon Jun 14
05:44:11 UTC 2021  1          1                      77144951  Mon Jun 14
05:44:11 UTC 2021  /user       ...

[user@host]$ ls -l /mapr/my.cluster.com/user/
total 1
drwxr-xr-x 2 mapr mapr 2 Jun 13 14:34 mapr

[user@host]$ ls -l /mapr/my.cluster.com/user/.snapshot
total 1
drwxr-xr-x 2 mapr mapr 2 Jun 13 14:37 uservolsnap

[user@host]$ cp /mapr/my.cluster.com/user/.snapshot/uservolsnap/mapr/* /
mapr/my.cluster.com/user/
```

Managing User Disk Usage

The **User Disk Usage** tab in the **Data** > **Volumes** page displays information about disk usage by cluster users. You can perform the following tasks to manage disk quotas using the MapR Control System and the CLI.

Viewing User Disk Usage Information

Explains how to view user disk usage information using either the Control System or the CLI.

Viewing User Disk Usage Information Using the Control System

To view information about disk usage by cluster users:

- Log in to the Control System and go to the **User Disk Usage** tab under **Data** > **Volumes**.

  Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

  The disk usage information for all the users displays. For each user, the **Accountable Entities** pane displays the following:

last-updated: Apr 11, 2022

Column Name	Column Description
Type	The type of *accountable entity (AE)*. Value can be User or Group.
Accountable Entity	The user or group responsible for the volume.
Disk Usage	The total disk space used by the user.
Volume Count	The number of volumes.
Hard Quota	The user's hard quota.
Advisory Quota	The user's advisory quota.
Email	The email address of the user.

Selecting the checkbox beside an accountable entity makes the **Edit Properties** button available. You can modify the quotas for the selected entities by clicking Edit Properties. Alternatively, you can click on an entity or associated to modify the email address and quotas for the entity.

Viewing User Disk Usage Information Using the CLI or REST API

The basic command to view user disk usage information is:

```
maprcli entity info -name <entity name> -type <type>
```

For complete reference information, see `entity info` on page 1646.

Set or Modify Quotas for Users and/or Groups
Explains how to set or modify quotas for one or more entities using either the Control System or the CLI.
Set or Modify Quotas for Multiple Users and/or Groups Using the Control System

To edit the quota, which limits the space used by all the volumes owned by a user or group, for one or more users, in the **User Disk Usage** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the users/groups from the list of users/groups in the **Accountable Entities** pane.
2. Click **Edit Properties**.
   The **Edit Properties** dialog displays.
3. Verify the list of users/groups and modify or set the following for the users/groups:
   a) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
   b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

   Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), or terabytes (TB).
4. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for an Entity Using the Control System

To edit the quota, which limits the space used by all the volumes owned by a user or group, for a user, in the **User Disk Usage** tab under **Data** > **Volumes**:

last-updated: Apr 11, 2022

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Click the user/group from the list of users/groups or the associated with the user/group in the **Accountable Entities** pane to display the **Edit Properties** window.
2. Modify or set the following for the user or group:
   a) Enter the email address of the user/group.
   b) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
   c) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.
   The advisory quota must be less than the hard quota.

   Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).
3. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for Users and/or Groups Using the CLI or the REST API

The basic command to set or modify quotas for multiple entities is:

```
maprcli entity modify
        -entities <entities>
        -advisoryquota <advisory quota>
        -quota <quota>
```

The basic command to set or modify quotas for an entity is:

```
maprcli entity modify
        -name <entityname>
        -type <type>
        -advisoryquota <advisory quota>
        -quota <quota>
```

For complete reference information, see `entity modify` on page 1649.

accountable entity (AE) on page 6593

Managing Schedules

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors and the offload of volume data to a storage tier; after you create a schedule, it appears as a choice in the scheduling menu when you are creating or editing a volume.

When you specify a *snapshot* schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume. A snapshot schedule for a promotable mirror volume has two purposes:

- It specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.

last-updated: Apr 11, 2022

- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

A *mirror* schedule specifies how frequently the mirror volume is synchronized with the source volume. In case of a disaster (or any type of data loss on a read-write source volume), the data can be recovered from the mirror volume, but any data written to the source volume since the last successful mirror operation will not be on the mirror volume. Therefore, you should set the mirror schedule such that it meets your RPO (Recovery Point Objective).

A *tier offload* schedule specifies how frequently data in the volume on the MapR cluster is offloaded to the tiered storage. The MAST Gateway uses this setting to automatically offload data to the storage tier.

Schedules require the Enterprise Edition license.

Viewing the List of Schedules
Explains how to view all the schedules using the Control System or the CLI.
Viewing the List of Schedules Using the Control System

To view all the schedules:

Log in to the Control System and go to the **Schedules** tab under **Data** > **Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The page displays all the schedules. For each schedule, the page displays the following:

Column Name	Column Description
Schedule Name	The name of the schedule.
ID	The schedule ID.
In Use	Checkmark (✓) indicates the schedule is currently being used.
Detail	The schedule details such as the recurring points in time when the associated actions occur and how long the data is preserved.

Selecting the checkbox associated with a schedule makes the **Remove Schedule** button available. You can:

- Create a new schedule by clicking **Create Schedule**
- Remove a schedule by selecting the checkbox beside the schedule (to remove) and then by clicking **Remove Schedule**
- Edit a schedule by clicking the schedule name

Retrieving the List of Schedules Using the CLI or REST API

The basic command to retrieve a list of schedules is:

```
maprcli schedule list
```

For complete reference information, see `schedule list` on page 1740.

Creating a Schedule
Explains how to create a schedule using the Control System or the CLI.

last-updated: Apr 11, 2022

Creating a Schedule Using the Control System

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors. To create a new schedule:

1. Log in to MCS and do one of the following:
   - Go to the **Schedules** tab in the **Data** > **Volumes** page to create a schedule.
   - Go to the **Schedules** tab in the **Create Volume**, **Edit Volume**, or **Edit Volumes** page to create a schedule and associate it with the volume.
2. Click one of the following based on the page you are on to display the **Create Schedule** window:
   - **Create Schedule** button in the **Schedules** tab of the **Data** > **Volumes** page.
   - **Create** link (associated with the type of schedule) in the **Schedules** tab of the **Create Volume**, **Edit Volume**, or **Edit Volumes** page.
3. Enter a name for the schedule in the **Schedule Name** text field.
4. Specify the schedule rules with the following components:

Frequency	Specify frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes).
Time	Specify the point of time within the specified frequency to perform the scheduled action. For example, if you selected Monthly from the first drop-down menu, select the day of the month from the second drop-down menu. Continue with each drop-down menu, proceeding to the right, to specify the time at which the scheduled action is to occur.  **Note:** This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily.
Retain for	Specify how long the data should be preserved. For example, if the schedule is attached to a volume for creating snapshots, the **Retain for** specifies how far after creation the snapshot expiration date is set.

   If necessary, click **Add Another** to add another rule to the schedule or  to remove a rule.
5. Click **Create Schedule** to create the schedule.
   After the schedule is created, it appears as a choice in the scheduling menu when you are creating a new volume or editing a volume.

Creating a Schedule Using the CLI or REST API

The basic command to create a schedule is:

```
maprcli schedule create -schedule <JSON>
```

For complete reference information, see `schedule create` on page 1739.

Guidelines for Setting Mirror Schedules

Although MapR allows mirroring frequencies up to once per minute, setting a schedule at this frequency is not practical nor advisable. When you choose the mirror schedule, consider the amount of data on the volume and the load on the cluster. Remember that the mirroring frequency must allow enough time to complete one mirror operation before the next scheduled mirror operation starts. In addition, if you have a cascaded mirror setup (where A mirrors to B which mirrors to C), you cannot set a mirror schedule for C that starts before B finishes mirroring from A.

 **Warning:** In general, you should not set a mirror schedule for more often than every 30 minutes.

last-updated: Apr 11, 2022

If you set a mirror schedule to start mirroring before the previous mirror operation finishes, you will see an error message similar to this:

```
WARN Alarms [pool-2-thread-1]: Alarm raised: VOLUME_ALARM_MIRROR_FAILURE;
Cluster: Cluster1; Volume: ; Message: Cannot start new scheduled mirror
because existing mirror is in progress
```

Modifying a Schedule
Explains how to modify a schedule using either the Control System or the CLI.
Modifying a Schedule Using the Control System

When you modify a schedule, the new set of rules replaces any existing rules for the schedule. To edit a schedule, in the **Schedules** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Click the schedule name of the schedule to edit.
   The **Edit Schedule** dialog displays.
2. Modify the schedule as desired:
   a) Change the schedule name in the **Schedule Name** field.
   b) Add, modify, or remove rules in the **SCHEDULE RULE** section.
   Here:

Frequency	Specifies the frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes).
Time	Specifies the point of time within the specified frequency to perform the scheduled action. This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily.
Retain for	Specifies how long the data should be preserved.

   To add another rule, click **Add Another** and to remove a rule, click  .
3. Click **Save Changes** for the changes to take effect.

Modifying a Schedule Using the CLI or REST API

The basic command to modify a schedule is:

```
maprcli schedule modify -id <schedule ID> -rules <JSON>
```

For complete reference information, see `schedule modify` on page 1744.

Removing one or more Schedules
Describes how to remove schedules not associated with any volumes using either the Control System or the CLI.

You can remove a schedule only if it is not associated with any volumes.

Removing one or more Schedules Using the Control System

To remove one or more schedules, in the **Schedules** tab under **Data** > **Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the schedule(s) to remove from the list of schedules.
2. Click **Remove Schedule** to display the **Remove Schedule** confirmation dialog.

3. Verify the list of schedules to remove click **Remove Schedule** to remove the schedules.
   When you remove a schedule, the schedule is removed from the system and cannot be restored.

Removing one or more Schedules Using the CLI or the REST API

The basic command to remove a schedule by ID is:

```
maprcli schedule remove -id <schedule ID>
```

For complete reference information, see `schedule remove` on page 1745.

Managing Tiers

You can create, modify, and remove tiers using the Control System and the CLI.

Enabling Tiering

Describes how to enable data tiering using both the Control System and the CLI.

For a primer on Data Tiering, see Data Tiering on page 469.

On all new installations, the data tiering functionality is enabled and available for all new volumes. If you are upgrading, you must enable data tiering; see Step 4: Enable New Features on page 330 for more information. If the data tiering functionality is enabled, you can then selectively enable tiering for a volume at the time of volume creation using the Control system and the CLI.

Data tiering is only available for new volumes; you cannot enable data tiering for existing volumes. Enable tiering for new volumes where read/write latency is not the dominant concern. You can decide later whether you want to do local (or warm) or remote (or cold) tiering. Data tiering cannot be disabled after it is enabled for a volume.

Enabling Tiering Using the Control System

1. Move the **Data Tier** slider to **Yes** (to enable tiering) in the **Create New Volume** page in the Control System.

   Proceed to the next step only if you wish to select a tier type for the volume. You can create a tiering-enabled volume without selecting a tier type and select a tier type later by editing the volume.

   Note: You cannot disable tiering for a volume after it is enabled.

2. (Optional) Select **Erasure Coding** (for warm tiering) or **Remote Archiving** (for cold tiering) from the **Tiering Type** drop-down menu.

   You:

   - Can enable a volume for either warm or cold tiering, but not for both.
   - Cannot modify the tier type after the volume is created.

3. Specify all other required and optional properties for creating the volume and click **Create Volume**.

   For information on required and optional properties, see Creating a Volume on page 864.

Enabling Tiering Using the CLI

- Run the following command to enable tiering:

  ```
  maprcli volume create -name <vol-name> -path <mount-path> -tieringenable
  true
  ```

  For more information, see `volume create` on page 1931.

last-updated: Apr 11, 2022

Advantages of Parallel Offload

Resiliency with Parallel Offload

Parallel Offload is resilient to the following scenarios:

Restart of the Primary Gateway	• Secondary gateways continue to run assigned tasks while the primary gateway is down or restarting. • CLDB reassigns the volume to another primary gateway. • CLDB restarts the tasks on the new primary gateway. • The primary gateway polls/reschedules the ongoing secondary gateway tasks.
Restart of the Secondary Gateway	• The primary gateway detects the failure of secondary gateway tasks when it polls the secondary gateway. • The primary gateway reschedules tasks that were terminated when the secondary gateway restarted.
Restart/Switchover of CLDB	• Reassign volume to the same primary gateway. • Reschedule pending volume task on the same primary gateway.

Load Balancing with Parallel Offload

Load Balancing involves:

Volume Level	• CLDB assigns each volume to a gateway with the least number of volumes. • Gateway Balancer reassigns volumes across gateways.
Task Level	CLDB balances tasks across MFS nodes.

Enabling Parallel Offload on an Upgraded Cluster

Creating a Storage Tier

Describes how to create a sotrage tier using the Control System and the CLI.

For a primer on Data Tiering, see Data Tiering.

You can create a tier using the Control System and the CLI.

When you create a tier, MapR File System creates a volume, whose mount point is `/var/mapr/tier/mapr.internal.tier.<tiername>`, for the tier. For warm tier volumes automatically created using the `ecenable` parameter or the Control System, by default, a corresponding tier volume named `mapr.internal.tier.autoec.<volName>.<creationTime>` is created in the `/var/mapr/autoectier` path. The tier volume is visible and stores all the metadata tables and information on all the jobs running on the tier. Do not modify, move, or remove this volume.

last-updated: Apr 11, 2022

Note: If the number of cluster nodes is more than five, by default, MapR (through the `enforceminreplicationforio` parameter) requires minimum number of copies of the tier volume for writes to succeed. If the number of cluster nodes is less than five, MapR does not enforce minimum number of copies for writes to succeed.

Creating a Warm Tier Using the Control System

When you create a volume enabled for erasure coding, the control system automatically creates a warm tier and associates the volume with that tier. See Creating a Volume on page 864 for more information. You cannot create a warm tier separately using the Control System.

Creating a Cold Tier Using the Control System

To create a cold tier:

1. Log in to the Control System, click **Data** > **Volumes**, and then do one of the following:
   - Go to the **Remote Targets** tab if you wish to create a remote target that is not (yet) associated with a volume.
   - Click **Create Volume** if you wish to create a remote target for a volume when you are creating the volume.

     Note: You must enable data tiering and select **Remote Archiving (Cold)** from the **Tiering Type** drop-down list to create the remote target.
   - Click **Edit Volume** in the volume information page if you want to create a remote target for the volume when you are editing the volume settings.

     Note: You can create a remote target only if a remote target is already not associated with the volume.
2. Click one of the following to display the **Create Remote Target** window.
   - **Create Target** if you are in the **Remote Targets** tab.
   - **Create** link associated with the **Remote Target** field if you are in the **Create New Volume** page.
   - **Create** link associated with the **Remote Target** field if you are in the **Edit Volume** page.
3. Specify a name for the tier in the **Remote Target Name** field.
4. Select a topology for the metadata volume associated with the tier from the list of topologies in the **Lookup Topology** drop-down menu.

   The volume stores all the metadata tables and information on all the jobs running on the tier. If many volumes share the same tier (and thus the same lookup topology), the lookups might have an adverse affect by inadvertently adding background load to nodes in that topology. This property allows you to setup the lookups on other nodes.
5. Specify the following properties.

last-updated: Apr 11, 2022

Vendor	The vendor from the **Vendor** drop-down list. **Note:** For cold tiering, MapR supports the following vendors: • AWS (Amazon AWS) • GCS (Google Cloud Platform) • HDS (Hitachi HCP) • IBM (IBM Cleversafe) • Azure Blob (Microsoft Azure) • Others (such as Minio) See Specifying the Vendor/Object Store for a Cold Tier on page 964 for more information on the supported vendors.
URL	The URL to use to connect to the tier in the following format: `<protocol>://<IP|hostname>.<domain>` If the protocol is `https`, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold-tier storage does not support HTTPS, all tier related operations will fail. If the cold tier does not support HTTPS, set the protocol to `http`. See Specifying the Vendor/Object Store for a Cold Tier on page 964 for more information on the tier endpoint URLs and supported authentication protocols.
Bucket Name	The name of the bucket on the tier. This cannot be modified once associated with a tier. If the bucket does not already exist on the tier, MapR will attempt to create the bucket. **Note:** For Azure, the bucket/container is created in the region that is specified in the parent storage account.
Region	The S3 region to create the bucket on. This cannot be modified once configured (explicitly or using the default) and associated with a tier. See region on page 963 for more information.

6. Enter the credentials for accessing the tier in the **Access Key** and **Secret Key** fields.

   Tip: For Azure Blobs, the storage account name is the access key.

7. Click **Create Target** to create the cold tier that you can associate with a volume.

Creating a Tier Using the CLI and the REST API

CLI	Run the following command to create a tier:

last-updated: Apr 11, 2022

- Cold tier:

```
$maprcli tier
create -name <tier_name> -type
cold -url <tier_url> -credential
<credentials_file_path>
```

For using the `-credential` option, you must have the credential file already set up as described in Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API on page 962. On the other hand, if you do not have the file already set up, use the `-credential_str` option as follows:

```
$maprcli tier create -name
<tier_name> -type cold -url
<tier_url> -credential_str
'<credential_string>'
```

- Warm tier with default values:

```
$maprcli tier create -name
<tier_name> -type ectier
```

Note: You can associate the same tier with multiple volumes with different erasure coding scheme.

REST

Send a request of type POST. For example:

- Cold Tier:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=egColdTier&type=cold&url=s3.am
azonaws.com&credential=credentials.
txt' --user mapr:mapr
{"timestamp":1525724933919,"timeofd
ay":"2018-05-07 01:28:53.919
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egColdTier'"]}
```

last-updated: Apr 11, 2022

- Warm tier:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=egWarmTier&type=ectier' --user
 mapr:mapr
{"timestamp":1525725105206,"timeofd
ay":"2018-05-07 01:31:45.206
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egWarmTier'"]}
```

Note: You can associate the same tier with multiple volumes with different erasure coding scheme.

For more information, see `tier create` on page 1874.

Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API

Describes how to create a credential file, with examples for AWS and Microsoft Azure.

Set up a credentials file on the host you plan to use for creating the cold tier if you are planning on using the `credential` option (and not pass the credentials on the command-line using the `credential_str` option).

For example, your `credentials.txt` file for AWS should look similar to the following sample file:

```
{
      "bucketName" : "defaultbucket3",
      "region": "us-east-1",
      "credentials" : {
         "accessKey" : "AB956CDE8F2GO7H9I4J2",
         "secretKey" : "5K1LmN92e65oPQRsTUvOfSbURxyEtYl2MmAocGi"
      }
}
```

The sample for Microsoft Azure is as follows:

```
maprcli tier create -name tier_azure_1 -type cold -url https://
myobjectpools1.blob.core.windows.net -credential ~/creds_azure.txt
$ cat creds_azure.txt
      {
      "bucketName" : "bucket4",
      "credentials" : {
      "accessKey" : "myobjectpools1",
      "secretKey" :
"N6GKkDPttqNc6rfTzhb2JNKwvdr9EraN89Mg8WaodrvPBeINBTZwhQu+Q3vX4ENeW+RQN42f+P8
nXN0YasZWNA=="
                     }
      }
```

The credentials file (`.txt` file) contains the following properties in JSON format:

bucketName	The name of the bucket on the tier. If the bucket does not already exist on the tier, the command to create the tier attempts to create the bucket using the credentials in the credentials file. You can modify the name of the bucket only by using the `-force` option with the `tier modify` on page 1882 command

region

The S3 region to create the bucket on. Use the information in the following table to specify region information.

Vendor	Default Value	Notes
AWS	us-east-1	Specify region information as defined here. On AWS, each region can have a different URL. The URL must be provided with the `maprcli tier create` command. **Note:** Because bucket names are unique across regions, make sure you specify the correct region for a given bucket in the credentials file. For example, suppose a bucket called myBucket3 in us-east-1; you cannot offload data to myBucket3 by specifying us-west-1 as the region in the credentials file.
GCS	us-east-1	Specify region information as described here.
HDP	N/A	Not required. If specified, MapR ignores the value.

last-updated: Apr 11, 2022

Vendor	Default Value	Notes
IBM	us-east-region	Not required. If specified, MapR ignores the value.
Azure-Blobs	N/A	Not required. The region of the storage account is determined from the URL and data is offloaded into that region.
Minio	us-east-1	If you specify region, export the `MINIO_REGION` environment variable on the minio server as described in the Configuration Guide.
Scality	us-east-region	Not required. If specified, MapR ignores the value.

You can modify the region only by using the `-force` option with the `tier modify` on page 1882 command.

accessKey and secretKey

The credentials for accessing the tier.

Tip: For Azure Blobs, the storage account name is the access key.

Note: Once the tier is created, MapR does not require this file because CLDB stores the bucket, region, and credentials information.

Specifying the Vendor/Object Store for a Cold Tier

Specify the vendor or object store where you plan to offload the (cold) data. The following table lists the supported vendors, URL of the tier endpoint, and authentication protocol supported by MapR:

last-updated: Apr 11, 2022

Supported Vendor/Object Store	Tier URL/Endpoint	Supported Authentication Protocol
AWS (Amazon AWS)	The URL varies based on the region. For: • us-east-1: https://s3.amazonaws.com • us-east-2: https://s3.us-east-2.amazonaws.com • us-west-1: https://s3-us-west-1.amazonaws.com • us-west-2: https://s3-us-west-2.amazonaws.com • ap-south-1: https://s3.ap-south-1.amazonaws.com • ap-southeast-1: https://s3-ap-southeast-1.amazonaws.com • ap-southeast-2: https://s3-ap-southeast-2.amazonaws.com • ap-northeast-1: https://s3-ap-northeast-1.amazonaws.com • ap-northeast-2: https://s3.ap-northeast-2.amazonaws.com • ap-northeast-3: https://s3.ap-northeast-3.amazonaws.com • ca-central-1: https://s3.ca-central-1.amazonaws.com • cn-north-1: https://s3.cn-north-1.amazonaws.com • cn-northwest-1: https://s3.cn-northwest-1.amazonaws.com • eu-central-1: https://s3.eu-central-1.amazonaws.com • eu-west-1: https://s3-eu-west-1.amazonaws.com • eu-west-2: https://s3.eu-west-2.amazonaws.com • eu-west-3: https://s3.eu-west-3.amazonaws.com	• HTTP • HTTPS

Supported Vendor/Object Store	Tier URL/Endpoint	Supported Authentication Protocol
GCS (Google Cloud Platform)	`https://storage.googleapis.com`	• HTTP • HTTPS
HDS (Hitachi HCP)	`http://<hcptenant>.<hcphostname>` `https://<hcptenant>.<hcphostname>`	• HTTP • HTTPS
IBM (IBM Cleversafe)	`http://lb1.ait.cleversafelabs.com`	HTTP
Azure Blob (Microsoft Azure)	`https://<azureaccount>.blob.core.windows.net`	• HTTP • HTTPS
Minio	`http://10.10.88.198:9000`	HTTP
Scality	`https://<scality-instance-hostname>:8000`	HTTP

Viewing the List of Tiers

Describes how to view the list of tiers using the Control System, the CLI, and the REST API.

For a primer on Data Tiering, see Data Tiering.

In the Control System, you can only see the list of cold tiers (referred to as remote targets). Use the CLI or REST API to retrieve the list of both cold and warm tiers.

Viewing the List of Remote Targets Using the Control System

- Log in to the Control System and click **Data** > **Volumes** > **Remote Targets**.

  The page displays the following for each remote target:

Column Name	Column Description
Remote Target Name	The name of the remote target.
External Storage Vendor	The name of the third-party storage vendor.
Bucket	The name of the bucket.
Region	The region where the bucket resides.
URL	The URL of the remote target.

You can:

- Create a remote target
- Remove a remote target

Viewing the List of Tiers Using the CLI and REST API

CLI	Run the following command to retrieve the list of (warm and cold) tiers: `/opt/mapr/bin/maprcli tier list`

last-updated: Apr 11, 2022

REST

Send a request of type GET. For example:

```
# curl -k -X GET 'https://
10.10.82.24:8443/rest/tier/
list' --user mapr:mapr
{"timestamp":1525725765483,"timeofday"
:"2018-05-07 01:42:45.483 GMT-0700
PM","status":"OK","total":0,"data":
[{"tierid":"79082078","tiername":"egWa
rmTier","tiertype":"ectier","volume":"
mapr.internal.tier.egWarmTier","topolo
gy":"/data"},
{"tierid":"120198852","tiername":"egCo
ldTier","tiertype":"cold","url":"s3.am
azonaws.com","bucketname":"ksekhar-tes
t","region":"us-east-1","volume":"mapr
.internal.tier.egColdTier","topology":
"/data","objectstoretype":"S3_AWS"},
{"tierid":"158778422","tiername":"auto
ec.vol_tiered.1525463214","tiertype":"
ectier","volume":"mapr.internal.tier.a
utoec.vol_tiered.1525463214","topology
":"/data"}]}
```

For more information, see `tier list` on page 1880.

Editing a Tier

Describes how to modify a cold tier using the Control System, the CLI and the REST API.

For a primer on Data Tiering, see Data Tiering.

You cannot modify a warm tier. You can modify a cold tier (referred to as Remote Target in the Control System) using the Control System, the CLI, and REST API.

Modifying a Remote Target Using the Control System

1. Log in to the Control System and go to the **Remote Target** tab under **Data** > **Volumes**.
2. Click the name of the remote target (cold tier) to display the **Edit Remote Target** window.
3. Make necessary changes to the **CREDENTIALS**.
4. Click **Save Changes** to save the changes.

Modifying a Cold Tier Using the CLI and REST API

CLI

Run the following command to modify a cold tier:

```
$maprcli tier
modify -name <tier_name> -credential
<credentials_file_path>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/modify?
name=<tier_name>&credential_str=<JSON>
' --user mapr:mapr
```

For more information, see `tier modify` on page 1882.

last-updated: Apr 11, 2022

Specifying a Tier

Describes how to associate a tier with a tiering-enabled volume using the Control System and the CLI.

Note:

For a primer on Data Tiering, see Data Tiering.

Using the Control System, you can only associate an exiting tier (referred to as **Remote Target** in the Control System) with a volume enabled for Remote Archiving (or cold-tier). You cannot associate an existing tier with a volume enabled for Erasure Coding (or warm-tier) because the Control System allows a new tier to be automatically created when you enable a volume for erasure coding. If you want to associate an existing tier with a volume enabled for erasure coding, use the CLI or REST API to create the volume.

Specifying a Remote Target Using the Control System

You can associate a remote target with a cold-tier enabled volume when you are:

- Creating the volume by clicking **Create Volume** button in the **Data** > **Volumes** page.
- Editing the volume by clicking **Edit Volume** button in the volume information page.

To associate a remote target with the volume, in the **Create Volume** or **Edit Volume** page:

1. Click the **Browse** link associated with the **Remote Target** field to display the **Browse Remote Target** window.
2. Review the name, vendor, bucket, region, and URL for each remote target and choose a remote target from the list.
3. Click **Select** to associate the remote target with the volume.
4. Complete the steps for creating or editing the volume.

Specifying a Tier Using the CLI and REST API

You can associate an existing tier with a volume when you are creating the tiering-enabled volume. You can associate an existing tier with a tiering-enabled volume when you are editing the volume only if the volume does not already have a tier associated with it. To associate an existing tier, you must specify the `tiername` parameter with the command.

CLI

Run a command similar to the following to associate a tier when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername <tierName> -json
```

For the list of all other required and optional parameters, see `volume create` on page 1931.

last-updated: Apr 11, 2022

- Editing the volume:

```
maprcli volume
modify -name <volName> -tiername
<tierName> -json
```

For the list of all other required and optional parameters, see volume modify on page 2005.

REST

Send a request of type POST. For example, to associate a tier when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
mapr:mapr
```

For the list of all other required and optional parameters, see volume create on page 1931.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

For the list of all other required and optional parameters, see volume modify on page 2005.

Removing a Tier

Describes how to remove a tier that is not associated with a tier, using the Control System, the CLI and the REST API.

For a primer on Data Tiering, see Data Tiering.

You can remove a tier that is not associated with a volume, using the Control System, the CLI, and REST API. In the Control System, a cold tier is referred to as remote target and you can only remove remote targets (or cold tiers) using the Control System. Use the CLI or REST API to remove cold and warm tiers.

Removing a Remote Target Using the Control System

1. Log in to the Control System and click **Data** > **Volumes** > **Remote Targets** to display the list of remote targets.
2. Select the checkbox associated with the tier to delete.
   Selecting the checkbox associated with a tier makes the **Remove Target** button available.
3. Click **Remote Target** to display the **Remove Remote Target** confirmation dialog.
4. Verify the list of remote targets to remove and click **Remove**.

last-updated: Apr 11, 2022

Removing a Tier Using the CLI and REST API

CLI

Run the following command to remove a tier:

```
/opt/mapr/bin/maprcli tier
remove -name <tier-name>
```

You cannot remove a tier associated with a volume. If you run the command to remove a tier that is associated with a volume, the command returns an error (shown in bold) similar to the following:

```
{
   "timestamp":1516771078126,
   "timeofday":"2018-01-23
09:17:58.126 GMT-0800",
   "status":"ERROR",
   "errors":[{
       "id":10003,
        "desc":"Cannot remove tier,
as some volumes are still using it."
   }]
}
```

REST API

Send a request of type POST to remove a tier. For example:

```
curl -k -X
POST 'https://abc.sj.us:8443/rest/
tier/remove?name=ksTestTier' --user
mapr:mapr
```

You cannot remove a tier associated with a volume. If you send a request to remove a tier that is associated with a volume, an error (shown in bold) similar to the following is returned:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/remove?
name=ksTestTier' --user mapr:mapr
{"timestamp":1524675381333,"timeofday"
:"2018-04-25 09:56:21.333 GMT-0700
AM","status":"ERROR","errors":
[{"id":10003,"desc":"Can not remove
tier, as some volumes are still using
it."}]}
```

For more information, see tier remove on page 1884.

Managing Storage Policies

Data offload is driven by rules, which are configured per volume. Data offload rule can be based on size of file (s), owner (u, g, or p) of the file, and/or file modification timestamp (m). You can apply one rule per volume.

When a rule is associated with a volume, the rule is first applied on the files in the tiering-enabled volume. When applied on the files in the tiering-enabled volume, the offload is triggered for all files in the snapshot chain as well when the criteria in the rule is met. If the file does not exist in the tiering-enabled volume, rule is applied on the latest state of the file in the snapshot chain. If the file exists in the tiering-enabled volume but has no latest state or if the file was deleted in the tiering-enabled volume, offload does not happen.

last-updated: Apr 11, 2022

Rules can be defined using a combination of the following:

`u`	Username or user ID, as configured in the OS registry (such as `/etc/passwd` file, LDAP, etc.), of a specific user. **Usage:** `u:<username or user ID>`
`g`	Group name or group ID, as configured in the OS registry (such as `/etc/group` file, LDAP, etc.), of a specific group. **Usage:** `g:<groupname or group ID>`
`m`	(`mtime`) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"m:<value>s"` — specifies mtime in seconds • `"m:<value>d"` — specifies mtime in days All files that are not modified since the specified amount of time, are offloaded. **Note:** If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.
`s`	The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. **Usage** • `"s:<value>b"` — specifies file size in bytes • `"s:<value>k"` — specifies file size in KB • `"s:<value>m"` — specifies file size in MB • `"s:<value>g"` — specifies file size in GB All files whose size exceeds the specified size are offloaded.

Or, use the following:

`p`	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
`""`	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

`&`	AND operation to combine multiple expressions as the criteria for the rule.
`|`	OR operation to indicate either of the expressions as the criteria for the rule.

last-updated: Apr 11, 2022

( )	Delimiters for subexpressions.

For volumes configured for erasure coding, a default storage policy, `default.ectier.rule` (ID `1` and expression p), is applied if one is not specified.

You can create, associate, and remove rules using the MapR Control System, the CLI, and REST API.

Creating a Storage Tier Policy
Explains how to create a tiering policy for storage using either the Control System, the CLI, or the REST API.
Creating a Storage Tier Policy Using the Control System

To create a storage tier policy (or rule) using the Control System:

1. Log in to the Control System, click **Data** > **Volumes**, and then do one of the following:

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - Go to the **Storage Policies** tab if you wish to create a storage policy that is not (yet) associated with a volume.
   - Click **Create Volume** if you wish to create a storage policy for a volume when you are creating the volume.

     Note: You must enable data tiering to create the storage policy.

   - Click **Edit Volume** in the volume information page if you wish to create a storage policy for a volume when you are editing the volume settings.

2. Click one of the following to display the **Create Storage Policy** dialog.
   - **Create Policy** if you are in the **Storage Policies** tab.
   - **Create** link associated with the **Storage Policy** field if you are in the **Create New Volume** page.
   - **Create** link associated with the **Storage Policy** field if you are in the **Edit Volume** page.
3. Enter a name for the storage policy in the **Storage Policy Name** text field.
4. Choose **Build rule** or **Rule expression** radio button to define the criteria for offloading data.

   Use the **Build rule** option to build simple rules. Click `Add Condition` to add one of the following entities:

   - Group
   - User
   - File size
   - Time since the file was modified
   - Time since the file was accessed

   Use a condition group, to add AND and OR conditions.

   Click `Add condition group` to add AND and OR conditions. You can toggle the AND and OR conditions as needed.

   Use the **Rule expression** option to create advanced rules that comprise a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as `/etc/passwd` file, LDAP, etc.), of a specific user. **Usage:** `u:<username or user ID>`
g	Group name or group ID, as configured in the OS registry (such as `/etc/group` file, LDAP, etc.), of a specific group. **Usage:** `g:<groupname or group ID>`
m	(`mtime`) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"m:<value>s"` — specifies mtime in seconds • `"m:<value>d"` — specifies mtime in days All files that are not modified since the specified amount of time, are offloaded. **Note:** If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.
s	The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. **Usage** • `"s:<value>b"` — specifies file size in bytes • `"s:<value>k"` — specifies file size in KB • `"s:<value>m"` — specifies file size in MB • `"s:<value>g"` — specifies file size in GB All files whose size exceeds the specified size are offloaded.

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
`""`	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
|	OR operation to indicate either of the expressions as the criteria for the rule.
( )	Delimiters for subexpressions.

last-updated: Apr 11, 2022

If a rule is not defined, the default rule, which is all files (p), is associated with the storage policy.

5. Click **Create Policy** to create the storage policy.

Creating a Rule Using the CLI and REST API

CLI

Run the following command to create a rule:

```
$ maprcli tier rule create -name
<rule_name> -expr <expressions>
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule1&expr=m:365d' --user
mapr:mapr
{"timestamp":1519681475025,"timeofday"
:"2018-02-26 01:44:35.025 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule1'"]}
```

For more information, see `tier rule create` on page 1885.

Viewing the List of Storage Tier Policies
Explains how to view tiering policies for storage using either the Control System, the CLI, or the REST API.
Viewing the List of Storage Tier Policies Using the Control System

- Log in to the Control System and click **Data** > **Volumes** > **Storage Policies**.

  Note: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

  The list of storage policies displays. For each storage policy, the page displays the following:

Column Name	Column Description
Policy Name	The name of the policy.
Detail	The policy details.

  You can:

  - Create a Policy
  - Edit a Policy
  - Remove a Policy

Viewing the List of Storage Tier Policies Using the CLI and REST API

CLI

Run the following command to retrieve the list of tiers:

```
# maprcli tier rule list
```

REST

Send a request of type GET. For example:

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/rule/
```

```
list' --user mapr:mapr
{"timestamp":1525728727729,"timeofday"
:"2018-05-07 02:32:07.729 GMT-0700
PM","status":"OK","total":6,"data":
[{"ruleid":"1","rulename":"default.ect
ier.rule","expression":"m:1d"},
{"ruleid":"2","rulename":"rule2","expr
ession":"s:5g"},
{"ruleid":"3","rulename":"rule1","expr
ession":"m:365d"},
{"ruleid":"4","rulename":"rule3","expr
ession":"u:m7user1"},
{"ruleid":"5","rulename":"rule4","expr
ession":"p"},
{"ruleid":"6","rulename":"testRule","e
xpression":"u:m7user1 | (u:mapr &
(s:5g | m:365d))"}]}
```

For more information, see `tier rule list` on page 1892.

Modifying a Storage Tier Policy
Explains how to modify a storage tier policy using either the Control System, CLI, or the REST API.

If you modify a rule that is currently in use, the changes in the rule are only applied on future offloads; data offloaded using existing rule is not impacted by the change in the rule.

Modifying a Rule Using the Control System

1. Log in to the Control System and go to **Storage Policies** tab in the **Data** > **Volumes** page.

   Note: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

   The list of storage policies displays.

2. Click the storage policy name to display the **Edit Storage Policy** window.

3. Make changes to the rule:
   You can modify the basic rule to:

   - Add (⊕) or remove (⊖) users and/or groups.
   - Change the name of the users and/or groups.
   - Change the number of days since the file was last modified for users and/or groups.

   If you switch from a basic rule to an advanced rule, all expressions from the basic rule are carried over to the advanced rule. You can modify an advanced rule using a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as `/etc/passwd` file, LDAP, etc.), of a specific user. **Usage:** `u:<username or user ID>`
g	Group name or group ID, as configured in the OS registry (such as `/etc/group` file, LDAP, etc.), of a specific group. **Usage:** `g:<groupname or group ID>`

`m`	(`mtime`) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"m:<value>s"` — specifies mtime in seconds • `"m:<value>d"` — specifies mtime in days All files that are not modified since the specified amount of time, are offloaded. **Note:** If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.
`s`	The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. **Usage** • `"s:<value>b"` — specifies file size in bytes • `"s:<value>k"` — specifies file size in KB • `"s:<value>m"` — specifies file size in MB • `"s:<value>g"` — specifies file size in GB All files whose size exceeds the specified size are offloaded.

Or, use the following:

`p`	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
`""`	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

`&`	AND operation to combine multiple expressions as the criteria for the rule.
`|`	OR operation to indicate either of the expressions as the criteria for the rule.
( )	Delimiters for subexpressions.

You cannot switch from an advanced rule that includes the following to a basic rule because the following are not supported in a basic rule:

- `p` — All the files
- `s` — The size of the file
- `&` — The AND operation used for specifying multiple users (u), groups (g), or criteria
- `|` — The OR operation used with `s` or `m`

last-updated: Apr 11, 2022

- "" — None of the files.
- ( ) — Subexpressions

Note: The basic rule must contain mtime (`m`). It can also include one or more users or groups separated by the OR operation (`|`).

4. Click **Save Changes** to save the storage policy changes.

Modifying a Rule Using the CLI and the REST API

CLI

Run the following command to modify a storage policy:

```
$ maprcli tier rule modify -name
<rule_name> -json
```

REST API

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/modify?
name=sampleRule&expr=m:3d' --user
mapr:mapr
{"timestamp":1523587392465,"timeofday"
:"2018-04-12 07:43:12.465 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
rule: 'sampleRule'"]}
```

For more information, see `tier rule modify` on page 1893.

Specifying a Storage Tier Policy
Explains how to associate a storage tier policy with a tiering-enabled volume using either the Control System or the CLI.

Specifying a Storage Tier Policy Using the Control System

You can associate a storage policy with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** in the **Data** > **Volumes** page.

  Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- Editing the tiering-enabled volume by clicking **Edit Volume** button in the volume information page.

To associate a storage policy with the volume, in the **Create Volume** or **Edit Volume** page:

1. Click the **Browse** link associated with the **Storage Policy** field to display the **Browse Storage Policies** window.
2. Review the name and detail of each storage policy and choose a storage policy from the list.
3. Click **Select** to associate the storage policy with the volume.
4. Complete the steps for creating or editing the volume.

Specifying a Storage Tier Policy Using the CLI and REST API

You can associate a rule with a tiering-enabled volume by specifying the `tieringrule` parameter with the `volume create` on page 1931 or `volume modify` on page 2005 command.

last-updated: Apr 11, 2022

CLI

Run a command similar to the following to associate a rule when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -tieringrule
<ruleName> -json
```

  For the list of all other required and optional parameters, see `volume create` on page 1931.

- Editing the volume:

```
maprcli volume modify -name
<volName> -tieringrule
<ruleName> -json
```

  For the list of all other required and optional parameters, see `volume modify` on page 2005.

REST

Send a request of type POST. For example, to associate a rule when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
mapr:mapr
```

  For the list of all other required and optional parameters, see `volume create` on page 1931.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

  For the list of all other required and optional parameters, see `volume modify` on page 2005.

Removing a Storage Policy

Explains how to remove tiering policies for storage using either the Control System, the CLI, or the REST API.

Warning: You cannot remove a storage policy that is associated with a volume.

Removing a Rule Using the Control System

1. Log in to the Control System and go to **Storage Policies** tab under **Data** > **Volumes**.

   Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   The list of storage policies displays.

2. Select the checkbox associated with the storage policy to remove and click **Remove Policy**.
   The **Remove Policy** confirmation window displays.

3. Review the list of policies to remove and click **Remove**.

Removing a Rule Using the CLI and the REST API

CLI

Run the following command to remove a storage policy that is not associated with a volume:

```
# maprcli tier rule remove -name
<rule_name>
```

If you try to remove a rule associated with a volume, the command returns an error (shown in bold) similar to the following:

```
# maprcli tier rule remove -name
rule1 -json
{
   "timestamp":1516771655669,
   "timeofday":"2018-01-23
09:27:35.669 GMT-0800",
   "status":"ERROR",
   "errors":[{
      "id":10003,
      "desc":"Cannot remove rule, as
some volumes are still using it."
   }]
}
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571783113,"timeofday"
:"2018-04-12 03:23:03.113 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully deleted
rule: 'sampleRule'"]}
```

If you try to remove a storage policy associated with a volume, the response contains an error (shown in bold) similar to the following:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571741636,"timeofday"
:"2018-04-12 03:22:21.636 GMT-0700
PM","status":"ERROR","errors":
```

```
[{"id":10003,"desc":"Can not remove
rule, as some volumes are still using
it."}]}
```

For more information, see `tier rule remove` on page 1895.

Administering Files and Directories

The following sections provide configuration information that you can use to set chunk size and compression in MapR File System, as well as information on hard links, extended attributes, and core files:

Using Global File System Checking

Describes how to use the `gfsck` command to check and repair filesystem errors.

You can use the `gfsck` on page 2102 (global filesystem check) command to perform a consistency check and repair operation on a volume or volume snapshot, including the following entities:

- All cross-container links (for example, from file to *filelet*, or from table to tablets)
- The tabletmap key range
- The attributes of *filelet* (uid/gid/mode)

This command identifies the unreachable files, directories, and tables in the volume, and moves them to */lost+found* to be repaired. It also identifies and fixes any unreachable DB inodes or dangling pointers to lost inodes.

1. Take the affected storage pools offline by running the mrconfig sp offline on page 2175 command.
   For example:

   ```
   /opt/mapr/server/mrconfig sp offline /dev/sdc
   ```

2. Execute the `fsck` on page 2100 command on the storage pools or disks.
3. Bring the storage pools back online by running the `mrconfig sp online` on page 2176 command.
   For example:

   ```
   mrconfig sp online /dev/sdc
   ```

4. Run the `gfsck` command on the affected volumes, or snapshots, with the appropriate options.
   If there are alarms, such as `DataUnavailableAlarm` or `DataUnderReplicatedAlarm`, do not run the `gfsck` command with the `-r` (`--repair`) option. Running the `gfsck` command with the `-r` (`--repair`) option, might result in data loss. If necessary, first run `gfsck` without the `-r` (`--repair`) option, and attempt to repair only after analyzing the command output.

Related reference

gfsck on page 2102
Describes how you can use the `gfsck` command, under the supervision of Map R Support or Engineering, to perform consistency checks and appropriate repairs on a volume, or a volume snapshot.

Setting MapR File System Permissions
