services -nodes <hostName> -name
<serviceName> -action enable
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
&action=enable' --user mapr:mapr
```

Note: When you enable a service, the service is started/restarted when Warden is started/restarted.

See [node services](#) on page 1939 for more information.

Related tasks

[Restarting the Services](#) on page 908

Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services

Explains how to start services using either the Control System, the CLI or the REST API.

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 905 for more information.

Starting the Services Running on the Nodes Using the Control System

To start the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.

3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

To start one or more services running on a node:

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click  for the service to start.
The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see [node services](#) on page 1939.

Stopping the Services

Describes how to stop services using either the Control System, the CLI or the REST API.

Stopping the Services Running on the Nodes Using the Control System

To stop the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.
 **Note:** The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

To stop one or more services running on a node:

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop. The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see [node services](#) on page 1939.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

When a HPE Ezmeral Data Fabric system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

Note: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that HPE Ezmeral Data Fabric currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 1278 for more information.

Restarting the Services Running on the Nodes Using the Control System

To restart the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.

3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click  associated with the service to restart.
The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see [node services](#) on page 1939.

Related tasks

[Enabling and Disabling a Service Using the CLI and REST API](#) on page 1278
Describes how to enable or disable a service using either the REST API or the CLI.

Changing the User for Data Fabric Services from the Command-Line

Explains how use the CLI to change the user that data-fabric services run as.

All services should run with the same uid/gid on all nodes in the cluster.

Running Data Fabric Services as the Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`

4. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

5. Start Warden.

```
service mapr-warden start
```

Running Data Fabric Services as a Non-Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.

4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.

5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.

6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing `NODE_ALARM_MAPRUSER_MISMATCH` alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Running Data-Fabric Services as the Root User

1. Stop Warden:

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it:

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`

4. If ZooKeeper is installed, start it:

```
service mapr-zookeeper start
```

5. Start Warden:

```
service mapr-warden start
```

Running Data-Fabric Services as a Non-Root User

1. Stop Warden:

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it:

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.
4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`
6. If Zookeeper is installed, start it:

```
service mapr-zookeeper start
```

7. Start Warden:

```
service mapr-warden start
```

8. After clearing `NODE_ALARM_MAPRUSER_MISMATCH` alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Managing Disks

Provides a brief overview of adding and removing disks from the HPE Ezmeral Data Fabric filesystem.

You can add and remove disks in the filesystem from the control system or using the `diskadd` and `diskremove` commands. filesystem groups disks into *storage pools*, usually made up of two or three disks. When adding disks to the filesystem, it is a good idea to add at least two or three at a time so that HPE Ezmeral Data Fabric can create properly-sized storage pools. Each node in a HPE Ezmeral Data Fabric cluster can support up to 36 storage pools.

To see which disks are used by filesystem, check the `disktab` file that HPE Ezmeral Data Fabric maintains on each node.

 **Warning:** For instructions on performing disk maintenance on a node, see [Performing Maintenance on a Node](#). If a disk failure alarm is raised (`NODE_ALARM_DISK_FAILURE`), see [Handling Disk Failures](#) for instructions.

Refer to the following procedures to manage disks using the Control System and the CLI.

Viewing the List of Disks

Explains how to view the disks on a node using either the Control System or the CLI.

Viewing the List of Disks Using the Control System

To view both the system and filesystem disks:

1. Log in to the Control System and go to the [node information page](#).
2. Go to the **Summary** tab.

On this page, the **Disks** and **System Disks** panes display the following for each disk:

| Column Name | Column Description |
|------------------|---|
| Status | The status of the disk. Value can be one of the following: <ul style="list-style-type: none"> ✔ — indicates disk is active or good. 🔌 — indicates disk is on standby. 🔴 — indicates disk is offline. |
| Device | The disk partition(s). |
| Mnt | Indicates whether (✔) or not the disk is mounted. |
| filesystem | (Displayed in the Disks pane only) The disks available for filesystem. A ✔ indicates that the disk was added to filesystem. |
| File System | (Displayed in the System Disks pane only) The disks for system use. |
| Allocated | The amount of space allocated, in gigabytes. |
| Used | The percentage of disk space used. |
| Model# | The disk model number. |
| Firmware Version | The disk firmware version. |
| Storage Label | The label assigned to the disk. |
| Storage Pool | The ID of the storage pool associated with the disk. |

Select the checkbox beside a disk in the **Disks** pane to:

- [Add Disk\(s\) to filesystem](#)
- [Remove Disk\(s\) from filesystem](#)

Note: Disks in the **System Disks** pane cannot be selected.

Retrieving the List of Disks Using the CLI or REST API

The basic command to list the disks on a node is:

```
maprcli disk list -host <host>
```

For complete reference information, see [disk list](#) on page 1791.

Setting Up Disks for HPE Ezmeral Data Fabric

This section describes how to set up disks during the normal installation process. Go to the [disksetup](#) on page 2372 command page for information about other uses of this command.

HPE Ezmeral Data Fabric formats and uses disks for the Lockless Storage Services layer (filesystem), and records these disks in the [disktab](#) on page 2473 file. In a production environment, or when testing performance, HPE Ezmeral Data Fabric should be configured to use physical hard drives and partitions. In some cases, it is necessary to reinstall the operating system on a node so that the physical hard drives are available for direct use by HPE Ezmeral Data Fabric. Reinstalling the operating system provides an unrestricted opportunity to configure the hard drives. If the installation procedure assigns hard drives to be managed by the Linux [Logical Volume Manager](#)(LVM) by default, you should explicitly remove the drives you plan to use with HPE Ezmeral Data Fabric from the LVM configuration. It is common to let LVM manage one physical drive containing the operating system partition(s) and to leave the rest unmanaged by LVM for use with HPE Ezmeral Data Fabric.

Note: It is not necessary to set up RAID (Redundant Array of Independent Disks) on disks used by filesystem. HPE Ezmeral Data Fabric uses the `disksetup` script to set up storage pools. In most cases, you should let HPE Ezmeral Data Fabric calculate storage pools using the default stripe width of two or three disks. If you anticipate a high volume of random-access I/O, you can use the `-w` option with `disksetup` to specify larger storage pools of up to 8 disks each.

Notice: For more information on setting up disks, see [Drive Configuration](#).

The following procedures are intended for use on physical clusters or Amazon EC2 instances. On EC2 instances, EBS volumes can be used as HPE Ezmeral Data Fabric storage, although performance will be slow.

Note: If you are using [HPE Ezmeral Data Fabric on Amazon EMR](#), you do not have to use this procedure; the disks are set up for you automatically.

Determine if a disk or partition is ready for use by HPE Ezmeral Data Fabric

Explains the procedure to determine whether a disk or partition is ready for use by HPE Ezmeral Data Fabric.

Any disk or partition that passes the following testing procedure can be added to the list of disks and partitions passed to the `disksetup` command.

1. Run the command `sudo lsof <partition>` to determine whether any processes are already using the disk or partition.

There should be no output when running `sudo fuser <partition>`, indicating there is no process accessing the specific disk or partition.

2. The disk or partition should not be mounted, as checked via the output of the `mount` command. If the disk or partition is mounted, unmount it using the `umount` command.
3. The disk or partition should not have an entry in the `/etc/fstab` file; comment out or delete any such entries.
4. The disk or partition should be accessible to standard Linux tools such as `mkfs`. You should be able to successfully format the partition using a command like `sudo mkfs.ext3 <partition>` as this is similar to the operations that HPE Ezmeral Data Fabric performs during installation. If `mkfs` fails to access and format the partition, then it is highly likely that HPE Ezmeral Data Fabric will encounter the same problem.

Specify disks or partitions for use by HPE Ezmeral Data Fabric

Describes the use of the `disksetup` script to format disks.

The `disksetup` script is used to format disks for use by the HPE Ezmeral Data Fabric cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by HPE Ezmeral Data Fabric on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run the `disksetup` script to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Note: The `disksetup` script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

 **Note:** Run the `disksetup` script only after running the `configure.sh` script.

Evaluate HPE Ezmeral Data Fabric using a flat storage file instead of formatting disks

For evaluation, you can use a flat storage file instead of formatting disks.

When setting up a small cluster for evaluation purposes, if a particular node does not have physical disks or partitions available to dedicate to the cluster, you can use a flat file on an existing disk partition as the node's storage. Create at least a 16GB file, and include a path to the file in the disk list file for the `disksetup` script.

The following example creates a 20 GB flat file (`bs=1G` specifies 1 gigabyte blocks, multiplied by `count=20`) at `/root/storagefile`:

```
dd if=/dev/zero of=/root/storagefile bs=1G count=20
```

Add the created flat file to the disk list file `/tmp/disks.txt` to be used by `disksetup`:

```
/root/storagefile
```

Adding Disks to filesystem

Describes how to add disks using either the Control System or the CLI.

You can add disks to filesystem using the Control System and the CLI. Before adding the disks to filesystem, add the physical disks to the node or nodes according to the correct hardware procedure.

- If you are removing and replacing failed disks, you must install the replacements, then re-add the replacement disks to filesystem, along with the other disks that were in the same storage pool(s) as the failed disks. See [Handling Disk Failures](#) for more details.
- If you are removing disks but not replacing them, you can just re-add the other disks that were in the same storage pool(s) as the failed disks.

 **Note:** Disks must be added on CLDB nodes one node at a time when Warden and HPE Ezmeral Data Fabric services are running.

 **Attention:** Disable write caching on all HPE Ezmeral Data Fabric disks if the disks are not battery backed.

Adding Disks Using the Control System

Complete the following steps to add disks of type filesystem using the Control System:

1. Log in to the Control System and go to the **Summary** tab in the [node information page](#).

 **Note:** The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the disks not yet added to filesystem in the **Disks** pane and click **Add Disks to File System**. The **Add Disks to File System** confirmation dialog displays.

 **Note:** You cannot select disks of type *System* to add.

3. Review the list and click **Add Disk**.
The disks are automatically formatted and properly-sized storage pools are automatically allocated.

Adding Disks Using the CLI or REST API

The basic command to add disks to a node is:

```
maprcli disk add -disks <disk names> -host <host>
```

Note: This step reformats the disks. Any data on these disks will be lost.

For complete reference information, see [disk add](#) on page 1786.

Removing Disks from the File System

Explains how to remove disks using either the Control System or the CLI.

When you remove a disk from the filesystem, other disks in the storage pool are also removed automatically from the filesystem and are no longer in use (they are available but off-line). Their disk storage goes to 0%, and they are eligible to be added again to the filesystem to build a new storage pool. You can either replace the disk and re-add it along with the other disks that were in the storage pool, or just re-add the other disks if you do not plan to replace the disk you removed. See [Adding Disks to filesystem](#) on page 914 for more information.

Warning: Removing a disk in the storage pool that contains Container ID 1 shuts down CLDB, triggering a CLDB failover. Container ID 1 contains CLDB data for the primary CLDB. From the command-line, run the `maprcli disk remove` command without the `-force 1` option first and examine the warning messages to make sure you are not removing the disk with Container ID 1. To safely remove such a disk, perform a [CLDB Failover](#) on page 1677 to make one of the other CLDB nodes the primary CLDB, then remove the disk as normal with addition of the `-force 1` option.

Before removing or replacing disks, make sure the Replication Alarm (VOLUME_ALARM_DATA_UNDER_REPLICATED), Data Alarm (VOLUME_ALARM_DATA_UNAVAILABLE), Warm-Tier Data Node Down (VOLUME_ALARM_DEGRADED_EC_STRIPES), and EC Degraded Alarm (VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES) are not raised. These alarms can indicate potential or actual data loss. If either alarm is raised, you might be able to repair the problem using the `/opt/mapr/server/fsck` utility before removing or replacing disks.

Note: Using the `/opt/mapr/server/fsck` utility with the `-r` flag to repair a filesystem risks data loss. Call HPE Ezmeral Data Fabric support before using `/opt/mapr/server/fsck -r`.

Removing Disks from filesystem Using the Control System

Complete the following steps to remove disks using the Control System:

1. Log in to the Control System and go to the **Summary** tab in the [node information page](#).
2. Select the disks to remove in the **Disks** pane and click **Remove Disk(s) from File System**. The **Remove Disk(s) from File System** confirmation dialog displays.

Warning: One or more disks you selected may have unreplicated data on it and this action will forcefully remove the disks.

3. Review the list and click **Remove Disk**.
Wait several minutes while the removal process completes. After you remove the disks, any other disks in the same storage pools are taken offline and marked as *available* (not in use by HPE Ezmeral Data Fabric).
4. Remove the physical disks from the node or nodes according to the correct hardware procedure.

- From a command line terminal, remove the failed disk log file from the `/opt/mapr/logs` directory. These log files are typically named like this:

```
diskname.failed.info
```

Removing Disks from filesystem Using the CLI or REST API

- On the node, determine which disk to remove/replace by examining **Disk** entries in the `/opt/mapr/logs/faileddisk.log` file.
- Run the following command, substituting the hostname or IP address for `<host>` and a list of disks for `<disks>`

```
maprcli disk remove -disks <disk names> -host <host>
```

Note: This command does not remove a disk containing unreplicated data unless forced.

For complete reference information, see [disk remove](#) on page 1797.

- Examine the screen output in response to the command you ran in step 2.

For example:

```
maprcli disk remove -host `hostname -f` -disks /dev/sdd
message  host    disk
removed. host1  /dev/sdd
removed. host1  /dev/sde
removed. host1  /dev/sdf
```

Make a note of the *additional* disks removed when the disk is removed. For example, the disks `/dev/sde` and `/dev/sdf` are part of the same storage pool and therefore removed along with the disk (`/dev/sdd`).

- Confirm that the removed disks do not appear in the `disktab` file.
- Remove the disk log file from the `/opt/mapr/logs` directory. For failed disks, these log files are typically named in the pattern `diskname.failed.info`.

When you replace a failed disk, [add it back to the filesystem](#) along with the other disks from the same storage pool that were previously removed. Adding only the replacement disk to the filesystem, results in a non-optimal storage pool layout, which can lead to degraded performance.

Once you add the disks to the filesystem, the cluster automatically allocates properly-sized storage pools. For example, if you add ten disks, HPE Ezmeral Data Fabric allocates two storage pools of three disks each and two storage pools of two disks each.

Determining the Amount of Free Disk From the Command-Line

Lists the command to display the amount of free disk space.

To determine the amount of used and available disk space on the filesystem, run `df -h`. When running this command, if:

- The given path points to the mount point, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/
Filesystem      Size  Used Avail Use% Mounted on
posix-client-basic 4.4T  9.7G  4.4T   1%  /mapr
```

- The given path points to a volume with no (hard) quota, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol3
Filesystem      Size  Used Avail Use% Mounted on
posix-client-basic 4.4T  9.7G  4.4T   1%  /mapr
```

- The given path points to a volume with (hard) quota set, the output will display the used and available disk space for the specific volume based on the allocated quota. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol2/
Filesystem      Size  Used Avail Use% Mounted on
posix-client-basic 5.0G  2.5G  2.6G  49%  /mapr
```

Tolerating Slow Disks

Explains how to tune disk response timeouts.

The parameter `mfs.io.disk.timeout` in `mfs.conf` determines how long HPE Ezmeral Data Fabric waits for a disk to respond before assuming it has failed. If healthy disks are too slow, and are erroneously marked as failed, you can increase the value of this parameter.

Formatting Disks on a Node From the Command-line

Provides an overview of the `disksetup` script to format disks from the command line.

The `disksetup` script is used to format disks for use by the HPE Ezmeral Data Fabric cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by HPE Ezmeral Data Fabric on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run `disksetup` to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Note: The `disksetup` script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

Warning: Run `disksetup` only after running `configure.sh`.

Handling Disk Failures

Explains how to handle disk failures.

When a disk fails, data-fabric raises the node-level alarm `NODE_ALARM_DISK_FAILURE` on the node with the failed disk (or disks). At the same time, other disks in the same storage pool as the failed disk are taken

offline. You can look at the Control System **Overview** page to view the health of the nodes and a list of alarms.

When you see a disk failure alarm, examine the log file at `/opt/mapr/logs/faileddisk.log` and check the **Failure Reason** field.

Examining the Cause of Failure

Names the log file that contains the cause of disk failures.

In the `faileddisk.log` file, you will see information on the cause of failure. In the following sample log output, the failure reason is *I/O error*. Notice that the log file also provides instructions for removing disks and adding them back to the filesystem.

```
##### Disk Failure Report
#####
Disk           : /dev/sdd
Vendor         : [vendor]
Model Number   : [model]
Serial Number  : [serial]
Firmware Revision : [firmware]
Size          : [total]
Failure Reason : I/O error
Time of Failure : Fri Jan 31 12:48:00 GMT 2014
Resolution    : Please refer to MapR's online documentation at
https://docs.datafabric.hpe.com on how to handle
disk failures.

In summary, run the following steps:
a. If this appears to be a software failure, go to step
b. Otherwise, physically remove the disk /dev/sdd. Optionally, replace it
with a new disk.
b. Run the command "maprcli disk remove -host 127.0.0.1 -disks /dev/sdd" to
remove
/dev/sdd from MapR-FS.
c. In addition to /dev/sdd, the above command removes all the disks that
belong to the same
storage pool, from MapR-FS. Note down the names of all removed
disks.
d. Add all the above removed disks (exclude /dev/sdd) and the new disk to
MapR-FS by
running the command:
"maprcli disk add -host 127.0.0.1 -disks <comma separated list of
disks>"
For example, If /dev/sdx is the new replaced disk, and /dev/
sdy, /dev/sdz were removed in
step c), the command would be:
"maprcli disk add -host 127.0.0.1 -disks /dev/sdx,/dev/sdy,/dev/
sdz"
If there is no new disk, the command would just
be:
"maprcli disk add -host 127.0.0.1 -disks
/dev/sdy,/dev/sdz"
```

Recovering from Disk Failure

Lists the disk errors and their resolution.

Most software failures can be remedied by running the `fsck` utility, which scans the storage pool to which the disk belongs and reports errors. For hardware failures, remove the failed disk and replace it according to the procedure in [Removing and Replacing Disks](#).

The following are the types of failures and the recommended courses of action:

I/OTimeout Error

Failure Reason: The default value for `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as stuck is 3 times the value of this parameter (3 x `mfs.disk.io.timeout`). The

disk will be taken offline even if a single IO has not completed.

Action:

1. Check if the disks are good and still reliable.
2. If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.

No Such Device

Failure Reason: The `$INSTALL_DIR/conf/disktab` file contains `"/MissingDisk"` or references a disk path not found in `/proc/partitions` file.

Action: Run `mrdisk <device path>` to determine whether a disk is formatted for filesystem. Also, check the device paths in `$INSTALL_DIR/conf/disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the filesystem. If the disk paths have been renamed, fix them or run `disksetup -X` command to regenerate the `disktab` from `/proc/partitions`. Alternatively, restart the filesystem to resolve disk name changes.

If the problem still persists, contact HPE Ezmeral Data Fabric support.

ENODEV: MissingDisk# Error: disktab file contains a /MissingDisk# entry

Failure Reason: A disk corresponding to a GUID is missing and the corresponding disk path in the `disktab` file belongs to another disk. When an attempt is made to automatically fix the `disktab` file, this entry is replaced with `/MissingDisk#` path.

Action: If a disk corresponding to a GUID is permanently lost, remove the line corresponding to it in the `disktab` file. Alternatively, run `maprcli disk remove _MissingDisk#` command, where `#` corresponds to the disk number, and restart the filesystem.

EIO Error

Failure Reason: I/O error. This could be due to a bad block or disk. The system will offline the SP after one final attempt to complete the IO.

Action: Check `/var/log/messages` for errors from the disk drivers.

CRC Error

Failure Reason: This could be due to a bad block or bit flip on the disk. The SP will be taken offline immediately.

Action: Run `fsck -n <sp> -d` to perform a CRC (Cyclic Redundancy Check) on the data blocks in the storage pool, then bring it back online.

To load all the SPs to the list of SPs, run:

```
mrconfig disk load or mrconfig sp load
```

To bring back all SPs online, run:

```
mrconfig sp refresh
```

To bring specific SPs back online, run:

```
mrconfig sp online <sp path>
```

SlowDisk Error

Failure Reason: The default value for the `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as slow is equal to the value of this parameter (1 x `mfs.disk.io.timeout`). Thirty or more slow IO completions in a short span of time (5 seconds) on the same disk is recorded as a slow event. The SP will be taken offline if 3 such events are recorded within an hour.

Note: After an hour, HPE Ezmeral Data Fabric filesystem will reset tracking (to 0).

Action:

1. Check if the disks are good and still reliable.
2. If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.

GUID of disk mismatches with the one in `$INSTALL_DIR/conf/disktab`

Failure Reason: Possible that disk names have changed.

Action: After a node restart, the operating system can reassign the drive labels (for example, `/sda`), resulting in drive labels no longer matching the entries in the `disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the filesystem. Run `$INSTALL_DIR/server/disksetup -X` to update the `disktab` file by looking up the disks in `/proc/partitions` and make the disk paths match the GUIDs.

Unknown Error

Failure Reason: Any reason

Action: Contact HPE Ezmeral Data Fabric support.

Addressing Data Alarms

Lists all the data alarms and their mitigation.

When a disk fails, data on that disk becomes unavailable. As a result, you will probably see one of these two data alarms along with a **Disk Failure** alarm:

- **Data Unavailable** (`VOLUME_ALARM_DATA_UNAVAILABLE`) - if there was only one copy of data and it was on the failed disk; or if data was replicated more than once, but all disks with that data failed
- **Data Under Replicated** (`VOLUME_ALARM_DATA_UNDER_REPLICATED`) - if data on the failed disk is replicated elsewhere, but the minimum replication factor is not met as a result of the failed disk

If you see a **Data Unavailable** volume alarm in the cluster, follow these steps to run the `/opt/mapr/server/fsck` utility on all the offline storage pools. On each node in the cluster that has raised a disk failure alarm:

1. Run the following command to identify which storage pools are offline:

```
[user@host] /opt/mapr/server/mrconfig sp list | grep Offline
```

- For each storage pool reported by the previous command, run the following command, where `<sp>` specifies the name of an offline storage pool:

```
[user@host] /opt/mapr/server/fsck -n <sp> -r
```

When you run `fsck` with the `-r` option, it identifies corrupt blocks and removes them. If there are no corrupt blocks, `fsck` clears the error condition so you can bring the storage pool back online.

Note: Using the `/opt/mapr/server/fsck` utility with the `-r` flag to repair a filesystem risks data loss. Call support before using `/opt/mapr/server/fsck -r`.

- Verify that all **Data Unavailable** volume alarms are cleared. If **Data Unavailable** volume alarms persist, contact support or post on answers.mapr.com.

If there are any **Data Under Replicated** volume alarms in the cluster, can repair the problem by automatically replicating data and putting it on another disk. After you allow a reasonable amount of time for re-replication, verify that the under-replication alarms are cleared.

Using the `/opt/mapr/server/fsck` utility with the `-r` option produces different results depending on the scenario. The `fsck` utility does not interpret the scenario nor does it have a safe mode.

- If a disk is offline because of an imbalanced b-tree, using `fsck -r` may result in data loss from bad containers and data loss if additional replicas are unavailable.
- If a disk is offline because of an I/O error, using `fsck -r` produces indeterminate results. A disk that is throwing I/O errors is questionable in terms of data content and reliability. For example, an operation that completed on the disk but was never returned may have partial data remaining on the disk. Using `fsck -r` retains any partial data.
- If a disk is offline because of a slow I/O, using `fsck -r` does not produce data loss.

The most conservative usage of `fsck -r` is to run `fsck` without the `-r` option (verification mode) and check the output. If the output is ok, then run `fsck` with the `-r` option.

Note: Disk Failure node alarms that persist require disk replacement. If **Data Under Replicated** volume alarms persist, contact support or post on answers.mapr.com.

Removing and Replacing Disks

If a disk fails due to a hardware problem, you will need to remove the disk. You can replace it, and then add that disk back to filesystem along with the other disks that were automatically removed at the same time.

Refer to the following for information on how to remove and replace disks using the MapR command-line interface and the MapR Control System:

- [Removing Disks from the File System](#) on page 915
- [Adding Disks to filesystem](#) on page 914

Designating NICs for HPE Ezmeral Data Fabric

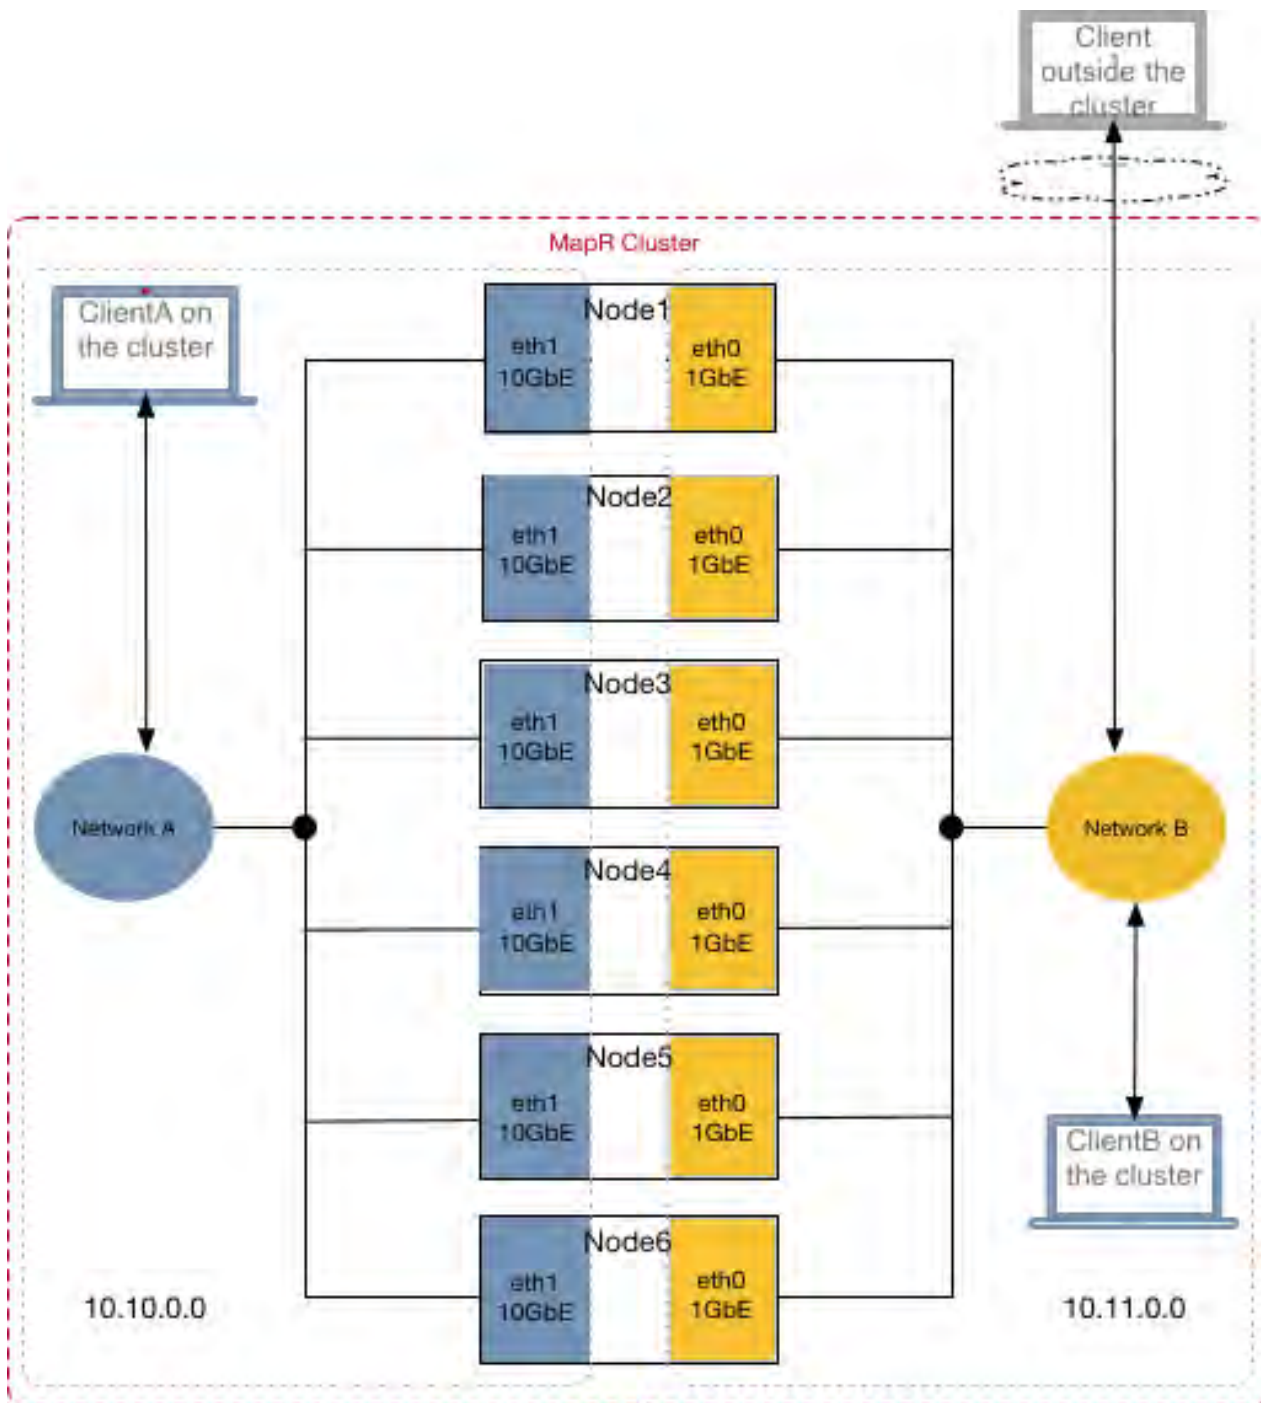

Explains how to assign IP address blocks for HPE Ezmeral Data Fabric.

By default, filesystem instances and the CLDB nodes advertise all the available IP addresses, and HPE Ezmeral Data Fabric automatically uses all available network interface cards (NICs) on each node for all communication. For nodes that have multiple NICs, HPE Ezmeral Data Fabric supports segregation of NICs such that certain IPs can be used for clients/communication within the cluster and certain IPs can be used for clients/communication from/to outside the cluster. Also, NICs can be segregated for specific (high-performance and/or low-performance) clients within the cluster.

For example, if you use multiple NICs of mixed speeds (such as 1GbE and 10GbE) on each node, you might want to separate them to two different networks depending on the Ethernet card speeds. You can assign IP addresses in the same network to the NICs of 1GbE and assign IP addresses in another network

to the NICs of 10GbE. That way, you can use the faster NICs for communication within the cluster or for certain high-performance clients (for example, FUSE-based POSIX client) and the slower NICs for external communication or for low-performance clients/jobs.

To illustrate this arrangement, the following diagram shows six nodes on a HPE Ezmeral Data Fabric cluster, each with a 1GbE NIC (eth0) and a 10GbE NIC (eth1). All the 1GbE NICs are networked together and connected to Network B. Likewise, all the 10GbE NICs are networked together (as part of a subnet written as 10.10.0/24 in CIDR notation) and connected to Network A, where peak performance is required. ClientA, which is within the cluster, communicates with cluster nodes over Network A and clients outside the cluster communicate with cluster nodes over Network B. The illustration also shows ClientB, which is a low-performance client inside the cluster, communicating with cluster nodes over Network B.

HPE Ezmeral Data Fabric provides two environment variables, `MAPR_SUBNETS` and `MAPR_EXTERNAL`, which can be used to segregate NICs for internal and external clients or to segregate NICs for high-performance and low-performance clients.

About `MAPR_SUBNETS` Environment Variable

The `MAPR_SUBNETS` environment variable can be used to restrict HPE Ezmeral Data Fabric to a subset of NICs. If `MAPR_SUBNETS` is not set, all IPs are available for all communication. When `MAPR_SUBNETS` is set on:

- filesystem nodes, filesystem registers these IP addresses with CLDB as internal IP addresses on which filesystem nodes can be reached.
- CLDB nodes, CLDB advertises the IP address to clients on the cluster.

You can set the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env_override.sh` file on all the nodes. On the cluster nodes, the value for this environment variable is a comma-separated list of subnet masks. For example:

```
export MAPR_SUBNETS=10.10.15.0/24,10.10.16.0/24
```

You can specify up to four NICs in the `MAPR_SUBNETS` environment variable. If your system has more than four NICs, HPE Ezmeral Data Fabric advertises the first four it finds or if `MAPR_SUBNETS` environment variable is set, HPE Ezmeral Data Fabric restricts the networks/IPs that are advertised based on the subnets specified therein.

The `MAPR_SUBNETS` environment variable can be set on the client if there is a NAT between the server and client. On the client, the value for this environment variable is an IP address of the client. For example:

```
export MAPR_SUBNETS=10.11.12.13/32
```

When specifying the IP address in the `MAPR_SUBNETS` environment variable on the client, use `/32` to specify a single IP address.

For more information on the `MAPR_SUBNETS` environment variable, see [Environment Variables](#) on page 2576.

About `MAPR_EXTERNAL` Environment Variable

If all the IP addresses on the servers are public and can be accessed from an external system, the `MAPR_EXTERNAL` environment variable need not be set. However, if your cluster nodes have private IP addresses, to allow clients outside the cluster to reach the cluster nodes (such as when data-fabric is installed on the cloud or Docker container), specify the public IP addresses in the `MAPR_EXTERNAL` environment variable.

On the cluster nodes, you can set this variable in the `/opt/mapr/conf/env_override.sh` file. When `MAPR_EXTERNAL` is set on:

- filesystem nodes, filesystem registers these IP addresses with CLDB as the IP addresses on which external clients can reach filesystem nodes. Communication between filesystem nodes on the cluster still occurs over the internal IP addresses.
- CLDB nodes, CLDB advertises these IPs addresses to clients outside the cluster or data center.
- MAST Gateway nodes, the gateway registers these IP addresses with CLDB as the IP addresses on which external clients can reach the MAST Gateway.

Note: Do not set the `MAPR_EXTERNAL` environment variable on the client(s).

The value for this environment variable is a comma-separated list of IP addresses; you cannot specify the hostname as value. For example:

```
ip1,ip2,ip3;
```

For example, you can specify the IP addresses of the 1GbE NICs (shown in the previous illustration) as the value for this environment variable, to allow external or low-performance clients to communicate with the cluster nodes.

```
export MAPR_EXTERNAL=10.11.0.0
```

For more information on the MAPR_EXTERNAL environment variable, see [Environment Variables](#) on page 2576.

About IP Addresses for ZooKeeper Nodes

You can specify the IP addresses of ZooKeeper nodes by running the `configure.sh` utility with both the `-z` and `-EZ` options during cluster configuration and list the:

- Internal IP addresses with the `-z` option
- External IP addresses with the `-EZ` option

When you specify the IP addresses using the `-z` and `-EZ` options, these IP addresses are registered with CLDB and included in the `cldb.conf` file. In the `cldb.conf` file, the internal IP addresses set using the `-z` option are the values for the `cldb.zookeeper.servers` parameter. The external IP addresses set using the `-EZ` option are the values for the `cldb.external.zookeeper.servers` parameter.

Note: You do not need to run the `configure.sh` command with the `-EZ` option during client configuration.

For more information, see [configure.sh](#) on page 2331.

If all the ZooKeepers have different IP addresses, port forwarding is not required and, optionally, you can specify the same port with all the IP addresses. However, in some cases, such as when there is a single external IP address being used by multiple ZooKeepers (as in a Docker container), you can specify ports for ZooKeepers when you run the `configure.sh` utility with the `-z` and `-EZ` options. For more information, see [Specifying Ports](#) on page 929.

About Internal and External Clients

Clients communicating with CLDB using internal IP address (of CLDB) are considered internal clients (or clients within the cluster) and clients communicating with CLDB using external IP address (of CLDB) are considered external clients (or clients outside the cluster).

To configure a client as an internal or high-performance client, include CLDB's internal IP address in the `mapr-clusters.conf` file on the client host. Similarly, to configure a client as an external or low-performance client, include CLDB's external IP address in the `mapr-clusters.conf` file on the client host.

The `mapr-clusters.conf` file on the client host should not contain both internal and external IP addresses of the server on a cluster. The `mapr-clusters.conf` file can contain internal and external IP addresses only when the entries in the file on the client host are for multiple clusters. For example, suppose a client, which is an internal client on one cluster and external client on another cluster. The `mapr-clusters.conf` file on the client host can contain CLDB's internal IP address for the cluster on which the client is considered an internal client and CLDB's external IP address for the cluster on which the client is considered an external client.

 **Note:** The `mapr-clusters.conf` file on the cluster nodes should not contain any external IP address.

Limitations

If:

- Both `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables are set, segregation of NICs for internal and external communication is possible. Internal communication happens over the IP addresses listed in the `MAPR_SUBNETS` environment variable and external communication happens over the IP addresses listed in the `MAPR_EXTERNAL` environment variable.
- Only `MAPR_SUBNETS` environment variable is set, filesystem registers the IP addresses (in the `MAPR_SUBNETS` environment variable) with CLDB as internal IPs.

 **Note:** Set both the environment variables in the `/opt/mapr/conf/env_override.sh` file to segregate internal or high performance clients, and external or low-performance clients.

You can specify up to 4 IP addresses in the `MAPR_SUBNETS` environment variable, and 4 IP addresses in the `MAPR_EXTERNAL` environment variable.

 **Note:** You must configure ZooKeeper with an IP address that is reachable by both internal and external clients.

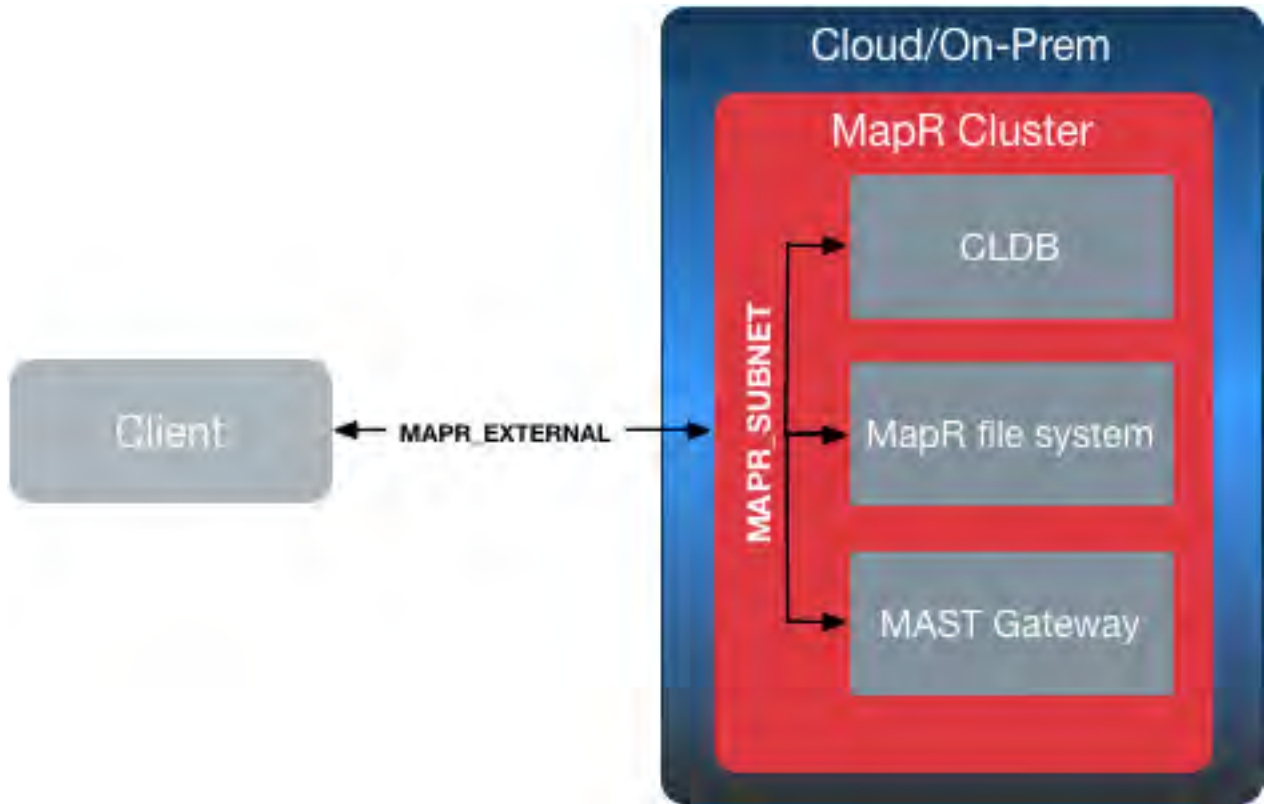

Summary

The following table describes the environment variables to set for the various services that use non-default ports and that support public IP address(es) for communication with external clients and remote clusters:

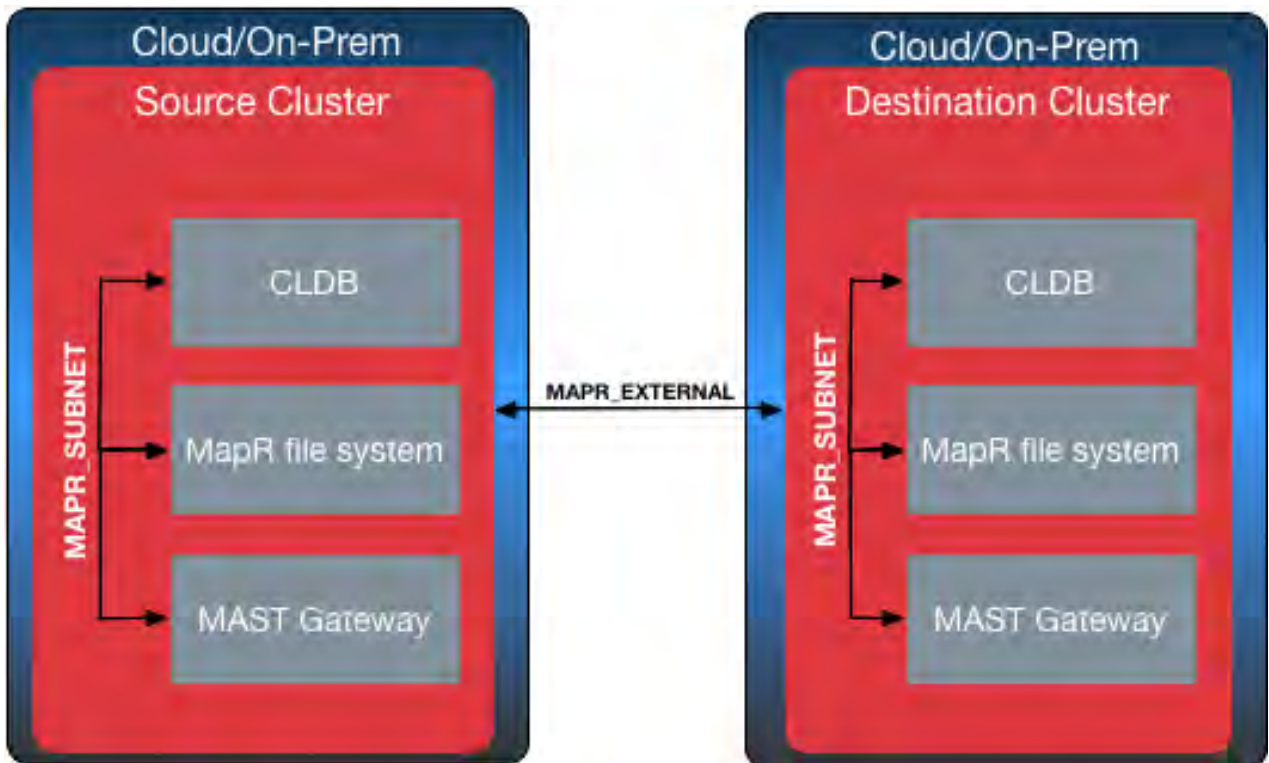

| Service | Environment variable to set... | |
|--------------|--|--|
| | Public IP Address for External Clients/ Remote Clusters | Non-default Port |
| CLDB | <code>MAPR_EXTERNAL</code> | <code>CLDB_EXTERNAL_RPC_PORT</code> |
| filesystem | <code>MAPR_EXTERNAL</code> | <code>MAPR_EXTERNAL</code> |
| MAST Gateway | <code>MAPR_EXTERNAL</code> | <code>MASTGATEWAY_EXTERNAL_RPC_PORT</code> |

The following illustration shows the client communicating with CLDB, HPE Ezmeral Data Fabric filesystem, and MAST Gateway using the IP address(es) defined in the `MAPR_EXTERNAL` environment variable because all the IP addresses on the servers are not public and accessible outside the cluster. All communication between CLDB, filesystem, and MAST Gateway on the same cluster happen over the IP address specified in the `MAPR_SUBNETS` environment variable because communication between the services and clients on the cluster is restricted to a subset of the available NICs.

When the client connects to the HPE Ezmeral Data Fabric filesystem from outside the cluster, the client uses either the default port (5660) or the port specified for the HPE Ezmeral Data Fabric filesystem in the `MAPR_EXTERNAL` environment variable. When communicating with CLDB, if the `CLDB_EXTERNAL_RPC_PORT` environment variable is set, the client communicates with CLDB over the port specified in this environment variable. Similarly for MAST Gateway, if the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable is set, the client communicates with MAST Gateway over the port specified in this environment variable. For both CLDB and MAST Gateway, if the ports are not set in the `CLDB_EXTERNAL_RPC_PORT` and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variables respectively, the client communicates over the default port.

The following illustration shows that during mirroring and other cross-cluster activities, the services on the destination cluster communicate with the services on the source cluster using the IP address defined in the `MAPR_EXTERNAL` environment variable. Similar to the external client, the services and clients in the remote destination cluster communicate with the services in the source cluster over the default ports or the port specified in the environment variable for the service.

Setting Environment Variables for NIC Segregation

Describes how to set environment variables to segregate NICs.

Use the `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables to segregate NICs for internal and external clients, or to segregate NICs for high-performance and low-performance clients.

Setting the `MAPR_SUBNETS` Environment Variable

To specify the internal IP addresses of CLDB and filesystem nodes:

1. Stop warden on all the nodes on the cluster.
2. Set the IP address range to use in the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see [About `env_override.sh`](#) on page 2576.

For example:

```
export MAPR_SUBNETS=10.10.0.0/24
```

To specify multiple subnets for HPE Ezmeral Data Fabric, use comma to separate the IP addresses.

Before specifying the IP address, make sure the client and cluster nodes can communicate using that IP address. That is, ensure that the client can send packets and that they can be routed to all the interfaces of the cluster nodes, and the cluster nodes all have a route that reaches back to the client IP address.

Note: For standalone programs (not using the `mapr` classpath), which do not pick up the settings in the `/opt/mapr/conf/env.sh` file, set `MAPR_SUBNETS` explicitly before the start of program.

3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add CLDB's internal IP address (or IP address specified in the `MAPR_SUBNETS` environment variable on the CLDB host) to the `mapr-clusters.conf` file on the (internal or high-performance) client host(s).

The `mapr-clusters.conf` file specifies IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see [mapr-clusters.conf](#) on page 2485.

When you restrict HPE Ezmeral Data Fabric to certain subnets, HPE Ezmeral Data Fabric clients have full access to the HPE Ezmeral Data Fabric cluster on the designated subnets.

Setting the `MAPR_EXTERNAL` Environment Variable

To specify the external IP addresses of CLDB, filesystem, and/or MAST Gateway nodes:

1. Stop warden on all the nodes on the cluster.
2. Set the IP addresses to use for external communication or for low-performance clients in the `MAPR_EXTERNAL` environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see [About `env_override.sh`](#) on page 2576.

For example:

```
export MAPR_EXTERNAL=10.11.0.0;
```

To specify multiple subnets for HPE Ezmeral Data Fabric, use a comma to separate the IP addresses.

3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add the following in the [mapr-clusters.conf](#) file on the (external or low-performance) client host(s):

- CLDB's external IP addresses, which is the IP addresses specified in the `MAPR_EXTERNAL` environment variable on the CLDB hosts.
- CLDB's external port, which is the value of the `CLDB_EXTERNAL_RPC_PORT` environment variable if this is set on the CLDB hosts. See [Specifying Ports for CLDB](#) for more information.

The [mapr-clusters.conf](#) file contains the IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see [mapr-clusters.conf](#) on page 2485.

Examples

Suppose the value for the `MAPR_EXTERNAL` environment variable on filesystem node is the following:

```
10.10.103.80,10.10.30.205
```

External clients can connect to filesystem on IPs 10.10.103.80, 10.10.30.205 and the ports on which the filesystem is reachable are the default ports. If filesystem is running 2 instances, then:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>

If filesystem is running 3 instances:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>
- Instance 3 is reachable on 10.10.103.80:<5662>, 10.10.30.205:<5662>

Suppose the value for the `MAPR_EXTERNAL` environment variable on a MAST Gateway node is the following:

```
10.20.30.100
```

External clients can connect to MAST Gateway on IP 10.20.30.100 and the port on which MAST Gateway is reachable is the default port (8660). If filesystem is also running on this node, then both filesystem and MAST Gateway are reachable on the IP 10.20.30.100 and the ports on which they are reachable are the default ports.

Specifying External IP Address of ZooKeeper Nodes

To specify the external IP addresses of ZooKeeper nodes, during cluster configuration:

- Run the [configure.sh](#) utility as follows:

```
/opt/mapr/server/configure.sh -C <hostname|IP>[,<hostname|IP>,..] -Z
<IP>[,<IP>..] \
-EZ <IP>[:<port>][,<IP>[:<port>]..] [-F <disk_list_file>] [-N
<cluster_name>]
```

In the preceding command:

- When each ZooKeeper node has a different external IP address, use the `-EZ` option to specify the IP address of each ZooKeeper node, and optionally the port as well (separated by a colon); the IP address can be different while the port number must be the same for every node.
- When there are multiple ZooKeeper nodes listening on the same external IP (such as in a Docker container), use the `-EZ` option to specify IP address and port (separated by a colon); the port can be different while the IP address is the same for every node.

For more information, see [Specifying Ports](#) on page 929.

Specifying Ports

On installations where the filesystem instances, CLDB, and/or MAST Gateway must be reached on non-standard ports, you can specify the ports to advertise in the `MAPR_EXTERNAL`, `CLDB_EXTERNAL_RPC_PORT`, and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variables respectively. This setting does not change the ports used by the servers, but changes the ports advertised to clients (to support port forwarding).

If the cluster nodes are no longer reachable on the standard ports, you can specify ports for filesystem using the `MAPR_EXTERNAL` environment variable. `MAPR_EXTERNAL` allows the specification of the advertised ports for the filesystem instances only; this environment variable cannot be used to specify ports for CLDB or the MAST Gateway. Instead, use `CLDB_EXTERNAL_RPC_PORT` environment variable to specify port for CLDB and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable to specify port for MAST Gateway. If ZooKeeper is not available on the default port or if there are multiple ZooKeepers listening on the same external IP address, you can specify ports for each ZooKeeper using the [configure.sh](#) utility.

See the following sections for more information on setting the ports.

Specifying Ports for filesystem

If the port forwarding table is set up, ports must be configured for every filesystem node on every filesystem instance. For more information on the number of ports used by filesystem instance(s), see [Ports Used by HPE Ezmeral Data Fabric Software](#) on page 2579. To specify the ports for filesystem:

1. Open the `$MAPR_HOME/conf/env_override.sh` file. If the `env_override.sh` file is not present, you might have to create it. See [About env_override.sh](#) on page 2576.
2. Set the value for the `MAPR_EXTERNAL` environment variable.
The value for the `MAPR_EXTERNAL` environment variable is a comma-separated list of IP addresses and colon-separated list of ports (to use for port forwarding).

For example:

```
export MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003
```

The following example shows 3 filesystem instances with 4 ports:

```
export
MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003:10000,10001,10002,10003:11000
,11001,11002,11003
```

To specify:

- Multiple IP addresses, use comma to separate the IP addresses.
- Ports for multiple instances, use:
 - comma (,) to separate the ports for an instance
 - colon (:) to separate the set of ports for each instance

If ports are not specified, filesystem is assumed to be reachable on the default ports.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

Specifying Ports for CLDB

The default port for CLDB is 7222. If you want to use another port:

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the CLDB host(s). If the [env_override.sh](#) file is not present, you might have to create it. See [About env_override.sh](#) on page 2576.
2. Set the value for the `CLDB_EXTERNAL_RPC_PORT` environment variable in the file.
The value for this environment variable is the port to use for CLDB.

For example:

```
export CLDB_EXTERNAL_RPC_PORT=5000
```

This is especially useful if HPE Ezmeral Data Fabric is installed in a Docker container or other guest hosts. If this is not set, CLDB must be reachable on the default port 7222.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.
4. Ensure that the [mapr-clusters.conf](#) file on the client host(s) contains the correct port number for CLDB.

Note: After setting this environment variable, make sure that `cldb.feature.external.ip` is enabled if you upgraded from a prior version of MapR to v6.0. For more information on enabling this feature, see [Step 4: Enable New Features](#) on page 281.

Specifying Port for MAST Gateway

The default port for MAST Gateway is 8660. If you want to use another port:

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the MAST Gateway host(s). If the [env_override.sh](#) file is not present, you might have to create it. See [About env_override.sh](#) on page 2576.
2. Set the value for the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable in the file.
The value for this environment variable is the port to use for MAST Gateway.

For example:

```
export MASTGATEWAY_EXTERNAL_RPC_PORT=15000
```

If this is not set, MAST Gateway must be reachable on the default port 8660.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

Specifying Ports for ZooKeeper

If ZooKeeper is not available on the default port or if all the ZooKeepers are listening on the same external IP address (such as in a Docker container), you can specify the port on which to reach each ZooKeeper. To specify the port on which to reach each ZooKeeper, during cluster configuration:

- Run the [configure.sh](#) utility with the `-EZ` option.

The value for the `-EZ` option is a comma-separated list of external IP addresses of the ZooKeeper nodes and the port (for each IP address), separated by a colon, on which ZooKeeper can be reached. For example:

```
/opt/mapr/server/configure.sh -C <IP|Hostname>[,<IP|Hostname>,...] -Z <IP|
Hostname>[,<IP|Hostname>,...] \
-EZ <IP|Hostname>:<Port>[,<IP|Hostname>:<Port>,...]
```

For example, you can specify:

- Different ports when the same external IP address is used for all ZooKeeper nodes as shown below:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172,17.0.3,172.17.0.4 -Z
172.17.0.2,172,17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.10.104.34:5182,10.10.104.34:5183 -N
my.cluster.com
```

- Same ports when different IP addresses are specified for ZooKeeper nodes:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172,17.0.3,172.17.0.4 -Z
172.17.0.2,172,17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.20.105.34:5181,10.30.106.34:5181 -N
my.cluster.com
```

Configuring MR AppMaster Port Mapping

1. Set the `yarn.app.mapreduce.am.job.client.port-range` parameter in the `yarn-site.xml` file to specific range of free ports in all the NodeManager nodes.

Specify the range of ports that the MapReduce AppMaster can use when binding. Do not specify a value for this parameter if you want all possible ports. For example:

```
50000-50050,50100-50200
```

Note: Each Docker instance where NodeManager is running should have different range and the range should be different across all NodeManager nodes.

For example:

The `yarn-site.xml` file in docker container 1:

```
<property>
  <name>yarn.app.mapreduce.am.job.client.port-range</name>
  <value>50000-50050</value>
</property>
```

The `yarn-site.xml` file in docker container 2:

```
<property>
  <name>yarn.app.mapreduce.am.job.client.port-range</name>
  <value>50100-50150</value>
</property>
```

The `yarn-site.xml` file in docker container 3:

```
<property>
  <name>yarn.app.mapreduce.am.job.client.port-range</name>
  <value>50151-50200,50250-50300</value>
</property>
```

2. Set the port forwarding rules in host machine for these specific ranges.

For example, if NM1 contains ranges from 50000 to 50050, then set the IP table rules such that when requests come on these ports, it is forwarded to NM1.

3. Specify the AWS or Docker host name for the IP address in the `/etc/hosts` file on the client system so that external clients can resolve Docker or AWS hostname properly when running the jobs.

For example, your entry in the `/etc/hosts` file should look similar to the following:

```
54.208.145.112 ip-10-10-0-103.ec2.internal
```

Working with a Logical Volume Manager

Explains the role and usage of a Logical Volume Manager.

The Logical Volume Manager creates symbolic links to each logical volume's block device, from a directory path in the form:

```
/dev/<volume group>/<volume name>
```

HPE Ezmeral Data Fabric needs the actual block location, which you can find by using the `ls -l` command to list the symbolic links.

1. Make sure you have free, unmounted logical volumes for use by HPE Ezmeral Data Fabric:
 - Unmount any mounted logical volumes that can be erased and used for HPE Ezmeral Data Fabric.
 - Allocate any free space in an existing logical volume group to new logical volumes.
2. Make a note of the volume group and volume name of each logical volume.
3. Use `ls -l` with the volume group and volume name to determine the path of each logical volume's block device. Each logical volume is a symbolic link to a logical block device from a directory path that uses the volume group and volume name:

```
/dev/<volume group>/<volume name>
```

The following example shows output that represents a volume group named `mapr` containing logical volumes named `mapr1`, `mapr2`, `mapr3`, and `mapr4`:

```
ls -l /dev/mapr/mapr*
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr1 -> /dev/mapper/
mapr-mapr1
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr2 -> /dev/mapper/
mapr-mapr2
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr3 -> /dev/mapper/
mapr-mapr3
lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr4 -> /dev/mapper/
mapr-mapr4
```

4. Create a text file `/tmp/disks.txt` containing the paths to the block devices for the logical volumes (one path on each line). Example:

```
cat /tmp/disks.txt
/dev/mapper/mapr-mapr1
/dev/mapper/mapr-mapr2
/dev/mapper/mapr-mapr3
/dev/mapper/mapr-mapr4
```

5. Pass `disks.txt` to [disksetup](#).

Tuning for SSDs

Lists the parameters to tune for optimal SSD performance.

On servers with SSDs:

1. Enable TRIM operation in the `mfs.conf` file, if recommended by the SSD vendor.
By default, TRIM is disabled. To enable, set the value for `mfs.ssd.trim.enabled` to 1 in the `mfs.conf` file. For example:

```
mfs.ssd.trim.enabled=1
```

2. Disable IO throttling in the `mfs.conf` file.
To disable, set the value for `mfs.disk.iothrottle.count` to 50000. The default value for `mfs.disk.iothrottle.count` is 100. For example:

```
mfs.disk.iothrottle.count=50000
```

3. Create storage pool with multiple SSDs (so that the throughput is less than 2GB/sec).

Note: Create one storage pool per SSD only if the device is high-end.

To create, run `disksetup`:

```
/opt/mapr/server/disksetup -W <n> disks.txt
```

For example, to create a storage pool with 2 SSDs, run the following command:

```
/opt/mapr/server/disksetup -W 2 disks.txt
```

For more information, see [disksetup](#) on page 2372.

Administering Volumes

This section provide information about how to organize and manage data using volumes, a unique feature of HPE Ezmeral Data Fabric clusters.

HPE Ezmeral Data Fabric provides volumes as a way to organize data and manage cluster performance. A volume is a logical unit that allows you to apply policies to a set of files, directories, and sub-volumes. You can use volumes to enforce disk usage limits, set replication levels, establish ownership and accountability, and measure the cost generated by different projects or departments. Create a volume for each user, department, or project.

You can mount volumes under other volumes to build a structure that reflects the needs of your organization. Sub-volumes are created by mounting a volume in a sub-directory of an already mounted volume. This establishes a parent-child relationship between the volumes whereas the parent volume is mounted in top-level directory and the child volume is mounted in the sub-directory. The volume structure defines how data is distributed across the nodes in your cluster. Create multiple small volumes with shallow paths at the top of your cluster's volume hierarchy to spread the load of access requests across the nodes.

A well-structured volume hierarchy is an essential aspect of your cluster's performance. As your cluster grows, keeping your volume hierarchy efficient maximizes data availability. Cluster performance is negatively affected when a volume structure is not in place.

The Control System **Volumes** page under **Data** contains the following tabs:

- [Summary](#)
- [Snapshots](#)
- [User Disk Usage](#)

- [Schedules](#)
- [Storage Policies](#)
- [Remote Targets](#)

Managing Data with Volumes

Provides an overview of how to manage volume data.

The **Summary** tab in the **Volumes** page displays the following panes:

- [Top Volume Utilization](#) — Volumes that use the most amount of disk space.
- [Active Alarms](#) — List of active volume alarms on the cluster.
- Local and Remote Tier Storage utilization.
- [Volumes](#) — List of volumes.

The page includes the **Create Volume** button to create standard or (local and/or remote) mirror volumes. You can perform the following procedures to manage volumes on the HPE Ezmeral Data Fabric cluster using the Control System and the CLI.

Viewing the List of Volumes

Explains how to view the list of volumes either through the Control Panel or the CLI.

Viewing All the Volumes Using the Control System

- Log in to the Control Panel and click **Data > Volumes > Summary**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The **Volumes** pane in the **Summary** tab (under **Data > Volumes**) displays the volumes in the cluster.

Note: By default, system volumes are not displayed. If you wish to view system volumes also, select the **Include System Volumes** checkbox.

If you are in another view, select **All Volumes** from the drop-down menu in the **Volumes** pane. Up to 10 volumes, sorted by name, are displayed in each page. For each volume, the pane displays the following information, by default:

| Column Name | Column Description |
|--------------|--|
| Volumes | The name of the volume (used for default sorting). |
| Data Tiering | Whether volume is enabled or disabled for data tiering. |
| Alarms | The number of alarms associated with the volume. Hover the cursor over the number for information on the alarm including alarm name, severity, and time when the alarm was raised. |
| Mnt | Specifies whether (✓) volume is mounted. |
| Type | The type of volume. Both standard and mirror volumes are displayed. |
| Mount Path | The path where the volume is mounted. |
| Creator | The user or group that owns the volume. |

| Column Name | Column Description |
|-------------------|--|
| Quota | The amount of disk space allocated and utilized by the volume and associated snapshots and the cluster reserve limit (in red). If quota is not set, displays option to Set Quota . |
| Total Size | The total physical size of the volume and associated snapshots. When you move the cursor over the value, the popover shows the total logical size (Data Size), the logical size of the volume (Volume Size), and the logical size of the snapshots (Snapshot Size). |
| RF | The replication factor that specifies the number of copies for the volume. |
| Physical Topology | The rack path to the volume. |

You can sort the list by volume name, mount, mount path, or creator.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) the selected volume(s)
- [Remove](#) the selected volume(s)
- [Create snapshot\(s\)](#) of the selected volume
- [Change](#) the selected mirror volume(s) to standard volume(s)
- [Start](#) the mirroring operation(s) for the selected mirror volume(s)
- [Stop](#) the mirroring operation(s) for the selected mirror volume(s)
- [Mount](#) the selected volume(s)
- [Unmount](#) the selected volume(s)
- [Offload](#) selected volume(s)
- [Recall](#) selected volume(s)
- [Abort](#) currently running tiering job for selected volume(s)

Viewing the List of Standard Volumes Using the Control System

The **Volumes** pane in the **Summary** tab under **Data > Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays all the volumes in the cluster by default. To view a list of only the standard volumes:

- Select **Standard Volumes** from the drop-down menu in the **Volumes** pane.

The list of standard volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the page displays the following information by default:

| Column Name | Description |
|-------------|--|
| Volumes | The name of the volume (used for default sorting). |
| Alarms | The number of alarms associated with the volume. You can view the Active Alarms pane for more information on the alarms associated with a volume. |
| Mnt | Specifies whether the volume is mounted. |

| Column Name | Description |
|-------------------|--|
| Type | The type of volume. Only standard volumes are displayed. |
| Mount Path | The path where the volume is mounted. |
| Data Tiering | Whether volume is enabled or disabled for data tiering. |
| Creator | The user or group that owns the volume. |
| Quota | The amount of disk space allocated and utilized by the volume and associated snapshots and the reserve limit (in red). If quota is not set, displays option to Set Quota . |
| Total Size | The size of the volume and associated snapshots. |
| RF | The replication factor that specifies the number of copies for the volume. |
| Physical Topology | The rack path to the volume. |

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) the selected volume(s)
- [Remove](#) the selected volume(s)
- [Create snapshot\(s\)](#) of the selected volume
- [Mount](#) the selected volume(s)
- [Unmount](#) the selected volume(s)

Viewing the List of Mirror Volumes Using the Control System

The **Volumes** pane in the **Summary** tab under **Data > Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of only the mirror volumes:

- Select **Mirror Volumes** from the drop-down menu in the **Volumes** pane.

The list of mirror volumes in the cluster displays. By default, the list is sorted by volume name and the following columns are displayed:

| Column Name | Description |
|---------------------|--|
| Volumes | The name of the volume (used for default sorting). |
| Alarms | The number of alarms associated with the volume. You can view the Active Alarms pane (above) for more information on the alarms associated with a volume. |
| Mnt | Specifies whether the volume is mounted. |
| Source Volume | The source volume name for the mirror volume. |
| Source Cluster | The source cluster name for the mirror volume. |
| Originating Cluster | The originating cluster for the data being mirrored. |
| Originating Volume | The originating volume for the data being mirrored. |
| Mirror Status | The status of the last mirroring operation. |
| Percentage Complete | The percentage of the in-progress mirroring operation that has been completed. |

| Column Name | Description |
|--------------|--|
| Data Tiering | Whether or not the volume is enabled or disabled for data tiering. |

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) the selected volume(s)
- [Remove](#) the selected volume(s)
- [Create snapshot\(s\)](#) of the selected volume
- [Change](#) the mirror volume to a standard volume
- [Start](#) the mirroring operation(s) for the selected mirror volume(s)
- [Stop](#) the mirroring operation(s) for the selected mirror volume(s)
- [Mount](#) the selected volume(s)
- [Unmount](#) the selected volume(s)

Viewing the List of Tiered Volumes Using the Control System

The **Volumes** pane in the **Summary** tab of the **Data > Volumes** page (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of tiered standard and mirror volumes:

- Select **Tiered Volumes** from the drop-down menu in the **Volumes** pane.

The list of tiered standard and mirror volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the pane displays the following information, by default:

| Column Name | Description |
|-----------------|---|
| Volumes | The name of the volume (used for default sorting). |
| Offload Tier | The name of the tier where the volume data is stored. |
| Job | The tiering operation that is currently running or was last performed on the volume. Value can be one of the following: <ul style="list-style-type: none"> • Offload — if volume data was offloaded or is currently being offloaded • Abort — if volume data offload or recall operation was aborted or is being aborted • Recall — if volume data was recalled or is being recalled from the tier |
| State | The status of the job. |
| Progress | The job completion percentage. |
| Start Date/Time | The date and time when the job was started. |
| End Date/Time | The date and time when the job completed. |
| Offload Speed | The amount of data (in MB) offloaded or being offloaded per second. |

| Column Name | Description |
|--------------|---|
| Recall Speed | The amount of data (in MB) recalled or being recalled per second. |

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- [Edit](#) selected volume(s)
- [Remove](#) selected volume(s)
- [Create snapshot\(s\)](#) of selected volume(s)
- [Change](#) the mirror volume to a standard volume
- [Start](#) the mirroring operation(s) for the selected mirror volume(s)
- [Stop](#) the mirroring operation(s) for the selected mirror volume(s)
- [Mount](#) selected volume(s), if they are not already mounted
- [Unmount](#) selected volume(s), if they are currently mounted
- [Offload](#) selected volume(s)
- [Recall](#) selected volume(s)
- [Abort](#) currently running tiering job for selected volume(s)

Retrieving the List of Volumes Using the CLI and REST API

The basic command to retrieve the list of volumes is:

```
maprcli volume list
```

For complete reference information, see [volume list](#) on page 2247.

Customizing the List of Columns/Fields

Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.

Customizing the Columns in the Control System

1. Log in to the Control System and go to:
 - **Data > Volumes** page to customize columns displayed in the **Volumes** pane.
 -  **Note:** The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.
 - **Nodes** page to customize columns displayed in the **Nodes** pane.
 -  **Note:** The **Nodes** page is not available on the Kubernetes version of the Control Panel.
2. Click the **Customize Columns** icon ().

In the **Customize Columns** dialog, the:

 - **Available** list displays the columns that are available for display.
 - **Selected** list displays the columns currently displayed in the pane.

3. Select the columns from the:
 - a) Available list of columns and click  to move selection to **Selected** columns (for display).
 - b) Selected list of columns and click  to remove selected columns from displaying.
4. (Optional) Click  and/or down  arrows to sort the order of columns.
5. Click **Save Changes** for the customization to take effect.

Tip: To reset the display to its default columns, click **Reset to default columns**.

Customizing the Fields Using the CLI or REST API

Use the `-column` parameter with the `maprcli` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

```
maprcli node list -columns service,health
```

For complete reference information, see the [node list](#) on page 1911 command.

- To view the volume name for the list of volumes being retrieved, run the following command:

```
maprcli volume list -columns volumename
```

For complete reference information, see [volume list](#) on page 2247 command.

Reverting to Default List of Columns

Describes how to revert to the default list of columns on the Control System

1. Log in to the Control System and click:
 - **Data > Volumes** to revert to the default list of columns in the **Volumes** pane.
 -  **Note:** The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.
 - **Nodes** to revert to the default list of columns in the **Nodes** pane.
 -  **Note:** The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Click the **Customize Columns** icon ().
3. Click **Reset to default columns**,
4. Click **Save Changes**.
The pane displays the default list of columns.

Filtering the List of Volumes

Explains how to filter the list of volumes using either the Control System or the CLI.

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

Filtering on the Control System

1. Log in to the Control System and click **Data > Volumes** to filter volumes in the **Volumes** pane.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select one of the following options from the **Add Filter** drop-down menu:
 - Volume — to filter the list by volume name
 - Usage — to filter the list by amount of disk used
 - Mount Path — to filter the list by mount path
 - Creator — to filter the list by entity or volume owner
 - Total Size — to filter the list by size of volume
 - Replication Factor — to filter the list by replication factor
 - Physical Topology — to filter by the rack path
 - Tier Type - to filter by a type of tier
 - Quota — to filter by hard quota
 - Data on Wire Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for on-wire encryption
 - Data at Rest Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for data-at-rest encryption (DARE)
 - Last Access Time - to filter by the [Last Access Time](#)
 - Coalesce Interval - to filter on the [coalesce interval](#)
3. Specify the value in the drop-down field for the selected filter (by which to filter the list of volumes) and click **Filter**.
As you make selections and specify the filtering criteria, the pane displays only the volumes that match the specified filtering criteria.
4. Click:
 - **Add Filter** to add another filtering criteria.
 -  to remove a filtering criteria.
 -  to clear all filter settings.

Filtering Using the CLI

The `volume list` on page 2247 command can be used with the `-filter` option, which let you specify large numbers of volumes by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all volumes whose owner is `root` and whose name begins with `test` as follows:

```
maprcli volume list -filter [n=="test*" ]and[on=="root" ]
```

For more information, see [Filters](#) on page 1703.

Creating a Volume

Describes how to create a volume using the Control System, CLI and the REST API.

You can create a new (Standard or Mirror) volume using the Control System, the CLI, and the REST API.

Creating a Volume Using the Control System

To create a new (Standard or Mirror) volume using the Control System:

1. Go to the **Data > Volumes** page and click **Create Volume** to display the **Create New Volume** page.

Note: When running on a Kubernetes cluster, the **Create Volume** option is on the **Volumes** page.

2. Choose the **Volume Type** in the **Properties** section. Choose:
 - **Standard Volume** to create a read-write volume.
 - **Mirror Volume** to create a volume that is a read-only copy of an existing volume.

Tip: See also: [Mirror Types](#) on page 420.

3. Specify the following required settings in the **Properties** section:

Standard Volume

| | |
|---------------------------|--|
| Volume Name | <p>Enter a name for the volume.</p> <p>The name should contain only the following characters:</p> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p>A-Z a-z 0-9 - - .</p> </div> <p> Note:</p> <ul style="list-style-type: none"> The volume name should not begin with <code>mapr.</code> because <code>mapr.</code> is used for system volumes. If you use <code>mapr.</code> at the start of the volume name, the volume may not display in the default view of the list of volumes in the Control System; you must select the Include System Volumes checkbox in the Volumes pane to view volumes with names beginning with <code>mapr.</code> For tiering-enabled volumes, volume name should not exceed ninety-eight characters. |
| Accountable Entity | <p>Specifies a user or group whose use of a volume can be subject to quotas. You can set or modify quotas that limit the space used by all the volumes owned by an accountable entity.</p> |

Mirror Volume

| | |
|--------------------|--|
| Volume Name | <p>Enter a name for the volume.</p> <p>The name should contain only the following characters:</p> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p>A-Z a-z 0-9 _ - .</p> </div> <p> Note:</p> <ul style="list-style-type: none"> • The volume name should not begin with <code>mapr.</code> because <code>mapr.</code> is used for system volumes. If you use <code>mapr.</code> at the start of the volume name, the volume may not display in the default view of the list of volumes in the Control System; you must select the Include System Volumes checkbox in the Volumes pane to view volumes with names beginning with <code>mapr.</code> • For tiering-enabled volumes, volume name should not exceed ninety-eight characters. |
|--------------------|--|

| | |
|-----------------------------------|---|
| <p>Source Cluster Name</p> | <p>Enter the name of the cluster on which the source volume exists.</p> <p>The name should contain only the following characters:</p> <div data-bbox="1175 369 1456 457" style="background-color: #f0f0f0; padding: 5px;"> <p>A-Z a-z 0-9 - .</p> </div> <p>Mirroring only works between two secure clusters or between two non-secure clusters. Mirroring does not work when one cluster is secure and the other is non-secure.</p> <p> Note: When setting up mirror volumes for mirroring between clusters, for the mirroring operation to run successfully, servers in one cluster cannot use the same IP addresses as servers in the other cluster. For example, if node A in cluster A has a private IP address of 10.10.20.29, no server in cluster B can have the same private IP address. Also, all the servers in destination cluster must be able to reach all the servers in the source cluster and vice versa. For example, suppose 10.10.20.29 is the only IP address used by node A in cluster A; then all servers in cluster B should be able to reach the IP address 10.10.20.29.</p> |
|-----------------------------------|---|

| | |
|----------------------------------|---|
| <p>Source Volume Name</p> | <p>Enter the name of the source volume, from which the mirror volume pulls data (after selecting the source volume cluster).</p> <p>The name should contain only the following characters:</p> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p>A-Z a-z 0-9 - .</p> </div> <p>If the source volume is on:</p> <ul style="list-style-type: none"> • Same cluster, you create a local mirror volume, which is useful for load balancing or for providing a read-only copy of a data set. See Local Mirroring on page 421 for more information. • Another cluster, you create a remote mirror volume, which is useful for offsite backup, for data transfer to remote facilities, and for load and latency balancing. See Creating Remote Mirrors on page 953 for more information. <p> Note: If you plan to enable tiering for the mirror volume, ensure that the selected source volume is also tiering-enabled. You cannot create tiering-enabled mirror volumes to mirror data in standard volumes that are not tiering-enabled.</p> <p>For information on setting up mirror cascades, see Mirror Cascades on page 422.</p> |
|----------------------------------|---|

| | |
|---------------------------|---|
| Accountable Entity | Specifies a user or group whose use of a volume can be subject to quotas. You can set or modify quotas that limit the space used by all the volumes owned by an accountable entity. |
|---------------------------|---|

Steps 4 to 10 are optional and allow you to define optional volume properties and optional settings for auditing, replication, data tiering, volume access, and volume administration. If you do not define these settings, default values, where available, are used. You can skip to:

- (Optional) Step 9 to associate a snapshot schedule and/or an offload schedule with the volume.
- Step 11 to create the volume with basic settings.

4. (Optional) Specify the following general settings under **Properties**:

| | |
|-----------------------------|--|
| Mount | Specifies whether to automatically mount (Yes) or not mount (No) the volume after creation. By default, volumes are mounted immediately after creation. If this is set to Yes , you must also specify the mount path. |
| Mount Path | The path to mount the volume. This is required if the value for Mount is Yes .  Note: The path must be relative to / and cannot be in the form of a global namespace path (for example, /mapr/<cluster-name>/). |
| Collect Metrics | Specifies whether (Yes) or not (No) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1421 and Enabling Volume Metric Collection on page 1423. |
| Volume Access | Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume. |
| Last Access Interval | Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 448 for more information. |

5. (Optional) Specify the following settings for data replication under **Replication and Storage** section:

Replication

| | |
|-----------------|--|
| Topology | Specifies the rack path to the volume. The default topology is / data. |
|-----------------|--|

| | |
|-----------------------------------|---|
| Optimize Replication for | <p>Specifies the basis for the replication factor:</p> <ul style="list-style-type: none"> • High throughput, or cascading replication, where volumes are replicated sequentially on intermediate and tail containers. • Low latency, or star replication, where volumes are replicated on multiple containers in parallel. <p>The default value is high throughput. See Selecting a Replication Type for High Availability on page 986.</p> |
| Guarantee Min Replication | <p>Specifies whether (Yes) or not (No) to enforce minimum number of copies. If this is enabled (Yes), writes succeed only when the minimum number of copies exist. If this is enabled (Yes) and minimum number of copies are not available, the client is asked to retry.</p> <p>For more information, see Understanding Replication on page 410.</p> |
| Replication | <p>Specifies the minimum (Minimum Replication) and desired (Target Replication) number of copies of the volume data. The default minimum is 2, and the default target is 3.</p> |
| Name Container Replication | <p>Specifies the minimum (Minimum Replication) and desired (Target Replication) number of copies of the name container associated with the volume. The default minimum is 2, and the default target is 3.</p> |

Storage

Data Tiering — Specifies whether to enable (**Yes**) or disable (**No**) data tiering for volume data.

By default, data tiering is enabled and volume data is stored in the hot tier (HPE Ezmeral Data Fabric

cluster). If you choose to enable data tiering for the volume, you can associate a tier type with the volume either now, or later by editing the volume. If you decide to associate a type of tier with the volume, proceed to the next step; otherwise, proceed to step 7.

6. (Optional) Associate a type of tier with the volume by selecting a tiering type from the **Tiering Type** drop-down list and specifying the following settings for the tier:

Erasure Coding (Warm)

For offloading data to an erasure coded volume, specify values for the following properties. If values are not specified, default values are applied.

| | |
|-----------------------|--|
| Topology | The topology of the erasure coded volume from the drop-down list. |
| Storage Policy | <p>The rule for offloading data in this volume. You can click:</p> <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See steps 3 - 5 in the Creating a Storage Tier Policy on page 1057 topic for more information. <p>If you do not select a storage policy, the default policy named <code>default.ectier.rule</code>, which is all files (p), is associated with the volume.</p> |

| | |
|----------------------|--|
| <p>Scheme</p> | <p>The erasure coding scheme, which is the number of data chunks and number of parity chunks. Set the required Parity Scheme. The system indicates in real-time whether or not the parity scheme is valid. Some valid parity schemes include:</p> <ul style="list-style-type: none"> • 3+2 — for 3 data chunks and 2 parity chunks. You must have 5 or more nodes on the cluster for this option. If selected, this scheme has 60% storage overhead and can tolerate failure of up to 2 nodes. • 4+2 — for 4 data chunks and 2 parity chunks. You must have 6 or more nodes on the cluster for this option. If selected, this scheme has 50% storage overhead and can tolerate failure of up to 2 nodes. • 5+2 — for 5 data chunks and 2 parity chunks. You must have 7 or more nodes on the cluster for this option. If selected, this scheme has 40% storage overhead and can tolerate failure of up to 2 nodes. • 6+3 — for 6 data chunks and 3 parity chunks. You must have 9 or more nodes on the cluster for this option. If selected, this scheme has 50% storage overhead and can tolerate failure of up to 3 nodes. <p>To use local parity, set the Local Parity slider to Yes. The system then displays a third slider to set the number of local parity blocks.</p> <p>As you set the parity scheme, irrespective</p> |
|----------------------|--|

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, specify values for the following properties.

| | |
|--|--|
| Storage Policy | The rule for offloading data in this volume. You can click: <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1057 for more information. |
| Remote Target | The location to which the data is offloaded. You can click: <ul style="list-style-type: none"> • Browse to select an existing tier. • Create to create a new tier. See Creating a Storage Tier on page 1044 for more information. |
| Retention Duration after Recall | The number of days to retain data recalled from the tier to the HPE Ezmeral Data Fabric cluster. Once the number of days is reached, recalled data on the HPE Ezmeral Data Fabric cluster is purged (if there are no changes), or offloaded (if there are changes). |
| Tier Encryption | Specifies whether (Yes) or not (No) to enable encryption of data on the tier. This cannot be modified once it is set. The default value is No (disabled). |

7. (Optional) To use Label-Based Storage, enter the label and the namespace label . See [Using Storage Labels](#) on page 1068 for more information.
8. (Optional) Configure security for volume data by setting values for the properties in the **Security** section.
 - a) Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the volume.
 - b) Enable (**Yes**) or disable (**No**) the following audit and encryption settings by selecting the desired option:

| | |
|--------------------------------|---|
| Auditing | Auditing of operations. You can either audit particular files or directories (By File or Directory) or audit all files and directories on the volume (All Volume Content). In either case, you can do the following: <ul style="list-style-type: none"> Choose either Default or Custom to specify the list of directory, file, table, and streams operations to audit. Specify a Coalesce Interval, which is the interval of time during which READ, WRITE, or GETATTR operations on one file from one IP address or UID are logged only once for a particular operation, if auditing is enabled.. The default value is 60 minutes. |
| Data on Wire Encryption | Encryption of data in the volume during transmission. By default, this is enabled (Yes) for all new volumes in secure cluster. This is not supported on insecure clusters. |
| Data at Rest Encryption | Encryption of data at rest. This should be enabled only if the feature is enabled at the cluster-level. By default, this is disabled (No). This is not supported on insecure clusters. |
| Coalesce Interval | The interval of time (in minutes) to use when logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled. The default value is 60 minutes. |

9. (Optional) Specify the users, groups, and/or roles that have and/or do not have permissions to read and/or write in the **Data Access Control** section:
 - a) Click **Add Data Access Control** to display the **Add Access Permissions** window.
 - b) Move the slider associated with **Public** to **Yes** to grant access to all or to **No** to specify a list of users, groups, and or roles and do one of the following:
 - Enter the users, groups, and/or roles in the respective text boxes.
 - Select the **Custom ACE** checkbox to enter the custom [ACE](#).
 - c) Click **Add** to select permissions for the specified users, groups, and/or roles.
 - d) Select the **Read** and/or **Write** checkbox in the **Permissions** column to grant that type of access to all (Public) or the specified users, groups, and/or roles.

Click:

-  to modify the users, groups, and/or roles.
- Add Another** to grant permissions for other users, groups, and/or roles and repeat steps b and c.
-  to create a copy of the permissions, which you can then modify.
-  to remove a data access control setting.

10. (Optional) Specify the users and groups that have volume administration permissions:
 - a) Select the type of entity, user or group, and enter entity name in the **Entities** field.
 - b) Select the checkbox associated with any of the following permissions to grant the user or group that type of administration control:

| | |
|-------------------------------|--|
| Dump & Backup | Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files. |
| Restore & Mirror | Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume. |
| Edit | Edit volume properties, create and delete snapshots. |
| Delete | Delete the volume. |
| Admin (Access Control) | View and edit access control settings (but cannot perform volume operations). |
| Full Control | Perform all volume-related administrative operations except changing access control settings. |

To define administrative access control settings for another user or group, click **Add Another** and repeat steps a and b.

Note: To perform this action from the command line, refer to [acl set](#) on page 1708.

By default, the root user and the volume creator have full control permissions on the volume.

11. Set read (**R**), write (**W**), and/or execute (**X**) permissions on the root directory for users, groups, and others by selecting the permission.

12. Click **Create Volume** to create the volume.

Creating a Volume Using the CLI and REST API

CLI

The basic command to create a (Standard) volume is:

```
/opt/mapr/bin/maprcli volume
create -name <volName> -path
<mountPath>
```

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

If you are creating a:

- Mirror volume, you must specify `-type mirror` and `-source <sourceVolName>@<cluster>` in the command.
- Tiering-enabled volume, you must specify `-tieringenable true` in the command.

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>' --use
r mapr:mapr
```

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

If you are creating a:

- Mirror volume, you must specify `type=mirror` and `source=<sourceVolName>@<cluster>` in the request.
- Tiering-enabled volume, you must specify `tieringenable=true` in the request. The `tieringenable` property of a mirror volume should be the same as the source volume.

For the complete list of parameters, see [volume create](#) on page 2190.

Creating Remote Mirrors

Describes the use of remote mirror volumes. The remote mirror volume is present on a different cluster from the source volume.

Creating remote mirrors is similar to creating local mirrors, except that the mirror volume resides in a different cluster from the source volume. To properly identify the source volume, you must specify the source cluster name when the mirror volume is created. In addition, you must edit the `mapr-clusters.conf` file so that each cluster can resolve the nodes in the other cluster.

To create a mirror on a remote cluster, you must have the same UID for the `MAPR_USER` (the cluster owner) for both the primary cluster (where the source volume resides) and the remote clusters (where the mirror volumes reside; also known as the destination clusters). You also need to have the following volume permissions:

- `dump` permission on the source volumes
- `restore` permission on the mirror volumes at the destination clusters

When a mirror volume is created on a remote cluster (according to the entries in the `mapr-clusters.conf` file), the CLDB checks that the local volume exists in the local cluster. If both clusters are not set up and running, the remote mirror volume cannot be created.

To summarize:

- Each cluster must be already set up and running.
- Each cluster must have a unique name.
- Every node in each cluster must be able to resolve all nodes in remote clusters, either through DNS or entries in `/etc/hosts`.
- The UID for the `MAPR_USER` (cluster owner) must be the same for the source and destination clusters, irrespective of which user account triggers the mirror operation.
- Volume permission must be set to `dump` on the source volumes.
- Volume permission must be set to `restore` on the mirror volumes.

See also: [Remote Mirroring](#) on page 421.

Setting Up Cross-Mirroring Between Unsecure Clusters

Describes how to edit the `mapr-clusters.conf` file to mirror volumes between unsecure clusters.

To mirror volumes between unsecure clusters, start by editing the `mapr-clusters.conf` on page 2485 file on the cluster of the source volume and create an entry for each additional cluster that hosts

a mirror of the volume. The entry must list the name of the cluster, followed by a space-separated list of hostnames and ports for the CLDB nodes of the cluster. In addition, use the `secure` parameter to specify whether the clusters are secure or non-secure. See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 1661 for more information about generating tickets for secure clusters.

Note: When mirroring between clusters, servers in one cluster cannot use the same IP addresses as servers in the other cluster. For example, if node A in cluster A has a private IP address 10.10.20.29, no server in cluster B can have the same private IP address. Also, all the servers in one cluster must be able to reach all the servers in the other cluster and vice versa. For example, suppose 10.10.20.29 is the only IP address used by node A in cluster A; then all servers in cluster B should be able to reach the IP address 10.10.20.29.

To set up cross-mirroring between unsecure clusters:

1. Review the requirements for [Creating Remote Mirrors](#) on page 953 before you begin.
2. On each cluster, make a note of the cluster name and CLDB nodes (the first line in `mapr-clusters.conf` on page 2485)
3. On each webserver and CLDB node, add the CLDB nodes of the remote cluster to `/opt/mapr/conf/mapr-clusters.conf`, using the following format:

```
clustername1 <CLDB> <CLDB> <CLDB>
[ clustername2 <CLDB> <CLDB> <CLDB> ]
[ ... ]
```

For example, suppose you have a cluster, `clusterA`, with two CLDB nodes, `nodeA` and `nodeB`. Now you want to add a second cluster called `clusterB` with CLDB nodes `nodeC` and `nodeD`. Edit the `mapr-clusters.conf` file and add the line for `clusterB` as shown:

```
clusterA nodeA:7222 nodeB:7222
clusterB nodeC:7222 nodeD:7222
```

Warning: You must include the port number in the CLDB hostname notation.

Here:

- a. First line contains cluster name and CLDB nodes of cluster A (the local cluster)
- b. Second line contains cluster name and CLDB nodes of cluster B (the remote cluster)

The `mapr-clusters.conf` file for cluster B with 2 CLDB nodes (`nodeC` and `nodeD`) looks as follows:

```
clusterB nodeC:7222 nodeD:7222
clusterA nodeA:7222 nodeB:7222
```

By creating additional entries in the `mapr-clusters.conf` file, you can mirror from one cluster to several others.

4. Set `secure=false` if both clusters are not secure. If both the clusters are secure, see [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 1661 for more information.

Warning: Mirroring only works between two secure clusters or between two non-secure clusters. Mirroring does not work when one cluster is secure and the other is non-secure.

5. On each cluster, restart the `mapr-apiserver` service on all nodes where it is running.

Creating a Volume for a Tenant

Provides an overview of how to create a volume for a tenant using the CLI.

To create a volume for a tenant (when you have [Multitenancy on File System](#) on page 450), do the following:

1. Log in to the cluster as administrator and ensure that the ticket for the tenant has already been generated and copied on to the tenant host.
If necessary, follow steps in [Generating a Ticket for a Tenant](#) on page 1546 to set up the ticket for the tenant.
2. Create a volume for the tenant by running the following command:

```
$ maprcli volume create -name <volumeName> -path
<path_to_volume> -tenantuser <tenant_user>
```

Note: For more information, see the `maprcli volume create` command.

Viewing Volume Information

Describes how to view volume information using either the Control System or the CLI.

You can retrieve and view volume information using either the Control System or the CLI.

1. Log in to the Control System and go to the **Summary** tab in the **Data > Volumes** page.

Note: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click the volume name in the **Volumes** pane.

The volume information page displays. On this page, you can perform the following actions based on the type of the volume.

Standard Volume

Click the **Select Action** drop-down menu to:

- Edit the volume
- [Remove](#) the volume
- [Snapshot](#) a volume
- [Change](#) the mount path and mount or unmount the volume
- [Convert](#) the volume to a mirror volume
- [Rename](#) the volume
- [Manage](#) Label
- [Manage](#) Name Space Label

Mirror Volume

Click the **Select Action** drop-down menu to:

- Edit the Volume
- [Remove](#) the volume
- [Snapshot](#) a volume
- [Start/stop](#) mirroring

- [Promote](#) the volume to a standard (read/write) volume
- [Change](#) volume mount information
- [Rename](#) the volume
- [Manage](#) Label

Tiering Volume

Click the **Select Action** drop-down menu to:

- Edit the Volume
- [Remove](#) the volume
- [Snapshot](#) a volume
- [Change](#) volume mount information
- [Rename](#) the volume
- [Manage](#) Label
- [Offload a volume to a tier](#)
- [Recall a volume from a tier](#)
- [Abort a volume tiering job](#)

The page displays tabs for viewing:

- [Summary](#) of the volume including:
 - All recent and active volume [alarms](#)
 - [Metrics](#) (such as disk usage) for the volume
 - Volume [details](#) such as the general, auditing, and tiering settings for the volume, ACLs and ACEs on the volume, and volume quotas and schedules
 - Labels associated with the volume
- [Snapshots](#) associated with the volume

Viewing Volume Details

Explains how to retrieve and view volume information using the Control System, the CLI, or the REST API.
Viewing Volume Details in the Control System

- Log in to the Control System and go to the **Summary** tab in the [volume information page](#) for the volume.

The page displays the following:

Quota Usage

Amount of disk space allocated to and utilized by the volume and associated snapshots. For more information, see [Monitoring Volume Disk Usage Using the Control System](#) on page 1421. You can set or edit hard and advisory quotas by clicking **Edit Quota**. See [Setting or Modifying Quota for a Volume](#) on page 990 for more information.

Active Alarms

Currently active alarms associated with the volume. For more information, see [Viewing Active Volume Alarms](#) on page 1439. You can [mute](#) or [dismiss](#) alarms by clicking the associated link.

Schedules

The schedules associated with the volume. Standard volumes can have associated snapshot schedule; mirror volumes can have associated snapshot and mirroring schedules; tiered volumes can have associated snapshot and tiering schedules. You can:

- [Create a new schedule](#) by clicking **Create Schedule**.
- [Set new or modify existing schedules](#) by clicking .

Properties

| | |
|-----------------------------|--|
| Created By | Indicates the user who created the volume. |
| Volume Type | Indicates the type of volume. Value can be one of the following: <ul style="list-style-type: none"> • Standard Volume • Mirror Volume |
| Volume Name | Indicates the name of the volume. |
| Accountable Entity | Indicates the name of the accountable entity. |
| Volume Access | Indicates the type of access allowed on the volume. Value can be one of the following: <ul style="list-style-type: none"> • Read/Write • Read-only |
| Mounted | Indicates whether or not volume is mounted. |
| Mount Path | Indicates the mount path of the volume. |
| Collect Metrics | Indicates if metrics collection is enabled for the volume. |
| Last accessed | Indicates the date when the volume was last accessed. |
| Last Access Interval | Indicates the frequency (in days) at which the last access time of a file is updated, |

Replication and Storage

REPLICATION

Table

| | |
|-----------------------------------|---|
| Topology | Denotes the location of the volume on the cluster rack. |
| Replication | Indicates the minimum (Min Target) and desired (Max Target) number of copies for the volume data. |
| Name Container Replication | Indicates the minimum (Min Target) and desired (Max Target) number of copies of the name container associated with the volume. |
| Optimize Replication | Indicates the basis for replication. Value can be one of the following: <ul style="list-style-type: none"> • High throughput, or cascading replication • Low latency, or star replication |

Table (Continued)

| | |
|----------------------------------|---|
| Guarantee Min Replication | Indicates whether or not to enforce minimum number of copies. |
| Actual Replication | Indicates the actual number of replicas as a percentage. |

STORAGE

The following information is common to all types of storage:

Table

| | |
|-------------------------------|--|
| Type | Indicates the storage type. |
| Label - Volume | Indicates the label assigned to the volume. |
| Label - Name Container | Indicates the label assigned to the volume's name container. |
| Usage | Displays disk usage details for the volume. |

Note: The following is visible only if warm tiering is enabled for the volume.

Table

| | |
|-----------------|---|
| Topology | Indicates the topology of the erasure-coded volume. |
|-----------------|---|

Table (Continued)

| | |
|--|---|
| Remote Target | Indicates the name of the tier. |
| Storage Policy Name | Indicates the name of the storage policy. |
| Policy Detail | Indicates the rules in the policy for offloading data. |
| Retention Duration after Recall | Indicates the period of time to keep recalled data in the hot tier. |
| Erasure Coding Scheme | Indicates the number of data and parity chunks. |
| Tier Purged | Indicates the amount of offloaded data. |

Note: The following is visible only if cold tiering is enabled for the volume.

Table

| | |
|----------------------------|--|
| Remote Target | Indicates the name of the remote storage. |
| Storage Policy Name | Indicates the name of the storage policy. |
| Policy Detail | Indicates the rules in the policy for offloading data. |

Table (Continued)

| | |
|--|---|
| Retention Duration after Recall | Indicates the number of days to keep recalled data in the data-fabric cluster (hot tier). |
| Tier Purged | Indicates the amount of offloaded data. |

Security

Enforcement Mode

The enforcement mode for the security settings. See [Volume-Level Security Policy Enforcement Mode](#) on page 678 for more information. You can [set new or modify existing enforcement mode](#) by clicking .

SECURITY POLICIES

The security policies associated with the volume. See [Policy-Based Security](#) on page 670 for more information.

DATA ACCESS CONTROL

Indicates the entities — public or user, group, and/or role — that have (read and/or write) access to volume data. See [Managing Access Control Expressions](#) on page 1565 for more information.

AUDIT AND ENCRYPTIONS

| | |
|-------------------------|---|
| Enable Auditing | Indicates whether auditing is enabled at the volume level. |
| Audit Operations | Indicates whether default or custom list of operations are being audited. |

| | |
|--------------------------------|--|
| Data on Wire Encryption | Indicates whether (Yes) or not (No) on-wire encryption is enabled for the volume. |
| Data at Rest Encryption | Indicates whether (Yes) or not (No) data-at-rest encryption (DARE) is enabled for the volume. |
| Coalesce Interval | Indicates the interval of time (in minutes) used for logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled. |

Volume Admin Control

Indicates the users and/or groups who have one or more of the following types of permissions on the volume:

- **Dump & Backup** — Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.
- **Restore & Mirror** — Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.
- **Edit** — Edit volume properties, create and delete snapshots.
- **Delete** — Delete the volume.
- **Admin** — View and edit access control settings (but cannot perform other volume administrative operations).
- **Full Control** — Perform all volume-related administrative operations except changing access control settings.

*Viewing Volume Information Using the CLI and the REST API***CLI**

The basic command to retrieve volume information is:

```
maprcli volume info (-name
<volume_name> | -path <volume_path>)
```

REST

Send a request of type GET. For example:

```
curl -k -X
GET 'https://<hostname>:8443/rest/
volume/info?name=<volName>' --user
mapr:mapr
```

You must specify either `name` or `path`, but not both. For more information, see [volume info](#) on page 2227.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

- The **Snapshots** tab under the **Data > Volumes** page displays all the snapshots on the cluster.

Note: When running on a Kubernetes cluster, the **Snapshots** tab is under the **Volumes** page that is under the **Volumes** menu.

For each snapshot, you can view the following:

| Column Name | Column Description |
|---------------|---|
| Snapshot Name | The name of the snapshot. |
| Volume | The volume with which the snapshot is associated. |
| Created On | The date when the snapshot was created. |
| Expires On | The date when the snapshot expires. |
| Reclaim Size | TBD |

You can select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing the Snapshots Associated with a Volume Using the Control System

- Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).

The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

| Column Name | Column Description |
|---------------|---|
| Snapshot Name | The name of the snapshot. |
| Volume | The volume with which the snapshot is associated. |
| Created On | The date when the snapshot was created. |
| Expires On | The date when the snapshot expires. |

| Column Name | Column Description |
|--------------|--------------------|
| Reclaim Size | TBD |

You can [create a snapshot](#) of the volume or select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing Snapshots Using the CLI or REST API

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see [volume snapshot list](#) on page 2303.

Removing Volumes

Explains how to remove a volume using either the Control System or the CLI.

Note: When you remove a volume enabled for:

- Cold tiering, the directory/folder for the volume in the metadata volume associated with the tier is also removed asynchronously.
- Warm tiering, the directory/folder for the volume in the metadata volume associated with the tier and the erasure-coded volume are also removed asynchronously.

Removing Volumes Using the Control System

To remove one or more volumes, in the **Summary** tab under **Data > Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the volumes to remove from the list of volumes in the **Volumes** pane.

Note: Alternatively, you can click the name of the volume to traverse to the volume details page.

2. Click **Remove Volume(s)** from the **Actions** drop-down menu.

The **Remove Volume(s)** confirmation dialog displays.

3. Choose one of the following:

- **Remove only if there are no dependent artifacts** — Specifies whether to check for dependencies before removing the volume. If the volume has dependencies, such as associated snapshots, the volume will not be deleted, but an alarm will be raised.

Note: Volume will not be deleted if mirroring is in progress as the mirror volume is synchronized from a hidden internal snapshot of the source volume.

- **Force remove even if there are dependent artifacts** — Indicates that volume must be removed forcefully, even if the volume has dependencies.

4. Click **Remove Volume**.

The selected volumes are removed.

Removing Volumes Using the CLI or REST API

The basic command to remove a volume is:

```
maprcli volume remove -name <volume name>
```

For complete reference information, see [volume remove](#) on page 2299.

Note: When a volume is removed, the data present in that volume is not purged from the filesystem immediately. The following parameters control when the deleted volumes are purged.

- `cldb.purge.delay.hours` — Time to wait (in hours) to trigger purge of any volume after CLDB becomes primary. The default value is 1 hour.
- `cldb.volumes.purge.frequency` — The frequency (in minutes) for purging the data of deleted volumes. The default value is 60 minutes.

Use the `maprcli` command to set these parameters. For example:

```
maprcli config save -values {"cldb.purge.delay.hours":"2"}
maprcli config save -values {"cldb.volumes.purge.frequency":"120"}
```

Modifying Multiple Volumes

Explains how to modify volumes using either the Control System or the CLI.

Modifying Volumes Using the Control System

To edit multiple volumes, in the **Summary** tab under **Data > Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the volumes to edit in the **Volumes** pane and click **Edit Volume(s)** from the **Actions** drop-down menu.

The **Edit Volumes** page displays. You can edit certain volume properties, authorization settings, usage settings, and schedule settings for the selected volumes.

2. Modify one or more of the following settings.

Note: If the selected volumes share the same settings, the fields are pre-populated with the current value. If the selected volumes contain different settings, only the fields that have been set in all the selected volumes display.

Properties

| | | |
|------------------------------|-----------------------------|---|
| SETTINGS AND AUDITING | Accountable Entity | The <i>entity</i> accountable for this volume's usage. |
| | Collect Metrics | Specifies whether (Yes) or not (No) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1421 and Enabling Volume Metric Collection on page 1423. |
| | Volume Access | Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume. |
| | Last Access Interval | Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 448 for more information. |
| | Enable Auditing | Select one of the following: <ul style="list-style-type: none"> • Disable auditing • Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume • Enable auditing of operations on all files |

| | | |
|--------------------------|-----------------------------------|---|
| REPLICATION (HOT) | Replication | Toggle Minimum Replication and set the desired and minimum number of copies of the volumes. |
| | Name Container Replication | Set the desired and minimum number of copies of the name container associated with the volumes. |

| | | |
|------------------------------|---------------------------|---|
| SETTINGS AND AUDITING | Accountable Entity | The <i>entity</i> accountable for this volume's usage. |
| | Collect Metrics | Specifies whether (Yes) or not (No) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1421 and Enabling Volume Metric Collection on page 1423. |
| | Volume Access | Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume. |
| | Enable Auditing | Select one of the following: <ul style="list-style-type: none"> • Disable auditing • Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume • Enable auditing of operations on all files, tables, streams in the volume whether or not auditing is enabled for files, tables, and streams in the volume. |

| | | |
|--------------------------|-----------------------------------|---|
| REPLICATION (HOT) | Replication | Toggle Minimum Replication and set the desired and minimum number of copies of the volumes. |
| | Name Container Replication | Set the desired and minimum number of copies of the name container associated with the volumes. |

Authorization

| | |
|--------------------------------|---|
| ADMINISTRATIVE CONTROLS | Users and groups that have permissions to perform administrative operations on this volume. |
|--------------------------------|---|

Usage

| | |
|------------------------------|--|
| Volume Advisory Quota | Allocated disk space, which when exceeded raises an alarm but does not prevent writes. |
| Volume Hard Quota | Allocated disk space, which when exceeded prevents further writes. |

Schedule

| | |
|--------------------------|--|
| Snapshot Schedule | Schedule for creating snapshots of this volume. |
| Mirror Schedule | Schedule for running mirroring operation for the volumes.  Note: This is available only if all the selected volumes are mirror volumes. |

Note: To undo a change to a specific setting, click the associated . This action will revert the value to the current setting.

- Click **Save Changes** for the changes to take effect.

Modifying Volumes Using the CLI or REST API

The basic command to modify a volume is:

```
maprcli volume modify -name <volume name>
```

For complete reference information including supported options, see [volume modify](#) on page 2275.

Modifying a Volume

Describes how to edit volume properties using the Control System, CLI and the REST API.

Modifying a Volume Using the Control System

1. Log in to the Control System and go to the [volume information page](#).
2. Click **Edit Volume** to display the **Edit Volume** page.

Modifying General Properties

3. Make changes, as needed, to the following general properties:

Standard Volume

| | |
|-----------------------------|--|
| Accountable Entity | The entity accountable for the volume's usage. |
| Collect Metrics | Whether (Yes) or not (No) to enable metrics collection for the volume. |
| Volume Access | Indicates whether volume is a read-only or read/write volume. |
| Last Access Interval | Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 448 for more information. |

Mirror Volume

| | |
|-----------------------------|---|
| Source Cluster Name | The name of the cluster on which the source volume exists. |
| Source Volume Name | The name of the source volume to mirror. |
| Accountable Entity | The entity accountable for this volume's usage. |
| Collect Metrics | Whether (Yes) or not (No) to enable metrics collection for the volume. |
| Volume Access | Indicates whether volume is a read-only (default) or read/write volume. To promote the mirror volume to a standard volume, you can switch to read/write volume; see Changing Mirror Volumes to Standard Volumes on page 983 for more information. |
| Last Access Interval | Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 448 for more information. |

Modifying Replication and Storage Settings

4. Make changes, as needed, to the following replication settings:

| | |
|-----------------------------------|---|
| Topology | The location of this volume in the cluster rack topology. |
| Guarantee Min Replication | (Available from v6.0.1) Specifies whether (true) or not (false) to enforce minimum number of copies for the (read-write) volume. If this is enabled (Yes), writes succeed only when the minimum number of copies exist.  Note: If this parameter was not already set on a volume or if you modify the setting for this property from No to Yes , restart all the nodes where the containers associated with the volume exist for the changes to take effect. |
| Replication | Desired and minimum number of copies of the volumes. |
| Name Container Replication | Desired and minimum number of copies of the name container associated with the volumes. |

5. Set new (if **Data Tiering** was enabled (**On**) during volume creation) or modify existing **DATA TIERING** settings.**Erasure Coding (Warm)**

For offloading data to a warm tier, set new or modify existing values for the following properties.

| | |
|-----------------------|--|
| Topology | The topology of the erasure coded volume from the drop-down list only if it is already not set. |
| Storage Policy | The rule (or criteria) for automatically offloading data in this volume. You can click: <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1057 for more information. |
| Scheme | The erasure coding scheme, which is the number of data chunks and number of parity chunks, only if it is already not set; you cannot modify existing scheme. See Erasure Coding Scheme for Data Protection and Recovery on page 1004 for more information. |

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, set new or modify existing values for the following properties.

| | |
|--|---|
| Storage Policy | The rule (or criteria) for offloading data in this volume. You can click: <ul style="list-style-type: none"> • Browse to select an existing rule. • Create to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1057 for more information. |
| Remote Target | The location to offload data to only if it is already not set; you cannot modify if it is already set. You can click: <ul style="list-style-type: none"> • Browse to select an existing tier. • Create to create a new tier. See Creating a Storage Tier on page 1044 for more information. |
| Retention Duration after Recall | The number of days to retain data recalled from the tier to the HPE Ezmeral Data Fabric cluster. Once the number of days is reached, recalled data on the HPE Ezmeral Data Fabric cluster is purged (if there are no changes) or offloaded (if there are changes). |
| Tier Encryption | The setting to enable (Yes) or disable (No) encryption of data on the tier only if it is already not set. |

Modifying Security Settings

6. Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the volume and click **Add** to tag the volume with the security policy.
7. Make changes to the auditing settings by moving the slider to **Yes** (to enable) or **No** (to disable).
If enabled (**Yes**), you can make the following changes also:
 - a) Choose the **Default** radio button to enable auditing of a default list of operations or choose the **Custom** radio button to select a custom list of directory, file, table, and streams operations to audit.
 - b) Specify a **Coalesce Interval**, which is the interval of time (in minutes) to use when logging multiple READ, WRITE, or GETATTR operations on one file from the same client IP address. The default value is 60 minutes.

8. Make changes to the following encryption settings by moving the slider to **Yes** (to enable) or **No** (to disable):

| | |
|--------------------------------|---|
| Data on Wire Encryption | Encryption of data in the volume during transmission. By default, this is enabled (Yes) for all new volumes in secure cluster. This is not supported on insecure clusters. |
| Data at Rest Encryption | Encryption of data at rest. This should be enabled only if the feature is enabled at the cluster-level. By default, this is disabled (No). This is not supported on insecure clusters. |

9. Make changes, as needed, to the users, groups, and/or roles that have and/or do not have permissions to read and/or write by clicking one of the following in the **Data Access Control** section:

-  — to modify the users, groups, and/or roles.
-  — to create a copy of the permissions, which you can then modify.
-  — to remove a data access control setting.
- Select or deselect **Read** and/or **Write** checkbox in the **Permissions** column — to grant or deny that type of access.
- **Add Data Access Control** or **Add Another** — to display the **Add Access Permissions** window. To specify the users, groups, and/or roles that have and/or do not have permissions to read and/or write, do the following:
 - a) Move the slider associated with **Public** to **Yes** to grant access to all or to **No** to specify a list of users, groups, and or roles and do one of the following:
 - Enter the users, groups, and/or roles in the respective text boxes.
 - Select the **Custom ACE** checkbox to enter the custom [ACE](#).
 - b) Click **Add** to select permissions for the specified users, groups, and/or roles.
 - c) Select the **Read** and/or **Write** checkbox in the **Permissions** column to grant that type of access to all (Public) or the specified users, groups, and/or roles.

Modifying Volume Administration Control Settings

10. Make changes to the users and/or groups that can perform the following administrative operations on this volume:

| | |
|-----------------------------|--|
| Dump & Backup | Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files. |
| Restore & Mirror | Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume. |
| Edit | Edit volume properties, create and delete snapshots. |
| Delete | Delete the volume. |
| Admin | View and edit access control settings (but cannot perform volume operations). |
| Full Control | Perform all volume-related administrative operations except changing access control settings. |

To:

- Modify access for existing users and/or groups, select or deselect permissions.
- Grant access to other users and/or groups, click **Add Another**, enter the user/group name, and select permissions to grant to the user/group.

11. Click **Save Changes** for the changes to take effect.

Modifying a Volume Using the CLI or REST API

CLI

The basic command to modify a volume is:

```
/opt/mapr/bin/maprcli volume
modify -name <volume name>
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<hostname>:8443/
rest/volume/modify?name=<volume
name>' --user mapr:mapr
```

For the complete list of editable parameters, see [volume modify](#) on page 2275.

Renaming a Volume

Describes how to rename a volume using the Control System, CLI or the REST API.

If you rename a volume, you must unmount and re-mount the volume to allow applications and/or users to continue accessing the volume.

Renaming a Volume Using the Control System

1. Log in to the Control System and go the [volume information page](#).
2. Click **Rename Volume** from the **Select Action** drop-down menu to display the **Rename Volume** window.
3. Enter the new name for the volume in the **New Volume Name** field and click **Save Changes** for the changes to take effect.

Note: For tiering-enabled volumes, volume name cannot exceed ninety-eight characters.

Renaming a Volume Using the CLI and REST API

CLI

The basic command to rename a volume is:

```
maprcli volume rename -name
<oldName> -newname <newName>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/volume/rename?
name=<oldName>&newname=<newName>' --us
er mapr:mapr
```

See [volume rename](#) on page 2300 for more information.

Manage a Label

Describes how to apply a storage label to a volume using the Control System.

Managing a Label Using the Control System

For an overview on Storage Labels, refer to [Using Storage Labels](#) on page 1068.

To apply a label to a volume:

1. Log in to the Control System and go the [volume information page](#).
2. Click **Manage Label** from the **Select Action** drop-down menu to display the **Manage Label** window.
3. Either select an existing label, or enter the name of a label to create, and click **Apply Label** to apply the label to the volume.

Related concepts

[Using Storage Labels](#) on page 1068

Describes the Storage Labels feature.

[node](#) on page 1900

Manages nodes in the cluster

Related reference

[disk add](#) on page 1786

Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

[disk setlabel](#) on page 1788

Adds a label to disks or a storage pool. Permissions required: `fc` or `a`.

[label add](#) on page 1891

Registers a label. Permissions required: `fc` or `a`.

[volume create](#) on page 2190

Creates a volume.

[volume move](#) on page 2294

Moves the specified volume or mirror to a different topology. Permissions required: `m` or `fc` on the volume.

[label list](#) on page 1895

Lists registered labels. Permissions required: `fc` or `a`.

[node list](#) on page 1911

Lists nodes in the cluster.

[dump volumeinfo](#) on page 1830

Returns information about volumes and the associated containers. For JSON formatted output, use the `-json` option from the command line.

[configure.sh](#) on page 2331

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Manage a Name Space Label

Describes how to apply a label to a namespace container of a volume using the Control System.

Managing a Name Space Label Using the Control System

For an overview on Storage Labels, refer to [Using Storage Labels](#) on page 1068.

To apply a label to a namespace container volume:

1. Log in to the Control System and go the [volume information page](#).
2. Click **Manage Namespace Label** from the **Select Action** drop-down menu to display the **Manage Name Space Label** window.
3. Either select an existing label, or enter the name of a label to create, and click **Apply Label** to apply the label to the namespace container of the volume.

Returns information about volumes and the associated containers. For JSON formatted output, use the `-json` option from the command line.

[configure.sh](#) on page 2331
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Specifying Volume Inheritance Using the CLI

Lists volume properties that can be inherited from other volumes.

Volumes can be mounted using the web console, the `maprcli` commands ([volume create](#) or [volume mount](#)), or the REST commands. If the mount point is specified while creating a volume, new volumes can inherit properties from the parent volume. Mirror volumes can also inherit properties from the source volume of the mirror.

Volume inheritance is a convenience that can only be used during volume creation.

The `maprcli volume modify` command can be used to change the volume inheritance settings of a volume. That is, you can toggle the flag (associated with `allowgrant`) that indicates whether a volume, as a parent volume, wants its properties to be inherited by default or not. When creating and mounting a volume, the location of the mount point can be specified using the `path` parameter. The volume that is last in the `path` parameter is referred to as the parent volume. (The parent volume is the volume on which the volume link is created.)

Inheritance applies during volume creation only. If the settings in the parent volume is modified after the child volumes are created, these modified properties do not propagate to the child volumes.

Inheritance

The following table shows the list of inheritable parameters that are (Yes) and are not (No) inherited by a:

- Mirror volume from the source volume on the same cluster
- Mirror volume from the source volume on a different cluster

Note: All (non-mirror) volumes inherit all the inheritable properties from the parent volume. For more information on the properties, refer to `volume create` [parameters](#).

| Inheritable Properties (which are inherited by non-mirror volumes by default) | Inherited by Mirror Volume on the same cluster as the source volume? | Inherited by Mirror Volume on a different cluster from the source volume? |
|---|--|---|
| advisoryquota | Yes | Yes |
| ae | Yes | No |
| aetype | Yes | No |
| allowgrant | Yes | Yes |
| allowinherit | Yes | Yes |
| auditenabled | Yes | Yes |
| coalesce | Yes | Yes |
| dare | Yes | Yes ¹ , No ² |
| dataauditops | Yes | Yes |
| dbindexlagsecalarmthresh | Yes | Yes |
| dbrepllagsecalarmthresh | Yes | Yes |
| enforcementMode | Yes | Yes |
| ecscheme | Yes | No |
| ectopology | Yes | No |
| group | Yes | Yes |
| inherit | Yes | Yes |
| localvolumehost | No | No |
| localvolumeport | No | No |
| maxinodesalarmthreshold | Yes | Yes |
| minreplication | Yes | Yes |
| mirrorschedule | Yes | No |
| mirrorthrottle | Yes | Yes |
| nsminreplication | Yes | Yes |
| nsreplication | Yes | Yes |
| ofloadschedule | Yes | No |
| quota | Yes | Yes |
| readonly | Yes | Yes |
| recallexpirytime | Yes | No |
| replication | Yes | Yes |
| replicationtype | Yes | Yes |
| rereplicationtimeoutsec | Yes | Yes |
| rootdirperms | Yes | Yes |
| schedule | Yes ³ | No |

| Inheritable Properties (which are inherited by non-mirror volumes by default) | Inherited by Mirror Volume on the same cluster as the source volume? | Inherited by Mirror Volume on a different cluster from the source volume? |
|---|--|---|
| securitypolicy | Yes | Yes |
| source | Yes | Yes |
| tierencryption | Yes | No |
| tieringenable | Yes | No |
| tieringrule | Yes | No |
| tierkey | Yes | No |
| tiername ⁴ | Yes | No |
| topology | Yes | No |
| type | Yes | Yes |
| user | Yes | Yes |
| wiresecurityenabled | Yes | Yes |

- ¹ If destination cluster is also enabled for data-at-rest encryption, `dare` setting is inherited by the mirror volume on the destination cluster.
- ² If destination cluster is not enabled for data-at-rest encryption, `dare` setting is not inherited by the mirror volume on the destination cluster.
- ³ If `schedule` keyword is specified with the `skipinherit` parameter, `schedule(s)` are not inherited while inheriting volume properties from the source volume.
- ⁴ If `tiername` keyword is specified with the `skipinherit` parameter:
 - The tiering properties are not inherited by the mirror volume while inheriting volume properties from the tiering-enabled source volume.
 - For volumes enabled for warm-tier, the backend erasure-coded volume is not created.

Setting Data ACEs

Describes how to set ACE expressions using both the GUI and the CLI.

To set data [ACE](#) using the **Add Access Permission** window in the MapR Control System:

1. Specify the entities to set permissions for by doing one of the following:
 - Move the slider associated with **Public** to **Yes** to grant access to all users or to **No** to set permissions for individual users, groups, and/or roles.
 - Specify the users, groups, and/or roles to set permissions for in the associated fields.
 - Select the **Custom ACE** checkbox and enter the access control expression in the field.
2. Click **Add** to set permissions for all or for the specified users, groups, and/or roles.
3. Select the permissions to grant the specified users, groups, and/or roles from the **Permissions** column associated with the entities.
4. Click **Save Changes** to save the [ACE](#) settings.

Setting Whole Volume ACEs Using the CLI

See [Setting Whole Volume ACEs](#) on page 1576.

Setting Table ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Setting Stream ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Changing or Setting Mount Information for a Volume

Describes how to set the mount path for a volume using either the Control System, the CLI, or the REST API.

You can set or change volume mount settings using the Control System, the CLI (`volume create` or `volume mount`), or the REST commands. To mount or unmount volumes under a directory, the user must have read/write permissions on the directory.

Changing or Setting Mount Information for a Volume Using the Control System

1. Log in to the Control System and go to the [volume information page](#).
2. Select **Change Mount Information** from the **Select Action** drop-down menu.
The **Change Mount Information** dialog displays.
3. Make the necessary changes.
 - a) Specify whether (**Yes**) or not (**No**) to mount the volume.
 - b) Enter the path in the **Mount Path** field.
The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).

**Restriction:**

The path should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

4. Click **Save Changes** for the changes to take effect.

Note: After changing the mount point, run `maprcli volume fixmountpath` command to notify CLDB of the change in the volume mount path.

Changing or Setting Mount Information Using the CLI or REST API

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

Restriction: The volume name and the path should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

For complete reference information including all available options, see [volume mount](#) on page 2293.

Mounting one or more Volumes

Explains how to set or change mount settings for volumes using the Control System or the CLI.

To mount volumes under a directory, you must have read/write permissions on the directory.

Changing or Setting Mount Information Using the Control System

To mount one or more volumes, in the **Summary** tab under **Data > Volumes**:

1. Select the volumes to mount from the list of volumes in the **Volumes** pane.
2. Select **Mount Volume(s)** from the **Actions** drop-down menu.
The **Mount Volume(s)** confirmation dialog displays.

Note: Only unmounted volumes with mount paths can be mounted. Volumes with no mount paths and volumes that are currently mounted, if selected, cannot be mounted.

3. Verify list of selected volumes.
If necessary, click **X** to remove a volume from the list of volumes to mount.
4. Click **Mount Volumes** to mount the selected volumes.

Changing or Setting Mount Information Using the CLI or REST API

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

For complete reference information including all available options, see [volume mount](#) on page 2293.

Unmounting one or more Volumes

Describes how to unmount a volume using either the Control System or the CLI.

You can unmount multiple volumes using the Control System or the CLI. To unmount volumes under a directory, you must have read/write permissions on the directory.

Unmounting one or more Volumes Using the Control System

To unmount one or more volumes, in the **Summary** tab under **Data > Volumes**:

Note: When running on a Kubernetes cluster, the **Summary** tab is in the **Volumes** page under the **Volumes** menu.

1. Select the volumes to unmount from the list of volumes in the **Volumes** pane.
2. Select **Unmount Volume** from the **Actions** drop-down menu.
The **Unmount Volume** confirmation dialog displays.

Note: Only mounted volumes can be unmounted. Volumes that are currently not mounted, if selected, cannot be unmounted.

3. Verify list of selected volumes.
4. Click **Unmount Volumes** to unmount the selected volumes.

Unmounting one or more Volumes Using the CLI or REST API

The basic command to unmount the volume is:

```
maprcli volume unmount -name <volume name>
```

For complete reference information including all available options, see [volume unmount](#) on page 2324.

Mounting a Tenant Volume

Describes the steps to mount and access a tenant volume.

After the tenant volume is created on the cluster (for a [multi-tenant environment](#)), access the tenant volume on the tenant host with the following steps:

1. Log in to the tenant host as the tenant admin (`root`) and verify that a valid tenant ticket is available on the tenant host.

For example, run the following command:

```
~tenantAdmin@tenantHost: maprlogin print -ticketfile /user/tenantAdmin/tenant_sample_ticket.txt
Opening keyfile /user/tenantAdmin/tenant_sample_ticket.txt
cHost: user = sampleTenant, created = 'Mon Jul 11 07:14:53 UTC 2016',
expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11
07:14:53 UTC 12016',
uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
```

2. Perform one of the following:
 - Set up the FUSE-based POSIX client configuration parameters (see [Configuring HPE Ezmeral Data Fabric FUSE-based POSIX Client for Tenant Environment](#) on page 1371) and mount the volume (see [Mounting the filesystem](#) on page 1375).
 - Set up an alias for NFS exports to export the tenant volume path (see [Setting Up Aliases for NFS Exports](#) on page 1303) and mount the volume for loopbacknfs service (see [Starting the mapr-loopbacknfs Service to Access a Cluster](#)).
3. Create accessible directories within the provisioned space for the tenant users.

Unmounting a Tenant Volume

Explains how unmount a tenant volume using the CLI.

To unmount a tenant volume and:

- Kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the POSIX client package that is installed on the system.

Note: For more information, see [Unmounting the FUSE Mount](#).

- Stop the loopbacknfs service, run the following command:

```
service mapr-loopbacknfs stop
```

Note: For more information, see [Managing the mapr-loopbacknfs Service](#) on page 1354

Changing Volume Type

You can convert a standard volume to a mirror volume and promote a mirror volume to a standard volume.

A standard volume with one or more associated mirror volumes can be converted to a mirror volume that mirrors one of the its associated mirror volumes. The mirror volume that the converted standard volume is set to mirror must then be promoted to a standard volume. The converted standard volume then becomes a read-only copy of the promoted mirror volume.

Note: Standard volumes that do not have one or more associated mirror volumes cannot be converted to mirror volumes.

A mirror volume is a read-only physical copy of a standard volume. In general, mirror volumes are created for the purpose of preventing or minimizing data loss. Mirror volumes are also used to improve performance or to make copies of data for use in other clusters without impacting production. Mirror volumes can be changed to read-write volumes by converting the mirror volumes to standard volumes.

The following topics include procedures for converting a standard volume to a mirror volume and vice versa.

Changing a Standard Volume to a Mirror Volume

Describes how to convert a standard volume to a mirror volume.

You can convert a standard volume to a mirror volume and set it up to mirror one of its associated mirror volumes using the Control System, the CLI, or the REST API.

Changing a Standard Volume to a Mirror Volume Using the Control System

1. Log in to the Control System and go to the [Viewing Volume Details](#) on page 956 page for the standard volume.
2. Select **Make Mirror Volumes** from the **Select Action** drop-down menu.
The **Mirror Volume** confirmation dialog displays.
3. Select the:
 - Name of the source cluster where the associated mirror volume that the converted volume will mirror, exists.
 - Name of the source volume that the converted volume will mirror, from the list of associated mirror volumes.

The standard volume, when converted, can only be a mirror of one of its associated mirror volumes.

4. Click **Save Changes** for the changes to take effect.

Note: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing a Standard Volume to a Mirror Volume Using the CLI or the REST API

CLI

To convert a standard volume to a mirror volume from the CLI, run the `maprcli volume modify` command with the `-type` option value set to `mirror`.

```
maprcli volume modify -name <volume name> -type mirror
```

REST

To convert a standard volume to a mirror volume, send a request of type POST. For example:

```
curl -k -X POST 'https://<hostname>:8443/rest/volume/modify?
```

```
name=<volName>&type=mirror' --user
mapr:mapr
```

For more information, see [volume modify](#) on page 2275.

 **Note:** It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing Mirror Volumes to Standard Volumes

Describes how to convert a mirror volume to a standard volume.

To change read-only mirror volumes to read-write (standard) volumes, you must promote the mirror volumes to standard volumes. After the mirror volume is promoted, the snapshot schedule specified for the mirror is used for the promoted read-write volume and the mirror schedule is disabled. You can promote a mirror volume to a standard volume using the Control System or the CLI.

 **Note:** When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror promotion time is typically negligible, but is dependent on the number of containers in the volume being promoted. For a volume with thousands of containers and a few terabytes of data, it may take a few seconds. For enormous volumes with tens of thousands of containers and hundreds of terabytes of data, promotion could take a few minutes.

After the promotion is complete, a status message is logged in the `cldb.log` file with the time taken. For example:

```
2021-06-27 22:47:00,563 INFO VolumeMirrorInfo [VolumeMirrorThread0]:
  Volume conversion successfully completed for volume
v100k.m@c.228toMirror false.
  Time taken : 142395ms
```

Changing Multiple Mirror Volumes to Standard Volumes Using the Control System

To change one or more mirror volumes to standard volumes, in the **Summary** tab under **Data > Volumes**:

 **Note:** The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the mirror volumes to promote from the list of volumes in **Volumes** pane.
2. Select **Change to Standard Volume(s)** from the **Actions** drop-down menu. The **Change to Standard Volume(s)** confirmation dialog displays.
3. Review the list of mirror volumes to promote and click **Change Volume(s)** to change the mirror volumes to standard volumes.

 **Note:** Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see [Handling Mount Points in Promoted Mirror Volumes](#) on page 984.

Changing a Mirror Volume to a Standard Volume Using the Control System

1. Log in to the Control System and go to the [volume information page](#) for the mirror volume.
2. Select **Change to Standard Volume(s)** from the **Select Action** drop-down menu.
The **Change to Standard Volume(s)** confirmation dialog displays.
3. Click **Change Volume(s)** to change the mirror volume to a standard volume.

 **Note:** Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see [Handling Mount Points in Promoted Mirror Volumes](#) on page 984.

Changing a Mirror Volume to a Standard Volume Using the CLI or REST API

For changing a mirror volume to a standard (read/write) volume using the CLI, run the `maprcli volume modify` command with the `-type` option value set to `rw` on the cluster where the mirror volume resides and specify the name of the mirror volume that is being promoted. In the following example, the mirror volume is named `volA`:

```
Cluster2> maprcli volume modify -name volA -type rw
```

For more information, see [volume modify](#) on page 2275.

 **Note:** Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see [Handling Mount Points in Promoted Mirror Volumes](#) on page 984.

Handling Mount Points in Promoted Mirror Volumes

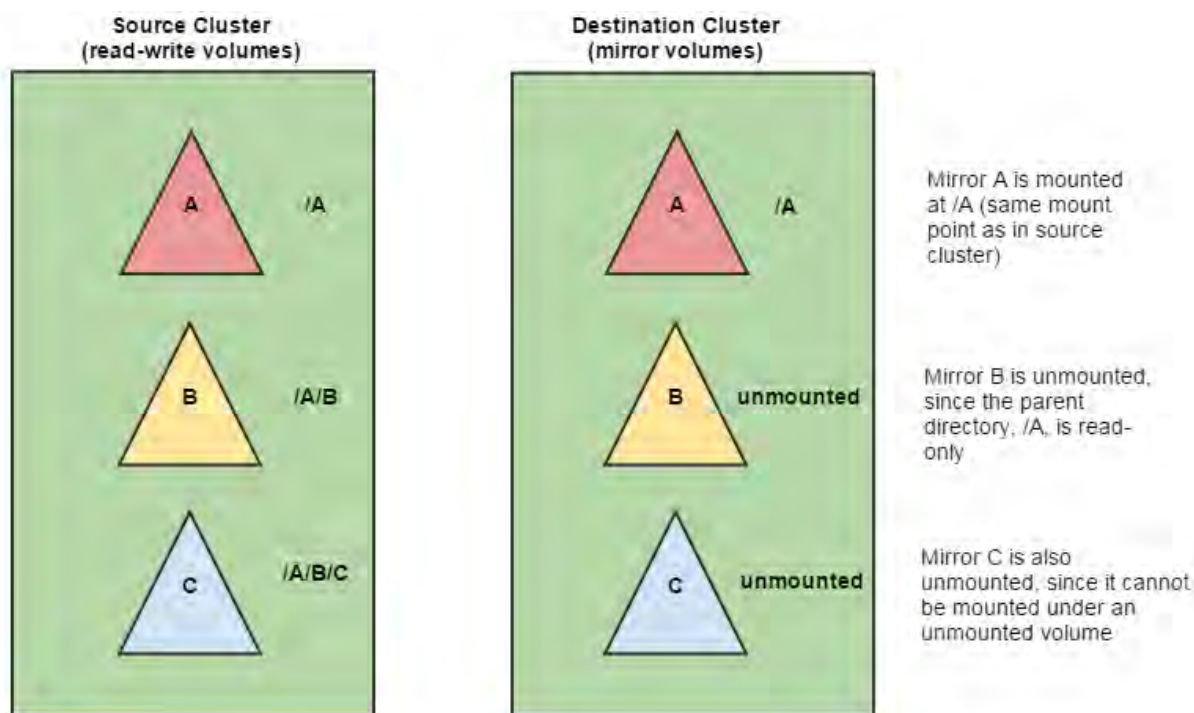

Explains how to use mount points in promoted mirror volumes.

After you promote read-only mirror volumes to read-write standard volumes, you must re-establish the mount points that were set up in the source cluster. To understand the steps in this process, consider the following scenario:

A source cluster has volumes A, B, and C, which are mounted at `/A`, `/A/B`, and `/A/B/C` respectively. Each source volume is mirrored to a volume in another cluster (the destination cluster). The names of the corresponding mirror volumes are also A, B, and C.

 **Note:** When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as `/A/B`) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror volume A is mounted at `/A`, but since the mirror is read-only, no mount point can be created beneath it for mirror B or mirror C.

Warning: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly.

Now suppose that all three mirror volumes are promoted to read-write volumes. Before any data can be written to these volumes, the volume links must be removed and the volumes must be remounted. The commands for each step are as follows:

- Promote A, B, and C to read-write volumes.

```
Cluster2> maprcli volume modify -name A -type rw
Cluster2> maprcli volume modify -name B -type rw
Cluster2> maprcli volume modify -name C -type rw
```

To promote using the Control System, see [Changing Mirror Volumes to Standard Volumes](#) on page 983.

- Remove the volume links located at /A/B and /A/B/C. Since mirror A was already mounted, its volume links do not need to be removed.

```
maprcli volume link remove -path /A/B
maprcli volume link remove -path /A/B/C
```

- Mount the promoted read-write volumes B and C at the same mount points used in the primary (source) cluster, in order to maintain an exact replica in the destination cluster.

```
Cluster2> maprcli volume mount -name B -path /A/B
Cluster2> maprcli volume mount -name C -path /A/B/C
```

To mount using the Control System, see [Mounting one or more Volumes](#) on page 979.

Now the promoted volumes are accessible for write operations.

Selecting a Replication Type for High Availability

Describes replication types for high-availability clusters, and the tradeoffs of using them.

HPE Ezmeral Data Fabric volumes, stored as pieces called containers, are replicated, typically three times, on separate nodes to protect data and provide uninterrupted access to data in the event of a node failure. Since all form of data is replicated, in the event of a node failure, after a brief delay while the failure is being detected, clients are simply directed to a replica, which serves as an alternative location for a data object, to continue normally. The latency as a result of the failure being detected can be reduced by adjusting the number of TCP retries. Furthermore, selecting a container replication type that is appropriate for your cluster layout allows for faster replication of container state, which in turn allows for retrieval of the most current data in the event of a node failure.

HPE Ezmeral Data Fabric supports two types of container replication -- high-throughput or cascading replication, where volumes are replicated sequentially on intermediate and tail containers and low-latency or star replication, where volumes are replicated on multiple containers in parallel.

Note: For more information, see [How filesystem and Associated Services Work](#).

The tradeoffs between the replication types is one of latency and throughput. While the low-latency replication delivers relatively lower throughput than the high-throughput replication, the high-throughput replication suffers from relatively higher latencies than the low-latency replication. Another advantage of low-latency replication is that since the primary container is connected to all other replica containers, there is no need to failover a replica container in the event of a failure thus reducing the duration of recovery. However, with high-throughput replication, in the event of a failure of an intermediate container, clients may experience increased latency while CLDB, after detecting the failure, attempts to update the replication chain by making the next or tail container (whichever comes immediately after the failed container) as the next container in the chain.

Converting Volume Replication Type (Low Latency to High Throughput) Using the CLI

Lists the process to convert a volume's replication type using the CLI.

A high throughput replication type allows for volumes to be replicated sequentially on intermediate and tail containers from a primary container.

To convert from a low-latency to a high throughput-replication type:

1. Change the permissions on the volume from read-write to read only.
For example:

```
maprcli volume modify -name mvoll,mvol2 -readonly true
```

Wait for the running operations to complete before proceeding to the next step.

- Convert the volume from `low_latency` replication type to `high_throughput` replication type using the `maprcli` command.

For example:

```
maprcli volume modify -name mvoll,mvol2 -replicationtype high_throughput
```

Wait till replication type conversion is complete and the first container of the volume acquires a primary container. If necessary, run the following command to see if replication type has been converted:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
```

If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (0). For example, the 0 in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the `volumename` column:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
ReplTypeConversionInProgress
volumename

```

3. Reset the permissions on the volume to read-write.
For example, to reset, run the following command:

```
maprcli volume modify -name vol1,vol2 -readonly false
```

Converting Volume Replication Type (High Throughput to Low Latency) Using the CLI

Lists the process to convert the replication type of a volume using the CLI.

A low latency replication type allows for volumes to be replicated on multiple containers (in parallel) from the primary container.

Note: Contact HPE Ezmeral Data Fabric support before converting volumes to the `low_latency` replication type.

To convert from a high-throughput to a low-latency replication type:

1. Change the permissions on the volume from read-write to read only.
For example:

```
maprcli volume modify -name mvoll,mvol2 -readonly true
```

Wait for the running operations to complete before proceeding to the next step.

- Convert the volume from `high_throughput` replication type to `low_latency` replication type using the `maprcli` command.

For example:

```
maprcli volume modify -name mvoll,mvol2 -replicationtype low_latency
```

Wait till replication type conversion is complete and all the containers of the volume acquire a primary container. If necessary, run the following command to see if replication type has been converted:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
```

If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to `false` (0). For example, the 0 in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the `volumename` column:

```
maprcli volume list -columns ReplTypeConversionInProgress,volumename
volumename
ReplTypeConversionInProgress
mapr.apps 0
mapr.cldb.internal 0
mapr.cluster.root 0
mapr.configuration 0
mapr.doc22.lab.local.audit 0
mapr.doc22.lab.local.logs 0
mapr.doc22.lab.local.mapred 0
mapr.doc22.lab.local.metrics 0
mapr.doc23.lab.local.audit 0
mapr.doc23.lab.local.logs 0
mapr.doc23.lab.local.mapred 0
mapr.doc23.lab.local.metrics 0
mapr.hbase 0
mapr.metrics 0
mapr.opt 0
mapr.resourcemanager.volume 0
mapr.tmp 0
mapr.var 0
users 0
```

- Reset the permissions on the volume to read-write. For example, to reset, run the following command:

```
maprcli volume modify -name voll1,vol2 -readonly false
```

Setting or Modifying Quota for a Volume

Describes how to set or modify a quota for a volume.

You can set hard and advisory quotas for a volume using the Control System, CLI, and REST API. Hard quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. When the threshold for the hard quota is reached, an alarm is raised and further writes are not allowed. Advisory quota does not prevent further writes when the threshold is reached, but an alarm is raised.

Setting Quota for a Volume Using the Control System

You can set quota for a volume in the Volumes page and set or modify quotas for a volume in the volume information page.

Setting Quota for a Volume in the Volumes Page

1. Log in to the Control System and click **Data > Volumes** to display the **Volumes** page.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Ensure that the **Quota** column is displayed in the **Volumes** pane.
If necessary, customize the columns to see the **Quota** column.
3. Click the **Set Quota** link associated with the volume for which you want to set quotas to display the **Set Quota** window.
4. Specify the following in the **Set Quota** window:
 - a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

Note: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

- b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

5. Click **Save Changes** for the changes to take effect.

Setting or Modifying Quotas for a Volume in the Volume Information Page

1. Log in to the Control System and go the **Summary** tab in the [volume information page](#).
2. Click the **Edit Quota** in the **Quota Usage** pane to display the **Set Quota** window.
3. Specify the following in the **Set Quota** window:
 - a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

Note: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

- b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

4. Click **Save Changes** for the changes to take effect.

Setting Quota for a Volume Using the CLI or the REST API

You can set quotas for a volume when creating a new or modifying an existing volume.

CLI

The basic command to set quota for a volume is:

```
maprcli volume
create -name <volName> -path
<mountPath> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

```
maprcli volume
modify -name <volName> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&adviso
ryquota=<advisoryQuota>&quota=<hardQuo
ta>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&advisoryquota=<advisory
Quota>&quota=<hardQuota>' --user
mapr:mapr
```

For the complete list of required and optional parameters, see [volume create](#) on page 2190 and [volume modify](#) on page 2275.

Migrating a Volume off a Node Using the CLI

When you need to migrate a data volume off a particular node, move that node from the `/data` path to the `/decommissioned` path to avoid data under-replication.

- Establish a `/data` topology path to serve as the default topology path for the volumes in that cluster.
- Establish a `/decommissioned` topology path that is not assigned to any volumes.

Tip: It is recommended that CLDB and ZooKeeper nodes are not in the same topology as the data nodes to ensure fast failover of the failed data node in the event of a data node failure.

Since no data volumes are assigned to the `/decommissioned` topology path, standard data replication will migrate the data off that node to other nodes that are still in the `/data` topology path.

You can run the following command to check if a given volume is present on a specified node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

Run this command for each non-local volume in your cluster. Once all the data has migrated off the node, you can decommission the node or place it in maintenance mode.

If you need to segregate CLDB data, create a `/cldb` topology node and move the CLDB nodes under `/cldb`. Point the topology for the CLDB volume (`mapr.cldb.internal`) to `/cldb`. See [Isolating CLDB Nodes](#) for details.

Note: To move an existing volume to another topology, you must have the [Converged Enterprise Edition](#). Without the Converged Enterprise Edition, when you run the `maprcli volume move` command to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology

Specifies how to use volume topology to place volumes on specific racks, nodes, or groups of nodes.

After you define the node topology for the nodes in your cluster, you can use volume topology to place volumes on specific racks, nodes, or groups of nodes.

This section describes the process of setting up:

- Default volume topology
- Local volume topology
- Custom topology for local volume replicas

Setting Up Volume Topology

Explains how to setup Volume Topology using either the Control System or the CLI.

HPE Ezmeral Data Fabric supports data placement control, in which you can place a volume on specific racks, nodes, or groups of nodes by setting its topology to an existing node topology. You can set volume topology using the Control System or with the [volume move](#) on page 2294 command.

To move an existing volume to another topology, you must have the [Converged Enterprise Edition](#) installed on your system. Without the Converged Enterprise Edition, when you try to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology Using the Control System

You can set up volume topology at the time of volume creation or change the volume topology after volume creation. To:

- Set up volume topology at the time of volume creation, see [Creating a Volume](#) on page 941.
- Modify volume topology, see [Modifying a Volume](#) on page 970.

Setting Up Volume Topology Using the CLI or REST API

To move a volume to a different topology, run the following command:

```
maprcli volume move -name <volume name> -topology <path>
```

For complete reference information, see [volume move](#) on page 2294.

Setting the Topology for Local Volume Replicas

Explains how to set the topology for local volume replicas using the CLI.

The primary copies for containers of local volumes are placed on the local node (specified with parameter `-localhost` in the `volume create` command). The nodes for the replica copies for containers of local volumes are chosen as follows:

1. If a topology is explicitly specified for replicas during `volume create` or `volume edit`, that topology will be used.

```
maprcli volume create -name egLocalVol -path /test/local/volumes/
examples/sample1 \
-localvolumehost 10.20.30.40 -topology /rack1/test
```

In the above example, the primaries for the volume are placed on node 10.20.30.40, and replicas will be placed on nodes in the topology `/rack1/test`.

The `-topology` parameter is optional, and if it is not specified, CLDB will fall back to 2 or 3 below.

2. If the configuration parameter that specifies a relative path for replicas of local volumes is set, that will be used.

```
maprcli config save -values
{"cldb.local.volume.topology.trim.index": "-1"}
```

This will trim the topology of the node specified by the `localhost` parameter and restrict the replicas to the resultant topology.

By default, this configuration parameter is not set. To set this configuration parameter, see [Creating Replicas of Local Volumes in Custom Topology Using the CLI](#) on page 994. If the configuration parameter is not set, CLDB will fall back to 3 below.

3. The default volume topology will be used.

The default volume topology is the value specified by the configuration parameter `cldb.default.volume.topology`. The default value for this parameter is `/data`. See [Setting Default Volume Topology Using the CLI](#) on page 995.

Creating Replicas of Local Volumes in Custom Topology Using the CLI

To set the configuration parameter for placing replicas of volumes in a topology relative to the local node, run the `maprcli config save` command. The value can be a:

- Positive number to indicate the number of paths to keep from the initial root (of the topology path). For example:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index": "1"}
```

- Negative number to indicate the number of paths to skip from the end of the topology path. For example:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index": "-2"}
```

For example, suppose the local volume is created on a node that is under the topology `/data-center1/lab2/rack3/shelf4/10.10.20.30`. To create a local volume where the replicas are restricted to `/data-center1/lab2/rack3` topology, run the following command:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index": "3"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.10.20.30
```

Alternatively, you can run the following command to specify the path for the volume from the end of the topology path:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/shelf4/10.10.20.30 -localvolumehost 10.20.30.40
```

The replicas for containers of the volume, egLocalVol, will be created on nodes under /data-center1/lab2/rack3.

Setting Default Volume Topology Using the CLI

Use the `config save` command to set the default topology for volumes.

By default, new volumes are created with a topology of /data. To change the default topology, use the [config save](#) on page 1768 command to change the `cldb.default.volume.topology` configuration parameter. Example:

```
maprcli config save -values "{\"cldb.default.volume.topology\":\"/data/rack02\"}"
```

After this command is run, new volumes have the volume topology /data/rack02 by default, which could be useful to restrict new volume data to a subset of the cluster.

Changing the Volume Topology

Describes how to move a volume from one topology to another using the Control System or the CLI.

Changing the Topology of a Volume Using the Control System

1. Go to the [Viewing Volume Details](#) on page 956 page, and select a volume. The **Change Topology** dialog displays, showing the current topology value.
2. Enter the new value for the topology.
3. Click **Save Changes** for the changes to take effect.

Changing the Topology of a Volume Using the CLI or REST API

The basic command to move a volume to a different topology is:

```
/opt/mapr/bin/maprcli volume move -name <volume name> -topology <topology>
```

For complete reference information, see [volume move](#) on page 2294.

Viewing Active Volume Alarms

Describes how to view volume alarms using the Control System and the CLI.

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

- Log in to the Control System and:
 - Click **Data > Volumes** to view all active volume alarms in the **Active Alarms** pane.
-  **Note:** The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.
- Go to the **Summary** tab in the [volume information page](#) to view the recent and active alarms for the selected volume in the **Alarms** pane.

- Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
- Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Volume Alarms](#) on page 2525 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 1724.

Working with Mirror Volumes

The mirroring process transmits the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations are generally very fast. The following sections describe how to manage the mirroring operation.

Setting up a Mirroring Schedule for a Mirror Volume

Explains how to set up a mirroring schedule for a mirror volume using the Control System, the CLI, or the REST API.

Setting up a Mirroring Schedule Using the Control System

1. Log in to the Control System and go to **Summary** tab in the [volume details](#) page.
2. Click the  associated with **Volume Mirroring** in the **Schedules** pane to display the **Browse Schedules** window.
3. Review the name and detail of each schedule and select a schedule from the list.
4. Click **Save Changes** to associate the schedule with the volume.

Setting up a Mirroring Schedule Using the CLI and REST API

CLI

You can associate a mirroring schedule with a mirror volume using the `mirrorschedule` parameter when creating or editing the volume. For example:

```
maprcli volume
create -name <volName> -path
<mountPath> -type mirror -source
<srcVolName> -mirrorschedule
<mirrorscheduleID>
```

```
maprcli volume modify -name
<volName> -mirrorschedule
<mirrorscheduleID>
```

REST

You can associate a mirroring schedule with a mirror volume using the `mirrorschedule` parameter when creating or editing the volume. Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<volPath>&type=mir
ror&source=<srcVolName>&mirrorschedule
=<mirrorscheduleID>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&mirrorschedule=<mirrors
cheduleID>' --user mapr:mapr
```

For the complete list of all required and optional parameters, see [volume create](#) on page 2190 and [volume modify](#) on page 2275.

Changing the Limit for Concurrent Mirror Operations Using the CLI

The system allows a maximum of 50 concurrent mirroring operations by default. Mirroring operations include both mirroring and promoting from read-only mirrors to read-write standard volumes. The system parameter that controls this limit is `mapr.mirror.concurrent.ops`.

For large-scale mirror operations involving many volumes, a script automates the process. For example, if a script queues 100 volumes for mirroring operations, and the `mapr.mirror.concurrent.ops` limit is set to 50, the mirroring operations start on the first 50 volumes in the queue. As soon as one volume completes, another volume is processed from the queue until all 100 are completed. Since volumes are processed from the queue in first-in first-out (FIFO) order, the script should specify the most critical volumes first.

If you want to process more volumes at a time, you can raise the limit of the `mapr.mirror.concurrent.ops` parameter. To tune this parameter for maximum efficiency, consider the number of containers per volume. A higher number of containers per volume requires a lower limit than a lower number of containers per volume. To raise the limit to 500 for example, run the following command:

```
maprcli config save -values {"mapr.mirror.concurrent.ops": "500"}
```

Pushing Changes to Mirrors Using the CLI

To *push* a mirror means to start pushing data from the source volume to all of its local mirrors. You can push source volume changes out to all mirrors using the [volume mirror push](#) command, which returns after the data has been pushed.

Moving Large Amounts of Data to a Remote Cluster Using the CLI

You can use the [volume dump create](#) command to create volume copies for transport on physical media. The [volume dump create](#) command creates backup files containing the volumes, which can be reconstituted into mirrors at the remote cluster with the [volume dump restore](#) command. Associate these mirrors with their source volumes with the [volume modify](#) command to re-establish synchronization.

Another way to transfer large amounts of data to a remote cluster is to create a small cluster locally and mirror to that local cluster. Then move that cluster to a remote location and enlarge it by adding more nodes.

Disabling Mirror Throttling Using the CLI

By default, mirror throttling is enabled, which means that the server that sends mirror data, restricts itself to about 30% of the available bandwidth, as measured in HPE Ezmeral Data Fabric's internal environment, with the default settings of the following parameters. Mirror throttling is based on the

number of outstanding requests on the network, and outstanding I/O requests on disk, and can be tuned using the parameters, `mfs.disk.iothrottle.count`, `mfs.disk.resynciothrottle.factor`, and `mfs.network.resynciothrottle.factor`, in the `mfs.conf` file. When other processes need more network bandwidth, the server throttles back to slow down the rate of data transfer.

By disabling throttling, the mirror operation completes faster. To disable mirror throttling from the command line, run the `volume modify` command on the `source` volume and set the `-mirrorthrottle` option to `false`, as shown in this example:

```
/opt/mapr/bin/maprcli volume modify -name volA -mirrorthrottle false
```

This command disables throttling for all mirror volumes whose source is `volA`. Note that the `-mirrorthrottle` option only applies to volumes that have mirrors.

Recovering Volumes from Mirrors Using the CLI

Lists the process to recover mirror volumes, using the CLI.

1. Use the `volume dump create` command to create a full volume dump for each mirror volume you want to restore. Example: `maprcli volume create -e statefile1 -dumpfile fulldump1 -name volume@cluster`
2. Transport the volume dump to the rebuilt cluster.
3. For each volume on the mirror cluster, set up a corresponding volume on the rebuilt cluster.
 - a. Restore the volume using the `volume dump restore` command. Example: `maprcli volume dump restore -name volume@cluster -dumpfile fulldump1`
 - b. Copy the files to a standard (non-mirror) volume.

Starting the Mirror

Explains how to start a mirror operation using either the Control System or the CLI.

When a mirror starts, all the data in the source volume is copied into the mirror volume. Starting a mirroring operation requires the mirror volume to exist and be associated with a source. After you start a mirror, synchronize it with the source volume regularly to keep the mirror current.

Note: The `getIPTypeForCluster` method in `CLDBRpcCommonUtils` is unable to determine whether the IP type is internal or external, if `mapr-clusters.conf` contains both internal and external IPs. The fix is to only put in the internal IP in `mapr-clusters.conf` and keep the external IP in the `env.sh` file, before starting the mirror.

Starting the Mirror for Multiple Mirror Volumes Using the Control System

To start mirroring, in the **Summary** tab under **Data > Volumes**:

Note: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

1. Select the mirror volume(s) to synchronize.
You *cannot* start mirror for:
 - Standard volumes
 - Mirror volumes currently mirroring
2. Select **Start Mirroring** from the **Actions** drop-down menu.
The **Start Mirroring Volume(s)** confirmation dialog displays.

3. Verify the list of volumes to synchronize and click **Start Mirroring**.

When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror for a Mirror Volume Using the Control System

To start mirroring:

1. Go to the [volume information page](#) for the mirror volume to synchronize.

2. Select **Start Mirroring** from the **Select Action** drop-down menu.

The **Start Mirroring Volume** confirmation dialog displays.

3. Click **Start Mirroring**.

When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror Using the CLI or REST API

The basic command to start a mirror is:

```
maprcli volume mirror start -name <volume name>
```

For complete reference information, see [volume mirror start](#) on page 2260.

Stopping the Mirror

Explains how to stop a mirror operation using either the Control System or the CLI.

Stopping a mirror halts any replication or synchronization process currently in progress. Stopping a mirror does not delete or remove the mirror volume.

Stopping the Mirror for Multiple Mirror Volumes Using the Control System

To stop mirroring, in the **Summary** tab under **Data > Volumes**:

Note: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

1. Select the mirror volume(s) to stop.

You *cannot* stop the mirror operation for:

- Standard volumes
- Mirror volumes that are currently not mirroring

2. Select **Stop Mirroring** from the **Actions** drop-down menu.

The **Stop Mirroring Volume(s)** confirmation dialog displays.

3. Verify the list of volumes to stop and click **Stop Mirroring**.

When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror for a Mirror Volume Using the Control System

To stop mirroring:

1. Go to the [volume information page](#) for the mirror volume to stop.

2. Select **Stop Mirroring** from the **Select Action** drop-down menu.
The **Stop Mirroring Volume** confirmation dialog displays.
3. Click **Stop Mirroring**.
When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror Using the CLI or REST API

The basic command to stop a mirror is:

```
maprcli volume mirror stop -name <volume name>
```

For complete reference information, see [volume mirror stop](#) on page 2274.

Viewing Mirror Status

List mirror volumes and their status using the Control System and the CLI.

You can see a list of all mirror volumes and their current status in the **Mirror Volumes** view (in the Control System, select **Mirror Volumes** from the drop-down menu in the **Volumes** page under **Data > Volumes**) or using the [volume list](#) on page 2247 command. Use the [volume mirror status](#) on page 2261 command to view the details of the mirroring operation that is in progress. The [volume mirror status](#) on page 2261 command helps in troubleshooting the mirroring operation. For more information on trouble shooting mirroring, see the support article titled [Monitor and Understand Volume Mirroring in HPE Ezmeral Data Fabric](#).

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

To use the volume list command to explicitly list mirror volumes, you must define a filter. For example:

```
maprcli volume list -filter [n==<mirror name>] -columns \
    n,p,mirror-percent-complete,mrt -cluster <target cluster>
```

Mirrors and Performance

Completion time for a mirroring operation is affected by the available network bandwidth, and the amount of data to transmit. For best performance, set the mirroring schedule according to the anticipated rate of data changes, and the available bandwidth for mirroring.

Using Promotable Mirrors for Disaster Recovery

The concept of promoting a mirror refers to the ability to make a read-only mirror volume into a read-write volume. The main use case for this feature is to support disaster-recovery scenarios in which a read-only mirror needs to be promoted to a read-write volume so that it can become the primary volume for data storage.

A MapR administrator can perform the following tasks from a remote datacenter before, during, and after a disaster:

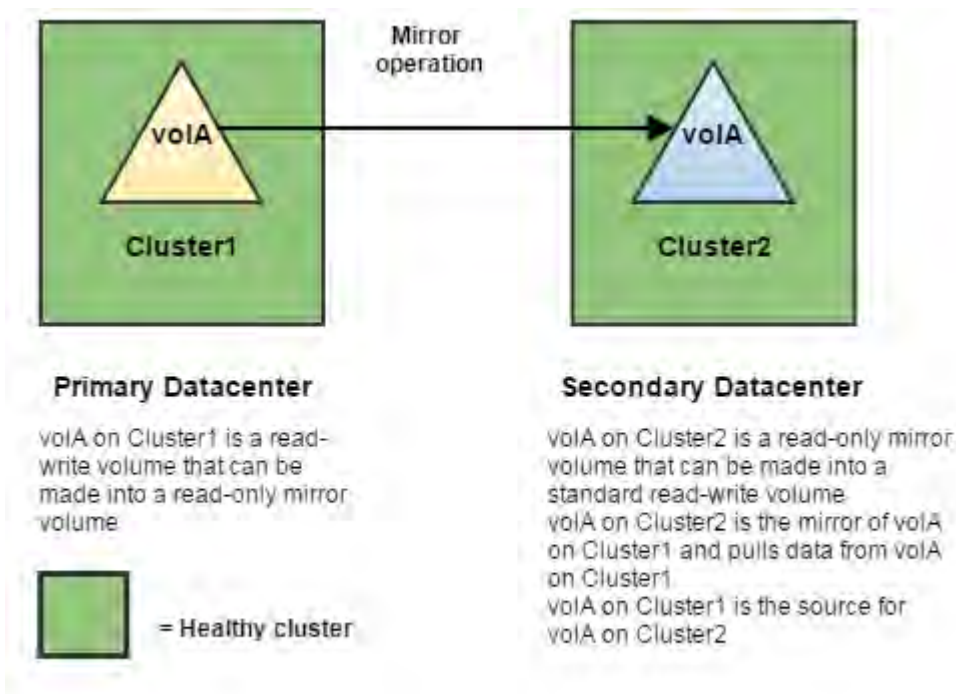

- Set up mirroring to a remote cluster
- Fail over to a mirror volume
- Restore the mirror relationship

For a brief overview of the terminology used to describe volume types, along with some basic commands, see the [Types of Volumes](#) on page 416.

The following sections provide information about how to use promotable mirrors for disaster recovery:

Setting up Mirroring to a Remote Cluster

Once data volumes are created in a primary datacenter, the MapR administrator creates mirror volumes in a remote secondary datacenter. The following diagram illustrates the mirror relationship between these two volumes:

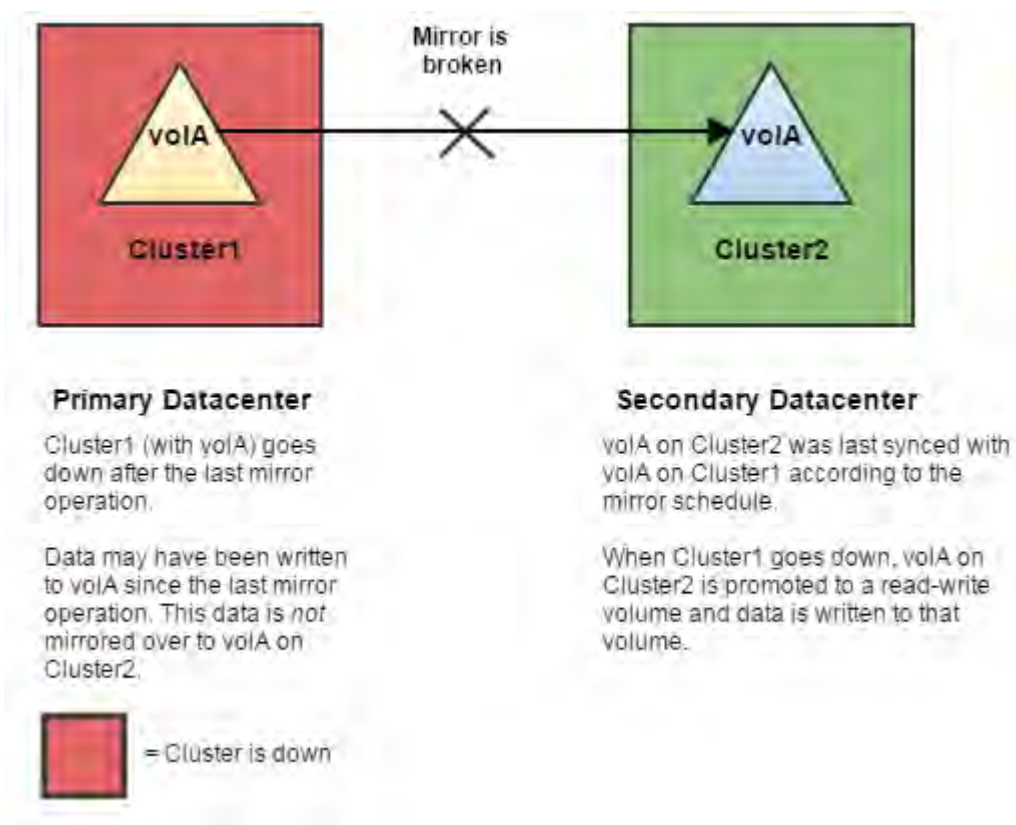

Note: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

The following sections provides information about how to set up mirroring to a remote cluster:

1. [Creating Remote Mirrors](#) on page 953
2. [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 1661
3. [Creating a Mirror Volume](#)
4. [Creating a Mirroring Schedule](#)

Failing Over to a Mirror Volume

When a disaster occurs at a primary datacenter, data can no longer be written to the volumes in that location, and the mirror operation cannot be performed. In order to maintain business continuity, the administrator at the secondary datacenter promotes the read-only mirror volume to a read-write volume, which breaks the mirror relationship. At this point, the promoted mirror volume contains all the data that was on the source volume at the time of the most recent successful mirror operation.

The following sections provide information about how to fail over to a mirror volume:

- [Changing Mirror Volumes to Standard Volumes](#) on page 983
- [Handling Mount Points in Promoted Mirror Volumes](#) on page 984
- [Changing the Limit for Concurrent Mirror Operations Using the CLI](#) on page 997

Restoring the Mirror Relationship

Explains how to restore the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

If the primary datacenter comes back online, the administrator can re-establish the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

Note that the two read-write volumes will have different data, since data was written to the promoted mirror while the original source volume was down. The original source volume might also have different data that was written after the last mirror operation, but before the cluster went down. The administrator must decide which data to keep and use as the source.

Warning: Some data loss is inevitable in a disaster recovery scenario. To minimize potential data loss, use mirrors to provide a synchronized copy of each volume with critical data, and in the event of discrepancies, decide which data to preserve based on your company's policies.

The following sections provide information about how to restore the mirror relationship:

Preserving volA/Cluster1's Data

Suppose that volA in the primary datacenter contains crucial data that must be preserved, and you want to mirror its data to volA in the secondary datacenter (the same mirror relationship that was established originally). To recreate the original mirror relationship, convert the promoted volume, volA/Cluster2, from a read-write volume to a mirror of volA/Cluster1 by running the following command:

```
Cluster2> maprcli volume modify -name
volA -type mirror -source
volA@Cluster1
```

To use the Control System to convert volA/Cluster2 from a read-write volume to a mirror of volA/Cluster1, follow steps for [Changing a Standard Volume to a Mirror Volume](#) on page 982.

Preserving volA/Cluster2's Data on volA/Cluster1

Now suppose you want to preserve the data on volA/Cluster2 (in the remote datacenter) but you still want volA/Cluster1 to be the primary volume with volA/Cluster2 as its mirror. From the command line or the Control System, you can save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

You can use either of the following methods to preserve the data:

From the Control System

Complete the following steps from the Control System to save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

1. Stop writing new data to volA/Cluster2 by making this volume read-only:
For detailed steps, see [Modifying a Volume](#) on page 970.
2. Make volA/Cluster1 a mirror of volA/Cluster2.
For detailed steps, see [Changing a Standard Volume to a Mirror Volume](#) on page 982.
3. Start mirroring.
For detailed steps, see [Starting the Mirror](#) on page 998.
4. Promote volA/Cluster1 to a read-write volume.
For detailed steps, see [Changing Mirror Volumes to Standard Volumes](#) on page 983.
5. Make volA/Cluster2 a mirror of volA/Cluster1.
For detailed steps, see [Changing a Standard Volume to a Mirror Volume](#) on page 982.

From the Command Line

1. Stop writing new data to volA/Cluster2. To be sure no data is written to this volume, make it read-only by running this command:

```
Cluster2> maprcli volume modify -name volA -readonly true
```

2. Pull the data from volA/Cluster2 to volA/Cluster1 by making volA/Cluster1 a mirror of volA/Cluster2.

```
Cluster1> maprcli volume modify -name volA -type mirror -source
volA@Cluster2
```

3. Start the mirror operation.

```
Cluster1> maprcli volume mirror start -name volA
```

4. Once mirroring is done, promote volA/Cluster1 to a read-write volume. Note that the mirror relationship breaks at this point.

```
Cluster1> maprcli volume modify -name volA -type rw
```

5. Make volA/Cluster2 a mirror of volA/Cluster1.

```
Cluster2> maprcli volume modify -name volA -type mirror -source
volA@Cluster1
```

Enabling and Restricting Access to Tenant Volume and Data

Describes how to restrict access to tenant volumes in a multi-tenant environment.

In a [multi-tenant environment](#), the tenant volume (share) can be accessed by all users on the tenant instance by default. To restrict access to specific users and/or groups:

1. Log in to the cluster as the cluster administrator and set [ACEs](#) on the volume using the volume commands.

For example:

```
/opt/mapr/bin/maprcli volume modify -name <volumename> -readAce
"u:<user>|g:<group>" -writeAce "u:<user>|g:<group>"
```

Here, value for <user> must be the UID of the user and value of <group> must be GID of the group on the tenant host.

Tip: For more information, see [maprcli volume modify](#) command.

2. Log in as the tenant admin and set permissions for data access.

You can set permissions using:

- Linux commands such as `chmod`, `chown`, and so on.
- [ACEs](#), which can be set on files and directories in the volume. For more information, see [Enabling Volume, Directory, and File Authorizations with ACEs](#) on page 1569.

Working with Tiered Volumes

This section describes how to create tiered volumes and manage automatic and manual tiering jobs on the tiered volume.

Erasure Coding Scheme for Data Protection and Recovery

Describes the erasure coding (EC) schemes for data protection and recovery.

Erasure coding (EC) is a data protection method in which data is broken into fragments, expanded and encoded with redundant data pieces, and stored across a set of different nodes or storage media.

EC ensures that if data becomes corrupted, it can be reconstructed using other data and parity fragments.

The time required to reconstruct data depends on the number of data fragments in the chosen EC scheme, and the number of failures that have occurred. For example, reconstruction of EC scheme $10+2$ takes longer compared to the reconstruction of EC scheme $3+2$, as a larger number of data and parity fragments must be read.

There are two kinds of EC schemes that you can use:

- **EC Schemes Without Local Parity:** Even for a single failure, for a $m+n$ scheme, the system must read a minimum of m other fragments to reconstruct data.
- **EC Schemes With Local Parity:** In such schemes, data fragments are logically divided in to groups with one local parity fragment per group, hence for a single failure the system reads just the remaining fragments in the affected group, along with the local parity fragment of the affected group, to rebuild data. Rebuilding data for a single failure is much faster on a scheme with a local parity, as a fewer number of fragments must be read.

Considerations When Selecting an EC scheme

As an administrator, consider the following points when selecting an EC scheme:

- How many nodes can you afford to have?
- How many failures might occur? Do you anticipate a single failure, or multiple failures?
- Consider the following when determining how long you are willing to wait for a node to be rebuilt:
 - Rebuilds overhead - For $4+2$, need to read data from 4 nodes to rebuild, for $6+3$, need to read from 6 nodes to rebuild.
 - Reads overhead - For $4+2$, need to read data from 4 nodes , for $6+3$, need to read from 6 nodes. For degraded states, parity calculation overhead is an add-on.
 - Data classification - High ecschemes $10+2$, $12+4$, are ideal for archived data, since data mostly remains untouched.

EC Schemes Without Local Parity

In an erasure coded volume, an erasure coding scheme without Local Parity has the stripe layout $m+n$. The stripe is an array of m data fragments and n parity fragments.

Each fragment is called a stripelet. Each stripelet is present on a container and one stripe is across different containers on different nodes. The default stripelet size is 4MB. For an EC scheme $4+2$ for example, the stripe size is 24MB.

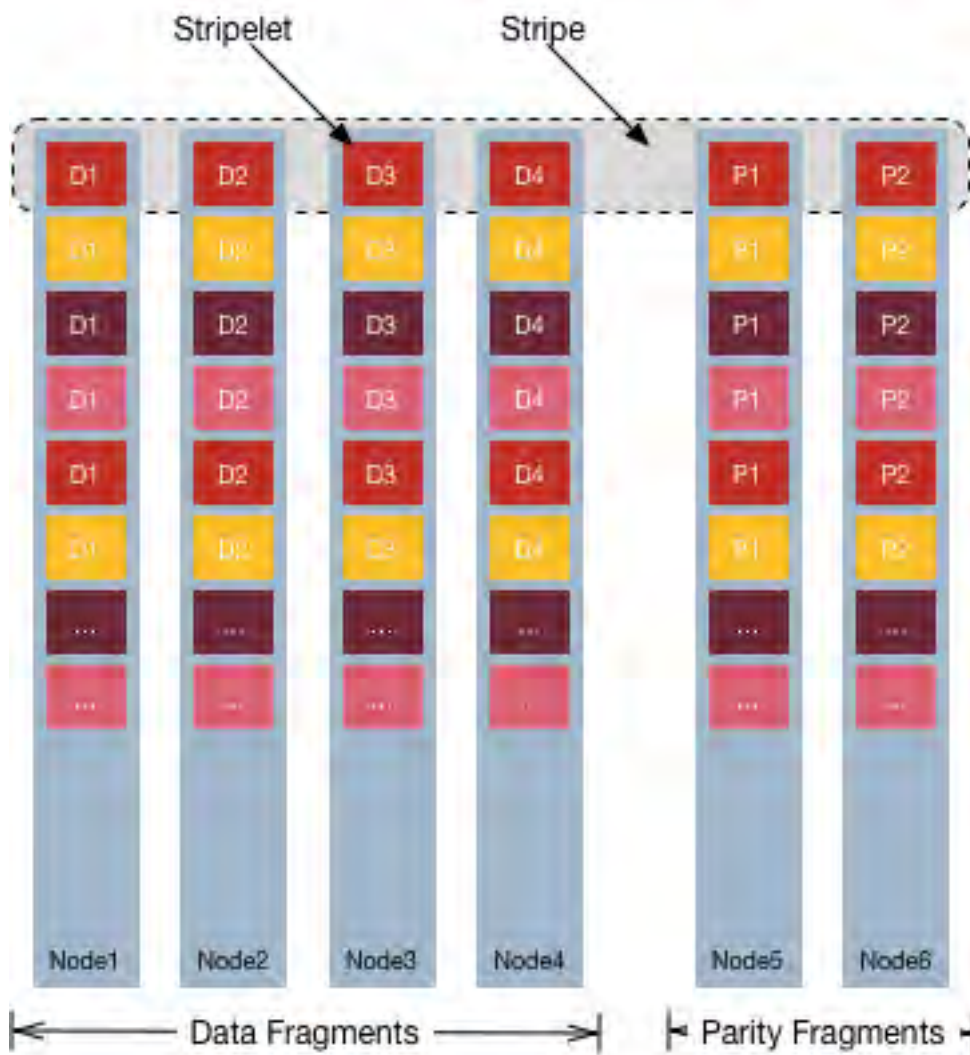

A Container Group (CG) is collection of such stripes. Based on the maximum size of a container (32 GB), the maximum number of stripes in a CG is 8K.

Each stripe is created by the same number of data fragments from all containers in the group of EC containers. Each container is placed on a different physical node.

- m is the number of data fragments.
- n is the number of redundant fragments (referred to as parity fragments).
- The parity is calculated using data from all data fragments.
- $m/(m+n)$ is the encoding rate.
- $m+n$ is the number of encoded fragments.
- You need to read a minimum of m blocks to recover data.

- You can recover data from a maximum of n failures.

For example, assume $m=4$, $n=2$, and stripe depth=4 MB.

- The number of data fragments is four (4), and while the number of parity fragments is two (2).
- The number of encoded fragments is six (6).
- The stripe size is 16 MB (4x4 MB) of user data, and 8 MB (2x4 MB) of parity fragments.
- The system can handle two (2) failures, and any fragment can be recovered from four (4) other fragments.

Requirements for using an erasure coding scheme without local parity

Requirements when using the Control System

- The number of data fragments must be 3 to 10.
- The number of parity fragments must be greater than 1 and less than the number of data fragments.
- The number of data fragments must be greater than the number of parity fragments.
- The number of nodes must be greater than or equal to the sum of data and parity fragments.

Requirements when using the CLI

- The number of data fragments must be 2 to 10.
- The number of parity fragments must be greater than or equal to 1 and less than or equal to the number of data fragments.
- The number of data fragments must be greater than or equal to the number of parity fragments.

Select from the following schemes for erasure-coded volumes:

| EC Scheme | | Number of Data Nodes | Number of Parity Nodes | Total Number of Nodes Needed | Number of Failures Recoverable | Number of Nodes to Read to Recover Data |
|---------------------------------------|----------------|----------------------|------------------------|------------------------------|--------------------------------|---|
| CLI | Control System | | | | | |
| 3+2 | 3, 2 | 3 | 2 | 5 | 2 | 3 |
| 4+2 | 4, 2 | 4 | 2 | 6 | 2 | 4 |
| 5+2 | 5, 2 | 5 | 2 | 7 | 2 | 5 |
| 6+3 | 6, 3 | 6 | 3 | 9 | 3 | 6 |
| 10+<x> where x is a value from 1 to 9 | N.A | 10 | x | 10+x | x | 10 |

Although you can create a volume without the required number of nodes for a specific scheme, volume offload fails if the required number of nodes are not present.

When choosing the scheme, note that more nodes leads to longer recovery time, resulting in degraded performance, network expense, and lengthy time to rebuild.

If you anticipate only a single failure, use an EC scheme with local parity, as the number of nodes needed to be read for recovery is fewer, when compared to an EC scheme without local parity.

For example, consider a 12 + 4 EC scheme represented as D0 + D1 + D2 + . . . +D10 + D11 + P0 +...+P3

Suppose node D4 goes down, now to rebuild, a total of 12 stripelets must be read. This leads to huge performance degradation in network bandwidth, CPU cycles, and Disk IO .

To reduce the reconstruction cost, use EC Local Parity, where the number of stripelets to be read reduces to 6 for a single failure in the 12+2+2 scheme.

 **Important:** The recommended number of nodes required for erasure coding is M+2N (rather than M+N) to ensure HPE Ezmeral Data Fabric self-healing and proper operation after N failures. N failures with only M+N nodes allows you to continue reading the data, but with significantly reduced performance because each read requires rebuilding data fragments. Also, manual intervention is required to protect the data from further failures. Currently, data will not be erasure coded if only M nodes are available. With M+2N nodes, N failures will self-heal with no operator intervention.

EC Schemes With Local Parity

Choosing an EC scheme with local parity, reduces EC storage overhead without incurring high rebuild costs and longer rebuild times while lowering the probability of data loss. HPE recommends the following tested local parity schemes:

| EC Scheme | | Number of Data Nodes | Number of Local Parity Nodes | Number of Global Parity Nodes | Total Number of Nodes Needed | Number of Failures Recoverable | Number of Nodes to Read to Recover Data |
|-----------|----------------|----------------------|------------------------------|-------------------------------|------------------------------|--|--|
| CLI | Control System | | | | | | |
| 10+2+2 | N/A | 10 | 2 | 2 | 14 | <ul style="list-style-type: none"> 3 all the time 4 most of the time | <ul style="list-style-type: none"> 5 for a single failure 10 for multiple failures |
| 12+2+2 | N/A | 12 | 2 | 2 | 16 | <ul style="list-style-type: none"> 3 all the time 4 most of the time | <ul style="list-style-type: none"> 6 for a single failure 12 for multiple failures |

Consider reading the following technical discussion only if you want to specify other local parity schemes.

Technical discussion on parity schemes

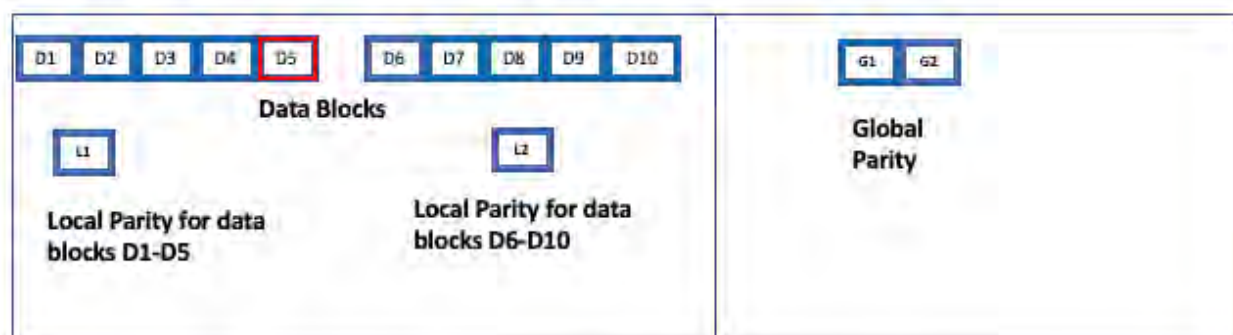

Local parity is calculated from a subset of data blocks.

Consider a 10+2 scheme *without* local parity.

In this example, if block D6 fails, the system needs to read a minimum of 10 other blocks, to recover data.

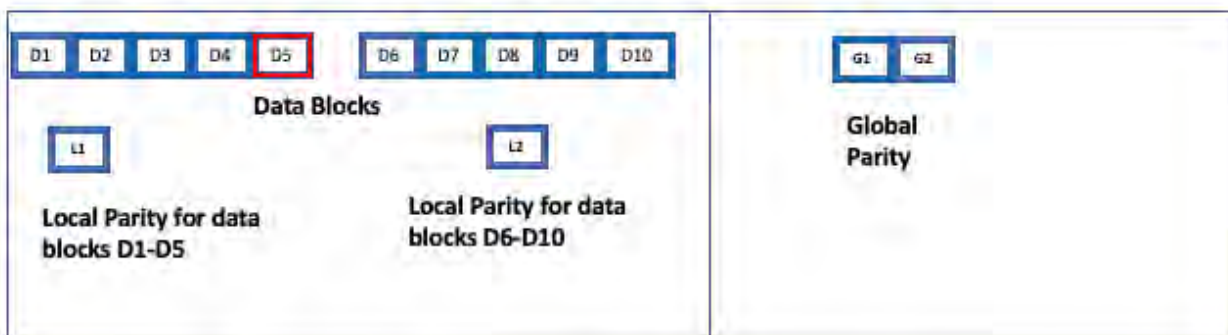

Now consider a 10+2+2 scheme with local parity. In this case, data fragments are divided into two (2) data groups, each containing five (5) data fragments, with a local parity for each group. The global parity blocks are common to both data groups. To recover from a single failure, the system must read only the four (4) remaining fragments in the affected data groups, and the corresponding local parity fragment:

In this example, since there is only a single failure in a data group (block D5), the system must only read fragments D1+D2+D3+D4+L1 (which is the local parity fragment of this data group). Recovery is much faster and more efficient, due to the local parity block.

Points to note for using an erasure coding scheme with local parity

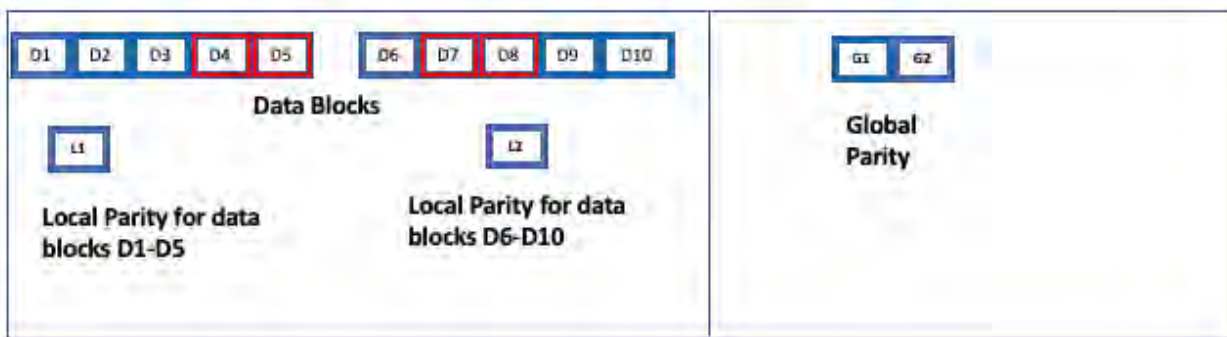

- In an EC scheme represented as $k+g+l$, k is the number of data blocks, g is the number of global parity blocks, and l is the number of local parity blocks.
- You need $k+g+l$ nodes for each local parity scheme.
- k must be divisible by l to get k/l data fragments in each data group. For example, in the $10+2+2$ EC scheme, there are $10/2=5$ data fragments in each data group.
- l must be greater than 1.
- k must be greater than $(g+l)$.
- With local parity, the system can recover from 1 to $g+1$ failures at any time. In the $10+2+2$ scheme, the system can recover from 1 to 3 failures at any time.
- The system can recover from $g+2$ to $g+l$ failures in certain cases. With the $10+2+2$ scheme, the system can recover from 4 failures, in certain cases.
- If none of the data fragments have failed in a data group, the system cannot use the corresponding local parity fragment, to recover from a failures in other data groups. For example:

To recover D5, the system reads only $D1+D2+D3+D4+L1$. It does not read $D1+D2+D3+D4+L2$, since there are no failures in the data group D6 to D10, for which L2 is the local parity fragment.

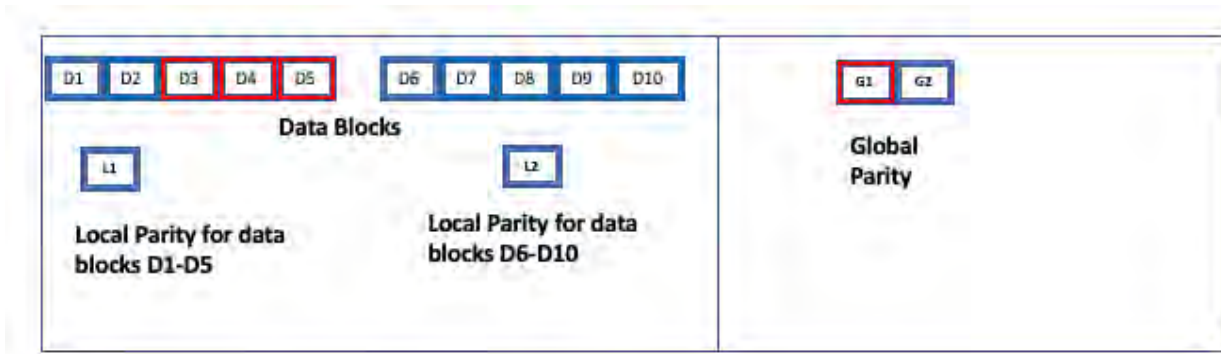

- For a single failure, the system needs to read k/l fragments to recover. For multiple failures, the system needs to read k fragments to recover.

With local parity, the system recovers from most of $g+l$ failures. For the $10+2+2$ scheme, the system can recover from most of 4 failures. For example:

Here, there are 4 failures. The required number of blocks to read (10 in this case) are available, for recovery. The system reads $D1+D2+D3+D6+D9+D10+L1+L2+G1+G2$.

However, consider the following example:

Although there are 4 failures, the system does not have the required number of fragments (10) to read and recover. The only fragments that can be read are D1+D2+L1+D6+D7+D8+D9+D10+G1. Fragment L2 cannot be read because there are no failures in its corresponding data group D6 to D10. Therefore in this case, data cannot be reconstructed.

Specifying a Schedule for Offloading Data

Explains how to create a schedule for automatic offloading of data, using the Control System, the CLI and the REST API.

You can create a schedule using the Control System, the CLI, and REST API. After creating a schedule, you can associate it with the tiering-enabled volume when you create or modify the volume. If a schedule for offloading data is associated with the volume, data is offloaded automatically as scheduled based on the rules associated with the volume for offloading data. You can also manually trigger the `maprccli` command to offload data.

The following schedules are available out-of-the-box for offloading data:

| Schedule Name | Schedule ID |
|-----------------------------|-------------|
| Critical data | 1 |
| Important data | 2 |
| Normal data | 3 |
| Automatic Tiering Scheduler | 4* |

* The Automatic Tiering Scheduler ID might be different on different clusters. To retrieve the correct ID, run the `schedule list` on page 1949 command.

For volumes enabled for warm tiering, the Automatic Tiering Scheduler is used by default for offloading data if you do not explicitly assign a schedule. The frequency of the Automatic Tiering Scheduler run is based on two the following:

time

The frequency. The `cldb.auto.offload.frequency.minutes` property stores the default value of 24 * 60 minutes. This can be configured using the `config save` on page 1768 command. The value for this property must be in minutes.

size

The amount of data (that has not yet been offloaded) in the volume. The `cldb.auto.offload.threshold.gb` property stores the global value for the size threshold. The default value for this property is 1024GB, which cannot be modified. However, you can override the global value at the volume-level using the `autooffloadthresholdgb` parameter with the

[Creating a Volume](#) on page 941 and [volume modify](#) on page 2275 commands.

The Automatic Tiering Scheduler run is based on the time setting. However, it runs sooner if the size of the volume in the hot tier reaches or exceeds the size threshold.

For volumes enabled for cold tiering, you must assign a schedule to automatically offload data; if you do not assign a schedule, data is not offloaded automatically and you must manually run the offload command to offload data. You can associate the Automatic Tiering Scheduler with the cold-tier enabled volume or create a custom schedule and associate it with the volume to automatically offload data.

To:

- Create a schedule before creating the volume, see [Creating a Schedule](#) on page 1038.
- Create a schedule when you are creating the volume, see step 9 in [Creating a Volume](#) on page 941.

Specifying a Schedule Using the Control System

You can associate a schedule with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** button in the **Data > Volumes** page.
- Editing the tiering-enabled volume by clicking **Edit Volume** button in the [volume information page](#).

To associate an offload schedule with the volume, see [Creating a Schedule](#) on page 1038 or [Selecting an Existing Schedule to Associate with a Volume](#) on page 1040.

Specifying a Schedule Using the CLI and REST API

You can associate a schedule with a tiering-enabled volume by specifying the `offloadschedule` parameter with the [volume create](#) on page 2190 or [volume modify](#) on page 2275 command.

CLI

Run a command similar to the following to associate a schedule when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -offloadschedule
<scheduleID> -json
```

For the list of all other required and optional parameters, see [volume create](#) on page 2190.

- Editing the volume:

```
maprcli volume modify -name
<volName> -offloadschedule
<scheduleID> -json
```

For the list of all other required and optional parameters, see [volume modify](#) on page 2275.

REST

Send a request of type POST. For example, to associate a schedule when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&offloadschedule=<scheduleID>' --us
er mapr:mapr
```

For the list of all other required and optional parameters, see [volume create](#) on page 2190.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&offloadschedule=<sch
eduleID>' --user mapr:mapr
```

For the list of all other required and optional parameters, see [volume modify](#) on page 2275.

To disable automatic schedule-based offload of data, set the value for the `offloadschedule` parameter to 0.

Creating a Tiering-Enabled Volume

You can create a tiering-enabled volume using the Control System, the CLI, and the REST API.

Creating a Tiering-Enabled Volume Using the Control System

1. Go to **Data > Volumes** and click **Create Volume**.
The **Create New Volume** page displays.
2. Select the **Volume Type**, specify values for required/optional settings and auditing, and move the slider to **Yes** for **Data Tier** in the **Properties** tab.
For information on all other properties and settings, see [Creating a Volume](#) on page 941.

Note: The source volume for a tiering-enabled mirror volume must also be tiering-enabled. You cannot set up a tiering-enabled mirror volume to mirror a volume that is not tiering-enabled.

3. Click **Create Volume** to create the tiering-enabled volume.

You can proceed to [associate a tier, tiering rule, and/or schedule with the volume](#).

Creating a Tiering-Enabled Volume Using the CLI and REST API

CLI

Run the following command to create a tiering-enabled volume:

```
$maprcli volume
create -name <volName> -path
<volmountpath> -tieringenable true
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
```

```
name=<volName>&path=<volmountpath>&tieringenable=true' --user mapr:mapr
```

For more information, see [volume create](#) on page 2190.

Associating a Tier and/or Tiering Rule with a Volume

You can associate a tier and/or tiering rule with a new volume or with an already tiering-enabled volume using the Control System, CLI, and the REST API.

Associating a Tier and/or Tiering Rule with a Volume Using the Control System

- Perform the steps in the following topics to associate a tier, tiering rule, and/or schedule with:
 - [A new volume](#)
 - [A tiering-enabled volume](#)

Associating a Tier and/or Tiering Rule with a Volume Using the CLI

- Run the following command to associate a tier and/or tiering rule with:
 - A new volume:

```
$maprcli volume create -name <vol_name> -path <vol_mount_path> -tieringenable true -tiername <tier_name> -tieringrule <rule_name>
```

For more information, see [volume create](#) on page 2190.

- An already tiering-enabled volume:

```
$maprcli volume modify -name <vol_name> -tiername <tier_name> -tieringrule <rule_name>
```

For more information, see [volume modify](#) on page 2275.

Note: You cannot change the tier type or the tier for a volume after it is set.

Associating a Tier and/or Tiering Rule with a Volume Using the REST API

- Send a request of type POST to associate a tier and/or tiering rule with:
 - A new volume. For example:

```
curl -k -X POST 'https://<host>:8443/rest/volume/create?name=<vol_name>&path=<vol_mount_path>&tieringenable=true&tiername=<tier_name>&tieringrule=<rule_name>' --user mapr:mapr
```

For more information, see [volume create](#) on page 2190.

- An already tiering-enabled volume. For example:

```
curl -k -X POST 'https://<host>:8443/rest/volume/modify?name=<vol_name>&tiername=<tier_name>&tieringrule=<rule_name>' --user mapr:mapr
```

For more information, see [volume modify](#) on page 2275.

Note: Volume's data tiering properties like tiername, ectopology, ecscheme, etc. cannot be modified after they are set.

Determining if a Volume is Enabled for Tiering

You can determine if a volume is enabled for tiering and if rules, schedules, and/or settings for recalled data are associated with the volume using the Control System and the CLI.

Determining if a Volume is Enabled for Tiering Using the Control System

- Log in to the Control System and click **Data > Volumes**.

In the list of volumes displayed in the **Volumes** pane, the **Data Tiering** column contains the value **Enabled** for a volume if the volume is enabled for tiering. If you do not see the column, you can see the column by [selecting the columns](#) to display in the Control System.

Determining if a Volume is Enabled for Tiering Using the CLI

- Run one of the following commands to determine if a volume is enabled for tiering:

```
maprcli volume list -json
```

```
maprcli volume info -name <volName> -json
```

The output, if the volume is tiering-enabled (and has associated settings), should look similar to the following:

```
{
  "timestamp":1533959507772,
  "timeofday":"2018-08-10 08:51:47.772 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "acl":{
        "Principal":"User root",
        "Allowed actions":"[dump, restore, m, a,
d, fc]"
      },
      ...
      ...
      "tierenable":"true",
      "tierid":"169211273",
      "tierruleid":"2",
      "tieroffloadscheduleid":"6",
      "tierencryption":"false",
      "tierrecallexpirytime":"1",
      "tiercompactionscheduleid":"4",
      "tiercompactionoverheadthresh":"30",
      "gateway":"10.10.108.120:8660",
      "cvttotalused":0
    }
  ]
}
```

Offloading a Volume to a Tier

Explains how to offload a volume to a tier using either the Control System, the CLI, or the REST API.

At the volume level, data can be offloaded automatically by creating and associating a schedule with the tiering enabled volume or manually by triggering the offload operation. See [Data Offload and Purge](#) on

page 430 for more information. The following sections describe how to set up an automatic offload of data and how to trigger a one-time manual offload data at the volume level using either the Control System, the CLI, or the REST API.

Note: For a tiered volume, there can be only one running job at any given time. For example, suppose another job is running on the tiered volume, if you trigger an offload operation, the offload operation will fail.

To offload volume data, you must have one of the following permissions:

- Cluster level fc permissions
- Volume level fc permissions
- Volume modify permissions

Note: You can also offload individual files in a tiering-enabled volume to the associated tier. See [Offloading a File to a Tier Using the CLI and REST API](#) on page 1104 for more information.

Important: EC volumes are automatically offloaded once they crossed the size of `autooffloadthresholdgb` even if they are not using the Automatic scheduler. The default size is 1024 GB (1 TB). You can modify this size as specified in [Offloading a Volume to a Tier](#) on page 1014.

Setting up Automatic Offload of Data Using the Control System

1. Create a tier.
See [Creating a Cold Tier Using the Control System](#) on page 1044 or [Creating a Warm Tier Using the Control System](#) on page 1044 for more information.
2. Create a storage policy to associate with the volume.
See [Creating a Storage Tier Policy Using the Control System](#) on page 1058 for more information.
3. Create an offload schedule.
See [Specifying a Schedule for Offloading Data](#) on page 1010 for more information.
4. Create a tiering enabled volume and associate the tier, the storage policy, and schedule with the volume.
See [Creating a Tiering-Enabled Volume Using the Control System](#) on page 1012 for more information.

Triggering an Offload of all Data in a Volume to a Tier Using the Control System

1. Log in to the Control System and click **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane.
Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Offload Data** from the **Actions** drop-down menu to display the **Offload Volume Data** confirmation window.
4. Review the list of volumes to offload and click **Offload**.

If the offload fails, CLDB retries the operation after some time. See [Retrying Failed Operation](#) on page 1020 for more information.

Setting up Automatic Offload of Data Using the CLI and REST API

To automatically offload data:

1. Create a tier, a rule that contains the criteria for offloading data to the tier, and a schedule to automatically offload data to the tier.

For example:

CLI

```
/opt/mapr/bin/maprcli tier
create -name <tier_name> -type
ectier
/opt/mapr/bin/maprcli tier
create -name <tier_name> -type
cold -url <tier_url> -credential
<credentials>.txt -json
/opt/mapr/bin/maprcli tier rule
create -name <rule_name> -expr
<expressions>
/opt/mapr/bin/maprcli schedule
create -schedule <JSON>
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=ectier' --user
mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=cold&url=<tier
_url>&credential=<credential_str>'
--user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/
create?
name=<rule_name>&expr=<expressions>'
--user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/schedule/create?
schedule=<JSON>' --user mapr:mapr
```

For more information, see [Managing Tiers](#) on page 1041 and [Managing Storage Policies](#) on page 1055.

2. Create a tiering-enabled volume and associate the tier, rule, and schedule (that you created in step 1) with the volume.

For example, to create a volume and enable it for:

- Warm tier:

CLI

```
/opt/mapr/bin/maprcli volume
create -name <vol_name> -path
<vol_mount_path> -tieringenable
true -tiername
<tier_name> -ecscheme
<coding_scheme> -ectopology
<ec_vol_topo> -tieringrule
<rule_name> -offloadschedule
<schedule_ID>
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_pat
h>&tieringenable=true&tiername=<tie
r_name>&ecscheme=<coding_scheme>&ec
topology=<ec_vol_topo>&tieringrule=
<rule_name>&offloadschedule=<schedu
le_ID>' --user mapr:mapr
```

- Cold tier:

CLI

```
/opt/mapr/bin/maprcli volume
create -name <vol_name> -path
<vol_mount_path> -tieringenable
true -tiername
<tier_name> -tieringrule
<rule_name> -offloadschedule
<schedule_ID> -recallexpirytime
2 -json
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_pat
h>&tieringenable=true&tiername=<tie
r_name>&tieringrule=<rule_name>&off
loadschedule=<schedule_ID>&recallex
pirytime=2' --user mapr:mapr
```

You can also specify the maximum amount of data (in GB) to offload automatically for warm-tier volumes using the `autooffloadthresholdgb` parameter. For more information, see [Working with Tiered Volumes](#) on page 1004.

*Triggering an Offload of all Data in a Volume to a Tier Using the CLI and REST API***CLI**

Run the following command to manually trigger an offload of all data in the volume:

```
maprcli volume offload -name
<volume-name>
```

If you run the command with the `ignorerule` option value set to `true`, rules for the volume where the data resides is ignored and data is offloaded immediately. If the `ignorerule` option value is not specified or is set to `false` (default), data is offloaded based on the rules associated with the volume where the data resides.

REST

Submit a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/offload?
name=sampleVol' --user mapr:mapr
{"timestamp":1519947659597,"timeofday"
:"2018-03-01 03:40:59.597 GMT-0800
PM","status":"OK","total":0,"data":
```

```
[ ], "messages": [ "Successfully started offload." ] }
```

For more information, see [volume offload](#) on page 2296.

If the offload fails, CLDB retries the operation after some time. See [Retrying Failed Operation](#) on page 1020 for more information.

Recalling a Volume to filesystem

Explains how to recall offloaded data to the filesystem.

When you:

- Read data offloaded to a remote target (or cold tier), data is automatically recalled to the filesystem to allow the read to succeed.
- Modify data offloaded to an erasure coded volume (or warm tier) or a remote target (or cold tier), data is automatically recalled to the filesystem to allow the write to succeed.

The recalled data is automatically:

- Purged based on the expiration time period set at the volume level for recalled data if there are no changes (for example, read operation).
- Offloaded based on the rule and the expiration time period set at the volume level for recalled data if there are changes (for example, overwrite operation).

See [Data Reads, Writes, and Recalls](#) on page 437 for more information. If the recall fails, CLDB retries the operation after some time. See [Retrying Failed Operation](#) on page 1020 for more information.

You can manually recall all data in a volume using the Control System, CLI, or the REST API.

Note: For a tiered volume, there can be only one running job at any given time. If you trigger a recall operation when another job is running on the tiered volume, the recall operation will fail.

You can also recall individual files from the tier. See [Recalling a File to filesystem Using the CLI and REST API](#) on page 1104 for more information.

Recalling Offloaded Volume Using the Control System

1. Log in to the Control System and click **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to recall from the list of volumes in the **Volumes** pane. Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Recall Data** from the **Actions** drop-down menu to display the **Recall Tiered Data** confirmation window.
4. Review the list of volumes to recall and click **Recall Volumes**.
For more information, see [Recall of Tiered Data](#) on page 440.

Recalling Offloaded Volume Using the CLI and REST API

CLI

Run the following command to recall volume data:

```
/opt/mapr/bin/maprcli volume recall -name <volName>
```

REST API

Send a request of type POST to URL. For example:

```
curl -k -X
POST 'https://abc.sj.us:8443/rest/
volume/recall?name=volName' --user
mapr:mapr
```

For more information, see [volume recall](#) on page 2298.

Viewing the List of Running Jobs

You can view the tiering jobs currently running for a volume using the CLI and REST API. For a tiered volume, at any given time, there can be only one running job.

- Run the following command or send a request of type GET to retrieve the list of currently running tiering operations for a volume:

CLI

```
maprcli volume tierjobstatus -name
<volName>
```

REST

```
curl -k -X
GET 'https://<host>:8443/rest/volume/
tierjobstatus?name=<volName>' --user
mapr:mapr
```

For more information, see [volume tierjobstatus](#) on page 2312.

Terminating a Running Volume-Level Tiering Job

Describes how to terminate a volume-level tiering job using either the Control System or the CLI.

You can terminate an ongoing offload or recall of a volume using the Control System or the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the [volume offload](#) on page 2296 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See [Recalling a Volume to filesystem](#) on page 1018 for more information.

You can check the status of an abort operation using the [volume tierjobstatus](#) on page 2312 command.

Note: If you terminate a job that CLDB was retrying after a prior failed attempt (FailureRetriable job), CLDB will stop trying to run the job again. For more information on FailureRetriable job, see [Retrying Failed Operation](#) on page 1020.

For information on terminating a file-level job, see [Terminating a Running File-Level Tiering Job](#) on page 1105 and [Running Tiering Commands when maprcli and hadoop Commands are not Available](#) on page 1106.

Terminating a Volume Offload or Recall Operation Using the Control System

1. Log in to the Control System and click **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane. Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Abort Tiering Job** from the **Actions** drop-down menu to display the **Abort Tiering Job** confirmation window.
4. Review the list of volumes and click **Abort Job**.

Aborting Volume Offload or Recall Operation Using the CLI and REST API

CLI

Run the following command to abort a running offload or recall operation:

```
maprcli volume tierjobabort -name
<volName>
```

For more information, see [volume tierjobabort](#) on page 2311.

REST API

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<host>:8443/rest/volume/
tierjobabort?name=<volName>' --user
mapr:mapr
```

Retrying Failed Operation

Volume-level

If an offload, recall, or abort operation for a volume fails, the [volume tierjobstatus](#) on page 2312 command shows one of the following statuses:

| | |
|------------------|---|
| FailureFatal | Indicates failure is fatal and CLDB cannot retry the operation again. |
| FailureRetriable | Indicates failure to offload; however, CLDB will try again if the job is not manually restarted again or aborted. |

CLDB tries the operation again (up to 5 times by default) after a specific wait time (of 30 minutes by default) for the following errors:

- EAGAIN
- ETIMEDOUT
- ENETUNREACH
- ENETDOWN
- ECONNRESET

The `RetryCount` field value in the [volume tierjobstatus](#) on page 2312 command output shows the number of times CLDB has retried so far. For example:

```
# maprcli volume tierjobstatus -name
testvol -json
{
```

```

"timestamp":1503308792266,
"timeofday":"2017-08-21 09:46:32.266
GMT+0000",
"status":"OK",
"total":1,
"data":[
{
"offload":{
"state":"FailureRetriable,
RetryCount: 5",
"startTime":"2017-08-21
09:07:17.506 GMT+0000",
"endTime":"2017-08-21
09:08:49.799 GMT+0000",
"gateway":"10.10.102.68:8660"
}
}
]
}
    
```

File-level

If the offload or recall operation for an individual file fails, the [file tierstatus](#) on page 1870 or [hadoop mfs](#) on page 5576 command returns one of the following:

| Code | Message | Description |
|------|-----------------|--|
| 0 | HAS_LOCAL_DATA | Indicates that the file is not yet fully offloaded. |
| 1 | NO_LOCAL_DATA | Indicates that the file was completely offloaded. |
| 2 | OP_FAIL | Indicates that the operation to retrieve the status failed. |
| 3 | INVALID_FILE | Indicates that the file does not exist. |
| 4 | FILE_NOT_TIERED | Indicates that the file is not in a tiered volume. |
| 5 | FILE_EMPTY | Indicates that the file specified for offload is an empty file. |
| 6 | NO_GATEWAY | Indicates that no MAST Gateways are available for offload operation. |

| Code | Message | Description |
|------|---------------------------|--|
| 7 | OP_TIMEOUT | Indicates that there was no response from the MAST Gateway (maybe as a result of an error) during the offload or recall operation. |
| 8 | FTOS_SUCCESS | Indicates that the file was successfully offloaded or recalled. |
| 9 | FTOS_ABORTED | Indicates that the file offload or recall operation was aborted. |
| 10 | FTOS_ABORT_IN_PROGRESS | Indicates that the file offload or recall job is being aborted. |
| 11 | FTOS_TRANSFER_IN_PROGRESS | Indicates that the file offload is in progress. |
| 12 | FTOS_REQ_QUEUED | Indicates that the file offload is scheduled, but has not yet started. |
| 13 | FTOS_JOB_NOT_AVAILABLE | Indicates that the job ID specified with the tierjobstatus command is not available. |

When a file-level offload or recall operation fails, CLDB **does not** retry the operation. For failed file-level:

- Offload operation, you can run the command to retry the operation. For more information, see [Offloading a File to a Tier Using the CLI and REST API](#) on page 1104. Alternatively, if the volume that the file is associated with has a data offload schedule, the file data is automatically offloaded based on the rules associated with the volume.
- Recall or abort operation, you can run the command again to retry the operation if the error returned is not EIO.

You can configure the number of times CLDB retries and the interval between retries using the CLI.

Configuring the Number of Retries

- Set the value for the `cldb.gateway.retry.count` parameter, whose default value is 5, to configure the number of times that CLDB tries again. For example, to configure CLDB to retry to offload, recall, or abort at least 10 times, run the following command:

```
# maprcli config save -values {"cldb.gateway.retry.count":"10"}
```

Configuring the Interval Between Retries

- Set the value for the `cldb.gateway.retry.waittime.seconds` parameter, whose default value is 1800 seconds (30 minutes), to configure the amount of time CLDB waits between retries. For example, to configure CLDB to wait for up to 4 hours (14400 seconds), run the following command:

```
# maprcli config save -values {"cldb.gateway.retry.waittime.seconds":"14400"}
```

Running the Compactor Using the CLI and REST API

You can trigger the compactor using the CLI and REST API to purge recalled data on the MapR cluster or to purge stale data on the tier. See [Data Compaction](#) on page 441 for more information.

Running the Compactor to Purge Recalled Data on the MapR Cluster

CLI

Run the following command to trigger the compactor and purge data whether or not the expiry time for recalled data has been reached:

```
maprcli volume compact -name <volName> -forcerecallexpiry true
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/rest/volume/compact?name=<volName>&forcerecallexpiry=true' --user mapr:mapr
```

For more information, see [volume compact](#) on page 2186.

Running the Compactor to Purge Stale Data on the Tier

CLI

Run the following command to trigger the compactor:

```
maprcli volume compact -name <volName>
```

REST

Send a request of type POST.

```
curl -k -X POST 'https://<host>:8443/rest/volume/compact?name=<volName>' --user mapr:mapr
```

When you trigger the compactor, the compactor purges stale data from the tier and also recalled data on the MapR cluster if the expiry time for recalled data has been reached. For more information, see [volume compact](#) on page 2186.

Retrieving the Status of a Volume-level Tiering Operation

You can check the status of an active volume offload, completed offload, aborted offload, and recall operations using the Control System, the CLI, and the REST API. For information on file level tiering job, see [Retrieving Status of File-level Tiering Operation and File Data](#) on page 1107.

Retrieving Status of Volume-level Operation Using the Control System

- Log in to the Control System and click **Data > Volumes**.

The **Volumes** pane in the page displays the following for tiered volumes:

- **Job** — The currently running or last completed tiering job for the volume.
- **State** — The status of the tiering job.
- **Progress** — The completion percentage of the tiering job.

Retrieving Status of Volume-level Operation Using the CLI and REST API

CLI

Run the following command to check the status of an active or completed offload, abort, and/or recall operation:

```
maprcli volume tierjobstatus -name
<volume_name> -json
```

Note: You must have full control (fc) permissions either at the cluster or at the volume level to run this command. To determine the status of a compaction operation, specify the `verbose` option with the `tierjobstatus` command. For example:

```
maprcli volume
tierjobstatus -name
<volume_name> -verbose true -json
```

REST

Send a request of type GET.

```
curl -k -X GET 'https://
<host>:8443/rest/volume/tierjobstatus?
name=<volume_name>' --user mapr:mapr
```

See [Statuses](#) on page 2313 for more information.

Retrieving Tiering Statistics Using guts

Explains how to use the `guts` utility to retrieve tiering statistics.

You can run the `/opt/mapr/bin/guts` utility to get granular information on ongoing offloads and recalls including:

- The number of objects that are offloaded to and recalled from the tier
- The number of reads and writes on HPE Ezmeral Data Fabric Database
- The number of reads and writes on filesystem

Syntax

```
/opt/mapr/bin/guts <argument>:<options>
```

Arguments

| Argument | Description |
|-------------|---|
| mastgateway | Refers to operations on the MAST Gateway node. See Usage on page 1025 for information on the syntax for running the <code>guts</code> command with this argument. |
| fstier | Refers to operations on filesystem node. See Usage on page 1025 for information on the syntax for running the <code>guts</code> command with this argument. |

Options

| Option | Description |
|--------|---|
| all | Statistics for all operations. |
| db | Statistics for MAST Gateway operations currently running on HPE Ezmeral Data Fabric Database. |
| mfsops | Statistics for MAST Gateway operations on filesystem. |
| none | Specifies the column(s) to exclude from the output. |
| tier | Statistics for MAST Gateway operations on the storage tier. |

Usage

MAST Gateway Node

```
/opt/mapr/bin/guts mastgateway:all
/opt/mapr/bin/guts mastgateway:db
/opt/mapr/bin/guts mastgateway:tier
/opt/mapr/bin/guts mastgateway:mfsops
/opt/mapr/bin/guts mastgateway:none
```

filesystem Node

```
/opt/mapr/bin/guts fstier:all
/opt/mapr/bin/guts fstier:none
```

Note: These commands might show statistics for several other fields. To skip, use `none` with the components whose fields you do not wish to retrieve. For example, to retrieve statistics for only the `mastgateway tier`, run the following command:

```
/opt/mapr/bin/guts allocator:none btree:none cache:none cleaner:none
client:none cpu:none db:none dbrepl:none disk:none fs:none fstier:none
gateway:none io:none kv:none log:none mastgateway:tier net:none
nfs:none rpc:none ssd:none streams:none time:none vcd:none
```

Output

`mastgateway:tier`

| | |
|------|---|
| objP | Number of objects (whose maximum size is 8MB for cold-tier or whose size is computed based on the erasure coding scheme for warm-tier) that were offloaded to the storage tier. |
|------|---|

| | |
|-------|--|
| objG | Number of objects (whose size is up to 1 MB for cold-tier and whose size is computed based on the erasure coding scheme for warm-tier) that were recalled from the storage tier. |
| objD | Number of deletions on the tier. |
| objPM | Amount of data (in MB) offloaded per second to the storage tier. |
| objGM | Amount of data (in MB) recalled per second from the storage tier. |

mastgateway:db

| | |
|------|--|
| tdbP | Number of <i>puts</i> on HPE Ezmeral Data Fabric Database tables. |
| tdbG | Number of <i>gets</i> on HPE Ezmeral Data Fabric Database tables. |
| tdbD | Number of <i>deletes</i> on HPE Ezmeral Data Fabric Database tables. |

mastgateway:mfsops

| | |
|------|--|
| moR | Number of <i>read</i> requests from client to the MAST Gateway service to read from cache volumes. |
| mp | Number of filesystem <i>purge</i> requests sent by the MAST Gateway service. |
| mrw | Number of filesystem <i>reads</i> from the MAST Gateway service to perform modify/write operation. |
| moRM | Amount of filesystem <i>reads</i> (in MB) sent by the MAST Gateway service to read offloaded data. |
| mrwM | Amount of <i>recall writes</i> (in MB) sent by the MAST Gateway service. |

fstier:all

| | |
|-----|--|
| tp | Number of blocks (of 64KB) <i>purged</i> during an offload operation. |
| trw | Number of blocks (of 64KB) <i>written</i> during recall of offloaded data. |

| | |
|-----|---|
| trr | Number of blocks (of 64KB) <i>read</i> during read of offloaded data. |
| twr | Number of blocks (of 64KB) <i>recalled</i> for partial overwrites. |

[guts](#) on page 2391

`guts` is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. `guts` is an internal utility, and is subject to change without notice.

[cldbguts](#) on page 2360

Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

Moving back end Volume from the Command Line

This section contains information on migrating the following volumes to a different topology:

- Metadata volume, which stores the DB tables for the metadata associated with the tier.
- Erasure-coded volume, which stores the erasure-coded data.

Moving Metadata Volume to Another Topology

By default, the volume, which stores the DB tables for the metadata associated with the tier, is created in `/var/mapr/tier/mapr.internal.tier.<volName>` and is in the `/data` topology. However, you can move the metadata volume to another topology using the [volume move](#) on page 2294 command. For example:

CLI

```
/opt/mapr/bin/maprcli
volume move -name
<metadataVolName> -topology <newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<metadataVolName>&topology=<newTo
po>' --user mapr:mapr
```

Moving Erasure-Coded Volume to Another Topology

The erasure-coded volume is by default created in the same topology as the front-end volume. You can specify a different topology for the erasure-coded volume when creating a front-end volume. You can also move the erasure coded volume to a different topology using the [volume move](#) on page 2294 command. For example:

CLI

```
/opt/mapr/bin/maprcli volume
move -name <volName> -ectopology
<newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
```

```
name=<volName>&ectopology=<newTopo>'
--user mapr:mapr
```

Here, the `name` parameter takes the name of the front-end volume and the `ectopology` parameter takes the topology to which to move the erasure-coded volume associated with the front-end volume. For more information, see [volume move](#) on page 2294.

Using Volume Links for Read and Write Operations

When you mirror a volume, read requests to the source volume can be served by any of its mirrors on the same cluster via a volume link of type `mirror`. A volume link is similar to a normal volume mount point, except that you can specify whether it points to the source volume or its mirrors.

- To write to (and read from) the source volume, mount the source volume normally.

As long as the source volume is mounted below a non-mirrored volume, you can read and write to the volume normally via its direct mount path. You can also use a volume link of type `writable` to write directly to the source volume regardless of its mount point.

- To read from the mirrors, use the [volume link create](#) command to make a volume link (of type `mirror`) to the source volume.

Any read requests from the volume link are distributed among the volume's mirrors. Since the volume link provides access to the mirror volumes, you do not need to mount the mirror volumes.

Managing Snapshots

This section provide information about managing snapshots.

A snapshot is a read-only image of a volume at a specific point in time. On clusters with an Enterprise Edition or higher license, you can create a snapshot manually or automate the process with a schedule. Snapshots are useful any time you need to be able to roll back to a known good data set at a specific point in time. For example, before performing a risky operation on a volume, you can create a snapshot to enable rollback capability for the entire volume.

A snapshot takes no time to create, and initially uses no disk space, because it stores only the incremental changes needed to roll the volume back to the state at the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota. When you view the list of volumes on your cluster in the Control System, the value of the Snap Size column is the disk space used by all of the snapshots for that volume.

Note: Snapshot volumes inherit the auditing configurations of their original read-write volumes. For details about auditing, see [Auditing](#).

You can perform the following tasks using the Control System and the CLI.

Associating a Snapshot Schedule with a Volume

Explains how to associate a snapshot schedule with a volume using the Control System, the CLI, or the REST API.

Associating a Snapshot Schedule Using the Control System

1. Log in to the Control System and go to **Summary** tab in the [volume details](#) page.
2. Click the  associated with **Volume Snapshot** in the **Schedules** pane to display the **Browse Schedules** window.
3. Review the name and detail of each schedule and select a schedule from the list.
4. Click **Save Changes** to associate the schedule with the volume.

Associating a Snapshot Schedule Using the CLI and REST API

CLI

You can associate a snapshot schedule with a volume using the `schedule` parameter when creating or editing the volume. For example:

```
maprcli volume create -name
<volName> -path <mountPath> -schedule
<scheduleID>
```

```
maprcli volume modify -name
<volName> -schedule <scheduleID>
```

REST

You can associate a mirroring schedule with a mirror volume using the `schedule` parameter when creating or editing the volume. Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<volPath>&schedule
=<scheduleID>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&schedule=<scheduleID>'
--user mapr:mapr
```

For the complete list of all required and optional parameters, see [volume create](#) on page 2190 and [volume modify](#) on page 2275.

Creating Volume Snapshots

Describes how to create snapshots of volumes using the Control System and the CLI.

You can create a snapshot manually using the Control System and the CLI, or use a schedule to automate snapshot creation.

Note: The maximum number of snapshots that you can create for each volume is 4092. Exceeding this limit raises the snapshot failure alarm with an appropriate entry in the CLDB logs.

Creating Snapshots of Multiple Volumes Using the Control System

To create snapshots of multiple (standard and/or mirror) volumes manually:

1. Log in to the Control System and go to the **Summary** tab in the **Data > Volumes** page.

Note: When running on a Kubernetes cluster, the **Summary** tab is on the **Volumes** page.

2. Select the volume(s) for which you need to create the snapshots.
3. Click **Snapshot Volume** from the **Actions** drop-down menu.
The **Snapshot Volume(s)** confirmation dialog displays.
4. Verify the list of volumes and enter a unique name for the snapshot in the **New Snapshot Name** field.
5. Click **Snapshot Volumes**.

Creating a Snapshot of a Volume Using the Control System

You can create a snapshot manually or use a schedule to automate snapshot creation. To create a snapshot of a volume manually:

1. Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
2. Click **Create Snapshot** to display the **Create Snapshot** window.
3. Enter a unique name for the snapshot in the **New Snapshot Name** field.
4. Click **Create Snapshot** to create a snapshot of the volume.
By default, manually created snapshots do not have an expiration date.

Creating Volume Snapshots Using the CLI or REST API

The basic command to create a snapshot is:

```
maprcli volume snapshot create -snapshotname <snapshot> -volume <volume>
```

For complete reference information, see [volume snapshot create](#) on page 2301.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

- The **Snapshots** tab under the **Data > Volumes** page displays all the snapshots on the cluster.

Note: When running on a Kubernetes cluster, the **Snapshots** tab is under the **Volumes** page that is under the **Volumes** menu.

For each snapshot, you can view the following:

| Column Name | Column Description |
|---------------|---|
| Snapshot Name | The name of the snapshot. |
| Volume | The volume with which the snapshot is associated. |
| Created On | The date when the snapshot was created. |
| Expires On | The date when the snapshot expires. |
| Reclaim Size | TBD |

You can select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing the Snapshots Associated with a Volume Using the Control System

- Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).

The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

| Column Name | Column Description |
|---------------|---------------------------|
| Snapshot Name | The name of the snapshot. |

| Column Name | Column Description |
|--------------|---|
| Volume | The volume with which the snapshot is associated. |
| Created On | The date when the snapshot was created. |
| Expires On | The date when the snapshot expires. |
| Reclaim Size | TBD |

You can [create a snapshot](#) of the volume or select one or more snapshots to:

- [Preserve](#)
- [Remove](#)

Viewing Snapshots Using the CLI or REST API

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see [volume snapshot list](#) on page 2303.

Filtering the List of Snapshots

Describes how to filter the list of snapshots using the Control System or the CLI.

The filter in the **Snapshots** tab on the **Data > Volumes** page lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

Note: When running on a Kubernetes cluster, the filter is present in the **Snapshots** tab on the **Volumes** page under the **Volumes** menu.

Filtering the List of Snapshots Using the Control System

1. Log in to the Control System and click **Data > Volumes > Snapshots** to filter list of snapshots in the **Snapshots** page.

Note: When running on a Kubernetes cluster, click **Volumes > Snapshots** to filter list of snapshots in the **Snapshots** page.

2. Click and select one of the following from the **Add Filter** drop down menu:
 - Snapshot Name — to filter the list by snapshot name
 - Volume — to filter the list by volume name
 - Created on — to filter the list by snapshot creation date range
 - Expires on — to filter the list by snapshot expiration date range
3. Specify the value in the drop-down field for the selected filter (on which to filter the list of snapshots) and click **Filter**.

As you make selections and specify the filtering criteria, the pane displays only the snapshots that match the specified filtering criteria.

4. Click:
 - **Add Filter** to add another filtering criteria.
 - to remove a filtering criteria.

-  to clear all filter settings.

Filtering the List of Snapshots Using the CLI and REST API

CLI

The [volume snapshot list](#) on page 2303 command can be used with the `-filter` option, which let you specify large numbers of snapshots by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all snapshots associated with the volume `test` as follows:

```
maprcli volume snapshot list -filter
[vn=="test"] -json
```

REST

Send a request of type GET. For example, to display all snapshots associated with the volume `test`, send a request similar to the following:

```
curl -k -X GET 'https://
<hostname>:8443/rest/volume/snapshot/
list?
filter=%5Bvn%3D%3D%22test%22%5D' --use
r <username>:<pwd>
```

For more information, see [volume snapshot list](#) on page 2303.

Viewing the Contents of a Snapshot from the Command Line

Describes how to view the contents of the `.snapshot` directory from the CLI.

At the top level of each volume is a directory named `.snapshot` containing all the snapshots for the volume. You can view the directory with `hadoop fs` commands or by mounting the cluster with NFS. To prevent recursion problems, `ls` and `hadoop fs -ls` do not show the `.snapshot` directory when you list the contents of the top-level volume directory. You must navigate explicitly to the `.snapshot` directory to view and list the snapshots for the volume.

Example:

```
hadoop fs -ls /myvol/.snapshot
Found 1 items
drwxrwxrwx - root root          1 2011-06-01 09:57 /myvol/.snapshot/
2011-06-01.09-57-49
```

In the preceding example, `/myvol` is the mount point of the volume for which the snapshot named `2011-06-01.09-57-49` was created and stored in the `.snapshot` directory.

Preserving one or more Snapshots

Describes how to preserve a snapshot using the [volume snapshot preserve](#) command, or using the Control System.

Preserving Snapshots Using the Control System

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots, in the **Snapshots** tab (under **Data > Volumes**):

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the snapshot(s) you want to preserve.

2. Click **Preserve Snapshot** to preserve the snapshot(s).
The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Associated with a Volume Using the Control System

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots (and prevent them from expiring) associated with a volume:

1. Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
The list of snapshots associated with the volume displays.
2. Select the snapshots to preserve and click **Preserve Snapshot**.
The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Using the CLI or the REST API

The basic command to preserve the snapshots is:

```
maprcli volume snapshot preserve
```

For complete reference information, see [volume snapshot preserve](#) on page 2308.

Removing one or more Snapshots

Explains how to remove a snapshot using the [volume snapshot remove](#) command or using the Control System.

Each snapshot has a date and time at which it expires. You can remove a snapshot manually before its expiration, or you can [preserve](#) a snapshot to prevent it from expiring.

Removing Snapshots Using the Control System

To remove one or more snapshots, in the **Snapshots** tab under **Data > Volumes**:

Note: The **Volumes** page is under the **Volumes** in the Kubernetes version of the Control System.

1. Select the snapshots to remove.
2. Click **Remove Snapshot**.
The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

Removing Snapshots Associated with a Volume Using the Control System

To remove one or more snapshots associated with a volume:

1. Log in to the Control System and go to the **Snapshots** tab in the [volume information page](#).
The list of snapshots associated with the volume displays.
2. Select the snapshots to remove and click **Remove Snapshot**.
The **Remove Snapshots** confirmation dialog displays.

3. Verify the list of snapshots to remove and click **Remove Snapshots**.

When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

Removing Snapshots Using the CLI or REST API

The basic command to remove a snapshot is:

```
maprcli volume snapshot remove
```

For complete reference information, see [volume snapshot remove](#) on page 2309.

Restoring Volume Snapshots Using the Control System

Describes how to restore snapshots of volumes using the Control System.

You can restore snapshots using the Control System.

For an overview on the Snapshot Restore functionality, refer to [Restoring a Volume From a Snapshot](#) on page 442.

To restore a snapshot, using the CLI, use the [volume snapshot restore](#) on page 2326 command.

To check the progress of a snapshot restore operation, use the [volume snapshot restorestatus](#) on page 2328 command.

Restoring Snapshots Using the Control System

To restore either a single or multiple snapshots of a single or multiple (standard and/or mirror) volumes:

1. Log in to the Control System and go to the **Snapshots** tab on the **Data > Volumes** page.

Note: When running on a Kubernetes cluster, the **Snapshots** tab is on the **Volumes** page under the **Volumes** menu .

2. Select a snapshot or multiple snapshots to restore.
3. Click **Restore Snapshot** from the menu.
4. Verify the list of snapshots, read through the information displayed, and click **Restore Snapshot**.

Tip: The Control System displays notifications that show the status of the Snapshot Restore operation.

Related concepts

[Restoring a Volume From a Snapshot](#) on page 442

Provides a synopsis of restoring a volume from a snapshot. Describes the implications, and the prerequisites.

Related reference

[volume snapshot restore](#) on page 2326

Restores a volume from a snapshot using the CLI.

[volume snapshot restorestatus](#) on page 2328

Displays the progress of the snapshot restore operation, in terms of percentage.

Copying From a Snapshot Using the CLI

Describes how to create a volume by copying data from a snapshot

Copying data from a snapshot involves a simple copy operation from the `.snapshot` directory to the destination, as in the following example. User input is marked in **bold**:

 **Note:** This example assumes that the file system is mounted on /mapr using FUSE as explained in [Mounting the Filesystem](#).

```
[user@host]$ maprcli volume snapshot create -snapshotname
uservolsnap -volume users
[user@host]$ maprcli volume snapshot list
snapshotid sharedSize volumename ownername cumulativeReclaimSizeMB
numSizeUpdates snapshotname enforcementMode ownedsize
sizeUpdateRequestedAt ownertype numSizeUpdatesDesired volumeid
creationtime volumepath volumeSnapshotAces
256000049 0 users mapr 0
0 uservolsnap PolicyAceAndDataAce 0 Mon Jun 14
05:44:11 UTC 2021 1 1 77144951 Mon Jun 14
05:44:11 UTC 2021 /user ...

[user@host]$ ls -l /mapr/my.cluster.com/user/
total 1
drwxr-xr-x 2 mapr mapr 2 Jun 13 14:34 mapr

[user@host]$ ls -l /mapr/my.cluster.com/user/.snapshot
total 1
drwxr-xr-x 2 mapr mapr 2 Jun 13 14:37 uservolsnap

[user@host]$ cp /mapr/my.cluster.com/user/.snapshot/uservolsnap/mapr/* /
mapr/my.cluster.com/user/
```

Managing User Disk Usage

The **User Disk Usage** tab in the **Data > Volumes** page displays information about disk usage by cluster users. You can perform the following tasks to manage disk quotas using the MapR Control System and the CLI.

Viewing User Disk Usage Information

Explains how to view user disk usage information using either the Control System or the CLI.

Viewing User Disk Usage Information Using the Control System

To view information about disk usage by cluster users:

- Log in to the Control System and go to the **User Disk Usage** tab under **Data > Volumes**.

 **Note:** The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The disk usage information for all the users displays. For each user, the **Accountable Entities** pane displays the following:

| Column Name | Column Description |
|--------------------|--|
| Type | The type of <i>accountable entity (AE)</i> . Value can be User or Group. |
| Accountable Entity | The user or group responsible for the volume. |
| Disk Usage | The total disk space used by the user. |
| Volume Count | The number of volumes. |
| Hard Quota | The user's hard quota. |
| Advisory Quota | The user's advisory quota. |
| Email | The email address of the user. |

Selecting the checkbox beside an accountable entity makes the **Edit Properties** button available. You can modify the quotas for the selected entities by clicking [Edit Properties](#). Alternatively, you can click on an entity or associated  to **modify** the email address and quotas for the entity.

Viewing User Disk Usage Information Using the CLI or REST API

The basic command to view user disk usage information is:

```
maprcli entity info -name <entity name> -type <type>
```

For complete reference information, see [entity info](#) on page 1840.

Set or Modify Quotas for Users and/or Groups

Explains how to set or modify quotas for one or more entities using either the Control System or the CLI.

Set or Modify Quotas for Multiple Users and/or Groups Using the Control System

To edit the quota, which limits the space used by all the volumes owned by a user or group, for one or more users, in the **User Disk Usage** tab under **Data > Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the users/groups from the list of users/groups in the **Accountable Entities** pane.
2. Click **Edit Properties**.
The **Edit Properties** dialog displays.
3. Verify the list of users/groups and modify or set the following for the users/groups:
 - a) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
 - b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), or terabytes (TB).

4. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for an Entity Using the Control System

To edit the quota, which limits the space used by all the volumes owned by a user or group, for a user, in the **User Disk Usage** tab under **Data > Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Click the user/group from the list of users/groups or the  associated with the user/group in the **Accountable Entities** pane to display the **Edit Properties** window.
2. Modify or set the following for the user or group:
 - a) Enter the email address of the user/group.
 - b) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
 - c) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.
The advisory quota must be less than the hard quota.

Note: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

3. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for Users and/or Groups Using the CLI or the REST API

The basic command to set or modify quotas for multiple entities is:

```
maprcli entity modify
  -entities <entities>
  -advisoryquota <advisory quota>
  -quota <quota>
```

The basic command to set or modify quotas for an entity is:

```
maprcli entity modify
  -name <entityname>
  -type <type>
  -advisoryquota <advisory quota>
  -quota <quota>
```

For complete reference information, see [entity modify](#) on page 1843.

[accountable entity \(AE\)](#) on page 6791

Managing Schedules

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors and the offload of volume data to a storage tier; after you create a schedule, it appears as a choice in the scheduling menu when you are [creating](#) or [editing](#) a volume.

When you specify a *snapshot* schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume. A snapshot schedule for a promotable mirror volume has two purposes:

- It specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.
- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

A *mirror* schedule specifies how frequently the mirror volume is synchronized with the source volume. In case of a disaster (or any type of data loss on a read-write source volume), the data can be recovered from the mirror volume, but any data written to the source volume since the last successful mirror operation will not be on the mirror volume. Therefore, you should set the mirror schedule such that it meets your RPO (Recovery Point Objective).

A *tier offload* schedule specifies how frequently data in the volume on the MapR cluster is offloaded to the tiered storage. The MAST Gateway uses this setting to automatically offload data to the storage tier.

Schedules require the Enterprise Edition license.

Viewing the List of Schedules

Explains how to view all the schedules using the Control System or the CLI.

Viewing the List of Schedules Using the Control System

To view all the schedules:

Log in to the Control System and go to the **Schedules** tab under **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The page displays all the schedules. For each schedule, the page displays the following:

| Column Name | Column Description |
|---------------|---|
| Schedule Name | The name of the schedule. |
| ID | The schedule ID. |
| In Use | Checkmark (✓) indicates the schedule is currently being used. |
| Detail | The schedule details such as the recurring points in time when the associated actions occur and how long the data is preserved. |

Selecting the checkbox associated with a schedule makes the **Remove Schedule** button available. You can:

- **Create** a new schedule by clicking **Create Schedule**
- **Remove** a schedule by selecting the checkbox beside the schedule (to remove) and then by clicking **Remove Schedule**
- **Edit** a schedule by clicking the schedule name

Retrieving the List of Schedules Using the CLI or REST API

The basic command to retrieve a list of schedules is:

```
maprcli schedule list
```

For complete reference information, see [schedule list](#) on page 1949.

Creating a Schedule

Explains how to create a schedule using the Control System or the CLI.

Creating a Schedule Using the Control System

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors. To create a new schedule:

1. Log in to the Control System and go to the **Schedules** tab in the **Data > Volumes** page.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Schedule**.

The **Create Schedule** dialog displays.

3. Enter a name for the schedule in the **Schedule Name** text field.

4. Specify the schedule rules with the following components:

| | |
|-----------|--|
| Frequency | Specify frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes). |
|-----------|--|

| | |
|------------|---|
| Time | Specify the point of time within the specified frequency to perform the scheduled action. For example, if you selected Monthly from the first drop-down menu, select the day of the month from the second drop-down menu. Continue with each drop-down menu, proceeding to the right, to specify the time at which the scheduled action is to occur.  Note: This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily. |
| Retain for | Specify how long the data should be preserved. For example, if the schedule is attached to a volume for creating snapshots, the Retain for specifies how far after creation the snapshot expiration date is set. |

If necessary, click **Add Another** to add another rule to the schedule or  to remove a rule.

5. Click **Create Schedule** to create the schedule.

After the schedule is created, it appears as a choice in the scheduling menu when you are creating a new volume or editing a volume.

Creating a Schedule Using the CLI or REST API

The basic command to create a schedule is:

```
maprcli schedule create -schedule <JSON>
```

For complete reference information, see [schedule create](#) on page 1948.

Guidelines for Setting Mirror Schedules

Although MapR allows mirroring frequencies up to once per minute, setting a schedule at this frequency is not practical nor advisable. When you choose the mirror schedule, consider the amount of data on the volume and the load on the cluster. Remember that the mirroring frequency must allow enough time to complete one mirror operation before the next scheduled mirror operation starts. In addition, if you have a cascaded mirror setup (where A mirrors to B which mirrors to C), you cannot set a mirror schedule for C that starts before B finishes mirroring from A.

 **Warning:** In general, you should not set a mirror schedule for more often than every 30 minutes.

If you set a mirror schedule to start mirroring before the previous mirror operation finishes, you will see an error message similar to this:

```
WARN Alarms [pool-2-thread-1]: Alarm raised: VOLUME_ALARM_MIRROR_FAILURE;
Cluster: Cluster1; Volume: ; Message: Cannot start new scheduled mirror
because existing mirror is in progress
```

Modifying a Schedule

Explains how to modify a schedule using either the Control System or the CLI.

Modifying a Schedule Using the Control System

When you modify a schedule, the new set of rules replaces any existing rules for the schedule. To edit a schedule, in the **Schedules** tab under **Data > Volumes**:

 **Note:** The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Click the schedule name of the schedule to edit.
The **Edit Schedule** dialog displays.
2. Modify the schedule as desired:
 - a) Change the schedule name in the **Schedule Name** field.

- b) Add, modify, or remove rules in the **SCHEDULE RULE** section.

Here:

| | |
|-------------------|--|
| Frequency | Specifies the frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes). |
| Time | Specifies the point of time within the specified frequency to perform the scheduled action. This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily. |
| Retain for | Specifies how long the data should be preserved. |

To add another rule, click **Add Another** and to remove a rule, click .

3. Click **Save Changes** for the changes to take effect.

Modifying a Schedule Using the CLI or REST API

The basic command to modify a schedule is:

```
maprcli schedule modify -id <schedule ID> -rules <JSON>
```

For complete reference information, see [schedule modify](#) on page 1953.

Selecting an Existing Schedule to Associate with a Volume

Explains how to associate an existing schedule with a volume using the Control System, the CLI, or the REST API.

Selecting an Existing Schedule Using the Control System

1. Log in to the Control System and go to **Summary** tab in the [volume details](#) page.
2. Click the  (associated with the type of schedule in the **Schedules** pane) to display the **Edit Schedules** window.
3. Review the name and detail of each schedule and select a schedule from the list.
4. Click **Save Changes** to associate the schedule with the volume.

Selecting an Existing Schedule Using the CLI and REST API

CLI

You can associate a schedule with a volume using the `schedule` parameter when creating or editing a volume. For example:

```
maprcli volume create -name
<volName> -path <mountPath> -schedule
<scheduleID>
```

```
maprcli volume modify -name
<volName> -schedule <scheduleID>
```

REST

You can associate a schedule with a volume using the `schedule` parameter when creating or editing a volume. Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
```

```
name=<volName>&path=<volPath>&schedule
=<scheduleID>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&schedule=<scheduleID>'
--user mapr:mapr
```

For the complete list of all required and optional parameters, see [volume create](#) on page 2190 and [volume modify](#) on page 2275.

Removing one or more Schedules

Describes how to remove schedules not associated with any volumes using either the Control System or the CLI.

You can remove a schedule only if it is not associated with any volumes.

Removing one or more Schedules Using the Control System

To remove one or more schedules, in the **Schedules** tab under **Data > Volumes**:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

1. Select the schedule(s) to remove from the list of schedules.
2. Click **Remove Schedule** to display the **Remove Schedule** confirmation dialog.
3. Verify the list of schedules to remove click **Remove Schedule** to remove the schedules.
When you remove a schedule, the schedule is removed from the system and cannot be restored.

Removing one or more Schedules Using the CLI or the REST API

The basic command to remove a schedule by ID is:

```
maprcli schedule remove -id <schedule ID>
```

For complete reference information, see [schedule remove](#) on page 1954.

Managing Tiers

You can create, modify, and remove tiers using the Control System and the CLI.

Enabling Tiering

Describes how to enable data tiering using both the Control System and the CLI.

For a primer on Data Tiering, see [Data Tiering](#) on page 425.

On all new installations, the data tiering functionality is enabled and available for all new volumes. If you are upgrading, you must enable data tiering; see [Step 4: Enable New Features](#) on page 281 for more information. If the data tiering functionality is enabled, you can then selectively enable tiering for a volume at the time of volume creation using the Control system and the CLI.

Data tiering is only available for new volumes; you cannot enable data tiering for existing volumes. Enable tiering for new volumes where read/write latency is not the dominant concern. You can decide later whether you want to do local (or warm) or remote (or cold) tiering. Data tiering cannot be disabled after it is enabled for a volume.

Enabling Tiering Using the Control System

1. Move the **Data Tier** slider to **Yes** (to enable tiering) in the **Create New Volume** page in the Control System.

Proceed to the next step only if you wish to select a tier type for the volume. You can create a tiering-enabled volume without selecting a tier type and select a tier type later by editing the volume.

Note: You cannot disable tiering for a volume after it is enabled.

2. (Optional) Select **Erasure Coding** (for warm tiering) or **Remote Archiving** (for cold tiering) from the **Tiering Type** drop-down menu.

You:

- Can enable a volume for either warm or cold tiering, but not for both.
- Cannot modify the tier type after the volume is created.

3. Specify all other required and optional properties for creating the volume and click **Create Volume**.

For information on required and optional properties, see [Creating a Volume](#) on page 941.

Enabling Tiering Using the CLI

- Run the following command to enable tiering:

```
maprcli volume create -name <vol-name> -path <mount-path> -tieringenable true
```

For more information, see [volume create](#) on page 2190.

Introduction to Parallel Offload

The [MAST Gateway](#) uses parallel threads to rapidly offload tiering-enabled volumes to either cold or warm tiers.

Prior to HPE Ezmeral Data Fabric version 6.2, for any given volume, by default, only one MAST Gateway is used to offload the data. All tiering tasks such as offloads, recall, and compaction are scheduled only on that one assigned gateway. This causes multiple tasks to contend for limited threads on that assigned node, resulting in slowdowns. EC encoding performance is limited because of a single gateway. S3 offload throughput is limited as well. MAST Gateway utilization is skewed as some nodes may be idle, while others may be over utilized. When the assigned gateway goes offline, the volume is assigned a new gateway and the tasks are restarted.

To mitigate these issues with a single gateway, when a new cluster is setup with version 6.2 software, multiple MAST Gateways are used in parallel to offload the data of a single volume.

Parallel Offload uses one primary MAST Gateway and multiple secondary MAST Gateways per volume. The primary gateway coordinates tasks across secondary gateways and reports their final status to CLDB.

Only volume level offload tasks are sharded. File level tasks and all non-offload volume tasks are run on the primary gateway itself.

Advantages of Parallel Offload

Multiple MAST Gateways provide the following advantages:

- Increased per-volume throughput
- Leverage idle/unused cluster nodes
- Increased per-gateway efficiency

- Efficient usage of network bandwidth
- Leverage local reads to improve offload efficiency
- Only a subset of tasks need to be rescheduled if a gateway goes offline
- Resilient to failures
- Efficient volume and tasks level load balancing

Resiliency with Parallel Offload

Parallel Offload is resilient to the following scenarios:

Restart of the Primary Gateway

- Secondary gateways continue to run assigned tasks while the primary gateway is down or restarting.
- CLDB reassigns the volume to another primary gateway.
- CLDB restarts the tasks on the new primary gateway.
- The primary gateway polls/reschedules the ongoing secondary gateway tasks.

Restart of the Secondary Gateway

- The primary gateway detects the failure of secondary gateway tasks when it polls the secondary gateway.
- The primary gateway reschedules tasks that were terminated when the secondary gateway restarted.

Restart/Switchover of CLDB

- Reassign volume to the same primary gateway.
- Reschedule pending volume task on the same primary gateway.

Load Balancing with Parallel Offload

Load Balancing involves:

Volume Level

- CLDB assigns each volume to a gateway with the least number of volumes.
- Gateway Balancer reassigns volumes across gateways.

Task Level

CLDB balances tasks across MFS nodes.

Enabling Parallel Offload on an Upgraded Cluster

When the cluster is upgraded to version 6.2 from a previous release, only one MAST Gateway is used to offload the data of a single volume. To use multiple MAST Gateways, to offload a volume's data in parallel, you have to enable parallel offloads feature:

```
maprcli cluster feature enable -name mfs.feature.container.sharding.support
```

To check whether parallel offloads are enabled, run:

```
maprcli config load -json | grep -i shard
```

A value of 0 indicates that parallel offloads are enabled. For example:

```
"mastgateway.disable.sharding": "0"
```

Creating a Storage Tier

Describes how to create a storage tier using the Control System and the CLI.

For a primer on Data Tiering, see [Data Tiering](#).

You can create a tier using the Control System and the CLI.

When you create a tier, filesystem creates a volume, whose mount point is `/var/mapr/tier/mapr.internal.tier.<tiername>`, for the tier. For warm tier volumes automatically created using the `ecenable` parameter or the Control System, by default, a corresponding tier volume named `mapr.internal.tier.autoec.<volName>.<creationTime>` is created in the `/var/mapr/autoectier` path. The tier volume is visible and stores all the metadata tables and information on all the jobs running on the tier. Do not modify, move, or remove this volume.

Note: If the number of cluster nodes is more than five, by default, HPE Ezmeral Data Fabric (through the `enforceminreplicationforio` parameter) requires minimum number of copies of the tier volume for writes to succeed. If the number of cluster nodes is less than five, HPE Ezmeral Data Fabric does not enforce minimum number of copies for writes to succeed.

Creating a Warm Tier Using the Control System

When you create a volume enabled for erasure coding, the control system automatically creates a warm tier and associates the volume with that tier. See [Creating a Volume](#) on page 941 for more information. You cannot create a warm tier separately using the Control System.

Creating a Cold Tier Using the Control System

To create a cold tier:

- Log in to the Control System, click **Data > Volumes**, and then do one of the following:
 - Go to the **Remote Targets** tab if you wish to create a remote target that is not (yet) associated with a volume.
 - Click **Create Volume** if you wish to create a remote target for a volume when you are creating the volume.
 - Note:** You must enable data tiering and select **Remote Archiving (Cold)** from the **Tiering Type** drop-down list to create the remote target.
 - Click **Edit Volume** in the [volume information page](#) if you want to create a remote target for the volume when you are editing the volume settings.
 - Note:** You can create a remote target only if a remote target is already not associated with the volume.
- Click one of the following to display the **Create Remote Target** window.
 - Create Target** if you are in the **Remote Targets** tab.
 - Create** link associated with the **Remote Target** field if you are in the **Create New Volume** page.
 - Create** link associated with the **Remote Target** field if you are in the **Edit Volume** page.

3. Specify a name for the tier in the **Remote Target Name** field.
4. Select a topology for the metadata volume associated with the tier from the list of topologies in the **Lookup Topology** drop-down menu.

The volume stores all the metadata tables and information on all the jobs running on the tier. If many volumes share the same tier (and thus the same lookup topology), the lookups might have an adverse affect by inadvertently adding background load to nodes in that topology. This property allows you to setup the lookups on other nodes.

5. Specify the following properties.

| | |
|--------------------|--|
| Vendor | <p>The vendor from the Vendor drop-down list.</p> <p> Note: For cold tiering, HPE Ezmeral Data Fabric supports the following vendors:</p> <ul style="list-style-type: none"> • AWS (Amazon AWS) • GCS (Google Cloud Platform) • HDS (Hitachi HCP) • IBM (IBM Cleversafe) • Azure Blob (Microsoft Azure) • Others (such as Minio) <p>See Specifying the Vendor/Object Store for a Cold Tier on page 1049 for more information on the supported vendors.</p> |
| URL | <p>The URL to use to connect to the tier in the following format:</p> <pre data-bbox="831 1136 1367 1178"><protocol>://<IP hostname>.<domain></pre> <p>If the protocol is <code>https</code>, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold-tier storage does not support HTTPS, all tier related operations will fail. If the cold tier does not support HTTPS, set the protocol to <code>http</code>.</p> <p>See Specifying the Vendor/Object Store for a Cold Tier on page 1049 for more information on the tier endpoint URLs and supported authentication protocols.</p> |
| Bucket Name | <p>The name of the bucket on the tier. This cannot be modified once associated with a tier. If the bucket does not already exist on the tier, HPE Ezmeral Data Fabric will attempt to create the bucket.</p> <p> Note: For Azure, the bucket/container is created in the region that is specified in the parent storage account.</p> |
| Region | <p>The S3 region to create the bucket on. This cannot be modified once configured (explicitly or using the default) and associated with a tier. See region on page 1048 for more information.</p> |

- Enter the credentials for accessing the tier in the **Access Key** and **Secret Key** fields.

Tip: For Azure Blobs, the storage account name is the access key.

- Click **Create Target** to create the cold tier that you can associate with a volume.

Creating a Tier Using the CLI and the REST API

CLI

Run the following command to create a tier:

- Cold tier:

```
$maprcli tier
create -name <tier_name> -type
cold -url <tier_url> -credential
<credentials_file_path>
```

For using the `-credential` option, you must have the credential file already set up as described in [Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API](#) on page 1047. On the other hand, if you do not have the file already set up, use the `-credential_str` option as follows:

```
$maprcli tier create -name
<tier_name> -type cold -url
<tier_url> -credential_str
'<credential_string>'
```

- Warm tier with default values:

```
$maprcli tier create -name
<tier_name> -type ectier
```

Note: You can associate the same tier with multiple volumes with different erasure coding scheme.

REST

Send a request of type POST. For example:

- Cold Tier:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=egColdTier&type=cold&url=s3.am
azonaws.com&credential=credentials.
txt' --user mapr:mapr
{"timestamp":1525724933919,"timeofd
ay":"2018-05-07 01:28:53.919
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egColdTier'"]}
```

- Warm tier:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=egWarmTier&type=ectier' --user
mapr:mapr
{"timestamp":1525725105206,"timeofd
ay":"2018-05-07 01:31:45.206
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egWarmTier'"]}
```

Note: You can associate the same tier with multiple volumes with different erasure coding scheme.

For more information, see [tier create](#) on page 2131.

Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API

Describes how to create a credential file, with examples for AWS and Microsoft Azure.

Set up a credentials file on the host you plan to use for creating the cold tier if you are planning on using the `credential` option (and not pass the credentials on the command-line using the `credential_str` option).

For example, your `credentials.txt` file for AWS should look similar to the following sample file:

```
{
  "bucketName" : "defaultbucket3",
  "region": "us-east-1",
  "credentials" : {
    "accessKey" : "AB956CDE8F2GO7H9I4J2",
    "secretKey" : "5K1LmN92e65oPQRsTUvOfSbURxyEtYl2MmAocGi"
  }
}
```

The sample for Microsoft Azure is as follows:

```
maprcli tier create -name tier_azure_1 -type cold -url https://
myobjectpools1.blob.core.windows.net -credential ~/creds_azure.txt
$ cat creds_azure.txt
{
  "bucketName" : "bucket4",
  "credentials" : {
    "accessKey" : "myobjectpools1",
    "secretKey" :
"N6GKkDPttqNc6rfTzhh2JNKwvdr9EraN89Mg8WaoDRVpBeINBTZwhQu+Q3vX4ENeW+RQN42f+P8
nXN0YasZWNA=="
  }
}
```

The credentials file (`.txt` file) contains the following properties in JSON format:

bucketName

The name of the bucket on the tier. If the bucket does not already exist on the tier, the command to create the tier attempts to create the bucket using the credentials in the credentials file. You can modify the name of the bucket only by using the `-force` option with the [tier modify](#) on page 2139 command

region

The S3 region to create the bucket on. Use the information in the following table to specify region information.

| Vendor | Default Value | Notes |
|--------|---------------|---|
| AWS | us-east-1 | <p>Specify region information as defined here.</p> <p>On AWS, each region can have a different URL. The URL must be provided with the <code>maprcli tier create</code> command.</p> <p> Note: Because bucket names are unique across regions, make sure you specify the correct region for a given bucket in the credentials file. For example, suppose a bucket called <code>myBucket3</code> in <code>us-east-1</code>; you cannot offload data to <code>myBucket3</code> by specifying <code>us-west-1</code> as the region in the credentials file.</p> |
| GCS | us-east-1 | Specify region information as described here . |
| HDP | N/A | Not required. If specified, MapR ignores the value. |

| Vendor | Default Value | Notes |
|-------------|----------------|---|
| IBM | us-east-region | Not required. If specified, MapR ignores the value. |
| Azure-Blobs | N/A | Not required. The region of the storage account is determined from the URL and data is offloaded into that region. |
| Minio | us-east-1 | If you specify region, export the MINIO_REGION environment variable on the minio server as described in the Configuration Guide . |
| Scality | us-east-region | Not required. If specified, MapR ignores the value. |

You can modify the region only by using the `-force` option with the `tier modify` on page 2139 command.

accessKey and secretKey

The credentials for accessing the tier.

Tip: For Azure Blobs, the storage account name is the access key.

 **Note:** Once the tier is created, MapR does not require this file because CLDB stores the bucket, region, and credentials information.

Specifying the Vendor/Object Store for a Cold Tier

Specify the vendor or object store where you plan to offload the (cold) data. The following table lists the supported vendors, URL of the tier endpoint, and authentication protocol supported by MapR:

| Supported Vendor/Object Store | Tier URL/Endpoint | Supported Authentication Protocol |
|-------------------------------|---|---|
| AWS (Amazon AWS) | <p>The URL varies based on the region. For:</p> <ul style="list-style-type: none"> • us-east-1: https://s3.amazonaws.com • us-east-2: https://s3.us-east-2.amazonaws.com • us-west-1: https://s3-us-west-1.amazonaws.com • us-west-2: https://s3-us-west-2.amazonaws.com • ap-south-1: https://s3.ap-south-1.amazonaws.com • ap-southeast-1: https://s3-ap-southeast-1.amazonaws.com • ap-southeast-2: https://s3-ap-southeast-2.amazonaws.com • ap-northeast-1: https://s3-ap-northeast-1.amazonaws.com • ap-northeast-2: https://s3-ap-northeast-2.amazonaws.com • ap-northeast-3: https://s3.ap-northeast-3.amazonaws.com • ca-central-1: https://s3.ca-central-1.amazonaws.com • cn-north-1: https://s3.cn-north-1.amazonaws.com • cn-northwest-1: https://s3.cn-northwest-1.amazonaws.com • eu-central-1: https://s3.eu-central-1.amazonaws.com • eu-west-1: https://s3-eu-west-1.amazonaws.com • eu-west-2: https://s3.eu-west-2.amazonaws.com • eu-west-3: https://s3-eu-west-3.amazonaws.com | <ul style="list-style-type: none"> • HTTP • HTTPS |

| Supported Vendor/Object Store | Tier URL/Endpoint | Supported Authentication Protocol |
|-------------------------------|---|---|
| GCS (Google Cloud Platform) | https://storage.googleapis.com | <ul style="list-style-type: none"> • HTTP • HTTPS |
| HDS (Hitachi HCP) | http://<hcptenant>.<hcphostname> https://<hcptenant>.<hcphostname> | <ul style="list-style-type: none"> • HTTP • HTTPS |
| IBM (IBM Cleversafe) | http://lbl.ait.cleversafelabs.com | HTTP |
| Azure Blob (Microsoft Azure) | https://<azureaccount>.blob.core.windows.net | <ul style="list-style-type: none"> • HTTP • HTTPS |
| Minio | http://10.10.88.198:9000 | HTTP |
| Scality | https://<scality-instance-hostname>:8000 | HTTP |

Viewing the List of Tiers

Describes how to view the list of tiers using the Control System, the CLI, and the REST API.

For a primer on Data Tiering, see [Data Tiering](#).

In the Control System, you can only see the list of cold tiers (referred to as remote targets). Use the CLI or REST API to retrieve the list of both cold and warm tiers.

Viewing the List of Remote Targets Using the Control System

- Log in to the Control System and click **Data > Volumes > Remote Targets**.

The page displays the following for each remote target:

| Column Name | Column Description |
|--------------------------------|---|
| Remote Target Name | The name of the remote target. |
| External Storage Vendor | The name of the third-party storage vendor. |
| Bucket | The name of the bucket. |
| Region | The region where the bucket resides. |
| URL | The URL of the remote target. |

You can:

- [Create a remote target](#)
- [Remove a remote target](#)

Viewing the List of Tiers Using the CLI and REST API

CLI

Run the following command to retrieve the list of (warm and cold) tiers:

```
/opt/mapr/bin/maprcli tier list
```

REST

Send a request of type GET. For example:

```
# curl -k -X GET 'https://
10.10.82.24:8443/rest/tier/
list' --user mapr:mapr
{"timestamp":1525725765483,"timeofday":
"2018-05-07 01:42:45.483 GMT-0700
PM","status":"OK","total":0,"data":
[{"tierid":"79082078","tiername":"egWa
rmTier","tiertype":"ectier","volume":"
mapr.internal.tier.egWarmTier","topolo
gy":"/data"},
{"tierid":"120198852","tiername":"egCo
ldTier","tiertype":"cold","url":"s3.am
azonaws.com","bucketname":"ksekhar-tes
t","region":"us-east-1","volume":"mapr
.internal.tier.egColdTier","topology":
"/data","objectstoretype":"S3_AWS"},
{"tierid":"158778422","tiername":"auto
ec.vol_tiered.1525463214","tiertype":"
ectier","volume":"mapr.internal.tier.a
utoec.vol_tiered.1525463214","topology
":"/data"}]}
```

For more information, see [tier list](#) on page 2137.

Editing a Tier

Describes how to modify a cold tier using the Control System, the CLI and the REST API.

For a primer on Data Tiering, see [Data Tiering](#).

You cannot modify a warm tier. You can modify a cold tier (referred to as Remote Target in the Control System) using the Control System, the CLI, and REST API.

Modifying a Remote Target Using the Control System

1. Log in to the Control System and go to the **Remote Target** tab under **Data > Volumes**.
2. Click the name of the remote target (cold tier) to display the **Edit Remote Target** window.
3. Make necessary changes to the **CREDENTIALS**.
4. Click **Save Changes** to save the changes.

Modifying a Cold Tier Using the CLI and REST API**CLI**

Run the following command to modify a cold tier:

```
$maprcli tier
modify -name <tier_name> -credential
<credentials_file_path>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/modify?
name=<tier_name>&credential_str=<JSON>
' --user mapr:mapr
```

For more information, see [tier modify](#) on page 2139.

Specifying a Tier

Describes how to associate a tier with a tiering-enabled volume using the Control System and the CLI.

Note:

For a primer on Data Tiering, see [Data Tiering](#).

Using the Control System, you can only associate an existing tier (referred to as **Remote Target** in the Control System) with a volume enabled for Remote Archiving (or cold-tier). You cannot associate an existing tier with a volume enabled for Erasure Coding (or warm-tier) because the Control System allows a new tier to be automatically created when you enable a volume for erasure coding. If you want to associate an existing tier with a volume enabled for erasure coding, use the CLI or REST API to create the volume.

Specifying a Remote Target Using the Control System

You can associate a remote target with a cold-tier enabled volume when you are:

- Creating the volume by clicking **Create Volume** button in the **Data > Volumes** page.
- Editing the volume by clicking **Edit Volume** button in the [volume information page](#).

To associate a remote target with the volume, in the **Create Volume** or **Edit Volume** page:

1. Click the **Browse** link associated with the **Remote Target** field to display the **Browse Remote Target** window.
2. Review the name, vendor, bucket, region, and URL for each remote target and choose a remote target from the list.
3. Click **Select** to associate the remote target with the volume.
4. Complete the steps for [creating](#) or [editing](#) the volume.

Specifying a Tier Using the CLI and REST API

You can associate an existing tier with a volume when you are creating the tiering-enabled volume. You can associate an existing tier with a tiering-enabled volume when you are editing the volume only if the volume does not already have a tier associated with it. To associate an existing tier, you must specify the `tiername` parameter with the command.

CLI

Run a command similar to the following to associate a tier when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername <tierName> -json
```

For the list of all other required and optional parameters, see [volume create](#) on page 2190.

- Editing the volume:

```
maprcli volume
modify -name <volName> -tiername
<tierName> -json
```

For the list of all other required and optional parameters, see [volume modify](#) on page 2275.

REST

Send a request of type POST. For example, to associate a tier when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
mapr:mapr
```

For the list of all other required and optional parameters, see [volume create](#) on page 2190.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

For the list of all other required and optional parameters, see [volume modify](#) on page 2275.

Removing a Tier

Describes how to remove a tier that is not associated with a tier, using the Control System, the CLI and the REST API.

For a primer on Data Tiering, see [Data Tiering](#).

You can remove a tier that is not associated with a volume, using the Control System, the CLI, and REST API. In the Control System, a cold tier is referred to as remote target and you can only remove remote targets (or cold tiers) using the Control System. Use the CLI or REST API to remove cold and warm tiers.

Removing a Remote Target Using the Control System

1. Log in to the Control System and click **Data > Volumes > Remote Targets** to display the list of remote targets.
2. Select the checkbox associated with the tier to delete.
Selecting the checkbox associated with a tier makes the **Remove Target** button available.
3. Click **Remote Target** to display the **Remove Remote Target** confirmation dialog.
4. Verify the list of remote targets to remove and click **Remove**.

Removing a Tier Using the CLI and REST API

CLI

Run the following command to remove a tier:

```
/opt/mapr/bin/maprcli tier
remove -name <tier-name>
```

You cannot remove a tier associated with a volume. If you run the command to remove a tier that is associated with a volume, the command returns an error (shown in **bold**) similar to the following:

```
{
  "timestamp":1516771078126,
  "timeofday":"2018-01-23
09:17:58.126 GMT-0800",
  "status":"ERROR",
  "errors":[{"
    "id":10003,
    "desc":"Cannot remove tier,
as some volumes are still using it."
  }]}
}
```

REST API

Send a request of type POST to remove a tier. For example:

```
curl -k -X
POST 'https://abc.sj.us:8443/rest/
tier/remove?name=ksTestTier' --user
mapr:mapr
```

You cannot remove a tier associated with a volume. If you send a request to remove a tier that is associated with a volume, an error (shown in **bold**) similar to the following is returned:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/remove?
name=ksTestTier' --user mapr:mapr
{"timestamp":1524675381333,"timeofday"
:"2018-04-25 09:56:21.333 GMT-0700

For more information, see [tier remove](#) on page 2142.

Managing Storage Policies

Data offload is driven by rules, which are configured per volume. Data offload rule can be based on size of file (**s**), owner (**u**, **g**, or **p**) of the file, and/or file modification timestamp (**m**). You can apply one rule per volume.

When a rule is associated with a volume, the rule is first applied on the files in the tiering-enabled volume. When applied on the files in the tiering-enabled volume, the offload is triggered for all files in the snapshot chain as well when the criteria in the rule is met. If the file does not exist in the tiering-enabled volume, rule is applied on the latest state of the file in the snapshot chain. If the file exists in the tiering-enabled volume but has no latest state or if the file was deleted in the tiering-enabled volume, offload does not happen.

Rules can be defined using a combination of the following:

| | |
|---|--|
| u | <p>Username or user ID, as configured in the OS registry (such as <code>/etc/passwd</code> file, LDAP, etc.), of a specific user.</p> <p>Usage: <code>u:<username or user ID></code></p> |
| g | <p>Group name or group ID, as configured in the OS registry (such as <code>/etc/group</code> file, LDAP, etc.), of a specific group.</p> <p>Usage: <code>g:<groupname or group ID></code></p> |
| a | <p>(<code>atime</code>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <code>s</code> to value and the number of days can be specified by appending <code>d</code> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "a:<value>s" — specifies <code>atime</code> in seconds • "a:<value>d" — specifies <code>atime</code> in days <p> Note: If the system time on CLDB and file server nodes are different, the <code>atime</code> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> 1. <code>atime</code> tracking is enabled at volume level 2. Time since <code>atime</code> that is configured on the volume is more than the time specified in the rule 3. Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <code>atime</code> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <code>atime</code> tracking is enabled, is more than 300s. The volume level parameter <code>atimeTrackingStartTime</code> denotes the start time of <code>atime</code>.</p> <p>For more information, see Tuning Last Access Time on page 448.</p> |

| | |
|---|--|
| m | <p>(mtime) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <code>s</code> to value and the number of days can be specified by appending <code>d</code> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> "m:<value>s" — specifies mtime in seconds "m:<value>d" — specifies mtime in days <p>All files that are not modified since the specified amount of time, are offloaded.</p> <p> Note: If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.</p> |
| s | <p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: <code>b</code> for bytes, <code>k</code> for kilobytes, <code>m</code> for megabytes, or <code>g</code> for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "s:<value>b" — specifies file size in bytes "s:<value>k" — specifies file size in KB "s:<value>m" — specifies file size in MB "s:<value>g" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p> |

Or, use the following:

| | |
|-----|---|
| p | (Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator. |
| " " | Indicates none of the files. Specifies that this operation cannot be performed on any of the files. |

Use the following to string multiple criteria for offload:

| | |
|-----|--|
| & | AND operation to combine multiple expressions as the criteria for the rule. |
| | OR operation to indicate either of the expressions as the criteria for the rule. |
| () | Delimiters for subexpressions. |

For volumes configured for erasure coding, a default storage policy, `default.ectier.rule` (ID 1 and expression `p`), is applied if one is not specified.

You can create, associate, and remove rules using the MapR Control System, the CLI, and REST API.

Creating a Storage Tier Policy

Explains how to create a tiering policy for storage using either the Control System, the CLI, or the REST API.

Creating a Storage Tier Policy Using the Control System

To create a storage tier policy (or rule) using the Control System:

1. Log in to the Control System, click **Data > Volumes**, and then do one of the following:

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- Go to the **Storage Policies** tab if you wish to create a storage policy that is not (yet) associated with a volume.
- Click **Create Volume** if you wish to create a storage policy for a volume when you are creating the volume.

Note: You must enable data tiering to create the storage policy.

- Click **Edit Volume** in the [volume information page](#) if you wish to create a storage policy for a volume when you are editing the volume settings.
2. Click one of the following to display the **Create Storage Policy** dialog.
 - **Create Policy** if you are in the **Storage Policies** tab.
 - **Create** link associated with the **Storage Policy** field if you are in the **Create New Volume** page.
 - **Create** link associated with the **Storage Policy** field if you are in the **Edit Volume** page.
 3. Enter a name for the storage policy in the **Storage Policy Name** text field.
 4. Choose **Build rule** or **Rule expression** radio button to define the criteria for offloading data. Use the **Build rule** option to build simple rules. Click `Add Condition` to add one of the following entities:
 - Group
 - User
 - File size
 - Time since the file was modified
 - Time since the file was accessed

Use a condition group, to add AND and OR conditions.

Click `Add condition group` to add AND and OR conditions. You can toggle the AND and OR conditions as needed.

Use the **Rule expression** option to create advanced rules that comprise a combination of the following expressions:

| | |
|---|---|
| u | Username or user ID, as configured in the OS registry (such as <code>/etc/passwd</code> file, LDAP, etc.), of a specific user. Usage: u:<username or user ID> |
|---|---|

| | |
|---|---|
| g | <p>Group name or group ID, as configured in the OS registry (such as <code>/etc/group</code> file, LDAP, etc.), of a specific group.</p> <p>Usage: <code>g:<groupname or group ID></code></p> |
| a | <p>(<code>atime</code>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <code>s</code> to value and the number of days can be specified by appending <code>d</code> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • <code>"a:<value>s"</code> — specifies <code>atime</code> in seconds • <code>"a:<value>d"</code> — specifies <code>atime</code> in days <p> Note: If the system time on CLDB and file server nodes are different, the <code>atime</code> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> <code>atime</code> tracking is enabled at volume level Time since <code>atime</code> that is configured on the volume is more than the time specified in the rule Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <code>atime</code> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <code>atime</code> tracking is enabled, is more than 300s. The volume level parameter <code>atimeTrackingStartTime</code> denotes the start time of <code>atime</code>.</p> <p>For more information, see Tuning Last Access Time on page 448.</p> |
| m | <p>(<code>mtime</code>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <code>s</code> to value and the number of days can be specified by appending <code>d</code> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • <code>"m:<value>s"</code> — specifies <code>mtime</code> in seconds • <code>"m:<value>d"</code> — specifies <code>mtime</code> in days <p>All files that are not modified since the specified amount of time, are offloaded.</p> <p> Note: If the system time on CLDB and file server nodes are different, the <code>mtime</code> rule for offloading data may not work as intended.</p> |

| | |
|---|--|
| s | <p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: <code>b</code> for bytes, <code>k</code> for kilobytes, <code>m</code> for megabytes, or <code>g</code> for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "s:<value>b" — specifies file size in bytes "s:<value>k" — specifies file size in KB "s:<value>m" — specifies file size in MB "s:<value>g" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p> |
|---|--|

Or, use the following:

| | |
|-----|---|
| p | (Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator. |
| " " | Indicates none of the files. Specifies that this operation cannot be performed on any of the files. |

Use the following to string multiple criteria for offload:

| | |
|-----|--|
| & | AND operation to combine multiple expressions as the criteria for the rule. |
| | OR operation to indicate either of the expressions as the criteria for the rule. |
| () | Delimiters for subexpressions. |

If a rule is not defined, the default rule, which is all files (p), is associated with the storage policy.

5. Click **Create Policy** to create the storage policy.

Creating a Rule Using the CLI and REST API

CLI

Run the following command to create a rule:

```
$ maprcli tier rule create -name
<rule_name> -expr <expressions>
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule1&expr=m:365d' --user
mapr:mapr
{"timestamp":1519681475025,"timeofday":
"2018-02-26 01:44:35.025 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule1'"]}
```

For more information, see [tier rule create](#) on page 2143.

Viewing the List of Storage Tier Policies

Explains how to view tiering policies for storage using either the Control System, the CLI, or the REST API.

Viewing the List of Storage Tier Policies Using the Control System

- Log in to the Control System and click **Data > Volumes > Storage Policies**.

Note: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

The list of storage policies displays. For each storage policy, the page displays the following:

| Column Name | Column Description |
|-------------|-------------------------|
| Policy Name | The name of the policy. |
| Detail | The policy details. |

You can:

- [Create a Policy](#)
- [Edit a Policy](#)
- [Remove a Policy](#)

Viewing the List of Storage Tier Policies Using the CLI and REST API

CLI

Run the following command to retrieve the list of tiers:

```
# maprcli tier rule list
```

REST

Send a request of type GET. For example:

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/rule/
list' --user mapr:mapr
{"timestamp":1525728727729,"timeofday"
:"2018-05-07 02:32:07.729 GMT-0700
PM","status":"OK","total":6,"data":
[{"ruleid":"1","rulename":"default.ect
ier.rule","expression":"m:1d"},
{"ruleid":"2","rulename":"rule2","expr
ession":"s:5g"},
{"ruleid":"3","rulename":"rule1","expr
ession":"m:365d"},
{"ruleid":"4","rulename":"rule3","expr
ession":"u:m7user1"},
{"ruleid":"5","rulename":"rule4","expr
ession":"p"},
{"ruleid":"6","rulename":"testRule","e
xpression":"u:m7user1 | (u:mapr &
(s:5g | m:365d))"}]}
```

For more information, see [tier rule list](#) on page 2149.

Modifying a Storage Tier Policy

Explains how to modify a storage tier policy using either the Control System, CLI, or the REST API.

If you modify a rule that is currently in use, the changes in the rule are only applied on future offloads; data offloaded using existing rule is not impacted by the change in the rule.

Modifying a Rule Using the Control System

1. Log in to the Control System and go to **Storage Policies** tab in the **Data > Volumes** page.

Note: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

The list of storage policies displays.

2. Click the storage policy name to display the **Edit Storage Policy** window.
3. Make changes to the rule:

You can modify the basic rule to:

- Add (+) or remove (-) users and/or groups.
- Change the name of the users and/or groups.
- Change the number of days since the file was last modified for users and/or groups.

If you switch from a basic rule to an advanced rule, all expressions from the basic rule are carried over to the advanced rule. You can modify an advanced rule using a combination of the following expressions:

| | |
|---|--|
| u | Username or user ID, as configured in the OS registry (such as <code>/etc/passwd</code> file, LDAP, etc.), of a specific user. Usage: u:<username or user ID> |
| g | Group name or group ID, as configured in the OS registry (such as <code>/etc/group</code> file, LDAP, etc.), of a specific group. Usage: g:<groupname or group ID> |

| | |
|---|---|
| a | <p>(<i>atime</i>) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "a:<value>s" — specifies <i>atime</i> in seconds • "a:<value>d" — specifies <i>atime</i> in days <p> Note: If the system time on CLDB and file server nodes are different, the <i>atime</i> rule for offloading data may not work as intended.</p> <p>This tier rule is matched and files are offloaded, when all of the following conditions are met:</p> <ol style="list-style-type: none"> <i>atime</i> tracking is enabled at volume level Time since <i>atime</i> that is configured on the volume is more than the time specified in the rule Duration since the file was last accessed is more than the time specified in the rule <p>Assume that the <i>atime</i> feature is enabled on the volume and that the time in the rule is set to a:300s. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since <i>atime</i> tracking is enabled, is more than 300s. The volume level parameter <i>atimeTrackingStartTime</i> denotes the start time of <i>atime</i>.</p> <p>For more information, see Tuning Last Access Time on page 448.</p> |
| m | <p>(<i>mtime</i>) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending <i>s</i> to value and the number of days can be specified by appending <i>d</i> to the value.</p> <p>Usage:</p> <ul style="list-style-type: none"> • "m:<value>s" — specifies <i>mtime</i> in seconds • "m:<value>d" — specifies <i>mtime</i> in days <p>All files that are not modified since the specified amount of time, are offloaded.</p> <p> Note: If the system time on CLDB and file server nodes are different, the <i>mtime</i> rule for offloading data may not work as intended.</p> |

| | |
|----------------|--|
| <code>s</code> | <p>The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: <code>b</code> for bytes, <code>k</code> for kilobytes, <code>m</code> for megabytes, or <code>g</code> for gigabytes.</p> <p>Usage</p> <ul style="list-style-type: none"> "<code>s:<value>b</code>" — specifies file size in bytes "<code>s:<value>k</code>" — specifies file size in KB "<code>s:<value>m</code>" — specifies file size in MB "<code>s:<value>g</code>" — specifies file size in GB <p>All files whose size exceeds the specified size are offloaded.</p> |
|----------------|--|

Or, use the following:

| | |
|------------------|---|
| <code>p</code> | (Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator. |
| <code>" "</code> | Indicates none of the files. Specifies that this operation cannot be performed on any of the files. |

Use the following to string multiple criteria for offload:

| | |
|--------------------|--|
| <code>&</code> | AND operation to combine multiple expressions as the criteria for the rule. |
| <code> </code> | OR operation to indicate either of the expressions as the criteria for the rule. |
| <code>()</code> | Delimiters for subexpressions. |

You cannot switch from an advanced rule that includes the following to a basic rule because the following are not supported in a basic rule:

- `p` — All the files
- `s` — The size of the file
- `&` — The AND operation used for specifying multiple users (`u`), groups (`g`), or criteria
- `|` — The OR operation used with `s` or `m`
- `" "` — None of the files.
- `()` — Subexpressions

Note: The basic rule must contain `mtime` (`m`). It can also include one or more users or groups separated by the OR operation (`|`).

4. Click **Save Changes** to save the storage policy changes.

Modifying a Rule Using the CLI and the REST API

CLI

Run the following command to modify a storage policy:

```
$ maprcli tier rule modify -name
<rule_name> -json
```

REST API

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/modify?
name=sampleRule&expr=m:3d' --user
mapr:mapr
{"timestamp":1523587392465,"timeofday"
:"2018-04-12 07:43:12.465 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
rule: 'sampleRule'"]}
```

For more information, see [tier rule modify](#) on page 2150.

Specifying a Storage Tier Policy

Explains how to associate a storage tier policy with a tiering-enabled volume using either the Control System or the CLI.

Specifying a Storage Tier Policy Using the Control System

You can associate a storage policy with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** in the **Data > Volumes** page.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- Editing the tiering-enabled volume by clicking **Edit Volume** button in the [volume information page](#).

To associate a storage policy with the volume, in the **Create Volume** or **Edit Volume** page:

1. Click the **Browse** link associated with the **Storage Policy** field to display the **Browse Storage Policies** window.
2. Review the name and detail of each storage policy and choose a storage policy from the list.
3. Click **Select** to associate the storage policy with the volume.
4. Complete the steps for [creating](#) or [editing](#) the volume.

Specifying a Storage Tier Policy Using the CLI and REST API

You can associate a rule with a tiering-enabled volume by specifying the `tieringrule` parameter with the [volume create](#) on page 2190 or [volume modify](#) on page 2275 command.

CLI

Run a command similar to the following to associate a rule when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -tieringrule
<ruleName> -json
```

For the list of all other required and optional parameters, see [volume create](#) on page 2190.

- Editing the volume:

```
maprcli volume modify -name
<volName> -tieringrule
<ruleName> -json
```

For the list of all other required and optional parameters, see [volume modify](#) on page 2275.

REST

Send a request of type POST. For example, to associate a rule when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
mapr:mapr
```

For the list of all other required and optional parameters, see [volume create](#) on page 2190.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

For the list of all other required and optional parameters, see [volume modify](#) on page 2275.

Removing a Storage Policy

Explains how to remove tiering policies for storage using either the Control System, the CLI, or the REST API.

Warning: You cannot remove a storage policy that is associated with a volume.

Removing a Rule Using the Control System

1. Log in to the Control System and go to **Storage Policies** tab under **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The list of storage policies displays.

2. Select the checkbox associated with the storage policy to remove and click **Remove Policy**. The **Remove Policy** confirmation window displays.
3. Review the list of policies to remove and click **Remove**.

Removing a Rule Using the CLI and the REST API

CLI

Run the following command to remove a storage policy that is not associated with a volume:

```
# maprcli tier rule remove -name
<rule_name>
```

If you try to remove a rule associated with a volume, the command returns an error (shown in bold) similar to the following:

```
# maprcli tier rule remove -name
rule1 -json
{
  "timestamp":1516771655669,
  "timeofday":"2018-01-23
09:27:35.669 GMT-0800",
  "status":"ERROR",
  "errors":[{"
    "id":10003,
    "desc":"Cannot remove rule, as
some volumes are still using it."
  }]}
}
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571783113,"timeofday"
:"2018-04-12 03:23:03.113 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully deleted
rule: 'sampleRule'"]}
```

If you try to remove a storage policy associated with a volume, the response contains an error (shown in bold) similar to the following:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571741636,"timeofday"
:"2018-04-12 03:22:21.636 GMT-0700
PM","status":"ERROR","errors":
```

```
[{"id":10003,"desc":"Can not remove rule, as some volumes are still using it."}]}
```

For more information, see [tier rule remove](#) on page 2152.

Using Storage Labels

Describes the Storage Labels feature.

Synopsis of the Storage Labels Feature

Different applications have different requirements such as low latency, high throughput, and low variance in response times. Storage devices with various characteristics, for example SSD over SATA or SSD over NVME, are available as off-the-shelf storage. Therefore, it is now possible to cater exactly to the storage requirements of each application.

The Storage Label feature allows you to store particular kinds of data on particular classes of devices. For example, you could place data that needs to be fetched with lower latency on Solid State Drives (SSD), while placing data that can afford to be fetched with higher latency on Hard Disk Drives (HDD). Both classes of devices can be on the same node.

Use Cases for Storage Labels

Example use cases include:

- Latency-sensitive data can be placed on SSD, while data that is very rarely read can be placed on HDD.
- Active (warm) data can be placed on SSD while rarely used (cold) and archived data can be placed on HDD.
- Local volumes for Map Reduce tasks can be placed on SSD.
- Data can be securely segregated. For example, all finance data can be placed on volumes marked *finance*, engineering data on volumes marked *engineering*, and HR on volumes marked *HR*.

Components of the Storage Labels Feature

Storage Labels help you confine volumes to specific storage pools, to meet your desired objectives (such as low latency).

The Storage Labels feature has three main components: Labels, Storage Pools and Volumes.

What is a Label?

The Label acts as the bridge between a Storage Pool and a Volume.

The Label is a tag that associates a Volume with a Storage Pool. For example, a volume marked *SSD* will always be placed on a Storage Pool marked with the name *SSD*.

Labels have the following characteristics:

- Are a string of printable ASCII characters that should begin with a letter or a number in most cases, except when they represent device classes. For a device class, the label may contain properties that are enforced when the label is assigned to a Storage Pool or a Volume. For example, label **SSD** could have the following properties:

```
{
  num_disks_per_instance; #used in partitioning disks among multiple
  instances of a file server
                        on the same node.
  max_active_io_per_disk; # Number of concurrent IO operations to be used
  on the disk.
}
```

- Are case-insensitive.
- Have a internal numeric value attached to each of them.
- Have to be registered with the CLDB before use.

What is a Storage Pool?

In the HPE Data Fabric platform, a storage pool (SP) constitutes a logical storage device. A SP can be composed of SSDs, while another SP can be composed of HDDs. A heterogeneous SP that is made up of different classes of devices is not permitted.

However, multiple classes of SPs can reside on the same node.

You can assign a single label to each SP to identify it. A SP that has not been labeled, automatically assumes the **default** label (with an internal numeric value of 0).

What is a Volume?

In the HPE Data Fabric platform, a volume is the logical unit for a class of data. Therefore, storing various types of data on various classes of devices is essentially placing particular volumes on the appropriate classes of devices.

Each volume can have only one label. Volumes that do not have a label, assume the **default** label with a numeric value of 0.

The CLDB servers are responsible for keeping track of these labels and moving volumes across storage pools based on these labels.

A volume is placed only on the SP matching its label. A volume labelled **SSD** is placed only on a SP with the label **SSD**. Similarly, a volume with the **default** label, will only be placed on a SP with the **default** label.

To override this matching placement, use the special label **anywhere** for a volume. A volume with the **anywhere** label is placed on any SP irrespective of its label. Use this label frugally as you might inadvertently end up storing a volume on your expensive disks where it is not needed to be stored.

The Disk Balancer takes care of moving volumes to appropriate SPs as needed. For example, assume that a volume with a label marked **anywhere** is stored on a SP with a label **SSD**. Now a request comes in to place volumes that are explicitly labelled as **SSD** but there are no more SPs labelled as **SSD**. The Disk Balancer will then move the volume marked **anywhere** off the SP labelled as **SSD** on to any other SP, and accommodate the volumes explicitly labelled as **SSD**.

You might assign a label to a namespace container of a volume. If a label is not assigned, the namespace container inherits the label of its data container. The namespace label is NOT changed when moving a volume from one label to another. The namespace inherits the data container label at the time of volume creation if you do not specify a label to a namespace container explicitly.

However, if you assign a label to a namespace container but not to a data container, the data container is assigned the **default** label.

Once the data container and the namespace container are labelled, their labels are independent of each other.

At the time of Volume creation, the system chooses the SPs with matching labels. If the volume or its namespace container is associated with a label, creation fails if there are insufficient nodes with SPs having the same label.

If only one matching SP is present for a 2/3-way replicated volume, only a single replica is created for that volume.

When creating containers, the system checks for nodes/storage pools with matching labels in the topology requested. Container creation fails if there are no nodes/storage pools with matching labels in the topology requested, even if there are such nodes/storage pools in other topologies.

When the label of a volume is changed, replicas cannot be migrated within the file server, from one SP with the old label to another SP with the desired label. If there are no other SPs, all old copies will not be fully migrated to the new desired label.

 **Attention:** CLDB volumes are an exception. CLDB volumes can be created on any storage pool. Labels do not apply to CLDB volumes.

Enable the Storage Labels Feature on an Upgraded Cluster

The Storage Labels feature is already enabled on a new HPE Data Fabric version 6.2 cluster.

On a cluster upgraded to version 6.2, enable the Storage Labels feature with the command:

```
maprcli cluster feature enable -name cldb.lbs.support
```

This feature takes effect immediately without the need to fail over CLDB. This feature cannot be disabled once it is enabled.

Usage Sequence

You must perform label creation and assignment in the following sequence:

1. [Register a label](#) - Ensures that random labels are not assigned to SPs and Volumes. A label once registered cannot be deleted or prevented from being used.
2. [Assign a label to a Storage Pool](#) - Select any disk in the SP to assign a label. You can [create a storage pool, and simultaneously set its label as well](#).
3. [Assign a label to a volume](#). You can assign a label at volume creation using the [volume create](#) on page 2190 command.

Override Topology and Storage Pool Adherences

You can override topology and SP adherences for critically under-replicated containers. The Storage Labels feature contains the following two settings.

- `honor.topology.for.critical.replication` - default value is `1` (true). When set to `0` (false), critically under-replicated containers are replicated outside their topology, if space is not available within their topology.

```
/opt/mapr/bin/maprcli config save -values
'{"honor.topology.for.critical.replication": "0"}'
```

- `honor.label.for.critical.replication` - default value is `1` (true). When set to `0` (false), critically under-replicated containers are replicated on other SPs, even if their labels do not match the labels of the SPs.

```
/opt/mapr/bin/maprcli config save -values
'{"honor.label.for.critical.replication":"0"}
```

Storage Label Commands

Use the [label add](#) on page 1891 command to register a label.

Use the [disk add](#) on page 1786 or the [disk setlabel](#) on page 1788 command to label an SP.

Use the [volume create](#) on page 2190 or the [volume move](#) on page 2294 command to label a volume.

Use the [label list](#) on page 1895 command to list all registered labels.

Use the [node list](#) on page 1911 command to list all labels associated with a node.

Use the [dashboard info](#) on page 1770 command to view the list of registered labels and the number of associated volumes and storage pools.

Use the [mrconfig sp list](#) command to view all storage pool information, including the labels associated with the storage pools.

Use the [disk list](#) command to view the labels associated with disks.

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Administering Files and Directories

The following sections provide configuration information that you can use to set chunk size and compression in filesystem, as well as information on hard links, extended attributes, and core files:

Using Global File System Checking

Describes how to use the `gfscck` command to check and repair filesystem errors.

You can use the [gfscck](#) on page 2383 (global filesystem check) command to perform a consistency check and repair operation on a volume or volume snapshot, including the following entities:

- All cross-container links (for example, from file to [filelet](#), or from table to tablets)
- The tabletmap key range
- The attributes of [filelet](#) (uid/gid/mode)

This command identifies the unreachable files, directories, and tables in the volume, and moves them to `/lost+found` to be repaired. It also identifies and fixes any unreachable DB inodes or dangling pointers to lost inodes.

1. Take the affected storage pools offline by running the [mrconfig sp offline](#) on page 2458 command.
For example:

```
/opt/mapr/server/mrconfig sp offline /dev/sdc
```

2. Execute the [fsck](#) on page 2380 command on the storage pools or disks.
3. Bring the storage pools back online by running the [mrconfig sp online](#) on page 2459 command.

For example:

```
mrconfig sp online /dev/sdc
```

4. Run the `gfscck` command on the affected volumes, or snapshots, with the appropriate options.

If there are alarms, such as `DataUnavailableAlarm` or `DataUnderReplicatedAlarm`, do not run the `gfscck` command with the `-r` (`--repair`) option. Running the `gfscck` command with the `-r` (`--repair`) option, might result in data loss. If necessary, first run `gfscck` without the `-r` (`--repair`) option, and attempt to repair only after analyzing the command output.

Related reference

[gfscck](#) on page 2383

Describes how you can use the `gfscck` command, under the supervision of HPE Ezmeral Data Fabric Support or Engineering, to perform consistency checks and appropriate repairs on a volume, or a volume snapshot.

Setting filesystem Permissions

The MapR filesystem permissions are similar to the POSIX permissions model. Each file and directory is associated with a user (the *owner*) and a group. You can set read, write, and execute permissions separately for:

- the owner of the file or directory.
- members of the group associated with the file or directory.
- all other users.

The permissions for a file or directory are called its *mode*. The mode of a file or directory can be expressed in two ways:

- Text - a string that indicates the presence of the read (r), write (w), and execute (x) permission or their absence (-) for the owner, group, and other users respectively. Example: `rwxr-xr-x`
- Octal - three octal digits (for the owner, group, and other users), that use individual bits to represent the three permissions. Example: `755`

Both `rwxr-xr-x` and `755` represent the same mode; the owner has all permissions, and the group and other users have read and execute permissions only.

When you [access the MapR filesystem layer over NFS](#), the file-level permissions are controlled through the Linux interface by using the `chmod` (change mode) command or the `chown` (change owner) command, as well as the `hadoop fs -chmod` and `hadoop fs -chown` equivalents. For example:

```
chown jsmith /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chown jsmith /mapr/my.cluster.com/jsmith/fileA
chmod 744 /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chmod 744 /mapr/my.cluster.com/jsmith/fileA
```

These commands grant a user whose username is `jsmith` the read, write, and execute privileges on `fileA`.

Once you set file permissions, authorization checks are performed when a file is opened, *and* on every file access.

Note: To further protect your data, the MapR filesystem data cache is never included in a file server core dump.

Text Modes

String modes are constructed from the characters in the following table:

| Text | Description |
|------|---|
| u | The file's owner. |
| g | The group associated with the file or directory. |
| o | Other users (users that are not the owner, and not in the group). |
| a | All (owner, group and others). |
| = | Assigns the permissions Example: "a=rw" sets read and write permissions and disables execution for all. |

| Text | Description |
|------|--|
| - | Removes a specific permission. Example: "a-x" revokes execution permission from all users without changing read and write permissions. |
| + | Adds a specific permission. Example: "a+x" grants execution permission to all users without changing read and write permissions. |
| r | Read permission |
| w | Write permission |
| x | Execute permission |

Octal Modes

To construct each octal digit, add the value of each permission that you want to grant:

- Read: 4
- Write: 2
- Execute: 1

For example, 7 which provides read, write, and execute permissions because $4+2+1=7$.

Syntax

You can change the modes of directories and files in the MapR storage using either the `hadoop fs` command with the `-chmod` option, or using the `chmod` command via NFS. The syntax for both commands is similar:

- `hadoop fs -chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]`
- `chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]`

Parameters and Options

The following table provides the command parameters and options with their descriptions:

| Parameter/Option | Description |
|------------------|--|
| -R | If specified, this option applies the new mode recursively throughout the directory structure. |
| MODE | A string that specifies a mode. |
| OCTALMODE | A three-digit octal number that specifies the new mode for the file or directory. |
| URI | A relative or absolute path to the file or directory for which to change the mode. |

Examples

The following examples are all equivalent:

- `chmod 755 script.sh`
- `chmod u=rwx,g=rx,o=rx script.sh`
- `chmod u=rwx,go=rx script.sh`

Managing File and Directory ACEs

Describes the implications of setting access control expressions on files and directories.

File [ACE](#) allows you to define access (whitelist and blacklist) to files and directories for a combination of users, groups, and roles. If [ACEs](#) are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set [ACEs](#), MapR sets or resets the corresponding POSIX mode bits to match the permissions granted through [ACEs](#). For more information, see [Setting/Modifying File and Directory ACEs](#).

- If both [ACEs](#) and POSIX mode bits are set, access is granted if access is allowed through [ACEs](#) or POSIX mode bits.
- If [ACEs](#) are not set, POSIX mode bits are used to grant access.
- If neither [ACEs](#) nor POSIX mode bits are set, access is denied.

The owner of the file or directory (and mapr and root users) can set, modify, and remove [ACEs](#) for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files using the `hadoop mfs` command or the [FileACE Java APIs](#) on page 1574 and [FileACE C APIs](#) on page 1574. Specifically, the following access types are supported.

| Access Type | | Description |
|---------------------------|-----------------|------------------|
| Command-Line | Java API (Enum) | |
| <code>-readfile</code> | READFILE | Read a file. |
| <code>-writefile</code> | WRITEFILE | Write to a file. |
| <code>-executefile</code> | EXECUTEFILE | Execute a file. |

For more information, see `hadoop mfs`, [FileACE Java APIs](#) on page 1574, and [FileACE C APIs](#) on page 1574.

Directory ACEs

You can set the same [ACEs](#) on directories as for files. In addition, directory [ACEs](#) support permissions to list, add child, delete child, and lookup directories using `hadoop mfs` command. Specifically, the following access types are supported.

| Access Type | | Description |
|-------------------------|-----------------|------------------|
| Command-Line | Java API (Enum) | |
| <code>-readfile</code> | READFILE | Read a file. |
| <code>-writefile</code> | WRITEFILE | Write to a file. |

| Access Type | | Description |
|--------------|-----------------|--|
| Command-Line | Java API (Enum) | |
| -executefile | EXECUTEFILE | Execute a file. |
| -readdir | READDIR | List the contents of a directory. This access is required to write and/or execute files in the directory. |
| -lookupdir | LOOKUPDIR | Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory. |
| -addchild | ADDCHILD | Add a file or subdirectory. |
| -deletechild | DELETECHILD | Delete a file or subdirectory. |

Although you can set both file and directory [ACEs](#) on directories, only the directory [ACEs](#) are used for determining access to the directory. The file [ACE](#) on the directory is used as the default [ACE](#) setting for new files under that directory.

By default, when you set [ACEs](#) on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.
- New files under that parent inherit the file [ACEs](#) and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default [ACE](#), the empty string (""), which indicates that no one has permissions to read, write, or execute the file; POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file [ACEs](#) and corresponding POSIX mode bits from the parent directory.

Note: When accessing files and directories, the [ACEs](#) on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACES are set on an executable file

When [ACEs](#) are set on any file, mode bits are cleared. However, for a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with [ACEs](#) set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRAces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set access control expressions (ACEs) for files and directories.

For files and directories, run the `hadoop mfs` command to set [ACEs](#). When [ACEs](#) are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding [ACEs](#). POSIX mode bits for others is set only if "P" is given as the value for an [ACE](#).

The following table lists the POSIX mode bits that correspond to the access types.

| | <i>ACE</i> | POSIX Mode Bits |
|------------------|-------------|-----------------|
| File | readfile | r |
| | writefile | w |
| | executefile | x |
| Directory | readdir | r |
| | addchild | w |
| | deletechild | w |
| | lookupdir | x |

The POSIX mode bit granting write (w) access to directory is set only if user, role, or group is granted permission for both (addchild and deletechild) access types.

The `hadoop` command, by default, sets the POSIX mode bits corresponding to the given *ACEs*, and:

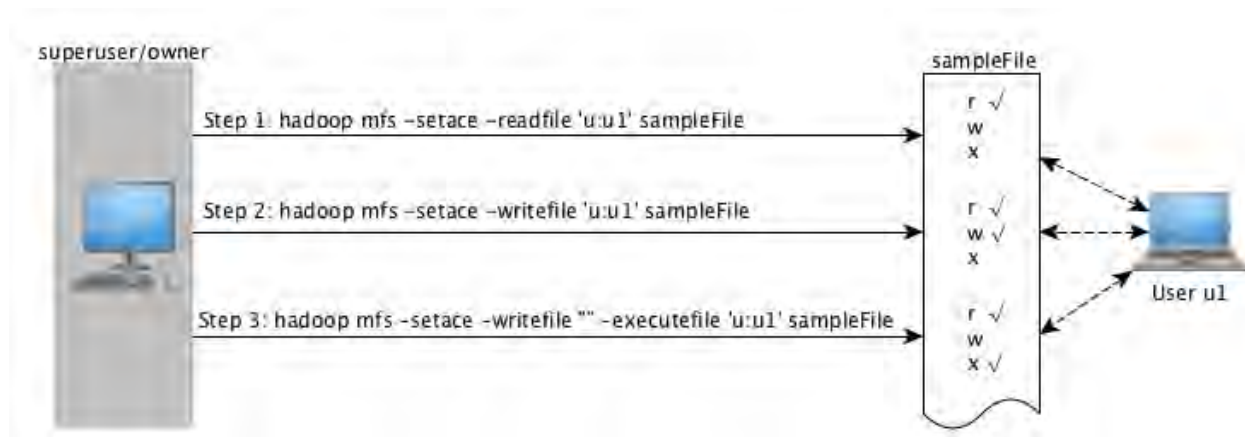

- Overwrites existing *ACE* values with new values, if specified, for access types that were previously set.
- Sets *ACE* values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, whether or not they were previously set.

Warning: Changing the POSIX mode bits using `chmod` does not change the corresponding *ACE* setting and may result in different, conflicting permissions to files and directories.

File ACE Example

Illustrates setting access control expressions for files.

Suppose the following sequence of file *ACE* settings (and corresponding POSIX mode bits) are set for user u1.

As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, `sampleFile`.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in *ACEs* or POSIX mode bits for all other (write and execute) access types.

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in **ACEs** or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

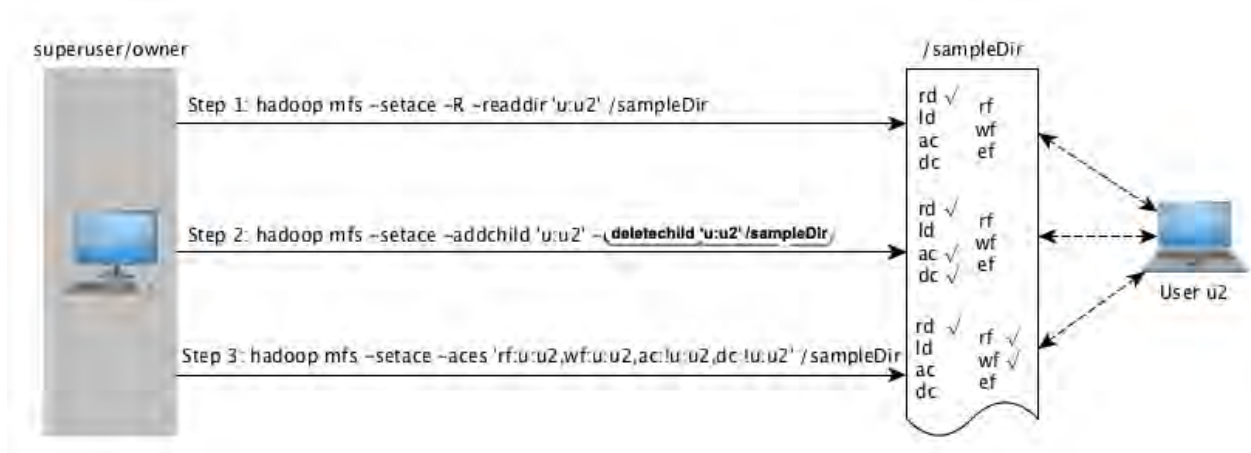

Note: When the empty string (" ") is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (!).

There is no change in **ACEs** or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory **ACE** settings for user u2:

As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory, and sampleDir, while all other directory/file **ACEs** are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (x) is set to u2 for owner/users.

Step 2:

There is no change in [ACEs](#) or POSIX mode bits for all other (file- and directory-level) access types.

User u2 is granted permission only to add and delete child directories, while all other directory/file [ACEs](#) are not specified.

After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (`w`) to the directory for owner/user is set to u2 because user u2 is granted access for both (`addchild` and `deletchild`) access types.

If user u2 creates child directories, the child directories, by default, inherit the [ACE](#) settings of the parent directory.

There is no change in [ACEs](#) or POSIX mode bits for all other (file- and directory-level) access types.

Step 3:

User u2's permissions are modified to grant access to read and write to files in the directory, user u2's permissions for adding and deleting child directories are removed (using the negation operator), and all other directory/file [ACEs](#) are not specified.

After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add and delete child directories. The POSIX mode bits for directory write access (`w`) is set to 0 for owner/user.

Although, at the directory level, user u2 has permissions to read and write to files in the directory, for existing files, the file level [ACEs](#) or the POSIX mode bits for the file are used to determine access. However, by default, user u2 gets read and write permissions to all new files created under the directory. If user u2 creates new files under the directory, the files inherit the file [ACEs](#) from the parent directory by default and the POSIX mode bits for read (`r`) and write (`w`) access are set to u2 for owner/user.

There is no change in [ACEs](#) or POSIX mode bits for all other (`lookupdir` and `executefile`) access types.

Deleting File and Directory ACEs

Describes how to delete file and directory ACEs using the CLI.

You can remove all [ACE](#) associated with a file or directory using the `hadoop mfs -delace` command. When you delete all the [ACEs](#), the system sets the [ACE](#) for the file or directory to the default value, which is the empty string (`" "`). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

You cannot remove specific access types that have been set; instead, use the empty string to deny specific types of access. When the empty string (`" "`) is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`). If you use the empty string (`" "`) or the negation operation (`!`) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the [ACE](#) setting.

Managing Chunk Size

Describes the considerations for managing the chunk size for map tasks.

Files in the HPE Ezmeral Data Fabric filesystem are split into *chunks* (similar to Hadoop *blocks*) that are normally 256 MB by default. Any multiple of 65,536 bytes is a valid chunk size, but tuning the size correctly is important:

- Smaller chunk sizes result in larger numbers of map tasks, which can result in lower performance due to task scheduling overhead.
- Larger chunk sizes require more memory to sort the map task output, which can crash the JVM or add significant garbage collection overhead. HPE Ezmeral Data Fabric can deliver a single stream at upwards of 300 MB per second, making it possible to use larger chunks than in the stock Hadoop implementation. Generally, it is wise to set the chunk size between 64 MB and 256 MB.

Chunk size is set at the directory level. Files inherit the chunk size settings of the directory that contains them, as do subdirectories on which chunk size has not been explicitly set. Any files written by a Hadoop application, whether using the file APIs or over NFS for the HPE Ezmeral Data Fabric, use chunk size specified by the settings for the directory where the file is written. If you change a directory's chunk size settings after writing a file, the file will keep the old chunk size settings. Further writes to the file will use the file's current chunk size.

Note: If chunk size is zero (0), when an application makes a request for block size, HPE Ezmeral Data Fabric will return 1073741824 (1GB); however, `hadoop mfs` on page 5576 commands will continue to display 0 for chunk size.

Configuring Chunk Size

Chunk size also affects parallel processing and random disk I/O during MapReduce applications. A higher chunk size means less parallel processing because there are fewer map inputs, and therefore fewer mappers. A lower chunk size improves parallelism, but results in higher random disk I/O during shuffle because there are more map outputs. Set the `io.sort.mb` parameter to a value between 120% and 150% of the chunk size.

Here are the general guidelines for chunk size:

- For most purposes, set the chunk size to the default 256 MB and set the value of the `io.sort.mb` parameter to the default 380 MB.
- On very small clusters or nodes with not much RAM, set the chunk size to 128 MB and set the value of the `io.sort.mb` parameter to 190 MB.
- If application-level compression is in use, the `io.sort.mb` parameter should be at least 380 MB.

Note: If you have Drill running in the cluster, change the `store.parquet.block-size` parameter in Drill so that the Parquet block size is the same as the chunk size in the HPE Ezmeral Data Fabric filesystem. See [Configuring the Parquet Block Size](#) for more information.

Setting Chunk Size

You can set the chunk size for a given directory in two ways:

- Change the `ChunkSize` attribute in the `.dfs_attributes` file at the top level of the directory
- Use the command `hadoop mfs -setchunksize <size> <directory>`

For example, if the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test` you can set the chunk size to 268,435,456 bytes by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `ChunkSize=268435456`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setchunksize 268435456 /mapr/my.cluster.com/projects/test
```

Managing Compression

Lists the advantages of using compression.

Data Fabric provides compression for files stored in the cluster. Compression is applied automatically to uncompressed files unless you turn compression off. The advantages of compression are:

- Compressed data uses less bandwidth on the network than uncompressed data.
- Compressed data uses less disk space.

Choosing a Compression Setting

Lists the compression algorithms supported by data-fabric.

Data Fabric supports three different compression algorithms:

- lz4 (default)
- lzf
- zlib

Compression algorithms can be evaluated for compression ratio (higher compression means less disk space used), compression speed and decompression speed. The following table gives a comparison for the three supported algorithms. The data is based on a single-thread, Core 2 Duo at 3 GHz.

| Compression Type | Compression Ratio | Compression Speed | Decompression Speed |
|------------------|-------------------|-------------------|---------------------|
| lz4 | 2.084 | 330 MB/s | 915 MB/s |
| lzf | 2.076 | 197 MB/s | 465 MB/s |
| zlib | 3.095 | 14 MB/s | 210 MB/s |

Note that compression speed depends on various factors including:

- block size (the smaller the block size, the faster the compression speed)
- single-thread vs. multi-thread system
- single-core vs. multi-core system
- the type of codec used

Related Link

- [LZO vs Snappy vs LZF vs ZLIB](#)

Setting Compression on Files

Compression is set at the directory level. Any files written by a Hadoop application, whether via the file APIs or over NFS, are compressed according to the settings for the directory where the file is written. Sub-directories on which compression has not been explicitly set inherit the compression settings of the directory that contains them.

If you change a directory's compression settings after writing a file, the file will keep the old compression settings—that is, if you write a file in an uncompressed directory and then turn compression on, the file does not automatically end up compressed, and vice versa. Further writes to the file will use the file's existing compression setting.

Warning: Only the owner of a directory can change its compression settings or other attributes. Write permission is not sufficient.

File Extensions of Compressed Files

Lists extensions of compressed files.

By default, HPE Ezmeral Data Fabric does not compress files whose filename extensions indicate they are already compressed. The default list of filename extensions is as follows:

- bz2
- gz
- lzo
- snappy
- tgz
- tbz2
- zip
- z
- Z
- mp3
- jpg
- jpeg
- mpg
- mpeg
- avi
- gif
- png

The list of filename extensions not to compress is stored as comma-separated values in the `mapr.fs.nocompression` configuration parameter and can be modified with the [config save](#) command. For example, you can add `parquet` to the default list:

```
maprcli config save -values
'{"mapr.fs.nocompression": "bz2,gz,lzo,snappy,tgz,tbz2,zip,z,Z,mp3, \
jpg,jpeg,mpg,mpeg,avi,gif,png,parquet"}'
```

The list can be viewed with the [config load](#) command. Example:

```
maprcli config load -keys mapr.fs.nocompression
```

Turning Compression On or Off on Directories Using the CLI

Explains how to turn off or turn on compression and optionally specify an algorithm, using the command line.

You can turn compression on or off for a given directory in two ways:

- Set the value of the `Compression` attribute in the [.dfs_attributes](#) file at the top level of the directory.
 - Set `Compression=lzf|lz4|zlib` to turn compression *on* for a directory.

- Set `Compression=false` to turn compression *off* for a directory.
- Use the command `hadoop mfs -setcompression on|off|lzf|lz4|zlib <dir|table>`.

If you choose `-setcompression on` without specifying an algorithm, lz4 is used by default. This algorithm has improved compression speeds for HPE Ezmeral Data Fabric's block size of 64 KB.

The symbols for the various compression settings are explained here:

| Symbol | Compression Setting |
|--------|---|
| Z | lz4 |
| z | zlib |
| L | lzf |
| U | Uncompressed, or previously compressed by another algorithm |

Example

Suppose the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test`. You can turn off compression by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `Compression=false`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setcompression off /projects/test
```

You can view the compression settings for directories using the `hadoop mfs -ls` command. For example,

```
vrwxr-xr-x  Z U U    3 mapr mapr          11 2017-12-01 14:00 268435456 /rw

```

Suppose three directories `abc`, `klm`, and `xyz`. You can turn on compression and set different compression algorithm for the directories by running the following commands:

```
hadoop mfs -setcompression on /ksTestVoll/abc
hadoop mfs -setcompression lzf /ksTestVoll/klm
hadoop mfs -setcompression zlib /ksTestVoll/xyz
```

You can then view the compression settings for the directories using the `hadoop mfs -ls` command. For example:

```
hadoop mfs -ls /ksTestVoll/
Found 3 items
drwxr-xr-x  Z U U  - root root    0 2017-12-11 08:41 268435456 /
ksTestVoll/abc
      p 2432.32.131194 doc24.lab:5660
drwxr-xr-x  L U U  - root root    0 2017-12-11 08:42 268435456 /
ksTestVoll/klm
      p 2432.34.131198 doc24.lab:5660

ksTestVoll/xyz
      p 2432.33.131196 doc24.lab:5660
```

Setting Compression During Shuffle

By default, MapReduce uses compression during the Shuffle phase. You can use the `-Dmapreduce.maprfs.use.compression` switch to turn compression *off* during the Shuffle phase of a MapReduce job. For example:

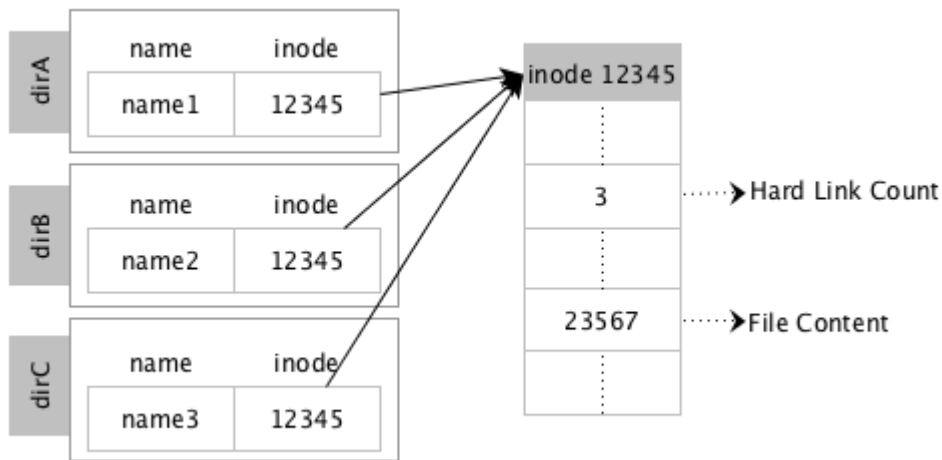

```
hadoop jar xxx.jar -Dmapreduce.maprfs.use.compression=false
```

Managing Hard Links

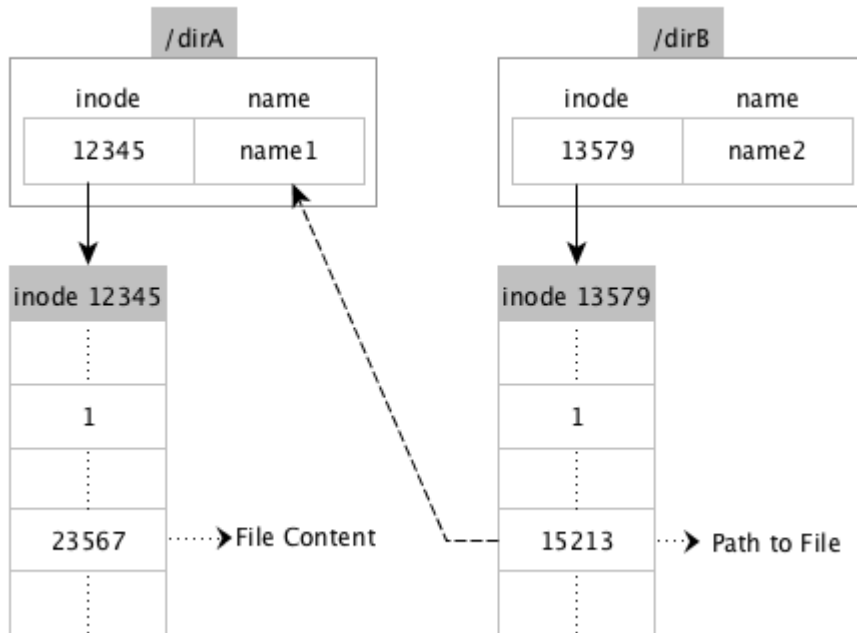

Explains what hard links are, and their limitations.

A hard link is a directory entry that associates a name with a file (or physical data) on the filesystem. Hard links allow multiple names to be associated with the same data (and associated inode) from within or outside of a directory. Every time a hard link is created, a directory entry is created and the inode (associated with the directory entry) remains the same across all hard links associated with that data. That is, all names associated with the data point to the same inode.

The following diagram illustrates the hard link semantics. Here, directory entries in `dirA`, `dirB`, and `dirC` for file names `name1`, `name2`, and `name3` respectively all point to the inode 12345, which contains metadata including the text in the file and a count of the number of hard links to the file (or physical data).

In contrast, when a symbolic link is created, a new inode is created and the text part of the inode (associated with the symlink file) contains the path to the actual file. The following diagram illustrates the symbolic link semantics. Here, the directory entry in dirA for file name, name1, is associated with inode 12345, which contains the text in the file. The directory entry in dirB for symbolic link file, name2, is associated with inode 13579, which contains the path to file in dirA (*/dirA/name1*). Deleting the file, name1, in dirA will result in the symlink file in dirB, name2, pointing to stale content, which in turn will return errors when accessed.

Hard links can be created on regular files, symlink files, device files, and tables.

Limitations

- Hard links cannot be created on directories.
- Hard links cannot be created across volumes or clusters. Instead, use symbolic link to link to a file on a different volume.

- Hard links within a volume are carried over to mirror volumes and volume snapshots. During cross-mirroring, there will be an error if support for hardlinks is not enabled on both the clusters.
- The `hadoop distcp` command cannot be used for creating and preserving copies of hard links.
- The maximum number of hard links is constrained by the integer width (32 bits), which means the maximum number possible for a file is 2^{32} .

Usage

Any user with access to the directory can create a hard link to any file under that directory. To create hard links, the user must have write permissions on the directory and execute permissions (to do the lookup for the path) on the target file. To read or modify the file, the user must have read or write permissions respectively on the file.

Errors

For information on the type of failures and errors, refer to the [man page](#). In addition, please note that the EXDEV error is returned if command is run to create cross-volume or cross-cluster hard links.

Enabling Hard Links

By default, this feature is enabled on all new installation. If you upgrade, you must enable this feature. To enable this feature, run the following command:

```
maprcli cluster feature enable -name mfs.feature.hardlinks.support
```

Setting a Hard Link

Explains how to create a hardlink to a file.

To set a hard link using:

- POSIX loopbacknfs client or NFS client, run the following command:

```
ln <sourcefile> <newfile>
```

where <sourcefile> is the name of the file to link to and <newfile> is the name of the hard link, which must *not* already be present.

- Hadoop, run the following command:

```
hadoop mfs -lnh <sourcefile> <newfile>
```

where <sourcefile> is the name of the file (including full path) to link to and <newfile> is the name of the hard link (including the full path). When running this command, specify the full path to both files.

Retrieving the Number of Hard Links

Explains how to retrieve the number of hard links to a file.

To retrieve the number of hard links associated with a file, run the following command:

```
ls -l
```

The command, `ls -l`, will print the number of hardlinks in the second column. For example, your output will look similar to the following:

```
ls -l sample-link
rw-r--r- 2 root root 0 Apr 21 11:09 sample-link
```

To retrieve the list of the hard links associated with a file, run the following command:

```
find <dirpath> -samefile <sourcefile>
```

where <dirpath> is the path to the source file and <sourcefile> is the source file for the hard link. For example, your output will look similar to the following:

```
find . -samefile file8
./file8-link2
./file8-link100
./file8-link101
./file8
./file8-link
```

For POSIX (loopback NFS for the HPE Ezmeral Data Fabric) clients, the number of hardlinks to a file can be retrieved using the `stat64` system call. For example, your output will look similar to the following:

```
stat samplefile
  File: 'samplefile'
  Size: 0                Blocks: 0                IO Block: 131072 regular empty
file
Device: 14h/20d Inode: 853785146   Links: 4
Access: (0644/-rw-r--r--)  Uid: (   0/   root)   Gid: (   0/   root)
Access: 2016-05-12 13:06:21.000000000 -0700
Modify: 2016-05-12 13:06:30.002560000 -0700
Change: 2016-05-12 13:06:30.002560000 -0700
```

If you are not using NFS for the HPE Ezmeral Data Fabric or the POSIX clients, to retrieve the number of hard links, you can run the `hadoop` command to retrieve the fid and then run the `maprcli` command to retrieve the number of hard links as follows. The `nlink` variable will print the number of links.

```
hadoop mfs -ls /p1
Found 1 items
-rw-r--r--  Z U U    3 root root          3054 2016-05-05 13:49  268435456 /p1
p 2049.40.262550  node-31.lab:5660

maprcli fid stat -fid 2049.40.262550
xattrInum uid atime      nblocks deleteFlags      mtime
parent      nlink type      version size mode networkencryption
subtype    gid  compression
0           0    1462481255  1      DeleteTypeNone  1462481376
2049.16.2  2   FTRegular  2097165 3054 644 false
FSTInval  0    lz4
```

Removing Hard Links

To remove a hard link using:

- Linux, run the following command:

```
rm -f <hard link>
```

- Hadoop, run the following command:

```
hadoop fs -rm <path to hard link>
```

Example

For example, suppose there are 4 hard links to file `cite75_99.txt`.

```

$ ls -l
total 1289433
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite75_99.txt
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link1
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link2
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link3
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link4

$ maprcli fid stat -fid 2142.34.131274
parent      deleteFlags      atime          gid  nlink  type      mtime
version  mode  uid  xattrInum  size          subtype  networkencryption
nblocks  compression
2142.16.2 DeleteTypeNone 1469738740 0    5      FTRegular 1469738771
1048600  755  0    0          264075431  FSTInval false
8        lz4

```

To remove a hard link using:

- Linux, run the following command:

```
rm -f cite-link1
```

To verify that the command ran successfully, run the following command:

```

$ ls -l
total 1031546
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite75_99.txt
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link2
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link3
-rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link4

```

- Hadoop, run the following command:

```

$ hadoop fs -rm /test-hl/cite-link2
16/07/28 13:52:00 INFO Configuration.deprecation: io.bytes.per.checksum
is deprecated. Instead, use dfs.bytes-per-checksum
16/07/28 13:52:00 INFO fs.TrashPolicyDefault: Namenode trash
configuration: Deletion interval = 0 minutes, Emptier interval = 0
minutes.
Deleted /test-hl/cite-link2

```

To verify that the command ran successfully, run the following command:

```

$ maprcli fid stat -fid 2142.34.131274
parent      deleteFlags      atime          gid  nlink  type      mtime
version  mode  uid  xattrInum  size          subtype  networkencryption
nblocks  compression
0.0.0    DeleteTypeNone 1469738740 0    3      FTRegular 1469738771
1048603  755  0    0          264075431  FSTInval false
8        lz4

```

Managing Extended Attributes

Describes what extended attributes are, and the POSIX permissions that you need to manage them.

Extended attributes (referred to as `xattrs`) allow user applications to associate additional metadata with a regular file or directory. Unlike system-level inode metadata, such as file permissions or modification time, extended attributes are not interpreted by the system but are instead used by applications to store additional information about an inode. Multiple extended attributes can be associated with a single inode. The maximum size allowed for an extended attribute is 64 KB.

An extended attribute is a name-value pair, with a string name and binary value. The extended attribute names are prefixed with a namespace. For example, an `xattr` named `myXattr` in the user namespace would be specified as `user.myXattr`.

Limitations

- For the five valid namespaces supported by HDFS, HPE Ezmeral Data Fabric supports the following:

| Namespace | HPE Ezmeral Data Fabric Functionality |
|-----------|--|
| user | Commonly used by client applications. Access to these extended attributes in the user namespace is controlled by corresponding file/directory permissions. For more information, see Permissions for Extended Attributes . |
| trusted | Available to superusers only. Access is denied for all other users. The extended attribute is not available through userspace methods. |

Note: HPE Ezmeral Data Fabric does not support the raw namespace.

- Extended attributes cannot be associated with symbolic links. If extended attributes are used on symbolic links, they are instead applied to the symbolic link target file.
- The preserve options of commands like `cp -px` and `distcp -px` will work on extended attributes only in the following cases:
 - With Hadoop commands such as `hadoop fs`.
 - On FUSE mounted file paths.

Note: Extended attributes are not supported on NFS for the HPE Ezmeral Data Fabric file paths.

Permissions for Extended Attributes

The following table lists the permissions (POSIX mode bits or [ACEs](#)) you will need to set, retrieve, or modify extended attributes.

| To... | For directories, you need... | For files, you need... |
|------------------------------|---|---|
| Set extended attributes | Mode bits: write (OR) ACE : addchild | Mode bits: write (OR) ACE : writefile |
| Remove extended attributes | Mode bits: write (OR) ACE : deletechild | Mode bits: write (OR) ACE : writefile |
| Retrieve extended attributes | Mode bits: read (OR) ACE : readdir | Mode bits: read (OR) ACE : readfile |

Enabling Extended Attributes

Extended attributes are enabled by default on all new installation. If you are upgrading, this feature must be explicitly enabled. To enable, run the following command:

```
maprcli cluster feature enable -name mfs.feature.fileace.support
```

Setting, Retrieving, and Removing Extended Attributes

You can set and retrieve extended attributes on files, directories, and FUSE mounted file path using [Hadoop](#) commands, [Linux](#) commands, and [Java APIs](#).

Hadoop Commands

Lists the Hadoop commands to set, retrieve, and remove extended attributes on files, directories and FUSE mounted paths.

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using the `hadoop fs` command. When setting an extended attribute:

- The name must be prefixed with a namespace.
- The extended attribute value must be encoded as one of the following:

| | |
|--------|--|
| text | The given string must be enclosed in double quotes to be treated as text. |
| hex | The given string must begin with 0x or 0X to be treated as hexadecimal number. |
| base64 | The given string must begin with 0s or 0S to be treated as base64 encoding. |

Note: You must have the right permissions to set, retrieve, and/or remove extended attributes.

Set Extended Attributes

To set an extended attribute name and value for a file or directory, run the following command:

```
hadoop fs -setfattr -n name [-v value] <path>
```

For example:

```
hadoop fs -setfattr -n system.name -v system-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n user.name -v user-hadoopfs /volforsnap/smallfile.txt
hadoop fs -setfattr -n security.name -v security-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n trusted.name -v trusted-hadoopfs /volforsnap/
smallfile.txt
```

Retrieve Extended Attributes

To retrieve the extended attributes associated with a file or directory, run the following command:

```
hadoop fs -getfattr [-R] -n name | -d [-e en] <path>
```

For example:

```
hadoop fs -getfattr -d /volforsnap/smallfile.txt
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding
in [jar:file:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/
slf4j-log4j12-1.7.10.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/opt/mapr/lib/
```

```
slf4j-log4j12-1.7.12.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an
explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
# file: /volforsnap/smallfile.txt
system.name="system-hadoopfs"
trusted.name="trusted-hadoopfs"
security.name="security-hadoopfs"
user.name="user-hadoopfs"
```

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
hadoop fs -setfattr -x name <path>
```

For example:

```
hadoop fs -setfattr -x user.key1 /xattrs/m7user1/dir1
```

Linux Commands

You can set, retrieve, restore, and remove extended attributes on files, directories, and FUSE mounted file paths using Linux commands. For more information, refer to the respective Linux man page.

To use extended attributes on files on a MapR cluster with a FUSE client mounted path, see [Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client](#) on page 1358 to enable extended attributes through FUSE client.

Set Extended Attributes

To set an extended attribute name and value on a file/directory and/or a FUSE mounted file path, run the following command:

```
setfattr [-h] -n name [-v value] pathname...
```

For example:

```
setfattr -n system.name -v system /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n security.name -v test /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n trusted.name -v trusted /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n user.name -v user /mapr_fuse/testcluster/volforsnap/
smallfile.txt
```

For more information, refer to the Linux [man page](#).

Retrieve Extended Attributes

To retrieve extended attributes, run one of the following commands:

```
getfattr [-hRLP] -n name [-e en] pathname...
getfattr [-hRLP] -d [-e en] [-m pattern] pathname...
```

For example:

```
getfattr -d -m - /mapr_fuse/testcluster/volforsnap/smallfile.txt
getfattr: Removing leading '/' from absolute path names
```

```
file: mapr_fuse/testcluster/volforsnap/smallfile.txt
security.name="test"
system.name="system"
trusted.name="trusted"
user.name="user"
```

For more information, refer to the Linux [man page](#).

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
setfattr [-h] -x name pathname...
```

For example:

```
setfattr -x user.test test2
```

For more information, refer to the Linux [man page](#).

Restore Extended Attributes

To restore extended attributes from a file, which must be in the format generated by the `getfattr` command with the `--dump` option, run the following command:

```
setfattr [-h] --restore=file...
```

For example:

```
setfattr --restore=testout
getfattr -d test2
file: test2
user.test="test"
```

For more information, refer to the Linux [man page](#).

C APIs

Java APIs

Java APIs to manage extended attributes

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using [Extended Attribute Java APIs](#).

Set Extended Attributes

To set extended attributes, use the following APIs:

```
public void setXAttr(Path path, String
name, byte[] value) throws IOException
```

Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr". By default, if a given extended attribute exists, then it will be replaced with the specified attribute.

```
public void setXAttr(Path path,
String name, byte[] value,
Enum<SetXAttrSetFlag> flag) throws
IOException
```

Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr". The `XAttrSetFlag` value can be:

- **CREATE** to create a new extended attribute. An error is returned if an extended attribute with the given name already exists.
- **REPLACE** to replace an existing extended attribute. An error is returned if the specified extended attribute does not already exist.

Retrieve Extended Attributes

To retrieve extended attributes, use the following APIs:

| | |
|--|--|
| <code>public byte[] getXAttr(Path path, String name) throws IOException</code> | Get an extended attribute name and value for a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr". |
| <code>public Map<String,byte[]> getXAttrs(Path path) throws IOException</code> | Get all the extended attribute name/value pairs for a file or directory. Only those extended attributes that the logged-in user has permissions to view, are returned. |
| <code>public Map<String,byte[]> getXAttrs(Path path, List<String> names) throws IOException</code> | Get the extended attributes specified by the given list of names. Only those extended attributes that the logged-in user has permissions to view, are returned. |
| <code>public List<String> listXAttrs(Path path) throws IOException</code> | Get all the extended attribute names for a file or directory. Only those extended attribute names that the logged-in user has permissions to view, are returned. |

Remove Extended Attributes

To remove an extended attribute associated with a file or directory, use the following API:

| | |
|---|---|
| <code>public void removeXAttr(Path path, String name) throws IOException</code> | Remove an extended attribute of a file or directory. The name must be prefixed with the namespace followed by ". ". For example, "user.attr". |
|---|---|

Managing Core Files

Describes how to set the location for core files.

The Linux `core_pattern` file (in `/proc/sys/kernel/core_pattern`) can be used to specify the location for storing core files. If any process launched by HPE Ezmeral Data Fabric crashes, the core files are created in the directory specified by the `core_pattern` file. A valid location in the `core_pattern` file is a full path to the directory you want to use. For example:

```
/tmp/dirl/cores/%e.core.%p.%h
```

Tip: For details about the standard Linux % specifiers that you can use to name core files, see the [core man page](#).

If the `core_pattern` file is empty, if the file does not contain a full path, or if it uses the "|" redirection feature, by default, HPE Ezmeral Data Fabric sets the location for core files (in the event of a core dump on a node) to `/opt/cores` directory when:

- The `configure.sh` utility is run.
- The Warden init script is run.
- The filesystem init script is run by Warden.

The default directory (`/opt/cores`) is also used if the `core_pattern` file contains the default HPE Ezmeral Data Fabric value for core files.

For HPE Ezmeral Data Fabric software, the directory being used to store core files should not be used for other purposes and should be empty. The `cores` directory cannot be the home directory, as it can cause problems during SSH access. The `hoststats` service monitors the directory specified in the `core_pattern` file and raises the node-level [alarm](#) if the directory contains any entry other than `.` and `..`. When Warden is started, sticky bit is set on the `cores` directory.

Migrating Files From MapR Edge Cluster to AWS S3

The File Migration service for [MapR Edge](#) on page 6777 clusters monitors a set of configured directory trees (referred to as *policies* in the service UI) on the MapR cluster for new and changed files. When the service detects new or changed files, it automatically uploads them to AWS S3 (Amazon's storage environment) using the AWS SDK TransferManager object. The File Migration service is a long-running process that is controlled by Warden.

Note: For information on installing File Migration Service on your Edge cluster, see [Installing the File Migration Service on the Edge Cluster](#) on page 209.

How the File Upload Process Works

The File Migration service maintains in memory information regarding directories, subdirectories, and files within each directory tree to monitor. When started, the service first looks for changed and new files in the configured directories. To detect changes to existing files, the service looks at the extended attribute `user.s3uploadtime`, which is set on each file and contains the modification time (in milliseconds) when the file was last uploaded to the AWS S3 bucket. It then places the new and changed files in a queue for upload, sorted by the oldest modification timestamp. The service then uploads multiple files in parallel and provides logs as files upload, fail to upload, or complete uploading.

Note: For each directory tree, you can set up any file or directory that matches a specified regex pattern to be ignored. For example, all files ending in `.tmp` or all files in `/tmp` directory can be set up to be ignored. Additionally, only files are considered for upload; empty directories, symbolic links, and tables or streams are ignored.

Scanning for New and Changed Files

The service scans for new and changed files in the monitored directories using a full scan or a lite scan.

Full Scan

The service performs a full scan when it is first started and periodically or randomly for a subset of the directories in the directory tree after. This allows you to spread the cost of the full scan over time rather than performing a full scan of all directories at once.

During a full scan, the service examines each file in a directory to determine if it has changed since the last time the directory was examined. If the file contains changes, then the file is examined more carefully.

If the file was uploaded, the service retrieves the modification time of the file, which was set on the file at the time the file was uploaded. If the file was not uploaded or if the file was uploaded but the modification time changed since the last upload, the service places the file in the queue for upload.

A full scan also discovers new directories and adds them to the list of directories to be monitored.

Lite Scan

The service performs an incremental scan to detect the last modified timestamp on each directory

recursively using the in-memory directory tree from the last scan. If there is no change in the timestamp since the last scan, the service does not examine the directory contents and proceeds to the next directory; this makes the incremental scan very fast. If there is a change in the timestamp since the last scan, the service performs a full scan on the directory.

Note: Before starting an incremental scan, the service checks to see if a directory tree is due for a full scan. Only a full scan allows the service to detect if a file was modified after upload. With a lite scan, the service checks only the modification time of the directory, which is not changed by the modification (such as due to late writes) of a file.

Queueing Files for Upload

Files are placed in the queue with a configurable delay from the last known modification time of the file to avoid uploading a file that is still changing.

For example, with the default of 15 seconds, a file that was modified 5 seconds ago would remain on the queue for another 10 seconds, whereas a file modified 5 minutes ago would be immediately considered for upload. This allows files to be uploaded roughly in order by last modification time.

The service places (by default, 10) files in the queue for parallel upload. The scanning service is paused if the pending queue exceeds 10 times the number of files allowed for parallel update to avoid too many pending files.

Uploading Files to S3

Uploads are in one of three states: waiting to be uploaded, uploading, finished with uploading. By default, the service performs a check on the status of the files being uploaded every 3 seconds and detects uploads that are approaching completion. The service then sets the extended attribute (`user.s3uploadtime`) to the file on filesystem to indicate that the file was uploaded.

If an error occurs during upload, the file is requeued for another try after a brief wait, which is 5 minutes by default. If the file could not be uploaded after a specified number of attempts, the file is dequeued to allow other files to upload. Note that the file is rediscovered, if it is still there, during the next full scan and queued for upload.

Note: When files are uploaded, although the file name remains the same, but the leading slash is removed and the full path is converted to a key on the AWS S3 bucket. For example, `/tmp/foo` after upload becomes the key `tmp/foo` on AWS S3 bucket.

Setting Extended Attributes

When the upload completes, the service uses an extended attribute, `user.s3uploadtime`, to set the timestamp on the file to when the file was uploaded. This extended attribute, which contains the last upload timestamp, is used by the service to determine if a file has changed since the file was last uploaded.

Purging the Files and Directories

The service also optionally deletes files after uploading and deletes empty directories. You can configure file deletion after upload in hours or fractions of an hour and configure empty directory deletion in minutes. Both can be set to zero, which disables the deletion function. Both functions are disabled by default.

Deletion of files and directories happen only during a full scan:

For files

For files, the modification timestamp on the file is examined to see how far back in time it was last modified.

If the file has been uploaded in its present form and if it matches or exceeds the interval configured for file deletion, the file is immediately deleted. If it does not match the configured interval for file deletion, a message is printed (to the log file, `filemigrate.log`) as to when the file will be deleted if it will be deleted fairly soon.

Files that were never uploaded (such as the files that were ignored) will not be deleted by the service.

For directories

For directories, the contents of the directory and the modification timestamp on the directory are examined.

If the directory is empty and the modification timestamp matches or exceeds the configured interval of time for directory deletion, the directory is deleted.

The act of deleting a file or directory from a parent directory causes the modification timestamp of the parent directory to change. Therefore, an idle or empty (parent) directory is deleted only after the configured interval of time since the deletion of its children (file or subdirectory).

The recursive deletion of directories has a slow bottom up behavior: first empty leaf directories are deleted and then the parents are deleted during a future full scan after the interval of time has elapsed.

If a directory contains files that were never uploaded (ignored), the directory will not be deleted.

Configuring HPE Ezmeral Data Fabric for HTTPS Upload to S3

Describes how to validate and trust security certificates to permit files to be uploaded to Amazon S3.

By default, HPE Ezmeral Data Fabric only trusts its own self-signed certificates. To configure HPE Ezmeral Data Fabric to trust the certificates used by AWS S3 for HTTPS upload, you must configure additional trusted certificates. Add one of the following to the `/opt/mapr/conf/ssl_truststore` file on every node in the cluster:

- The actual certificate used by the S3 endpoints you are using
- A signer of the actual certificate used by the S3 endpoints you are using
- A certificate higher in the trust chain that ultimately does sign the certificate for the S3 endpoint

Note: Currently, the root certificate used by AWS S3 is the Baltimore CyberTrust root certificate provided by [Digicert](#).

The following instructions are based on the assumption that you are adding the root certificate (known as the Baltimore CyberTrust root) provided by Digicert with a fingerprint of `D4DE20D05E66FC53FE1A50882C78DB2852CAE474` and an expiration date of May 12, 2025. You can also add other certificates to the truststore.

 **Warning:** Most Baltimore CyberTrust root certificates will expire in 2025 and expired certificates cannot be used for connecting to S3. When Amazon replaces its certificates with those issued by new certificate authorities, you must update the truststore to hold both the old and new root certificates for a smooth transition.

1. Download the Baltimore CyberTrust root certificate from the URL specified by Digicert, as in the following example:

```
cd /tmp
wget https://www.digicert.com/CACerts/BaltimoreCyberTrustRoot.crt
```

2. Add the certificate to the HPE Ezmeral Data Fabric truststore.
 - a) Go to the directory where the `ssl_truststore` file is located.

For example:

```
cd /opt/mapr/conf
```

- b) Run the command to add the certificate.

For example:

```
keytool -importcert -file /tmp/BaltimoreCybrTrustRoot.crt -keystore
ssl_truststore
```

- c) Enter the keystore password when prompted.

The default password is `mapr123`.

- d) Specify whether to trust this certificate by entering `y` when prompted.

Note: The default value is **[no]**.

For example:

```
cd /opt/mapr/conf
keytool -importcert -file /tmp/BaltimoreCyberTrustRoot.crt -keystore
ssl_truststore
Enter keystore password:
Owner: CN=Baltimore CyberTrust Root, OU=CyberTrust, O=Baltimore, C=IE
Issuer: CN=Baltimore CyberTrust Root, OU=CyberTrust, O=Baltimore,
C=IE
Serial number: 20000b9
Valid from: Fri May 12 14:46:00 EDT 2000 until: Mon May 12 19:59:00
EDT 2025
Certificate fingerprints:
  MD5: AC:B6:94:A5:9C:17:E0:D7:91:52:9B:B1:97:06:A6:E4
  SHA1: D4:DE:20:D0:5E:66:FC:53:FE:1A:50:88:2C:78:DB:28:52:CA:E4:74
  SHA256:
16:AF:57:A9:F6:76:B0:AB:12:60:95:AA:5E:BA:DE:F2:2A:B3:11:19:D6:44:AC:9
5:CD:4B:93:DB:F3:F2:6A:EB
  Signature algorithm name: SHA1withRSA
  Version: 3
...

Trust this certificate? [no]: y
Certificate was added to keystore
```

Wait for the message "Certificate was added to keystore" before proceeding.

- e) Copy the `ssl_truststore` file to all other HPE Ezmeral Data Fabric nodes in the same location (for example, `/opt/mapr/conf/`).

Ensure that the correct truststore is available on all nodes because the service can be run on any node.

Accessing the Service UI

Describes how to access the HPE Ezmeral Data Fabric Service interface.

You can access the service UI directly and using the Control System.

Accessing the Service UI Using the Control System (from HPE Ezmeral Data Fabric v6.0.1)

- Log in to the Control System and click **Services**.
The list of services installed on the cluster displays.
- Locate File Migrate service in the list and click **File Migrate**.
The login page for the service UI displays.
- Enter the credentials (username and password) to log in to the page and click **login**.

Accessing the Service UI Directly

- Enter the following URL in your browser (for both secure and unsecure clusters):

```
https://<hostname>:9444/
```

To change the port:

- a) Modify the environment variable property that specifies the `JETTY_PORT` (whose default value is 9444) in the `/opt/mapr/conf/conf.d/warden.filemigrate.conf` file, as shown in the following example:

```
service.env=JAVA_HEAP=200m,JETTY_PORT=9444
```

- b) Wait for a few minutes and then restart the service by running the following command:

```
maprcli node services -name filemigrate -nodes <node to restart> -action restart
```

Setting up Authentication for Users

The File Migration service uses PAM Shiro to authenticate the user in a dialog presented when opening the UI. The service authentication consults the PAM configurations in `/etc/pam.d` in the following order (first file in list that exists in that directory is the one used):

1. `mapr-admin`
2. `sudo`
3. `sshd`
4. `passwd`

The UI authorizes the following users to login and use the filemigrate service:

- The owner of the filemigrate process (on the cluster, this will be the `MAPR_USER`).
- Any users belonging to comma-separated list of authorized users in the properties file.
- Any users belonging to any group in comma-separated list of authorized groups in the properties file.

Setting up Authentication for Users in the Properties File

Specify a comma-separated list of users and/or groups who are authorized to log in to the UI in the `FileMigrate.properties` file in `maprfs:///var/mapr/filemigrate` directory. If the properties file is not in the directory, follow the steps in [Configuring the File Migration Service Using the Properties File](#) on page 1101.

To set up the list of users and/or groups manually, set the following properties in the `FileMigrate.properties` file:

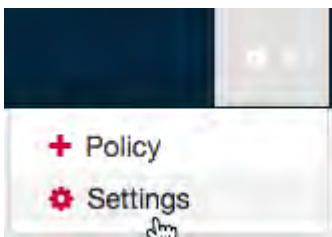

- `authorized.users`
- `authorized.groups`

To edit the file, see [Managing Policies](#) on page 1102. For more information on the properties, see [FileMigrate.properties](#) on page 2476.

Setting up Authentication for Users Using the UI

Only authorized users can log in to the UI. To set up authentication for other users:

1. Log in to the UI and select Settings from the  drop-down menu.

2. Specify a comma-separated list of:
 - Users in the **Authorized Users** field under **Upload Settings**.
 - Groups in the **Authorized Groups** field under **Upload Settings**.
3. Click **Save Changes** for the changes to take effect.

Configuring File Migration Service Using the UI

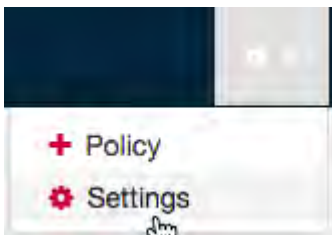

After installing and starting the service, you can access the service UI by directly entering the URL in the browser. You can then proceed to configure the properties for scanning, uploading, and monitoring the files.

Configuring Settings

Describes the interface settings for scanning and uploading files.

You can configure the settings in the interface for scanning and uploading the files.

1. Log in to the interface and select Settings from the  drop-down menu.

The **File Migration Settings** page displays.

2. Optionally, set the following for file upload:

- Full Scan Frequency
- Upload Scan Frequency
- Completion Scan Frequency
- Minimum Wait Before Upload
- Maximum Active Uploads
- Minimum Wait After Failure
- Maximum Retries Per File
- Maximum System Retries
- Minimum Idle Time Before Error

See [FileMigrate.properties](#) on page 2476 for more information.

3. Set the following to enable the service to connect and upload to AWS S3:

- Proxy Host
- Proxy Port
- Proxy Username
- Proxy Password

See [FileMigrate.properties](#) on page 2476 for more information.

4. Click **Save Changes** for the changes to take effect.

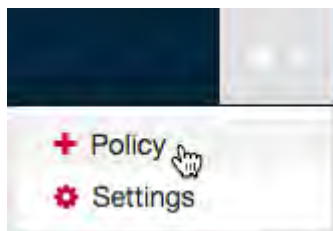

Setting up Policy

To add a new policy for file upload:

1. Log in to the UI and click **Add New File Migration Policy**.

Alternatively, select Policy from the  drop-down menu.

2. Create policies in the **Add Data Migration Policy** page.

To create a new policy, set the following:

- Directory Path
- Target Bucket
- Purge Interval

- Delete Empty Directories
- Ignore Files Regex
- X-Attributes

See [FileMigrate.properties](#) on page 2476 for more information.

3. Click **Create New Policy**.
4. Click **Restart File Migration Service**.

Configuring the File Migration Service Using the Properties File

Lists the procedure to configure the File Migration Service using a properties file.

To configure the File Migration Service:

1. Stop the service (if it is currently running).
See [Starting, Stopping, and Restarting the Service Using the CLI](#) on page 1102 for more information.
2. Make a copy of the `/opt/mapr/filemigrate/filemigrate-1.0.0/conf/FileMigrate.properties.default` file and rename it to `FileMigrate.properties` if you have not yet set any properties and wish to start from the defaults, as in the following example.

```
cp /opt/mapr/filemigrate/filemigrate-1.0.0/conf/
FileMigrate.properties.default FileMigrate.properties
```

Alternatively, you can use the `maprfs:///var/mapr/filemigrate/FileMigrate.properties` file if you have already used the interface to set some properties and want to perform further edits manually. See [Managing Policies](#) on page 1102 for more information.

3. Edit the `FileMigrate.properties` file to change the settings for the service, if/where necessary, and save the file.
For more information, see [FileMigrate.properties](#) on page 2476.
4. Copy the `FileMigrate.properties` file to the `/var/mapr/filemigrate/` directory, as in the following example.

```
hadoop fs -copyFromLocal /tmp/FileMigrate.properties /var/mapr/
filemigrate
```

Note: If the directory does not already exist, create it by running the `hadoop fs -mkdir` command. The `FileMigrate.properties` file contains sensitive information and the recommendation is to limit read access to the directory. If the service creates the directory, by default, only the `MAPR_USER` and `MAPR_GROUP` have read access to the directory.

5. Restart the service using the `maprcli` command, as in the following example.

```
maprcli node services -name filemigrate -nodes <node to restart> -action
restart
```

Managing the Service

Describes how to start, stop, and restart services using either the Control System or the CLI.

You can start, stop, and restart the service and view the service dashboard.

Starting, Stopping, and Restarting the Service Using the Control System

1. Log in to the Control System and click **Services** to display the list of services installed on the cluster.
2. See [Managing Services](#) on page 904 for information on starting, stopping, and restarting the services using the Control System.

Starting, Stopping, and Restarting the Service Using the CLI

- To:
 - Start the service, run the following command:

```
maprcli node services -name filemigrate -nodes <node to start> -action start
```

- Stop the service, run the following command:

```
maprcli node services -name filemigrate -nodes <node to start> -action stop
```

- Restart the service, run the following command:

```
maprcli node services -name filemigrate -nodes <node to start> -action restart
```

Restarting the Service Using the Service UI

- Log in to the UI and click **Restart File Migration Service**.

Viewing the Service Dashboard

- Log in to the service UI to view the following:
 - **Uploaded Files** - Displays the number of files uploaded in the last hour.
 - **Waiting Uploads** - Displays the number of files waiting to be uploaded.
 - **Uploaded Data** - Displays the number of bytes uploaded in the last hour.

Managing Policies

Explains how to edit the Purge Interval policy and enable or disable Server Side encryption.

You can modify the Purge Interval policy and Server Side Encryption settings using the UI. You can also modify the properties directly in the properties file.

Note: Editing the properties both through the service UI and directly in the properties file may lead to inconsistencies.

Modifying Purge Interval

1. Log in to the UI and click associated with the purge interval value to edit.
2. Enter the value you want in the field.
3. Click to save the changes.
If you want, you can click to cancel the edit operation.
4. Restart the service for the changes to take effect.
See [Restarting the Service Using the Service UI](#) on page 1102.

Enabling or Disabling Server Side Encryption

1. Log in to the UI and select (to enable) or clear (to disable) the checkbox () associated with the policy.
2. Restart the service for the changes to take effect.
See [Restarting the Service Using the Service UI](#) on page 1102.

Editing Properties in the Properties File

You can directly edit the `maprfs:///var/mapr/filemigrate/FileMigrate.properties` file. See [FileMigrate.properties](#) on page 2476 for complete list of properties that can be set or modified in the file.

1. Stop the File Migration service.
2. Make the necessary changes.
3. Restart the service using the `maprcli` command.
See [Starting, Stopping, and Restarting the Service Using the CLI](#) on page 1102.

Note: If you modified the file directly, you must restart the service using the `maprcli` command.

Removing a Policy

- Log in to the UI and click associated with the policy to remove.

Configuring Logging

Provides an overview of standard Log4J configuration.

The service uses standard Log4J configuration to control its logging. The `log4j.properties` file can be found in `<MAPR_HOME>/filemigrate/filemigrate-1.0.0/conf/` directory. By default, INFO logging is enabled. You can edit the file and restart the service to change the logging behavior.

The service logs the key actions related to scanning, uploading files, and deleting files at the INFO level in the `filemigrate.log` file. The log file also includes WARN and ERROR messages if there were problems preventing the upload of files (for example, AWS S3 was unreachable). If additional detail is needed, edit the `log4j.properties` file to increase logging to the DEBUG or TRACE levels in the properties file.

Troubleshooting

Determining if a File was Uploaded

The service externalizes the status of file uploads as an extended attribute on the files uploaded. Therefore, the service recovers easily from arbitrary crashes and restarts. Files not uploaded will be rediscovered and then uploaded.

To determine if a particular file has been uploaded by the service to AWS S3, you can examine the extended attribute on the file as shown in the following example using the unsupported script `printupload.sh`, which is included in `<MAPR_HOME>/filemigrate/filemigrate-1.0.0/bin/` directory:

```
/opt/mapr/filemigrate/filemigrate-1.0.0/bin/printupload.sh /tmp/afile
Thu Jan 5 00:32:26 EST 2017
```

Ensuring that Login is Successful

If the username and password do not work correctly, make sure that the following properties are configured correctly in the properties file:

- `authorized.users`

- `authorized.groups`

See [FileMigrate.properties](#) on page 2476 for information on these properties.

Managing Tiered Files from the Command-line

After creating a tiered volume and associating a tier with the volume, you can manually trigger offload and recall of individual files in the volume using the CLI. This section describes how to offload file to and recall file from the tier, retrieve status of a file-level tiering operation, and how to perform certain tiering operations when `hadoop` and `maprcli` are not available on the host you wish to use for triggering the tiering operation.

Offloading a File to a Tier Using the CLI and REST API

Describes how to offload files to a tier using the CLI and the REST API.

Files, in tiering-enabled volumes, can be offloaded individually using the CLI and REST API. See [Data Offload and Purge](#) on page 430 for more information. For information on offloading files using (loopbacknfs or FUSE-based) POSIX or NFS clients when `maprcli` or `hadoop` commands are not available, see [Running Tiering Commands when maprcli and hadoop Commands are not Available](#) on page 1106.

Note: Offloading a single file to a warm-tier might result in wasted space. See [Data Offload and Purge](#) on page 430 for more information

The user offloading the file data must have write permission (mode bit or [ACE](#)) on the file to offload data.

You can also offload all data in a tiering-enabled volume to the associated tier. see [Offloading a Volume to a Tier](#) on page 1014 for more information.

CLI

Run one of the following commands to offload file data to a tier:

- `hadoop mfs -offload <file-path>`

For more information, see [hadoop mfs](#) on page 5576.

- `/opt/mapr/bin/maprcli file offload -name <file>`

For more information, see [file offload](#) on page 1853.

REST API

Send a request of type POST. For example:

```
curl -k -X
POST 'https://abc.sj.us:8443/rest/
file/offload?name=fileName' --user
mapr:mapr
```

If the manual offload succeeds, the command returns nothing. If the offload fails, the command returns an error code. For more information on the codes, see [Retrying Failed Operation](#) on page 1020.

Recalling a File to filesystem Using the CLI and REST API

You can recall individual files from a storage tier. When you recall a file, the MAST Gateway fetches a copy of the data to the cluster. Based on the expiration time setting on the volume, recalled data is automatically:

- Offloaded again based on the storage policy (rules) if there are changes to the recalled data.
- Purged when the compactor runs if there are no changes to the recalled data.

See [Data Reads, Writes, and Recalls](#) on page 437 for more information.

Note: You can recall all data from the tier to the volume. See [Recalling a Volume to filesystem](#) on page 1018 for more information.

Recalling a File Manually Using the CLI

- Run one of the following commands to recall a file:

- ```
hadoop mfs -recall <pathToFile>
```

For more information, see [hadoop mfs](#) on page 5576.

- ```
maprcli file recall -name <pathToFile>
```

For more information, see [file recall](#) on page 1854.

Note: For information on recalling files using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprcli or hadoop commands are not available, see [Running Tiering Commands when maprcli and hadoop Commands are not Available](#) on page 1106.

Recalling a File Using the REST API

- Send a request of type POST to the URL. For example, send a request similar to the following:

```
curl -k -X POST 'https://abc.sj.us/rest/file/recall?name=fileName' --user mapr:mapr
```

Terminating a Running File-Level Tiering Job

Explains how to terminate file tiering jobs using the Control System and the CLI.

You can terminate an ongoing offload or recall of a file using the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the [file offload](#) on page 1853 or [hadoop mfs](#) on page 5576 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See [Recalling a Volume to filesystem](#) on page 1018 for more information.

For information on terminating a running offload or recall operation using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprcli or hadoop commands are not available, see [Running Tiering Commands when maprcli and hadoop Commands are not Available](#) on page 1106. For information on terminating a running volume-level job, see [Terminating a Running Volume-Level Tiering Job](#) on page 1019.

Terminating a Running File-Level Offload or Recall Operation Using the CLI and REST API

CLI

Run the following command to terminate a currently running file-level offload or recall operation:

```
maprcli file tierjobabort -name <filePath>
```

For more information, see [file tierjobabort](#) on page 1855.

REST API

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<host>:8443/rest/file/
tierjobabort?name=<filePath>' --user
mapr:mapr
```

Running Tiering Commands when maprcli and hadoop Commands are not Available

You can offload and/or recall a file with NFS, loopbacknfs, and FUSE-based POSIX clients even if [maprcli](#) or [hadoop](#) commands are not available. To perform file-level data tiering operations like offload and/or recall using NFS, loopbacknfs, and FUSE-based POSIX clients when [maprcli](#) or [hadoop](#) commands are not available, after mounting, provide the tiering command such as [offload](#), [recall](#), [tierjobstatus](#), and/or [tierjobabort](#) as described below. When you run the command, the command creates a hidden `.tier_attributes` file (similar to `.dfs_attributes` file) that is purged immediately after the operation is submitted to the server.

Note: When you run the command, the tiering command is triggered immediately and storage policy (or rule), if any, at the volume-level is ignored.

Usage

```
/bin/echo "<command> <file-name>" > .tier_attributes
```

Note: Do not use `echo` in the terminal; instead, use `/bin/echo`.

Options

| Option | Description |
|-----------|--|
| command | The tiering related command to run. The following commands are supported: <ul style="list-style-type: none"> • offload • recall • tierjobstatus • tierjobabort |
| file-name | The name of the file. |

Return Values

On success, the command returns nothing. Otherwise, the command returns one of the following `/bin/echo` return codes, which are displayed as write errors:

| Code | Message | Description |
|-----------|---------------------|---|
| EEXIST | File exists | Indicates tier job is queued or is already in progress. |
| ENOTEMPTY | Directory not empty | Indicates that tier job queue is full. |

| Code | Message | Description |
|--------|---------------------------|--|
| ENOENT | No such file or directory | Indicates that the specified file or job ID does not exist. |
| EIO | I/O error | Indicates that the job could not be submitted. Run the <code>tierjobstatus</code> command to determine the reason for this error. |
| EINVAL | Invalid argument | Indicates that the given command is invalid or not available. See Options on page 1106 for the list of supported commands. |

Examples

Offload file named test

```
# /bin/echo "offload test"
> .tier_attributes
/bin/echo: write error: File exists
```

Recall a file named test

```
# /bin/echo "recall test"
> .tier_attributes
/bin/echo: write error: File exists
```

Check the status of a running job for a file

```
# /bin/echo "tierjobstatus test"
> .tier_attributes
```

Abort a running job

```
# /bin/echo "tierjobabort test"
> .tier_attributes
/bin/echo: write error: No such file
or directory
```

Retrieving Status of File-level Tiering Operation and File Data

You can retrieve the status of a file-level tiering operation using the CLI and REST API. For information on volume-level tiering operation, see [Retrieving the Status of a Volume-level Tiering Operation](#) on page 1023.

Retrieving the Status of a Running Tiering Operation

- Run the `maprcli` command or send a request of type GET to check the status of an active or completed offload, abort, and/or recall operation.

See [file tierjobstatus](#) on page 1857 for more information. For example:

CLI

```
maprcli file tierjobstatus -name
<file_name> -json
```

REST

```
curl -k -X
GET 'https://<host>:8443/rest/file/
tierstatus?name<file_name>' --user
mapr:mapr
```

See [Output](#) on page 1857 for more information.

Retrieving Status of File Data

- Run the `maprcli` command or send a request of type GET to determine the status of file data. See [file tierstatus](#) on page 1870 for more information. For example:

CLI

```
maprcli file tierstatus -name
<file_name>
```

REST

```
curl -k -X
GET 'https://<host>:8443/rest/file/
tierstatus?name=<file_name>' --user
mapr:mapr
```

See [Output](#) on page 1871 for more information.

Administering Tables

Administration of the HPE Ezmeral Data Fabric Database is done primarily via the command line (`maprcli`) or with the Managed Control System (MCS). Regardless of whether the HPE Ezmeral Data Fabric Database table is used for binary files or JSON documents, the same types of commands are used with slightly different parameter options. HPE Ezmeral Data Fabric Database administration is associated with tables, columns and column families, and table regions.

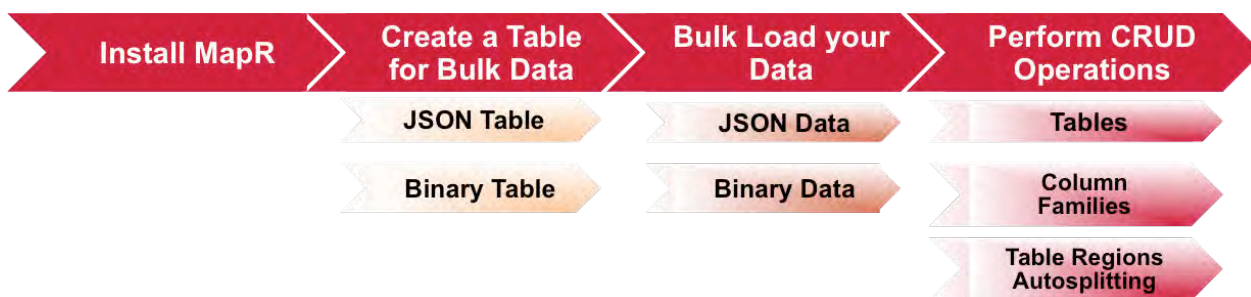

Why use HPE Ezmeral Data Fabric Database?

From an administrator's point-of-view, HPE Ezmeral Data Fabric Database provides the following capabilities:

- **Minimal administration:** Single namespace for files, tables and streams, flexible schema that allows built-in data management and protection, automatic splits and merges as data grows and shrinks, and easy bulk data loading.
- **Self-healing from HW and SW failures:** Replicated state and data for instant recovery and automated re-replication of data.
- **Global low-latency replication:** Multi-master (that is, active to active) replication which is important for disaster recovery. Includes reduced risk of data loss, application failover, and faster data access.
- **High performance and low latency:** Integrated system with fewer software layers, single hop to data, and no compactions with low I/O amplification.
- **Fine-grained security:** Access permissions can be granted to tables (as well as files and streams) at a granular level using [MapR Access Control Expressions \(ACEs\)](#), which are designed for flexibility and ease-of-use.

How Do I Get Started?

The following graphic shows the basics steps (with hotspot links) for getting started.

1. [Install MapR](#)
2. [Creating a table for bulkloading data involves specifying the table type \(JSON or binary\) and setting the bulkload flag.](#)
3. [Bulkloading can be done either as a full or incremental bulkload. Different utilities are used for the bulk load depending on what you are trying to accomplish.](#)
4. [Both full and incremental bulkloads can be performed for HPE Ezmeral Data Fabric Database JSON tables. This topic describes the three command-line utilities available for loading documents into JSON tables.](#)
5. [Administration of tables describes how to create, read, update, and delete tables as well as other tasks such as managing permissions and auditing.](#)
6. [This section cover the administration of column families including how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.](#)
7. [This topic describes administrative tasks associated with table regions including how to set autosplitting.](#)

Useful Administrator Resources

| Links to Resources | Descriptions |
|---|--|
| maprccli and REST API Syntax on page 1699 | Command line reference for MapR operations. For HPE Ezmeral Data Fabric Database, the commands particularly applicable are associate with the maprccli table on page 2029 command. These commands include not only table CRUD operations but also table column family, table region, and table replication operations. |
| Utilities for HPE Ezmeral Data Fabric Database JSON Tables on page 5515 | Utilities for HPE Ezmeral Data Fabric Database JSON tables. These utilities are used form managing JSON tables including importing and exporting data to and from JSON tables. Particularly useful are: <ul style="list-style-type: none"> • HPE Ezmeral Data Fabric Database JSON ImportJSON on page 5525 utility with imports JSON documents into a HPE Ezmeral Data Fabric Database JSON table. • HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5488utility which performs CRUD operations on JSON documents and tables. |

| Links to Resources | Descriptions |
|---|---|
| Utilities for HPE Ezmeral Data Fabric Database Binary Tables on page 5532 | Utilities for HPE Ezmeral Data Fabric Database binary tables. These utilities are used for managing binary tables. Particularly useful is HPE Ezmeral Data Fabric Database Binary CopyTable on page 5533 which is used to copy data from one HPE Ezmeral Data Fabric Database binary table to another.  Note: To import HFile or Result files in a HPE Ezmeral Data Fabric Database binary table, the hbase command can be used. See Loading Data into Binary Tables on page 1144. |
| Configuring Security on page 1514 | Information on security tasks for configuring MapR security, managing secure clusters, and administering auditing. |
| Hadoop and Big Data Security | MapR information on Security and Big Data Governance that identified key unique advantages including authentication, authorization, auditing, and encryption. |
| Provisioning Secure Access Controls in HPE Ezmeral Data Fabric Database | MapR blog discussing MapR's boolean Access Control Expressions (ACEs) which provide granular-level permissions including topics and examples of best practices. |

Managing Tables

HPE Ezmeral Data Fabric Database supports two types of table: binary tables and JSON tables. This section covers how to create, edit, and delete tables, as well as how to set parameter values, display parameter values, grant permissions and access, replicate tables, and more using the Control System and the CLI.

When you log in to the Control System and click **Data > Table**, the **Tables** page displays the following in the various panes:

- **Active Alarms** — The active table (replication) alarms
- **Recently Viewed Tables** — The tables that were most recently accessed from the Control System
- List of volumes that you have access to and a search field to retrieve a table by table path

Click **Create Table** button to create a new binary or JSON table. For a conceptual overview of:

- Binary tables, see [HPE Ezmeral Data Fabric Database Binary Tables](#) on page 502.
- JSON tables, which contain JSON documents, see [HPE Ezmeral Data Fabric Database JSON Tables](#) on page 486.

Creating a New Table

Explains how to create both binary tables and JSON tables using either the Control System, the CLI, or the REST API.

There are several methods that you can use to create HPE Ezmeral Data Fabric Database tables including the maprccli, and hbase shell, mapr dbshell commands, and through the Control System.

Creating a Table Using the Control System

1. Log in to the Control System and click **Create Table** in the **Data > Tables** page.

Note: This option is not available on the Kubernetes version of the Control System.

The **Create New Table** page displays.

2. Choose the table type:

- JSON — see [HPE Ezmeral Data Fabric Database as a Document Database](#) on page 469
- Binary — see [HPE Ezmeral Data Fabric Database as a Column-Oriented Database](#) on page 501

3. Specify values for the following properties under **Properties** section.

a) Enter path to the table in the **Table Path** field.

Tables are stored in the HPE Ezmeral Data Fabric filesystem. When providing the path to a table, use these conventions.

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named test under a volume with a mount point at /volume1, specify the following path: /volume1/test
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named customer in volume1 in the sanfrancisco cluster, specify the following path: /mapr/sanfrancisco/volume1/customer

b) Select the interval of time to apply when logging table metrics.

You can choose to log metrics every 10 seconds, 1 minute (default), or 10 minutes. For visualizing the metrics, see [Visualizing Table Metrics in the Control System](#) on page 1425.

c) Enable (**Yes**) or disable (**No**) auto-splitting of table.

If enabled, the table will be split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this is enabled.

d) Choose whether to do a full bulkload or incremental bulkload of the table.

For more information, see [Loading Documents into JSON Tables](#) on page 1140. The default value is incremental bulkload.

4. (Optional) Configure the following **Security** settings (JSON tables only):

a) Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the table.

For more information, see [Tagging JSON Tables, Column Families, and Fields with Security Policies](#) on page 1628.

b) Enable (**Yes**) or disable (**No**) auditing of table operations.

If auditing is enabled at the cluster and volume levels, enabling auditing will cause auditing to start for the table operations. For more information, see [Auditing of Operations on HPE Ezmeral Data Fabric Database Binary Tables and JSON Tables](#) on page 667.

c) Specify public (to grant access to all user) or the individual users, groups, and/or roles that have and/or do not have the following types of access, by default, to data in the column families under **DEFAULT DATA ACCESS CONTROL FOR COLUMN FAMILIES**.

JSON Table

| | |
|-----------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
|-----------|--|

| | |
|-----------------|---|
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Traverse Data | <p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre data-bbox="1187 590 1458 898"> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a . b, but not on a. For sjohnson to read a . b, the user needs the traverse permission on a. The user can then pass over field a to a . b. This permission is inherited by fields within the column family.</p> |
| Set Compression | Can set or change the compression setting for the column family. |

Binary Table

| | |
|------------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |

| | |
|-----------------|---|
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |
| Set Version | Can set or change the maximum and minimum number of versions of column values to keep. |
| Set Compression | Can set or change the compression setting for the column family. |

5. Specify Public (to grant access to all users) or the individual users, groups, and/or roles that have and/or do not have the following types of access to administer the table under **Table Administration Control**.

JSON Table

| | |
|-----------------------------|--|
| Administration | Can view and edit the permissions for the table. |
| Force Pack | Can pack table regions. |
| Split Merge | Can take the following actions: <ul style="list-style-type: none"> • Split the table into regions or merge regions of the table together. • Change the size of the region. |
| Index | Can create index for this table. |
| Bulkload | Can load this table with bulk loads if the table was created with bulk load support. |
| Replication Access | Can set up replication either to or from a table. |
| Create/Rename Column Family | Can create column families for this table or rename existing column families. |
| Delete Column Family | Can delete column families associated with the table. |

Binary Table

| | |
|----------------|--|
| Administration | Can view and edit the permissions for the table. |
| Force Pack | Can pack table regions. |

| | |
|-----------------------------|--|
| Split Merge | Can take the following actions: <ul style="list-style-type: none"> • Split the table into regions or merge regions of the table together. • Change the size of the region. |
| Bulkload | Can load this table with bulk loads if the table was created with bulk load support. |
| Replication Access | Can set up replication either to or from a table. |
| Create/Rename Column Family | Can create column families for this table or rename existing column families. |
| Delete Column Family | Can delete column families associated with the table. |

By default, all permissions are given to the user creating the table.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

Tip: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
 - $!$ — Negation operator.
 - $\&$ — AND operation.
 - $|$ — OR operation.

Use (), parentheses, for subexpressions.

Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 1590 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

6. Click **Create Table** to create the table.

You can proceed to:

- [Add](#) column families to the table.
- [View](#) the table information for the newly created table.

Creating a Table Using the CLI or the REST API

CLI

The basic command to create a binary table is:

```
maprcli table create -path <path>
```

To create a JSON table, include the `-tabletype` parameter and set it to `json`:

```
maprcli table create -path  
<path> -tabletype json
```

The `-tabletype` parameter is set to `binary` by default.

REST

Send a request of type POST. For example, to create a:

- Binary table:

```
curl -k -X  
POST 'https://<hostname>:8443/rest/  
table/create?path=<path>' --user  
mapr:mapr
```

- JSON table:

```
curl -k -X POST 'https://  
<hostname>:8443/rest/table/create?  
path=<path>&tabletype=json' --user  
mapr:mapr
```

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{}&()/" (or)
maprcli table create -path '/^=#;{}&()/'
```

To use either the ' or the " character in the table name, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table create -path "'^=#;{}&()/" (or)
maprcli table create -path '/"^=#;{}&()/'
```

When you create a table, you can set a number of properties. See [table create](#) on page 2029.

Creating Tables Using shell Command

JSON Tables

The HPE Ezmeral Data Fabric Database shell command is used on JSON tables only. To run this command, execute the following:

```
mapr dbshell
```

After starting the shell, run the `create` command. See [HPE Ezmeral Data Fabric Database Shell \(JSON Tables\)](#) on page 5488.

Binary Tables

The HBase shell command is used on binary tables only. To run this command, execute the following:

```
hbase shell
```

After starting the HBase shell, run the `create` command. Type `help` to see a list of commands and their syntax. See [HPE Ezmeral Data Fabric Database HBase Shell \(Binary Tables\)](#) on page 5528.

Configuring Maximum Row Sizes Using the CLI

The default maximum row size at installation is 32MB. You can configure this maximum by changing the value of the `dfs.db.max.rowsize.kb` parameter with the `maprcli config save` command.

Tables support rows up to 2 GB in size. Rows in excess of 100MB might show decreased performance.

Here is an example of changing the maximum row size:

```
maprcli config save -values {"dfs.db.max.rowsize.kb":<value in KB>}
```

The value of this parameter affects both JSON tables and binary tables.

To view the current setting of this parameter, use the `maprcli config load` command, as in this example:

```
maprcli config load -json | grep mfs.db.max.rowsize.kb
```

Editing Tables

Explains how to edit binary and JSON tables using either the Control System, the CLI, or the REST API.

You can use the Control System, the CLI, or the REST API to edit the attributes of a HPE Ezmeral Data Fabric Database binary or JSON table. You can also use the HBase shell to edit a binary table. To edit a table, you must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Editing Tables Using the Control System

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Edit Table** to display the **Edit Table** page.
3. Make changes to the following **Properties**, where necessary:

| | |
|-------------------------|--|
| Metrics Interval | The interval of time for logging metrics. |
| Auto Split | Enable (Yes) or disable (No) auto-splitting of table. If enabled, the table will be split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this is enabled. |
| Bulkload | Enable (Yes) or disable (No) full bulk load of the table. |

4. Make changes to the following **Security** settings, where necessary:
 - a) Enable (**Yes**) or disable (**No**) auditing of table operations.
If auditing is enabled at the cluster and volume levels, enabling auditing will cause auditing to start for the table.
 - b) Make changes as needed to **DEFAULT DATA ACCESS CONTROL FOR COLUMN FAMILIES**.

JSON Table

Modify the list of users, groups, and/or roles that have and/or do not have the following types of access to the default column family:

| | |
|-----------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
|-----------|--|

| | |
|-----------------|---|
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Traverse Data | <p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre data-bbox="1185 588 1458 924"> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.</p> |
| Set Compression | Can set or change the compression setting for the column family. |

Binary Table

Modify the list of users, groups, and/or roles that have and/or do not have the following types of access to the default column family:

| | |
|-----------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
|-----------|--|

| | |
|-----------------|--|
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |
| Set Compression | Can set or change the compression setting for the column family. |

To:

- Grant access to a new user, group, or role, click **Add Another**, select entity **Type**, enter entity **Name**, and select the permissions to grant the entity.
- Create a copy of an existing entity settings, which you can then modify, click .
- Delete permissions for an entity, click .

5. Make changes as needed to **Table Administration Control** settings.

Modify the list of users, groups, and/or roles that have and/or do not have the following types of administration permissions on the table:

JSON Table

| | |
|--------------------|--|
| Admin | Can view and edit the permissions for the table. |
| Index | Can create an index for the table. |
| Force Pack | Can pack table regions. |
| Split Merge | Can take the following actions: <ul style="list-style-type: none"> • Split the table into regions or merge regions of the table together. • Change the size of the region. |
| Bulkload | Can load this table with bulk loads if the table was created with bulk load support. |
| Replication Access | Can set up replication either to or from a table. |

| | |
|-----------------------------|---|
| Create/Rename Column Family | Can create column families for this table or rename existing column families. |
| Delete Column Family | Can delete column families associated with the table. |

Binary Table

| | |
|-----------------------------|--|
| Admin | Can view and edit the permissions for the table. |
| Force Pack | Can pack table regions. |
| Split Merge | Can take the following actions: <ul style="list-style-type: none"> Split the table into regions or merge regions of the table together. Change the size of the region. |
| Bulkload | Can load this table with bulk loads if the table was created with bulk load support. |
| Replication Access | Can set up replication either to or from a table. |
| Create/Rename Column Family | Can create column families for this table or rename existing column families. |
| Delete Column Family | Can delete column families associated with the table. |

To:

- Grant access to a new user, group, or role, click **Add Another**, select entity **Type**, enter entity **Name**, and select the permissions to grant the entity.
- Create a copy of an existing entity settings, which you can then modify, click .
- Delete permissions for an entity, click .

6. Click **Save Changes** for the changes to take effect.

Editing Tables Using the CLI or the REST API

CLI

The following is the command to edit a table:

```
maprcli table edit -path <path>
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<hostname>:8443/rest/
table/edit?path=<path>' --user
<username>:<pwd>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

**Note:** You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{}&()/" (or)
maprcli table create -path '/^=#;{}&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "'^=#;{}&()/" (or)
maprcli table create -path '/"^=#;{}&()/'
```

When you edit a table, you can change a number of properties including:

- Enable or disable auditing, autosplitting, and bulkloading
- Set permissions on table
- Set permissions for default column families

For full reference for this command, see [table edit](#) on page 2076.**Editing Binary Tables Using HBase Shell**After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.**Removing a Table**Use either the Control System or the `maprcli table delete` command to drop a HPE Ezmeral Data Fabric Database table.

Removing a Table Using the Control System

To remove a table:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Remove Table**.
The **Remove Table** confirmation window displays.
3. Click **Remove Table** to remove the table.
After the table is removed, data in the table cannot be recovered.

Removing a Table Using the CLI or REST API

Run the command `maprcli table delete -path <path>`.

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{ }&()/" (or)
maprcli table create -path '/^=#;{ }&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "'/^=#;{ }&()/" (or)
maprcli table create -path '/"^=#;{ }&()/'
```

For more information, see [table delete](#) on page 2075.

Defining ACEs Using the Access Control Expression Builder

Indicates how to build access control expressions (ACEs) using the Expression Builder.

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.
Here:

| | | |
|------------|-------------------|---|
| All | AND (&) operation | Indicates that all of the conditions must be met for public or user, group, and/or role to access the volume. |
| Any | OR () operation | Indicates that any one of the conditions must be met for public or user, group, and/or role to access the volume. |

2. Click:

| | |
|-----|---|
| + | To add an expression. |
| () | To add a subexpression. |
| x | To remove an expression or subexpression. |

3. Select Public or User, Group, or Role from the drop-down menu and:

- a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
- b) Enter name of the user, group, or role.

4. Click **Save Changes** to create an Access Control Expression.

Setting Whole Volume ACEs Using the CLI

See [Setting Whole Volume ACEs](#) on page 1576.

Setting Table ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Setting Stream ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Viewing the List of Tables

Describes how to view the list of tables using either the Control System or the CLI.

Viewing the Tables in a Volume Using the Control System

1. Log in to the Control System and click **Data > Tables** to view all the volumes to which you have access.

Note: This option is not applicable on the Kubernetes version of the Control System.

For each volume, the pane displays the following:

| Column Name | Column Description |
|---------------|--|
| Name | The name of the volume. |
| Type | The type. Value can be: <ul style="list-style-type: none"> •  — Volume •  — Directory •  — Table |
| Owner | The name of the owner. |
| Last Modified | The last modification date and timestamp. |

- Click on the name of the volume (to browse to the path to the table) or enter the name of the volume in the text field.
The tables in the selected volume display. If necessary, click the name of the directory to browse further or  to return to **All** volumes view.

Viewing a Table by Table Path Using the Control System

- Log in to the Control System and click **Data > Tables**.

Note: This option is not applicable on the Kubernetes version of the Control System.

- Enter the path to the table and click **GO**.
The tables information page for the specified table displays.

Listing the Tables in a Directory From the Command-line

Method for Binary Tables Only (HBase Shell)

After starting the HBase shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory. Type `help` to see a list of commands and their syntax.

Method for JSON Tables Only (mapr dbshell)

After starting the shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory. See [HPE Ezmeral Data Fabric Database Shell \(JSON Tables\)](#) on page 5488.

Retrieving a Table by Table Path Using the CLI or the REST API

To retrieve table details for a table by specifying the table path from the CLI, run the following command:

```
maprcli table info -path <table-path>
```

For information on this command, see [table info](#) on page 2093.

Viewing Table Information

Explains how to view table information using either the Control System, the CLI or the REST API.

You can view table information including table properties, column families, regions, replicas, upstream source, indexes, and metrics. Use either the `maprcli` command, REST API, or the Control System to display all of the information that HPE Ezmeral Data Fabric Database stores about a particular table.

Viewing Table Information Using the Control System

- Search and retrieve the table either by volume or by table path.
For information on retrieving, see:
 - [Viewing the Tables in a Volume Using the Control System](#) on page 1123
 - [Viewing a Table by Table Path Using the Control System](#) on page 1124
- Click the name of the table to see the table details.
The page displays the following tabs:
 - [Summary](#)
 - [Column Families](#)
 - [Regions](#)
 - [Replication](#)

- [Change Data Capture](#)
- [Indexes](#)
- [Metrics](#)

On this page, you can:

- [Edit](#) the table
- [Remove](#) table

Viewing Table Information Using the CLI or REST API

CLI

The basic command to retrieve table information is the following:

```
maprcli table info -path
<tablePath> -json
```

REST

Send a request of type GET to retrieve table details. For example:

```
curl -k -X
GET 'https://<hostname>:8443/rest/
table/info?path=<tablePath>' --user
<username>:<pwd>
```

For more information, see [table info](#) on page 2093.

Viewing Table Settings

Describes how to view table settings using the Control System, the CLI or the Rest API.

Viewing Table Settings Using the Control System

- Log in to the Control System and go to the **Summary** tab in the [table information page](#) to view the following settings.

Throughput - By Op Type

This pane displays a graph for the operations on the table in the last hour. For more information, see [Monitoring Tables](#) on page 1424.

Region Data Distribution by Node

This pane shows the distribution of the table or secondary index regions across the nodes in the cluster. For more information, see [Monitoring Tables](#) on page 1424.

Properties

This pane shows the current value for the following table properties:

| | |
|------------|--|
| Table Path | The path to the table on the filesystem. |
| Table Type | The type of table. Value can be one of the following: <ul style="list-style-type: none"> • JSON • Binary |
| Total Rows | The total number of rows in the table. |

| | |
|---------------------|--|
| Region Size | The average size of the regions into which HPE Ezmeral Data Fabric Database tries to split the table as the table grows. The default is 4096 MB. |
| Total Logical Size | The estimated size (in bytes) of uncompressed data stored in table (excluding replication). |
| Total Physical Size | The estimated size (in bytes) of actual data stored in table (excluding replication). This includes internal metadata and reflects compressed data size when compression is enabled. |
| Auditing | The setting to enable or disable auditing of operations on the table. |
| Auto Split | The setting to automatically split the table into regions as the table grows. |
| Bulkload Type | The setting to allow a full bulk load of the table. |
| Metrics Interval | The table metrics collection interval, in seconds. |

Security

This pane shows the following security settings on the table:

| | |
|-----------------|--|
| Security Policy | The security policies associated with this table including: <ul style="list-style-type: none"> Name of the security policy Status of the security policy Access control expression in the security policy |
| Audit | Whether or not auditing is enabled for table operations. |

Table Admin Control

This pane shows the entities (users, groups, and/or roles) that have and/or do not have one or more of the following types of permissions to administer the table:

| | |
|-----------------------------|--|
| Admin (Access Control) | Can view and edit the permissions for the table. |
| Force Pack | Can pack table regions. |
| Split Merge | Can take the following actions: <ul style="list-style-type: none"> • Split the table into regions or merge regions of the table together. • Change the size of the region. |
| Index | Can create index for this table. This permission is for JSON tables only. |
| Bulkload | Can load this table with bulk loads if the table was created with bulk load support. |
| Replication Access | Can set up replication either to or from a table. |
| Create/Rename Column Family | Can create column families for this table or rename existing column families. |
| Delete Column Family | Can delete column families associated with the table. |

Viewing Table Settings Using the CLI and REST API

CLI

The basic command to retrieve table information is the following:

```
/opt/mapr/bin/maprcli table
info -path <tablePath> -json
```

REST

Send a request of type GET to retrieve table details. For example:

```
curl -k -X
GET 'https://<hostname>:8443/rest/
table/info?path=<tablePath>' --user
<username>:<pwd>
```

For more information on the settings, see [table info](#) on page 2093.

Listing Column Families

Explains how to view the column families for a table using either the Control System or the CLI.

Viewing Table Column Families Using the Control System

To view the column families for a table:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.

2. Click **Column Families**.

The page displays the default permissions for the column families in the **Default Column Family Authorization** pane and for each column family, the **All** pane displays:

| Column Name | Column Description |
|--------------------|---|
| Column Family Name | The name of the column family. |
| JSON Path | The JSON path for the column in the JSON file in dotted notation. |
| Compression | The compression scheme used for the column family. |
| Time-to-Live | The amount of time to keep the data in the column family. |
| In Memory | Whether or not this column value resides in memory. |

Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

- [Add](#) a column family to the table
- [Remove](#) a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{ }&()/" (or)
maprcli table create -path '/^=#;{ }&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "'^=#;{}&()/'" (or)
maprcli table create -path "'^=#;{}&()/'"
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the paths
- `adminaccessperm` on the table

For complete reference, see [table cf list](#) on page 2060.

Viewing Table Regions

Use either the Control System or the CLI to list the regions in which a table's data is located.

HPE Ezmeral Data Fabric Database tables are split into regions on an ongoing basis. Administrators and developers do not need to manage these regions or restructure data on disk when data is added and deleted. These operations happen automatically. You can view region information for tables to get a sense of the size and location of table data on the data-fabric cluster.

Displaying the Regions Using the Control System

To display the regions of a table:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Do one of the following:
 - Click **Regions** to view the list of regions for the table.
 - Click the name of the index in the **Indexes** tab to view the regions for the index.

For each region, the **Regions** pane displays the following:

| Column Name | Column Description |
|-------------------|---|
| Start Key | Value of the start key for this region. For the first region in a table, this value is exclusive. For all other regions, it is inclusive. |
| End Key | Value of the end key for this region. This value is always exclusive. |
| Physical Size | The physical size of the region with data compression (excluding replication). |
| Logical Size | The logical size of the region without data compression (excluding replication). |
| No of Rows | Number of rows in the region. |
| Primary Node | The host name and port of the primary node for this region. |
| Secondary Node | The host names and ports of the secondary nodes where this region is replicated. |
| Last HB | The time since last heartbeat from the region's primary node. |
| Region Identifier | The region's FID. |

Displaying Region Information Using the CLI or the REST API

The basic command to retrieve the list of regions that make up the table is:

```
maprcli table region list -path <path>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{ }&()/" (or)
maprcli table create -path '/^=#;{ }&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "'^=#;{ }&()/" (or)
maprcli table create -path '/"^=#;{ }&()/'
```

The `json` parameter displays the output as a JSON document.

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path

See [table region list](#) on page 2098.

Displaying the List of Table Replicas

Describes how to view information on the table replicas using the Control System or the CLI.

Displaying the List of Table Replicas Using the Control System

To view table replicas:

1. Log in to the Control System and go to the [table information page](#).
2. Click **Replication**.

The page displays all the replicas and for each replica, the pane displays the following statistics:

| Column Name | Column Description |
|---------------------|--|
| Paused | Whether replication is paused. |
| Destination Cluster | The cluster on which the replica resides. |
| Destination Path | The path to the destination. |
| Status | The status of the replica. Replicas can be in one of the following states: <ul style="list-style-type: none"> In-Synch — indicates replica is in synch with the source table and there are no more bytes to be sent from the source. Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. Broken — indicates there was an error during replication. If necessary, remove and re-create the replica. |
| Earliest | The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica. |
| Latest | The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica. |
| Errors | Error () information, if any. |
| Compression Type | The type of on-wire compression. |
| Synchronous | Whether replication is synchronous or asynchronous. |
| Throttled | Whether replication is throttled. |
| Encrypted | Whether replication is encrypted. |

Retrieving List of Table Replicas Using the CLI or the REST API

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see [table replica list](#) on page 2117

Viewing the List of Change Logs

Explains how to view the list of change logs using the Control System or the CLI.

Viewing the List of Change Logs Using the Control System

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).

For each change log, the page displays the following:

| Column Name | Column Description |
|---------------------|---|
| Edit Change Log | Shortcut to the Edit Change Log window for editing a change log. |
| Paused | Specifies whether the change propagation is paused for the associated change log. |
| Destination Cluster | Specifies the destination cluster on which the stream exists. |

| Column Name | Column Description |
|-------------------------------|--|
| Destination Stream Topic Name | Specifies the name of the stream associated with the change log. |
| Up to Date | Specifies whether (Yes) or not (No) the change log is up to date. If value is No , hover the cursor over the value to see the number of pending bytes, puts, and buckets. |
| Errors | Indicates whether there were any errors during change propagation. |
| Compression Type | The type of compression for data transfer between filesystem and gateway for the associated change data log instance |
| Synchronous | Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data. |
| Throttle | Specifies whether data transfer to the stream for the associated change data log is throttled. |
| Encrypted | Specifies whether the data transfer between filesystem and gateway for the associated change data log is encrypted. |
| Field Path | Specifies whether only specific field paths are being published to the stream topic. |

Retrieving the List of Change Logs Using the CLI or REST API

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

For complete reference, see [table changelog list](#) on page 2071.

Listing Secondary Indexes

Describes how to list information about the secondary indexes created on HPE Ezmeral Data Fabric Database JSON tables.

You can view secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

Note: The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

- Log in to the Control System and go to the **Indexes** tab in the [table information page](#).

The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

| Column Name | Column Description |
|----------------|---|
| Index Name | The name of the index |
| Fields Indexed | The number of fields on the JSON table that are indexed and used for ordering |

| Column Name | Column Description |
|----------------|--|
| Fields Covered | The number of fields on the JSON table that are indexed, but not used for ordering |
| State | The replication state of the index |
| Up to Date | Whether the index is up to date |
| Hashed | Whether the index is hashed |
| Size | The size of the index |

To view more details on individual indexes, see [Viewing Secondary Index Details](#) on page 1220.

Listing Indexes Using the CLI

The following is basic command for listing secondary indexes.

```
maprcli table index list
    -path <path>
    -refreshnow < true | false >
```

See [table index list](#) on page 2089 for more information.

Viewing Table Metrics in the Control System

Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

- View these metrics in the Control System, see [Monitoring Tables](#) on page 1424.
- Customize the charts you see on the page, see [Creating a Custom Board for the Charts](#) on page 1411.
- Customize columns you see on the page, see [Adding and Removing Columns from the List View](#) on page 1412.

| Chart/Column Name | Metric | Description |
|-------------------------------|----------------------------|---|
| Table Bytes Read Per Node | Throughput - bytes read | The number of bytes read from the primary table per node for all RPC types. |
| Table and Index Bytes Read | | The number of bytes read across a primary table and its secondary indexes for all RPC types. |
| Table Bytes Written Per Node | Throughput - bytes written | The number of bytes written to the primary table per node for all RPC types. |
| Table and Index Bytes Written | | The number of bytes written across a primary table and its secondary indexes for all RPC types. |
| Table Rows Read Per Node | Throughput - rowCount read | The number of rows read from the primary table per node for all RPC types. |
| Table and Index Rows Read | | The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node. |

| Chart/Column Name | Metric | Description |
|------------------------------------|--------------------------------|---|
| Table Rows Written Per Node | Throughput - rowCount written | The number of rows written to the primary table per node for all RPC types. |
| Table and Index Rows Written | | The number of rows written across a primary table and its secondary indexes for all RPC types. |
| All Tables Written Rows Throughput | | Number of rows written by RPC operation type. |
| Table Rows Responded Per Node | Throughput - rowCount returned | The number of rows returned from the primary table per node for all RPC types. |
| Table and Index Rows Responded | | The number of rows returned across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node. |
| Scan Throughput | | Compares the scan throughput for rows read versus rows returned. This is displayed in the default chart view for a node and for a table. |

| Chart/Column Name | Metric | Description |
|--|--|--|
| All Tables Throughput | Throughput - rpcCount/second | Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables. |
| Throughput by Rpc Type | | The combined RPC load for the primary table and its indexes. |
| All Tables RPC Byte Throughput | | The number of bytes processed by RPC operation type. |
| All Tables Read Rows Throughput | | Number of rows processed by RPC operation type. |
| All Tables Returned Rows Throughput | | Number of rows returned by RPC operation type. |
| Put and Append Operation Throughput | | Number of put and append RPC operations for the table, including its indexes. |
| Table Check and Put Ops Per Node | | The number of check and put operations completed for a primary table and for a node. |
| Table Update and Get Ops Per Node | | The number of update and get operations completed for a primary table and for a node. |
| Table Get and Index Scans | | The number of get and index scans completed for a primary table and for a node. |
| Table Write and Index Maintenance Activity | | The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index. |
| Table Get Ops Per Node | | The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table. |
| Table Get Throughput Per Node | | The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table. |
| Table Increment Ops Per Node | | The number of increment operations completed for a primary table and for a node. |
| Table Put Ops Per Node | | The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table. |
| Table Scan Ops Per Node | | The number of scan operations completed for a primary table and for a node. |
| Table Append Ops Per Node | | The number of append operations completed for a primary table and for a node. |
| Table Write Throughput Per Node | The number of put and append operations per second completed | |

| Chart/Column Name | Metric | Description |
|---|--|--|
| Table and Index Scan Latency | Latency | The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index. |
| Table and Index Scan Latency Per node | | The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency. |
| Table Append Latency Per Node | | The 99th percentile latency of append operations on the primary table per node. |
| Table Increment Latency Per Node | | The 99th percentile latency of increment operations on the primary table per node. |
| Table Put Latency Per Node | | The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table. |
| Table Get Latency Per Node | | The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table. |
| Table Scan Latency Per Node | | The 99th percentile latency of scan operations on the primary table per node. |
| Table Get Latency Percentiles* | | The get operation latency by percentile for the primary table and its secondary indexes. |
| Primary Table Put & Append Latency Percentiles* | | The pure write operation latency by percentile for the primary table and its secondary indexes. |
| Table Write Throughput Latency Percentiles | | The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table. |
| Table Get Throughput Latency Percentiles | | The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table. |
| Table Check and Put Latency Per Node | | The 99th percentile latency of check and put operations on the primary table per node. |
| Table Update and Get Latency Per Node | | The 99th percentile latency of update and get operations on the primary table per node. |
| Index Put Latency | The 99th percentile latency of put operations per secondary index of the | |

| Chart/Column Name | Metric | Description |
|--------------------------------------|---------------------------------------|--|
| All Tables Replication Sent Bytes | Replication - rows/bytes sent | The number of bytes of replication data sent. |
| All Tables Replication Pending Bytes | Replication - rows/bytes pending | The number of bytes of replication data not yet sent. |
| All Tables Replication Activity | Replication - rows/bytes sent/pending | Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables. |
| Index Throughput by RPC Type | Index - Throughput | The combined RPC load for the primary table and its secondary indexes. |
| Index Put Ops | | The number of put operations completed per secondary index of the primary table. |
| Index Put Ops Per Node | | The number of put operations completed per secondary index of the primary table per node. |
| Index Scan Ops | | The number of scan operations completed per secondary index of the primary table. |
| Index Scan Ops Per Node | | The number of scan operations completed per secondary index of the primary table per node. |
| Index Bytes Read | Index - rows/bytes read | The number of bytes read per secondary index of the primary table for all RPC types. |
| Index Bytes Read Per Node | | The number of bytes read per secondary index of the primary table per node for all RPC types. |
| Index Bytes Written Per Node | | The number of bytes written per secondary index of the primary table per node for all RPC types. |
| Index Rows Read | | The number of rows read per secondary index of the primary table for all RPC types. |
| Index Rows Read Per Node | | The number of rows read per secondary index of the primary table per node for all RPC types. |
| Index Rows Responded | Index - rows/bytes returned | The number of rows returned per secondary index of the primary table for all RPC types. |
| Index Rows Responded Per Node | | The number of rows returned per secondary index of the primary table per node for all RPC types. |
| Index Scan Read vs Returned Rows | Index - rows/bytes read | The number of secondary index rows that were read versus returned. |

| Chart/Column Name | Metric | Description |
|-------------------------------------|------------------------------|--|
| Index Bytes Written | Index - rows/bytes write | The number of bytes written per secondary index of the primary table for all RPC types. |
| Index Rows Written | | The number of rows written per secondary index of the primary table for all RPC types. |
| Index Rows Written Per Node | | The number of rows written per secondary index of the primary table per node for all RPC types. |
| All Tables Index Sent Bytes | Index - rows/bytes sent | The number of bytes sent for secondary index updates. |
| All Tables Index Pending Bytes | Index - rows/bytes pending | The number of bytes of secondary index data remaining to be sent. |
| All Index Maintenance Activity | | Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables. |
| All Tables CDC Sent Bytes | CDC - rows/bytes sent | The number of bytes of CDC data sent. |
| All Tables CDC Pending Bytes | CDC - rows/bytes pending | The number of bytes of CDC data per node not yet sent. |
| All Tables CDC Propagation Activity | | The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables. |
| All Streams Producer Ops | Streams Throughput, RPCs | The number of Streams producer RPCs. |
| All Streams Consumer Ops | | The number of Streams consumer RPCs. |
| All Streams Producer Messages | Streams Throughput, messages | The number of Streams messages produced. |
| All Streams Consumer Messages | | The number of Streams messages read by consumers. |
| Table Value Cache All Lookups | Value Cache Lookups | All operations for a primary table and for a node that performed a cache lookup. |
| Table Value Cache Lookups | | The number of get operations for a primary table and for a node that performed a cache lookup. |
| Table Value Cache Lookups Per Index | | The number of get operations for a primary table and for a node that performed a cache lookup. |

| Chart/Column Name | Metric | Description |
|---|----------------------|---|
| Table and Index Value Cache All Lookups | Value Cache Hits | All operations across the primary table and its secondary indexes that performed a cache lookup. |
| Table and Index Value Cache Lookups Per Index | | The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index. |
| Table and Index Value Cache Lookups | | The number of get operations across the primary table and its secondary indexes that performed a cache lookup. |
| Table Value Cache All Hits | | All operations for a primary table and for a node that resulted in a cache hit. |
| Table Value Cache Hits | | The number of get operations for a primary table and for a node that resulted in a cache hit. |
| Table Value Cache Hits Per Index | | The number of get operations for a primary table and for a node that resulted in a cache hit. |
| Table and Index Value Cache All Hits | | All operations across the primary table and its secondary indexes that resulted in a cache hit. |
| Table and Index Value Cache Hits | | The number of get operations across the primary table and its secondary indexes that resulted in a cache hit. |
| Table and Index Value Cache Hits Per Index | | The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index. |
| Value Cache Utilization | Value Cache | Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table. |
| All Tables Flushes | Bucket Flushes | The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables. |
| All Tables Flushes | | The number of total table flushes that were manually versus automatically triggered. |
| All Tables Force Flushes | Bucket Force Flushes | The number of table flushes that were not automatically triggered. |

| Chart/Column Name | Metric | Description |
|------------------------------|----------------|---|
| All Tables Compactions | Compaction | Number of table compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables. |
| All Tables Full Compactions | | Number of full compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, HPE Ezmeral Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files. |
| All Tables Mini Compactions | | Number of partial compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, HPE Ezmeral Data Fabric Database needs to read only two spill files. |
| All Tables TTL Compactions | | Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families. |
| All Tables Free Index Memory | Memindex Usage | The number of available MB in the in-memory bucket file cache. |

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Loading Documents into JSON Tables

There are three command-line utilities for loading documents into JSON tables: `mapr copytable`, `mapr importtable` (which works in conjunction with the `mapr exporttable` utility), and `mapr importJSON`

You can choose whether to have these utilities perform bulk loads or incremental loads.

For bulk loads, the `-bulkload` parameter of the JSON table must be set to `true`. During a bulk load, client applications are unable to access the table. After the utility is finished, you must set the table's `-bulkload` parameter to `false`, so that client applications can access the table again.

When you set the `-bulkload` parameter to `true`, you cannot enable replication on the table. Since this effectively disables logging on the table, HPE Ezmeral Data Fabric Database also does not capture log data that Elasticsearch can use to index the table.

Note: Incremental loads allow client applications to access the table as the documents are loaded. However, incremental loads are slower than bulk loads.

mapr copytable

The `mapr copytable` utility copies documents -- all documents or a subset determined by a range of row keys, and all fields or a subset of fields -- directly from one JSON table to another.

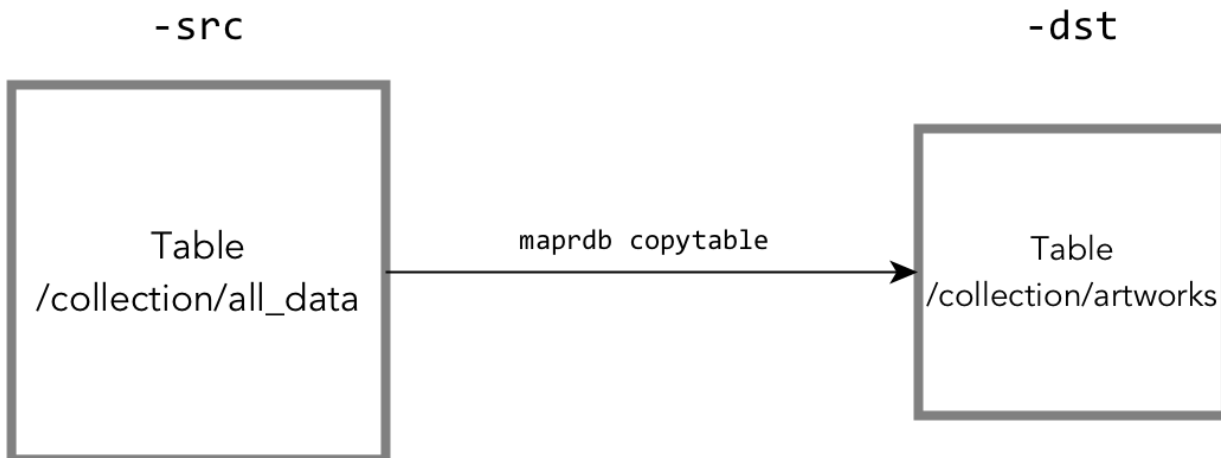

Figure 14: Copying a subset of data from one table to another

For reference information about this utility, see [mapr copytable](#).

mapr exporttable and mapr importtable

The `mapr exporttable` utility exports data from a JSON table to binary sequence files that you can import into another JSON table by using the `mapr importtable` utility.

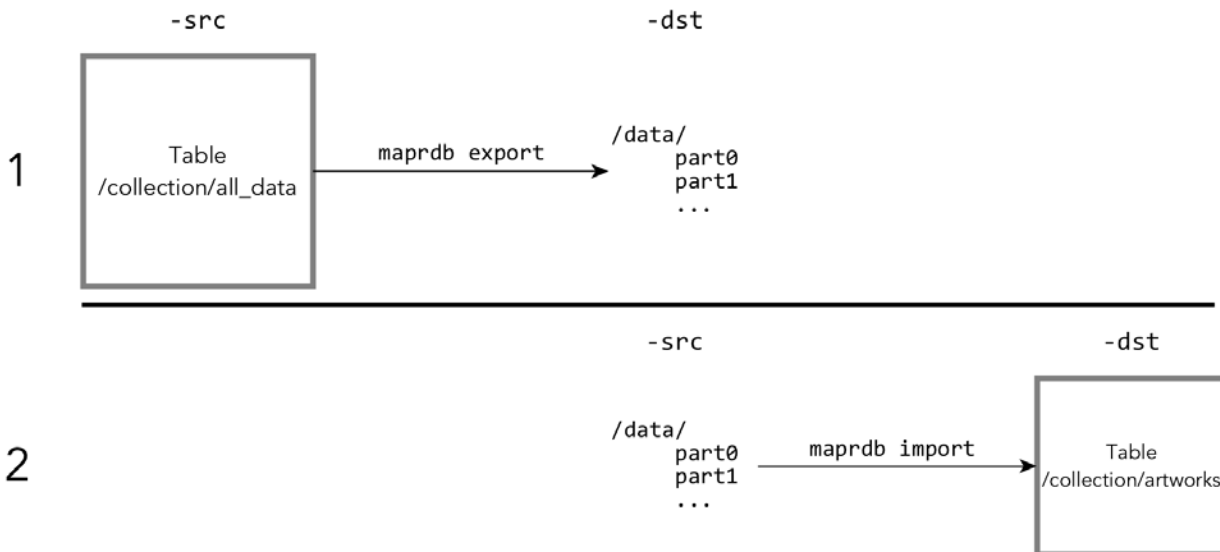

Figure 15: JSON documents exported from a JSON table as binary sequence files and then imported into another JSON table

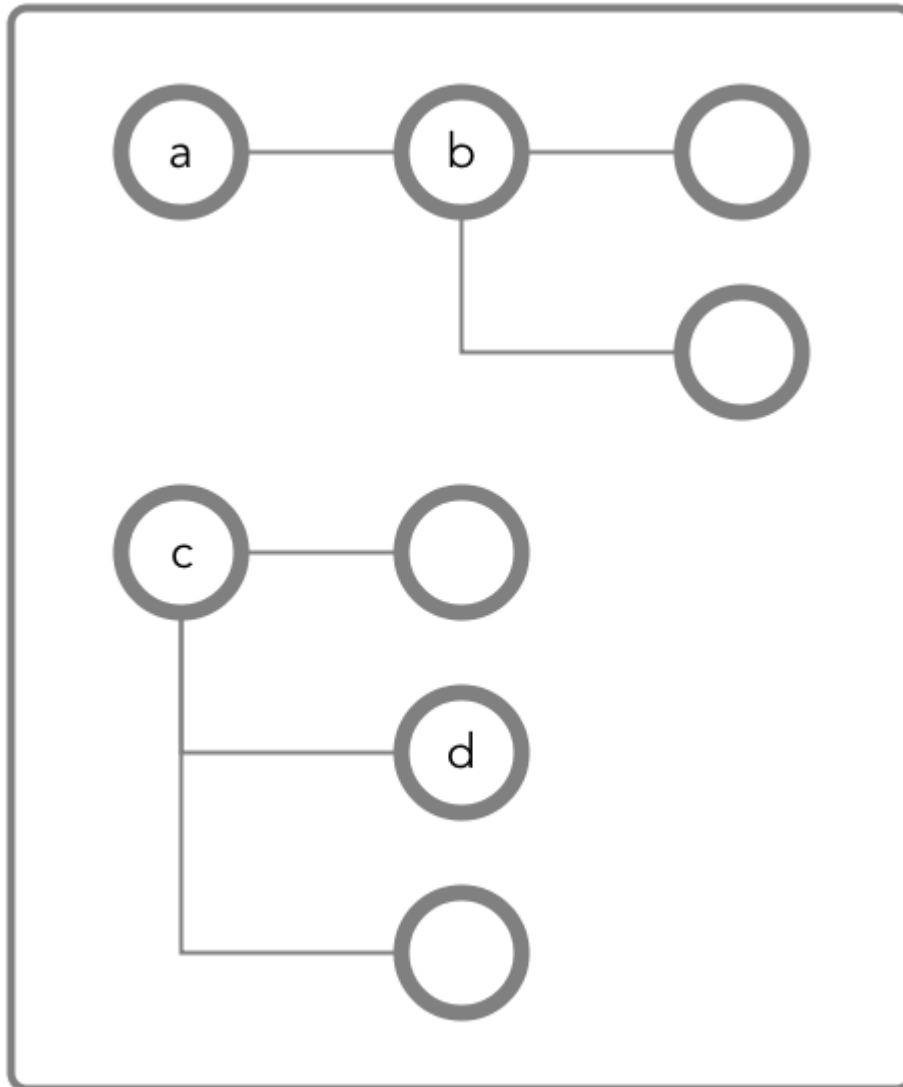

The destination directory is created by the `mapr exporttable` utility. To prevent accidental overwriting of data, the `mapr exporttable` utility fails if the destination directory already exists.

The command for running the `mapr importtable` utility in step 2 of the diagram above would look like this:

```
mapr importtable -src /data/* -dst /collection/artworks
```

The `-columns` parameter of the `mapr exporttable` utility lets you export subsets of the fields in the documents that are in a table. For example, to export field `b`, the fields under it, and field `d` from documents with the following structure, the command to run the `mapr exporttable` utility would look like this:

```
mapr exporttable -columns a.b,c.d -src /collection/all_data -dst /data
```

For reference information about these commands, see [HPE Ezmeral Data Fabric Database JSON ExportTable and ImportTable](#) on page 5523.

`mapr importJSON`

This utility imports one or more JSON documents that are text files into a JSON table.

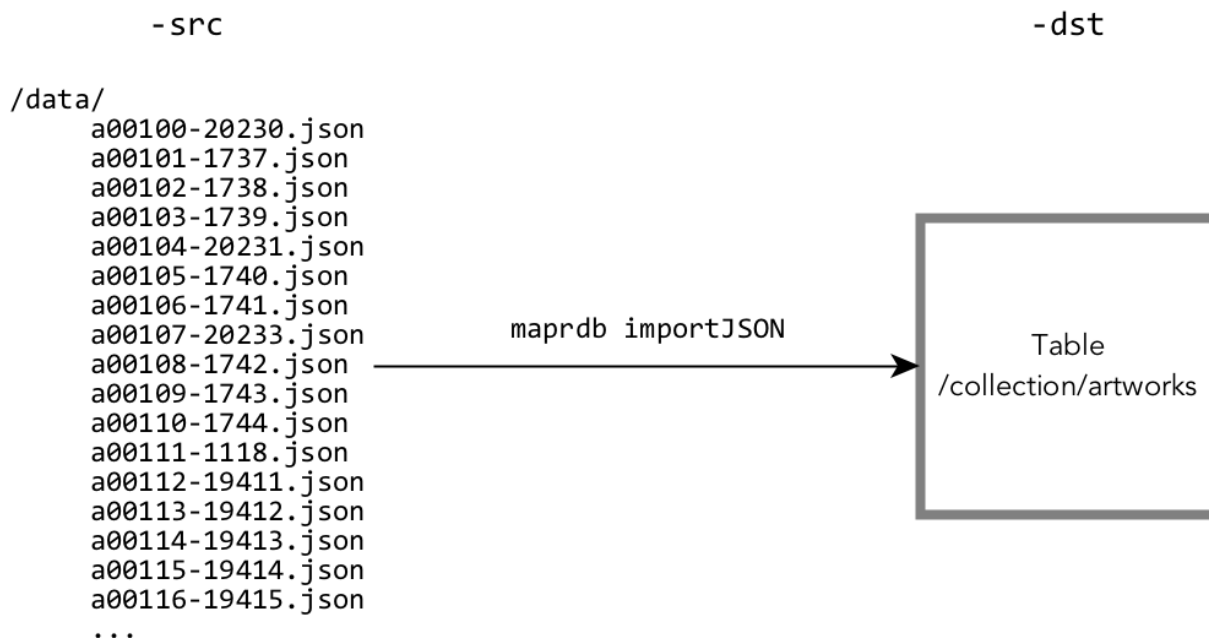

Figure 16: JSON documents in a folder named `/data` being imported into a JSON table

If each document does not already contain an `_id` field to use as a document ID, the `mapr importJSON` utility adds an `_id` field during the import. Use the `-idfield` parameter to specify the name of the field that contains the value to copy into the value of the `_id` field.

For example, each document might have a `product_ID` field that contains a universally unique identifier. You could run the utility with this command:

```
mapr importJSON -idfield "product_ID" -src /data/* -dst /collection/artworks
```

For reference information about this command, see [mapr importJSON](#).

Accessing HPE Ezmeral Data Fabric Database Binary Tables Using HBase APIs

This section describes how to access HPE Ezmeral Data Fabric Database binary tables via HBase APIs, HBase Shell, and MapReduce applications.

MapR Core extends the HBase component to handle access to HPE Ezmeral Data Fabric Database binary tables. HPE Ezmeral Data Fabric Database binary tables do not support low-level HBase API calls that are used to manipulate the state of an Apache HBase cluster.

For a full list of supported HBase Java APIs, see [Creating Java Apps - Binary Tables](#) on page 2760.

For a full list of supported commands in the HBase shell, see [HBase Shell for HPE Ezmeral Data Fabric Database](#).

To enable the HBase API and `hbase shell` access, install the `mapr-hbase` package on every node in the cluster. The HBase component of the MapR distribution for Hadoop is typically installed under `/opt/mapr/hbase`. Install the `mapr-hbase` package that provides the version that corresponds with the current EEP and MapR version you are running.

For MapR installation procedures, see [Installing Core and Ecosystem Components](#) on page 87.

Note: The version of HBase provided by MapR has been modified to work with HPE Ezmeral Data Fabric Database binary tables. Do not download and install stock Apache HBase on a MapR cluster that uses MapR tables.

Note: If you use fat JARs to deploy your application as a single JAR including all dependencies, be aware that the fat JAR may contain versions of HBase that override the installed MapR versions, leading to problems. Check your fat JARs for the presence of stock HBase to prevent this problem.

Loading Data into Binary Tables

Bulkload operations can be performed as a full bulkload or as an incremental bulkload.

The most common way of loading data into a HPE Ezmeral Data Fabric Database Binary Tables is with a put operation. However, at large scales, bulk loads offer a performance advantage over put operations.

Bulk loading is supported by the following tools, which can be used for both full and incremental bulkload operations:

- Hbase [HPE Ezmeral Data Fabric Database Binary CopyTable](#) on page 5533 utility which copies HPE Ezmeral Data Fabric Database binary table data, table metadata, access control expressions, and more to another HPE Ezmeral Data Fabric Database binary table.

```
hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable
```

- Hbase `ImportFiles` utility which imports HFile or Result files into HPE Ezmeral Data Fabric Database binary tables. For example:

```
hbase com.mapr.fs.hbase.tools.mapreduce.ImportFiles
-Dmapred.reduce.tasks=2
-inputDir < input directory, for example: /test/tabler.kv >
-table < table name, for example: /table2 >
[ -format < Result|HFile > ]
[ -sample < true|false > ]
[ -mapOnly < true|false > ]
```

Full Bulk Loads

Full bulkload operations offer the best performance advantage because it skips the write-ahead log (WAL) typical of HPE Ezmeral Data Fabric Database binary table operations. Full bulkload operations can only be performed on empty tables that have the `bulkload` attribute set to **true**. This value is set only when creating a table.

When you set the `bulkload` attribute, you cannot enable replication on the table. Since this effectively disables logging on the table, HPE Ezmeral Data Fabric Database also does not capture log data that Elasticsearch can use to index the table.

Important: Tables are unavailable for normal client operations, including put, get, and scan operations, while a full bulkload operation is in progress.

To create a HPE Ezmeral Data Fabric Database binary table for bulkloading, use one of the following:

- `maprccli table create` command with the `-bulkload` parameter set to `true`.
- Apache HBase shell `create` command with the `BULKLOAD` parameter set to `true`. For example:

```
hbase> create '/a0','f1', BULKLOAD => 'true'
```

If you want to pre-split a table, separate the `BULKLOAD` parameter from the `SPLITS` parameter. For example:

```
hbase> create '/t1', 'f1', {SPLITS => ['10', '20', '30']}, {BULKLOAD => 'true'}
```

- Control System with **Will table be bulkload?** option set to **Yes** under table **PROPERTIES**.

 **Note:** Attempting a full bulkload on a table that does not have the bulkload attribute set to true results in an incremental bulkload being performed instead.

After you perform a full bulkload on a table, you cannot perform a full bulkload on it again. For example:

- You cannot use the `maprcli table edit` command to set the `bulkload` parameter to `TRUE` again.
- You cannot use the Apache HBase shell `alter` command to set the `BULKLOAD` parameter to `TRUE` again.
- In the Control System, the **Will table be bulkload?** option cannot be modified after table creation.

Incremental Bulk Loads

Incremental bulk loads can add data to existing tables concurrently with other table operations, with better performance than put operations. This type of bulk load makes use of write-ahead log files.

 **Note:** Tables are available for client operations, such as put, get, and scan operations, during incremental bulk loads.

You can use incremental bulk loads to ingest large amounts of data to an existing table. Tables remain available for standard client operations such as put, get, and scan while the bulk load is in process. A table can perform multiple incremental bulk load operations simultaneously.

 **Note:** Whether you create a table with the `maprcli table create` command, with the hbase shell's `create` command, or in the Control System, incremental loads are supported by default.

Performing File System Operations on HPE Ezmeral Data Fabric Database Tables

The data-fabric file system stores tables in the same namespace as files. You can move and delete tables in much the same way as you can with files. All file system operations remain accessible with the `hadoop fs` command.

Volume properties, such as replication factor or rack topology, that apply to the specified location also apply to tables stored at that location. You can move a table with the Linux `mv` command or the `hadoop fs -mv` command.

When you use Direct Access NFS or the `hadoop fs -ls` command to access a MapR cluster, tables and files are listed together. Because the client's Linux commands are not table-aware, other Linux file manipulation commands, notably file read and write commands, are not available for HPE Ezmeral Data Fabric Database tables.

This section describes the operations that you can perform on HPE Ezmeral Data Fabric Database tables through a Linux command line when you access the cluster through NFS or with the `hadoop fs` commands.

Setting Permissions

HPE Ezmeral Data Fabric Database tables do not support setting user permissions through the UNIX `chmod` command or the `hadoop fs -chmod` analogue. Instead, HPE Ezmeral Data Fabric Database table access is controlled with Access Control Expressions (ACEs). See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Read and Write

You cannot perform read or write operations on a HPE Ezmeral Data Fabric Database table from a Linux file system context. For example, you cannot use the `cat` command to view the content of a table or search through a table with the `grep` command. `filesystem` returns an error when an application attempts to read or write to a HPE Ezmeral Data Fabric Database table.

Move

You can move a HPE Ezmeral Data Fabric Database table within a volume with the `mv` command over NFS or with the `hadoop fs -mv` command. These moves are subject to the standard permissions restrictions. Moves across volumes are not currently supported.

Remove

You can remove a table with the `rm` command over NFS or with the `hadoop fs -rm` command. These commands remove the table from the namespace and asynchronously reclaims the disk space. You can remove a directory that includes both files and tables with the `rm -r` or `hadoop fs -rmr` commands.

Note: To prevent users from deleting a particular table, you must ensure that users do not have WRITE permission on the folder in which the table is located. Permissions on the table itself are not used in evaluating whether a user can delete the table. This convention follows standard UNIX rules for file and directory permissions.

Copy and Recursive/Directory Copy

Table copying at the file-system level is not supported. See [Migrating Between Apache HBase Tables and HPE Ezmeral Data Fabric Database Tables](#) for information on copying tables using the HBase shell.

Managing Column Families and Columns

This section covers overviews of column families in binary tables and JSON tables, how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.

For a conceptual overview of column families in binary tables, see [Column Families in Binary Tables](#).

For a conceptual overview of column families in JSON tables, see [Managing Column Families](#).

Creating Column Families

Explains how to create column families using either the Control System, the CLI, or the HBase shell.

There are several methods that you can use to create column families in HPE Ezmeral Data Fabric Database tables. To create column families, you must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path to the table
- `createrenamefamilyperm` on the table

Creating Column Families Using the Control System

To create a column family from the Control System, under **Data > Tables**:

Note: This option is not available on the Kubernetes version of the Control System.

1. Click:
 - **Take me to Add Column Family** after creating a new table.
 - **Add Column Family** in the **Column Families** tab in the table information page.
See [Viewing Table Information](#) on page 1124.
2. Specify the following properties to set up column families.

JSON Table

| | |
|--------------------|--------------------------------|
| Column Family Name | The name of the column family. |
|--------------------|--------------------------------|

| | |
|-------------|--|
| JSON Path | <p>The path to the column family in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:</p> <pre data-bbox="1175 380 1458 915"> { "_id" : "ID", "a" : { "b" : { "c" : "value", }, "e" : "value" } } </pre> <p>If you want to create a column family at the field <code>d</code> nested within <code>b</code>, your new path would be <code>a.b.d</code>.</p> <p> Note: Ensure that the field at which you want to create the column family does not yet exist. If the field exists, it could become inaccessible after the column family is created.</p> |
| Compression | <p>The compression setting to use for the column family. Valid options are <code>off</code>, <code>lzf</code>, <code>lz4</code>, and <code>zlib</code>. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 1082.</p> |

| | |
|--------------|---|
| Time-to-Live | <p>Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.</p> <p> Note: If the value for an existing column family in a JSON table is not 0, you cannot add another column family.</p> |
|--------------|---|

| | |
|-----------|---|
| In Memory | <p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <p> Note: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</p> <p>By default, this is enabled.</p> |
|-----------|---|

Binary Table

| | |
|--------------------|---|
| Column Family Name | The name of the column family. |
| Version | <ul style="list-style-type: none"> • Minimum — The minimum number of versions of column values to keep. The default is zero. • Maximum — Maximum number of versions of column values to keep. The default is one. |
| Compression | The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 1082. |
| Time-to-Live | Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever. |

| | |
|------------------|---|
| <p>In Memory</p> | <p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <p> Note: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</p> <p>By default, this is enabled.</p> |
|------------------|---|

3. Set up access to column families for users, groups, and/or roles.

You can use either the default permissions or proceed to define new permissions for this column family.

JSON Table

| | |
|-----------------|---|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Traverse Data | <p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.</p> |
| Set Version | Can set or change the maximum and minimum number of versions of column values to keep. |
| Set Compression | Can set or change the compression setting for the column family. |

Binary Table

| | |
|-----------------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |
| Set Version | Can set or change the maximum and minimum number of versions of column values to keep. |
| Set Compression | Can set or change the compression setting for the column family. |

By default, all permissions are given to the user creating the table.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

Tip: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (**p**) or user (**u**), group (**g**), and/or role (**r**) who have or do not have the type of access using the following boolean expressions and subexpressions:
 - **!** — Negation operator.
 - **&** — AND operation.
 - **|** — OR operation.

Use **()**, parentheses, for subexpressions.

Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 1590 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

4. Specify:

Field Permissions (for JSON Tables)

Specify a name for the field and the permissions to access the field. By default, a field inherits permissions from the column in which the field is located. Permissions set at this level override permissions inherited from the column. You can set the following permissions by selecting the associated checkbox:

| | |
|---------------|--|
| Read Data | Can read from the field. This permission extends to fields that are nested below as well unless explicitly denied on any of the nested fields. |
| Write Data | Can delete the field, insert a value into the field, or overwrite the field's value. Note: Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied. |
| JSON Traverse | Can descend a hierarchy of fields to access the fields to read or write. |

By default, all permissions are given to the user creating the table. See [Permission Types for Fields and Column Families in JSON Tables](#) on page 1157 for more information.

Column Permission (for Binary Tables)

Create (by clicking **Add Column** and specifying a name in the **Column Name** field) and set permissions for columns in the column family. You can set the following permissions by selecting the associated checkbox:

| | |
|-----------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
|-----------|--|

| | |
|-------------|--|
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |

Note: When a user, group, or role requests to read data from, write data to, or append data to a column, HPE Ezmeral Data Fabric Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. HPE Ezmeral Data Fabric Database checks whether this user has write permission on `cf1 AND col1 AND col2`. If the user does not have all three permissions, HPE Ezmeral Data Fabric Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, HPE Ezmeral Data Fabric Database would simply not return the data. If the user tried to read from those two columns and additional columns on which the user had read permissions, the results would contain the data for those additional columns, but exclude the data for `col1` and `col2`.

You can add columns to a table at any time. Null columns for a given row don't take up any storage space.

Note: Extremely wide tables with very large numbers of columns can sometimes reach the recommended size for a table split at a comparatively small number of rows because HPE Ezmeral Data Fabric Database tables split at the row level, not the column level.

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

Tip: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (**p**) or user (**u**), group (**g**), and/or role (**r**) who have or do not have the type of access using the following boolean expressions and subexpressions:
 - **!** — Negation operator.
 - **&** — AND operation.
 - **|** — OR operation.

Use **()**, parentheses, for subexpressions.

Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 1590 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

5. Click **Add Column Family** to add the column family to the table.

Creating Column Families Using CLI or the REST API

JSON Table

To create a column family in a JSON table, include the parameters `-jsonpath` and `-force`:

```
maprcli table cf
create -path <path> -cfname
<name_of_column_family> -jsonpath

<path> -force true
```

For the full list of options for this command, see [table cf create](#) on page 2048.

The `-jsonpath` parameter specifies the path to the column family. The path is in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
  "_id" : "ID",
  "a" :
  {
    "b" :
    {
      "c" :
      "value",
    },
    "e" : "value"
```

```
}
}
```

You want to create a column family at the field `d` in the new path `a.b.d` because you plan to store image files in fields in that column family.

Important: Ensure that the field at which you want to create the column family does not yet exist. Also ensure that there are no secondary indexes defined on the field. If the field does exist or is a field in an index, the data in the field could become inaccessible after you create the column family.

By default, every time you try to create a non-default column family in a JSON table, this command fails and returns a warning message that you should ensure there is no existing data at the specified path. Set the `-force` parameter to `true` if you want to override this warning mechanism and create a column family.

The command to create a column family for a binary table is:

```
maprcli table cf create -path
<path> -cfname <name_of_column_family>
```

For the full list of options for this command, see [table cf create](#) on page 2048.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster.

Binary Table

Creating a Column Family for a Binary Table Using HBase Shell

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Permission Types for Fields and Column Families in JSON Tables

By using access-control expressions (ACEs), you can grant or deny access to fields and column families that are in JSON tables.

For an explanation of the syntax of ACEs, see [ACE Syntax](#).

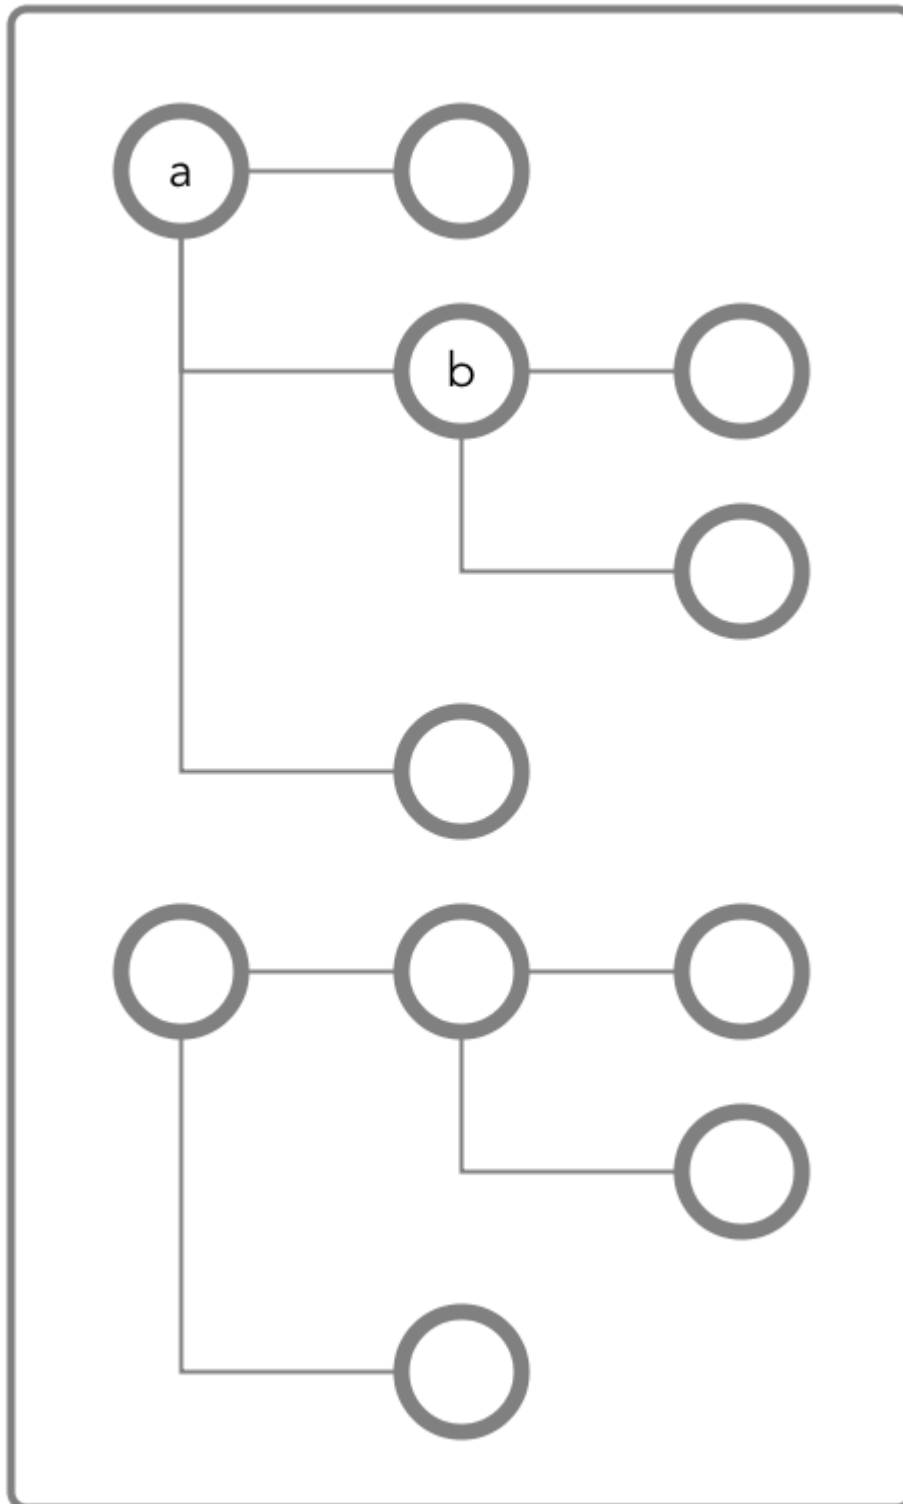

There are three types of permission:

- **Traverse** (`traverseperm`)
- **Read** (`readperm`)
- **Write** (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access the fields that the grantee has write or read permission on.

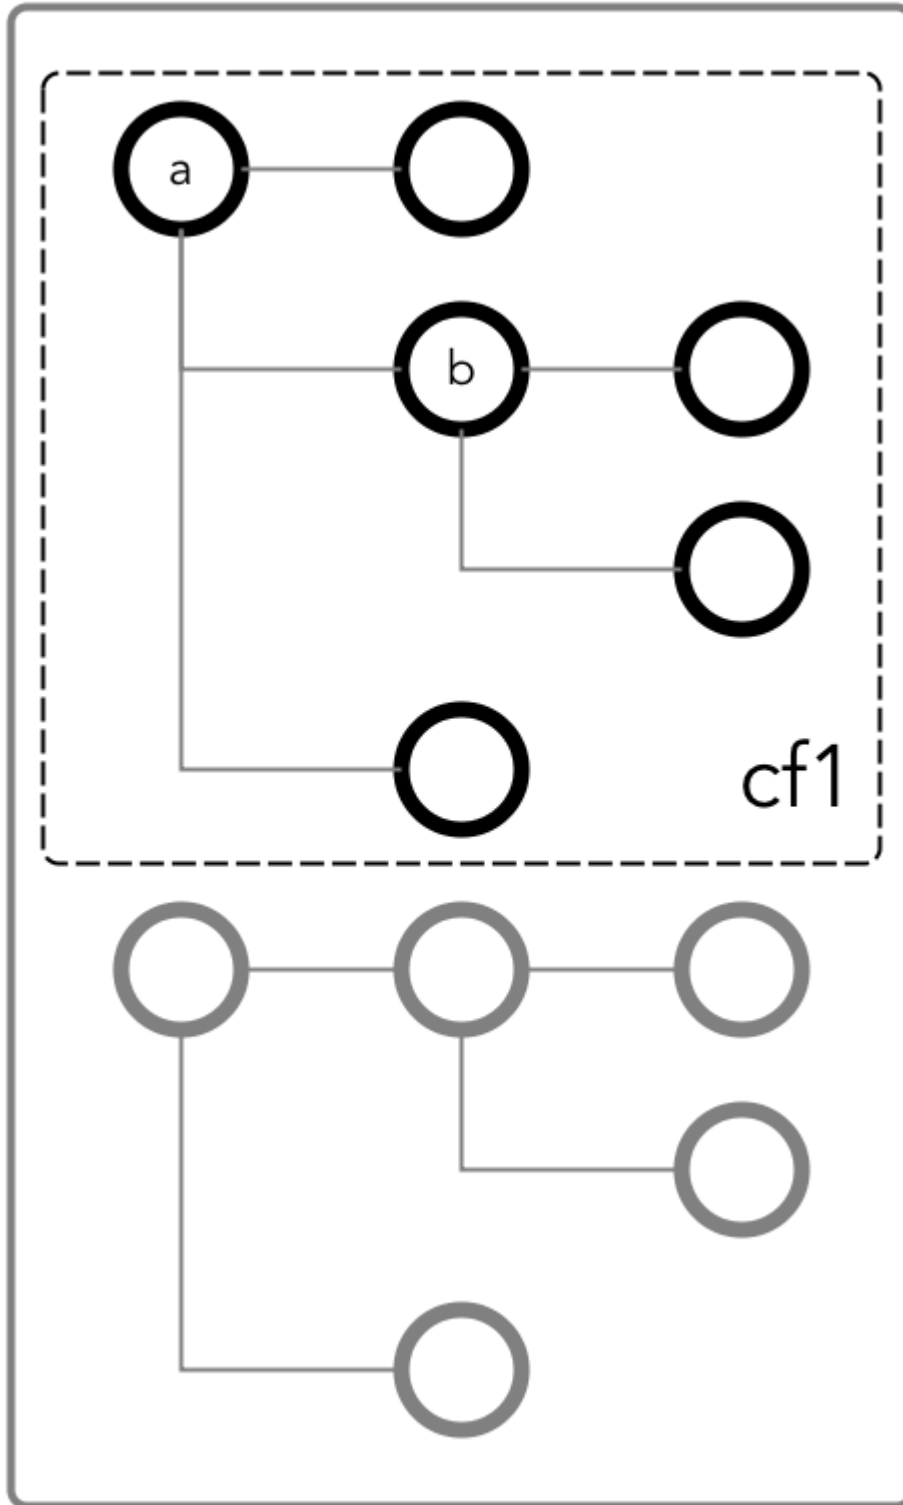

For example, suppose that a user has read and write access only on field `b` in this document.

To access field *b*, the user would need to be able to traverse (pass through) field *a*. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field *a* would inherit the traverse permission.

If traverse permission on the default column family were denied the user, it would not be possible for the user to access field *b*. Granting traverse permission on field *a* in this case would have no effect.

In the next example, field `a` is a column family named `cf1`.

To be able to read and write at field `b`, the user could be granted the traverse permission on the column family.

Read (readperm)

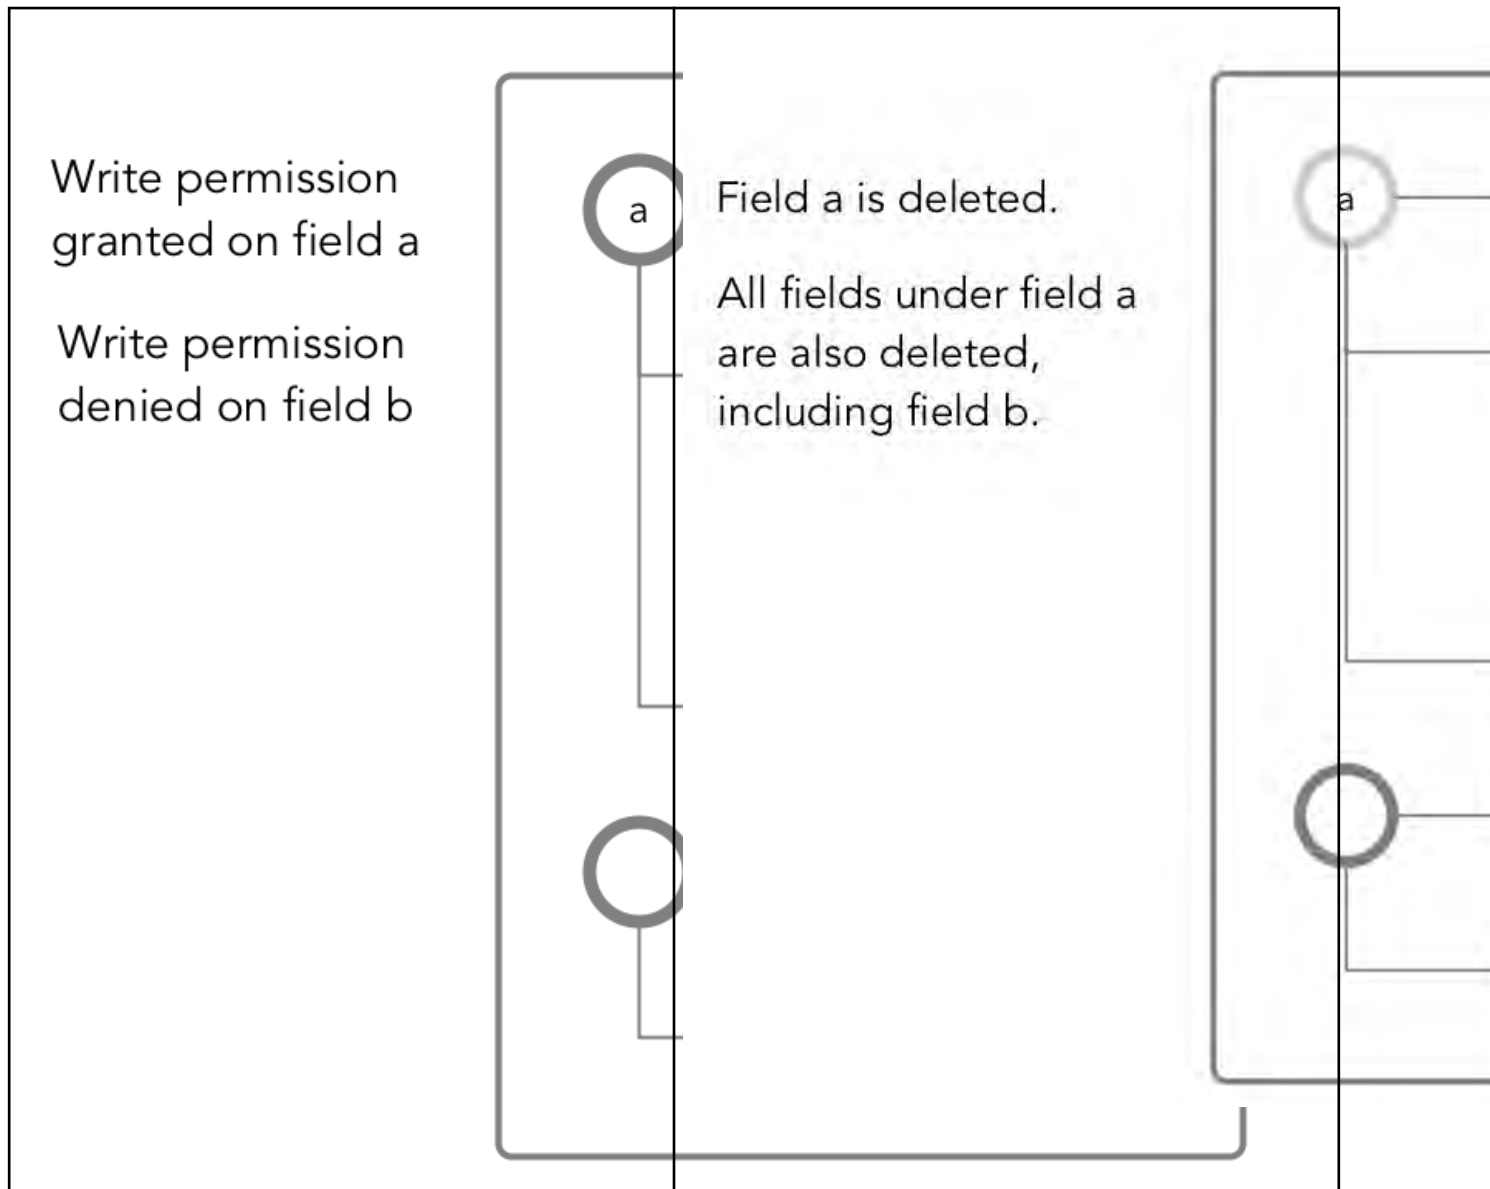

This permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field that the permission was granted on. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (writeperm)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite a field's value.

As illustrated in the following two diagrams, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

*Obtaining readperm and writeperm on Fields*

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the document below, you want to perform an operation on field `c`, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field `c`.

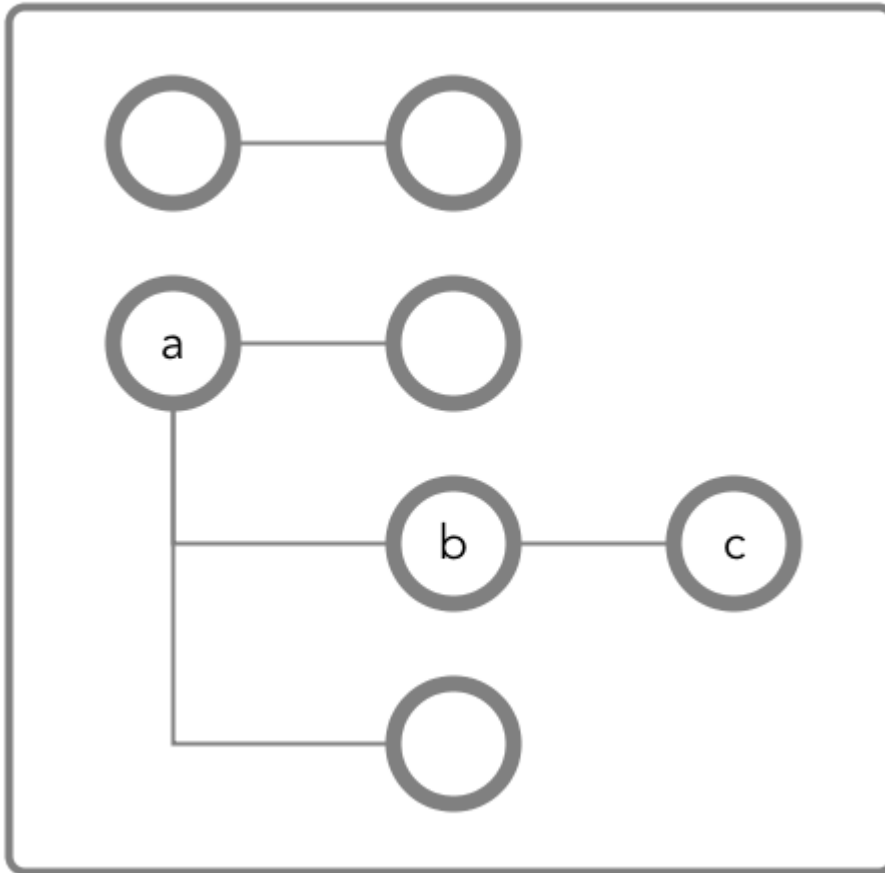

Figure 17: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field `c` inherits these permissions, assuming that the permissions were not denied on field `a` or `b`.

If you do not have `readperm` and `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field `c`. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```

maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
  
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields `a` and `b` inherit this permission. You also need `readperm` and `writeperm` on field `c`.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON table](#).

In the following document, you want to perform an operation on field `c`, which is in the column family `cf1` that is defined at field `b` with the path `a.b`.

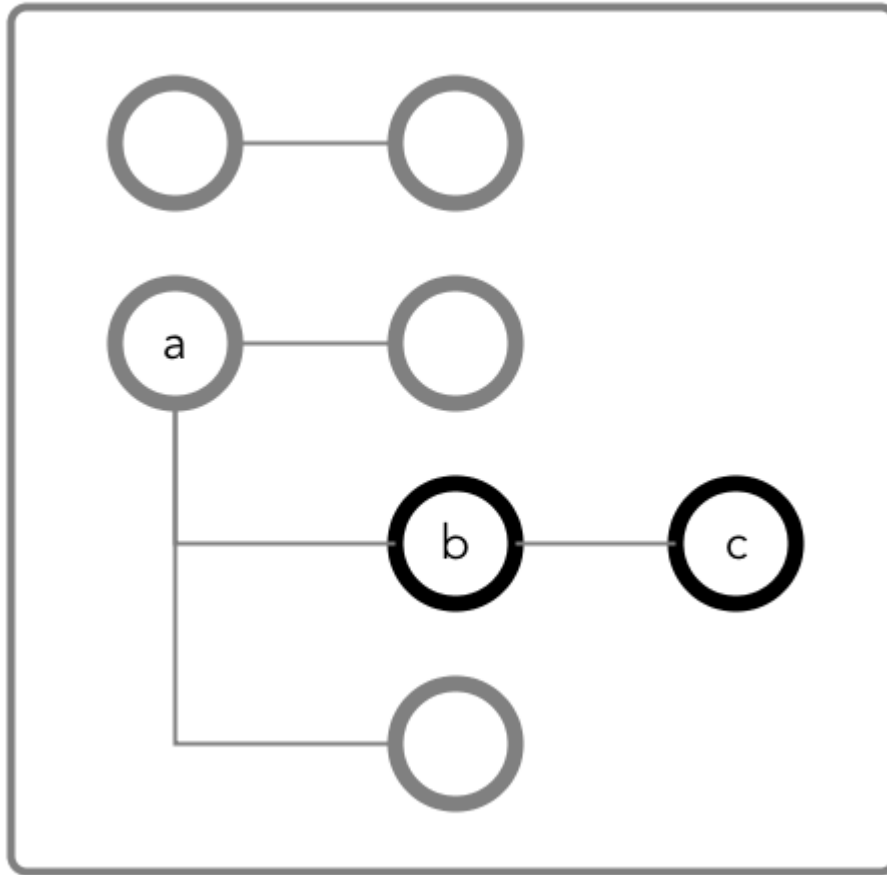

Figure 18: Schematic diagram of an JSON document in which fields `b` and `c` are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`

You need `traverseperm` on field `b` and both `readperm` and `writeperm` on field `c`. You can be granted these permissions with commands similar to these:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
cf1 -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

Case 2: You do have `readperm` and `writeperm` on field `b`

You do not need any further permissions. Field `c` inherits your `readperm` and `writeperm` permissions from field `b`.

Obtaining readperm or writeperm on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have `readperm` or `writeperm` permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the following document, you want to perform an operation on field `c`, which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

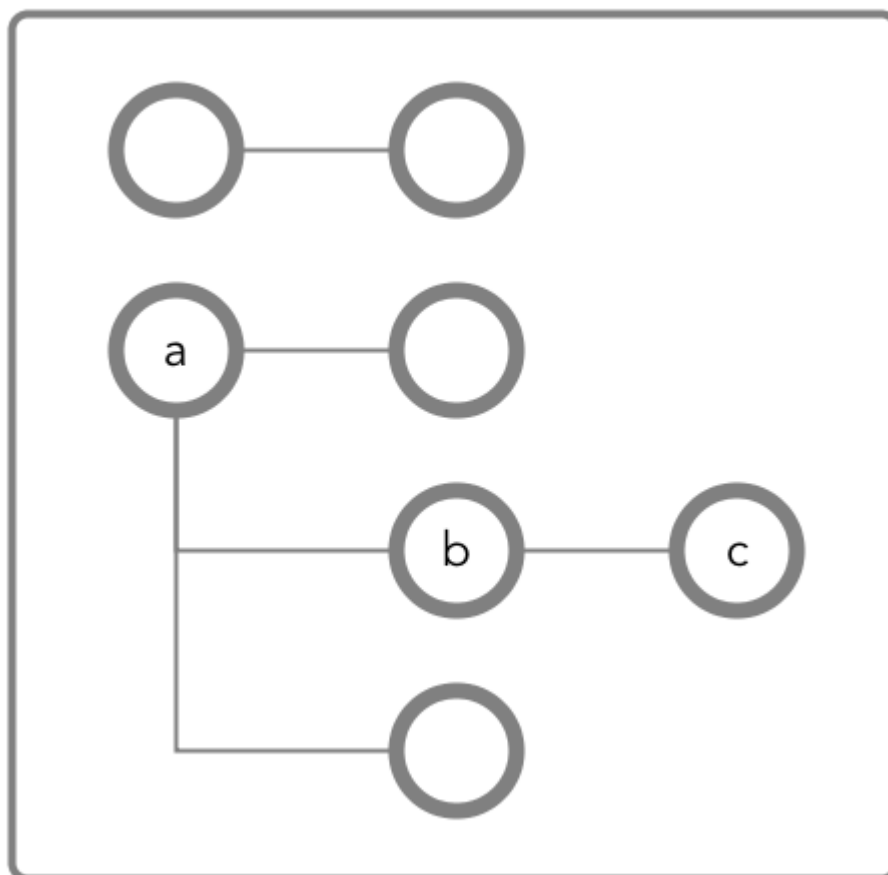

Figure 19: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family

In this case, field `c` inherits the permission, assuming that the permission was not denied on field `a` or `b`.

If you do not have `readperm` or `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
```

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON Tables](#).

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field `b` with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

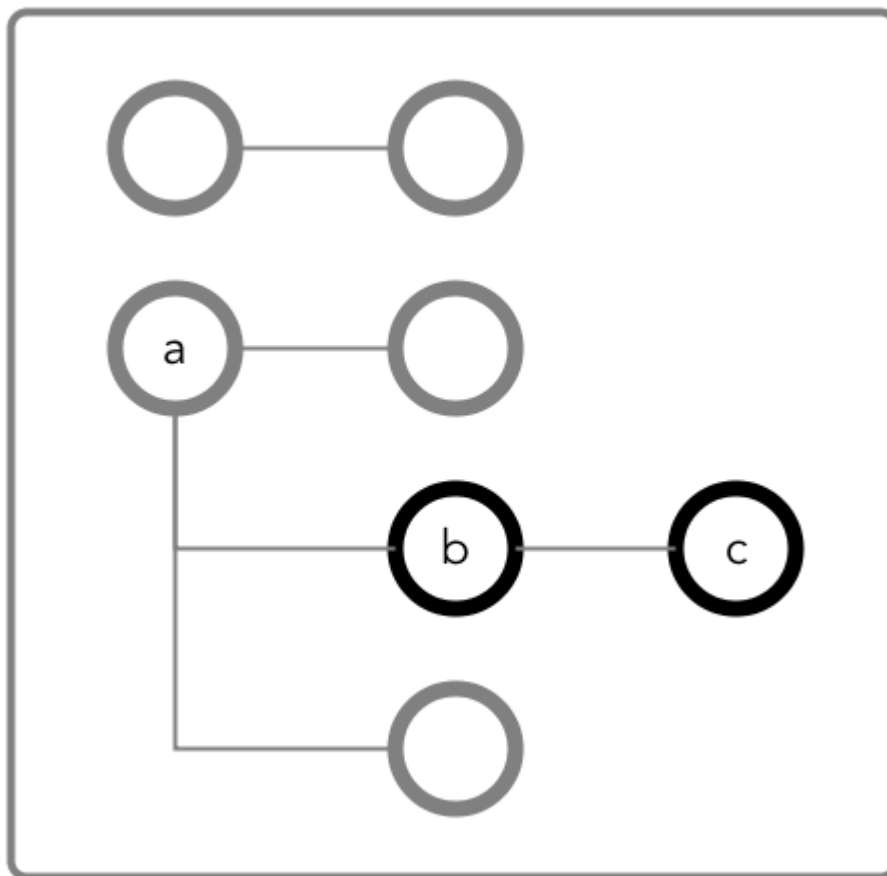

Figure 20: Schematic diagram of an JSON document in which fields `b` and `c` are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`

You need `traverseperm` on field `b`, and you need `readperm` or `writeperm` granted to you explicitly on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`

You do not need any further permissions. Field `c` inherits your `readperm` and `writeperm` permissions from field `b`.

Setting Permissions on Arrays

When granting permissions on a field, if the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

Note: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
  "_id" : "id001",
  "person" : [
    { "name" : { "last" : "Smith", "first" : "John" } },
    { "name" : { "last" : "Subramanium", "first" : "Ananya" } }
  ]
}
{
  "_id" : "id002",
  "person" : { "name" : { "last" : "Doe", "first" : "Jane" } }
}
{
  "_id" : "id003",
  "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person`, to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents, for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the

previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables

This page summarizes the default access-control expressions for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

| Action | Method | Permissions | Default Access-Control Expressions |
|--|------------------------------|---|---|
| Set default permissions on new column families when creating a JSON table. | Java API | -defaultreadperm -defaulttraverseperm -defaultwriteperm | u:<ID of the process> |
| | maprcli table create | | u:<user ID of table creator> |
| | mapr dbshell | | |
| | Control System | | |
| Set default permissions on new column families when editing a JSON table. | maprcli table edit | | Current ACEs |
| | Control System | | |
| Set permissions on a column family when creating the column family. | maprcli table cf create | -readperm -traverseperm -writeperm -indexperm | ACEs for -defaultreadperm, -defaulttraverseperm, and -defaultwriteperm |
| | Control System | | |
| Set permissions on a column family when editing the column family. | maprcli table cf edit | | Current ACEs |
| | Control System | | |
| Set permissions on individual fields. | maprcli table cf colperm set | | Inherited from column family or parent field |
| | Control System | | |

Listing Column Families

Explains how to view the column families for a table using either the Control System or the CLI.

Viewing Table Column Families Using the Control System

To view the column families for a table:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.

2. Click **Column Families**.

The page displays the default permissions for the column families in the **Default Column Family Authorization** pane and for each column family, the **All** pane displays:

| Column Name | Column Description |
|--------------------|---|
| Column Family Name | The name of the column family. |
| JSON Path | The JSON path for the column in the JSON file in dotted notation. |
| Compression | The compression scheme used for the column family. |

| Column Name | Column Description |
|--------------|---|
| Time-to-Live | The amount of time to keep the data in the column family. |
| In Memory | Whether or not this column value resides in memory. |

Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

- [Add](#) a column family to the table
- [Remove](#) a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{ }&()/" (or)
maprcli table create -path '/^=#;{ }&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "'/^=#;{ }&()/' (or)
maprcli table create -path '/"^=#;{ }&()/'
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the paths

- `adminaccessperm` on the table

For complete reference, see [table cf list](#) on page 2060.

Removing Column Families

Explains how to delete column families using either the Control System or the CLI.

 **Important:** Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Removing Column Families Using the Control System

To remove one or more column families:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Column Families** tab.
The page displays:
 - Default column family permissions
 - All the column families for the table
3. Select the checkbox associated with the column families to delete in the **All** pane.
4. Click **Remove Column Family**.
The **Remove Column Families** confirmation dialog displays.
5. Verify the list of column families and click **Remove Column Family**.
If necessary, click **X** to remove a column family from the list of column families to delete.

Removing a Column Family Using the CLI or the REST API

To remove a column family by name using the CLI or the REST API, run the following command:

```
maprcli table cf delete -path <path> -cfname <name>
```

See [table cf delete](#) on page 2054 for more information.

Altering Column Families

Explains how to modify the permissions and properties of column families using either the Control System, the CLI, or the HBase shell.

There are several methods that you can use to edit column families in HPE Ezmeral Data Fabric Database tables. These methods also let you change permissions on column families.

Modifying a Column Family Using the Control System

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Column Families** tab.
The page displays:
 - Default column family permissions
 - All the column families for the table
3. Click the name of the column family to modify.
The **Edit Column Family** page displays.

4. Make changes to the following properties (under **PROPERTIES**) as desired.

JSON Table

| Column Family Name | The name of the column family. |
|--------------------|---|
| Compression | The compression setting to use for the column family. Valid options are off, lz4, lz4hc, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 1082. |

| | |
|-----------|---|
| In Memory | <p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <p> Note: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</p> <p>By default, this is enabled.</p> |
|-----------|---|

Binary Table

| | |
|--------------------|---|
| Column Family Name | The name of the column family. |
| Version | <ul style="list-style-type: none"> • Minimum — The minimum number of versions of column values to keep. The default is zero. • Maximum — Maximum number of versions of column values to keep. The default is one. |
| Compression | The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located. To find out whether a directory is compressed and the type of compression, see Turning Compression On or Off on Directories Using the CLI on page 1082. |
| Time-to-Live | Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever. |

| | |
|-----------|---|
| In Memory | <p>Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.</p> <p>For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled.</p> <p>If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled.</p> <p> Note: All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family.</p> <p>By default, this is enabled.</p> |
|-----------|---|

5. Make changes to permissions as desired.
 - a) Modify USER ACCESS CONTROLS for the column family as desired.

JSON Table

Modify or set the following permissions for the column family:

| | |
|-----------------|---|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Traverse Data | <p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre style="background-color: #f0f0f0; padding: 10px;"> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.</p> |
| Set Compression | Can set or change the compression setting for the column family. |

Binary Table

Modify or set the following permissions for the column family:

| | |
|-----------------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |
| Set Version | Can set or change the maximum and minimum number of versions of column values to keep. |
| Set Compression | Can set or change the compression setting for the column family. |

b) Modify or set:

Field Permission (for JSON Tables)

Modify permissions for the following on existing fields and/or create new fields and set permissions for the following on the new fields:

| | |
|------------|--|
| Read Data | Can read from the field. This permission extends to fields that are nested below as well unless explicitly denied on any of the nested fields. |
| Write Data | Can delete the field, insert a value into the field, or overwrite the field's value.  Note: Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied. |

| | |
|---------------|--|
| JSON Traverse | Can descend a hierarchy of fields to access the fields to read or write. |
|---------------|--|

Column Permission (for Binary Tables)

Modify following permissions for existing columns and/or create new columns and set permissions for the following:

| | |
|-------------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |

To grant or block access to users, groups, and/or roles, from the:

- Basic settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

Tip: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

- Advanced settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
 - ! — Negation operator.
 - & — AND operation.
 - | — OR operation.

Use (), parentheses, for subexpressions.

Note: You *cannot* specify user, group, or role individually if access is granted to all users (public).

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 1590 for more information.

Note: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

6. Click **Save Changes** for the changes to take effect.

Modifying a Column Family Using the CLI or REST API

The basic command to edit a column family is:

```
maprcli table cf edit -path <path> -cfname <name_of_column_family> options
```

For the full list of options for this command, see [table cf edit](#) on page 2055.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Note: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
 ; | ( ) /
```

For example:

```
maprcli table create -path "/^=#;{ }&()/" (or)
maprcli table create -path '/^=#;{ }&()/'
```

To use either the `'` or the `"` character in the table name, enclose:

- the `'` character within double quotes (`"`)
- the `"` character within single quote (`'`)

For example:

```
maprcli table create -path "'/^=#;{ }&()/'" (or)
maprcli table create -path '/"^=#;{ }&()/'
```

Modifying a Column Family in a Binary Table Using HBase shell

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Displaying Default Column Family Permissions

Use either the Control System or the `maprcli` command to find out the users, groups, or roles that have permissions on the default column family.

Viewing Default Column Family Permissions in the Control System

- Log in to the Control System and go to the **Column Families** tab in the [table information page](#). The **Default Column Family Authorization** pane displays the following permissions for users, groups, and roles.

Binary Table

| | |
|-----------------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Append Data | Can do column appends. Column appends require permission both at the column-family level and at the column level. |
| Set Version | Can set or change the maximum and minimum number of versions of column values to keep. |
| Set Compression | Can set or change the compression setting for the column family. |

JSON Table

| | |
|------------|--|
| Read Data | Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |
| Write Data | Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family. |

| | |
|------------------------|---|
| <p>Traverse Data</p> | <p>Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure:</p> <pre> { "_id" : "ID", "a" : { "b" : "value", "c" : "value" } } </pre> <p>Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.</p> |
| <p>Set Version</p> | <p>Can set or change the maximum and minimum number of versions of column values to keep.</p> |
| <p>Set Compression</p> | <p>Can set or change the compression setting for the column family.</p> |

Retrieving the Default Column Family Permissions Using the CLI

To display the permissions on a column family, run this command:

```
maprcli table cf colperm get -path <path> -cfname <name of column family> -json
```

To display the permissions on a column, add the `-name` parameter:

```
maprcli table cf colperm get -path <path> -cfname <name of column family> -name <name of column> -json
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster.

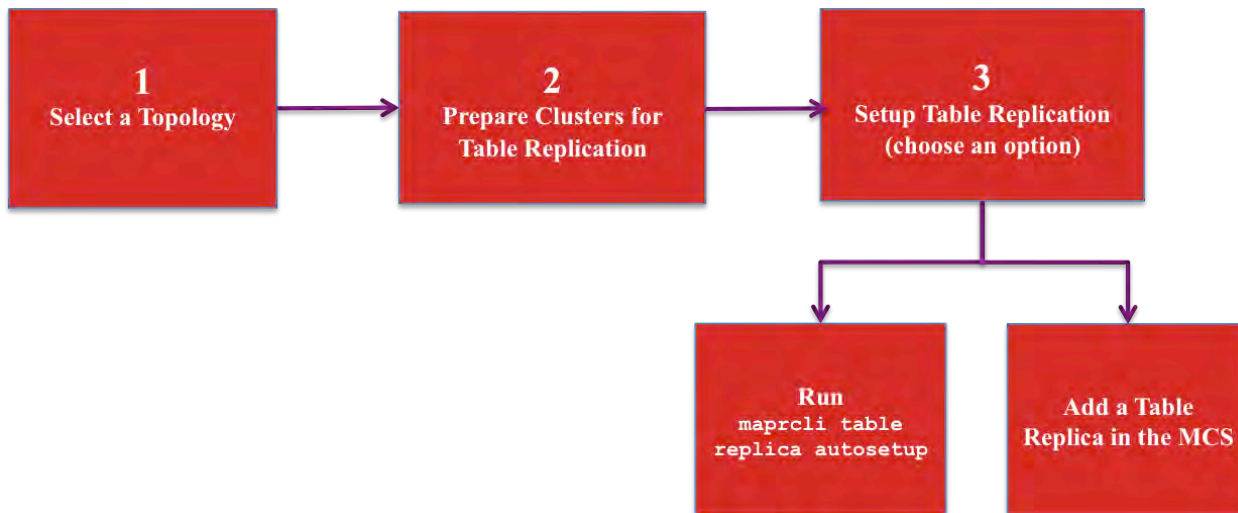

The `json` parameter displays the output as a JSON document.

Managing Table Replication

This section contains topics about setting up table replication and administering existing replicas.

The process to set up table replication consists of the following steps:

1. [Select a Topology](#)
2. [Prepare Clusters for Table Replication.](#)
3. Set up Table Replication using one of the following options:
 - [Run `maprccli table replica autoseup`.](#)
 - [Add a Table Replica in the Control System.](#)

1. [Select a Table Topology](#)
2. [Prepare Clusters for Table Replication](#)
3. [Run `maprccli table replica autoseup`](#)
4. [Add a Table Replica in the MCS](#)

Note: After setting up replication, replicas can be administered using either the Control System or the CLI.

Preparing Clusters for Table Replication

Preparing clusters for table replication includes configuring gateways on destination clusters, configuring the `mapr-clusters.conf` file on the source cluster, and, if the clusters are secure, setting up secure communications between the clusters. After you prepare the clusters for table replication, you can setup replication between tables.

Before You Begin

The following topics identify concepts and tasks that you need to do before setting up your environment for table replication.

- Plan which replication topology you want to use. For information about the various topologies, see [Supported replication topologies](#) on page 574.

- In general, if you are replicating tables, you should store them in their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a table in a promoted mirror lags behind the table's replica.

For example, suppose `/vol` mirrors to `/vol.mirror` and contains a table `srcTab` that replicates to `/replVol/replTab`. If `/vol` fails, `/vol.mirror/srcTab` may lag `/replVol/replTab` when `/vol.mirror` is promoted.

To avoid this problem, starting with the 6.1 release, after HPE Ezmeral Data Fabric Database promotes a mirror volume, replication terminates with `REPLICA_STATE_UNEXPECTED` for any tables in that volume.

The following sample output shows this behavior:

```
[mapr]# /opt/mapr/bin/maprcli table replica list -path /vol.mirror/
srcTab -refreshnow true -json
{
  "timestamp":1534805233244,
  "timeofday":"2018-08-20 03:47:13.244 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"mirrorSrc",
      "table":"/replVol/replTab",
      "type":"MapRDB",
      "replicaPath":"/replVol/replTab",
      "replicaState":"REPLICA_STATE_UNEXPECTED",
      "paused":false,
      "throttle":false,
      "idx":1,
      "networkencryption":false,
      "synchronous":false,
      "networkcompression":"lz4",
      "propagateExistingData":false,
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "uuid":"8b4563e1-884d-7852-f257-078c397b5b00",
      "copyTableCompletionPercentage":0,
      "errors":{"
        "Code":"ErrReplicaTableUpstreamMismatch",
        "Host":"10.10.104.35",
        "Msg":"OpenStream: Upstream table does not match original
Upstream cluster mirrorSrc table /replVol/replTab"
      }}
    ]
  }
```

This change in behavior applies to only tables that have replication enabled starting in 6.1. See [Table Replication States](#) on page 588 for more details.

- Ensure that your user ID has the `readAce` permission on the volume where the source tables are located and the `writeAce` permission on the volumes where the replicas are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.
- Ensure that you have administrative authority on the clusters that you plan to use.

- If you upgraded your source cluster from a previous version of data-fabric, enable table replication by running this `maprcli` command: `maprcli cluster feature enable -name mfs.feature.db.repl.support`
- Depending on your use case, replication requires the installation of gateways and may also require the HBase client. For more information about installation requirements, see [Service Layout Guidelines for Replication](#) on page 75

Setting Up Table Replication

The following steps show how to set up your environment for table replication including setup for secure clusters.

1. In the `mapr-clusters.conf` file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster. This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See [mapr-clusters.conf](#) for the format to use for the entries.
2. On the destination cluster, configure gateways through which the source cluster sends updates to the destination cluster. See [Configuring Gateways for Table and Stream Replication](#) on page 1271.
3. If your clusters are secure, configure each cluster so that you can access them all from one cluster. This way, you need not log into each secure cluster separately and run `maprcli` commands locally on them. See [Configuring Secure Clusters for Running Commands Remotely](#) on page 1658 for more information.
4. If your clusters are secure, add a cross-cluster ticket to the source cluster, so that it can replicate data to the destination cluster. See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 1661.
5. **Optional:** If your clusters are secure, configure your source cluster so that you can use the Control System to set up and administer table replication from the source to the destination cluster.

These steps make it convenient to use the Control System for setting up and managing replication involving two secure clusters. However, before following them, perform these prerequisite tasks.

Note:

- Ensure that both clusters are managed by the same team or group. The UIDs and GIDs of the users that are able to log in to the Control System on the source cluster must exactly match their UIDs and GIDs on the destination cluster. This restriction applies only to access to both clusters through the Control System, and does not apply to access to both clusters through the `maprcli`. If the clusters are managed by different teams or groups, use the `maprcli` instead of the Control System to set up and manage table replication involving two secure clusters.
- Ensure that the proper file-system and table permissions are in place on both clusters. Otherwise, any user who can log into the Control System and has the same UID or GID on the destination cluster will be able to set up replication either from the source cluster to the destination cluster or vice versa. A user could create one or more tables on the destination cluster, enable replication to them from the source cluster, load the new tables with data from the source cluster, and start replication. A user could also create tables on the source cluster, enable replication to them from tables in the destination cluster, load the new tables with data from the destination cluster, and start replication.

- a. On the source cluster, generate a service ticket by using the `maprlogin` command:

```
maprlogin generateticket -type service -cluster <destination cluster>
-user mapr -duration <duration> -out <output folder>
```

Where `-duration` is the length of time before the ticket expires. You can specify the value in either of these formats:

- `[Days:]Hours:Minutes`
 - `Seconds`
- b. To every node of the source cluster, add the service ticket to the file `/opt/mapr/conf/mapruserticket` file that was created when you secured the source cluster:

```
at <path and filename of the service ticket> >> /opt/mapr/conf/
mapruserticket
```

- c. Restart the web server by running the `maprcli node services` command. For the syntax of this command, see [node services](#) on page 1939.
- d. Add the following two properties to the `core-site.xml` file. For Hadoop 2.7.0, edit the file `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml`.

```
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

Setting Up Table Replication Using the CLI

You can run the `maprcli table replica autoseup` command to set up primary-secondary or multi-master replication from an existing source table.

Note: This procedure describes how to use the `maprcli` to automatically set up table replication. As an alternative, you can use the [Control System to automatically setup table replication](#) or use the `maprcli` command to [manually setup primary-secondary replication](#) or [manually setup multi-master replication](#).

Before you begin, complete the following steps:

- Verify that you have completed the steps to configure the clusters for table replication. For more information, see [Preparing Clusters for Table Replication](#) on page 1181.
- On the source table, run the `maprcli table info` command to verify that you have the following permissions:
 - `readperm`, which is required for reading from the table.
 - `replperm`, which is required for replicating from the table.

On the destination table (if it already exists), run the `maprcli table info` command to verify that you have the following permissions:

- `bulkload`, which is required for the initial copy of source data into the destination table.

- `replperm`, which is required for receiving replicated updates from the source table.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permissions for updates to column families and columns are irrelevant; gateways have implicit authority to update replicas.

Note: If you are setting up a primary-secondary replication loop for n clusters, repeat these steps for $n-1$ primary-secondary relationships to set up basic primary-secondary topologies.

1. Log into both the source and destination clusters.
2. Run the `maprcli table replica autosetup` command.
 - For primary-secondary replication:

```
maprcli table replica autosetup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table>
```

- For multi-master replication:

```
maprcli table replica autosetup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table> -multimaster true
```

Note:

The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

For example, to set up multi-master replication between the `customers` table in the `sanfrancisco` cluster and a new `customers` table in the `newyork` cluster, you could use this command:

```
maprcli table replica autosetup -path /mapr/sanfrancisco/customers -replica /mapr/newyork/customers -multimaster true
```

To set up primary-secondary replication between the `customersA` table in the `sanfrancisco` cluster and a new `customersB` table in the same cluster, you could use this command:

```
maprcli table replica autosetup -path /mapr/sanfrancisco/customersA -replica /mapr/sanfrancisco/customersB
```

Note: For information about additional parameters that you can configure, see [table replica autosetup](#) on page 2108.

3. To check the replication status, run [table replica list](#) on page 2117.

Additional Information:

- With multi-master replication, if one of the tables goes offline, you can direct client applications to the other table. For more information, see [Multi-Master Replication](#) on page 579.
- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see [Adding a Column Family to a Replica](#) on page 1201
- Check the Control System for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication. See [Table-Replication Alarms](#).

Setting Up Primary-Secondary Replication Manually

You can run `maprcli` commands to set up primary-secondary replication manually.

1. Ensure that you have followed these prerequisite steps:
 - Verify that you have complete the steps to configure the clusters for table replication. For more information, see [Preparing Clusters for Table Replication](#) on page 1181.
 - Run the `maprcli table info` command on the source table to verify that you have the following permissions:
 - `readperm`, which is required for reading from the table.
 - `replperm`, which is required for replicating from the table.
 - Run the `maprcli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
 - `bulkload`, which is required for the initial copy of source data into the destination table.
 - `replperm`, which is required for receiving replicated updates from the source table.
2. Create the replica manually with the `maprcli` command `table create`. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

```
maprcli table create -path <path to the replica> -copymetafrom <path to the source table>
```

For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table create -path /mapr/newyork/customers -copymetafrom /mapr/sanfrancisco/customers
```

3. Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica <path to the replica> -paused true
```

For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table replica add -path /mapr/sanfrancisco/customers -replica /mapr/newyork/customers -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step 4.

Note: For more information about additional parameters that you can configure, see [table replica add](#) on page 2105.

4. Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

To verify that the `customers` table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprcli table replica list -path /mapr/sanfrancisco/customers
```

5. Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream <path to the source table>
```

To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

```
maprcli table upstream add -path /mapr/newyork/customers -upstream /mapr/sanfrancisco/customers
```

6. Verify that you specified the correct source table by running the `maprcli table upstream list` command.

```
maprcli table upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli table upstream list -path /mapr/newyork/customers
```

7. If you set `-paused` to `true` when adding the replica, follow these steps:
 - a) Load the replica with data from the source table by using the HPE Ezmeral Data Fabric Database [CopyTable](#) utility for binary tables or the [HPE Ezmeral Data Fabric Database JSON CopyTable](#) on page 5515 utility for JSON tables.
 - b) Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

```
maprcli table replica resume -path <path to the source table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli table replica resume -path mapr/sanfrancisco/customers -replica /mapr/newyork/customers
```

- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see [Adding a Column Family to a Replica](#) on page 1201
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See [Table-Replication Alarms](#).

Setting Up Multi-Master Replication Manually

You can run `maprcli` commands to set up multi-master replication, first establishing replication in one direction, and then establishing it in the other direction.

- Verify that you have complete the steps to configure the clusters for table replication. For more information, see [Preparing Clusters for Table Replication](#) on page 1181.
 - Run the `maprcli table info` command on the source table to verify that you have the following permissions:
 - `readperm`, which is required for reading from the table.
 - `replperm`, which is required for replicating from the table.
 - Run the `maprcli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
 - `bulkload`, which is required for the initial copy of source data into the destination table.
 - `replperm`, which is required for receiving replicated updates from the source table.
1. For manual setup in one direction, follow these steps:
 - a) Create the replica manually with the `maprcli table create` command. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

```
maprcli table create -path <path to the replica> -copymetafrom <path to the source table>
```

For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table create -path /mapr/newyork/customers -copymetafrom /mapr/sanfrancisco/customers
```

- b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica <path to the replica> -paused true
```

For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table replica add -path /mapr/sanfrancisco/customers -replica /mapr/newyork/customers -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step d.

- c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

To verify that the `customers` table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprcli table replica list -path /mapr/sanfrancisco/customers
```

- d) Authorize replication between the tables by registering the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream <path to the source table>
```

To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

```
maprcli table upstream add -path /mapr/newyork/customers -upstream /mapr/sanfrancisco/customers
```

- e) Verify that you specified the correct source table by running the `maprcli table upstream list` command.

```
maprcli table upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli table upstream list -path /mapr/newyork/customers
```

- f) If you set `-paused` to `true` when adding the replica, follow these steps:
1. Load the replica with data from the source table by using the HPE Ezmeral Data Fabric Database [CopyTable](#) utility for binary tables or the [HPE Ezmeral Data Fabric Database JSON CopyTable](#) on page 5515 utility for JSON tables.
 2. Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

```
maprcli table replica resume -path <path to the source table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli table replica resume -path mapr/sanfrancisco/customers -replica /mapr/newyork/customers
```

2. For manual setup in the other direction, follow these steps:
 - a) Log into both the source and destination clusters.

- b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica
<path to the replica>
```

- c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

- d) Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream
<path to the source table>
```

- With multi-master replication, if one of the tables goes offline, direct client applications to the other table. For more information, see [Multi-Master Replication](#) on page 579.
- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see [Adding a Column Family to a Replica](#) on page 1201
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See [Table-Replication Alarms](#).

Adding Table Replicas

Explains how to add table replicas using either the Control System, the CLI or the REST API.

You can register a HPE Ezmeral Data Fabric Database binary or JSON table as a replica of another HPE Ezmeral Data Fabric Database binary or JSON table using the Control System and the CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Ezmeral Data Fabric Database Binary or JSON table to a replica HPE Ezmeral Data Fabric Database Binary or JSON table. Before you begin, complete the steps to [prepare HPE Ezmeral Data Fabric clusters for table replication](#).

Adding Table Replica Using the Control System

To replicate a table:

1. Log in to the Control System and go to the **Replication** tab in the [table information page](#).
2. Click **Add Replica** and follow the steps for:
 - [Adding JSON Table Replicas](#) on page 1191
 - [Adding Binary Table Replicas](#) on page 1193
3. Click **Add Replica**.

Adding Table Replica Using the CLI or the REST API

To add a replica, run the following command:

```
/opt/mapr/bin/maprcli table replica add -path <table path> -replica
<replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see [table replica add](#) on page 2105.

Note: You also have the option to setup table replication with `maprcli table replica autoseup` which will setup and start replication. For more information, see [Setting Up Table Replication Using the CLI](#) on page 1184.

Adding JSON Table Replicas

Explains how to add replicas of JSON tables using either the Control System, the CLI or the REST API.

You can register a HPE Ezmeral Data Fabric Database JSON table as a replica of another HPE Ezmeral Data Fabric Database JSON table using either the Control System or the CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Ezmeral Data Fabric Database JSON table to a replica HPE Ezmeral Data Fabric Database JSON table. Before you begin, complete the steps to [prepare HPE Ezmeral Data Fabric clusters for table replication](#).

Adding JSON Table Replica Using the Control System

To create a replica:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Replicas** tab.
The list of replicas associated with the table displays.
3. Click **Add Replica**.
The **Add Replica** page displays.
4. Specify the following settings:

| | |
|---------------------|---|
| Destination Cluster | The destination cluster for the replica, where gateways are configured to allow source cluster to send updates. |
| Path to Replica | <p>The path to the replica.</p> <ul style="list-style-type: none"> • For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code> • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code> <p> Note: For replication to a table, the command will fail if the replica path you specify points to table that already exists.</p> |
| Replication State | <p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. |

| | |
|--------------------|---|
| | <ul style="list-style-type: none"> • Pause Replication — Registers the table on the destination cluster as a replica and adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. <p> Note: Although visible, this option is not supported if the source or replica is on a remote secure cluster.</p> |
| Multi-Master Setup | <p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both the primary and secondary roles. Client applications update both tables and each table replicates updates to the other.</p> <p>See Multi-Master Replication on page 579.</p> <p>If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.</p> <p>See Primary-Secondary Replication on page 574.</p> <p> Note: Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.</p> |

5. Set the following optional properties:

| | |
|-------------------------|--|
| Throttle | Specify whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. |
| Replicate Synchronously | Specify whether replication is synchronous (Yes) or asynchronous (No). See Modes of replication on page 574 for more information. |
| Encrypt On Wire | Specify whether (Yes) or not (No) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security. |
| Compress On Wire | <p>The type of on-wire compression. Choose one of the following:</p> <ul style="list-style-type: none"> • Inherited • OFF • LZF • LZ4 • ZLib |

6. Choose whether to:

- **Replicate Entire Document**
- **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
  "_id" : "ID",
  "a" :
```

```

    {
      "b" :
      {
        "c" : "value",
      },
      "e" : "value"
    }
  }

```

To replicate field `c`, you must specify `a.b.c` as the field path. Do not use quotation marks and do not include spaces after each dot. Click:

- **Add Field** to add another field to replicate.
-  to remove a field.

By default, the entire document in the source table is replicated.

Note: If a field is added at a later date, replication for that field will start at that time.

7. Click **Add Replica**.

A table with the specified fields is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding JSON Table Replica Using the CLI or the REST API

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see [table replica add](#) on page 2105.

Note: You also have the option to use `maprcli table replica autoseup` which will setup and start replication. For more information, see [table replica autoseup](#) on page 2108.

Adding Binary Table Replicas

Explains how to add replicas of binary tables using either the Control System or the CLI.

You can register a HPE Ezmeral Data Fabric Database Binary table as a replica of another HPE Ezmeral Data Fabric Database Binary table using the Control System and CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Ezmeral Data Fabric Database Binary table to a replica HPE Ezmeral Data Fabric Database Binary table. Before you begin, complete the steps to [prepare HPE Ezmeral Data Fabric clusters for table replication](#).

Adding Binary Table Replica Using the Control System

To create a replica:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Replicas** tab.
The list of replicas associated with the table displays.

3. Click **Add Replica**.

The **Add Replica** page displays.

4. Specify the following settings:

| | |
|---------------------|---|
| Destination Cluster | The destination cluster for the replica, where gateways are configured to allow source cluster to send updates. |
| Path to Replica | <p>The path to the replica.</p> <ul style="list-style-type: none"> For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code> For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code> <p> Note: For replication to a table, the command will fail if the replica path you specify points to table that already exists.</p> |
| Replication State | <p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. <p> Note: Although visible, this option is not supported if the source or replica is on a remote secure cluster.</p> |
| Multi-Master Setup | <p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other.</p> <p>See Multi-Master Replication on page 579.</p> <p>If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.</p> <p>See Primary-Secondary Replication on page 574.</p> <p> Note: Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.</p> |

5. Set the following optional properties:

| | |
|-------------------------|--|
| Throttle | Specify whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. |
| Replicate Synchronously | Specify whether replication is synchronous (Yes) or asynchronous (No). See Modes of replication on page 574 for more information. |

| | |
|------------------|---|
| Encrypt On Wire | Specify whether (Yes) or not (No) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security. |
| Compress On Wire | The type of on-wire compression. Choose one of the following: <ul style="list-style-type: none"> • Inherited • OFF • LZF • LZ4 • ZLib |

6. Choose whether to:

- **Replicate all column families**
- **Replicate Selected Column Families** — Specify the column family name and select:
 - **Include All Columns** — to replicate all the columns associated with the column family.
 - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

By default, all columns in the source table are replicated.

Note: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If a column is added at a later date, replication for that column will start at that time.

7. Click **Add Replica**.

A table with the specified column families is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding Binary Table Replica Using the CLI or the REST API

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see [table replica add](#) on page 2105.

Note: You also have the option to use `maprcli table replica autoseup` which will setup and start replication. For more information, see [table replica autoseup](#) on page 2108.

Displaying the List of Table Replicas

Describes how to view information on the table replicas using the Control System or the CLI.

Displaying the List of Table Replicas Using the Control System

To view table replicas:

1. Log in to the Control System and go to the [table information page](#).
2. Click **Replication**.

The page displays all the replicas and for each replica, the pane displays the following statistics:

| Column Name | Column Description |
|---------------------|---|
| Paused | Whether replication is paused. |
| Destination Cluster | The cluster on which the replica resides. |
| Destination Path | The path to the destination. |
| Status | <p>The status of the replica. Replicas can be in one of the following states:</p> <ul style="list-style-type: none"> • In-Synch — indicates replica is in synch with the source table and there are no more bytes to be sent from the source. • Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. • Broken — indicates there was an error during replication. If necessary, remove and re-create the replica. |
| Earliest | The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica. |
| Latest | The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica. |
| Errors | Error () information, if any. |
| Compression Type | The type of on-wire compression. |
| Synchronous | Whether replication is synchronous or asynchronous. |
| Throttled | Whether replication is throttled. |
| Encrypted | Whether replication is encrypted. |

Retrieving List of Table Replicas Using the CLI or the REST API

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see [table replica list](#) on page 2117

Modifying Table Replica

Explains how to edit the properties of a replica using the Control System and the CLI.

Modifying a Table Replica Using the Control System

To modify the properties of a table replica:

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.

2. Click **Replicas** to go to that tab.
3. Click  associated with the replica to modify.
The **Edit Replica** page displays.
4. Make changes to the following as desired:

| | |
|--------------------|--|
| Path to Replica | <p>The path to the replica.</p> <ul style="list-style-type: none"> • For a table on the local cluster, start the path at the volume mount point. For example, for a table named <code>testdst</code> under a volume with a mount point at <code>/volume1</code>, specify the following path: <code>/volume1/testdst</code> • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named <code>customerdst</code> under <code>volume1</code> in the <code>sanfrancisco</code> cluster, specify the following path: <code>/mapr/sanfrancisco/volume1/customerdst</code> <p> Note: For replication to a table, the command will fail if the replica path you specify points to a table that already exists.</p> |
| Replication State | <p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and start replication. • Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. |
| Multi-Master Setup | <p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other.</p> <p>See Primary-Secondary Replication on page 574.</p> <p>If this is not selected, table replication will be basic primary-secondary topology, which is the default. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.</p> <p>See Primary-Secondary Replication on page 574.</p> <p> Note: Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.</p> |

5. Set the following optional properties:

| | |
|-------------------------|--|
| Throttle | Specify whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. |
| Replicate Synchronously | Specify whether replication is synchronous (Yes) or asynchronous (No). |
| Encrypt On Wire | Specify whether (Yes) or not (No) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security. |

| | |
|------------------|---|
| Compress On Wire | <p>The type of on-wire compression. Choose one of the following:</p> <ul style="list-style-type: none"> • Inherited • OFF • LZF • LZ4 • ZLib |
|------------------|---|

6. Choose whether to:

- For JSON table replica:
 - **Replicate Entire Document**
 - **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
  "_id" : "ID",
  "a" : {
    "b" : {
      "c" : "value",
    },
    "e" : "value"
  }
}
```

To replicate field `c`, you must specify `a.b.c` as the field path. Do not use quotation marks and do not include spaces after each dot. Click:

- **Add Field** to add another field to replicate.
-  to remove a field.
- For Binary table replica:
 - **Replicate All Column Families**
 - **Replicate Selected Column Families** — Specify the column family name and select:
 - **Include All Columns** — to replicate all columns associated with the column family.
 - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

7. Click **Edit Replica** for the changes to take effect.

Modifying a Table Replica Using the CLI or REST API

The basic command to modify a table replica is:

```
maprcli table replica edit -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume

- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see [table replica edit](#) on page 2113.

Removing Table Replicas

Explains how to un-register one or more replicas using either the Control System or the CLI.

Removing Replication Using the Control System

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Replication** to go to that tab.
3. Select the replicas to remove by clicking the associated checkbox.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Remove Replica(s)** from the **Actions** drop-down menu.
The **Remove Replica(s)** confirmation window displays.
5. Verify the list of replicas to remove and click **Remove Replica**.
If necessary, click **X** to remove a replica.

The selected replicas are no longer replicas of the source table and will no longer receive updates from the source table. You must also remove upstream source to remove the association between the source table and the replica table. For more information, see [Removing Upstream Sources](#).

Removing Replication Using the CLI or REST API

The un-register a replica, run the following command:

```
maprcli table replica remove -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see [table replica remove](#) on page 2121.

Pausing Table Replication

Explains how to pause table replication of data from a source HPE Ezmeral Data Fabric Database binary or JSON table to a replica HPE Ezmeral Data Fabric Database binary or JSON table respectively using either the Control System or the CLI.

Pausing Table Replication Using the Control System

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Replicas** to go to that tab.
3. Select the replicas to pause by clicking the associated checkbox.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.

4. Select **Pause Replication** from the **Actions** drop-down menu.
The **Pause Replication** confirmation window displays.
5. Verify the list of replicas to pause and click **Pause Replication** to pause replication on the selected replicas.
If necessary, click **X** to remove a replica from being paused.

Pausing Table Replication Using the CLI or REST API

The pause replication, run the following command:

```
maprcli table replica pause -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see [table replica pause](#) on page 2120.

Resuming Table Replication

Explains how to resume replication between a source HPE Ezmeral Data Fabric Database binary or JSON table and a replica of that table when the replication state is set to paused from the Control System or by the `maprcli table replica add` or the `maprcli table replica pause` command.

Resuming Replication Using the Control System

1. Go to the table information page.
See [Viewing Table Information](#) on page 1124.
2. Click **Replicas** to go to that tab.
3. Select the replicas in paused state by clicking the associated checkbox.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Resume Replication** from the **Actions** drop-down menu.
The **Resume Replication** confirmation window displays.
5. Verify the list of replicas for which to resume replication and click **Resume Replication**.
If necessary, click **X** to leave the replica in paused state.

Resuming Replication Using the CLI or REST API

The resume replication, run the following command:

```
maprcli table replica resume -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see [table replica resume](#) on page 2123.

Adding a Column Family to a Replica

Changes to the structure of a source table are not automatically replicated to replica table. You must complete the following steps to add a column family to a replica.

When an entire table is being replicated, new column families are not automatically created at the replica. However, once you add the new column family to the replica then updates to the new column family will immediately start being replicated.

When you are replicating a subset of column families and columns, you must add the new column family to the replica and also run the copytable utility to initially populate the new column family in the replica table.

1. Pause replication by running the `maprcli table replica pause` command.
2. Add the new column family to the replica by running the `maprcli table replica edit` command.
3. If the replica includes a subset of column families and columns from the source table, copy the data from the new column family from the source table into the replica by using the [CopyTable](#) utility. Use the `-columns` parameter to specify the name of the column family.
4. Resume replication by running the `maprcli table replica resume` command.

Viewing Active Table Replication Alarms

Describes how to view active table replication alarms using the Control System and the CLI.

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

- Log in to the Control System and click **Data > Tables** to view table replication alarms in the **Active Alarms** pane.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Table-Replication Alarms](#) on page 2522 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 1724.

Viewing Table Replication Alarms in the Log Files

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Managing Upstream Source for Table Replicas

You can set up a table to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Setting Table as Upstream Source for a Replica

Explains how to set up the current table as the upstream source for a replica if the replica was not configured to automatically re-sync with the current table.

Setting Up Current Table as Upstream Source for a Replica Using the Control System

To set up a table as the upstream source for replicas:

1. Go to the **Replication** tab in the [table information page](#).
2. Select the checkbox beside the replicas that do not have the current table configured as upstream source for automatic re-sync.
Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Table as Upstream Source** from the **Actions** drop-down menu.
The **Set Current Table as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
The current table will automatically send updates to the replica(s).

Setting Up Table as Upstream Source for a Replica Using the CLI or REST API

The basic command to set a table as the upstream source for a replica is:

```
maprcli table upstream add -path <replica table path> -upstream <source table path>
```

See [table upstream add](#) on page 2127 for complete reference information.

Adding Upstream Source for Table

Describes how to add an upstream source for a table using either the Control System or the CLI.

Adding Upstream Source Using the Control System

To add an upstream source for the current table:

1. Log in to the Control System and go to the **Replication** tab in the [table information page](#).
2. Click **Add Upstream Source Table** in the **Upstream Sources** pane.
The **Add Upstream Source Table** window displays.
3. Enter the path to the upstream source table.
 - For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under `volume1` which has a mount point at `/volume1`, specify the following path: `/volume1/testsrc`
 - For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customersrc`
4. Click **Add Upstream Source Table**.

Adding Upstream Source Using the CLI or the REST API

The basic command to add upstream source is:

```
maprcli table upstream add -path <table path> -upstream <upstream table path>
```

See [table upstream add](#) on page 2127 for complete reference information.

Listing all Upstream Sources for a Table

Explains how to retrieve and view the list of upstream sources for a table using either the Control System, or the CLI.

Viewing Upstream Sources Using the Control System

To view the list of upstream sources:

- Log in to the Control System and go to the **Replication** tab in the [table information page](#).
The list of upstream sources for the table displays in the **Upstream Source** pane. For each upstream source, the pane displays the following:

| Column Name | Column Description |
|-------------------------|--|
| IDX | The index number of the replica table. |
| Upstream Source Cluster | The cluster on which the upstream table resides. |
| Upstream Source Path | The path to the upstream source table. |
| UUID | The replica table's universally unique identifier. |

Selecting the checkbox beside an upstream source makes the **Remove Upstream Source(s)** button available. You can:

- [Add](#) an upstream source table
- [Remove](#) an upstream source table

Retrieving Upstream Sources Using the CLI or the REST API

The basic command to retrieving the list of upstream sources for a table is:

```
maprcli table upstream list -path <table path>
```

See [table upstream list](#) on page 2129 for complete reference information.

Removing Upstream Source

Explains how to remove a table as an upstream source using either the Control System or the CLI.

Removing Upstream Source Using the Control System

To remove upstream source:

- Log in to the Control System and go to the **Replication** tab in the table information page.
See [Viewing Table Information](#) on page 1124.
- Select the upstream sources to remove in the **Upstream Source** pane by clicking the associated checkbox.
- Click **Remove Upstream Source Table** in the **Upstream Source** pane.
The **Remove Upstream Source Table** confirmation dialog displays.
- Verify the list of upstream sources to remove and click **Remove Upstream Source Table**.

Removing Upstream Source Using the CLI or the REST API

The basic command to remove upstream source is:

```
maprcli table upstream remove -path <table path> -upstream <upstream table path>
```

See [table upstream remove](#) on page 2130 for complete reference information.

Managing Secondary Indexes

Describes how to manage secondary indexes, including adding, deleting, and listing indexes, setting up your cluster for querying, and troubleshooting index usage.

You can add and manage secondary indexes using either the `maprcli table index` commands or the Control System. The `maprcli table index` commands are also available using the REST API. The following diagram provides links to information about managing indexes.

1. [Describes the tasks needed to prepare your environment so you can query HPE Ezmeral Data Fabric Database JSON tables using secondary indexes.](#)
2. [Describes how to add secondary indexes on HPE Ezmeral Data Fabric Database JSON tables.](#)
3. [Describes how to view information about secondary indexes. This includes information about whether an index is lagging its parent JSON table.](#)
4. [Describes how to use the HPE Ezmeral Data Fabric Database shell to examine the contents of a secondary index. This includes displaying information about errors encountered inserting into the index.](#)
5. [Describes how to verify that the data in a secondary index is consistent with its JSON table.](#)
6. [This topic describes how to remove secondary indexes that are no longer needed.](#)
7. [Describes how to debug and troubleshoot usage of secondary indexes.](#)

The following permissions are required to add, remove, and list indexes. Indexes share the same volume and topology as its JSON table, so the applicable permissions are on the volume and JSON table path.

- `readAce` on the volume
- `lookupdir` on directories in the table path

Note: The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Also, to add or remove an index, the user must be the creator of the table or a user with `indexperm` permission.

Preparing Clusters for Querying using Secondary Indexes on JSON Tables

Describes the tasks needed to prepare your environment so you can query HPE Ezmeral Data Fabric Database JSON tables using secondary indexes.

Installing with the MapR Installer

To install MapR using the MapR installer, follow the steps outlined at [Installing with the Installer](#) on page 127.

Starting with MapR 6.0.1, you do not have to enable a separate query service to use secondary indexes. The **Operational Applications with HPE Ezmeral Data Fabric Database** template installs and configures the replication gateways needed to update secondary indexes in HPE Ezmeral Data Fabric Database JSON and includes the components needed to run OJAI queries.

You must enable the [OJAI Distributed Query Service](#) on page 467 to use certain features. The following table summarizes the differences in the functionality of OJAI queries when you do and do not have the service enabled:

| Service Not Enabled | Service Enabled |
|---|---|
| <ul style="list-style-type: none"> • Can run queries that use a single secondary index • Can sort data in your queries up to a configurable limit | <ul style="list-style-type: none"> • Can run queries that use multiple secondary indexes • Can sort data in your queries without any limit • Can run queries in parallel |

Selecting any of the following templates enables the OJAI Distributed Query Service:

- **Operational Applications with HPE Ezmeral Data Fabric Database and Distributed Query Service**
- **MapR Converged Cluster: Batch, interactive and real-time analytics**
- **Analytics with HPE Ezmeral Data Fabric Database**

You can also explicitly enable the OJAI Distributed Query Service by selecting the service in the **Custom Services** template.

For more information about installer templates, see [Auto-Provisioning Templates](#) on page 5651.

For more information about how secondary index selection and execution works in HPE Ezmeral Data Fabric Database JSON, see [Selection and Execution of Secondary Indexes](#) on page 545.

Note: The **OJAI Query Service** has been renamed to the **OJAI Distributed Query Service** in MapR 6.0.1. All information about the OJAI Distributed Query Service applies to the OJAI Query Service, except where noted.

Installing without the MapR Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the MapR installer. Generally, you need to perform the following steps:

1. Install software.

To install MapR without using the MapR installer, follow the steps outlined at [Installing without the Installer](#) on page 127. In addition to installing MapR core packages, you also need to [install MapR Drill](#) if you want advanced secondary index selection, sorts on large data sets, and parallel query execution. When installing Drill, make sure to [Configure the OJAI Distributed Query Service](#) on page 172.

2. Install and configure replication gateways.

Updates are propagated from the JSON tables using the [Gateways for Replicating HPE Ezmeral Data Fabric Database Tables](#) on page 584. You need to install the replication gateways. Since the source JSON table and the secondary index are on the same volume within a cluster, configure an [intracluster gateway](#). In this type of gateway, the source and destination clusters are the same.

If your gateways are running on the same nodes as CLDB, then no additional configuration steps are required. See [Configuring Gateways for Table and Stream Replication](#) on page 1271 for details about this scenario and other options for configuring your gateways.

Upgrades

Other sections of the documentation describe the detailed steps for upgrades. Generally, you need to perform the following steps:

1. Upgrade your MapR software by following the instructions at [Upgrading Core or EEP Components](#) on page 236.
2. [Install MapR Drill](#), if you have not already done so and want to sort large data sets and run queries in parallel.
3. When installing Drill, make sure to [Configure the OJAI Distributed Query Service](#) on page 172.
4. If you are upgrading without the MapR installer, follow step 2 in the previous section to install and configure replication gateways.
5. Enable the replication support needed to propagate index updates by running the following command:

```
maprcli cluster feature enable -name mfs.feature.db.streams.v6.support
```

See [Step 4: Enable New Features](#) on page 281 for further details.

 **Important:** If you are using a [Manual Rolling Upgrade Description](#) on page 268, you must upgrade all nodes running replication gateways before performing updates on tables with indexes. Otherwise, the index updates will hang.

Adding Secondary Indexes on JSON Tables

Describes how to add secondary indexes on HPE Ezmeral Data Fabric Database JSON tables.

You can add secondary indexes using the Control System, or the `maprcli table index` commands.

If you are adding an index on a large table, particularly if it contains complex data, you should consider modifying the `mfs.db.parallel.copyregions` parameter using the `maprcli config save` command. The parameter controls the degree of parallel processing in your HPE Ezmeral Data Fabric cluster. Increasing parallelism can improve the index build time by optimizing the build's intermediate copy operation.

Permissions

You need the following permissions to add an index:

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table

If you created the table in version 6.0 or later, you automatically have `indexperm` permission. For tables created before 6.0, even if you are the owner of the table, you must explicitly add `indexperm` permission.

 **Note:** The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

See [Restrictions on Secondary Indexes](#) on page 527 for information about other restrictions.

Adding Indexes Using the Control System

1. Log in to the Control System and go to the **Indexes** tab in the [table information page](#).
2. Click **Add Index** to display the **Add Index** page.
3. Specify the following settings:

- a) Specify the name of the index in the **Index Name** field.
 - b) Specify whether (**Yes**) or not (**No**) the index is hashed in the **Hashed** field. If **Yes**, specify the number of hash index partitions for distributing the keys.
See [Hashed Indexes](#) on page 517 for information about whether you should create a hashed index.
4. Specify the list of indexed fields under **FIELDS INDEXED**.
- a) Specify the name of the indexed field in the **Field Name** text field.
 - b) Select the ordering (**Ascending** or **Descending**) for the field from the **Order** drop-down menu.
 - c) Select the function of the field from the **Function** drop-down menu.
Before defining an index that specifies index keys with CAST functions, see [Using Casts in Secondary Indexes](#) on page 519 for more information on creating indexes using CAST functions.

Tip: To add more indexed fields, click **Add Another** and repeat step 4.

5. Specify the names of the included fields under **INCLUDED FIELDS**.
For more information, see [Covering Indexes](#) on page 522.

Tip: To add additional included fields, click **Add Another** and repeat step 5.

6. Click **Add Index** to create the index.

Adding Indexes Using the CLI

The following is the basic command for adding a secondary index on a JSON table.

```
maprcli table index add
-path <path>
-index <index name>
-indexedfields < indexed field names >
```

See [table index add](#) on page 2081 for a description of the complete syntax.

Troubleshooting Secondary Indexes

Describes how to debug and troubleshoot usage of secondary indexes.

The following table lists problems you may encounter when using secondary indexes. Based on the symptoms listed in the first column, refer to the section in the third column to further troubleshoot the issue.

| Symptom | Possible Cause | Troubleshooting Steps |
|---------------------------|---|--|
| Query performance is slow | Query is not using secondary indexes | <ol style="list-style-type: none"> Determining the Query Execution Path for OJAI Queries on page 1212 Determining Secondary Index Usage on page 1213 |
| | Non-optimal OJAI query plan chosen | Examining the OJAI Query Plan on page 1213 |
| | Non-optimal query plan chosen by OJAI Distributed Query Service | Determining Index Use on page 3576 |

| Symptom | Possible Cause | Troubleshooting Steps |
|----------------------------|--|--|
| Inconsistent query results | Secondary index update lag | Identifying Secondary Index Lag on page 1214 |
| | Unresolved encoding errors | Troubleshooting Secondary Index Encoding Errors on page 1216 |
| Query runs out of memory | Memory configuration in the OJAI Distributed Query Service set too low | Adjusting Memory Settings in the OJAI Distributed Query Service on page 1218 |

Secondary Index Restrictions

When troubleshooting secondary indexes, you should also keep in mind the following restrictions:

Name Restrictions

You cannot use the following characters in the index name and in the indexed fields:

```
< > ? % \
```

To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1 ^=#;{}&()/" \
-indexedfields "_timestamp":desc,"
","LOTNo" -includedfields \
" "," ^=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1 ^=#;{}&()/' \
-indexedfields "_timestamp":desc,"
","LOTNo" -includedfields \
' ',' ^=#;{}&()/'
```

To use either the ' or the " character in the index name and in the indexed fields, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
" 'MYTABLE1_ANALYSIS_1 ^=#;{}&()/" \
-indexedfields "_timestamp":desc,"
","LOTNo" -includedfields \
" ' ',' ^=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
' "MYTABLE1_ANALYSIS_1 ^=#;{}&()/' \
-indexedfields "_timestamp":desc,"
```

```
" , "LOTNo" -includedfields \
  ' " ' , "^=#;{ }&() / "
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

For example, you cannot create an index with the following indexed fields:

```
a.b[] .c , a.b.d
```

Although subfield `b` appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

See [Composite Indexes and Container Field Paths](#) on page 516 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (`INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG`).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.
- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:
 - The indexed field is a container field path:

```
maprcli table index add -path /
people \
  -index phoneNumberIdx \
  -indexedfields
Phones[] .Number \
  -includedfields
Phones[] .Number
```

- The field specifies a cast to another type.

You can create an index in which the `score` field is an indexed field cast as a `double` type, and `score` is also an included field. The included field retains the original data type of the `score` field:

```
maprcli table index add -path /
castTable \
  -index castIdx1 \
  -indexedfields
'$CAST(score@DOUBLE)' \
  -includedFields score
```

You can create an index in which the `score` field is an indexed field, cast as a `double` type, and the `score` field is also another indexed field, cast as a `long` type:

```
maprcli table index add -path /
castTable \
  -index castIdx2 \
  -indexedfields
'$CAST(score@DOUBLE)', '$CAST(score@LONG)'
```

- You cannot use casts with included fields.
- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

For example, suppose you have the following JSON table:

```
{
  "_id" : "ID",
  "a" :
    {
      "b" :
        {
          "c" :
            "value",
          "d" :
            "value"
        },
      "e" : "value"
    }
}
```

If you create a column family at field `c` in the JSON path `a.b.c`, you cannot define field `a.b.c` as either an indexed or included field. You can define the fields `a`, `a.b`, and `a.b.d` as either indexed or included fields.

- You cannot specify an included field in which the data in the field spans more than one column family.

In the following example, the included field `s11.s12` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm readperm
traverseperm jsonfamilypath
writeperm minversions
maxversions compression
ttl          inmemory cfname
memoryperm
u:root          u:root
u:root
u:root          0
1                lz4
2147483647      false      default
u:root
u:root          u:root
u:root          s11
u:root          0
1                lz4
2147483647      false      cf1
u:root
u:root          u:root
u:root          s11.s12.s13
u:root          0

    "status":"ERROR",
    "errors":[
        {
            "id":22,

"desc":"Data for included field
s11.s12 may not span more than one
column family."
        }
    ]
}
```

- You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same.

See [Composite Indexes and Container Field Paths](#) on page 516 for more details.

- You cannot specify a composite index with an indexed field that is a subfield of another indexed field.

For example, you cannot create an index with the following indexed fields:

```
a, a.b
```

The indexed field `a.b` is a subfield of the indexed field `a`.

Option Restrictions

- As indexes are automatically split, you cannot disable splits when you create your index.

Index Use Restrictions

- Indexes do not optimize non-existence filter conditions.

[table index list](#) on page 2089

This topic describes how to list information about the secondary indexes created on HPE Ezmeral Data Fabric Database JSON tables.

[HPE Ezmeral Data Fabric Database JSON verifyindex](#) on page 5527

Describes how to use the HPE Ezmeral Data Fabric Database JSON `verifyindex` command to verify that the data in a secondary index is consistent with its JSON table.

[dbshell indexscan](#) on page 5501

Determining the Query Execution Path for OJAI Queries

You can determine whether an OJAI query directly accesses HPE Ezmeral Data Fabric Database JSON or leverages the OJAI Distributed Query Service by enabling Java OJAI tracing. Java OJAI tracing logs information that enables you to determine which execution path your queries use.

Follow the instructions at [Enable OJAI Tracing](#) on page 2943 to output tracing messages that include query plans.

If the query does not use the OJAI Distributed Query Service, you will see tracing like the following:

```
2017-07-17 17:35:59 TRACE OjaiDocumentStore:132 -
Query Plan: '[{"streamName": "DBDocumentStream", "parameters":
{"queryConditionPath": false, "indexName": "abc_Idx", "projectionPath":
["c", "b", "a"], "primaryTable": "/tmp/test-728918932/ei_suffix_sort"}}]'
```

If a query uses the OJAI Distributed Query Service, you will see tracing like the following instead:

```
2017-07-17 18:51:13 TRACE OjaiDocumentStore:132 - Query
Plan: '[{"streamName": "DrillDocumentStream", "parameters": {"sql": "select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC"}]'
```

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
```

```
2692966d-0888-96e2-fa09-0d9befcd3173 ,sql string = select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC)
```

Note that the **Query Plan** in the second trace fragment above contains a **DrillDocumentStream** instead of a **DBDocumentStream**. The **sql** parameter in that stream shows a SQL query. This is also missing in the first trace fragment above. The presence of the SQL query indicates that OJAI passes the query to the OJAI Distributed Query Service, as noted in the third trace fragment.

For further information about OJAI query plans, see [Examining the OJAI Query Plan](#) on page 1213. For background information about different query execution paths, see [OJAI Distributed Query Service](#) on page 467.

Determining Secondary Index Usage

This section describes how to determine whether a query is using secondary indexes, depending on the query execution path used.

Determine whether your query uses the OJAI Distributed Query Service by following the steps outlined at [Determining the Query Execution Path for OJAI Queries](#) on page 1212. The following sections describe next steps depending on the execution path.

Simple OJAI Queries

Using the tracing described at [Determining the Query Execution Path for OJAI Queries](#) on page 1212, you will see the following in the log output:

```
2017-07-17 17:35:59 TRACE MapRDBTableImplHelper:703 - Scan on Index:
'testIndex', Primary Table is: '/tmp/testTable', Index Scan QueryCondition:
'((field < {"$numberLong":101}))',
Index Scan startRow: '\x0FZ', Index Scan stopRow: '\x0F\x89\xCA\x80\x00'
```

The "**Scan on Index**", highlighted in bold, indicates OJAI used a secondary index to process the query.

Queries Requiring the OJAI Distributed Query Service

The tracing output described at [Determining the Query Execution Path for OJAI Queries](#) on page 1212 contains a **queryId**, highlighted in bold:

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
2692966d-0888-96e2-fa09-0d9befcd3173 ,
sql string = select t.`$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from
dfs.`/tmp/testTable` t where (t.`l0_a4_int` = -92) order by t.`l0_a4_int`
ASC,t.`_id` DESC)
```

Use this **queryId** to retrieve more information through the Drill Web Console, including the query plan selected by the OJAI Distributed Query Service. See [Query Profile](#) on page 3577 for details.

Examining the OJAI Query Plan

This section describes two ways to access a Java OJAI query plan and provides general information about how to interpret the query plan. You can examine the query plan to determine if the Java OJAI client chooses an appropriate execution path.

Using OJAI Tracing

After following the steps at [Determining the Query Execution Path for OJAI Queries](#) on page 1212, if you determine that your query directly accesses HPE Ezmeral Data Fabric Database JSON and does not use the OJAI Distributed Query Service, you can further examine the query plan in the trace output.

As noted in the referenced topic, to enable tracing, set the following property in your `log4j.properties` file, located in the `/opt/mapr/conf` directory:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

In the following logged output, the query plan uses an index named `i1_idx` and projects field `id1`. It also limits the result to two documents:

```
2017-10-18 11:29:32,876 TRACE
[main] com.mapr.ojai.store.impl.OjaiDocumentStore -
Query Plan: '[{"streamName": "DBDocumentStream", "parameters":
{"queryConditionPath": false, "indexName": "i1_idx", "projectionPath":
["id1"], "primaryTable": "/tmp/test-728918932/tab"}},
{"streamName": "LimitStream", "parameters": {"limit": 2}}]'
```

Calling `QueryResult.getQueryPlan`

Instead of using OJAI tracing, you can programmatically retrieve query plans by calling [`QueryResult.getQueryPlan`](#). The method returns a JSON document that is a list of `Maps`. Each `Map` in the list represents a `DocumentStream` in the query plan, which corresponds to an operation. The order of the list represents the order the HPE Ezmeral Data Fabric Database client processes each operation. Each `Map` entry contains the name of the `DocumentStream` (`streamName`) and its parameters. You may see `Map` entries corresponding to the following `DocumentStreams` in a query plan:

- `DBDocumentStream` - Accesses HPE Ezmeral Data Fabric Database without the OJAI Distributed Query Service
- `DrillDocumentStream` - Uses the OJAI Distributed Query Service to process the query
- `LimitStream` - Limits the number of documents to return
- `OffsetStream` - Skips past specified number of documents before reading

Important: The `DocumentStream` names and their parameters are subject to change from one release to the next. Take that into consideration if you plan to write tools that interpret the contents of an OJAI query plan

Identifying Secondary Index Lag

This section describes the commands you use to determine if updates to a secondary index are lagging.

Secondary index lag can occur due to [asynchronous secondary index updates](#). Use [`maprcli table index list`](#) and [`mapr verifyindex`](#) to assess if there is update lag in an index and to see details on the updates that are lagging.

Run `maprcli table index list`

The `maprcli table index list` command lists information about indexes created on a table. To retrieve the most current status, specify the optional `refreshnow` parameter. Examine the values of the following fields to determine if an index is lagging:

- `isUptodate` - True if the index is up-to-date
- `bytesPending` - The number of bytes pending propagation to the index
- `putsPending` - The number of puts pending propagation to the index
- `minPendingTS` - The timestamp of the oldest put pending propagation to the index
- `maxPendingTS` - The timestamp of the most recent put pending propagation to the index

In the sample output below, the index is up-to-date.

```
maprcli table index list -path /demo/business -json
{
  "timestamp":1506617667735,
  "timeofday":"2017-09-28 04:54:27.735 GMT+0000 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"my.cluster.com",
      "type":"maprdb.si",
      "indexFid":"2049.93.10257820",
      "indexName":"i1",
      "hashed":false,
      "indexState":"REPLICA_STATE_REPLICATING",
      "idx":1,
      "indexedFields":"a.b:ASC",
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "copyTableCompletionPercentage":100,
      "numTablets":1,
      "numRows":4,
      "totalSize":24576
    }
  ]
}
```

Run mapr verifyindex

If `maprcli table index list` shows that an index is lagging, use the [mapr verifyindex](#) command to gather more information. The following example illustrates the output in the case where an index is lagging. The following updates have not yet propagated to the index:

- Document with `_id=997` not yet inserted into the index.
- Update to the `city` field in document with `_id=998` not yet propagated to the index.

```
// Display contents of parent JSON table
# mapr dbshell

maprdb root:> find /t1
{"_id":"1000","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"997","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"998","city":"city4","misc":{"a":"misc.a","b":2}}
{"_id":"999","city":"city3","misc":{"a":"misc.a","b":2}}
4 document(s) found.

// Display contents of an index that is lagging.
// Document with _id=997 is missing from the index and
// there is a mismatch in the index data for document with _id=998
maprdb root:> indexscan /t1 --indexname i2
{"_id":"1000","city":"city3"}
{"_id":"998","city":"city3"}
{"_id":"999","city":"city3"}
3 document(s) found.
maprdb root:> quit
```

```
// Output of verifyindex
# mapr verifyindex -path /t1 -index i2

Missing Document in Index:
{"_id":"997","city":"city3"}

Mismatch Document Found!!
Table side-->{"_id":"998","city":"city4"}
Index side-->{"_id":"998","city":"city3"}

Number of rows in table but not in index: 1
Number of rows in index but not in table: 0
Mismatch row count: 1
```

Troubleshooting Secondary Index Encoding Errors

This section describes how to locate secondary index encoding errors in log files, and then resolve them.

Unresolved secondary index encoding errors can result in queries returning incomplete results. See [Secondary Index Encoding Error](#) on page 2525 for details.

To troubleshoot secondary index encoding errors, follow these steps:

1. Determine whether any table has index encoding alarms by using one of the following two options:

- Run the following `grep` command, searching for the strings `index` and `encoding` in the `mfs.log-5` file:

```
# grep -i "index.*encoding" /opt/mapr/logs/mfs.log-5
2018-07-10 11:06:07,7042 INFO DB db/repl/aragggregator.cc:524 Table
2050.43.262440 hit index row-key encoding error
2018-07-10 11:06:07,7042 INFO DB db/repl/aragggregator.cc:914 Raising
alarm VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR for volume 195503497
```

The fid, 2050.43.262440, in the sample output indicates the table corresponding to the alarm. If you are not sure which table this corresponds to, you can convert the fid to a table path by following the instructions at [Converting fid and volid](#) on page 2721.

- Check for any table index encoding alarms in the MapR Control System, as described at [Viewing Active Table Replication Alarms](#) on page 1440.

The alarm details indicate the table corresponding to the alarm.

2. Find the index on the table from step 1 that is causing the error.

Run [dbshell indexscan](#) on page 5501 with `--mode` set to `err` on each index to see the index's error output. You need to run the command multiple times if a table has multiple indexes with errors.

For example, if `table1` has three secondary indexes and all three secondary indexes have errors, you must run `indexscan` three times:

```
indexscan /table1 --indexname index1 --mode err
indexscan /table1 --indexname index2 --mode err
indexscan /table1 --indexname index3 --mode err
```

The following example shows error output from running the `dbshell indexscan` command:

```
maprdb root:> indexscan /IndexEncodingErrorAlarmsTest1/tab1 --indexname
idx1 --mode err
{"_id":"100","$ERROR":"Index field 1: INVALID_CAST"}
```

3. Address the identified errors by attempting the following suggested resolutions:

| Error | Suggested Resolutions |
|--|--|
| <p>KEY_TOO_LONG: The collective size of the index key is limited to less than 32 KB.</p> | <ul style="list-style-type: none"> • Reinsert the row in the JSON table so the collective size of all the indexed fields is less than 32 KB. • Redesign the secondary index so fields with large values are included fields instead of indexed fields. • Reduce the number of indexed fields in the secondary index. |
| <p>INVALID_CAST: An error was encountered applying the CAST function on an indexed field.</p> | <ul style="list-style-type: none"> • Verify that you have specified the correct types when using the CAST function with indexed fields. • If the types are correct, reinsert the row in the JSON table so the values of indexed fields can be cast to the specified type. <p>See Using Casts in Secondary Indexes on page 519.</p> |

Adjusting Memory Settings in the OJAI Distributed Query Service

This section describes how to verify, through log output, that your OJAI query is running out of memory due to memory limits in the OJAI Distributed Query Service. It then describes how to adjust the memory settings in the service.

1. Before adjusting the OJAI Distributed Query Service memory settings, first confirm that your query has run out of memory due to limits in the service.

You should see output like the following in your client application log:

```
15:32:46.465 [Thread-21] - Error caused in scan Drill submissionFailed
for "select t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/
business` t where ((t.`city` = 'Currie') and (t.`state` = 'PA') and
(t.`review_count` > 5100)) limit 1
org.ojai.exceptions.OjaiException: Drill submissionFailed for "select
t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/business` t where
((t.`city` = 'Currie') and (t.`state` = 'PA') and (t.`review_count` >
5100)) limit 128" please ch
    at

a:617)
    at java.lang.Thread.run(Thread.java:745)
Caused by: org.apache.drill.common.exceptions.UserRemoteException:
RESOURCE ERROR: One or more nodes ran out of memory while executing the
query.

Failure trying to allocate initial reservation for Allocator. Attempted
to allocate 5000000 bytes and received an outcome of FAILED_LOCAL.
Fragment 0:0
```

In the OJAI Distributed Query Service, log files are in the `/opt/mapr/drill/<drill-version>/logs/drillbit.log` on each node where the Query Service is running.

You should see output like the following:

```
2017-10-07 15:32:41,693 [BitServer-3] INFO
o.a.drill.exec.ops.FragmentContext - User Error Occurred: One or more
nodes ran out of memory while executing the query. (Failure trying to
allocate initial reservation for Allocator. Attempted
org.apache.drill.common.exceptions.UserException: RESOURCE ERROR: One or
more nodes ran out of memory while executing the query.

Failure trying to allocate initial reservation for Allocator. Attempted
to allocate 7000000 bytes and received an outcome of FAILED_LOCAL.
Fragment 1:1
```

2. After confirming, increase the Query Service memory settings by editing the `/opt/mapr/conf/conf.d/warden.drill-bits.conf` file on each Drillbit node. The file contains the following entries:

```
service.env=DRILL_HEAP=3072m,DRILL_MAX_DIRECT_MEMORY=1024m,DRILLBIT_CODE_CACHE_SIZE=512m
service.heapsize.min=4608
service.heapsize.max=4608
```

Perform the following steps on **each** Drillbit node:

- a) Modify `DRILL_HEAP` and `DRILL_MAX_DIRECT_MEMORY` in the `service.env` entry based on your requirements.
- b) Update `service.heapsize.min` and `service.heapsize.max` to reflect the updates you made. The numbers sum to the 3 memory settings in the `service.env` entry.
- c) Restart warden on the node by running the following command:

```
service mapr-warden restart
```

Listing Secondary Indexes

Describes how to list information about the secondary indexes created on HPE Ezmeral Data Fabric Database JSON tables.

You can view secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

Note: The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

- Log in to the Control System and go to the **Indexes** tab in the [table information page](#).

The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

| Column Name | Column Description |
|----------------|--|
| Index Name | The name of the index |
| Fields Indexed | The number of fields on the JSON table that are indexed and used for ordering |
| Fields Covered | The number of fields on the JSON table that are indexed, but not used for ordering |
| State | The replication state of the index |
| Up to Date | Whether the index is up to date |
| Hashed | Whether the index is hashed |
| Size | The size of the index |

To view more details on individual indexes, see [Viewing Secondary Index Details](#) on page 1220.

Listing Indexes Using the CLI

The following is basic command for listing secondary indexes.

```
maprcli table index list
    -path <path>
    -refreshnow < true | false >
```

See [table index list](#) on page 2089 for more information.

Viewing Secondary Index Details

Describes how to use the Control System to view more specific details on secondary indexes.

You can view secondary index details using the Control System.

1. Go to the **Indexes** tab in the [table information page](#) for the JSON table.
2. Click the name of the index to display the details.
The page displays **Summary** and **Metrics** tabs.

Summary

The **Summary** tab displays the following:

| | |
|--------------------------------|---|
| Throughput - By Op Type | See Viewing Throughput by Operation Type Using the Control System on page 1424 |
| Region Distribution | See Viewing Region Distribution on page 1427. |
| SETTINGS AND AUDITING | Displays the index name, whether or not the index is hashed and if hashed, the number of hashed partitions, the status of the index and if the index is current, and the number of bytes, puts, and buckets that are yet to be replicated to the index. |
| INCLUDED FIELDS | The fields in the JSON table that are indexed, but not used for ordering. |
| FIELDS INDEXED | The fields in the JSON table that are indexed and used for ordering. |

Metrics

The **Summary** tab displays charts for the secondary index metrics. For more information, see [Viewing Secondary Index Metrics](#) on page 1426.

Removing Secondary Indexes on JSON Tables

Describes how to remove secondary indexes that are no longer needed.

You can remove secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

- `indexperm` permission on the table, if you did not create the table

Note: The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Removing Indexes Using the Control System

1. Log in to the Control System and go to the **Indexes** tab in the [table information page](#).
2. Select the indexes to remove and click **Remove Index**.
The **Remove Index** confirmation window displays.
3. Review the index(es) to remove and click **Remove Index**.

Removing Indexes Using the CLI

The following is the basic command for removing a secondary index on a JSON table.

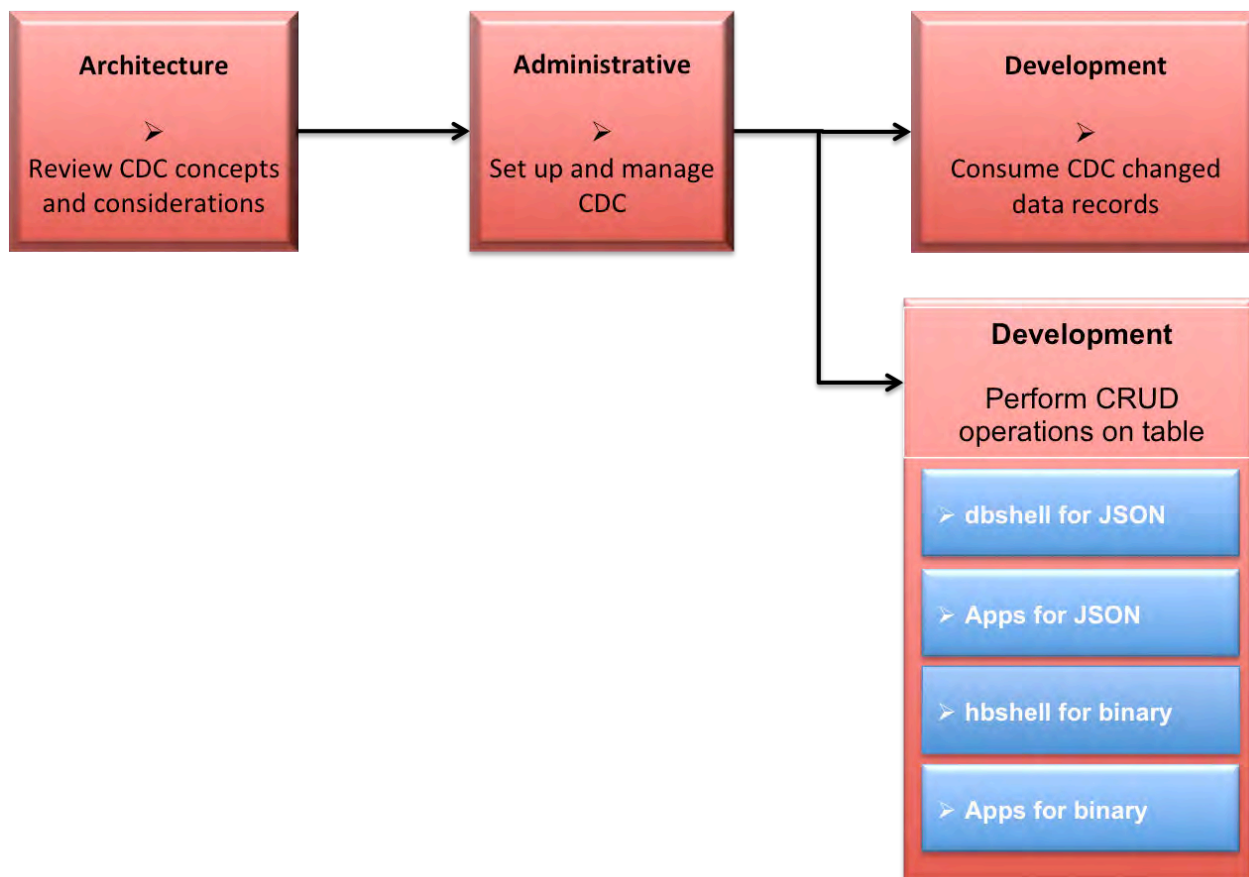

```
maprcli table index remove  
-path <path>  
-index <index name>
```

See [table index remove](#) on page 2092 for more information.

Administering Change Data Capture

This topic covers the Control System and `maprcli` tools for managing the Change Data Capture (CDC) feature.

The following topics provide information you need to understand the CDC feature, to setup and use CDC and the `maprcli` commands used to perform tasks.

1. [Learning about CDC](#)
2. [Setting up the CDC environment](#)
3. [Consuming CDC changed data records](#)
4. [Using dbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database JSON tables](#)
5. [Developing client applications for HPE Ezmeral Data Fabric Database JSON tables.](#)
6. [Using hbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database binary tables.](#)
7. [Developing client applications for HPE Ezmeral Data Fabric Database binary tables.](#)

Additional Information

- [table changelog](#) on page 2068: The `maprcli table changelog` commands for managing the changelog relationship between the source table and the destination stream topic.

Setting Up CDC

To set up the Change Data Capture (CDC) feature, the following must exist or be created: a HPE Ezmeral Data Fabric Database source table (JSON or binary), a HPE Ezmeral Data Fabric Event Streams changelog stream, a HPE Ezmeral Data Fabric Event Streams stream topic, and a HPE Ezmeral Data Fabric Database table changelog relationship between the source table and the destination stream topic.

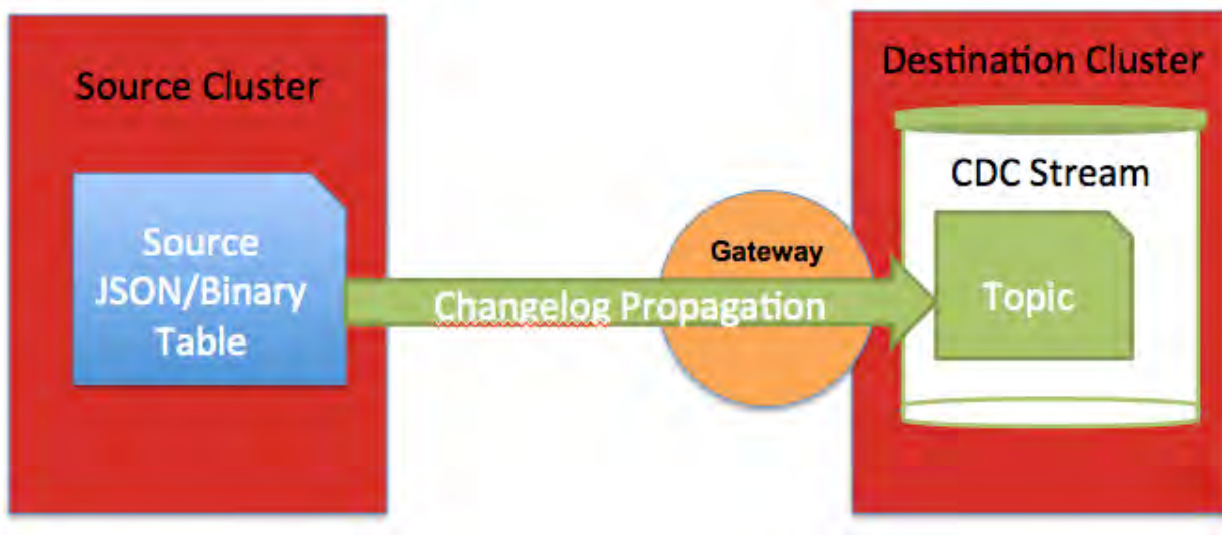

Before Setting Up CDC

The destination HPE Ezmeral Data Fabric Event Streams stream can be in same cluster as the HPE Ezmeral Data Fabric Database source table or it can be on a remote HPE Ezmeral Data Fabric cluster. If

you are propagating changed data from a source table on a source cluster to a destination stream topic on a remote destination cluster, a gateway must be setup. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See [Administering Data Fabric Gateways](#) on page 1269 and [Configuring Gateways for Table and Stream Replication](#) on page 1271.

The following diagram shows a simple CDC data model, with one source table to one destination topic on one stream. Because this scenario has the destination stream topic on a remote destination cluster, a gateway must be setup and configured.

 **Note:** More complex CDC scenarios can be implemented and multiple gateways can be setup. See [Data Modeling and CDC](#) on page 567 for more information about CDC data models.

 **Important:** If you have a secure cluster, secure configuration must be setup. See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 1661.

Create Table

A HPE Ezmeral Data Fabric Database table (JSON or binary) must be established for the CDC data. You can create a new table and add data or use an existing table with data. See [maprcli table create](#) for creating a new table or use the Control System. Example code is provided for completing this task using either the maprcli or REST. Alternatively, depending on whether you are establishing JSON documents or binary files, you can use the following:

- [mapr dbshell for HPE Ezmeral Data Fabric Database JSON documents](#)
- [hbshell for HPE Ezmeral Data Fabric Database binary data](#)

 **Attention:** Ensure that a volume exists and mounted for both tables and streams. Even though HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Event Streams stream can exist in the same volume, for organizational purposes, you could create separate volumes for both tables and streams.

The following code examples show how to:

- Create and mount a volume for a source table.
- Create a new binary table. The `-tabletype` parameter's default setting is binary so you don't need to specify this parameter.
- Create a new JSON table.

CLI

```
// Create Volume for table
maprcli volume create -name
tableVolume -path /tableVolume

// Create Binary table
maprcli table create -path /
tableVolume/cdcTable

// Create JSON table
maprcli table create -path /
tableVolume/cdcTable -tabletype json
```

REST

```
// Create Volume for table
https://10.10.100.17:8443/rest/
volume/create?name=tableVolume&path=/
tableVolume

// Create Binary table
https://10.10.100.17:8443/rest/table/
create?path=/tableVolume/cdcTable

// Create JSON table
https://10.10.100.17:8443/rest/
table/create?path=/tableVolume/
cdcTable&tabletype=json
```

Create Stream

A HPE Ezmeral Data Fabric Event Streams changelog stream must be created for the propagated changed data records using the `maprcli stream create -ischangelog` parameter. See [maprcli stream create](#) or use the Control System.

Note: Ensure that a volume exists and mounted for both tables and streams. Even though HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Event Streams stream can exist in the same volume, for organizational purposes, you could create separate volumes for tables and streams.

Important: The changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change.

- If the `stream topic create` command is used to create a stream topic, then the number of topic partitions can be set at creation time and then is *locked*.
- If the `table changelog add` command is used to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.

The following code examples show how to:

- Create and mount a volume for a changelog stream.
- Create a changelog stream using the default partitions value of one (1).
- Create a changelog stream changing the default partitions to three (3).

CLI

```
// Create Volume for stream
maprcli volume create -name
streamVolume -path /streamVolume

// Create stream (default partitions:
1)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog true

// Create stream (default
partitions: 3)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog
true -defaultpartitions 3
```

REST

```
// Create Volume for stream
https://10.10.100.17:8443/rest/volume/
create?name=streamVolume&path=/
streamVolume

// Create stream (default partitions:
1)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true

// Create stream (default partitions:
3)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true&defau
ltpartitions=3
```

Create Topic

A HPE Ezmeral Data Fabric Event Streams stream topic must be created for the changed data records. This can be accomplished in a variety of ways:

- Use the [maprcli table changelog add](#) command. This command establishes a changelog relationship between the source table and the destination stream topic.
- Use the [maprcli stream topic create](#) command.
- Use the REST equivalent of the above maprcli commands.
- Use the Control System.

 **Important:** Once a changelog relationship is established between the source table and the destination stream topic, the number of topic partitions is *locked*. (The `maprcli table changelog add` command is used to establish the changelog relationship.) The `stream topic edit` command can not be used to modify the topic's number of partitions.

The following describes when to create a stream topic a specific way.

- If the changelog stream's default partitions are acceptable for the stream topic (because the topic inherits the stream's default partitions), you can either:

- Go directly to adding the changelog relationship with the `maprcli table changelog add` command and create the topic there.
- Create the topic with the `stream topic create` command and *not* specify the `-partitions` parameter.
- If you want to change the topic's partitions, create the topic with the `stream topic create` command and set the `-partitions` parameter.
- If you use the Control System, either of the above methods are available.

The following code examples show how to create a stream topic and change the default partition to five (5).

CLI

```
// Create topic (default partitions: 5
maprcli stream topic create -path /
streamVolume/changelogStream -topic
cdcTopic1 -partitions 5
```

REST

```
// Create topic (default partitions: 5
https://10.10.100.17:8443/rest/stream/
topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1&partit
ions=5
```

Add Changelog

A table changelog relationship must be added between the source table and the destination stream topic by using the [maprcli table changelog add](#) command or the Control System. By adding a table changelog relationship, you are creating an environment that propagates changed data records from a source table to a HPE Ezmeral Data Fabric Event Streams stream topic.

- If you are creating a changelog relationship and the stream topic does not exist, you specify the stream path and topic.
- If you are creating a changelog relationship and the stream topic *does* exist, specify the stream path and topic plus the `-useexistingtopic` parameter. The `-useexistingtopic` parameter can only be used with a changelog stream's newly created topic or a previous changelog stream topic *for the same source table*.

Note: Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

Note: Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See [table changelog resume](#) on page 2074 for more information.

The following code examples show how to:

- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does not* exist.
- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does* exist.

CLI

```
maprcli table changelog add -path /
tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1
```

```
maprcli table changelog add -path /
tableVolume/cdcTable -changelog /
streamVolume/
changelogStream:cdcTopic1 -useexisting
topic true
```

REST

```
https://10.10.100.17:8443/rest/table/
changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1
```

```
https://10.10.100.17:8443/rest/table/
changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1&useexistingt
opic=true
```

The following example verifies that the table changelog relationship exists:

```
maprcli table changelog list -path /tableVolume/cdcTable
```

What's Next: Modifying and Consuming Data

To have CDC changed data records to consume, you need to perform inserts, updates, and deletes on the HPE Ezmeral Data Fabric Database table data. See CRUD operations on documents using mapr dbshell for JSON documents, mapr hbshell for binary data, Java applications for HPE Ezmeral Data Fabric Database JSON, C or Java applications for HPE Ezmeral Data Fabric Database Binary.

A HPE Ezmeral Data Fabric Event Streams Kafka/OJAI consumer application subscribes to the topic and consumes the change data records. See [Consuming CDC Records](#) on page 3000 for more information.

Example: Setting Up CDC with Default Topic Partitions

This example creates the following: a volume for a HPE Ezmeral Data Fabric Database table, a HPE Ezmeral Data Fabric Database JSON table, a HPE Ezmeral Data Fabric Event Streams changelog stream without changing the default partitions, creates a topic while adding a table changelog relationship from the source table to the destination stream topic and and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
maprcli table create -path /tableVolume/cdcTable -tabletype json

// Creating a stream for CDC data
maprcli stream create -path /streamVolume/changelogStream -ischangelog
true

// Creating a changelog relationship between the source table and the stream
maprcli table changelog add -path /tableVolume/cdcTable -changelog /
```

```
streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
maprcli table changelog info -changelog /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true

// Creating a changelog relationship between the source table and the stream
https://10.10.100.17:8443/rest/table/changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Example: Setting Up CDC with Non-default Topic Partitions

This example creates the following: a volume for a HPE Ezmeral Data Fabric Database table, a HPE Ezmeral Data Fabric Database JSON table, a HPE Ezmeral Data Fabric Event Streams changelog stream with default partitions, a stream topic with custom partitions, a table changelog relationship from the source table to the destination stream topic, and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
maprcli table create -path /tableVolume/cdcTable -tabletype json

// Creating a stream for CDC data
maprcli stream create -path /streamVolume/changelogStream -ischangelog
true -defaultpartitions 3

// Creating a stream topic that overrides the stream's default partitions
maprcli stream topic create -path /streamVolume/changelogStream -topic
cdcTopic1 -partitions 5

// Creating a changelog relationship between the source table and the
stream plus using an existing topic that has custom partitions
maprcli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1 -useexistingtopic true

// Viewing the changelog information
```

```
maprcli table changelog info -changelog /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&isChangelog=true&defaultpartitions=3

// Creating a stream topic that overrides the stream's default partitions
https://10.10.100.17:8443/rest/stream/topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1&partitions=5

// Creating a changelog relationship between the source table and the
stream plus using an existing topic that has custom partitions
https://10.10.100.17:8443/
rest/table/changelog/add?path=/tableVolume/cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1&useexistingtopic=true

// Viewing the changelog information
https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Managing Table Changelogs

Describes how to manage CDC table changelogs through the Control System and maprcli.

Adding a Change Data Log

Explains how to add a change data log using the Control System and the CLI.

To add a change data log, you must have the following permissions:

- **Replication Access** (UI) or `replperm` (CLI) on the source table on the source cluster
- **Topic** (UI) or `topicperm` (CLI) on the destination stream in the destination cluster

If you are a normal user and want to create a changelog between your own HPE Ezmeral Data Fabric Database table and someone else's stream topic, you must have **Topic** (UI) permission or `topicperm` (CLI) on the destination stream.

Adding a Change Data Log Using the Control System

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
2. Click **Add Change Log** to display the **Add Change Log** page.
3. Set values for the following.

| | |
|--------------------------------------|---|
| Destination Cluster | (Required) The path to the cluster on which the changelog stream exists. If the destination stream is on a remote secure cluster, then a gateway and secure configuration must first be setup. For more information, see Table Replication on page 573, Administering Data Fabric Gateways on page 1269, and Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1661. |
| Destination Stream Topic Name | (Required) The target of the changelog stream, specified as <code><stream_path>:<topic_name></code> , to which all change data records will be published. The stream must exist as a changelog stream or the operation fails. |
| Publish to Existing Topic | Whether (Yes) or not (No) to publish to existing topic. If value is No and the topic does not already exist, it will be created. |
| Publish Existing Data | Whether (Yes) or not (No) to initiate publishing of the existing data to the stream. If value is No , only new changes will be propagated. |
| Defer Publishing | Whether (Yes) or not (No) to pause propagation after creating the change log. |
| Throttle | Whether (Yes) or not (No) the data transfer to the stream for this change log must be throttled. |
| Synchronously | Whether (Yes) or not (No) to acknowledge the client writes to the table before the CDC gateway receives the data. |
| Encrypt on Wire | Whether (Yes) or not (No) the data transfer between filesystem and gateway for this change log is encrypted. |
| Compress on Wire | The compression scheme of the data transfer between filesystem and gateway for this change log instance. |

4. Choose one of the following:

- For JSON table:
 - **Publish Entire Document** — to publish the entire document to the stream topic.
 - **Publish Selected Field Path** — to specify the paths to the fields to publish to the stream topic.
- For Binary table:
 - **Publish Entire Document** — to publish the entire document to the stream topic.
 - **Publish Selected Column Families** — to specify the column families to publish to the stream topic.

5. Click **Add Change Log**.

Adding a Change Data Log Using the CLI and REST API

The basic command to add a change data log to a table is:

```
maprcli table changelog add
```

For complete reference, see [table changelog add](#) on page 2068.

Viewing the List of Change Logs

Explains how to view the list of change logs using the Control System or the CLI.

Viewing the List of Change Logs Using the Control System

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
For each change log, the page displays the following:

| Column Name | Column Description |
|-------------------------------|--|
| Edit Change Log | Shortcut to the Edit Change Log window for editing a change log. |
| Paused | Specifies whether the change propagation is paused for the associated change log. |
| Destination Cluster | Specifies the destination cluster on which the stream exists. |
| Destination Stream Topic Name | Specifies the name of the stream associated with the change log. |
| Up to Date | Specifies whether (Yes) or not (No) the change log is up to date. If value is No , hover the cursor over the value to see the number of pending bytes, puts, and buckets. |
| Errors | Indicates whether there were any errors during change propagation. |
| Compression Type | The type of compression for data transfer between filesystem and gateway for the associated change data log instance |
| Synchronous | Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data. |
| Throttle | Specifies whether data transfer to the stream for the associated change data log is throttled. |
| Encrypted | Specifies whether the data transfer between filesystem and gateway for the associated change data log is encrypted. |
| Field Path | Specifies whether only specific field paths are being published to the stream topic. |

Retrieving the List of Change Logs Using the CLI or REST API

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

For complete reference, see [table changelog list](#) on page 2071.

Viewing Change Log Information

Explains how to view information about a specific change log using the CLI.

Retrieving Change Log Information Using the CLI or REST API

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog info
```

For complete reference, see [table changelog info](#) on page 2070.

Editing a Change Log

Explains how to modify a change log associated with a table using either the Control System or the CLI.

Editing a Change Log Using the Control System

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).

- Click  associated with the change log to modify.
The **Edit Change Log** window displays.

- Make the necessary changes to any of the following:

| | |
|-------------------------|---|
| Throttle | Whether (Yes) or not (No) the data transfer must be throttled. |
| Synchronously | Whether (Yes) or not (No) to acknowledge the client writes to the table before the CDC gateway receives the data. |
| Encrypt on Wire | Whether (Yes) or not (No) the data transfer is encrypted. |
| Compress on Wire | The compression scheme of the data propagation. |

- Click **Save Changes** for the changes to take effect.

Editing a Change Log Using the CLI or REST API

The basic command to modify the change log is:

```
maprcli table changelog edit
```

For complete reference, see [table changelog edit](#).

Pausing Data Propagation

Explains how to pause data propagation using either the Control System or the CLI.

Pausing Data Propagation Using the Control System

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
- Select the change log(s) to pause.
Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
- Select **Pause Data Propagation** from the **Actions** drop-down menu to display the **Pause Data Capture** confirmation dialog.
- Review the change log(s) to pause and click **Pause Data Capture**.

Pausing Data Propagation Using the CLI or REST API

The basic command to pause change data propagation is:

```
maprcli table changelog pause
```

For complete reference, see [table changelog pause](#).

Resuming Data Propagation

Explains how to resume a paused change log using either the Control System or the CLI.

Resuming Data Propagation Using the Control System

- Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
- Select the change log(s) to resume.
Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
- Select **Resume Data Propagation** from the **Actions** drop-down menu to display the **Resume Data Capture** confirmation dialog.
- Review the change log(s) to resume and click **Resume Data Capture**.

Resuming Data Propagation Using the CLI or REST API

The basic command to resume change data propagation is:

```
maprcli table changelog resume
```

For complete reference, see [table changelog resume](#).

Removing Change Logs

Describes how to remove change logs using either the Control System or the CLI.

Removing Change Logs Using the Control System

1. Log in to the Control System and go to the **Change Data Capture** tab in the [table information page](#).
2. Select the change log(s) to remove.
Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Remove Change Logs** from the **Actions** drop-down menu to display the **Remove Change Log(s)** confirmation dialog.
4. Review the change log(s) to remove and click **Remove Change Logs**.

Removing Change Logs Using the CLI or REST API

The basic command to remove a change log is:

```
maprcli table changelog remove
```

For complete reference, see [table changelog remove](#).

Troubleshooting Changelogs

checkandcreate topic failed with error 17

I'm getting a **checkandcreate topic** error while trying to edit a changelog topic.

Because the `maprcli table changelog add` command is an asynchronous command, the CDC relationship (same as replication relationship) involves storing information at both the source and destination sides. This results in the following behavior:

- When the `maprcli table changelog add` operation succeeds, it means that the add request is received. To check whether there is an error during the add operation, run the `maprcli table changelog list` operation.
- The `maprcli table changelog edit` operation only modifies the information on the source side, even if an error is display in the `maprcli table changelog list` output, the changelog can still be modified.

Troubleshooting methods:

- If the stream topic already exists in the destination and you are getting an error, delete the topic. The `maprcli table changelog add` operation automatically retries and finishes.
- If the error can not be fixed, delete the partial relationship from the source side with the `maprcli table changelog remove` operation and retry.

Enabling/Disabling Propagation

Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See [table changelog resume](#) on page 2074 for more information.

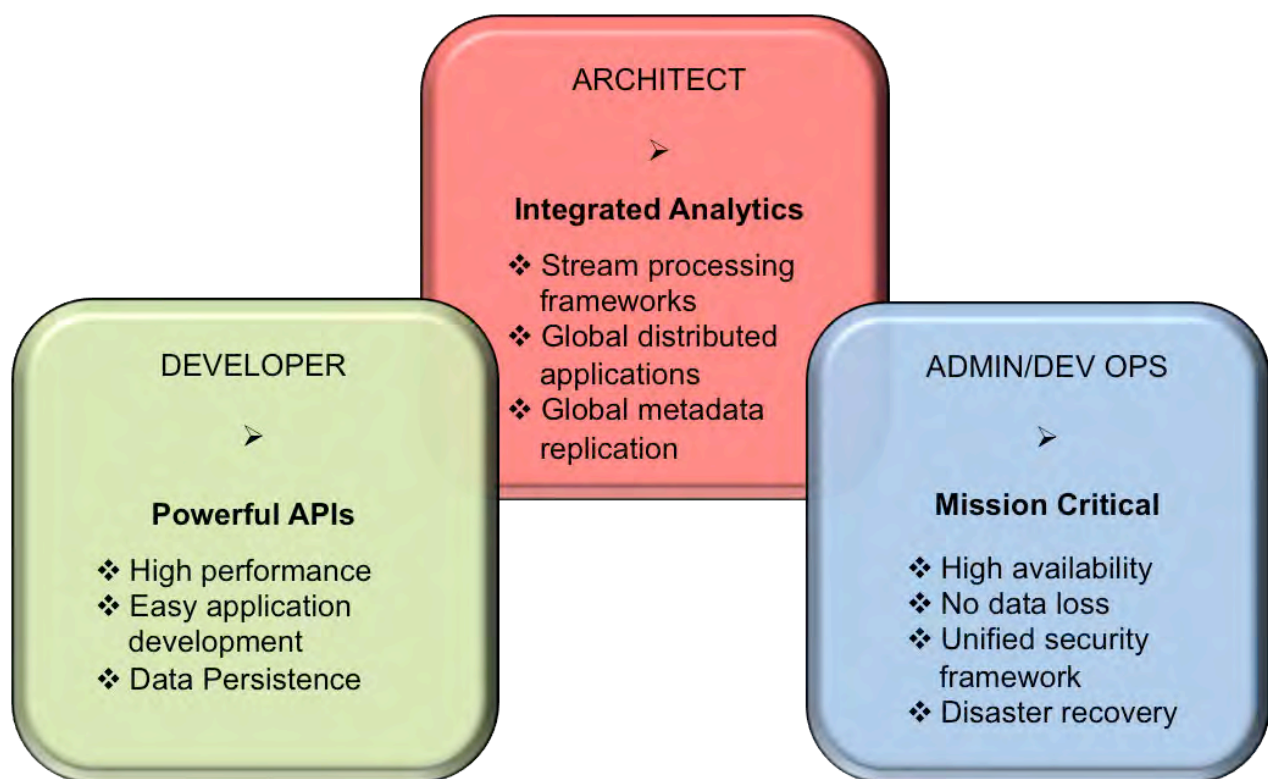

Indexing HPE Ezmeral Data Fabric Database Binary Tables with Elasticsearch

As of with MapR 6.0, HPE Ezmeral Data Fabric Database Elastic Search integration capability is deprecated and no longer available in the HPE Ezmeral Data Fabric Database product.

! **Attention:** HPE Ezmeral Data Fabric Database Change Data Capture (CDC) framework can be used to integrate with latest versions of Elasticsearch. See [Change Data Capture](#) on page 560 for more information.

Administering Streams

HPE Ezmeral Data Fabric Event Streams brings integrated publish and subscribe messaging to the HPE Ezmeral Data Fabric. Producer applications can publish messages to topics, which are logical collections of messages, and Consumer applications can read those messages at their own pace. Topics are grouped into streams, for which administrators can apply security, retention, and replication policies.

1. [The HPE Ezmeral Data Fabric Event Streams and Apps section information and examples for developing Producer and Consumer applications.](#)
2. [The HPE Ezmeral Data Fabric Event Streams section provides conceptual information.](#)
3. [The Administering Streams section provides information about creating and managing streams, topics, and stream replication.](#)

Managing Streams

This topic provides information about managing streams in HPE Ezmeral Data Fabric Event Streams.

Creating a Stream

Explains how to create a stream using the Control System and the CLI.

Your decision about what streams to create should take into account whatever topics you want to replicate. Replication is between streams, not individual topics.

For example, suppose that you plan to create the stream `pollution_monitors` to collect various measurements about pollution levels in cities in Europe. However, during a planning session, the representative from Amsterdam says that her country wants to perform analyses of the data for its cities, and would like your company to replicate the data to its own HPE Ezmeral Data Fabric cluster, where its own consumers can read the replicated messages.

You would create a separate stream of topics that contain data from only the pollution sensors in the cities in that country. You might even decide to do the same for each center, in case other centers eventually want to perform their own analyses, too. The streams you might decide to create could be `pollution_monitors_netherlands`, `pollution_monitors_sweden`, and so on.

Creating a Stream Using the Control System

To create a stream:

1. Log in to the Control System and click **Create Stream** under **Data > Streams**.

Note: This option is not available in the Kubernetes version of the Control System.

The **Create New Stream** page displays.

2. Specify the following properties.

| Property | Description |
|---------------------|---|
| Stream Path | <p>The path and name of the stream to create.</p> <p>The path to the stream can include any character allowed by HPE Ezmeral Data Fabric. For example, <code>/my/path/with:/to/mystream:topic1</code> is valid, but <code>/my/path/with:/to/mystream:withcolon:topic1</code> is invalid.</p> <p>The name of the stream cannot include a colon (<code>:</code>) or a forward slash (<code>/</code>).</p> |
| Time To Live | <p>The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose:</p> <ul style="list-style-type: none"> • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. <p>Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 600 for details.</p> |

| Property | Description |
|---------------------------|---|
| Compression | <p>The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompresses it, and passes it to client applications.</p> <p>Choose one of the following:</p> <ul style="list-style-type: none"> • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB |
| Auto Create Topics | Whether (Yes) or not (No) to create a topic automatically when a producer tries to write the first message to it. |
| Default Partitions | <p>The default number of partitions to allocate to new topics in the stream. When deciding how many partitions to create by default for new topics in a stream, consider the expected volume of messages that will be published to the topics in the stream. High message volumes can be handled more efficiently by multiple consumers in consumer groups reading from multiple partitions than by individual consumers reading from a single partition.</p> <p> Note: You can override the default and specify a different number of partitions for each topic in the stream at the time of creating the topic or after creating the topic.</p> |
| Use for Change Log | Whether (Yes) or not (No) to create the stream for changed data records (as a result of inserts, updates, and deletes) in a HPE Ezmeral Data Fabric Database table. |

3. Set up access to streams for users, groups, and roles.

For each user, group, and/or role, you can grant (by selecting the associated check box) or block (by deselecting the associated checkbox) the following types of access:

| | |
|--------------------|---|
| Administer | <p>Can modify the access-control expressions for the stream, set up replication from the stream, and modify attributes of the stream.</p> <p>This permission includes the topic permission.</p> |
| Copy Stream | <p>Can copy data from one HPE Ezmeral Data Fabric stream to another HPE Ezmeral Data Fabric stream (using the <code>mapr copystream</code> utility) and compare the message IDs, metadata, and data in two HPE Ezmeral Data Fabric streams (using the <code>mapr diffstreams</code> utility).</p> |
| Topic | Can create, edit, or remove topics in the stream. |

| | |
|-----------------|---|
| Producer | Can publish messages to topics in the stream. |
| Consumer | Can listen to topics in the stream. |

By default, all permissions are given to the user creating the stream. To grant or block access to other users, groups, and/or roles, choose one of the following:

- **Basic Settings:** Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

Tip: Click  to create a copy of the associated access control setting. Click  to remove the associated access control expression.

Click **Add Another** to add permissions for another user, group, or role.

- **Advanced Settings:** Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:
 - ! — Negation operator.
 - & — AND operation.
 - | — OR operation.

Use (), parentheses, for subexpressions.

Alternatively, click  associated with the type of access to use the **Create Access Control Expression** window to define access for public or users, group, and/or role.

Note: If you switch from Basic to Advanced, the basic settings, if any, will be carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings will be lost because the subexpressions and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add access control expressions for another user, group, or role, click **Add Another** and repeat this step.

4. Click **Create Stream** to create the stream.

Creating a Stream Using the CLI or REST API

The basic command to create a stream is:

```
maprcli stream create -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

For complete reference information, see [stream create](#) on page 1999.

Editing a Stream

Describes how to edit streams using the Control System and the CLI.

Editing a Stream Using the Control System

1. Log in to the Control System and go to the [stream information page](#).

2. Click **Edit Stream**.
The **Edit Stream** page displays.
3. Make necessary changes to one or more of the following:

| Property | Description |
|---------------------------|---|
| Time To Live | <p>The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose:</p> <ul style="list-style-type: none"> • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. <p>Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 600 for details.</p> |
| Compression | <p>The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompress it, and pass it to client applications.</p> <p>Choose from one of the following compression settings:</p> <ul style="list-style-type: none"> • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB |
| Auto Create Topics | Whether (Yes) or not (No) to create a topic automatically when a producer tries to write the first message to it. |
| Default Partitions | The default number of partitions to allocate to new topics in the stream. |
| Compact | Enable (Yes) or disable (No) log compaction. If enabled, obsolete records from topics are detected and deleted. By default, this is disabled (No) . |

4. Add, modify, or remove access to streams for users, groups, and roles.
For each user, group, and/or role, you can grant (by selecting the associated check box) or deny (by deselecting the associated checkbox) the following types of access:

| | |
|-------------------|--|
| Administer | <p>Can modify the ACE for the stream, set up replication from the stream, and modify attributes of the stream.</p> <p>This permission includes the topic permission.</p> |
|-------------------|--|

| | |
|--------------------|--|
| Copy Stream | Can copy data from one HPE Ezmeral Data Fabric stream to another HPE Ezmeral Data Fabric stream (using the <code>mapr copystream</code> utility) and compare the message IDs, metadata, and data in two HPE Ezmeral Data Fabric streams (using the <code>mapr diffstreams</code> utility). |
| Topic | Can create, edit, or remove topics in the stream. |
| Producer | Can publish messages to topics in the stream. |
| Consumer | Can listen to topics in the stream. |

To grant or deny access to users, groups, and/or roles, choose one of the following:

- **Basic Settings:** Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

Tip: Click  to create a copy of the associated [ACE](#) setting. Click  to remove the associated [ACE](#).

Click **Add Another** to add permissions for another user, group, or role.

- **Advanced Settings:** Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:
 - `!` — Negation operator.
 - `&` — AND operation.
 - `|` — OR operation.

Use `()`, parentheses, for subexpressions.

Alternatively, click  associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See [Defining ACEs Using the Access Control Expression Builder](#) on page 1590 for more information.

Note: If you switch from Basic to Advanced, the basic settings, if any, are carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings are lost because the subexpressions, and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add [ACEs](#) for another user, group, or role, click **Add Another** and repeat this step.

5. Click **Save Changes** for the changes to take effect.

Editing a Stream Using the CLI or REST API

The basic command to edit a stream is

```
/opt/mapr/bin/maprcli stream edit -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the stream

For complete reference information, see [stream edit](#) on page 2006.

Encrypting a Stream

Apply an additional layer of security to streams by encrypting them.

To set encryption on a stream:

1. Before encrypting a stream, ensure that wire-level security is enabled for the cluster. See [Enabling Wire-level Security](#) on page 1527.
2. Determine whether a directory or stream is encrypted by running the following command:

```
hadoop mfs -ls <path>
```

Note: Streams inherit the value of the `-setnetworkencryption` setting from the directory in which they are created.

3. If the directory is not encrypted, set the encryption on the streams with the following command:

```
hadoop mfs -setnetworkencryption on <path of stream>
```

Example

Suppose that the streams that you want to encrypt are all in the `/test` directory. You run this command to discover whether the directory is encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z U U - root root          0 2015-09-07 02:37 268435456 /test
p 2049.43.131260 localhost:5660
```

The second flag `U` after the permissions indicates that the directory `test` is unencrypted. Because you want to encrypt your stream to enhance data security, you run this command, which encrypts the entire directory:

```
hadoop mfs -setnetworkencryption on /test
```

If you run the `-lsd` command again, you will see that the `U` is replaced by an `E`, indicating that the directory is now encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z E U - root root          0 2015-09-07 02:40 268435456 /test
p 2049.43.131260 localhost:5660
```

Defining ACEs Using the Access Control Expression Builder

Indicates how to build access control expressions (ACEs) using the Expression Builder.

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.

Here:

| | | |
|-----|-------------------|---|
| All | AND (&) operation | Indicates that all of the conditions must be met for public or user, group, and/or role to access the volume. |
|-----|-------------------|---|

| | | |
|------------|------------------|---|
| Any | OR () operation | Indicates that any one of the conditions must be met for public or user, group, and/or role to access the volume. |
|------------|------------------|---|

2. Click:

| | |
|------------|---|
| + | To add an expression. |
| () | To add a subexpression. |
| x | To remove an expression or subexpression. |

3. Select Public or User, Group, or Role from the drop-down menu and:

- a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
- b) Enter name of the user, group, or role.

4. Click **Save Changes** to create an Access Control Expression.

Setting Whole Volume ACEs Using the CLI

See [Setting Whole Volume ACEs](#) on page 1576.

Setting Table ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Setting Stream ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Removing Streams

Explains how to delete a stream using either the Control System or the CLI.

Deleted streams cannot be recovered unless they were replicated before deletion. After a stream is deleted, producers will not be able to publish messages to topics in the stream, and consumers will not be able to read messages from topics in the stream.

Removing a Stream Using the Control System

1. Log in to the Control System and go to the [stream information page](#).
2. Click **Remove Stream** to display the **Remove Stream** confirmation dialog.
3. Confirm the action by clicking **Remove Stream**.

Removing a Stream Using the CLI or REST API

The command to delete a stream is:

```
stream delete -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- [readAce](#) and [writeAce](#) on the volume
- [lookupdir](#) on directories in the path

For complete reference, see [stream delete](#) on page 2005.

Viewing a List of Streams

Describes how to view the list of streams using the Control System.

Listing Streams by Type

1. Log in to the Control System and click **Data > Streams**.

Note: This option is not available in the Kubernetes version of the Control System.

2. Choose one of the following HPE Ezmeral Data Fabric Event Streams stream type:

- **Multiple Topics** — to display the list of streams with multiple topics
- **Single Topic** — to display the list of streams with a single topic

Listing Streams in a Volume

1. Log in to the Control System and click **Data > Streams** to view all the volumes that you have access to.

Note: This option is not available in the Kubernetes version of the Control System.

For each volume, the pane displays the following:

| Column Name | Column Description |
|---------------|--|
| Name | The name of the volume. |
| Type | The type. Value can be: <ul style="list-style-type: none"> • — Volume • — Directory • — Stream |
| Owner | The name of the owner. |
| Last Modified | The last modification date and timestamp. |

2. Click the name of the volume (to browse to the path to the stream) or enter the name of the volume in the text field.

The streams in the selected volume display. If necessary, click to return to **All** volumes view.

Listing Streams by Stream Path

1. Log in to the Control System and click **Data > Streams**.

Note: This option is not available in the Kubernetes version of the Control System.

2. Enter the path to the stream in the search field and click **GO**.

Viewing Stream Information

Explains how to view stream information including stream properties, topics, and replication settings using the Control System and the CLI.

Viewing Stream Information Using the Control System

To view stream information:

1. Log in to the Control System and click **Data > Streams**.

Note: This option is not available in the Kubernetes version of the Control System.

2. Locate the stream (by [searching or browsing the volumes or by entering the full path to the stream](#)) and click on the stream name.

The stream information page displays the following tabs:

- Summary
- [Topics](#)
- [Replication](#)

You can:

- [Modify the stream](#)
- [Remove the stream](#)

The **Summary** tab displays:

- The active and recent alarms in the **Alarms** pane.
- The stream settings and permissions in the **Detail** pane.

Retrieving Stream Information Using the CLI or REST API

The basic command to retrieve stream information is:

```
maprcli stream info -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- [readAce](#) on the volume
- [lookupdir](#) on directories in the path
- **adminperm**

When a user with this permission runs the command, the output includes the access-control expressions for the `adminperm` and `topicperm` permissions.
- **produceperm, consumeperm, or topicperm**

When a user with one of these permissions runs the command, the output does not include any access-control expressions.

For complete reference information, see [stream info](#) on page 2009.

Managing Topics

Topics are logical collections of messages. The following sections describe how to create and manage topics.

Adding a Topic to a Stream

Explains how to add a topic to a stream using either the Control System or the CLI.

Adding a Topic to a Stream Using the Control System

1. Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
2. Click **Add Topic** in the **All** topics pane.
3. Specify the name of the topic in the **Topic Name** field.
A name can include alphanumeric characters and the following characters: . (dot), _ (underscore), and - (hyphen).

- Specify the number of partitions to use for the topic.
After you create the topic, you can increase the number of partitions, but you cannot reduce the number. If the topic is associated with a stream for change log, you cannot modify the partitions after you create the topic.
- Click **Add Topic** to create the topic.

Adding a Topic to a Stream Using the CLI or the REST API

The basic command to create a topic is:

```
maprcli stream topic create -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see [stream topic create](#) on page 2022.

Removing Topics in a Stream

Describes how to delete one or more topics from the stream using either the Control System or the CLI.

Consumers do not have to stop consuming from a topic before the topic is deleted.

Removing Topics in a Stream Using the Control System

- Log in to the Control System and the go to the **Topics** tab in the [stream information page](#).
- Select the topics to remove in the **All** topics pane and click **Remove Topic(s)**.
The **Remove Topic(s)** confirmation window displays.
- Verify the list of topics and click **Remove Topic**.
The topic and the messages are immediately deleted.

Removing Topics in a Stream Using the CLI or REST API

The command to delete a topic is:

```
maprcli stream topic delete -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see [stream topic delete](#) on page 2024.

Viewing the List of Topics in a Stream

Explains how to view the list of topics in a stream using the Control System and the CLI.

Viewing the List of Topics in a Stream Using the Control System

- Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
The All topics pane displays the list of topics in the stream and for each topic, the pane displays the following:

| Column Name | Column Description |
|---------------|--|
| Topic Name | The name of the topic. |
| Maximum Lag | The consumer lag time (in milliseconds). |
| Partitions | The number of partitions in the topic. |
| Consumers | The number of consumers for the topic. |
| Physical Size | The physical size (in MB) of the topic. |

You can view a topic from the list of topics by entering the topic name in the search field. You can also:

- [Add](#) a topic to the stream.
- [Remove](#) one or more topics.

- [Modify](#) the number of partitions for a topic.

Viewing the List of Topics in a Stream Using the CLI or REST API

The command to view the list of topics in a stream is:

```
stream topic list -path <Stream Path>
```

For complete reference information, see [stream topic list](#) on page 2028.

Modifying Topic Partitions

Explains how to modify the number of partitions using the Control System and the CLI.

Note: In general, you can increase the number of partitions, but you cannot reduce the number. However, if the topic is associated with a stream for change logs, you *cannot* modify the number of partitions.

Modifying Topic Partitions Using the Control System

1. Log in to the Control System and go to the **Topics** tab in the [stream information page](#).
2. Click  in the **Partitions** column for the topic. The **Edit Partition** window displays.
3. Modify the number of partitions and click **Save Changes** for the changes to take effect.

Modifying Topic Partitions Using the CLI or REST API

The command to modify topic partitions is:

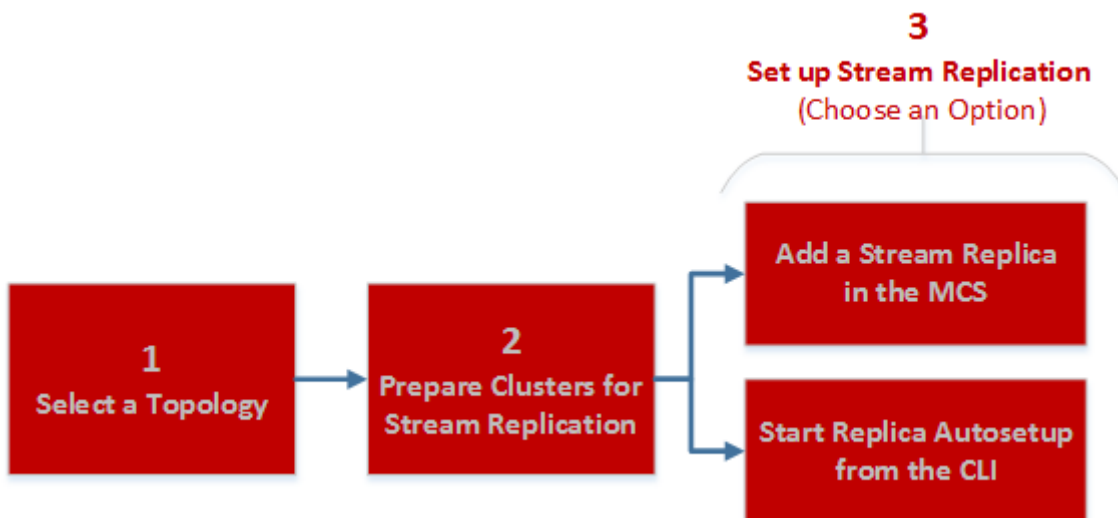

```
stream topic edit -path <stream path> -topic <topic name> -partitions <number of partitions>
```

For complete reference information, see [stream topic edit](#) on page 2025.

Managing Stream Replication

This section contains topics about setting up stream replication and administering existing replicas.

The process to set up stream replication consists of 3

steps:

1. [Stream Replication](#) on page 619

2. [Preparing Clusters for Stream Replication](#) on page 1246
3. [Adding Stream Replicas](#) on page 1246
4. [Setting Up Stream Replication Using the CLI](#) on page 1249

After you set up replication, you can administer replicas using the Control System or the CLI. To view the replication status, run [stream replica list](#) on page 2016.

Preparing Clusters for Stream Replication

Configuring clusters for participation in the replication of HPE Ezmeral Data Fabric Event Streams streams involves configuring two or more gateways on destination clusters and, if the clusters are secure, setting up secure communications between the clusters.

- Plan which replication topology you want to use: basic primary-secondary, multi-master, or a combination of these. For more information about replication topologies, see [Stream Replication](#) on page 619.
- Ensure that you have administrative authority on the clusters that you plan to use.
- Replicating streams requires the installation of gateways. For more information about installation requirements, see [Service Layout Guidelines for Replication](#) on page 75

To configure clusters for replication between streams:

1. In the `mapr-clusters.conf` file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster.

Note:

This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See [mapr-clusters.conf](#) on page 2485 for the format to use for the entries.

2. Configure gateways on the destination clusters.
See [Configuring Gateways for Table and Stream Replication](#).
3. **For secure clusters:** Optionally, configure source clusters so that you can locally run `maprccli` commands that are executed on the destination cluster.
See [Configuring Secure Clusters for Running Commands Remotely](#).
4. **For secure clusters:** Add one cross-cluster ticket to each source cluster for each cluster that it replicates to.
See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#).
5. Ensure that the user ID of the person who starts the replication process has the `readAce` permission on the volume where the source streams are located and the `writeAce` permission on the volumes where the replica streams are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1576.

Adding Stream Replicas

You can create stream replicas using the Control System and the CLI. When you add a replica using the Control System, you can also set up and start replication between a source and replica stream.

Before creating a replica:

1. Review the following:
 - [Modes of Stream Replication](#) on page 622
 - [Security for Stream Replication](#) on page 625

- [Preparing Clusters for Stream Replication](#) on page 1246

Note:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In
 - Multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
 - Many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

Adding a Replica Using the Control System

To add a replica using the Control System:

1. Log in to the Control System and go to the **Replication** tab in the [Viewing Stream Information](#) on page 1242.
2. Click **Add Replica**.
The **Add Replica** page displays.
3. Specify the following settings.

| | |
|------------------------------|---|
| Path to Source Stream | The path and name of the stream that you want to create a replica for. |
| Destination Cluster | The destination cluster for the replica, where gateways are configured to allow source cluster to send updates. |
| Path to Replica | The path and name of the replica stream. |

| | |
|---------------------------|--|
| Replication State | <p>Specify whether or not to start replication by choosing one of the following:</p> <ul style="list-style-type: none"> • Automatic Setup — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, copies the content of the current stream into the replica, and starts replication. In this case, the replica stream starts empty and accumulates messages over time. • Pause Replication — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current stream, after which you can restart replication. <p> Note: If you are interested only in the messages that are published to the source stream after replication starts, then you do not need to pause replication initially. However, if you want the full set of messages from the source stream that have not yet been purged or marked for deletion, then pause replication initially.</p> |
| Multi-Master Setup | <p>(Available only with Automatic Setup) Multi-master topology, in which there are two primary-secondary relationships, with each stream playing both the primary and secondary roles. Client applications update both streams and each stream replicates updates to the other.</p> <p>If this is not selected, stream replication will be basic primary-secondary topology. In this topology, you replicate in one direction.</p> <p>See Stream Replication on page 619 for more information.</p> |

4. Select values for the following optional settings.

| | |
|--------------------------------|---|
| Throttle | <p>Specifies whether (Yes) or not (No) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled.</p> <p>Throttling has two effects, both of which allow HPE Ezmeral Data Fabric Event Streams to use more system resources to process new messages:</p> <ul style="list-style-type: none"> • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk. |
| Replicate Synchronously | <p>Specifies whether replication is synchronous (Yes) or asynchronous (No). The default value is asynchronous replication.</p> |
| Encrypt On Wire | <p>Specifies whether (Yes) or not (No) to enable on-wire encryption. By default, this is disabled (No). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.</p> |
| Compress On Wire | <p>Specifies the type of compression to use when replicating messages.</p> |

5. Click **Add Replica** to create the replica.

Adding a Replica Using the CLI or REST API

The basic command to create a replica is:

```
maprcli stream replica add -path <stream path> -replica <remote stream path>
```

To run this command, your user ID must have the following permissions on the:

- Source cluster:
 - `readAce` and `writeAce` on the volume
 - `lookupdir` on directories in the path
 - `adminperm` and `copyperm` permissions on the source stream
- Target cluster:
 - `readAce` and `writeAce` on the volume
 - `lookupdir` on directories in the path

For complete reference, see [stream replica add](#) on page 2010.

Note: You also have the option to set up replication with `maprcli table replica autosetup` which will set up and start replication. For more information, see [Setting Up Stream Replication Using the CLI](#) on page 1249.

Setting Up Stream Replication Using the CLI

Describes how to run the `maprcli stream replica autosetup` command to set up primary-secondary or multi-master replication from an existing source stream.

Note: This procedure describes how to use the `maprcli` to automatically set up stream replication. As an alternative, you can use the [Control System to automatically set up table replication](#) or use the `maprcli` command to [manually set up primary-secondary replication](#).

Before you begin, review the following requirements:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
- In many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

In general, you should store your streams on their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a stream in the promoted mirror lags behind the stream's replica. See [Preparing Clusters for Table Replication](#) on page 1181 for more details.

Set up replication automatically by following these steps:

1. Log into both the source and destination clusters.
2. Run the command `maprcli stream replica autosetup`:

- For primary-secondary replication:

```
maprcli stream replica autosetup -path <path to source stream> -replica <path to replica stream>
```

For example, to set up primary-secondary replication from the `activity` stream in the `sanfrancisco` cluster to a new `activity` stream in the `newyork` cluster, you could use this command:

```
maprcli stream replica autosetup -path /mapr/sanfrancisco/activity -replica /mapr/newyork/activity
```

- For multi-master replication:

```
maprcli stream replica autosetup -path <path to source stream> -replica <path to replica stream> -multimaster yes
```

For example, to set up multi-master replication between the `activity` stream in the `sanfrancisco` cluster and a new `activity` stream in the `newyork` cluster, you could use this command:

```
maprcli stream replica autosetup -path /mapr/sanfrancisco/activity -replica /mapr/newyork/activity -multimaster yes
```

Note: The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

Note: By default, `maprcli stream replica autosetup` sets up asynchronous replication. If you want to set up synchronous replication or use any of the other optional parameters, see [stream replica autosetup](#) on page 2012.

3. To check the replication status, run [stream replica list](#) on page 2016.

Setting Up Primary-Secondary Stream Replication Manually

Describes how to setup a primary-secondary stream replica that replicates in one direction.

Replica streams can be in a remote data-fabric cluster or in the data-fabric cluster where their source streams are located. All updates from a source stream arrive at a replica stream after having been authenticated at a gateway. Therefore, the `produceperm` access control expressions on the replica stream is irrelevant; gateways have the implicit authority to publish messages to topics in replica streams.

To set up primary-secondary replication of streams:

1. Create the replica manually with the `maprcli stream create` command. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source stream.

```
maprcli stream create -path <path to replica> -copymetafrom <path to source stream>
```

For example, to create the `activity` replica in the `newyork` cluster and use the metadata from the source stream in the `sanfrancisco` cluster, you could use this command:

```
maprcli stream create -path /mapr/newyork/activity -copymetafrom /mapr/sanfrancisco/activity
```

2. Register the replica as a replica of the source stream by running the `maprcli stream replica add` command.

```
maprcli stream replica add -path <path to source stream>
-replica <path to replica> -paused true
```

For example, to register the activity stream in the `newyork` cluster as a replica of the activity stream in the `sanfrancisco` cluster, you could use this command:

```
maprcli stream replica add -path /mapr/sanfrancisco/activity
-replica /mapr/newyork/activity -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source stream as a source for this replica. You do this registration in step 4.

3. Verify that you specified the correct replica by running the `maprcli stream replica list` command.

```
maprcli stream replica list -path <path to source stream>
```

To verify that the activity stream in the `newyork` cluster is a replica of the activity stream in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprcli stream replica list -path /mapr/sanfrancisco/activity
```

4. Authorize replication between the streams by defining the source stream as the upstream stream for the replica by running the `maprcli stream upstream add` command.

Definition of the upstream stream ensures that a stream cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two streams.

```
maprcli stream upstream add -path <path to replica> -upstream
<path to source stream>
```

To add the activity stream in the `sanfrancisco` cluster as an upstream source for the activity stream in the `newyork` cluster:

```
maprcli stream upstream add -path /mapr/newyork/activity -upstream
/mapr/sanfrancisco/activity
```

5. Verify that you specified the correct source stream by running the `maprcli stream upstream list` command.

```
maprcli stream upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli stream upstream list -path /mapr/newyork/activity
```

6. Load the replica with data from the source stream by using the [mapr copystream](#) on page 5542 utility.

7. Start replication with the command `maprcli stream replica resume`.

```
maprcli stream replica resume -path <path to the source stream>
-replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli stream replica resume -path mapr/sanfrancisco/activity
-replica /mapr/newyork/activity
```

Viewing the List of Stream Replicas

Explains how to view the list of replicas for a stream using the Control System and the CLI.

Viewing the List of Stream Replicas Using the Control System

- Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
The **Replicas** pane displays the the list of replicas for the selected stream and for each replica, the pane displays the following:

| Column Name | Column Description |
|----------------------------|---|
| Paused | Specifies whether replication is paused. |
| Destination Cluster & Type | The cluster on which the replica stream resides. |
| Destination Path | Specifies the name and path of the replica stream. |
| Status | The status of the replica. Replicas can be in one of the following states: <ul style="list-style-type: none"> In-Synch — indicates replica is in synch with the source stream and there are no more bytes to be sent from the source. Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. Broken — indicates there was an error during replication. If necessary, remove and re-create the replica. |
| Earliest | The date of the oldest message that has yet to be replicated. |
| Latest | The date of the newest message that has yet to be replicated. |
| Errors | Indicates if there were errors during replication. |
| Compression Type | The type of on-wire compression. |
| Synchronous | Specifies whether replication is synchronous. |
| Throttled | Specifies whether replication operations are throttled. |
| Encrypted | Specifies whether on-wire encryption is enabled. |

Selecting the checkbox beside a replica makes the Actions drop-down menu available. You can:

- [Add](#) a replica
- [Edit](#) a replica
- [Pause](#) a replica

- [Resume](#) replication
- [Un-register](#) replica(s)
- [Set](#) current stream as an upstream source

Viewing the List of Stream Replicas Using the CLI or REST API

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica pause](#) on page 2018.

Editing a Stream Replica

Explains how to edit a stream replica using the Control System and the CLI to modify the way in which messages are replicated from the source stream to the replica.

Editing a Stream Replica Using the Control System

To un-register one or more stream replicas from the Control System:

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Click  associated with the replica to edit in the **Replicas** pane. The **Edit Replica** page displays.
3. Make necessary changes to any of the following properties.

| | |
|--------------------------------|--|
| Path to Replica | Specify path and name of the replica stream. |
| Throttle | <p>Enable (Yes) or disable (No) throttling of replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled.</p> <p>Throttling has two effects, both of which allow HPE Ezmeral Data Fabric Event Streams to use more system resources to process new messages:</p> <ul style="list-style-type: none"> • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk. |
| Replicate Synchronously | Set up synchronous (Yes) or asynchronous (No) replication. |
| Encrypt On Wire | Enable (Yes) or disable (No) on-wire encryption. By default, this is disabled (No). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security. |
| Compress On Wire | Specify type of compression to use when replicating messages. |

4. Click **Save Changes** for the changes to take effect.

Editing a Stream Replica Using the CLI or REST API

The basic command to modify a replica is:

```
stream replica edit -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica edit](#) on page 2014.

Removing Stream Replicas

Explains how to unregister one or more replicas using the Control System and the CLI.

Removing Stream Replicas Using the Control System

To un-register one or more stream replicas from the Control System:

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Select the replicas to remove in the **Replicas** pane.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Remove Replica(s)** from the **Actions** drop-down menu.
The **Remove Replica(s)** confirmation window displays.
4. Verify the list of replicas to remove and click **Remove Replica**.
This action un-registers the stream as the replica of the source stream.

Removing a Stream Replica Using the CLI or REST API

The command to remove a replica is:

```
stream replica remove -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica remove](#) on page 2019.

Pausing Stream Replication

Explains how to pause replication from a source stream to a replica stream using the Control System and the CLI.

Pausing Stream Replication Using the Control System

To pause one or more replications:

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
2. Select the replicas to pause in the **Replicas** pane.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Pause Replication** from the **Actions** drop-down menu.
The **Pause Replication** confirmation window displays.
4. Verify the list of replicas to pause and click **Pause Replication**.
This action pauses replication from the source stream to the selected replica stream(s).

Pausing Stream Replication Using the CLI or REST API

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica pause](#) on page 2018.

Resuming Stream Replication

Explains how to resume replication from one stream to another stream using either the Control System or the CLI.

Resuming Stream Replication Using the Control System

To resume one or more replications:

1. Log in to the Control System and go to the **Replication** tab in the [stream information page](#).

2. Select the replicas (in **Paused** state) in the **Replicas** pane.
Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Resume Replication** from the **Actions** drop-down menu.
The **Resume Replication** confirmation window displays.
4. Verify the list of replicas to resume and click **Resume Replication**.
This action resumes replication from the source stream to the selected replica stream(s).

Resuming Stream Replication Using the CLI or REST API

The command to resume a replication is:

```
maprcli stream replica resume -path <stream path> -replica <remote stream path>
```

For complete reference information, see [stream replica resume](#) on page 2019.

Managing Upstream Sources for Stream Replicas

You can set up a stream to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Set up Stream as Upstream Source

Describes how to set up the current stream as the upstream source for a replica if the replica was not set up to automatically resync with the current stream.

Setting Up Current Stream as Upstream Source for a Replica Using the Control System

To set up a stream as the upstream source for a replica:

1. Go to the **Replication** tab in the [stream information page](#)
2. Select the checkbox beside the replica(s) that do not have the current stream configured as upstream source for automatic resync.
Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Stream as Upstream Source** from the **Actions** drop-down menu.
The **Set Current Stream as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
The current stream will automatically send updates to the replica(s).

Setting Up Stream as Upstream Source for a Replica Using the CLI or REST API

The basic command to set a table as the upstream source for a replica is:

```
maprcli stream upstream add -path <replica stream path> -upstream <source stream path>
```

See [stream upstream add](#) on page 2020 for complete reference information.

Adding Upstream Source for a Stream

Explains how to add an upstream source for a stream using either the Control Panel or the CLI.

You can register a stream as an upstream source for a stream using the Control System and the CLI. When you register a stream as an upstream source, the registered upstream source stream will send updates to the stream.

Adding Upstream Source for a Stream Using the Control System

To register a stream as an upstream source:

1. Log in to the Control System and go the [stream information page](#).
2. Click **Add Upstream Source** in the **Upstream Sources** pane.
The **Add Upstream Sources** window displays.
3. Specify the path and name of the source stream in the **Upstream Source** field.
4. Click **Add Upstream Source** to register the source stream as an upstream source for this stream.

Adding Upstream Source for a Stream Using the CLI or REST API

The command to add an upstream source is:

```
maprcli stream upstream add -path <stream path> -upstream <upstream stream path>
```

For complete reference information, see [stream upstream add](#) on page 2020.

Listing all Upstream Sources for a Stream

Describes how to list all the upstream sources for a stream using the Control System and the CLI.

Listing all Upstream Sources for a Stream Using the Control System

- Log in to the Control System and go to the **Replication** tab in the [stream information page](#).
The **Upstream Sources** pane displays the list of upstream sources for the selected stream and for each upstream source, the pane displays the following:

| Column Name | Column Description |
|-------------------------|--|
| IDX | The index number of the upstream stream. |
| Upstream Source Cluster | The name of the data-fabric cluster in which the upstream stream is located. |
| Upstream Source Path | The path and name of the upstream stream. |
| UUID | The upstream stream's universally unique identifier. |

You can [add](#) an upstream source and by selecting the checkbox beside a stream, you can decouple the selected upstream stream.

Listing all Upstream Sources for a Stream Using the CLI or REST API

The command to list all upstream sources for a stream is:

```
maprcli stream upstream list -path <stream path>
```

For complete reference information, see [stream upstream list](#) on page 2021.

Removing Upstream Sources for a Stream

Explains how to un-register a stream as an upstream source for a stream using either the Control System or the CLI.

When you remove a stream as an upstream source for a stream, the upstream source stream will stop sending updates to the stream.

Removing Upstream Sources for a Stream Using the Control System

1. Log in to the Control System and go the **Replication** tab in the [stream information page](#).

2. Select the upstream sources to remove in the **Upstream Sources** pane and click **Remove Upstream Source(s)**.

The **Remove Upstream Source(s)** confirmation window displays.

3. Verify the list and click **Remove Upstream Source**.

This action un-registers the selected stream(s) as upstream source(s) for this stream.

Removing Upstream Sources for a Stream Using the CLI or REST API

The command to decouple upstream sources is:

```
maprcli stream upstream remove -path <stream path> -upstream <upstream
stream path>
```

For complete reference information, see [stream upstream remove](#) on page 2022.

Preparing Clusters for Log Compaction

Describes how to prepare your environment so you can use log compaction.

Installing with the MapR Installer

When you use the MapR Installer to install HPE Ezmeral Data Fabric Event Streams, a local gateway is also locally installed so that log compaction can be implemented. To configure for log compaction, see [maprcli stream create](#) on page 1999 and [stream edit](#) on page 2006.

Installing without the MapR Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the MapR installer. Generally, you need to perform the following steps:

1. Install the MapR software. To install MapR without using the MapR installer, follow the steps outlined at [Installing without the Installer](#) on page 127.
2. Install the MapR gateway on your local cluster. Since gateways for log compaction are installed on the local cluster, no configuration is needed. See [Gateways and Stream Replication](#) on page 625 for general information about gateways.

Adding Gateways for Load Balancing

Since the number of gateways impacts the compaction process, you might want to increase the number of gateways on the cluster to improve the load distribution. To add gateways for log compaction, you install additional MapR gateways on your local cluster. See [Gateways and Stream Replication](#) on page 625 for general information about gateways.

Note: No configuration is required because the additional gateways are installed on the local cluster.

For More Information

See the following topics for more information:

- [maprcli stream create](#) on page 1999 and [stream edit](#) on page 2006
- [HPE Ezmeral Data Fabric Event Streams Java Applications](#) on page 3031, [HPE Ezmeral Data Fabric Event Streams Java API Library](#) on page 3033, and [Enabling Log Compaction](#) on page 3041

Mirroring Topics with Apache Kafka MirrorMaker

Use the Apache Kafka MirrorMaker utility either to mirror topics that are in Apache Kafka clusters to streams that are in HPE Ezmeral Data Fabric clusters or to Mirror topics that are in HPE Ezmeral Data Fabric clusters to Apache Kafka clusters.

Mirroring is a type of replication that takes place in this sequence of steps:

1. Messages that are published to topics in a source cluster are read by consumers that MirrorMaker manages.
2. These consumers send the messages to producers that MirrorMaker also manages.
3. The producers publish the messages in topics that are in the destination cluster.

Mirroring can continue indefinitely. Alternatively, you can mirror your data as a way of migrating it from Apache Kafka to HPE Ezmeral Data Fabric Event Streams. If you use it for this purpose, you can stop mirroring after migrating your producers and consumers to use HPE Ezmeral Data Fabric Event Streams, as described in [Migrating Apache Kafka 0.9.0 Applications to HPE Ezmeral Data Fabric Event Streams](#).

 **Attention:** MirrorMaker does not provide the same reliability guarantees as the replication features in HPE Ezmeral Data Fabric Event Streams. In particular, MirrorMaker does not replicate cursors or message positions, which makes disaster recovery much more difficult than with replication of HPE Ezmeral Data Fabric Event Streams. Therefore, HPE Ezmeral Data Fabric recommends MirrorMaker for use only for mirroring between HPE Ezmeral Data Fabric Event Streams and Apache Kafka, not for replication of HPE Ezmeral Data Fabric Event Streams.

Prerequisites

- Ensure that the destination stream in the HPE Ezmeral Data Fabric cluster exists. To create a stream, run the command `maprcli stream create`.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the stream.

Command Syntax and Descriptions of Parameters

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to
mirror>
```

| Parameter | Description |
|------------------------------|---|
| <code>consumer.config</code> | The path and name of the file that lists the consumer properties. See the Consumer Properties and Descriptions on page 1259 section for detailed information. |
| <code>num.streams</code> | Use the <code>--num.streams</code> option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption). |

| Parameter | Description |
|------------------------------|---|
| <code>producer.config</code> | The path and name of the file that lists the producer properties. See the Producer Properties and Descriptions on page 1259 section for detailed information. |
| <code>whitelist</code> | A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol (' '). This parameter is required. |

Consumer Properties and Descriptions

```
group.id=<ID>
bootstrap.servers=<IP address>:<port>
shallow.iterator.enable=false
```

| Property | Description |
|--------------------------------------|---|
| <code>group.id</code> | A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using <code>subscribe(topic)</code> or the Kafka-based offset management strategy. If <code>group.id</code> is not set and the value of the <code>num.streams</code> option is <code>> 1</code> , messages might go multiple times to a stream. |
| <code>bootstrap.servers</code> | A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1,host2:port2,...</code> . Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down). |
| <code>shallow.iterator.enable</code> | Set this value to <code>false</code> . |

Producer Properties and Descriptions

```
key.serializer=<serializer class>
value.serializer=<serializer class>
streams.producer.default.stream=<Path and name of the stream to copy the topics to>
auto.create.topics.enable=true
```

| Property | Description |
|-------------------------------|--|
| <code>key.serializer</code> | The name of the appropriate serialization class in the <code>org.apache.kafka.common.serialization</code> package or a class that implements the <code>Serializer</code> interface for serializing keys. |
| <code>value.serializer</code> | The class that implements the <code>Serializer</code> interface for serializing values. |

| Property | Description |
|--|--|
| <code>streams.producer.default.stream</code> | Specifies the path and name of stream that the topics will be copied to. |
| <code>auto.create.topics.enable</code> | Enables auto-creation of topics within the stream specified with the <code>streams.producer.default.stream</code> parameter. |

Mirroring Topics from an Apache Kafka Cluster to the HPE Cluster

You can use MirrorMaker to mirror data continuously from Apache Kafka clusters to streams in HPE Ezmeral Data Fabric Event Streams clusters.

- Because this procedure requires that MirrorMaker be run from the HPE Ezmeral Data Fabric cluster, ensure that the `mapr-kafka` package is installed on the node that you choose to run MirrorMaker from.
- Configure the node as a `mapr` client.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the destination stream.

Alternatively, you can stop mirroring after you migrate the consumers and producers for your applications from your Apache Kafka cluster to your data-fabric cluster where the stream is located. See in [Migrating Apache Kafka 0.9.0 Applications to HPE Ezmeral Data Fabric Event Streams](#) for details. After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a Kafka cluster and a number of producers to write the messages from those topics into topics in HPE Ezmeral Data Fabric Event Streams.

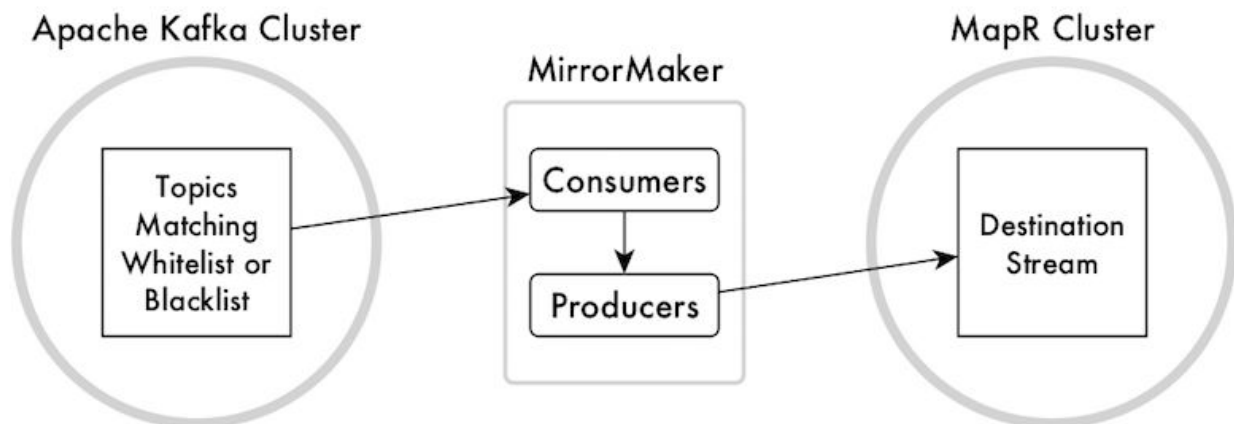

Figure 21: Mirroring from Apache Kafka to HPE Ezmeral Data Fabric Event Streams

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the Apache Kafka cluster. You also create a file that contains the required configuration parameters for the producers that publish to the stream in the HPE Ezmeral Data Fabric cluster. You point to these files in the MirrorMaker command.

To specify which topics you want to mirror, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want mirrored.

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.
The descriptions of these properties, except for the last, are taken from the documentation for Apache Kafka. The last property is not documented.

| Property | Description |
|--------------------------------|---|
| <code>group.id</code> | A unique string that identifies the consumer group the consumers started by MirrorMaker belong to. |
| <code>bootstrap.servers</code> | A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1,host2:port2,...</code> . Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down). |

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

| Property | Description |
|--|---|
| <code>streams.producer.default.stream</code> | Specifies the path and name of the stream in the HPE Ezmeral Data Fabric cluster that the topics will be mirrored to. |
| <code>auto.create.topics.enable</code> | Set the value to <code>true</code> . The producers will therefore be able to create topics in the destination stream automatically. |

3. Run MirrorMaker with this command to start mirroring topics from Apache Kafka to HPE Ezmeral Data Fabric Event Streams:

Syntax

```
/opt/mapr/kafka/kafka-0.9.0/bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to mirror>
```

| Parameter | Description |
|------------------------------|---|
| <code>consumer.config</code> | The path and name of the file that lists the consumer properties and their values. |
| <code>num.streams</code> | Use this option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption). |
| <code>producer.config</code> | The path and name of the file that lists the producer properties and their values. |

| Parameter | Description |
|-----------|--|
| whitelist | A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol (' '). This parameter is required. |

Example

In this example, the file that lists the properties and values for the consumers that will read messages from the topics in Apache Kafka is named `consumers.props`. It contains this list:

```
group.id=cgl
bootstrap.servers=10.10.100.87:9093
shallow.iterator.enable=false
```

The file that lists the properties and values for the producers that will publish messages to topics in HPE Ezmeral Data Fabric Event Streams is named `producers.props`. It contains this list:

```
streams.producer.default.stream=/newStream
auto.create.topics.enable=true
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the `whitelist` parameter.

Here is the command:

```
bin/kafka-mirror-maker.sh --consumer.config consumers.props
--num.streams 2 --producer.config producers.props --whitelist="na_west.*"
```

Mirroring Topics from the HPE Cluster to an Apache Kafka Cluster

You can use MirrorMaker to mirror data continuously from streams in HPE Ezmeral Data Fabric clusters to Apache Kafka clusters.

- This procedure requires MirrorMaker to run from the HPE Ezmeral Data Fabric cluster. Verify that the `mapr-kafka` package is installed on the node that you choose to run MirrorMaker on.
- Configure the node as a `mapr` client.
- Ensure that the ID of the user who runs MirrorMaker has the `consumeperm` permission on the stream.

After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a stream in a HPE Ezmeral Data Fabric cluster and a number of producers to write the messages from those topics into topics in an Apache Kafka cluster.

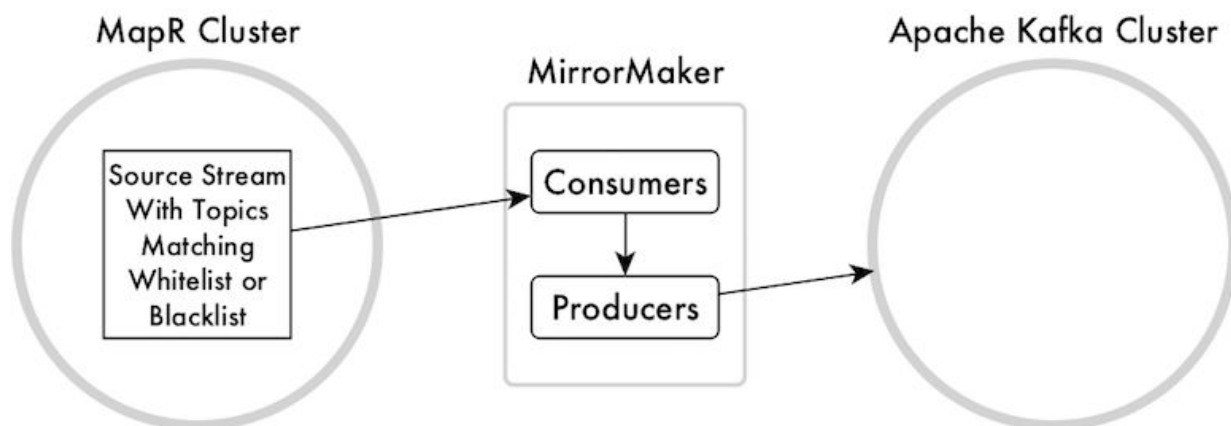

Figure 22: Mirroring from HPE Ezmeral Data Fabric Event Streams to Apache Kafka

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the stream in the HPE Ezmeral Data Fabric cluster. You also create a file that contains the required configuration parameters for the producers that publish to the Apache Kafka cluster. You point to these files in the MirrorMaker command.

To specify which topics you want to mirror, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want mirrored.

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

| Property | Description |
|--|---|
| <code>streams.record.strip.streampath</code> | Set the value of this property to true. In messages that are written to streams, the names of topics include the paths and names of the streams in which those topics are located. Apache Kafka needs only the names of the topics. This parameter removes the path and name of the stream that the topics will be mirrored from. |
| <code>streams.consumer.default.stream</code> | Specifies the path and name of the stream that the topics will be mirrored from. |
| <code>group.id</code> | A unique string that identifies the consumer group the consumers started by MirrorMaker belong to. |

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

| Property | Description |
|--------------------------------|--|
| <code>bootstrap.servers</code> | A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The producers will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1,host2:port2,...</code> . Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down). |

| Property | Description |
|--------------------------------|--|
| <code>producer.type</code> | Specifies whether the messages are published asynchronously in batches or as data is received by producers. The values are <code>async</code> and <code>sync</code> . |
| <code>compression.codec</code> | Specifies the compression codec for all messages that are generated by producers. The possible values are <code>none</code> , <code>gzip</code> , <code>snappy</code> , and <code>lz4</code> . |

- Run MirrorMaker with this command to start mirroring topics from HPE Ezmeral Data Fabric Event Streams to Apache Kafka:

Syntax

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to mirror>
```

| Parameter | Description |
|------------------------------|--|
| <code>consumer.config</code> | The path and name of the file that lists the consumer properties and their values. |
| <code>new.consumer</code> | Specifies to use consumers that use the Apache Kafka 0.90 API library. |
| <code>num.streams</code> | Use this parameter to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption). |
| <code>producer.config</code> | The path and name of the file that lists the producer properties and their values. |
| <code>whitelist</code> | A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol (' '). This parameter is required. |

Example

In this example, the file that lists the properties and values for the consumer that will read messages from the topics in HPE Ezmeral Data Fabric Event Streams is named `consumers.props`. It contains this list:

```
streams.record.strip.streampath=true
streams.consumer.default.stream=/myStream
group.id=cgl
```

The file that lists the properties and values for the producers that will publish messages to topics in Apache Kafka is named `producers.props`. It contains this list:

```
bootstrap.servers =10.10.83.93:9092
```

```
producer.type=sync
compression.codec=none
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the whitelist parameter.

```
bin/kafka-mirror-maker.sh --new.consumer
--consumer.config consumers.props --num.streams 2 --producer.config
producers.props
--whitelist="na_west.*"
```

Mirroring Topics with HPE Ezmeral Data Fabric MirrorMaker 2

MirrorMaker 2.0 is a multi-cluster, cross-data-center replication engine based on the Kafka Connect framework. MirrorMaker 2 is available starting in EEP 8.0.0.

Mirror Maker 2.0 replicates data in topics from one Kafka cluster to another. HPE Ezmeral Data Fabric Mirror Maker 2 can mirror data:

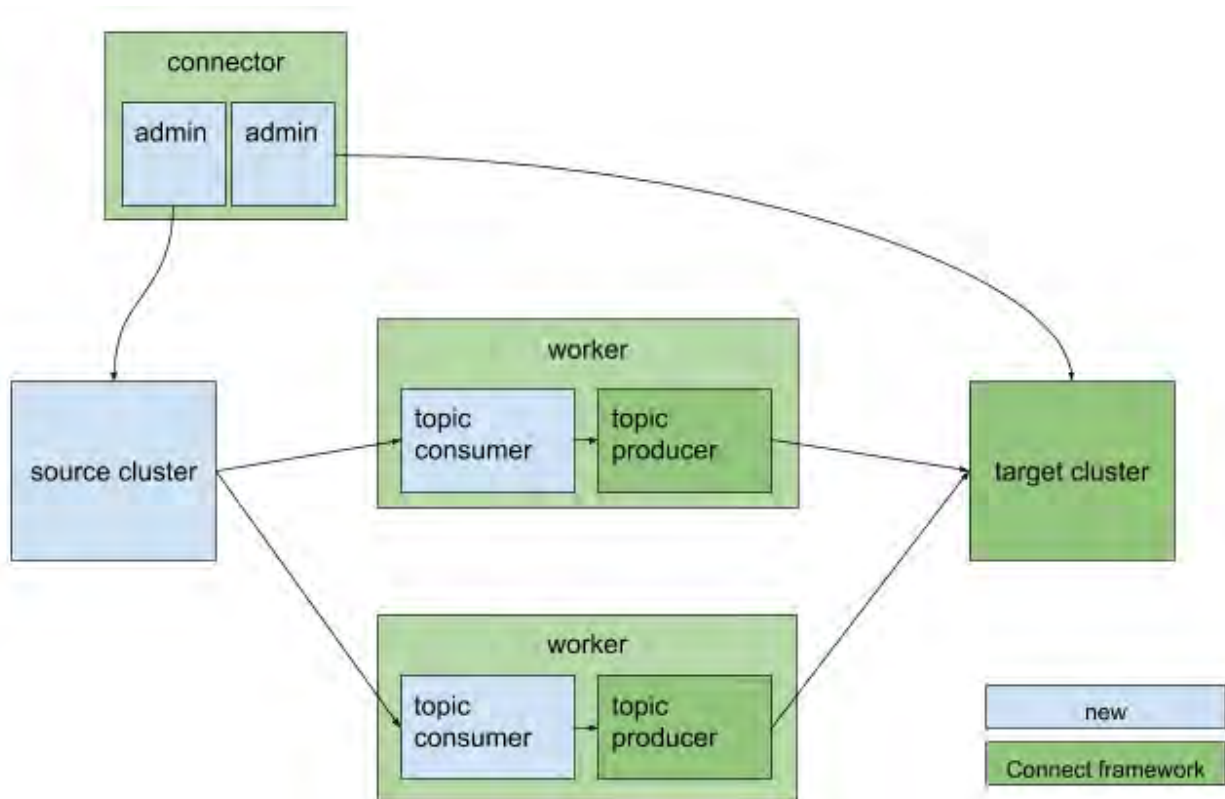

- from Apache Kafka clusters to Apache Kafka clusters.
- from Apache Kafka clusters to streams in HPE Ezmeral Data Fabric clusters.
- from streams in HPE Ezmeral Data Fabric clusters to Apache Kafka clusters.
- between streams in HPE Ezmeral Data Fabric clusters.

MirrorMaker 2 Architecture

MirrorMaker 2 uses the Kafka Connect framework to simplify configuration and scaling. Both source and sink connectors are provided to enable complex flows between multiple Kafka clusters and across data centers via existing Kafka Connect clusters. The main MirrorMaker 2 components are actually Kafka connectors, as described in the following list:

- The MirrorSourceConnector replicates records from local to remote clusters and enables offset synchronization.
- The MirrorCheckpointConnector manages consumer offset synchronization, emits checkpoints, and enables failover.
- The MirrorHeartbeatConnector provides heartbeats, monitoring of replication flows, and client discovery of replication topologies, which can be more complex than for the original MirrorMaker.

As shown in the following MirrorMaker 2 architecture diagram, the source and sink connectors contain a pair of producers and consumers to replicate records, and a pair of AdminClients to propagate configuration changes:

Prerequisites

When using HPE Ezmeral Data Fabric streams as the source or target:

- Ensure that the destination stream in the HPE Ezmeral Data Fabric cluster exists. To create a stream, run the `maprcli stream create` command.
- Ensure that the ID of the user that runs MirrorMaker 2 has the `produceperm` and `topicperm` permissions on the stream.

When using an Apache Kafka cluster as the source or target:

- Verify that a connection to the Apache Kafka cluster exists.

Connector Configuration Properties for MirrorMaker 2

Use the `.stream` property instead of the `.bootstrap.servers` property when an HPE Ezmeral Data Fabric stream is the source or the target.

The following table lists the properties common to the SourceConnectors and SinkConnector:

| Property | Default | Description |
|------------------|--|--|
| name | required | name of the connector, e.g. "us-west->us-east" |
| topics | empty string | regex of topics to replicate, e.g. "topic1 topic2 topic3". Comma-separated lists are also supported. |
| topics.blacklist | ".*\.\internal, .*\.\replica, __consumer_offsets" or similar | topics to exclude from replication |
| groups | empty string | regex of groups to replicate, e.g. ".*" |

| Property | Default | Description |
|-----------------------------------|--|--|
| groups.blacklist | empty string | groups to exclude from replication |
| source.cluster.alias | required | name of the cluster being replicated |
| target.cluster.alias | required | name of the downstream Kafka cluster |
| source.cluster.stream | required or can be replaced by bootstrap.servers | stream from upstream HPE Ezmeral Data Fabric cluster to replicate |
| target.cluster.stream | required or can be replaced by bootstrap.servers | Stream from downstream HPE Ezmeral Data Fabric cluster |
| source.cluster.bootstrap.servers | required or can be replaced by stream | upstream cluster to replicate |
| target.cluster.bootstrap.servers | required or can be replaced by stream | downstream cluster |
| sync.topic.configs.enabled | true | whether or not to monitor source cluster for configuration changes |
| sync.topic.acls.enabled | true | whether to monitor source cluster ACLs for changes |
| emit.heartbeats.enabled | true | connector should periodically emit heartbeats |
| emit.heartbeats.interval.seconds | 5 (seconds) | frequency of heartbeats |
| emit.checkpoints.enabled | true | connector should periodically emit consumer offset information |
| emit.checkpoints.interval.seconds | 5 (seconds) | frequency of checkpoints |
| refresh.topics.enabled | true | connector should periodically check for new topics |
| refresh.topics.interval.seconds | 5 (seconds) | frequency to check source cluster for new topics |
| refresh.groups.enabled | true | connector should periodically check for new consumer groups |
| refresh.groups.interval.seconds | 5 (seconds) | frequency to check source cluster for new consumer groups |
| readahead.queue.capacity | 500 (records) | number of records to let consumer get ahead of producer |
| replication.policy.class | org.apache.kafka.connect.mirror.DefaultReplicationPolicy | use LegacyReplicationPolicy to mimic legacy MirrorMaker |
| heartbeats.topic.retention.ms | 1 day | used when creating heartbeat topics for the first time |
| checkpoints.topic.retention.ms | 1 day | used when creating checkpoint topics for the first time |
| offset.syncs.topic.retention.ms | max long | used when creating offset sync topic for the first time |
| replication.factor | 2 | used when creating remote topics |

The following table lists internal client properties that you can override:

| Property | Description |
|---------------------------|---|
| source.cluster.consumer.* | overrides for the source-cluster consumer |

| Property | Description |
|---------------------------|---|
| source.cluster.producer.* | overrides for the source-cluster producer |
| source.cluster.admin.* | overrides for the source-cluster admin |
| target.cluster.consumer.* | overrides for the target-cluster consumer |
| target.cluster.producer.* | overrides for the target-cluster producer |
| target.cluster.admin.* | overrides for the target-cluster admin |

Example Configuration File

The following `mm2.properties` configuration file example shows the configuration for an HPE Ezmeral Data Fabric stream to Apache Kafka cluster workflow.

```
# Datacenters.
clusters = source, target
source.stream = /str
target.bootstrap.servers = 192.168.33.12:9092

# Source and target cluster configurations.
source.config.storage.replication.factor = 1
target.config.storage.replication.factor = 1

source.offset.storage.replication.factor = 1
target.offset.storage.replication.factor = 1

source.status.storage.replication.factor = 1
target.status.storage.replication.factor = 1

source->target.enabled = true
target->source.enabled = false

# Mirror maker configurations.
offset-syncs.topic.replication.factor = 1
heartbeats.topic.replication.factor = 1
checkpoints.topic.replication.factor = 1

topics = .*
groups = .*

tasks.max = 1
replication.factor = 1
refresh.topics.enabled = true
sync.topic.configs.enabled = true
refresh.topics.interval.seconds = 30

topics.blacklist = .*[\-\.]internal, .*\.replica, __consumer_offsets
groups.blacklist = console-consumer-.*, connect-.*, __.*

# Enable heartbeats and checkpoints.
source->target.emit.heartbeats.enabled = true
source->target.emit.checkpoints.enabled = true
```

Command Syntax

To start the MirrorMaker 2 connectors, run the following command:

```
/opt/mapr/kafka/kafka-<version>/bin/connect-mirror-maker.sh mm2.properties
```

Logs are written to the console instead of log files. You can change where logs are written by editing the `/opt/mapr/kafka/kafka-<version>/config/connect-mirror-maker-log4j.properties` file.

Limitations

There are several limitations that differentiate HPE Ezmeral Data Fabric MirrorMaker 2 from Apache Kafka MirrorMaker 2:

- MirrorCheckpointConnector is not supported by HPE Ezmeral Data Fabric MirrorMaker 2; therefore, mirroring is based only on MirrorSourceConnector and MirrorHeartbeatConnector.
- Access Control Lists (ACLs) synchronization is not supported because HPE Ezmeral Data Fabric streams are not supported ACL.
- Broker configurations that include any of the `log.*` properties are not synchronized. For example, if the broker configuration contains the `log.dir` property, the broker configuration is not synchronized across all brokers in the cluster.

Administering Data Fabric Gateways

A HPE Ezmeral Data Fabric gateway mediates one-way communication between a source HPE Ezmeral Data Fabric cluster and a destination cluster. You can replicate HPE Ezmeral Data Fabric Database tables (binary and JSON) and HPE Ezmeral Data Fabric Event Streams streams. HPE Ezmeral Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

The initial task for setting up your gateways is to decide where you want to put them:

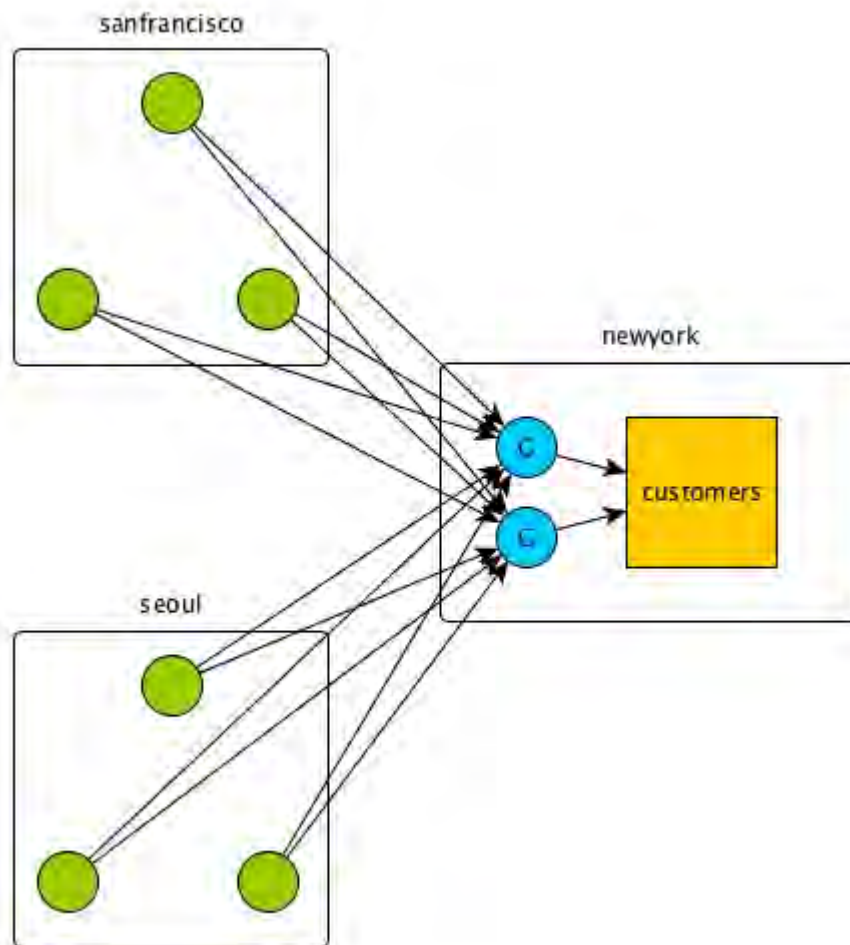

- If you are going to replicate HPE Ezmeral Data Fabric Database tables, see [Gateways for Replicating HPE Ezmeral Data Fabric Database Tables](#) on page 584.
- If you are going to replicate streams, see [Gateways and Stream Replication](#) on page 625.
- If your HPE Ezmeral Data Fabric Database JSON tables have secondary indexes, see [Preparing Clusters for Querying using Secondary Indexes on JSON Tables](#) on page 1204.
- If you are using CDC, see [Getting Started with CDC](#) on page 563.

Note: Gateways perform negligible disk I/O and use negligible amounts of memory, though gateways require significant CPU usage.

However, the resource that gateways use the most is network bytes. For example, if the peak network throughput for puts is about 40 MB per second per node, in a 10-node source cluster the peak network throughput will be about 400 MB per second. So, the aggregate network throughput required on the nodes running gateways will be 400 MB per second for both incoming and outgoing traffic. The aggregate network throughput for a 50 node cluster would be 2GB per second.

For another example, in the following diagram there are two source clusters of three nodes each and the clusters are replicating to one destination cluster. The peak traffic on the gateways will be 40MB per second per cluster node, which means that these gateways together will experience a peak network load of 240MB per second.

Although the load is balanced across the two gateways, so that each gateway experiences a peak network load of 120MB per second, each gateway should be able to tolerate the full aggregate network load in case the other gateway fails unexpectedly.

Configuring Gateways for Table and Stream Replication

Configuring gateways involves installing the `mapr-gateway` package on nodes on a data-fabric destination cluster and then configuring the data-fabric source cluster to communicate with the destination cluster. The data-fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

How Many Gateways to Configure?

Although it is possible to use a single gateway, the recommended practice is to configure at least two (2) gateways, so that replication can continue if one gateway fails. Data Fabric source clusters distribute requests among the gateways in a round-robin fashion. See [Gateways for Replicating HPE Ezmeral Data Fabric Database Tables](#) on page 584, [Table Replication](#) on page 573, and [Preparing Clusters for Stream Replication](#) on page 1246 for more information about replication.

For more information about setting up cross-cluster security, including cross-cluster security for table and stream replication, see [Setting Up Cross-Cluster Security](#) on page 1657.

Default Gateway Configuration for Replication

If you do not perform any of these options, HPE Ezmeral Data Fabric Database uses the configuration from the `mapr-clusters.conf` file. It uses the cluster name specified in that file as the destination cluster, and the CLDB node addresses as the gateway nodes. You must have gateways running on these CLDB nodes.

Configuration Procedure

Tip: To list the current gateways, see [cluster gateway get](#) on page 1745.

1. On the destination cluster, install the `mapr-gateway` package on each node where you want to run a gateway. See [Installing data-fabric Software](#).

Note: On the gateway nodes in the destination cluster, when you run (or re-run) the `configure.sh` script (in addition to your regular parameters) be sure to specify the `-N` parameter with the name of the cluster to which the gateway belongs. For more information about `configure.sh` usage, options, and examples, see [configure.sh](#) on page 2331.

2. To change the port that a gateway uses (by default, gateways use port 7660):
 - a. On the node where the gateway is running, edit the `/opt/mapr/conf/gateway.conf` file, ensure that the line `#gateway.port=7660` is not commented, and change the port number. For more information about `gateway.conf` configuration properties, see [gateway.conf](#) on page 2482.
 - b. After saving the file, restart the gateway by running this command: `maprcli node services -name gateway -action restart`
3. On the source cluster, specify the destination cluster's name and gateway nodes by using one of the following methods:
 - Run the `maprcli cluster gateway set` command:

```
maprcli cluster gateway set -dstcluster <cluster name> -gateways
"<space-delimited list of gateways>"
```

The following sample command sets two gateway nodes on the destination cluster `my.cluster.com`:

```
maprcli cluster gateway set -dstcluster my.cluster.com -gateways
"node1.com node2.com"
```

- Add a DNS record to your DNS server's zone file for your domain.

See [Managing Gateways](#) on page 1273 for more information about using these methods.

[Managing Gateways](#) on page 1273

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

Managing Gateways

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

You can run the following commands to perform operations on your gateways.

Note: If you have configured an intra-cluster gateway, the source and destination clusters are the same.

- To see a list of the gateways for a particular destination cluster:

Run the `maprcli cluster gateway get` command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To see a list of the gateways for all of the destination clusters to which the source cluster is replicating:

Run the `maprcli cluster gateway list` command on the source cluster. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To remove the list of gateways that you specified for a destination cluster by using the `maprcli cluster gateway set` command:

Run the `maprcli cluster gateway delete` command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To find out how HPE Ezmeral Data Fabric Database or HPE Ezmeral Data Fabric Event Streams is finding gateways (for example, from DNS records, lists created by the `maprcli cluster gateway set` command or the `mapr-clusters.conf` file):

Run the command `maprcli cluster gateway resolve` on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To stop and start one or more gateways:

Run the `maprcli node services -name gateway -action stop|start` on the clusters where the gateways are running.

```
/opt/mapr/bin/maprcli node services -name gateway -action stop -nodes
<hostnames or IP addresses separated by spaces>
```

```
/opt/mapr/bin/maprcli node services -name gateway -action start -nodes
<hostnames or IP addresses separated by spaces>
```

- To check the status of a gateway service on a particular node:
Run the command `maprcli service list` on the clusters where the gateways are running.

Running the `maprcli cluster gateway set` command

The syntax of the `maprcli cluster gateway set` command is:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster <cluster name> -gateways "<space-delimited list of gateways>"
```

To generate a list of the existing gateways in a data-fabric cluster, use the `maprcli cluster gateway list` command. You can then copy this list and paste it into the `maprcli cluster gateway set` command. Alternatively, to generate a list of the gateways on a local cluster, run the `maprcli cluster gateway local -format text` command. If you want to run the command from a different cluster and point to the cluster where the gateways are located, use the `-cluster` parameter to provide the name of that cluster.

For example, suppose that you are configuring table replication from the cluster `sanfrancisco` to the cluster `newyork`, and want to use two gateways. The nodes on which these gateways are located are named `gw1` and `gw2`.

The command that you run will be as follows:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster newyork -gateways "gw1.bigcompany.com gw2.bigcompany.com"
```

Adding a DNS record to your DNS server's zone file for your domain

In your DNS server's zone file for your domain, you can add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you can copy into a DNS configuration file, run a `maprcli` command to generate the record, or create a record manually.

For details, see [Specifying the Location of Gateways](#) on page 859.

If a Gateway Fails

If a gateway fails, the warden service tries three (3) times to restart it automatically. After an interval, the warden tries again three times to start the gateway. You can configure the interval by using the parameter `services.retryinterval.time.sec` in the `warden.conf` file. The default is 30 minutes.

During the time that the gateway is down, source clusters will resend updates to other gateways. Source clusters will also ping the failed gateway with an exponentially increasing backoff.

If all of the gateways fail in a destination cluster, source clusters will ping the failed gateways in the same manner. Updates pending replication are stored on disk in an internal data structure until at least one gateway in the destination cluster comes back online. Therefore, you will see additional storage costs during a gateway outage. The Gateway Service Down alarm in the Control System will notify you when none of the gateways in a destination cluster can be reached.

If the additional storage becomes too costly, you can follow either of these procedures:

If you are replicating to a HPE Ezmeral Data Fabric Database binary table:

1. Run the `maprcli table replica remove` command to stop replicating to the replica. This action deletes the pending updates.
2. Resolve the gateway outage.

3. Recreate the replica and start replicating to it by running the `maprcli table replica autoseup` command.

If you are replicating to a HPE Ezmeral Data Fabric Event Streams stream:

1. Run the `maprcli stream replica remove` command to stop replicating to the replica stream. This action cancels the pending updates to the replica stream.
2. Resolve the gateway outage.
3. Run the command `maprcli stream replica autoseup` to recreate the replica stream and start replicating to it.

Troubleshooting

You can refer to two log files for each gateway when troubleshooting. Both these files are in the `/opt/mapr/logs` directory on the node where the gateway is running:

- `gateway.log`
- `gatewayinit.log`

HPE Ezmeral Data Fabric Database Lookup Order

HPE Ezmeral Data Fabric Database uses the following order to locate the gateways that are running in a destination cluster.

- Look up the destination cluster's name and gateway addresses in the information specified by the `maprcli cluster gateway set` command. If a list of gateways, then a DNS lookup is performed.
- Perform a DNS lookup of the destination cluster and the addresses of the gateways. If no DNS record for the destination cluster is found, then the lookup goes to the `mapr-clusters.conf` file.
- Look up the destination cluster's name and the CLDB node addresses in the `mapr-clusters.conf` file under the assumption that gateways are running on all of the CLDB nodes and only on those nodes.

Administering Services

The various topics in this section describe how to manage (start, stop, restart, etc.) the various services installed on the MapR cluster using the MapR Control System (click **Services**) and the CLI.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, HPE Ezmeral Data Fabric recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services

Explains how to view the list of services using either the Control System or the CLI.

Viewing the Services Installed on the Cluster Using the Control System

- Log in to the Control System and click **Services**.

The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

| Column Name | Column Description |
|---------------|--|
| Service | The name of the installed service. |
| Running Nodes | The number of nodes on which the associated service is running. The service can be stopped (■) or restarted (↺). Click the number in this column to view the nodes on which the service is running. |
| Standby Nodes | The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service is in standby state. |

| Column Name | Column Description |
|---------------|---|
| Failed Nodes | The number of nodes on which the service has failed. The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service has failed. |
| Stopped Nodes | The number of nodes on which the associated service is stopped (and not running). The service can be started (▶) or restarted (↺). Click the number in this column to view the nodes on which the service has been stopped. |
| Log Viewer | (Displays only if Kibana is installed on a node) The link (🔗) to the Kibana UI. |

You can filter the list of services displayed by:

- **EEP**, which includes services such as Hive, Drill, etc.
- **Core**, which includes services such as CLDB, Hoststats, File server, etc.
- **Monitoring**, which includes services such as Grafana, Kibana, etc.

Viewing the Services Running on a Node Using the Control System

1. Log in to the Control System and click **Nodes**.

Note: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:

- Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.
- Go to the **Summary** tab in the [node information page](#) to view detailed information on the services installed on a node.

In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

| Column Name | Column Description |
|------------------------|--|
| Service | The name of the service. |
| State | The current state of the service. Value can be: <ul style="list-style-type: none"> • Running • Stopped |
| Memory Allocated | The amount of system memory allocated to the service. |
| System Memory Utilized | The percentage of memory utilized by the service. |
| CPU Usage | The CPU used by the service. |
| Log Path | The path to the service log file. |
| Log Viewer | The link to the Kibana UI (only if Kibana is installed). |

You can select the checkbox beside one or more services to take the following actions:

- [Start Services](#)
- [Stop Services](#)

- [Restart Services](#)

Note: If Kibana is installed, you can click  to view the logs. See [Kibana User Guide](#) for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see [service list](#) on page 1987.

Enabling and Disabling a Service Using the CLI and REST API

Describes how to enable or disable a service using either the REST API or the CLI.

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

Disabling a Service Using the CLI or REST API

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action disable
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
&action=disable' --user mapr:mapr
```

Note: When you disable a service, the service is stopped and the service is not automatically started/restarted when Warden is started/restarted.

See [node services](#) on page 1939 for more information.

Enabling a Service Using the CLI or REST API

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action enable
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
&action=enable' --user mapr:mapr
```

Note: When you enable a service, the service is started/restarted when Warden is started/restarted.

See [node services](#) on page 1939 for more information.

Related tasks

[Restarting the Services](#) on page 908

Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services

Explains how to start services using either the Control System, the CLI or the REST API.

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 905 for more information.

Starting the Services Running on the Nodes Using the Control System

To start the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

To start one or more services running on a node:

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.

The **Start Services** confirmation dialog displays.

4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click  for the service to start. The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see [node services](#) on page 1939.

Stopping the Services

Describes how to stop services using either the Control System, the CLI or the REST API.

Stopping the Services Running on the Nodes Using the Control System

To stop the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

Note: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

To stop one or more services running on a node:

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop.
The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see [node services](#) on page 1939.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

When a HPE Ezmeral Data Fabric system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

Note: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that HPE Ezmeral Data Fabric currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See [Enabling and Disabling a Service Using the CLI and REST API](#) on page 1278 for more information.

Restarting the Services Running on the Nodes Using the Control System

To restart the services running on the nodes:

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

Note: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System

1. Go to the **Summary** tab in the [node information page](#).
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click  associated with the service to restart.
The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see [node services](#) on page 1939.

Related tasks

[Enabling and Disabling a Service Using the CLI and REST API](#) on page 1278
Describes how to enable or disable a service using either the REST API or the CLI.

Viewing a Service Information Page

Describes how to view the information pages for the installed services using the Control System.

1. Log in to the Control System and click **Services**.

Note: The **Services** page is not available on the Kubernetes version of the Control System.

The **Services** pane displays the list of services that are installed on the cluster.

2. Click the name of the service from the list.
The information page for the service displays.

Changing the User for Data Fabric Services from the Command-Line

Explains how use the CLI to change the user that data-fabric services run as.

All services should run with the same uid/gid on all nodes in the cluster.

Running Data Fabric Services as the Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`

4. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

5. Start Warden.

```
service mapr-warden start
```

Running Data Fabric Services as a Non-Root User

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.

4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.

5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.

6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing `NODE_ALARM_MAPRUSER_MISMATCH` alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Viewing the Service Log

Explains how to view service logs using Kibana.

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

1. Log in to the Control System and do one of the following:
 - Click **Services** to display the list of services installed on the cluster.
 - Go to the **Summary** tab in the [service information page](#) for the service.
2. Click  in the **Log Viewer** column to view the log for the associated service in the Kibana UI. See [Kibana User Guide](#) for more information.

Setting Up Central Configuration from the Command-Line

Describes the concept of a central location where customized data-fabric configuration files for data-fabric services are stored.

Data Fabric provides a central location where you can place customized configuration files for all the services running on the data-fabric cluster. As a result, you do not have to edit the configuration files on each node individually.

Default configuration files for each service are stored locally under `/opt/mapr/`. You can edit these files to create customized versions of the configuration files. To push these changes to other nodes in the cluster, copy the customized files to the `mapr.configuration` volume in the data-fabric filesystem. When the `pullcentralconfig` script runs, it overwrites the local configuration file in `/opt/mapr` with the customized files on all nodes on which the change applies.

The `mapr.configuration` volume is mounted at `maprfs://var/mapr/configuration`. The `mapr.configuration` volume mount location is not configurable and is only used for central configuration.

Using Central Configuration

Lists the steps to configure and use central configuration of files.

HPE Ezmeral Data Fabric provides a central location where you can place customized configuration files for all the services running on the HPE Ezmeral Data Fabric cluster. As a result, you do not have to edit the configuration files on each node individually.

Default configuration files for each service are stored locally under `/opt/mapr/`. You can edit these files to create customized versions of the configuration files. To push these changes to other nodes in the cluster, copy the customized files to the `mapr.configuration` volume in the filesystem. When the `pullcentralconfig` script runs, it overwrites the local configuration file in `/opt/mapr` with the customized files on all nodes to which the change applies.

The `mapr.configuration` volume is mounted at `maprfs://var/mapr/configuration`. The `mapr.configuration` volume mount location is not configurable and is only used for central configuration.

Complete the following steps to use the Central Configuration (`pullcentralconfig` script) to push a customized configuration file from the `mapr.configuration` volume in filesystem to nodes in the cluster.

1. Customize a configuration file on any node in the cluster. See [Listing the Configuration Files for Each Service](#) to determine which files you can customize.

2. Create the directory structure for the configuration file that is relative to \$MAPR_HOME based on the number of nodes to which the file applies:

| Scope | HPE Ezmeral Data Fabric File System Location |
|--|--|
| Use this file on all nodes that use the configuration file unless a node-specific file exists in the <code>mapr.configuration</code> volume. | <code>/var/mapr/configuration/default/<directory path to the configuration file></code> |
| Use this file for a specific node. | <code>/var/mapr/configuration/nodes/<hostname>/<directory path to the configuration file></code> |

3. Copy the customized file to the `mapr.configuration` volume in the directory that you created. For example, to create a directory to update the web server configuration file, which is in `/opt/mapr/conf`, you would create directory path `/var/mapr/configuration/default/conf` and then copy the updated file to this directory.
4. Run the `pullcentralconfig` script or wait until the script acknowledges the update. For more information, see [About the pullcentralconfig Script](#).
5. Restart the services associated with the updated configuration files to ensure that the latest version is used for each service.

Scenario

Lists an example scenario to demonstrate customized configuration for a 8-node cluster.

In the following example, you have a cluster with eight nodes, and five of them (`host1`, `host2`, `host3`, `host4`, and `host5`) are running the NodeManager service.

You want to create one customized configuration file (`mapred-site.xml`) that applies to `host2` through `host5` and assign a different customized configuration file to `host1`.

| Hostname | Customized Configuration Files |
|--------------------|---|
| <code>host1</code> | <code>/var/mapr/configuration/nodes/host1/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml</code> |
| <code>host2</code> | <code>/var/mapr/configuration/default/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml</code> |
| <code>host3</code> | <code>/var/mapr/configuration/default/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml</code> |
| <code>host4</code> | <code>/var/mapr/configuration/default/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml</code> |
| <code>host5</code> | <code>/var/mapr/configuration/default/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml</code> |
| <code>host6</code> | Not applicable. No customized configuration files are used. |
| <code>host7</code> | Not applicable. No customized configuration files are used. |
| <code>host8</code> | Not applicable. No customized configuration files are used. |

Warning: Do *not* change the name of the new configuration file - it must match the name of the original version.

Step 1. Create a customized configuration file and copy it to a volume

Use the CLI to create a customized configuration file and copy it to a volume.

Complete the following steps to create a customized configuration file for host2 through host5 and copy it to the `mapr.configuration` volume:

1. Make a copy of the existing default version of the `mapred-site.xml` file (so you can use it as a template), and store it in `/tmp`. You can perform this step on any node in the cluster that contains the configuration file.

```
cp /opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml /tmp/
mapred-site.xml
```

2. Edit the copy and put in the changes you want for host2 through host5.
3. Create the directories required to store the file under `/var/mapr/configuration/default`.

```
hadoop fs -mkdir -p /var/mapr/configuration/default/hadoop/
hadoop-2.7.0/etc/hadoop
```

4. Store the new configuration file in the `/var/mapr/configuration/default` directory.

```
hadoop fs -put /tmp/mapred-site.xml /var/mapr/configuration/default/
hadoop/hadoop-2.7.0/etc/hadoop
```

Step 2. Create a node-specific configuration file and copy it to a volume

Use the CLI to create a node-specific configuration file and copy it to a volume.

Complete the following steps to create a node-specific configuration file for host1 and copy it to the `mapr.configuration` volume:

1. Edit the `mapred-site.xml` configuration file in `/tmp` (or you could copy the default version into `/tmp` again and edit that) and create the node-specific configuration file for host1.
2. Create the directories required to store the file under `/var/mapr/configuration/nodes`:

```
hadoop fs -mkdir -p /var/mapr/configuration/nodes/host1/hadoop/
hadoop-2.7.0/etc/hadoop
```

3. Store the new configuration file for host1 in the node-specific directory you just created.

```
hadoop fs -put /tmp/mapred-site.xml /var/mapr/configuration/nodes/host1/
hadoop/hadoop-2.7.0/etc/hadoop
```

Step 3. Verify the changes

Explains the use of the `pullcentralconfig` script in verifying file changes.

Now that you have two separate customized configuration files for your NodeManager nodes, the `pullcentralconfig` script will detect the new files in `/var/mapr/configuration` the next time it is launched. It overwrites the local version in `/opt/mapr` with the appropriate customized version for each of the five NodeManager nodes.

1. To launch the `pullcentralconfig` script, perform one of the following operations:

- Run `pullcentralconfig` from the command line to overwrite the old files immediately.

```
/opt/mapr/server/pullcentralconfig
```

- Wait five minutes (the interval between successive checks for updated configuration files) for the script to run automatically.
2. Look at the information messages in `pullcentralconfig.log`. Whenever the timestamp comparison is `false`, an INFO message indicates that the older file under `/opt/mapr` is copied into a backup file (`.bkp`) and the newer version is copied to replace it. Sample log output is as follows:

```
cat pullcentralconfig.log
  Header: hostName: doc22.lab, Time Zone: Pacific Standard Time,
processName: CentralConfig, processId: 16701
  2017-07-17 13:13:01,842 INFO
com.mapr.centralconfig.CentralConfigCopyHelper [main]: Copied /var/mapr/
configuration/default//hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml
to /opt/mapr//hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml using
mapreexecute.
```

3. [Restart the service.](#)

About the `pullcentralconfig` Script

Provides a brief synopsis about the `pullcentralconfig` script.

The `pullcentralconfig` script runs on each node in the cluster. The `pullcentralconfig` script is launched automatically at specified intervals (the default interval is 300 seconds, which is five minutes). For each service listed in `/opt/mapr/roles`, the `pullcentralconfig` script searches for corresponding configuration files in the central configuration location, `/var/mapr/configuration`. If any configuration files are found, it compares the timestamp (`mtime`) of the files in the central configuration location to the timestamp of the local version in `/opt/mapr`. If the central configuration version is newer, `pullcentralconfig` overwrites the local version with the central configuration file. To ensure that the newer version gets used, you need to [restart the associated service](#).

Checking for Node-specific vs. Cluster-wide Configuration Files

Explains the order in which the `pullcentralconfig` script checks for central configuration files.

The `pullcentralconfig` script checks for central configuration files in this order:

1. Node-specific configuration files under `/var/mapr/configuration/nodes/<hostname>`. If configuration files are found here, `pullcentralconfig` does not check `/var/mapr/configuration/default`.
2. Cluster-wide configuration files under `/var/mapr/configuration/default`. The `pullcentralconfig` script only searches here if no node-specific configuration files are found.

If no configuration files are found in either location, the script finishes and no changes are made to the files in `/opt/mapr`.

Changing the Polling Frequency

Explains how to change the polling frequency of the `pullcentralconfig` script.

By default, the `pullcentralconfig` script polls the central configuration location every five minutes (300 seconds) to check for configuration files.

1. You can change the polling frequency by editing the following variable in `warden.conf`:

```
pollcentralconfig.interval.seconds
```

- To make the change take effect, restart Warden:

```
root$> service mapr-warden restart
```

Listing the Configuration Files for Each Service

Explains how to use the CLI to list all the configuration files for each service.

Each service on a node has one or more configuration files associated with it. The default version of each configuration file can be used as a template that you can modify as needed.

Files in the following directory contain the list of configuration files for each installed service: `/opt/mapr/servicesconf/<service>`.

- Use the following command to display the configuration files or the directory that contains the configuration files for each service:

```
cat /opt/mapr/servicesconf/<service>
```

For example, the following command displays the configuration files for NodeManager:

```
cat /opt/mapr/servicesconf/nodemanager
    hadoop/hadoop-2.7.4/etc/hadoop
```

The following table contains the configuration files and configuration file directories available for Hadoop and Hbase:

| Service | Pathnames of Configuration Files |
|----------------------|--|
| cldb | <code>/opt/mapr/conf/BaseLicense.txt</code> |
| | <code>/opt/mapr/conf/cldb.conf</code> |
| | <code>/opt/mapr/hadoop/hadoop-xxx/etc/hadoop/hadoop-metrics.properties</code> |
| | <code>/opt/mapr/conf/log4j.cldb.properties</code> |
| | <code>/opt/mapr/conf/log4j.properties</code> |
| | <code>/opt/mapr/conf/MapRLicenseIssuerCert.der</code> |
| fileserver | <code>/opt/mapr/conf/mfs.conf</code> |
| historyserver | <code>/opt/mapr/conf/conf.d/warden.historyserver.conf</code> |
| |  Attention: You can perform additional configuration of the historyserver in <code>/opt/mapr/hadoop/hadoop-xxx/etc/hadoop/yarn-site.xml</code> |
| nfs | <code>/opt/mapr/conf/nfsserver.conf</code> |
| | <code>/opt/mapr/conf/exports</code> |
| nodemanager | <code>/opt/mapr/conf/conf.d/warden.nodemanager.conf</code> |
| | <code>/opt/mapr/conf.new/hadoop_version</code> |

| Service | Pathnames of Configuration Files |
|-----------------|--|
| resourcemanager | /opt/mapr/conf/conf.d/ warden.resourcemanager.conf  Attention: You can perform additional configuration of the resourcemanager in /opt/mapr/hadoop/hadoop-xxx/etc/hadoop/yarn-site.xml |
| webserver | /opt/mapr/apiserver/conf/properties.cfg |

Preserving Multiple Versions of Configuration Files

- If you want to save multiple versions of customized configuration files, you can take snapshots of `mapr.configuration` to preserve each version you create.

This may be helpful if you want to try various versions of the configuration files on the cluster.

-  **Warning:** Before a local configuration file is updated by the `pullcentralconfiguration` script, a backup of the current version is created. The file extension `.bkp` indicates the back-up configuration file.

Disabling Automatic Central Configuration

Explains how to stop automatic runs of the `pullcentralconfig` script.

- Automatic central configuration is enabled by default. You can configure central configuration to stop automatic runs of the `pullcentralconfig` script by editing `warden.conf` and setting the following variable to `false`: `centralconfig.enabled=false`
- To make the change take effect, restart Warden:

```
root$> service mapr-warden restart
```

-  **Note:** When automatic central configuration is disabled, you can still manually run the `pullcentralconfig` script to push the latest configuration files to nodes in the cluster.

Viewing CLDB Information

Describes how to view CLDB information from the CLDB page, and provides an explanation of each field that the page displays.

The CLDB page on the Control Panel provides information about the Container Location Database (CLDB). The CLDB is a management service that tracks container locations and the root of volumes.

To display the CLDB information page, log in to the Control System and go to the [service information page](#) for CLDB. Alternatively, you can use the following links to access the CLDB page:

- For a *secure* cluster, access the CLDB view at `https://<cldbmaster>:7443/cldb.jsp`.
- For an *non-secure* cluster, access the CLDB view at `http://<cldbmaster>:7221/cldb.jsp`.

The CLDB page displays the following information:

Container Location Database

Description: This section displays:

- CLDB Mode: The CLDB node can be in one of the following modes: `MASTER_READ_WRITE` or `SLAVE_READ_ONLY`.

- CLDB BuildVersion: Lists the build version.
- Master for CLDB volume ready: Indicates whether the CLDB volume is ready for use.
- CLDB Status: The status of the CLDB node.
- Cluster Capacity: The storage capacity for the cluster.
- Cluster Used: The amount of storage in use.
- Cluster Available: The amount of available storage.
- Cluster Used Percentage: The percentage of storage in use.

Active FileServers

Description: Displays information about the File Servers in use:

- ServerID (Hex): The server's ID in hexadecimal notation.
- ServerId: The server's ID in decimal notation.
- HostPort: The IP address of the file server.
- HostName: The hostname assigned to the file server.
- Network Location: The network topology for the file server.
- Last Heartbeat (s) : The timestamp for the last received heartbeat.
- State: Is the file server ACTIVE (in use at present)
- Capacity (MB): Total storage capacity on the file server.
- Used (MB): Storage used on the file server.
- Available (MB): Storage available on the file server.
- In Transit (MB): Amount of data in transit

Active NFS Servers

Description: Displays information about the NFS Servers in use:

- ServerID (Hex): The server's ID in hexadecimal notation.
- ServerId: The server's ID in decimal notation.
- HostPort: The IP address of the NFS server.
- HostName: The hostname assigned to the NFS server.
- Last Heartbeat (s) : The timestamp for the last received heartbeat.
- State: Is the NFS server ACTIVE (in use at present)

Volumes

Description: Displays information about the volumes on the container:

- **Volume Name:** The name of the volume. Click the name of the volume to view the containers of the volume (including the container ID, size (in MB), container primary location and container locations, and replication type, which can be *S* for sequential and *C* for cascading).
- **Mount Point:** The path in which the volume is mounted over NFS.
- **Mounted:** Specifies whether volume is mounted. Value can be Y or N.
- **ReadOnly:** Specifies whether volume is a read-only or read/write volume. Value can be Y (if volume is read-only) or N (if volume is read/write).
- **Volume ID:** The Volume ID.
- **Volume Topology:** The path describing the topology to which the volume is assigned.
- **Quota:** The total size of the volume's quota. A quota of 0 means no quota is assigned.
- **Advisory Quota:** The usage level that triggers a disk usage warning.
- **Used:** Total size of data written to the volume after compression.
- **LogicalUsed:** Actual size of data written to the volume.
- **Root Container ID:** The ID of the root container.
- **Replication:** The number of copies of the volume.
- **Guaranteed Replication:** The minimum number of copies of the volume.

Accountable Entities

Description: Displays information about users and groups:

- **AE Name:** The name of the accountable entity.
- **AE Type:** The type of accountable entity.
- **AE Quota:** The hard quota allocated to the accountable entity.
- **AE Advisory Quota:** The advisory quota limit for the accountable entity.
- **AE Used:** The amount of disk space used by the accountable entity.

Mirrors Information

Description: Contains a link to the Mirrors page, which displays information about volume mirrors:

- **Mirror Volume Name:** The name of the mirror volume.

- **Mirror ID:** The ID of the mirror volume used for the last successful mirroring. This ID starts with 1 and is incremented by 1 after each mirroring.
- **Mirror NextID:** The ID to be used for the next mirroring operation.
- **Mirror Status:** The status of the mirroring operation.
- **Last Successful Mirror Time:** The date and time stamp from the last successful mirroring operation.
- **Mirror SrcVolume:** The source volume for the mirror volume.
- **Mirror SrcRootContainerID:** The source container ID for the mirror volume.
- **Mirror SrcClusterName:** The source cluster name for the mirror volume.
- **Mirror SrcSnapshot:** The source snapshot associated with the mirror volume.
- **Mirror DataGenerator Volume:** The first volume that generates data (RW Volume) in the mirror chain.
For example, if the mirror chain is **A > B > C**, then at C, the Mirror DataGenerator volume is A while the source volume is B.
- **Mirror DataGenerator snapshot time:** The time at which the last snapshot for the Mirror DataGenerator Volume was generated.

Snapshots Information

Description: Contains a link to the Snapshots page, which displays information about snapshots:

- **Snapshot ID:** The ID of the snapshot.
- **RW Volume ID:** The ID of the standard (or read/write) volume associated with the snapshot.
- **Snapshot Name:** The name of the snapshot.
- **Root Container ID:** The ID of the container.
- **Snapshot Size:** The size of the snapshot.
- **Snapshot InProgress:** The status of the snapshot if it is currently in progress.

The page also displays a list of snapshot containers, and the following information about each:

- **Snapshot Container ID:** The unique ID of the container.
- **Snapshot ID:** The ID of the snapshot corresponding to the container.
- **RW Container ID:** The corresponding source container ID.

- Latest Epoch: The latest sequence number of the snapshot. Higher the number, the newest and most up-to-date is the snapshot.
- SizeMB: The container size, in MB.
- Container Master Location: The location of the container's primary replica.
- Container Locations: The location of the data containers.
- Inactive Locations: The location of inactive containers.

Storage Pools

Description: Displays information about storage pools:

- SP: The ID of the storage pool.
- ServerId: The ID of the server associated with the storage pool.
- Spldx: The index of the storage pool.
- Last Heartbeat(s): TBD
- Capacity: The total capacity of the storage pool.
- Used: The amount of space used on the storage pool.
- Disk Fullness Level (percentage): The percentage of disk space (associated with the storage pool) that is full.
- InTransit: Indicates that some containers in the storage pool are being resynced.
- OutTransit: Indicates that none of the containers in the storage pool are being resynced.

Active Container Moves

Description: Displays information about the containers being moved:

- Container ID: The ID of the container being moved.
- SizeMB: The size (in MB) of the container being moved.
- From Location: The location from where the container is being moved.
- From SP: The SP out of which the container is being moved.
- To Location: The location to which the container is being moved.
- To SP: The SP to which the container is being moved.

Managing Drill

Provides a short description on managing Drill services.

You can install and run a Drillbit service on one node or on all of the nodes on a data-fabric cluster to form a distributed cluster environment. After you have installed Drill and configured connections to your data sources, you can view Drill metrics and manage Drillbits using the Control System.

Viewing Drill Information

Explains how to view Drill information using the Control System.

Viewing Drill Information Using the Control System

1. Log in to the Control System and click **Services**.

Note: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Drill** in the **Services** pane.

The **Drill** information page displays the following:

Summary

The **Summary** tab displays the following panes:

| | |
|-----------------------------|--|
| Information | Displays the number of Drillbits and the number of completed and in-progress queries. |
| Resource Utilization | The percentage of CPU, memory, and disk space utilized by Drill. |
| Running Fragments | The number of query fragments running in the Drillbit during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. For more information on fragments, see Drill Query Execution . |
| Memory Used | The amount of direct memory used by the JVM during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. To configure the amount of direct memory allocated to a Drillbit for query processing in a Drill cluster, see Configuring Drill Memory . |
| Queries | The number of queries during the selected time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. |

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

Drill Bits

The **Drill Bits** tab displays the list of Drillbits. See [Viewing the List of Drillbits](#) on page 1294.

Viewing the List of Drillbits

Explains how to view the list of Drillbits using the Control System.

- Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill. For each Drillbit, the pane displays the following:

| Column Name | Column Description |
|-------------------------|---|
| Drill Bit ID | The ID of the Drillbit. |
| Node | The node on which the Drillbit is installed. |
| Service State | The status of the service. Value can be: <ul style="list-style-type: none"> Running Stopped |
| Queries in Progress | The number of queries currently in progress. |
| Resource Usage - Memory | The percentage of memory being used. |
| Resource Usage - CPU | The percentage of CPU being used. |

Select the checkbox beside one or more Drillbit IDs to:

- Stop the Service(s)**
- Start the Service(s)**
- Restart the Service(s)**

For more information, see [Stopping, Starting, and Restarting Drillbits](#) on page 1294.

Stopping, Starting, and Restarting Drillbits

Explains how to stop, start and restart Drillbits using the Control System.

Stopping Drillbits

- Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.
- Select the checkbox associated with the Drillbit(s) and click **Stop Service(s)** to display the **Stop Service** confirmation dialog.

You can only stop Drillbits that are currently in running state.

- Review the list of Drillbits and click **Stop Service** to stop the Drillbits.

Starting Drillbits

- Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.

2. Select the checkbox associated with the Drillbit(s) and click **Start Service(s)** to display the **Start Service** confirmation dialog.

You can only start Drillbits that are currently in stopped state.

3. Review the list of Drillbits and click **Start Service** to start the Drillbits.

Restarting Drillbits

1. Log in to the Control System and go to the **Drill Bits** tab in the [service information page](#) for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Restart Service(s)** to display the **Restart Service** confirmation dialog.
3. Review the list of Drillbits and click **Restart Service** to restart the Drillbits.

Managing the HPE Ezmeral Data Fabric NFS Service

Provides an overview of managing the NFS for the HPE Ezmeral Data Fabric service on a licensed cluster.

The data-fabric NFS for the HPE Ezmeral Data Fabric service lets you access data on a licensed HPE Ezmeral Data Fabric cluster using the [NFS](#) protocol:

- Community Edition license: one NFS for the HPE Ezmeral Data Fabric node allows you to access your cluster as a standard POSIX-compliant filesystem.
- Enterprise Edition or Enterprise Database Edition license: multiple NFS servers allow each node to mount its own data-fabric filesystem on NFS for the HPE Ezmeral Data Fabric enabled with VIPs for high availability (HA) and load balancing.

You can mount the data-fabric cluster using NFS for the HPE Ezmeral Data Fabric, and use standard shell scripting to read and write live data on the cluster. NFS for the HPE Ezmeral Data Fabric access to cluster data can be faster than accessing the same data with the `hadoop` commands. To mount the cluster using NFS for the HPE Ezmeral Data Fabric from a client machine, see [Accessing Data with NFS v3](#).

Managing VIPs for NFS

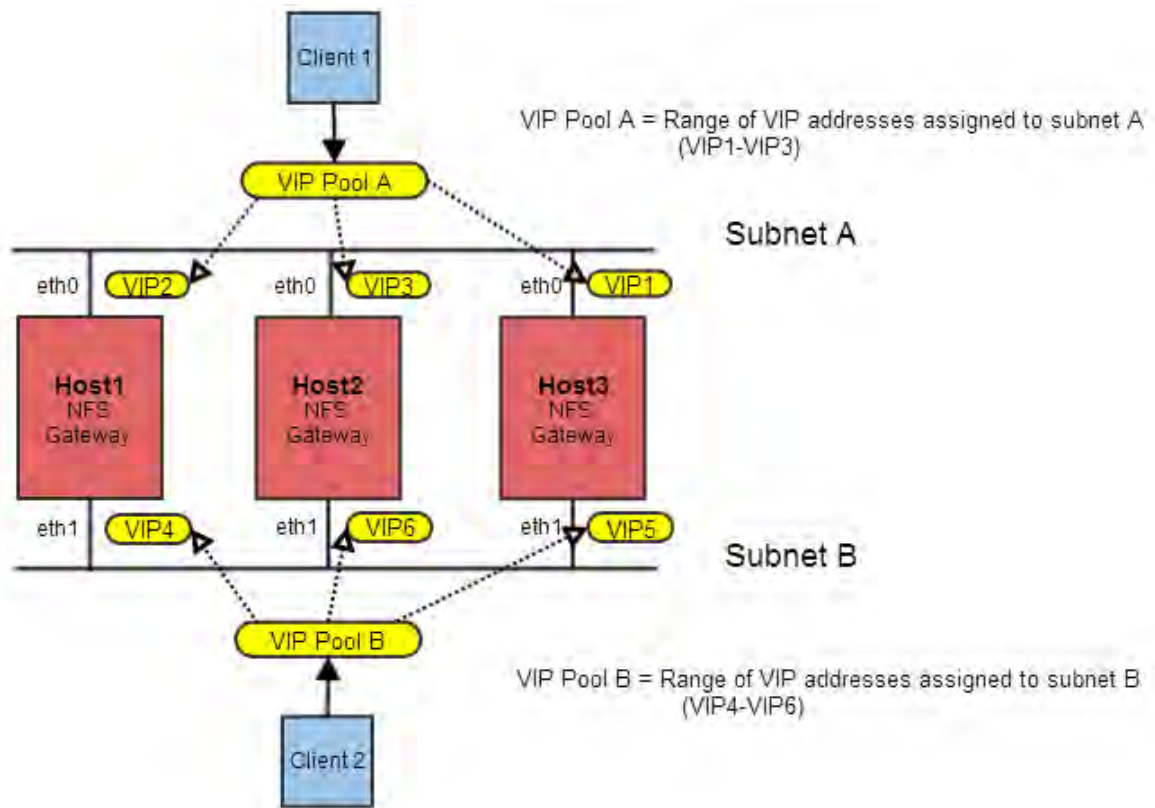

Explains how to use virtual IP addresses (VIPs) on NFS servers.

You can set up a pool of NFS servers on various nodes in your cluster and connect to them using virtual IP addresses (VIPs) to achieve High Availability (HA) with failover; if one node fails, the VIP will automatically be reassigned to another NFS node in the pool. If you do not specify a list of NFS nodes to form a pool, then data-fabric uses any available node running the data-fabric NFS Gateway service. VIPs are not assigned to any nodes that are not on the list, regardless of whether they are running NFS.

Note: To add a server to an NFS pool that is not divided into subnets, start the data-fabric NFS service on that server. The data-fabric cluster automatically detects it and adds it to the pool.

The following illustration shows three nodes (Host1, Host2, and Host3) acting as NFS servers. Each node has two NICs whose ports are labeled eth0 and eth1. The NICs are grouped into two subnets, called Subnet A and Subnet B. Clients can access any of the NFS servers through a pool (or range) of VIPs assigned to each subnet. Data Fabric assigns each VIP address in the pool at random to a MAC address in the subnet (with its corresponding physical IP address).

The initial VIP assignment shown above is summarized in the following table. If one NFS server becomes unavailable, the VIP assigned to that server is automatically assigned to another server on the same subnet.

| Server | Subnet | VIPs (randomly assigned) |
|--------|--------|--------------------------|
| NFS1 | A | VIP2 |
| NFS2 | A | VIP3 |
| NFS3 | A | VIP1 |
| NFS1 | B | VIP4 |
| NFS2 | B | VIP6 |
| NFS3 | B | VIP5 |

If the cluster's NFS nodes have multiple network interface cards (NICs) connected to different subnets, you should restrict VIP assignment to the NICs that are on the correct subnet: for each NFS server, choose whichever MAC address is on the subnet from which the cluster will be NFS-mounted, then add it to the list.

Warning: If you add a VIP that is not accessible on the subnet, then failover will not work. Also, do not use duplicate MAC addresses. For example, for bonding interfaces on the cluster nodes, do not use the same MAC address for bond0 and bond0.X, as then the failover of VIP might not work.

You can only set up VIPs for failover between network interfaces that are in the same subnet. In large clusters with multiple subnets, you can set up multiple groups of VIPs to provide NFS failover for the different subnets.

VIPs are evenly distributed across NFS nodes. For example, if six VIP addresses are available for three NFS servers, two VIPs are assigned to each server. If the previous example did not have two separate subnets, the six VIP addresses might be assigned like this:

| Server | VIPs (randomly assigned) |
|--------|--------------------------|
| N/FS1 | VIP1, VIP3 |
| NFS2 | VIP4, VIP5 |
| NFS3 | VIP2, VIP6 |

The following sections describe how to set up, edit, and remove VIPs using the Control System and the CLI.

Using Consistent Export Rules

Lists the default NFS export rules.

Export rules (stored in `conf/exports`) should be the same across all NFS nodes that are in the same VIP pool, and for nodes that are configured for the same VIP failover. The default version of `conf/exports` is as follows:

```
# Sample Exports file

# for non /mapr exports
# <Path> <comma separated cldb addresses=host:port> <exports_control>

# for /mapr exports
# <Path> <exports_control>

#access_control -> order is specific to default
# list the hosts before specifying a default for all
# a.b.c.d,1.2.3.4(ro) d.e.f.g(ro) (rw)
# enforces ro for a.b.c.d & 1.2.3.4 and everybody else is rw

# special path to export clusters in mapr-clusters.conf. To disable
exporting,
# comment it out. to restrict access use the exports_control
#
/mapr (rw)

#to export only certain clusters, comment out the /mapr & uncomment.
# Note: this will cause /mapr to be unexported
#/mapr/clustername (rw)

#to export /mapr only to certain hosts (using exports_control)
#/mapr a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster1 rw to a.b.c.d & ro to e.f.g.h (denied for others)
#/mapr/cluster1 a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster2 only to e.f.g.h (denied for others)
#/mapr/cluster2 e.f.g.h(rw)

# export /mapr/cluster3 rw to e.f.g.h & ro to others
#/mapr/cluster2 e.f.g.h(rw) (ro)
```

Setting Up VIPs for NFSv3

Explains how to set up VIPs for NFS version 3 using either the Control System or the CLI.

Note: The NFSv3 server (`mapr-nfsserver`) nodes cannot failover to NFSv4 server (`mapr-nfs4server`) nodes and vice versa. Ensure that different sets of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary when both NFSv3 and NFSv4 are going to be set up on the same cluster). The MACs should be mutually exclusive as both NFSv3 and NFSv4 servers cannot run on the same node.

Adding VIPs Using the Control System

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure:

- You have installed NFS on at least three nodes (recommended).
 - You have started the NFS gateway service on the servers to which you plan to assign VIPs.
1. Log in to the Control System, click **Services**, and go to the [NFS service information page](#) where you can configure VIPs for NFSv3 nodes.

Note: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.
HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.
If you are assigning only one VIP, you can leave the field blank. HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
5. Enter the Netmask for the VIP range in the **Netmask** field.
For example: `255 . 255 . 255 . 0`. HPE Ezmeral Data Fabric assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
 - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.
If additional NFS Gateway services are started, the network interfaces on their nodes will automatically become candidates for the VIPs in this range.
 - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:
A list of available and selected node names, physical IP addresses, and MAC addresses displays. Select from the:
 - Available list and click ► to move selection to **Selected** VIPs.
 - Selected list and click ◀ to remove from selected list of VIPs.

See [Designating NICs for HPE Ezmeral Data Fabric](#) on page 921.

8. Confirm the actual VIP assignment by clicking **Save Changes.**

It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Adding VIPs Using the CLI and REST API

CLI

The basic command to set up VIPs is:

```
maprcli virtualip
add -netmask <netmask> -virtualip
<virtualip> -service nfs3 -json
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/virtualip/add?
service=nfs3&netmask=<netmask>&virtual
ip=<vip>' --user mapr:mapr
```

For the complete list of required and optional parameters, see [virtualip add](#) on page 2161.

Setting Up VIPs for NFSv4

Describes how to setup Virtual IPs (VIPs) for high availability of NFSv4 servers, using either the Control System or the CLI.

Virtual IP addresses (VIPs) allow you to achieve high availability with failover when the NFS servers use them to connect to your cluster. When configuring VIPs for NFSv4 servers, ensure that you select NFSv4 server nodes only. HPE Ezmeral Data Fabric does not support failing over between NFSv3 and NFSv4 servers.

Adding VIPs Using the Control System

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure that:

- You have installed NFS on at least three nodes (recommended).
 - You have started the NFS gateway service on the servers to which you plan to assign VIPs.
1. Log in to the Control System and go to the [NFS4 service information page](#) where you can configure VIPs for NFSv4 nodes.
 2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
 3. Enter the start of the VIP range in the **Starting Virtual IP** field.
HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
 4. Enter the end of the VIP range in the **Ending Virtual IP** field.
If you are assigning only one VIP, you can leave the field blank. HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.

5. Enter the Netmask for the VIP range in the **Netmask** field.
For example: 255.255.255.0. HPE Ezmeral Data Fabric assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
 - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.
If additional NFS Gateway services are started, the network interfaces on their nodes automatically become candidates for the VIPs in this range.
 - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:
The system displays a list of available and selected node names, physical IP addresses, and MAC addresses. Do one of the following:
 - Select from the available list and click ► to move the selection to **Selected** VIPs.
 - Choose from the selected list and click ◀ to remove the chosen entries from the selected list of VIPs.

See [Designating NICs for HPE Ezmeral Data Fabric](#) on page 921.
8. Confirm the actual VIP assignment by clicking **Save Changes**.
It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Setting up VIPs for NFSv4 Server from the Command-Line

To set up VIPs for NFSv4 server:

1. Add VIPs to the NFS server nodes in the cluster by running the `virtualip add` on page 2161 command.

```
maprcli virtualip add -virtualip <vip> -virtualipend <vipend> -service
nfs4 -netmask <netmask> -macs <mac>
```

For example, for a range of virtual IPs use:

```
maprcli virtualip add -virtualip 10.10.104.203 -virtualipend
10.10.104.206 -service nfs4 -netmask 255.255.255.0 -macs
"18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
```

For a single virtual IP, do not include the `-virtualipend` parameter. For example:

```
maprcli virtualip add -virtualip 10.10.104.203 -service nfs4 -netmask
255.255.255.0 -macs
"18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
```

For the complete list of required and optional parameters, see `virtualip add` on page 2161.

2. Add the hostname for each VIP in the `/etc/hosts` file on all the nodes in the cluster.
3. Add the principal for each VIP and generate the keytab file. That is, repeat this step in the following order for each VIP:

- a) Add the principals for the following:
 - NFS server hostnames in the kerberos server.
 - VIP hostname in the kerberos server.
 - b) Generate the keytab file, which contains entries for all the NFS server and VIP hostname principals.
4. Restart the `rpc.gssd` service on all the NFSv4 server nodes.
To restart, run the following command:

```
service rpcgssd start
```

5. Mount the cluster.

Editing a VIP

Explains how to modify the Virtual IP (VIP) range using either the Control System or the CLI.
Editing a VIP Using the Control System

1. Log in to the Control System and go to the [service information page](#) for NFS.
2. Click the **VIP Range** to modify.
The **Edit Virtual IP** page displays.
3. Modify changes to one or more of the following as needed.

| | |
|---------------------------|--|
| Preferred MAC Address | The preferred MAC for this virtual IP. When an NFS server restarts, the HPE Ezmeral Data Fabric system attempts to move all of the virtual IP addresses that list a MAC address on this node as a preferred MAC to this node. If the new value is null, this field resets the preferred MAC value. |
| Select network interfaces | The list of MAC addresses that represent the NICs on the nodes to which the VIPs in the VIP range can be associated. Use this list to limit VIP assignment to NICs on a particular subnet when your NFS server is part of multiple subnets. |

4. Click **Save Changes** for the changes to take effect.

Editing a VIP Using the CLI and REST API

CLI

The basic command to modify a VIP range is:

```
maprccli virtualip edit -netmask <netmask> -virtualip <virtualip>
```

REST

Send a request of type POST. For example:

```
durl -k -X POST 'https://<host>:8443/rest/virtualip/edit?netmast<netmask>&virtualip=<vip>' --user mapr:mapr
```

For the complete list of required and optional parameters, see [virtualip edit](#) on page 2164.

Viewing the List of Virtual IPs

Explains how to view the list of VIPs using either the Control System or the CLI.
Viewing the List of VIPs Using the Control System

- Log in to the Control System and go to the [service information page](#) for NFS.

The page displays the following:

| Column Name | Column Description |
|-------------|--|
| VIP Range | The Virtual IP range. |
| Virtual IP | The VIP (in the range) of the associated node. |
| Node Name | The host name of the node. |
| Physical IP | The physical IP of the associated node. |
| MAC Address | The MAC address of the network interface that is assigned to the associated VIP. |

You can add and remove VIPs.

Retrieving the List of VIPs Using the CLI and REST API

CLI

The basic command to retrieve a list of VIPs is:

```
maprcli virtualip list
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://<host>:8443/rest/virtualip/list' --user mapr:mapr
```

For complete reference, see [virtualip list](#) on page 2165.

Removing a VIP

Explains how to remove a VIP range using either the Control System or the CLI.

Removing a VIP Range Using the Control System

1. Log in to the Control System and go the [service information page](#) for NFS.
2. Select the VIP range(s) to remove and click **Remove Virtual IP**.
The **Remove Virtual IP** confirmation dialog displays.
3. Review the VIP range(s) to remove and click **Remove Virtual IP**.

Removing a VIP Range Using the CLI or REST API

The basic command to remove a VIP range is:

```
maprcli virtualip remove -virtualip <virtual IP>
```

For complete reference information, see [virtualip remove](#) on page 2169.

Accessing Data with NFS v3

Describes how data-fabric works with NFS v3.

Unlike other Hadoop distributions that only allow cluster data import or import as a batch operation, Data Fabric lets you mount the cluster itself using NFS for the HPE Ezmeral Data Fabric so that your applications can read and write data directly. Data Fabric allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With a NFS-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS for the HPE Ezmeral Data Fabric.

Data Fabric exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and

NFS v3 paths to the cluster will be the same. This makes it easy to work on the same files using NFS v3 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

 **Warning:** Data Fabric uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS v3.

 **CAUTION:** It is observed that NFS v3 clients are caching older [atime values](#) from previous history. Therefore, you might observe wrong `atime` values. To mitigate, make sure to clear caches, before checking file timestamps.

You can mount the cluster on a Linux, Mac, or Windows client. Before you begin, make sure you know the hostname and directory of the NFS v3 share you plan to mount.

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3

Explains how to start, stop, and restart NFS version 3 using either the Control System or the CLI.

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3 Using the Control System

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 907
- [Stopping a Service on the Cluster Using the Control System](#) on page 908
- [Restarting the Services on the Cluster Using the Control System](#) on page 909

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3 Using the CLI and REST API

NFSv3 Server

The command to stop, start, or restart HPE Ezmeral Data Fabric NFSv3 server is:

```
maprcli node services -nodes <node
names> -nfs stop|start|restart
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<host>:8443/rest/node/
services?nodes=<nodeName>&nfs=stop|
start|restart' -- user mapr:mapr
```

Note: When NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers. For the complete list of parameters, see [node services](#) on page 1939.

Setting Up Aliases for NFS Exports

When provisioning filesystem for various tenants, you can set up an alias for the path in filesystem, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in filesystem.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in filesystem (`/mapr`). To set up an alias for a path in filesystem:

1. Open the NFS exports file in `/opt/mapr/conf/` directory.

- Specify the alias name for the mount path using the following syntax:

```
<path in MFS> /<alias name> <options>
```

Here:

| | |
|---------------|---|
| <path in MFS> | Refers to the filesystem mount path. If this points to a: <ul style="list-style-type: none"> Volume, the user can access the snapshots associated with the volume. Directory, the user cannot access the snapshots. |
| /<alias name> | Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in filesystem will be exported. |
| <options> | The list of available/supported options. |

For example, suppose a filesystem mount path of `/mapr/samplecluster/samplevolume` for tenant `samplecustomer`. To set up an alias, add the following to the exports file:

```
/mapr/samplecluster/samplevolume /samplecustomer (rw)
```

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

Note: Only the alias will be visible/exposed to the NFS client.

- Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprcli nfsmgmt refreshexports
```

- Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Mounting NFS for the HPE Ezmeral Data Fabric to filesystem on a Cluster Node

You can *automatically* or *manually* mount NFS for the HPE Ezmeral Data Fabric to the filesystem on a cluster node.

Automatically Mount

Use this procedure to *automatically* mount NFS for the HPE Ezmeral Data Fabric to filesystem on the cluster `my.cluster.com` at the `/mapr` mount point.

- Set up the mount point by creating the directory.

```
sudo mkdir /mapr
```

2. Add the following line to `/opt/mapr/conf/mapr_fstab`:

```
<hostname>:/mapr /mapr hard,nolock
```

Note: The change to `/opt/mapr/conf/mapr_fstab` will not take effect until Warden is restarted.

Every time your system is rebooted, the mount point is automatically re-established according to the `mapr_fstab` configuration file.

Manually Mount

Use this procedure to *manually* mount NFS for the HPE Ezmeral Data Fabric to filesystem on the cluster `my.cluster.com` at the `/mapr` mount point.

1. Set up a mount point for a NFS for the HPE Ezmeral Data Fabric share.

```
sudo mkdir /mapr
```

2. Mount the cluster via NFS for the HPE Ezmeral Data Fabric.

```
sudo mount -o hard,nolock usa-node01:/mapr /mapr
```

Note: When you mount manually from the command line, the mount point does not persist after a reboot.

Mounting NFS on a Linux Client

Explains how to mount NFS on a Linux client either automatically at start up or manually.

You can *automatically* or *manually* mount NFS on a Linux client when your system starts up.

Automatically Mount

Use this procedure to *automatically* mount to NFS on a Linux client when your system starts up.

Add an NFS mount to `/etc/fstab`.

| # | device | mountpoint | fs-type | options | dump | fsckorder |
|-----|------------------|------------|---------|---------|------|-----------|
| ... | | | | | | |
| | usa-node01:/mapr | /mapr_nfs/ | nfs | rw | 0 | 0 |
| ... | | | | | | |

Manually Mount

Use this procedure to *manually* mount to NFS on a Linux client.

1. Install the NFS client.

- `sudo yum install nfs-utils` (Red Hat or CentOS)
- `sudo apt-get install nfs-common` (Ubuntu)
- `sudo zypper install nfs-client` (SLES)

- List the NFS shares exported on the server. For example:

```
showmount -e usa-node01
```

Note: If the NFS protocol is v4 only, the `showmount` command does not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

- Set up a mount point for an NFS share. For example:

```
sudo mkdir /mapr_nfs/
```

- Mount the cluster using NFS. Use the command as in the following example:

```
sudo mount -t nfs -o sec=mode vers=NFS_version usa-node01:/mapr /mapr_nfs/
```

where `mode` is one of the following:

- `krb5` for Kerberos version 5 authentication service.
- `krb5i` for Kerberos version 5 with integrity.
- `krb5p` for Kerberos version 5 with privacy.
- `none` for no authentication.

and `NFS_version` is either 3 or 4.

Restriction: You can use the `sec=mode` option only for NFS version 4. NFS version 3 does not support this option.

Tip: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs -o sec=krb5,vers=4.0 usa-node01:/mapr /mapr_nfs/
```

For NFS v3, use the command as in the following example:

```
mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
```

Note: The mount point does not persist after reboot when you mount manually from the command line.

- List all mounted file systems to verify that the cluster is mounted. For example:

```
$ mount | grep nfs4
usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
```

Mounting NFS on a Mac Client

Describes how to mount a NFS server on a Mac client.

Use this procedure to mount to the cluster *manually* from the command line:

1. Open a terminal. For example, you can click on **Launchpad > Open terminal**.
2. At the command line, enter the following command to become the root user:

```
sudo bash
```

3. List the NFS shares exported on the server. For example:

```
showmount -e usa-node01
```

4. Set up a mount point for an NFS share. For example:

```
sudo mkdir /mapr_nfs/
```

5. Mount the cluster using NFS. Use the command as in the following example:

```
sudo mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
```

Note: The mount point does not persist after reboot when you mount manually from the command line.

6. List all mounted file systems to verify that the cluster is mounted. For example:

```
$ mount | grep nfs
usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
```

Mounting NFS on a Windows Client

Describes how to mount an NFS share on a Windows client, and configure the relevant user and group IDs.

To set up the Windows NFS client, mount the cluster, map a network drive, and configure the user ID (UID) and group ID (GID). The Windows client must access NFS using a valid UID and GID from the Linux domain. Mismatched UID or GID results in permission problems when MapReduce jobs try to access files that were copied from Windows over an NFS share.

Due to Windows directory caching, the `.snapshot` directory may not appear in the root directory of each volume. As a workaround, you can force Windows to re-load the volume's root directory by updating its modification time (for example, by creating an empty file or directory in the volume's root directory).

With Windows NFS clients, use the `-o nolock` option on the NFS server to prevent the Linux NLM from registering with the portmapper. The native Linux NLM conflicts with the HPE Ezmeral Data Fabric NFS server.

Complete the following steps to mount NFS on a Windows client:

1. Mount the Cluster.

Windows 10 Enterprise

Complete the following steps for *Windows 10 Enterprise*

- a. Open **Start > Control Panel > Programs**.
- b. Select **Turn Windows features on or off**.
- c. Select **Services for NFS**.

- d. Click **OK**.
- e. Enable write permissions for the anonymous user as the default options only grant read permissions when mounting a UNIX share using the anonymous user.

To grant write permissions, make a change to the Windows registry by performing the following steps:

1. Open `regedit` by typing it in the search box and pressing **Enter**.
 2. Create a new **New DWORD (32-bit) Value** inside the `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default` folder named `AnonymousUid` and `AnonymousGid` and assign the UID and GID found on the UNIX directory as shared by the NFS system.
- f. Restart the NFS client or reboot the machine to apply the changes.
 - g. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o anon usa-node01:/mapr z:
```

For more information, see step 2.

Windows 7 Enterprise

Complete the following steps for *Windows 7 Ultimate* or *Windows 7 Enterprise*

- a. Open **Start > Control Panel > Programs**.
- b. Select **Turn Windows features on or off**.
- c. Select **Services for NFS**.
- d. Click **OK**.
- e. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr z:
```

For more information, see step 2.

Other Versions of Windows

Complete the following steps for all other versions of Windows:

- a. Download and install Microsoft Windows Services for Unix (SFU). You only need to install the NFS Client and the User Name Mapping.

- b. Configure the user authentication in SFU to match the authentication used by the cluster (LDAP or operating system users). You can map local Windows users to cluster Linux users, if desired.
- c. Once SFU is installed and configured, mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr
z:
```

For more information, see step 2.

2. Map a network drive with the Map Network Drive tool.
 - a) Open **Start > My Computer**.
 - b) Select **Tools > Map Network Drive**.
 - c) In the Map Network Drive window, choose an unused drive letter from the **Drive** drop-down list.
 - d) Specify the folder by browsing for the MapR cluster, or by typing the hostname and directory into the text field.
 - e) Browse for the MapR cluster or type the name of the folder to map. This name must follow UNC. Alternatively, click **Browse...** to find the correct folder by browsing available network shares.
 - f) Select **Reconnect at login** to reconnect automatically to the MapR cluster whenever you log into the computer.
 - g) Click **Finish**.

3. Configure the UID and GID for NFS access.

System that is part of Active Directory Domain

For a system that is part of the Active Directory Domain, you must instruct the NFS client to access an AD server to get `uidNumber` and `gidNumber`.

- a. Ensure that the AD Users schema has auxiliary class `posixAccount`.
- b. Populate the AD `uidNumber` and `gidNumber` fields with the matching `uid` and `gid` from Linux.
- c. Configure the NFS client to look up `uid` and `gid` in the AD DS store.
- d. Refer to details here:
[http://technet.microsoft.com/en-us/library/hh509016\(v=ws.10\).aspx](http://technet.microsoft.com/en-us/library/hh509016(v=ws.10).aspx)

System not using Active Directory

For a standalone Windows 7 or Vista machine (not using Active Directory), Windows always uses its configured anonymous UID and GID for NFS access, which by default are `-2`. However, you can configure Windows to use specific values, which results in being able to access NFS using those values.

The UID and GID values are set in the Windows Registry and are global on the Windows NFS client box. This solution might not work well if your Windows box has multiple users who each need access to NFS with their own permissions, but there is no obvious way to avoid this limitation.

The values are stored in the registry path `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default`. The two DWORD values are `AnonymousUid` and `AnonymousGid`. If they do not exist, you must create them.

Refer to details here: <https://docs.microsoft.com/en-us/archive/blogs/msdn/sfu/can-i-set-up-user-name-mapping-in-windows-vista>.

4. (Optional) Deactivate the `nlockmgr` service.

If the `nlockmgr` service is active on a Windows machine, attempts to mount a HPE Ezmeral Data Fabric NFS share fail with the following message:

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr / g:
Network Error - 53
Type 'NET HELPMSG 53' for more information.
```

a) Run the `rpcinfo` command to confirm that the `nlockmgr` service is active.

```
C:\Users\administrator.Client1>rpcinfo -p ClusterNode1
program version protocol      port
-----
100000      4      tcp        111      portmapper
100024      1      udp       60588    status
100007      2      udp        817      ypbind
100021      1      udp       47016    nlockmgr
100021      3      udp       47016    nlockmgr
100021      4      udp       47016    nlockmgr
100021      1      tcp       34254    nlockmgr
100021      3      tcp       34254    nlockmgr
100021      4      tcp       34254    nlockmgr
```

b) Check the output for the presence of `nlockmgr`. To deregister `nlockmgr` services on the node, use the `-d` switch in `rpcinfo` on the HPE Ezmeral Data Fabric node.

```
rpcinfo -d 100021 1
rpcinfo -d 100021 2
rpcinfo -d 100021 3
rpcinfo -d 100021 4
```

- c) Re-check `rpcinfo` output to verify that no `nlockmgr` services are registered. The NFS mount completes successfully at this point.

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr/ Z:
Z: is now successfully connected to ClusterNode1:/mapr/
The command completed successfully.
```

Configuring Access When ACES are set

Some NFS clients, such as the Microsoft native Windows NFSv3 client, check mode bits to determine if access is allowed even before contacting the NFS server. If [ACEs](#) are set on a directory or file, the client-side permission checks based solely on mode bits prevent the client from accessing the file or directory. You can set the value for the `WindowsAceSupport` property to `true` in the `nfsserver.conf` on page 2491 file to allow the Windows client access to the file or directory. The default value for this property is `false`, and denies access to the client even before contacting the NFS server.

When the `WindowsAceSupport` property value is set to `true`, HPE Ezmeral Data Fabric returns mode bits 777 to the client if [ACE](#) is set on the file or directory, thus allowing the client to establish a connection to the server. However, when the client actually tries to read or write from the server, HPE Ezmeral Data Fabric performs permission checks against the mode bits and [ACEs](#) on the directory and/or file, ensuring proper access.

Note: When the `WindowsAceSupport` property value is set to `true`:

- Tools that visually display access information might show read/write access for users who do not have that access.
- Files that are not executables might appear executable.
- You cannot use the NFSv3 to access an NFSv4 server, because the NFSv4 server only supports the v4 protocol.

Configuring the Linux NFS Client

Describes how to set the optimal number of RPC requests to the NFS server.

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
```

2. To enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway, issue the following `echo` commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway. For example, the following commands unmount and mount NFS for the HPE Ezmeral Data Fabric assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

Note: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfssserver.log`:

```
ERROR nfssserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

Tip: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Accessing Data with NFS v4

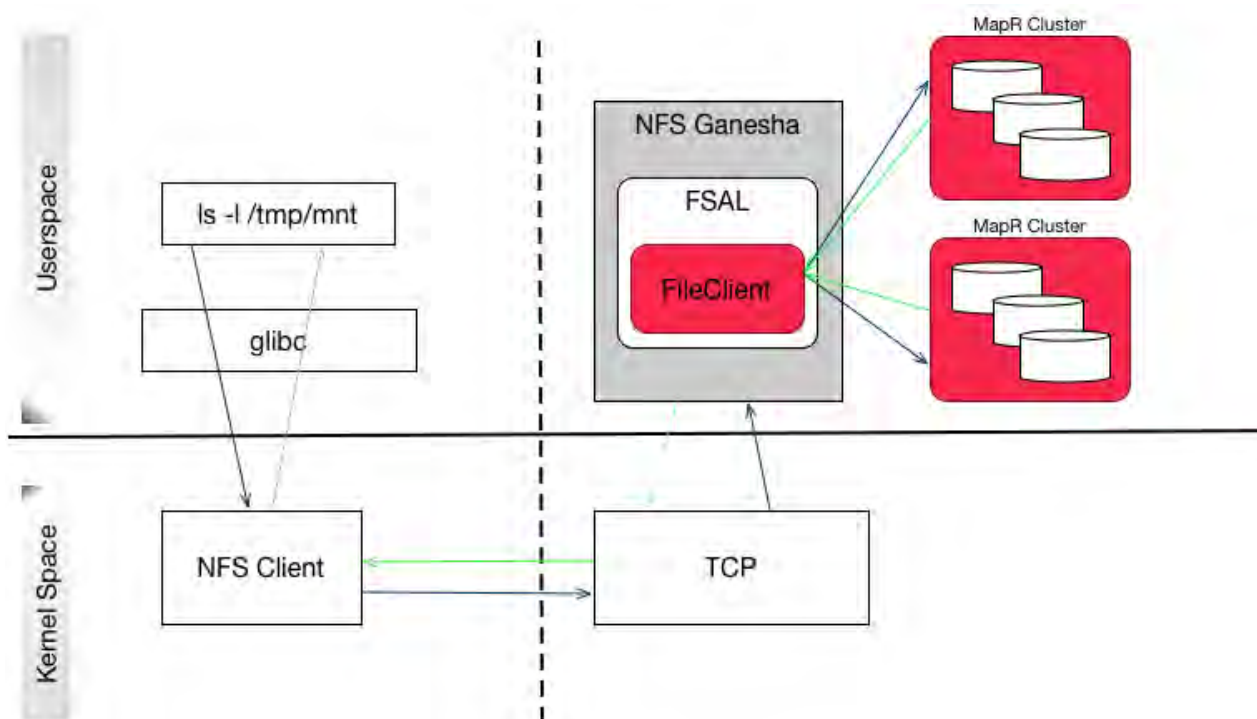

Describes how HPE Ezmeral Data Fabric works with the NFS v4 protocol. Presents an overview of the process flow to read and write HPE Ezmeral Data Fabric processes with NFS v4, and a list of NFS v4 features that HPE Ezmeral Data Fabric does not support.

HPE Ezmeral Data Fabric lets you mount the cluster using NFS v4 so that your applications can read and write data directly. HPE Ezmeral Data Fabric allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With an NFS v4-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS v4.

HPE Ezmeral Data Fabric uses NFS Ganesha for supporting NFS v4 features. NFS Ganesha is an Open Source userspace implementation of the NFS v4 server. MapR version 6.1 uses NFS Ganesha version 2.3, while HPE Ezmeral Data Fabric 6.2 uses an upgraded version 3.3 of NFS Ganesha.

The HPE Ezmeral Data Fabric NFS v4, running as a userspace process, registers callbacks with NFS Ganesha through the File System Abstraction Layer (FSAL), which is a shared library (`libfsalmapr.so`). NFS Ganesha loads and uses this library whenever the filesystem is exported/mounted. The FSAL, in turn, uses `FileClient (libMapRClient.so)` to connect to the cluster.

The following diagram illustrates how the HPE Ezmeral Data Fabric processes read and write operations to the HPE Ezmeral Data Fabric cluster using NFS v4. When the user enters a command (such as `ls`), the NFS client submits the request over TCP to the HPE Ezmeral Data Fabric NFS v4 server. The NFS v4 server uses the HPE Ezmeral Data Fabric `FileClient` to perform the requested operation on the cluster and returns the response to the NFS v4 client over TCP.

HPE Ezmeral Data Fabric exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v4 paths to the cluster are the same. This makes it easy to work on the same files using NFS v4 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

For NFS v4, HPE Ezmeral Data Fabric also requires alias or pseudo-path, which when specified masks the mount path from the NFS v4 client. HPE Ezmeral Data Fabric's NFS v4 server provides a pseudo-filesystem where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. For more information, see [NFS v4 RFC](#).

CAUTION: It is observed that NFS v4 clients are caching older `atime` values from previous history. Therefore, you might observe wrong `atime` values. To mitigate, make sure to clear caches, before checking file timestamps.

Unsupported NFS v4 Features

HPE Ezmeral Data Fabric does not currently support the following NFS v4 features:

- pNFS
- Delegations
- Mandatory locking
- Lock upgrades and downgrades
- Deny share
- [ACL](#)
- Namespaces
- Persistent reply cache

- Data retention
- Attributes such as `time_access`, `FATTR4_ARCHIVE`, `FATTR4_FILES_AVAIL`, `FATTR4_FILES_FREE`, `FATTR4_FILES_TOTAL`, `FATTR4_FS_LOCATIONS`, `FATTR4_MIMETYPE`, `FATTR4_QUOTA_AVAIL_HARD`, `FATTR4_QUOTA_AVAIL_SOFT`, `FATTR4_QUOTA_USED`, `FATTR4_TIME_BACKUP`, and `FATTR4_ACL`

Configuring NFSv4 Server

You can configure NFSv4 server by setting the values for the parameters in the `/opt/mapr/conf/nfs4server.conf` file. The configuration parameters are defined within blocks in the file. The following sections describe the blocks and required parameters (within each block) for the MapR NFSv4 server.

NFS_CORE_PARAM

Contains the general settings for the daemon. The parameters in this block should not be modified.

| | |
|---------------------------------------|--|
| <code>Clustered</code> | The value is <code>false</code> . Do not modify this parameter. |
| <code>Plugins_Dir</code> | The directory for the FSAL libraries. The value is <code>/opt/mapr/lib</code> . Do not modify this parameter. |
| <code>DRC_TCP_Size</code> | The maximum number of results stored in the DRC. The default value is 16. |
| <code>DRC_TCP_Recycle_Expire_S</code> | The amount of time after which to expire results stored in DRC. The default value is 60 seconds. |
| <code>Dirent_Entries_Track</code> | Specifies whether (<code>true</code>) or not (<code>false</code>) to monitor dirent entries. If <code>true</code> , the process restarts if the number of dirent entries exceeds limit. |
| <code>Num_Log_Files</code> | The maximum number of log files. The default value is 1. |
| <code>Max_Logfile_Size</code> | <p>The maximum amount of space for each log file. The default value is 1073741824. The total amount of disk space for log files is calculated using the following:</p> $\text{Num_Log_Files} * \text{Max_LogFile_Size}$ <p>For example, suppose <code>Num_Log_Files = 32</code> and <code>Max_LogFile_Size = 1GB</code>. Then, the total disk space for log files is 32GB.</p> |

| | |
|---------------|--|
| Enable_RQUOTA | Specifies whether (<code>true</code>) or not (<code>false</code>) to enable support for remote quotas. The default value is <code>false</code> . |
| NFS_Protocols | The supported NFS protocols. The only supported value is 4. |

NFSV4

Contains settings for NFSv4 protocol. The following parameter should not be modified.

| | | |
|------------------------|---------|---|
| Delegations | boolean | Specifies whether delegation is supported. The default value is <code>false</code> and should not be modified (cannot be set to <code>true</code>) as delegation is not supported. |
| Dirent_Cache_Threshold | 128 | The threshold for caching directory entries. If directory entries exceed threshold, the entries are not cached; caching is enabled only if entries are below this threshold.  Note: This should be used only if <code>readdir</code> plus is <code>true</code> . |

EXPORT_DEFAULTS

Contains default values for all subsequent EXPORT blocks. The settings in subsequent EXPORT blocks can override these default values on a per export basis.

| | |
|---------------|--|
| Anonymous_Uid | The anonymous UID. The default value is <code>-2</code> , which is converted to a 32 bit unsigned integer (4294967294) when <code>root</code> squash is enabled. |
|---------------|--|

| | |
|---------------|---|
| Anonymous_Gid | The anonymous GID. The default value is -2, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled. |
| Protocols | The supported NFS protocols. The default value is 4. This cannot be changed. |

EXPORT

Contains settings for exporting a filesystem.

| | |
|---------|---|
| SecType | <p>The comma-separated list of supported authentication flavors for the export or the type of security. Value can be comma-separated list of:</p> <ul style="list-style-type: none"> • krb5 — authentication • krb5i — integrity • krb5p — privacy <p> Note: This <i>must</i> be specified if you want the clients to use kerberos ticket for secure access.</p> |
| Path | <p>(Required) The (cluster) path to export via NFS. The path should have a leading slash. If just /mapr is specified as the path, all the clusters (listed in the <code>mapr-clusters.conf</code> file) will be visible. To export only a specific cluster, specify the complete path to the cluster to export.</p> <p> Note: Exporting will not be successful if extra forward slash (/) characters are in the path. For example, the following path will not be exported because of the extra slash (shown in bold) in the path: /mapr/Test3//ATS-VOLUME</p> |

| | |
|-----------|--|
| Pseudo | (Required for NFSv4 protocol for every directory or volume to export) The pseudo path, which when specified, masks the mount path from the NFS client, for the NFSv4 exports. MapR's NFSv4 server provides a pseudo-filesystem where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. When mounting with NFSv4, use the pseudo path. Value can be the volume or directory path. |
| Export_Id | (Required) The tag used to set the ID for the export or the unique ID to associate with each export. Value should not be 0.  Note: The export ID associated with each export must be the same across all NFSv4 servers on the cluster. |
| Clients | The list of clients these export permissions apply to. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients. |

| | |
|-------------|---|
| Squash | Specifies whether to enable or disable root squashing. By default, root squashing is disabled. If root squashing is enabled, the values substituted for the root user will be anonymous user (<code>Anonymous_Uid</code> and <code>Anonymous_Gid</code>); that is, the UID and GID of a file created will not be <code>nfsnobody</code> because the default value of -2 is converted to a 32 bit unsigned integer (4294967294) instead of the 16 bit equivalent (65534), which is the value of <code>nfsnobody</code> . |
| Access_Type | (Required) The type of access on the mount point. Valid values include: <ul style="list-style-type: none"> • RO — for read-only mount point • RW — for read/write mount point • MDONLY — for read/write access to metadata only • MDONLY_RO — for read-only access to metadata only |
| FSAL | (Required) The filesystem to use. Value must be MAPR to use the filesystem <code>libfsalmapr.so</code> library, which contains the shared library (<code>libMapRClient</code>) and the callbacks. |

LOG

Contains configuration for logging. The default log level is INFO. Value can be one of the following:

- FATAL
- MAJ
- CRIT
- WARN
- EVENT
- INFO

- DEBUG
- MID_DEBUG
- FULL_DEBUG

MAPRFS

Contains configurations for NFS gateway access to MapR filesystem.

| Parameter | Default Value | Description |
|-------------|-------------------------|---|
| log_path | /opt/mapr/ logs/nfs4 | Path for the log files. |
| ra_sessions | 5 | <p>Number of parallel read ahead sessions per client library (libMapRClient.so). Each open file acts as one read ahead session. For example, if value is set to 5, up to 5 files can have read ahead sessions per client library (libMapRClient.so). To disable read ahead sessions, set value to 0.</p> <p> Note: The number of client libraries is 3 by default and cannot be configured.</p> |

| Parameter | Default Value | Description |
|---------------------|---------------|--|
| flush_inline | true | <p>Specifies whether or not to flush all writes inline. Value can be:</p> <ul style="list-style-type: none"> • true — flush all writes inline • false — disable inline flushing <p>If enabled (default), writes are sent to server directly. If disabled, for all open files, the buffer is flushed automatically every 3 seconds or when it reaches 64KB.</p> |
| fast_local_directio | false | <p>Specifies whether to optimize or disable NFS client for local direct IO. Value can be:</p> <ul style="list-style-type: none"> • true — optimize • false — disable |
| nfs_track_memory | false | <p>Specifies whether to enable (true) or disable (false) memory tracking for NFS.</p> |

| Parameter | Default Value | Description |
|---------------|---------------|---|
| hb_interval | 5 | The interval (in seconds) for sending heartbeat to CLDB to allow CLDB to determine whether server is running. The CLDB will declare the NFS gateway dead when it loses about 8 heartbeats in a row and will trigger a failover. |
| req_threshold | 5 | The amount of time (in seconds) for processing requests. If the threshold is exceeded, warnings will be logged. |

| Parameter | Default Value | Description |
|-----------------|---------------|---|
| client_lib_path | /tmp/nfs4 | <p>The location for the client library (libMapRClient).</p> <p> Note: To install and use NFSv4 and FUSE-based POSIX client on the same node, ensure that the path for the client library for the NFSv4 and FUSE-based POSIX client is not /tmp. Specify a different location for the client libraries. For example, /tmp/nfs4lib.</p> |
| readdirplus | true | <p>Specifies whether (<code>true</code>) or not (<code>false</code>) to enable extended read from the directory. If enabled (<code>true</code>), each entry returns the name, the file ID, attributes (including the field), and file handle.</p> |

**Note:**

- The `libnfsidmap` must be configured to use `nsswitch`, a translation mechanism for mapping names to IDs, in the `/etc/idmapd.conf` file.
- The NFSv3 (`mapr-nfsserver`) nodes cannot failover to NFSv4 server nodes and vice versa. Ensure that different set of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary if both NFSv3 and NFSv4 are going to be set up for same cluster). The MACs should be mutually exclusive as both NFSv4 and NFSv3 servers cannot run on the same node.

Sample Configurations

You can refer to the following sections, which contain blocks for the various required configurations using sample values.

Configuration for Supported NFS Protocols

To specify the supported NFS protocols, set the value for the `NFS_Protocols` parameter in the `/opt/mapr/conf/nfs4server.conf` file. For example, for NFSv4 protocol, in the `/opt/mapr/conf/nfs4server.conf` file, set the value for the `NFS_Protocols` parameter as shown (in bold) below.

```
NFS_CORE_PARAM
{
    Plugins_Dir = /opt/mapr/lib;
    NFS_Protocols = 4;
    Clustered = false;
}
```

Note: The only supported protocol is 4.

For NFSv4, the `showmount` command does not return the list of exported NFS shares.

Configuration for Mounting the Cluster

Add the `MAPRFS` block in the `/opt/mapr/conf/nfs4server.conf` file as shown below.

```
MAPRFS
{
    #Directory path where nfsv4 logs should be stored
    log_path = /opt/mapr/logs/nfs4;

    #Set number of readahead sessions
    ra_sessions = 5;

    #Flush all writes inline
    flush_inline = true;

    #Optimize for local direct writes
    fast_local_directio = false;

    #Set security ticket file
    tkt_location = /tmp/maprticket_XXX;

    #Hearbeat interval for NFSv4 (in seconds)
    hb_interval = 5;

    #Request threshold, logs warning if any request takes more time (in
    seconds)
```

```

req_threshold = 5;
}

```

Configuration for Exporting the File System

Modify the `EXPORT` block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below. The following sample block shows a standard configuration where the exported path and the actual path are the same.

```

EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /mapr;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
    Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
    FSAL {
        Name = MAPR;
    }
}

```

Note: If you change anything in the export block, restart NFSv4 service and remount the path.

Configuration for Pseudo Path

To mask the path to the volume from the client, set the pseudo path. For the pseudo path, you can specify a value that is different from the path parameter to hide the true path name. To hide the full path to volumes and/or directories, specify the complete path in the `EXPORT` block.

For example, modify the `EXPORT` block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below to mask the path and show only the name of the volume to the client. Note that the following sample block shows a pseudo path that is different from the exported path.

```

EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /vol1;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead

```

```

    Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
    FSAL {
        Name = MAPR;
    }
}

```

Configuration for Security

The NFS client to NFS Server can be secured using Kerberos. Before configuring Kerberos to work with MapR, modify the `/opt/mapr/conf/nfs4server.conf` file to specify the security type. For example, modify the `EXPORT` block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below.

```

EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /voll;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
    Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
    FSAL {
        Name = MAPR;
    }
}

```

The NFSv4 server uses the ticket in `/opt/mapr/conf` directory, if it is present, to secure communication between the NFS server and the MapR cluster.

Configuration for Clients

You can add a client block to the NFSv4 server configuration specifying the list of clients to which the export permissions apply. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients. For example:

```

EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;
}

```

```

# Pseudo Path (required for NFS v4)
Pseudo = /mapr;

# Defining the clients who are allowed to export
CLIENT
{
# Required for access (default is None)
Clients=192.168.0.10, 192.168.1.0/8;
Access_Type = RW;
Squash = No_root_squash;
SecType=krb5;
}
# Exporting FSAL
FSAL{
    Name = MAPR;
}
}

```

Configuration for NFS Ganesha Debug Logging

Add the following block in the `/opt/mapr/conf/nfs4server.conf` file.

```

LOG {
    COMPONENTS {
        ALL = DEBUG;
    }
}

```

Default NFSv4 Server Configuration File

The `nfs4server.conf` file is available in `/opt/mapr/conf` directory.

```

Configuring NFSv4 Server for Kerberos

Describes how to configure and use NFSv4 on Kerberos.

You can configure data-fabric NFSv4 server to use Kerberos-based authentication. Data Fabric supports configuration of [NFSv4 server for Kerberos with Active Directory server](#) and Kerberos with LDAP. You can also configure data-fabric NFSv4 server to work with [other Kerberos installations](#). Before configuring data-fabric NFSv4 server for Kerberos, you must have performed the following:

- Installed packages for Kerberos server.
- Installed NFSv4 server. See [Installing NFS for the HPE Ezmeral Data Fabric](#) on page 337 for more information.
- Installed packages for Kerberos client.

Note: The steps in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

Configure NFSv4 Server for Kerberos with Active Directory Server

The following procedure describes how to configure the data-fabric NFSv4 server to work with the Kerberos available with Active Directory server. Before configuring the data-fabric NFSv4 server, ensure

that Active Directory server is installed and all the nodes on the cluster have joined that Active Directory server. The following procedure requires the NFSv4 server to run under user `mapr` and group `maprgrp`.

1. In an Active Directory server environment, join the cluster nodes to the Active Directory server. Follow the sample procedure [here](#) or consult with your system administrator for assistance with installing and joining the nodes to Active Directory server.
2. Check if Kerberos tickets for host and NFS service principal are present, by running the following command:

```
# klist
klist: No credentials cache found (filename: /tmp/krb5cc_0)
```

3. Ensure host principal is available by checking to see if existing keys are present on the node. For example, when you run the following command, the output should look similar to the following output for `nfs4ad.com` domain:

```
# klist -kt
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp Principal
-----
2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
```

4. Generate the host ticket by running the `kinit` command.

For example:

```
[root@atsqa4-161 ~]# kinit -k ATSQA4-161$
[root@atsqa4-161 ~]# klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: ATSQA4-161$@NFS4AD.COM
Valid starting Expires Service principal
04/11/2018 03:04:38 04/11/2018 13:04:38 krbtgt/NFS4AD.COM@NFS4AD.COM
renew until 04/18/2018 03:04:38
```

5. Add NFS service principal entry for the host in the AD server by running the `setspn` command. For example, for `nfs4ad.com` domain, run the following command:

```
C:\Users\Administrator>setspn -A nfs/atsqa4-161.nfs4ad.com mapr
Checking domain DC=nfs4ad,DC=com
Registering ServicePrincipalNames for CN=mapr,CN=Users,DC=nfs4ad,DC=com
nfs/atsqa4-164.nfs4ad.com
Updated object
```

6. Get the latest service ticket for the host from the AD server by running the `kvno` command. For example:

```
# kvno nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM: kvno = 46
kvno nfs/qa108-43.nfs4ad.com@NFS4AD.COM
```

7. Add entry for NFS service principal key in the Kerberos keytab file, `/etc/krb5.keytab`:

```
# ktutil
ktutil: addent -password -p nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM -k
46 -e RC4-HMAC
Ex: addent -password -p nfs/qa108-43.nfs4ad.com@NFS4AD.COM -k 46 -e
RC4-HMAC
Password for nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM:
( Give mapr user password i.e nfs4AD123 )
ktutil: l
slot KVNO Principal
-----
      1      46      nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
ktutil: wkt /etc/krb5.keytab
ktutil: q
```

8. Verify that NFS service principal and host principal are in the `/etc/krb5.keytab` file by running the `klist` command.

For example, for domain `nfs4ad.com`, run the following command and verify the entries in the file:

```
# klist -kt /etc/krb5.keytab
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp                Principal
-----
4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
4 08/01/2018 00:29:21 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
4 08/01/2018 00:29:21 host/ATSQA4-161@NFS4AD.COM
4 08/01/2018 00:29:21 ATSQA4-161$@NFS4AD.COM
4 08/01/2018 00:29:21 ATSQA4-161$@NFS4AD.COM
4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
46 08/01/2018 02:58:01 nfs/atsqa4-161.nfs4ad.com@NFS4AD.COM
```

9. Ensure that `/etc/krb5.keytab` file is owned by user `mapr` and if necessary, change ownership to user `mapr`.

For example:

```
[root@qa108-41 ~]# chown mapr:root /etc/krb5.keytab
[root@qa108-41 ~]# ls -l /etc/krb5.keytab
-rw----- 1 mapr root 4175 Jul 22 23:53 /etc/krb5.keytab
```

10. Restart the `rpcgssd` service on the host to establish GSS security contexts.

CentOS

```
service rpcgssd start
```

Ubuntu

```
service gssd restart
```

11. Enable security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.

For example:

```
# Security type (krb5,krb5i,krb5p)
SecType = krb5;
```

12. Start the NFSv4 server.

For more information, see [Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4](#) on page 1335.

13. List the shares exported on the server by running `showmount -e` command.

If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

14. Ensure that the `list-exports` command runs successfully.

For example:

```
# maprcli nfs4mgmt list-exports
Export Id      Path
30             /mapr
0              /
```

15. (Troubleshooting) Run the following command to restart the services if you see security-related issues.

CentOS

```
maprcli node services -nfs4
stop -nodes `hostname` ; service
rpcgssd restart; sleep 1; service
rpcbind restart ; sleep 1;
service nfs restart ; service
nfs stop ; sleep 2; maprcli
node services -nfs4 start -nodes
`hostname`
```

Ubuntu

```
maprcli node services -nfs4
stop -nodes `hostname` ; service
gssd restart; sleep 1; service
rpcbind restart ; sleep 1; service
nfs-kernel-server restart ; service
nfs-kernel-server stop ; sleep
2; maprcli node services -nfs4
start -nodes `hostname`
```

16. Set up VIPs for the NFSv4 servers:

- a) Add entries for IPs and names of VIPs in the `/etc/hosts` file on the NFSv4 server host first and then on the AD server host.

For example:

```
10.10.88.14 nfsvirtualip1
10.10.88.15 nfsvirtualip2
```

- b) Add NFS service principal for the virtual IP by running the `setspn` command.

For example:

```
C:\Users\Administrator>setspn -A host/nfsvirtualip1 nfsserver
C:\Users\Administrator>setspn -A nfs/nfsvirtualip1 nfsserver

C:\Users\Administrator>setspn -A host/nfsvirtualip2 nfsserver
C:\Users\Administrator>setspn -A nfs/nfsvirtualip2 nfsserver
```

- c) Restart the `rpcgssd` service on the host to re-establish GSS security contexts.

For example:

```
service rpcgssd restart
```

Configuring NFSv4 Server for Other Kerberos Installations

1. Configure NFS server for Kerberos.

Consult with your system administrator for assistance with the commands for configuring the NFS server for Kerberos-based authentication. For example, you must do the following:

- Create a service principal with `nfs` as the service name.

For example: `nfs/host.domain.com@REALM`

- Generate a keytab for the NFS service principal, store it in the `/etc/krb5.keytab` file, and set correct permissions on the file.

2. Enable the security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.

For example:

```
# Security type (krb5,krb5i,krb5p)
SecType = krb5;
```

3. Start the NFSv4 server.

For more information, see [Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4](#) on page 1335.

4. List the shares exported on the server by running `showmount -e` command.

If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

5. Ensure that the `list-exports` command runs successfully.

For example:

```
# maprcli nfs4mgmt list-exports
Export Id      Path
30             /mapr
0              /
```

Configuring NFSv4 Client

1. Ensure that NFS client has a `/etc/krb5.keytab` file with a valid principal similar to one of the following: `nfs/<client_fqdn>@<domain>@<REALM>`, `host/<client_fqdn>@<domain>@<REALM>`, or `<HOSTNAME>@$@<REALM>`.

If the principal is not present, create the `keytab` file with the principal, which will be used to mount the share, for the OS (as mentioned in the OS vendor documentation).

2. Mount the cluster by running the `mount` command.

For example:

```
mount -t nfs4 -o sec=<security-type> <nfs4-server-hostname>:/
<pseudo-path> <mount-point>
```

For example:

```
# mount -t nfs4 -o sec=krb5 <FQDN>:/mapr /mnt/nfs4mnt
```

3. Generate user ticket for the user to access the mount path.

For example, for user `mapr` on domain `nfs4ad.com`, run one of the following commands to generate the ticket:

- ```
kinit mapr@NFS4AD.COM
<Enter password>
```

- ```
echo usr2AD123 | kinit user2@NFS4AD.COM
```

Note: You must renew the user ticket before it expires; otherwise, the mount path returns permissions denied error after the ticket expires.

4. (Troubleshooting) Restart the services and mount again to avoid security-related issues.

CentOS

```
service rpcgssd restart; sleep 1;
service rpcbind restart ; sleep 1;
service nfs stop
```

Ubuntu

```
service rpcgssd restart; sleep 1;
service rpcbind restart ; sleep 1;
service nfs stop
```

Troubleshooting: Any running IO on NFSv4 mount (with Kerberos) is stuck if the `krb5` ticket expires for the current user. The mount point also hangs and becomes inaccessible.

Workaround: Restart the `rpcgssd` service with the new ticket to make the mount point accessible and re-trigger the IO to proceed.

Configuring NFSv4 Server Without Kerberos

To start using NFSv4 server without Kerberos, do the following:

1. Start the NFSv4 server.

For more information, see [Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4](#) on page 1335.

2. Verify that the `list-exports` command runs successfully.

For example:

```
# maprcli nfs4mgmt list-exports
Export Id      Path
30             /mapr
0             /
```

3. Mount the cluster by running the `mount` command.

For example:

```
mount -t nfs4 <nfs4-server-hostname>:/<pseudo-path> <mount-point>
```

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4

Describes how to start, stop and restart the NFS version 4 service using either the Control System, the CLI, or the REST API.

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 Using the Control System

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 907
- [Stopping a Service on the Cluster Using the Control System](#) on page 908
- [Restarting the Services on the Cluster Using the Control System](#) on page 909

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 Using the CLI and REST API

Note: On Ubuntu 20, run the following commands before starting NFSv4, Else, NFS fails to start as it cannot find the jemalloc library.

```
apt-get install libjemalloc2

ln /usr/lib/x86_64-linux-gnu/libjemalloc.so.2 /opt/mapr/lib/
libjemalloc.so.1
```

CLI

To stop, start, or restart the HPE Ezmeral Data Fabric NFSv4 server, run:

```
maprcli node services -nodes <node
names> -nfs4 stop|start|restart
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<host>:8443/rest/node/
services?nodes=<nodeName>&nfs4=stop|
start|restart' --user mapr:mapr
```

Note: When the NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers.

For the complete list of parameters, see [node services](#) on page 1939.

Mounting NFS on a Linux Client

Describes how to mount a NFS server on a Linux client.

You can manually mount NFS on a Linux client when your system starts up.

Note: On nodes running CentOS, use the VIP for mounting because, by default, the mount command will use the physical IP of the node.

1. List the NFS shares exported on the server.

For example, run the following command for NFS version 4 servers:

```
/opt/mapr/server/nfs4mgr list-exports
```

If the NFS protocol is not version 4 only, use the `showmount` command to retrieve the list of exported NFS shares. For example:

```
showmount -e usa-node01
```

2. Mount the cluster using NFS.

For example:

```
mount -t nfs4 -o sec=krb5 usa-node01:/<psuedo_mapr> /mapr
```

Tip: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs4 -o sec=krb5,vers=4.0 usa-node01:/<psuedo_mapr> /mapr
```

Note: When you mount manually from the command line, the mount point does not persist after a reboot.

Configuring the Linux NFS Client

Describes how to set the optimal number of RPC requests to the NFS server.

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
```

2. To enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway, issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

- Remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway. For example, the following commands unmount and mount NFS for the HPE Ezmeral Data Fabric assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

Note: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfsserver.log`:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

Tip: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Advisory Locking in NFS v4

Explains NFS v4 support for Advisory Locking.

Data Fabric NFS v4 service includes support for (advisory) file locking. Data Fabric keeps track of the locks on a file in the NFS for the HPE Ezmeral Data Fabric gateway, but does not prevent a client process from writing to a file that is locked by another process. The locks are not shared with other NFS for the HPE Ezmeral Data Fabric gateways. Since the locks are enforced locally, it is the responsibility of the client process to check for write locks on a file before attempting to perform write operations on the file.

To ensure that a file is locked and not available for changes by other processes and to ensure that the lock on a file by a process is honored by other processes, add a program similar to the following for the process.

Sample Program Description

The following program demonstrates how to open a file, check if the file has a write lock, and wait if another process currently has locked the file.

Before running this application, ensure that you have access to a cluster running filesystem.

Opens a file

```
if (argc > 1) {
    int fd
    = open(argv[1],
    O_WRONLY);
    if(fd == -1)
    {
        printf("Unable
        to open the
        file\n");
        exit(1);
    }
}
```

Checks if the file is locked for a write operation

```
lock.l_type
= F_WRLCK;
lock.l_start
= 0;
```

```
lock.l_whence =
SEEK_SET;
    lock.l_len =
0;
    lock.l_pid =
getpid();
```

Gets lock, else waits

```
int ret
= fcntl(fd,
F_SETLKW,
&lock);

printf("Return
value of
fcntl:%d\n",ret);
if(ret==0) {
    while (1) {

scanf("%c",
NULL);
    }
}
```

Sample Program Code

```
#include <stdio.h>
#include <fcntl.h>

int main(int argc, char **argv) {
    if (argc > 1) {
        int fd = open(argv[1], O_WRONLY);
        if(fd == -1) {
            printf("Unable to open the
file\n");
            exit(1);
        }
        static struct flock lock;

        lock.l_type = F_WRLCK;
        lock.l_start = 0;
        lock.l_whence = SEEK_SET;
        lock.l_len = 0;
        lock.l_pid = getpid();

        int ret = fcntl(fd, F_SETLKW,
&lock);
        printf("Return value of
fcntl:%d\n",ret);
        if(ret==0) {
            while (1) {
                scanf("%c", NULL);
            }
        }
    }
}
```

NFSv4 Troubleshooting**Issues with listing the exports:**

If `nfs4mgr list-exports` command returns the error, Error

org.freedesktop.DBus.Error.ServiceUnknown: The name org.ganesha.nfsd was not provided by any .service files, do the following to resolve the error:

1. Open the `/etc/dbus-1/system.conf` file.
2. Find and replace the following in the file:
 - a. Find:

```
<deny
send_destination="org.freedesktop.DBus"

send_interface="org.freedesktop.DBus"

send_member="UpdateActivationEnvironment"/>
```

- b. Replace with:

```
<!-- Allow anyone to talk to
the message bus -->
<allow
send_destination="org.freedesktop.DBus"/>
<!-- But disallow some
specific bus services -->
<allow send_interface="*" />
<allow receive_interface="*" />
<allow own="*" />
```

3. Save and close the file.
4. Restart the messagebus and NFSv4 service.

To restart the messagebus service, run the following command:

```
service messagebus restart
```

To restart NFSv4 service, see [Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4](#) on page 1335.

Lock expires as a result of problems in node connection or node failover:

If the lock expires as a result of problems in node connection or node failover, all IOs from the application will fail with EIO message to prevent the file from getting corrupted. You can tune the kernel to reclaim lost locks and not fail writes on lock lease expiration. To tune the kernel, run the following command:

```
echo Y > /sys/module/nfs/parameters/
recover_lost_locks
```

Warning: This kernel tuning this might result in data corruption.

User ID mapping is not working when NFSv4 server and client are in two different sub-domains:

If user ID (with FQDN user names) mapping is not working with the installed `libnfsidmap` library (for example, `libnfsidmap-0.25-19` on CentOS), do the following:

1. Download the latest `libnfsidmap` library for the OS.
For CentOS:
 - a. Download the library source with the patches.
 - b. Apply the patches till `libnfsidmap-0.25-dns-resolved.patch`.
 - c. Build the new library.
2. Stop NFSv4 service and replace the old library with the new library.
3. Replace the old `nsswitch.so` file with the new `nsswitch.so` file that is compiled.
4. Restart `rpcidmapd` service and NFSv4 service.

NFS Ganesha crashes when unmounting the cluster:

NFS Ganesha crashes when unmounting the cluster as a non-root user. Download and install the following Kerberos 16 package:

- `sssd-krb5-common-1.16.0-19.el7.x86_64`
- `sssd-krb5-1.16.0-19.el7.x86_64`

Discover realm command fails:

If the `realm discover` command fails with following error: `realm: Couldn't connect to realm service: Error calling StartServiceByName for org.freedesktop.realmd: GDBus.Error:org.freedesktop.DBus.Error.TimedOut: Activation of org.freedesktop.realmd timed out`, reboot the node and add Active Directory information in the `/etc/resolv.conf` again. For example, your entry in the `/etc/resolv.conf` file should look similar to the following:

```
# cat /etc/resolv.conf
nameserver 10.10.111.41
domain nfs4ad.com
search nfs4ad.com lab qa.lab
scale.lab perf.lab ipmi.lab
```

Unable to start the service:

If you or the warden is unable to restart the NFS service, do the following:

1. Review the warden logs (in `$MAPR_HOME/logs/warden.log` file) to determine when the [NFSv4 Service Alarm](#) on page 2518 was raised.

2. Review the following NFSv4 server logs in `$MAPR_HOME/logs/nfs4/nfs4server.log-0` and `$MAPR_HOME/logs/nfs4/fsal.log-0`, and other logs under `$MAPR_HOME/logs/nfs4` on the node where the service went down to determine the cause for the error.

The following example logs show some common causes for NFSv4 service shutting down such as license not present or an issue in the configuration.

```

3. Take corrective action to rectify the cause for the error.

Viewing the List of NFS Servers

Explains how to view the list of NFS servers using the Control System.

- Log in to the Control System and go to the [service information page](#) for CLDB.

The **Active NFS Servers** section displays the following:

| Column Name | Column Description |
|----------------|--|
| Server ID-HEX | The server's ID in hexadecimal notation. |
| Server ID | The server's ID in decimal notation. |
| Host Port | The IP address of the NFS server host. |
| Hostname | The hostname of the NFS server host. |
| Last heartbeat | The timestamp for the last received heartbeat. |

| Column Name | Column Description |
|-------------|--|
| State | The status of the NFS server. Value can be: <ul style="list-style-type: none"> Active |

Handling Heavy Write Loads on Red Hat Enterprise Linux

Describes a fix to mitigate resource contention between NFS Clients and the NFS Server on Red Hat Linux.

If you are operating on RHEL and have a heavy NFS write load, you might experience resource contention between the NFS client and the NFS server. This resource contention can cause the NFS server to be unresponsive. To avoid this potential problem, try one of following approaches. These approaches work on all versions of Red Hat (5.x, 6.x and 7.x).

- Edit `/etc/sysctl.conf` and apply these settings on each NFS server:

```
vm.dirty_ratio=10
vm.dirty_background_ratio=5
```

Reboot the server so the changes will take effect. To make the settings take effect immediately, issue the `echo` command as shown:

```
% echo 10 > /proc/sys/vm/dirty_ratio
% echo 5 > /proc/sys/vm/dirty_background_ratio
```

- Separate the NFS client from the NFS server so they do not compete for memory on the same system.

Configure NFS Write Performance

Describes how to set the optimal value for outstanding Remote Procedure Call (RPC) requests to the NFS server.

The default Remote Procedure Call (RPC) requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128, for optimal performance. The NFS client uses this value to determine when to send requests to the NFS server, along with the number of parallel requests to send.

- If the value is too small, the NFS client does not send many parallel requests. This scenario results in decreased performance.
- If the value is too high, the NFS client sends a lot of parallel requests, but the NFS server discards some requests, as it has a limit on the number of requests it can handle. This scenario causes the NFS client to resend the requests, and negatively affects performance.

The kernel tunable value `sunrpc.tcp_slot_table_entries` represents the number of simultaneous RPC requests. The default value of this tunable is 16 (on Red Hat versions prior to version 6.3). On Red Hat versions 6.3 and above, the default value of this tunable is set at 65536. Increasing or decreasing this value to 128 (depending on the Red Hat version in use), may improve write speeds. Use the command `sysctl -w sunrpc.tcp_slot_table_entries=128` to set the value. Add an entry to your `sysctl.conf` file to make the setting persist across reboots.

Perform the following steps as the root user, on each NFS client machine:

1. Issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration. These commands enable the configuration to persist after a reboot of the NFS client machine.

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
```

2. Issue the following `echo` commands. These commands enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway.

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway. Mount the data-fabric NFS server with a `rsize` and `wsize` of 128K, as this value significantly cuts down NFS server requests for a given transfer, and improves the overall performance. For example, the following commands unmount and mount the NFS server, assuming that the cluster is mounted at `/mapr`.

```
umount /mapr
mount -o nolock,rsize=131072,wsize=131072 <hostname>:/mapr /mapr
```

4. After rebooting the node, if the `/proc/sys/sunrpc` directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service, using the following command: `service rpcidmapd start`.

Failure to set this tunable to an optimum value, may result in the following error in the `/opt/mapr/logs/nfsserver.log` file:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot
allocate more OncRpcContexts: [numDropped=2556001] dropping connection from
nfs=10.13.64.225:0
```

NFS for the HPE Ezmeral Data Fabric write performance varies between different Linux distributions. The recommended value of this tunable may have no effect, or even a negative effect on your particular cluster.

Adjusting NFS Memory Settings

The memory allocated to each MapR service is specified in the `/opt/mapr/conf/warden.conf` file, which MapR automatically configures based on the physical memory available on the node. You can adjust the minimum and maximum memory used for NFS, as well as the percentage of the heap that it tries to use, by setting the `percent`, `max`, and `min` parameters in the `warden.conf` file on each NFS node.

Example:

```
...
service.command.nfs.heapsize.percent=3
service.command.nfs.heapsize.max=1000
service.command.nfs.heapsize.min=64
...
```

The percentages need not add up to 100; in fact, you can use less than the full heap by setting the `heapsize.percent` parameters for all services to add up to less than 100% of the heap size. In general, you should not need to adjust the memory settings for individual services, unless you see specific memory-related problems occurring.

Running NFS on a Non-standard Port

1. To run NFS on an arbitrary port, modify the following line in `warden.conf`:

```
service.command.nfs.start=/etc/init.d/mapr-nfssserver start
```

Add `-p <portnumber>` to the end of the line, as in the following example:

```
service.command.nfs.start=/etc/init.d/mapr-nfssserver start -p 12345
```

2. After modifying `warden.conf`, restart the MapR NFS server by issuing the following command:

```
maprcli node services -nodes <nodename> -nfs restart
```

3. You can verify the port change with the `rpcinfo -p localhost` command.

Warning: MapR uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS version 3.

Enabling Debug Logging for NFS Using the CLI

Debug-level logging is available to help you isolate and identify NFS-related issues.

Enabling Debug Logging for NFSv3

1. To enable logging at the debug level, enter this command at the command line:

```
maprcli trace setlevel -port 9998 -level debug
```

where `-port 9998` indicates NFS.

Warning: The debug log level provides much more information than the default log level of `info`.

2. In default mode, information is logged to a buffer and dumped periodically. To display information immediately instead, enable continuous mode by entering:

```
maprcli trace setmode -port 9998 -mode continuous
```

Sample log output from an `ls` command is shown here:

From `/opt/mapr/logs/nfssserver.log`:

```

2013-06-10 16:13:28,9432 DEBUG nfsserver[30283] fs/nfsd/
nfsserver.cc:1022 127.0.0.1[0x6a349889] NFS FileHandle:
0.3410106368.2535.16.2
2013-06-10 16:13:28,9432 DEBUG nfsserver[30283] fs/nfsd/cache.cc:659
127.0.0.1[0x6a349889] Sending CLDB Lookup for cid=3410106368.2535
(sleep=0) ip= cldb=10.10.80.41:7222

```

The log shows every operation sent to and received from an NFS client.

3. To return to the default log level and log mode, enter:

```

maprcli trace setlevel -port 9998 -level default
maprcli trace setmode -mode default

```

Enable Debug Logging for NFSv4

1. Modify `core-site.xml` file to add the following:

```

<property>
  <name>fs.mapr.trace</name>
  <value>DEBUG</value>
  <description> </description>
</property>

```

2. Save and close the file.

Run the `/opt/mapr/server/nfs4mgr` command for debugging NFS Ganesha.

Unmounting the MapR Cluster from the Command-Line

- To unmount the MapR cluster, run the `umount` command.

For example, to unmount the cluster in `/mapr`, run the following command:

```
umount /mapr
```

If a process is busy on the mount point, the `umount` command will fail. To unmount the cluster after the process completes, run the following command:

```
umount -l /mapr
```

Managing Data Fabric POSIX Clients

Provides a brief synopsis of data-fabric POSIX clients.

The data-fabric POSIX clients allow app servers, web servers, and other client nodes and apps to read and write data directly and securely to a data-fabric cluster. The following topics describe the steps for configuring and managing loopback NFS POSIX and FUSE-based POSIX clients.

Apart from the clients that are EOL, all others are supported. However, newer clients might have features that may not be supported in older clients.

Difference between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients

The following table summarizes the differences between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients:

| | Data Fabric POSIX Loopback NFS Client | Data Fabric FUSE-based POSIX Basic/Platinum Client |
|----------------------------------|---|---|
| Throughput | <ul style="list-style-type: none"> 500MB/s for remote read/write 1G/s for local read/write | Greater than 2G/s for remote and local read/write |
| Client OS | Supported Linux and Ubuntu distributions only. | |
| Installs On Node Type | <ul style="list-style-type: none"> Client node Cluster node | |
| Access to Cluster | Must have direct network access to all data-fabric cluster nodes. | Must have direct network access to all data-fabric cluster nodes. However, each client only supports up to 16 clusters. |
| Connection to File System | <ul style="list-style-type: none"> Proxied on host to regular data-fabric client traffic Direct, no NFS for the HPE Ezmeral Data Fabric gateway No single point of failure | |
| Security | Fully secured. | |
| Caching | Buffered writes are cached in the kernel. | Buffered writes are cached (only in kernel \geq 3.15) if writeback option is enabled. |

HPE Ezmeral Data Fabric loopbacknfs POSIX Client

Explains the differences between the HPE Ezmeral Data Fabric POSIX client and the Linux native NFS client.

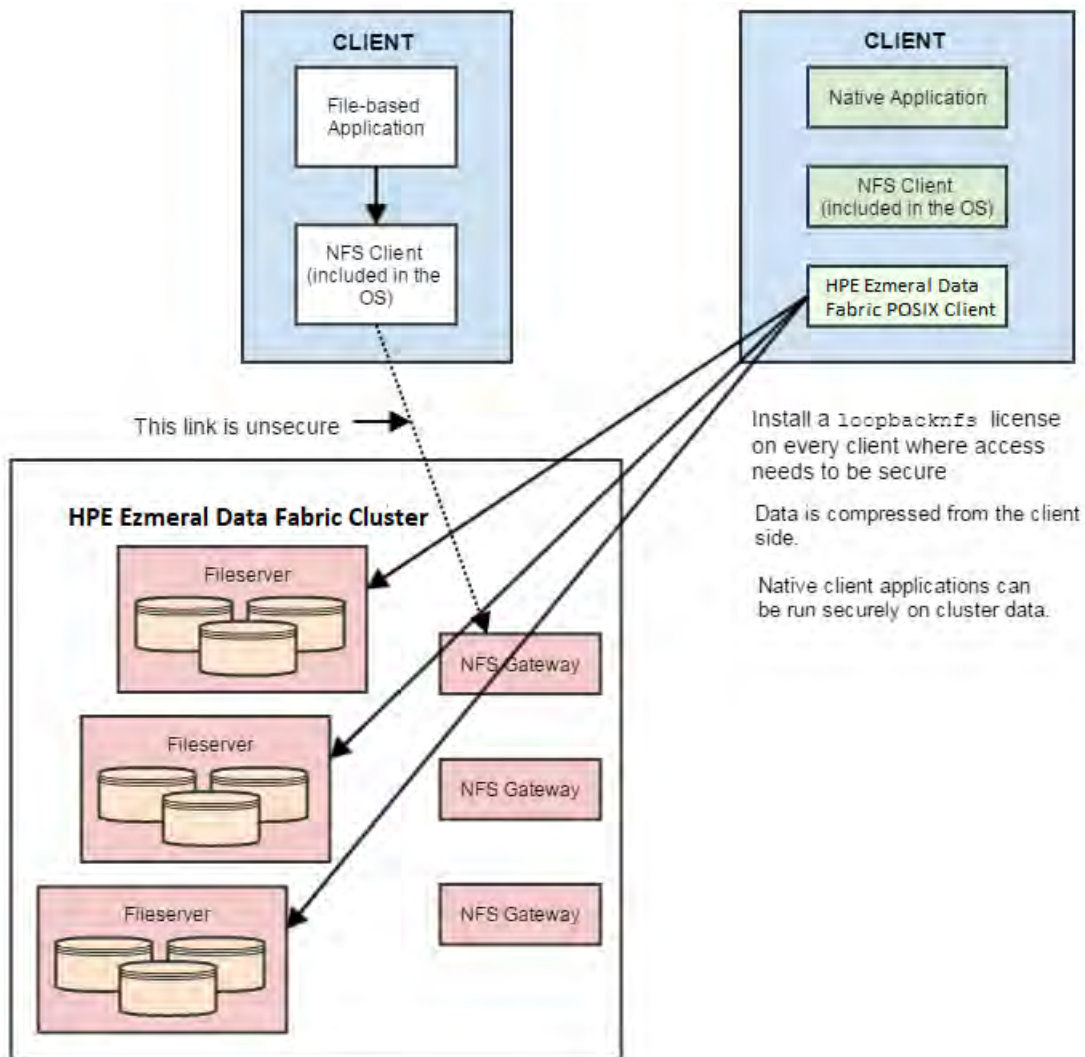

The HPE Ezmeral Data Fabric POSIX Client feature allows app servers, web servers, and other client nodes and apps to read and write directly to a HPE Ezmeral Data Fabric cluster. Starting with the 4.0.2 release, HPE Ezmeral Data Fabric provides single-user `loopbacknfs` licenses that give access to one or more clusters.

The table below summarizes the differences between the basic Linux OS NFS client and the HPE Ezmeral Data Fabric POSIX client:

| | Linux OS Client | HPE Ezmeral Data Fabric POSIX Client |
|----------------------------------|---|---|
| Client OS | <ul style="list-style-type: none"> Supported Linux distributions and desktop systems (Mac OS X and Windows) | <ul style="list-style-type: none"> Supported Linux distributions only No version for Mac OS X |
| Installs On Node Type | <ul style="list-style-type: none"> Client node - not part of the HPE Ezmeral Data Fabric cluster No <code>mapr-fileserver</code> or other Hadoop services | <ul style="list-style-type: none"> Client node Cluster node |
| Access to Cluster | <ul style="list-style-type: none"> Must have direct network access to NFS Gateways. | <ul style="list-style-type: none"> Must have direct network access to all HPE Ezmeral Data Fabric cluster nodes |
| Supported Interfaces | <ul style="list-style-type: none"> POSIX-NFS | <ul style="list-style-type: none"> POSIX-NFS |
| Connection to File System | <ul style="list-style-type: none"> Point to point Via an NFS gateway Single point of failure | <ul style="list-style-type: none"> Proxied on host to regular HPE Ezmeral Data Fabric client traffic Direct, no NFS gateway No single point of failure |
| Security | <ul style="list-style-type: none"> Link to NFS gateway is insecure | <ul style="list-style-type: none"> Fully secured |

The Linux OS NFS client must go through an NFS gateway, the link to the gateway is not secured, and transmitted data is not compressed.

The following diagram illustrates how the HPE Ezmeral Data Fabric POSIX client (`mapr-loopbacknfs`) works, in comparison with the Linux OS NFS client (left).

The instructions on this page are for the HPE Ezmeral Data Fabric POSIX client. For instructions on setting up NFS on a HPE Ezmeral Data Fabric cluster, see [Managing the HPE Ezmeral Data Fabric NFS Service](#) on page 1295.

The table below summarizes the differences in the HPE Ezmeral Data Fabric POSIX client deployment behavior when installed with a HPE Ezmeral Data Fabric cluster where security is disabled or enabled:

| | Cluster Security Disabled | Cluster Security Enabled |
|---------------------|---|--|
| Client Node | <ul style="list-style-type: none"> HPE Ezmeral Data Fabric cluster looks exactly like network attached storage (NAS) POSIX permissions are enforced | <ul style="list-style-type: none"> Single-user authentication Write access is supported only for applications with UID matching authenticated user |
| Cluster Node | <ul style="list-style-type: none"> HPE Ezmeral Data Fabric cluster looks exactly like NAS POSIX permissions are enforced | <ul style="list-style-type: none"> Secure cluster access is key Best Practice: Use ticket from <i>mapr</i> user |

Specifying Environment Variables

Explains how to set environment variables on a client node.

A subset of the environment variables defined on the servers for the HPE Ezmeral Data Fabric cluster must be defined, with the same values, on the client. You can add environment variables directly to the startup script, or create a local `env.sh` file in `/usr/local/mapr-loopbacknfs/conf`. You cannot simply copy the `env.sh` file from a server node in the cluster because the `MAPR_HOME` setting would be different.

Complete the following steps to specify environment variables:

1. On a server node in the HPE Ezmeral Data Fabric cluster, locate the `env.sh` and `env_override.sh` files in the `/opt/mapr/conf` directory. If the `env_override.sh` file is not present, use the `env.sh` file. For more information about these files, see [About `env_override.sh`](#) on page 2576.
2. Retrieve the `MAPR_SUBNETS` and `JAVA_HOME` settings from the server files and clone them to `/usr/local/mapr-loopbacknfs/conf/env.sh` on the client node.
3. (Optional) Set the `NFS_LOOPBACK_HONOUR_SUBNETS` environment variable to avoid re-registration whenever there is a change in any network interface. Value can be:
 - `true` to consider the `MAPR_SUBNETS` while registering with CLDB. If set to `true`, re-registration does not happen whenever there is a change in any network interface.
 - `false` to ignore the `MAPR_SUBNETS`. If set to `false`, re-registration happens whenever there is a change in any network interface.

For example:

```
# export NFS_LOOPBACK_HONOUR_SUBNETS=true
# export MAPR_SUBNETS=10.10.104.0/24

# env | grep SUBNET
NFS_LOOPBACK_HONOUR_SUBNETS=true
MAPR_SUBNETS=10.10.105.0/24,10.10.104.0/24
```

4. Change the `JAVA_HOME` setting to point to the location where Java is installed on the client.
5. Add the following lines to the client node `env.sh` file:

```
export MAPR_HOME=/usr/local/mapr-loopbacknfs
export MAPR_TICKETFILE_LOCATION=/usr/local/mapr-loopbacknfs/initscripts/
mapr-loopbacknfs/longlived_ticket
```

Note: To allow impersonation, set the value for `MAPR_TICKETFILE_LOCATION` to the path to the `mapr` user ticket.

6. Save and close the `env.sh` file.
7. Restart the `loopbacknfs` service for the changes to take effect.

Copying Configuration Files from a Server Node

Settings in the `nfsserver.conf` and `mapr-clusters.conf` files on server nodes in the MapR cluster are also needed by the POSIX client. Complete the following steps to copy configuration files from a server node:

1. On a server node in the MapR cluster, locate the `nfsserver.conf` and `mapr-clusters.conf` files in the `/opt/mapr/conf/` directory.
2. Copy both of those files to the `/usr/local/mapr-loopbacknfs/conf/` directory on the client machine.

Starting the `mapr-loopbacknfs` Service to Access a Cluster

Describes the prerequisites and the process of starting the `mapr-loopbacknfs` service to access a secure cluster.

The following instructions explain how to start the `loopbacknfs` service so you can access either a non-secure or secure cluster.

To access multiple clusters, ensure that the first cluster that you configure is a HPE Ezmeral Data Fabric 4.0.2 or later cluster, with available POSIX client licenses.

Prerequisites for accessing a secure cluster:

- Ensure that the stock Linux NFS service is not running. Linux NFS and HPE Ezmeral Data Fabric NFS cannot run concurrently.
- Disable the lock manager (`nlockmgr`).
- Check that the `rpcbind` service is running on RHEL and CentOS v6.0 and higher. You can use the command `ps ax | grep rpcbind` to check.
- Check that the `portmapper` service is running on RHEL and CentOS v5.x and lower, and on Ubuntu and SLES. You can use the command `ps ax | grep portmap` to check.
- Make sure you have applied a Community Edition (M3) license or an Enterprise Edition (M5) license (paid or trial) to the cluster. See [Adding a License](#) on page 854.
- Enable security for the cluster. See [Enabling Wire-level Security](#) on page 1527 and [Disabling Wire-level Security](#) on page 1528 wire-level security.
- Generate a user ticket. See [Generating a HPE Ezmeral Data Fabric User Ticket](#) on page 1543 for instructions. If you do not already have a HPE Ezmeral Data Fabric user ticket, with full control [ACL](#) authorization on the cluster, you must have a cluster administrator do this for you.
 - In the HPE Ezmeral Data Fabric cluster, navigate to the server node to which you want to connect.
 - First, run `maprlogin password` to login. The user who logs in must be a privileged user, such as the `mapr superuser`.
 - Next, run `maprlogin generateticket -type service -user <user> -duration 365:0:0 -out <file>` to generate the user ticket. The `<user>` for whom the ticket is generated can be any user. If the service ticket expires, the POSIX client:
 - Automatically uses the renewed service ticket without requiring a restart, if the ticket is replaced before expiration (ticket expiry time + grace period of 55 minutes). If the ticket is replaced after expiration (which is ticket expiry time + grace period of 55 minutes), the POSIX `loopbacknfs` client does not refresh the ticket as the mount becomes stale.
 - Allows impersonation if a service ticket is replaced before ticket expiration (which is ticket expiry time + grace period of 55 minutes) with a `servicewithimpersonation` ticket.
 - Honor all changes in user/group IDs of the renewed ticket.
- Copy the user ticket file from the cluster server node where you generated it to the `/usr/local/mapr-loopbacknfs/conf` directory on the client machine where the HPE Ezmeral Data Fabric POSIX client runs.

Note: Since the NFS server runs based on a single user's ticket, it can act on behalf of only one user. Therefore, the UID or GID associated with the ticket must match the UID or GID of any user who accesses the NFS server through the HPE Ezmeral Data Fabric POSIX Client.

 **Note:** Securing the cluster so that only one user can have secure access provides tight control over cluster access, but it also means that any user on the client who is able to read the generated ticket has read access to all data in the cluster.

Start the `mapr-loopbacknfs` service and mount the volume

Complete the following steps from your client node, except where noted, to start the `mapr-loopbacknfs` service and mount the volume:

 **Note:** If cluster security is enabled, the ticket that you generated using the preceding procedure, must be available or the NFS server does not start.

1. Start the `mapr-loopbacknfs` service from the command line.

```
service mapr-loopbacknfs start
```

2. Create a mount point at `/mapr` and mount the client node to it.

```
mkdir /mapr
mount localhost:/mapr /mapr
```

3. You can also automate the mounting of the volume with every launch of the `mapr-loopbacknfs` service. On the POSIX client node, create `/usr/local/mapr-loopbacknfs/conf/mapr_fstab` and add the following line:

```
localhost:/mapr /mapr hard,nolock
```

Securing the Mountpoint

POSIX permissions are the only limitation on read access by the MapR POSIX client, whether the cluster connected to has security enabled or disabled. By securing the mountpoint, you can limit access to a single user.

Complete the following steps to secure the mountpoint:

1. On the client system, create `/mapr/<clustername>`:

```
mkdir -p /mapr/<clustername>
```

2. Set ownership and permissions:

```
chown user1:<posix_user> /mapr
chmod 700 /mapr
```

3. Mount the cluster:

```
mount localhost:/mapr/<clustername> /mapr/<clustername>
```

Now only the `<posix_user>` can access the cluster with the POSIX client.

Registering a POSIX Client with Additional Clusters

The first time you start the `loopbacknfs` service, you edit the `mapr-loopbacknfs` init script by defining the `CLUSTER_NAME` and `CLDB_IPS` variables, then run the script. These actions update the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file.

However, when you want to register a client with a new cluster or an additional cluster, you must add entries directly to the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file. Editing the `mapr-loopbacknfs` script and restarting the `loopbacknfs` service does not update the `mapr-clusters.conf` file.

Configuring the HPE Ezmeral Data Fabric POSIX Client

Explains how to set the number of RPC requests that POSIX clients send to a cluster.

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the cluster to be 128.

Perform the following steps as the root user on each POSIX client machine:

1. Issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/sunrpc.conf
```

These commands enable the configuration to persist after a reboot of the NFS client machine.

2. Issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

The commands enable the configuration to take effect after you remount the POSIX client to the HPE Ezmeral Data Fabric cluster.

3. Remount the POSIX client to the HPE Ezmeral Data Fabric cluster. For example, the following commands unmount and mount the NFS assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock 127.0.0.1:/mapr /mapr
```

Note: Failure to configure this property may result in the following error in `/usr/local/mapr-loopbacknfs/log`: `ERROR nfserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot allocate more OncRpcContexts: [numDropped=2556001] dropping connection from nfsc=10.13.64.225:0`

CentOS Troubleshooting Tip

After the reboot of the node, if the `/proc/sys/sunrpc` directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command: `service rpcidmapd start`.

Verifying Data Fabric POSIX Client Licenses

Use the Control System, to check how many data-fabric POSIX client licenses are available and being used.

1. Log in to the Control System and click **Admin > Cluster Settings**.
2. Look at the **LICENSES** pane for the number of POSIX Client nodes that are available and currently being used.

Managing the mapr-loopbacknfs Service

Explains how to start/stop and manage the `loopbacknfs` service from the command line.

To manually start or stop the service:

```
service mapr-loopbacknfs [start|stop]
```

To have the service start automatically when the OS starts up:

```
systemctl enable mapr-loopbacknfs
```

To monitor the service:

```
service mapr-loopbacknfs status
showmount -e localhost
```

The showmount command displays:

```
Export list for <host>
/mapr 127.0.0.1
/mapr/<clustername> 127.0.0.1
```

Setting Up Aliases for NFS Exports

When provisioning filesystem for various tenants, you can set up an alias for the path in filesystem, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in filesystem.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in filesystem (/mapr). To set up an alias for a path in filesystem:

1. Open the NFS exports file in /opt/mapr/conf/ directory.
2. Specify the alias name for the mount path using the following syntax:

```
<path in MFS> /<alias name> <options>
```

Here:

| | |
|---------------|---|
| <path in MFS> | Refers to the filesystem mount path. If this points to a: <ul style="list-style-type: none"> • Volume, the user can access the snapshots associated with the volume. • Directory, the user cannot access the snapshots. |
| /<alias name> | Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in filesystem will be exported. |
| <options> | The list of available/supported options. |

For example, suppose a filesystem mount path of /mapr/samplecluster/samplevolume for tenant samplecustomer. To set up an alias, add the following to the exports file:

```
/mapr/samplecluster/samplevolume /samplecustomer (rw)
```

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out /mapr and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

Note: Only the alias will be visible/exposed to the NFS client.

3. Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprcli nfsmgmt refreshexports
```

4. Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Troubleshooting mapr-loopbacknfs Service Issues

Describes solutions for mapr-loopbacknfs issues.

To debug authentication issues, follow these steps:

1. If you receive a standard error (stderr):
 - Make sure `rpcinfo/portmap` is installed and/or run `service portmap start`.
 - Run `service rpcbind restart`.
2. Examine the log files for error messages:

```
/usr/local/mapr-loopbacknfs/logs/loopbacknfs.log
/usr/local/mapr-loopbacknfs/logs/mount_local_fs.log
```

Error messages in `loopbacknfs.log` file:

| Error Message | Solution |
|---|--|
| Refresh User tickets failed as security layer could not be initialized with user ticket /tmp/maprticket_0 | Unset <code>MAPR_TICKETFILE_LOCATION</code> in <code>initscripts/mapr-loopbacknfs</code> . |
| exiting: license only allows 10 NFS/mfs server(s), currently alive=10 | If you have multiple clusters listed in the <code>mapr-clusters.conf</code> file on the client, make sure the first one listed is a MapR 4.0.2 or later cluster. If that is not the problem, you will probably need to purchase additional licenses, or reduce number of installations of the <code>mapr-loopbacknfs</code> service. |
| mount.nfs: Protocol not supported | The NFS directory with <code>mapr-loopbacknfs</code> is already mounted. |

3. Verify that settings in configuration files are correct.
 - For all clusters: `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf`
 - For secure clusters: `MAPR_TICKETFILE_LOCATION`
4. Check for “stale” mounts.
 - The `mount_local_fs.pl` script can cause the initscript wrapper to force unmounts of the mounted file systems.

- Always check for stale mounts after stopping the service:
 - `df -k` should return instantly.
 - Use `umount -f <mount_point>` to force the unmount.
 - Use `ps -ef | grep mount_local` to confirm that the script is not stuck.

Data Fabric FUSE-Based POSIX Client

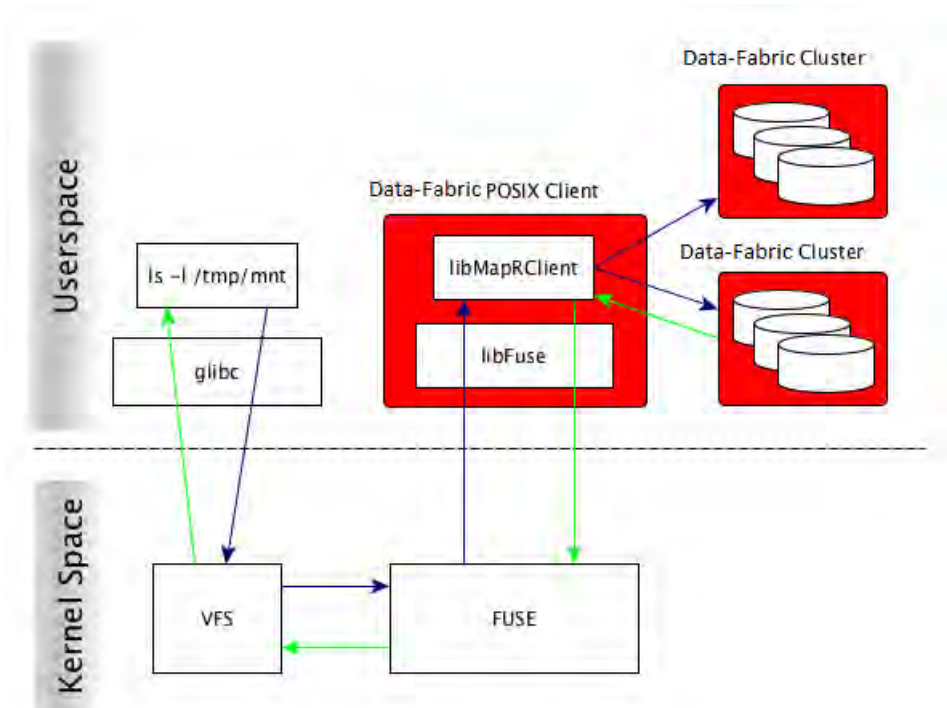

Provides a brief description of the FUSE-based POSIX client.

The data-fabric FUSE-based POSIX client (either *mapr-posix-client-basic* or *mapr-posix-client-platinum*) allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a data-fabric cluster like a Linux filesystem.

The same data-fabric client can access both secure and nonsecure clusters; however, a data-fabric client that is configured to access a secure cluster can access a nonsecure cluster only if these conditions are met:

1. The secure cluster must be listed in the `mapr-clusters.conf` file.
2. A user must obtain a ticket for the secure cluster even if the user wants to access only the nonsecure cluster.

The FUSE-based data-fabric POSIX client runs as a userspace process to connect to one or more data-fabric clusters. The necessary FUSE (Filesystem in Userspace) library (`libfuse`) is bundled with the POSIX client package. With the installation of the POSIX client package, the data-fabric POSIX client performs operations such as read and write on the filesystem exposed by FUSE. The following diagram illustrates how the data-fabric FUSE-based POSIX client works.

Example of Mounting FUSE

This example shows you how to mount FUSE and perform operations as a regular user.

The following example is a quick introduction to mounting FUSE and accessing the mount point as a regular user.

Assume that you have a mount point `/mapr` that you want to mount on FUSE and access as user *kate*.

Perform the following steps:

1. Create the user *kate*: Run

```
adduser kate
```

2. Generate a ticket with impersonation as user *kate*. You will use this ticket to mount and access FUSE. Run:

```
maprlogin generateticket -type servicewithimpersonation -user kate -out /var/tmp/sample_ticket
```

Note: For more information on generating a ticket with impersonation, see [How Impersonation Works](#) on page 1652 and [Generating a Service with Impersonation Ticket](#) on page 1545

3. Edit the `/opt/mapr/conf/fuse.conf` file and set `fuse.ticketfile.location=/var/tmp/sample_ticket`
4. The mount point `/mapr` is already set in the `fuse.conf` file.

Note: Change `fuse.mount.point=/mapr` if your mount point is different from `/mapr`.

5. Create the `/mapr` directory. Run:

```
mkdir /mapr
```

6. Start the MapR FUSE POSIX client, either *basic* or *platinum* as per your licence. For example:

```
service mapr-posix-client-basic start
```

The `/mapr` directory is now mounted on FUSE. You can perform all operations on `/mapr/` as the user *kate*.

[Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client](#) on page 1358

Lists FUSE configuration parameters.

[Managing the FUSE-Based POSIX Client](#) on page 1374

Describes how to use the FUSE-based POSIX client.

[How Impersonation Works](#) on page 1652

Introduces impersonation functionality, limitations, and core requirements.

[Generating a Service with Impersonation Ticket](#) on page 1545

Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client

Lists FUSE configuration parameters.

FUSE Parameters

You can set the POSIX client configuration values in the `/opt/mapr/conf/fuse.conf` file. After [installing the FUSE-based POSIX client](#), you can edit the configuration file to define the values for the following parameters and save the file.

To retrieve the list of configuration parameters, run the following command:

```
/opt/mapr/bin/posix-client-* --help
```

Here * refers to the basic or platinum client package installed on the system. If necessary, set the shared `LD_LIBRARY_PATH` environment variable to run the `help` option with the command. For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

Note: The HPE Ezmeral Data Fabric FUSE-based POSIX clients support only the configuration parameters in the `fuse.conf` file. All other FUSE configuration parameters are not supported. For more information on the non-mapr configuration parameters, refer to FUSE [documentation](#).

`fuse.access.type`

Default Value: `rw`

Sets the type of access on the mount point. Value can be:

- `ro` — Read only
- `rw` — Read and write

`fuse.affinity`

Default Value: `0` (Disabled)

Specifies whether to enable (1) or disable (0) NUMA affinity. If enabled, sets the NUMA affinity for the POSIX client.

`fuse.allow.other`

Default Value: `1`

Allow other users to access the mount point. Value can be one of:

- `0` - do not allow other users
- `1` - allow other users

Set this to 1 if the `root` user starts the FUSE service. Set to 0 or comment out this parameter if a non-root user starts the FUSE service. If set to 1, also add the `user_allow_other` parameter to the `/etc/fuse.conf` file.

`fuse.asyncdirect.io`

Default Value: `1`

Specifies whether to enable asynchronous direct IO. Value can be one of:

- `0` - disable
- `1` - enable

`fuse.attr.timeout`

Default Value: `3.0`

The timeout value in seconds for file/directory (regular) attributes (such as file size, UID, and GID, which are normally stored inside the inode) cache. This value is used to determine whether to use the cached attribute information (only if within the specified timeout window) or fetch attribute information again. The default is 3.0 seconds, which specifies that cached attribute information must be considered stale and refreshed after 3.0 seconds. You can assign fractions of a second as well (for example, `fuse.attr.timeout=2.8`).

Set the value for this parameter to 0 to compare POSIX (pjd) compliance with the ext3/4 file system. A value of 0 disables caching. For better performance, avoid disabling caching.

| | |
|---|--|
| <code>fuse.auto.inval.data</code> | <p><i>Default Value:</i> 1</p> <p>Specifies whether (1) or not (0) to automatically invalidate the kernel FUSE cache for any data change that causes mtime change, on the files. If set to 1, when the file is read, the correct file data is returned. If set to 0, the kernel cache of the data, which might not have the most current change, is returned.</p> |
| <code>fuse.auto.unmount</code> | <p><i>Default Value:</i> 1</p> <p>Specifies whether to automatically unmount the filesystem when the process is terminated. Value can be one of:</p> <ul style="list-style-type: none"> • 0 - disable • 1 - enable |
| <code>fuse.big.writes</code> | <p><i>Default Value:</i> 1</p> <p>Specifies whether to enable writes larger than 4KB. Value can be one of:</p> <ul style="list-style-type: none"> • 0 - disable • 1 - enable <p>Sets the size of the data/buffer that can be transferred from the kernel to the FUSE library, per request. If enabled, FUSE allows writes of 128KB from the kernel. If disabled, FUSE allows writes of 4KB from the kernel.</p> |
| <code>fuse.client.lib.path</code> | <p><i>Default Value:</i> <code>/tmp</code></p> <p>Specifies the path to store the client libraries.</p> <p> Note: To install and use FUSE-based POSIX client and NFS v4 on the same node, ensure that the path for both the client library for the FUSE-based POSIX client, and NFS v4 is not <code>/tmp</code>, which is the default. Specify a different location for the client libraries. For example, <code>/tmp/fuselib</code>.</p> |
| <code>fuse.cluster.conf.location</code> | <p><i>Default Value:</i> <code>/opt/mapr/conf/mapr-clusters.conf</code></p> <p>The path to the configuration file to use.</p> |
| <code>fuse.congestion.threshold</code> | <p><i>Default Value:</i> 10</p> <p>Specifies the kernel's congestion threshold.</p> |
| <code>fuse.disable.shardcache</code> | <p><i>Default Value:</i> 0 (false)</p> <p>Specifies whether to disable shard cache, which is a cache of lookups. Value can be:</p> <ul style="list-style-type: none"> • 0 - false • 1 - true <p>If true, more number of lookup calls are used. The FUSE client uses the shard cache to ensure that requests for data related to the same file are served by the same library. This is done using hash to improve performance. In very rare circumstances, it might make sense to disable this cache in conjunction with HPE Ezmeral Data Fabric support.</p> |

fuse.disable.writeback*Default Value:* 0

Specifies whether (1) or not (0) to disable the writeback cache. This parameter is applicable only in kernel versions ≥ 3.15 . By default, in kernel versions ≥ 3.15 , writeback is enabled. To disable writeback cache, set the value for this parameter to 1. If enabled, the writes are buffered in the kernel. However, when multiple FUSE clients work on the same file, writes to a file by one FUSE client might never be seen by other FUSE clients performing a read because the kernel does not update the attributes of the file unless the file is modified locally. You can disable the writeback cache to allow the kernel to perform a write through.

fuse.enforce.core.pattern*Default Value:* false

Specifies whether (true) or not (false) to write to `/proc/sys/kernel/core_pattern` file when the FUSE-based POSIX starts. The default value is false. If true, the `core_pattern` file contains an `/opt/cores/%e.core.%p.%h` entry and if false, the file is not touched.

fuse.entry.timeout*Default Value:* 3

The timeout value in seconds for the name lookup cache. Use this parameter to determine whether to use the cached entry for the name lookup (if within the specified timeout window) or lookup the name again. The default is 3 seconds, which specifies that cached name lookup information must be considered stale and refreshed after 3 seconds. For this option, it is possible to give fractions of a second as well (for example, `fuse.entry.timeout=2.8`).

Set the value for this parameter to 0 to compare POSIX (pjd) compliance with the ext3/4 file system. Avoid retaining this value as 0 as it disables the cache, and impacts performance.

fuse.evenly.spread.data*Default Value:* 0

Specifies whether (1) or not (0) to evenly spread writes across the nodes on the cluster. If set to 0, writes are always sent to the local primary node, from where data is replicated on all the other nodes. If set to 1, writes are distributed across different nodes. Set the value to 1 in case of reduced performance resulting from a large number of writes on the local primary node.

fuse.export*Default Value:* /mapr

Denotes the fully-qualified cluster path to the volume or directory under the mount point.

When you do not specify a value, all clusters found in `mapr-clusters.conf` are mounted under the entity specified by the `fuse.mount.point` property (`/mapr` by default). If `mapr-clusters.conf` contains two clusters A and B, there are directories pointing to the root directories of those clusters, for example `/mapr/A` and `/mapr/B`.

When you specify a value, it overrides the default behavior, and causes exactly one path from one cluster to be exposed at the entity specified by the `fuse.mount.point` property. You can either fully expose a single cluster, or expose only a subset of a single cluster.

If you set `fuse.export` to the name of a cluster, enclosed within `/`, then that cluster is mounted at `/mapr`. For example if `fuse.export=/A/`, then the path `/mapr` shows the root directory of cluster A.

If you set `fuse.export` to a path within a cluster, then `/mapr` points to that path. For example, if `fuse.export=/A/var/`, then `/mapr` displays the directory contents of `/var` from the HPE Ezmeral Data Fabric cluster A.

Note: If the value is not a valid path to the name of a volume or directory, the FUSE service does not start. The value *cannot* be the path to a file.

`fuse.fast.local.directio`

Default Value: 0

Specifies whether to optimize (1) or disable (0) FUSE client for local direct IO. Value can be one of:

- 0 - disable
- 1 - optimize

`fuse.flush.inline`

Default Value: 0

Specifies whether (1) or not (0) to flush all writes inline. Value can be one of:

- 0 - disable inline flushing
- 1 - flush all writes inline

If disabled, for all open files, by default, the buffer is flushed automatically every 3 seconds or when it reaches 64KB. If enabled, writes are sent to server directly.

`fuse.fsname`

Default Value: FUSE mount point

Specifies the filesystem source, which is the first field in the `/etc/mtab` file. The default value is the FUSE mount point that is denoted by the parameter `fuse.mount.point`.

`fuse.hb.interval`

Default Value: 5

Specifies the heartbeat interval (in seconds) for the FUSE-based POSIX client.

`fuse.log.debug_level`

Default Value: error

The FUSE-based POSIX client log level. The value can be one of:

- fatal
- error
- warn
- info
- debug

`fuse.log.path`

Default Value: `/opt/mapr/logs`

Specifies the path to store the log files.

`fuse.max.background`

Default Value: 64

fuse.max.cache.pages Specifies the maximum number of asynchronous requests that can be submitted. IO requests beyond the maximum limit are blocked.
Default Value: 1048576 (1 Million pages)

fuse.max.read Specifies the maximum number of pages (each page is 8KB) in the page cache that each HPE Ezmeral Data Fabric Client library in FUSE process can use when working with a large number of open files. This setting limits the amount of memory consumed by FUSE.
Default Value: 131072

fuse.max.readahead Specifies the maximum size (in bytes) of read requests.
Default Value: 131072

fuse.max.write Specifies the maximum number of bytes to read ahead.
Default Value: 131072

fuse.mount.point Specifies the maximum number of bytes that is allowed in a single write request.
Default Value: /mapr

This parameter is mandatory. Specifies the mount point where the HPE Ezmeral Data Fabric filesystem must be mounted. Ensure that the specified mount point is empty before starting the service. Once mounted, the POSIX client has access to all the clusters specified in /opt/mapr/conf/mapr-clusters.conf file. The value should not be /mapr if you wish to mask HPE Ezmeral Data Fabric branding.

Note: If NFS server is also running on this node, ensure that the FUSE mount point is different from the NFS server mount point.

fuse.mount.setuid *Default Value:* 0

By default, FUSE mounts with the `nosuid` option. This prevents users other than root from running executable files with the SUID bit set, on FUSE. Enable this parameter (set to 1), to allow users other than root to run executable files with the SUID bit enabled, on the HPE Ezmeral Data Fabric Fuse FileSystem.

This parameter works in conjunction with the `allowreadforexecute` parameter in [volume create](#) on page 2190 and [volume modify](#) on page 2275 commands.

The following table describes how both parameters work together to permit running SUID binaries:

Table

| fuse.mount.setuid | allowreadforexecute | Result |
|--------------------------|----------------------------|--|
| Disabled | Does not matter | SUID binaries cannot be executed by users other than <i>root</i> . |

Table (Continued)

| fuse.mount.setuid | allowreadforexecute | Result |
|-------------------|---------------------|--|
| Enabled | Disabled | Users other than <i>root</i> can run the SUID binaries only when the binary has both read and execute permissions. |
| Enabled | Enabled | Users other than <i>root</i> can execute the SUID binaries either when the binary has both read and execute permissions OR execute permission alone. |

fuse.negative.timeout

Default Value: 3

Applicable for the Container, Basic, and Platinum POSIX clients.

Indicates the duration in seconds to cache negative lookup results.

Negative lookup results that are returned when a file does not exist (lookup returned ENOENT), are cached for the specified number of seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

The default value of 3 indicates that negative lookup results are cached for 3 seconds.

Set this value to 0 to disable the negative lookup cache.

When patching or upgrading the client from an older release, this parameter is automatically applied. However, new parameters are not automatically written to `fuse.conf`. Make sure to copy this parameter from `fuse.conf.new` to `fuse.conf`, only if you want to change the default value, or disable this cache.

fuse.nonempty

Default Value: 0

Specifies whether FUSE can be mounted on a non-empty mount point (1) or on an empty mount point (0). Value can be:

- 0 - indicates that mount point should be empty
- 1 - indicates that mount point need not be empty

fuse.num.libs

Default Value:

- Container - 1

- Basic - 1
- Platinum - 5

Specifies the number of client libraries to run with. For:

- Container client, value must be 1.
- Basic client, value must be 1.
- Platinum client, default value is 5 and can be set to a value greater than 5.

More than one library allows for more than 1GB/sec throughput on remote operations as each additional library increases the throughput by sharding operations across libraries (for parallelism).

Note: Each additional library will consume additional memory and CPU.

`fuse.num.threads`

Default Value: 64

Specifies the number of FUSE threads in userspace per mount point. A higher number allows parallel processing of multiple operations. Recommended value is only up to 64.

`fuse.ra.sessions`

Default Value:

- Container - 1
- Basic - 1
- Platinum - 5

Specifies the number of parallel read ahead sessions per library. Each open file acts as one read ahead session. For example, for the default value of 5, up to 5 files can have read ahead sessions per library. If value is set to 0, readahead is disabled.

Note: A greater value allows larger number of parallel read ahead sessions, which is useful if more number of files need to be opened simultaneously. However, each additional read ahead session consumes additional memory (512K per read ahead session) and threads.

`fuse.readdirplus`

Default Value: 1

Enables (1) or disables (0) `readdirplus` functionality for high latency networks. The `readdirplus` attribute returns the file handle and attribute information such as the name and the file ID, along with the directory entries, unlike the `readdir` attribute that requires the client to query the server separately for each directory entry. For the best performance, do not disable this parameter.

`fuse.sync.read`

Default Value: 0

Specifies whether to enable or disable synchronized reads. Value can be:

- 0 - disable
- 1 - enable

fuse.ticketfile.location*Default Value:* /opt/mapr/conf/maprfuseticket

Specifies the ticket to use to start the service in secure mode. Generate the required ticket and place it in /opt/mapr/conf/<maprfuseticket>.

Note: To support impersonation, provide the mapr user ticket file location or the user's servicewithimpersonation ticket file location. You can use the mapr user ticket on the server node, and service with impersonation ticket on client node. The FUSE service must be started by the root user if servicewithimpersonation ticket is specified. In case of non-impersonated ticket, the ticket credentials becomes the identity for all the requests, no matter which user is accessing the fuse mount point.

See also: [Setting up a Ticket for the POSIX Client](#).

fuse.track.memory*Default Value:* false

Specifies whether to enable (*true*) or disable (*false*) memory tracking for FUSE.

fuse.use.compressed.inode.format*Default Value:* 0

Specifies whether or not to use compressed inode format. When enabled, a 16-bit unique identifier is used to avoid inode cache collisions when multiple clients are modifying (creating, deleting, and similar operations) the same directories/files. The value can be one of:

- 0 — (default) do not use compressed inode format
- 1 — use compressed inode format including unique identifier

Note: Even when set to 1, EBUSY errors are returned if client accesses more than 32k volumes at the same time.

Enabling this flag may not completely avoid inode cache collisions when too many modifications such as creation, and deletion are performed on the same directories or files. Give the kernel sufficient time to purge inode cache entries between modifications.

fuse.xattr.enable*Default Value:* 0 (false)

Specifies whether (*true*) or not (*false*) to enable extended attributes through the FUSE client. Value can be one of:

- 0 - false
- 1 - true

The default value is 0 (false). This is disabled by default because if enabled, during operations, the kernel might make a lot of extended attribute calls for security checks resulting in performance degradation even when there are no extended attributes on the inode. When disabled, extended attributes can still be added using the `hadoop fs` command; however, this must be enabled to perform any operations on

extended attributes using the FUSE-based POSIX client.

Note: Of the five types of extended attribute namespaces in Linux, system, trusted, user, raw, and security, only user namespace is supported. For all other namespaces, EINVAL is returned.

You must start/restart the FUSE-based POSIX client for the changes to take effect. See [Starting and Stopping the POSIX Client](#) for more information.

Configuration Backup When Installing/Upgrading POSIX Clients

When you install a patch, the `/opt/mapr/conf/fuse.conf.new` file contains the new settings. You can copy the new parameters (with default values) to your existing `fuse.conf` file and restart FUSE for the settings to take effect.

When you upgrade from a prior release, on all supported OS other than Ubuntu, the old `fuse.conf` file is backed up as `fuse.conf.backup`, before being overwritten with the new settings. This backup is available in the `/opt/mapr/conf` directory.

On Ubuntu, the upgrade process does not create a backup copy of the file. You need to manually backup the `fuse.conf` file before upgrading, as this file is overwritten with the new settings after upgrading.

To continue using FUSE with your custom settings, and take advantage of the new settings, manually copy your custom settings in the `fuse.conf.backup` file to the `fuse.conf` file, set custom values for the new parameters in the `fuse.conf` file where necessary, and restart FUSE for the settings to take effect.

To restart FUSE, use one of the following commands depending on the POSIX client of your choice:

- For POSIX container: `service mapr-posix-client-container restart`
- For POSIX basic: `service mapr-posix-client-basic restart`
- For POSIX platinum: `service mapr-posix-client-platinum restart`

Optimizing FUSE performance when running the Flexible I/O tester (fio tool)

Performance Tips

- With Linux kernels prior to version 4.8, size extending writes are serialized by the kernel, and result in degraded write performance. For optimized write performance, ensure that the Linux kernel in use, is at least version 4.8.
- With kernel 4.8 and above, fio performance improves when using larger block sizes and larger number of jobs (numjobs). Keep numjobs constant and use larger block sizes (>128k) for enhanced performance.

For example, for optimised performance, the `fio` command could be as follows:

```
fio --ioengine=libaio --direct=1 --gtod_reduce=1 --name=perftest --filename=
perfile
    --bs=16m --iodepth=64 --size=4G --rw=write --numjobs=4
```

Configuring Timeout for Inactive Connections

In cases where the file client connects infrequently to a remote CLDB node that is firewalled, TCP segments on the connection are silently dropped by the firewall due to the long idle time. However, the client keeps waiting for the response till RPC times out. To mitigate this scenario, you can now configure

the timeout for inactive connections. Use the `fs.mapr.binding.inactive.threshold` parameter in the `core-site.xml` file to set this threshold in seconds. For example:

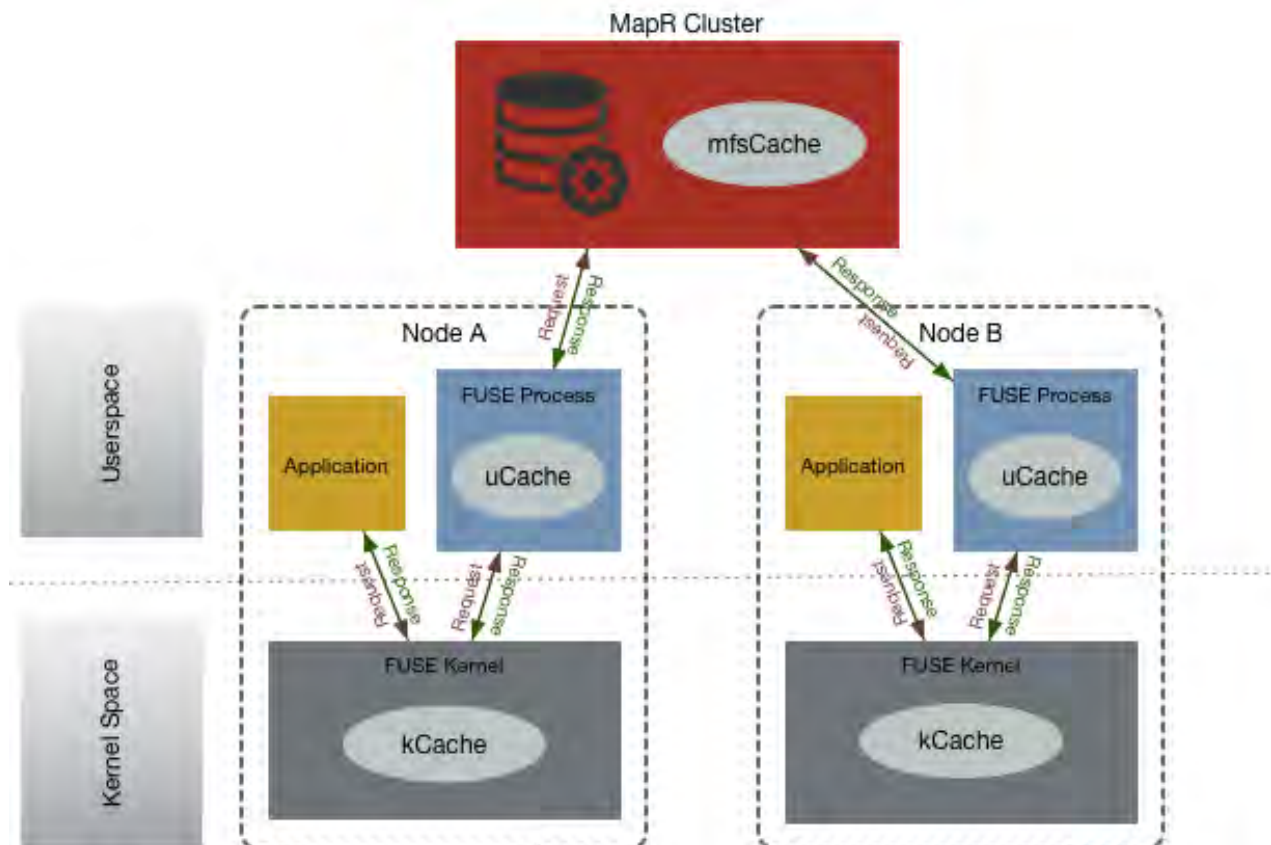

```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, that is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLBD to use for communication.

Tuning the Cache for FUSE-Based POSIX Clients

Describes performance tuning measures for FUSE clients.

The FUSE kernel and the FUSE userspace process caches both data and metadata. When an application performs a read of a file using the FUSE-based POSIX client, data is generally returned from the local FUSE kernel cache if that portion of the file resides in cache from a previous read or write operation. However, if the file has been modified on the HPE Ezmeral Data Fabric cluster by a different client, the data in the local kernel cache may be stale. The following illustration shows the layers of cache — FUSE kernel cache (referred to as kCache), the FUSE userspace cache (referred to as uCache), HPE Ezmeral Data Fabric filesystem cache (referred to as mfsCache) — and the following sections describe how these affect reads and writes and how the FUSE attributes can be used to tune the caching behavior.

Inode Attribute Cache

Inode attributes are cached in the FUSE kernel cache (kCache) and in the userspace cache (uCache). When the same file is accessed from multiple FUSE clients, writes on the file through one mountpoint may not be seen by other applications performing a read on the file (through a different client). The inode

attributes are cached in the kernel because of which another application modifying the file might not see the updates instantly. For example, the inode attributes, to name a few, such as size, or modification timestamp (mtime) of the file, in the kCache and uCache on Node A might be stale if the file is being modified concurrently by an application on Node B.

Tuning the attribute timeout in kCache

The FUSE kernel refreshes inode attributes from the userspace FUSE process once every 3 seconds by default. This can be tuned through the `fuse.attr.timeout` parameter in the `fuse.conf` file. The `fuse.attr.timeout` parameter specifies the interval of time at which to refresh the inode attributes in kernel and can be used to minimize the amount of time it takes to refresh the cache. Even if `fuse.attr.timeout` is set to 0, Node A might still not see the latest writes from Node B because there is cached metadata in the userspace FUSE process on Node A; metadata can be served from the uCache and the application might not see current updates for attributes like size. To see the latest changes on a file, see [Tuning the attribute timeout in uCache](#) on page 1369.

Tuning the attribute timeout in uCache

The userspace FUSE process caches both data and metadata and refreshes the inode attributes from the HPE Ezmeral Data Fabric filesystem once every 3 seconds; *this is not tunable*. Even if the `fuse.attr.timeout` is set to 0, because there is cached data and metadata in the userspace FUSE process (uCache), stale data or metadata can be served from the userspace FUSE process, which only refreshes inode attributes every 3 seconds. However, the userspace FUSE process updates the inode attributes every time a file is opened. To see the latest changes on a file, applications, especially readers on a file, that require to see updates on the file within 3 seconds can close and open the file to refresh the attributes and see instant updates.

Readdir Cache

Directory entries (files within a directory) are not cached in the uCache, but are cached in the kCache. The kCache can be stale on Node A if there are files being created in the directory by an application from the mountpoint on Node B. That is, a user listing directory entries on Node A for a directory (using a command like `ls`) might not see the files that were just created from Node B.

Tuning the entry timeout in kCache

The `fuse.entry.timeout` parameter specifies the interval of time at which to refresh the readdir (or lookup) cache in the kernel (kCache). The default value is 3 seconds and this can be configured in the `fuse.conf` file.

Data Cache

By default:

- Reads are buffered both in the kCache and the uCache.
- Writes are not buffered in the kCache, but are buffered in the uCache.

An application trying to read a file on Node A might not see the latest updates to the file (written from node B) for the following reasons:

- Reads on Node A might have been served either from the kCache or the uCache of Node A.
See [Tuning the cache for reads](#) on page 1370 for information on invalidating the cache.
- The writes might have been buffered in the uCache of Node B.
See [Tuning the cache for writes](#) on page 1370 for information on disabling buffering at a file level or altogether.

Tuning the cache for reads**Tuning the kCache**

The `fuse.auto.inval.dat` a parameter specifies whether or not to automatically invalidate the kCache for any data change, which causes mtime change, on the files. If enabled, any mtime update on the file automatically invalidates the page cache of the file. The mtime is an inode attribute; for information on refreshing the cache for inode attributes, see Inode Attributes.

Tuning the uCache

Every read cache page is valid for 3 seconds. After 3 seconds, the read cache page is dropped from uCache. *This is not tunable.*

Tuning the cache for writes**Tuning the kCache**

The `fuse.writeback.cach`e parameter specifies whether to buffer writes in the kernel or to perform a write through. If enabled, the writes are buffered in the kernel. If disabled, writes are not buffered in the kernel and are directly sent to the FUSE process.

By default, writeback caching is disabled; that is, the kernel sends all writes to the FUSE process directly. If an application does small writes, then the FUSE process might run out of CPU because of the overhead involved in small writes. To mitigate this, the FUSE kernel can be configured to enable caching in the kernel using the `fuse.writeback.cach`e attribute. However, this can be enabled only on

kernels running version
>= 3.15.

Tuning the uCache

The `fuse.flush.inline` attribute can be used to disable data buffering in the uCache. By default, the userspace FUSE process caches the writes locally. This parameter specifies whether to cache writes (for up to 3 seconds or 64KB in size) or write directly to server. This can be disabled at both the file and FUSE process levels.

If the application does buffering before writing to filesystem, to avoid redundant buffering, you can disable buffering at the FUSE level by setting the `fuse.flush.inline` parameter value to 1 in the `fuse.conf` file. Caching can be disabled at a file-level by opening the file in `O_DIRECT` mode.

Caching Negative Lookup Results

FUSE issues thousands of lookup calls for the file, even when the initial lookup call has returned `ENOENT`, indicating that the file does not exist. This behaviour is in contrast to NFS for the HPE Ezmeral Data Fabric, which caches the lookup result for a specified time. For example, when running a `git clone` operation on the `mapr-core` repository, testing indicated that FUSE issued 870k calls, while NFS for the HPE Ezmeral Data Fabric issued 82k calls, for files that are non-existent.

To reduce the number of negative lookups, and optimize performance, the FUSE configuration contains the `fuse.negative.timeout` parameter.

By default, this parameter is set to 3 seconds. Negative lookup results that are returned when a file does not exist (lookup returned `ENOENT`), are cached for 3 seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

For more information on this parameter, check the [FUSE configuration](#).

Configuring HPE Ezmeral Data Fabric FUSE-based POSIX Client for Tenant Environment

Explains the parameters to set to enable tenant user access to tenant shares from the FUSE-based POSIX client.

To enable tenant users to access the tenant share from the FUSE-based POSIX client, set the following configuration parameters in the `fuse.conf` file on the tenant host:

fuse.mount.point

Specifies the local mount path to where the cluster filesystem is going to mount. To mask the HPE Ezmeral Data Fabric branding from the tenant user, do not specify `/mapr` as the value for this parameter.

| | |
|---------------------------------|---|
| fuse.export | Specifies the path to the tenant volume mount path or directory under the tenant volume mount point. This is disabled by default, allowing users to access all the clusters specified in the <code>/opt/mapr/conf/mapr-clusters.conf</code> file. This must be set to enable the user on the tenant host to directly access only the specified volume or directory. |
| fuse.ticketfile.location | Specifies the path to the tenant ticket file to start the service in secure mode. |

For more information on all other available and supported parameters, see [Configuring the MapR FUSE-based POSIX Client](#).

Sample MapR FUSE-Based POSIX Client Configuration File

```
#Set path to the mount point
fuse.mount.point=/mapr

#Set path where logs shall be stored
fuse.log.path=/opt/mapr/logs

#Set path where client libraries shall be stored
fuse.client.lib.path=/tmp

#Allow all users to access the filesystem
fuse.allow.other=1

#Enable larger than 4kB writes
fuse.big.writes=1

#Enable NUMA affinity
fuse.affinity=0

#Auto unmount on process termination
fuse.auto.unmount=1

#Set number of libMapRClient libraries to run with
#fuse.num.libs=DEFAULT_NUM_LIBS

#Set number of readahead sessions
#fuse.ra.sessions=1

#Enable/Disable memory tracking for fuse
fuse.track.memory=false

#Set number of FUSE threads
#fuse.num.threads=64

#Enable async direct io
fuse.asyncdirect.io=1

#Set the maximum size of read requests
#fuse.max.read=128

#Set the maximum bytes to readahead
#fuse.max.readahead=128k

#Set the maximum size in a single write request
#fuse.max.write=128

#Enable sync reads
#fuse.sync.read=0
```

```

#Set number of maximum background requests
fuse.max.background=64

#Set kernel's congestion threshold
#fuse.congestion.threshold=10

#Flush all writes inline
#fuse.flush.inline=0

#Optimize for local direct writes
#fuse.fast.local.directio=0

#Optimize by evenly distribute data across cluster
#fuse.evenly.spread.data=0

#Disable shard cache
#fuse.disable.shardcache=0

#Sets the filesystem source (first field in /etc/mtab).
#The default is the mount program name.
#fuse.fsname=NAME

#Set fuse ticket file
fuse.ticketfile.location=/opt/mapr/conf/maprfuseticket

#fuse nonempty option to enable mounting at nonempty mount point
#fuse.nonempty=0

#by default, we support user namespace xattr.
#setting below option to 1 will enable the user xattr.
#fuse.xattr.enable=1

#Attribute timeout for inodes
#fuse.attr.timeout=3.0

#Entry timeout for inodes
#fuse.entry.timeout=3.0

#Hearbeat interval for FUSE in seconds
#fuse.hb.interval=5

#fuse sub exports
#fuse.export=/clus.default/voll

#fuse core pattern
#fuse.enforce.core.pattern=true

#Readonly or readwrite, values are ro,rw
#fuse.access.type=rw

#Auto invalidation of data on mtime change
fuse.auto.inval.data=1

#Disable writeback cache
#If multiple fuse servers are operating on the same file then enabling
#this option will break consistency among different fuse servers i.e.
#writes to file1 on server1 will not be seen by an application reading
#file1 on server2 forever.
fuse.disable.writeback=1

#Set cluster configuration file
#fuse.cluster.conf.location=/opt/mapr/conf/mapr-clusters.conf

```

```
#Sets client debug level, values are fatal, error, warn, info, debug
fuse.log.debug_level = error;

#Inode compressed format
fuse.use.compressed.inode.format=0
```

Managing the FUSE-Based POSIX Client

Describes how to use the FUSE-based POSIX client.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the HPE Ezmeral Data Fabric filesystem. You need to open the relevant ports for **TCP** connectivity from POSIX clients to the HPE Ezmeral Data Fabric file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports.

- CLDB - Ports 7222 and 7223.
- Filesystem Server - 5660, 5692, 5724, 5756, and 6660.

You can open additional CLDB ports for better performance. See [Ports Used by HPE Ezmeral Data Fabric Software](#) on page 2579 for more information.

When using Multi-MFS instances, open the relevant ports for these instances to work. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756 (5660+96), instance 1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. See [Working with Multiple Instances of the File System](#) on page 867 for more information.

Setting up a Ticket for the POSIX Client

The POSIX client can be accessed using user and service tickets. The service tickets have long lifetimes, by default, for ease of administration. This is useful for running application processes that should not be bounded by the CLDB duration (`cldb.security.user.ticket.duration.seconds`) and renewal (`cldb.security.user.ticket.max.duration.seconds`) properties, which limit the lifetime of user tickets. If you plan to use a user ticket, ensure that the user has read permissions on the ticket file.

Irrespective of the ticket type, after generating the ticket, set the `fuse.ticketfile.location` parameter value in the `fuse.conf` file to point to the ticket file to use.

For more information, see:

- [Generating a HPE Ezmeral Data Fabric User Ticket](#) on page 1543
- [Generating a Service Ticket](#) on page 1545

Note: If the UID/GID in the ticket (without impersonation capability) is different from the UID/GID of the logged-in user, all operations are performed using the UID/GID of the ticket and not that of the logged-in user.

Starting and Stopping the POSIX Client

To ensure that the service can be started and stopped and to run the help option, set the shared `LD_LIBRARY_PATH` environment variable. Update the shared library environment variable to include the paths to the following:

- Full path to the directory containing `libjvm.so` file
- `$MAPR_HOME/lib` (that is, `/opt/mapr/lib` directory)

For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

To allow a non-root user to start this service, as administrator or `root` user, run the following command:

```
chmod u+s /opt/mapr/bin/fusermount
```

Verify that permissions have been set for non-root user to start the service. For example:

```
ls -l /opt/mapr/bin/fusermount
```

Your output should look similar to the following:

```
-rwsr-xr-x 1 root root 39704 Feb 16 19:41 /opt/mapr/bin/fusermount
```

Ensure that the non-root user has full permissions on the mount point and log files.

To manually start or stop the service:

```
service mapr-posix-client-* [start|stop|status]
```

When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

Note: The POSIX client service cannot be stopped or restarted if any other process is accessing the mount point. With `systemd` (on CentOS/RH 7.x and SLES 12), the service will enter failed state (if you tried to stop) or activating state (if you tried to restart) and you must manually kill the client processes.

Running the POSIX Client in Secure Mode

The POSIX client reads the `mapr-clusters.conf` file to determine whether the process must start in secure or non-secure mode. If security is configured, the `servicewithimpersonation` ticket file must be present in the default `/tmp` directory. If the ticket file is not in the default `/tmp` directory, specify the location of the ticket file using the `fuse.ticketfile.location` configuration parameter in the `fuse.conf` file

Tip: See also: [Enabling Impersonation for the HPE Ezmeral Data Fabric Superuser](#) on page 1654 and [Enabling Impersonation for any User](#) on page 1655.

If the ticket expires after a connection has been established between the POSIX client and the cluster, the connection can stay alive for up to an hour. No new connections will be allowed. If the ticket was blacklisted, restart POSIX client to refresh the ticket.

Mounting the filesystem

To mount the HPE Ezmeral Data Fabric filesystem at the mount point specified in the `/opt/mapr/conf/fuse.conf` file, create the mountpoint specified in the `fuse.conf` file and start the service. For example:

```
mkdir /mapr
service mapr-posix-client-* start
```

Note: When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

Attention: Remember the following points when using a FUSE mounted filesystem:

- When trying to open a FIFO on a FUSE mounted filesystem, permissions to perform the operation are not checked.
- Any user can set time using `touch -t` for any file on a FUSE mounted filesystem.

See also: [Enabling Soft Mount and Setting the Timeout](#) on page 374

Monitoring the POSIX Client

To determine whether the POSIX client is running, run the following command:

```
service mapr-posix-client-* status
```

Note: When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

Adding and Removing Users

Before you add and/or remove users using the POSIX client, make a note of the following:

- Invalid UID/GID cannot perform operations on the system.
- When you add or remove users, it may take up to 30 minutes for the changes to take effect.

By default, the UID cache will expire in 30 minutes. To disable UID cache, set the value (in seconds) for `fs.mapr.uid.cache.timeout.seconds` parameter in the `core-site.xml` file. You can set the value to:

- 0 to fetch the GID information from the `idstore` directly
- >0 to specify the amount of time to keep the UID information in cache

For example, your `core-site.xml` entry would look similar to the following for:

- Disabling cache:

```
<property>
  <name>fs.mapr.uid.cache.timeout.seconds</name>
  <value>0</value>
  <description>disable UID cache</description>
</property>
```

- Setting 3 minutes as the amount of time to keep the UID information in cache:

```
<property>
  <name>fs.mapr.uid.cache.timeout.seconds</name>
  <value>180</value>
  <description>UID cached for 3 minutes</description>
</property>
```

Registering POSIX Client with Additional Clusters

To register the POSIX client with additional clusters, you must add entries directly to the `/opt/mapr/conf/mapr-clusters.conf` file. The clusters will be visible after few minutes.

Note: Each client supports up to 16 clusters.

Configuring the FUSE Read Chunk Size

The POSIX FUSE platinum client can break large reads into multiple pieces to be handled in parallel, if you set the FUSE read chunk size of a file. This process is called sharding.

By default, the FUSE read chunk size is set to 2 MB. To change the chunk size used by the FUSE platinum client for parallel reads, set the value (in bytes) for the `fs.mapr.fuseshard.chunksize` configuration field in the `core-site.xml` file. To set the chunksize to 5 MB (5242880 bytes), use:

```
<property>
  <name>fs.mapr.fuseshard.chunksize</name>
  <value>5242880</value>
  <description>setting chunk size</description>
</property>
```

For example, if the FUSE read chunk size is set to 1 MB, and the FUSE platinum client is configured with 5 libraries, then the platinum client reads 5 MB in parallel.

Unmounting the FUSE Mount

To unmount the mountpoint and kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

Note: When you run the command, replace `*` with `basic` or `platinum`, which corresponds with the package that is installed on the system.

Troubleshooting the FUSE-Based POSIX Client

Explains how to enable and collect the stack trace to troubleshoot POSIX client issues.

This section contains information for troubleshooting the FUSE-based POSIX client.

Enabling Traces

To enable traces at system startup, set the property `fs.mapr.trace` in the `core-site.xml` file. For example:

```
<property>
  <name>fs.mapr.trace</name>
  <value>DEBUG | INFO | WARN | ERROR | CRITICAL | OFF</value>
  <description> </description>
</property>
```

Collecting the Stack Trace

If the mountpoint is not responding or if the filesystem operations are taking too much time, collect the stack trace of all the threads to debug. To collect the stack trace of all threads, run the following command:

```
gstack <fuse-process-id> > ./gstack.log
```

If the filesystem commands fail, repeat the filesystem command with `strace` and collect the log file:

```
strace <filesystem command> > ./strace.log
```

Managing the MAST Gateway

You can start, stop, and restart the MAST Gateway using the MapR Control System and the CLI. You can also configure how frequently MapR runs the load balancer to balance the load on the MAST Gateway.

Configuring the MAST Gateway Service

After installing MAST Gateway service, perform the following steps on the node if filesystem is not installed on the node. If filesystem is (also) installed on the node, start at step 4:

1. Run `configure.sh` on page 2331 utility.

For example:

```
/opt/mapr/server/configure.sh -C <CLDB nodes> -Z <Zookeeper nodes> -N
<ClusterName>
```

2. Start Warden if it is already not running.

```
service mapr-warden start
```

3. Run `jps` or `/etc/init.d/mapr-mastgateway status` to check whether MAST Gateway is running on the node.

4. Open the `/opt/mapr/conf/mastgateway.conf` file and set values for the following parameters:

| Parameter | Default Value | Description |
|---|---------------|--|
| <code>mastgateway.port</code> | 8660 | The port on which the MAST Gateway process runs. Default value is 8660. |
| <code>mastgateway.worker.numthreads</code> | 16 | The number of threads to execute tiered data operations such as read and modify part of the offloaded data. The default value is 16. You can modify this based on the machine's configuration. |
| <code>mastgateway.cntr.worker.numthreads</code> | 16 | The number of threads to use to execute container-based tiered data operations such as offload and recall of file-level and volume-level data in parallel. The default value is 16. Tip: For faster offload, modify this value based on the machine's configuration. |
| <code>mastgateway.logfile.size.mb</code> | 1024 | The maximum size (in MB) of the MAST Gateway log file. When the size limit is reached, the logs get rolled over. |

Note: If you modify the `mastgateway.conf` file, you must restart the MAST Gateway for the changes to take effect.

5. (Optional) Add the following parameters in the `/opt/mapr/conf/mastgateway.conf` file only if you wish to customize libcurl.

The MAST Gateway uses libcurl to perform tiering-related operations. The following table lists the customizable libcurl options and their default values. If these are not set in the `mastgateway.conf` file, the default values are used.

Note: In the `mastgateway.conf` file, add only the parameters that you wish to customize.

| Parameter | Default Value | Description |
|---------------------------------|---------------|---|
| mastgateway.curl.timeout | 300000 | Timeout for the entire request. |
| mastgateway.curl.connecttimeout | 60000 | Timeout for the connection phase. |
| mastgateway.curl.nosignal | 0 | Do not install signal handlers. |
| mastgateway.curl.followlocation | 0 | Follow HTTP redirects. |
| mastgateway.curl.maxsendspeed | 0 | Limit on data upload speed. |
| mastgateway.curl.maxrecvspeed | 0 | Limit on data download speed. |
| mastgateway.curl.maxconnections | 5 | Maximum number of connections in the connection pool. |
| mastgateway.curl.dnsservers | null | Preferred DNS servers. |
| mastgateway.curl.interface | null | Bind connection locally to this. |
| mastgateway.curl.verifypeer | 1 | Verify the SSL certificate. |
| mastgateway.curl.verifyhost | 2 | Verify the host name in the SSL certificate. |
| mastgateway.curl.cainfo | null | CA cert bundle. |
| mastgateway.curl.issuercert | null | Issuer certificate. |
| mastgateway.curl.sslcert | null | Client cert. |
| mastgateway.curl.sslcerttype | null | Client cert type. |
| mastgateway.curl.sslkey | null | Client key. |
| mastgateway.curl.sslkeytype | null | Client key type. |
| mastgateway.curl.sslkeypasswd | null | Client key password. |
| mastgateway.curl.proxy | null | Proxy to use. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |
| mastgateway.curl.preproxy | null | Socks proxy to use. |
| mastgateway.curl.proxyport | 0 | Proxy port to use. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |

| Parameter | Default Value | Description |
|------------------------------------|---------------|---|
| mastgateway.curl.proxytype | 0 | Proxy type. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |
| mastgateway.curl.httpproxytunnel | 0 | Tunnel through the HTTP proxy. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |
| mastgateway.curl.proxyuser | null | Proxy user name. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |
| mastgateway.curl.proxypasswd | null | Proxy password. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |
| mastgateway.curl.proxyauth | 1 | HTTP proxy authentication methods. Note: Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information. |
| mastgateway.curl.proxyverifypeer | 1 | Verify the proxy's SSL certificate. |
| mastgateway.curl.proxyverifyhost | 2 | Verify the proxy certificate's name against host. |
| mastgateway.curl.proxycainfo | null | Path to proxy Certificate Authority (CA) bundle. |
| mastgateway.curl.proxysslcert | null | SSL proxy client certificate. |
| mastgateway.curl.proxysslcerttype | null | Type of the proxy client SSL certificate. |
| mastgateway.curl.proxysslkey | null | Private keyfile for TLS and SSL proxy client cert. |
| mastgateway.curl.proxysslkeytype | null | Type of proxy private key file. |
| mastgateway.curl.proxysslkeypasswd | null | Passphrase for proxy private key. |

For example, to configure the MAST Gateway for proxy server, your `mastgateway.conf` file settings for proxy server should look similar to the following:

```
mastgateway.curl.proxy=10.20.30.140

mastgateway.curl.preproxy=null

mastgateway.curl.proxyport=3128

mastgateway.curl.proxytype=0

mastgateway.curl.httpproxytunnel=0

mastgateway.curl.proxyuser=proxyuser

mastgateway.curl.proxypasswd=proxyuserpwd

mastgateway.curl.proxyauth=1
```

6. Save and close the `/opt/mapr/conf/mastgateway.conf` file.
7. (Optional) Configure memory for the MAST Gateway in the `/opt/mapr/conf/conf.d/warden.mastgateway.conf` file by setting values for the following parameters:

| Parameter | Default Value | Description |
|---------------------------------------|---------------|--|
| <code>service.heapsize.min</code> | 2048 | The minimum amount of node memory (in MB) to allocate. |
| <code>service.heapsize.max</code> | 20480 | The maximum amount of node memory (in MB) allocate. |
| <code>service.heapsize.percent</code> | 10 | The percentage of node memory to allocate. |

By default, 10% of the node memory or 20GB, whichever is lower, is allocated to MAST Gateway. If the MAST Gateway is processing jobs for both warm and cold tiers, memory consumption can increase up to 7GB or more. If you see high memory alarms for small memory consumption also, tune the percentage of memory allocated for MAST Gateway. Ensure that the percentage of memory allocated through `service.heapsize.percent` is available for MAST Gateway.

8. (Optional) Set the value for `fs.mapr.pool.queue.max_size` parameter to 20000 in the `/opt/mapr/conf/dbclient.conf` file.

If compression is enabled on the data in a tiering-enabled volume, tiering jobs can fail and return errors because of the large number of operations sent to the DB (where metadata for offloaded data is stored). To prevent errors, add the `fs.mapr.pool.queue.max_size` parameter to the `/opt/mapr/conf/dbclient.conf` file and set the value for this parameter to a large number, such as 20000. For example, your entry in the `/opt/mapr/conf/dbclient.conf` file should look similar to the following:

```
fs.mapr.pool.queue.max_size = 20000
```

- Restart the MAST Gateway for the changes to take effect.
See [Starting, Stopping, and Restarting the MAST Gateway](#) on page 1382 for more information.

Configuring Secure Access

If the MapR cluster is a secure cluster and the MAST Gateway is installed on a cluster node, no additional configuration is needed for the MAST Gateway to access data. On the other hand, if the MapR cluster is a secure cluster and if MAST Gateway is installed on an edge node, to enable the MAST Gateway to communicate with the secure MapR cluster, do the following:

- Copy the `/opt/mapr/conf/maprserverticket`, `/opt/mapr/conf/ssl_keystore`, and `/opt/mapr/conf/ssl_truststore` files on the CLDB node to the `/opt/mapr/conf` directory on the edge node.
- Run `configure.sh` as shown below:

```
/opt/mapr/server/configure.sh -C <cldb-node-IP-addresses> -Z
<zookeeper-node-IP-addresses> -secure -N <cluster-name>
```

See [configure.sh](#) on page 2331 for more information.

Starting, Stopping, and Restarting the MAST Gateway

You can start, stop, and restart the MAST Gateway using the Control System and the CLI.

Starting, Stopping, and Restarting the MAST Gateway Using the Control System

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 907
- [Stopping a Service on the Cluster Using the Control System](#) on page 908
- [Restarting the Services on the Cluster Using the Control System](#) on page 909

Starting, Stopping, and Restarting the MAST Gateway Using the CLI

- Run the following command to:
 - Start the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action start
```

- Stop the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action stop
```

- Restart the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action restart
```

Balancing Gateway Load

Explains how CLDB balances MAST Gateway loads.

CLDB assigns volumes to MAST Gateways so that any tiering-related operation for a volume is performed by the MAST Gateway assigned to the volume. This assignment is sticky and the volume remains assigned to the same gateway across CLDB, MAST Gateway, and cluster restarts. When a MAST Gateway goes

down, volumes assigned to the MAST Gateway are not re-assigned immediately. Instead, when a tiering operation needs to be run and the assigned MAST Gateway is down, CLDB assigns a new MAST Gateway to the volume, and the operation is performed using the newly assigned MAST Gateway.

Volumes are assigned to gateways with the lowest load (or lowest number of volumes currently assigned to it) to ensure equal distribution. Whenever a volume is created or removed or whenever a MAST Gateway is added or removed, the load on the gateways require rebalancing. HPE Ezmeral Data Fabric automatically balances the load on the gateways after a certain (configurable) amount of time since the occurrence of the event that necessitates a rebalance. The delay after which HPE Ezmeral Data Fabric tries to rebalance varies based on the type of event that necessitates a rebalance. See [Configuring the Delay After Which Load Balancer runs for Events](#) on page 1383 for more information.

Each volume in the cluster is assigned a weight, which is 1 for all volumes. The load on a gateway is the sum of weights of all the volumes that are assigned to the gateway. Load balancer tries to ensure that the load on a gateway is at least the average weight.

```
avg weight = (sum(weight of all tiered vols) + num active gws - 1) / num
active gws
```

When the balancer needs to pick volumes from a gateway for reassignment, it first picks the volume with max weight and one that currently has no activity (volume level offload, recall, or compaction). To minimize the interruptions in gateway activity, the balancer first considers idle volumes and picks volumes with active tasks after. However, any balancing and/or reassignment is skipped if there is already assignment related flux in the cluster (such as volumes with gateway assignment currently in progress). If this happens, load balancer runs again with a shorter time delay of 10 minutes.

HPE Ezmeral Data Fabric performs load balancing in batches of 5 volumes per run. That is, it assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). HPE Ezmeral Data Fabric figures out the next batch of volumes by re-evaluating the current assignment state. When the load on the gateway is balanced, the balancer is disabled and the load balancer is run again only by any of the 4 events.

Configuring Interval Between Load Balancer Runs

- HPE Ezmeral Data Fabric assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). Run the following command to configure the interval between runs:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.recheck": "<time-in-seconds>" }
```

Configuring the Delay After Which Load Balancer runs for Events

HPE Ezmeral Data Fabric runs the load balancer automatically for any of the following events. You can configure the delay after which HPE Ezmeral Data Fabric runs the load balancer.

Create Volume

When you create a tiering-enabled volume, it is assigned the gateway with the lowest load. If gateways are not available for the volume at the time of creation, the volume might stay unassigned. To ensure that the volume has an associated gateway for handling the tiering operations, HPE Ezmeral Data Fabric runs the gateway load balancer after a delay of 2 hours (7200 seconds) by default for this event.

To configure the delay, set the value for `cldb.tier.gw.balance.delay.vol.create`

property (in seconds) using the `config save` on page 1768 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.vol.create": "<time-in-seconds>"}
```

Remove Volume

When you remove a volume, the distribution of volumes across gateways can become uneven, and the balancer must be run to redistribute the volumes. For this event, HPE Ezmeral Data Fabric runs the load balancer to redistribute the volumes and rebalance the gateways after a delay of 2 hours (7200 seconds) by default for this event.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.vol.delete` property (in seconds) using the `config save` on page 1768 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.vol.delete": "<time-in-seconds>"}
```

Add Gateway

When you install a new gateway on a cluster, volumes are assigned to the new gateway only if a new volume is created or an existing volume has a pending task, but no active assigned gateway. Volumes that have active gateways are not re-assigned by default. For this event, HPE Ezmeral Data Fabric runs the load balancer to re-distribute the volumes and rebalance the gateway load after a delay of 2 hours (7200 seconds) by default.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.new.gw` property (in seconds) using the `config save` on page 1768 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.new.gw": "<time-in-seconds>"}
```

Remove Gateway

When you remove a gateway or when a gateway goes down, all the volumes assigned to the gateway are not re-assigned by default; only volumes with pending tasks are assigned to new gateways. For this event, HPE Ezmeral Data Fabric runs the load balancer to re-distribute the volumes after 6 hours (21600 seconds) by default.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.dead.gw` property (in seconds) using the `config save` on page 1768 command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.dead.gw": "<time-in-seconds>"}
```

Determining the Volumes Assigned to MAST Gateways

- Run one of the following commands to determine the volumes that are assigned to MAST Gateways:

- `/opt/mapr/server/mrconfig info mastgateway`
- `/opt/mapr/server/mrconfig info volume mastgateway`

For more information, see [mrconfig info](#) on page 2434.

Enabling Debug Logging for MAST Gateway

The MAST Gateway service log file contains alarm messages, error codes, and information on the errors. When the `mastgateway.log` file reaches `mastgateway.logfile.size.mb/5`, a roll over happens and the `mastgateway.log` file is renamed as `mastgateway.log.1`; also, a new `mastgateway.log` file is created. When the newly created `mastgateway.log` reaches `mastgateway.logfile.size.mb/5`, a roll over happens again and:

- The `mastgateway.log.1` is renamed as `mastgateway.log.2`
- The `mastgateway.log` is renamed as `mastgateway.log.1`
- A new `mastgateway.log` is created

This process continues and up to 5 files, whose size is `mastgateway.logfile.size.mb/5`, are created before the oldest log file, `mastgateway.log.4`, is deleted.

- Run the following command to enable debug logging for MAST Gateway:

```
maprcli trace setlevel -module MASTGateway -level Debug -port 8660
```

Configuring YARN for Control Groups

Control groups (cgroups) are a Linux kernel feature available through the LinuxContainerExecutor program that you can configure to limit and monitor the CPU resources available to YARN container processes on a node.

Configure YARN to use cgroups through properties in the `yarn-site.xml` file and then restart each NodeManager and ResourceManager service after you update `yarn-site.xml` for changes to take effect.

Important:

- Control groups (cgroups) mounted by YARN are deprecated due to a security issue with the `container-executor.cfg` option. By default, `feature.mount-cgroup.enabled=0`. To enable this feature, set `feature.mount-cgroup.enabled=1`.
- The HPE Ezmeral Data Fabric does not support YARN cgroups on RHEL 7. In RHEL 7, `libcgroup` is deprecated, and `systemd` maintains cgroups. Moving default hierarchies that `systemd` manages might generate unexpected results.
- RHEL 8 officially supports cgroups. Starting from EEP 7.0.x with RHEL 8, you no longer have to manually unmount and mount `/sys/fs/cgroup/cpu,cpuacct` to make YARN cgroups work; you can use `automount`.

The following sections describe how to configure mount paths for cgroups when `automount` is enabled and disabled, how to use an alternative method for configuring a mount path, and the `yarn-site.xml` properties related to YARN cgroup configuration.

Enabling Automount

Before you enable automount, set `feature.mount-cgroup.enabled=1` in the `container-executor.cfg` file.

To enable automount, set `yarn.nodemanager.linux-container-executor.cgroups.mount` to `true`, and define the mount path in the `yarn-site.xml` file, as shown in the following example:

```
<property>
  <name>yarn.nodemanager.linux-container-executor.cgroups.mount</name>
  <value>true</value>
</property>
<property>
  <name>yarn.nodemanager.linux-container-executor.cgroups.mount-path</name>
  <value>/mycgroup</value>
</property>
```

Create the mount path, as shown in the following example:

```
mkdir -p /mycgroup/cpu
chown -R mapr:mapr /mycgroup/cpu
```

Based on the settings, NodeManager will mount cgroups under `/mycgroup/cpu` automatically.

Note: If NodeManager restarts (without the node shutting down or restarting), you must manually unmount `/mycgroup/cpu` or set the `yarn.nodemanager.linux-container-executor.cgroups.mount` property to `false` before NodeManager restarts. However, if the NodeManager node restarts, you do not have to perform the manual unmount; the `/mycgroup/cpu` path is unmounted automatically during restart.

Disabling Automount

To disable automount, set `yarn.nodemanager.linux-container-executor.cgroups.mount` to `false` in `yarn-site.xml`.

When automount is disabled, the default mount path is `/sys/fs/cgroup/`. Beginning with EEP 8.0.0, the default directory for the cgroups, `/sys/fs/cgroup/cpu,cpuacct/hadoop-yarn`, is created automatically.

For EEPs 7.x.x and earlier, when each node running NodeManager restarts, you must manually create the `hadoop-yarn` directory under `/sys/fs/cgroup/cpu,cpuacct`, as shown in the following example:

```
mkdir -p /sys/fs/cgroup/cpu,cpuacct/hadoop-yarn
chown -R mapr:mapr /sys/fs/cgroup/cpu,cpuacct/hadoop-yarn
```

Alternative Method to Configure a Mount Path for Control Groups (cgroups)

For pre-EEP 7.0.x and RHEL 8 environments, you can unmount the default mount path and configure a new mount path.

First, set `yarn.nodemanager.linux-container-executor.cgroups.mount` to `false` in `yarn-site.xml`.

To unmount the default path and create a new mount path, run the following commands:

```
umount /sys/fs/cgroup/cpu,cpuacct
cgroup -o 'cpu' none '/opt/mapr/cgroup'
mkdir /opt/mapr/cgroup/hadoop-yarn
chown -R mapr:mapr /opt/mapr/cgroup/hadoop-yarn
chmod 750 /opt/mapr/cgroup/hadoop-yarn
```

Properties in yarn-site.xml Related to YARN Control Groups

The following table lists and describes the properties related to YARN cgroups and cpu settings in `yarn-site.xml`:

| Properties | Configuration Description |
|--|--|
| <code>yarn.nodemanager.container-executor.class</code> | Set this property to <code>org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor</code> . |
| <code>yarn.nodemanager.linux-container-executor.resources-handler.class</code> | Set this property to <code>org.apache.hadoop.yarn.server.nodemanager.util.CgroupsLCEResourcesHandler</code> . |
| <code>yarn.nodemanager.linux-container-executor.cgroups.hierarchy</code> | Set this property to the location of the Cgroups hierarchy. If <code>yarn.nodemanager.linux-container-executor.cgroups.mount</code> is <code>false</code> then this cgroup's hierarchy must already exist in this location. By default, this is set to <code>/hadoop-yarn</code> . |
| <code>yarn.nodemanager.linux-container-executor.cgroups.mount</code> | If the cgroup hierarchy is already configured, verify that this value is set to the default, <code>false</code> . Otherwise, set this value to <code>true</code> . |
| <code>yarn.nodemanager.linux-container-executor.cgroups.mount-path</code> | Set this property to the path where the <code>LinuxContainerExecutor</code> should attempt to mount cgroups if the hierarchy is not found. The container-executor binary will try to mount to <code><mountPath>/cpu</code> , which must exist before the <code>NodeManager</code> service is started on this node. |
| <code>yarn.nodemanager.linux-container-executor.group</code> | Verify that this setting matches the <code>yarn.nodemanager.linux-container-executor.group</code> setting in <code>container-executor.cfg</code> (<code>/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/container-executor.cfg</code>). |
| <code>yarn.nodemanager.resource.percentage-physical-cpu-limit</code> | Limits the CPU resources available to container processes. Set <code>yarn.nodemanager.resource.percentage-physical-cpu-limit</code> to the percentage that you want to limit the CPU usage of all YARN containers to. For example, if you set this value to 75, YARN containers on this node cannot use more than 75% of the CPU available on the node. |
| <code>yarn.nodemanager.linux-container-executor.cgroups.strict-resource-usage</code> | Specifies whether the CPU allocation should have a hard or soft limit. If containers should not use more CPU than what was originally allocated, set <code>yarn.nodemanager.linux-container-executor.cgroups.strict-resource-usage</code> to <code>true</code> . Set <code>yarn.nodemanager.linux-container-executor.cgroups.strict-resource-usage</code> to <code>false</code> if containers can use additional amounts of unused, available CPU. |

[Restarting Services](#) on page 908

Describes how to restart a service using either the Control System, the CLI or the REST API.

Configuring NodeManager Restart

NodeManager restart is enabled by default. Active containers will keep running in the event that the NodeManager shuts down.

When the NodeManager restart is enabled, it stores the container state of active containers in a recovery directory; when the NodeManager restarts, it retrieves the container state from the recovery directory.

If you disable NodeManager restart, active containers are shut down when the NodeManager shuts down and containers need to be reallocated when the NodeManager starts again.

To configure NodeManager restart, enable the NodeManager recovery and also specify a port that can be dedicated to run the NodeManager service.

1. Add the following parameters to the `yarn-site.xml` on each NodeManager node:
 - a) Set `yarn.nodemanager.recovery.enabled` to `true`.
 - b) Set `yarn.nodemanager.address` to include a port that is dedicated to run the NodeManager on this node.
 - c) Optionally, set `yarn.nodemanager.recovery.dir` to a different recovery directory for this node.

By default, the recovery directory is set to `$hadoop.tmp.dir/yarn-nm-recovery` which resolves to `tmp/hadoop-mapr/nm-local-dir/yarn-nm-recovery`. See the following example configuration:

```
<property>
  <name>yarn.nodemanager.recovery.enabled</name>
  <value>>true</value>
</property>
<property>
  <name>yarn.nodemanager.address</name>
  <value>0.0.0.0:8099</value>
</property>
```

2. Restart the NodeManager Service.

For more information, see [Managing Services](#) on page 904.

Managing Jobs and Applications

If you have used Hadoop in the past to run MapReduce applications, then running jobs on the HPE Ezmeral Data Fabric platform will be very familiar to you. HPE Ezmeral Data Fabric is a full Hadoop distribution, API-compatible with all versions of Hadoop. HPE Ezmeral Data Fabric provides additional capabilities not present in any other Hadoop distribution.

You can perform the following procedures to manage applications in a HPE Ezmeral Data Fabric cluster:

Job Scheduling

You can use job scheduling to prioritize the YARN applications that run on your MapR cluster.

The MapReduce system supports a minimum of one queue, named `default`. Hence, this parameter's value should always contain the string `default`. Some job schedulers, like the Capacity Scheduler, support multiple queues.

The default job scheduler is the Fair Scheduler, which is designed for a production environment with multiple users or groups that compete for cluster resources.

The MapR Converged Data Platform supports these job schedulers:

- **FIFO queue-based scheduler:** The FIFO queue scheduler runs jobs based on the order in which the jobs were submitted. You can prioritize a job by changing the value of the `mapred.job.priority` property or by calling the `setJobPriority()` method.
- **Fair Scheduler:** This is the default scheduler. The Fair Scheduler allocates a share of cluster capacity to each user over time. The design goal of the Fair Scheduler is to assign resources to jobs so that each job receives an equal share of resources over time. The Fair Scheduler enforces fair sharing within each queue. Running jobs share the queue's resources.
- **Capacity Scheduler:** The Capacity Scheduler enables users or organizations to simulate an individual hadoop cluster with FIFO scheduling for each user or organization. You can define organizations using *queues*.

The following sections provide more information about job scheduling:

Hadoop 2.x Fair Scheduler

The FairScheduler is a pluggable scheduler for Hadoop that allows YARN applications to share resources in a large cluster fairly. Fair scheduling is a method of assigning resources to applications such that all applications get, on average, an equal share of resources over time. Hadoop 2.x is capable of scheduling multiple resource types.

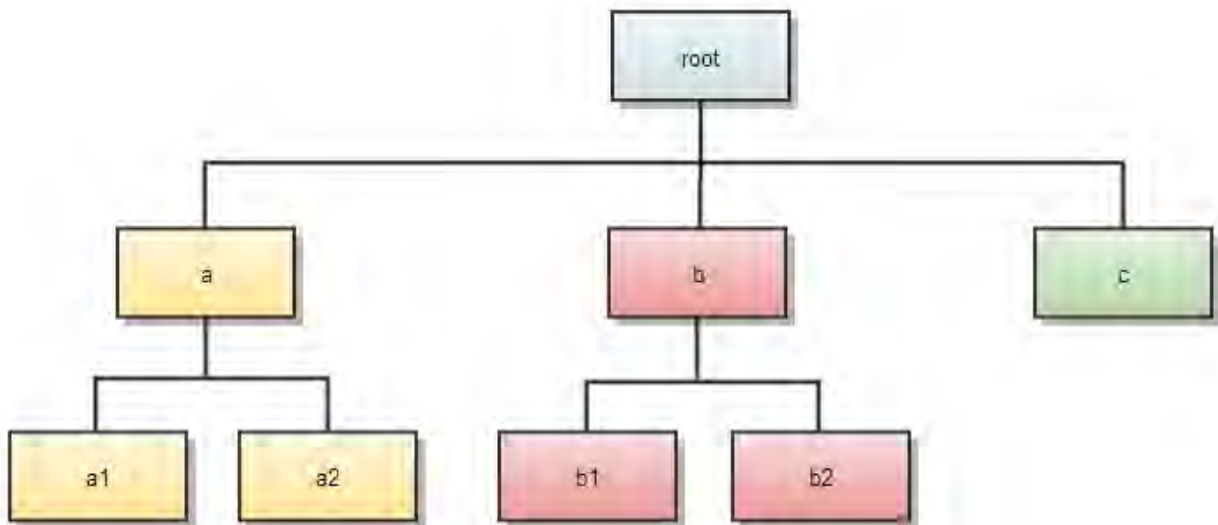

By default, the Fair Scheduler bases scheduling fairness decisions only on memory. It can be configured to schedule resources based on memory, CPU, and disk usage. When only one application is running, that application uses the entire cluster. When other applications are submitted, resources that free up are assigned to the new applications, so that each application eventually gets approximately the same amount of resources. Unlike the default Hadoop scheduler, which forms a queue of applications, this lets short applications finish in reasonable time while not starving long-lived applications. It is also a reasonable way to share a cluster between a number of users. Finally, fair sharing also uses priorities applied as weights to determine the fraction of total resources that each application should get.

For additional information about Hadoop Fair Scheduler, you can also refer to the [open source documentation](#).

Scheduling Queues

The scheduler organizes applications further into *queues*, and shares resources fairly between these queues. By default, all users share a single queue, named `default`. If an application specifically lists a queue in a container resource request, the request is submitted to that queue. You can also assign queues based on the user name included with the request through configuration. Within each queue, a scheduling policy is used to share resources between the running applications. The default is memory-based fair sharing, but FIFO and multi-resource with Dominant Resource Fairness can also be configured.

Queues can be arranged in a hierarchy to divide resources, and they can be configured with weights to share the cluster in specific proportions. The Fair Scheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root*. The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:

In addition to providing fair sharing, the Fair Scheduler allows assigning guaranteed minimum shares to queues, which is useful for ensuring that certain users, groups or production applications always get sufficient resources. When a queue contains apps, it gets at least its minimum share, but when the queue does not need its full guaranteed share, the excess is split between other running apps. This lets the scheduler guarantee capacity for queues while utilizing resources efficiently when these queues do not contain applications.

Configuring the Fair Scheduler

The Fair Scheduler lets all applications run by default, but you can also limit the number of running applications per user and per queue through the configuration file. This can be useful when a user must submit hundreds of applications at once, or in general to improve performance if running too many applications at once would cause too much intermediate data to be created or too much context-switching. Limiting the applications does not cause any subsequently submitted applications to fail; it only causes them to wait in the scheduler's queue until earlier applications finish.

To customize the Fair Scheduler, set the [configuration properties](#) in `yarn-site.xml` and update the allocation file to list existing queues and their respective weights and capacities. The allocation file is automatically created during HPE Ezmeral Data Fabric installation in the following directory:

```
{ $MAPR_HOME } /hadoop/hadoop-2.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

Specifying Fair Scheduler Configuration Properties in yarn-site.xml

Lists the properties in the `yarn-site.xml` file for Fair Scheduler.

The `yarn-site.xml` file contains the following parameters that determine scheduler-wide options.

yarn.scheduler.fair.allocation.file

Default Value: `fair-scheduler.xml`

Description: Specifies the path to the allocation file. If a relative path is given, the file is searched for on the classpath.

yarn.scheduler.fair.user-as-default-queue

Default Value: `true`

Description: Determines whether to use the username associated with the allocation file as the default queue name, if a queue name is not specified.

yarn.scheduler.fair.preemption

Note: If a queue placement policy is given in the allocations file, this property is ignored.

Default Value: false

Description: Indicates whether to use preemption.

Note: Do not use preemption when FairScheduler DominantResourceFairness is in use and node labels are present.

yarn.scheduler.fair.sizebasedweight

Default Value: false

Description: Indicates whether to assign shares to individual applications based on their size, rather than providing an equal share to all applications regardless of size. When set to true, applications are weighted by $(\ln 1 + \text{application's total requested memory}) / \ln 2$.

yarn.scheduler.fair.assignmultiple

Default Value: false

Description: Indicates whether to allow multiple container assignments in one heartbeat.

yarn.scheduler.fair.resources-based-on-labels-enabled

Default Value: false

Description: Indicates whether to allow container allocation on all nodes by recomputing fair shares based on labels.

yarn.scheduler.fair.preemption.cluster-utilization-threshold-based-on-labels-enabled

Default Value: false

Description: Indicates whether to enable/disable preemption of the threshold per-label.

Fair Scheduler Allocation File

Describes an allocation file and the entities within an allocation file.

An allocation file is an XML manifest that describes queues and their properties, as well as certain policy defaults. The allocation file is automatically created during HPE Ezmeral Data Fabric installation in the following directory:

```
{ $MAPR_HOME } /hadoop/hadoop-2.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

The allocation file contains the following types of elements:

Queue Elements

Queue elements represent queues and can contain the following elements:

- minResources
- maxResources
- maxRunningApps

Tip: The queueMaxAppsDefault value is used for any parent queue that does not set a value for the maxRunningApps element.

- weight

- `schedulingPolicy`
- `aclSubmitApps`
- `aclAdministerApps`
- `minSharePreemptionTimeout`
- `maxContainerAllocation`

Tip: The `maxContainerAllocation` property sets a limit on the resources a queue can allocate for a single container. The value cannot exceed `maxResources`. If you do not set `maxContainerAllocation`, the value is inherited from a parent queue. The default values are set through the `yarn.scheduler.maximum-allocation-mb`, `yarn.scheduler.maximum-allocation-vcores`, and `yarn.scheduler.maximum-allocation-disks` properties, which you can modify in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`. The `maxContainerAllocation` element is not valid for the root queue.

For more information on these elements, see [Hadoop: Fair Scheduler](#).

User Elements

User elements represent settings that govern the behavior of individual users. They can contain a single property, `maxRunningApps`, which limits the number of running applications for a particular user. It contains the following elements:

- `userMaxAppsDefault`
- `queueMaxAppsDefault`
- `fairSharePreemptionTimeout`
- `defaultQueueSchedulingPolicy`
- `queuePlacementPolicy`

For more information on these elements, see [Hadoop: Fair Scheduler](#).

Tip: If you set a value for `queueMaxAppsDefault` and do not set a value for `maxRunningApps` for the root queue, the value of `queueMaxAppsDefault` sets the application limit for all queues under the root queue hierarchy.

Example Allocation File

See example allocation file in [Hadoop: Fair Scheduler](#).

Queue Access Control Lists

Queue Access Control Lists (*ACLs*) allow administrators to control who may take actions on particular queues. They are configured with the `aclSubmitApps` and `aclAdministerApps` properties, which can be set per queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as `user1,user2 group1,group2` or `group1,group2`. An action on a queue is permitted if its user or group is in the *ACL* of that queue or in the *ACL* of any of that queue's ancestors. Therefore, if `queue2` is inside `queue1`, and `user1` is in `queue1`'s *ACL*, and `user2` is in `queue2`'s *ACL*, then both users may submit to `queue2`.

For more information, see [Hadoop: Fair Scheduler](#).

The `yarn.admin.acl` and `yarn.acl.enable` Properties

By default, on a secure cluster, users cannot kill jobs that do not belong to them.

On a secure cluster, you do not need to set the `yarn.acl` or the `yarn.admin.acl` properties. By default, they are set as follows. On unsecured clusters, these properties are not set by default.

```
<property>
  <name>yarn.acl.enable</name> >
  <value>>true</value> >
</property>
<property>
  <name>yarn.admin.acl</name> >
  <value> </value> >
</property>
```

The `yarn.admin.acl` property is set by default to "", meaning that an administrator is not specified on a cluster.

To allow users to kill jobs that do not belong to them, or to get access to their logs, you need to set the `yarn.admin.acl` property with the user or group name.

Fair and Capacity scheduler root queue admins

For both the Fair scheduler and Capacity scheduler, the default value of the administrators for the root queues is " " .

Hadoop 2.x Capacity Scheduler

The `CapacityScheduler` is a pluggable scheduler for Hadoop that allows multiple tenants to securely share a large cluster. Resources are allocated to each tenant's applications in a way that fully utilizes the cluster, governed by the constraints of allocated capacities.

Queues are typically set up by administrators to reflect the economics of the shared cluster. The Capacity Scheduler supports hierarchical queues to ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources.

The following sections provide more information about the `CapacityScheduler`:

Capacity Scheduler Features

The `CapacityScheduler` supports these features:

- **Hierarchical Queues** Hierarchical queues ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources, thereby providing more control and predictability.
- **Capacity Guarantees** Queues are allocated a fraction of the capacity of the grid, which means that a certain capacity of resources are at their disposal. All applications submitted to a queue have access to the capacity allocated to the queue. Administrators can configure soft limits and optional hard limits on the capacity allocated to each queue.
- **Security** Each queue has strict Access Control Lists (ACLs). The ACLs control which users can submit applications to individual queues. Also, safeguards ensure that users cannot view or modify applications from other users. Per-queue and system administrator roles are also supported.

- **Elasticity** Free resources can be allocated to any queue beyond its capacity allocation. As tasks scheduled on these resources complete, the resources become available to be reassigned to applications on queues running below their capacity. (Note that pre-emption is not supported.) This ensures that resources are available in a predictable and elastic manner to queues, thus preventing artificial silos of resources in the cluster and improving cluster utilization.
- **Multi-tenancy** A comprehensive set of limits is provided to prevent a single application, user, or queue from monopolizing resources of the queue or the cluster as a whole. This ensures that the cluster is not overwhelmed.
- **Operability**
 - **Runtime Configuration** The queue definitions and properties, such as capacity or ACLs, can be changed in a secure manner by administrators at runtime, which minimizes disruption to users. Also, a console is provided for users and administrators to view the current allocation of resources to various queues in the system. Administrators can add queues at runtime, but queues cannot be deleted at runtime.
 - **Drain applications** Administrators can stop queues at runtime to ensure that while existing applications run to completion, no new applications can be submitted. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. Existing applications continue to completion, so the queue can be drained gracefully. Administrators can also start the stopped queues.
 - **Resource-based Scheduling** Support for resource-intensive applications, where an application can optionally specify higher resource requirements than the default, thereby accommodating applications with differing resource requirements. Currently, *memory* is the only supported resource requirement.

Setting Up ResourceManager to Use CapacityScheduler

To configure the ResourceManager to use the CapacityScheduler, set the following property in the `yarn-site.xml` file:

| Property Name | Value |
|---|---|
| <code>yarn.resourcemanager.scheduler.class</code> | <code>org.apache.hadoop.yarn.server.resourcemanager.scheduler.capacity.CapacityScheduler</code> |

Setting Up Queues

The ResourceManager uses the configuration file `capacity-scheduler.xml`, where you can configure various scheduling parameters related to queues. These parameters include:

- the short queue name
- the full queue path name
- a list of associated child queues and applications
- the guaranteed capacity (expressed as a percentage of total resources in the cluster) available to the jobs in the queue
- the maximum capacity of the queue
- a list of active users and their resource allocation limits
- the state of the queue (running or stopped)
- access control lists that determine who can access the queue

The CapacityScheduler has a pre-defined queue called *root*. All queues in the system are children of the *root* queue. Further queues can be set up by configuring `yarn.scheduler.capacity.root.queues` with a list of comma-separated child queues.

Queue Properties

The `capacity-scheduler.xml` file includes three types of queue properties:

Resource Allocation Properties

The following table lists resource allocation properties:

| Property | Description |
|--|---|
| <code>yarn.scheduler.capacity.<queue-path>.capacity</code> | Queue <i>capacity</i> in percentage (%) expressed as a float (for example, 12.5). The sum of capacities for all queues, at each level, must equal 100. Applications in the queue may consume more resources than the queue's capacity if there are free resources, which provides elasticity. |
| <code>yarn.scheduler.capacity.<queue-path>.maximum-capacity</code> | Maximum queue capacity in percentage (%) expressed as a float. This property limits the elasticity for applications in the queue. The default is -1 which disables it. |
| <code>yarn.scheduler.capacity.<queue-path>.minimum-user-limit-percent</code> | Sets the minimum value, expressed as an integer, on the percentage of resources allocated to a user, if there is a demand for resources. A value of 100 implies no user limits are imposed. The default is 100. The maximum value depends on the number of users who have submitted applications. For example, if this property is set to 25 and two users have submitted applications to a queue, the maximum percent of queue resources for each user is 50%. If a third user submits an application, no single user can use more than 33% of the queue resources. With four or more users, no user can use more than 25% of the queue resources. |
| <code>yarn.scheduler.capacity.<queue-path>.user-limit-factor</code> | The multiple of the queue capacity that can be configured to allow a single user to acquire more resources. Value is specified as a float. The default is 1, which ensures that a single user can never take more than the queue's configured capacity no matter how idle the cluster is. |

| Property | Description |
|--|---|
| <code>yarn.scheduler.capacity.resource-calculator</code> | <p>Specifies the <code>ResourceCalculator</code> implementation to be used to compare resources in the scheduler. The default value is <code>DiskBasedResourceCalculator</code>, which uses memory, CPU and disk. Other values for this parameter include:</p> <ul style="list-style-type: none"> <code>DefaultResourceCalculator</code>, which uses memory only <code>DominantResourceCalculator</code>, which uses <code>dominant-resource</code> to compare multi-dimensional resources such as memory and CPU <code>DiskBasedDominantResourceCalculator</code>, which uses <code>dominant-resource</code> to compare multi-dimensional resources, such as memory, CPU and disk |

Running and Pending Application Limits

Applications are considered active if they are either running or pending. The following table lists properties that specify running and pending application limits:

| Property | Description |
|---|--|
| <code>yarn.scheduler.capacity.maximum-applications</code> | <p>Maximum number of applications in the system that can be concurrently active, both running and pending.</p> <p>Limits on each queue are directly proportional to their queue capacities and user limits.</p> <p>This is a hard limit; any applications submitted when this limit is reached will be rejected. The default is 10000. This applies to all queues.</p> |
| <code>yarn.scheduler.capacity.<queue-path>.maximum-applications</code> | <p>Overrides <code>yarn.scheduler.capacity.maximum-applications</code> on a per queue basis.</p> |
| <code>yarn.scheduler.capacity.maximum-am-resource-percent</code> | <p>Maximum percent of resources in the cluster that can be used to run application masters - controls the number of concurrent active applications.</p> <p>Limits on each queue are directly proportional to their queue capacities and user limits. Specified as a float. For example, 0.5 = 50%.</p> <p>The default is 0.1. This can be set for all queues with <code>yarn.scheduler.capacity.maximum-am-resource-percent</code></p> |
| <code>yarn.scheduler.capacity.<queue-path>.maximum-am-resource-percent</code> | <p>Overrides <code>yarn.scheduler.capacity.maximum-am-resource-percent</code> on a per queue basis.</p> |

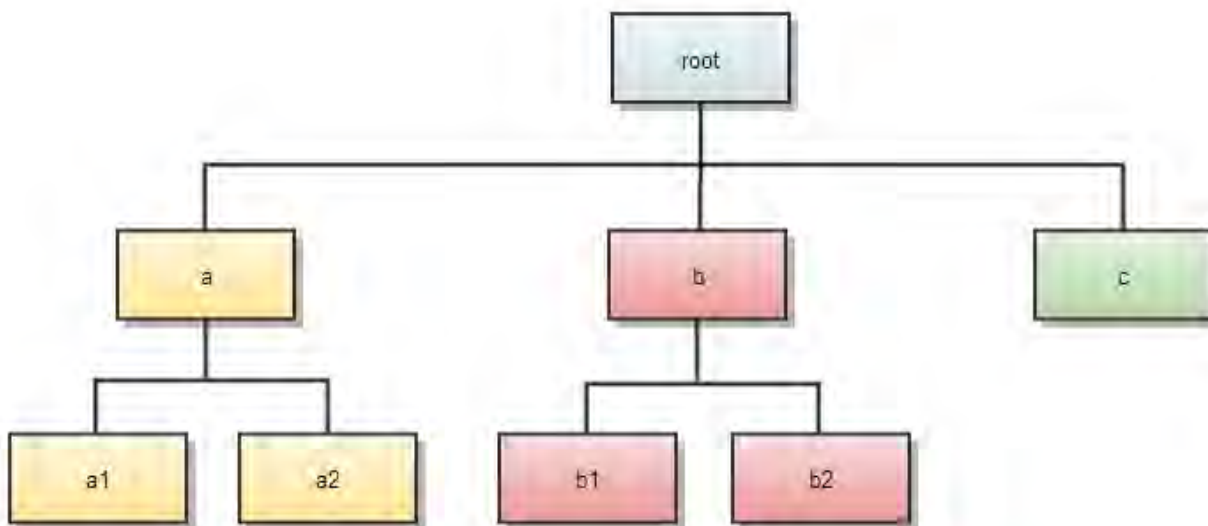

Queue Administration and Permissions

The following table lists queue administration and permission properties:

| Property | Description |
|--|--|
| <code>yarn.scheduler.capacity.<queue-path>.state</code> | The <i>state</i> of the queue. Possible values are RUNNING or STOPPED. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. If the <i>root</i> queue is STOPPED, no applications can be submitted to the entire cluster. Existing applications continue to completion, so the queue can be <i>drained</i> gracefully. |
| <code>yarn.scheduler.capacity.root.<queue-path>.acl_submit_applications</code> | The <i>ACL</i> that controls who can <i>submit</i> applications to the given queue. If the given user/group belongs to the <i>ACL</i> on a given queue or one of the parent queues in the hierarchy, they can submit applications. <i>ACLs</i> for this property <i>are</i> inherited from the parent queue if not specified. |
| <code>yarn.scheduler.capacity.root.<queue-path>.acl_administer_queue</code> | The <i>ACL</i> that controls who can <i>administer</i> applications on the given queue. If the given user/group has the necessary <i>ACLs</i> on the given queue or one of the parent queues in the hierarchy, they can administer applications. <i>ACLs</i> for this property <i>are</i> inherited from the parent queue if not specified. |

Setting Up a Hierarchy of Queues

CapacityScheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root*. The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:

Queue paths are defined for each level under the *root* queue. A queue's children are defined with the parameter `yarn.scheduler.capacity.<queue-path>.queues`, where `<queue-path>` takes the form `root.<child>`, `root.<child>.<child>`, and so on. For example, the queue path to `a2` is designated as `root.a.a2`.

Warning:

Children do not inherit properties directly from the parent unless otherwise noted.

The corresponding queue definition block of the `capacity-scheduler.xml` file is shown below.

```
<property>
  <name>yarn.scheduler.capacity.root.queues</name>
  <value>a,b,c</value>
  <description>The queues at this level (root is the root queue).
</description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.a.queues</name>
  <value>a1,a2</value>
  <description>The queues at this level (root is the root queue).
</description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.b.queues</name>
  <value>b1,b2,b3</value>
  <description>The queues at this level (root is the root queue).
</description>
</property>
```

Changing Queue Configuration

You can change queue properties and add new queues by editing `capacity-scheduler.xml`. Make sure that the updated queue configuration is valid and that the queue-capacity at each level equals 100%.

For the changes to take effect, run the following command:

```
yarn radmin -refreshQueues
```

Warning:

Queues cannot be deleted, only added.

Queue Access Control Lists

Describes how to restrict access to queues using Access Control Lists (ACLs).

Queue [ACLs](#) allow administrators to control who may take actions on particular queues. They are configured with the following properties:

```
yarn.scheduler.capacity.root.support.acl_submit_applications
yarn.scheduler.capacity.root.support.acl_administer_queue
```

You can set these properties for each queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as `user1,user2 group1,group2` or `group1,group2`. An action on a queue is permitted if its user or group is in the [ACL](#) of that queue, or in the [ACL](#) of any of that queue's ancestors. So if `queue2` is inside `queue1`, and `user1` is in `queue1`'s [ACL](#), and `user2` is in `queue2`'s [ACL](#), then both users may submit to `queue2`.

The root queue's [ACLs](#) are "*" by default. Since [ACLs](#) are passed down, by default, everyone may submit to, and kill applications from every queue. To restrict access, change the root queue's [ACLs](#) to something other than *.

By default, the `yarn.admin.acl` property in `yarn-site.xml` is also set to `*`, which means that any user can be the administrator. If queue [ACLs](#) are enabled, you also need to set the `yarn.admin.acl` property to the correct admin user for the YARN cluster. For example:

```
<property>
<name>yarn.admin.acl</name> >
<value>mapr</value> >
</property>
```

If you do not set this property correctly, users can kill YARN jobs even when they do not have access to the queues for those jobs.

Label-based Scheduling

Label-based scheduling provides a way to allocate shared cluster resources on particular nodes in a cluster. First, you assign node labels in a text file. The node labels map to one or more nodes. Next, you can create queue labels and job labels based on the node labels.

When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label). This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

The following sections provide more information about label-based scheduling:

Label-based Scheduling for YARN Applications

Label-based scheduling provides job placement control on a multi-tenant hadoop cluster. Using label-based scheduling, an administrator can control exactly which nodes are chosen to run jobs submitted by different users and groups. This is useful for data locality and multi-tenancy use cases.

To use label-based scheduling, an administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label).

This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

YARN Resource Calculation Based on Labels

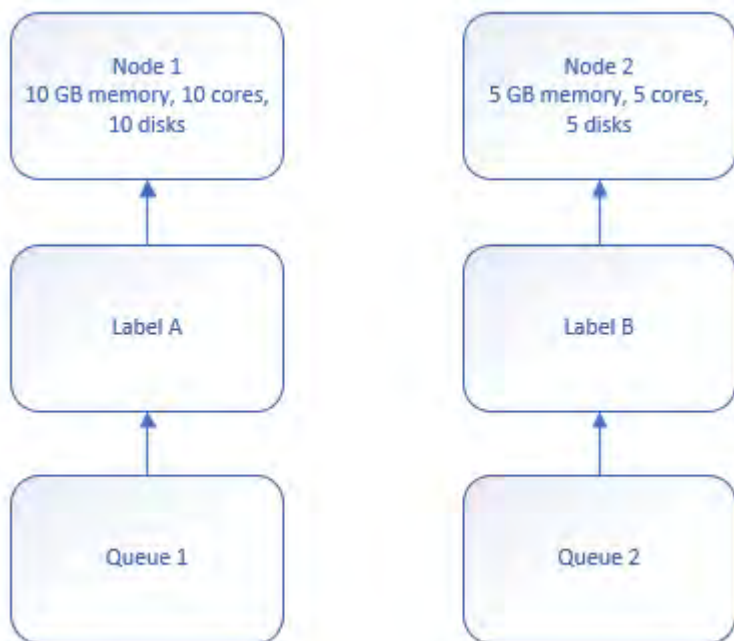

MapR 6.1.0 implements correct steady/instantaneous Fair Scheduler shares, headroom, and maximum resource calculation for queues with label-based scheduling (LBS).

This new approach to YARN resource allocation enables the cluster LBS configuration to compute the resources that are allowed for each queue. It also uses LBS to assign containers to the correct queues to preempt containers, and to prevent resource overuse. The LBS approach to YARN resource allocation relies on:

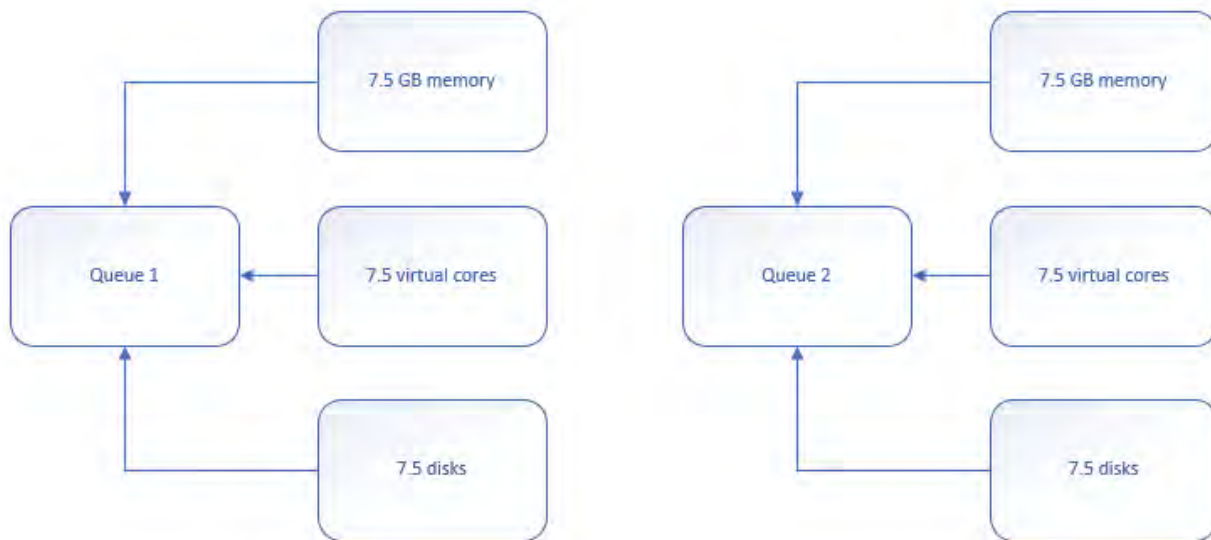

1. Resource computation (memory, CPU, disks) based on labels for each queue.
2. Per-label preemption threshold.

Example of LBS Resource Computation

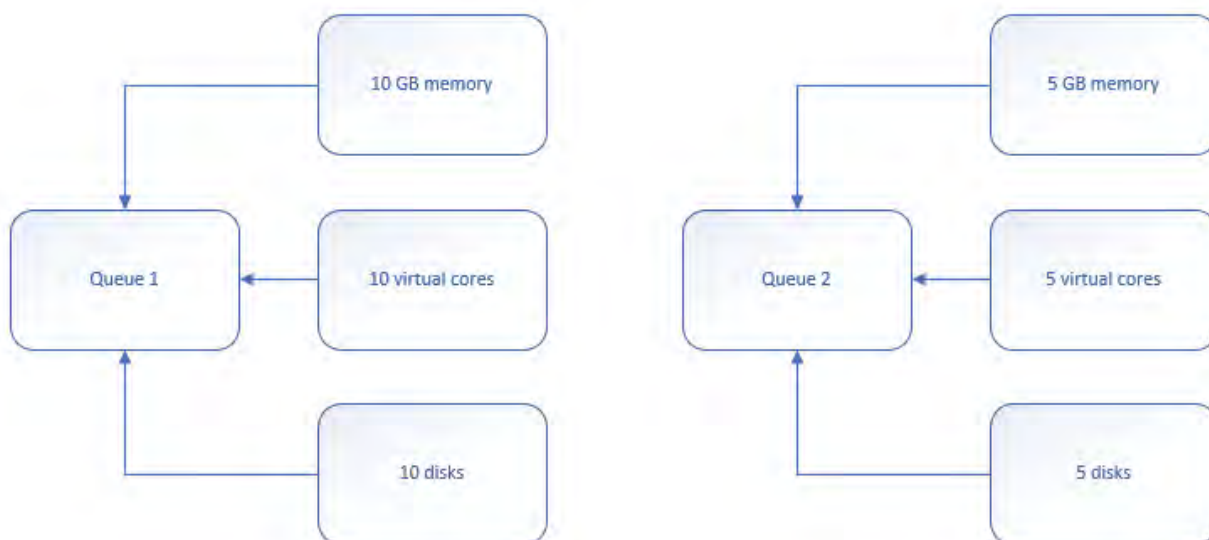

For example, imagine that you have the following resources:

Using the former fair-share resource distribution results in the following:

Using the new LBS resource distribution results in the following:

Understanding LBS preemption thresholds

Before LBS, preemption occurred by default when an entire cluster became 80% full (`yarn.scheduler.fair.preemption.cluster-utilization-threshold=0.8f`). With LBS, preemption occurs per labeled resource, as that resource becomes 80% full.

Descriptions of New Properties When Using LBS

- `defaultQueueLabel`

Assigned to all new queues and existing queues that do not have a label (excluding the `root` queue).

For example, `root.%username% queue` is created if you submit a new job without queue information and property `yarn.scheduler.fair.user-as-default-queue` is true.

You can specify this property in `fair-scheduler.xml`:

```
<allocations>
  <defaultQueueLabel>LabelA</defaultQueueLabel>
  <queue name="root">
    ...
  <queue name="queue1">
</queue>
  <queue name="queue2">
    <label>LabelB</label>
  </queue>
    ...
  </queue>
</allocations>
```

See [Specifying Fair Scheduler Configuration Properties in yarn-site.xml](#) on page 1390 for more information.

- `yarn.scheduler.fair.resources-based-on-labels-enabled`

Used to enable or disable recomputing of fair shares based on labels. It allows container allocation on all nodes.

You can specify this property in `yarn-site.xml`:

```
<property>
  <name>yarn.scheduler.fair.resources-based-on-labels-enabled</name>
  <value>>false</value>
</property>
```

- `yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled`

Allows enabling or disabling (default) preemption of the threshold per-label. To overcome the default and start container preemption when the threshold of the label is exceeded, change this property to `true`.

You can specify this property in `yarn-site.xml`:

```
<property>
  <name>yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled</name>
  <value>>false</value>
</property>
```

See [Specifying Fair Scheduler Configuration Properties in yarn-site.xml](#) on page 1390 for more information.

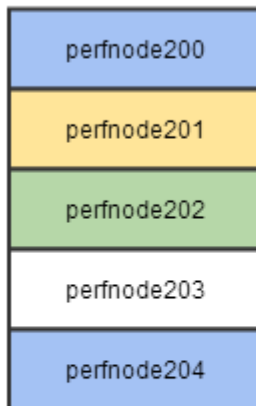

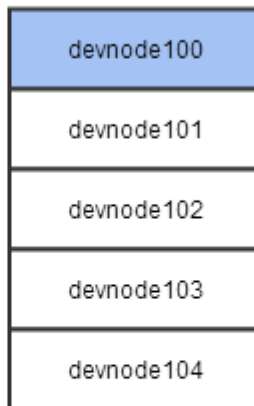

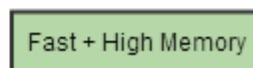

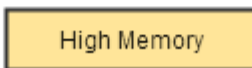

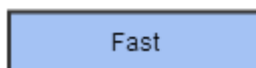

LBS Requirements and Restrictions?

Before you adopt LBS, you should be aware of two issues:

- Multiple labels for a node and label expression at the queue level are not supported.
- Except for `root`, all queues including the default, must be labeled, either independent or through inheritance.

Sample Cluster Configuration

To illustrate the concept of label-based scheduling, consider a cluster with two racks: RackA and RackB. The nodes in RackA are dedicated to the Production group, and the nodes in RackB are dedicated to the Development group. In addition, some nodes are configured with a fast CPU, one node is configured with high memory, and one node is configured with both a fast CPU and high memory. The following diagram illustrates the cluster configuration:

RackA - Production**RackB - Development****Key:****Creating a Node Labels File**

The node labels file is a text file stored in MapR filesystem that maps labels to nodes. A node label applies a name to a cluster node, to identify it for the purpose of specifying where to run MapReduce YARN applications (MRv2).

Syntax for Node Labels File

Each line in the node labels file consists of an identifier (a regular expression that identifies one or more nodes), whitespace to separate the identifier from the labels, then one or more labels (separated by commas, whitespace, or both) to apply to the specified nodes. If a label contains two or more words (such as "High Memory"), enclose the name in single or double quotation marks so the whitespace will not be interpreted as a delimiter between two labels.

```
<identifier> <label1>[,<label2>,...,<labeln>]
```

**Warning:**

Labels must *not* start with a digit.

The identifier specifies nodes by matching the node names or IP addresses in one of two ways:

- Unix-style [glob](#) which supports the ? and * wildcards
- Java regular expressions (refer to <http://docs.oracle.com/javase/6/docs/api/java/util/regex/Pattern.html> for more information)

**Warning:**

The identifier *must* match the fully qualified domain name (FQDN). To determine the FQDN, run the command `hostname --fqdn`.

Sample Node Labels File

The following node labels file is written for the sample cluster configuration and uses glob identifiers. Note that the FQDNs include the realm `company.com`.

```
perfnode20*.company.com RackA
perfnode200.company.com Fast
perfnode201.company.com 'High Memory'
perfnode202.company.com Fast
perfnode204.company.com Fast

devnode10*.company.com RackB
devnode100.company.com Fast
```

Using Node Labels to Schedule YARN Applications

To set up node labels for the purpose of scheduling YARN applications (including MapReduce applications) on a specific node or group of nodes:

1. Create a text file and specify the labels you want to use for the nodes in your cluster. In this example, the file is named `node.labels`.
2. Copy the file to a location on data-fabric filesystem where it will not be modified or deleted, such as `/var/mapr`.

```
hadoop fs -put ~/node.labels /var/mapr
```

3. Edit `yarn-site.xml` on all ResourceManager nodes and set the `node.labels.file` parameter and the optional `node.labels.monitor.interval` parameter as shown:

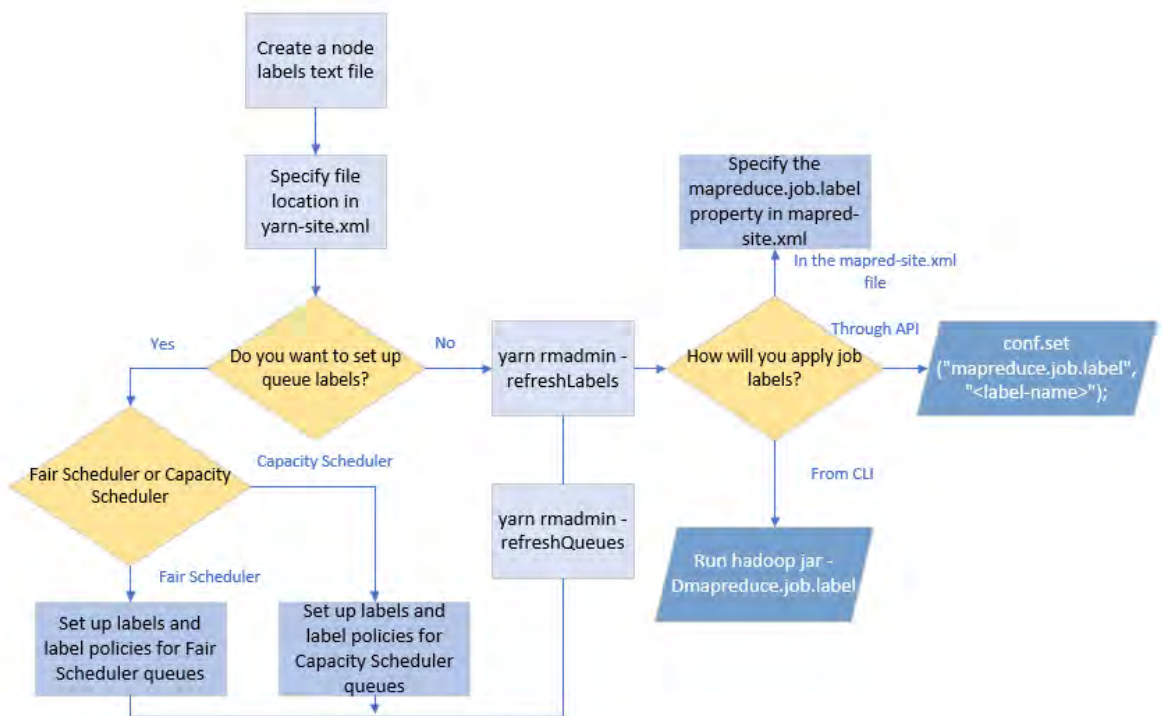

```
<property>
  <name>node.labels.file</name>
  <value>/var/mapr/node.labels</value>
  <description>The path to the node labels file.</description>
</property>

<property>
  <name>node.labels.monitor.interval</name>
  <value>120000</value>
  <description>Interval for checking the labels file for updates
  (default is 120000 ms)</description>
</property>
```

4. For this and subsequent changes to take effect, issue either of the following commands to manually tell the ResourceManager to reload the node labels file:
 - For any YARN applications, including MapReduce applications, enter `yarn rmdadmin -refreshLabels`
 - For MapReduce applications, enter `mapred job -refreshLabels`
5. Verify that labels are implemented correctly by running either of the following commands:

```
yarn rmdadmin -showLabels
mapred job -showlabels
```

The following flowchart summarizes these steps. In addition, the flowchart introduces the concept of queue labels for the Fair Scheduler and the Capacity Scheduler.

Creating Queue Labels

Queue labels are optional with label-based scheduling. You can use queue labels to determine which nodes an application or job can run on (subject to the queue label policy). A queue label is created from node labels as explained below.

Defining Queue Labels for Fair Scheduler

Explains how to customize the Fair Scheduler.

By default, all users share a single queue, named *default*.

To customize the Fair Scheduler, create an allocation file that lists existing queues and their respective weights and capacities, as explained in [Hadoop 2.x Fair Scheduler](#). In the allocation file, add the following property within the `queue` section:

```
<label>labelname</label>
```

For example:

```
<queue name="Customer Data Analysis">
  <weight>2.0</weight>
  <label>Fast</label>
</queue>
```

For a hierarchical queue, note that labels and label policies can be defined on any level of the queue. If a child queue does not have its own labels or label policies, the labels and label policies of the closest level are used.

Defining Queue Labels for Capacity Scheduler

The Capacity Scheduler has a pre-defined queue called *root*. All queues in the system are children of the root queue. Further queues can be set up by configuring `yarn.scheduler.capacity.root.queues` with a list of comma-separated child queues.

If a parent queue has child queues, this is how labels and label policies are applied to the child queues:

- If the child queues have their own labels or label policies, they are used.
- If the child queues do not have their own labels or label policies, the parent queue's labels and label policies apply.

To use label-based scheduling with the Capacity Scheduler, add the following property to the `capacity-scheduler.xml` file:

```
yarn.scheduler.capacity.root.<queue-name>.label
```

For example, for a queue named `alpha`, the label could be defined like this:

```
<property>
  <name>yarn.scheduler.capacity.root.alpha.label</name>
  <value>Fast || Development</value>
</property>
```

When you make changes to queue labels or queue policies, remember to refresh them by running the following command:

```
yarn radmin -refreshQueues
```

Defining a Queue Label Policy

A queue label policy determines whether an application label or a queue label prevails when there is a conflict between the two. For YARN applications, you can set the following queue label policies:

- `PREFER_QUEUE` — always use label set on queue
- `PREFER_APP` — always use label set on application
- `AND` (default) — application label AND queue label
- `OR` — application label OR queue label

See the following sections for directions on setting the queue label policy for Fair Scheduler and Capacity Scheduler.

Setting Queue Label Policies for Fair Scheduler

To set a queue label policy for a Fair Scheduler queue, specify the label policy in the corresponding `queue` section of the allocation file, as shown here:

```
<queue name="CustomerDataAnalysis">
  <weight>2.0</weight>
  <labelPolicy>OR</labelPolicy>
  <label>Fast</label>
</queue>
```

Setting Queue Label Policies for Capacity Scheduler

To set a queue label policy for a capacity queue, add the following property to the `capacity-scheduler.xml` file:

```
yarn.scheduler.capacity.root.<queue-name>.label-policy
```

For example:

```
<property>
  <name>yarn.scheduler.capacity.root.alpha.label-policy</name>
```

```
<value>PREFER_APP</value>
</property>
```

Examples of Queue Policy Behavior

The following examples show the job placement policy behavior in various scenarios, based on the sample node labels file:

| Application Label | Queue Label | Queue Policy | Outcome |
|-------------------|-------------|--------------|---|
| Fast | High Memory | PREFER_APP | The job runs on nodes labeled Fast (hostnames match perfnode200, perfnode202, perfnode204, or devnode100) |
| Fast | High Memory | PREFER_QUEUE | The job runs on nodes labeled High Memory (hostnames match perfnode201 or perfnode202) |
| Fast | High Memory | AND | The job runs on nodes only if they are labeled both Fast and High Memory (hostname matches perfnode202) |
| Fast | High Memory | OR | The job runs on nodes if they are labeled either Fast or High Memory (hostnames match perfnode200, perfnode201, perfnode202, perfnode204, or devnode100) |

Creating Job Labels

Explains the use of job labels to place jobs on particular nodes.

To place an individual job on a particular node, use a *job label*. You can apply job labels in three ways:

- Use `set()` from the Hadoop configuration API in your Java application. For example:

```
conf.set("mapreduce.job.label", "Production");
```

- At the command line, pass the label in `-Dmapreduce.job.label` when you run the job with the `hadoop jar` command. For example:

```
hadoop jar /opt/mapr/hadoop/hadoop-2.4.1/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.4.1-mapr-4.0.1-20140804.191359-4.jar \
teragen -Dmapreduce.job.label=Production 10000000 /teragen
```

- Set the `mapreduce.job.label` parameter in `mapred-site.xml`. For example, to configure an application label expression for a MapReduce application that can run on any Development node or Fast node (including a Fast node from the Production rack), set the `mapreduce.job.label` parameter as shown:

```
<property>
  <name>mapreduce.job.label</name>
  <value>Development || Fast</value>
  <description>Label expression for MapReduce application</description>
</property>
```

Warning:

If an application is submitted with a label that does not correspond to any nodes, the application will run as though no label had been specified. Consult the ResourceManager log for more information (look for 'invalid label' error messages).

Submitting Jobs and Applications to the Cluster

You can submit YARN applications (MapReduce version 2 and other applications that run on YARN) to the same cluster. An application can be submitted to the cluster in the following ways:

- The `hadoop jar` command submits an MRv2 application.
- The `yarn jar` command submits an application.
- An external application submits an application.
- An ecosystem component generates and submits an application.
- The `hadoop job` command submits an MRv2 application.
- The `mapred job` command submits an MRv2 application.

When you submit a non-MapReduce application to the cluster, such as a Spark application, it is automatically processed using `yarn` mode (ResourceManager, NodeManager, and MapReduce ApplicationMaster).

Note: The method to submit Hadoop commands from a Windows or Mac client is different, For details, see [Setting Up the Client](#).

Configuration Files for Jobs and Applications

Lists the locations of the MapReduce configuration files.

To override the MapReduce default configuration, use the following MapReduce configuration files:

| MapReduce Version | Configuration File Locations |
|---------------------|--|
| MapReduce Version 2 | <ul style="list-style-type: none"> • <code>/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/mapred-site.xml</code> • <code>/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml</code> |

To override the default configuration for applications, use the `yarn-site.xml` file that is present in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

YARN Container Resources

Provides an overview of YARN.

A YARN application can be a MapReduce version 2 (MRv2) application or a non-MapReduce application. The Warden on each node calculates the resources that can be allocated to process YARN applications. Each application has an ApplicationMaster that negotiates YARN container resources. For MapReduce applications, YARN processes each map or reduce task in a container. The ApplicationMaster requests resources from the ResourceManager based on memory, CPU, and disk requirements for the YARN containers. For YARN containers that process MRv2 tasks, there are additional considerations. See [YARN Container Resources for MapReduce Version 2 Applications](#) on page 1410 for details.

The ApplicationMaster requests YARN container resources based on the values of the following parameters:

yarn.scheduler.minimum-allocation-mb

Default: 1024

Description: Defines the minimum memory allocation available for a container in MB.

To change the value, edit the [yarn-site.xml](#) file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.

yarn.scheduler.maximum-allocation-mb

Default: 8192

Description: Defines the maximum memory allocation available for a container in MB.

To change the value, edit the [yarn-site.xml](#) file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.

yarn.nodemanager.resource.memory-mb

Default: Variable. This value is calculated by Warden.

Description: Defines the memory available to processing Yarn containers on the node in MB.

Warden uses the following formula to calculate this value: [total physical memory on node] - [memory required by the operating system, filesystem, and HPE Ezmeral Data Fabric services installed on the node].

To determine the value, go to the ResourceManager UI and view the memory available for that node.

yarn.nodemanager.resource.cpu-vcores

Default: Variable. This value is calculated by Warden.

Description: Defines the number of CPUs available to process YARN containers on this node.

Warden uses the following formula to calculate this value: [Number of CPU cores on node] - [Number of CPU cores assigned to filesystem].

To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the number of CPUs available for that node.

To change the value, edit the [yarn-site.xml](#) file for the node, assign the new value to this property, then restart the NodeManager.

yarn.nodemanager.resource.io-spindles

Default: Variable. This value is calculated by Warden.

Description: Defines the number of disks available to process YARN containers. Warden uses the following formula to calculate this value: [Number of disks on the node].

To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the disk information for this node.

YARN Container Resources for MapReduce Version 2 Applications

In addition to the YARN container resource allocation parameters, the MapReduce ApplicationMaster also considers the following container requirements when it sends requests to the ResourceManager for containers to run MapReduce applications:

| Parameter | Default | Description |
|---|---|--|
| <code>mapreduce.map.memory.mb</code> | 1024 | Defines the container size for map tasks in MB. |
| <code>mapreduce.reduce.memory.mb</code> | 3072 | Defines the container size for reduce tasks in MB. |
| <code>mapreduce.reduce.java.opts</code> | <code>-Xmx2560m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC</code> | Java options for reduce tasks. |
| <code>mapreduce.map.java.opts</code> | <code>-Xmx900m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC</code> | Java options for map tasks. |
| <code>mapreduce.map.disk</code> | 0.5 | Defines the number of disks a map task requires. For example, a node with 4 disks can run 8 map tasks at a time. Note: If I/O intensive tasks do not run on the node, you may want to change this value. |
| <code>mapreduce.reduce.disk</code> | 1.33 | Defines the number of disks that a reduce task requires. For example, a node with 4 disks can run 3 reduce tasks at a time. Note: If I/O intensive tasks do not run on the node, you might want to change this value. |

You can use one of the following methods to change the default configuration:

- Provide updated values in the `mapred-site.xml` file on the node that runs the job. You can use central configuration to change this value on each node that runs the NodeManager in the cluster. Then, restart NodeManager on each node in the cluster. The `mapred-site.xml` file for MapReduce ve applications is located in the following directory: `opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`
- Override the default values from the command line for each application that requires a non-default value.

Monitoring the Cluster

This section describes how to monitor the health and performance of a MapR cluster.

Monitoring Using the Control System and the CLI

Describes the Overview page in the Control System, which displays information about the cluster.

The **Overview** displays a summary of information about the cluster in six panes including information on cluster health, activity, and usage.

Note: During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the **Overview** page. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the **Overview** page. If you want, you can install metrics collection or logging at any time by selecting the feature during an [Incremental Install](#).

The following sections provide information about each pane.

Setting the Refresh Rate on the Control System

Explains how to configure how frequently you want to refresh the graphs and data in the panes.

To set the refresh rate:

1. Log in to the Control System and click **Settings** from the  drop-down menu.
2. Enter the refresh rate in seconds for the following.
 - Data refresh rate
 - Metrics and charts refresh rate

The default refresh rate is 30 seconds. The minimum refresh rate is:

- 5 seconds for data.
 - 30 seconds for metrics and charts.
3. Set the User Session Inactivity Timer in minutes. The user is logged out from the Control System after the specified number of minutes if there is no activity on the Control System. The default value is 30 minutes.
 4. Click **Save Changes** for the changes to take effect.

Customizing the List of Metric Charts and Columns on the Control System

Explains how to customize the list of metric charts and columns on the Control System.

You can customize the list of table metric charts and columns that you see on the Control System.

Creating a Custom Board for the Charts

To view a custom set of charts on the Control System, you can create a custom board. To create a board:

1. Log in to the Control System and go to one of the following pages:
 - **Metrics** tab of the [node details page](#).
 - **Metrics** tab in the **Data > Tables** page.
 - **Metrics** tab of the [table information page](#).
 - **Metrics** tab of the [secondary index details page](#).
2. Select **Create new Board** from the **Boards** drop-down list to display the **Create New Chart Board** window.
3. Enter a unique name for the new Board in the **Board Name** field.
4. Select the charts from the **Available** list of charts and click **>** to move selection to **Selected** charts to display on page.
You can select up to six charts to display at a time on the page.
5. (Optional) Click **▲** and/or down **▼** arrows to sort the order of charts.

6. Click **Create and Apply** to create a new Board and view the selected charts in the Board.

Editing a Chart Board

You can modify an existing chart Board to add or remove charts from the board:

1. Log in to the Control System and go to one of the following pages to view the board to modify:
 - **Metrics** tab of the [node details page](#).
 - **Metrics** tab in the **Data > Tables** page.
 - **Metrics** tab of the [table information page](#).
 - **Metrics** tab of the [secondary index details page](#).
2. Click  associated with the Board to modify from the **Boards** drop-down list. The **Edit Chart Board** window displays.
3. You can make the following changes:
 - a) Modify the Board name.
 - b) Select the charts from the:
 - Selected list of charts and click  to remove selected charts.
 - Available list of charts and click  to move selection to **Selected** charts to display on page.
You can select up to six charts to display at a time on the page.
 - c) Click  and/or down  arrows to sort the order of charts.
4. Click **Save and Apply** for the changes to take effect.

Removing a Chart Board

To remove charts from a Board, see [Editing a Chart Board](#) on page 1412. To remove a chart Board, do the following:

1. Log in to the Control System and go to one of the following pages to view the list of Boards:
 - **Metrics** tab of the [node details page](#).
 - **Metrics** tab in the **Data > Tables** page.
 - **Metrics** tab of the [table information page](#).
 - **Metrics** tab of the [secondary index details page](#).
2. Click  associated with the Board to remove from the **Boards** drop-down list. The **Delete Board** window displays.
3. Click **Submit** to remove the Board.

Adding and Removing Columns from the List View

1. Log in to the Control System and do one of the following:
 - Go to the **Metrics** tab of the [node details page](#) and select **Activity by Tables** from the drop-down menu to view the metrics for all table-related activities on the node.
 - Go to the **Metrics** tab of the [table information page](#) and select:

- **Activity by Nodes** (default selection) from the drop-down menu to view the metrics for table activity across nodes.
 - **Activity by Indexes** from the drop-down menu to view metrics for all index-related activity on the table.
 - Go to the **Metrics** tab of the [secondary index details page](#) and select **Activity by Nodes** to view metrics for index-related activity across nodes.
2. Click  to switch to a list view.
 3. Click  to display the **Customize Columns** window.
In the **Customize Columns** window, the:
 - **Available** list displays the columns available, but currently not displayed.
 - **Selected** list displays the columns currently displayed in the page.
 4. Select the columns from the:
 - a) Selected list of columns and click  to remove selected columns from the view.
 - b) Available list of columns and click  to move selection to **Selected** columns (for display).
For the list of metrics that can be viewed in the columns, see [Viewing Table Metrics in the Control System](#) on page 1428
 5. (Optional) Click  and/or down  arrows to sort the order of columns.
 6. Click **Save** to view the selected columns.

Monitoring the Cluster

Explains how to view the cluster health, disk, memory, CPU utilization metrics, and alarms on the cluster using either the Control System or the CLI.

Monitoring Cluster Health Using the Control System

- Log in to the Control System and click **Overview**.
The **Overview** page displays the following panes:
 - [Node Health](#) — the health of the nodes on the cluster, by service (default) or topology
 - [Active Alarms](#) — a summary of active alarms for the cluster
 - [Cluster Utilization](#) — CPU, memory, and disk space usage
 - [Yarn](#) — the number of running and queued applications, number of Node Managers, and percent of memory and CPU's used relative to the amount configured

Note: During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the panes. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the various panes. If you want, you can install metrics collection or logging by selecting the feature during an [Incremental Install](#).

Viewing Cluster Utilization Information on the Control System

The **Cluster Utilization** pane in the **Overview** page displays the following for:

- CPU — Percentage of cores currently utilized and total cores

- Memory — Percentage of memory (in GB) currently utilized and total memory (in GB)
- Disk — Percentage of space (in GB) currently utilized and total disk space (in GB)

The **Cluster Utilization** pane also shows the amount of raw data and the savings (in percentage) after compression.

The **Utilization Trend** pane shows CPU, memory, and disk usage trend for the last 24 hours by default. You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot).

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view. If there were any alarms during the selected date/time range, the **Alarms** pane above shows:

- When the alarm was raised
- The severity of the alarm
 -  — an error
 -  — a warning
 -  — information

Monitoring Cluster Alarms on the Control System

See [Viewing Active Cluster Alarms](#) on page 1438 for more information.

Retrieving Cluster Information Using the CLI or REST API

The basic command to retrieve cluster health and disk space information is:

```
maprcli dashboard info -cluster <cluster>
```

The `utilization` field in the output shows the total and utilized amount of disk space, memory, and CPU for the cluster, which can also be visualized on the Control System. For example:

```
# /opt/mapr/bin/maprcli dashboard info -json
{
  "timestamp":1525230746268,
  "timeofday":"2018-05-01 08:12:26.268 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      ...
      "utilization":{
        "cpu":{
          "util":7,
          "total":8,
          "active":0
        },
        "memory":{
          "total":15886,
          "active":11281
        },
        "disk_space":{
          "total":273,
          "active":0
        },
        "compression":{
```

```

        "compressed":0,
        "uncompressed":0
    },
    "tiering":{
        "logicalUsed":0,
        "replicatedLogicalUsed":0,
        "replicatedTotalUsed":0,
        "ecTotalUsed":0,
        "cvTotalUsed":0,
        "offloaded":0,
        "recalled":0
    }
},
...
}
]
}

```

For information on all the fields returned by this command, see [dashboard info](#) on page 1770.

Monitoring Nodes

Explains how to monitor nodes using either the Control System or the CLI.

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

 **Note:** The metrics collection infrastructure must be installed during installation to visualize the graphs and charts. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

 **Note:** The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

To monitor the health of nodes:

1. Log in to the Control System and click:
 - **Overview** to view the health of the nodes in the **Node Health** pane.
 - **Nodes** to view the health of the nodes in the **Node Health** pane.
2. Select one of the following from the drop-down menu in the **Node Health** pane.
 - **By Service** to organize the display of nodes by services.

This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running (■) and is down (■).

 **Note:** The color of the node (which reflects the status of the service) is ■ even when a service is stopped (not running) on the node.

- **By Topology** to view the display of nodes by topology.

This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

| | |
|---|--|
| ■ | Indicates the node is healthy. |
| ■ | Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: |

| | |
|---|--|
| | <ul style="list-style-type: none"> • There is no heartbeat from the HPE Ezmeral Data Fabric filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node. |
| ■ | Indicates the node is in maintenance mode. |
| ■ | <p>Indicates critical issue(s) on the node. A node is considered to be in critical state if:</p> <ul style="list-style-type: none"> • There is no heartbeat from the node for more than 5 minutes. • All HPE Ezmeral Data Fabric files system disks on the node are dead or are offline. • All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour. • File server is dead/inactive because there is no heartbeat for a long time. • NFS server on node is dead. • HPE Ezmeral Data Fabric install directory is full. • Node reported high HPE Ezmeral Data Fabric filesystem memory usage. |

Monitoring Node Resource Utilization from the Control System

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

Monitoring Active Node Alarms from the Control System

See [Viewing Active Node Alarms](#) on page 1439 for more information.

Monitoring Node Health Using the CLI or REST API

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see [node heatmap](#) on page 1908.

Viewing Node Metrics

Explains how to view node metrics using the Control System.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to visualize the metrics that are described in the following section.

Monitoring Node Metrics Using the Control System

- Log in to the Control System and go to the **Metrics** tab in the [node information page](#).

By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

Time Range

From:

To:

Apply

| | | | |
|--------------|----------------------|-------------------|-----------------|
| Last 2 days | Yesterday | Today | Last 5 minutes |
| Last 7 Days | Day before yesterday | Today so far | Last 15 Minutes |
| Last 30 Days | This day last week | This week | Last 30 minutes |
| | Previous week | This week so far | Last 1 Hour |
| | Previous month | This month | Last 3 hours |
| | | This month so far | Last 6 hours |
| | | | Last 12 Hours |
| | | | Last 24 Hours |

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- > to shift time window forwards.
- < to shift time window backwards.

Click i associated with the chart to view information about the graph. Click 🔧 to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

| Metric | Charts |
|-----------|--|

* This metric is displayed in the default chart view for a node.

** This metric is displayed in the default chart view for a node and in the default list view for a table.

*** This metric is displayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see [Viewing Per Node Metrics for Table Activities](#) on page 1419.
- All stream activities on a node, see [Monitoring Streams Operations Using the Control System](#) on page 1435.

Viewing Per Node Metrics for Table Activities

Describes how to view per node metrics for table activities using the Control System and Grafana.

This section describes how to view the metrics as charts and lists in the Control System. For information on visualizing the [metrics](#) in the Grafana UI, see [Metric Visualization](#) on page 1493

Note: The metrics collection infrastructure must be installed to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to visualize the metrics as described below.

1. Log in to the Control System and go the **Metrics** tab in the [node information page](#).
2. Select **Activity by Tables** from the drop-down menu.

By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

The charts show metrics for the node across tables. Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window, where you can select charts to display and remove from the **Available** and **Selected** lists. You can view up to 6 charts at a time in the page.

You can switch to the list view by clicking . In the list view, you can:

- Click the table name to go to the metrics page for the table.
- Select one or more tables and switch to charts view (by clicking) to visualize metrics for the selected tables only.

For the complete list of metrics that you can view at both the node and table levels, see [Viewing Table Metrics in the Control System](#) on page 1428.

Monitoring YARN

- Log in to the MapR Control System and:
 - Click **Overview** to view the following in the **YARN** pane:
 - Number of node managers, running applications, and queued jobs.
 - Memory and CPU utilization metrics.

- Go to the [service information page](#) for YARN. The YARN information page displays the following panes:

Summary

Displays:

- Total number of nodes and number of active and unhealthy nodes.
- Allocated, pending, and reserved number of Resource Manager containers.

Top Queues by CPU Utilization

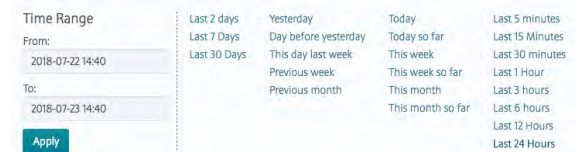

Displays the queues that utilize the most CPU (in percentage).

Top Queues by Memory Consumption

Displays the queues that consume the most memory (in percentage).

Applications

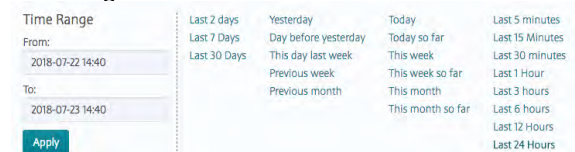

Displays the number of submitted, completed, running, pending, and failed applications during a selected date and time range. You can select a preset or specify a custom time range.

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Resource Manager (CPU)

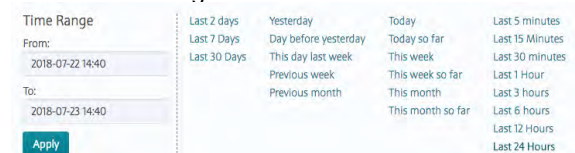

The number of cores allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Resource Manager (Memory)

The amount (in MB) of memory allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to install the metrics collection infrastructure.

Monitoring Volumes

Explains how to monitor volume parameters using the Control System.

You can monitor volume:

- [Disk usage](#)
- [Alarms](#)

Monitoring Volume Disk Usage Using the Control System

- You can view:
 - Volumes that use the most amount of allocated disk space in the **Top Volume Utilization** pane under **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

Note: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an [Incremental Install](#) to view the charts described here.

- Disk usage trend for a volume in the **Usage Trends** pane in the **Summary** tab of the [volume information page](#). You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot). You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view.

Monitoring Volume Alarms in the Control System

See [Viewing Active Volume Alarms](#) on page 1439.

Monitoring Local and Remote Storage for Volumes

You can view the following storage utilization metrics for tiered volumes in the **Data > Volumes > Local & Remote Usage** pane.

Note: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

- **Local** — The total disk space (in GB) used (before compression) for the volumes in the HPE Ezmeral Data Fabric cluster. This value does not include erasure-coded backend volumes and cache-volumes because their logical usage is already accounted for by the front-end and parent volumes respectively.
- **Cold Offloaded** — The total physical data (in GB) offloaded to the cold tier. This is calculated using the following: *amount of data purged from the hot tier (HPE Ezmeral Data Fabric cluster) + amount of data recalled to the hot tier (HPE Ezmeral Data Fabric cluster)*.
- **Warm Offloaded** — The total physical data (in GB) offloaded to the erasure coded volume (warm tier). This is calculated using the following: *amount of data purged from the hot tier (HPE Ezmeral Data Fabric cluster) + amount of data recalled to the hot tier (HPE Ezmeral Data Fabric cluster)*.

Collecting Volume Metrics

Describes how to enable and collect operational metrics for volumes.

You can collect the following volume metrics on filesystem after you enable metrics collection as described in [Enabling Volume Metric Collection](#) on page 1423:

| | |
|------------------|------------------------|
| Read I/Os | Number of reads |
| Write I/Os | Number of writes |
| Read throughput | Amount of data read |
| Write throughput | Amount of data written |

| | |
|---------------|--------------------------------|
| Read latency | Time taken by read operations |
| Write latency | Time taken by write operations |

If you enable metrics collection on a volume, for each filesystem instance, on every node where the volume containers reside, metrics for the volume (for a day) are captured every 10 seconds and logged to files in a local volume, which is two way replicated. The metrics log file, `Metrics.log-<date>-<n>.json`, is available at `/var/mapr/local/<hostname>/audit/<mfs-port>` directory. Here:

- `mfs-port` is the port on which the filesystem instance listens.
- `date` is the record date in the format `yyyy-mm-dd`. A new file is created at the beginning of each day.
- `n` is the iteration of the log file represented by 3 digits. A new file is created every time Warden is restarted on the node. For the first file, `<n>` is 001 and `<n>` is incremented every time warden restarts. For example: `Metrics.log-2017-08-18-001.json` and `Metrics.log-2017-08-18-002.json`. When a new file is created, the old file is purged based on the CLDB audit log retention period, which is 30 days by default.

Each record in the file looks similar to the following:

```
{
  "ts":1503048590000,
  "vid":35211529,
  "RDT":0.0,
  "RDL":0.0,
  "RDO":0.0,
  "WRT":308085.8,
  "WRL":2434.0,
  "WRO":2192.0
}
```

Here:

- `ts` — timestamp in milliseconds
- `vid` — volume ID
- `RDT` — read throughput in KB (cumulative for 10 seconds)
- `RDL` — amount of time taken by read operations (average for 10 seconds)
- `RDO` — number of read operations (cumulative for 10 seconds)
- `WRT` — write throughput in KB (cumulative for 10 seconds)
- `WRL` — amount of time taken by write operations (average for 10 seconds)
- `WRO` — number of write operations (cumulative for 10 seconds)

The `collectd` service reads up to 16 MB of data every ten seconds from each file, then aggregates and writes one minute worth of data to OpenTSDB. When reading the file, the `collectd` service stores offsets (as to how much has been read) as extended attributes (`trusted.dispatchedOffset`) on the file. In addition to the default tags assigned to each metric when `collectd` writes metrics to OpenTSDB, the following tags are assigned to volume metrics:

- `mapr.volmetrics.[read_|write_] [throughput|latency|ops]` — Displays the type of metric
- `volume_name` — Displays the name of the volume

For more information on the default tags, see [Metric Collection](#) on page 1445.

For each metrics file, MapR also creates a file, `Vollist_metrics.log-<date>-<n>`, in the `/var/mapr/local/<hostname>/audit/<mfs-port>/` directory. This file is purged based on the CLDB audit log retention period, which is 30 days by default. This file contains a comma separated list of volume name and volume ID (for volumes for which metrics are captured) and is associated with the `Metrics.log-<date>-<n>.json` file. For example, the record in the file looks similar to the following:

```
<volumeid>,<volume name>,<volumeid>,<volume name>,...
```

You can visualize the metrics in the dashboards on Grafana. See [Metric Visualization](#) on page 1493 for more information.

Enabling Volume Metric Collection

Describes how to enable metric collection for a volume, and gather volume statistics.

On all new installations, this feature is enabled by default and you only need to enable metrics collection for each volume. If you are upgrading from a version prior to MapR version 6.0, to start collecting volume metrics that you can then visualize in Grafana, you must enable the metrics collection feature and then enable metrics collection for each volume.

You can enable metrics collection from the command-line and using the Control System.

Enabling the Metric Collection Feature

- Enable the feature by running the following command:

```
/opt/mapr/bin/maprcli cluster feature enable -name
mfs.feature.metrics.support
```

Enabling Metric Collection for New Volumes Using the Control System

1. Log in to the Control System and click **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Volume** to display the **Create New Volume** page.
3. Enter values for the required settings and move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.
For more information, see [Creating a Volume](#) on page 941.
4. Click **Create Volume** to create the volume.

Enabling Metric Collection for Existing Volumes Using the Control System

1. Log in to the Control System and click **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the **Volumes** to edit and **Edit Volume** from the **Actions** drop-down menu or go the [volume info page](#) and click **Edit Volume**.
3. Move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.
For more information, see [Creating a Volume](#) on page 941.
4. Click **Save Changes** for the changes to take effect.

Enabling Metric Collection for Volumes Using the CLI

- Enable metrics collection on:
 - A new volume by running the following command:

```
/opt/mapr/bin/maprcli volume create -name <volume-name> -path
<volume-mount-path> -type <volume-type> -metricsenabled true
```

For more information, see [volume create](#) on page 2190.

- An existing volume by running the following command:

```
/opt/mapr/bin/maprcli volume modify -name <volume-name> -metricsenabled
true
```

For more information, see [volume modify](#) on page 2275.

- All volumes that do not have mapr in the name by running the following script:

```
for i in ` /opt/mapr/bin/maprcli volume list -columns n | grep -v
mapr | grep -v volumename`; do echo $i; /opt/mapr/bin/maprcli volume
modify -name $i -metricsenabled true; done
```

Monitoring Tables

Explains how to monitor table alarms and view table metrics in the Control System.

Monitoring Table Alarms in the Control System

See [Viewing Active Table Replication Alarms](#) on page 1440.

Viewing Throughput by Operation Type Using the Control System

- Log in to the Control System and do one of the following:
 - Go to the **Summary** tab in the [table information page](#).

The **Throughput - By Op Type** pane displays a graph for the following operations on the table in the last hour:

- Gets
- Puts
- Scans
- Increments
- Appends
- Checks and Puts
- Updates and Gets

- Go to the **Summary** tab in the [index details page](#).

The **Throughput - By Op Type** pane displays a graph for the following operations on the index in the last hour:

- Puts
- Scans

You can move the cursor over the graph to view the number of operations on the table (across nodes).

Visualizing Table Metrics in the Control System

In the Control System, you can visualize node-level metrics for table operations on a node. You can view charts that show metrics for all tables across all nodes, metrics per table aggregated across nodes, metrics per table per node, and metrics per node across tables. In addition, you can view metrics for activity by indexes and for the table and its secondary indexes.

For the full list of metrics (and associated charts/columns) that you can view in the Control System, see [Viewing Table Metrics in the Control System](#) on page 1428.

- Log in to the Control System and do one of the following to view table metrics:
 - Go to the **Metrics** tab in the [node information page](#) and select **Activity by Tables** from the drop-down menu.

In this tab, you can view charts/columns that show metrics for all table operations on the node, operations on streams, and other node metrics described [here](#).
 - Go to the **Metrics** tab in the **Data > Tables** page.

In this tab, you can view charts/columns that show metrics per node for all tables.
 - Go to the **Metrics** tab in the [table information page](#).

In this tab, you can view charts/columns that show operations on the table and its secondary indexes across nodes.
 - Go to the **Metrics** tab in the [index details page](#) and select **Activity by Nodes** from the drop-down menu.

In this tab, you can view charts that show all index operations and index operations per node.

You can select the charts to view by creating a custom chart Board or by modifying an existing Board. See [Creating a Custom Board for the Charts](#) on page 1411 or [Editing a Chart Board](#) on page 1412 for more information.

The charts on the page show the metrics for the last 24 hours by default. You can select a preset or specify a custom time range.

The screenshot displays a 'Time Range' configuration panel. On the left, there are two input fields: 'From:' with the value '2018-07-22 14:40' and 'To:' with the value '2018-07-23 14:40'. Below these fields is a blue 'Apply' button. To the right of the input fields is a grid of preset time range options:

| | | | |
|--------------|----------------------|-------------------|-----------------|
| Last 2 days | Yesterday | Today | Last 5 minutes |
| Last 7 Days | Day before yesterday | Today so far | Last 15 Minutes |
| Last 30 Days | This day last week | This week | Last 30 minutes |
| | Previous week | This week so far | Last 1 Hour |
| | Previous month | This month | Last 3 hours |
| | | This month so far | Last 6 hours |
| | | | Last 12 Hours |
| | | | Last 24 Hours |

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- [➤](#) to shift time window forwards.
- [⏪](#) to shift time window backwards.

Note: When you select a granular view, the chart might not show the most accurate data because of the difference between the interval at which the metrics are logged and the downsampling (lowering the sampling rate) for the interval being viewed.

You can switch to a list view, where available, by clicking . In this view, you can select metrics to view by clicking . See [Adding and Removing Columns from the List View](#) on page 1412 for more information.

In the list view, you can:

- Filter the list by clicking .
- Click the node name to go to the node-level metrics page.
- Select one or more nodes and switch to charts view by clicking to visualize metrics for the selected nodes only. The legends for the charts reflect the selected nodes.

Note: Certain grouping of metrics, available in the charts view, are not available in the list view. All the metric grouping available in the list view are available in the charts view as well. When you switch from charts to list view and vice versa, your selection of metrics in one view is not carried over to the other view.

The chart and list views allow you to detect and diagnose bottlenecks and performance issues on individual tables and nodes. You can use the charts for measuring the throughput and latency of different RPC operations on a table and for determining which operations on a table are slow or which tables are most frequently accessed.

For example:

- Suppose your node is busy and you are noticing intermittent latency spikes on your table. You can compare throughput and latency in the **Metrics** tab of the [table information page](#) and investigate if the latency spike is due to node being very busy or node having high CPU utilization by switching to the list view from where you can navigate to the **Metrics** tab of the [node details page](#).
- Suppose your index queries take minutes instead of seconds to complete. You can compare the get latency percentile with the scan read/response in the **Metrics** tab of the [table information page](#) by zooming in to the area where you see the spike. Switch to **Activity by Index** to view the index vs primary table scans where you can determine whether excessive scan load went to the primary table.
- Suppose you are noticing latency spikes on one of your table as a result of a lot of activity on another table. Observe the get latency percentile spikes in the **Metrics** tab of the [table information page](#) and switch to **Activity by Node** list view to identify the nodes with high overall aggregate table RPC load and node IOps. Select the saturated nodes in the list view and switch to the chart view. Go back to the list view and click the saturated node to navigate to the **Metrics** tab of the [node details page](#). Switch to **Activity by Tables** to determine the most active table.

Viewing Secondary Index Metrics

You can visualize the secondary index metrics in the Control System.

- Log in to the Control System and do one of the following:
 - Go to the **Metrics** tab in the [table information page](#) and select **Activity by Indexes** from the drop-down menu to view all index-related activity on the table.
 - Go to the **Metrics** tab in the [secondary index page](#) to view metrics for index-related activity across tables or per node.

By default, the page displays metrics for the last 24 hours. You can select a preset or specify a custom time range.

You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

The page displays charts by default. When viewing activity by nodes, you can switch to a list view by clicking and return to charts view by clicking .

Charts view

You can select the charts to view by creating a custom chart Board or by modifying an existing Board. See [Creating a Custom Board for the Charts](#) on page 1411 or [Editing a Chart Board](#) on page 1412 for more information. Click the associated with the chart to view information about the graph.

List view

The list view shows the metrics in the columns. You can customize the columns by clicking . See [Adding and Removing Columns from the List View](#) on page 1412 for more information. In addition, you can:

- Click the column name to sort the table by that column.
- Click the node name to go to the metrics page for the node.
- Click one or more checkboxes next to the node name and switch to the charts view to visualize metrics for the secondary index activities on those nodes only.

You can use the charts to diagnose and troubleshoot bottlenecks and performance issues. For the complete list of metrics that you can view for secondary indexes, see [Viewing Table Metrics in the Control System](#) on page 1428.

Viewing Region Distribution

- Log in to the Control System and go to one of the following pages:
 - **Summary** tab in the [table information page](#) to view the region distribution for a table.
 - **Summary** tab in the [index details page](#) to view the region distribution for a secondary index.

The **Region distribution** pane shows the distribution of the table or secondary index regions across the nodes in the cluster. The shade of the node reflects the sum of the physical size of data on the node with the darker shade indicating increased resource utilization on the node. You can move the cursor over a node to view the following:

- Hostname of the node
- Number of regions on the node
- Total size of data (across regions) on the node

You can click a node to go to the [node information page](#).

Viewing Table Metrics in the Control System

Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

- View these metrics in the Control System, see [Monitoring Tables](#) on page 1424.
- Customize the charts you see on the page, see [Creating a Custom Board for the Charts](#) on page 1411.
- Customize columns you see on the page, see [Adding and Removing Columns from the List View](#) on page 1412.

| Chart/Column Name | Metric | Description |
|------------------------------------|-------------------------------|---|
| Table Bytes Read Per Node | Throughput - bytes read | The number of bytes read from the primary table per node for all RPC types. |
| Table and Index Bytes Read | | The number of bytes read across a primary table and its secondary indexes for all RPC types. |
| Table Bytes Written Per Node | Throughput - bytes written | The number of bytes written to the primary table per node for all RPC types. |
| Table and Index Bytes Written | | The number of bytes written across a primary table and its secondary indexes for all RPC types. |
| Table Rows Read Per Node | Throughput - rowCount read | The number of rows read from the primary table per node for all RPC types. |
| Table and Index Rows Read | | The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node. |
| Table Rows Written Per Node | Throughput - rowCount written | The number of rows written to the primary table per node for all RPC types. |
| Table and Index Rows Written | | The number of rows written across a primary table and its secondary indexes for all RPC types. |
| All Tables Written Rows Throughput | | Number of rows written by RPC operation type. |

| Chart/Column Name | Metric | Description |
|--------------------------------|--------------------------------|---|
| Table Rows Responded Per Node | Throughput - rowCount returned | The number of rows returned from the primary table per node for all RPC types. |
| Table and Index Rows Responded | | The number of rows returned across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node. |
| Scan Throughput | | Compares the scan throughput for rows read versus rows returned. This is displayed in the default chart view for a node and for a table. |

| Chart/Column Name | Metric | Description |
|--|--|--|
| All Tables Throughput | Throughput - rpcCount/second | Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables. |
| Throughput by Rpc Type | | The combined RPC load for the primary table and its indexes. |
| All Tables RPC Byte Throughput | | The number of bytes processed by RPC operation type. |
| All Tables Read Rows Throughput | | Number of rows processed by RPC operation type. |
| All Tables Returned Rows Throughput | | Number of rows returned by RPC operation type. |
| Put and Append Operation Throughput | | Number of put and append RPC operations for the table, including its indexes. |
| Table Check and Put Ops Per Node | | The number of check and put operations completed for a primary table and for a node. |
| Table Update and Get Ops Per Node | | The number of update and get operations completed for a primary table and for a node. |
| Table Get and Index Scans | | The number of get and index scans completed for a primary table and for a node. |
| Table Write and Index Maintenance Activity | | The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index. |
| Table Get Ops Per Node | | The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table. |
| Table Get Throughput Per Node | | The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table. |
| Table Increment Ops Per Node | | The number of increment operations completed for a primary table and for a node. |
| Table Put Ops Per Node | | The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table. |
| Table Scan Ops Per Node | | The number of scan operations completed for a primary table and for a node. |
| Table Append Ops Per Node | | The number of append operations completed for a primary table and for a node. |
| Table Write Throughput Per Node | The number of put and append operations per second completed | |

| Chart/Column Name | Metric | Description |
|---|--|--|
| Table and Index Scan Latency | Latency | The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index. |
| Table and Index Scan Latency Per node | | The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency. |
| Table Append Latency Per Node | | The 99th percentile latency of append operations on the primary table per node. |
| Table Increment Latency Per Node | | The 99th percentile latency of increment operations on the primary table per node. |
| Table Put Latency Per Node | | The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table. |
| Table Get Latency Per Node | | The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table. |
| Table Scan Latency Per Node | | The 99th percentile latency of scan operations on the primary table per node. |
| Table Get Latency Percentiles* | | The get operation latency by percentile for the primary table and its secondary indexes. |
| Primary Table Put & Append Latency Percentiles* | | The pure write operation latency by percentile for the primary table and its secondary indexes. |
| Table Write Throughput Latency Percentiles | | The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table. |
| Table Get Throughput Latency Percentiles | | The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table. |
| Table Check and Put Latency Per Node | | The 99th percentile latency of check and put operations on the primary table per node. |
| Table Update and Get Latency Per Node | | The 99th percentile latency of update and get operations on the primary table per node. |
| Index Put Latency | The 99th percentile latency of put operations per secondary index of the | |

| Chart/Column Name | Metric | Description |
|--------------------------------------|---------------------------------------|--|
| All Tables Replication Sent Bytes | Replication - rows/bytes sent | The number of bytes of replication data sent. |
| All Tables Replication Pending Bytes | Replication - rows/bytes pending | The number of bytes of replication data not yet sent. |
| All Tables Replication Activity | Replication - rows/bytes sent/pending | Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables. |
| Index Throughput by RPC Type | Index - Throughput | The combined RPC load for the primary table and its secondary indexes. |
| Index Put Ops | | The number of put operations completed per secondary index of the primary table. |
| Index Put Ops Per Node | | The number of put operations completed per secondary index of the primary table per node. |
| Index Scan Ops | | The number of scan operations completed per secondary index of the primary table. |
| Index Scan Ops Per Node | | The number of scan operations completed per secondary index of the primary table per node. |
| Index Bytes Read | Index - rows/bytes read | The number of bytes read per secondary index of the primary table for all RPC types. |
| Index Bytes Read Per Node | | The number of bytes read per secondary index of the primary table per node for all RPC types. |
| Index Bytes Written Per Node | | The number of bytes written per secondary index of the primary table per node for all RPC types. |
| Index Rows Read | | The number of rows read per secondary index of the primary table for all RPC types. |
| Index Rows Read Per Node | | The number of rows read per secondary index of the primary table per node for all RPC types. |
| Index Rows Responded | Index - rows/bytes returned | The number of rows returned per secondary index of the primary table for all RPC types. |
| Index Rows Responded Per Node | | The number of rows returned per secondary index of the primary table per node for all RPC types. |
| Index Scan Read vs Returned Rows | Index - rows/bytes read | The number of secondary index rows that were read versus returned. |

| Chart/Column Name | Metric | Description |
|-------------------------------------|------------------------------|--|
| Index Bytes Written | Index - rows/bytes write | The number of bytes written per secondary index of the primary table for all RPC types. |
| Index Rows Written | | The number of rows written per secondary index of the primary table for all RPC types. |
| Index Rows Written Per Node | | The number of rows written per secondary index of the primary table per node for all RPC types. |
| All Tables Index Sent Bytes | Index - rows/bytes sent | The number of bytes sent for secondary index updates. |
| All Tables Index Pending Bytes | Index - rows/bytes pending | The number of bytes of secondary index data remaining to be sent. |
| All Index Maintenance Activity | | Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables. |
| All Tables CDC Sent Bytes | CDC - rows/bytes sent | The number of bytes of CDC data sent. |
| All Tables CDC Pending Bytes | CDC - rows/bytes pending | The number of bytes of CDC data per node not yet sent. |
| All Tables CDC Propagation Activity | | The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables. |
| All Streams Producer Ops | Streams Throughput, RPCs | The number of Streams producer RPCs. |
| All Streams Consumer Ops | | The number of Streams consumer RPCs. |
| All Streams Producer Messages | Streams Throughput, messages | The number of Streams messages produced. |
| All Streams Consumer Messages | | The number of Streams messages read by consumers. |
| Table Value Cache All Lookups | Value Cache Lookups | All operations for a primary table and for a node that performed a cache lookup. |
| Table Value Cache Lookups | | The number of get operations for a primary table and for a node that performed a cache lookup. |
| Table Value Cache Lookups Per Index | | The number of get operations for a primary table and for a node that performed a cache lookup. |

| Chart/Column Name | Metric | Description |
|---|----------------------|---|
| Table and Index Value Cache All Lookups | Value Cache Hits | All operations across the primary table and its secondary indexes that performed a cache lookup. |
| Table and Index Value Cache Lookups Per Index | | The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index. |
| Table and Index Value Cache Lookups | | The number of get operations across the primary table and its secondary indexes that performed a cache lookup. |
| Table Value Cache All Hits | | All operations for a primary table and for a node that resulted in a cache hit. |
| Table Value Cache Hits | | The number of get operations for a primary table and for a node that resulted in a cache hit. |
| Table Value Cache Hits Per Index | | The number of get operations for a primary table and for a node that resulted in a cache hit. |
| Table and Index Value Cache All Hits | | All operations across the primary table and its secondary indexes that resulted in a cache hit. |
| Table and Index Value Cache Hits | | The number of get operations across the primary table and its secondary indexes that resulted in a cache hit. |
| Table and Index Value Cache Hits Per Index | | The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index. |
| Value Cache Utilization | Value Cache | Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table. |
| All Tables Flushes | Bucket Flushes | The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables. |
| All Tables Flushes | | The number of total table flushes that were manually versus automatically triggered. |
| All Tables Force Flushes | Bucket Force Flushes | The number of table flushes that were not automatically triggered. |

| Chart/Column Name | Metric | Description |
|------------------------------|----------------|---|
| All Tables Compactions | Compaction | Number of table compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables. |
| All Tables Full Compactions | | Number of full compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, HPE Ezmeral Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files. |
| All Tables Mini Compactions | | Number of partial compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, HPE Ezmeral Data Fabric Database needs to read only two spill files. |
| All Tables TTL Compactions | | Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families. |
| All Tables Free Index Memory | Memindex Usage | The number of available MB in the in-memory bucket file cache. |

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Monitoring Streams

Explains how to monitor streams using either the Control System or the CLI.

The speed at which messages flow from producers to partitions, and from partitions to consumers depends on the performance of your producers, the cluster nodes hosting partitions, and your consumers.

Monitoring Streams Operations Using the Control System

- Log in to the Control System and go to the **Metrics** tab in the [node information page](#) to select the charts that show the following when you filter the list of charts by table activities:
 - **All Streams Producer Messages:** The number of Streams messages produced on the node
 - **All Streams Consumer Messages:** The number of Streams messages on the node read by consumers
 - **All Streams Producer Ops:** The number of Streams producer RPCs on the node
 - **All Streams Consumer Ops:** The number of Streams consumer RPCs on the node

For more information, see [Creating a Custom Board for the Charts](#) on page 1411.

Monitoring Active Stream Alarms

See [Viewing Active Stream Alarms](#) on page 1440.

Monitoring Cluster Nodes that Host Partitions

You can find out which nodes in a MapR cluster are being used for topics in a stream by running the command `maprcli stream topic info`. The nodes are listed in the `servers` field.

The `guts` utility can show you whether there are any I/O bottlenecks on these nodes. This utility can also show you whether there is any capacity on other nodes in the cluster that you can take advantage of by creating additional partitions for topics.

To run this utility, issue this command after logging into the MapR cluster that you want statistics for:

```
/opt/mapr/bin/guts
```

You can also use the `guts` utility to show only these statistics from HPE Ezmeral Data Fabric Event Streams:

Table

| Name | Description |
|------|--|
| mpr | The number of RPCs from HPE Ezmeral Data Fabric Event Streams producers to the server. |
| mpm | The number of messages that have been published to the server. |
| mpMB | The total size in MB of the messages that have been published to the server. |
| mlr | The number of RPCs from HPE Ezmeral Data Fabric Event Streams consumers to the server. |
| mlm | The number of messages that have been read from the server. |
| mcl | The number of concurrent RPCs from consumers to the server. |
| mlMB | The total size in MB of the messages that have been read from the server. |

To see these statistics, run this command:

```
/opt/mapr/bin/guts streams:all
```

Note: These statistics are for the most recent sample period at the time the command is run, and are not cumulative. Sample periods are one second.

Monitoring Producers

To get a sense of how quickly producers are sending messages to the producer client library, you can run the command `stream topic info` at intervals.

Doing so will show you changes over time in the rate at which the values for `maxoffset` and `maxtimestamp` increase for the partitions in the topics that your producers are publishing to.

For example, if you have a script that runs the command at intervals of 10 seconds, the change per second would be $(\text{Value at first run} - \text{Value at second run})/10$.

This is an indirect measure of the speed of the producers because the producer client library batches messages before publishing them to partitions. The faster the producers send messages to the client, the faster the client publishes message batches, and the greater the change per second.

If producers do not seem to be sending messages quickly enough, and this problem is not caused by server-side I/O bottlenecks, you can spawn more producer threads.

See [stream topic info](#) for the syntax of this command.

Monitoring Consumers

There are two commands that you can run at intervals to get a sense of how far behind a consumer is in a partition. The consumer must belong to a consumer group, even if the consumer is the only member of that group.

To find the lag in milliseconds between the timestamp of the most recently published message in a stream, topic, or partition and the timestamp of a consumer's most recently committed cursor, run the command [stream cursor list](#). The lag is the value of the `consumerlagmillis` parameter.

To find the timestamp of the most recently committed cursor for the consumer that is furthest back in a partition compared to all other consumers reading from the same partition, run the command [stream topic info](#). This timestamp is the value of the `mintimestampacrossconsumers` parameter. Use this timestamp together with the values of the following parameters to get a sense of where this cursor is in the partition:

| | |
|---------------------------|---|
| <code>mintimestamp</code> | This parameter shows the timestamp of the oldest message in the partition. |
| <code>maxtimestamp</code> | This parameter shows the timestamp of the most recently published message in the partition. |

If a consumer's configuration for cursor commits is the default (the configuration parameter `enable.auto.commit` is set to `true` and `auto.commit.interval.ms` is set to 1000 milliseconds), the consumer will be only about one second ahead of the offset and timestamp reported for the consumer's most recently committed cursor.

If it seems that consumers are falling behind and that this problem is not caused by server-side I/O bottlenecks, you can start more consumer threads.

If the current number of consumers in a consumer group is equal to the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, add a partition to this topic before adding a consumer. The consumer client library dynamically reassigns the existing partitions in the topic to the consumers in the consumer group, as well as assigning the new partition to a consumer.

If the current number of consumers in a consumer group is less than the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, you don't need to add any partitions before adding a consumer.

Monitoring Alarms

Provides an overview of how to monitor alarms using the Control Panel and the CLI.

On a cluster with an Enterprise Edition or Enterprise Database Edition license, HPE Ezmeral Data Fabric raises alarms to alert you to information about the cluster:

- Cluster health, including disk failures
- Volumes that are under-replicated or over quota
- Services not running

You can see any currently raised alarms in the **Active Alarms** pane and the **Alarm Summary** page of the Control System (click  in the Control System) or using the [alarm list](#) on page 1724 command. For a list of all alarms, see the [Alarms Reference](#).

When you click , the **Alarm Summary** page displays all active alarms and for each alarm, the **All** active alarms pane displays the following:

| Column Name | Column Description |
|-------------|---|
| Severity | The severity of the alarm. Value can be: <ul style="list-style-type: none">  — Critical  — Warning  — Information |
| Status | The status of the alarm. Value can be: <ul style="list-style-type: none"> Active Muted |
| Time | The date and time stamp from when the alarm was raised. |
| Name | The name of the alarm. |
| Info | The notes associated with the alarm, which contains description of the alarm and the recommended action to take. |
| Entity | The entity on which the alarm was raised. |
| Type | The type of alarm. Value can be: <ul style="list-style-type: none"> CLUSTER NODE VOLUME USER/GROUP |

You can select the checkbox beside one or more alarms to:

- Dismiss the alarms
- Mute the alarms

Viewing Active Cluster Alarms

Describes how to view cluster alarms using the Control System and the CLI.

You can view cluster alarms using the Control System and the CLI.

Viewing Active Cluster Alarms in the Control System

- Log in to the Control System and click:
 - Overview** to view all the alarms on the cluster in the **Active Alarms** pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **Active Alarms** pane.
 -  (Alarm Summary) to view all the alarms on the cluster in the **All** alarms pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **All** alarms pane.

You can:

- View alarm information

- [Dismiss](#) an alarm
- [Mute](#) an alarm

Retrieving Cluster Alarms Using the CLI or REST API

The basic command to retrieve the alarms for a cluster is:

```
maprcli alarm list -cluster <cluster name> -type cluster
```

For complete reference information, see [alarm list](#) on page 1724.

Viewing Active Node Alarms

Describes how to view active node alarms using the Control System and the CLI.

Viewing Active Node Alarms in the Control System

-  **Note:** The **Nodes** page is not available in the Kubernetes version of the Control System.

Log in to the Control System and:

- Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
- Go to the [node information page](#) to view alarms in the **Alarms** pane for the selected node.
- Click  (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
- Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

You can:

- [View](#) alarm notes
- [Mute](#) an alarm
- [Dismiss](#) an alarm

Retrieving Active Node Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

For complete reference information, see [alarm list](#) on page 1724.

Viewing Active Volume Alarms

Describes how to view volume alarms using the Control System and the CLI.

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

- Log in to the Control System and:
 - Click **Data > Volumes** to view all active volume alarms in the **Active Alarms** pane.
-  **Note:** The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.
- Go to the **Summary** tab in the [volume information page](#) to view the recent and active alarms for the selected volume in the **Alarms** pane.

- Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
- Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Volume Alarms](#) on page 2525 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 1724.

Viewing Active Table Replication Alarms

Describes how to view active table replication alarms using the Control System and the CLI.

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

- Log in to the Control System and click **Data > Tables** to view table replication alarms in the **Active Alarms** pane.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Table-Replication Alarms](#) on page 2522 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 1724.

Viewing Table Replication Alarms in the Log Files

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Viewing Active Stream Alarms

Describes how to view active stream alarms using the Control System and the CLI.

You can view stream alarms using the Control System and the CLI.

Viewing Active Stream Alarms in the Control System

- Log in to the Control System and:
 - Click **Data > Streams** to view all stream alarms in the **Active Alarms** pane.
 - Go to the **Summary** tab in the [stream information page](#) to view the recent and active alarms for the selected stream in the **Active Alarms** pane.

You can:

- [View](#) information related to the alarm.
- [Dismiss](#) an alarm.
- [Mute](#) an alarm.

See [Alarms Reference](#) on page 2507 for more information on the stream alarms.

Retrieving Active Stream Alarms Using the CLI or REST API

The basic command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see [alarm list](#) on page 1724.

Monitoring Errors

Explains how to monitor errors using the Control System.

To view the errors on the cluster:

1. Log in to the Control System and click  to display the **Recent Errors** window. The **Recent Errors** window displays only if there are any errors. For each error, the window displays the following:

| Column Name | Column Description |
|-------------|--|
| Name | The name of the error. |
| Type | The type of error. |
| Action | The type of operation during which the error occurred. |
| Date & Time | The date and time when the error occurred. |
| Description | A brief description of the error. |

2. Choose one of the following from the drop-down menu to filter the list of errors by a specific type:
 - All Types — to display all types of errors.
 - Data — to display errors related to data
 - Disk Usage — to display errors related to disk usage
 - Nodes — to display errors on nodes
 - Schedules — to display errors related to schedules
 - Services — to display service-related errors
 - Snapshots — to display errors during snapshot

- Volumes — to display errors on volumes
- Tables — to display errors on tables

Using HPE Ezmeral Data Fabric Monitoring (Spyglass Initiative)

HPE Ezmeral Data Fabric Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

Metric Monitoring

Administrators can monitor the current status of the cluster and anticipate future cluster requirements with dashboards. For example, you can use metrics dashboards to visualize the following:

Storage Utilization

Use metrics dashboards to monitor storage trends. For example, you can compare the volume of filesystem usage at different times to the filesystem capacity and then allocate resources to the filesystem accordingly.

Node Utilization

Use metrics dashboards to check for node overload. For example, if the CPU usage is high on a few nodes, you may want to distribute the load across more nodes for better performance and efficiency.

HPE Ezmeral Data Fabric Database Operational Trends

Use metrics dashboards to display historical trends for HPE Ezmeral Data Fabric Database operations. For example, if a user reports HPE Ezmeral Data Fabric Database slowness, the historical trends associated with row scans, get, and put operations can be used to identify the node(s) on which the performance degradation occurs.

Log Monitoring

Administrators can use dashboards to visualize, search, and review logs when troubleshooting issues. For example, you can use log dashboards to troubleshoot the following issues:

Service Failures

When metrics indicate that one or more services are down, use log dashboards to check the logs for each failed service and drill-down to each associated node.

Application Failures

When an application or job fails, use log dashboard to identify possible bottlenecks. For example, you can search the logs for a given application ID across all the nodes in the cluster.

filesystem Performance

When users experience filesystem or NFS for the HPE Ezmeral Data Fabric slowness, use log dashboards to search the HPE Ezmeral Data Fabric filesystem logs for service errors or application issues.

Related Information

- [Using HPE Ezmeral Data Fabric Monitoring \(Spyglass Initiative\)](#) on page 1442
- [Data Fabric Monitoring Storage Options](#) on page 75
- [Step 8: Install Metrics Monitoring](#) on page 154
- [Step 9: Install Log Monitoring](#) on page 156

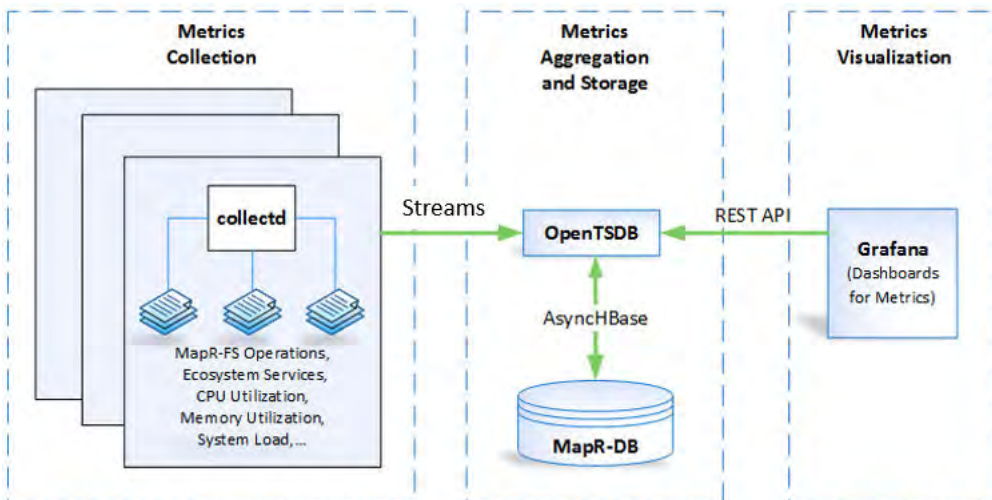

HPE Ezmeral Data Fabric Monitoring Architecture

HPE Ezmeral Data Fabric Monitoring integrates with open-source components to collect, aggregate, store, and visualize metrics and logs.

Note: The HPE Ezmeral Data Fabric Monitoring architecture is designed for use on HPE Ezmeral Data Fabric cluster nodes. Installing monitoring components on client nodes or edge nodes is not supported.

Metric Monitoring Architecture

To visualize cluster metrics, HPE Ezmeral Data Fabric Monitoring integrates with the following components:

collectd

The `collectd` service runs on each node in the cluster to collect metrics. It uses streams to send the metrics to `opentsdb`. For more information, see [Metric Collection](#) on page 1445.

OpenTSDB

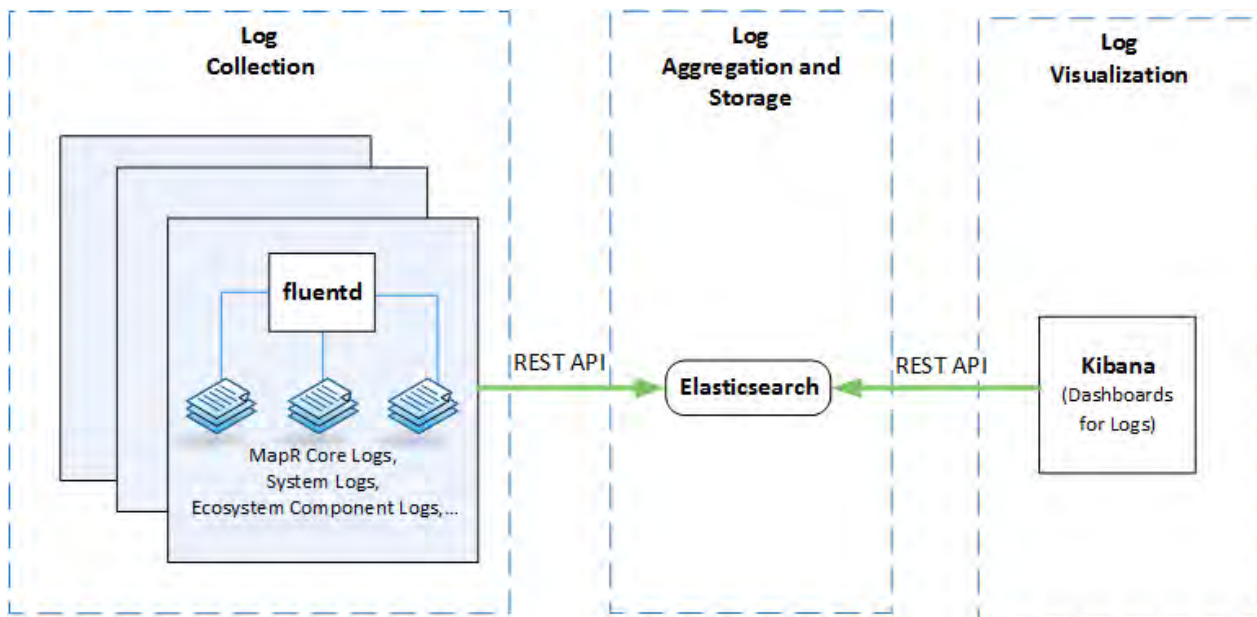

`OpenTSDB` aggregates the metrics and runs as the time-series database on top of HPE Ezmeral Data Fabric Database, the metrics data store. Based on your cluster requirements, it runs on one or more nodes in the cluster.

Grafana

`Grafana` uses REST API to access metrics data from `OpenTSDB`. Using a single instance of `Grafana`, users can build custom dashboards or use sample dashboards to visualize the metric. For more information about dashboards, see [Metric Visualization](#) on page 1493.

Log Monitoring Architecture

To visualize logs, MapR Monitoring integrates with the following components:

**fluentd**

fluentd runs on each node in the cluster to collect and parse logs. It uses REST API to send the logs to ElasticSearch. For more information, see [Log Collection](#) on page 1498.

Elasticsearch

Elasticsearch indexes the logs so that they are easily accessed and searchable. Based on your cluster requirements, it runs on one or more nodes in the cluster. For more information, see [Log Aggregation and Storage](#) on page 1503.

Kibana

Kibana uses REST API to access and search the logs available in Elasticsearch. Using a single instance of Kibana, users can create visualizations and dashboards to analyze their logs. For more information, see [Log Visualization](#) on page 1508.

Spyglass on Streams

Release 6.0 of the HPE Ezmeral Data Fabric introduced Spyglass on Streams. When you install release 6.0 or later, Streams is the default mechanism through which metrics flow from the Collectd service to OpenTSDB. Moving metrics through streams secures the data and provides a mechanism to perform real-time data analytics.

Note: Currently, Spyglass on Streams is not available for logs. Fluentd continues to use the REST API to send logs to ElasticSearch for the indexing of logs.

The Flow of Metrics via Streams

The Collectd service collects node-level and service-level metrics from each node in the cluster. The Collectd service hashes metrics to a stream and writes the metrics into topics in that stream.

In release 6.1.0 and later, Collectd creates one stream per cluster: `/var/mapr/mapr.monitoring/metricstreams/0`. Topic names use the format `<hostname>`. For example: `mfs81.qa.lab`.

The Streams server distributes metrics to the available OpenTSDB nodes, and OpenTSDB consumes the metrics.

Note: Writing to an external OpenTSDB is not supported from release 6.0 onwards. In addition, inserting non-data-fabric data into the provided OpenTSDB is not supported. Any custom data added to the provided OpenTSDB will be removed by the purge script (`tsdb_cluster_mgmt.sh`) that runs periodically.

Determining How Many OpenTSDB Nodes to Install

Having multiple OpenTSDB nodes in the cluster distributes the workload. The number of partitions and OpenTSDB nodes determines the level of parallelism for consumption.

Each OpenTSDB node can consume one partition at a time. By default, metrics data is divided across 12 partitions in each topic and optimal parallelism is reached if there are five OpenTSDB nodes to consume the partitions. See [Parallelism When Consuming Messages](#). Note that the term “consumer” in the topic equates to an OpenTSDB node in Spyglass on Streams.

A general guideline for the minimum number of OpenTSDB nodes in a cluster is one for every 10x increase in nodes beyond 10, for example:

- Three OpenTSDB nodes in a 10-node cluster
- Four OpenTSDB nodes in a 100-node cluster
- Five OpenTSDB nodes in a 1000-node cluster

If your cluster has 10 or more nodes, at least three OpenTSDB nodes should be available to consume metrics. Typically, for every 10x increase in nodes, you should add another OpenTSDB node. For example, if your cluster reaches a size of 100 nodes, have four OpenTSDB nodes available for consumption.

These guidelines do not guarantee optimal performance. Evaluate the performance of the streams to determine if your cluster would benefit from additional OpenTSDB nodes.

Note: If all configured OpenTSDB nodes have been offline for several hours, you may notice an initial spike in memory and CPU usage by OpenTSDB processes as they aggressively try to keep up with the metrics. You can reduce the number of AsyncHBase threads to reduce the CPU and memory usage. By default, AsyncHBase runs 128 threads. To modify the number of threads, add or modify the following property in the `/opt/mapr/asynchbase/asynchbase-<version>/conf/asynchbase.conf` file on the OpenTSDB nodes:

```
"fs.mapr.async.worker.threads=<value>"
```

Increasing the Number of Streams

For release 6.1 and later, the default setting for the number of streams is one. Even if your cluster grows to 1000 nodes or more, you do not need to increase the number of streams. For release 6.0.x, increasing the number of streams is recommended as you add more nodes (see the release 6.0 documentation), but this practice is not required in release 6.1 and later.

Changing the Automatic Stream Cursor Commits

You can adjust the frequency of automatic stream cursor commits for OpenTSDB. Modify the `tsd.streams.autocommit.interval` in `opentsdb.conf`. The unit is thousands of seconds. The default value is '60000' which is 60 secs. For a system with heavy loads, consider changing the value to something like 5 minutes.

Metric Collection

Metrics are collected from each node in the cluster so that administrators can use the data to monitor the cluster. In general, the `collectd` service collects metrics every 10 seconds. The exception is volume metrics which are collected every 10 minutes.

When `collectd` writes metrics to streams, tags are assigned to each metric so that administrators can filter metric data to create dashboards that are specific to their needs.

By default, each metric contains the following tags:

- `fqn`: Displays values for a specified node.

- `clusterid`: Displays values for a specific cluster.
- `clustername`: As of EEP 3.0, displays values for a specific cluster.

However, many metrics have additional tags that you can use to filter metric data.

Streams store metrics in OpenTSDB with the following schema:

```
<metrictype.name> <fqdn:fqdnvalue> <clusterid:clusteridvalue>
<clustername:clusternamevalue>[<AdditionalTagA:AdditionalTagAvalue>
<AdditionalTagB:AdditionalTagBvalue>...] <metricvalue> <timestamp>
```

Note: A negative value shown in the metrics indicates that the maximum value configured for that metric is exceeded. The maximum value for GUT metrics is int32 ($2^{31}-1$).

For more information on using tags and dashboards, see [Metric Visualization](#) on page 1493.

Configure Metric Retention

By default, OpenTSDB stores two weeks of metrics. Based on your requirements, you can change metric retention period.

The following cron job runs each day to purge metrics based on the retention period.

```
$min $hour * * * $OTSDB_HOME/bin/tsdb_cluster_mgmt.sh -purgeData >>
$OTSDB_HOME/var/log/opentsdb/purgeData.log 2>&1
```

Complete the following steps to edit the metric retention period:

1. Open the `/opt/mapr/opentsdb/opentsdb-<version>/bin/tsdb_cluster_mgmt.sh` file.
2. In the following line, update the value of '2 weeks ago' to the new retention period.

```
$OT_HOME/bin/tsdb scan --delete 2000/01/01 $(date --date='2 weeks ago'
+'%Y/%m/%d') sum $metric
```

For example, to delete metrics from 1/1/2000 to [current date - 2 days]:

```
$OT_HOME/bin/tsdb scan --delete 2000/01/01 $(date --date='2 days ago'
+'%Y/%m/%d') sum $metric
```

Warning: MapR monitoring uses 2 MB disk space per minute per node when HPE Ezmeral Data Fabric Event Streams metrics is enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with a 3X replication. This stream metrics data is automatically deleted every 30 days.

Note: For more information, see the [OpenTSDB scan command documentation](#).

Configure Queue Filters for `mapr.rm.<value>` Metrics

The YARN application metrics that are collected by JMX have the metric name syntax `mapr.rm.<metric_name>` and the metric values are aggregated among all the queues in the default queue. However, you can configure `collectd` to create a filter for each queue. As an alternative, you can use the REST API queue metrics (`mapr.rm_queue.<metric_name>`) which are by default set up for filtering by queue.

To configure `collectd` to create queue filters for `mapr.rm.*` metrics, define each queue that you want to create filters for in the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file. You

can configure collectd to generate filters for every queue or only for specific queues. Changes that you make to the collectd.conf file only apply to metrics collected after you restart the collectd service.

1. Open the collectd.conf file and locate the MBean "QueueMetrics" block.

```
<MBean "QueueMetrics">
  ObjectName
  "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "default-queue"
  </Value>

  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "default-queue"
  </Value>

  ...
</MBean>
```

This block specifies that there is one queue named `root` and that the filter for this queue is named `default-queue`.

2. Create copy of the MBean "QueueMetrics" block.
3. Configure the ObjectName option in the MBean "QueueMetrics" block copy, with the queue path for the queue that you want to create a filter for.
 - To define the a child queue named `alpha` under the `root` queue:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
```

- To define a child queue named `beta` which is under a child queue named `alpha`:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=beta"
```

4. For each Value block within the MBean "QueueMetrics" block you are defining, replace `default-queue` with the queue name that you want to create a filter for.

- To define filter value alpha for the rm_queue tag, set the InstancePrefix to alpha:

```
<MBean "QueueMetrics">
  ObjectName
  "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
  InstancePrefix "rm"
  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "alpha"
  </Value>
  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "alpha"
  </Value>
  ...
</MBean>
```

- To define a filter value beta for the rm_queue tag, set the InstancePrefix to beta::

```
<MBean "QueueMetrics">
  ObjectName
  "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=beta"
  InstancePrefix "rm"
  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "beta"
  </Value>
  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "beta"
  </Value>
  ...
</MBean>
```

5. Repeat steps 2 and 3 for each queue that you want to create a filter value for.
6. Save the collectd.conf file.
7. Repeat steps 1 through 6 on each ResourceManager node.
8. Restart the collectd service.

```
maprcli node services -name collectd -nodes <space separated list of
ResourceManager Nodes> -action restart
```

In the following example, rm_queue tag will have the following filter values: alpha , beta (child of alpha), and highpriority (child of root):

```
<MBean "QueueMetrics">
  ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "alpha"
  </Value>
```

```

    <Value "ActiveApplications">
      Type "active_applications"
      InstancePrefix "alpha"
    </Value>
    ...
    <Value "ReservedVCores">
      Type "reserved_vcores"
      InstancePrefix "alpha"
    </Value>
  </MBean>

<MBean "QueueMetrics">
  ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha q2=beta"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "beta"
  </Value>

  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "beta"
  </Value>
  ...
  <Value "ReservedVCores">
    Type "reserved_vcores"
    InstancePrefix "beta"
  </Value>
</MBean>

<MBean "QueueMetrics">
  ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=highpriority"
  InstancePrefix "rm"

  <Value "AppsRunning">
    Type "apps_running"
    InstancePrefix "highpriority"
  </Value>

  <Value "ActiveApplications">
    Type "active_applications"
    InstancePrefix "highpriority"
  </Value>
  ...
  <Value "ReservedVCores">
    Type "reserved_vcores"
    InstancePrefix "highpriority"
  </Value>
</MBean>

```

Configure the Collectd Service Heap Size

The `collectd` service uses an embedded JVM when it gathers metrics from the CLDB, Node Manager, Resource Manager, and Drill. You can edit the Plugin Java section of `collectd.conf` to configure limits to the `collectd` virtual memory footprint.

Note: The Plugin Java section of the `collectd.conf` file may be commented or uncommented. The [configure.sh](#) utility will uncomment the Plugin Java section when `collectd` runs on a node that requires an embedded JVM. Therefore, when you update the file, do not add or remove comment symbols (`#`) in the Plugin java section

Complete the following steps on each `collectd` node:

1. Open the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file.
2. Look for the following section:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
<Plugin java>
JVMArg "-Djava.class.path=....."
```

3. Update `Xms` and `Xmx` options in the `Plugin java` section.

`Xms` defines the amount of memory allocated to the service when it starts. `Xmx` defines the maximum amount of memory allocated to the service.

If the `<Plugin java>` section is not commented out, the configuration may look like this:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
<Plugin java>
JVMArg "-Djava.class.path=....."
JVMArg "-Xms32m"
JVMArg "-Xmx128m"
```

If the `<Plugin java>` section is commented out, the configuration may look like this:

```
### **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
#<Plugin java>
# JVMArg "-Djava.class.path=....."
# JVMArg "-Xms32m"
# JVMArg "-Xmx128m"
```

4. Restart the `collectd` service.

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

CPU Metrics

Every 10 seconds, the `collectd` service uses the `cpu` plugin to gather the following CPU metrics on each node in the cluster.

| Name | Description | Additional Tag(s) |
|-------------------------------|--|---|
| <code>cpu.percent</code> | The aggregate percentage of all CPUs. | <ul style="list-style-type: none"> <code>cpu_core</code>: Display values specified core. Core values: 0,1, and 2 <code>cpu_class</code>: Display values for a specified class of CPU. CPU class values: idle, user, nice, system. |
| <code>thread.cpu_usage</code> | The percentage of CPU used by each thread. | <ul style="list-style-type: none"> <code>thread_name</code>: Indicates if thread belongs to RPC, HPE Ezmeral Data Fabric Database, filesystem, or an instance of filesystem. |

Disk Free Metrics

Every 10 seconds, the collectd service uses the df plugin to gather the following disk free metrics on each node in the cluster.

| Name | Description | Additional Tag(s) |
|------------------|--|--|
| df.df_complex | The aggregate number of bytes for disk partitions. | <ul style="list-style-type: none"> df_partition: Display values for a specified disk. Disk values: dev or boot. df_type: Display values for a certain type. Type values: free, reserved, and used. |
| df.percent_bytes | The aggregated percentage of disk partitions. | <ul style="list-style-type: none"> df_partition: Display values for a specified disk. Disk values: dev or boot. df_type: Display value for a certain type. Type values: free, reserved, and used. |

Disk Metrics

Every 10 seconds, the collectd service uses the disk plugin to gather the following disk metrics on each node in the cluster.

| Name | Description | Additional Tag(s) |
|------------------------------------|---|---|
| disk.disk_await | The average time in milliseconds to complete I/O requests. This includes the time request are waiting in queue and the time spent processing the request. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_avg_requests_size | The average size in kilobytes for I/O requests issued to the disk. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_avg_queue_size | The average number of requests issued to the disk. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_io_time.io_time | The disk I/O time in milliseconds (ms). | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_io_time.weighted_io_time | The aggregate time in milliseconds (ms) spent on I/O operations that are either in progress or have completed | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_merged.read | The number of physical read operations. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_merged.write | The number of physical write operations. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_octets.read | The number of bytes read from disk. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_octets.write | The number of bytes written to disk. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |

| Name | Description | Additional Tag(s) |
|-------------------------|--|---|
| disk.disk_ops.read | The number of completed read operations. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_ops.write | The number of completed write operations. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_time.read | The average time in milliseconds(ms) to read from disk. | <ul style="list-style-type: none"> disk_name: Display values for a specified disk. |
| disk.disk_time.write | The average time in milliseconds(ms) to write to disk. | <ul style="list-style-type: none"> disk_name: Display values for a specific disk. |
| disk.disk_utilization | The disk utilization percentage. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> disk_name: Display values for a specific disk. |
| disk.pending_operations | The number of pending disk operations. | <ul style="list-style-type: none"> disk_name: Display values for a specific disk. |

Drill Metrics

Every 10 seconds, the collectd service uses the plugin to gather the following Drill metrics on each node in the cluster.

| Name | Description |
|--------------------------------|--|
| mapr.drill.allocator_root_used | The amount of memory used in bytes by the internal memory allocator. |
| mapr.drill.allocator_root_peak | The peak amount of memory used in bytes by the internal memory allocator. |
| mapr.drill.blocked_count | The number of threads that are blocked because they are waiting for a monitor lock. |
| mapr.drill.count | The number of live threads (including both daemon and non-daemon threads). |
| mapr.drill.fd_usage | The ratio of used to total file descriptors. |
| mapr.drill.fragments_running | The number of query fragments currently running in the drillbit. |
| mapr.drill.heap_used | The amount of heap memory used in bytes by the JVM. |
| mapr.drill.non_heap_used | The amount of non-heap memory used in bytes by the JVM. |
| mapr.drill.queries_completed | The number of completed, canceled or failed queries for which this drillbit is the foreman. |
| mapr.drill.queries_running | The number of running queries for which this drillbit is the foreman. |
| mapr.drill.runnable_count | The number of threads executing in the JVM. |
| mapr.drill.waiting_count | The number of threads that are waiting to be executed. This can occur when a thread must wait for another thread to perform an action before proceeding. |

Hive JMX Metrics

Every 10 seconds, the collectd service uses the Hive plug-in to gather the following Hive JMX metrics on each node in the cluster. Descriptions for the Hive metrics are not currently available.

Metric Collection

Metrics collected in Hive relate specifically to the HiveServer2 and Hive metastore processes. Each process runs in a separate JVM, and the JVMs provide values for the metrics.

Starting in EEP 6.3.2 and EEP 7.0.1, the `hive.exec.submit.local.task.via.child` option (in `hive-site.xml`) is set to `true`, by default, and enables HiveServer2 to spawn local tasks (typically mapjoin hashtable generation phase) in child JVMs. The system does not collect metrics for the child JVMs. The system only collects metrics for the HiveServer2 and Hive metastore processes.

Hive Metastore Metrics

The following are the JMX metrics provided for the Hive metastore:

- `mapr.hivemetastore.hivemetastore_buffers_direct_capacity`
- `mapr.hivemetastore.hivemetastore_buffers_direct_count`
- `mapr.hivemetastore.hivemetastore_buffers_direct_used`
- `mapr.hivemetastore.hivemetastore_buffers_mapped_capacity`
- `mapr.hivemetastore.hivemetastore_buffers_mapped_count`
- `mapr.hivemetastore.hivemetastore_buffers_mapped_used`
- `mapr.hivemetastore.hivemetastore_class_loading_loaded`
- `mapr.hivemetastore.hivemetastore_class_loading_unloaded`
- `mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_count`
- `mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_time`
- `mapr.hivemetastore.hivemetastore_gc_ps_scavenge_count`
- `mapr.hivemetastore.hivemetastore_gc_ps_scavenge_time`
- `mapr.hivemetastore.hivemetastore_init_total_count_dbs`
- `mapr.hivemetastore.hivemetastore_init_total_count_partitions`
- `mapr.hivemetastore.hivemetastore_init_total_count_tables`
- `mapr.hivemetastore.hivemetastore_memory_heap_committed`
- `mapr.hivemetastore.hivemetastore_memory_heap_init`
- `mapr.hivemetastore.hivemetastore_memory_heap_max`
- `mapr.hivemetastore.hivemetastore_memory_heap_usage`
- `mapr.hivemetastore.hivemetastore_memory_heap_used`
- `mapr.hivemetastore.hivemetastore_memory_non_heap_committed`
- `mapr.hivemetastore.hivemetastore_memory_non_heap_init`
- `mapr.hivemetastore.hivemetastore_memory_non_heap_max`
- `mapr.hivemetastore.hivemetastore_memory_non_heap_usage`

- mapr.hivemetastore.hivemetastore_memory_non_heap_used
- mapr.hivemetastore.hivemetastore_memory_pools_code_cache_usage
- mapr.hivemetastore.hivemetastore_memory_pools_compressed_class_space_usage
- mapr.hivemetastore.hivemetastore_memory_pools metaspace_usage
- mapr.hivemetastore.hivemetastore_memory_pools_ps eden_space_usage
- mapr.hivemetastore.hivemetastore_memory_pools_ps_old_gen_usage
- mapr.hivemetastore.hivemetastore_memory_pools_ps_survivor_space_usage
- mapr.hivemetastore.hivemetastore_memory_total_committed
- mapr.hivemetastore.hivemetastore_memory_total_init
- mapr.hivemetastore.hivemetastore_memory_total_max
- mapr.hivemetastore.hivemetastore_memory_total_used
- mapr.hivemetastore.hivemetastore_threads_blocked_count
- mapr.hivemetastore.hivemetastore_threads_count
- mapr.hivemetastore.hivemetastore_threads_daemon_count
- mapr.hivemetastore.hivemetastore_threads_deadlock_count
- mapr.hivemetastore.hivemetastore_threads_deadlocks
- mapr.hivemetastore.hivemetastore_threads_new_count
- mapr.hivemetastore.hivemetastore_threads_runnable_count
- mapr.hivemetastore.hivemetastore_threads_terminated_count
- mapr.hivemetastore.hivemetastore_threads_timed_waiting_count
- mapr.hivemetastore.hivemetastore_threads_waiting_count
- mapr.hivemetastore.hivemetastore_active_calls_api_get_all_databases
- mapr.hivemetastore.hivemetastore_active_calls_api_get_all_functions
- mapr.hivemetastore.hivemetastore_active_calls_api_get_all_tables
- mapr.hivemetastore.hivemetastore_active_calls_api_get_database
- mapr.hivemetastore.hivemetastore_active_calls_api_get_multi_table
- mapr.hivemetastore.hivemetastore_active_calls_api_get_table_objects_by_name_req
- mapr.hivemetastore.hivemetastore_active_calls_api_init
- mapr.hivemetastore.hivemetastore_jvm_pause_extra_sleep_time
- mapr.hivemetastore.hivemetastore_open_connections
- mapr.hivemetastore.hivemetastore_api_get_all_databases_count

- mapr.hivemetastore.hivemetastore_api_get_all_databases_max
- mapr.hivemetastore.hivemetastore_api_get_all_databases_mean
- mapr.hivemetastore.hivemetastore_api_get_all_databases_min
- mapr.hivemetastore.hivemetastore_api_get_all_databases_p50
- mapr.hivemetastore.hivemetastore_api_get_all_databases_p75
- mapr.hivemetastore.hivemetastore_api_get_all_databases_p95
- mapr.hivemetastore.hivemetastore_api_get_all_databases_p98
- mapr.hivemetastore.hivemetastore_api_get_all_databases_p99
- mapr.hivemetastore.hivemetastore_api_get_all_databases_p999
- mapr.hivemetastore.hivemetastore_api_get_all_databases_stddev
- mapr.hivemetastore.hivemetastore_api_get_all_databases_m15_rate
- mapr.hivemetastore.hivemetastore_api_get_all_databases_m1_rate
- mapr.hivemetastore.hivemetastore_api_get_all_databases_m5_rate
- mapr.hivemetastore.hivemetastore_api_get_all_databases_mean_rate
- mapr.hivemetastore.hivemetastore_api_get_all_functions_count
- mapr.hivemetastore.hivemetastore_api_get_all_functions_max
- mapr.hivemetastore.hivemetastore_api_get_all_functions_mean
- mapr.hivemetastore.hivemetastore_api_get_all_functions_min
- mapr.hivemetastore.hivemetastore_api_get_all_functions_p50
- mapr.hivemetastore.hivemetastore_api_get_all_functions_p75
- mapr.hivemetastore.hivemetastore_api_get_all_functions_p95
- mapr.hivemetastore.hivemetastore_api_get_all_functions_p98
- mapr.hivemetastore.hivemetastore_api_get_all_functions_p99
- mapr.hivemetastore.hivemetastore_api_get_all_functions_p999
- mapr.hivemetastore.hivemetastore_api_get_all_functions_stddev
- mapr.hivemetastore.hivemetastore_api_get_all_functions_m15_rate
- mapr.hivemetastore.hivemetastore_api_get_all_functions_m1_rate
- mapr.hivemetastore.hivemetastore_api_get_all_functions_m5_rate
- mapr.hivemetastore.hivemetastore_api_get_all_functions_mean_rate
- mapr.hivemetastore.hivemetastore_api_get_all_tables_count
- mapr.hivemetastore.hivemetastore_api_get_all_tables_max

- `mapr.hivemetastore.hivemetastore_api_get_all_tables_mean`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_min`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_p50`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_p75`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_p95`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_p98`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_p99`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_p999`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_stddev`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_m15_rate`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_m1_rate`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_m5_rate`
- `mapr.hivemetastore.hivemetastore_api_get_all_tables_mean_rate`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_count`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_max`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_mean`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_min`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_p50`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_p75`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_p95`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_p98`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_p99`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_p999`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_stddev`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_m15_rate`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_m1_rate`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_m5_rate`
- `mapr.hivemetastore.hivemetastore_api_get_multi_table_mean_rate`
- `mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_count`
- `mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_max`
- `mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_mean`

- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_min
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_p50
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_p75
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_p95
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_p98
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_p99
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_p999
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_stddev
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_m15_rate
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_m1_rate
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_m5_rate
- mapr.hivemetastore.hivemetastore_api_get_table_objects_by_name_req_mean_rate
- mapr.hivemetastore.hivemetastore_api_init_count
- mapr.hivemetastore.hivemetastore_api_init_max
- mapr.hivemetastore.hivemetastore_api_init_mean
- mapr.hivemetastore.hivemetastore_api_init_min
- mapr.hivemetastore.hivemetastore_api_init_p50
- mapr.hivemetastore.hivemetastore_api_init_p75
- mapr.hivemetastore.hivemetastore_api_init_p95
- mapr.hivemetastore.hivemetastore_api_init_p98
- mapr.hivemetastore.hivemetastore_api_init_p99
- mapr.hivemetastore.hivemetastore_api_init_p999
- mapr.hivemetastore.hivemetastore_api_init_stddev
- mapr.hivemetastore.hivemetastore_api_init_m15_rate
- mapr.hivemetastore.hivemetastore_api_init_m1_rate
- mapr.hivemetastore.hivemetastore_api_init_m5_rate
- mapr.hivemetastore.hivemetastore_api_init_mean_rate

HiveServer2 Metrics

The following are the JMX metrics provided for HiveServer2 (hs2):

- mapr.hiveserver2.hiveserver2_buffers_direct_capacity
- mapr.hiveserver2.hiveserver2_buffers_direct_count

- `mapr.hiveserver2.hiveserver2_buffers_direct_used`
- `mapr.hiveserver2.hiveserver2_buffers_mapped_capacity`
- `mapr.hiveserver2.hiveserver2_buffers_mapped_count`
- `mapr.hiveserver2.hiveserver2_buffers_mapped_used`
- `mapr.hiveserver2.hiveserver2_class_loading_loaded`
- `mapr.hiveserver2.hiveserver2_class_loading_unloaded`
- `mapr.hiveserver2.hiveserver2_exec_async_pool_size`
- `mapr.hiveserver2.hiveserver2_exec_async_queue_size`
- `mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_count`
- `mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_time`
- `mapr.hiveserver2.hiveserver2_gc_ps_scavenge_count`
- `mapr.hiveserver2.hiveserver2_gc_ps_scavenge_time`
- `mapr.hiveserver2.hiveserver2_active_sessions`
- `mapr.hiveserver2.hiveserver2_open_sessions`
- `mapr.hiveserver2.hiveserver2_init_total_count_dbs`
- `mapr.hiveserver2.hiveserver2_init_total_count_partitions`
- `mapr.hiveserver2.hiveserver2_init_total_count_tables`
- `mapr.hiveserver2.hiveserver2_memory_heap_committed`
- `mapr.hiveserver2.hiveserver2_memory_heap_init`
- `mapr.hiveserver2.hiveserver2_memory_heap_max`
- `mapr.hiveserver2.hiveserver2_memory_heap_usage`
- `mapr.hiveserver2.hiveserver2_memory_heap_used`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_committed`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_init`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_max`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_usage`
- `mapr.hiveserver2.hiveserver2_memory_non_heap_used`
- `mapr.hiveserver2.hiveserver2_memory_pools_code_cache_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools_compressed_class_space_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools metaspace_usage`
- `mapr.hiveserver2.hiveserver2_memory_pools_ps eden_space_usage`

- mapr.hiveserver2.hiveserver2_memory_pools_ps_old_gen_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_survivor_space_usage
- mapr.hiveserver2.hiveserver2_memory_total_committed
- mapr.hiveserver2.hiveserver2_memory_total_init
- mapr.hiveserver2.hiveserver2_memory_total_max
- mapr.hiveserver2.hiveserver2_memory_total_used
- mapr.hiveserver2.hiveserver2_threads_blocked_count
- mapr.hiveserver2.hiveserver2_threads_count
- mapr.hiveserver2.hiveserver2_threads_daemon_count
- mapr.hiveserver2.hiveserver2_threads_deadlock_count
- mapr.hiveserver2.hiveserver2_threads_deadlocks
- mapr.hiveserver2.hiveserver2_threads_new_count
- mapr.hiveserver2.hiveserver2_threads_runnable_count
- mapr.hiveserver2.hiveserver2_threads_terminated_count
- mapr.hiveserver2.hiveserver2_threads_timed_waiting_count
- mapr.hiveserver2.hiveserver2_threads_waiting_count
- mapr.hiveserver2.hiveserver2_active_calls_api_get_all_databases
- mapr.hiveserver2.hiveserver2_active_calls_api_get_all_functions
- mapr.hiveserver2.hiveserver2_active_calls_api_get_all_tables
- mapr.hiveserver2.hiveserver2_active_calls_api_get_database
- mapr.hiveserver2.hiveserver2_active_calls_api_get_multi_table
- mapr.hiveserver2.hiveserver2_active_calls_api_get_table_objects_by_name_req
- mapr.hiveserver2.hiveserver2_active_calls_api_init

Load Metrics

Every 10 seconds, the collectd service uses the load plugin to gather the following load metrics on each node in the cluster.

| Name | Description |
|---------------------|---|
| load.load.longterm | The number of tasks running on the node every 15 minutes. |
| load.load.midterm | The number of tasks running on the node every 10 minutes. |
| load.load.shortterm | The number of tasks running on the node every minute. |

MapR Alarm Metrics

Every 10 seconds, the collectd service uses a plugin to gather the cluster alarms.

| Name | Description | Additional Tag(s) |
|--------------------------|--|--|
| mapr.alarms.alarm_raised | The number of alarms raised. The timestamp for each alarm is based on the time that MapR raised the alarm, not the time when the collectd service gathered the alarm data. | <ul style="list-style-type: none"> alarm_name: Display values for a specified alarm name. alarm_entity: . Display values for a specified volume, node, user, or group. |

MapR Cache Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following MapR filesystem cache metrics on each node in the cluster.

| Name | Description |
|------------------------------|--|
| mapr.cache.lookups_data | The number of cache lookups in the block cache. |
| mapr.cache.lookups_dir | The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages. |
| mapr.cache.lookups_inode | The number of cache lookups in the inode cache. |
| mapr.cache.lookups_largefile | The number of cache lookups in the large file LRU cache. The large file LRU is used for storing files with size greater than 64K and also HPE Ezmeral Data Fabric Database data pages. |
| mapr.cache.lookups_meta | The number of cache lookups on the meta LRU cache. The meta LRU is used for storing internal B-Tree pages. |
| mapr.cache.lookups_smallfile | The number of cache lookups on the small file LRU cache. This LRU is used for storing files with size less than 64K and also HPE Ezmeral Data Fabric Database index pages. |
| mapr.cache.lookups_table | The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages. |
| mapr.cache.misses_data | The number of cache misses in the block cache. |
| mapr.cache.misses_dir | The number of cache misses on the table LRU cache. |
| mapr.cache.misses_inode | The number of cache misses in the inode cache. |
| mapr.cache.misses_largefile | The number of cache misses on the large file LRU cache. |
| mapr.cache.misses_meta | The number of cache misses on the meta LRU cache. |
| mapr.cache.misses_smallfile | The number of cache misses on the small file LRU cache. |
| mapr.cache.misses_table | The number of cache misses on the table LRU cache. |

MapR CLDB Metrics

Every 10 seconds, the collectd service uses a HPE Ezmeral Data Fabric plugin to gather the following CLDB metrics on the primary CLDB node in the cluster.

| Name | Description |
|-----------------------------------|---|
| mapr.cldb.cluster_cpu_total | The number of physical CPUs in the cluster. |
| mapr.cldb.cluster_cpubusy_percent | The aggregate percentage of busy CPUs in the cluster. |
| mapr.cldb.cluster_disk_capacity | The storage capacity for HPE Ezmeral Data Fabric disks in GB. |

| Name | Description |
|-----------------------------------|---|
| mapr.cldb.cluster_diskspace_used | The amount of HPE Ezmeral Data Fabric disks used in GB. |
| mapr.cldb.cluster_memory_capacity | The memory capacity in MB. |
| mapr.cldb.cluster_memory_used | The amount of used memory in MB. |
| mapr.cldb.containers | The number of containers currently in the cluster. |
| mapr.cldb.containers_created | The cumulative number of containers created in the cluster. This value includes containers that have been deleted. |
| mapr.cldb.containers_unusable | The number of containers that are no longer usable. The CLDB marks a container as unusable when the node that stores the container is offline for 1 hour or more. |
| mapr.cldb.disk_space_available | The amount of disk space available in GB. |
| mapr.cldb.nodes_in_cluster | The number of nodes in the cluster. |
| mapr.cldb.nodes_offline | The number of nodes in the cluster that are offline. |
| mapr.cldb.rpc_received | The number of RPCs received. |
| mapr.cldb.rpcs_failed | The number of RPCs failed. |
| mapr.cldb.storage_pools_cluster | The number of storage pools. |
| mapr.cldb.storage_pools_offline | The number of offline storage pools. |
| mapr.cldb.volumes | The number of volumes created, including system volumes. |

HPE Ezmeral Data Fabric Database Metrics

Every 10 seconds, the collectd service uses a plugin to gather HPE Ezmeral Data Fabric Database metrics on each node in the cluster. HPE Ezmeral Data Fabric Database provides both node and table metrics.

Node metrics capture data for operations across a MapR node. You can use them to assess the performance of individual nodes in your MapR cluster.

Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports table metrics. Table metrics provide more granular metrics. They allow you detect and diagnose bottlenecks and performance issues that are specific to individual tables. For example, suppose a node metric shows a spike in a particular RPC. Knowing this, you can use the corresponding table metric to determine if the spike originates from a single table.

Examples of other use cases that benefit from table metrics are the following:

- You want to measure the latency of different RPC operations on a table
- You want to determine which operations on a table are slow
- You want to determine which tables are most frequently accessed

HPE Ezmeral Data Fabric Database Node Metrics

This section describes the available HPE Ezmeral Data Fabric Database node metrics.

The following table lists HPE Ezmeral Data Fabric Database node metrics:

| Metric Category | Name | Description |
|--------------------------------|--|--|
| Throughput - RPC counts | mapr.db.append_rpcs | The number of HPE Ezmeral Data Fabric Database append RPCs completed |
| | mapr.db.checkandput_rpcs ¹ | The number of HPE Ezmeral Data Fabric Database check and put RPCs completed |
| | mapr.db.get_currpcs | The number of HPE Ezmeral Data Fabric Database get RPCs in progress |
| | mapr.db.get_rpcrows | The number of get rows completed. Each get RPC can include multiple get rows. |
| | mapr.db.get_rpcs | The number of HPE Ezmeral Data Fabric Database get RPCs completed |
| | mapr.db.increment_rpcs ¹ | The number of HPE Ezmeral Data Fabric Database increment RPCs completed |
| | mapr.db.put_currpcs | The number of HPE Ezmeral Data Fabric Database put RPCs in progress |
| | mapr.db.put_rpcs | The number of HPE Ezmeral Data Fabric Database put RPCs completed |
| | mapr.db.scan_currpcs | The number of HPE Ezmeral Data Fabric Database scan RPCs in progress |
| | mapr.db.scan_rpcrows | The number of scan rows completed. Each scan RPC can include multiple scan rows. |
| | mapr.db.scan_rpcs | The number of HPE Ezmeral Data Fabric Database scan RPCs completed |
| | mapr.db.updateandget_rpcs | The number of HPE Ezmeral Data Fabric Database update and get RPCs completed |
| Throughput - Row count written | mapr.db.append_rpcrows ¹ | The number of rows written by append RPCs |
| | mapr.db.checkandput_rpcrows ¹ | The number of rows written by check and put RPCs |
| | mapr.db.increment_rpcrows ¹ | The number of rows written by increment RPCs |
| | mapr.db.put_rpcrows | The number of rows written by put RPCs. Each HPE Ezmeral Data Fabric Database put RPC can include multiple put rows. |
| Throughput - Rows returned | mapr.db.get_resprows ¹ | The number of rows returned from get RPCs |
| | mapr.db.scan_resprows ¹ | The number of rows returned from scan RPCs |
| Throughput - Row count read | mapr.db.get_readrows ¹ | The number of rows read by get RPCs |
| | mapr.db.put_readrows ¹ | The number of rows read by put RPCs |
| | mapr.db.scan_readrows ¹ | The number of rows read by scan RPCs |

| Metric Category | Name | Description |
|----------------------------|---|--|
| Throughput - Bytes written | mapr.db.append_bytes ¹ | The number of bytes written by append RPCs |
| | mapr.db.checkandput_bytes ¹ | The number of bytes written by check and put RPCs |
| | mapr.db.put_bytes | The number of bytes written by put RPCs |
| | mapr.db.increment_bytes ¹ | The number of bytes written by increment RPCs |
| | mapr.db.updateandget_bytes ¹ | The number of bytes written by update and get RPCs |
| Throughput - Bytes read | mapr.db.get_bytes ¹ | The number of bytes read by get RPCs |
| | mapr.db.scan_bytes ¹ | The number of bytes read by scan RPCs |
| Value cache usage | mapr.db.valuecache_hits | The number of HPE Ezmeral Data Fabric Database operations that utilized the HPE Ezmeral Data Fabric Database value cache |
| | mapr.db.valuecache_lookups | The number of HPE Ezmeral Data Fabric Database operations that performed a lookup on the HPE Ezmeral Data Fabric Database value cache |
| | mapr.db.valuecache_usedSize | The HPE Ezmeral Data Fabric Database value cache size in MB |
| Compactions | mapr.db.fullcompacts ¹ | <p>The number of compactions that combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file.</p> <p>HPE Ezmeral Data Fabric Database creates a spill file each time it flushes files containing unsorted data (known as buckets). Full compactions improve read performance because after compaction, HPE Ezmeral Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.</p> |
| | mapr.db.minicompacts ¹ | <p>The number of compactions that combine multiple small data files containing sorted data (known as spills) into a single spill file.</p> <p>HPE Ezmeral Data Fabric Database creates a spill file each time it flushes files containing unsorted data (known as buckets). After a mini compaction, HPE Ezmeral Data Fabric Database needs to read only two spill files.</p> |
| | mapr.db.ttlcompacts ¹ | <p>The number of compactions that result in reclamation of disk space due to removal of stale data.</p> <p>You can configure the TTL for a table if it has only a default column family. See table of edit on page 2055 for details.</p> |

| Metric Category | Name | Description |
|----------------------------------|---|---|
| Table flushes | <code>mapr.db.flushes</code> ¹ | The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold |
| | <code>mapr.db.forceflushes</code> ¹ | The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the in-memory bucket file cache fills up |
| CDC - Data sent | <code>mapr.db.cdc.sent_bytes</code> ¹ | The number of bytes of CDC data sent |
| | <code>mapr.db.cdc.sent_rows</code> ¹ | The number of rows of CDC data sent |
| Secondary indexes - Data sent | <code>mapr.db.index.sent_bytes</code> ¹ | The number of bytes sent for secondary index updates |
| | <code>mapr.db.index.sent_rows</code> ¹ | The number of rows sent for secondary index updates |
| Replication - Data sent | <code>mapr.db.repl.sent_bytes</code> ¹ | The number of bytes sent to replicate data |
| | <code>mapr.db.repl.sent_rows</code> ¹ | The number of rows sent to replicate data |
| CDC - Data pending | <code>mapr.db.cdc.pending_bytes</code> ¹ | The number of bytes of CDC data remaining to be sent |
| | <code>mapr.db.cdc.pending_rows</code> ¹ | The number of rows of CDC data remaining to be sent |
| Secondary indexes - Data pending | <code>mapr.db.index.pending_bytes</code> ¹ | The number of bytes of secondary index data remaining to be sent |
| | <code>mapr.db.index.pending_rows</code> ¹ | The number of rows of secondary index data remaining to be sent |
| Replication - Data pending | <code>mapr.db.repl.pending_bytes</code> ¹ | The number of bytes of replication data remaining to be sent |
| | <code>mapr.db.repl.pending_rows</code> ¹ | The number of rows of replication data remaining to be sent |

¹ Available starting in MapR 6.1

HPE Ezmeral Data Fabric Database Table Metrics

Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports table metrics. This section describes the available HPE Ezmeral Data Fabric Database table metrics. It also describes how to configure metrics per table, disable them in your cluster, and how to filter them by operation and table.

Table metrics are collected per node. By default, these metrics are written to OpenTSDB every minute. Pre-existing tables in your HPE Ezmeral Data Fabric cluster inherit this default setting. You can change this default per table using either the [table create](#) on page 2029 or [table edit](#) on page 2076 command. Secondary indexes inherit their metric configuration from their parent table.

You cannot disable metrics on individual tables. During installation, you can disable table metrics across your entire cluster. If you are using the installer, select the minimum metrics collection configuration option.

The following table lists HPE Ezmeral Data Fabric Database table metrics:

mapr.db.table.latency

The latency of RPC operations on tables, represented as a histogram. Endpoints identify histogram bucket boundaries.

Note: Put latency metrics for indexes reflect only the index update time. They do not include lag time due to [asynchronous index updates](#).

| | |
|--|--|
| mapr.db.table.read_bytes | The number of bytes read from tables. |
| mapr.db.table.read_rows | The number of rows read from tables. |
| mapr.db.table.resp_rows | The number of rows returned from tables. |
| mapr.db.table.rpcs | The number of RPC calls completed on tables. |
| mapr.db.table.value_cache_hits | The number of HPE Ezmeral Data Fabric Database operations on tables that utilized the HPE Ezmeral Data Fabric Database value cache. |
| mapr.db.table.value_cache_lookups | The number of HPE Ezmeral Data Fabric Database operations on tables that performed a lookup on the HPE Ezmeral Data Fabric Database value cache. |
| mapr.db.table.write_rows | The number of rows written to tables. |
| mapr.db.table.write_bytes | The number of bytes written to tables. |

Tags for Table Metrics

Each table metric collects data across all operations on tables and secondary indexes in a HPE Ezmeral Data Fabric node. To view metrics for a particular RPC operation on a specific table, you must filter the metric by RPC type and table path, as described in the following list:

| | |
|-------------------|--|
| rpc_type | <p>The name of the RPC:</p> <ul style="list-style-type: none"> • <code>append</code> • <code>check_and_put</code> • <code>get</code> • <code>increment</code> • <code>put</code> • <code>scan</code> • <code>update_and_get</code> |
| table_path | <p>The path of the HPE Ezmeral Data Fabric Database table.</p> <p>OpenTSDB supports only the following characters:</p> <ul style="list-style-type: none"> • Alphanumeric characters • Dot (.) • Underscore (_) • Dash (-) • Slash (/) • Space () • Unicode letters |

If a table path contains characters that are not in this list, HPE Ezmeral Data Fabric cannot collect those table metrics.

index

The name of the secondary index defined on the table specified in `table_path`, if you want to filter on a specific index. When you specify this tag, you cannot specify the `noindex` tag.

Note: You can use regular expressions when specifying the index name to filter for a group of indexes.

noindex

Set to `//primary` if you want to filter metrics for only the primary table and exclude metrics for secondary indexes defined on the table. When you specify this tag, you cannot specify the `index` tag.

The following list shows examples of the table-specific tags to use to filter different table metrics:

mapr.db.table.write_rows

Tag Name: `table_path`

Tag Value: `/var/mapr/mapr.monitoring/tsdb-meta`

Description: The number of rows written to a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, including writes to its secondary indexes.

mapr.db.table.rpcs

- • *Tag Name:* `rpc_type`
- *Tag Value:* `get`
- • *Tag Name:* `table_path`
- *Tag Value:* `/var/mapr/mapr.monitoring/tsdb-meta`
- • *Tag Name:* `noindex`
- *Tag Value:* `//primary`

Description: The number of completed `get` RPCs for a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, excluding metrics on the table's secondary indexes.

mapr.db.table.read_rows

- • *Tag Name:* `table_path`
- *Tag Value:* `/var/mapr/mapr.monitoring/tsdb-meta`
- • *Tag Name:* `index`
- *Tag Value:* `tsdbIdx`

Description: The number of rows read from a secondary index named `tsdbIdx`, defined on the table in the path `/var/mapr/mapr.monitoring/tsdb-meta`.

Note: In addition to these table-specific tags, [Metric Collection](#) on page 1445 describes other available tags.

HPE Ezmeral Data Fabric Event Streams Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following Streams metrics on each node in the cluster.

Warning: MapR monitoring uses 2 MB disk space per minute per node when HPE Ezmeral Data Fabric Event Streams metrics is enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with a 3X replication. This stream metrics data is automatically deleted every 3 days.

| Name | Description |
|-----------------------------|---|
| mapr.streams.produce_rpcs | The number of Streams producer RPCs. This metric is available as of EEP 2.0. |
| mapr.streams.produce_msgs | The number of Streams messages produced. This metric is available as of EEP 2.0. |
| mapr.streams.produce_bytes | The number of megabytes produced by Streams messages. This metric is available as of EEP 2.0. |
| mapr.streams.listen_rpcs | The number of Streams consumer RPCs. This metric is available as of EEP 2.0. |
| mapr.streams.listen_msgs | The number of Streams messages read by the consumer. This metric is available as of EEP 4.0.  Note: If you upgrade to EEP 4.0, all Streams messages are consumed, however this metric only reports a count on messages that were produced in EEP 4.0. Messages produced prior to EEP 4.0 are consumed, but not counted. In this scenario, the metric reports a partial count or a zero count if all messages were produced prior to EEP 4.0. |
| mapr.streams.listen_currpcs | The number of concurrent Stream consumer RPCs. This metric is available as of EEP 2.0. |
| mapr.streams.listen_bytes | The number of megabytes consumed by Streams messages. This metric is available as of EEP 2.0. |

filesystem Metrics

Every 10 seconds, the collectd service uses a HPE Data Fabric plugin to gather the following filesystem metrics on each node in the cluster.

| Name | Description |
|--------------------------|--|
| mapr.fs.bulk_writes | The number of bulk-write operations. Bulk-write operations occur when the primary filesystem container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes. |
| mapr.fs.bulk_writesbytes | The amount of MB written by bulk-write operations. Bulk-write operations occur when the primary filesystem container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes. |
| mapr.fs.kvstore_delete | The number of delete operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database. |
| mapr.fs.kvstore_insert | The number of insert operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database. |

| Name | Description |
|--------------------------|---|
| mapr.fs.kvstore_lookup | The number of lookup operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database. |
| mapr.fs.kvstore_scan | The number of scan operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database. |
| mapr.fs.local_readbytes | The amount of MB read by applications that are running on the filesystem node where the data resides. |
| mapr.fs.local_reads | The number of file read operations by applications that are running on the filesystem node where the data resides. |
| mapr.fs.local_writebytes | The amount of MB written by applications that are running on the filesystem node where the data resides. |
| mapr.fs.local_writes | The number of file write operations by applications that are running on the filesystem node where the data resides. |
| mapr.fs.read_bytes | The amount of data (in MB) read remotely. |
| mapr.fs.read_cachehits | The number of cache hits for file reads. This value includes pages that filesystem populates using the readahead mechanism. |
| mapr.fs.read_cachemisses | The number of cache misses for file read operations. |
| mapr.fs.reads | The number of remote reads. |
| mapr.fs.statstype_create | The number of file create operations. |
| mapr.fs.statstype_lookup | The number of lookup operations. |
| mapr.fs.statstype_read | The number of file read operations. |
| mapr.fs.statstype_write | The number of file write operations. |
| mapr.fs.write_bytes | The amount of data (in MB) written remotely. |
| mapr.fs.writes | The number of remote writes. |

MapR Process Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following MapR process metrics on each node in the cluster.

| Name | Description | Additional Tag(s) |
|---|--|--|
| mapr.process.context_switch_involuntary | The number of involuntary context switches for MapR processes. An involuntary context switch occurs when a process consumes more CPU time than what it was allocated by the kernel. When an involuntary context switch occurs, the kernel stops a process to provide resources to another process. | <ul style="list-style-type: none"> <code>process_name</code>: Display values for a specified process. Process values: <code>hoststats,mfs,warden,</code> etc. |

| Name | Description | Additional Tag(s) |
|---------------------------------------|---|--|
| mapr.process.context_switch_voluntary | The number of voluntary context switches for MapR processes. A voluntary context switch occurs when a process does not require the entire CPU time it was allocated by the kernel or when a process is suspended. When a voluntary context switch occurs, the kernel provides CPU resources to another process. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.cpu_percent | The percentage of CPU used for MapR processes. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.cpu_time.syst | The amount of time, measured in seconds, that the process has been in kernel mode. | |
| mapr.process.cpu_time.user | The amount of time, measured in seconds, that the process has been in user mode | |
| mapr.process.data | The amount memory, in MB, used by the data segments of MapR processes. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.disk_octets.read | The number of bytes read from disk for MapR processes. | |
| mapr.process.disk_octets.write | The number of bytes written to disk for MapR processes. | |
| mapr.process.disk_ops.read | The number of read operations for MapR processes. | |
| mapr.process.disk_ops.write | The number of write operations for MapR processes. | |
| mapr.process.mem_percent | The percentage of total system memory (not capped by MapR processes) used for MapR processes. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.page_faults.majflt | The number of major MapR process faults that required loading a memory page from disk. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.page_faults.minflt | The number of minor MapR process faults that required loading a memory page from disk. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.rss | The actual amount of memory, in MB, used by MapR processes. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |
| mapr.process.vm | The amount of virtual memory, in MB, used by MapR processes. | <ul style="list-style-type: none"> process_name: Display values for a specified process. Process values: hoststats,mfs,warden,.etc. |

MapR I/O Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following MapR I/O metrics on each node in the cluster.

| Name | Description |
|---------------------|---|
| mapr.io.read_bytes | The number of MB read from disk. |
| mapr.io.reads | The number of filesystem disk read operations. |
| mapr.io.write_bytes | The number of MB written to disk. |
| mapr.io.writes | The number of filesystem disk write operations. |

MapR RPC Metric

Every 10 seconds, the collectd service uses a plugin to gather the following MapR RPC metrics on each node in the cluster.

| Name | Description |
|---------------------|--|
| mapr.rpc.bytes_recd | The number of bytes received by the filesystem over RPC. |
| mapr.rpc.bytes_sent | The number of bytes sent by the filesystem over RPC. |
| mapr.rpc.calls_recd | The number of RPC calls received by the filesystem. |

Spark JMX Metrics

Every 10 seconds, the collectd service gathers the following Spark JMX metrics on each node in the cluster.

For detailed information about Spark metrics, see the Apache Spark [documentation](#).

- mapr.spark.driver_block_manager_disk_space_used_mb
- mapr.spark.driver_block_manager_memory_max_mem_mbb
- mapr.spark.driver_block_manager_memory_max_off_heap_mem_mb

MapR Topology Metrics

Every 60 seconds, the `collectd` service uses a plugin to gather the following topology metrics on each node in the cluster. Use these metrics to understand disk utilization across a topology or rack. By default, these

metrics include all racks and topologies associated with the cluster. However, you can use tags to specify which rack(s) or topologies(s) to include. **Note:** Racks and topologies can span multiple nodes and one rack can be associated with multiple topologies.

| Name | Description | Tag |
|------------------------------------|--|--|
| mapr.topology.disks_total_capacity | The disk capacity in gigabytes. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> rack_name: Display values for a specified rack. topology_name: Display values for a specified topology. Provide the full topology path. |
| mapr.topology.disks_used_capacity | The amount disk space used in gigabytes. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> rack_name: Display values for a specified rack. topology_name: Display values for a specified topology. Provide the full topology path. |
| mapr.topology.utilization | The aggregate percentage of CPU utilization. This metric is available as of EEP 3.0. | <ul style="list-style-type: none"> rack_name: Display values for a specified rack. topology_name: Display values for a specified topology. Provide the full topology path. |

MapR Volume Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following MapR volume metrics on each CLDB node in the cluster.

For volumes prefixed with `mapr.internal*`, the reported volume metrics are not meaningful.

| Name | Description | Tag(s) |
|---------------------------|--|--|
| mapr.volume.logical_used | The number of MBs used for logical volumes before compression is applied to the files. | <ul style="list-style-type: none"> volume_name: Display values for a specified volume. entity_name: Display values for a specified user or group. |
| mapr.volume.snapshot_used | The number of MBs used for snapshots. | <ul style="list-style-type: none"> volume_name: Display values for a specified volume. entity_name: Display values for a specified user or group. |
| mapr.volume.total_used | The number of MB used for volumes and snapshots. | <ul style="list-style-type: none"> fqn: Display values for a specified node. volume_name: Display values for a specified volume. entity_name: Display values for a specified user or group. |

| Name | Description | Tag(s) |
|-------------------|--|---|
| mapr.volume.used | The number of MB used for volumes after compression is applied to the files. | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. entity_name: Display values for a specified user or group. |
| mapr.volume.quota | The number of megabytes(MB) used for volume quota. | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. entity_name: Display values for a specified user or group. |

Every 10 seconds, the collectd service uses a plugin to gather the following MapR volume metrics on each CLDB node in the cluster.

| Name | Description | Tag(s) |
|----------------------------------|---|---|
| mapr.volmetrics.read_throughput | The per volume read throughput in KB | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. clusterid: Display values for a cluster specified by ID. clustername: Display values for a cluster specified by name. |
| mapr.volmetrics.write_throughput | The per volume write throughput in KB | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. clusterid: Display values for a cluster specified by ID. clustername: Display values for a cluster specified by name. |
| mapr.volmetrics.read_latency | The per volume read latency in milliseconds | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. clusterid: Display values for a cluster specified by ID. clustername: Display values for a cluster specified by name. |

| Name | Description | Tag(s) |
|-------------------------------|--|---|
| mapr.volmetrics.write_latency | The per volume write latency in milliseconds | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. clusterid: Display values for a cluster specified by ID. clustername: Display values for a cluster specified by name. |
| mapr.volmetrics.read_ops | A count of the read operations per volume | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. clusterid: Display values for a cluster specified by ID. clustername: Display values for a cluster specified by name. |
| mapr.volmetrics.write_ops | A count of the write operations per volume | <ul style="list-style-type: none"> fqdn: Display values for a specified node. volume_name: Display values for a specified volume. clusterid: Display values for a cluster specified by ID. clustername: Display values for a cluster specified by name. |

Virtual Memory Metrics

Every 10 seconds, the collectd service uses the vmem plugin to gather the following memory metrics on each node in the cluster.

| Name | Description |
|---------------------------|---|
| vmem.vmpage_faults.majflt | The number of major page faults. Major page faults require pages to be accessed from disk. |
| vmem.vmpage_faults.minflt | The number of minor page faults. Minor page faults can be resolved by sharing pages that are already in memory. |

Memory Metrics

Every 10 seconds, the collectd service uses the memory and swap plugins to gather the following memory metrics on each node in the cluster.

| Name | Description | Additional Tag(s) |
|---------------|---|---|
| memory.memory | The amount of physical memory in bytes. | <ul style="list-style-type: none"> memory_type: Display values for a specified memory type. Memory type values: free, used, buffered, etc. |

| Name | Description | Additional Tag(s) |
|--------------|------------------------------------|---|
| swap.swap | The amount of swap space in bytes. | <ul style="list-style-type: none"> swap_type: Display values for a specified swap type. Swap type values: used and free. |
| swap.swap_io | The amount of swap I/O in bytes. | |

Network Metrics

Every 10 seconds, the collectd service uses the interface plugin to gather network metrics on each node in the cluster.

| Name | Description | Additional Tag(s) |
|-------------------------|--|--|
| interface.if_errors.rx | The number of network errors received. | <ul style="list-style-type: none"> interface_name: Display values for a specified interface. Interface values: eth0, eth1, etc. |
| interface.if_errors.tx | The number of network errors transmitted. | <ul style="list-style-type: none"> interface_name: Display values for a specified interface. Interface values: eth0, eth1, etc. |
| interface.if_octets.rx | The number of bytes received over the network per second. | <ul style="list-style-type: none"> interface_name: Display values for a specified interface. Interface values: eth0, eth1, etc. |
| interface.if_octets.tx | The number of bytes transmitted over the network per second. | <ul style="list-style-type: none"> interface_name: Display values for a specified interface. Interface values: eth0, eth1, etc. |
| interface.if_packets.rx | The number of packets received over the network per second. | <ul style="list-style-type: none"> interface_name: Display values for a specified interface. Interface values: eth0, eth1, etc. |
| interface.if_packets.tx | The number of packets transmitted over the network per second. | <ul style="list-style-type: none"> interface_name: Display values for a specified interface. Interface values: eth0, eth1, etc. |

Node Manager Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following Node Manager metrics on each node in the cluster.

| Name | Description |
|------------------------------|---|
| mapr.nm.allocated_GB | The amount of memory allocated to the Node Manager in GB. |
| mapr.nm.allocated_containers | The number of containers allocated to the Node Manager. |
| mapr.nm.allocated_vcores | The number of CPUs allocated to the Node Manager. |
| mapr.nm.available_vcores | The number of CPUs available to the Node Manager. |
| mapr.nm.available_GB | The amount of memory available to the Node Manager in GB. |
| mapr.nm.containers_completed | The number of containers that have completed. |
| mapr.nm.containers_failed | The number of containers that have failed. |

| Name | Description |
|--|---|
| mapr.nm.containers_initing | The number of containers that are initializing. |
| mapr.nm.containers_killed | The number of containers that have been killed by the Node Manager. |
| mapr.nm.containers_running | The number of containers that are running. |
| mapr.nm.containers_launched | The number of containers started by the Node Manager. |
| mapr.nm.jvm.gc_count | The number of garbage collections. |
| mapr.nm.jvm.gc_count_ps_mark_sweep | The number of parallel scavenge mark sweep collections. |
| mapr.nm.jvm.gc_count_ps_scavenge | The number of parallel scavenge collections. |
| mapr.nm.jvm.gc_time_millis | The amount of time spent on garbage collection in milliseconds. |
| mapr.nm.jvm.gc_time_millis_ps_mark_sweep | The amount of time spent on parallel scavenge mark sweep collection in milliseconds. |
| mapr.nm.jvm.gc_time_millis_ps_scavenge | The amount of time in milliseconds spent on parallel scavenge collection. |
| mapr.nm.jvm.log_error | The total number of ERROR logs. |
| mapr.nm.jvm.log_fatal | The total number of FATAL logs. |
| mapr.nm.jvm.log_info | The total number of INFO logs |
| mapr.nm.jvm.log_warn | The total number of WARN logs. |
| mapr.nm.jvm.mem_heap_committed_m | The amount of heap memory committed to the Node Manager in megabytes. |
| mapr.nm.jvm.mem_heap_max_m | The maximum amount of heap memory that can be committed to the Node Manager in megabytes. |
| mapr.nm.jvm.mem_heap_used_m | The amount of heap memory used by the Node Manager in megabytes. |
| mapr.nm.jvm.mem_max_m | The maximum amount of memory that can be committed to the Node Manager in megabytes. |
| mapr.nm.jvm.mem_non_heap_committed_m | The amount of non-heap memory committed to the Node Manager in megabytes. |
| mapr.nm.jvm.mem_non_heap_max_m | The maximum amount of non-heap memory that can be committed to the Node Manager in megabytes. |
| mapr.nm.jvm.mem_non_heap_used_m | The maximum amount of non-heap memory that can be used by the Node Manager in megabytes. |
| mapr.nm.jvm.threads_blocked | The number of Node Manager threads in BLOCKED state. |
| mapr.nm.jvm.threads_new | The number of Node Manager threads in NEW state. |
| mapr.nm.jvm.threads_runnable | The number of Node Manager threads in RUNNABLE state. |
| mapr.nm.jvm.threads_terminated | The number of Node Manager threads in TERMINATED state. |
| mapr.nm.jvm.threads_time_waiting | The number of Node Manager threads in TIMED_WAITING state. |
| mapr.nm.jvm.threads_waiting | The number of Node Manager threads in WAITING state. |
| mapr.nm.shuffle.shuffle_connection | The number of Node Manager shuffle connections. |

| Name | Description |
|--|--|
| mapr.nm.shuffle.shuffle_output_bytes | The amount of Node Manager shuffle output in bytes. |
| mapr.nm.shuffle.shuffle_outputs_failed | The number of failed Node Manager shuffle outputs. |
| mapr.nm.shuffle.shuffle_outputs_ok | The number of completed Node Manager shuffle outputs. |
| mapr.nm.ugi.get_groups_avg_time | The average amount of time spent by Node Manager on group resolution. |
| mapr.nm.ugi.get_groups_num_ops | The number of group resolutions completed by the Node Manager. |
| mapr.nm.ugi.login_failure_avg_time | The average amount of time spent by Node Manager on failed login attempts. |
| mapr.nm.ugi.login_failure_num_ops | The number of failed login attempts by the Node Manager. |
| mapr.nm.ugi.login_success_avg_time | The average amount of time spent by Node Manager to successfully login. |
| mapr.nm.ugi.login_success_num_ops | The number of successful logins by the Node Manager. |

Resource Manager Metrics

Every 10 seconds, the `collectd` service uses a HPE Ezmeral Data Fabric plugin to gather Resource Manager metrics on the active Resource Manager. `Collectd` gathers metrics on the Resource Manager JVM process, YARN applications, and nodes that are managed by the Resource Manager. The method used to gather the metrics differs based on the metric type.

YARN Application Metrics

`Collectd` gathers YARN application metrics via JMX and REST API. The application metrics that are collected by JMX have the metric name `mapr.rm.<metric_name>`. Application metrics collected via REST API have the metric name `mapr.rm_queue.<metric_name>`.

Metrics Collected Using JMX

The following metrics are collected using JMX. To filter these metrics by queue using the `rm_queue` tag, see [Configure Queue Filters for mapr.rm.<value> Metrics](#) on page 1446.

| | |
|---|--|
| mapr.rm.active_applications | <i>Additional Tags:</i> <code>rm_queue</code> : Display values for a specified queue. <i>Description:</i> The number of active applications. |
| mapr.rm.active_users | <i>Additional Tags:</i> <code>rm_queue</code> : Display values for a specified queue. <i>Description:</i> The number of users with active applications. |
| mapr.rm.aggregate_containers_allocated | <i>Additional Tags:</i> <code>rm_queue</code> : Display values for a specified queue. <i>Description:</i> The number of allocated containers. |
| mapr.rm.aggregate_containers_released | <i>Additional Tags:</i> <code>rm_queue</code> : Display values for a specified queue. <i>Description:</i> The number of released containers. |
| mapr.rm.allocated_MB | <i>Additional Tags:</i> <code>rm_queue</code> : Display values for a specified queue. <i>Description:</i> The amount of memory allocated to the Resource Manager in MB. |

| | |
|-----------------------------------|--|
| mapr.rm.allocated_vcores | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of CPUs allocated to the Resource Manager.</p> |
| mapr.rm.apps_completed | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of completed applications.</p> |
| mapr.rm.apps_failed | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of failed applications.</p> |
| mapr.rm.apps_killed | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of killed applications.</p> |
| mapr.rm.apps_pending | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of pending applications.</p> |
| mapr.rm.apps_running | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of running applications.</p> |
| mapr.rm.apps_submitted | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of submitted applications.</p> |
| mapr.rm.available_MB | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The amount of memory available to the Resource Manager in MB.</p> |
| mapr.rm.available_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of disks available to the Resource Manager.</p> |
| mapr.rm.available_vcores | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of CPUs available to the Resource Manager.</p> |
| mapr.rm.pending_MB | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The amount of memory, in MB, waiting to be allocated by the Resource Manager.</p> |
| mapr.rm.pending_containers | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of containers waiting to be allocated by the Resource Manager.</p> |
| mapr.rm.pending_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> |

| | |
|------------------------------------|--|
| mapr.rm.pending_vcores | <p><i>Description:</i> The number of disks waiting to be allocated by the Resource Manager.</p> <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of CPUs waiting to be allocated by the Resource Manager.</p> |
| mapr.rm.reserved_MB | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The amount of memory reserved by the Resource Manager in MB.</p> |
| mapr.rm.reserved_containers | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of containers reserved by the Resource Manager.</p> |
| mapr.rm.reserved_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of disks reserved by the Resource Manager.</p> |
| mapr.rm.reserved_vcores | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of CPUs reserved by the Resource Manager.</p> |

Metrics Collected Using REST API

The following YARN application metrics are collected using REST API.

| | |
|---|--|
| mapr.rm_queue.aggregate_containers_allocated | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of containers allocated for applications in the default and custom queues.</p> |
| mapr.rm_queue.appmaster_used_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks used by the Application Master for applications in the default and custom queues.</p> |
| mapr.rm_queue.appmaster_used_memory | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, used by the Application Master for applications in the default and custom queues.</p> |
| mapr.rm_queue.appmaster_used_vcores | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the Application Master for applications in the default and custom queues.</p> |

| | |
|---------------------------------------|--|
| mapr.rm_queue.apps_pending | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of pending applications in the default and custom queues.</p> |
| mapr.rm_queue.apps_running | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of applications running in the default and custom queues.</p> |
| mapr.rm_queue.fairshare_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Fair Scheduler, this parameter is the number of disks allocated to default and custom queues.</p> |
| mapr.rm_queue.fairshare_memory | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Fair Scheduler, this parameter denotes the amount of memory, in MB, allocated to default and custom queues.</p> |
| mapr.rm_queue.fairshare_vcores | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Fair Scheduler, this parameter denotes the number of CPUs used by applications in the default and custom queues.</p> |
| mapr.rm_queue.used_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of disks used by applications in the default and custom queues.</p> |
| mapr.rm_queue.used_memory | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The amount of memory, in MB, used by applications in the default and custom queues.</p> |
| mapr.rm_queue.used_vcores | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> The number of CPUs used by applications in the default and custom queues.</p> |
| mapr.rm_queue.max_disks | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum number of disks available to default and custom queues.</p> |
| mapr.rm_queue.max_memory | <p><i>Additional Tags:</i> <code>rm_queue</code>: Display values for a specified queue.</p> <p><i>Description:</i> When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum amount of memory, in MB, available to default and custom queues.</p> |

mapr.rm_queue.max_vcores

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum number of CPUs available to default and custom queues.

mapr.rm_queue.user_allocated_disks

Additional Tags:

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks allocated to the queues.

mapr.rm_queue.user_allocated_memory

Additional Tags:

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, allocated to the queues.

mapr.rm_queue.user_allocated_vcores

Additional Tags:

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs allocated to queues.

mapr.rm_queue.user_appmaster_used_disks

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks used by the queues.

mapr.rm_queue.appmaster_used_memory

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory used by the queues.

mapr.rm_queue.appmaster_used_vcores

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the queues.

mapr.rm_queue.user_apps_pending

Additional Tags:

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of applications pending in the queues.

mapr.rm_queue.user_apps_running*Additional Tags:*

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of applications running in the queues.

mapr.rm_queue.user_used_disks*Additional Tags:*

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of number of disks used by the queues.

mapr.rm_queue.user_used_memory*Additional Tags:*

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, used by the queues.

mapr.rm_queue.user_used_vcores*Additional Tags:*

- `rm_queue`: Display values for a specified queue.
- `rm_user`: Display values for a specified user.

Description: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the queues.

Resource Manager Node Metrics

The following are the Node metrics:

mapr.rm_cluster.active_nodes

The number of nodes in the cluster where containers are running.

mapr.rm_cluster.total_nodes

The number of nodes in the cluster.

mapr.rm_cluster.unhealthy_nodes

The number of nodes in the cluster that are unable to accept applications.

Resource Manager JVM Metrics

The following Resource Manager metrics are collected using JMX:

mapr.rm.jvm.gc_count

The number of garbage collections.

mapr.rm.jvm.gc_count_ps_mark_sweep

The number of parallel scavenge mark sweep collections.

mapr.rm.jvm.gc_count_ps_scavenge

The number of parallel scavenge collections.

| | |
|---|---|
| <code>mapr.rm.jvm.gc_time_millis</code> | The amount of time, in milliseconds, spent on garbage collection. |
| <code>mapr.rm.jvm.gc_time_millis_ps_mark_sweep</code> | The amount of time, in milliseconds, spent on parallel scavenge mark sweep collection. |
| <code>mapr.rm.jvm.gc_time_millis_ps_scavenge</code> | The amount of time, in milliseconds, spent on parallel scavenge collection. |
| <code>mapr.rm.jvm.log_error</code> | The total number of ERROR logs. |
| <code>mapr.rm.jvm.log_fatal</code> | The total number of FATAL logs. |
| <code>mapr.rm.jvm.log_info</code> | The total number of INFO logs. |
| <code>mapr.rm.jvm.log_warn</code> | The total number of WARN logs. |
| <code>mapr.rm.jvm.mem_heap_committed_m</code> | The amount of heap memory, in megabytes, committed to the Resource Manager. |
| <code>mapr.rm.jvm.mem_heap_max_m</code> | The maximum amount of heap memory, in megabytes, that can be committed to the Resource Manager. |
| <code>mapr.rm.jvm.mem_heap_used_m</code> | The amount of heap memory, in megabytes, used by the Resource Manager. |
| <code>mapr.rm.jvm.mem_max_m</code> | The maximum amount of memory, in megabytes, that can be committed to the Resource Manager. |
| <code>mapr.rm.jvm.mem_non_heap_committed_m</code> | The amount of non-heap memory, in megabytes, committed to the Resource Manager. |
| <code>mapr.rm.jvm.mem_non_heap_max_m</code> | The maximum amount of non-heap memory, in megabytes, that can be committed to the Resource Manager. |
| <code>mapr.rm.jvm.mem_non_heap_used_m</code> | The maximum amount of non-heap memory, in megabytes, that can be used by the Resource Manager. |
| <code>mapr.rm.jvm.threads_blocked</code> | The number of Resource Manager threads in BLOCKED state. |
| <code>mapr.rm.jvm.threads_new</code> | The number of Resource Manager threads in NEW state. |
| <code>mapr.rm.jvm.threads_runnable</code> | The number of Resource Manager threads in RUNNABLE state. |
| <code>mapr.rm.jvm.threads_terminated</code> | The number of Resource Manager threads in TERMINATED state. |
| <code>mapr.rm.jvm.threads_time_waiting</code> | The number of Resource Manager threads in TIMED_WAITING state. |
| <code>mapr.rm.jvm.threads_waiting</code> | The number of Resource Manager threads in WAITING state. |

Configure the OpenTSDB Service Heap Size

By default, the OpenTSDB service is configured to use a default heap size of 6 gigabytes. The default heap size can be adjusted by modifying certain configuration files.

In EEPs 6.0.1 and later, the OpenTSDB service is configured to use a default heap size of 6 GB. In earlier EEPs, the default was configured to be 2 GB. If you configure a custom value for the OpenTSDB service heap size and then upgrade to EEPs 6.0.1 or later, you will see the 6-GB default implemented in the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file.

To change the heap size to a different setting, edit the configuration files on all OpenTSDB nodes as follows. The following steps change the heap size from 2 GB to 6 GB. The default heap size might need further adjustment if your cluster grows to a large number of nodes. If the 6-GB heap size is insufficient, you can use these same steps to adjust it:

1. Edit the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file to change:

```
service.heapsize.max=2000
service.heapsize.min=2000
```

to

```
service.heapsize.max=6000
service.heapsize.min=6000
```

2. Edit the `/opt/mapr/opentsdb/opentsdb-*/etc/init.d/opentsdb` file to change:

Note: Step 2 is not required for EEPs 6.0.1 and later, which contain logic to edit the `opentsdb` file automatically.

```
$
{JVMXMX:=-Xmx2000m -Xss1m -XX:MaxMetaspaceSize=128m}
```

to

```
$
{JVMXMX:=-Xmx6000m -Xss1m -XX:MaxMetaspaceSize=128m}
```

3. Restart the OpenTSDB service:

```
maprcli node services -name opentsdb -nodes <space-separated list of
OpenTSDB nodes> -action restart
```

Metric Visualization

Use dashboards to visualize metrics across multiple nodes and clusters.

You can use a single dashboard to visualize metrics for multiple nodes in the cluster, for an entire cluster, or for multiple clusters. In a dashboard, you can use metric tags to filter the type of data that you want to see. To learn more about the tags available for each metric, see [Metric Collection](#) on page 1445.

Before you start visualizing metrics, review the following notes:

Sample Dashboards

As of EEP 1.1, the Grafana UI includes sample CLDB, node, and volume dashboards. For more information, see [Sample Dashboards in Grafana](#) on page 1496.

Grafana Documentation

For information about creating and using dashboards, see the [Grafana documentation](#).

The Embedded Grafana Database

Grafana uses an embedded database to store configuration data such as users, data sources, and dashboards. When used with the HPE Ezmeral Data Fabric, Grafana uses SQLite for its embedded database. Other databases, such as MySQL and PostgreSQL, are not supported for use with the data-fabric implementation of Grafana.

Note also that in a data-fabric cluster, each instance of Grafana has its own embedded SQLite database. Therefore, if you make a change to the Grafana configuration data (for example, if you add a new user) on one node, you must repeat the change on all other nodes where Grafana is installed.

Access the Grafana UI

You can launch the Grafana UI from the Control System or directly from a web browser.

- Use one of the following methods to launch the Grafana UI:
 - In the Control System, go to the **Services** page and click **Grafana** to launch the Grafana UI in another tab.
 - From a web browser, launch the following URL: `http://<IPAddressOfGrafanaNode>:3000`
- Provide user credentials. See [Logging on to Grafana](#) on page 1494.
- Click **Log in**.

Logging on to Grafana

This page describes the credentials needed to log on to Grafana for secure and nonsecure clusters for HPE Ezmeral Data Fabric 6.0 and later.

EEP 5.0.0 and Installer 1.9.0 implemented some changes in security that affect the user IDs and passwords you need to log on to Grafana. Beginning with EEP 5.0.0, Grafana no longer uses its own database to authenticate on secure HPE Ezmeral Data Fabric clusters. On secure clusters, when you enter your user name and password into the browser, the Grafana server sends the user name and password to the CLDB, and the CLDB authenticates using the Pluggable Authentication Module (PAM) and HTTPS. Grafana still relies on its database for some user information. However, because authentication relies on the CLDB, any new user that you add to Grafana must also exist on the HPE Ezmeral Data Fabric cluster.

EEP 4.x.x (Grafana 4.4.2) and Earlier

To log on, enter the default Grafana `admin` user and password:

- User:** `admin`
- Password:** `admin`

EEP 5.x.x (Grafana 4.6.1) and Later

To log on, specify the user and password as follows:

| | Secure Cluster | Nonsecure Cluster |
|-------------|---|--|
| User | Type the HPE Ezmeral Data Fabric cluster <code>admin</code> user ID.  Note: If the cluster <code>admin</code> user has no password or is not able to log in, see Logging on to Grafana Without Using the Cluster Admin on page 1495. | Type the Grafana <code>admin</code> user ID. |

| | Secure Cluster | Nonsecure Cluster |
|-----------------|---|---|
| Password | Type the HPE Ezmeral Data Fabric cluster admin password that you specified during cluster installation. | Type the password for the Grafana admin user that you specified during cluster installation. (During cluster installation, the Installer web interface asks you to provide this password. You can also provide the password by using <code>configure.sh</code> during a manual installation.) |

For More Information

To change the Grafana password, see [Changing the Password for Grafana](#) on page 1495.

For more information about the Grafana versions supported by each EEP, see [EEP Components and OS Support](#) on page 5739.

For information about the EEPs supported by different HPE Ezmeral Data Fabric Core versions, see [EEP Support and Lifecycle Status](#) on page 5734.

Logging on to Grafana Without Using the Cluster Admin

In secure Grafana installations where the cluster admin (typically `mapr`) has no password and is not allowed to log in as a user, special steps are required to enable login with a user other than the cluster admin.

Use this procedure only if the cluster admin has no password. After an upgrade or a new installation of Grafana, perform these steps on the Grafana nodes:

1. Remove the old Grafana database. You will be able to access the Grafana database later using the new Grafana admin user:

```
cd /opt/mapr/grafana/grafana-<version>/var/lib/grafana
mv grafana.db grafana.db.sv
```

2. Use the `export` command to specify the new Grafana admin user:

```
export GRAFANA_ADMIN_ID=<username>
```

3. Run `configure.sh` with the `-R` option:

```
configure.sh -R
```

4. Restart Grafana.

Changing the Password for Grafana

Describes how to change the Grafana password for secure and nonsecure clusters.

Secure Clusters

To change the Grafana password for a secure cluster, you must change the password for the data-fabric cluster admin user. The security implementation determines how you change the password. For example, if your security implementation is PAM and LDAP, you need to use LDAP to change the cluster admin password.

Note: If the cluster is secure, attempting to change the Grafana password using the Grafana interface has no effect.

Nonsecure Clusters

For a nonsecure cluster:

1. Log in to the interface using the `admin` user ID and the password that you specified for the `admin` user ID when you installed the cluster.
2. Select **Home > Admin > Profile**.
3. On the **User Profile** screen, click **Change Password**, located near the bottom of the screen.
4. Enter and save the new password.

Adding a New Grafana User to a Secure MapR Cluster

In a secure data-fabric cluster, adding a new Grafana user requires an extra step to ensure that the user can be authenticated through the CLDB.

Beginning with EEP 5.0.0, Grafana no longer uses its own database to authenticate on secure data-fabric clusters. On secure clusters, when you enter your user name and password into the browser, the Grafana server sends the user name and password to the CLDB, and the CLDB authenticates using the Pluggable Authentication Module (PAM) and HTTPS.

Because authentication relies on the CLDB, any new user that you add to Grafana must also exist on the data-fabric cluster. Therefore, to add a new Grafana user in a secure data-fabric cluster:

1. Add the user to the Linux system first. This user must have the same Linux UID and GID on every node in the data-fabric cluster.
2. Add the same user to Grafana, making sure that you use the user ID you added to the Linux system. In Grafana: **Settings > ServerAdmin > Users > Add new user**.

Sample Dashboards in Grafana

Use the sample dashboards to get familiar with the types of graphs you can create. As of EEP 1.1, sample dashboards are available by default in Grafana.

Displaying the Sample Dashboards

For Grafana 4.x, 5.x, and 6.x, navigate to the **Welcome to Grafana** page, and click the **Home** drop-down menu to display the sample dashboards. Once you select a dashboard, it displays in the **Recently viewed dashboards** list on the Home page.

In Grafana 7.5.x and later, use these steps to display the dashboards:

1. Navigate to the **Welcome to Grafana** page.
2. On the left-side icon menu, click **Dashboard > Manage**. The list of dashboards is displayed.
3. Click a dashboard in the list to load the dashboard. The **General / Node Dashboard** page is displayed.
4. Loading the dashboard adds the dashboard to the **Recently viewed dashboards** list on the **General / Home** page.

Sample Dashboard Descriptions

CLDB Dashboard

The CLDB dashboard provides a high-level view of the data-fabric cluster. It displays the following information about the cluster: number of nodes, status of nodes, number of volumes, container information, disk capacity, and the utilization of CPU, memory, and disks across the cluster.

Node Dashboard

The Node dashboard provides node-specific information. It displays the following information for the selected node: CPU, memory, network I/O, filesystem I/O, HPE Ezmeral Data Fabric Database operations, and Node Manager metrics. All the metrics are tagged with node hostname and the `fqn` drop-down menu on the top left can be used to switch between nodes.

Volume Dashboard

The Volume dashboard provides volume-specific information. It displays the following information for the selected volume: raw data size, snapshot size, total size (including the snapshot size), volume utilization trends, read/write latency, number of reads/writes, and read/write throughput. All the metrics are tagged with volume name. Use the `VolumeName` drop-down menu on the top left to switch between volumes.

Troubleshooting Sample Dashboards

The sample dashboards should display metrics automatically. However, with certain EEPs, some manual configuration may be required to view sample dashboard metrics.

Configure the ClusterID in the CLDB dashboard

When the `ClusterID` drop-down menu on the CLDB dashboard is set to `None`, you must manually enter the ClusterID. You can determine the ClusterID from the Manage Licenses page on the Control System. ClusterID is usually an eighteen digit number.

Configure the Hostname in the Node dashboards

When the `fqn` drop-down menu on the Node dashboard is set to `None`, you must manually enter the hostname for the node that you want to view metrics for.

Configure the Volume in the Volume dashboard

When the `VolumeName` drop-down menu on the Volume dashboard is set to `None`, you must manually enter the volume name for the volume that you want to view metrics for. The Volumes page on the Control System lists the volume names in the format required by the field. For example, you can enter `mapr.cluster.root` in the `VolumeName` drop-down menu.

Note: You must apply the manual configuration each time you view a dashboard.

Update the OpenTSDB Data Source For Grafana

Grafana connects to a single OpenTSDB node to read metrics. If Grafana cannot read the metrics because an OpenTSDB node has failed, you must configure Grafana to connect to a different OpenTSDB node.

Note: The OpenTSDB node that Grafana connects to by default is determined by the first OpenTSDB node that was specified when the cluster was configured to use metrics monitoring.

1. Use one of the following methods to launch the Grafana user interface:
 - From the Control System, select the **Grafana** view. After you select the **Grafana** view, you might also need to select the **Pop-out page into a tab** option.
 - From a web browser, launch the following URL: `http://<IPAddressOfGrafanaNode>:3000`
2. Click the Grafana icon in the upper left corner to toggle the side-menu bar.
3. Select **Data Sources** from the menu.
4. Click the **MapRMonitoringOpenTSDB** data source.

5. In the **Http setting** section, update the **Url** field to point to an active OpenTSDB node.

6. Click **Save & Test**.

Log Collection

Fluentd collects log events from each node in the cluster and stores them in a centralized location so that administrators can search the logs when troubleshooting issues in the cluster. The process that fluentd uses to parse and send log events to Elasticsearch differs based on the formatting of log events in each log file.

Fluentd uses one or both of the following mechanisms to parse logs:

multi-line matching

Using the log time stamp as a delimiter, multi-line matching uses the `tail` plugin to read logs and determine the end of a log event. Each log event is sent to Elasticsearch when the next log event is written to the log file. This mechanism is often used when each log event starts with a timestamp and then includes a stack trace.

multi-pattern matching

Multi-pattern matching uses the `grok` plugin to parse logs events using complex expressions. This mechanism is often used to parse logs events that have non-uniform log formatting.

Before Fluentd sends the log entries to Elasticsearch, Fluentd assigns the following columns to each log event:

| Tag | Description |
|--------------|---|
| level | The message level of the log entry. For example, info, warning, or error. |
| class | Java or C++ process name associated with the log entry. |
| message | The log message. |
| event_time | The time, with millisecond precision, when the log entry was written to the log file. |
| service_name | The name of the service that generated the log entry. |
| @timestamp | The time, with second precision, when fluentd read the message. |
| fqdn | The node on which the log entry was written. |
| clusterid | The clusterid of the cluster on which the log was written. |

Note: The log event contents differs based on the service that logs it and the type of log. Therefore, the log events sent to Elasticsearch may include empty columns.

For more information about Elasticsearch, see the [Elasticsearch website](#).

Configure Logs to Index

Edit the `fluentd.conf` file (`/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf`) to enable or disable the indexing of a specific log.

The `fluentd.conf` file includes a source parameter for each log file that it indexes.

1. To disable the indexing of a log, comment all lines for the associated source parameter.
2. To enable the indexing of a log, for example syslogs, uncomment the lines for the associated source parameter.

- Restart `fluentd` on each node in the cluster which is impacted by changes to the index configuration. For example, if you disable the indexing of Kibana logs, restart `fluentd` on the node that runs Kibana.

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> \
-action restart
```

For example, in this excerpt of the `fluentd.conf` file, `NodeManager` error logs are disabled and `ResourceManager` logs are enabled:

```
# yarn nodemanager log
# <source>
# @type tail
# @id yarn_nodemanager_input
# format multiline
# format_firstline /\d{4}-\d{1,2}-\d{1,2}/
# format1 /^(?<my_event_time>[^\ ]* [^\ ]*) (?<level>[^\ ]*) (?<class>[^\:]*):
(?<message>.*)$/
# time_key my_event_time
# keep_time_key true
# path /opt/mapr/hadoop/hadoop-*/logs/yarn-*-nodemanager-*.log
# tag nodemanager
# pos_file /opt/mapr/fluentd/fluentd-0.14.00/var/log/fluentd/tmp/
nodemanager.pos
# </source>

# yarn resourcemanager log
<source>
  @type tail
  @id yarn_resourcemanager_input
  format multiline
  format_firstline /\d{4}-\d{1,2}-\d{1,2}/
  format1 /^(?<my_event_time>[^\ ]* [^\ ]*) (?<level>[^\ ]*) (?<class>[^\:]*):
(?<message>.*)$/
  time_key my_event_time
  keep_time_key true
  path /opt/mapr/hadoop/hadoop-*/logs/yarn-*-resourcemanager-*.log
  tag resourcemanager
  pos_file /opt/mapr/fluentd/fluentd-0.14.00/var/log/fluentd/tmp/
resourcemanager.pos
</source>
```

Forward Logs to Syslog Server

You can configure `fluentd` to send logs to a syslog server in addition to Elasticsearch. This topic provides instructions for configuring `fluentd` to send logs to syslog compatible collectors. However, it only provides guidelines for the syslog configuration, as syslog parameters differ by version. Knowledge of how to configure a syslog compatible collector is required to complete this configuration.

Complete the following steps:

- Configure `fluentd` to send logs to the syslog server.
- Configure `syslog` server to accept logs from `fluentd`.

Step 1: Configure `fluentd` to send logs to the syslog server

Complete the following steps on each `fluentd` node.

- Open the `fluentd.conf` file (`/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf`).

- Remove the # to uncomment the following store section:

```
# <store>
# @type remote_syslog
# host 10.10.100.92
# port 51400
# severity debug
# tag fluentd
# </store>
```

- Update the `host` parameter to the hostname/IP address of the receiving `syslog` server.
- Update the `port` parameter to match the port that the receiving `syslog` server is expecting remote logging information on.
- Restart the `fluentd` service:

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

Note: You can run this command after completing the steps on a node or run this command with a list of nodes once you have configured each `fluentd` node.

Step 2: Configure syslog to accept logs from fluentd

In general, you need to perform the following steps on the `syslog` collection server:

- Configure `syslogd` to listen for logs outside of the `syslog` node.
- Set up rules for how `syslog` handles the logs once it receives it.

- In `/etc/rsyslog.d/listen.conf`, comment out the following parameter:

```
$SystemLogSocketName /run/systemd/journal/syslog
```

- In `/etc/rsyslog.conf`, uncomment the following properties:

```
#$ModLoad imudp
#$UDPServerRun 514
```

- In `/etc/rsyslog.conf`, update the `UDPServerRun` to a value above 1000 that matches the port you configured in `fluentd.conf`. For example: Set `UDPServerRun` to 51400
- In `/etc/rsyslog.conf`, configure rules for handling logs. For example, add the following before the `RULES` section to route messages from the `fluentd` node to a log file named `qa-node91.log`.

```
if $fromhost-ip == '10.10.100.91' then /var/log/qa-node91.log
& ~
```

Note: In this example, the IP address must match the IP address of the `fluentd` node.

Data Fabric Core Logs

The `fluentd` component reads and parses the following Data Fabric Core log files on each node in the cluster.

| Service Name | Parsing Method | Description |
|-----------------|------------------------------|--|
| adminuiapp | Multi-line | Control System logs from /opt/mapr/apiserver/logs/apiserver.log. |
| cldb | Multi-line | CLDB server logs from \$MAPR_HOME/logs/cldb.log. |
| cldbsummary | Multi-line | Summary of the CLDB server logs from \$MAPR_HOME/logs/cldbsummary.log |
| mfs_maprdb | Multi-line | HPE Ezmeral Data Fabric Database logs from \$MAPR_HOME/logs/mfs.log-5.  Note: If nodes in the cluster run two filesystem instances, Fluentd only reads and parses logs from primary fileserver instance. Therefore, logs from the secondary fileserver instance will not be indexed by Elasticsearch. |
| mfs | Multi-line | Data Fabric filesystem logs from \$MAPR_HOME/logs/mfs.log-3.  Note: If nodes in the cluster run two filesystem instances, Fluentd only reads and parses logs from primary fileserver instance. Therefore, logs from the secondary fileserver instance will not be indexed by Elasticsearch. |
| nfserver | Multi-line and Multi-pattern | NFS for the HPE Ezmeral Data Fabric server log from \$MAPR_HOME/logs/nfserver.log |
| nodemanager | Multi-line | Node Manager logs from \$MAPR_HOME/hadoop/hadoop-*/logs/yarn-*-nodemanager-*.log. |
| resourcemanager | Multi-line | ResourceManager logs from \$MAPR_HOME/hadoop/hadoop-*/logs/yarn-*-resourcemanager-*.log |
| warden | Multi-line and Multipattern | Warden logs from \$MAPR_HOME/logs/warden.log. |
| zookeeper | Multi-line | Zookeeper logs from \$MAPR_HOME/zookeeper/zookeeper-*/logs/zookeeper.log |

Data Fabric Ecosystem Logs

The `fluentd` component reads and parses the following data-fabric ecosystem component logs on each node in the cluster.

| Service Name | Parsing Method | Description |
|-------------------|-----------------------------|--|
| drill | Multi-line | Drill logs from \$MAPR_HOME/drill-*/logs/drillbit.log. |
| drillbitsSqlline | Multi-line | Drill SQL query logs from \$MAPR_HOME/drill/drill-*/logs/sqlline.log. |
| hbasest | Multi-line and Multipattern | HBase REST Server logs from \$MAPR_HOME/hbase/hbase-*/logs/hbase-*-rest-*.log. |
| hbasethriftserver | Multi-line | Hbase Thrift Server logs from \$MAPR_HOME/hbase/hbase-*/logs/hbase-*-thrift-*.log. |
| hive | Multi-line | HiveServer logs from \$MAPR_HOME/hive/hive-*/logs/root/hive.log. |
| httpfs | Multi-line | HttpFS logs from \$MAPR_HOME/httpfs/httpfs-*/logs/httpfs.log. |
| hue | Multi-line | Hue logs from \$MAPR_HOME/hue/hue-*/logs/hue-mapr-runcpserver-*.out. |
| oozie | Multi-line | Oozie logs from \$MAPR_HOME/oozie/oozie-*/logs/oozie.log. |
| oozieOps | Multi-line | Oozie operation logs from \$MAPR_HOME/oozie/oozie-*/logs/oozie-ops.log. |
| oozieCatalina | Multi-line and Multipattern | Oozie Catalina logs from \$MAPR_HOME/oozie/oozie-*/logs/catalina.out. |
| sparkhistory | Multi-line | Spark HistoryServer logs from \$MAPR_HOME/spark/spark-*/logs/spark-mapr-org.apache.spark.deploy.history.HistoryServer-1-*.out. |

System Logs

The `fluentd` component does not collect the following system logs by default because they require the configuration of additional permissions for the `$MAPR_USER`.

| Service name | Parsing Method | Description |
|--------------|----------------|--|
| kernlog | Multi-line | Kernel logs from <code>/var/log/kern.log</code> . |
| syslog | Multi-line | System logs from <code>/var/log/syslog</code> and <code>/var/log/messages</code> . |
| mysql_errors | Multi-line | MySQL errors from <code>/var/log/mysql/error.log</code> . |

Note: To enable `fluentd` to read and parse these logs, see [Configure Logs to Index](#) on page 1498 and also perform the following:

- On Ubuntu and RHEL/CentOS, add `$MAPR_USER` to the `admin` group.
- On RHEL/CentOS, change the ownership of the log file so that it is owned by both the `root` user and the `admin` group.

MapR Monitoring Logs

The `fluentd` component reads and parses the following MapR Monitoring component logs on each node in the cluster.

| Service Name | Parsing Method | Description |
|--------------|----------------|--|
| collectd | Multi-line | The collectd component logs from <code>\$MAPR_HOME/collectd/collectd-*/var/log/collectd/collectd_daemon.log</code> |
| fluentd | Multi-line | The fluentd component logs from <code>\$MAPR_HOME/fluentd/fluentd-*/var/log/fluentd/fluentd.log</code> , |
| grafana | Multi-line | Grafana logs from <code>\$MAPR_HOME/grafana/grafana-*/var/log/grafana/grafana.log</code> . |
| kibana | Multi-line | Kibana logs from <code>\$MAPR_HOME/kibana/kibana-*/var/log/kibana/kibana.log</code> . |

Log Aggregation and Storage

`Fluentd` uses a round-robin approach when writing logs to Elasticsearch nodes. If an Elasticsearch node is unavailable, `Fluentd` can fail over log storage to another Elasticsearch node.

Each `Fluentd` service connects to each Elasticsearch node that you configure to aggregate and store logs. The Elasticsearch nodes are set when you configure Monitoring with the Installer or when you run `configure.sh` with the `-ES` parameter.

The Elasticsearch index directory is shared among all the Elasticsearch nodes in the cluster. When you use the Installer to install Elasticsearch, each Elasticsearch node writes index data to `/opt/mapr/es_db`, unless you specified a different location during the installation. When you manually install Elasticsearch, each Elasticsearch node writes index data to `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/`, unless you specified a different location using the `configure.sh -ESDB` option. For a cluster with one Elasticsearch node, the index directory is allocated 5 shards. For clusters with 2 or more Elasticsearch nodes, the index directory is allocated a number of shards equal to 3 times the number of Elasticsearch nodes in the cluster.

`Fluentd` does not require additional configuration to enable automatic failover to an available Elasticsearch node. However, it is important that at least three Elasticsearch nodes are configured to aggregate and store logs so that failure of one node does not prevent logs from being used for monitoring purposes. Based on your environment, more Elasticsearch nodes may be required. [Service Layout Guidelines for Large Clusters](#) on page 74.

For more information about Elasticsearch, see the [Elastic website](#).

Configure Log Retention

By default, Elasticsearch indexes 2 days of logs. Based on your requirements, you can configure a different retention period for Elasticsearch.

The following cron job runs each day to purge logs based on the retention period.

```
$min $hour * * * $ES_HOME/bin/curator --config $ES_HOME/etc/elasticsearch/
curator.yml \
  $ES_HOME/etc/elasticsearch/curator_actions/delete_indices.yml >>
  $ES_HOME/var/log/elasticsearch/purgeData.log 2>&1 "
```

Log Retention for Elasticsearch

Complete the following steps to edit the log retention period for Elasticsearch:

1. Open the `/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator_actions/delete_indices.yml` file.
2. Update the `unit` and `unit_count` to the new retention period.

unit The unit of measure for the retention period. Valid parameter values: days and weeks.

unit_count The number of days or weeks.

For example, this version of the `delete_indices.yml` file retains logs for 2 days.

```
actions:
  1:
    action: delete_indices
    description: >-
      Delete indices older than 2 days (based on index name), for
mapr_monitoring-
    prefixed indices. Ignore the error if the filter does not result
in an
    actionable list of indices (ignore_empty_list) and exit cleanly.
    options:
      ignore_empty_list: True
      timeout_override:
      continue_if_exception: False
      disable_action: False
    filters:
      - filtertype: pattern
        kind: prefix
        value: mapr_monitoring-
        exclude:
      - filtertype: age
        source: name
        direction: older
        timestring: '%Y.%m.%d'
      unit: days
      unit_count: 2
    exclude:
```

Log Retention for Kibana

Each time you start Kibana, it logs data to its log file. You cannot delete the log file while Kibana is running.

To purge the log files:

1. Restart Kibana so that a new log file is created.

```
maprcli node services -name kibana -nodes <kibana hostname/
IPaddress> -action restart
```

2. Delete all the old log files (`kibana.*.<#>`) from the following location: `/opt/mapr/kibana/kibana-<version>/var/log/kibana/`.

Configure Purge Duration

Based on your requirements, you can configure a purge duration for Elasticsearch.

To update the purge duration on node with installed Elasticsearch 6.5.3, run the following command:

```
/opt/mapr/elasticsearch/elasticsearch-<Version>/usr/share/elasticsearch/bin/es_cluster_mgmt.sh --purgeAge <newValue>
```

This command will automatically update the `delete_indices.yml` file. This change updates only the `unit_count` value to `newValue`, without changing the unit value.

Configure Log Rotation Policies for Monitoring Services

New log files are created based on the log rotation policy. By default, each Monitoring service has a log rotation policy. In most cases, you can change the policy based on your requirements.

OpenTSDB Log Rotation Policy

By default, OpenTSDB creates a new log file when each log file reaches the maximum file size of 128MB. After 4 log files are generated, it deletes the oldest log file.

To change the log rotation policy, edit the following file: `/opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/logback.xml`. For more information, see the [OpenTSDB Logging documentation](#).

Fluentd and CollectD Log Rotation Policy

By default, Fluentd and Collectd create a new log file each day and they both retain 30 log files. Log rotation for Fluentd and Collectd logs is managed by `logrotate`.

To change the log rotation policies, edit the following files: `/etc/logrotate.d/fluentd` and `etc/logrotate.d/collectd`. For details on how to update the log rotation policy, see the [logrotate documentation](#).

Elasticsearch Log Rotation Policy

By default, Elasticsearch creates a new log file each day and it retains 7 days of logs.

To change the log rotation policy, edit the following file `/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/logging.yml`. For details on how to update `logging.yml`, see the [Elasticsearch documentation](#).

Grafana Log Rotation Policy

By default, Grafana creates a new log file whenever the current log file exceeds the 256MB. It retains log files that were generated in the last 7 days.

To change the log rotation policy, edit the `[log]` section of the following file: `/opt/mapr/grafana/grafana-<version>/etc/grafana/grafana.ini`. For details on how to update the `grafana.ini`, see the [Grafana documentation](#).

Kibana Log Rotation Policy

Each time you start Kibana, it logs data to its log file and it does not automatically delete old log files. A new log file is created when you restart Kibana. To purge the log files, see [Configure Log Retention](#) on page 1503.

Configure the Elasticsearch Service Heap Size

The Elasticsearch service is memory-intensive. By default, the Elasticsearch service is configured to use a minimum and maximum heap size of 2 GB. You can override these default values by making changes in the Elasticsearch Warden configuration file and the `jvm.options` file. Restart Elasticsearch after you modify the settings.

Configuring Memory in the Warden Configuration File

You can enable memory settings in the Elasticsearch Warden configuration file, located in the `/opt/mapr/conf/conf.d/warden.elasticsearch.conf` directory. Modify the `service.heapsize.min` and `service.heapsize.max` values set in `warden.elasticsearch.conf`, as shown:

```
service.heapsize.min=2000
service.heapsize.max=2000
```

The `service.heapsize.min` and `service.heapsize.max` values are set in megabytes as an integer. For older EEPs, you must make sure that the `-Xms` and `-Xmx` values in the `jvm.options` file match the settings in the Warden configuration file.

About the `jvm.options` File

The `jvm.options` file centralizes arguments to the Java Virtual Machine to simplify the management of the JVM options. You can no longer set the JVM options through the `ES_MIN_MEM`, `ES_MAX_MEM`, `ES_HEAP_SIZE`, `ES_HEAP_NEWSIZE`, `ES_DIRECT_SIZE`, `ES_USE_IPV4`, `ES_GC_OPTS`, `ES_GC_LOG_FILE`, and `JAVA_OPTS` environment variables.

If you installed the Elasticsearch service from the TAR or ZIP distributions, you can locate the `jvm.options` file in `config/jvm.options`. If you installed Elasticsearch from the Debian or RPM packages, you can locate the `jvm.options` file in the `$ES_HOME/etc/elasticsearch/jvm.options` directory, for example:

```
/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch
```

To specify an alternative location, set the `ES_JVM_OPTIONS` environment variable to the file path.

Configuring Memory in the `jvm.options` File

Note: If you configured Elasticsearch memory in the Warden configuration file, configuring memory in the `jvm.options` file is not required for EEPs 6.2.0, 6.1.1, 6.0.2 and later, which contain logic to edit the `jvm.options` file automatically. For other EEPs, you must ensure that memory-configuration changes are made *both* in the Warden configuration file and in the `jvm.options` file.

The `-Xms` and `-Xmx` values in the `jvm.options` file set the Elasticsearch heap size, as shown:

```
-Xms2g
-Xmx2g
```

The `-Xms` parameter sets the minimum heap size in gigabytes. The `-Xmx` parameter sets the maximum heap size in gigabytes. Elasticsearch recommends that both parameters have the same value.

Restarting the Elasticsearch Service

After you modify memory settings, issue the following command to restart the Elasticsearch service:

```
maprcli node services -name elasticsearch -nodes <space separated list of
Elasticsearch nodes> -action restart
```

Tip:

- On a production cluster, you can lock Elasticsearch memory to improve performance. To lock Elasticsearch memory, set the `bootstrap.mlockall: true` option in `$ES_HOME/etc/elasticsearch/elasticsearch.yml`.
- If Elasticsearch uses more than 75% of the configured heap size, you may want to increase the maximum heap size value.

For more information, see the [Elasticsearch documentation](#).

Configure Fluentd Services to Write to Elasticsearch Nodes on the Same Rack

On clusters with high-density racks, ensure you have at least one Elasticsearch server per rack and configure each Fluentd service to write to Elasticsearch nodes that run on the same rack as the Fluentd service. This configuration minimizes the impact of log aggregation on other processes that run on the cluster and in particular, minimizes the amount of backbone bandwidth used by the log aggregation.

Complete the following steps on each node that runs the Fluentd service.

1. Open the `/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/es_config.conf` file.
2. Edit the `hosts` property to only include Elasticsearch nodes that are on the same rack as the Fluentd service.
Example:

```
hosts qa-node90:9200,qa-node91.qa.lab:9200,qa-node92.qa.lab:9200
```

3. Restart Fluentd.

```
maprcli node services -name fluentd -nodes <space separated list of
fluentd nodes> -action restart
```

Warning: Changes to the `es_config.conf` files are overridden by `configure.sh`. Therefore, you will need reconfigure the `hosts` property in the `es_config.conf` file after `configure.sh` is run on Fluentd nodes.

60-mapr_elasticsearch.conf

The `/etc/sysctl.d/60-mapr_elasticsearch.conf` file is created when you install Elasticsearch. This file specifies a Docker host setting for Elasticsearch.

The `vm.max_map_count` setting is a tuning parameter that limits the number of discrete mapped memory areas for the Linux VM:

Example

```
vm.max_map_count=262144
```

For more information about the `max_map_count` parameter, see the [Linux Kernel documentation](#).

60-mapr_fluentd.conf

The `/etc/sysctl.d/60-mapr_fluentd.conf` file is created when you install Fluentd. This file contains Linux kernel tuning parameters.

The `tcp_tw_reuse` parameter allows you to reuse sockets in the `TIME_WAIT` state for new connections.

The `ip_local_port_range` parameter defines the local port range that is used by TCP and UDP to choose the local port.

Example

```
net.ipv4.tcp_tw_reuse = 1
net.ipv4.ip_local_port_range = 10240 65535
```

Log Visualization

Use dashboards to visualize the logs across multiple nodes and clusters.

For information about creating and using dashboards, see the [Kibana documentation](#).

Access the Kibana UI

You can launch the Kibana UI from the Control System or directly from a web browser.

- Use one of the following method to launch the Kibana UI:
 - In the Control System, go to **Services** and click **Kibana** to launch the Kibana UI in another tab.
 - From a web browser, launch the following URL: `http://<IPaddressOfKibanaNode>:5601`
- Log on as needed. See [Logging on to Kibana](#) on page 1508.

Logging on to Kibana

This page describes the credentials needed to log on to Kibana for secure and nonsecure clusters for HPE Ezmeral Data Fabric 6.0 and later.

Elasticsearch has its own user database, which also serves Kibana. EEP 5.0.0 and Installer 1.9.0 implemented some changes in security that affect the user IDs and passwords you need to log on to Kibana.

EEP 4.x.x

To log on, specify the user and password as follows:

| | Secure Cluster | Nonsecure Cluster |
|-----------------|--|--------------------|
| User | Type the Kibana <code>admin</code> user. | No logon required. |
| Password | Type <code>admin</code> . | No logon required. |

EEP 5.0.0 and Later

To log on, specify the user and password as follows:

| | Secure Cluster | Nonsecure Cluster |
|-----------------|--|--------------------|
| User | Type the Kibana <code>admin</code> user ID. | No logon required. |
| Password | Type the Elasticsearch/Kibana password that you specified during cluster installation. | No logon required. |

For More Information

To change the Elasticsearch/Kibana password, see [Changing the Password for Elasticsearch and Kibana](#) on page 1509.

For more information about the Grafana versions supported by each EEP, see [EEP Components and OS Support](#) on page 5739.

For information about the EEPs supported by different HPE Ezmeral Data Fabric Core versions, see [EEP Support and Lifecycle Status](#) on page 5734.

Changing the Password for Elasticsearch and Kibana

Describes how to change the password for Elasticsearch / Kibana.

Kibana gets its password from Elasticsearch. To change the password for the `admin` user for Elasticsearch and Kibana:

1. On one of the Elasticsearch nodes, run these commands:

```
ESHOME=/opt/mapr/elasticsearch/elasticsearch-<es_version>
cd $ESHOME/usr/share/elasticsearch/usr/share/elasticsearch/plugins/
search-guard-6
bash tools/hash.sh -p "NewPasswordYouWantForAdmin"
$2a$12$6ASxMQEBKYPyGUcl0RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq
```

The `es_version` depends on the EEP that you have installed. To determine the `es_version`, use the following table, or refer to [Component Versions for Released EEPs](#) on page 5789:

| Core Version | EEP Version | <es_version> |
|-------------------|-------------|--------------|
| 6.2.0 | 8.0.0 | 6.8.8 |
| 6.2.0 | 7.1.1 | 6.8.8 |
| 6.2.0 | 7.1.0 | 6.8.8 |
| 6.2.0 | 7.0.1 | 6.8.8 |
| 6.2.0 | 7.0.0 | 6.8.8 |
| 6.1.1 | 6.3.5 | 6.8.8 |
| 6.1.1 or 6.1.0 | 6.3.4 | 6.8.8 |
| 6.1.1 or 6.1.0 | 6.3.3 | 6.8.8 |
| 6.1.0 | 6.3.2 | 6.8.8 |
| 6.1.0 | 6.3.1 | 6.8.8 |
| 6.1.0 | 6.3.0 | 6.5.3 |
| 6.1.0 | 6.2.0 | 6.5.3 |
| 6.1.0 | 6.1.1 | 6.5.3 |
| 6.1.0 | 6.1.0 | 6.5.3 |
| 6.1.0 | 6.0.2 | 6.2.3 |
| 6.1.0 | 6.0.1 | 6.2.3 |
| 6.1.0 | 6.0.0 | 6.2.3 |

- Using the hash generated in step 1, edit the `sgconfig/sg_internal_users.yml` file. Change this:

```
admin:
hash: $2a$12$VcCDgh2NDk07JGN0rjGbM.Ad41qVR/YFJcgHp0UGns5JDymv..TOG
#password is: <PasswordSpecifiedAtClusterInstallation>
```

to this:

```
admin:
hash: $2a$12$6ASxMQEBKYPyGUcl0RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq
#password is: <NewPasswordYouWantForAdmin>
#hash: $2a$12$VcCDgh2NDk07JGN0rjGbM.Ad41qVR/YFJcgHp0UGns5JDymv..TOG
#password is: <PasswordSpecifiedAtClusterInstallation>
```

- Save the file.
- Load the new users database into Elasticsearch:

```
KSPW=$(cat $ESHOME/etc/elasticsearch/.keystore_password)
./tools/sgadmin.sh -h <esHostname> -f sgconfig/sg_internal_users.yml -t
internalusers -ks
../../../../../../../../etc/elasticsearch/keystores/
admin-usr-keystore.jks -kspass $KSPW -ts
../../../../../../../../etc/elasticsearch/keystores/truststore.jks -tspass
$KSPW -cn MaprMonitoring
```

Related concepts

[Checking the EEP Version](#) on page 5618

Some Installer operations require you to know the version of the currently installed Ezmeral Ecosystem Pack (EEP). You can check the EEP version easily from within the Installer user interface or derive the EEP version from your repository information.

Related tasks

[Checking the Installer Version](#) on page 5617

Some Installer features require you to use the latest version of the Installer. You can check the Installer version easily from within the user interface.

Display Logs Chronologically

To display logs chronologically in Kibana, sort the log events by the `event_time` column.

`@timestamp` indicates the time with second precision and is not as precise as `event_time` which indicates the time with millisecond precision. Therefore, if you want to display logs chronologically in Kibana, sort the log events by the `event_time` column, not the `@timestamp` column.

Update the Elasticsearch URL for Kibana

Kibana connects to a single Elasticsearch node to read logs. In the event that Kibana is unable to read logs due to the failure of an Elasticsearch node, configure Kibana to connect to an available Elasticsearch node.

Note: The Elasticsearch node that Kibana connects to by default is determined by the first Elasticsearch node that was specified when the cluster was configured to use Monitoring

- Open `/opt/mapr/kibana/kibana-<version>/config/kibana.yml`.
- Update the `elasticsearch.url` parameter to point to an available Elasticsearch node.

Tip: If you want to configure Kibana to work even if the Elasticsearch node is unavailable, see the [Kibana documentation](#) for the steps to configure Kibana to load balance across multiple Elasticsearch nodes.

HPE Ezmeral Data Fabric Monitoring Tips and Troubleshooting

Lists the nuances of monitoring clusters.

Monitoring a Secure Cluster

After regenerating the HPE Ezmeral Data Fabric user ticket, service failures occur for `collectd` and `OpenTSDB`

If you delete or regenerate the HPE Ezmeral Data Fabric user ticket, the running `collectd` and `OpenTSDB` services will fail. After updating the HPE Ezmeral Data Fabric user ticket, restart `collectd` and `OpenTSDB` services.

Monitoring Logs

I notice a sudden increase in `fluentd` logs. What can I do?

A sudden increase in the log file for `fluentd` could mean that a feedback loop is occurring where `fluentd` logs an error in the log file for a `fluentd` issue and that log entry causes yet another error when `fluentd` tries to parse it. In this case, consider disabling the index of `fluentd` logs. See [Configure Logs to Index](#) on page 1498.

I see "400 - Rejected by Elasticsearch" messages in the `fluentd` logs. What can I do?

Messages such as the following can accumulate in the `fluentd` log when a process does not produce logs with valid UTF-8 output:

```
2019-04-25 17:00:11 -0700 [warn]: #0
dump an error event:
error_class=Fluent::Plugin::Elasticsearch
ErrorHandler::ElasticsearchError
error="400 - Rejected by
Elasticsearch" location=nil
after setting this option in
es_config.conf
```

In a message such as the following, you might see invalid characters represented as

a diamond with a question mark: . The "service_name": "collectd" part of the message indicates that `collectd` is generating the invalid UTF-8 output:

```
[2019-04-30T19:06:29,495][DEBUG]
[o.e.a.b.TransportShardBulkAction]
[mfs73] [mapr_monitoring-2019.05.01]
[4] failed
to execute bulk item (index) index
{[mapr_monitoring-2019.05.01]
[mapr_monitoringv1]
[taQkcWoBCeW3tMASnlcW],
source[{"my_event_time": "2019-04-30
18:36:39", "level": "info", "message": "wr
ite_maprstreams plugin: Produced:
Offset: 1247132; Size: 152;
[{"metric": "mapr.streams.produce_ms
gs", "value": 448, "tags":
{"fqdn":
"qa-node91.qa.lab", "clusterid": "63
78079583755418855", "clustername":
"my.cluster.com"}]}]
```

```
\n", "@timestamp": "2019-04-30T18:36:39.000000000-07:00", "service_name": "collected" ]}]
org.elasticsearch.index.mapper.MapperParsingException: failed to parse field [message] of type [text]
Caused by:
com.fasterxml.jackson.core.JsonParseException: Invalid UTF-8 middle byte 0x5c
```

One workaround is to comment out the log producing the invalid character. You can do this in the `fluentd.conf` file. For more information, see [Configure Logs to Index](#) on page 1498.

Another workaround is to fix the application that produces the error message. If the log file is produced by an application that you control, change the output of the log producing the invalid character.

Monitoring Metrics

Where should I store the Elasticsearch index?

Elasticsearch requires a lot of disk space. Also, when you upgrade Elasticsearch, the default index directory is removed along with the package update. Therefore, it is recommended to configure a separate filesystem for the index data. It is not recommended to store index data under the `/` or the `/var` filesystem.

Note: If you store the Elasticsearch index on a filesystem that is locally hosted, you will be able to access logs in the event that the HPE Ezmeral Data Fabric cluster is not available.

For more information about the Elasticsearch index and the default index directory, see [Log Aggregation and Storage](#) on page 1503.

I see a "Bad Request" error message for my HPE Ezmeral Data Fabric Database metrics? What can I do?

If you have more than 1000 active tables in HPE Ezmeral Data Fabric Database and the HPE Ezmeral Data Fabric monitoring request size to OpenTSDB is more than 4 KB, you may see the following error message:

```
"Sorry but your request was rejected as being invalid.
The reason provided was: Chunked request not supported."
```

You can increase the maximum request size of OpenTSDB to up to 64 KB by setting the following parameters in the `opentsdb.conf` file:

```
tsd.http.request.enable_chunked=true
tsd.http.request.max_chunk=65536
```

For more information, see the [OpenTSDB configuration guide](#).

Installation and Configuration Errors

See [Troubleshoot Monitoring Installation Errors](#) on page 160

Reconfiguring MapR Monitoring

Changes to an existing cluster, such as the addition of services, may require additional steps to enable the collection of metrics and logs.

Configure Monitoring for Additional Services

When you add services to a cluster where MapR Monitoring is already configured, you must restart collectd and Fluentd services to enable the collection of logs and metrics for the newly added services.

1. Restart the collectd service on each node that runs the service that was added to the cluster.

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

2. Restart the Fluentd service on each node that runs the service that was added to the cluster.

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

Update the Monitoring Storage Nodes

You must reconfigure HPE Ezmeral Data Fabric Monitoring when you add additional OpenTSDB or Elasticsearch nodes, or when you change the OpenTSDB or Elasticsearch node locations.

1. Run [configure.sh](#) on each node in the HPE Ezmeral Data Fabric cluster with the `-R`, `-ES`, and `-OT` parameters. Optionally, you can include the `-ESDB` parameter.

```
/opt/mapr/server/configure.sh -R -ES <comma-separated list of
Elasticsearch nodes> \
-OT <comma-separated list of OpenTSDB nodes> [-ESDB <filepath>]
```

For the entire list of available `configure.sh` parameters, see [configure.sh](#)

If you encounter any errors after running `configure.sh`, see [Troubleshoot Monitoring Installation Errors](#) on page 160

2. If you updated the list of Elasticsearch nodes, restart the all the Fluentd, Elasticsearch, and Kibana services.

```
maprcli node services -name fluentd -nodes <space separated list of
Fluentd nodes> -action restart
```

```
maprcli node services -name elasticsearch -nodes <space separated list
of Elasticsearch nodes> -action restart
```

```
maprcli node services -name kibana -nodes <space separated list of
Kibana nodes> -action restart
```

3. If you updated the list of OpenTSDB nodes, restart the collectd, OpenTSDB, and Grafana services.

```
maprcli node services -name opentsdb -nodes <space separated list of
OpenTSDB nodes> -action restart
```

```
maprcli node services -name collectd -nodes <space separated list of
collectd nodes> -action restart
```

```
maprcli node services -name grafana -nodes <space separated list of
Grafana nodes> -action restart
```

Configuring Security

Describes how to configure security and manage secure clusters.

Configuring Data-Fabric Security

Provides usage information for frequently used security functionality, including Access Control Lists (ACLs), Access Control Expressions (ACEs), file permissions, and subnet whitelisting.

Note: Release 6.1 makes it easier to secure new data-fabric installations. See [Using the Enable Secure Cluster Option](#) on page 5630 in the [Installer](#) on page 5599.

Wired encryption and authentication (including impersonation) for the data-fabric platform and for all supported ecosystem products are enabled on all new installations through [Installer](#) on page 5599 and through manual installation by running the [configure.sh](#) on page 2331 command with the `-secure` option.

You can enable security features at any time, but additional configuration is required for the individual components to work with security enabled. This section discusses initial configuration of a secure cluster as well as other forms of security.

The following access control elements are available irrespective of whether you have enabled security features for your cluster. Additionally, once security features are enabled, these elements benefit from encrypted traffic within the cluster and strong authentication to the cluster.

- Access Control Lists (ACLs) for the cluster, the volumes in the cluster, and the MapReduce application queue
- [ACEs](#) control user permissions for directories, files, and HPE Ezmeral Data Fabric Database tables that are stored natively
- File permissions for objects in the filesystem layer
- Subnet whitelisting restricts access to the cluster's FileServer service

On clusters with security features enabled, ecosystem components may require additional configuration. For example, Hive functionality has different security requirements depending on the interaction between the HiveServer2 component, the Hive command-line interface, and the Hive metastore.

See the [Security Support Matrix](#) on page 5805 for more information about supported security options for Ecosystem components. See the specific Ecosystem component in [Ecosystem Components](#) on page 3378 for information on security configuration.

See [Security Vulnerabilities](#) on page 6767 for a list of known vulnerabilities.

Verifying if Files Needed for Security are Present

When you run `configure.sh` with the `-secure` option, the following files are automatically created in the `/opt/mapr/conf` directory. To ensure that security is properly configured, navigate to the `/opt/mapr/conf` directory and verify that the files are present.

| | |
|--|---|
| Master value controlling the cluster secure or non-secure state | <p><i>File or command:</i> <code>/opt/mapr/conf/mapr-clusters.conf</code></p> <pre>maprcli dashboard info -cluster <clusterName> -json grep secure</pre> <p><i>Default secure setting:</i> <code>secure=true</code></p> <p><i>Alternate possible values/notes:</i> <code>secure=false</code> disables security on restarting the cluster.</p> |
| Data-fabric service account | <p><i>File or command:</i> <code>sudo passwd -S mapr</code></p> <p><i>Default secure setting:</i> Site Specific Password</p> <p><i>Alternate possible values/notes:</i> No password. Use <code>su</code> to access.</p> |
| CLDB key file | <p><i>File or command:</i> <code>/opt/mapr/conf/cldb.key</code></p> <p><i>Default secure setting:</i> Created at install, do not change</p> <p><i>Alternate possible values/notes:</i> Must exist on all CLDB nodes and be identical.</p> |
| Server ticket | <p><i>File or command:</i> <code>/opt/mapr/conf/maprserverticket</code></p> <p><i>Default secure setting:</i> Created at install, do not change</p> <p><i>Alternate possible values/notes:</i> Must exist on all cluster nodes and be identical.</p> |
| User ticket | <p><i>File or command:</i> <code>/opt/mapr/conf/mapruserticket</code></p> <p><i>Default secure setting:</i> Created at install, do not change</p> <p><i>Alternate possible values/notes:</i> Must exist on all cluster nodes and be identical. This ticket is owned and used by the service account as needed.</p> |
| SSL keys | <p><i>File or command:</i> <code>/opt/mapr/conf/ssl_truststore</code></p> <p><code>/opt/mapr/conf/ssl_keystore</code></p> <p><i>Default secure setting:</i> Created at install, and should rarely change. These keys are used by web and REST HTTPS interfaces.</p> <p><i>Alternate possible values/notes:</i> Add site specific certificates with the keytool utility.</p> |
| Java (JAAS) authentication service settings | <p><i>File or command:</i> <code>/opt/mapr/conf/mapr.login.conf</code></p> <p><i>Default secure setting:</i> Created at install, do not change</p> <p><i>Alternate possible values/notes:</i> Must exist on all cluster nodes and be identical.</p> |

Roles for use with ACEs

File or command: /opt/mapr/conf/m7_permissions_roles_refimpl.conf

Default secure setting: Specific roles defined using automation

Alternate possible values/notes: Use should be deprecated. Linux groups are a much better method, centralized and consistent with enterprise standards.

Default security settings for some data-fabric services

File or command: /opt/mapr/conf/env.sh

Default secure setting: Created at install, do not change

Alternate possible values/notes: Must exist on all cluster nodes and be identical. You can view the list of settings by using this command: `grep -i secure env.sh`

ZooKeeper security setting

File or command: /opt/mapr/zookeeper/zookeeper-\$zkver/conf/zoo.cfg

Default secure setting:
authMech=MAPR-SECURITYauthProvider.l=org.apache.zookeeper.server.auth.SASLAuthenticationProvider

Alternate possible values/notes:
authMech=SIMPLE-SECURITY

JMX remote access (debug and metrics monitoring)

File or command: /opt/mapr/conf/jmxremote.{access,password}

Default secure setting: read-only and with the password limited to the data-fabric service account.

Alternate possible values/notes: read-write but is not recommended

Determining if Wire-Level Security is Enabled Using the CLI

When you run `configure.sh` with the `-secure` option, wire-level security is automatically enabled at the cluster level. You can, optionally, disable wire-level security at the individual volume-level. To determine if wire-level security is enabled for a volume, run the following command:

```
/opt/mapr/bin/maprcli volume list -json |grep wire
```

This command returns the value of `wireSecurity` as 1 if wire-level security is enabled for the volume; 0 otherwise.

Enabling Cluster Wide Data Access Auditing

To enable auditing data access operations at a cluster level, run:

```
/opt/mapr/bin/maprcli audit data -enabled
```

Determining if per Volume Data Access Auditing is Enabled

To determine if auditing data access operations is enabled for a volume, run:

```
/opt/mapr/bin/maprcli volume info -name <volume_name> -json | grep -i 'audited\|coalesce'
```

This command returns the value of `audited` as 1 if data access auditing is enabled for the volume; 0 otherwise.

Getting Started with HPE Ezmeral Data Fabric Security

Describes quick implementation of security.

MapR 6.1 introduced enhanced security settings that simplify the process of creating secure clusters. For a brief introduction, see [Security](#). To learn how to secure a cluster, see [this course](#).

To set up a secure cluster:

1. Enable cluster security, authentication, and wire-level encryption by running [configure.sh](#) if you performed a manual installation.

See [Enabling Security](#) on page 1517 for more information.

Note: If you selected the [Using the Enable Secure Cluster Option](#) on page 5630 when installing with the [Installer](#) on page 5599, you can proceed to the next step.

2. Generate HPE Ezmeral Data Fabric user tickets to authenticate with your username and password.
See [Generating a HPE Ezmeral Data Fabric User Ticket](#) on page 1543 for more information.
3. Configure each Ecosystem component, where necessary, for security.
See [Security and Ecosystem Components](#) on page 787 for more information.
4. (Optional) Enable encryption of data at rest at the cluster level and selectively for volumes as well.
See [Enabling Encryption of Data at Rest](#) on page 1529 for more information.
5. (Optional) Turn on auditing for the cluster and for directories that contain sensitive data.
See [Enabling and Disabling Auditing of Cluster Administration](#) on page 834 and [Enabling and Disabling Auditing of Data Access Operations](#) on page 834 for more information.
6. (Optional) Enable authorization using ACEs for files, tables, streams, or volumes and ACLs for administrative activities that can be performed on the cluster.
See [Managing Access Control Expressions](#) on page 1565 and [Managing Access Control Lists](#) on page 1562 for more information.

Tip: After you enable security, review the [System Behavior Changes After Enabling Security](#) on page 1527.

Enabling Security

Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

The following steps enable:

- Security for the cluster nodes
- Wire-level encryption for the platform and ecosystem components
- Authentication for all network-based connections
- (Optional) Data-at-rest encryption on the cluster

When you set up a cluster, you must run the [configure.sh](#) on page 2331 script on each node that you want to add to the cluster. After you enable security, review the [System Behavior Changes After Enabling Security](#) on page 1527.

Basic Procedure

To enable security for the cluster, follow these steps in order:

1. If the cluster is running, [shut it down](#).
2. Delete the `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, `ssl_truststore.pem`, `ssl-server.xml`, `ssl-client.xml`, `ssl_usertruststore`, and `ssl_userkeystore` files on a machine where wire-level security is not enabled, as the `configure.sh` script fails if you already have these files in the directory.

Note: The `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, `ssl_truststore.pem`, `ssl-server.xml`, and `ssl-client.xml` files are generated during installation of the Web server even if you did not enable security.

For example, to delete the files, run the following commands:

```
cd /opt/mapr/conf
/bin/rm -f ssl_keystore ssl_keystore.p12 ssl_keystore.pem \
    ssl_truststore ssl_truststore.p12 ssl_truststore.pem ssl-server.xml
ssl-client.xml \
    ssl_usertruststore ssl_userkeystore
```

If you are re-running the script due to an invocation error from a previous run, the `cldb.key` and `maprserverticket` files may have already been created. Delete these files, as the script fails if you already have these files in the directory. For example, run the following command to delete these files:

```
cd /opt/mapr/conf
/bin/rm -f cldb.key maprserverticket ssl_keystore ssl_keystore.p12
ssl_keystore.pem \
    ssl_truststore ssl_truststore.p12 ssl_truststore.pem ssl-server.xml
ssl-client.xml \
    ssl_usertruststore ssl_userkeystore
```

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

```
/opt/mapr/server/configure.sh -secure -dare -genkeys -Z
<Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
```

where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify a fully-qualified domain name (FQDN) as described in [Connectivity](#) on page 119. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

Important: You must run `configure.sh -dare -genkeys` only *once* on one CLDB node, since the resulting files must be copied to other nodes.

The `configure.sh -dare -genkeys` command generates the following files in the `/opt/mapr/conf` directory:

- `cldb.key`
- `dare.master.key`
- `maprserverticket`

- `ssl_keystore`
- `ssl_keystore.p12`
- `ssl_keystore.pem`
- `ssl_keystore-signed.pem`
- `ssl_truststore`
- `ssl_truststore.p12`
- `ssl_truststore.pem`
- `ssl-server.xml`
- `ssl-client.xml`
- `ssl_userkeystore`
- `ssl_userkeystore.csr`
- `ssl_userkeystore.p12`
- `ssl_userkeystore.pem`
- `ssl_userkeystore-signed.pem`
- `ssl_usertruststore`
- `ssl_usertruststore.p12`
- `ssl_usertruststore.pem`

The command generates the following files in the `opt/mapr/conf/ca` directory:

- `chain-ca.pem`
- `root-ca.pem`
- `signing-ca.pem`

Note: The `dare.master.key` file is generated only if data-at-rest encryption is enabled on the cluster.

Tip: A comprehensive listing of the Trust and Key Store files is at: [Understanding the Key Store and Trust Store Files](#) on page 1524.

4. Copy the `cldb.key` to any node with the CLDB or Zookeeper service installed, and copy the `dare.master.key` to any node with the CLDB service installed.

Note: Copy the `dare.master.key` file only if you are enabling data at rest encryption on the cluster.

5. Verify ownership and permissions:
 - a. Verify that the following files in the `/opt/mapr/conf` directory are owned by the user that runs cluster services. This user is `mapr` by default:

- `ssl_keystore`
 - `ssl_keystore.csr`
 - `ssl_keystore.p12`
 - `ssl_keystore.pem`
 - `ssl_keystore-signed.pem`
 - `ssl_truststore`
 - `ssl_truststore.p12`
 - `ssl_truststore.pem`
 - `ssl-server.xml`
 - `ssl-client.xml`
 - `ssl_userkeystore`
 - `ssl_userkeystore.csr`
 - `ssl_userkeystore.p12`
 - `ssl_userkeystore.pem`
 - `ssl_userkeystore-signed.pem`
 - `ssl_usertruststore`
 - `ssl_usertruststore.p12`
 - `ssl_usertruststore.pem`
- b.** Verify that the `maprserverticket` has its permission-mode bits set to 600
- c.** Verify that the following files have their UNIX permission-mode bits set to 400:
- `ssl_keystore`
 - `ssl_keystore.csr`
 - `ssl_keystore.p12`
 - `ssl_keystore.pem`
 - `ssl_keystore-signed.pem`
 - `ssl_userkeystore`
 - `ssl_userkeystore.csr`
 - `ssl_userkeystore.p12`
 - `ssl_userkeystore.pem`
 - `ssl_userkeystore-signed.pem`

d. Verify that the following files are readable to all users:

- `ssl_truststore`
- `ssl_truststore.p12`
- `ssl_truststore.pem`
- `ssl_usertruststore`
- `ssl_usertruststore.p12`
- `ssl_usertruststore.pem`

6. Copy the following files to the `/opt/mapr/conf` directory of every node in the cluster:

- `maprserverticket`
- `ssl_keystore`
- `ssl_keystore.csr`
- `ssl_keystore.p12`
- `ssl_keystore.pem`
- `ssl_keystore-signed.pem`
- `ssl_truststore`
- `ssl_truststore.p12`
- `ssl_truststore.pem`
- `ssl-server.xml`
- `ssl-client.xml`
- `ssl_userkeystore`
- `ssl_userkeystore.csr`
- `ssl_userkeystore.p12`
- `ssl_userkeystore.pem`
- `ssl_userkeystore-signed.pem`
- `ssl_usertruststore`
- `ssl_usertruststore.p12`
- `ssl_usertruststore.pem`

Copy the following files to the `/opt/mapr/conf/ca` directory of every node in the cluster. Create the `/opt/mapr/conf/ca` directory if it does not exist:

- `chain-ca.pem`
- `root-ca.pem`

- signing-ca.pem

7. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

```
/opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
<CLDB_node_list> -N <cluster_name>
```

The `-secure` option indicates that security must be enabled on the node where the command is run. The `-dare` option indicates that data-at-rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

 **Important:** You must also do this on any nodes that you add to the cluster in the future.

8. Copy the `ssl_truststore`, `ssl_truststore.p12`, `ssl_truststore.pem` and `ssl-client.xml` files to any client nodes outside the cluster.

 **Important:** If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

9. When using [KMIP](#), after [rekeying](#), copy the contents of `/opt/mapr/conf/tokens` to all the CLDB nodes in the cluster.
10. Optionally, enable encrypted quorum ZooKeeper communication. See [zoo.cfg](#) on page 2505 for more information.
11. Log in as the `mapr` superuser using the [maprlogin](#) command: `maprlogin password` (in this command, `password` is literal text).
12. If clients will connect to multiple secure clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. See [Setting Up the Client](#) for more information on data-fabric clients.

Use one of the following three ways to merge tickets:

- a. Create a file with password of sourceTruststore (can be obtained from the `ssl-client.xml` file of the source cluster) as the content, and pass the filename as the argument to merge:

```
manageSSLKeys.sh merge <in trust store> <out trust store>
[inPasswordField (needed to override default password)]
```

- b. Use the `copytruststore` option of `manageSSLKeys.sh` and create a copy of truststore. Then copy it to the destination node using SCP, and finally run merge without any additional options. For example:

```
[root@perfnod223 ~]# ./manageSSLKeys.sh copytruststore /tmp/
ssl_truststore2
[root@perfnod223 ~]# ./manageSSLKeys.sh merge /tmp/
ssl_truststore2 /opt/mapr/conf/ssl_truststore
Merging certificates from /tmp/ssl_truststore2 into existing /opt/
mapr/conf/ssl_truststore
```

- c. Use the `copytruststore` option of `manageSSLKeys.sh` and create a custom password for the copy of truststore. Copy this truststore to the destination node using SCP. Then create a file with password of the copied truststore as the content, and pass the filename as the argument to `merge`. For example:

```
[root@perfnode223 ~]# ./manageSSLKeys.sh copytruststore /tmp/
ssl_truststore3 abcdef
[root@perfnode223 ~]# echo abcdef >/tmp/a
[root@perfnode223 ~]# ./manageSSLKeys.sh merge /tmp/
ssl_truststore3 /opt/mapr/conf/ssl_truststore /tmp/a
Merging certificates from /tmp/ssl_truststore3 into existing /opt/
mapr/conf/ssl_truststore
```

Regenerating the Truststore Password

The truststore password is generated when you run `/opt/mapr/server/configure.sh -genkeys`. This password is stored in the `/opt/mapr/conf/ssl-server.xml` and the `/opt/mapr/conf/ssl-client.xml` files. For example:

```
<property>
  <name>ssl.server.truststore.password</name>
  <value>EfbNb2qPAW3iH4D_Foyl8jHWFPjEL81D</value>
  <description>Optional. Default value is "".
</description>
</property>

<property>
  <name>ssl.client.truststore.password</name>
  <value>EfbNb2qPAW3iH4D_Foyl8jHWFPjEL81D</value>
  <description>Optional. Default value is "".
</description>
</property>
```

Data Fabric clients use this password information. If you change the password, you must copy the `ssl-client.xml` and `ssl_truststore` files from the cluster to the client. The upgrade instructions for each of the data-fabric clients include this step.

To regenerate the truststore password, run:

```
/opt/mapr/server/manageSSLKeys.sh createrandompassword oldpassword
```

Here `oldpassword` is the password that is already present in the `/opt/mapr/conf/ssl-server.xml` and the `/opt/mapr/conf/ssl-client.xml` files.

The system then regenerates the password. The command returns the temporary location where the output is generated, the source files, and the destination where they are to be copied. Copy them manually as directed.

Advanced Procedure

In certain situations, you may opt for variant of the basic procedure. Such situations include, but are not limited to the following:

- You are running the script on a host that is configured without a domain name.
- You have a cluster where all the machines do not have the same domain name.
- You wish to import your own custom certificates instead of the self-signed certificates generated by the `configure.sh` utility.

Running on Hosts with no Configured Domain Name

When used without the `-certdomain` argument, the `configure.sh` script discovers the domain name of the node on which it is being executed using the `hostname -d` command and then creates a 100-year self-signed certificate using the PKCS#1 v1.5 with SHA-512 hash function (SHA512withRSA) with a wildcard certificate with the common name (CN) `*.<domain>`. For example, if `hostname -d` returns the domain name `mycompany.com`, then the CN of the certificate is `*.mycompany.com`. This certificate works for all machines within the `mycompany.com` domain and can therefore be copied to all cluster nodes as specified in Step 5 in the Basic Procedure.

Certificate generation fails if the host that you are running the script from is configured without a domain name. To fix this, modify your machine configuration so that `hostname -d` returns a non-empty string and then run the `configure.sh` script.

Alternatively, re-run the script with the `-certdomain` option as shown in Step 3 of the Basic Procedure:

```
/opt/mapr/server/configure.sh -secure -genkeys -certdomain <domain_name> -Z
<Zookeeper_node_list> -C <CLDB_node_list> [ -N <cluster_name> ]
```

Securing Clusters with Multiple Domain Names

Generally, all machines within a cluster should belong to the same domain. In the unusual case where you have a cluster with different machines belonging to different domains, applications that perform hostname verification can fail if you run the `configure.sh` script (as described in Step 3 of the [Basic Procedure](#) on page 1518) to generate a single-domain wildcard certificate. In this case, you must provide your own multi-domain wildcard certificate and import the custom certificate into the keystore as described in [Importing a Certificate Authority Signed \(CA Signed\) SSL Certificate Into a Data Fabric Cluster](#).

Using Custom Certificates

To import your own custom certificates into the keystore instead of using the self-signed certificates, see [Importing a Certificate Authority Signed \(CA Signed\) SSL Certificate Into a Data Fabric Cluster](#).

Understanding the Key Store and Trust Store Files

Provides a comprehensive listing of the key store and trust store files.

Key Stores and Trust Stores Added for Release 6.2.0

The following key store and trust store files were added at release 6.2.0 to support SSL security for the log stack (Kibana, Elasticsearch, and Fluentd). As part of [Enabling Security](#) on page 1517, you must copy these files from the `/opt/mapr/conf` directory of the security master node to the `/opt/mapr/conf` directory on all other nodes, and assign the [appropriate ownership and permissions](#):

`ssl_userkeystore`

Location: `/opt/mapr/conf`

Description: The key store containing the private keys and the certificates for log-stack users.

`ssl_userkeystore.csr`

Location: `/opt/mapr/conf`

Description: The certificate-signing request created when the certs are signed using the CA chain.

`ssl_userkeystore.p12`

Location: `/opt/mapr/conf`

Description: The PKCS#12 version of the `ssl_userkeystore`. The `.p12` version of the file is reserved for future use.

`ssl_userkeystore.pem`

Location: `/opt/mapr/conf`

| | |
|------------------------------------|--|
| ssl_userkeystore-signed.pem | <p><i>Description:</i> The key store containing all of the certs from the <code>ssl_userkeystore</code> in the <code>.pem</code> format.</p> <p><i>Location:</i> <code>/opt/mapr/conf</code></p> |
| ssl_usertruststore | <p><i>Description:</i> The key store containing all of the signed certs from the <code>ssl_userkeystore</code> in the <code>.pem</code> format.</p> <p><i>Location:</i> <code>/opt/mapr/conf</code></p> |
| ssl_usertruststore.p12 | <p><i>Description:</i> The trust store containing the public keys, and no private keys, for the log-stack users.</p> <p><i>Location:</i> <code>/opt/mapr/conf</code></p> |
| ssl_usertruststore.pem | <p><i>Description:</i> The PKCS#12 version of the <code>ssl_usertruststore</code>. The <code>.p12</code> version of the file is reserved for future use.</p> <p><i>Location:</i> <code>/opt/mapr/conf</code></p> |
| | <p><i>Description:</i> The key store containing all of the certs from the <code>ssl_usertruststore</code> in the <code>.pem</code> format.</p> |

Certificate Files in 6.2.0

The following files were added at release 6.2.0 to facilitate self-signing of data-fabric certificates. Previously, data-fabric certificates were unsigned. As part of [Enabling Security](#) on page 1517, you must copy these files from the `/opt/mapr/conf` directory of the security master node to the `/opt/mapr/conf` directory on all other nodes, and assign the appropriate ownership and permissions:

| | |
|-----------------------|--|
| root-ca.pem | <p><i>Location:</i> <code>/opt/mapr/conf/ca</code></p> <p><i>Description:</i> The root signing certificate authority.</p> |
| chain-ca.pem | <p><i>Location:</i> <code>/opt/mapr/conf/ca</code></p> <p><i>Description:</i> The chain certificate authority, which contains both the root CA and signing CA.</p> |
| signing-ca.pem | <p><i>Location:</i> <code>/opt/mapr/conf/ca</code></p> <p><i>Description:</i> The signing certificate authority.</p> |

KMIP Tokens Added in 6.2.0

External key store (KMIP) tokens were also added as part of release 6.2.0. The KMIP tokens are used for authentication and communication with an external key store. The tokens are contained in `/opt/mapr/conf/tokens` and must be copied to all the CLDB nodes in the cluster.

Key Stores and Trust Stores in Release 6.1.0

The following files are generated by running `configure.sh -dare -genkeys` on a CLDB node. Alternatively, you can generate them by running the [manageSSLKeys.sh](#) on page 2401 script. The `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files are also generated during installation of the Web server, even if you did not enable security. For more information, see [Enabling Security](#) on page 1517.

| | |
|------------------------|--|
| cldb.key | <p><i>Location:</i> <code>/opt/mapr/conf</code></p> <p><i>Description:</i> The CLDB key file. This file must exist on all CLDB nodes and be identical.</p> |
| dare.master.key | <p><i>Location:</i> <code>/opt/mapr/conf</code></p> <p><i>Description:</i> The key file that enables data-at-rest encryption. The <code>dare.master.key</code> file is generated</p> |

| | |
|---------------------------|--|
| | only if data at rest encryption is enabled on the cluster. This file must be copied to all the nodes with the CLDB service installed. |
| maprservticket | <i>Location:</i> /opt/mapr/conf <i>Description:</i> The server ticket. This file must exist on all cluster nodes and be identical. |
| ssl-client.xml | <i>Location (symlink):</i> /opt/mapr/conf <i>Location (file):</i> \${MAPR_HOME}/hadoop/hadoop-<version>/etc/hadoop/ssl-client.xml <i>Description:</i> Contains the SSL configuration for the client in XML format. |
| ssl_keystore | <i>Location:</i> /opt/mapr/conf <i>Description:</i> This file is needed on all nodes where the webserver is running. |
| ssl_keystore.p12 | <i>Location:</i> /opt/mapr/conf <i>Description:</i> When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the ssl_keystore.p12 and ssl_truststore.p12 files, and copy them to the /opt/mapr/conf directory on all nodes in the cluster. The .p12 files are required to generate the .pem files needed by Grafana and the Data Access Gateway. This step is necessary only for manual upgrades. |
| ssl_keystore.pem | <i>Location:</i> /opt/mapr/conf <i>Description:</i> When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the ssl_truststore.pem and ssl_keystore.pem files, and copy them to the /opt/mapr/conf directory on all nodes in the cluster. The Data Access Gateway, Grafana, and Hue components use these files. This step is necessary only for manual upgrades. |
| ssl-server.xml | <i>Location (symlink):</i> /opt/mapr/conf <i>Location (file):</i> \${MAPR_HOME}/hadoop/hadoop-<version>/etc/hadoop/ssl-server.xml <i>Description:</i> Contains the SSL configuration for the server in XML format. |
| ssl_truststore | <i>Location:</i> /opt/mapr/conf <i>Description:</i> contains the certificates required by nodes initiating communication over TLS. |
| ssl_truststore.p12 | <i>Location:</i> /opt/mapr/conf <i>Description:</i> When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the ssl_keystore.p12 and ssl_truststore.p12 files, and copy them to the /opt/mapr/conf directory on all nodes in the cluster. The .p12 files are required to generate the .pem files needed by Grafana and the Data Access Gateway. This step is necessary only for manual upgrades. |
| ssl_truststore.pem | <i>Location:</i> /opt/mapr/conf <i>Description:</i> When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the |

`ssl_truststore.pem` and `ssl_keystore.pem` files, and copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The Data Access Gateway, Grafana, and Hue components use these files. This step is necessary only for manual upgrades.

Disabling Security

To disable security features for your cluster:

1. If the cluster is running, [shut it down](#).
2. On all nodes, run the `configure.sh` on page 2331 script with the `-unsecure` option and specify the CLDB and ZooKeeper nodes.

```
configure.sh -unsecure -C <CLDB_Node> -Z <ZK_Node> -N <cluster_name>
```

3. [Start the cluster](#).

System Behavior Changes After Enabling Security

After enabling security features for your cluster, the following behaviors change:

- Users must authenticate with the `maprlogin` utility.
- Components that have web UIs, such as the Control System, Hive, and Oozie, require authentication.
-  **Warning:** Note that you must also complete the [PAM configuration](#) to set up user authentication for the Control System logins.
- Several components that communicate over HTTP use HTTPS instead.
- Encryption is used for network traffic.
- Access to a cluster using URIs that use the CLDB node's name or IP address, instead of the cluster name, is no longer supported, as in the following examples. The following URIs no longer work after enabling security:

```
http://cldb1.cluster.com:7222/f1
```

```
http://10.10.20.10:7221/f1
```

The following URIs work after enabling security:

```
http:///f1 <access f1 in default cluster>
```

```
http://my.cluster.com/f1
```

Managing Encryption for MapR Core

Provides information that allows you to use encryption across the MapR platform.

This section describes how to enable security for data at rest and on the wire as well as general security components and system changes.

Enabling Wire-level Security

Wire-level security encrypts data transmission between the nodes in your cluster.

You can enable encryption for data on the wire at the volume level only if security is enabled at the cluster level. If necessary, refer to [Determining if a Cluster is Secure Using the CLI and REST API](#) on page 1538

to determine if the cluster is secure before enabling wire-level encryption on a volume. If your cluster is enabled for security, wire-level security is enabled by default on all new volumes and no additional steps are required. This section describes how to enable wire-level security on new and existing volumes (if the volume is already not enabled for wire-level security).

Enabling Wire-level Security for a Volume Using the Control System

1. Log in to the Control System and click **Data > Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page or go to the [Edit Volume](#) page.
3. Set the value for the **Data on Wire Encryption** property to **Yes** (to enable).
See [Creating a Volume](#) on page 941 or [Modifying a Volume](#) on page 970 for more information.
4. Complete the steps to create or modify the volume.
See [Creating a Volume](#) on page 941 or [Modifying a Volume](#) on page 970 for more information.

Enabling Wire-Level Security for a Volume Using the CLI and REST API

CLI

Set the value for the `wiresecurityenabled` parameter to `true` when you:

- Create the volume. For example:

```
maprcli volume create -name
<volName> -path
<volMountPath> -wiresecurityenabled
true
```

- Modify the volume. For example:

```
maprcli volume modify -name
<volName> -wiresecurityenabled true
```

REST

Send a request of type POST and set the value for the `wiresecurityenabled` parameter to `true` when you:

- Create the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
wiresecurityenabled=true' --user
mapr:mapr
```

- Modify the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=<volName>&wiresecurityenabled=
true' --user mapr:mapr
```

See [volume create](#) on page 2190 and [volume modify](#) on page 2275 for more information.

Disabling Wire-level Security

You can disable wire encryption for a volume using the Control System, the CLI, and REST API.

Disabling Wire-level Security for a Volume Using the Control System

1. Log in to the Control System and click **Data > Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page or go to the [Edit Volume](#) page.
3. Set the value for the **Data on Wire Encryption** property to **No** (to disable).
See [Creating a Volume](#) on page 941 or [Modifying a Volume](#) on page 970 for more information.
4. Complete the steps to create or modify the volume.
See [Creating a Volume](#) on page 941 or [Modifying a Volume](#) on page 970 for more information.

Disabling Wire-Level Security for a Volume Using the CLI and REST API

You can disable encryption of data on wire at the volume level.

CLI

Set the value for the `wiresecurityenabled` parameter to `false` when you:

- Create the volume. For example:

```
maprcli volume create -name
<volName> -path
<volMountPath> -wiresecurityenabled
false
```

- Modify the volume. For example:

```
maprcli volume modify -name
<volName> -wiresecurityenabled
false
```

REST

Send a request of type POST and set the value for the `wiresecurityenabled` parameter to `false` when you:

- Create the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
wiresecurityenabled=false' --user
mapr:mapr
```

- Modify the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=<volName>&wiresecurityenabled=
false' --user mapr:mapr
```

See [volume create](#) on page 2190 and [volume modify](#) on page 2275 for more information.

Enabling Encryption of Data at Rest

You can enable or disable data at rest encryption at the volume level using the Control System, CLI, and REST API if encryption of data at rest is enabled at the cluster level. If you installed using the [Installer](#) on page 5599 and selected the **Enable DARE** option, the cluster is automatically enabled for data at rest encryption during installation. If you are upgrading or if you did not enable data at rest encryption at the time of installation, you can enable encryption of data at rest at the cluster level if the cluster is a secure

cluster. See [Enabling Data at Rest Encryption at the Cluster Level from the Command-Line](#) on page 1530 below for more information.

If encryption is enabled at the cluster level, data at rest encryption is also enabled at the volume level by default through the `mapr.volume.dare.default` configuration parameter. If you do not wish to encrypt data at rest in a volume, you can disable encryption when you create a volume; you cannot modify data at rest encryption setting on a volume after the volume is created. See [Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System](#) on page 1531 or [Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API](#) on page 1531 below for more information.

Standard volumes inherit the data at rest encryption setting from a volume by default if the `inherit` property is specified. If you create a mirror volume for a (source) volume enabled for data at rest encryption, the mirror volume:

- Inherits the data at rest encryption setting from the source volume if the mirror volume is in the same cluster as the source volume or if the mirror volume is on a remote cluster enabled for encryption of data at rest.
- Does not inherit the data at rest encryption setting from the source volume if the mirror volume is on an unsecure cluster or if the mirror volume is on a secure cluster that is not enabled for encryption of data at rest.

Note: If you want to create a mirror volume enabled for data at rest encryption for a source volume not enabled for data at rest encryption, set the value to `true` for `dare` property when creating the mirror volume.

This section describes how to enable data at rest encryption at the cluster and volume levels.

Enabling Data at Rest Encryption at the Cluster Level from the Command-Line

To enable encryption at the cluster level:

1. Run [configure.sh](#) on page 2331 with the `-dare` and `-genkeys` option on a CLDB node.

For example:

```
/opt/mapr/server/configure.sh -N
<cluster-name> -secure -dare -genkeys -C <CLDB-node-list> -Z
<ZK-node-list>
```

The Master Key is generated and stored in a master key file at `/opt/mapr/conf/dare.master.key`. When CLDB comes up, it sets the value for the following CLDB configuration properties to `1` to allow encryption of data at the volume level:

- `mfs.enable.dare`
- `mapr.volume.dare.default`

You can verify that these parameter values are correctly set by running the [config load](#) on page 1766 command. For example:

```
# maprcli config load -json
{
  "timestamp":1524669009979,
  "timeofday":"2018-04-25 08:10:09.979 GMT-0700 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "bulk.container.create.support":"1",
      "cldb.accept.unknown.replica.delay.mins":"5",
```

```

    ...,
    "mapr.volume.dare.default": "1",
    ...,
    "mfs.enforce.dare": "1",
    ...,
    "pernode.numcntrs.alarm.thr": "50000"
  }
]
}

```

Note: An informational alarm, reminding you to create a copy of the master key, is raised on the CLDB node. This is because, the loss of the master key can be catastrophic and irreversible. Loss of this key might result in loss of data. Before clearing the alarm, it is strongly recommended to create a copy of this file in other location(s) for backup purposes.

2. Copy the master key file (generated in step 1 above) to `/opt/mapr/conf` directory on all the other CLDB nodes in the cluster.
3. Run `configure.sh` on page 2331 on all the nodes, except the node on which the command was run to generate the master key (in step 1), with the `-dare` option.

For example:

```

/opt/mapr/server/configure.sh -N <cluster-name> -secure -dare -C
<CLDB-node-list> -Z <ZK-node-list>

```

If this is a new installation, no additional steps are needed. You have enabled data at rest encryption at the cluster level and, by default, all new volumes are enabled for data at rest encryption. You can, however, still create volumes that are not enabled for encryption of data at rest. See [Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System](#) on page 1531 or [Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API](#) on page 1531 for more information.

Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System

You can enable data at rest encryption at the volume level only if data at rest encryption is enabled at the cluster level. If necessary, refer to [Determining if a Secure Cluster is Enabled for Encryption Using the Control System](#) on page 1538 to determine if the cluster is enabled for encryption of data at rest before enabling data at rest encryption on a volume.

Note: If you do not wish to encrypt data-at-rest in a volume, you can disable encryption when you create a volume; you cannot modify data-at-rest encryption setting on a volume after the volume is created.

To enable or disable data-at-rest encryption for a new volume using the Control System:

1. Log in to the Control System and click **Data > Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page.
3. Select volume type, specify values for required and optional properties, and set the value for the **Data at Rest Encryption** property to **Yes** (to enable) or **No** (to disable).
See [Creating a Volume](#) on page 941 for more information.
4. Click **Create Volume** to create a volume enabled for encryption of data at rest.

Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API

You can enable DARE at the volume level only if data at rest encryption is enabled at the cluster level. If necessary, refer to [Determining if a Secure Cluster is Enabled for Encryption of Data at Rest Using the CLI](#)

and [REST API](#) on page 1539 to determine if the cluster is enabled for encryption of data at rest before enabling a volume for data at rest encryption.

Note: If you do not wish to encrypt data-at-rest in a volume, you can disable encryption when you create a volume; you cannot modify data-at-rest encryption setting on a volume after the volume is created.

CLI

Set the value for the `dare` parameter to one of the following when you create the volume:

- `true` to enable data-at-rest encryption.

Note: This is the default value.

For example:

```
maprcli volume create -name
<volName> -path <volMountPath>
[-dare true]
```

- `false` to disable data-at-rest encryption.

For example:

```
maprcli volume
create -name <volName> -path
<volMountPath> -dare false
```

REST

Send a request of type POST and set the value for the `dare` parameter to one of the following when you create the volume:

- `true` to enable data-at-rest encryption.

Note: This is the default value.

For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>[
&dare=true]' --user mapr:mapr
```

- `false` to disable data-at-rest encryption.

For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
dare=false' --user mapr:mapr
```

See [volume create](#) on page 2190 for more information.

Converting to Cluster Enabled for Data at Rest Encryption

Enable Data-At-Rest Encryption for a Cluster.

HPE Ezmeral Data Fabric's [data-at-rest encryption](#) allows you to protect the data in the event a disk is compromised. Using the [Installer](#) on page 5599, you can select the **Enable MapR DARE** option during an incremental install after upgrading. You can also convert a cluster not enabled for encryption at rest to a cluster enabled for encryption at rest from the command-line during a [Manual Rolling Upgrade Description](#) on page 268 or after an [Offline and Manual Upgrade Procedure](#) on page 265.

Note: Encryption of data at rest can only be enabled on a secure cluster.

To convert:

1. Perform the following steps on a CLDB node to generate the master key for encryption of data at rest:
 - a) Stop Warden on a CLDB node by running the following command:

```
/bin/systemctl stop mapr-warden
```

- b) Install HPE Ezmeral Data Fabric packages if this is a rolling upgrade.
See [Upgrading Core Without the Installer](#) on page 258. You can skip this step if you have already installed the HPE Ezmeral Data Fabric packages.

- c) Run the `configure.sh` on page 2331 command as follows:

```
/opt/mapr/server/configure.sh -genkeys -nocerts -dare -R
```

When you run the `configure.sh` on page 2331 command with the `genkeys` and `dare` options, a MasterKey file is generated and stored in `/opt/mapr/conf/dare.master.key`.

Important: You must create a copy of this file in other location(s) for backup purposes. Loss of this key will result in loss of cluster.

- d) Start Warden by running the following command:

```
/bin/systemctl start mapr-warden
```

2. Copy the data at rest encryption master key file (generated above) to the `/opt/mapr/conf` directory on all the other CLDB nodes on the cluster.

3. Perform the following steps on all the nodes, one node at a time if you are doing a rolling upgrade, in the cluster:

- a) Stop Warden by running the following command:

```
/bin/systemctl stop mapr-warden
```

- b) Install HPE Ezmeral Data Fabric packages if this is a rolling upgrade.
See [Upgrading Core Without the Installer](#) on page 258. You can skip this step if you have already installed the HPE Ezmeral Data Fabric packages.

- c) Run the `configure.sh` on page 2331 command as follows:

```
/opt/mapr/server/configure.sh -dare -R
```

- d) Start Warden by running the following command:

```
/bin/systemctl start mapr-warden
```

4. Enable encryption of data at rest through the `mfs.feature.dare` property, and optionally enable other features, if they are not yet enabled.

Run `maprcli cluster feature enable -name mfs.feature.dare` to enable encryption of data at rest.

See [Step 4: Enable New Features](#) on page 281 for information on enabling other features.

5. Specify whether (1) or not (0) to convert all existing volumes not enabled for encryption of data at rest to volumes enabled for encryption of data at rest by setting the value for the `cldb.enforce.old.volumes.dare` property using the `config save` on page 1768 command. By default, all existing volumes are converted to volumes enabled for data at rest encryption because the default value for `cldb.enforce.old.volumes.dare` property is 1. To not convert all existing volumes to volumes enabled for data at rest encryption, run the following command:

```
maprcli config save -values '{"cldb.enforce.old.volumes.dare": "0"}
```

6. Format the storage pools (SPs) on the nodes for data at rest encryption, one node and one SP at a time. That is:

- a) Decommission the node.

See [Decommissioning a Node for Enabling Encryption of Data at Rest](#) on page 1534 for more information.

- b) Format the SPs on the node.

See [Formatting a Storage Pool for Encryption of Data at Rest](#) on page 1535 for more information.

- c) Move the node back to the original topology.

See [Changing the Topology of one or more Nodes](#) on page 882 for more information.

CAUTION: Wait for few minutes and make sure that the [Under Replicated Alarm](#) is cleared for all the Volumes on a SP, before formatting the next SP.

7. Enable encryption of data at rest at the cluster-level by running the following command:

```
maprcli config save -values '{"mfs.enforce.dare": "1"}
```

8. Verify that encryption of data at rest is enabled at the cluster-level by running the following command:

```
maprcli config load -json | grep dare
```

Your output should look similar to the following:

```
"cldb.enforce.old.volumes.dare": "1",
"mapr.default.dare.alarm.pending": "0",
"mapr.volume.dare.default": "1",
"mfs.enforce.dare": "1",
"mfs.feature.dare": "1",
```

Encryption of data at rest is enabled by default for all new volumes on the cluster. You can disable data at rest encryption for volumes that do not require encryption of data at rest. See [Enabling or Disabling Data at Rest Encryption at the Volume Level Using the Control System](#) on page 1531 or [Enabling or Disabling Data at Rest Encryption at the Volume Level Using the CLI and REST API](#) on page 1531.

Decommissioning a Node for Enabling Encryption of Data at Rest

Decommission Node to Enable DARE.

Use the following procedure to decommission a node for preparing the node for data at rest encryption.

1. Drain the node of data by moving the node to the `/decommissioned` physical topology.
See [Changing the Topology of one or more Nodes](#) on page 882 for more information. By default, all the data on a node in the `/decommissioned` topology is migrated to volumes and nodes in the `/data` topology.

2. Run the following command to check if volumes are present on the node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

Note: Run this command for each non-local volume in your cluster to verify that the node being decommissioned is not storing any volume data.

3. Stop Warden on the node as the root user or use `sudo`.
For example, run the following command to stop Warden using `sudo`: `sudo /bin/systemctl stop mapr-warden`
4. Run `configure.sh` on page 2331 utility with the `-C` and `-Z` options on all the other nodes if the node you moved is a CLDB or ZooKeeper node.
5. Remove the node.
See [Removing One or More Nodes](#) on page 887 for more information.
6. Verify that the SPs associated with the node (that you removed in the previous step) are not displayed in the list of storage pools in the CLDB service information page.
See [Viewing CLDB Information](#) on page 1288 for more information.

Formatting a Storage Pool for Encryption of Data at Rest

This section describes how to reformat a storage pool for data at rest encryption and determine if a storage pool is enabled for data at rest encryption.

Formatting a Storage Pool on a Node for Encryption of Data at Rest

1. Determine the number of SPs on the node by running the following command:

```
/opt/mapr/server/mrconfig sp list
```

2. Select the SP to reformat and run the following command:

```
mrconfig sp offline <sp path>
```

3. Wait for the [Data Under-Replicated](#) on page 2526 alarm to clear and ensure that there are no [Data Unavailable](#) on page 2526 alarms.
4. Remove the disk from filesystem.
See [Removing Disks from the File System](#) on page 915 for more information.
5. Format the disk on the node.
See [Formatting Disks on a Node From the Command-line](#) on page 917 for more information.
6. Add disk to filesystem.
See [Adding Disks to filesystem](#) on page 914 for more information.

Determining if a Storage Pool is Enabled for Data at Rest Encryption

- Run the following command to determine if an SP is enabled for data-at-rest encryption:

```
/opt/mapr/server/mrconfig sp list -v
ListSPs resp: status 0:2
No. of SPs (2), totalsize 3518339 MB, totalfree 691937 MB

SP 0: name SP1, Online, size 1761217 MB, free 377127 MB, path /dev/
sdb, log 200 MB, port 5660, guid 9dd586829e179476005b0ce23f0dae3c,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sdb /dev/
sdd, dare 1
SP 1: name SP2, Online, size 1757121 MB, free 314809 MB, path /dev/
sde, log 200 MB, port 5660, guid daa5916af8909118005b0ce2430d6d54,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sde /dev/
sdf, dare 1
```

If enabled, the value for `dare` in the output is 1 (as shown in bold in the above sample command output) and if disabled, the value is 0.

Managing SSL Certificates

This section describes how to manage certificates and keystores such as when encryption is initially not enabled or when a custom certificate is used.

Re-running `configure.sh` after Configuration

If the `configure.sh` script is initially run without the `-genkeys` option, the script generates a `ssl_keystore` file for use by the web server for the Control System.

Then if the `configure.sh` script is re-run with the `-genkeys` option, the system detects the existing `ssl_*` files and exits with an error to prevent inadvertent deletion or reuse of the `ssl_keystore` file.

Note: For general information on certificates, see [SSL Certificates](#) on page 657.

To re-run `configure.sh` on clusters without security features enabled:

1. Manually delete the `ssl_keystore` file on each node.
2. Run the `configure.sh -genkeys -R` command.

Note: The contents of the `ssl_keystore` file are unique to each node.

To re-run `configure.sh` on clusters where the contents of the `ssl_keystore` file are customized:

1. Run the `configure.sh -genkeys -nocerts -R` command to preserve your customizations.

SSL Keys Error Message

The error message will look similar to the following example:

```
/opt/mapr/server/configure.sh
-secure -genkeys -C $CLDB_GRP -Z $ZK_GRP -RM $RM -HS
$HISTORYSERVER
<hostname1>: Configuring Hadoop-2.x at
/opt/mapr/hadoop/hadoop-2.x
<hostname1>: Done configuring Hadoop
<hostname1>: CLDB node list:

<hostname1>: Zookeeper node
list: <hostname1>:5181,<hostname2>:5181,<hostname3>:5181

<hostname1>: Node setup configuration: cldb fileserver
```

```

historyserver nfs nodemanager resourcemanager webserver
zookeeper
<hostname1>: Log can be found at:
/opt/mapr/logs/configure.log
<hostname1>: /opt/mapr/conf/ssl_keystore already exists
<hostname1>: ERROR: could not generate ssl keys. See log file
for more details
clush: <hostname1>: exited with exit code 1

```

General Security for Ecosystem Components

Ecosystem components in the MapR Converged Data Platform use the Java Authentication and Authorization Service (JAAS) for security configuration.

- `/opt/mapr/conf/mapr.login.conf` file-defines JAAS configurations
- `MAPR_ECOSYSTEM_LOGIN_OPTS` environment variable in the `/opt/mapr/conf/env.sh` file-specifies the JAAS configuration used by installed Ecosystem components

Note: See the [Ecosystem Guide](#) for component-specific security configuration information.

When security is [enabled](#), the value of the `MAPR_ECOSYSTEM_LOGIN_OPTS` is modified to include the hybrid JVM option for `hadoop.login`. This is equivalent to setting the `-Dhadoop.login=hybrid` flag at the command line. This setting specifies a mixed security environment using Kerberos and MapR tickets.

The `mapr.login.conf` file has two stanzas for hybrid security:

```

/**
 * authenticate using hybrid of kerberos and MapR
 * maprticket must already exist on filesystem as MapR login module
 * cannot get kerberos identity from subject for implicit login.
 */

hadoop_hybrid {
    org.apache.hadoop.security.login.KerberosBugWorkAroundLoginModule optional
        useTicketCache=true
        renewTGT=true
        doNotPrompt=true;
    com.mapr.security.maprsasl.MaprSecurityLoginModule required
        checkUGI=false;
    org.apache.hadoop.security.login.GenericOSLoginModule required;
    org.apache.hadoop.security.login.HadoopLoginModule required
        principalPriority=com.mapr.security.MapRPrincipal;
};

hadoop_hybrid_keytab {
    org.apache.hadoop.security.login.KerberosBugWorkAroundLoginModule optional
        refreshKrb5Config=true
        doNotPrompt=true
        useKeyTab=true
        storeKey=true;
    com.mapr.security.maprsasl.MaprSecurityLoginModule required
        checkUGI=false
        useServerKey=true;
    org.apache.hadoop.security.login.GenericOSLoginModule required;
    org.apache.hadoop.security.login.HadoopLoginModule required
        principalPriority=com.mapr.security.MapRPrincipal;
};

```

Determining if a Cluster is Secure and Enabled for Encryption

Explains how to use the Control System, the CLI, and the REST API to determine whether or not a cluster is secure and whether or not on-wire encryption and data at rest encryption are enabled at the cluster and volume levels.

Determining if a Cluster is Secure Using the Control System

- Log in to the Control System and click  to display the **Security** page.
The **Security** page contains information for determining whether or not the cluster is secure and enabled for on-wire encryption and/or data-at-rest encryption.

Determining if a Secure Cluster is Enabled for Encryption Using the Control System

- Log in to the Control System on a secure cluster and click  to display the **Security** page.
The page displays the following:
 - Cluster-level Settings** — whether or not on-wire encryption and authentication, and data-at-rest encryption is enabled at the cluster-level. The pane shows:
 -  — if enabled
 -  — if disabled
 - Volume Settings** — the number of volumes that are not enabled for:
 - Data on Wire Encryption
 - Data at Rest Encryption

You can click the number associated with Data on Wire Encryption or Data at Rest Encryption to display the list of volumes filtered by Data on Wire Encryption or Data at Rest Encryption respectively.

Determining if a Cluster is Secure Using the CLI and REST API

CLI

Run the following command to determine if a cluster is secure or unsecure:

```
/opt/mapr/bin/maprcli dashboard
info -cluster <clusterName> -json |
grep secure
```

The value for `secure` is `true` if secure and `false` if unsecure in the command output.

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
10.10.82.24:8443/rest/dashboard/
info' --user mapr:mapr
{"timestamp":1525198793701,"timeofday"
:"2018-05-01 11:19:53.701 GMT-0700
AM","status":"OK","total":1,"data":
[{"version":"6.1.0.20180501072815.GA",
"cluster":
{"name":"ksTest","secure":true,"dare":
true,"ip":"10.10.82.24","id":"60002141
79272613712","nodesUsed":1,"totalNodes
Allowed":-1},"volumes":{"mounted":
{"total":17,"size":0},"unmounted":
{"total":1,"size":1}},"utilization":
{"cpu":
```

```

{"util":1,"total":8,"active":0},"memory":
{"total":15886,"active":10268},"disk_s
pace":
{"total":273,"active":0},"compression"
:
{"compressed":0,"uncompressed":0},"tie
ring":
{"logicalUsed":0,"replicatedLogicalUse
d":0,"replicatedTotalUsed":0,"ecTotalU
sed":0,"cvTotalUsed":0,"offloaded":0,"
recalled":0}},"clusterReplication":
{"bytesReceived":0,"bytesSend":0},"str
eamThroughput":
{"bytesProduced":0,"bytesConsumed":0},
"services":{"fileserver":
{"active":1,"stopped":0,"failed":0,"to
tal":1},"resourcemanager":
{"active":1,"standby":0,"stopped":0,"f
ailed":0,"total":1},"cldb":
{"active":1,"stopped":0,"failed":0,"to
tal":1},"nfs4":
{"active":0,"stopped":0,"failed":0,"to
tal":1},"mastgateway":
{"active":1,"stopped":0,"failed":0,"to
tal":1},"nodemanager":
{"active":1,"stopped":0,"failed":0,"to
tal":1},"gateway":
{"active":1,"stopped":0,"failed":0,"to
tal":1},"hoststats":
{"active":1,"stopped":0,"failed":0,"to
tal":1},"apiserver":
{"active":1,"stopped":0,"failed":0,"to
tal":1}},"yarn":
{"running_applications":0,"queued_appl

al_memory_mb":5120,"total_vcores":4,"t
otal_disks":3,"used_memory_mb":0,"used
_vcores":0,"used_disks":0}}]}

```

The value for `secure` is `true` if secure and `false` if insecure.

If the value for `secure` is `true`, your cluster is enabled for on-wire encryption. See [dashboard info](#) on page 1770 for more information.

Determining if a Secure Cluster is Enabled for Encryption of Data at Rest Using the CLI and REST API

CLI

Run the following command to determine if a cluster is enabled or disabled for data at rest encryption:

```

/opt/mapr/bin/maprcli dashboard
info -name <clusterName> -json | grep
dare

```

The value for `dare` is `true` if enabled and `false` if disabled in the command output.

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
10.10.82.24:8443/rest/dashboard/
info' --user mapr:mapr
{"timestamp":1525198793701,"timeofday":
:"2018-05-01 11:19:53.701 GMT-0700
AM","status":"OK","total":1,"data":
[{"version":"6.1.0.20180501072815.GA",
"cluster":
{"name":"ksTest","secure":true,"dare":
true,"ip":"10.10.82.24","id":"60002141
79272613712","nodesUsed":1,"totalNodes
Allowed":-1},"volumes":{"mounted":
{"total":17,"size":0},"unmounted":
{"total":1,"size":1}},"utilization":
{"cpu":
{"util":1,"total":8,"active":0},"memor
y":
{"total":15886,"active":10268},"disk_s
pace":
{"total":273,"active":0},"compression"
:
{"compressed":0,"uncompressed":0},"tie

_vcores":0,"used_disks":0}}]}
```

The value for dare is true if enabled and false if disabled.

See [dashboard info](#) on page 1770 for more information.

Configuring Authentication

Provides information about MapR ticket, Kerberos, Pluggable Authentication Module (PAM) authentication.

Robust authentication prevents third parties from representing themselves as legitimate users. The core component of user authentication in MapR is the *ticket*. A ticket is an object that contains specific information about a user, an expiration time, and a key. Tickets uniquely identify a user and are encrypted to protect their contents. Tickets are used to establish sessions between a user and the cluster.

MapR supports two methods of authenticating a user and generating a ticket:

- Kerberos
- Username/password pairing with PAM

Both of these methods are mediated by the [maprlogin](#) on page 2412 utility. When you authenticate with a username/password pair, the system verifies credentials using Pluggable Authentication Modules (PAM). You can configure the cluster to use any registry that has a PAM module.

Managing Tickets

Introduces authentication using tickets for users and HPE Ezmeral Data Fabric servers.

HPE Ezmeral Data Fabric implements authentication with tickets. *Tickets* contain keys, and are used to authenticate users and HPE Ezmeral Data Fabric servers. In addition, *certificates* are used to implement server authentication. Every user who wants to access a cluster must have a HPE Ezmeral Data Fabric user ticket (`maprticket_<uid>`) and every node in the cluster must have a HPE Ezmeral Data Fabric server ticket (`maprserverticket`).

A ticket is an object that contains specific information about a user and a key. A ticket authenticates a user to the cluster. Tickets are encrypted to protect their contents. The following table describes the tickets used by HPE Ezmeral Data Fabric for internal cluster operations, the user who can generate the ticket, and the command used to generate the ticket. This type of ticket should only be placed on cluster nodes.

| Ticket Type | Description | Permissions/Command to Generate Ticket |
|--------------|---|--|
| maprserver | For (internal) cluster operations. This type of ticket can be long lasting. | user root using the configure.sh on page 2331 utility |
| crosscluster | For (internal) cross-cluster operations such as mirroring and replication. This type of ticket can be long lasting. | user mapr using the maprlogin on page 2412 utility. The UID of the ticket (mapr) is always used as the identity of the entity using this ticket. |

The following table describes the type of tickets supported by HPE Ezmeral Data Fabric for users and services and whether the ticket can be used to impersonate another user. All these tickets, except the user ticket, can only be generated by the cluster administrator using the [maprlogin](#) on page 2412 utility; the user ticket can be generated by any valid user using the [maprlogin](#) on page 2412 utility. These type of tickets can be placed on both cluster and client nodes and support (FUSE-based and loopbacknfs) POSIX clients and HDFS APIs.

| Ticket Type | Description | Impersonation support | Notes |
|-------------|--|-----------------------|--|
| user | For granting access to individual users. This type of ticket has a short duration. | N/A* | The UID of the ticket (implicit or explicit value of the <code>-user</code> parameter to <code>maprlogin</code> command) is used as the identity of the entity using this ticket, except for the exceptions noted here for user <code>root</code> and user <code>mapr</code> . |

| Ticket Type | Description | Impersonation support | Notes |
|---------------------------------------|--|-----------------------|--|
| service | For accessing services running on client nodes. This type of ticket can have long duration. | N/A* | The UID of the ticket (explicit value of the <code>-user</code> parameter to <code>maprlogin</code> command) is used as the identity of the entity using this ticket, except for the exceptions noted here for user <code>root</code> and user <code>mapr</code> . |
| servicewithimpersonation (not scoped) | For accessing services running on client nodes to run jobs on behalf of any user (except user <code>mapr</code>). This type of ticket can have long duration. | Yes | The ticket cannot be used to impersonate user <code>root</code> or user <code>mapr</code> . |
| servicewithimpersonation (scoped) | For accessing services running on client nodes to run jobs on behalf of the users (except user <code>root</code> and user <code>mapr</code>) specified in the ticket. This type of ticket can have long duration. | Yes | At ticket generation time, you cannot specify UID/GID of user <code>root</code> or user <code>mapr</code> to impersonate user <code>root</code> or user <code>mapr</code> respectively.  Note: In release 6.0.1, scoped impersonation works with FUSE-based POSIX clients; scoped impersonation cannot be used with NFS and loopbacknfs POSIX clients. To use scoped impersonation in release 6.0.1, obtain the 6.0.1 EBF patch for RPM or DEB-based distributions from HPE Ezmeral Data Fabric Support, and install the patch. |
| tenant | For tenant user(s) to access tenant volume(s) in a multi-tenant environment. This type of ticket can have long duration. | Yes | The ticket can be used to impersonate user <code>root</code> but cannot be used to impersonate user <code>mapr</code> . |

* Exceptions:

- User `mapr` can impersonate other users (including user `root`)
- User `root` can impersonate other users (excluding user `mapr`)

 **Important:** The identity of the user that authenticates with the `maprlogin` utility is independent from the identity of the user of the client OS.

HPE Ezmeral Data Fabric tickets contain the following information:

- UID (generated from the UNIX user ID)

- GIDs (group IDs for each group the user belongs to)
- ticket creation time
- ticket expiration time (initial duration of the ticket)
- renewal expiration time (maximum lifetime of the ticket)
- Whether user can (true) or cannot (false) impersonate another user

Since a ticket contains the GIDs for a user at the time the ticket is generated, a user must re-generate their ticket after changing group memberships.

Syntax and Examples of Creating and Managing User Tickets

For complete syntax, see [The maprlogin Utility](#). For examples of creating and managing user tickets, see [maprlogin Command Examples](#) on page 2416

How Tickets Work

Explains the concept of tickets and their working.

When an authenticated user runs a client, the client uses that user's ticket to communicate securely with the server. After [Enabling Wire-level Security](#) on page 1527, supported communications channels between client and server are encrypted.

Nodes use tickets to identify themselves to one another in order to prevent *spoofing*, a condition where an untrusted machine presents itself as a trusted machine to gain access to the cluster.

User Blocking

System administrators can use the [command line interface](#) to *block* a user. The command to block invalidates all of a user's tickets. Once a block command is received by the CLDB, the name of the blocked user is sent to all FileServer nodes, which reject any request sent by that user that has a ticket older than the block time stamp. Due to the nature of this check, there is no explicit removal of a blocked user. Issuing a new ticket with a time stamp more recent than the block time stamp implicitly permits the user. To permanently prevent a user from logging in again, revoke the user's credentials in the PAM registry.

What Blocking Affects

A blocked user cannot access the HPE Ezmeral Data Fabric filesystem or the CLDB, but since blocking only revokes a user's *existing valid tickets*, be aware of the following interactions:

- Blocking has no effect on Oozie's cached credentials in `~/ .oozie-auth-token`, and has no effect on Oozie in general, even after a restart.
- Blocking does not affect a new authentication with user ID and password or with existing Kerberos credentials.
- Since NFS does not use HPE Ezmeral Data Fabric tickets, blocking does not affect NFS access.
- Blocked users can still be impersonated as impersonation does not check whether a user is blocked or not.
- Blocking has no effect on ZooKeeper. Blocked users can still connect to the ZooKeeper server and execute commands. The workaround to resolve this issue is to delete the ticket file.

Generating a HPE Ezmeral Data Fabric User Ticket

Describes what a user ticket is, and how to generate a user ticket.

A user ticket file is stored in `/tmp` and can only be read by that user. To generate a HPE Ezmeral Data Fabric user ticket, run the following command:

```
maprlogin password
```

This command prompts for the user's password, then generates a HPE Ezmeral Data Fabric user ticket associated with the UNIX user ID. By default, tickets on Linux systems are generated in the `/tmp` directory and are named in the form `maprticket_<UID>`. Tickets on Windows systems are generated in the `%TEMP%` directory and are named in the form `maprticket_<username>`. To change the default location, change the value of the `MAPR_TICKETFILE_LOCATION` environment variable.

Note: The `mapr` user can impersonate any user, including user `root`.

Note: There are no notifications to indicate that a ticket is about to expire. Use the `maprlogin print` command, with the ticket file, to see when the ticket expires. You can renew the ticket until the renewal date mentioned.

To illustrate a typical work flow, suppose a user wants to access two clusters, `cluster1` and `cluster2`. During this session, a user logs in as `root` to `cluster1`, gets a HPE Ezmeral Data Fabric user ticket, and displays the ticket contents with the `maprlogin print` command.

```
root@qa-nodell13:~/SecurityInstall# maprlogin password
[Password for user 'root' at cluster 'cluster1': ]
MapR credentials of user 'root' for cluster 'cluster1' are written to '/tmp/
maprticket_0'
root@qa-nodell13:~/SecurityInstall#
```

First Ticket for Cluster 1

```
root@qa-nodell13:~/SecurityInstall# maprlogin print
Opening keyfile /tmp/maprticket_0
qasecurity1: user = root, created = 'Wed Sep 11 14:19:02 PDT 2013', expires
= 'Wed Sep 25 14:19:02 PDT 2013', RenewalTill = 'Fri Oct 11 14:19:02 PDT
2013', uid = 0, gids = 0, 42
root@qa-nodell13:~/SecurityInstall#
```

Now the `root` user logs in to `cluster2`. The `maprlogin` command returns a ticket for `cluster2`. This ticket is stored in the common ticket file. Commands now have access to both tickets.

```
root@qa-nodell13:/opt/mapr/conf# maprlogin password -cluster cluster2
[Password for user 'root' at cluster 'cluster2': ]
MapR credentials of user 'root' for cluster 'cluster2' are written to '/tmp/
maprticket_0'
```

Showing Tickets for both Clusters

```
root@qa-nodell13:/opt/mapr/conf# maprlogin print
Opening keyfile /tmp/maprticket_0
qasecurity1: user = root, created = 'Thu Sep 12 11:07:54 PDT 2013', expires
= 'Thu Sep 26 11:07:54 PDT 2013', RenewalTill = 'Sat Oct 12 11:07:54 PDT
2013', uid = 0, gids = 0, 42
qasecurity2: user = root, created = 'Thu Sep 12 15:20:49 PDT 2013', expires
= 'Thu Sep 26 15:20:49 PDT 2013', RenewalTill = 'Sat Oct 12 15:20:49 PDT
2013', uid = 0, gids = 0, 500
root@qa-nodell13:/opt/mapr/conf#
```

Generating a Service Ticket

Applications may have service processes that run outside the MapR cluster but need to access the cluster to run MapR commands. For security reasons, you may not want to run these services as the `mapr` user. Instead, you can use the `maprlogin` utility to generate a "service ticket" that can be used to access the cluster for the user account that runs the service. The `maprlogin` utility uses the current user's ticket (the user running the `maprlogin` command) to send an authenticated request for a newly generated service ticket.

This type of ticket has a specified duration (expiration), a renewal period (maximum lifetime), and a designated location where the ticket is safely stored. The service process that uses the ticket can access it based on the definition of the `MAPR_TICKETFILE_LOCATION` environment variable, which points to the location of the ticket and should be set for the service process when it starts. Short duration and renewal values may be used for security reasons, but much longer lifetimes are supported for ease of administration.

For example:

```
# maprlogin generateticket -type service -out /tmp/
longlived_ticket -duration 30:0:0 -renewal 90:0:0 -user mapr
MapR credentials of user 'mapr' for cluster 'xxxx' are written to '/tmp/
longlived_ticket'
```

This command generates a service ticket that expires after 30 days and is stored in `/tmp/longlived_ticket`. The ticket may be renewed at any time before the 30 days pass, extending its lifetime to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Note: This type of ticket can only be generated by a user with full control on a cluster's Access Control List (ACL).

Generating a Service with Impersonation Ticket

Impersonation allows a user to access data and submit jobs on behalf of another user. You may want to allow users, other than the `mapr` user, to impersonate other users. You can use the `maprlogin` utility to generate a "servicewithimpersonation ticket" that can be used to access a secure cluster impersonating another user. That is, the `servicewithimpersonation` ticket provides the user the ability to impersonate other users (except the `mapr` user) in addition to the ability to access a secure cluster. This type of ticket can only be generated by a user with full control on a cluster's Access Control List (ACL).

If this type of ticket is generated and saved in the location specified with the `-out` option, after generating the ticket, do the following:

1. Reset the permissions on the ticket to grant the user, for whom the ticket was generated, read permissions on the ticket.
2. Set the `MAPR_TICKETFILE_LOCATION` environmental variable to point to the ticket file location if the path specified for the `-out` option was not `/tmp/maprticket_<uid>`.

This type of ticket, similar to a service ticket, has a specified duration (expiration), a renewal period (maximum lifetime), and a location where the ticket is safely stored. It grants the specified user the ability to impersonate other users, except the `mapr` user.

The default duration for this type of ticket is `LIFETIME` and the duration is not bounded by the `CLDB` duration properties. Short duration and renewal values may be used for security reasons, but much longer lifetimes are supported for ease of administration.

For example:

```
# maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration 30:0:0 -renewal
90:0:0
```

The above command generates a service with impersonation ticket that expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time before the 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires. The ticket allows the user to impersonate all users on the cluster.

To allow a user to impersonate only specific users and/or groups, use the `impersonateduids` and/or `impersonatedgids` options with the `maprlogin` command. For example:

```
# maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration
30:0:0 -impersonateduids 1002,1003 -impersonatedgids 1005,1006 -renewal
90:0:0
```

The above command generates a service with impersonation ticket. The ticket holder can impersonate users whose UIDs are 1002 and 1003 and users in the groups with GIDs 1005 and 1006. The ticket expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time before the 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Generating a Ticket for a Tenant

Explains what tenant tickets are and how to generate a tenant ticket.

Tenant tickets allow tenant users to access the tenant volume on the cluster (when you have a [multi-tenant environment on filesystem](#)). Generate the tenant ticket on the cluster and copy it to the tenant host(s) to grant tenant users access to the provisioned storage.

- To generate a tenant ticket, run one of the following commands on the cluster:

```
maprlogin generateticket -type tenant -cluster <cluster_name> -user
<tenant_admin_user> \
-duration <seconds> -out <ticket_file_path>.txt
```

Note: For more information, see the [maprlogin](#) command.

By default:

- Tenant ticket is stored in `/tmp` and can only be read by that user. To change the default location, specify the path to the desired location with the `out` parameter.
- Tenant ticket has no expiration. To change the expiration time, specify `duration` for the ticket with the command.

In the tenant tickets, the value for `CanImpersonate` and `tenant` will always be `true`. For example, when you run the `maprlogin print` command, your output should look similar to the following:

```
Opening keyfile /user/clstrAdmin/tenant_user_ticket.txt
tenantHost: user = tenant_user, created = 'Mon Jul 11 07:14:53 UTC 2016',
expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11
07:14:53 UTC 12016',
uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
```

To grant access to tenant users, the tenant ticket must be copied over to the tenant hosts.

After generating the ticket, do the following:

1. Reset the permissions on the ticket to grant the tenant admin read permissions on the ticket.
2. Move the ticket out of the default `/tmp` directory to a secure location on the tenant host(s).

Generating a Data Fabric Ticket from a Kerberos Ticket

On clusters that use Kerberos for authentication, a Data Fabric ticket is implicitly obtained for a user that runs a Data Fabric command without first using the `maprlogin` utility.

If you want to use a Kerberos ticket to generate a `maprticket`, follow these steps:

1. Obtain a Kerberos identity by running `kinit` or by another mechanism.
2. Run `maprlogin kerberos` to indicate that you have an existing Kerberos ticket. You can also specify these options: [`-cluster`] The name of the cluster. [`-duration`] The ticket duration in seconds.

Configuring PAM Authenticator

The Converged Data Platform supports [Pluggable Authentication Modules \(PAM\)](#) in the UNIX authentication stack. HPE Ezmeral Data Fabric provides a PAM Authenticator module that generates HPE Ezmeral Data Fabric tickets in conjunction with the `maprlogin` utility. After you install the Converged Data Platform, the PAM Authenticator module is located at `$INSTALL_DIR/lib/libmapr_pam.so`. Configuration files for PAM are located in the `/etc/pam.d` directory, and each UNIX operation, such as `su`, `login`, or `ssh`, has a specific PAM configuration file in that directory.

Configure the PAM Authenticator on Ubuntu or SLES

To configure the PAM Authenticator, append the following line to the end of the `/etc/pam.d/common-auth` file:

```
auth optional /opt/mapr/lib/libmapr_pam.so # MapR PAM module
```

 **Warning:** An absolute path to the location of the `libmapr_pam.so` file is required. By default, this location is `$MAPR_HOME/lib/libmapr_pam.so`.

Configure the PAM Authenticator on Red Hat or CentOS

1. Insert the following line in the `/etc/pam.d/system-auth` file immediately before the first module that uses the `auth sufficient` configuration:

```
auth optional libmapr_pam.so # MapR PAM module
```

- Append the string `try_first_pass` to the end of the module that uses `auth sufficient`, as in this example:

Before modification:

```
auth required pam_env.so
auth sufficient pam_unix.so nullok
auth requisite pam_succeed_if.so uid >= 500 quiet
auth required pam_deny.so
```

After modification, changes in **bold**:

```
auth required pam_env.so
auth optional libmapr_pam.so # MapR PAM module
auth sufficient pam_unix.so nullok try_first_pass
auth requisite pam_succeed_if.so uid >= 500 quiet
auth required pam_deny.so
```

Enable Debugging for PAM

To enable debugging for the client traffic used by the `maprlogin` utility, update the `/opt/mapr/conf/log4j.properties` file with the following line:

```
log4j.logger.com.mapr.login=DEBUG
```

After updating the `log4j.properties` file, trace the `com.mapr.login` package at the `DEBUG` level.

Be sure to update the correct instance of the `log4j.properties` file. Traffic specific to HPE Ezmeral Data Fabric, such as `maprlogin` and Control System traffic, uses the instance in the `/opt/mapr/conf` directory. Hadoop applications use the `log4j.properties` file in the `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop` directory.

To perform the same tracing activity on the server side, modify the appropriate instance of the `log4j.properties` file on the server, or specify the page `com.mapr.login` in the Control System UI's tracing/logger settings. To trace PAM activity from the server, add the following line to the server's `log4j.properties` instance:

```
log4j.logger.net.sf.jpam=DEBUG
```

After modifying this setting, the server log will contain a message similar to the following:

```
2013-07-23 16:05:25,200 DEBUG Pam [1068409264@qtp-874242484-3]: Debug mode active.
```

Detailed information about PAM activity is written to the `/opt/mapr/logs/pam.log` file.

Other Packages

The following packages are not directly related to PAM, but can provide useful insights for subtler errors.

- `org.apache.hadoop.security` - This package contains Apache security code, including HPE Ezmeral Data Fabric enhancements. Tracing this package can provide information about what login configuration is in use.
- `com.mapr.fs.cldb.http.login` - This package contains code that the CLDB uses to validate `maprlogin` calls.

Common Issues

The Linux Documentation Project's HOWTO on LDAP Implementation has a [section](#) on PAM and NSS that may prove helpful.

If a user's credentials appear valid, for example in a case where the `su` and `ssh` commands work normally, but PAM does not correctly authenticate, the issue may relate specifically to HPE Ezmeral Data Fabric's use of PAM as a normal user, compared to the usual case where PAM consumers run as the root user, causing permissions issues. The two most common issues relating to this condition are:

- The `/etc/shadow` directory is not readable to the `mapr` user. This directory is made readable to the `mapr` user during install, but some secure environments and configuration management tools undo these changes.
- A Kerberos PAM module is attempting to create and change the ownership of a kerberos ticket file. This attempt fails, since these changes require root privileges. Different Kerberos PAM modules can report errors differently, leading to difficulty tracking down root causes of errors. To address permissions problems with Kerberos PAM modules, configure the Kerberos PAM module to skip creating a ticket file, using the KDC only to validate the password. PAM configuration information is located in the `/etc/pam.d` directory. HPE Ezmeral Data Fabric can use a custom PAM configuration specified in the `web.conf` file.

Configuring Kerberos

Describes how Kerberos works with HPE Ezmeral Data Fabric tickets.

HPE Ezmeral Data Fabric does not directly support Kerberos. However, Kerberos is indirectly supported through the HPE Ezmeral Data Fabric login utility, which is used to generate HPE Ezmeral Data Fabric tickets. This topic describes how Kerberos works with HPE Ezmeral Data Fabric tickets.

Kerberos Compatibility with RHEL 8

When you install Kerberos out of the box with RHEL 8, it uses the new default Kerberos Cache Manager (KCM) credentials cache type, which fails to work with the `maprlogin kerberos` command. To resolve this issue, disable KCM.

Open the file `/etc/krb5.conf.d/kcm_default_ccache` and comment out the following lines:

```
[libdefaults]
    default_ccache_name = KCM:
```

Alternatively, remove this file.

Configuring Kerberos for Authentication Using HPE Ezmeral Data Fabric Tickets

To use Kerberos to generate HPE Ezmeral Data Fabric [tickets](#) for users, enable Kerberos on CLDB by creating a Kerberos identity on the Kerberos server used by the cluster and distributing that identity to the other CLDB nodes in the cluster.

Note: You must enable wire-level security on your clusters before using Kerberos. See [Enabling Wire-level Security](#).

HPE Ezmeral Data Fabric clusters do not provide Kerberos infrastructure. This section assumes you have a functioning Kerberos realm and your systems have the Kerberos client installed. The tips in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

Important: If you are using strong encryption with Kerberos with the Oracle JDK, you will require a new [Java Cryptography Extension \(JCE\)](#) policy file.

Creating a Kerberos Identity for the CLDB

The CLDB requires a Kerberos server identity, but no other nodes do. By default, this identity takes the form `mapr/<cluster name>`. You can use [configure.sh](#) on [page 2331](#) or edit the

`mapr-clusters.conf` file to change this default. Use the following commands in a Linux-based Kerberos environment to set up the identity:

```
kadmin
: addprinc -randkey mapr/my.cluster.com
: ktadd -k /opt/mapr/conf/mapr.keytab mapr/my.cluster.com
```

Copy the resulting `mapr.keytab` file to the same location on every CLDB node. The `mapr.keytab` file must be owned and readable only by the `mapr` user. You can specify the location of the `mapr.keytab` file in the `conf/mapr.login.conf` file. The default location for `mapr.keytab` is `/opt/mapr/conf`.

Updating the keytab File

You can use the `kadmin` tool to update the server keys that are stored in the keytab file. Because the server tickets used to authenticate to the CLDB use the new keys immediately, you must copy the new keytab file to all the CLDB servers in the cluster immediately after updating the server keys.

To update the keytab file with a new key, run the following command:

```
kadmin
: ktadd -k /opt/mapr/conf/mapr.keytab mapr/my.cluster.com
```

The CLDB automatically detects changes to the keytab file on systems that use Java 7 or later. Systems that use Java 6 require a CLDB restart to detect changes to the keytab file.

Note: Starting with the 4.0.1 release of the MapR software, Java 6 is deprecated in favor of Java 7 and Java 8.

Running `configure.sh`

After a Kerberos principal is created for the CLDB, that principal is added to the `mapr.keytab` file, and the `mapr.keytab` file is copied to all the CLDB servers, Kerberos user authentication is fully enabled for the HPE Ezmeral Data Fabric cluster.

Two `configure.sh` parameters are important for Kerberos:

- `-K|-kerberosEnable` — lets the rest of the cluster know that Kerberos is enabled, so that clients can auto detect Kerberos tickets and use them to get HPE Ezmeral Data Fabric tickets.
- `-P "<cldbPrincipal>"` — specifies the Kerberos instance which is used to form the CLDB Kerberos principal in the form of `mapr/<instance-name>@<realm-name>`. Enclose this value in quotes (").

Run `configure.sh` on each HPE Ezmeral Data Fabric cluster node, and on each HPE Ezmeral Data Fabric client node that will communicate with one or more clusters. For more information, see [configure.sh](#) on page 2331.

```
configure.sh -K -P "<cldbPrincipal>"
```

Running `configure.sh` on each node enters the Kerberos information into the local `clusters.conf` file, so that the following command is all that is required for the client to access the cluster:

```
hadoop fs -ls
```

If you do not run `configure.sh` on each node, the following two commands are required from the client:

```
maprlogin kerberos
hadoop fs -ls
```

Kerberos Command Summary

- **kinit**: Creates a Kerberos ticket. Prompts the user for userid and password. After validating, Kerberos creates a ticket file in `/tmp` that is owned by the user. Use the `-R` option to renew an existing ticket. Kerberos credentials expire in 8-10 hours. Expired credentials must be renewed or replaced. By default, tickets can be renewed for up to 24 hours.
- **klist**: Lists the contents of the user's ticket file.
- **kdestroy**: Destroys the contents of the user's ticket file. The user is no longer authenticated.
- **kadmin**: Used to administer Kerberos. The login for this command is implicitly `<userid>/admin`, since administrator IDs typically end in `/admin`.
- **ktutil**: Kerberos keytab maintenance utility. Used to combine, or alter Kerberos keytabs.

Disabling Replay Detection for Kerberos Authentication

You can set an option in `mapr-clusters.conf` file to disable replay detection for Kerberos runtime authentication.

```
disableReplayDetection=true
```

By default, this parameter is set to `false`, meaning that HPE Ezmeral Data Fabric clients enable Kerberos replay detection. Typically, replay detection is enabled to prevent potential attacks such as the replay of Kerberos packets or multiple login attempts with the same user ID. Set this parameter to `true` only if you want HPE Ezmeral Data Fabric clients not to enforce this detection.

This parameter applies when users attempt an implicit or explicit `maprlogin`, such as by using the `maprlogin kerberos` command or by submitting jobs and other operations with `kerberosEnable=true` set in the `mapr-clusters.conf` file.

This parameter is used when applications connect to the cluster using Kerberos; `mapr-clusters.conf` only needs to be updated when it is used by such applications. If all Kerberos access to the cluster is from clients outside the cluster, only the `mapr-clusters.conf` file on those client machines has to be updated. If Kerberos is used from applications running on the cluster, `mapr-clusters.conf` file should be updated there as well.

Configuring YARN with Kerberos

Lists the process to use YARN with Kerberos.

Make sure that the following tasks are already completed, as directed in earlier sections of this guide:

- [Enabling Wire-level Security](#) on page 1527 by running `configure.sh` with the security options.
- [Configuring Kerberos](#) on page 1549 by creating a Kerberos principle and keytab file.

Note: To enable YARN REST SPNEGO, see [Configuring SPNEGO on MapR](#) on page 1553.

Now complete the following tasks.

Configure the `yarn-site.xml` File

Add the following properties to the `yarn-site.xml` file on every node in the cluster.

```
/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml
```

Note: You need to use `/opt/mapr/conf/mapr.keytab` for the keytab property and `mapr` instead of `yarn` for the principal property.

```
<!-- ResourceManager security configs -->
<property>
  <name>yarn.resourcemanager.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value>    <!-- path to the YARN
keytab -->

</property>
<property>
  <name>yarn.resourcemanager.principal</name>
  <value>mapr/clustername@YOUR-REALM.COM</value>
</property>

<!-- NodeManager security configs -->
<property>
  <name>yarn.nodemanager.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value>    <!-- path to the YARN
keytab -->

</property>
<property>
  <name>yarn.nodemanager.principal</name>
  <value>mapr/clustername@YOUR-REALM.COM</value>
</property>
<property>
  <name>yarn.nodemanager.container-executor.class</name>
  <value>org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor</
value>
</property>
<property>
  <name>yarn.nodemanager.linux-container-executor.group</name>
  <value>mapr</value>
</property>
```

Configure the `mapred-site.xml` File

Add the following properties to the `mapred-site.xml` file on every node in the cluster.

```
/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml
```

Note that you need to use `/opt/mapr/conf/mapr.keytab` for the keytab property and `mapr` instead of `yarn` for the principal property.

```
<!-- MapReduce Job History Server security configs -->
<property>
  <name>mapreduce.jobhistory.address</name>
  <value>host:port</value> <!-- Host and port of the MapReduce Job History
Server; default port is 10020 -->
</property>
<property>
  <name>mapreduce.jobhistory.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value><!-- path to the YARN
keytab -->
</property>
<property>
  <name>mapreduce.jobhistory.principal</name>
  <value>mapr/clustername@YOUR-REALM.COM</value>
</property>
```

Modifying the `env_override.sh` File

Either the `/opt/mapr/conf/env.sh` file or the `/opt/mapr/conf/env_override.sh` file contains a setting for HPE Ezmeral Data Fabric login option that defaults to the value `maprsasl`. Change this value to `hybrid`, which includes Kerberos and other security protocols. For more information about the `env_override.sh` file, see [About `env_override.sh`](#) on page 2576.

The new line (after the change) should be as follows:

```
MAPR_LOGIN_OPTS="-Dhadoop.login=hybrid ${MAPR_JAAS_CONFIG_OPTS} $
{MAPR_ZOOKEEPER_OPTS}"
```

Restart ResourceManager, NodeManager, and JobHistoryServer

Restart the NodeManager, ResourceManager, and JobHistoryServer services, using either the `maprcli node services` command (with the `name` option) or the Control System. After restarting the services, make sure you can run simple Hadoop jobs by running:

```
hadoop jar /opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/
hadoop-mapreduce-examples-<version>.jar pi
```

Configuring SPNEGO on MapR

HPE Ezmeral Data Fabric uses the Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO) to secure several Web UIs in a secure cluster, as well as the REST calls to the Control System.

Configuring SPNEGO for the Web Server Nodes on Secure Clusters

The following procedure configures SPNEGO support for the `apiserver` nodes on your secure cluster.

1. Generate a Kerberos principal with the user name `HTTP`, of the form `HTTP/<webserver name>` on each node in the secure cluster that will receive inbound SPNEGO traffic.

Use the fully qualified domain name (FQDN) as the name in the principal. Although you could also use a short name or the IP address for the principal name, using the FQDN keeps the name consistent with principal names that `configure.sh` generates and includes in the `mapr.login.conf` file.

Whatever you use as the principal name is what users will have to match exactly in a browser to access the web pages that are protected.

Note: Several services and components in a HPE Ezmeral Data Fabric cluster handle SPNEGO traffic, including the Control System. You can name the keytab file `mapr.keytab` if that file does not already exist. If the `mapr.keytab` file already exists, generate the new principal to a different file name and merge it to the `mapr.keytab` file using the `ktutil` tool. For example:

```
kadmin
: addprinc -randkey HTTP/<webserver name>
: ktadd -k /opt/mapr/conf/mapr.keytab HTTP/<webserver name>
```

2. Verify that the `/opt/mapr/conf/mapr.login.conf` file lists the correct principal in the `MAPR_WEBSERVER_KERBEROS` section.

To enable SPNEGO for the Control System Web UI or for the Control System REST calls, on all nodes with the `webservice` role, add the following line to the `/opt/mapr/apiserver/conf/properties.cfg` file. For example:

```
mapr.rest.auth.methods=kerberos,basic
```

Important: The `mapr.rest.auth.methods=kerberos,basic` option, which is shown above, is valid only on a secure cluster. If a cluster is not secure, only basic authentication (`WWW-Authenticate: Basic`) is available to clients.

3. Restart the Control System for the changes to take effect.

Testing SPNEGO With curl

This example tests that the Control System is using GSS for REST calls made with `curl`.

Use the following command to verify that your version of `curl` supports SPNEGO. Under the **Features** header, output of the command should show either **GSS-Negotiate** or SPNEGO. For example:

```
# curl --versioncurl 7.22.0 (x86_64-pc-linux-gnu) libcurl/7.22.0
OpenSSL/1.0.1 zlib/1.2.3.4 libidn/1.23 librtmp/2.3Protocols:
dict file ftp ftps gopher http https imap imaps ldap pop3 pop3s rtmp rtsp
smtp smtps telnet tftp
Features: GSS-Negotiate IDN IPv6 Largefile NTLM NTLM_WB SSL libz TLS-SRP
```

Verify that you have a valid Kerberos ticket-granting-ticket (TGT) with the `kinit -p <user>` command. Then, test `curl` with the following command:

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt
https://<web server node>:8443/rest/<API call> -k -v
```

This command returns HTTP/1.1 200 OK when `curl` is working correctly with SPNEGO.

Configuring Browsers for SPNEGO

Use the following processes to configure browsers for SPNEGO connections.

Firefox

The process below configures your Firefox browser for SPNEGO connections.

Note: These instructions are specific for Firefox version 40.0.3xj. The details may differ slightly if you are using a different version.

1. Open the Firefox configuration page by navigating to the address `about:config`.
2. In the **Search** text field, enter `network.negotiate-auth.trusted-uris` to bring up that property.
3. Right-click on `network.negotiate-auth.trusted-uris` and select **Modify** to edit the property and enter the hostnames of the web server nodes in your cluster as a comma-separated list.
4. Click **OK**.

Chromium on Ubuntu

To configure the Chromium browser on Ubuntu for SPNEGO, edit the `/etc/chromium-browser/default` file and add the following property:

```
CHROMIUM_FLAGS="--user-data-dir --auth-server-whitelist=<web server host names>"
```

The `--user-data-dir` flag enables the root user to launch the browser.

The `--auth-server-whitelist` flag specifies the web servers that support SPNEGO authentication.

Troubleshooting Kerberos

Java errors from Kerberos problems can be obscure and difficult to interpret. To see the Kerberos error messages, enable Kerberos debugging by adding these settings to your JVM:

```
-Dsun.security.krb5.debug=true -Dsun.security.spnego.debug=true -Djavax.net.debug=all
```

You can also enable Kerberos debugging for the HPE Ezmeral Data Fabric-provided `maprcli` and Hadoop clients by adding the following line to the `/opt/mapr/conf/env_override.sh` shell script:

```
#MAPRLOGIN_OPTS="$
{MAPRLOGIN_OPTS} -Dsun.security.krb5.debug=true -Dsun.security.spnego.debug=
true -Djavax.net.debug=all"
```

The `env.sh` script reads this file as part of its execution. For more information, see [About env_override.sh](#) on page 2576.

Capture the Kerberos error to research the issue.

The following sections list common Kerberos error conditions:

Incorrect JVM

Nodes often have multiple Java Virtual Machines (JVM) installed. The HPE Ezmeral Data Fabric `env.sh` script automatically configures a JVM to use. To change the automatically configured JVM, set the value of the `JAVA_HOME` environment variable in the `/opt/mapr/conf/env_override.sh` file. The `env.sh` script reads this file as part of its execution. For more information, see [About env_override.sh](#) on page 2576.

Incorrect Server Name

The following error message is caused by an incorrect CLDB server name in the `mapr.login.conf` file. The error message mentions passwords, but the error condition is unrelated to password authentication.

```
2018-04-25 16:46:02,324 ERROR MapRLoginServlet [185087767@qtp-648535353-2]:

Invalid or missing keytab file

The keytab file must be consistent with the key versions of the Kerberos principal. The following example shows an inconsistent keytab file:

```

kadmin:  getprinc mapr/realml
Principal: mapr/realml@mapr
Expiration date: [never]
Last password change: Thu May 23 15:36:01 PDT 2013
Password expiration date: [none]
Maximum ticket life: 0 days 10:00:00
Maximum renewable life: 7 days 00:00:00
Last modified: Thu May 23 15:36:01 PDT 2013 (mapr/admin@mapr)
Last successful authentication: Thu May 23 19:31:59 PDT 2013
Last failed authentication: Thu May 23 15:35:41 PDT 2013
Failed password attempts: 0
Number of keys: 8
Key: vno 15, aes256-cts-hmac-shal-96, no salt
Key: vno 15, arcfour-hmac, no salt
Key: vno 15, des3-cbc-shal, no salt
Key: vno 15, des-cbc-crc, no salt
Key: vno 15, des-cbc-md5, Version 4
Key: vno 15, des-cbc-md5, Version 5 - No Realm
Key: vno 15, des-cbc-md5, Version 5 - Realm Only
Key: vno 15, des-cbc-md5, AFS version 3
MKey: vno 1

ktutil:  rkt mapr.keytab
ktutil:  1
slot KVNO Principal

```

```

-----
1  14          mapr/realml@mapr
2  14          mapr/realml@mapr
3  14          mapr/realml@mapr
4  14          mapr/realml@mapr
ktutil:  q

```

Note that the key versions in the Kerberos principal `/realml` are 15, and the versions in the keytab file are 14. This mismatch can result in errors about missing keys or mismatched encryption.

Note:

This error state can also be caused by the `/opt/mapr/conf/mapr.keytab` file not being owned by the user `mapr` or not being present. The keytab file is owned by `root` at generation. Be sure to use the `chown` command to set the `mapr` user as the owner:

```
$ chown mapr:mapr /opt/mapr/conf/mapr.keytab
```

Incompatible encryption on Java runtime

Incompatible cryptography between the KDC and the JDK results in failed handshakes, leading to errors similar to the following:

```
Caused by: javax.security.auth.login.LoginException: Unable to obtain
Principal Name for authentication
```

With debugging active, the following message is displayed:

```
>>>DEBUG <CCacheInputStream> client principal is username@hostname
>>>DEBUG <CCacheInputStream> server principal is X-CACHECONF:/
krb5_ccache_conf_data/fast_avail/krbtgt/user@hostname
>>>DEBUG <CCacheInputStream> key type: 0
>>>DEBUG <CCacheInputStream> auth time: Wed Dec 31 16:00:00 PST 1969
>>>DEBUG <CCacheInputStream> start time: null
>>>DEBUG <CCacheInputStream> end time: Wed Dec 31 16:00:00 PST 1969
>>>DEBUG <CCacheInputStream> renew_till time: null
>>> CCacheInputStream: readFlags()
>>> unsupported key type found the default TGT: 18
Negotiate support not initiated, will fallback to other scheme if
allowed. Reason:
```

This debug message indicates that the problem is an unsupported key type.

Incompatible encryption errors can occur due to a `keytab` file that is not present or contains outdated keys.

Be sure to update the Java jurisdiction policy file. Jurisdiction policy files are available from [Oracle](#).

A persistent encryption incompatibility problem may require you to edit the `krb5.conf` file to ensure compatible algorithms between Java and Kerberos.

Bugs in Java

The following error occurs in Java version 1.6.0_25. Upgrade to 1.6.0_45 to resolve the error.

level: Failed to find any Kerberos tgt)]

```

Note:

Starting with the 4.0.1 release of the HPE Ezmeral Data Fabric software, Java 6 is deprecated in favor of Java 7 and Java 8.

Kerberos and PAM validation

Standard Kerberos implementations are predicated on access to elevated user privileges that are not present on secure HPE Ezmeral Data Fabric clusters. In a HPE Ezmeral Data Fabric cluster, the Control System console and other components call PAM as an ordinary user process. This discrepancy in expected and actual privileges can cause a variety of obscure file permission errors. Since different Kerberos PAM modules are available, error reports can vary.

To diagnose this issue, attempt starting the Control System as the root user, or clear out the `/tmp` folder. If there are no problems when starting the Control System as root, or if clearing out the `/tmp` folder enables a single login before errors appear again, the problem may lie in the Kerberos PAM configuration.

To resolve this condition, prevent Kerberos from creating a ticket file. HPE Ezmeral Data Fabric security does not use Kerberos tickets. The Kerberos KDC is used to validate passwords. Typically the configuration file for PAM is in the `/etc/pam.d` directory. See the documentation for your specific Kerberos PAM module for more information.

Configuring PAM

Describes how PAM works with MapR.

MapR uses [Pluggable Authentication Modules \(PAM\)](#) for password verification in a variety of places. Make sure PAM is installed and configured on the node running the `mapr-apiserver`, or other components that will use PAM to verify passwords.

There are typically several PAM modules (profiles), configurable via configuration files in the `/etc/pam.d/` directory. Any component verifying user passwords tries the following three profiles in order:

1. `sudo (/etc/pam.d/sudo)`
2. `sshd (/etc/pam.d/sshd)`
3. `mapr-admin` (If you have created the `/etc/pam.d/mapr-admin` profile and the component checks beyond the first two profiles.)

The profile configuration file (for example, `/etc/pam.d/sudo`) should contain an entry corresponding to the authentication scheme used by your system. For example, if you are using the simplest form of local OS authentication, check for an entry similar to the following - consult with your Unix system administrator if you are uncertain:

```
auth    sufficient    pam_unix.so # For local OS Auth
```

Component-specific PAM Configurations

Some ecosystem components have unique requirements that require setup of a component-specific PAM configuration. See the [Ecosystem Guide](#) for the specific Ecosystem component.

Configuring PAM for the Control System and the REST API

Describes how to create a custom PAM profile and use a specific PAM file for authentication.

Starting in HPE Ezmeral Data Fabric v6.0, no additional configuration is needed to use PAM files for authentication. The `apiserver` supports PAM and automatically loads the following PAM files, if they exist, in the following order for authentication:

```
/etc/pam.d/mapr-admin
/etc/pam.d/sudo
/etc/pam.d/sshd
/etc/pam.d/chkpasswd
/etc/pam.d/passwd
```

However, you can [create a custom PAM profile](#) and set the admin server property to point to a specific PAM file to use for authentication:

1. Open the `/opt/mapr/apiserver/conf/properties.cfg` file and set the PAM file as the value for the `authentication.pam.service` property.

For example, to set `mapr-admin` as the file to use for authentication, your entry in the file should look similar to the following:

```
ojai.cache.size=64
mapr.webui.https.port=8443
doc.url=https://docs.datafabric.hpe.com/home
proxy.zkservices=elasticsearch,opentsdb
authentication.pam.service=mapr-admin
```

2. Save and close the file.

Configuring PAM to use LDAP

For instructions, refer to your operating system vendor documentation.

Configuring PAM to use Kerberos

To configure PAM with Kerberos:

1. Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
2. Install the appropriate PAM packages:
 - On Redhat/Centos, `sudo yum install pam_krb5`
 - On Ubuntu, `sudo apt-get install -krb5`

Creating a Custom PAM Profile

If you wish to ensure that MapR uses a MapR-unique PAM configuration, you can:

- Leave the `/etc/pam.d/sudo` file as is - MapR strongly recommends against manually editing the `/etc/pam.d/sudo` file.
- Create your own PAM profile in `/etc/pam.d`, naming it `mapr-admin`.
- Manually edit `mapr.login.conf` and other ecosystem component configuration files to use `mapr-admin` only.

Example `/etc/pam.d/mapr-admin` File

Below are some simple examples of what might work in the PAM profile by editing `mapr-admin` or a different PAM profile.

 **Note:** Be sure to consult with your Linux administrator before modifying PAM profiles.

```

account    required    pam_unix.so
account    sufficient  pam_succeed_if.so uid < 1000 quiet
account    [default=bad success=ok user_unknown=ignore] pam_ldap.so
account    required    pam_permit.so

auth       sufficient  pam_unix.so nullok_secure
auth       requisite   pam_succeed_if.so uid >= 1000 quiet
auth       sufficient  pam_ldap.so use_first_pass
auth       required    pam_deny.so

password   sufficient  pam_unix.so md5 obscure min=4 max=8 nullok
password   try_first_pass
password   sufficient  pam_ldap.so
password   required    pam_deny.so

session    required    pam_limits.so
session    required    pam_unix.so
session    optional    pam_ldap.so

```

 **Note:** The file `/etc/pam.d/sudo` should be modified only with care and only when absolutely necessary.

Example for Hue

- In Hue, you can set which PAM profiles to use by modifying `pam_service` option in the `<HUE_HOME>/desktop/conf/hue.ini` file:

```
[desktop]
...
# Configuration options for user authentication into the web application
# -----
[[auth]]
# Authentication backend...
backend=desktop.auth.backend.PamBackend
...
# The service to use when querying PAM.
## pam_service=sudo sshd login
```

Note: The `mapr-admin` profile is not used in the default Hue configuration.

Note: Hue respects only `auth` section from the PAM profiles.

Example for Livy

- With Livy you can authenticate users with PAM only by using MapR MultiMechs authentication, so it uses the configuration from `/opt/mapr/conf/mapr.login.conf`.

Managing Access Controls

Describes how to create, enable, and use ACLs and ACEs.

ACLs specify users or system processes that can perform specific actions on an object. ACEs are Boolean expressions that defines a combination of users, groups, or roles that have access to an object.

Managing Access Control Lists

Defines and describes how to create ACLs.

An access control list (ACL) specifies users or system processes that can perform specific actions on an object.

Creating Cluster-level ACLs

A cluster-level Access Control List (ACL) determines who has access to a cluster and which actions they are allowed to perform. ACLs on a secure HPE Ezmeral Data Fabric cluster are predicated on a locally managed OS registry.

Important: Before you create an ACL that applies to a particular group, you must create that group and assign users to it.

For example, the Red Hat Linux commands for creating a group called `developers` and adding a user named `jsmith` on a locally managed OS registry are:

```
groupadd developers
useradd -g developers jsmith
```

Once users and groups have been defined, an administrator can create a cluster-level ACL using the Control System and the CLI.

Creating an ACL from the Control System

- Click **Admin > User Settings > Permissions**.
- Follow steps for [Adding Cluster Permissions](#) on page 830.

Each allowed action has a permission code associated with it. The codes are explained below.

| Permission Code | Allowed Action |
|-----------------|--|
| login | Log in to the MapR Control System, use the API and command-line interface, read access on cluster and volumes.  Note: Read access allows you to only view the MapR objects that already exist. You cannot create volumes, policies, schedules, snapshots, nor any other MapR objects. |
| ss | Start/stop services |
| cv | Create volumes |
| cp | Create security policies |
| a | Administrative access to cluster ACLs. Grants no other permissions. |
| fc | Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster ACLs. |

Creating an ACL from the Command Line

To create an ACL at the command line, use the `acl set` command. Include spaces between multiple entries, such as a list of usernames and their associated permission levels (or *actions*).

The syntax is:

```
maprcli acl set -type volume -name <volume name>
                [-group <groupname>:<action> -user <username>:<action>]
```

 **Note:** The `acl set` command *removes* previously set permissions if they are not explicitly called out in the command line.

Other ACL commands include:

- `acl edit` - to modify permissions in an ACL (use this command instead of `acl set` to change some permissions while leaving others intact)
- `acl show` - to display permissions in an ACL

Example

To create an ACL for a cluster named `my.cluster.com` that allows administration of cluster ACLs to user `root` and control over all other aspects of the cluster to all users in the `developers` group, enter this command:

```
maprcli acl set -type cluster -cluster my.cluster.com -user root:a -group
developers:fc
```

Now suppose you want to change the `developers` group permissions so they can only log in and start or stop services. Use the `acl edit` command as shown:

```
maprcli acl edit -type cluster -cluster my.cluster.com -group
developers:login,ss
```

Note that only the `developers` group's permissions change, while the user named `root` retains control over the cluster's ACL settings.

Creating Job Queue ACLs

A job queue ACL controls who can submit jobs to a queue, kill jobs, or modify their priority. The default behavior is that any user can submit a job, and jobs can only be seen and killed by the administrator or the user that submitted those jobs.

To create a job queue ACL, specify the following parameters in the `mapred-queue-acls.xml` file:

| Parameter | What it does |
|---|---|
| <code>mapred.queue.names queue1,queue2,...</code> | Names the queues to which jobs can be submitted. |
| <code>mapred.acls.enabled=true</code> | Indicates that ACLs will be checked whenever a user or group submits a job, tries to kill a job, or tries to change its priority. This parameter is set to true by default when security features for your cluster are enabled. |
| <code>mapred.queue.<queue-name>.acl-submit-job user1,user2,... group1,group2,...</code> | Identifies the users and groups that can submit jobs to the specified <i>queue-name</i> . |
| <code>mapred.queue.<queue-name>.acl-administer-job user1,user2,... group1,group2,...</code> | Identifies the users and groups that can change the priority or kill jobs submitted to the specified <i>queue-name</i> . Note that the job owner can always kill his own job or change its priority. |

For information on configuring queue properties, see [Configuring Properties for Queues](#). You can also set job initialization parameters for a queue.

Creating Volume-level ACLs

MapR provides volumes as a way to organize data and manage cluster performance. For example, you might want to create a volume for each user, department, or project. You can then create a volume-level ACL that controls which users and groups have access to that volume, and what actions they may perform.

You can create volume-level ACLs from the Control System or from the command line.

Creating Volume-level ACLs from the Control System

- For:
 - New volumes, see [Creating a Volume](#) on page 941 to set volume-level ACLs.
 - Existing volumes, see [Modifying a Volume](#) on page 970 to modify volume-level ACLs.

Creating Volume-level ACLs from the Command Line

To create an ACL at the command line, use the `acl set` command to specify a list of authorized users (or groups) and the actions they are allowed to perform.

The syntax is:

```
maprcli acl set -type volume -name <volume name> [-user
<username>:<action> -group <groupname>:<action>]
```

Include spaces between multiple entries, such as a list of usernames and their associated permission levels (or *actions*). Each allowed action has a permission code associated with it. The codes are explained below.

| Permission Code | Allowed Action |
|-----------------|--------------------------------|
| dump | Dump or back up the volume |
| restore | Restore or mirror the volume |
| m | Modify the volume's properties |
| d | Delete the volume |

| Permission Code | Allowed Action |
|-----------------|--|
| a | Administrator (can edit and view ACLs, but cannot perform volume operations) |
| fc | Full control over the volume (this enables all volume-related administrative options with the exception of changing the volume ACLs) |

Example

This example shows how to create an ACL for a volume named `test-volume` that allows full control over volume ACLs for user `rjones`. In addition, all users in the `developers` group are given permission to dump, restore, and modify volume properties.

```
maprcli acl set -type volume -name test-volume -user rjones:fc
-group developers:dump,restore,m
```

Managing Access Control Expressions

Defines and describes how to create, enable, and use ACEs.

Access Control Expressions (ACEs) are defined by a combination of user, group, or role definitions.

ACE Syntax

Describes how to construct access control expressions (ACEs).

An [ACE](#) is defined by a combination of user, group, or *role* definitions. You can combine these definitions using the following syntax:

| Operator | Description |
|----------|--|
| u | Username or user ID, as they appear in <code>/etc/passwd</code> , of a specific user. Usage: <code>u:<username or user ID></code> |
| g | Group name or group ID, as they appear in <code>/etc/group</code> , of a specific group. Usage: <code>g:<group name or group ID></code> |
| r | Name of a specific role. Usage: <code>r:<role name></code> . |
| p | Public. Specifies that this operation is available to the public without restriction. Cannot be combined with any other operator. API request or CLI command to save such settings will return an error. |
| ! | Negation operator. Usage: <code>!<operator></code> . |
| & | AND operation. |
| | OR operation |
| () | Delimiters for subexpressions. |
| "" | The empty string indicates that no user has the specified permission. |

An example definition is `u:1001 | r:engineering`, which restricts access to the user with ID 1001 or to any user with the role `engineering`.

In this next example, members of the group `admin` are given access, and so are members of the group `qa`:

```
g:admin | g:qa
```

For another example, suppose that you have this list of groups to which you want to give read permissions:

- The `admin` group as a whole, but not the `admins` for a particular cluster (which is named `c13`).

- Members of the `qa` group who are responsible for testing the two applications (named `app2` and `app3`).
- The business analysts (group `ba`) in department 7A (group `dept_7a`)
- All of the data scientists (group `ds`) in the company.

To grant the read permission, you construct this boolean expression:

```
u:cfkane | (g:admin & !g:c13) | (g:qa & (g:app2 | g:app3)) | (g:ba &
g:dept_7a) | g:ds
```

This expression is made up of five subexpressions which are separated by OR operators.

- The first subexpression `u:cfkane` grants the read permission to the username `cfkane`.
- The subexpression `(g:admin & !g:c13)` grants the read permission to the admins for all clusters except cluster `c13`. The operator `g` is the group operator, the value `admin` is the name of the group of all admins. The `&` operator limits the number of administrators who have read permission because only those administrators who meet the additional condition will have it.

The condition `!g:c13` is a limiting condition. The operator `!` is the NOT operator. Combined with the group operator, this operator means that this group is excluded and does not receive the read permission.

Warning: Be careful when using the NOT operator. You might exclude fewer people than you intended. For example, suppose that you do not want anyone in the group `group_a` to have access. You therefore define this **ACE**: `!g:group_a`. You might think that the data is now protected because members of `group_a` do not have access to it. However, you have not restricted access for anyone else except the members of `group_a`. The rest of the world can access the data. You should not define **ACEs** through exclusion by using the NOT operator. You should define them by inclusion and use the NOT operator to limit further the access of the groups or roles that you have included.

In the subexpression `(g:admin & !g:c13)`, the NOT operator limits the number of members within the admin group who have access. The `admin` group is included, and all users who are also part of the `c13` group are excluded.

- The subexpression `(g:qa & (g:app2 | g:app3))` demonstrates that you can use a subexpression within a subexpression. The larger subexpression means that only members of group `qa` who are also members of group `app2` or `app3` have read access to the data. The smaller subexpression limits the number of people who have this permission in the `qa` group.
- The next two subexpressions -- `(g:ba & g:dept_7a)` and `g:ds` -- grant the read permission to the members of group `ba` who are also in the group `dept_7a`. It also grants permission to the members of the group `ds`.

Creating User Roles for ACEs

Describes how to create and use roles for access control.

Note: MapR recommends that you use Unix Groups over Roles whenever possible, for centralized maintenance. Use Roles only when you are unable to modify LDAP or AD groups easily.

A role is a label attached to a set of users, which defines a common task, or set of behaviors for those users. Roles enable you to use functionality similar to Unix groups for your users, without requiring you to alter the existing group hierarchy of your system. Role names can be up to 64 characters long, and cannot use the `:`, `&`, `|`, or `!` characters.

Standard Reference Implementation

User Information

The standard reference implementation is a library called `libmapr_roles_refimpl.so`. This library is located at `/opt/mapr/server/permissions`. This library opens a configuration file named `m7_permissions_roles_refimpl.conf`, which should contain a list of all the roles, and the users associated with those given roles. This configuration file is located at `/opt/mapr/conf`, and should be identical across all clusters.

The structure of the configuration file is as follows. Roles end with `:`, while user names are written on each subsequent line. For example:

```
Role_1:
    user_a
    user_b

Role_2:
    user_b
    user_c
    user_d
    #comment
```

This example file states that there are two roles to choose from when assigning permissions - `Role_1` and `Role_2`. The users located under `Role_1` are `user_a` and `user_b`. `Role_2` contains `user_b`, `user_c`, and `user_d`. Blank lines, and lines beginning with `#` are ignored.

Assume a table has permissions `r:Role_2`. `user_b` has access to this table, while `user_a` does not have access.

After adding a new role to the `m7_permissions_roles_refimpl.conf` file, you must issue the following command to enable the filesystem layer to pick up the new role: `$ /opt/mapr/server/mrconfig dbrolescache invalidate`

Run this command on all the nodes, whenever there is a change in the roles configuration file.

Developer Information

The functions that the `libmapr_roles_refimpl.so` exposes, are found in the extensibility implementation. When the library is called initially through `GetSecurityMembership`, it parses the `m7_permissions_roles_refimpl.conf` file, and loads it into memory. All user names are read, and parsed into user IDs (`uid_t`). If a user ID is not found, the ID is skipped.

The library uses a HashTable. The roles are the keys. The values are a Binary Tree of user IDs.

Each call checks the given user ID and role. The HashTable keys off the role, and then searches the Binary Tree for the user ID. If the HashTable finds a user ID, it sets the boolean value of that role to `true`. If the HashTable does not find a user ID, or if any errors occur, such as `Role not found`, it sets the boolean value to `false`.

There is also a cleanup method which frees the memory allocated to the HashTable, along with all of its children. If the `GetSecurityMembership` method is called again, the library reloads the configuration file, and loads all the values into memory.

Extensible Implementation

If users decide not to use the reference implementation, they can replace the shared library with their own. In the `mfs.conf` file, add a parameter that specifies the name of the file. If the name of the file is changed, then MFS searches `/opt/mapr/server/permissions` for the new file. If the file is found, it is loaded into memory. If not, then all roles evaluate to `false`.

The user's shared library should contain two functions specified under the `mapr::fs` namespace:

```
extern "C"
    void GetSecurityMembership(uid_t uid, const char *roles[], int
numRoles, bool truthValue[]) {
    }
```

```
extern "C"
    void cleanup() {
    }
```

`GetSecurityMembership` takes the given user ID along with a list of all the roles, the amount of roles in the array, and an array of all the results, as booleans.

Users must code their own implementation of populating the `truthValue` array with either `true` or `false`. The `truthValue` array has the same length as `numRoles`, and is initialized. Do not modify any other variables.

Use the `cleanup` method to reset the shared library to an initialized state. This method resets all values, and frees memory, since the shared library is not closed, till the class calling it, gets destructed.

Invoke Shared Library from MFS

The `TablePermissions` class handles opening, and closing the shared library. During class initialization, the name of the shared library that is read from the `mfs.conf`, file, is passed to the constructor. The constructor loads the shared library into memory, using the `LoadSO` method from `filterutils.cc`. The constructor also loads the `GetSecurityMembership` method, along with the `cleanup` method, as variables that can be called.

`TablePermissions` contains two methods that can be called, to access the shared library:

- The `GetSecurityMembership` method takes 3 arguments - the user ID, the array of roles, and the amount of roles in the array. This method returns a `RolePermission` structure, which contains all the same data, as well as the boolean of the successful roles for that given user ID. To evaluate the user roles, pass this `RolePermission` structure to the `TablePermission::checkTablePermissions` method.
- The `cleanup` method calls the `cleanup` method in the shared library. This method takes no arguments.

The entity that allocates the `RolePermission` structure into memory, also needs to deallocate this structure.

Deallocating the `TablePermissions` class, calls the `cleanup` method, and closes the shared library.

Shared Library Security

The `/opt/mapr/server/permissions` folder is initialized with 755 permissions. This implies that only the user who installed MapR has access to writing to that folder. These permissions prevent a user from replacing a shared library with a malicious file.

The `m7_permissions_roles_refimpl.conf` file has 755 permission, which means that only an administrator can make changes to this file.

The Roles Library Shared Object and Access Control Expressions

When you access an object that is secured by an [ACE](#), the filesystem layer calls the roles library shared object, and checks the permissions of the entity requesting access against the contents of the roles file. The roles library shared object reads the roles file every 600 seconds. You can specify your own roles

library shared object, and specify the location of that object, using the parameter `mfs.dbroles.sopath` in the `/opt/mapr/conf/mfs.conf` file.

Enabling Volume, Directory, and File Authorizations with ACEs

Describes how to set access control expressions for volumes, directories and files.

ACEs allow you to define whitelists (to grant access) and blacklists (to deny access) for a combination of users, roles, and groups. You can grant different permissions to multiple users, groups, and roles for filesystem files, directories, and whole volume data using boolean expressions and subexpressions.

ACEs for Files, Directories, and Whole Volume

An **ACE** is defined by a combination of user, group, and/or role definitions. You can combine these definitions using the supported syntax. For more information, see [Syntax of Access Control Expressions](#).

The examples in the following table demonstrate how **ACEs** can be used to create whitelists to grant access, and blacklists to deny access.

| This Access Control Expression... | Grants access to... | Denies access to... |
|---|--|---|
| <code>(u:u1&g:g1)</code> | only user 'u1', if user 'u1' is a member of group 'g1' | users who are not 'u1' and members of group 'g1' |
| <code>(g:g1&g:g2) r:r1</code> | only users who are in both the groups 'g1' and 'g2', or users who are assigned role 'r1' | users who are not in both the groups 'g1' and 'g2', and users who are not assigned role 'r1' |
| <code>(g:g1&!g:g2)</code> | only users who are in group 'g1' and not in group 'g2' | users who are in group 'g2', even if they are in group 'g1', and all other users |
| <code>(g:g1 g:g2)</code> | users who are in groups 'g1' or 'g2' only | users who are not in groups 'g1' or 'g2' |
| <code>(g:g1 g:g2)&!r:r1</code> | only users in groups 'g1' or 'g2' and who are not assigned role 'r1' | users who are not members of groups 'g1' or 'g2', users who are assigned role 'r1', even if they are in group 'g1' or 'g2', and all other users |
| <code>(p)</code> | everyone | none |
| <code>(!g:g1&!g:g2&!g:g3)</code> | users who are not in groups 'g1', 'g2', and 'g3' | only users who are in groups 'g1', 'g2', or 'g3' |
| <code>((u:u1 u:u2 u:u3)&g:g1&g:g2)&!r:r1</code> | only users 'u1', 'u2', or 'u3', who are also members in groups 'g1' and 'g2', but not assigned role 'r1' | users who are not 'u1', 'u2', or 'u3' and members of groups 'g1' and 'g2', and users who are assigned role 'r1' |
| <code>(u:u1 u:u2 u:u3)&g:g1 g:g2</code> | only users who are 'u1', 'u2', or 'u3' and who are members in groups 'g1' or 'g2' | users who are not 'u1', 'u2', or 'u3' and members of groups 'g1' or 'g2' |

Note: The entities — user, group, role, and public — must be the same for filesystem and HPE Ezmeral Data Fabric Database **ACEs**.

Managing File and Directory ACEs

Describes the implications of setting access control expressions on files and directories.

File **ACE** allows you to define access (whitelist and blacklist) to files and directories for a combination of users, groups, and roles. If **ACEs** are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set **ACEs**, MapR sets or resets the corresponding POSIX mode bits to match the permissions granted through **ACEs**. For more information, see [Setting/Modifying File and Directory ACEs](#).

- If both [ACEs](#) and POSIX mode bits are set, access is granted if access is allowed through [ACEs](#) or POSIX mode bits.
- If [ACEs](#) are not set, POSIX mode bits are used to grant access.
- If neither [ACEs](#) nor POSIX mode bits are set, access is denied.

The owner of the file or directory (and mapr and root users) can set, modify, and remove [ACEs](#) for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files using the `hadoop mfs` command or the [FileACE Java APIs](#) on page 1574 and [FileACE C APIs](#) on page 1574. Specifically, the following access types are supported.

| Access Type | | Description |
|---------------------------|-----------------|------------------|
| Command-Line | Java API (Enum) | |
| <code>-readfile</code> | READFILE | Read a file. |
| <code>-writefile</code> | WRITEFILE | Write to a file. |
| <code>-executefile</code> | EXECUTEFILE | Execute a file. |

For more information, see `hadoop mfs`, [FileACE Java APIs](#) on page 1574, and [FileACE C APIs](#) on page 1574.

Directory ACEs

You can set the same [ACEs](#) on directories as for files. In addition, directory [ACEs](#) support permissions to list, add child, delete child, and lookup directories using `hadoop mfs` command. Specifically, the following access types are supported.

| Access Type | | Description |
|---------------------------|-----------------|--|
| Command-Line | Java API (Enum) | |
| <code>-readfile</code> | READFILE | Read a file. |
| <code>-writefile</code> | WRITEFILE | Write to a file. |
| <code>-executefile</code> | EXECUTEFILE | Execute a file. |
| <code>-readdir</code> | READDIR | List the contents of a directory. This access is required to write and/or execute files in the directory. |
| <code>-lookupdir</code> | LOOKUPDIR | Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory. |
| <code>-addchild</code> | ADDCHILD | Add a file or subdirectory. |
| <code>-deletechild</code> | DELETECHILD | Delete a file or subdirectory. |

Although you can set both file and directory [ACEs](#) on directories, only the directory [ACEs](#) are used for determining access to the directory. The file [ACE](#) on the directory is used as the default [ACE](#) setting for new files under that directory.

By default, when you set [ACEs](#) on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.

- New files under that parent inherit the file [ACEs](#) and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default [ACE](#), the empty string (""), which indicates that no one has permissions to read, write, or execute the file; POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file [ACEs](#) and corresponding POSIX mode bits from the parent directory.

Note: When accessing files and directories, the [ACEs](#) on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACES are set on an executable file

When [ACEs](#) are set on any file, mode bits are cleared. However, for a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with [ACEs](#) set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRaces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set access control expressions (ACEs) for files and directories.

For files and directories, run the `hadoop mfs` command to set [ACEs](#). When [ACEs](#) are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding [ACEs](#). POSIX mode bits for others is set only if "p" is given as the value for an [ACE](#).

The following table lists the POSIX mode bits that correspond to the access types.

| | ACE | POSIX Mode Bits |
|------------------|---------------------|-----------------|
| File | readfile | r |
| | writefile | w |
| | executefile | x |
| Directory | readdir | r |
| | addchild | w |
| | deletechild | w |
| | lookupdir | x |

The POSIX mode bit granting write (w) access to directory is set only if user, role, or group is granted permission for both (addchild and deletechild) access types.

The `hadoop` command, by default, sets the POSIX mode bits corresponding to the given [ACEs](#), and:

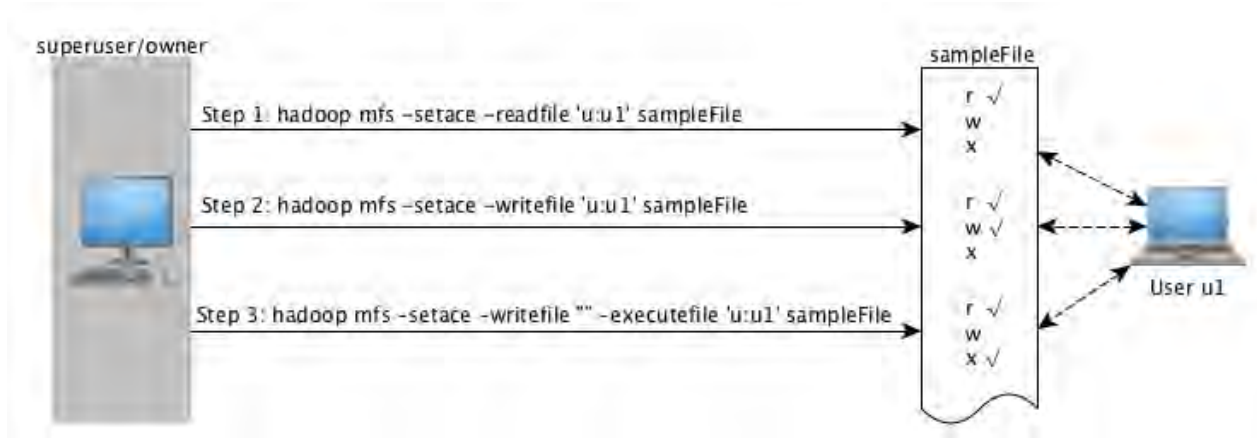

- Overwrites existing [ACE](#) values with new values, if specified, for access types that were previously set.
- Sets [ACE](#) values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, whether or not they were previously set.

Warning: Changing the POSIX mode bits using `chmod` does not change the corresponding **ACE** setting and may result in different, conflicting permissions to files and directories.

File ACE Example

Illustrates setting access control expressions for files.

Suppose the following sequence of file **ACE** settings (and corresponding POSIX mode bits) are set for user u1.

As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, `sampleFile`.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in **ACEs** or POSIX mode bits for all other (write and execute) access types.

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in **ACEs** or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

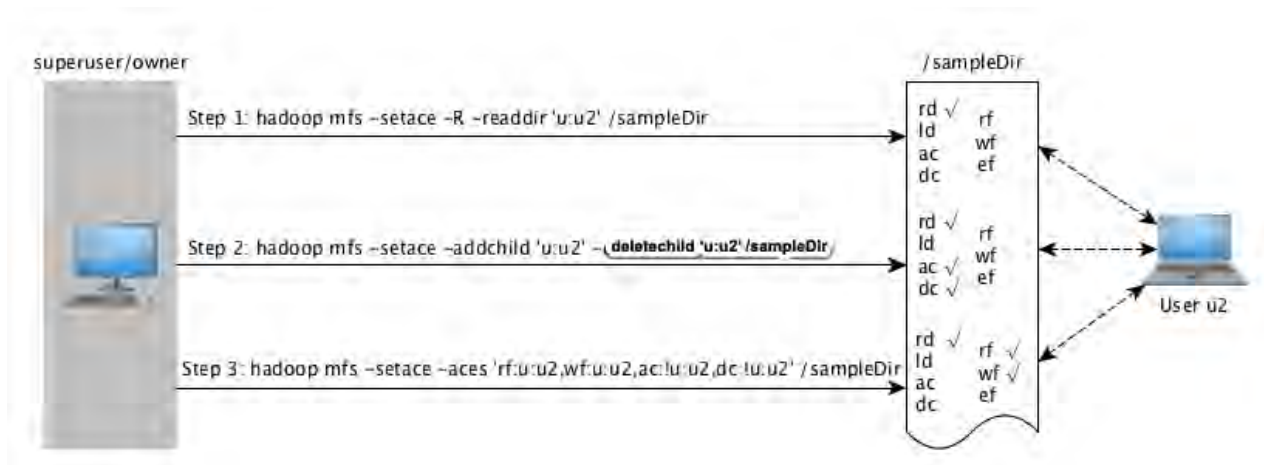

Note: When the empty string (" ") is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (!).

There is no change in **ACEs** or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory **ACE** settings for user u2:

As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory, and sampleDir, while all other directory/file **ACEs** are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (*x*) is set to u2 for owner/users.

There is no change in **ACEs** or POSIX mode bits for all other (file- and directory-level) access types.

Step 2:

User u2 is granted permission only to add and delete child directories, while all other directory/file **ACEs** are not specified.

After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (*w*) to the directory for owner/user is set to u2 because user u2 is granted access for both (addchild and deletchild) access types.

If user u2 creates child directories, the child directories, by default, inherit the **ACE** settings of the parent directory.

There is no change in **ACEs** or POSIX mode bits for all other (file- and directory-level) access types.

Step 3:

User u2's permissions are modified to grant access to read and write to files in the directory, user u2's permissions for adding and deleting child directories are removed (using the negation operator), and all other directory/file **ACEs** are not specified.

After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add

and delete child directories. The POSIX mode bits for directory write access (`w`) is set to 0 for owner/user.

Although, at the directory level, user `u2` has permissions to read and write to files in the directory, for existing files, the file level [ACEs](#) or the POSIX mode bits for the file are used to determine access. However, by default, user `u2` gets read and write permissions to all new files created under the directory. If user `u2` creates new files under the directory, the files inherit the file [ACEs](#) from the parent directory by default and the POSIX mode bits for read (`r`) and write (`w`) access are set to `u2` for owner/user.

There is no change in [ACEs](#) or POSIX mode bits for all other (`lookupdir` and `executefile`) access types.

Deleting File and Directory ACEs

Describes how to delete file and directory ACEs using the CLI.

You can remove all [ACE](#) associated with a file or directory using the `hadoop mfs -delace` command. When you delete all the [ACEs](#), the system sets the [ACE](#) for the file or directory to the default value, which is the empty string (`" "`). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

You cannot remove specific access types that have been set; instead, use the empty string to deny specific types of access. When the empty string (`" "`) is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`). If you use the empty string (`" "`) or the negation operation (`!`) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the [ACE](#) setting.

FileACE Java APIs

Contains the path to the Java FileACE APIs.

The Java FileACE APIs are located at [File ACE APIs](#).

FileACE C APIs

Describes the C FileACE APIs.

The FileACE C APIs are defined in the header file `hdfs.h` and are as follows:

hdfsSetAces

Sets the ACEs for a file or directory.

Syntax

```
int hdfsSetAces(hdfsFS fs, const char *path, hdfsFileAces *faces, int
isSet, int isRecursive);
```

Parameters

- `fs`: The configured filesystem handle
- `path`: The path to the file or directory for which the ACEs need to be set.
- `faces`: The ACEs to set
- `isSet`: Set to 0 to merge with any existing ACEs, or set to 1 to replace all existing ACEs.
- `isRecursive`: Set to 1 to apply ACEs recursively when setting on a directory.

Return Value

0 on success, else an error code.

hdfsGetAces

Gets the ACEs from a file or directory.

Syntax

```
int hdfsGetAces(hdfsFS fs, const char *path, void *aceBuf, int bufLen,
hdfsFileAces *faces);
```

Parameters

- fs: The configured filesystem handle
- path: The path to the file or directory from which the ACEs need to be fetched.
- aceBuf: The buffer to hold the ACEs.
- bufLen: Length of the ACE buffer (*aceBuf*)
- faces: The structure that contains the returned ACEs.

Return Value

0 on success, else error ERANGE, which indicates that the buffer is too small to hold the ACE entries.

hdfsDeleteAces

Deletes all ACEs from a file or directory.

Syntax

```
int hdfsDeleteAces(hdfsFS fs, const char *path);
```

Parameters

- fs: The configured filesystem handle
- path: The path to the file or directory from which the ACEs need to be deleted.

Return Value

0 on success, else an appropriate error.

Managing Whole Volume ACEs

Describes how to grant permissions to users, groups, and roles for the volume data using whole volume access control expressions (ACEs).

Whole volume [ACEs](#) allow you to define whitelists to grant access, and blacklists to deny access, for files and tables within a volume.

Volume administrators and mapr user can set and modify whole volume [ACEs](#). By default, [ACEs](#) grant everyone access to read and write to files and tables in the volume at the volume-level; however, inside the volume, to determine access for:

- Files, the file [ACEs](#) or POSIX mode bits are used.
- Tables, the table [ACEs](#) are used.

Supported Access Types

At the volume level, the following access types are supported:

| Access Type | Description |
|-------------|---|
| -readAce | Read files, HPE Ezmeral Data Fabric Database binary tables, HPE Ezmeral Data Fabric Database JSON tables, and MapR streams in the volume. By default, this is set to <code>p</code> to grant all users this permission. |
| -writeAce | Write to files, HPE Ezmeral Data Fabric Database binary tables, HPE Ezmeral Data Fabric Database JSON tables, and MapR streams in the volume. By default, this is set to <code>p</code> to grant all users this permission. |

ACE Behavior on Snapshots and Mirrors

Volume Snapshots

Volume snapshots reflect the [ACEs](#) of the volume at that point in time. Changes in volume [ACEs](#):

- Are carried over to a new snapshot of the volume.
- Do not propagate to older snapshots of the volume.

Volume Mirrors

[ACEs](#) of a volume are propagated to mirror volumes. After each mirroring operation, mirror volumes reflect the current [ACE](#) setting of their source volume. After a mirror volume is promoted to a read-write volume, you can modify the [ACEs](#) on the mirror volume from the command line. [ACEs](#) on the promoted mirror volume can be different from the source volume.

Setting Whole Volume ACEs

Describes how to set ACE expressions when creating or modifying volumes.

You can set [ACEs](#) at the time of volume creation using the `volume create` on page 2190 command and modify them at a later time using the `volume modify` on page 2275 command. When you run the command to set or modify [ACEs](#), the command does the following:

- Overwrites existing values with new values, if specified, for access types that were previously set.
- Sets values for access types that have not yet been set, if specified.
- Does not modify access types that were not specified with the command, whether they were previously set or are unset.

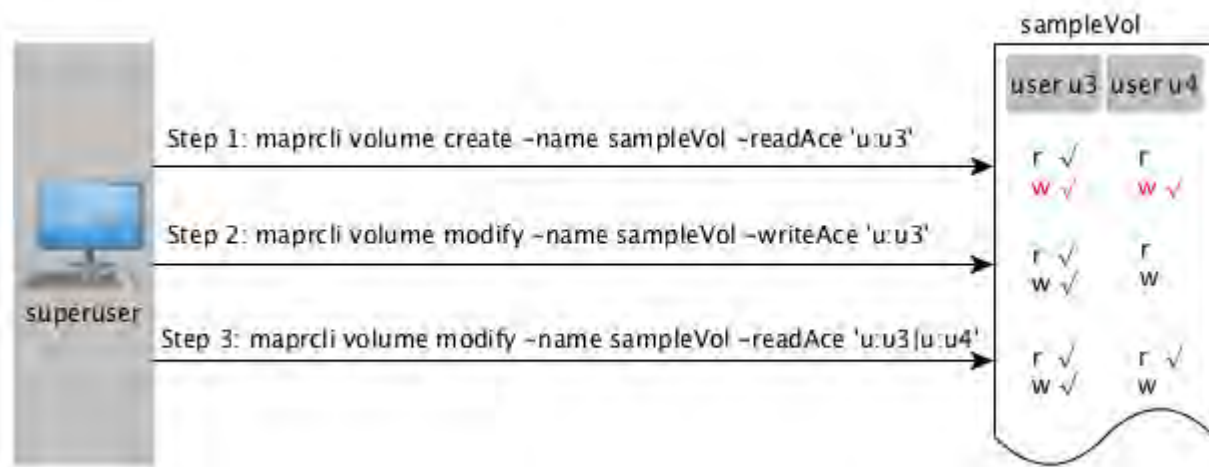

When you set whole volume [ACEs](#), permissions on files and tables under that volume remain unchanged. Also, new files and tables in the volume do not inherit the whole volume [ACEs](#) of that volume. Instead, whole volume [ACEs](#), if set, are used to determine volume level access to tables and files within the volume. To gain access to volume data, the user must have access at both the volume and file/table levels.

Whole Volume [ACE](#) Example

For example, suppose the following sequence of whole volume [ACE](#) settings for users u3 and u4 is as follows.

Note: In the following illustration, default [ACE](#) values are shown in red.

As shown in the illustration above, in:

Step 1:

User u3 is granted permissions to read.

User u3: User u3 has permissions to read files and tables at the volume level and by default, user u3 has write permission (shown in red) at the volume level. However, for:

- Files in the volume, file [ACE](#) or POSIX mode bits are used to determine read and write access for user u3.
- Tables in the volume, table [ACEs](#) are used to determine read and write access for user u3.

User u4: User u4 cannot read files and tables within the volume because the [ACE](#) for the volume does not explicitly grant access to user u4. Although user u4 has write permission by default, user u4 cannot write to files/tables in the volume because user u4 does not have read permission.

Step 2:

User u3 is granted permissions to write.

User u3: User u3's read access remains unchanged and although user u3 has permissions to write to files and tables, for:

- Files in the volume, file [ACE](#) or POSIX mode bits are used to determine write access for user u3.
- Tables in the volume, table [ACEs](#) are used to determine write access for user u3.

User u4: User u4 cannot write to files/tables in the volume.

Step 3

User u4 is granted read access.

User u3: User u3's read and write access remains unchanged.

User u4: User u4 has permissions to read files and tables at the volume-level; however, for:

- Files in the volume, file [ACE](#) or POSIX mode bits are used to determine read access for user u4.
- Tables in the volume, table [ACEs](#) are used to determine read access for user u4.

Deleting Whole Volume ACEs

You cannot remove ACEs that have been set; instead, if necessary, use the empty string (" ") to deny specific types of access. If the empty string is used to deny a specific type of access, that type of access is denied to all users. To deny access to specific users only, use the negation operator (!).

Enabling Table and Stream Authorizations with ACEs

Permissions for MapR tables, column families, and columns are defined by Access Control Expressions (ACEs). You can set permissions for tables when you create or edit tables. You can set default permissions for column families when you create or edit tables, and you can override these defaults when you create column families.

For the syntax to use when creating Access Control Expressions, see [ACE Syntax](#) on page 1565.

When a user, group, or role requests to read data from, write data to, or append data to a column, HPE Ezmeral Data Fabric Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. HPE Ezmeral Data Fabric Database checks whether this user has write permission on `cf1` AND `col1` AND `col2`. If the user does not have all three permissions, HPE Ezmeral Data Fabric Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, HPE Ezmeral Data Fabric Database would simply not return the data. If the user tried to read from those two columns and additional columns on which he had read permissions, the results would contain the data for those additional columns but exclude the data for `col1` and `col2`.

Note: Table Permissions for Older Releases: Because MapR tables are stored at the file-system level, you can also set permissions for HPE Ezmeral Data Fabric Database tables directly in the file system, if your version of MapR does not support Access Control Expressions (ACEs). Support for ACEs was introduced in version 3.1.

To set permissions directly in the filesystem, see [Performing File System Operations on HPE Ezmeral Data Fabric Database Tables](#) on page 1145.

Setting Table ACEs Using the CLI

You can set ACEs with the following commands:

- `table create` on page 2029 — Creates a new MapR table.
- `table edit` on page 2076 — Edits a MapR table.
- `table cf create` on page 2048 — Creates a column family for a MapR table.
- `table cf edit` on page 2055 — Edits a column-family definition.
- `table cf colperm set` on page 2037 — Set Access Control Expressions (ACEs) for a specified column.

Setting Stream ACEs Using the CLI

You can set ACEs with the following commands:

- `stream create` on page 1999 — Creates a new MapR stream.
- `stream edit` on page 2006 — Edits a MapR stream.

Permission Types for Fields and Column Families in JSON Tables

By using access-control expressions (ACEs), you can grant or deny access to fields and column families that are in JSON tables.

For an explanation of the syntax of ACEs, see [ACE Syntax](#).

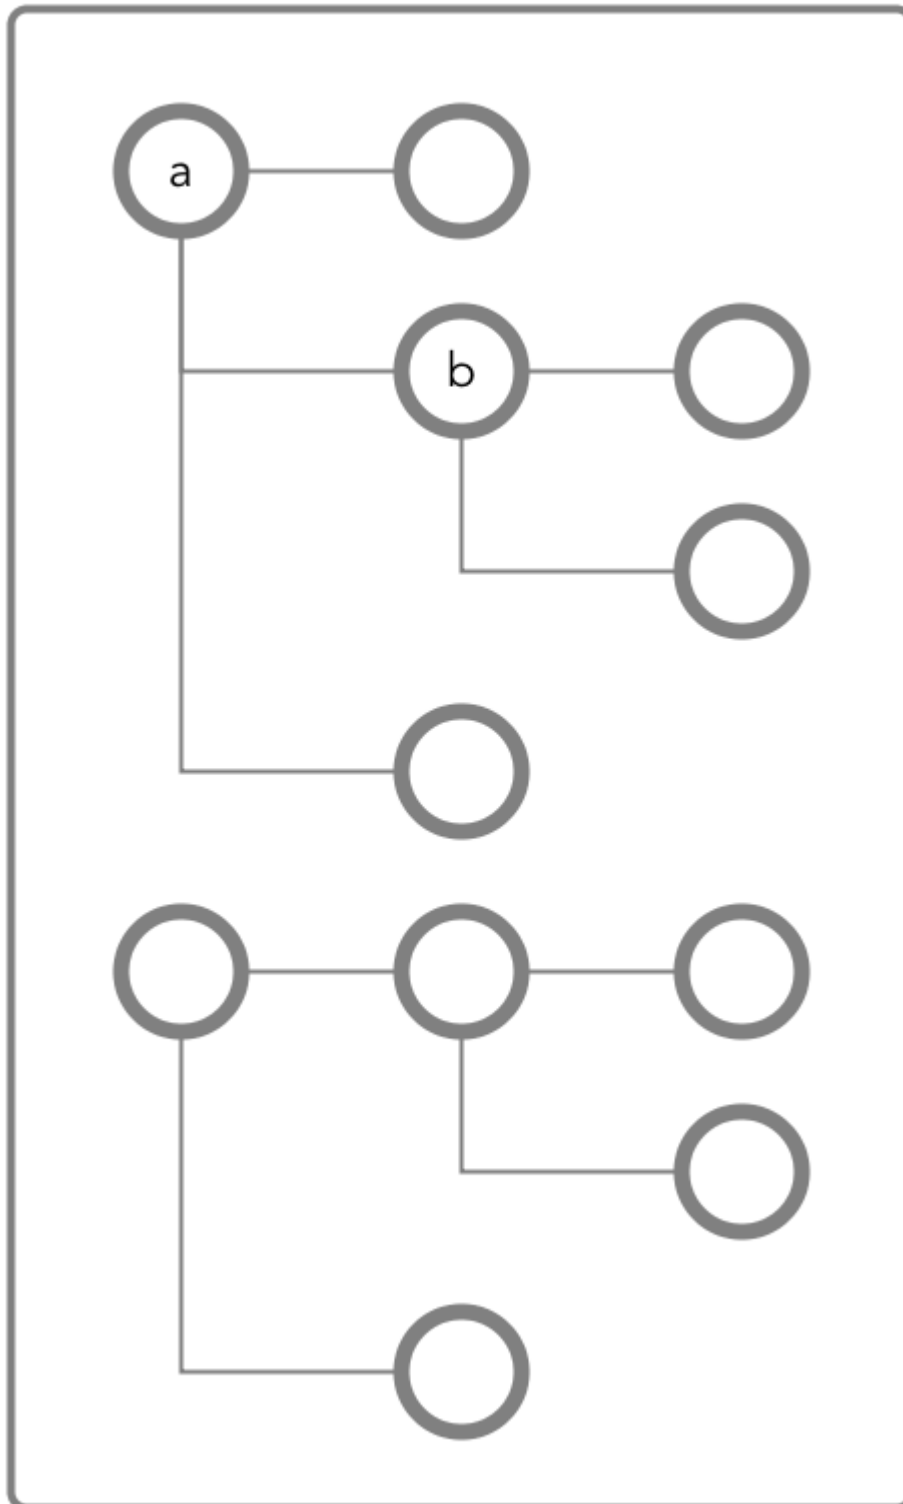

There are three types of permission:

- `Traverse` (`traverseperm`)
- `Read` (`readperm`)
- `Write` (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access the fields that the grantee has write or read permission on.

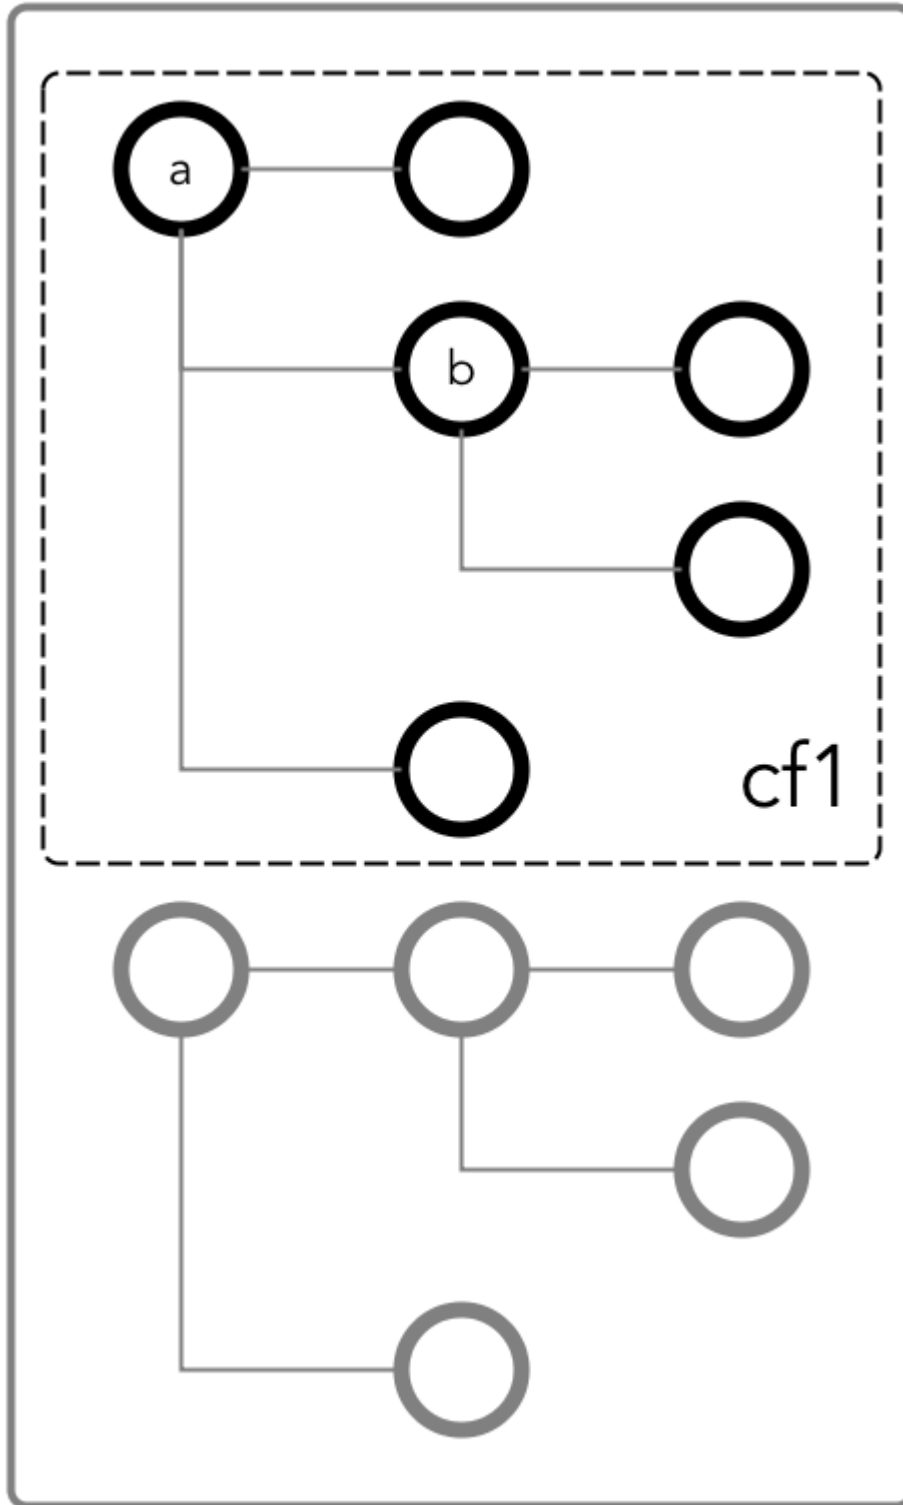

For example, suppose that a user has read and write access only on field b in this document.

To access field **b**, the user would need to be able to traverse (pass through) field **a**. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field **a** would inherit the traverse permission.

If traverse permission on the default column family were denied the user, it would not be possible for the user to access field **b**. Granting traverse permission on field **a** in this case would have no effect.

In the next example, field `a` is a column family named `cf1`.

To be able to read and write at field `b`, the user could be granted the traverse permission on the column family.

Read (readperm)

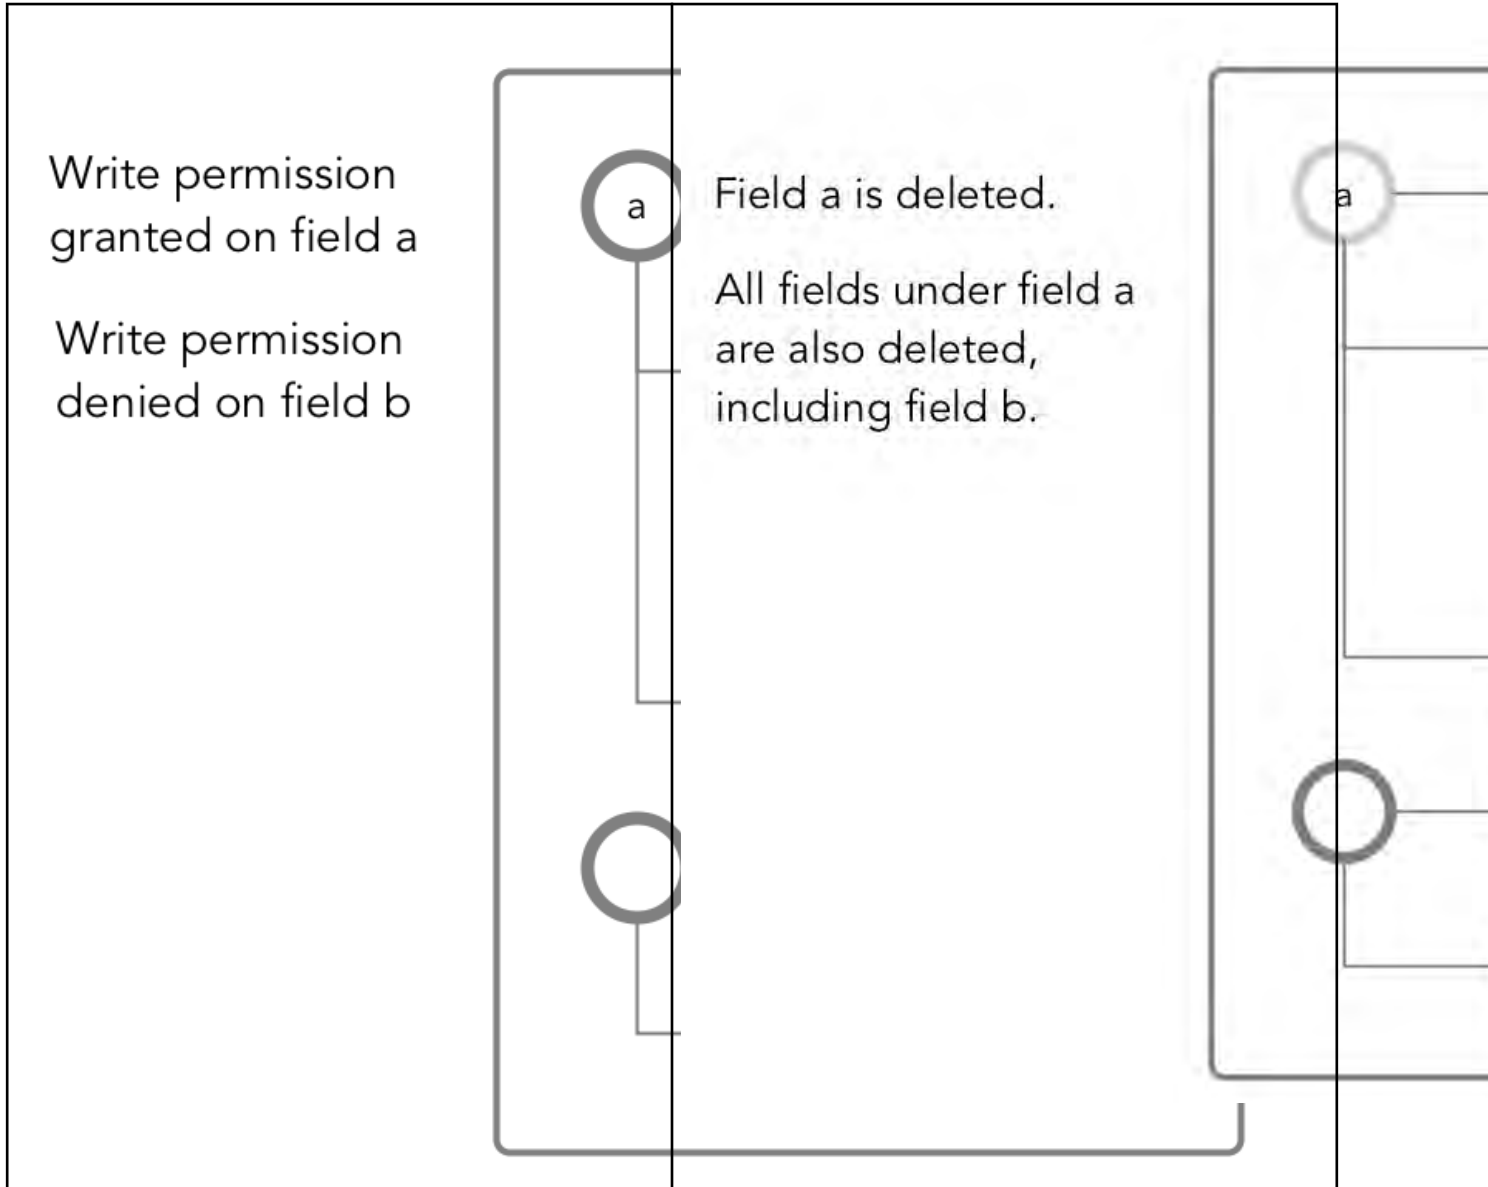

This permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field that the permission was granted on. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (writeperm)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite a field's value.

As illustrated in the following two diagrams, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

Obtaining readperm and writeperm on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the document below, you want to perform an operation on field `c`, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field `c`.

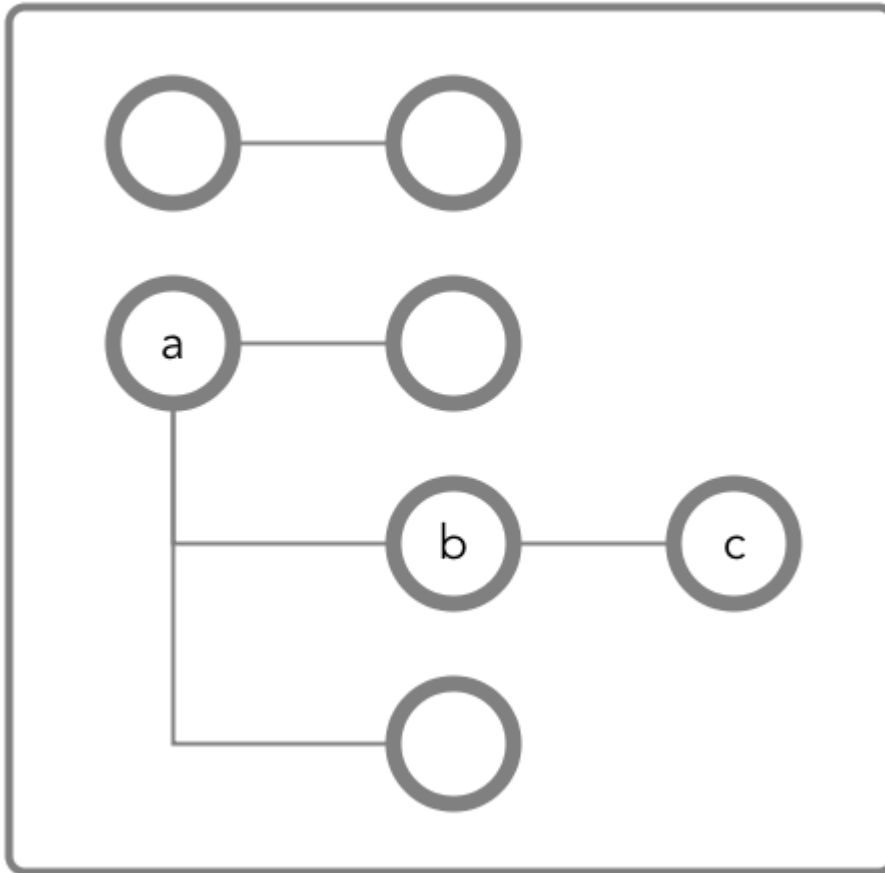

Figure 23: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field `c` inherits these permissions, assuming that the permissions were not denied on field `a` or `b`.

If you do not have `readperm` and `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field `c`. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```

maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
  
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields `a` and `b` inherit this permission. You also need `readperm` and `writeperm` on field `c`.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON table](#).

In the following document, you want to perform an operation on field `c`, which is in the column family `cf1` that is defined at field `b` with the path `a.b`.

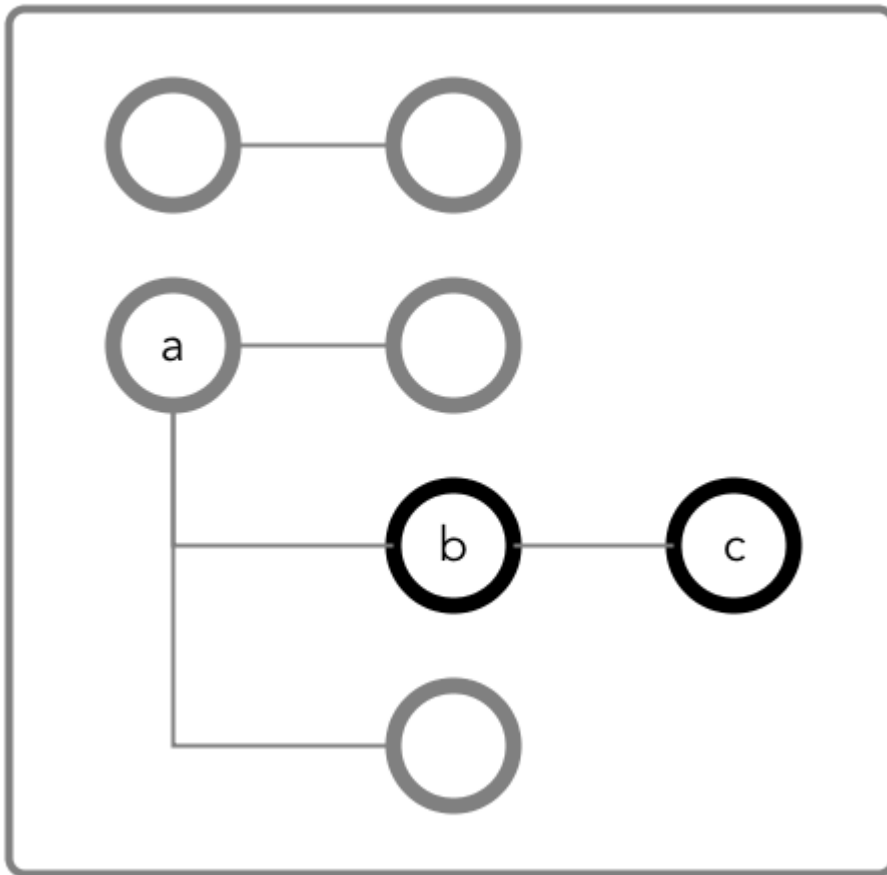

Figure 24: Schematic diagram of an JSON document in which fields `b` and `c` are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writperm` on field `b`

You need `traverseperm` on field `b` and both `readperm` and `writperm` on field `c`. You can be granted these permissions with commands similar to these:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
cf1 -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writperm u:<user
ID> |
<existing ACE for this field>
```

Case 2: You do have `readperm` and `writperm` on field `b`

You do not need any further permissions. Field `c` inherits your `readperm` and `writperm` permissions from field `b`.

Obtaining `readperm` or `writperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have `readperm` or `writeperm` permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

When the field is in the default column family

In the following document, you want to perform an operation on field `c`, which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

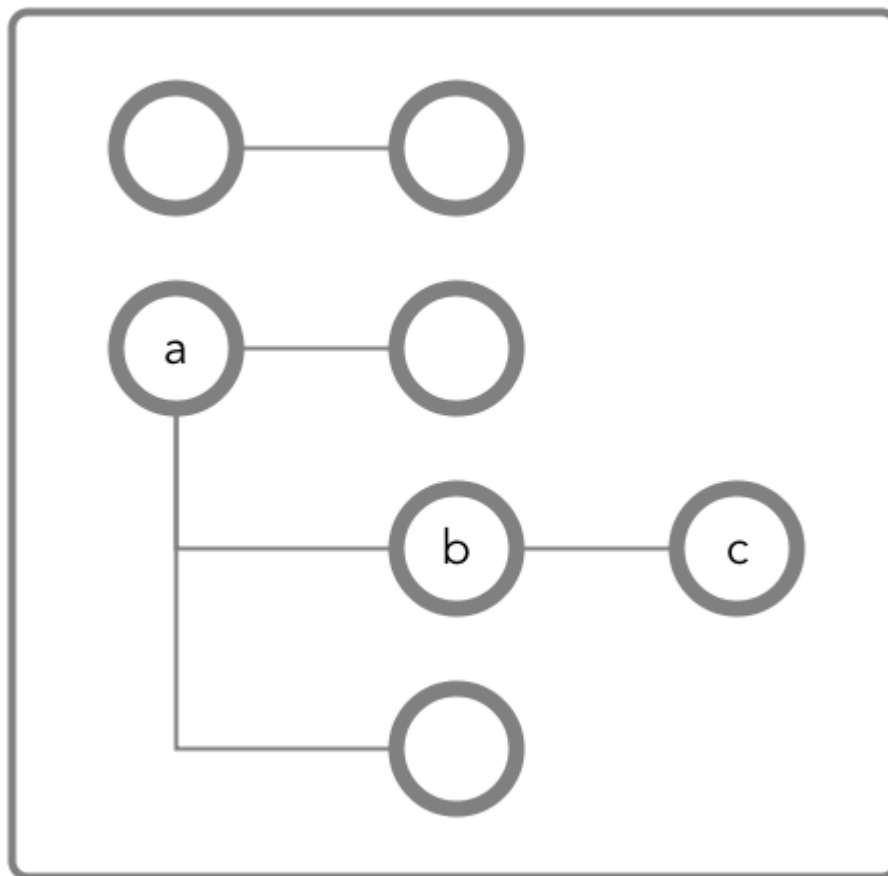

Figure 25: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family

In this case, field `c` inherits the permission, assuming that the permission was not denied on field `a` or `b`.

If you do not have `readperm` or `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b -traverseperm
```

```
u:<user ID> | <existing ACE for this field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cfl
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cfl
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

When the field is in a non-default column family

Note: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON Tables](#).

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field `b` with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

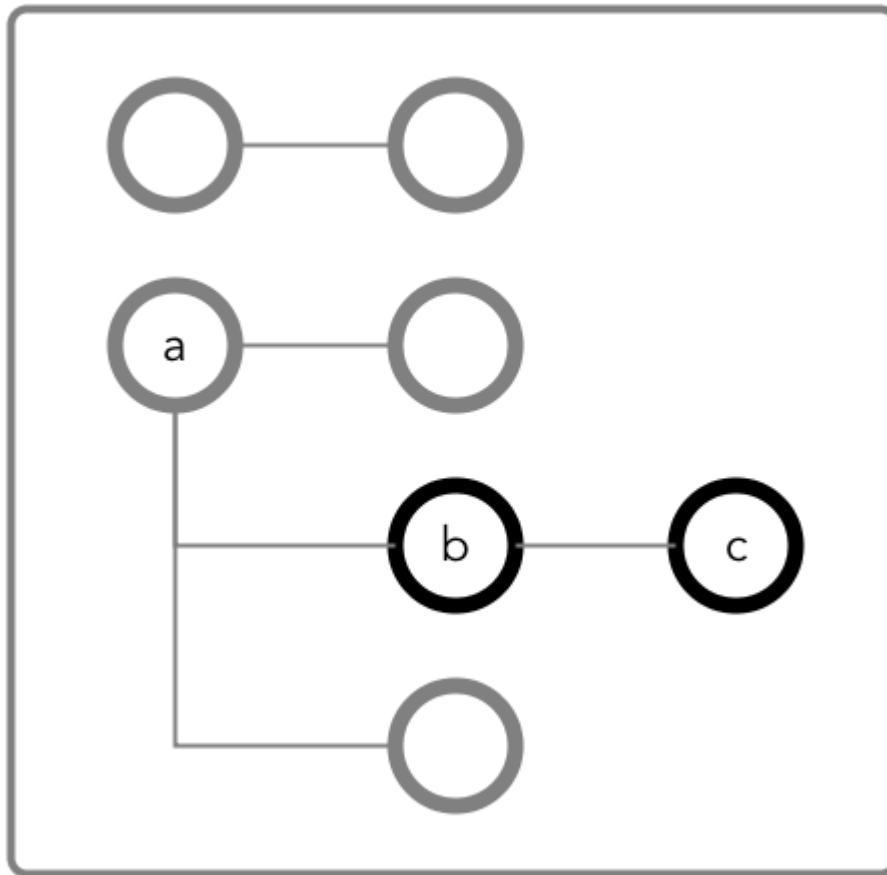

Figure 26: Schematic diagram of an JSON document in which fields `b` and `c` are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`

You need `traverseperm` on field `b`, and you need `readperm` or `writeperm` granted to you explicitly on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`

You do not need any further permissions. Field `c` inherits your `readperm` and `writeperm` permissions from field `b`.

Setting Permissions on Arrays

When granting permissions on a field, if the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

Note: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
  "_id" : "id001",
  "person" : [
    { "name" : { "last" : "Smith", "first" : "John" } },
    { "name" : { "last" : "Subramanium", "first" : "Ananya" } }
  ]
}
{
  "_id" : "id002",
  "person" : { "name" : { "last" : "Doe", "first" : "Jane" } }
}
{
  "_id" : "id003",
  "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person`, to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents, for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the

previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables

This page summarizes the default access-control expressions for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

| Action | Method | Permissions | Default Access-Control Expressions |
|--|---|---|---|
| Set default permissions on new column families when creating a JSON table. | Java API | -defaultreadperm -defaulttraverseperm -defaultwriteperm | u:<ID of the process> |
| | <code>maprcli table create</code> | | u:<user ID of table creator> |
| | <code>mapr dbshell</code> | | |
| | Control System | | |
| Set default permissions on new column families when editing a JSON table. | <code>maprcli table edit</code> | | Current ACEs |
| | Control System | | |
| Set permissions on a column family when creating the column family. | <code>maprcli table cf create</code> | -readperm -traverseperm -writeperm -indexperm | ACEs for -defaultreadperm, -defaulttraverseperm, and -defaultwriteperm |
| | Control System | | |
| Set permissions on a column family when editing the column family. | <code>maprcli table cf edit</code> | | Current ACEs |
| | Control System | | |
| Set permissions on individual fields. | <code>maprcli table cf colperm set</code> | | Inherited from column family or parent field |
| | Control System | | |

Defining ACEs Using the Access Control Expression Builder

Indicates how to build access control expressions (ACEs) using the Expression Builder.

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.

Here:

| | | |
|------------|-------------------|---|
| All | AND (&) operation | Indicates that all of the conditions must be met for public or user, group, and/or role to access the volume. |
| Any | OR () operation | Indicates that any one of the conditions must be met for public or user, group, and/or role to access the volume. |

2. Click:

| | |
|-----|---|
| + | To add an expression. |
| () | To add a subexpression. |
| x | To remove an expression or subexpression. |

3. Select Public or User, Group, or Role from the drop-down menu and:

- a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
- b) Enter name of the user, group, or role.

4. Click **Save Changes** to create an Access Control Expression.

Setting Whole Volume ACEs Using the CLI

See [Setting Whole Volume ACEs](#) on page 1576.

Setting Table ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Setting Stream ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Setting Data ACEs

Describes how to set ACE expressions using both the GUI and the CLI.

To set data [ACE](#) using the **Add Access Permission** window in the MapR Control System:

1. Specify the entities to set permissions for by doing one of the following:
 - Move the slider associated with **Public** to **Yes** to grant access to all users or to **No** to set permissions for individual users, groups, and/or roles.
 - Specify the users, groups, and/or roles to set permissions for in the associated fields.
 - Select the **Custom ACE** checkbox and enter the access control expression in the field.
2. Click **Add** to set permissions for all or for the specified users, groups, and/or roles.
3. Select the permissions to grant the specified users, groups, and/or roles from the **Permissions** column associated with the entities.
4. Click **Save Changes** to save the [ACE](#) settings.

Setting Whole Volume ACEs Using the CLI

See [Setting Whole Volume ACEs](#) on page 1576.

Setting Table ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Setting Stream ACEs Using the CLI

See [Enabling Table and Stream Authorizations with ACEs](#) on page 1578.

Granting Access Using Security Policy

Describes how to grant access to objects, using access control expressions in a security policy.

You can define access controls in a security policy using the Control System, CLI, and REST API.

Defining Access Controls in Security Policy Using the Control System

1. Log in to the Control System and go to the **Create Security Policy** page.
See [Creating a Security Policy](#) on page 1602 for more information.

2. Grant or deny access to all users (Public) or to specific users or groups in the **Data Access Control** Section.

The following types of access can be granted to all (Public) or specific users or groups:

| Object | Permission |
|-------------|--|
| Directories | <ul style="list-style-type: none"> • Read the contents of a directory. If you do not select this permission, mode bits are used to determine read access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, the parent directory (if any), and the file. • Lookup or list the contents in a directory. If you do not select this permission, mode bits are used to determine lookup access. To lookup a file of directory that is tagged with this security policy, the user must also have read permissions on the volume and the lookup permission on the directory. • List the contents of a directory. If you do not select this permission, mode bits are used to determine directorylist access. To list the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in the path (if any). • Add a file or subdirectory. If you do not select this permission, mode bits are used to determine permissions to create files or subdirectories. To add a child to a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, add child permission on the parent directory, and read and execute permissions on all directories in the path. • Delete a file or subdirectory. If you do not select this permission, mode bits are used to determine permissions to create files and/or subdirectories. To delete a child of a directory that is tagged with this security policy, the user must also have write permissions on the volume and delete child permission on the parent directory, and lookup permissions on all directories in the path. <p>For more information, see Managing File and Directory ACEs on page 1569.</p> |

| Object | Permission |
|--------|---|
| Files | <ul style="list-style-type: none"> • Read a file. If you do not select this permission, mode bits are used to determine read access to file. To read a file that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in path. • Write to a file. If you do not select this permission, mode bits are used to determine read access to the file. To write to a file that is tagged with this security policy, the user must also have write permissions on the volume, and lookup permission on all directories in the path. • Execute a file. If you do not select this permission, mode bits are used to determine execute access to the file. To execute a file that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in the path. <p>For more information, see Managing File and Directory ACEs on page 1569.</p> |
| Tables | <ul style="list-style-type: none"> • Read new column families that are created in the table. • Traverse to descend a hierarchy of column families. • Write to new column families that are created in the table. <p>For more information, see Enabling Table and Stream Authorizations with ACEs on page 1578.</p> |

3. Complete the steps to create the security policy.

See [Creating a Security Policy](#) on page 1602 for more information.

Granting Access Using the CLI and REST API

You can grant access to filesystem and HPE Ezmeral Data Fabric Database data objects using a security policy at the time of creating or modifying a security policy.

CLI

Use the following command to set access controls when creating a security policy:

```
/opt/mapr/bin/maprcli security policy
create -<ACEparam> <ACEsyntax>
```

Use the following command to specify [ACEs](#) when modifying a security policy:

```
/opt/mapr/bin/maprcli security policy
modify -<ACEparam> <ACEsyntax>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/security/policy/
create?
```

```
name=<policyName>&<ACEparam>=<ACEsyntax>' --user <username>:<pwd>
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/security/policy/
modify?
name=<policyName>&<ACEparam>=<ACEsyntax>' --user <username>:<pwd>
```

For more information on the [ACE](#) syntax, refer to the [ACE Syntax](#) on page 1565. The following sections describe the [ACE](#) parameter to specify for a specific type of access on a data object.

Directories

- `readdirace` to read the contents of a directory. See **Read** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information.
- `lookupdirace` to lookup or list the contents in a directory. See **Lookup** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information.
- `addchildace` to add a file or subdirectory. See **Add** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information.
- `deletechildace` to delete a file or subdirectory. See **Delete** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information.

For more information, see [Managing File and Directory ACEs](#) on page 1569.

Files

- `readfileace` to read a file. See **Read** for Files in the *Defining Access Controls in Security Policy Using the Control System* section for more information.
- `writefileace` to write to a file. See **Write** for Files in the *Defining Access Controls in Security Policy Using the Control System* section for more information.
- `executefileace` to execute a file. See **Execute** for Files in the *Defining Access Controls in Security Policy Using the Control System* section for more information.

For more information, see [Managing File and Directory ACEs](#) on page 1569.

JSON Tables

- `readdbace` to read new column families that are created in the table.
- `traversedbace` to descend a hierarchy of column families.
- `writedbace` to write to new column families that are created in the table.

For more information, see [Enabling Table and Stream Authorizations with ACEs](#) on page 1578 .

Creating Subnet Whitelists

Provides the procedure necessary to restrict access to cluster data.

To provide additional cluster security, you can limit cluster data access to a whitelist of trusted subnets. The `dfs.subnets.whitelist` parameter in `dfs.conf` accepts a comma-separated list of subnets in CIDR notation. When this parameter is set, the FileServer service only accepts requests from the specified subnets.

1. Edit `/opt/mapr/conf/dfs.conf` and modify the `dfs.subnets.whitelist` parameter.
2. Add a comma-separated list of subnets in CIDR notation.
3. Restart the FileServer.

Configuring Policy-Based Security

Starting in HPE Ezmeral Data Fabric 6.2.0 (EEP 7.0.0), HPE Ezmeral Data Fabric supports Policy-Based Security. Policy-Based Security is a mechanism that enables administrators to create security policies for simplified data management. Administrative users can create and manage security policies through the control system, `maprcli`, REST API, Hadoop and Linux commands, and Java APIs.

 **Important:** Some setup and configuration is required before you can create and manage security policies in a cluster. Read [Policy-Based Security](#) on page 670 for an overview of the process.

The following sections provide information and instruction for several tasks related to security policies:

Setting Global Configuration Options for Policy-Based Security

The CLDB stores global configuration settings for Policy-Based Security. Before creating any security policies, an administrator must designate a master security policy cluster through the `cldb.pbs.global.master` option.

You can modify global configuration settings through the `maprcli config save` command and the REST API.

The following table describes the global configuration settings related to Policy-Based Security:

| Parameter | Default | Description |
|---|---------|--|
| <code>cldb.pbs.max.security.policy</code> | 10000 | Maximum number of configured security policies allowed. Prevents users from arbitrarily creating numerous security policies, which could impact performance. |
| <code>cldb.pbs.global.master</code> | 0 | <p>(Required) Sets the master security policy cluster for the global namespace. You can configure a cluster to perform one of the following roles:</p> <ul style="list-style-type: none"> • Master — A master security policy cluster is required to create and manage security policies. Only one master security policy cluster should be chosen among clusters sharing data (via mirroring). • Member — On a cluster designated as Member, you can view the security policies available for tagging and tag data objects. <p>By default, the host is set to member (0) upon a new installation or upgrade. To set the host to master and enable the creation and modification of security policies, set the value of this property to 1.</p> <p> Note: Policy creation or modification on a member cluster is not allowed.</p> |

| | | |
|---|---|--|
| <code>cldb.pbs.audit.only.policy.check</code> | 0 | Set the value to 1 to enforce permissive mode across all volumes in the cluster. In permissive mode, the system only enforces resource-level ACEs and POSIX mode bits. The system checks the security policies for access and audits access denied events, but does not actually deny access. See Volume-Level Security Policy Enforcement Mode on page 678. |
| <code>cldb.pbs.access.control.enabled</code> | 1 | Enables and disables policy access controls (ACEs set in security policies) at the cluster-level. Set to 0 to disable policy access checks across all volumes in the cluster. The DataAce enforcement mode is automatically enabled. See Disabling Policy Access Controls at the Cluster-Level on page 1597 and Volume-Level Security Policy Enforcement Mode on page 678 for additional information. |

Setting the Policy-Based Security Mode Using the CLI and REST API

CLI

Run the following command to set a cluster as the Master for security policies:

```
maprcli config save -values
 '{"cldb.pbs.global.master":"1"}
```

REST

Send a request of type POST. For example, to designate a cluster as the Master for policy-based security creation and management, send a request similar to the following:

```
curl -k -X POST 'https://
 <hostname>:8443/rest/config/save?
 values={"cldb.pbs.global.master":"1"}'
 --user mapr:mapr
```

Setting the Policy-Based Security Mode Using the Control System

From the Control System, to set the cluster as the Master for security policies, perform the following steps:

1. Click the **Security Settings** icon.
2. Click the **PBS Mode** setting.
3. Select the **PBS Mode** as **Master** from the drop-down.
4. Click **Submit** to save the setting.

Changing the Policy-Based Security Global Master

To elect a new PBS master, perform the following steps:

1. Make sure that the cluster to be set as the master is still a member and not a master already. The value of `cldb.pbs.global.master` on this cluster should be 0.
2. Ensure that no policies are being created or modified on the current master cluster.
3. **Export** all policies from the current master cluster and then **import** them to the cluster you want to set as the new master.
4. Demote the current master cluster to a member by setting `cldb.pbs.global.master` to 0.
5. Promote the cluster to be set as the master to be the global master by setting `cldb.pbs.global.master` to 1.

Disabling Policy Access Controls at the Cluster-Level

You can disable policy access controls (ACEs set in security policies) at the cluster-level through the `cldb.pbs.access.control.enabled` option in the CLI and REST API and through the Ignore Policy Access Control option in the Control System.

Typically, you would only disable security policies at the cluster-level if they are causing issues. The `cldb.pbs.access.control.enabled` option is the fastest way for administrators to turn security policies off in a cluster.

 **CAUTION:** Before you disable policy access controls at the cluster-level, verify that POSIX mode bits or ACEs are directly applied to data objects to prevent unauthorized access to data. See [hadoop mfs](#) on page 5576, and refer to the `-getace` parameter.

The following table summarizes how security policy enforcement works when policy access controls are enabled and disabled in a cluster:

| Policy Access Controls | Description |
|------------------------|---|
| Enabled | <ul style="list-style-type: none"> • Default. • The system enforces all policy access controls (ACEs set in security policies). |
| Disabled | <ul style="list-style-type: none"> • The system does not enforce any policy access controls (ACEs set in security policies). ACEs set in security policies are not applied during any data operations in the cluster. • Policy access controls (ACEs set in the security policies) are disabled only for the indicated cluster. It does not matter if the cluster is a master or member security policy cluster; disabling the access controls does not affect the security policy settings and behaviors in any other cluster. • The system still enforces: <ul style="list-style-type: none"> • Resource controls (POSIX mode bits and ACEs) directly applied to data objects to determine data access. • Wire-level encryption and auditing settings in the security policies. |

The following sections describe how to enable and disable policy access controls (ACEs set in security policies) at the cluster-level:

Disable Policy Access Controls Using the Control System

1. Log in to the Control System and click  to display the **Security** settings page.
2. Move the slider associated with **Ignore Policy Access Control** to **Yes** to disable access control or **No** to enable access control using security policies.

If set to **Yes**, access control enforcement is disabled for all the security policies on the cluster. If set to **No**, you can set the enforcement mode setting at the volume level to **Policy Ace and Data Ace** or **Policy Ace Only** to enable access control enforcement using security policy ACEs.

Disable Policy Access Controls Using the CLI

- Run the `config save` on page 1768 command and set the `cldb.pbs.access.control.enabled` property to one of the following values:
 - 0 — disables security policy ACE enforcement for data operations in the cluster
 - 1 — enables security policy ACE enforcement for data operations in the cluster

Example:

```
/opt/mapr/bin/maprcli config save -values
'{"cldb.pbs.access.control.enabled":"0"}'
/opt/mapr/bin/maprcli config save -values
'{"cldb.pbs.access.control.enabled":"1"}'
```

Granting Security Policy Permissions

Permissions define which administrative users can create, view, and modify security policies. Administrators set the permissions on security policies through cluster-level and security policy-level ACLs.

Permission Levels

Policy-Based Security supports cluster-level and policy-level permissions.

The following table describes the two permission levels:

| Permission Level | Description |
|------------------|---|
| Cluster-level | <ul style="list-style-type: none"> Controls which administrators can create and view security policies in a cluster. Administrators with cluster-level <code>cp</code> permission can create security policies. Administrators with cluster-level <code>fc</code> permission can view all the security policies created. |
| Policy-level | <ul style="list-style-type: none"> Controls which administrators can view and modify security policies. Policy-level permissions are set on a per-policy basis. Permissions set on one security policy do not apply to other security policies. |

Administrators with cluster-level permissions can set cluster-level and security policy-level permissions through any of the following tools:

- Control System
- REST API commands
- `maprcli acl set|edit` commands
- `maprcli security policy create` commands

For additional information, refer to the section [Setting Permissions on Security Policies](#) on page 1602.

Important: Note these important considerations for security-policy permissions:

- On a fresh cluster install, the `root` user and the [data-fabric user](#) (typically named `mapr` or `hadoop` on each node) have `cp` permission. On an upgraded cluster, only the [data-fabric user](#) has `cp` permission.
- As the cluster owner, the [data-fabric user](#) (typically named `mapr` or `hadoop` on each node), has overriding permission on security policies, including the administrative ACLs. The data-fabric user can create, view, and modify security policies, regardless of the cluster-level and policy-level permission specified.
- By default, [administrators](#) do not have permission to create security policies. Administrators need cluster-level `cp` (`create security policy`) permission to create security policies. Administrators with cluster-level `a` (`admin`) permission can grant `cp` permission to themselves or other administrators.

Tip: You must designate a cluster as the global policy master before you create security policies. Setting a global policy master creates a global namespace for security policies. See [Security Policy Domain and Policy Management](#) on page 674.

- Any user with a valid data-fabric ticket can view security policy IDs and names. This allows non-administrative users to determine which security policies to apply to data objects.

Permission Codes

Cluster-level and security policy-level permission codes, set through ACLs, grant security policy access to administrators. An administrator (with cluster-level `a` (`admin`) and `cp` (`create security policy`) permissions) that creates a security policy has full control over the security policy unless they specifically grant other administrators access to the security policy through policy-level permissions.

The following sections describe the cluster-level and policy-level permission codes for security policy access:

Cluster-Level Permission Codes

The following table lists some cluster-level permission codes and how they relate to security policies. For a complete list of cluster-level permission codes, see [acl](#).

| Cluster-level permission code | Description |
|--|--|
| <code>a</code> (<code>admin</code>) | <ul style="list-style-type: none"> • Grants administrative access to cluster ACLs. • Can grant <code>create security policy</code> (<code>cp</code>) permission to themselves or other administrators. • Cannot view or edit the details of any security policy created by other admins; can only view the security policy ID and name. • Needs security policy-level permissions to view or edit security policies created by other admins. |

| Cluster-level permission code | Description |
|--------------------------------|--|
| cp (create security policy) | <p> Attention: Administrators need this permission to create security policies.</p> <ul style="list-style-type: none"> Administrators with a (admin) cluster-level permission can grant cp permission to themselves or other administrators. Administrators can view and edit all parts of the security policies they create, including the ACEs and permissions on the security policies. Grants the administrator that creates a security policy the following security <i>policy-level</i> permissions on the security policy: <ul style="list-style-type: none"> Full Control (fc) Admin (a) Read (r) Administrators who create security policies can override their access to the security policies by designating policy owners who can then manage the security policies. See policy create on page 1955, policy modify on page 1977, and refer to the <code>-user</code> parameter. |
| fc (full control) | <ul style="list-style-type: none"> Grants full control over the cluster and enables all cluster-level administrative options. Cannot change the cluster-level ACLs. Can view all security policies. Cannot create security policies. Cannot edit the details of any security policy unless specifically granted access to a security through policy-level permissions. |

Policy-Level Permission Codes

There are separate read (r) and edit (fc) permissions for policy owners, which allows some policy owners to view policy information, while others can edit policy information. This allows most administrators to administer the system without seeing the data and also prevents some policy owners from adding their credentials to the administrative ACLs to manipulate the data access ACEs.

Policy-level permissions are set on a per-policy basis. Permissions set on one security policy do not apply to other security policies.

The following table lists the policy-level permission codes needed to perform actions on security policies.

| Policy-level permission code | Description |
|------------------------------|--|
| a (admin) | <ul style="list-style-type: none"> Can view and modify permissions on the security policy. Cannot view or modify the security policy; can only view the security policy name and ID. |
| fc (full control) | <ul style="list-style-type: none"> Can view and edit any part of the security policy, including the data access ACEs. Cannot view or modify permissions on the security policy. |
| r (read) | Can view all parts of a security policy, but cannot modify any part of the security policy. |

Permissions Table

The following table lists the cluster-level and policy-level permissions needed to perform specific actions on security policies:

Note: Administrators who create a security policy have policy-level r, a, and fc permission on the security policy.

| Action | Cluster-Level | Policy-Level |
|--|---------------|--------------|
| Create a security policy | cp | -- |
| View details of all security policies | fc | -- |
| View details of a security policy | -- | r |
| View and edit permissions on a security policy (ACLs) | -- | a |
| View and edit the details of a security policy (ACEs, auditing, wire-level encryption) | -- | fc |

Setting Permissions on Security Policies

An administrator with cluster-level permissions can set security policy permissions during policy creation. Administrators with proper edit permissions on a security policy can modify security policy permissions.

Setting Permissions from the Control System

- To set permissions during security policy creation, see [Creating a Security Policy](#) on page 1602.
- To modify permissions on existing security policies, see [Modifying a Security Policy](#) on page 1610.

Setting Permissions from the CLI and REST API

- To grant cluster-level (`cp`) permission to a cluster administrator, see [acl](#) on page 1705.
- To set permissions during security policy creation, see [policy create](#) on page 1955.
- To modify permissions on existing security policies, see [policy modify](#) on page 1977, [acl set](#) on page 1708, and [acl edit](#) on page 1706.

Viewing Security Policy Permissions

To display cluster-level permissions, run:

```
/opt/mapr/bin/maprcli acl show -type cluster
```

To display policy-level permissions, run:

```
/opt/mapr/bin/maprcli security policy info -name <policy name> \
[-cluster cluster name ] [-output terse|verbose ] \
[ -columns <comma-separated list of column names> ] \
[ -expandaces true|false ] -json
```

Related concepts

[Example Using Security Policies](#) on page 690

This example demonstrates how to secure data, set permissions, and create, view, and modify a security policy.

Creating a Security Policy

Describes how to create a security policy using the Control System, CLI, and REST API.

Administrators with cluster-level `cp` ([create security policy](#)) permission can create security policies from the Control System, CLI, and REST API. Before creating security policies, you must first set a cluster as the [global policy master](#). After you create the policy, as the owner of the policy, you can edit all parts of the policy, including the [ACEs](#) on the policy. When you create a security policy, the policy is in a `disarmed` state with the `AllowTagging` setting set to `false`, by default, which makes the policy unavailable for tagging. You can modify the policy state to make it available for tagging. See [Changing the State of a Security Policy](#) on page 1618 for more information.

Creating a Security Policy Using the Control System

1. Log in to the Control System and click  to display the **Security** page.
2. Click **Create Policy** to display the **Create Security Policy** page.
3. Specify the following properties:

- a) Specify a name for the policy in the **Name** field and a brief description of the policy in the **Description** text box.
Security policy names must be unique within the cluster and must contain only alphanumeric characters, hyphen (-), and underscore (_). The maximum length of the security policy name is 32 characters.
- b) Specify whether (**Yes**) or not (**No**) to enable wire-level encryption by moving the slider.
By default, this setting is enabled on secure clusters and disabled on insecure clusters.
- c) Specify whether (**Yes**) or not (**No**) to enable auditing by moving the slider.
If auditing is enabled, you can choose the **Default** radio button to accept the default list of operations to audit or choose the **Custom** radio button to select/deselect the operations to audit.
- d) Specify whether (**Yes**) or not (**No**) to allow data-fabric data objects to be tagged with this security policy.
For more information, see [Changing the State of a Security Policy](#) on page 1618.

4. Select one of the following access control states in the **Data Access Control** section:

- Armed — enforce the [ACEs](#) in the security policy on the data-fabric data objects tagged with the policy
- Disarmed — do not enforce the [ACEs](#), if any, in the policy on the data-fabric data objects tagged with the policy
- Denied — to deny all access to the data-fabric data objects tagged with the policy and log any attempt to access

For more information, see [Changing the State of a Security Policy](#) on page 1618.

5. Set data access controls by clicking **Add Access Permissions** in the **Data Access Control** section. The **Add Access Permission** window displays.

You can either set the policy to be `Public` or customize the access permissions. Setting the **Public** slider to `Yes`, makes this policy accessible to everyone. Leave this slider at its default setting of `No` to customize access permissions.

- a) Enter comma-separated list of users, groups, or roles to grant access to in the **Users**, **Groups**, and **Roles** text boxes respectively or select the **Custom ACE** checkbox to manually enter the access control expression in the text box below.
For more information on how to build the custom access control expression, see [Managing Access Control Expressions](#) on page 1565.
- b) Click **Next: Select Permissions** to display the **Add Access Permissions** page.
The following table describes the permissions that can be granted to the specified users, groups, and/or roles in this page:

| Object | Permission |
|-------------|---|
| Directories | <ul style="list-style-type: none"> <li data-bbox="818 216 1458 443"> <p>• Read the contents of a directory. If this is not selected, mode bits are used to determine read access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, the parent directory (if any), and the file.</p> <p>This is the same as the <code>readdirace</code> property in the CLI.</p> <li data-bbox="818 474 1458 701"> <p>• Lookup or list the contents in a directory. If this is not selected, mode bits are used to determine lookup access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume and the directory.</p> <p>This is the same as the <code>lookupdirace</code> property in the CLI.</p> <li data-bbox="818 732 1458 1003"> <p>• Add Child to add a file or subdirectory. If this is not selected, mode bits are used to determine permissions to create files and/or subdirectories. To add child to a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, add child permission on the parent directory, and read and execute permissions on all directories in the path.</p> <p>This is the same as the <code>addchildace</code> property in the CLI.</p> <li data-bbox="818 1035 1458 1346"> <p>• Delete Child to delete a file or subdirectory. If this is not selected, mode bits are used to determine permissions to create files and/or subdirectories. To delete a child of a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, delete child permission on the parent directory, and read and execute permissions on all directories in the path.</p> <p>This is the same as the <code>deletchildace</code> property in the CLI.</p> <p data-bbox="818 1377 1458 1423">For more information, see Managing File and Directory ACEs on page 1569.</p> |

| Object | Permission |
|--------|---|
| Files | <ul style="list-style-type: none"> <li data-bbox="818 216 1458 323">• Read a file. If this is not selected, mode bits are used to determine read access to file. To read a file that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the <code>readfileace</code> property in the CLI. <li data-bbox="818 422 1458 529">• Write to a file. If this is not selected, mode bits are used to determine read access to the file. To write to a file that is tagged with this security policy, the user must also have write permissions on the volume. This is the same as the <code>writefileace</code> property in the CLI. <li data-bbox="818 627 1458 735">• Execute a file. If this is not selected, mode bits are used to determine execute access to the file. To execute a file that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the <code>executefileace</code> property in the CLI. <p data-bbox="818 854 1458 907">For more information, see Managing File and Directory ACEs on page 1569.</p> |

- c) Select the checkbox associated with the individual permission to grant that type of permission to the user, group, and/or role or click the following:
- **Reads** to grant:
 - read permission on directories and files
 - lookup permission on directories

This is the same as the `readaces` property in the CLI.
 - **Writes** to grant:
 - write permission on files
 - add and delete child permissions on directories

This is the same as the `writeaces` property in the CLI.
 - **Executes** to grant execute permission on files.

This is the same as the `executefileace` property in the CLI.
- d) Click **Add** to add the data access permissions to the policy.
- e) Proceed to the next step to set up access controls on the policy or click one of the following to add additional data access controls:
- **Add Another** button to repeat steps 4.a to 4.d to add access permission for other users, groups, and/or roles.
 -  to create a copy of the data access controls, which can then be modified by clicking .

6. Grant users and/or groups permissions to perform administrative operations on the policy in the **Policy Administration Control** section.

- a) Select the entity type, user or group, from the **Type** drop-down list and enter the entity name in the **Entities** field.
- b) Select the checkbox associated with the following permissions to grant the entity the type of permission:
 - Read access for the policy
 - Admin access to set and modify ACLs on the policy
 - Full control over the policy
- c) Proceed to the next step or click one of the following to add access controls for other users and/or groups:
 - **Add Another** button to repeat steps 5.a and 5.b to add access controls for other users and/or groups.
 -  to create a copy of the access control.

7. Click **Save** to create the security policy.

Creating a Security Policy Using the CLI and REST API

CLI

The basic command to create a security policy is the following:

```
/opt/mapr/bin/maprcli security policy
create -name <policyName>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/security/policy/
create?name=<policyName>' --user
mapr:mapr
```

For more information, see [policy create](#) on page 1955.

Viewing the List of Security Policies

View the list of security policies using the Control System and extended attributes.

You can retrieve and view the list of security policies using the Control System, the CLI, and REST API.

Viewing the List of Security Policies Using the Control System

- Log in to the Control System and go to the **Security Policies** tab in the **Admin > Cluster Settings** page.

The list of security policies display in the **Security Policies** pane. You can filter the list of policies by one of the following Access Control statuses: All, Armed, Disarmed, Denied. For each security policy, the page displays the following:

| Column Name | Description |
|--------------------|-------------------------|
| Policy Name | The name of the policy. |

| Column Name | Description |
|-----------------------|--|
| Access Control | Indicates whether access control is enforced by the ACE setting in the policy: <ul style="list-style-type: none"> • Armed • Disarmed • Denied See Changing the State of a Security Policy on page 1618. |
| Tagging | Indicates whether data objects can be tagged with the policy. See Changing the State of a Security Policy on page 1618. |
| Description | The description of the policy. |
| Date Created | The date when the policy was created. |
| Date Modified | The date when the policy was last modified. |

Viewing the List of Security Policies Using the CLI and REST API

CLI

The basic command to retrieve the list of security policies that you are allowed to view is:

```
/opt/mapr/bin/maprcli security policy
list -json
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://<host>:8443/
rest/security/policy/list' --user
mapr:mapr
```

For more information, see [policy list](#) on page 1967.

Retrieving Security Policies Using Extended Attributes

Describes how to retrieve security policies that are tagged using extended attributes.

Linux Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To retrieve extended attributes, you run one of the following commands:

- `getfattr [-hRLP] -n name pathname...`
- `getfattr [-hRLP] -d [-m pattern] pathname...`

These commands retrieve both policy tags as well as other extended attributes.

For example, to retrieve all extended attributes for the file `/mapr/lab/foo.txt`, use:

```
getfattr -d /mapr/lab/foo.txt
# file: /mapr/lab/foo.txt

security.mapr.policy="Lab_Security_Pol
```

```

icy,Sensitive_data"  policy tag
user.test="test"
                other
attributes

```

To retrieve the security policy tags without retrieving the rest of the extended attributes, use the `-n` option to match the security policy extended attribute name:

```

getfattr -d -n security.mapr.policy /
mapr/lab/foo.txt
# file: /mapr/lab/foo.txt

security.mapr.policy="Lab_Security_Pol
icy,Sensitive_Data"

```

Hadoop Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To retrieve security policy attributes, use the command:

```

hadoop fs -getfattr [-R] -n
security.mapr.policy | -d <pathname>

```

For example, to retrieve security policy attributes for the file `/mapr/lab/foo.txt`, use:

```

hadoop fs -getfattr -n
security.mapr.policy | -d /mapr/lab/
foo.txt

```

Alternatively, use the Hadoop MFS command to retrieve security policy attributes.

```

hadoop mfs -getsecuritypolicytag [-R]
<path>

```

Java APIs

To retrieve security policy attributes, use the following Java APIs:

- `public byte[] getXAttr(Path path, String name) throws IOException` Gets an extended attribute name and value for a file or directory. The name must be prefixed with the namespace, followed by ".". For security policy tags, the extended attribute name is `security.mapr.policy`.
- `public Map<String,byte[]> getXAttrs(Path path) throws IOException` Gets all the extended attribute name/value pairs for a file or directory. Only those extended attributes that the logged-in user has permissions to view, are returned.

- `public Map<String,byte[]> getXAttrs(Path path, List<String> names) throws IOException` Gets the extended attributes specified by the given list of names. Only those extended attributes that the logged-in user has permissions to view, are returned.
- `public List<String> listXAttrs(Path path) throws IOException` Gets all the extended attribute names for a file or directory. Only those extended attribute names that the logged-in user has permissions to view, are returned.

C APIs

Security policies use a special format for the extended attribute name, and is always set to the keyword `security.mapr.policy`.

Retrieve extended attribute values

The `getxattr`, `lgetxattr`, and `fgetxattr` system calls are used to retrieve an extended attribute value associated with a file system object, which may be either a file or directory. The synopsis of these commands are as follows. For details, refer to the `getxattr(2)` Linux manual page.

NAME

`getxattr`, `lgetxattr`, `fgetxattr` - retrieve an extended attribute value

SYNOPSIS

```
#include <sys/types.h>
#include <attr/xattr.h>
ssize_t getxattr (const char *path,
const char *name, void *value,
size_t size);
ssize_t lgetxattr (const char *path,
const char *name, void *value,
size_t size);
ssize_t fgetxattr (int filedes,
const char *name, void *value,
size_t size);
```

List extended attribute values

Use the `listxattr`, `llistxattr`, and `flistxattr` to list extended attribute names. For more details, refer to the `listxattr(2)` Linux manual page.

NAME

`listxattr`, `llistxattr`, `flistxattr` - list extended attribute names

```
#include <sys/types.h>
#include <attr/xattr.h>
ssize_t listxattr (const char *path,
char *list, size_t size);
ssize_t llistxattr (const char
```

```
*path, char *list, size_t size);
    ssize_t flistxattr (int
filedes, char *list, size_t
size);
```

Modifying a Security Policy

Describes how to modify a security policy.

You can modify a security policy using the Control System, the CLI, and REST API. You can change the following settings when you edit a security policy:

- Security policy state
- Wire-level encryption and auditing
- Data access control
- Security policy administration control

If you modify a security policy that is currently tagged (or in use), changes to the policy are enforced within **5 minutes**.

Modifying a Security Policy Using the Control System

1. Log in to the Control System and go to the **Security Policies** tag in the **Admin > Cluster Settings** page to view the list of security policies that you are allowed to see.
2. Click the name of the security policy to display the **Edit Security Policy** page.
3. Make changes to the security policy status by selecting the state to transition to from the drop-down list of statuses next to the **Edit Security Policy** label.
See [Changing the State of a Security Policy](#) on page 1618 for more information on the various states and the valid state to which you need to transition a security policy.
4. Modify any of the following properties:

| | |
|-------------------------------------|---|
| Description | The description of the policy. The maximum length of the description is 128 characters. |
| Enable Wire-level Encryption | The wire-level encryption setting. You can enable (Yes) or disable (No) wire-level encryption by moving the slider. |
| Enable Audit Operations | The audit setting for files, directories, tables, and streams. You can enable (Yes) or disable (No) auditing of operations on files, directories, tables, and streams by moving the slider. |
| Audit Operations | (Visible only if auditing is enabled) The list of file, directory, table, and stream operations to audit. You can select the default list of operations to audit by choosing the Default radio button or select specific file, directory, table, and streams operations to audit by choosing the Custom radio button. |
| Allow Tagging | The setting to allow (Yes) or disable (No) tagging for this security policy. If Yes , users can tag data objects with this policy. If No , users cannot tag data objects with this security policy. See Changing the State of a Security Policy on page 1618 for more information. |

5. Make changes to data access control as needed in the **Data Access Control** section.
 - a) Select one of the following state for access control.

- **Disarmed** — indicates access control is not enforced by the [ACE](#) settings defined in the policy
- **Armed** — indicates access control is enforced by the [ACE](#) settings defined in the policy
- **Denied** — indicates access control is always denied.

For more information on access control states, see [Changing the State of a Security Policy](#) on page 1618.

- b) Set new or modify existing [ACEs](#) for users, groups, and/or roles.

You can:

- Create a copy of an existing [ACE](#) setting for an entity (user, group, or role) by clicking , which you can then modify.
- Remove [ACEs](#) for an entity (user, group, or role) by clicking .
- Set new [ACEs](#), if you have not set [ACEs](#) before, for users, groups, or roles by clicking **Add Access Permission**.
- Add [ACEs](#) for another user, group, or role by clicking **Add Another**.
- Modify an existing [ACE](#) setting for an entity (user, group, or role) by clicking .

When you click **Add Access Permission**, **Add Another**, or , the **Add Access Permission** window displays. You can:

1. Enter new or modify the existing comma-separated list of users, groups, or roles to grant access to in the **Users**, **Groups**, and **Roles** text boxes respectively or select the **Custom ACE** checkbox to manually enter the [ACE](#) in the text box that appears.

For more information on how to build the custom access control expression, see [Managing Access Control Expressions](#) on page 1565.

2. Click **Next: Select Permissions** to display the **Add Access Permissions** page.

The following table describes the permissions that can be granted to the specified users, groups, or roles in this page:

| Object | Permission |
|-------------|--|

3. Select the checkbox associated with the individual permission to grant that type of permission to the user, group, or role, or click the following:

- **Reads** to grant:

- read permission on directories, files, and tables
- lookup permission on directories
- traverse column family permission on tables

This is the same as the `readaces` property in the CLI.

- **Writes** to grant:

- write permission on files and tables
- add and delete child permissions on directories

This is the same as the `writeaces` property in the CLI.

- **Executes** to grant execute permission on files.

This is the same as the `executefileace` property in the CLI.

4. Click **Add** to add the data access permissions to the policy.

6. Make changes as needed to perform administrative operations on the policy in the **Policy Administration Control** section.

You can:

- Create a copy of an existing policy administration control setting for an entity by clicking , which you can then modify.

- Remove a policy administration control setting for an entity by clicking .
- Add a policy administration control setting for another user or group by clicking **Add Another**.
- Modify an existing policy administration control setting for an entity.

To add or modify an existing policy administration control setting for an entity, you can:

- Select new or modify an existing entity type, user or group, from the **Type** drop-down list, or enter a new or modify an existing entity name in the **Entities** field.
 - Select or deselect the checkbox associated with the following permissions to grant or deny (respectively) that type of permission for the entity:
 - Read access for the policy
 - Admin access to set and modify ACLs on the policy
 - Full control over the policy

7. Click **Save** for the changes to take effect.

Modifying a Security Policy Using the CLI and REST API

CLI

The basic command to modify an existing security policy is:

```
/opt/mapr/bin/maprcli security policy
modify -name <policyName> -json
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<host>:port/rest/security/policy/
modify?name=<policyName>' --user
mapr:mapr
```

For more information, see [policy modify](#) on page 1977.

Removing Security Policies

You can remove security policies associated with data objects using the Control System, CLI, or REST API.

 **Warning:** You must remove a security policy from data objects before you retire the policy. The system will deny all access to data objects tagged with a retired security policy. See [Changing the State of a Security Policy](#) on page 1618.

The following table lists the methods for removing security policies for each type of data object and provides links to command references where applicable:

| HPE Ezmeral Data Fabric Component | Data Object | How to Remove Security Policies |
|------------------------------------|-------------|---|
| HPE Ezmeral Data Fabric Filesystem | Volume | <ul style="list-style-type: none"> • Control System (See Removing Security Policies Using the Control System on page 1615 below) • <code>maprcli volume modify -securitypolicy "</code> |

| HPE Ezmeral Data Fabric Component | Data Object | How to Remove Security Policies |
|-----------------------------------|---------------|--|
| | Directory | <ul style="list-style-type: none"> Extended attributes using Linux, Hadoop, Java API, or C API commands (See Removing Security Policies Using Extended Attributes on page 1616 below) <code>hadoop mfs -removeallsecuritypolicytag [-R] <path></code> <code>hadoop mfs -removesecuritypolicytag [-R] <comma-separated list of security policy tags> <path></code> |
| | File | <ul style="list-style-type: none"> Same as directory |
| HPE Ezmeral Data Fabric Database | JSON Table | <ul style="list-style-type: none"> Control System (See Removing Security Policies Using the Control System on page 1615 below) <code>maprcli table securitypolicy remove -path <path> -securitypolicy <comma-delimited list of policies></code> |
| | Column family | <ul style="list-style-type: none"> Control System (See Removing Security Policies Using the Control System on page 1615 below) <code>maprcli table cf securitypolicy remove -path <path> -cfname <column family name> -securitypolicy <comma-delimited list of policies></code> |
| | Field | <ul style="list-style-type: none"> Control System (See Removing Security Policies Using the Control System on page 1615 below) <code>maprcli table cf column securitypolicy remove -path <path> -cfname <column family name> -column <JSON table field> -securitypolicy <comma-delimited list of policies></code> |

The following sections describe how to remove security policies from data objects through the Control System and extended attributes.

Removing Security Policies Using the Control System

You can remove security policies from volumes, JSON tables, JSON column families, and JSON fields using the Control System.

Removing Security Policies from Volumes

1. Log in to the Control System, and select **Data > Volumes**.

Note: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. On the **Volumes** page, locate and select the volume that is tagged with the security policy you want to remove.
3. Click **Edit Volume**.

Removing Security Policies from Tables, Column Families, and Fields

4. In the **Security** section, click on the red circle (-) next to the security policy associated with the volume to remove the security policy.
 5. Click **Save Changes**.
1. Log in to the Control System, and select **Data > Tables**.
 2. In the **Tables** view, locate and select the table with the security policy you want to remove. If you want to remove a security policy from a column family or field, select the table that contains the column family or field.
 3. On the **Summary** tab, locate the **Security** section.
 4. In the **Security** section, click the red circle (-) next to the security policy associated with the table to remove the security policy.
 - To remove a security policy from a column family, click on the table to expand the view. Click the red circle (-) next to security policy associated with the column family to remove the security policy.
 - To remove a security policy from a field, click the column family name to expand the view, and remove the security policy.

Removing Security Policies Using Extended Attributes

The following sections describe how you can use extended attributes to remove security policies.

Linux Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To remove the extended attribute by name, run the `setfattr` command with the `-x` option:

```
setfattr [-h] -x name pathname...
```

Remove all security policy tags

Use the `-x` option to remove *all* security policy tags from the specified File Store object. For example, to remove all security policies for the file `/mapr/lab/foo.txt`, use the following command:

```
setfattr -x security.mapr.policy /mapr/lab/foo.txt
```

Replace a security policy tag

The `setfattr` command replaces any existing security policy tags with the specified policy tags. For example, to remove a security policy named `Sensitive_Data` tagged to a data object, but keep the security policy named `Lab_Security_Policy` tagged to the data object, specify the `Lab_Security_Policy` tag in the `-v` argument without the `Sensitive_Data` policy tag:

```
setfattr -n security.mapr.policy -v "Lab_Security_Policy" /mapr/lab/foo.txt
```

Hadoop Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To remove security policy tags, run the `hadoop fs -setfattr` command with one of the following parameters:

- `-x` to remove all security policy tags
- `-v` to remove the specified security policy tags

For example, to remove all the security policy tags for the file `/mapr/lab/foo.txt`, use:

```
hadoop fs -setfattr -x
security.mapr.policy /mapr/lab/foo.txt
```

To remove some security policy tags, and keep the rest, use the `-v` parameter.

This parameter replaces existing security policy tags with the ones specified.

For example, if there two security policies tagged to the file `/mapr/lab/foo.txt`, namely `Sensitive_Data` policy and `Lab_Security_Policy`, and you want to remove the `Sensitive_Data` policy tag, specify just the `Lab_Security_Policy` tag in the `-v` parameter:

```
hadoop fs -setfattr -n
security.mapr.policy -v
"Lab_Security_Policy,Sensitive_Data" /
mapr/lab/foo.txt
```

Alternatively, use the `hadoop mfs` command to remove security policies.

For example, to remove particular security tags, use the format:

```
hadoop mfs [-removesecuritypolicytag
[-R] <comma-separated list of
security policy tags> <path>]
```

To remove all security tags, use the format:

```
hadoop mfs
[-removeallsecuritypolicytags [-R]
<path>]
```

Java APIs

To remove an extended attribute associated with a file or directory, use the following Java API:

```
public void removeXAttr(Path path,
String name) throws IOException
```

The name must be prefixed with the namespace, followed by `."`. For data-fabric security policy tags, the attribute name is `security.mapr.policy`.

C APIs

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To remove an extended attribute value, use the `removexattr` or `fremovexattr` system calls. The

brief synopsis is as follows. For more details, refer to the `removexattr(2)` Linux manual page.

NAME

`removexattr`, `fremovexattr` -- remove an extended attribute value

SYNOPSIS

```
#include <sys/xattr.h>
int removexattr(const char *path,
const char *name, int options);
int fremovexattr(int fd, const char
*name, int options);
```

Changing the State of a Security Policy

The security policy state indicates whether users can apply a security policy to data objects and whether the system enforces the ACEs set in the security policy. An administrator can change the state of a security policy through the `allowtagging` and `accesscontrol` parameters when creating or modifying a security policy from the `maprcli` or equivalent REST API commands.

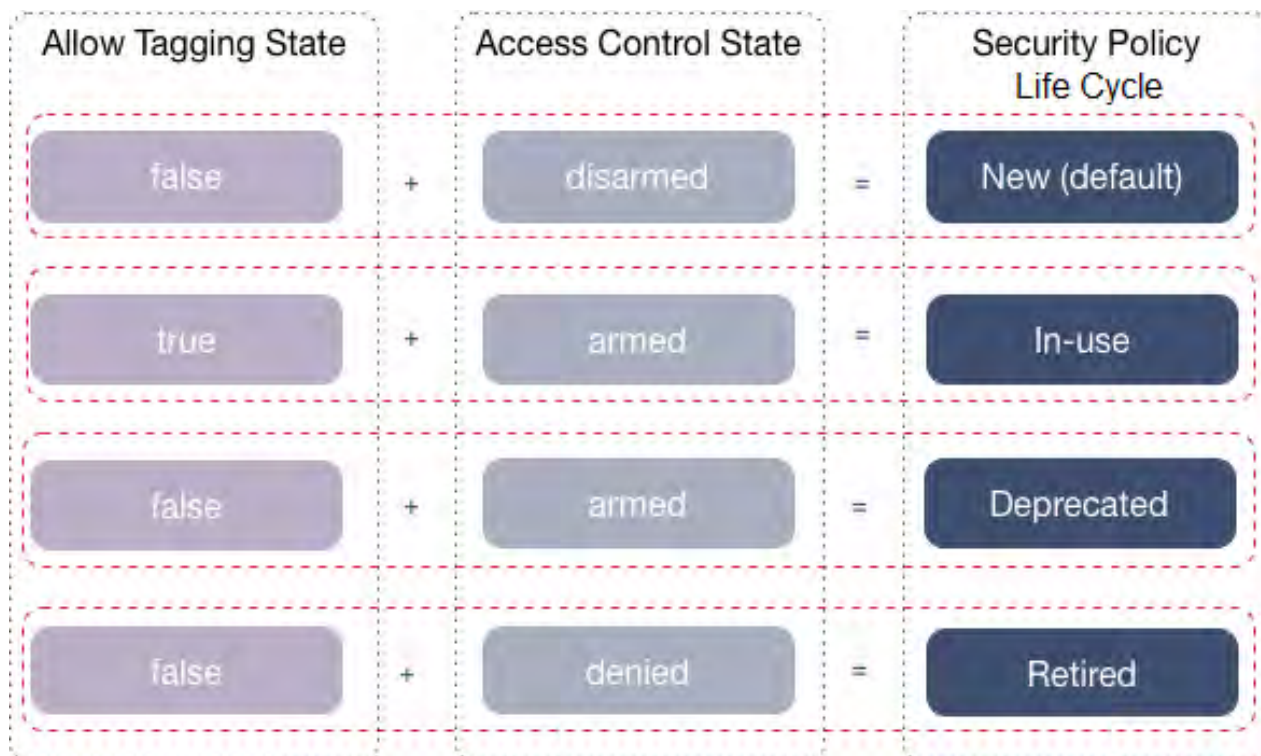

The following table describes the `allowtagging` and `accesscontrol` parameters:

| Parameter | Default | Accepted Values and Descriptions |
|---------------------------|---------|--|
| <code>allowtagging</code> | false | <p>false</p> <ul style="list-style-type: none"> Disables tagging; users cannot apply the security policy to data objects. This is the default setting when an administrator creates a security policy, unless the administrator changes the setting when creating the security policy. In cases where a security policy was active (<code>allowtagging=true</code>), but needs to be deprecated, modify the policy and set <code>allowtagging=false</code>. This prevents users from tagging any other data objects with the policy. Note that the system will continue to enforce the security controls set in the security policy for data objects that were already tagged with the security policy. <p>true</p> <ul style="list-style-type: none"> Enables tagging; users can apply the security policy to data objects. When creating or modifying a security policy, an administrator can set <code>allowtagging=true</code>. When creating a security policy, the administrator may want to set this parameter to true to test the security settings in the policy, or to use tagging tools to discover data content and tag the data. An administrator can set <code>allowtagging=true</code> to enable a deprecated security policy. |

| Parameter | Default | Accepted Values and Descriptions |
|---------------|----------|--|
| accesscontrol | Disarmed | <p>Disarmed</p> <ul style="list-style-type: none"> This is the default setting when an administrator creates a security policy, unless the administrator changes the setting when creating the security policy. The system does not enforce the ACEs set in the security policy during data operations on the data objects tagged with the security policy. <p>Armed</p> <ul style="list-style-type: none"> The system enforces the ACEs set in the security policy during data operations on the data objects tagged with the security policy. When creating or modifying a security policy, an administrator can set <code>accesscontrol=Armed</code>. When creating a security policy, the administrator may want to set this parameter to <code>Armed</code> to verify that the ACEs are correctly defined in the policy and the system correctly enforces them. An administrator can set <code>accesscontrol=Armed</code> to enforce ACEs set in a deprecated security policy, and the system will continue to enforce ACEs set in the security policy for all data operations on the data objects tagged with the policy. <p>Denied</p> <ul style="list-style-type: none"> Denies all access to data objects tagged with the security policy. |

Changing the State of a Security Policy

An administrator can change the state of a security policy through the `allowtagging` and `accesscontrol` parameters to move a security policy through a life cycle, as shown in the following image where the security policy moves from new to retired.

The following table describes each of the stages in the security policy life cycle:

| Stage | Description |
|---------------|---|
| New (default) | <ul style="list-style-type: none"> • Default upon security policy creation. • Users cannot tag data objects with the security policy. • The system does not enforce ACEs set in the security policy. |
| In-use | <ul style="list-style-type: none"> • Users can tag data objects with the security policy. • The system enforces all security controls set in the security policy during data operations on data objects tagged with the security policy. Security controls set in the policy can include ACEs, auditing, and wire-level encryption. |
| Deprecated | <ul style="list-style-type: none"> • Users can no longer tag the security policy to data objects. • The system still enforces the security controls set in the security policy for all data operations on the data objects tagged with the policy; however, users cannot tag any additional data objects with the policy. |
| Retired | <ul style="list-style-type: none"> • Users cannot tag the security policy to data objects. • All data operations on the data objects tagged with the security policy are denied by the system. <p> Warning: Remove a security policy from data objects before retiring it. The system denies all access to data objects tagged with a retired security policy. See Removing Security Policies on page 1614.</p> |

Related concepts

[Tagging Data Objects with Security Policies](#) on page 1621

Once security policies are configured (with tagging enabled), permitted users can associate the security policies with data objects through the Control System, CLI, and REST API. A data object can be associated with one or multiple security policies.

Tagging Data Objects with Security Policies

Once security policies are configured (with tagging enabled), permitted users can associate the security policies with data objects through the Control System, CLI, and REST API. A data object can be associated with one or multiple security policies.

 **Attention:** Verify that the security policy state is set to allow tagging. By default, a security policy has `allowtagging=false` and `accesscontrol=Disarmed` when created. See [Changing the State of a Security Policy](#) on page 1618.

Supported Data Objects

The following table lists the data objects in the data-fabric platform that users can tag with security policies:

| filesystem | HPE Ezmeral Data Fabric Database |
|---|--|
| <ul style="list-style-type: none"> Volumes Directories Files | <ul style="list-style-type: none"> JSON tables JSON table column families JASON table fields <p> Note: If you upgrade your data-fabric cluster to version 6.2.x from a pre-6.2.0 version, you can apply security policies to existing tables if Policy-Based Security is enabled. See Policy-Based Security Quick Reference on page 1643.</p> |

Permissions Required to Tag Data Objects

Users must have the required permissions to tag security policies to data objects. Permission requirements vary depending on the data-fabric platform core component.

The following table lists the users that can tag data objects in the data-fabric filesystem and database:

| filesystem | HPE Ezmeral Data Fabric Database |
|---|--|
| <ul style="list-style-type: none"> Owner of the data object Data Fabric administrator (typically <code>mapr</code>) Superuser (<code>root</code>) <p>The superuser cannot tag filesystem objects when the <code>cldb.reject.root</code> flag is set.</p> | <ul style="list-style-type: none"> Data Fabric administrator (typically <code>mapr</code>) User with ACE administrative access (<code>adminaccessperm</code> permission) |

The following sections describe how to tag data objects in the filesystem and HPE Ezmeral Data Fabric Database with security policies

Tagging Volumes, Directories, and Files with Security Policies

Associate security policies with data objects in the file system, including volumes, directories, and files. You can associated up to sixteen security policies with a data object in the file system.

Tagging Volumes

Associate security policies when you create or modify a volume from the Control System, CLI, or REST API. Note that security policies are not supported with tenant volumes and tenant volume resources, and tagging via `nfsv3/nfsv4` is not supported since these protocols do not support extended attributes.

You can associate security policies with a volume, the volume mount path, or both the volume and the volume mount path. However, you can only tag a volume mount path through the `maprcli create`

`volume` command with the `rootdirsecuritypolicy` option. You cannot tag a volume mount path through the Control System.

Important: A snapshot contains the security policy that was tagged on the volume when the snapshot was taken. If you modify the security policy on the volume after you create the snapshot, the snapshot will continue to use the older security policy.

CLI

The basic command to tag a volume with a security policy is:

```
/opt/mapr/bin/maprcli volume
create -name <volName> -path
<mountPath> -securitypolicy
<policy1,policy2,...>
```

REST API

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<volPath>&security
Policy=<policy>' --user mapr:mapr
```

Tip: For more information, including a complete list of required and optional properties, see [volume create](#) on page 2190.

Control System

1. Log in to the Control System and go to the [Create New Volume](#) page or the [Edit Volume](#) page.
2. Enter or select the name of the security policies to associate with the volume in the **SECURITY POLICIES** field under the **Security** section.
3. Complete the steps to create or modify the volume.

Tip: See [Creating a Volume](#) on page 941 or [Modifying a Volume](#) on page 970 for more information.

Tagging Directories and Files

Associate security policies with directories and files using `hadoop mfs`, extended attributes, and Java APIs.

`hadoop mfs`

Use the following command syntax to tag a directory or file with one or more security policies:

```
hadoop mfs -setsecuritypolicytag
<policyName> <filePath>
```

Tip: For more information, see [hadoop mfs](#) on page 5576.

Extended attributes

- For **Linux**, use the `setfattr` command to tag and restore security attributes. Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.
- For **Hadoop**, security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.
- For **Java and C APIs**, security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

| Comm and Type | | |
|---------------|--|--|
| Linux | Tag an extended attribute name | Use the following command to set an extended attribute name on a file/directory and/or a FUSE-mounted file path: <pre data-bbox="1149 842 1455 978">setfattr {-n attribute-name} [-v value] [-h] pathToDataObject</pre> |
| | Associate one or more security policies | To associate one or more security policies with the file <code>/mapr/lab/foo.txt</code> , specify a comma-separated list of security policy names. For example, to associate two security policies named <code>Lab_Security_Policy</code> and <code>Sensitive_Data</code> to <code>/mapr/lab/foo.txt</code> , use: <pre data-bbox="1149 1367 1455 1541">setfattr -n security.mapr.policy -v "Lab_Security_Policy,Sensitive_Data" /mapr/lab/foo.txt</pre> |

| Comm and Type | | |
|---------------|---|--|
| | <p>Replace security policies</p> | <p>The <code>setfattr</code> command replaces any existing security policies with the specified policies. To remove the <code>Sensitive_Data</code> policy and keep the <code>Lab_Security_Policy</code>, specify the <code>Lab_Security_Policy</code> in the <code>-v</code> argument without the <code>Sensitive_Data</code> policy:</p> <pre data-bbox="1149 653 1458 852">setfattr -n security.mapr.poli cy -v "Lab_Security_Poli cy" /mapr/lab/ foo.txt</pre> |

| Comm and Type | | |
|---------------|--|---|
| | <p>Associate a security policy with a directory</p> | <p>Use a similar command to associate a security policy to a directory:</p> <pre data-bbox="1144 378 1445 567">setfattr -n security.mapr.policy -v "Lab_Security_Policy,Sensitive_Data" /mapr/lab</pre> <p>When a directory is tagged with one or more security policies:</p> <ul data-bbox="1144 672 1445 1386" style="list-style-type: none"> • The data access ACEs in the security policy tags apply when files and sub-directories are created within that directory. • These tags are inherited by new files and directories created within the directory, if the <code>setinherit</code> flag is set to <code>true</code> (default). • If the <code>setinherit</code> flag is set to <code>false</code>, then new files and directories are created with no tags. The files and directories get the default ACE, which is the empty string for all access types; POSIX mode bits are set on the files and directories in the traditional way. |

| Command Type | | |
|--------------|--------------------------------|--|
| Hadoop | Set security policy attributes | <pre>hadoop fs -setfattn -n security.mapr.poli cy -v comma-separated list of policy names path</pre> <p>The <code>-v</code> parameter is mandatory, and is a comma-separated list of security policy tags.</p> <p>For example, to associate a security policy <code>Lab_Security_Policy</code> with the file <code>/mapr/lab/foo.txt</code>, use the command:</p> <pre>hadoop fs -setfattn -n security.mapr.policy -v "Lab_Security_Policy " /mapr/lab/foo.txt</pre> <p>If security policy tags already exist for the specified object, this command replaces any existing security policies with the specified policies. Assume that there are two security policies - <code>Sensitive_Data_Policy</code> and <code>Lab_Security_Policy</code> tagged to the file <code>/mapr/lab/foo.txt</code>.</p> <p>To remove <code>Sensitive_Data_Policy</code>, and keep <code>Lab_Security_Policy</code>, specify only <code>Lab_Security_Policy</code> in the <code>-v</code> parameter:</p> <pre>hadoop fs -setfattn -n security.policy -v "Lab_Security_Policy " /mapr/lab/foo.txt</pre> <p>You can use the <code>hadoop mfs</code> command as well.</p> <p>To add policies to an already existing set of policies, use the format:</p> <pre>hadoop mfs [-addsecuritypoli ctag [-R] <comma-separated list of security policy tags> <path>]</pre> |

| Comm and Type | | |
|---------------|--------------------------------|---|
| Java API | Tag security policy attributes | <pre data-bbox="1157 300 1365 464">public void setXAttr(Path path, String name, byte[] value) throws IOException</pre> <p data-bbox="1143 499 1453 764">The following example demonstrates how to use the Java API to tag the security policy as an extended attribute <code>security.mapr.policy</code> with the value <code>Lab_Security_Policy</code> for the file <code>/mapr/lab/foo.txt</code>:</p> <pre data-bbox="1157 800 1438 1444">import java.net.*; import org.apache.hadoop. fs.*; import org.apache.hadoop. conf.*; ... Configuration conf = new Configuration(); FileSystem fs = FileSystem.get(con f); Path path = Paths.get("/ mapr/lab/ foo.txt"); fs.setXAttr(path, "security.mapr.pol icy", "Lab_Security_Poli cy");</pre> |

| Comm and Type | | |
|---------------|---|---|
| C APIs | Associate a security policy with a file system object in C | <p>Use the <code>setxattr</code> or <code>fsetxattr</code> system call. The brief synopsis is as follows; for more details, refer to the <code>setxattr(2)</code> Linux manual pages.</p> <p>NAME</p> <p><code>setxattr</code>, <code>fsetxattr</code> -- set an extended attribute value</p> <p>SYNOPSIS</p> <pre>#include <sys/xattr.h> int setxattr (const char *path, const char *name, void *value, size_t size, u_int32_t position, int options); int fsetxattr (int fd, const char *name, void *value, size_t size, u_int32_t position, int options);</pre> |

Java APIs

Associate security policies with data objects using the filesystem Java APIs. See [Security Policy Java APIs](#) on page 1634 for more information.

Related information

[Security Policy Inheritance and Replication](#) on page 687

Security policies are inherited during data-object creation and copied over during mirroring and replication.

Tagging JSON Tables, Column Families, and Fields with Security Policies

Associate security policies with HPE Ezmeral Data Fabric Database JSON tables, column families, and fields.

You can apply security policies to HPE Ezmeral Data Fabric Database objects from the Control System, `maprccli`, and the REST API. Tagging via `nfsv3/nfsv4` is not supported since these protocols do not support extended attributes. There is no limit on the number of policies you can tag to a database object, but be cautious of conflicts that can occur due to conflicting settings in the policies.

Note: You cannot tag binary tables or stream topics; however, if you apply a policy to a volume, the rules set in the policy apply to all the content in the volume.

Tagging JSON Tables

Associate security policies with JSON tables.

CLI

To associate a comma-separated list of security policies with a table at the time of table creation:

```
maprcli table create -path
<tablePath> -securitypolicy
<policyName,...>
```

To associate a comma-separated list of security policies with a table without replacing existing security policies, run the following command:

```
maprcli table securitypolicy
add -path <tablePath> -securitypolicy
<policyName,...>
```

To replace security policies on a table with a comma-separated list of new security policies, run the following command:

```
maprcli table securitypolicy
set -path <tablePath> -securitypolicy
<policyName,...>
```

To remove one or more security policies from a table, run the following command:

```
maprcli table
securitypolicy remove -path
<tablePath> -securitypolicy
<policyName,...>
```

REST API

Send a request of type POST. For example, to associate a comma-separated list of security policies with a table at the time of table creation, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
create?
path=<tablePath>&securitypolicy=<polic
yName,...>
```

To associate a comma-separated list of security policies with a table without replacing existing security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
securitypolicy/add?
path=<tablePath>&securitypolicy=<polic
yName,...>
```

To replace security policies on a table with a comma-separated list of new security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
securitypolicy/set?
path=<tablePath>&securitypolicy=<polic
yName,...>
```

Control System

Tip: For more information, see:

- [Creating a New Table](#) on page 1110
- [Editing Tables](#) on page 1117
- [table create](#) on page 2029
- [table securitypolicy add](#) on page 2124
- [table securitypolicy set](#) on page 2126
- [table securitypolicy remove](#) on page 2125

Tagging Column Families

Associate security policies with JSON table column families.

CLI

To remove one or more security policies from a table, run the following command:

```
https://<hostname>:8443/rest/table/
securitypolicy/remove?
path=<tablePath>&securitypolicy=<poli
cyName,...>
```

1. Log in to the Control System and go to the [Create New Table](#) page or the [Edit Table](#) page.
2. Select the security policies to associate with the table in the **Security** section.
3. Specify all other required settings and click **Save Changes**.

To associate a comma-separated list of security policies with a column family when the column family is created:

```
maprcli table cf
create -path <tablePath> -cfname
<column-family-name> -jsonpath
<family path> -securitypolicy
<policyName,...> -force true
```

To associate a comma-separated list of security policies with a column family without replacing existing security policies, run the following command:

```
maprcli table cf securitypolicy
add -path <tablePath> -cfname
<column-family-name> -securitypolicy
<policyName,...>
```

To replace security policies on a column family with a comma-separated list of new security policies, run the following command:

```
maprcli table cf securitypolicy
set -path <tablePath> -cfname
```

```
<column-family-name> -securitypolicy
<policyName,...>
```

To remove one or more security policies from a column family, run the following command:

```
maprcli table cf securitypolicy
remove -path <tablePath> -cfname
<column-family-name> -securitypolicy
<policyName,...>
```

REST API

Send a request of type POST. For example, to associate a comma-separated list of security policies with a column family at the time of table creation, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
create?
path=<tablePath>&cfname=<column-famil
y-name>&securitypolicy=<policyName,...
>
```

To associate a comma-separated list of security policies with a column family without replacing existing security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
securitypolicy/add?
path=<path>&cfname=<column-family-name
>&securitypolicy=<policyName,...>
```

To replace security policies on a column family with a comma-separated list of new security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
securitypolicy/set?
path=<path>&cfname=<column-family-name
>&securitypolicy=<policyName,...>
```

To remove one or more security policies from a column family, run the following command:

```
https://<hostname>:8443/rest/table/cf/
securitypolicy/remove?
path=<path>&cfname=<column-family-name
>&column=<JSON-table-field>&securitypo
licy=<policyName,...>
```

Control System

1. Log in to the Control System, and select **Data > Tables**.
2. Locate and select the table that contains the column family you want to secure.
3. On the **Summary** tab, locate the **Security** section.

4. In the **Security** section, click on the table name to expand the list of column families associated with the table.
5. Click the **+** icon in the **Security Policy** column next to the column family you want to secure with a security policy.
6. In the **Tag Security Policy to Column Family:** window, select the security policy you want to apply to the column family.
7. Click **Add**.

Tip: For more information, see:

- [table cf create](#) on page 2048
- [table cf securitypolicy add](#) on page 2064
- [table cf securitypolicy set](#) on page 2066
- [table cf securitypolicy remove](#) on page 2065

Tagging Fields

Associate security policies with JSON fields.

CLI

To associate a comma-separated list of security policies with a JSON table field, without replacing existing security policies, run the following command:

```
maprcli table cf
column securitypolicy
add -path <tablePath> -cfname
<column-family-name> -column
<column-name> -securitypolicy
<policyName,...>
```

To replace security policies on a JSON table field with a comma-separated list of new security policies, run the following command:

```
maprcli table cf
column securitypolicy
set -path <tablePath> -cfname
<column-family-name> -column
<column-name> -securitypolicy
<policyName,...>
```

To remove one or more security policies from a JSON table field, run the following command:

```
maprcli table cf
column securitypolicy
remove -path <tablePath> -cfname
<column-family-name> -column
<column-name> -securitypolicy
<policyName,...>
```

REST API

Send a request of type POST. For example, to associate a comma-separated list of security policies with a column family at the time of table creation, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
create?
path=<tablePath>&securitypolicy=<policyName,...>
```

To associate a comma-separated list of security policies with a JSON table field without replacing existing security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
column/securitypolicy/add?
path=<path>&cfname=<col-family-name>&securitypolicy=<policyName,...>
```

To replace security policies on a JSON table field, with a comma-separated list of new security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
column/securitypolicy/set?
path=<path>&cfname=<column-family-name>&securitypolicy=<policyName,...>
```

To remove one or more security policies from a JSON table field, run the following command:

```
https://<hostname>:8443/rest/table/cf/
column/securitypolicy/remove?
path=<path>&cfname=<column-family-name>&column=<JSON-table-field>&securitypolicy=<policyName,...>
```

Control System

1. Log in to the Control System, and select **Data > Tables**.
2. Locate and select the table that contains the field you want to secure.
3. On the **Summary** tab, locate the **Security** section.
4. In the **Security** section, click on the table name to expand the list of column families and then click on the column family that contains the field you want to secure.
5. Click the **+** icon in the **Security Policy** column next to the field you want to secure with a security policy.
6. In the **Tag Security Policy to Column Family** window, select the security policy you want to apply to the column family.
7. Click **Add**.

Tip: For more information, see:

- [table of column securitypolicy add](#) on page 2041
- [table of column securitypolicy set](#) on page 2047
- [table of column securitypolicy remove](#) on page 2046

[Removing Security Policies](#) on page 1614

You can remove security policies associated with data objects using the Control System, CLI, or REST API.

Security Policy Java APIs

You can create, retrieve, and remove security policies, and associate security policies with a data object using filesystem APIs.

The standard Linux extended attributes to tag filesystem objects are POSIX-compliant. You can use these attributes on any Linux or POSIX-compliant client without installing additional MapR software.

However, with the extended attribute syntax, applications need to ensure that to combine tags, they first retrieve the old tags and then combine them with the new tags. Otherwise, the new tags replace the old tags. Alternatively, your applications can use an API with the following features:

1. Setting tags should be additive, that is, new tags should be added to the existing tags, and not replace the existing tags.
2. Set multiple tags for the same resource in a single API.
3. Set tags for multiple filesystem resources in a single operation.

The extended `MapRFileSystem` Java class provides such an API for setting policy tags.

The list of `MapRFileSystem` API methods for data tagging is as follows:

```
public class MapRFileSystem extends FileSystem;
```

| Method and Description | Modifier and Type |
|--|-------------------|
| Add a Security Policy Tag | |
| <code>addSecurityPolicyTag (Path path, String securityPolicyTag) throws IOException;</code> Use this method to add a single security policy tag to the list of existing security policy tags (if any) for the file or directory specified in <i>path</i> . The <i>securityPolicyTag</i> parameter contains a security policy tag. | public int |
| <code>addSecurityPolicyTag (Path path, List<String>securityPolicyTags) throws IOException;</code> Use this method to add one or more security policies to the list of existing security policies (if any) for the file or directory specified in <i>path</i> . The <i>securityPolicyTags</i> parameter contains a list of one or more security policy tags. | public int |
| Replace a Security Policy Tag | |

| Method and Description | Modifier and Type |
|---|-------------------|
| <pre>setSecurityPolicyTag (Path path, String securityPolicyTag) throws IOException;</pre> <p>Use this method to set the security policy tag to the file or directory specified in <i>path</i>, replacing all existing tags. The <i>securityPolicyTag</i> parameter contains a security policy tag.</p> | public int |
| <pre>setSecurityPolicyTag (Path path, List<String>securityPolicyTags) throws IOException;</pre> <p>Use this method to set one or more security policy tags for the file or directory specified in <i>path</i>, replacing any existing security policy tags. The <i>securityPolicyTags</i> parameter contains a list of one or more security policy tags.</p> | public int |
| Remove a Security Policy Tag | |
| <pre>removeSecurityPolicyTag (Path path, String securityPolicyTag) throws IOException;</pre> <p>Use this method to remove the security policy tag contained in the <i>securityPolicyTag</i> parameter from the list of existing security policy tags (if any) for the file or directory specified in <i>path</i>.</p> | public int |
| <pre>removeSecurityPolicyTag (Path path, List<String>securityPolicyTags) throws IOException;</pre> <p>Use this method to remove one or more security policy tags from the list of existing security policy tags (if any) for the file or directory specified in <i>path</i>. The <i>securityPolicyTags</i> parameter contains a list of one or more security policy tags.</p> | public int |
| <pre>removeAllSecurityPolicyTags (Path path) throws IOException;</pre> <p>Use this method to remove all security policies tagged to the file or directory specified by <i>path</i>.</p> | public int |
| Retrieve Security Policy Tags | |
| <pre>getSecurityPolicyTag (Path path, List<String>securityPolicyTags) throws IOException;</pre> <p>Use this method to retrieve the security policy tags associated with the file or directory specified in <i>path</i>. The <i>securityPolicyTags</i> parameter contains a list of one or more security policy tags.</p> | public int |

The following example illustrates the usage of filesystem APIs, and the interchangeability of using the filesystem API with the extended attribute APIs:

1. Set three security policy tags, `general`, `hipaa`, and `pci`, on the file `/mapr/lab/foo.txt`.
2. Retrieve these security policy tags using the extended attribute commands and the `getSecurityPolicyTag` API.
3. Remove the tag `pci`. Two tags remain: `hipaa` and `general`.

4. Add a new tag `topsecret`.

The two existing tags, `general` and `hipaa`, are preserved. Finally, there are three tags: `general`, `hipaa`, and `topsecret`.

Step 1: Set Security Policy Tags

Use the Java `addSecurityPolicyTag` API to set three security policies, `pci`, `general`, and `hipaa`, for the file `/mapr/lab/foo.txt` as follows.

```
import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;
import com.mapr.fs.MapRFileSystem;
import java.util.List;
import java.util.ArrayList;
...
Configuration conf = new Configuration();
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
List<String> securityPolicies = new ArrayList<String>();
securityPolicies.add ("pci");
securityPolicies.add ("general");
securityPolicies.add ("hipaa");
((MapRFileSystem fs).addSecurityPolicyTag (path, securityPolicies);
```

Step 2: Retrieve Security Policy Tags

The `getSecurityPolicyTag` API returns the same set of security policies `general`, `hipaa`, and `pci` in a `List of String` object, instead of a comma-separated list:

```
List<String> securityPolicies = new ArrayList<String>();
int status = getSecurityPolicyTag (path, securityPolicies);
```

Alternatively, use the `getfattr` extended attribute API, to retrieve the three security policy tags:

```
getfattr -d /mapr/lab/foo.txt
# file: /mapr/lab/foo.txt
security.mapr.policy="general,hipaa,pci"
```

The tags are always returned in alphabetical order regardless of the tags that you set first. All security policies are considered equal in terms of determining access rights.

Use the extended attribute Java API `getXAttr` to obtain the same result: retrieve the three security policy tags. The following segment prints the comma-separated list: `general,hipaa,pci`.

```
import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;
...
Configuration conf = new Configuration();
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
byte[] securityPolicyBytes = fs.getXAttr(path, "security.mapr.policy");
System.out.println ("Security Policies: " + securityPolicyBytes.toString());
```

Step 3: Remove a Security Policy Tag

At this point, the example has three tags for `/mapr/lab/foo.txt`: `general`, `hipaa`, and `pci`. Now, remove the tag `pci` using the `removeSecurityPolicyTag` API:

```

Configuration conf = new Configuration();
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
...
((MapRFileSystem fs).removeSecurityPolicyTag (path, "pci");

```

Use any of the methods listed in step 2, to see that the `pci` tag is removed.

Step 4: Add a Security Policy Tag

Add a tag `topsecret` using the `addSecurityPolicyTag` API:

```

FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
...
((MapRFileSystem fs).addSecurityPolicyTag (path, "topsecret");

```

Since this API sets the tags in an additive fashion, it preserves the two existing tags `general` and `hipaa`. The final output is three tags: `general`, `hipaa` and `topsecret`.

Complete Example of Setting and Retrieving Security Policies

The following sample program uses the tagging APIs on the file `/user/root/disks.txt`.

This program does the following tasks:

1. Tags the file with two tags, namely `general`, and `pci`.
2. Retrieve the tags. The output should display `general`, and `pci`.
3. Remove the tag `pci`.
4. Retrieve the tags. The output should display `general`.
5. Add the tag `hipaa`.
6. Retrieve the tags. The output should display `general`, and `hipaa`.

```

package com.mapr.fs;
import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;
import java.io.*;
import com.mapr.fs.MapRFileSystem;
import java.util.List;
import java.util.ArrayList;

class SecurityPolicyTest
{
    public static void main (String [] args) throws IOException
    {
        Configuration conf = new Configuration();
        if (args.length != 1) {
            System.out.println ("Usage: com.mapr.fs.SecurityPolicyTest <path>");
            System.exit(-1);
        }
    }
}

```

```

String pathName = args[0];
System.out.println ("Path name: " + pathName);
FileSystem fs = FileSystem.get(conf);
Path path = new Path (pathName);
List<String> securityPolicies = new ArrayList<String>();
System.out.println ("Adding general,pci");
securityPolicies.clear();
securityPolicies.add ("general");
securityPolicies.add ("pci");
((MapRFileSystem)fs).setSecurityPolicyTag(path, securityPolicies);
List<String> tags = new ArrayList<String>();
int status = ((MapRFileSystem)fs).getSecurityPolicyTag(path, tags);
if (status == 0) {
    System.out.println ("Tags:");
    for (int i=0; i<tags.size(); i++) {
        System.out.println (tags.get(i));
    }
}
System.out.println ("Removing pci");
((MapRFileSystem)fs).removeSecurityPolicyTag (path,"pci");
tags.clear();
status = ((MapRFileSystem)fs).getSecurityPolicyTag(path, tags);
if (status == 0) {
    System.out.println ("Tags:");
    for (int i=0; i<tags.size(); i++) {
        System.out.println (tags.get(i));
    }
}
System.out.println ("Add hipaa");
((MapRFileSystem)fs).addSecurityPolicyTag(path, "hipaa");
tags.clear();
status = ((MapRFileSystem)fs).getSecurityPolicyTag(path,
tags);
if (status == 0) {
    System.out.println ("Tags:");
    for (int i=0; i<tags.size(); i++) {
        System.out.println (tags.get(i));
    }
}
}
}

```

Output

```

# sh RUN
# export CLASSPATH=`mapr classpath`
# java -cp $CLASSPATH com.mapr.fs.SecurityPolicyTest /user/root/disks.txt
Path name: /user/root/disks.txt
Adding general,pci
Tags:
    general,pci
Removing pci
Tags:
    general
Add hipaa
Tags:
    general,hipaa

```

Enforcing Security Policies at the Volume-Level

Describes how to set enforcement modes for security policies at the volume-level.

The system enforces data access controls during data operations. Data access controls are the ACEs defined in security policies and ACEs and POSIX mode bits directly defined on data objects. The

enforcement mode tells the system which of these data access controls to evaluate and enforce during data operations.

You can set the enforcement mode to one of the following values from the Control System, CLI, or the REST API:

| Enforcement Mode | Enforce Security Policies | Enforce Data ACEs and POSIX Mode Bits |
|--|--|---------------------------------------|
| PolicyAceAndDataAce (Default) | Yes | Yes |
| PolicyAceOnly | Yes | No |
| DataAceOnly | No | Yes |
| PolicyAceAuditAndDataAce (Permissive mode) | Performs checks, but does not fail; audits instead | Yes |

For detailed information about the enforcement mode options, see [Volume-Level Security Policy Enforcement Mode](#) on page 678.

Set the Enforcement Mode from the Control System

1. Log in to the Control System, and go to the [volume information page](#).
2. In the **Security** pane, click  associated with **Enforcement Mode** to display the **Change Enforcement Mode** window.
3. Select the enforcement mode you want to apply to the volume.
4. Click **Save Changes** for the changes to take effect.

Set the Enforcement Mode from the CLI or REST API

CLI

Set the enforcement mode when you create a volume:

```
/opt/mapr/bin/maprcli volume
create -name <volName> -path
<mountPath> -securitypolicy
<policyName> -enforcementmode
PolicyAceAndDataAce|PolicyAceOnly|
DataAceOnly
```

Set the enforcement mode when you modify a volume:

```
/opt/mapr/bin/maprcli
volume modify -name
<volName> -enforcementmode
PolicyAceAndDataAce|PolicyAceOnly|
DataAceOnly
```

REST

Send a POST request to set the enforcement mode when you create a volume:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&securi
typolicy=<policyName>&enforcementmode=
PolicyAceAndDataAce|PolicyAceOnly|
DataAceOnly' --user <username>:<pwd>
```

Send a request of type POST to set enforcement mode when you edit a volume:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&enforcementmode=PolicyA
ceAndDataAce|PolicyAceOnly|
DataAceOnly' --user <username>:<pwd>
```

For more information, see [volume create](#) on page 2190 and [volume modify](#) on page 2275.

Troubleshooting Security Policies

This topic describes problems that you may encounter when creating and using security policies. It includes recommendations on how to troubleshoot and resolve problems.

Cannot Create a Security Policy

Suppose you encounter the following error when attempting to create a security policy:

```
ERROR (1) - Security policy create of XXX failed: Security policy creation
failed: No privileges to create a security policy
```

You must have cluster-level create/delete security policy (`cp`) permission to create a security policy.

To check your cluster-level permissions, assuming you have cluster-level `login` permission, you can run the following command:

```
maprcli acl show -type cluster
```

The following shows sample output for a user with the necessary `cp` permission:

| Allowed actions | Principal |
|-----------------|------------------|
| [login, cp] | User PolicyAdmin |

Cannot view a Security Policy

If you receive an error when running the `maprcli security policy info` command, the root cause depends on the error you encounter:

No MapR Ticket

```
ERROR (22) - You do not
have a ticket to communicate
with 10.10.20.40:7222. Retry after
obtaining a new ticket using maprlogin
```

This indicates that you do not have a MapR ticket to access the secure MapR cluster.

Create a MapR ticket by running [maprlogin password](#).

No Policy-Level Permission

```
ERROR (2) - Security policy lookup
of XXX failed, Operation not permitted
```

The possible reasons for this error are as follows:

| Possible Cause | Troubleshooting Steps |
|---|--|
| Either you or the group that you belong to does not have the policy-level read permission. | <ol style="list-style-type: none"> 1. Ask the user who granted you access to confirm your policy-level permission by running: <pre>maprcli security policy info \ -name XXX \ -columns acl -json</pre> 2. Request access if you do not have the read permission. |
| You are not a member of a group that has policy-level permission. | <ol style="list-style-type: none"> 1. Run the <code>id</code> command to verify your group membership. 2. If you are not a member of the group, request an administrator to add you. 3. If you are using MapR tickets, recreate your ticket after updating your group membership. |
| Your MapR ticket does not reflect your updated group membership because you created the ticket before changing your group membership. | <ol style="list-style-type: none"> 1. Verify your MapR ticket by examining the output from <code>maprlogin print</code>. 2. If the ticket does not include the group that has policy-level permission, then recreate your MapR ticket. |

Cannot Modify a Security Policy

Depending on the property you are trying to modify, you must have certain policy-level permissions:

Update Non-Permission Properties of a Policy

If you encounter the following error:

```
ERROR (1) - Security policy
update of XXX failed: Insufficient
privileges to update general section
for security policy XXX
```

You must have one of the following cluster-level or policy-level permissions:

- Cluster-level `cp`, `a`, or `fc` permission
- Policy-level `a` or `fc` permission

Update Permission Properties of a Policy

If you encounter the following error:

```
ERROR (1) - Security policy
update of XXX failed: Insufficient
privileges to update ACL for security
policy XXX
```

You must have one of the following cluster-level or policy-level permissions:

- Cluster-level `cp` or `admin` permission
- Policy-level `admin` permission

Cannot tag a security policy to a data object

If you cannot tag a policy to a data object or the volume page search in the Control System is not displaying a security policy, verify that `allowtagging` is set to `true`, as described in [Changing the State of a Security Policy](#) on page 1618.

Policies not visible after the CLDB starts

After the CLDB master starts, it can take a couple of minutes for the `policyserver` to come up. Currently, only the policy server on the cluster designated as the global policy master serves operations. Member clusters standby and do not serve operations. Wait for the `policyserver` to come up.

Mirroring/Restore fails due to no policies

If mirroring or restore fails due to no policies, import the policies from the global policy master or a member cluster that has the policies, as described in [Security Policy Domain and Policy Management](#) on page 674.

Access check on mirror source and destination clusters differ

The policies may have been modified on the global policy master and not propagated to either of them. Get the latest policies, as described in [Security Policy Domain and Policy Management](#) on page 674.

Access checks fail

View the filesystem audit logs on the master node.

Where are the logs?

The following table lists the log locations for components related to security policies:

| Component | Location |
|----------------------|--|
| PolicyServer | <code>cldb.log</code> |
| Access Check | MFS |
| Audit Logs | NC master node FS Audit Logs |
| Client (For tagging) | Regular Client logs (<code>ffs.log</code> or enable Hadoop debug then <code>stdout</code>) |

Related concepts

[Granting Security Policy Permissions](#) on page 1598

Permissions define which administrative users can create, view, and modify security policies. Administrators set the permissions on security policies through cluster-level and security policy-level ACLs.

Customizing Security in HPE Ezmeral Data Fabric

Describes the `.customSecure` file and how HPE Ezmeral Data Fabric 6.x handles custom security settings.

This topic contains the following subsections:

- [What is Custom Security?](#) on page 1649
- [Identifying the Current Security State of the Cluster](#) on page 1649
- [About the .customSecure File](#) on page 1650
- [Forcing a Change to the Security Configuration](#) on page 1650
- [Custom Security and the HPE Ezmeral Data Fabric Installer](#) on page 1650
- [Adding a Node to a Cluster with Custom Security](#) on page 1650
- [Adding a Service to a Cluster with Custom Security](#) on page 1651

Note: Implementing custom security is not recommended unless your installation demands it. Using the custom security option means that HPE Ezmeral Data Fabric software does not ensure that your system is secure by default, and that you need to manually perform all security configuration.

In HPE Ezmeral Data Fabric 6.x, the [configure.sh](#) script detects that a cluster is in one of three security states:

| | |
|---------------|---|
| Secure | The cluster is configured with the default HPE Ezmeral Data Fabric security settings. |
| Unsecure | No security settings are configured for the cluster. |
| Custom secure | The cluster has a mixture of HPE Ezmeral Data Fabric security settings and custom settings. |

Understanding how `configure.sh` handles custom security settings is important when you upgrade a cluster, add services, add nodes, or change security settings.

What is Custom Security?

Any change to the default HPE Ezmeral Data Fabric configuration for authentication, authorization, or encryption represents a "custom security" change. Users who make such changes are encouraged to create a `.customSecure` file to ensure that `configure.sh` does not remove these changes. Custom security changes include any change to the keystore or truststore passwords or the number of keys in those files or the names of the keys.

Other examples of custom security changes include:

- Implementing Kerberos security
- Changing the Hive authorization model
- Changing the Oozie authorization model

Identifying the Current Security State of the Cluster

If the current security state of the cluster (secure, unsecure, or custom secure) is unknown, you can use one of these checks to identify which state the cluster is in:

- Check the security value in the `/opt/mapr/conf/mapr-clusters.conf` file. For example:

```
<clusternam1> secure=true <CLDB> <CLDB> ... <CLDB>
```

For more information, see [mapr-clusters.conf](#) on page 2485.

- Check for the presence of the `.customSecure` file:

```
/opt/mapr/conf/.customSecure
```

If the file is present, `configure.sh` treats the cluster as custom secure.

About the `.customSecure` File

If you customized the security settings for your cluster and you want to ensure that `configure.sh` does not change any of the settings, you can create a `.customSecure` file. Create the file in the following location on every node:

```
/opt/mapr/conf/.customSecure
```

The `.customSecure` file does not contain any information. The presence of the file tells `configure.sh` that the cluster has security settings that must not be changed by `configure.sh`.

Typically, you create the `.customSecure` file manually. However, in some cases, `configure.sh` creates or removes the `.customSecure` file for you. For example, if `configure.sh` detects that it is being run after an upgrade from a MapR 5.x secure cluster, it creates the `.customSecure` file automatically. If you use the `-forceSecurityDefaults` option and `-secure` or `-unsecure` with `configure.sh`, the script removes the `.customSecure` file because you are forcing the removal of custom security settings.

Forcing a Change to the Security Configuration

If your HPE Ezmeral Data Fabric 6.x cluster has custom security settings (the `.customSecure` file is present), and you want to change to the default HPE Ezmeral Data Fabric secure or non-secure settings, you can use the `-forceSecurityDefaults` option of `configure.sh` to make the change. Note these considerations:

- Using the `-forceSecurityDefaults` option removes the `.customSecure` file. You must specify the `-secure` or `-unsecure` option with `-forceSecurityDefaults`. Otherwise, the command will have no effect.
- The `-forceSecurityDefaults` option might not remove all of your custom settings. Some manual editing might be necessary to return the cluster to a usable state.
- When forcing a custom-secured cluster to be HPE Ezmeral Data Fabric secure, you still need to include other `configure.sh` options that are required for security. And you need to perform any steps required to add security. For example, see [Enabling Wire-level Security](#) on page 1527.

Custom Security and the HPE Ezmeral Data Fabric Installer

Using the HPE Ezmeral Data Fabric Installer or HPE Ezmeral Data Fabric Installer Stanzas is not supported on clusters with custom security or customized configurations.

Adding a Node to a Cluster with Custom Security

Adding a node to a cluster with custom security is similar to adding a node to a cluster with HPE Ezmeral Data Fabric security, but there are some additional steps:

1. Add the node with default HPE Ezmeral Data Fabric security as described in [Adding Nodes to a Cluster](#) on page 883.
2. To support your custom security mode, copy any custom resources or settings as needed from existing nodes to the added node.

3. Create the `/opt/mapr/conf/.customSecure` file on the added node:

```
/usr/bin/touch /opt/mapr/conf/.customSecure
```

Adding a Service to a Cluster with Custom Security

If you add a new service (ecosystem component) to a secure or custom-secure cluster, `configure.sh` configures the service for HPE Ezmeral Data Fabric security automatically. If the cluster is custom secure, you need to change the security settings for the service to be compatible with the current cluster settings and restart the service. Any subsequent use of `configure.sh -R` will leave the customization in place.

Managing Impersonation

Provides instructions for enabling and using MapR impersonation features.

Impersonation, also known as identity assertion, is one user accessing data and submitting jobs on behalf of another user. Impersonation in MapR allows centralized control of access to resources in the filesystem and HPE Ezmeral Data Fabric Database.

Example: Access Control and Impersonation

As an example of impersonation, consider user Bob and a generic Service X:

1. Bob launches a client for the service and may or may not provide credentials.
2. Service X authenticates Bob and establishes a connection for him to use.
3. Bob issues a command to the service that will produce a query.
4. The service uses any user's `servicewithimpersonation` ticket to authenticate with the datastore - filesystem/HPE Ezmeral Data Fabric Database.
5. The datastore authenticates the user with the impersonation ticket - the service can now proceed.
6. The service sends the datastore a query, as user Bob.
7. The datastore checks permissions for Bob on the assets that the query will access.
8. If Bob has permissions, the datastore returns the query results to the service, which relays the results to the client, and the query succeeds.
9. If Bob does not have permissions, the datastore sends an access error to the service, which relays the error to the client, and the query fails.

When you use impersonation in MapR:

- The datastore permissions are authoritative.
- The process has end-to-end security.
- Users can do nothing more and nothing less than what they are authorized to do.
- This control is independent of remote authentication and security mechanisms that control user access to application features.
- Any permissions set up within applications, or within the UNIX filesystem permissions on servers where MapR components reside, have no effect on user access to MapR resources.

- The `mapr` superuser is allowed to impersonate any MapR user in any group, connecting from any host. Other users with impersonation capability can impersonate any MapR user in any group, except the `mapr` superuser and the root user.

Using Impersonation without Security

Although it is possible to enable impersonation in a non-secure MapR installation, MapR strongly recommends against doing this. The implementation rules are different, and setting up the MapR environment with impersonation operating under those rules makes it very difficult to enable security at a later date. Disabling security in a secure MapR installation is easy, if the need arises.

If you choose to implement impersonation in a non-secure MapR cluster, see [Configuring Impersonation when Cluster Security is not Enabled](#).

Using Impersonation with Security

In general, this documentation assumes that security is enabled in your MapR installation. See [Enabling Wire-level Security](#) on page 1527 and [Enabling Encryption of Data at Rest](#) on page 1529.

You can use the `maprlogin` utility to generate a **servicewithimpersonation** ticket that can be used to access a secure cluster impersonating another user. That is, the **servicewithimpersonation** ticket provides the user the ability to impersonate other users (except the `mapr` user) in addition to the ability to access a secure cluster. The `servicewithimpersonation` ticket generated with the list of `impersonatedgids` and `impersonateduids` cannot be used to impersonate user `root` or user `mapr`. If the user is other than `root` or `mapr`, CLDB resolves the username to UID locally and then checks if the resolved UID can be impersonated (i.e., if it is a part of the ticket's `impersonateduids`) or at least one of the GIDs of the resolved UID can be impersonated (i.e., if at least one of the GIDs should be part of the ticket's `impersonatedgids`). The `servicewithimpersonation` ticket can only be generated by a user with full control on a cluster's Access Control List (ACL).

If you are setting up user impersonation in a secure cluster, you need to generation an impersonation ticket. See the *Generating and Printing Service with Impersonation Ticket* section in the [maprlogin Command Examples](#) on page 2416 topic and [Generating a Service with Impersonation Ticket](#) on page 1545 for information on generating an impersonation ticket.

After generating the ticket:

1. Ensure that `mapruser1` has read permissions on the ticket.
2. If you moved the `ticketfile` to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable.

How Impersonation Works

Introduces impersonation functionality, limitations, and core requirements.

When a user attempts to impersonate another user to the filesystem or HPE Ezmeral Data Fabric Database systems and the configuration parameters for resolving the UID and GIDs on the server (see [Resolving Username with UID and GIDs During Impersonation](#)) are disabled:

1. The MapR client looks for that user name in the local operating system registry.
2. If the user name is:
 - Found, MapR sends the user's UID and GID to the server for impersonation.
 - Not found in the local operating system registry, the user action is not processed.

When a user attempts to impersonate another user to the filesystem or HPE Ezmeral Data Fabric Database systems and if the configuration parameters for resolving the UID and GIDs on the server (see [Resolving Username with UID and GIDs During Impersonation](#)) are enabled:

1. The MapR client asks CLDB to look for that user name and resolve the UID and GIDs for that user on the server.
2. If the user name is:
 - Found on the server, the server allows the user to proceed with the impersonation.
 - Not found, the user action is not processed.

Note: If the configuration property for resolving the username is set on the client and the configuration property for resolving the username is not set on CLDB, the operation will fail with an error.

Limitations on Impersonation

Service with impersonation tickets cannot be used to impersonate user `mapr` or user `root`. A scoped service with impersonation ticket cannot contain the UID of user `root` or user `mapr` (in the impersonated UIDs) and the GID of user `root` or user `mapr` (in the impersonated GIDs). User `mapr` can impersonate any user, including user `root`.

Core Requirements for Impersonation

The `mapr` superuser is allowed to access to the filesystem and HPE Ezmeral Data Fabric Database systems. The following conditions must be met in order for the `mapr` superuser to be able to impersonate another MapR user:

1. The `hadoop.proxyuser.mapr.groups` and `hadoop.proxyuser.mapr.hosts` parameters must be set correctly in the `core-site.xml` file.

See [Enabling Impersonation for the mapr Superuser](#).

These settings are not always required. The `hadoop proxy user` functionality is only applicable to ecosystem components included in the MapR distribution for Apache Hadoop. If the MapR client accesses an ecosystem component, such as HiveServer2, these settings may be required. These settings are never needed when the MapR client accesses filesystem or HPE Ezmeral Data Fabric Database directly. Enabling impersonation here ensures that the correct settings are in place if they are needed.

2. The name of the MapR user that you want the `mapr` superuser to be able to impersonate must appear in the local operating system registry where the MapR client is running if server-side [resolution of UID and GIDs](#) is not enabled.
3. The UID and GUID of the user name under which the MapR client is running must match exactly the UID and GUID for that user name on the server.

Note: The user `mapr` can impersonate any user, including user `root`.

For all other users with access to the filesystem and HPE Ezmeral Data Fabric Database systems, the following conditions must be met for the user to impersonate another user.

1. A valid `servicewithimpersonation` ticket must be present for the user who intends to impersonate on the system.
2. The name of the MapR user to impersonate must appear in the local operating system registry where the MapR client is running if server-side [resolution of UID and GIDs](#) is not enabled.
3. The UID and GUID of the user name under which the MapR client is running must match exactly the UID and GUID for that user name on the server.

Note: If a user is not authorized to impersonate, then the operations will proceed as the user, not the target user, and some operations will succeed, and some will not even if the user has all the permissions for these operations. Also, if a user with full access and impersonating capability tries to impersonate another user, the operations will succeed only if the target user has permissions on the directory.

Component Requirements for Impersonation

Some MapR ecosystem components have additional requirements to enable impersonation.

The following components must have settings that support impersonation in the configuration files indicated, on each node where the component resides:

- **Drill:** Edit the `drill-env.sh` file. See [Configuring User Impersonation](#) in the Apache Drill documentation.
- **Flume:** Edit the `flume.conf` file. See [Configure User Impersonation for Flume](#).
- **HBase:** Edit the `hbase-site.xml` file. See [Impersonation via the HBase REST Gateway](#).
- **HiveServer2:** Edit the `hive-site.xml` file. See [Hive User Impersonation](#).
- **Hue:** Edit the `hue.ini` file. See [Configure Hue with Impala](#).
- **Impala:** Does not support impersonation.
- **Oozie:** Edit the `oozie-site.xml` file. See [User Impersonation for Oozie](#).
- **Spark:** No special settings are required for Spark in MapReduce 2 (YARN) mode, since Spark automatically inherits the correct behavior from YARN. When running standalone, Spark cannot perform impersonation and should not be used if security is important.

Application Development Requirements

You can set up impersonation in an application programmatically.

- **C/C++:** Use `hb_connection_create_as_user()`. See the “C API for impersonation” section of [Creating C Apps - Binary Tables](#) on page 2735 and [Impersonation Example](#) on page 2739..
- **Java:** Use `UserGroupInformation.doAs()`. See [Class UserGroupInformation](#) in the Hadoop documentation.

Enabling Impersonation for the HPE Ezmeral Data Fabric Superuser

Provides a procedure necessary to implement superuser impersonation.

To enable impersonation in your HPE Ezmeral Data Fabric installation:

1. Open the following file in a text editor:

```
/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml
```

2. Add the following `hadoop.proxyuser` properties:

```
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
</property><property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

The `hosts` setting (*) allows the `mapr` superuser to connect from any host to impersonate a user.

The `groups` setting (*) allows the `mapr` superuser to impersonate any user in any group.

Note: Do not use anything other than a single asterisk here. Other parts of HPE Ezmeral Data Fabric ignore the values here and treat them as if each is set to a single asterisk.

3. Close the file, saving any changes that you made.

Enabling Impersonation for any User

Provides a procedure necessary to implement impersonation for any data-fabric user.

To enable impersonation for any data-fabric user:

1. Log in to the system as `root`, `mapr` user, or any user with full control.
2. Generate a `servicewithimpersonation` ticket for the data-fabric user.

For example:

```
$ maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/sample_ticket
```

Warning: The `mapr` user ticket can be used to impersonate any user, including user `root`.

You can generate a scoped `servicewithimpersonation` ticket for the user. The scoped impersonation tickets allows the user using the ticket to impersonate only the UIDs and or GIDs specified in the ticket. For example:

```
$ maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -impersonateduids 550 -impersonatedgids 500 -out /var/tmp/
sample_ticket
```

Note: When generating a scoped impersonation ticket, the impersonated UIDs cannot contain the UID of user `root` or user `mapr`, and the impersonated GIDs cannot contain the GID of user `root` or user `mapr`.

For more information, see [maprlogin](#) on page 2412.

3. Move the ticket to a secure location and share the ticket with the user (for whom this ticket was generated).
4. (Optional) Copy the file to a permanent directory.

Configuring Impersonation without Cluster Security

Describes how to use impersonation on a non-secure cluster.

To configure impersonation without enabling cluster security, perform the following steps on the client:

1. Enable impersonation for each ecosystem component you will use that supports impersonation. See *Component Requirements for Impersonation* in [How Impersonation Works](#).
2. Enable impersonation for the data-fabric core components. See [Enabling Impersonation for the mapr Superuser](#).
3. On each client system from which you wish to be able to use impersonation:
 - a) Set a `MAPR_IMPERSONATION_ENABLED` environment variable with the value `true`. This value must be set in the environment of any process you start that does impersonation.
 - b) Create a file in `/opt/mapr/conf/proxy/` that has the name of the data-fabric superuser or any other user. For the data-fabric superuser, the default file name would be `mapr`. For all other users, you can use their username for the proxy file.

If the data-fabric superuser has a different name in your cluster, use that name for the proxy file.

To verify the data-fabric superuser name, check the `mapr.daemon.user=` line in the `/opt/mapr/conf/daemon.conf` file on a data-fabric cluster server.

Resolving Username with UID and GIDs During Impersonation

Lists parameters for configuring impersonation.

To resolve username with UID and GIDs on the server (and not the local operating system registry) during impersonation, you can set the following configuration parameters on the client and CLDB:

| Parameter | Description |
|--|---|
| <code>fs.mapr.server.resolve.user</code> | <p>Must be set in <code>core-site.xml</code> file on the client machine. Value can be one of the following:</p> <ul style="list-style-type: none"> • <code>true</code> - enable • <code>false</code> - disable <p>By default, this is disabled. If enabled, client will request CLDB to resolve user with UID/GIDs. For example, to enable this property, your entry in <code>core-site.xml</code> file should be as shown below:</p> <pre><configuration> <property> <name>fs.mapr.server.resolve.user</name> <value>true</value> </property> </configuration></pre> |

| Parameter | Description |
|---|---|
| <code>cldb.security.resolve.user</code> | <p>Must be set using the <code>config</code> command. Value can be one of the following:</p> <ul style="list-style-type: none"> • 0 - disable • 1 - enable <p>By default, this is disabled. If enabled, CLDB will resolve the user with UID/GIDs for all incoming client requests. For example, to enable this property, run the following command:</p> <pre>maprcli config save -values {cldb.security.resolve.user:1}</pre> |

Note: Both the configuration parameters must be set to enable support for UID/GID resolution on the server. If the configuration parameter is set on the client to resolve on the server, and if the configuration parameter is not set on CLDB, the operation will fail with an error.

Managing Secure Clusters

Provides procedures that will enable you to use MapR clusters securely.

Administrative topics such as configuring cross-cluster security, managing mirror volumes in secure clusters, running commands on remote secure clusters are discussed. In addition, access scenarios for secure and non-secure MapR clusters and HDFS clusters are described.

Setting Up Cross-Cluster Security

Provides an overview of the `configure-crosscluster.sh` utility that is used to set up security between two clusters.

When all local and remote CLDB nodes are reachable from the local node, you can run the [configure-crosscluster.sh](#) on page 2345 utility on any CLDB node to automatically set up a trust relationship between clusters.

For two or more HPE Ezmeral Data Fabric clusters to communicate with one another, a secure trust relationship must exist between the clusters. A secure trust relationship between clusters is required for running commands remotely, creating remote replicas and mirror copies of volumes, and accessing data using NFS on the other cluster. The following sections describe the [quick](#) way to configure both the clusters for mirroring, replication, and remote access, and the [advanced manual](#) way to configure the clusters for mirroring, replication, remote access, and/or NFS server access.

Quick Configuration

You can run the [configure-crosscluster.sh](#) on page 2345 utility on any CLDB node in a cluster to automatically set up a trust relationship between the cluster and another cluster. To automatically configure two clusters for remote access, mirroring, and replication in both directions:

1. Log in to the CLDB node on a cluster.
2. Run the [configure-crosscluster.sh](#) on page 2345 utility with the `all` parameter.

For example:

```
# /opt/mapr/server/configure-crosscluster.sh create all -remoteip
<remote_node_IP>
```

When the utility runs, it performs the following actions on all the clusters:

- a. Updates the `/opt/mapr/conf/mapr-clusters.conf` file to include the first entry from the `/opt/mapr/conf/mapr-clusters.conf` file on the other cluster.
- b. Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.
- c. Generates a cross-cluster ticket for the other cluster, copies the ticket to the CLDB node on the other cluster, merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node in the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all other CLDB nodes on the other cluster.

For more information on the arguments, syntax, and options, see the [configure-crosscluster.sh](#) on page 2345 utility.

3. Verify access to the remote cluster by:

- Running remote commands on a node in either cluster.
- Creating mirror volumes on any node in the destination cluster.
- Setting up table and stream replication on tables and streams in the source cluster.

To configure access over NFS, see [Configuring Secure Clusters for Cross-Cluster NFS Access](#) on page 1666.

Advanced Configuration

Using the [configure-crosscluster.sh](#) on page 2345 utility with the default configuration works only when all local and remote CLDB nodes are reachable from the local node. It does not work, for example, if you set up multi-homed clusters as documented in the MAPR_SUBNETS section in [Designating NICs for HPE Ezmeral Data Fabric](#) on page 921, because the [configure-crosscluster.sh](#) on page 2345 utility cannot traverse between local and remote IPs (for example, from the external IP 23.21.203.95 to internal IP 10.10.100.100). In such environments, run the [configure-crosscluster.sh](#) on page 2345 utility with the `-remotehosts` parameter.

You can configure the clusters manually for unidirectional or bidirectional remote access, mirroring, or replication only. The following sections describe the manual steps for:

Configuring Secure Clusters for Running Commands Remotely

Describes how to configure secure clusters to access them all from a single cluster and run commands remotely on them.

You can configure a number of secure clusters to access them all from one cluster. You need not log into each secure cluster separately and run `maprcli` commands locally on them.

For example, suppose you need to manage two secure clusters, clusterA and clusterB. One method is to log into each cluster separately and run commands locally on each. However, it is possible to log into clusterA only and manage both clusters from clusterA, running commands locally for clusterA and remotely for clusterB. When you type the `maprcli` commands, you must use the `-cluster` parameter in those commands to specify the cluster on which you want the commands to run.

You can configure the secure clusters for remote access manually (as described in the following section) or automatically by running the `configure-crosscluster.sh` utility. If you run the `configure-crosscluster.sh` utility, the utility configures the clusters for running commands remotely in both directions. See [configure-crosscluster.sh](#) on page 2345 for more information.

Prerequisite

Ensure that you have the [relevant ports open](#) for secure cluster communication.

Setting Up Secure Clusters Manually for Cross-Cluster Access

To manually configure two secure clusters for remote access:

1. Log in to the secure cluster from which you want to run commands.
In the rest of this procedure, this cluster is referred to as clusterA and the remote cluster is referred to as clusterB.
2. Configure clusterA for communicating with the other clusters by editing `mapr-clusters.conf` file on each node clusterA to specify the hostname or IP address of the CLDB nodes on the other clusters.

For example, suppose:

- clusterA's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

```
clusterA.cluster.com secure=true perfnode50.lab:7222
```

- clusterB's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

```
clusterB.cluster.com secure=true perfnode100.lab:7222
```

Perform the following steps to configure the nodes on the clusters:

- a) On any node in clusterA, append the first entry from clusterB's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of clusterA's `mapr-clusters.conf` file.

Note that clusterA's entry must be the first line of the `mapr-clusters.conf` file:

```
clusterA.cluster.com secure=true perfnode50.lab:7222
clusterB.cluster.com secure=true perfnode100.lab:7222
```

The clusterA's `mapr-clusters.conf` file now contains two entries.

- b) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the other nodes in clusterA.
- c) On any node in clusterB, append the first entry from clusterA's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of the remote cluster's `mapr-clusters.conf` file.

Note that clusterB's entry must be the first line of `mapr-clusters.conf` file:

```
clusterB.cluster.com secure=true perfnode100.lab:7222
clusterA.cluster.com secure=true perfnode50.lab:7222
```

The clusterB's `mapr-clusters.conf` file now contains two entries.

- d) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the nodes in clusterB.

See [mapr-clusters.conf](#) on page 2485.

3. Perform the following steps on clusterA to ensure that the `ssl_truststore` file has signers for all the clusters:

- a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterB into a temporary directory on clusterA.

For example:

```
# scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterB_ssl_truststore
```

- b) Merge the `ssl_truststore` of clusterB with the `ssl_truststore` of clusterA using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterB as `/tmp/clusterB_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterB_ssl_truststore /opt/mapr/conf/ssl_truststore
```

- c) Copy the merged `ssl_truststore` file to every node on clusterA.

4. Perform the following steps on clusterB *only* if you want to set up access to clusterA from clusterB:

- a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterA into a temporary directory on clusterB.

For example:

```
# scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterA_ssl_truststore
```

- b) Merge the `ssl_truststore` of clusterB with the `ssl_truststore` of clusterA using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterA as `/tmp/clusterA_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterA_ssl_truststore /opt/mapr/conf/ssl_truststore
```

- c) Copy the merged `ssl_truststore` file to every node on clusterB.

5. For crossclusters to work using the Control System, place the `mapruserticket` of the remote cluster into the local cluster.

- a) Generate a `mapruserticket` for the remote cluster as `mapr` user:

```
maprlogin password -cluster demo
[Password for user 'mapr' at cluster 'demo': ]
MapR credentials of user 'mapr' for cluster 'demo' are written to
'/tmp/maprticket_5000'
```

- b) Merge the generated `maprticket`:

```
cat /tmp/maprticket_5000 >>/opt/mapr/conf/
mapruserticket
```

6. Verify access by running remote commands on clusterA.

See [Verifying Access to run Remote Commands](#) on page 1661.

Verifying Access to run Remote Commands

1. Log in to any node on clusterA and run the `maprlogin` on page 2412 utility from clusterA to obtain user ticket for accessing the remote cluster.

For example, to obtain tickets for managing the remote cluster from clusterA, run the following command::

```
# /opt/mapr/bin/maprlogin password -cluster clusterB.cluster.com
```

2. Verify access by running remote commands on clusterA.

For example, the following command, executed from a node in clusterA, lists the volumes on clusterB:

```
# /opt/mapr/bin/maprcli volume list -cluster clusterB.cluster.com
```

Configuring Secure Clusters for Cross-Cluster Mirroring and Replication

Describes configuring clusters for cross-cluster operations such as mirroring and replication.

Cross-cluster tickets are required on secure clusters that need to pull data from another secure cluster and on secure clusters that need to push data to another secure cluster. For example:

- Volume mirroring is a pull operation. The volume data is pulled by the destination cluster from the source cluster. Since the destination cluster performs the operation, the destination cluster receives a ticket that is generated on the source cluster.
- Table and streams replication is a push operation. The table or stream data is pushed from the source cluster to the destination cluster. Since the source cluster performs the operation, the source cluster receives a ticket that is generated on the destination cluster.

You can configure secure clusters for cross-cluster mirroring and replication manually (as described in [Setting up Secure Clusters Manually for Cross-Cluster Mirroring](#) on page 1661 and [Setting up Secure Clusters Manually for Cross-Cluster Replication](#) on page 1665). You can configure secure clusters automatically, by running the `configure-crosscluster.sh` utility. This utility configures the clusters for both mirroring and replication in both directions. For more information, see [configure-crosscluster.sh](#) on page 2345.

Setting up Secure Clusters Manually for Cross-Cluster Mirroring

To set up secure clusters for cross-cluster mirroring:

1. Verify that the user for whom you are configuring access, exists in the registry on both the clusters and has the following permissions:
 - Permissions to create volumes on the source cluster.
 - Permissions to mirror volumes on the destination cluster.

You can set up access for the `mapr` user, who already has permissions to create volumes and mirror volumes.

2. Configure clusterA for communicating with the other clusters by editing `mapr-clusters.conf` file on each node clusterA to specify the hostname or IP address of the CLDB nodes on the other clusters.

For example, suppose:

- clusterA's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

```
clusterA.cluster.com secure=true perfnode50.lab:7222
```

- clusterB's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

```
clusterB.cluster.com secure=true perfnode100.lab:7222
```

Perform the following steps to configure the nodes on the clusters:

- a) On any node in clusterA, append the first entry from clusterB's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of clusterA's `mapr-clusters.conf` file.

Note that clusterA's entry must be the first line of the `mapr-clusters.conf` file:

```
clusterA.cluster.com secure=true perfnode50.lab:7222
clusterB.cluster.com secure=true perfnode100.lab:7222
```

The clusterA's `mapr-clusters.conf` file now contains two entries.

- b) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the other nodes in clusterA.
- c) On any node in clusterB, append the first entry from clusterA's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of the remote cluster's `mapr-clusters.conf` file.

Note that clusterB's entry must be the first line of `mapr-clusters.conf` file:

```
clusterB.cluster.com secure=true perfnode100.lab:7222
clusterA.cluster.com secure=true perfnode50.lab:7222
```

The clusterB's `mapr-clusters.conf` file now contains two entries.

- d) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the nodes in clusterB.

See [mapr-clusters.conf](#) on page 2485.

3. Log in to any node on the source cluster (ClusterA) and perform the following steps:

- a) Generate a cross-cluster ticket for the destination cluster for this user.

For example, to generate a cross-cluster for destination cluster, run the following command on the source cluster:

```
source$ /opt/mapr/bin/maprlogin generateticket -type
crosscluster -out /tmp/crossclusterticket -user destinationclusteruser
```

- b) Copy the cross-cluster ticket file to any node on the destination cluster (clusterB).

For example:

```
source$ scp /tmp/crossclusterticket mapr@<dest-ip>:/tmp/
sourceClusterTicketFile
```

4. Log in to the node on the destination cluster (clusterB) where the cross-cluster ticket was copied, and perform the following steps:

- a) Merge the cross-cluster ticket file with the `/opt/mapr/conf/maprserverticket` file on the node.

For example, to merge, run the following command:

```
dest$ cat /tmp/sourceClusterTicketFile >> /opt/mapr/conf/
maprserverticket
```

- b) Copy the `/opt/mapr/conf/maprserverticket` file to the CLDB nodes on the destination cluster.

5. Perform the following step on clusterB to ensure that the `ssl_truststore` file has signers for all the clusters. Merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool.

Use one of the following three ways to merge tickets:

- a. Make a copy of the source `ssl_truststore`. Create a file with the password of the source truststore. Finally, merge the source and the destination truststores.

1. Copy the `ssl_truststore` file from cluster A:

```
scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterA_ssl_truststore
```

2. Create a file with password of the source truststore (can be obtained from the `ssl-client.xml` file of clusterA) as the content. Assume you copied it to file `/tmp/stpassword`.

3. Merge on cluster B:

```
manageSSLKeys.sh merge /tmp/clusterA_ssl_truststore /opt/mapr/conf/
ssl_truststore /tmp/stpassword
```

- b. Use the `copytruststore` option of `manageSSLKeys.sh` on page 2401 and create a copy of the truststore. Then copy it to the destination node using SCP, and finally run merge without any additional options. For example:

1. Create new `ssl_truststore` using the `copytruststore` option on cluster A:

```
manageSSLKeys.sh copytruststore /tmp/clusterA_ssl_truststore
```

2. Copy the `ssl_truststore` from cluster A:

```
scp mapr@<remote-ip>:/opt/mapr/conf/clusterA_ssl_truststore /tmp/
clusterA_ssl_truststore
```

3. Merge on cluster B:

```
manageSSLKeys.sh merge /tmp/clusterA_ssl_truststore /opt/mapr/conf/
ssl_truststore
```

- c. Use the `copytruststore` option of `manageSSLKeys.sh` on page 2401 and create a custom password for the copy of truststore. Copy this truststore to the destination node using SCP. Then create a file with password of the copied truststore as the content, and pass the filename as the argument to merge. For example:

1. Create a custom password for the copy of truststore:

```
manageSSLKeys.sh copytruststore /tmp/ssl_truststore3 abcdef
```

2. Copy this password to a file:

```
echo abcdef >/tmp/a
```

3. Copy the `ssl_truststore` and password from cluster A to cluster B:

```
scp mapr@<remote-ip>:/tmp/ssl_truststore3 /tmp/ssl_truststore3
```

```
scp mapr@<remote-ip>:/tmp/a /tmp/a
```

4. Merge on cluster B:

```
manageSSLKeys.sh merge /tmp/ssl_truststore3 /opt/mapr/conf/  
ssl_truststore /tmp/a
```

6. Copy the merged `ssl_truststore` file to every node on clusterB.

7. **Optional:** If your clusters are secure, configure your source cluster so that you can use the Control System to set up and administer table replication from the source to the destination cluster.

These steps make it convenient to use the Control System for setting up and managing replication involving two secure clusters. However, before following them, perform these prerequisite tasks.

Note:

- Ensure that both clusters are managed by the same team or group. The UIDs and GIDs of the users that are able to log in to the Control System on the source cluster must exactly match their UIDs and GIDs on the destination cluster. This restriction applies only to access to both clusters through the Control System, and does not apply to access to both clusters through the `maprccli`. If the clusters are managed by different teams or groups, use the `maprccli` instead of the Control System to set up and manage table replication involving two secure clusters.
 - Ensure that the proper file-system and table permissions are in place on both clusters. Otherwise, any user who can log into the Control System and has the same UID or GID on the destination cluster will be able to set up replication either from the source cluster to the destination cluster or vice versa. A user could create one or more tables on the destination cluster, enable replication to them from the source cluster, load the new tables with data from the source cluster, and start replication. A user could also create tables on the source cluster, enable replication to them from tables in the destination cluster, load the new tables with data from the destination cluster, and start replication.
- a. On the source cluster, generate a service ticket by using the `maprlogin` command:

```
maprlogin generateticket -type service -cluster <destination cluster>  
-user mapr -duration <duration> -out <output folder>
```

Where `-duration` is the length of time before the ticket expires. You can specify the value in either of these formats:

- `[Days:]Hours:Minutes`

- Seconds

- To every node of the source cluster, add the service ticket to the file `/opt/mapr/conf/mapruserticket` file that was created when you secured the source cluster:

```
at <path and filename of the service ticket> >> /opt/mapr/conf/
mapruserticket
```

- Restart the web server by running the `maprcli node services` command. For the syntax of this command, see [node services](#) on page 1939.
- Add the following two properties to the `core-site.xml` file. For Hadoop 2.7.0, edit the file `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml`.

```
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

- Perform the steps to [verify configuration for mirroring](#).

You can now create mirror volumes on the destination cluster and set up a schedule to pull data from the volumes on the source cluster. However, you cannot create volumes on the source cluster that pull data from volumes in the destination cluster, because the setup described above is unidirectional. To configure the clusters for bidirectional mirroring, repeat the steps above, by switching the source and destination clusters.

For example, suppose there are two clusters, clusterA and clusterB, and you performed the steps above for clusterA as the source cluster and clusterB as the destination cluster. After you complete the steps above, your destination cluster, clusterB can pull data from volumes on clusterA. For clusterA to mirror data on clusterB, perform the steps above with clusterB as the source cluster and clusterA as the destination cluster.

Setting up Secure Clusters Manually for Cross-Cluster Replication

To set up secure clusters for cross-cluster replication:

- Verify that the user, for whom you are configuring access, exists in the registry on the destination cluster.
- Log in to any node on the destination cluster and perform the following steps:
 - Generate a cross-cluster ticket for the source cluster.

For example, to generate a cross-cluster for the source cluster, run the following command on the destination cluster:

```
dest$ /opt/mapr/bin/maprlogin generateticket -type
crosscluster -out /tmp/crossclusterticket -user destinationclusteruser
```

- b) Copy the cross-cluster ticket file to any node on the source cluster.

For example:

```
dest$ scp /tmp/crossclusterticket mapr@<source-ip>:/tmp/
sourceClusterTicketFile
```

3. Log in to the node in the source cluster where the cross-cluster ticket was copied, and perform the following steps:

- a) Merge the cross-cluster ticket file with the `/opt/mapr/conf/maprserverticket` file on the node.

For example, to merge, run the following command:

```
cat /tmp/destinationClusterTicketFile >> /opt/mapr/conf/
maprserverticket
```

- b) Copy the `/opt/mapr/conf/maprserverticket` file to all the nodes on the source cluster.

4. Configure the Gateway for table and streams replication.

See [Configuring Gateways for Table and Stream Replication](#) on page 1271 for more information.

5. Perform the steps to [verify configuration for replication](#).

You can now set up volumes on the source cluster to push data to replicas on the destination cluster. However, you cannot create replicas on the source cluster that get data from volumes in the destination cluster because the setup described above is unidirectional. To configure the clusters for bidirectional replication, repeat the steps above by switching the source and destination clusters.

For example, suppose there are two clusters, clusterA and clusterB, and you performed the steps above for clusterA as the source cluster and clusterB as the destination cluster. After you complete the steps above, your source cluster, clusterA can push data to replicas on clusterB. For clusterB to replicate data on clusterA, perform the steps above with clusterB as the source cluster, and clusterA as the destination cluster.

Verifying Cross-Cluster Configuration for Mirroring and Replication

You can verify the cross-cluster configuration for:

1. Mirroring by logging in to a node on the destination cluster as the user for whom access was configured, and creating a mirror volume on the destination cluster for a volume on the source cluster. You can create mirror volumes using [the Control System](#) and/or the [CLI](#).
2. Replication by logging in to a node on the source cluster as the user for whom access was configured and creating a replica in the destination cluster for a volume, table, and stream on the source cluster. You can create replicas using the Control System and the CLI. To set up replication on secure clusters for:
 - Tables, refer to the documentation for [the Control System](#) and/or the [CLI](#).
 - Streams, refer to the documentation for [the Control System](#) and/or the [CLI](#).

Configuring Secure Clusters for Cross-Cluster NFS Access

Describes how to manually set up cross-cluster NFS access.

HPE Ezmeral Data Fabric-NFS offers many usability and interoperability advantages to the customer, and makes big data radically easier and less expensive to use. In a secure environment, however, you must configure NFS carefully because the NFS protocol is inherently insecure. Running the NFS server on any cluster node might expose the filesystem to be world readable and writable to any machine that knows the IP address of the cluster node running the NFS server and has access to the network, regardless of the

permissions, passwords and other security mechanisms. At the minimum, you should configure iptables firewall rules for all the cluster nodes where the NFS server is running, to restrict incoming NFS traffic to authorized client IP addresses.

Configuring cross-cluster NFS access might expose the entire filesystem of the other cluster to be world readable and writeable as well. Therefore, automated configuration for cross-cluster NFS access is not available with the `configure-crosscluster.sh` on page 2345 utility. You should manually configure cross-cluster NFS access only if you are fully aware of the security risks, and taken appropriate steps to mitigate the risks by securing both your NFS gateway, and incoming client traffic.

This section describes the manual configuration process on a secure cluster for accessing another secure cluster using NFS. There are two methods by which an NFS client can access file systems from multiple clusters:

1. Run the NFS server on one cluster.

For this method, configure cross-cluster NFS security for the NFS gateway on one cluster, so that the NFS client can mount the mapr filesystem once from the NFS gateway, and then access the file systems for both clusters.

2. Run the NFS server on both clusters.

For this method, cross-cluster NFS configuration is not needed. The NFS client can mount the HPE Ezmeral Data Fabric filesystem individually for each cluster. This method requires that the NFS gateway to be run on each cluster, and the client performs one NFS mount for each NFS filesystem to be accessed.

The following procedure describes how to setup NFS for the first method:

1. Log in to any node on the secure cluster where the NFS server is running.

In the rest of this procedure, this cluster is referred to as `clusterA.cluster.com` and the remote cluster is referred to as `clusterB.cluster.com`.

2. Set up the `/opt/mapr/conf/maprserverticket` file on `clusterA.cluster.com` to include the server ticket from `clusterB.cluster.com`. To set up:
 - a) Copy the `/opt/mapr/conf/maprserverticket` file from any node on `clusterB.cluster.com` to any directory on the node you are logged into on `clusterA.cluster.com`.
 - b) Append `maprserverticket` entry in the `maprserverticket` file from `clusterB.cluster.com` to the `/opt/mapr/conf/maprserverticket` file on the node you are logged into on `clusterA.cluster.com`.

Note: If you configured cross-cluster security either automatically using the `configure-crosscluster.sh` on page 2345 utility or manually before, there can be multiple entries in the `maprserverticket` file; copy the first entry with the alias matching the remote cluster name.

For example, to add `maprserverticket` of `clusterB.cluster.com` into the `/opt/mapr/conf/maprserverticket` file of `clusterA.cluster.com`, run the following command:

```
cat /tmp/remoteclusterticketfile | grep B.cluster.com |
head --lines=+1 >> /opt/mapr/conf/maprserverticket
```

- c) Copy the `/opt/mapr/conf/maprserverticket` file (on the node you are logged into in `clusterA.cluster.com`) to all the other nodes running NFS server on `clusterA.cluster.com`.

3. Verify data access on both clusters using NFS.

Users with access to the NFS servers must be able to access data in both clusters by providing the correct path. For example, users with NFS server access can verify access by running commands similar to the following:

```
# ls /mapr
clusterA.cluster.com clusterB.cluster.com
# ls /mapr/clusterB.cluster.com/
apps file CLUSTERB hbase opt tmp user var
```

Accessing External HDFS Clusters

Outlines how to use protocols to connect to other clusters.

HPE Ezmeral Data Fabric clusters can access an external HDFS cluster with the `webhdfs://` protocols.

Prerequisites

Before you begin, verify the following:

- The HPE Ezmeral Data Fabric node accessing the HDFS cluster must have the `mapr-core` or `mapr-client` package installed.
- The HDFS cluster is installed and configured according to the vendor's specifications.
- To use the `hdfs://` protocol, edit the `fs.hdfs.impl` property in the `$HADOOP_HOME/conf/core-site.xml` file to include the value `org.apache.hadoop.hdfs.DistributedFileSystem`.

The following cases provide information about HPE Ezmeral Data Fabric and accessing HDFS clusters.

Configuring Access Between Non-Secure MapR and HDFS Clusters

If the MapR and HDFS clusters are both non-secure, verify that the `fs.hdfs.impl` property in the `$HADOOP_HOME/conf/core-site.xml` file has the following value:

```
org.apache.hadoop.hdfs.DistributedFileSystem
```

No additional configuration is required.

Verifying access to HDFS cluster

Use the following commands to verify access to the remote HDFS cluster from the MapR cluster.

CDH3 Only

```
hadoop fs -ls hdfs://<namenode_host:port>/
```

Other HDFS Versions

```
hadoop fs -ls webhdfs://<namenode_host_running_webhdfs_service>/
```

Using Java Applications with Secure Clusters

Describes ramifications associated with using Java applications in a MapR secure environment.

A secure computing environment places additional requirements on the Java Virtual Machine (JVM) properties of Java clients. The JVMs launched by MapR with scripts, such as those used by the `maprcli`, `hadoop`, or `hbase` commands, have those properties automatically set by the MapR software. The MapR software attempts to set useful values for these properties.

When a JVM is used or launched directly, such as when you write a stand-alone Java program, any Java code that sets values for the following properties may cause issues on your cluster.

| Property | Default Value | Description |
|---------------------------------|---|---|
| java.security.auth.login.config | /opt/mapr/conf/mapr.login.conf | Path to the file that specifies JAAS configurations used by MapR. |
| javax.net.ssl.trustStore | /opt/mapr/conf/ssl_truststore | Controls the truststore used by MapR clients for HTTPS connections. |
| http.auth.preference | basic | The default setting disables JVM's default handling of SPNEGO, enabling MapR's Hadoop code to handle SPNEGO authentication. |
| zookeeper.saslprovider | com.mapr.security.maprsasl.MaprSaslProvider | Enables ZooKeeper security. |
| hadoop.login | hadoop_default | Controls the JAAS configuration used by MapR security. |

Administering the Data Access Gateway

The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Installing the Data Access Gateway Service

The HPE Ezmeral Data Fabric Data Access Gateway is installed when you install the HPE Ezmeral Data Fabric Database using the HPE Ezmeral Data Fabric Installer. To manually install the service, see [Installing Data Access Gateway](#) on page 195. For conceptual information, see [Understanding the HPE Ezmeral Data Fabric Data Access Gateway](#) on page 826.

Shutting Down and Upgrading the Data Access Gateway Service

When the Data Access Gateway receives a shutdown request, it stops accepting new requests and returns an error to the client. Any in-progress requests are allowed to complete before shutting down the service. This allows you to perform rolling upgrades.

Modifying Configuration Settings for the Data Access Gateway Service

Logging Properties

The HPE Ezmeral Data Fabric Data Access Gateway uses standard Log4J configuration to control its logging. The log4j properties are in the `/opt/mapr/data-access-gateway/conf/log4j2.xml` file on nodes where you have installed the service. After modifying any properties on a node, restart the service. For details, see [Administering the Data Access Gateway Service](#) on page 1671.

Log data is stored in the `/opt/mapr/data-access-gateway/logs/data-access-gateway.log` file.

Application Properties

To configure HPE Ezmeral Data Fabric Data Access Gateway properties, modify `/opt/mapr/data-access-gateway/conf/properties.cfg` on nodes where you have installed the service.

The following table lists the properties you can configure:

| | |
|---|--|
| auth.token.expiration | <p><i>Default:</i> 1800 seconds</p> <p><i>Description:</i> Expiration time (in seconds) for the authentication token.</p> |
| grpc.service.max-message-size | <p><i>Default:</i> 32MB</p> <p><i>Description:</i> The maximum message size that the gRPC service accepts. The default is set to 32MB, as this is the default maximum document size for HPE Ezmeral Data Fabric Database JSON tables. This property is available in Data Access Gateway 2.0.202104302209 and later or 3.0.0.0.202104302219 and later.</p> |
| grpc.service.ojai.query.result-limit | <p><i>Default:</i> 5000</p> <p><i>Description:</i> Limit on the number of documents returned in retrieval requests using the Node.js and Python OJAI clients.</p> |
| grpc.service.port | <p><i>Default:</i> 5678</p> <p><i>Description:</i> Port number gRPC clients use to connect to the Data Access Gateway. The Node.js and Python OJAI clients are gRPC clients.</p> |
| grpc.service.ssl.enabled | <p><i>Default:</i> cluster</p> <p><i>Description:</i> Controls whether TLS is enabled for the gRPC Service.</p> <p>Values: cluster true false</p> <p>If set to cluster:</p> <ul style="list-style-type: none"> • TLS is enabled if your HPE Ezmeral Data Fabric cluster is secure. • TLS is disabled if your HPE Ezmeral Data Fabric cluster is not secure. <p>When TLS is enabled, the SSL provider is OpenSSL.</p> |
| rest.https.port | <p><i>Default:</i> 8243</p> <p><i>Description:</i> Port number used to connect to the Data Access Gateway using HTTPS.</p> |
| rest.result.limit | <p><i>Default:</i> 5000</p> <p><i>Description:</i> Limit the number of documents returned in retrieval requests using the HPE Ezmeral Data Fabric Database JSON REST API.</p> |

There is also a configuration file `/opt/mapr/data-access-gateway/conf/ojai-config.json` for parameters used by Data Access Gateway clients:

- HPE Ezmeral Data Fabric Database JSON REST API
- Node.js OJAI
- Python OJAI
- C# OJAI
- Go OJAI
- Java OJAI Thin Client

A parameter you can modify is the client sort limit:

```
{
  "ojai": {
    "mapr": {
      "query": {
        "max-client-sort-limit": 6000
      }
    }
  }
}
```

To understand why you might want to modify this parameter, see [Comparisons and Sorts in OJAI Queries](#) on page 2862.

After modifying any parameters on a node, restart the service as described in [Administering the Data Access Gateway Service](#) on page 1671.

Warden Configuration

The Warden configuration for the HPE Ezmeral Data Fabric Data Access Gateway is in the `/opt/mapr/data-access-gateway/conf/warden.data-access-gateway.conf` file on nodes where you have installed the Data Access Gateway. To control the amount of memory allocated to the service, modify the following settings:

| | |
|-----------------------------|--|
| service.heapsize.max | <i>Default:</i> 3000 <i>Description:</i> Defines the maximum heap size (in MB) for the service. |
| service.heapsize.min | <i>Default:</i> 3000 <i>Description:</i> Defines the minimum heap size (in MB) for the service. |

After modifying the warden configuration file on a node, run `configure.sh -R`, and restart the service:

```
/opt/mapr/server/configure.sh -R
maprcli node services -nodes <node name> -name data-access-gateway -action
restart
```

Administering the Data Access Gateway Service

The HPE Ezmeral Data Fabric Data Access Gateway is a service that you administer in the same manner as other HPE Ezmeral Data Fabric services. The name of the service is `data-access-gateway`.

To restart the service through the CLI, run the following command:

```
maprcli node services -nodes <node name> -name data-access-gateway -action
restart
```

For details about other operations you can perform on the service, see [Managing Services](#) on page 904.

Related concepts

[Understanding the HPE Ezmeral Data Fabric Data Access Gateway](#) on page 826

The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster.

[Using the HPE Ezmeral Data Fabric Database JSON REST API](#) on page 2973

Starting in the EEP 5.0 release, you can use a REST API to access HPE Ezmeral Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables.

[Using the Node.js OJAI Client](#) on page 2949

Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

[Using the Python OJAI Client](#) on page 2954

Starting with EEP 6.0, you can use the Python OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

[Using the C# OJAI Client](#) on page 2964

Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

[Using the Go OJAI Client](#) on page 2968

Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

[Using the Java OJAI Thin Client](#) on page 2946

Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Ezmeral Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

L3/L4 Load Balancing with the MapR Data Access Gateway

You can use `haproxy` for L3/L4 load balancing of clients that use the MapR Data Access Gateway. This topic describes how to install, configure, and run `haproxy`, and how to set your client connection string to connect to the load balancing service.

Determine the server where you want to run the load balancing service. The server must be reachable by the clients using the Data Access Gateway. It also must be able to connect to the Data Access Gateway.

1. Install the `haproxy` service on the server you have identified:

CentOS

```
sudo yum install haproxy
```

Ubuntu

```
sudo add-apt-repository ppa:vbernat/haproxy-1.7
sudo apt update
sudo apt install haproxy
```

SLES

```
sudo zypper install haproxy
```

2. Configure the `haproxy` service by setting the following parameters in the configuration file at `/etc/haproxy/haproxy.cfg`:

- a) Create a `frontend` section with the following parameters:

```
frontend <section_name>
  mode tcp
  bind *:<port_to_use_in_the_client_connection_string>
  default_backend <backend_section_name>
```

- b) Create a `backend` section with one `server` entry for each Data Access Gateway server:

```
backend <backend_section_name>
  mode tcp
  server <DAG_server_name1> <DAG_server_host1>:<DAG_server_port1>
  server <DAG_server_name2> <DAG_server_host2>:<DAG_server_port2>
  ...
  server <DAG_server_nameN> <DAG_server_hostN>:<DAG_server_portN>
```

The `<backend_section_name>` is the parameter you specified in Step 2a.

3. Restart the `haproxy` service:

```
sudo service haproxy restart
```

Setting Your Client Connection String

Assume you have the following `haproxy` configuration settings and you have installed `haproxy` on `node1.cluster.com`:

```
frontend connection_input
  mode tcp
  bind *:8553
  default_backend maprdb_servers

backend maprdb_servers
  mode tcp
  server srv01 node1.cluster.com:5678
  server srv02 node2.cluster.com:5678
```

You can use the following client connection string with this sample configuration:

DAG with HTTPS | TLS

```
node1.cluster.com:8553?
auth=basic;user=mapr;password=mapr;ssl
=true;sslCA=/opt/mapr/conf/
ssl_truststore.pem;sslTargetNameOverri
de=node1.cluster.com
```

DAG with HTTP

```
node1.cluster.com:8553?
auth=basic;user=mapr;password=mapr;ssl
=false
```

L7 Load Balancing with the Data Access Gateway

You can use `nginx` for L7 load balancing of clients that use the Data Access Gateway. This topic describes how to install, configure, and run `nginx`, and how to set your client connection string to connect to the load balancing service.

Determine the server where you want to run the load balancing service. The server must be reachable by the clients using the Data Access Gateway. It also must be able to connect to the Data Access Gateway.

1. Install the `nginx` service on the server you have identified:

CentOS

```
sudo yum install nginx
```

Ubuntu

```
sudo apt install nginx
```

SLES

```
sudo zypper install nginx
```

2. Configure the `nginx` service by setting the following parameters in the configuration file at `/etc/nginx/nginx.conf`:

- a) In the `http` section, create an `upstream` block with one `server` entry for each Data Access Gateway server:

```
upstream <upstream_name> {
    server <DAG_server_host1>:<DAG_server_port1>;
    server <DAG_server_host2>:<DAG_server_port2>;
    ...
    server <DAG_server_hostN>:<DAG_server_portN>
}
```

- b) Create (or modify) the `server` block, depending on whether your cluster is secure or nonsecure:

Secure Cluster

For a secure cluster, you must specify the following SSL parameters:

- Listen port and protocol
- Path to the SSL certificate
- Path to the SSL key
- Path to the file containing the SSL password

```
server {
    listen 80 ssl http2;
    listen [::]:80;

    ssl_certificate
    <path_to_certificate>;
    ssl_certificate_key
    <path_to_key>;
    ssl_password_file
    <path_to_password_file>;

    access_log logs/access.log
    main;

    location / {
        grpc_pass grpcs://
    <upstream_name>;
    }
}
```

Nonsecure Cluster

```
server {
    listen 80 http2;
    listen [::]:80;

    access_log logs/access.log
    main;

    location / {
        grpc_pass grpc://
        <upstream_name>;
    }
}
```

The `<upstream_name>` is the parameter you specified in Step 2a.

3. Restart the nginx service:

```
sudo service nginx restart
```

Setting Your Client Connection String

Assume you have the following `nginx` configuration settings and you have installed `nginx` on `node1.cluster.com`:

Secure Cluster

```
user mapr;
worker_processes 1;
error_log /var/log/nginx/error.log
warn;
pid /var/run/nginx.pid;
events {
    worker_connections 1024;
}
http {
    log_format main '$remote_addr -
    $remote_user [$time_local] "$request"
    ' $status
    $body_bytes_sent "$http_referer"
    '"$http_user_agent"';
    upstream servers {
        server node1.cluster.com:5678;
        server node2.cluster.com:5678;
    }
    server {
        listen 80 ssl http2;
        listen [::]:80;

        ssl_certificate /opt/mapr/
        conf/ssl_keystore.pem;
        ssl_certificate_key /opt/mapr/
        conf/ssl_keystore.pem;
        ssl_password_file /root/
        passwd;

        access_log logs/access.log
    main;

    location / {
        grpc_pass grpcs://servers;
```

```

    }
  }
}

```

You can use the following client connection string with this sample configuration:

```

node1.cluster.com:80?
auth=basic;user=mapr;password=mapr;ssl
=true;sslCA=/opt/mapr/conf/
ssl_truststore.pem;sslTargetNameOverri
de=node1.cluster.com

```

Nonsecure Cluster

```

user mapr;
worker_processes 1;
error_log /var/log/nginx/error.log
warn;
pid /var/run/nginx.pid;
events {
    worker_connections 1024;
}
http {
    log_format main '$remote_addr -
$remote_user [$time_local] "$request"
                    '$status
$body_bytes_sent "$http_referer"
                    "$http_user_agent"';
    upstream servers {
        server node1.cluster.com:5678;
        server node2.cluster.com:5678;
    }
    server {
        listen 80 http2;
        listen [::]:80;

        access_log logs/access.log
    }
}
main;

    location / {
        grpc_pass grpc://servers;
    }
}

```

You can use the following client connection string with this sample configuration:

```

node1.cluster.com:80?
auth=basic;user=mapr;password=mapr;ssl
=false

```

Planning for High Availability

Configuring a cluster for HA (High Availability) involves running redundant instances of specific services, and configuring NFS properly. When properly licensed and configured for HA, the MapR cluster provides *automatic failover* for continuity throughout the stack.

The following table provides the minimum number of instances of each core service required for HA:

| Service | Minimum Number of Instances | Comments |
|-----------------|-----------------------------|--|
| CLDB | 2 | |
| ZooKeeper | 3 | At least 3 are needed to maintain a quorum in case one instance fails. |
| NFS | 2 | NFS can be configured for HA using virtual IP addresses (VIPs). |
| ResourceManager | 2 | |

In HA clusters, it is appropriate to run more than one instance of the WebServer with a load balancer to provide failover. NFS can be configured for HA using VIPs.

The following sections provide information about HA planning:

CLDB Failover

Explains the concept of CLDB failover, and its advantages.

The CLDB service automatically replicates its data to other nodes in the cluster, preserving at least two (and generally three) copies of the CLDB data. If the CLDB process dies, it is automatically restarted on the node. All jobs and processes wait for the CLDB to return, and resume from where they left off, with no data or job loss.

If the node itself fails, the CLDB data is still safe, and the cluster can continue normally as soon as the CLDB is started on another node. In an Enterprise Edition-licensed cluster, a failed CLDB node automatically fails over to another CLDB node without user intervention, and without data loss. It is possible to recover from a failed CLDB node on a Community Edition cluster, but the procedure is different.

Complete the following steps to recover from a failed CLDB node on a community edition cluster:

1. Restore ZooKeeper

If the CLDB node that failed was also running ZooKeeper, install ZooKeeper on another node to maintain the minimum required number of ZooKeeper nodes. Before installing ZooKeeper on another node, ensure that the ZooKeeper role is deleted on the failed node. See [Removing ZooKeeper Role](#) for more information.

2. Locate the CLDB Data

After restoring the ZooKeeper service on the HPE Ezmeral Data Fabric cluster, use the `maprcli dump zkinfo` command to identify the latest epoch of the CLDB, identify the nodes where replicates of the CLDB are stored, and select one of those nodes to serve the new CLDB node.

Secure cluster must first be converted to non-secure cluster before running the `maprcli dump zkinfo` command. Perform the following steps as root or use sudo:

Note: For non-secure clusters, skip to step 4.

1. On the ZooKeeper nodes, stop Warden and ZooKeeper by running the following commands:

```
service mapr-warden stop
service mapr-zookeeper stop
```

- Convert the secure cluster to non-secure cluster by running the following command on the ZooKeeper nodes:

Note: The script `configure.sh` takes comma-separated lists of cluster names and ZooKeeper host names (and optionally ports) or IP addresses.

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>:
[<port>]...] | <IP>[,<IP>...] -Z <host>[:<port>][,<host>: [<port>]...] |
<IP>[,<IP>...] -unsecure -R
```

- Restart ZooKeeper:

```
service mapr-zookeeper restart
```

- Issue the `maprcli dump zkinfo` command using the `-json` flag.

```
maprcli dump zkinfo -zkconnect localhost:5181 -json | grep -i "Container
ID"
```

The output displays the ZooKeeper znodes. For example:

```
maprcli dump zkinfo -zkconnect localhost:5181 -json | grep -i "Container
ID" | more
  "/datacenter/controlnodes/cldb/epoch/1/KvStoreContainerInfo": "
Container ID:1
  VolumeId:1 Master:10.10.104.34:5660-10.10.105.34:5660--9-VALID
Servers:
  10.10.104.34:5660-10.10.105.34:5660--9-VALID
  10.10.104.33:5660-10.10.105.33:5660--9-VALID
  10.10.104.32:5660-10.10.105.32:5660--9-VALID
Inactive Servers:  Unused Servers:  Latest epoch:9"
```

In the above example output, the latest epoch is 9.

- In the `/datacenter/controlnodes/cldb/epoch/1` directory, locate the CLDB with the latest epoch.

The Latest Epoch field identifies the current epoch of the CLDB data.

- Select a CLDB from among the copies at the latest epoch. For example, `10.10.105.32:5660--9-VALID` indicates that the node has a copy at epoch 9 (the latest epoch).

You can now install a new CLDB on the selected node.

To convert the non-secure cluster to a secure cluster, run the the following command:

Note: The script `configure.sh` takes comma-separated lists of cluster names and ZooKeeper host names (and optionally ports) or IP addresses.

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>:
[<port>]...] | <IP>[,<IP>...] -Z <host>[:<port>][,<host>: [<port>]...] |
<IP>[,<IP>...] -secure -R
```

3. Stop the Selected Node

Perform the following steps on the node you have selected for installation of the CLDB:

- Change to the root user (or use `sudo` for the following commands).

2. Stop the Warden:

```
service mapr-warden stop
```

4. Remove the CLDB Role on the Failed Node

To remove the CLDB role on the failed node, perform the following steps:

1. Stop Warden on the node.

```
service mapr-warden stop
```

2. Purge the CLDB package mapr-cldb with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.**5. Install the CLDB on the Selected Node**

Perform the following steps on the node you have selected for installation of the CLDB:

1. Login as `root` or use `sudo` for the following commands.**2. Install the CLDB service on the node:**

- RHEL/CentOS: `yum install mapr-cldb`
- Ubuntu: `apt-get install mapr-cldb`

6. Configure the Selected Node

The script `configure.sh` configures a node to be part of a HPE Ezmeral Data Fabric cluster, or modifies services running on an existing node in the cluster. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run `configure.sh`, make sure you have a list of the hostname of the ZooKeeper nodes. You can optionally specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

| Service | Default Port # |
|-----------|----------------|
| CLDB | 7222 |
| ZooKeeper | 5181 |

The script `configure.sh` takes an optional cluster name and log file, the CLDB hostname, and comma-separated list of ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>] -Z <host>[:<port>]
[,<host>[:<port>]...] \
[-L <logfile>][-N <cluster name>]
```

Note: Each time you specify the `-Z <host>[:<port>]` option, you must use the *same order* for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example

```
/opt/mapr/server/configure.sh -C r1n1.sj.us:7222 \
-Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5
181 -N MyCluster
```

7. Start the Nodes

Perform the following steps on the node you have selected for installation of the CLDB:

Start the Warden:

```
service mapr-warden start
```

After the CLDB restarts, there is a 15-minute delay before replication resumes, in order to allow all nodes to register and heartbeat. This delay can be configured using the `config save` command to set the `cldb.replication.manager.start.mins` parameter.

8. Restart All Nodes

To restart all nodes in the cluster, stop each node, configure the node with the new CLDB and ZooKeeper addresses, and start the node.

Complete the following steps on each node in the cluster:

1. Stop the node.
 - a. Change to the root user (or use sudo for the following commands).
 - b. Stop the Warden:

```
service mapr-warden stop
```

2. Configure all the nodes with the new CLDB and ZooKeeper addresses.

The script `configure.sh` configures a node to be part of a HPE Ezmeral Data Fabric cluster, or modifies services running on an existing node in the cluster. You must run this script to configure a node. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run `configure.sh`, make sure you have the hostname of the CLDB node and the hostnames of the ZooKeeper nodes. You can, optionally, specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

| Service | Default Port # |
|-----------|----------------|
| CLDB | 7222 |
| ZooKeeper | 5181 |

The script `configure.sh` takes an optional cluster name and log file, the CLDB hostname, and comma-separated list of ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>] -Z <host>[:<port>]
[,<host>[:<port>]...] [-L <logfile>][-N <cluster name>]
```

Note: Each time you specify the `-Z <host>[:<port>]` option, you must use the same order for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example:

```
/opt/mapr/server/configure.sh -C r1n1.sj.us:7222 -Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5181 -N MyCluster
```

3. Start Warden.

```
service mapr-warden start
```

Best Practices for Running a Highly Available Cluster

Lists high availability cluster replication types, and the best practices for running such a cluster.

Data Fabric runs a wide variety of concurrent applications in a highly available fashion. Node failures do not have cluster-wide impact, and activities on other nodes in the cluster can continue normally. In parallel, data-fabric components detect failures and automatically recover from them. During the recovery process, clients may experience latency, the duration of which depends on the nature of the failure.

Node Shutdown Instances

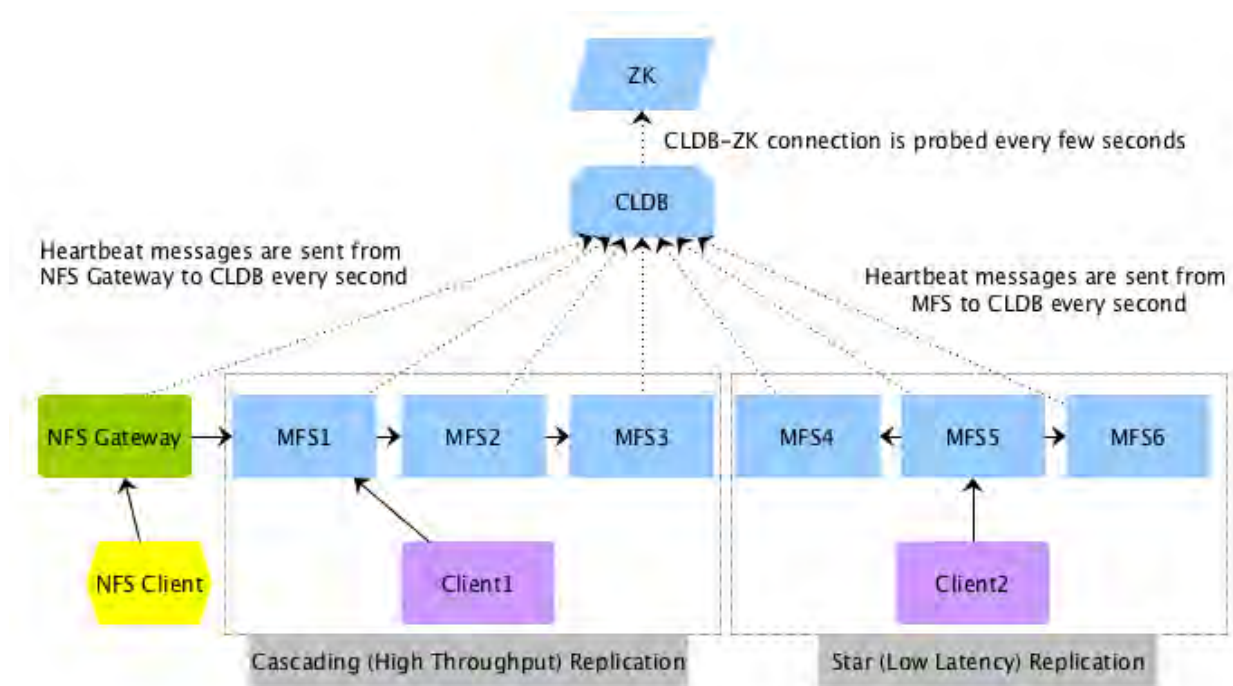

The cause of a service failure can be one of the following:

| | |
|-------------------------|---|
| Planned shutdown | A planned/controlled failure. In this case, data-fabric is informed that a file server will be stopped. Data Fabric services use this information to improve recovery behavior. |
| Unexpected shutdown | Data Fabric services (filesystem, NFS server etc..) are stopped. However, the host operating system continues to run and failure detection is fast. |
| Hard unplanned shutdown | A power off, network down, or some other kind of unplanned stop. A node is stopped in a way that it is no longer reachable. Packets sent to this node do not get an error response and failure is detected through network layer's timeout mechanism. This results in longer failure detection times. |

In all of these instances, the recovery process typically involves detecting that a node is unreachable, and contacting another available node for the same piece of information (either for reads, writes, or administrative operations).

How filesystem and Associated Services Work

Let's review how filesystem and associated services typically work, using the following illustration.

High-throughput or Cascading Replication Type: As shown in the illustration, the client, Client1, writes to a data-fabric filesystem, MFS1, which in turn talks to MFS2, which in turn talks to MFS3 for cascading (high throughput) replication. The replication is inline and synchronous, which means MFS1 replies to the client only after it receives a response from MFS2. MFS2, in turn, only responds to MFS1 after MFS3 has replied to it. Client1 can read from any MFS, but write only to MFS1.

Low-latency or Star Replication Type: As shown in the illustration, the client, Client2, writes to MFS5. This illustration shows an example of star (low latency) replication where MFS5 replicates to both MFS4 and MFS6 in parallel. Again, the replication is inline and synchronous, which means that MFS5 responds to Client2 only after it has received responses from both MFS4 and MFS6.

Recommended Settings for Running a Cluster with Low Latency and Fast Failover Characteristics

A well designed cluster provides automatic failover for continuity throughout the stack. For an example of a large, high-availability Enterprise Edition cluster, see [Example Cluster Designs](#) on page 77. On a large cluster designed for high availability, services should be assigned according to the service layout guidelines. For more information, see [Service Layout Guidelines for Large Clusters](#) on page 74. In general, services, specifically CLDB and ZooKeeper, should be installed on separate nodes to prevent the failure of multiple services at the same time and to enable the cluster to recover quickly.

Recommended Settings to Recover from Unplanned Shutdown

Latencies as a result of unplanned or unexpected failures/shutdowns can be improved by performing the following:

Enabling Fast Failover of Services

Describes the Fast Failover feature that allows a cluster to rapidly detect and recover from network failures.

For running a cluster with Fast Failover characteristics, enable the Fast Failover feature:

```
/opt/mapr/bin/maprcli config save -values {mfs.feature.fastfailover:1}
```

If you have enabled the fast failover feature, when the filesystem detects a failed node, it very quickly declares the node as being down. Clients experience a short latency period while the failure is being detected. Once MapR detects the failure, MapR redirects clients of the failed node to an alternate location

(a replica container) for the data. If you have not enabled the fast failover feature, the filesystem repeatedly contacts the failed node.

This feature is enabled on all new installations. For upgrade installations, this feature is not enabled by default. You need to evaluate whether this feature works well with your existing infrastructure, before enabling it. You cannot turn this feature off after turning it on.

Tuning the TCP for Fast Failure Detection

Describes how to tune the TCP stack to detect node or network failures rapidly.

An unplanned failure chiefly takes the form of a node failure or a network failure. In both instances, the network layer retries to connect to the failed node. The number of retry attempts is dictated by the TCP parameter `/proc/sys/net/ipv4/tcp_syn_retries`. The default value of that parameter is 5 (in Linux), resulting in a latency of more than a minute to detect the node failure. The problem is compounded when the same failed node is contacted repeatedly in the context of a long operation, such as when a client accesses multiple data objects present on that node.

The data-fabric stack solves the problem by remembering (caching) the information about a node's failure, and by not contacting that node for subsequent operations on data objects present on that node. Since all form of data is replicated, data-fabric services find alternative locations for a data object. This feature is in-built into the current software and does not have to be enabled explicitly. Hence, the communication between a client and a recently failed node incurs a one-time long-duration latency. As mentioned before, that latency is governed by the number of retries at the TCP level. Hence, to further improve the one-time longer latency of an operation between a pair of nodes, it is recommended that the number of TCP retries be decreased from 5 to 4, resulting in a latency of about 30 seconds.

Setting the Timeout for TCP Connections

To set the TCP retry count, set the value of `tcp_syn_retries` to 4 in the `/proc/sys/net/ipv4/` directory (for IPv4 connections). For example:

```
echo 4 > /proc/sys/net/ipv4/tcp_syn_retries
```

Similarly for IPv6 connections, set:

```
echo 4 > /proc/sys/net/ipv6/tcp_syn_retries
```

This TCP setting of 4 ensures that the TCP stack takes about 30 seconds to detect failure of a remote node. To ensure that this setting is persistent across system reboots, set this value in the `/etc/sysctl.conf` file.

 **Warning:** This setting impacts all TCP connections to and from a node. Hence, caution must be exercised when lowering this further. Also, in some instances, reducing this further may result in a node being incorrectly flagged as unavailable.

Reducing Failure Detection Time for File Clients

Describes how to set the time for Hadoop and POSIX clients to detect node failures.

To reduce the amount of time it takes (Hadoop and FUSE-based POSIX) clients to detect (CLDB and data node) failure, define the property, `fs.mapr.connect.timeout`, in the `core-site.xml` file. The value for this property can be set in 100 milliseconds and will be rounded up to the nearest 100 milliseconds. The minimum value for this property is 100 milliseconds, which can be incremented only by units of 100 milliseconds. Suppose a value of 260 milliseconds is specified, by default, the value will automatically be rounded up to 300 milliseconds. The default value for this property is 0, which means that the Linux TCP timeout setting will be used for connections if this property is not set.

Your entry in `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.connect.timeout</name>
```

```
<value>200</value>
<description>file client wait time of 200 milliseconds</description>
</property>
```

This setting (for hadoop and FUSE-based POSIX clients) ensures that the clients wait only for the specified amount of time to establish a connection. That is, it is used only for the first request sent to CLDB or a data node before or after a failure. For subsequent requests, the default system connection timeout value is used. In the event of a failure after a connection has been established, the client will wait for the connection to timeout (based on the system timeout value) before it contacts the next (CLDB or data) node to process the request.

For example, suppose the value for this parameter is 100 milliseconds and the Linux TCP connection timeout value is 30 seconds. When a hadoop or FUSE-based POSIX client contacts CLDB or a data node for the first time to establish a connection, the client will wait for 100 milliseconds before trying the next CLDB or data node. After a connection is established, for subsequent requests, the client will wait for 30 seconds for a response. If the node goes down after a connection has been established, the client will wait for 30 seconds before trying the next node. If the client contacts a recovered node for the first time, it will wait for 100 milliseconds to establish the connection.

Note: HPE Ezmeral Data Fabric filesystem does not use this property internally; it is used by Hadoop and FUSE-based POSIX clients only. This setting is not applicable to NFS gateway and loopbacknfs POSIX clients.

Detecting CLDB failures

When a connection with CLDB is established, CLDB returns the list of reachable and unreachable CLDB nodes on the cluster.

Populating the cache

The client stores information about the unreachable CLDB nodes in `/tmp/cldbinfo/unreachableCldbs` file on the client host. The format of this file is the same as the `mapr-clusters.conf` file (i.e., "clustername ip:port"). For example:

```
cat /tmp/cldbinfo/unreachableCldbs
object_pools 10.10.104.33:7222
10.10.104.34:7222
```

The client reads the `mapr-clusters.conf` file and the `unreachableCldbs` file to determine the CLDB to connect to. It then tries to reach the available CLDB nodes first; it tries the unreachable CLDB nodes only if the available CLDB is unable to service its request.

Invalidating the cache

If the available CLDB is unable to service the client request, the client tries the unreachable CLDB. If an unreachable CLDB becomes reachable again, it is removed from the `/tmp/cldbinfo/unreachableCldbs` file, making it reachable for all subsequent IOs and if a reachable CLDB becomes unreachable, it is added to the `/tmp/cldbinfo/unreachableCldbs` file.

Recommended Settings for Planned Shutdown

Explains the modalities of a planned shutdown.

The HPE Ezmeral Data Fabric stack improves the latencies for planned shutdowns by implementing a fast failover mechanism where different services respond to the intimation of a failure.

Notifying CLDB to Allow Fast Failover

When planning to shutdown a node, notifying CLDB of an impending shutdown allows CLDB to update the replication chain such that primary and intermediate containers, if any, are not on the node and re-assign VIPs on the node when the node actually goes down. This, in turn, allows clients to continue activities on available nodes.

MapR (v5.1) includes an argument, `node failover`, to the `maprcli` command that notifies CLDB of impending node shutdown so that CLDB can ensure that the specified node does not have any primary containers and intermediate containers (in a cascaded chain), and VIPs are re-assigned.

Shutting Down a Node

To notify CLDB of a planned shutdown of a node:

1. Enable the fast failover behavior.
Refer to [Enabling Fast Failover](#) for more information.
2. Reset the value of `tcp_syn_retries` parameter.
Refer to [Tuning TCP](#) for more information.
3. (Optional) Get the hostname of the node to put in maintenance mode by running the following command:

```
/opt/mapr/bin/maprcli node list -columns hostname
```

4. Run the `failover` command for that node.

For example:

```
/opt/mapr/bin/maprcli node failover -nodes <node-hostname>
```

Wait for few minutes (to allow containers to failover) before proceeding to the next step.

5. Stop warden on that node by running the following command:

```
service mapr-warden stop
```

6. Notify HPE Ezmeral Data Fabric that the node is in maintenance mode and when the maintenance task is complete, remove the node from maintenance mode.

See [Performing Maintenance on a Node](#) for the commands to run to `put` and `take` a node out of maintenance mode.

Warning: Shut down only one node at a time. Do not take down multiple nodes for maintenance at the same time.

ResourceManager High Availability

Provides an overview of how high availability for Resource Manager works.

The ResourceManager service tracks a cluster's resources and schedules YARN applications. Configure high availability for the ResourceManager so that the failure of the ResourceManager service is not a single point of failure for the cluster. The high availability of ResourceManager is based on the cluster configuration of the restart, recovery, and failover features.

Restart

By default, the Warden attempts to restart a failed service three times. You can configure the frequency that Warden attempts to restart failed services before initializing failover in the [warden.conf](#) file. For more information, see [warden.conf](#).

Recovery

When a ResourceManager restarts or fails over, the active ResourceManager can recover the state of the previously running ResourceManager. By default, ResourceManager recovery is enabled and it uses the `FileSystemRMStateStore` implementation to store the ResourceManager state in the filesystem. You can configure the ResourceManager to have no recovery or you can enable the recovery. You can also configure the state store implementation that you want to use. For more information, see [Recovery for the ResourceManager](#).

Failover

When a ResourceManager fails, the cluster can fail over the ResourceManager process to another node. To configure failover, the cluster must have one or more nodes with the ResourceManager role.

Note:

Starting in Version 4.0.2, zero configuration failover provides automatic failover without requiring that you specify the ResourceManager nodes when you run [configure.sh](#). It also does not require any further configuration to [yarn-site.xml](#).

Upgrade any client nodes to the 4.0.2 client to ensure proper communication with the ResourceManager service. Earlier versions of the MapR client do not support the zero configuration feature.

You can select one of the following failover implementations when you use the [configure.sh](#) utility to configure each node:

- **Zero Configuration Failover.** With zero configuration failover, the ResourceManager process only runs on one node in the cluster. When the active ResourceManager fails, one of the standby ResourceManager nodes automatically loads the working state from the state store and continues providing services to the cluster. Zero configuration failover is the default, recommended setting for the following reasons:
 - **Only one ResourceManager process consumes cluster resources.** With the manual or automatic failover option, the active and standby ResourceManagers consume cluster resources.
 - **Warden initiates failover automatically.** With the manual failover, you need to manually run the [yarn rmdadmin](#) command for failover to occur.
 - **Simplified clients connectivity.** Clients identify the active ResourceManager with a single request to the Zookeeper. With the manual or automatic failover option, ResourceManager clients connect to each ResourceManager in a round-robin fashion until they locate the active ResourceManager; this results in delays when launching or querying jobs.
 - **Consistent Configuration.** All cluster nodes and clients can use the same [yarn-site.xml](#) configuration file. With manual or automatic failover, you must maintain a customized [yarn-site.xml](#) file for each node that runs the ResourceManager.

For more information, see [Zero Configuration Failover for the ResourceManager](#).

- **Manual or Automatic Failover.** With manual failover or automatic failover, one active ResourceManager and one or more standby Resource Managers run in the cluster. The standby ResourceManager nodes run the ResourceManager process without loading the working state. When the active ResourceManager fails, one of the standby ResourceManager nodes can load the working state from the state store and continue providing services to the cluster. For more information, see [Manual or Automatic Failover for the ResourceManager](#).

You can perform the following procedures to manage ResourceManager:

Manual or Automatic Failover for the ResourceManager

With manual or automatic failover, an active ResourceManager and two standby ResourceManager processes run in the cluster. The standby ResourceManager nodes run the ResourceManager process without loading the working state. When the active ResourceManager fails, one of the standby ResourceManager nodes can load the working state from the ZooKeeper and continue providing services to the cluster.

ResourceManager clients (HPE Ezmeral Data Fabric client nodes, ApplicationMaster processes, and NodeManager nodes) attempt connections to the ResourceManager nodes in a round-robin fashion until they hit an active ResourceManager node. If the active ResourceManager node is down, ResourceManager clients resume round-robin polling until an active ResourceManager node is detected.

For web requests, including REST API requests, standby ResourceManager nodes automatically redirect web requests to the active ResourceManager node.

The difference between manual and automatic failover is how the transition from standby to active occurs for the ResourceManager process.

- With manual failover, you manually invoke the transition of the ResourceManager from standby to active with the `yarn rmdadmin` command.
- With automatic failover, the ResourceManager processes have an embedded ZooKeeper-based ActiveStandbyElector, which chooses the active ResourceManager. This ActiveStandbyElector also detects failures in the currently active ResourceManager and automatically transitions one of the standby ResourceManagers to an active state.

If you specify multiple ResourceManagers when you run `configure.sh`, automatic failover is configured. However, you can edit the `yarn-site.xml` file to enable manual failover instead.

Automatic Failover Administration

The Zookeeper-based ActiveStandbyElector on each ResourceManager node detects failures in the currently active ResourceManager and automatically transitions one of the standby ResourceManagers to an active state. Therefore, `rmdadmin -transitionToStandby` and `-transitionToActive` are disabled.

Configuring Automatic Failover for the ResourceManager

To use automatic failover, specify multiple ResourceManagers when you run `configure.sh` on each node in the cluster.

The following `configure.sh` script syntax configures three ResourceManager nodes (one active and two standby) and one HistoryServer node:

```
/opt/mapr/server/configure.sh -C <CLDB node list> -Z <ZK node list> -RM
<hostname1,hostname2,hostname3> -HS <hostname1> [additional parameters]
```

Note: After you run `configure.sh`, each ResourceManager node contains a different value for the `yarn.resourcemanager.ha.id` property in the `yarn-site.xml`.

Example yarn-site.xml file

The following configure.sh syntax specifies three ResourceManager nodes (nodeA, nodeB, and nodeC) and a HistoryServer node (nodeA):

```
/opt/mapr/server/configure.sh -C node1,node2,node3 -Z node1,node2,node3 -RM
nodeA,nodeB,nodeC -HS nodeA [additional parameters]
```

Manual Failover Administration

Configure manual failover for the ResourceManager if you want to manually transition the state of ResourceManagers in the cluster. In the event of a ResourceManager failure, you use `rmadmin` commands to check the status of each ResourceManager and then transition a standby ResourceManager to the active state.

Configuring Manual Failover for the ResourceManager

To configure manual failover, specify multiple ResourceManagers when you run `configure.sh` on each node in the cluster and then edit `yarn-site.xml` to disable automatic failover.

1. Specify multiple ResourceManagers when you run `configure.sh` on each cluster and client node. The following the `configure.sh` script syntax configures three ResourceManager nodes (one active and two standby):

```

/opt/mapr/server/configure.sh -C <CLDB node list> -Z <ZK node list> -RM
<hostname1,hostname2,hostname3> -HS <hostname1> [additional parameters]

```

Note: After you run `configure.sh`, each ResourceManager node contains a different value for the `yarn.resourcemanager.ha.id` property in the `yarn-site.xml`.

2. Disable the following automatic failover properties in the `yarn-site.xml` on each node with the ResourceManager role:
 - `yarn.resourcemanager.ha.automatic-failover.enabled`
 - `yarn.resourcemanager.ha.automatic-failover.embedded`
3. Restart the ResourceManager service. For more information, see [Restarting the Services](#) on page 908.

Transitioning a Standby ResourceManager to Active

The `yarn rmadmin` command includes options to manage high availability for the ResourceManager, including transitioning a ResourceManager node between active and standby modes. These commands take the ResourceManager service ID as an argument and can be run on any node in the cluster. The `serviceID` of a ResourceManager is set in the `yarn.resourcemanager.ha.rm-ids` property of the `yarn-site.xml` file.

Transition a standby ResourceManager to the active state when the active ResourceManager process has failed or the node that runs the process is no longer accessible.

1. Determine if an active ResourceManager is running in the cluster. See [Checking the ResourceManager State](#).
2. Run the following command to set the current active ResourceManager to standby:

```

yarn rmadmin -transitionToStandby <serviceID>

```

- Run the following command to transition the standby ResourceManager to the active state:

```
yarn rmadmin -transitionToActive <serviceID>
```

Checking the ResourceManager State

When you configure manual or automatic failover, the ResourceManager is either in active or standby state. Each ResourceManager has a serviceID that identifies the service.

- To check the state of a ResourceManager, run the following command with the serviceID:

```
yarn rmadmin -getServiceState <serviceID>
```

The command returns `active` or `standby` based on the state of the ResourceManager associated with the serviceID that you provide.

Note: Tip To determine the serviceIDs associated with the ResourceManagers in the cluster, run `hadoop conf | grep yarn.resourcemanager.ha.rm-ids`

Using Central Configuration with Manual and Automatic Failover

When you configure manual or automatic failover for the ResourceManager, the contents of the `yarn-site.xml` configuration file are slightly different on each ResourceManager node as the value of the `yarn.resourcemanager.ha.id` property is distinct for each ResourceManager node. If your cluster is using the [central configuration](#) feature, configure central configuration overrides for each ResourceManager node:

- Keep a central copy of the file at `/var/mapr/configuration/default/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml`.

- Configure central configuration overrides in the following manner:

```
/var/mapr/configuration/nodes/<HOSTNAME FOR RM 1>/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml /var/mapr/configuration/nodes/<HOSTNAME FOR RM 2>/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml /var/mapr/configuration/nodes/<HOSTNAME FOR RM 3>/hadoop/hadoop-2.x/etc/hadoop/yarn-site.xml
```

Zero Configuration Failover for the ResourceManager

As of MapR 4.0.2, you can use zero configuration failover. With zero configuration failover, the ResourceManager role is installed on two or more nodes but the ResourceManager process only runs on one node in the cluster.

If the node running the ResourceManager process fails and the Warden on that node is unable to restart it, the Warden on each node and Zookeeper work together to start a ResourceManager process on the cluster. ResourceManager clients connect to the Zookeeper to determine which ResourceManager node is active. Therefore, when failover occurs, the Resource Manager clients are not affected as they automatically connect to the active ResourceManager.

Note: When you run `maprcli service list` command, the state of the active ResourceManager process displays as 2 (running) but the other ResourceManagers displays as 5 (stand by).

Enabling Zero Configuration Failover for the ResourceManager

To enable zero configuration failover, do not specify the `-RM` parameter when you run `configure.sh` on each node in the cluster. However, for failover to occur, at least two nodes in the cluster must have the ResourceManager role.

For example, if the cluster includes multiple nodes with the ResourceManager role, you can run the following `configure.sh` command on each cluster node and no further configuration is required:

```
/opt/mapr/server/configure.sh -N mycluster -C centos21 -Z centos21 -HS
centos22 -F /tmp/disks.txt -disk-opts F
```

`configure.sh` automatically populates `yarn-site.xml` with the following configuration:

```
<configuration>
<!-- Resource Manager MapR HA Configs -->
<property>
  <name>yarn.resourcemanager.ha.custom-ha-enabled</name>
  <value>>true</value>
  <description>MapR Zookeeper based RM Reconnect Enabled.
  If this is true, set the failover proxy to be the class
  MapRZKBasedRMFailoverProxyProvider</description>
</property>
<property>
  <name>yarn.client.failover-proxy-provider</name>
  <value>org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider</
  value>
  <description>Zookeeper based reconnect proxy provider. Should
  be set if and only if mapr-ha-enabled property is true.</description>
</property>
<property>
  <name>yarn.resourcemanager.recovery.enabled</name>
  <value>>true</value>
  <description>RM Recovery Enabled</description>
</property>
<!-- :::CAUTION::: DO NOT EDIT ANYTHING ON OR ABOVE THIS LINE -->
</configuration>
```

For more information about the ResourceManager properties in `yarn-site.xml`, see [ResourceManager Configuration Properties](#).

Updating ResourceManager Ports

To simplify the failover configurations in the `yarn-site.xml` file, Warden maintains the list of ResourceManager ports in the `warden.resourcemanager.conf` file. For a list of the default port numbers, see [Ports Used by HPE Ezmeral Data Fabric Software](#) on page 2579. If you want to edit the default ResourceManager ports, edit the `warden.resourcemanager.conf` file and the `yarn-site.xml` file on each ResourceManager node.

Note: If each node requires different ResourceManager ports, you must maintain a separate `yarn-site.xml` file for each node. Therefore, to you use Central Configuration, you must create a customized configuration file for each ResourceManager node in the cluster.

To update the port numbers, edit the values in the `warden.resourcemanager.conf` file and add the values in the `yarn-site.xml` file.

1. Open the `warden.resourcemanager.conf` file (`/opt/mapr/conf/conf.d/warden.resourcemanager.conf`).

2. Edit the port numbers, which are listed using the following format: `service.extinfo.<port>=<port number>`

| Port Name | Property Name in <code>warden.resourcemanager.conf</code> |
|---|---|
| ResourceManager Scheduler RPC (for ApplicationMasters) | <code>service.extinfo.SCHEDULER_PORT</code> |
| ResourceManager Resource Tracker RPC (for NodeManagers) | <code>service.extinfo.RESOURCETRACKER_PORT</code> |
| ResourceManager Client RPC | <code>service.port</code> |
| ResourceManager Admin RPC | <code>service.extinfo.ADMIN_PORT</code> |
| ResourceManager Web UI (HTTP) | <code>service.extinfo.WEBAPP_PORT</code> |
| ResourceManager Web UI (HTTPS) | <code>service.extinfo.WEBAPP_HTTPS_PORT</code> |

3. Open the `yarn-site.xml` file (`/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`).
4. For each port that you edited, add the associated property to the `yarn-site.xml` file:

| Port Name | Property Name in <code>yarn-site.xml</code> |
|---|--|
| ResourceManager Scheduler RPC (for ApplicationMasters) | <code>yarn.resourcemanager.scheduler.address</code> |
| ResourceManager Resource Tracker RPC (for NodeManagers) | <code>yarn.resourcemanager.resource-tracker.address</code> |
| ResourceManager Client RPC | <code>yarn.resourcemanager.address</code> |
| ResourceManager Admin RPC | <code>yarn.resourcemanager.admin.address</code> |
| ResourceManager Web UI (HTTP) | <code>yarn.resourcemanager.webapp.address</code> |
| ResourceManager Web UI (HTTPS) | <code>yarn.resourcemanager.webapp.https.address</code> |

For example, to update the port number for the ADMIN_PORT to 9000 on each node, enter the following in the `yarn-site.xml` file on each node:

```
<property>
  <name>yarn.resourcemanager.adminaddress</name>
  <value>10.10.30.140:9000</value>
</property>
```

5. Restart the Warden and the ResourceManager services.

Switching from Zero Configuration to Manual or Automatic Failover

You can change your ResourceManager failover implementation from zero configuration to manual or automatic failover by re-configuring all the cluster and client nodes.

For more information, see [Configuring Manual Failover for the Resource Manager](#) or [Configuring Automatic Failover for the Resource Manager](#).

Recovery for the ResourceManager

After a restart or failover, the active ResourceManager recovers the ResourceManager state based on the checkpoints provided in the ResourceManager state store. During recovery, the ResourceManager resumes applications and tasks that were running prior to the failover but were not completed.

Two implementations of the ResourceManager state store are available:

- **FileSystemRMStateStore.** Enables implicit write access to a single ResourceManager node. filesystem provides fencing implicitly and its state store implementation provides better scalability and failover performance than the ZKRMStateStore. The state store is also naturally protected by filesystem replication. By default, FileSystemRMStateStore is the state store implementation for the ResourceManager and the ResourceManager state store is maintained in the following MapR filesystem volume: `/var/mapr/cluster/yarn/rm/system`.
- **ZKRMStateStore.** Enables implicit write access to a single ResourceManager node. This is usually recommended for HA implementations where YARN is running on HDFS. However, FileSystemRMStateStore is recommended in a MapR cluster.

Note: For recovery to occur, all ResourceManager nodes must have access to the ResourceManager state store.

ResourceManager Recovery Administration

To change the default behavior, update the ResourceManager configuration in the `yarn-site.xml` files and restart the ResourceManager(s). The `yarn-site.xml` is located in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`

You may want to perform the following tasks:

Disabling the restart of applications after failover

You can configure the ResourceManager to not recover its state after a restart or failover occurs.

- Set the value of `yarn.resourcemanager.recovery.enabled` to `false` in `yarn-site.xml` on each ResourceManager node.

Configuring Maximum Attempts for Applications

Describes how to set the maximum number of restart attempts for all applications run by the data-fabric ResourceManager and the ApplicationMaster.

When an ApplicationMaster fails, the ResourceManager restarts the ApplicationMaster as long as the number of restart attempts does not exceed the `max-attempt` values set at the ResourceManager and ApplicationMaster level. By default, the maximum attempt value is set to 2.

- To configure the maximum number of ApplicationMaster attempt retries for all applications run by the ResourceManager:
Set the value of `yarn.resourcemanager.am.max-attempts` in the `yarn-site.xml` file. The value defaults to 2.
- To configure the number of ApplicationMaster attempts allowed for the MapReduce ApplicationMaster:
Set the value of `mapreduce.am.max-attempts` in the `mapred-site.xml` file. The value defaults to 2.

Configuring the filesystem State Store

Describes the configuration of the data-fabric state store.

By default, the Resource Manager stores its state in the data-fabric filesystem. However, you can change the values for the following properties related to the data-fabric filesystem state store:

- To configure the URI to the state store location:
Set the value of `yarn.resourcemanager.fs.state-store.uri` in the `yarn-site.xml` file. The value defaults to the ResourceManager volume (`/var/mapr/cluster/yarn/rm/system`).
- To configure the retry policy used by the state store client to connect with data-fabric file system:
Set the value of `yarn.resourcemanager.fs.state-store.retry-policy-spec` in the `yarn-site.xml` file. The value defaults to (2000,500).

- To configure the number of completed applications retained by the state store:
Set the value of `yarn.resourcemanager.state-store.max-completed-applications` in the `yarn-site.xml` file. The value defaults to 10000.

Enabling ZooKeeper Based State Store

By default, the Resource Manager stores its state in the filesystem. However, you can use the Zookeeper based state store instead. To configure the ResourceManager to use the Zookeeper state store:

- Set the value of `yarn.resourcemanager.store.class` to `org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore` in the `yarn-site.xml`.
- Set the value of `yarn.resourcemanager.zk-address` to a comma-separated list of host:port pairs for each ZooKeeper server used by the ResourceManager. This property needs to be set in `yarn-site.xml`.

ResourceManager Configuration Properties

The following sections describe the properties that you can configure for the ResourceManager. The default values for these properties are defined in the `yarn-default.xml` or by MapR. You can configure overrides to the default by adding to or editing the properties in `yarn-site.xml`.

The following sections provide information about ResourceManager failover and recovery properties:

ResourceManager Failover Properties

The following table describes the configuration properties for ResourceManager failover:

| Property | Description |
|--|---|
| <code>yarn.resourcemanager.ha.custom-ha-enabled</code> | When <code>yarn.client.failover-proxy-provider</code> is set to <code>org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider</code> , this property must be <code>true</code> . The default, set by <code>configure.sh</code> in <code>yarn-site.xml</code> when the cluster uses zero configuration failover for the ResourceManager, is <code>true</code> . |
| <code>yarn.resourcemanager.ha.enabled</code> | Enables high availability for the ResourceManager. The default, set by MapR in the <code>yarn-site.xml</code> , is <code>true</code> . This property must be set to <code>true</code> for failover to occur. |
| <code>yarn.resourcemanager.ha.automatic-failover.enabled</code> | When <code>yarn.resourcemanager.ha.enabled</code> is <code>true</code> , this property enables the ResourceManager to automatically failover. The default, set in <code>yarn-default.xml</code> , is <code>true</code> . |
| <code>yarn.resourcemanager.ha.automatic-failover.embedded</code> | When <code>yarn.resourcemanager.ha.enabled</code> is <code>true</code> , this property enables the ResourceManager to use the embedded automatic failover. The default, set in <code>yarn-default.xml</code> , is <code>true</code> . |
| <code>yarn.resourcemanager.cluster-id</code> | Specifies the cluster that the ResourceManager belongs to. This value is originally set by <code>configure.sh</code> in the <code>yarn-site.xml</code> and the value is required for failover to occur. |
| <code>yarn.resourcemanager.ha.rm-ids</code> | The ResourceManager service ID. <code>Configure.sh</code> adds this property to each node with the ResourceManager role. |

| Property | Description |
|---|--|
| yarn.resourcemanager.ha.id | Specifies the serviceID of the ResourceManager on the current node. |
| yarn.resourcemanager.zk-address | <p>Specifies the zookeeper quorum that the ResourceManager belongs to.</p> <p>This value is originally set by configure.sh in the yarn-site.xml when you configure failover.</p> |
| yarn.client.failover-proxy-provider | <p>Specifies the ResourceManager failover implementation used by clients, ApplicationMasters, and NodeManagers.</p> <p>configure.sh sets this value based on the type of failover that you configure.</p> <ul style="list-style-type: none"> For automatic or manual failover, configure.sh sets this value to org.apache.hadoop.yarn.client.ConfiguredRMFailoverProxyProvider For zero configuration failover, configure.sh sets this value to org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider <p>This value is set by configure.sh in yarn-site.xml when you configure failover. Otherwise, the default, set in yarn-default.xml is org.apache.hadoop.yarn.client.DefaultFailoverProxyProvider.</p> |
| yarn.resourcemanager.scheduler.address[.<serviceID>] | <p>The address of the scheduler interface</p> <p>This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover.</p> <p>For zero configuration failover, this property is not needed unless you have configured custom port values. When you specify the custom port number, the serviceID is not required.</p> |
| yarn.resourcemanager.resource-tracker.address[.<serviceID>] | <p>The address of the resource tracker interface. ResourceManager listens for container requests and heartbeats from the NodeManagers on this port.</p> <p>This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover.</p> <p>For zero configuration failover, this property is not needed unless you have configured custom port values. When you specify the custom port number, the serviceID is not required.</p> |
| yarn.resourcemanager.address[.<serviceID>] | <p>The address of the client interface. The ResourceManager listens for client requests on this port.</p> <p>This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover.</p> <p>For zero configuration failover, this property is not needed unless you have configured custom port values. When you specify the custom port number, the serviceID is not required.</p> |

| Property | Description |
|---|--|
| yarn.resourcemanager.admin.address[.<serviceID>] | <p>The address of the administrative interface. ResourceManager listens for administrative requests from the yarn radmin command on this port.</p> <p>This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover.</p> <p>For zero configuration failover, this property is not needed unless you have configured custom port values. When you specify the custom port number, the serviceID is not required.</p> |
| yarn.resourcemanager.webapp.address[.<serviceID>] | <p>The address of the ResourceManager web UI.</p> <p>This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover.</p> <p>For zero configuration failover, this property is not needed unless you have configured custom port values. When you specify the custom port number, the serviceID is not required.</p> |
| yarn.resourcemanager.webapp.https.address[.<serviceID>] | <p>The address of the secure ResourceManager web UI.</p> <p>This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover.</p> <p>For zero configuration failover, this property is not needed unless you have configured custom port values. When you specify the custom port number, the serviceID is not required.</p> |
| yarn.client.failover-max-attempts | <p>The max number of times FailoverProxyProvider should attempt failover.</p> <p>The default is -1.</p> |
| yarn.client.failover-sleep-base-ms | <p>The sleep base (in milliseconds) to be used for calculating the exponential delay between failovers.</p> <p>The value defaults to the value set by yarn.resourcemanager.connect.retry-interval.ms, which is 30000 ms.</p> |
| yarn.client.failover-sleep-max-ms | <p>The maximum sleep time (in milliseconds) between failovers.</p> <p>The value defaults to the value set by yarn.resourcemanager.connect.retry-interval.ms, which is 30000 ms.</p> |
| yarn.client.failover-retries | <p>The number of times a client attempts to reconnect to a ResourceManager.</p> <p>The default, set in yarn-default.xml, is 0 (infinite).</p> |
| yarn.client.failover-retries-on-socket-timeouts | <p>The number of times a client attempts to reconnect to a ResourceManager on socket timeouts.</p> <p>The default, set in yarn-default.xml, is 0 (infinite).</p> |

ResourceManager Recovery Properties

The following table describes the configuration properties for ResourceManager recovery:

| Property | Description |
|---|---|
| yarn.resourcemanager.recovery.enabled | <p>Enables the ResourceManager to recovery based on the information in the ResourceManager state store.</p> <p>The default, set by configure.sh, is <code>true</code>.</p> |
| yarn.resourcemanager.am.max-attempts | <p>The maximum number of application attempts. This is a global setting for all ApplicationMaster nodes.</p> <p>You can configure an individual maximum number of application attempts for each ApplicationMaster node, but this property sets a global upper bound that overrides the individual node configuration.</p> <p>The default, set in yarn-default.xml, is 2.</p> |
| mapreduce.am.max-attempts | <p>The maximum number of MapReduce application attempts. If this value is larger than the value set by the ResourceManager, the ResourceManager value will override this value. The default number is set to 2, to allow at least one retry for AM. This property is set in mapred-default.xml.</p> |
| yarn.resourcemanager.fs.state-store.uri | <p>URI pointing to the location of the FileSystem path where the ResourceManager state is stored.</p> <p>The default value is configured to the path for the ResourceManager volume (<code>/var/mapr/cluster/yarn/rm/system</code>).</p> <p>If the FileSystem name is not provided, the system uses the value specified in the <code>fs.default.name</code> specified in the <code>core-site.xml</code> file.</p> |
| yarn.resourcemanager.fs.state-store.retry-policy-spec | <p>Specifies the retry policy for the filesystem client.</p> <p>This policy is specified in pairs of values for the sleep time, in milliseconds, and number of retries.</p> <p>Each pair is enclosed in parentheses, such as <code>(1000,20)</code>, <code>(2000,30)</code>.</p> <p>The previous example sleeps for 1000 milliseconds for twenty retries, then thirty more retries 2000 milliseconds apart.</p> <p>The default, set in yarn-default.xml, is <code>(2000,500)</code>.</p> |
| yarn.resourcemanager.store.class | <p>The class name of the state-store to be used for saving application/attempt state and the credentials.</p> <p>The available state-store implementations are <code>org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore</code>, a ZooKeeper based state-store implementation, and <code>org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore</code>, a state-store implementation based on filesystem.</p> <p>The default, yarn-default.xml, is <code>org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore</code>.</p> |

| Property | Description |
|---|---|
| yarn.resourcemanager.state-store.max-completed-applications | <p>The maximum number of completed applications that the state store retains, which is a number less than or equal to \$ {yarn.resourcemanager.max-completed-applications}.</p> <p>The default value is 10000. This setting ensures that the applications kept in the state store are consistent with the applications in ResourceManager memory.</p> <p>Any value larger than \$ {yarn.resourcemanager.max-completed-applications} is reset to the default.</p> <p>The value of this property affects ResourceManager recovery performance. Typically, a smaller value optimizes performance for recovery.</p> |
| yarn.resourcemanager.zk-address | <p>A comma-separated list of Host:Port pairs. Each corresponds to a ZooKeeper server, such as 127.0.0.1:5181,127.0.0.1:5181,127.0.0.1:5181.</p> <p>These hosts are used by the ResourceManager to store state.</p> |
| yarn.resourcemanager.zk-state-store.parent-path | <p>The full path of the root znode where ResourceManager state is stored. The default value is /rmstore.</p> |
| yarn.resourcemanager.zk-num-retries | <p>Number of times the ResourceManager tries to connect to the ZooKeeper server when the connection is lost.</p> <p>The default value is 500.</p> |
| yarn.resourcemanager.zk-retry-interval-ms | <p>The interval between retries, in milliseconds, when connecting to a ZooKeeper server. The default value is 2000.</p> |
| yarn.resourcemanager.zk-timeout-ms | <p>The ZooKeeper session timeout in milliseconds. The ZooKeeper server uses this configuration to determine session expiration.</p> <p>Sessions expire when the server does not receive a heartbeat from the client within the session timeout period. The default value is 10000.</p> |
| yarn.resourcemanager.zk-acl | <p>ACLs that set permissions on ZooKeeper znodes. The default value is world:anyone:rwcd</p> |

Administrator's Reference

This section contains in-depth reference information for the administrator.

maprcli and REST API Syntax

This section provides information about the HPE Ezmeral Data Fabric command API. Most commands can be run on the command-line interface (CLI), or by making REST requests programmatically or in a browser.

To run CLI commands, use an ssh connection to any node in the cluster. To use the REST interface, make HTTP requests to a node that is running the WebServer service.

Overview

Each command reference page includes the command syntax, a table that describes the parameters, and examples of command usage.

In each parameter table, required parameters are in **bold** text. For output commands, the reference pages include tables that describe the output fields. Values that do not apply to particular combinations are marked **NA**.

REST API Syntax

Describes the MapR REST API syntax format.

MapR REST calls use the following format:

```
https://<host>:<port>/rest/<command>[/<subcommand>...]?<parameters>
```

Construct the `<parameters>` list from the required and optional parameters, in the format `<parameter>=<value>` separated by the ampersand (&) character. Example:

```
https://rln1.qa.sj.ca.us:8443/rest/volume/mount?name=test-volume&path=/test
```

Values in REST API calls must be URL-encoded. For readability, the values in this document use the actual characters, rather than the URL-encoded versions.

Authentication

To make REST calls using `curl` or `wget`, provide the username and password. To configure PAM for REST API, see [PAM Configuration](#).

Curl Syntax

```
curl -k -u <username> https://<host>:<port>/rest/<command>...
```

 **Warning:** To keep your password secure, do not provide it on the command line. Curl will prompt you for your password, and you can enter it securely.

Wget Syntax

```
wget --no-check-certificate --user <username> --ask-password https://<host>:<port>/rest/<command>...
```

 **Warning:** To keep your password secure, do not provide it on the command line. Use the `--ask-password` option instead; then `wget` will prompt you for your password and you can enter it securely.

To authenticate to the REST interface, use basic authentication or SPNEGO.

Basic Authentication

To authenticate using basic authentication, send a request with a basic authorization header, which has a user ID and password. For example, to authenticate using basic authentication, run the following command:

```
curl https://<webserver-hostname>:8443/login -d 'username=root&password=mapr'
```

On the other hand, if you do not wish to reauthenticate with every request, you can save the cookie and send the cookie with every subsequent request. For example, to authenticate and save the cookie in a text

file named `cookiejar.txt` in `/tmp` directory, run the following command:

```
curl -X POST -c /tmp/
cookiejar.txt "https://
<webserver-hostname>:8443/login -d"
'username=<name>&password=<pwd>'
```

To send the cookie with subsequent requests, for example to retrieve the list of nodes on the cluster, you can submit a request similar to the following:

```
curl -L -b /tmp/cookiejar.txt
"https://<webser-hostname>:8443/rest/
node/list/"
```

SPNEGO

To authenticate using SPNEGO, ensure that the apiserver nodes are [configured for SPNEGO](#). After configuring, send a negotiate authorization header. For example, to authenticate with the SPNEGO token and save the cookie in a text file named `cookiejar.txt` in your home directory, run the following command:

```
curl --negotiate -u : -b ~/
cookiejar.txt -c ~/cookiejar.txt
https://<web server node>:8443/rest/
<API call> -k -v
```

The contents of the cookie is something similar to the following:

```
cat /tmp/cookiejar.txt
# Netscape HTTP Cookie File
# https://curl.haxx.se/docs/http-cookies.html
# This file was generated by libcurl! Edit at your own risk.

#HttpOnly_<webserver-hostname> FALSE / TRUE 1509486224
MAPR.APISERVER.JSESSIONID node014ukard563rhulns8umn2s6uft3709.node0
#HttpOnly_<webserver-hostname> FALSE / FALSE 0
MAPR.APISERVER.SESSIONID HZA9C20D084E614E36AA567F47FC9105A4
```

REST API Calls to Remote Cluster

If you have secure clusters and you wish to make REST API calls to a remote secure cluster, you can specify the `cluster` parameter in the request if you have your environment configured for remote access. To set up your environment for API calls to remote secure cluster:

1. Follow the steps for [configuring secure clusters for running commands remotely](#).
2. [Verify access](#) to run remote commands.
3. Rename the ticket file generated using the `maprlogin password` command to `mapruserticket` and move the file to `/opt/mapr/conf` directory.

Command-Line Interface

Describes how the MapR CLI command syntax is documented.

The MapR CLI commands are documented using the following conventions:

- `[Square brackets]` indicate an optional parameter

- <Angle brackets> indicate a value to enter

The following syntax example shows that the `volume mount` command requires the `-name` parameter, for which you must enter a list of volumes, and all other parameters are optional:

```
maprcli volume mount
  [ -cluster <cluster> ]
  -name <volume list>
  [ -path <path list> ]
```

For clarity, the syntax examples show each parameter on a separate line; in practical usage, the command and all parameters and options are typed on a single line. Example:

```
maprcli volume mount -name test-volume -path /test
```

Common Parameters

Describes parameters that are available for many commands.

The following parameters are available for many commands in both the REST and command-line contexts.

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| zkconnect | A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: '<host>[:<port>][,<host>[:<port>]...]' Default: 'localhost:5181' In most cases the ZooKeeper connect string can be omitted, but it is useful in certain cases when the CLDB is not running. |

Common Options

Describes options that are available for many commands.

The following options are available for most commands in the command-line context.

| Option | Description |
|-----------|---|
| -noheader | When displaying tabular output from a command, omits the header row. |
| -long | Shows the entire value. This is useful when the command response contains complex information. When <code>-long</code> is omitted, complex information is displayed as an ellipsis (...). |
| -json | Displays command output in JSON format. When <code>-json</code> is omitted, the command output is displayed in tabular format. |

| Option | Description |
|---------------|--|
| -cli.loglevel | Specifies a log level for API output. Legal values for this option are: <ul style="list-style-type: none"> • DEBUG • INFO • ERROR • WARN • TRACE • FATAL |

Filters

Describes the use of filters with MapR CLI commands.

Some MapR CLI commands use *filters*, which let you specify large numbers of nodes or volumes by matching specified values in specified fields rather than by typing each name explicitly.

Filters use the following format:

```
[<field><operator>"<value>" ]<and>[<field><operator>"<value>" ] ...
```

| | |
|----------|---|
| field | Field on which to filter. The field depends on the command with which the filter is used. |
| operator | An operator for that field: <ul style="list-style-type: none"> • == - Exact match • != - Does not match • > - Greater than • < - Less than • >= - Greater than or equal to • <= - Less than or equal to |
| value | Value on which to filter. Wildcards (using *) are allowed for operators == and !=. There is a special value <code>all</code> that matches all values. |

You can use the wildcard (*) for partial matches. For example, you can display all volumes whose owner is `root` and whose name begins with `test` as follows:

```
maprcli volume list -filter [n=="test*"]and[on=="root"]
```

Note: maprcli commands and REST APIs do not support OR conditions.

Response

Describes the different return responses.

The commands return responses in JSON or in a tabular format. When you run commands from the command line, the response is returned in tabular format unless you specify JSON using the `-json` option; when you run commands through the REST interface, the response is returned in JSON.

Note: The columns returned by operations such as `get`, `list`, `info`, and so on are not sorted in any particular order.

Success

On a successful call, each command returns the error code zero (OK) and any data requested. When JSON output is specified, the data is returned as an array of records along with the status code and the total number of records. In the tabular format, the data is returned as a sequence of rows, each of which contains the fields in the record separated by tabs.

JSON

```
{
  "status": "OK",
  "total": <number of
records>,
  "data": [
    {
      <record>
    }
    ...
  ]
}
```

Tabular

```
status      0
```

Or

```
<heading>  <heading>  <heading> ...
            <field>   <field>
<field> ...
            ...
```

Error

When an error occurs, the command returns the error code and descriptive message.

JSON

```
{
  "status": "ERROR",
  "errors": [
    {
      "id": <error code>,
      "desc": "<command>: <error
message>"
    }
  ]
}
```

Tabular

```
ERROR (<error code>) - <command>:
<error message>
```

acerole validate

Verifies given user roles for ACEs exists in the `/opt/mapr/conf/m7_permissions_roles_refimpl.conf` file.

This command returns `true` if role exists in the `/opt/mapr/conf/m7_permissions_roles_refimpl.conf` file and `false` if given role is not in the file. If the `MAPR_ROLES_LIB_ENABLE_TRACE` environment variable is set to `TRUE`, the command returns also the number of users assigned to the specified role and the number of roles in the file.

Syntax

```
/opt/mapr/bin/maprcli acerole validate -role <role to validate>
```

Parameters

| Parameter | Description |
|-----------|-----------------------|
| role | The role to validate. |

Examples

Verifies whether given role exists when the `MAPR_ROLES_LIB_ENABLE_TRACE` environment variable is not set:

```
$ maprcli acerole validate -role Role_1
maprcli acerole validate command returned : true
```

Verifies whether given role exists when the `MAPR_ROLES_LIB_ENABLE_TRACE` environment variable is set:

```
$ export MAPR_ROLES_LIB_ENABLE_TRACE=TRUE
$ echo $MAPR_ROLES_LIB_ENABLE_TRACE
TRUE
$ maprcli acerole validate -role Role_1
RoleMap: Added user 500 with role 'Role_1'
RoleMap: Added user 1000 with role 'Role_1'
RoleMap: found 2 users and 2 roles.
maprcli acerole validate command returned : true
```

acl

Describes the `acl` commands used to access control lists (ACLs).

Specifying Permissions

Specify permissions for a user or group with a string that lists the permissions for that user or group. To specify permissions for multiple users or groups, use a string for each, separated by spaces. The format is as follows:

- Users -

```
<user>:<action>[,<action>...][<user>:<action>[,<action>...]]
```

- Groups -

```
<group>:<action>[,<action>...][<group>:<action>[,<action>...]]
```

To use the `acl edit` command, you must have full control (`fc`) permission on the cluster or volume for which you are running the command.

The following tables list the permission codes used by the `acl` commands.

Cluster Permission Codes

| Permission Code | Allowed Action |
|-----------------|---|
| login | Log in to the MapR Control System, use the API and command-line interface, read access on cluster and volumes. |
| ss | Start/stop services. |
| cv | Create volumes. |
| a | Administrative access to cluster ACLs. Grants no other permissions. |
| fc | Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster ACLs. |
| cp | Create security policies |

Volume Permission Codes

| Code | Allowed Action |
|---------|--|
| dump | Dump the volume. |
| restore | Mirror or restore the volume. |
| m | Modify volume properties, create and delete snapshots. |
| d | Delete a volume. |
| a | Administrative access to volume ACLs. |
| fc | Full control (admin access and permission to change volume ACL). |

Security Policy Permission Codes

| Code | Allowed Action |
|-------------------|--|
| a (admin) | View and modify the permissions on a security policy; cannot view or modify the security policy. |
| fc (full control) | View and modify the security policy, including data access ACEs; cannot view or modify the permissions on a security policy. |
| r (read) | View all parts of a security policy; cannot modify the security policy. |

acl edit

Modifies a specific user's access to a cluster, volume, or security policy.

Permissions Required

The `acl edit` command grants one or more specific volume or cluster permissions to a user. To use the `acl edit` command, you must have administrative (a) permissions on the volume and cluster for which you are running the command. The permissions are specified as a comma-separated list of permission codes. See [acl](#) on page 1705.

Syntax

CLI

```
/opt/mapr/bin/maprcli acl edit
[ -cluster <cluster name> ]
[ -group <group> ]
[ -name <name> ]
-type cluster|volume|
securitypolicy
[ -user <user> ]
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/acl/edit?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. |
| group | Groups and allowed actions for each group. See acl on page 1705. Format: <group>:<action>[,<action>...] [<group>:<action>[,<action>...]]. You must specify either a user or a group. |
| name | The object name. For a volume, specify the name of the volume in this parameter. To set security policy level permissions, specify the name of the security policy in this parameter. |
| type | The object type. Allowed values are <code>cluster</code> , <code>volume</code> or <code>securitypolicy</code> . |
| user | Users and allowed actions for each user. See acl on page 1705. Format: <user>:<action>[,<action>...] [<user>:<action>[,<action>...]]. You must specify either a user or a group. |

Examples

Give the user `jsmith` dump, restore, and delete permissions for "test-volume":

CLI

```
/opt/mapr/bin/maprcli acl edit -type
volume -name test-volume -user
jsmith:dump,restore,d
```

REST

```

```

acl set

Modifies the Access Control List (ACL) for a cluster, volume, or security policy.

The `acl set` command specifies the [ACL](#) for a cluster or volume. Any previous permissions are overwritten by the new values, and any permissions omitted are removed. To use the `acl set` command, you must have administrative (a) permissions on the volume and cluster for which you are running the command. The [ACL permissions](#) are specified as a comma-separated list of permission codes. See [acl](#) on page 1705. You must specify either a `user` or a `group`. When the `type` is `volume`, you must specify a volume name using the `name` parameter.

The `acl set` command removes any previous [ACL](#) values. To preserve some of the permissions, you should either use the `acl edit` command instead of `acl set`, or use `acl show` to list the values before overwriting them.

Syntax**CLI**

```
/opt/mapr/bin/maprcli acl set
[ -cluster <cluster name> ]
[ -group <group> ]
[ -name <name> ]
-type cluster|volume|
securitypolicy
[ -user <user> ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/acl/set?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. |
| group | Groups and allowed actions for each group. See acl on page 1705. Format: <group>:<action>[,<action>...] [<group>:<action>[,<action>...]] |

| Parameter | Description |
|-----------|---|
| name | The object name. For a volume, specify the name of the volume in this parameter. To set security policy level permissions, specify the name of the security policy, in this parameter. |
| type | The object type. Allowed values are <code>cluster</code> , <code>volume</code> or <code>securitypolicy</code> . |
| user | Users and allowed actions for each user. See acl on page 1705. Format: <code><user>:<action>[,<action>...]</code> [<code><user>:<action>[,<action>...]</code>] |

Examples

Give the user `root` full control of the `my.cluster.com` cluster and remove all permissions for all other users:

CLI

```
/opt/mapr/bin/maprcli acl set -type
cluster -user user10:fc
```

REST

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/acl/set?
type=cluster&user=user10%3Afc' --user
mapr:mapr
{"timestamp":1525462091620,"timeofday"
:"2018-05-04 12:28:11.620 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

Usage Example

```
# /opt/mapr/bin/maprcli acl show -type cluster
Allowed actions      Principal
[login, ss, cv, a, fc, cp] User mapr
[login, ss, cv, a, fc, cp] User root
[login, cp] User fuser1

# /opt/mapr/bin/maprcli acl set -type cluster -cluster my.cluster.com -user
root:fc
# /opt/mapr/bin/maprcli acl show -type cluster
Principal  Allowed actions
User root  [login, ss, cv, a, fc, cp]
```

Warning: Notice that the specified permissions have overwritten the existing [ACL](#).

Give multiple users specific permissions for the `egVoll` volume and remove all permissions for all other users:

CLI

```
# /opt/mapr/bin/maprcli acl
set -type volume -name
egVoll -user m7user5:dump,restore,m
m7user4:fc -json
{
  "timestamp":1525462647371,
  "timeofday":"2018-05-04
12:37:27.371 GMT-0700 PM",
```

```
"status": "OK",
"total": 0,
"data": [
]
}
```

REST

```
# curl -k -X POST 'https://
10.10.82.24:8443/rest/acl/set?
type=volume&name=egVoll&user=m7user5%3
Adump,restore,m%20m7user4%3Afc' --user
mapr:mapr
{"timestamp":1525463080941,"timeofday"
:"2018-05-04 12:44:40.941 GMT-0700
PM","status":"OK","total":0,"data":[]}
```

acl show

Displays the ACL associated with an object (cluster or a volume).

Syntax

An ACL contains the list of users who can perform specific actions.

CLI

```
/opt/mapr/bin/maprcli acl show
    -type object type [cluster|
volume|securitypolicy]
    [ -name name ]
    [ -cluster cluster name ]
    [ -user userName whose ACL is
queried ]
    [ -group groupName whose ACL is
queried ]
    [ -output output format short|
long|terse (default short). default:
short ]
    [ -perm list of available
permissions Parameter takes no
value ]
```

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/acl/show?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The name of the cluster on which to run the command. |
| group | The group for which to display permissions. |

| Parameter | Description |
|-----------|---|
| name | The object name. To view security policy level permissions, specify the name of the security policy in this parameter. This parameter is required for the securitypolicy ACL type. |
| output | The output format: <ul style="list-style-type: none"> • long • short • terse The default format is short. |
| perm | When you specify this option, <code>acl show</code> displays the permissions available for the object type specified in the <code>type</code> parameter. |
| type | The object type. Allowed values are <code>cluster</code> , <code>volume</code> or <code>securitypolicy</code> . To get security policy level permissions, specify the type as <code>securitypolicy</code> . |
| user | The user for whom to display permissions. |

Output

The actions that each user or group is allowed to perform on the cluster or the specified volume. For information about each allowed action, see [acl](#) on page 1705.

```
Principal    Allowed actions
User root   [login, ss, cv, a, fc, cp]
Group root  [login, ss, cv, a, fc, cp]
All users   [login]
```

Examples

Show the ACL for the cluster:

CLI

```
# /opt/mapr/bin/maprcli acl
show -type cluster -json
{
  "timestamp":1555494572399,
  "timeofday":"2019-04-17
02:49:32.399 GMT-0700 AM",
  "status":"OK",
  "total":2,
  "data":[
    {
      "Principal":"User mapr",
      "Allowed
actions":"[login, ss, cv, a, fc, cp]"
    },
    {
      "Principal":"User root",
      "Allowed
actions":"[login, ss, cv, a, fc, cp]"
    }
  ]
}
```

```
    ]
  }
}
```

REST

```
curl -u mapr:mapr -X GET -k "https://
host:8443/rest/acl/show?type=cluster"
{"timestamp":1555494852652,"timeofday"
:"2019-04-17 02:54:12.652 GMT-0700
AM","status":"OK","total":2,"data":
[{"Principal":"User mapr","Allowed
actions":["login, ss, cv, a, fc,
cp]"}, {"Principal":"User
root","Allowed actions":["login, ss,
cv, a, fc, cp]}]}
```

Show the ACL for "test-volume":**CLI**

```
# /opt/mapr/bin/maprcli acl
show -type volume -name sampleVoll
Allowed actions
Principal
[dump, restore, m, a, d, fc] User
mapr
[dump, restore, m, d, fc] User
foo
[dump, restore, a] User
bar
[m, d] User abc
```

REST

```
# curl -u mapr:mapr -X GET -k
"https://host:8443/rest/acl/show?
type=volume&name=sampleVoll"
{"timestamp":1525461068100,"timeofday"
:"2018-05-04 12:11:08.100 GMT-0700
PM","status":"OK","total":4,"data":
[{"Principal":"User mapr","Allowed
actions":["dump, restore, m, a, d,
fc]"}, {"Principal":"User
foo","Allowed actions":["dump,
restore, m, d, fc]"},
{"Principal":"User bar","Allowed
actions":["dump, restore, a]"},
{"Principal":"User abc","Allowed
actions":["m, d]}]}
```

Show the permissions that can be set on a cluster:**CLI**

```
# /opt/mapr/bin/maprcli acl
show -type cluster -perm
Permissions
Description
login Login
access
ss Start/stop services in
the cluster
cv Create
volumes
```

```
a
Administrator
fc          Full
control
cp          Create security policies
```

REST

```
# curl -u mapr:mapr -X GET -k
"https://host:8443/rest/acl/show?
type=cluster&perm"
{"timestamp":1555497261931,"timeofday"
:"2019-04-17 03:34:21.931 GMT-0700
AM","status":"OK","total":6,"data":
[{"Permissions":"login","Description":
"Login access"},
{"Permissions":"ss","Description":"Sta
rt/stop services in the cluster"},
{"Permissions":"cv","Description":"Cre
ate volumes"},
{"Permissions":"a","Description":"Admi
nistrator"},
{"Permissions":"fc","Description":"Ful
l control"},
{"Permissions":"cp","Description":"Cre
ate security policies"}]}
```

Display the available security-level permissions:

CLI

```
# /opt/mapr/bin/maprcli acl
show -type securitypolicy -perm -name
hipaa
Permissions
Description
r          Read
a          Admin
fc         Full control
```

REST

```
# curl -u mapr:mapr -X GET -k
"https://10.10.82.29:8443/rest/acl/
show?
type=securitypolicy&perm&name=hipaa"
{"timestamp":1525459863777,"timeofday"
:"2019-02-04 11:51:03.777 GMT-0700
AM","status":"OK","total":3,"data":
[{"Permissions":"r","Description":"Rea
d"},
{"Permissions":"a","Description":"Read
"},
{"Permissions":"fc","Description":"Ful
l control"}]}
```

Display list of users and security policy permissions:

CLI

Run the `/opt/mapr/bin/maprcli acl show -type securitypolicy` command without the `-perm` option, to display the list of users who have

security policy level permissions for the policy, and the respective permissions:

```
# /opt/mapr/bin/maprcli acl
show -type securitypolicy -name hipaa
    Allowed actions Principal
    [r, a, fc]      User tom
    [a]             User harry
```

REST

```
# curl -u mapr:mapr -X GET -k
"https://host:8443/rest/acl/show?
type=securitypolicy&name=hipaa"
{"timestamp":1555498377874,"timeofday"
:"2019-04-17 03:52:57.874 GMT-0700
AM","status":"OK","total":2,"data":
[{"Principal":"User tom","Allowed
actions":"[r, a, fc]"},
{"Principal":"User harry","Allowed
actions":"[a]"}]}
```

Displays only name, ID and ACL for a user having ONLY policy level admin permissions.

CLI

```
# /opt/mapr/bin/maprcli security
policy create -name testpolicy1 -user
root:r,a,fc fuser1:a
fuser2:fc -readfileace u:fuser1

# /opt/mapr/bin/maprcli acl
show -type securitypolicy -name
testpolicy1 -user fuser2
    Allowed actions Principal
    [r, fc] User fuser2

# /opt/mapr/bin/maprcli acl
show -type securitypolicy -name
testpolicy1 -user fuser1
    Allowed actions Principal
    [a] User fuser1

# /opt/mapr/bin/maprcli security
policy info -name testpolicy1 -json
{
"timestamp":1551432309820,
  "timeofday":"2019-03-01
01:25:09.820 GMT-0800 AM",
  "status":"OK",
  "total":1,
  "data":[
  {
"policyname":"testpolicy1",
  "policyid":19,
  "acl":[
  {
"Principal":"User root",
"Allowed actions":"[r,
a, fc]"
```

```

    },
    {
      "Principal": "User
fuser1",
      "Allowed actions": "[a]"
    },
    {
      "Principal": "User
fuser2",
      "Allowed actions": "[r,
fc]"
    }
  ]
}

```

alarm

Describes the alarm commands that perform functions related to system alarms.

Alarm Notification Fields

The following fields specify the configuration of alarm notifications.

| Field | Description |
|------------|--|
| alarm | The named alarm. |
| individual | Specifies whether individual alarm notifications are sent to the default email address for the alarm type: <ul style="list-style-type: none"> • 0 - do not send notifications to the default email address for the alarm type • 1 - send notifications to the default email address for the alarm type |
| email | A custom email address for notifications about this alarm type. If specified, alarm notifications are sent to this email address, regardless of whether they are sent to the default email address. |

Alarm Types

See [Alarms Reference](#).

Alarm History

To see a history of alarms that have been raised, look at the file `/opt/mapr/logs/cldb.log` on the master CLDB node. Example:

```
grep ALARM /opt/mapr/logs/cldb.log
```

alarm clear

Clears one or more alarms. Permissions required: `fc` or `a`.

Syntax**CLI**

```
maprcli alarm clear
  -alarm <alarm>
  [ -cluster <cluster> ]
  [ -entity entity (hostname OR
volume name OR Ae name) ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/alarm/clear?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| alarm | The named alarm to clear. See Alarm Types . |
| cluster | The cluster on which to run the command. |
| entity | The entity on which to clear the alarm. |

Examples**Clear a specific alarm:****CLI**

```
maprcli alarm clear -alarm
NODE_ALARM_DEBUG_LOGGING
```

REST

```
https://abc.sj.us:8443/rest/alarm/
clear?alarm=NODE_ALARM_DEBUG_LOGGING
```

alarm clearmulti

Clears all alarm occurrences of specified multiple alarm types. Permissions required: fc or a.

Syntax**CLI**

```
maprcli alarm clearmulti
  [ -cluster cluster_name ]
  -alarm alarm[:entity][:aetype]
  <comma seperated alarms>
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/alarm/clearmulti?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| alarm | Comma separated list of alarm types to clear. |
| cluster | The cluster on which to run the command. Default is the current cluster. |

Examples**Clear a specific alarm:****CLI**

```
maprcli alarm clear -alarm
NODE_ALARM_DEBUG_LOGGING,VOLUME_ALARM_
COMPACTION_FAILURE
```

REST

```
https://abc.sj.us:8443/rest/alarm/
clear?
alarm=NODE_ALARM_DEBUG_LOGGING,VOLUME_
ALARM_COMPACTION_FAILURE
```

alarm clearall

Clears all alarms. Permissions required: fc or a.

Syntax**CLI**

```
maprcli alarm clearall
[ -cluster <cluster> ]
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/alarm/clearall?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |

Examples**Clear all alarms:****CLI**

```
maprcli alarm clearall
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
clearall
```

alarm config load

Displays the configuration of alarm notifications. Permission required: login

Syntax

CLI

```
maprcli alarm config load
  [ -cluster <cluster> ]
  [ -output terse|verbose ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/alarm/config/load?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |
| output | Whether the output should be terse or verbose. |

Output

A list of configuration values for alarm notifications.

Output Fields

See [Alarm Notification Fields](#).

Sample output

```
alarm                individual  email
CLUSTER_ALARM_UPGRADE_IN_PROGRESS      1

| NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED | 1 |
| VOLUME_ALARM_TABLE_REPL_ASYNC | 1 |
| NODE_ALARM_SERVICE_RESOURCEMANAGER_DOWN | 1 |
| NODE_ALARM_SERVICE_HISTORYSERVER_DOWN | 1 |

Examples

Display the alarm notification configuration:

CLI

```
maprcli alarm config load
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
config/load
```

alarm config save

Sets notification preferences for alarms. Permissions required: `fc` or `a`.

Alarm notifications can be sent to the default email address and a specific email address for each named alarm. If `individual` is set to 1 for a specific alarm, then notifications for that alarm are sent to the default email address for the alarm type. If a custom email address is provided, notifications are sent there regardless of whether they are also sent to the default email address.

Syntax**CLI**

```
maprcli alarm config save
[ -cluster <cluster> ]
-values <values>
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/alarm/config/save?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |
| values | A comma-separated list of configuration values for one or more alarms, in the following format: <alarm>,<individual>,<email> See Alarm Notification Fields . |

Examples

Send alert emails for the AE_ALARM_AEQUOTA_EXCEEDED alarm to the default email address and a custom email address:

CLI

```
maprcli alarm config save -values
"AE_ALARM_AEQUOTA_EXCEEDED,1,test@example.com"
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
config/save?
values=AE_ALARM_AEQUOTA_EXCEEDED,1,tes
t@example.com
```

alarm group

Alarm groups are groups of alarms for which email addresses of users/groups can be set (to send alert to when an alarm is raised) and removed.

Permissions required: fc or a

alarm group addalarms

Add alarms to a group.

Syntax**CLI**

```
maprcli alarm group addalarms
-groupname <group name>
-alarms <alarm name>
```

REST API

N/A

Parameters

| Parameter | Description |
|-----------|---|
| groupname | The name of the alarm group to create. If necessary, run <code>listGroup</code> to retrieve the list of alarm groups. |
| alarms | The comma-separated list of alarms to add to the group. |

Examples

Add alarms to alarm group:

```
maprcli alarm group addAlarms
  -groupname cldb.alarm.group.info
  -alarms NODE_ALARM_HB_PROCESSING_SLOW,CLUSTER_ALARM_CLUSTER_ALMOST_FULL
```

alarm group addemails

Adds the email addresses of users/groups to send alert to when an alarm is raised.

Syntax

CLI

```
maprcli alarm group addEmails
  [ -cluster <cluster_name> ]
  -groupname <group name>
  -emails <email addresses>
```

REST API

N/A

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |
| groupname | The name of the alarm group to add the email addresses to. When an alarm in the group is raised, an alert email will be sent to the users/groups. If necessary, run <code>listgroup</code> to retrieve the list of alarm groups. |
| emails | The comma-separated list of email addresses of users to send alert emails to when an alarm is raised. |

Examples

Add email addresses to `cldb.alarm.group.error` group.

```
maprcli alarm group addEmails -groupname cldb.alarm.group.error -emails
  abc@gmail.com,xyz@gmail.com
```

alarm group deletealarms

Delete alarms in an alarm group.

Syntax**CLI**

```
maprcli alarm group deletealarms
  -groupname <group name>
  -alarms <alarm name>
```

REST API

N/A

Parameters

| Parameter | Description |
|-----------|--|
| groupname | The name of the alarm group to remove alarms from. |
| alarms | The comma-separated list of alarms to remove from the group. |

Examples

Delete `NODE_ALARM_HB_PROCESSING_SLOW` and `CLUSTER_ALARM_CLUSTER_ALMOST_FULL` alarms in the `cldb.alarm.group.info` group:

```
maprcli alarm group deleteAlarms
  -groupname cldb.alarm.group.info
  -alarms NODE_ALARM_HB_PROCESSING_SLOW,CLUSTER_ALARM_CLUSTER_ALMOST_FULL
```

alarm group deleteemails

Deletes the email addresses of users/groups.

Syntax**CLI**

```
maprcli alarm group deleteEmails
  [ -cluster <cluster_name> ]
  -groupname <group name>
  -emails <email addresses>
```

REST API

N/A

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |
| groupname | The name of the alarm group to remove the email addresses from. If necessary, run <code>listgroup</code> to retrieve the list of alarm groups. |
| emails | The comma-separated list of email addresses of users/groups to remove. |

Examples

Delete the given emails associated with the `cldb.alarm.group.error` group:

```
maprcli alarm group deleteEmails -groupname cldb.alarm.group.error -emails
xyz@gmail.com,abc@gmail.com
```

alarm group listgroup

Lists the alarm groups.

Note: The three dots in the output indicate multiple alarms in the group. Use `-json` to format the output.

Syntax

CLI

```
maprcli alarm group listGroup
  [ -cluster <cluster_name> ]
  [ -start ]
  [ -limit ]
  [ -output <verbose> ]
```

REST API

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. |
| start | The list offset at which to start. Default: 0 |
| limit | The number of records to retrieve. Default value is 2147483647. |
| output | The output format: <ul style="list-style-type: none"> • terse • verbose Default value is verbose. |

Examples

Return the list of alarms and associated email addresses.

```
# maprcli alarm group listGroup
alarm name emails group name
... abc@mapr.com cldb.alarm.group.error
... cldb.alarm.group.info
... cldb.alarm.group.warn
```

Return the list of alarms and associated email addresses in JSON format.

```
root@saradaqa4:~# maprcli alarm group listGroup -json
{
  "timestamp":1495018857252,
  "timeofday":"2017-05-17 11:00:57.252 GMT+0000",
  "status":"OK",
  "total":3,
  "data":[
    {
      "group name":"cldb.alarm.group.error",
      "emails":"abc@mapr.com",
      "alarm name":[
        "NODE_ALARM_DISK_FAILURE",
        "CLUSTER_ALARM_LICENSE_EXPIRED",
```

}

```

alarm list

Lists alarms in the system. Permissions required: login.

You can list all alarms, alarms by type (Cluster, Node or Volume), or alarms on a particular node or volume. To retrieve a count of all alarm types, pass 1 in the `summary` parameter. You can specify the alarms to return by filtering on type and entity. Use `start` and `limit` to retrieve only a specified window of data.

Syntax

CLI

```

maprcli alarm list
  [ -alarm alarm name ]
  [ -all list all raised alarms
including the ones which are muted
Parameter takes no value ]
  [ -cluster cluster_name ]
  [ -entity entity (hostname OR
volume name OR Ae name) ]
  [ -entitylimit entitylimit ]
  [ -filter none. default: none ]
  [ -from alarms raised after
time(in millis) ]
  [ -getcount Send count of
currently raised alarms Parameter
takes no value ]
  [ -history list cleared up alarms
only Parameter takes no value ]
  [ -limit limit. default:
2147483647 ]
  [ -muted list alarms configured
to be mute Parameter takes no value ]
  [ -output output. default:
verbose ]
  [ -sortby <alarmname|
alarmdescription|alarmtype|alarmstate|
alarmraised|alarmcleared|alarmentity|
alarmmutetime|alarmmuteupto|
alarmmuteduration|alarmgroups> ]
  [ -sortorder <asc|desc> ]
  [ -start start. default: 0 ]
  [ -summary summary ]

```

```
[ -till alarms raised
before time(in millis) ]
[ -type type (CLUSTER
OR NODE OR VOLUME OR AE) ]
```

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/alarm/list?<parameters> |

Parameters

| Parameter | Description |
|-------------|--|
| alarm | The alarm name for which to return information. |
| all | The list of all raised and muted alarms. |
| cluster | The cluster on which to list alarms. |
| entity | The name of the cluster, node, volume, user, or group to check for alarms. |
| entitylimit | The number of alarm occurrences to return per alarm type. For example, if there are 10 alarms of type VOLUME_ALARM_COMPACTON_FAILURE and the entity limit is set to 4, then only the four latest alarm occurrences of type VOLUME_ALARM_COMPACTON_FAILURE are listed. |
| filter | A filter specifying alarms to list. See Filters for more information. Default: none |
| from | The list of alarms raised after a moment in time (specified in ms). Use <code>from</code> in conjunction with <code>till</code> to list alarms that have been raised within the specified period. |
| getcount | The count of all alarms raised at the moment in time when you invoke this command. |
| history | The list of all alarms cleared in the last 30 days. Muted alarms are not displayed in the output. |
| limit | The number of records to retrieve. Default: 2147483647 |
| muted | The list of alarms that are muted. |
| output | Indicates whether the output should be <code>terse</code> or <code>verbose</code> . Default: <code>verbose</code> |
| sortby | Specifies one of the following attributes by which to sort the list of alarms: <code>alarmname</code> , <code>alarmdescripton</code> , <code>alarmtype</code> , <code>alarmstate</code> , <code>alarmraised</code> , <code>alarmcleared</code> , <code>alarmentity</code> , <code>alarmmutetime</code> , <code>alarmmuteupto</code> , <code>alarmmuteduration</code> , <code>alarmgroups</code> . By default, the list of alarms is sorted by <code>alarmtype</code> . |
| sortorder | Sorts the output in either ascending or descending order. |
| start | The list offset at which to start. Default: 0 |

| Parameter | Description |
|-----------|--|
| summary | Specifies the type of data to return: <ul style="list-style-type: none"> • 1 = count by alarm type • 0 = List of alarms Default: false (0) |
| till | The list of alarms raised before a moment in time (specified in ms). Use <code>till</code> in conjunction with <code>from</code> to list alarms that have been raised within the specified period. |
| type | The entity type: <ul style="list-style-type: none"> • cluster • node • volume • ae |

Output

Information about one or more named alarms on the cluster, or for a specified node, volume, user, or group.

Output Fields

| Field | Description |
|------------------------|---|
| alarm state | State of the alarm: <ul style="list-style-type: none"> • 0 = Clear • 1 = Raised |
| description | A description of the condition that raised the alarm. |
| entity | The name of the volume, node, user, or group. |
| alarm name | The name of the alarm. |
| alarm statechange time | The date and time when the alarm was most recently raised. |

Sample Output

```
alarm state

```

REST API

```
https://rln1.sj.us:8443/rest/alarm/
list?muted
```

alarm mute

Mutes an active alarm for the specified amount of time.

Syntax

CLI

```
maprcli alarm mute
  -alarm alarm[:entity][:aetype]
  [:mute_duration] <comma seperated
  alarms>
  [ -cluster cluster_name ]
  [ -muteminutes <mute_period> ]
```

REST API

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/alarm/mute?<parameters> |

Parameters

| Parameter | Description |
|-------------|---|
| alarm | The comma-separated list of the active alarms to mute. To mute an active alarm associated with an entity (such as volume, node, etc.) or type of accountable entity, you must also specify the name of the entity or the type of accountable entity separated by a colon (:). |
| cluster | The cluster on which to run the command. |
| muteminutes | <p>The amount of time, in minutes, to mute the alarm.</p> <p>This can be specified separately or specified after the colon (:<mute_period>) immediately following the alarm name. For example, if multiple alarms are being muted for different periods of time, use colon (:<mute_period>) to specify the mute period for each alarm.</p> <p>Specifying this separately is optional if colon (:<mute_period>) is used to specify the amount of time to mute an alarm. For example, when specifying a list of alarms to mute, use this parameter to specify the amount of time to mute the alarm for which no time period is specified using colon (:<mute_period>).</p> <p> Note: Either the value for this parameter or colon (:<mute_period>) is required to specify the amount of time for which to mute the alarm.</p> |

Examples

Mute an active alarm for 10 minutes using one of the following:

```
maprcli alarm mute -alarm CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION:10
```

```
maprcli alarm mute -alarm
  CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION -muteminutes 10
```

Mute an active volume alarm on volume1 for 10 minutes using one of the following:

```
maprcli alarm mute -alarm VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1:10
```

```
maprcli alarm mute -alarm
VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1 -muteminutes 10
```

Mute active volume alarm on volume1 for 10 minutes, active cluster alarm for 20 minutes, and active volume alarm on volume2 for 30 minutes using one of the following:

```
maprcli alarm mute -alarm
VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1:10,
CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION:20,
VOLUME_ALARM_DATA_UNDER_REPLICATED:volume2:30
```

```
maprcli alarm mute -alarm
VOLUME_ALARM_DATA_UNDER_REPLICATED:volume1:10,
CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION:20,
VOLUME_ALARM_DATA_UNDER_REPLICATED:volume2
-muteminutes 30
```

alarm names

Displays a list of alarm names. Permissions required: login

Syntax

CLI

```
maprcli alarm names
```

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/alarm/names |

Output

 **Attention:** The list of alarms depends on the ecosystem components installed. Your output may vary depending on the ecosystem components that you have installed.

Examples

Display all alarm names:

CLI

```
maprcli alarm names
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
names
```

alarm raise

Raises a specified alarm or alarms. Permissions required: fc or a.

Syntax

CLI

```
maprcli alarm raise
  -alarm <alarm>
  [ -cluster <cluster> ]
  [ -description <description> ]
  [ -entity <cluster, entity, host,
node, or volume> ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/alarm/raise?<parameters> |

Parameters

| Parameter | Description |
|--------------|--|
| alarm | The alarm type to raise. See Alarm Types . |
| cluster | The cluster on which to run the command. |
| description | A brief description. |
| entity | The entity on which to raise alarms. |

Examples**Raise a specific alarm:****CLI**

```
maprcli alarm raise -alarm
NODE_ALARM_DEBUG_LOGGING
```

REST

```
https://r1n1.sj.us:8443/rest/alarm/
raise?alarm=NODE_ALARM_DEBUG_LOGGING
```

alarm unmute

Unmute a muted alarm.

Syntax**CLI**

```
maprcli alarm unmute
-alarm [<alarm
name>[:<entity>[:<aetype>]]]+
[ -cluster cluster_name ]
```

REST API

| | |
|--------------|---|
| Request Type | POST |
| Request URL | <pre>http[s]://<host>:<port>/ rest/alarm/unmute? <parameters></pre> |

Parameters

| Parameter | Description |
|-----------|--|
| alarm | The comma-separated list of the muted alarms to unmute. To unmute an alarm associated with an entity (such as volume, node, etc.) or type of accountable entity, you can specify also the name of the entity or the type of accountable entity separated by a colon (:). |
| cluster | The name of the cluster on which to run the command. |

audit

Describes commands used to audit operations related to cluster management and data access.

audit cluster

Enables and disables auditing of operations that are related to the administration of a data-fabric cluster.

Only the `mapr` user for the cluster can run this command. For more information about the `mapr` user, see [Managing Users and Groups](#).

For information about auditing cluster-administration operations, see [Auditing of Activity Related to Cluster Administration](#).

Syntax

CLI

```
maprcli audit cluster
-enabled <true | false>
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/audit/cluster?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| enabled | The value <code>true</code> enables auditing, the value <code>false</code> disables it. |

audit data

Enables and disables auditing of filesystem and table operations.

For a list of these operations, see [Auditing of Filesystem Operations and Table Operations](#).

All administrative users for the cluster can run this command. For more information, see [Managing Users and Groups](#) on page 828.

Syntax

CLI

```
maprcli audit data
[ -cluster <cluster name> ]
[ -enabled <true | false> ]
[ -maxsize <GB> ]
[ -retention <number of days> ]
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/audit/data?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The path and name of a remote MapR cluster. |

| Parameter | Description |
|-----------|---|
| enabled | The value <code>true</code> enables auditing, the value <code>false</code> disables it. |
| maxsize | The size in GB at which an alarm is sent to the dashboard in the MapR Control Service. The alarm is to notify the cluster administrator that the audit log is becoming large enough that the administrator might want to take action. For more information about this parameter, the alarm, and possible actions to take, see Managing Audit Logs for Filesystem and Table Operations . The audit log continues to grow until the administrator takes action or until the retention period ends. The default value is 32. |
| retention | The period of time in days for which to keep the data in the audit log for the data access. After this period elapses, the content of the file is deleted and new entries are added to the file until the next retention period elapses. |

audit info

Displays whether auditing of cluster-management operations and auditing data-access operations are enabled. Also, displays the `maxSize` and `retention` values for these two levels of auditing.

Only the `mapr` user for the cluster can run this command. For more information about the `mapr` user, see [Managing Users and Groups](#).

Syntax**CLI**

```
maprcli audit info
[ -cluster <cluster_name> ]
-json
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | <code>http[s]://<host>:<port>/rest/audit/info?<parameters></code> |

Parameter

| Parameter | Description |
|-----------|---|
| cluster | The name of the cluster on which to run the command. |
| json | Displays command output in JSON format. When <code>-json</code> is omitted, there is no output. |

Example Output

This output shows that auditing of operations on data and auditing of cluster-level operations are both enabled. For descriptions of `maxSizeGB` and `retentionDays`, see the commands [maprcli audit cluster](#) and [maprcli audit data](#).

```

]# maprcli audit info -json
{
  "timestamp":1434458923034,
  "timeofday":"2015-06-16 12:48:43.034 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "data":{
        "enabled":"1",
        "maxSizeGB":"32",
        "retentionDays":"30"
      },
      "cluster":{
        "enabled":"1",
        "maxSizeGB":"NA",
        "retentionDays":"NA"
      }
    }
  ]
}
    
```

blacklist

Describes commands used to blacklist and to list blacklisted users.

blacklist user

Blocks a user on a specific cluster.

This action cancels all existing tickets for the specified user. There is no REST equivalent command. For information about blocking, see [How Tickets Work](#).

Syntax

CLI

```

maprcli blacklist user
  -name <user name>
  [ -blacklisttime <millis from
    epoch> or <MM/DD/YYYY> ]
  [ -cluster <cluster name> ]
    
```

REST

N/A

Parameters

| Parameter | Description |
|---------------|--|
| name | Username to block. |
| blacklisttime | Invalidates all user's tickets that were raised prior to the specified date (in the format <MM/DD/YYYY>). Alternatively, you can specify the time in milliseconds from epoch time (the number of milliseconds that have elapsed since Jan 1, 1970 midnight UTC). |
| cluster | Name of the cluster from which to block the user. |

Example

Block the *rogueuser* user name from the cluster *my.cluster.com*:

CLI

```
maprcli blacklist user -name
rogueuser -cluster my.cluster.com
```

Block the *rogueuser* user's tickets that were raised prior to 1st September 2020 from the cluster *my.cluster.com*:

CLI

```
maprcli blacklist
user -name rogueuser -cluster
my.cluster.com -blacklisttime
09/01/2020
```

Block the *rogueuser* user's tickets that were raised prior to 1605418200155 milliseconds from epoch, from the cluster *my.cluster.com*:

CLI

```
maprcli blacklist
user -name rogueuser -cluster
my.cluster.com -blacklisttime
1605418200155
```

The value 1605418200155 corresponds to the time November 15th 2020, 11:00:00 am IST+05:30. Therefore, all *rogueuser* tickets that were raised prior to November 15th 2020, 11:00:00 am IST+05:30 are blocked.

Related Log File

The log file `/opt/mapr/logs/cldbauidit.log.json` contains the log of the block operation including the updated block time. For example:

```
{ "timestamp" :
  { "$date" : "2020-11-13T08:37:36.524Z" }, "resource" : "mapruser4", "operation" : "bla
cklist",

  "username" : "root", "uid" : 0, "clientip" : "10.10.50.42", "properties" :

  [ { "property" : "blacklisttime", "oldvalue" : "1605254599376", "newvalue" : "16058757
66173" } ],

    "status" : 0 } { "timestamp" :
  { "$date" : "2020-11-13T08:37:45.020Z" }, "resource" : "cluster",
  "operation" : "listBlacklist", "username" : "root", "uid" : 0,
  "clientip" : "10.10.50.42", "status" : 0 }
```

Here the old block list time was 1605254599376 milliseconds (November 13, 2020 1:33:19 PM IST) and is now updated to 1605875766173 milliseconds (Friday, November 20, 2020 6:06:06 PM IST).

blacklist listusers

Lists blocked users on a specific cluster.

By default, this command lists users that have been blocked from the cluster where the command is run. There is no REST equivalent command. For information about blocking, see [How Tickets Work](#).

Syntax**CLI**

```
maprcli blacklist listusers
[ -cluster <cluster name> ]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | Name of the cluster for which the blocked users must be listed. |

Examples**Show blocked users for the cluster my.cluster.com:****CLI**

```
maprcli blacklist listusers -cluster
my.cluster.com
```

cluster

Manages cluster features, gateways, and cluster-wide settings.

cluster feature enable

Allows features to be enabled. Used after upgrading.

Note: Run `cluster feature list` on page 1738 command to retrieve the list of features that can be enabled.

Syntax**CLI**

```
maprcli cluster feature enable
[ -name <feature name > ]
[ -force ]
[ -all ]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| name | Name of the feature. |
| force | Forces the enabled and disabled dependency features. No value is taken. |
| all | Enables all of the features. No value is taken. |

Note: Once a feature is enabled, it can not be disabled.

Examples

To enable all features, use the `cluster feature enable -all` command.

```
maprcli cluster feature enable -all
```

To enable a specific feature, use the `cluster feature enable -name` command. For example:

```
maprcli cluster feature enable -name mfs.feature.audit.support
```

cluster feature list

Allows features to be listed. Used after upgrading.

Syntax

CLI

```
maprcli cluster feature list
    [ -name <Feature name > ]
    [ -enabled ]
    [ -disabled ]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| name | Lists the named feature. Displays whether the feature is enabled or disabled along with the feature name. |
| enabled | Lists only the enabled features. No value is taken. |
| disabled | Lists only the disabled features. No value is taken. |

Tip: The three dots in the output indicate multiple entries. Use `-json` to format the output.

Examples

Lists the disabled features.

```
maprcli cluster feature list -disabled
dependency
name
description      enabled

mfs.feature.audit.support
false
```

Lists all the features.

```
maprcli cluster feature list

dependency

name

description
```

```

                                enabled

                                Support for Disk
Flush

```

Tip: Use `-json` to format the output.

cluster gateway delete

Deletes the list of data-fabric gateways from a source data-fabric cluster.

Source data-fabric clusters can use such lists to locate the gateways that enable replication of table data to a particular data-fabric cluster or indexing of table data in a particular Elasticsearch cluster. You create lists of gateways by running the `cluster gateway set` on page 1753 command.

There are three methods of specifying the location of gateways to a data-fabric cluster that is a source for table replication or indexing in Elasticsearch. If a source data-fabric cluster relies on DNS records to find out where gateways are located, or the cluster relies on the `mapr-clusters.conf` file to locate gateways, there is no list for the `cluster gateway delete` command to delete.

Note: Deleting a list of gateways with the `maprcli cluster gateway delete` command does not uninstall the listed gateways from the data-fabric cluster where they are located.

Syntax**CLI**

```
/opt/mapr/bin/maprcli cluster gateway
delete
  [ -cluster <cluster on which
command needs to be run> ]
  -dstcluster <cluster name>
```

REST

```
http[s]://<host>:<port>/rest/cluster/
gateway/delete?dstcluster=<path>
```

Parameters

| Parameter | Description |
|------------|---|
| cluster | If you are not on the source cluster, provide the name of the source cluster on which this command should be run. |
| dstcluster | The name of the cluster on which the gateways are located. If you are replicating table data to another data-fabric cluster, specify the name of that destination cluster. This destination cluster could be the source cluster if you are performing intra-cluster replication. If you are indexing table data in an Elasticsearch cluster, specify the name of the source data-fabric cluster because that is where the gateways are located. |

Example

Deletes a list of gateways that is stored on a source data-fabric cluster. The gateways are being used for table replication are located in the destination data-fabric cluster `newyork`.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
delete -dstcluster newyork
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/delete?dstcluster=newyork
```

Lists the gateways that are configured on the data-fabric cluster where this command is run.

[cluster gateway resolve](#) on page 1751

Lists the gateways configured on a data-fabric cluster that are up and running at the time that the command is issued.

[cluster gateway set](#) on page 1753

Specifies the locations of the data-fabric gateways that a source data-fabric cluster can use for table replication to a destination data-fabric cluster, or for indexing table data in an Elasticsearch cluster.

Related information

[Managing Gateways](#) on page 1273

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

cluster gateway get

Lists the data-fabric gateways that a source data-fabric cluster is using.

The source data-fabric cluster could be using the data-fabric gateways either for replication of table data to a destination data-fabric cluster or for the indexing of data in an Elasticsearch cluster.

This list of gateways is created by the [cluster gateway set](#) on page 1753 command.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
get
    [ -cluster <sourceCluster> ]
    -dstcluster
    <destinationCluster>
```

REST

```
http[s]://<host>:<port>/
rest/cluster/gateway/get?
dstcluster=<path>&cluster=<path>
```

Parameters

| Parameter | Description |
|-----------|--|
| cluster | If you are not on the source cluster, provide the name of the source cluster on which this command should run. |

| Parameter | Description |
|------------|--|
| dstcluster | <p>The name of the cluster on which the gateways are located.</p> <p>If you are replicating table data to another data-fabric cluster, specify the name of that destination cluster. This destination cluster could be the source cluster if you are performing intra-cluster replication.</p> <p>If you are indexing table data in an Elasticsearch cluster, specify the name of the source data-fabric cluster because that is where the gateways are located.</p> |

Example

Gets the list of gateways that is stored on a source data-fabric cluster. The gateways are being used for table replication and are located in the destination data-fabric cluster `sfcluster`.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
get -dstcluster sfcluster
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/get?dstcluster=sfcluster
```

Example Output

```
cluster gatewayConfig
sfcluster gw1 gw2
```

Specifies the locations of the data-fabric gateways that a source data-fabric cluster can use for table replication to a destination data-fabric cluster, or for indexing table data in an Elasticsearch cluster.

Related information

[Managing Gateways](#) on page 1273

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

cluster gateway list

Lists all of the gateways that a source data-fabric cluster is using.

The source data-fabric cluster is using gateways either for replication of table data to destination data-fabric clusters or for the indexing of table data in Elasticsearch clusters.

This list is created by the [cluster gateway set](#) on page 1753 command.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
list
    [ -cluster <sourceCluster> ]
```

REST

```
http[s]://<host>:<port>/rest/cluster/
gateway/list
```

Parameters

| Parameter | Description |
|-----------|--|
| cluster | If you are not on the source cluster, provide the name of the source cluster on which this command should run. |

Example

Lists all the gateways that a source data-fabric cluster can use when replicating table data in data-fabric clusters or indexing data in Elasticsearch clusters. In this example, assuming `newyork` to be the name of a data-fabric cluster that is a destination for table replication, the output shows two gateways that are available for replicating to this cluster.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
list
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/list
```

Example Output

```
cluster gatewayConfig
newyork gw1 gw2
```

cluster gateway local

Lists the gateways that are configured on the data-fabric cluster where this command is run.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
local
    [ -cluster cluster on which
command to be run ]
    [ -format dns/text. default:
text ]
```

REST

```
http[s]://<host>:<port>/rest/cluster/
gateway/local
```

Parameters

| Parameter | Description |
|-----------|--|
| format | <p>The output format. Value types: dns or text. Default: text.</p> <p> Note:</p> <ul style="list-style-type: none"> If the output is formatted as DNS, you can copy and paste the output into a DNS record in the zone file for your domain. The source data-fabric cluster can then locate the gateways by doing a DNS lookup. If the output is formatted as text, you can copy and paste that text into the <code>-gateways</code> parameter of the <code>maprcli cluster gateway set</code> command. Running this command is an alternative way of specifying the location of these gateways to the source data-fabric cluster. |
| cluster | <p>If you are not on a data-fabric cluster where one or more gateways are configured, provide the name of the cluster.</p> <ul style="list-style-type: none"> When replicating HPE Ezmeral Data Fabric Database table data to one or more replicas on this cluster, then the cluster is a destination data-fabric cluster. When indexing HPE Ezmeral Data Fabric Database table data in one or more Elasticsearch cluster, then the current cluster is a source data-fabric cluster where the tables being indexed are located. |

Example

This example shows text output of the list of gateways that are configured on a data-fabric cluster:

CLI

```
/opt/mapr/bin/maprcli cluster gateway
local
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/local
```

Example Output

```
gatewayinfo
centos23 centos22
```

This example shows DNS output of the list of gateways that are configured on a data-fabric cluster:

CLI

```
/opt/mapr/bin/maprcli cluster gateway
local -format dns
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/local?format=dns
```

Example Output

```
gatewaydnsinfo
; TXT Record addresses
gateway.mycluster IN TXT "centos23
centos22"
```

Specifies the locations of the data-fabric gateways that a source data-fabric cluster can use for table replication to a destination data-fabric cluster, or for indexing table data in an Elasticsearch cluster.

Related information

[Managing Gateways](#) on page 1273

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

cluster gateway resolve

Lists the gateways configured on a data-fabric cluster that are up and running at the time that the command is issued.

Run this command on a source data-fabric cluster to find out how many gateways are available for table replication to a destination data-fabric cluster, or for indexing table data in an Elasticsearch cluster.

This command uses the following criteria to get the list:

- If you specified the locations of the gateways with the [cluster gateway set](#) on page 1753 command, the `maprcli cluster gateway resolve` command returns the list of the gateways.
- If you specified the locations of the gateways only with a DNS record, this command performs a DNS lookup for gateways on the specified data-fabric cluster and returns the list that it finds.
- If you did not specify the locations of the gateways using the previously listed methods, this command assumes that gateways are located on the CLDB nodes configured in the `mapr-clusters.conf` file on the data-fabric cluster where the command is run.

Note: Unresponsive gateways are not included in the list.

For more information about gateways, see [MapR Gateways](#).

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
resolve
    [ -cluster <cluster on which the
command is to be run> ]
    -dstcluster <destination cluster
name>
```

REST

```
http[s]://<host>:<port>/rest/
cluster/gateway/resolve?
dstcluster=<clustername>
```

Parameters

| Parameter | Description |
|-----------|--|
| cluster | If you are not on the source data-fabric cluster, provide the name of the source cluster on which this command should run. |

| Parameter | Description |
|------------|--|
| dstcluster | <p>The name of the cluster for which you want to list the available gateways.</p> <p>If you are replicating table data to another data-fabric cluster, specify the name of that destination cluster. This destination cluster can be the source cluster if you are performing intra-cluster replication.</p> <p>If you are indexing table data in an Elasticsearch cluster, specify the name of the source data-fabric cluster because that is where the gateways are located.</p> |

Example

This example shows that only one gateway is up and running on the data-fabric cluster `cluster1`. The IP address of this gateway was found in a DNS record, as indicated by the `Source` field.

CLI

```
/opt/mapr/bin/maprcli cluster gateway
resolve -dstcluster cluster1 -json
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/resolve?dstcluster=cluster1
```

Example Output

```
{
  "timestamp":1424266395862,
  "timeofday":"2015-02-18
01:33:15.862 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "GatewayHosts":"10.10.20.12:7660",
      "Source":"DNS"
    }
  ]
}
```

cluster gateway set

Specifies the locations of the data-fabric gateways that a source data-fabric cluster can use for table replication to a destination data-fabric cluster, or for indexing table data in an Elasticsearch cluster.

In addition to this method, there are two other methods that you can use to specify the locations of gateways that a source data-fabric cluster can use when replicating to a particular data-fabric cluster or when indexing in an Elasticsearch cluster. See [Configuring Gateways for Table and Stream Replication](#) for details about them.

Syntax

CLI

```
/opt/mapr/bin/maprcli cluster gateway
set
  [ -cluster <cluster on which
command to be run> ]
  -dstcluster <cluster name>
  -gateways <space-separated list of
hostnames>
```

REST

```
http[s]://<host>:<port>/
rest/cluster/gateway/set?
dstcluster=<path>&gateways=<list
of gateways>
```

Parameters

| Parameter | Description |
|------------|---|
| cluster | If you are not on the source data-fabric cluster, provide the name of that cluster. |
| dstcluster | The name of the data-fabric cluster in which the gateways are located. If you are replicating table data to another data-fabric cluster, specify the name of that destination cluster. This destination cluster could be the source cluster if you are performing intra-cluster replication. If you are indexing table data in an Elasticsearch cluster, specify the name of the source data-fabric cluster because that is where the gateways are located. |
| gateways | A space-delimited list of gateway hostnames or IP addresses. Place double quotation marks around the list of gateways, as in this example: <code>-gateways "gateway1 gateway2"</code> |

Example

This example specifies the hostnames of two gateways that are in the data-fabric cluster `newyork`. This command could be used in any of these situations:

- The cluster `newyork` is the destination cluster for table replication from the source data-fabric cluster.
- The cluster `newyork` is both a source and destination cluster for intra-cluster table replication.
- The cluster `newyork` is a source data-fabric cluster that contains tables being indexed in one or more Elasticsearch clusters.

CLI

```
/opt/mapr/bin/maprcli cluster
gateway set -dstcluster
newyork -gateways "gw1.bigcompany.com
gw2.bigcompany.com"
```

REST

```
https://<host>:<port>/rest/cluster/
gateway/set?
dstcluster=newyork&gateways=gw1.bigcom
pany.com%20gw2.bigcompany.com
```

Related concepts

[Administering Data Fabric Gateways](#) on page 1269

A HPE Ezmeral Data Fabric gateway mediates one-way communication between a source HPE Ezmeral Data Fabric cluster and a destination cluster. You can replicate HPE Ezmeral Data Fabric Database tables (binary and JSON) and HPE Ezmeral Data Fabric Event Streams streams. HPE Ezmeral Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

[Configuring Gateways for Table and Stream Replication](#) on page 1271

Configuring gateways involves installing the `mapr-gateway` package on nodes on a data-fabric destination cluster and then configuring the data-fabric source cluster to communicate with the destination cluster. The data-fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

[gateway.conf](#) on page 2482

[Gateways for Replicating HPE Ezmeral Data Fabric Database Tables](#) on page 584

In HPE Ezmeral Data Fabric Database table replication, HPE Ezmeral Data Fabric Database replicates updates to tables (binary and JSON) on source data-fabric clusters to replicas of those tables on destination data-fabric clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Related tasks

[Specifying the Location of Gateways](#) on page 859

Describes how to set the location of the HPE Ezmeral Data Fabric gateways using either the Control System or the CLI.

Related reference

[cluster gateway delete](#) on page 1743

Deletes the list of data-fabric gateways from a source data-fabric cluster.

[cluster gateway get](#) on page 1745

Lists the data-fabric gateways that a source data-fabric cluster is using.

[cluster gateway list](#) on page 1747

Lists all of the gateways that a source data-fabric cluster is using.

[cluster gateway local](#) on page 1748

Lists the gateways that are configured on the data-fabric cluster where this command is run.

[cluster gateway resolve](#) on page 1751

Lists the gateways configured on a data-fabric cluster that are up and running at the time that the command is issued.

Related information

[Managing Gateways](#) on page 1273

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

cluster info

Returns minimum and maximum values for the following attributes:

- `VolumeSize` — The size of the volume.
- `VolumeQuotaSize` — The hard quota (disk space) for the volume.
- `VolumeAdvisoryQuota` — The advisory quota (disk space) for the volume.
- `VolumeLogicalUsedSize` — The logical size used by the volume.
- `VolumeNumContainers` — The number of replicas for the volume.
- `VolumeGuaranteedNumContainers` — The number of guaranteed replicas for the volume.
- `VolumeNumNamespaceContainers` — The number of replicas for the name container associated with the volume.
- `VolumeGuaranteedNumNamespaceContainers` — The number of guaranteed replicas for the name container associated with the volume.
- `VolumeNumSnapshots` — The number of snapshots of the volume.
- `VolumeCoalesceInterval` — The coalesce interval setting for the volume.
- `VolumeMaxInodesAlarmThreshold` — The threshold for triggering the `VOLUME_ALARM_INODES_EXCEEDED` alarm.

- `VolumeMaxNsSizeMbAlarmThreshold` — The threshold for triggering the `VOLUME_ALARM_INODES_EXCEEDED` alarm.
- `VolumeReReplicationTimeOut` — The timeout value for re-replication.
- `StoragePoolCapacitySize` — The total amount of disk space on the storage pool.
- `StoragePoolUsedSize` — The amount of used space on the storage pool.
- `StoragePoolAvailableSize` — The amount of available space on the storage pool.

Syntax

CLI

```
maprcli cluster info -getminmax
<attributes>
```

REST API

N/A

Parameters

| Parameter | Description |
|------------------------|--|
| <code>getminmax</code> | The comma-separated list of attributes to return minimum and maximum values for. To retrieve the minimum and maximum values for all the attributes, use the keyword <code>all</code> . |

Examples

Retrieve the minimum and maximum values for all the attributes:

```
maprcli cluster info -getminmax all
```

Output

```
# maprcli cluster info -getminmax all
min      unit  max      name
1804262  MB    2703486  StoragePoolAvailableSize
0        MB    32768    VolumeAdvisoryQuota
2        Num   6        VolumeNumContainers
0        MB    47152    VolumeLogicalUsedSize
60       Min   60       VolumeCoalesceInterval
0        MB    0        VolumeMaxNsSizeMbAlarmThreshold
0        MB    0        VolumeSharedSize
1826966  MB    2738572  StoragePoolCapacitySize
2        Num   6        VolumeNumNamespaceContainers
0        MB    6020     VolumeOwnedSize
22704    MB    35086    StoragePoolUsedSize
0        Num   0        VolumeNumSnapshots
0        Sec   0        VolumeReReplicationTimeOut
0        MB    6020     VolumeSize
1        Num   2        VolumeGuranteedNumNamespaceContainers
0        Sec   5        VolumeMaxInodesAlarmThreshold
1        Num   2        VolumeGuranteedNumContainers
0        MB    0        VolumeQuotaSize
```

Retrieve the minimum and maximum values for the given attributes:

```
# maprcli cluster info
-getminmax
VolumeNumContainers,VolumeGuranteedNumContainers,VolumeGuranteedNumNamespace
Containers,VolumeNumNamespaceContainers
```

Output

```
# maprcli cluster info -getminmax
VolumeNumContainers,VolumeGuranteedNumContainers,VolumeGuranteedNumNamespace
Containers,VolumeNumNamespaceContainers
min unit max name
1 Num 2 VolumeGuranteedNumNamespaceContainers
2 Num 6 VolumeNumContainers
2 Num 6 VolumeNumNamespaceContainers
1 Num 2 VolumeGuranteedNumContainers
```

cluster mapreduce get

Displays the cluster-wide default for the MapReduce mode.

Warning: This command is deprecated alongside MapReduce v1.

Syntax**CLI**

```
maprcli cluster mapreduce get
```

REST

```
http[s]://<host>:<port>/rest/cluster/
mapreduce/get
```

Output Fields

| Field | Description |
|-------------------|---|
| default_mode | Displays either <code>yarn</code> or <code>classic</code> . |
| mapreduce_version | Displays the hadoop version associated with the <code>default_mode</code> . |

Sample Output

```
default_mode  mapreduce_version
classic       0.20.2
```

Examples**CLI**

```
maprcli cluster mapreduce get
```

REST

```
https://r1n1.sj.us:8443/rest/cluster/
mapreduce/get
```

cluster mapreduce set

Sets the cluster-wide MapReduce mode.

 **Warning:** This command is deprecated alongside MapReduce v1.

Syntax

CLI

```
maprcli cluster mapreduce set -mode
yarn
```

REST

```
http[s]://<host>:<port>/rest/cluster/
mapreduce/set?<parameters>
```

Parameters

| Parameter | Description |
|-----------|--|
| mode | The MapReduce mode of the cluster. Enter <code>yarn</code> to use Resource Manager and Node Manager to run MapReduce jobs or applications. |

Examples

Sets the MapReduce mode for the cluster to classic.

CLI

```
maprcli cluster mapreduce set -mode
yarn
```

REST

```
https://r1n1.sj.us:8443/rest/cluster/
mapreduce/set?mode=yarn
```

cluster queryservice

Describes the commands to enable/disable and view the settings for the OJAI Distributed Query Service.

Enable the [OJAI Distributed Query Service](#) on page 467 if you want the following functionality when querying HPE Ezmeral Data Fabric Database JSON tables:

- Advanced secondary index selection
- Sorts of large data sets
- Parallel query execution

Permissions Required

If you enable the OJAI Distributed Query Service during installation, then you must be user 'mapr' to run these commands. If you disable the service, and later re-enable it, then the command needs to be run by the user that re-enabled the service.

cluster queryservice getconfig

Retrieves the configuration of the OJAI Distributed Query Service.

Permissions Required

Only the user that enabled the OJAI Distributed Query Service can run this command. If the service was enabled during installation, user 'mapr' must run the command.

Syntax**CLI**

```
maprcli cluster queryservice
getconfig -cluster < cluster-name >
```

REST

Not available

Parameters

| Parameter | Description |
|----------------|---|
| cluster | (Optional) Name of the cluster that is using secondary indexes to query HPE Ezmeral Data Fabric Database JSON table |

Example

```
maprcli cluster queryservice getconfig -cluster my.cluster.com
```

cluster queryservice setconfig

Enables or disables the OJAI Distributed Query Service. When enabling the service, you can specify the configuration of the service.

Permissions Required

Only the user that enabled the OJAI Distributed Query Service can run this command. If the service was enabled during installation, user 'mapr' must run the command.

Syntax**CLI**

```
maprcli cluster queryservice
setconfig
    [ -cluster <
cluster-name > ]
    -enabled < true | false
>
    -clusterid < cluster-id
of MapR Drill cluster >
    -storageplugin < Name
of MapR Drill Storage plug-in >
    -znode < Root Zookeeper
node user by MapR Drill cluster >
```

REST

Not available

Parameters

| Parameter | Description |
|----------------|--|
| cluster | (Optional) Name of the cluster that is using secondary indexes to query HPE Ezmeral Data Fabric Database JSON tables |

| Parameter | Description |
|----------------------|--|
| enabled | (Required) Whether the OJAI Distributed Query Service is enabled Values: true or false |
| clusterid | (Required) Cluster ID of your MapR Drill cluster Refer to the value of the <code>cluster-id</code> parameter in the <code>drill-distrib.conf</code> file. You can find this file in the <code>/opt/mapr/drill/drill-<version number>/conf</code> directory. |
| storageplugin | (Required) Name of the MapR Drill Storage plug-in instance used to run OJAI queries (usually dfs) |
| znode | (Required) Name of the root Zookeeper node used by the MapR Drill cluster (usually /drill) |

Example

```
maprcli cluster queryservice setconfig \
  -enabled true \
  -clusterid mycluster \
  -storageplugin dfs \
  -znode /drill
```

config

Lists configuration values for the data-fabric cluster.

Configuration Fields

The following fields are configurable.

| | |
|--|---|
| <code>cldb.balancer.disk.max.switches.in.nodes.percentage</code> | <i>Default Value:</i> 10 The maximum number of containers that can be balanced in parallel by the disk balancer. The value is a percentage of the number of nodes in the system. |
| <code>cldb.disk.balancer.enable</code> | <i>Default Value:</i> 1 (Disk Balancer is enabled) Enables (1) or disables (0) the Disk Balancer. |
| <code>cldb.balancer.disk.sleep.interval.sec</code> | <i>Default Value:</i> 120 The sleep interval (in seconds) between two successive runs of the Disk Balancer. |
| <code>cldb.balancer.disk.threshold.percentage</code> | <i>Default Value:</i> 70 Percentage of used space that causes containers in a storage pool to be distributed across other less used storage pools. |
| <code>cldb.balancer.logging</code> | <i>Default Value:</i> 0 Disables (0) or enables (1) the logging of messages in the Disk Balancer and Role Balancer. |
| <code>cldb.balancer.role.max.switches.in.nodes.percentage</code> | <i>Default Value:</i> 10 The percentage (of the number of nodes in the system) to use to determine the maximum number of containers whose roles (Masters and Tails) are balanced in parallel by the Role Balancer. |

| | |
|---|--|
| | For example, suppose there are 500 nodes and the value of this parameter is 10(%). The number of containers whose roles are balanced in parallel is $(10/100)*500=50$. |
| <code>cldb.balancer.role.paused</code> | <i>Default Value:</i> 1 Enables (0) or Disables (1) the Role Balancer. |
| <code>cldb.balancer.role.sleep.interval.sec</code> | <i>Default Value:</i> 900 The sleep interval (in seconds) between two successive runs of the Role Balancer. |
| <code>cldb.balancer.startup.interval.sec</code> | <i>Default Value:</i> 1800 The initial startup delay (in seconds) of the Role Balancer for existing clusters. |
| <code>cldb.cluster.almost.full.percentage</code> | <i>Default Value:</i> 90 The percentage at which the <code>CLUSTER_ALARM_CLUSTER_ALMOST_FULL</code> alarm is triggered. |
| <code>cldb.container.alloc.selector.algo</code> | <i>Default Value:</i> 0 The allocation algorithm to use when creating new containers. The value can be one of: <ul style="list-style-type: none"> • 0 - indicates Round Robin algorithm if the number of nodes is less than or equal to 100, Randomized algorithm otherwise. • 1 - indicates Round Robin algorithm. If selected, containers are allocated across nodes in a topology in a round robin fashion. • 2 - indicates Randomized algorithm. If selected, containers are allocated across nodes in a randomized way. |
| <code>cldb.container.assign.buffer.sizemb</code> | <i>Default Value:</i> 1024 The size of the container (in MB) that should be used as a buffer. When allocating a new container, this size is deducted from the maximum container size. <p> Note: When you modify the value of <code>cldb.container.sizemb</code>, check and update the value of <code>cldb.container.assign.buffer.sizemb</code> to prevent new containers from being created when existing containers are not full.</p> |
| <code>cldb.container.create.diskfull.threshold</code> | <i>Default Value:</i> 85 The percentage of space on a file server to use to classify the file server as full. |
| <code>cldb.container.sizemb</code> | <i>Default Value:</i> 32768 The maximum size for containers (in MB). This is a soft limit. <p> Note: When <code>cldb.container.sizemb</code> value is modified, check and update the value of <code>cldb.container.assign.buffer.sizemb</code> to prevent new containers from being created when existing containers are not full.</p> |

| | |
|---|---|
| <code>cldb.default.chunk.size</code> | <i>Default Value:</i> 256 The size of each chunk (in MB) that make up a file in the data-fabric filesystem. |
| <code>cldb.default.volume.topology</code> | <i>Default Value:</i> /data The default topology for new volumes. |
| <code>cldb.dialhome.metrics.file.rotation.period</code> | <i>Default Value:</i> 365 The retention period of the files (in days) that is used to record Dialhome metrics. Files that are past their retention period are automatically deleted. |
| <code>cldb.disable.alarm.history</code> | <i>Default Value:</i> 0 (false) Set this to 1 (true) to disable CLDB alarm history, as tracking and fetching the alarm history can degrade the performance of CLDB on large clusters. |
| <code>cldb.fs.mark.rereplicate.sec</code> | <i>Default Value:</i> 3600 The number of seconds that a node can fail to heartbeat before it is considered dead. Once a node is considered dead, the CLDB re-replicates any data contained on the node. |
| <code>cldb.fs.reregistration.wait.time</code> | <i>Default Value:</i> 15 The amount of time (in minutes) to wait before checking for inactive nodes.  Note: Reduce the value to raise the No Heartbeat Alarm on page 2518 without delay, after CLDB failover. To avoid spurious alarms, do not reduce this value below 5 (minutes). |
| <code>cldb.log.fileserver.timeskew.interval.mins</code> | <i>Default Value:</i> 60 The frequency (in minutes) at which CLDB should log messages about the time skew on the file server. |
| <code>cldb.max.parallel.resyncs.star</code> | <i>Default Value:</i> 3 The number of container replicas that can resync in parallel from the source for low-latency (star-replicated) volumes. |
| <code>cldb.max.snapshots.per.volume</code> | <i>Default Value:</i> 4096 The maximum number of snapshots that you can create for a volume. CLDB will fail snapshot creation once the number of snapshots reaches this limit. Increasing this value has performance implications. This should only be changed in consultation with the HPE data-fabric support team. |
| <code>cldb.mfs.heartbeat.timeout.multiple</code> | <i>Default Value:</i> 10 Specifies a multiple heartbeat timeout. For small clusters, the heartbeat interval is 1 second and the multiple is 10 by default, which makes the heartbeat timeout 10 seconds. |
| <code>cldb.min.fileservers</code> | <i>Default Value:</i> 1 The number of file servers hosting the CLDB volume that is required for the master CLDB to complete the bootstrap process. |
| <code>cldb.num.active.cg.containers</code> | <i>Default Value:</i> 20 |

| | |
|---|--|
| | Number of containers to be assigned for a CG assign request. The value can be any integer between 0 and 100. |
| <code>cldb.pbs.access.control.enabled</code> | <p><i>Default Value:</i> 1</p> <p>Enables and disables policy access controls (ACEs set in security policies) at the cluster level. When set to 0, the system does not enforce security policy ACEs for data operations in the cluster. See Disabling Policy Access Controls at the Cluster-Level on page 1597 for additional information.</p> |
| <code>cldb.pbs.audit.only.policy.check</code> | <p><i>Default Value:</i> 0</p> <p>Set the value to 1 to enable audit-only policy checks (permissive mode). Permissive mode is useful during initial deployment when testing security policies. When permissive mode is enabled, the volume-level enforcementmode option <code>PolicyAceAuditAndDataAce</code> can be set. In this mode:</p> <ul style="list-style-type: none"> • Resource-level ACEs are enforced. • If security policies are tagged to data objects, the security policies are checked for access; any access denied events will be audited, but access will be allowed. <p>See Setting Global Configuration Options for Policy-Based Security on page 1595 for additional information.</p> |
| <code>cldb.pbs.max.security.policy</code> | <p><i>Default Value:</i> 10000</p> <p>Maximum number of configured security policies allowed. Prevents users from arbitrarily creating numerous security policies, which could impact performance.</p> |
| <code>cldb.pbs.global.master</code> | <p><i>Default Value:</i> 0</p> <p>Sets the master security policy cluster for the global namespace. You can configure a cluster to perform one of the following roles:</p> <ul style="list-style-type: none"> • Master — A master security policy cluster is required to create and manage security policies. Only one master security policy cluster can exist. • Member — On a cluster designated as Member, you can view the security policies available and apply them to data objects. <p>By default, the host is set to member (0) upon a new installation or upgrade. To set the host to master, and enable the creation and modification of security policies, set the value of this property to 1.</p> <p>For more information, see the config save on page 1768.</p> |
| <code>cldb.replication.manager.critical.paused</code> | <p><i>Default Value:</i> 0</p> <p>Disables (0) or enables (1) the processing of critically under-replicated containers. If enabled, the critically under-replicated containers are processed on a priority basis to increase the number of copies.</p> |
| <code>cldb.replication.manager.max.resyncs.in.nodes.percentage</code> | <p><i>Default Value:</i> 1200</p> |

| | |
|---|--|
| | The number of containers that can be replicated in parallel, expressed as a percentage of the number of active nodes. If the value is 1200, the number of containers that can be replicated is 12 times the number of active nodes. |
| <code>cldb.replication.manager.over.paused</code> | <i>Default Value:</i> 0 Disables (0) or enables (1) the processing of over-replicated containers. Over-replicated containers are processed to delete extra copies, which is when the number of copies is more than the desired replication factor. |
| <code>cldb.replication.manager.start.mins</code> | <i>Default Value:</i> 15 The delay (in minutes) between CLDB startup and replication manager startup, to allow all nodes to register and heartbeat. |
| <code>cldb.replication.max.in.transit.containers.per.sp</code> | <i>Default Value:</i> 4 The maximum number of containers that can be in transit on a storage pool (SP). Containers that serve either as the source or destination of a resync operation are considered as being in 'transit'. |
| <code>cldb.replication.sleep.interval.sec</code> | <i>Default Value:</i> 15 The sleep duration (in seconds) between consecutive runs of the Replication Manager. |
| <code>cldb.replication.tablescan.interval.sec</code> | <i>Default Value:</i> 120 The sleep duration (in seconds) between consecutive runs of the Replication Scanner. While the Replication Scanner classifies containers into different buckets, the Manager thread either replicates or removes additional copies. |
| <code>cldb.rm.wait.rack.violated.fork.copy.mins</code> | <i>Default Value:</i> 720 The buffer time (in minutes) after which all container copies found on the same rack are fixed. |
| <code>cldb.rm.wait.fork.on.same.rack.mins</code> | <i>Default Value:</i> 180 The time (in minutes) to defer creating containers on the same rack, for critically under-replicated containers, if there are at least two copies of the containers. |
| <code>cldb.security.user.ticket.duration.seconds</code> | <i>Default Value:</i> 1209600 The length of time (in seconds) before the user ticket (generated using the <code>maprlogin password</code> command) expires. |
| <code>cldb.security.user.ticket.max.duration.seconds</code> | <i>Default Value:</i> 2592000 The maximum amount of time (in seconds) allowed for the user ticket (generated using the <code>maprlogin password</code> command). |
| <code>cldb.security.user.ticket.renew.duration.seconds</code> | <i>Default Value:</i> 2592000 The length of time (in seconds) to renew the user ticket (generated using the <code>maprlogin password</code> command). |
| <code>cldb.security.user.ticket.renew.max.duration.seconds</code> | <i>Default Value:</i> 7776000 The maximum duration allowed for a user ticket (generated using <code>maprlogin password</code> command) renewal. |

| | |
|---|--|
| <code>cldb.snapshot.restore.on.volume.unmount.only</code> | <p><i>Default Value:</i> 1 (true)</p> <p>Indicates whether the Snapshot Restore operation is allowed without first checking whether the volume is unmounted or not.</p> <p>By default, the volume restore operation is allowed only if the volume is unmounted, ensuring that no application is accessing any data in the volume.</p> <p>Set this flag to 0 (false) to perform the restore operation in a single step, without verifying whether the volume is unmounted or not.</p> <p>To set this flag to 0, run:</p> <pre style="background-color: #f0f0f0; padding: 5px;">/opt/mapr/bin/maprcli config \ save -values '{"cldb.snapshot.restore.on.volume.unmount.only":"0"}' -json</pre> |
| <code>cldb.topology.almost.full.percentage</code> | <p><i>Default Value:</i> 90</p> <p>The threshold percentage that is used to raise alarms when the used space on the nodes of a topology exceed a certain percentage of total space.</p> |
| <code>cldb.volume.epoch</code> | <p><i>Default Value:</i> Not Applicable</p> <p>The starting epoch of a new Container. Epoch is used internally in the selection of the master container.</p> |
| <code>cldb.volumes.namespace.default.min.replication</code> | <p><i>Default Value:</i> 2</p> <p>The minimum replication factor for the name container. Containers with fewer copies than this value are replicated on a priority basis.</p> <p> Note: To modify, run the <code>maprcli volume modify -name <volume name> -nsminreplication <replication factor></code> command.</p> |
| <code>cldb.volumes.namespace.default.replication</code> | <p><i>Default Value:</i> 3</p> <p>The desired replication factor for the name container.</p> <p> Note: To modify, run the <code>maprcli volume modify -name <volume name> -nsreplication <replication factor></code> command.</p> |
| <code>mapr.fs.nocompression</code> | <p><i>Default Value:</i> "bz2,gz,tgz,tbz2, zip,z,Z,mp3,jpg, jpeg,mpg,mpeg,avi, gif,png,lzo,jar"</p> <p>The file types that should not be compressed. See File Extensions of Compressed Files on page 1082.</p> |
| <code>mapr.fs.permissions.supergroup</code> | <p><i>Default Value:</i> root</p> <p>The <i>super group</i> of the data-fabric filesystem layer.</p> |
| <code>mapr.fs.permissions.superuser</code> | <p><i>Default Value:</i> mapr</p> <p>The <i>super user</i> of the data-fabric filesystem layer.</p> |
| <code>mapr.targetversion</code> | <p><i>Default Value:</i> Not Applicable</p> <p>The configuration variable to set the current version of the data-fabric distribution. Failing to set this variable on an upgrade causes alarms to be missed when all</p> |

mfs.db.parallel.copyregions

the nodes in a cluster are not at the same version of the software.

Default Value: Not Applicable

The number of parallel copy regions per MFS instance. Setting this field to a larger value increases the parallelism for data transfers during index updates, CDC propagation, and table replication. A larger value increases the transfer rate and reduces the initial synchronization time, but uses more system resources. The latter may impact the response time and performance of applications that read data from the same nodes.

mfs.high.memory.alarm.threshold

Default Value: 110 (percentage of allocated memory)

On initialization, the data-fabric filesystem is allocated a certain amount of memory. There is some additional headroom that can be used if the data-fabric filesystem is under memory pressure. However, if the data-fabric filesystem exceeds the high memory threshold (default 10% over the allocated memory, that is 110%), the [High FileServer Memory Alarm](#) on page 2516 is raised. This threshold can be 8% to 30% over the allocated memory (that is 108% to 130%) .

mfs.feature.db.json.support

Default Value:

- 1 for new data-fabric installations
- 0 for upgraded data-fabric installations

Disables (0) or enables (1) data-fabric streams and support in HPE Ezmeral Data Fabric Database for JSON documents and tables..

mfs.feature.devicefile.support

Default Value: 1

Disables (0) or enables (1) usage of Named Pipes over NFS.

pernode.numcntrs.alarm.thr

Default Value: 50000

The maximum number of Read/Write (RW) containers on each node beyond which performance may not be optimal. The optimal number for RW and snapshot containers combined is 10 times the value of this parameter.

config load

Displays information about the cluster configuration.

Syntax**CLI**

```
maprcli config load
  [ -cluster <cluster> ]
  [ -keys <keys> ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/config/load?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster for which to display values. |
| keys | This parameter is used to specify which information to display. Comma-separated fields are used to display values; see the Configuration Fields table. |

Output

Information about the cluster configuration. See the [Configuration Fields](#) table.

Sample Output

```
{
  "status": "OK",
  "total": 1,
  "data": [
    {
      "mapr.webui.http.port": "8080",
      "mapr.fs.permissions.superuser": "root",
      "mapr.smtp.port": "25",
      "mapr.fs.permissions.supergroup": "supergroup"
    }
  ]
}
```

Examples

Display several keys:

CLI

```
/opt/mapr/bin/maprcli config
load -keys
mapr.webui.http.port,mapr.webui.https.
port,mapr.webui.https.keystorepath,ma
pr.webui.https.keystorepassword,mapr.we
bui.https.keypassword,mapr.webui.timeo
ut
```

REST

```
https://abc.sj.us:8443/rest/config/
load?

timeout
```

View the security policy limit:

CLI

```
/opt/mapr/bin/maprcli config
load -keys cldb.max.security.policies
```

REST

```
https://abc.sj.us:8443/rest/config/
load?keys=cldb.max.security.policies
```

View the master security policy cluster:**CLI**

```
/opt/mapr/bin/maprcli config
load -keys cldb.pbs.global.master
```

REST

```
https://abc.sj.us:8443/rest/config/
load?keys=cldb.pbs.global.master
```

View the number of containers to be assigned for a CG assign request:**CLI**

```
/opt/mapr/bin/maprcli
config load -keys
cldb.num.active.cg.containers
```

REST

```
https://abc.sj.us:8443/
rest/config/load?
keys=cldb.num.active.cg.containers
```

config save

Saves configuration information, specified as key/value pairs. Permissions required: `fc` or `a`.

See the [Configuration Fields](#) table.

Warning: Changing cluster configuration may have an impact on the way the cluster functions. Make sure you understand the change well or else make the change under the guidance of data-fabric support.

Syntax**CLI**

```
maprcli config save
[ -cluster cluster name ]
-test test only. default: 0
-values JSON Object to
comprise all config properties to save
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/config/save?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |
| values | A JSON object containing configuration fields; see the Configuration Fields table. |

| Parameter | Description |
|-----------|--|
| test | Set this to 1 to test SMTP configuration without actually saving the values. The system sends a test email to check if the configuration is correct. This parameter is applicable only for SMTP configuration. |

Examples

Configure data-fabric SMTP settings:

CLI

```
/opt/mapr/bin/maprcli config
save -values
'{"mapr.smtp.provider":"gmail","mapr.smtp.server":"smtp.gmail.com","mapr.smtp.sslrequired":"true","mapr.smtp.port":"465","mapr.smtp.sender.fullname":"AbCd","mapr.smtp.sender.email":"xxx@gmail.com","mapr.smtp.sender.username":"xxx@gmail.com","mapr.smtp.sender.password":"abc"}'
```

REST

```
https://abc.sj.us:8443/rest/config/save?
values={"mapr.smtp.provider":"gmail","mapr.smtp.server":"smtp.gmail.com","mapr.smtp.sslrequired":"true","mapr.smtp.port":"465","mapr.smtp.sender.fullname":"AbCd","mapr.smtp.sender.email":"xxx@gmail.com","mapr.smtp.sender.username":"xxx@gmail.com","mapr.smtp.sender.password":"abc"}
```

Define maximum number of configured security policies:

CLI

```
/opt/mapr/bin/maprcli config
save -values
'{"cldb.max.security.policies":"2048"}'
```

REST

```
https://abc.sj.us:8443/rest/config/save?
values={"cldb.max.security.policies":"2048"}
```

Set the master security policy cluster:

CLI

```
/opt/mapr/bin/maprcli
config save -values
'{"cldb.pbs.global.master":"1"}'
```

REST

```
https://abc.sj.us:8443/
rest/config/save?
values={"cldb.pbs.global.master":"1"}
```

Set the number of volumes to balance at a time:**CLI**

```
maprcli config save -values
'{"cldb.tier.gw.balance.num.vols.per.batch":"500"}'
```

REST

```
https://abc.sj.us:8443/rest/config/
save?
values={"cldb.tier.gw.balance.num.vols
.per.batch":"500"}
```

Note: The maximum number of volumes that can be balanced at a time is 1000.

Related concepts

[config](#) on page 1760

Lists configuration values for the data-fabric cluster.

dashboard info

Displays a summary of information about the cluster.

Syntax**CLI**

```
/opt/mapr/bin/maprcli dashboard info
[ -cluster <cluster name> ]
[ -multi_cluster_info true|false ]
[ -version true|false ]
[ -zkconnect <ZooKeeper connect
string> ]
-json
```

Note: The `-json` option is required.

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/dashboard/info[?<parameters>] |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. By default, the cluster is the local cluster. |

| Parameter | Description |
|--------------------|--|
| multi_cluster_info | Specifies whether to display cluster information from multiple clusters. Values: true or false. Default: false. |
| version | Specifies whether to display the version. Values: true or false. Default: false. |
| zkconnect | Common Parameters on page 1702 |
| json | Formats the output. |

Output

A summary of information about the services, volumes, MapReduce applications, health, and utilization of the cluster.

Output Fields

| Field | Description |
|-----------|--|
| timestamp | The time at which the <code>dashboard info</code> data was retrieved, expressed as a Unix epoch time. |
| timeofday | The local time and date of the query. |
| status | The success status of the <code>dashboard info</code> command. |
| total | The number of clusters for which data was queried in the <code>dashboard info</code> command. |
| version | The data-fabric software version running on the cluster. |
| cluster | Determines the following information about the cluster: <ul style="list-style-type: none"> <code>name</code> — the cluster name <code>secure</code> — whether the cluster is secure or not. Value: true (if enabled) or false (if disabled) <code>dare</code> — whether the cluster is enabled for data at rest encryption or not. Value: true (if enabled) or false (if disabled) <code>globalPolicyMaster</code> — whether the cluster is the master cluster for Policy Based Security. Yes if true, and no if false. You can create security policies only from the master cluster. <code>ip</code> — the IP address of the active CLDB <code>id</code> — the cluster ID <code>nodesUsed</code> — number of nodes in the cluster <code>totalNodesAllowed</code> — number of allowed nodes |

| Field | Description |
|---------|--|
| volumes | The number and size (in GB) of volumes that are: <ul style="list-style-type: none"><li data-bbox="818 268 954 296">• Mounted<li data-bbox="818 321 987 348">• Unmounted |

| Field | Description |
|-------------|--|
| utilization | <p>The following utilization information:</p> <ul style="list-style-type: none"> • CPU — utilization, total and active. CPU utilization % is calculated as (100% - idle%) on each node and then averaged across all nodes where hoststats is running. • Memory — total and active in MB. • Disk space — total and active in GB. • Compression — compressed and uncompressed data size • Tiering — following cluster level tiering information: <ul style="list-style-type: none"> • <code>logicalUsed</code> — The total gigabytes of disk space used (before compression) for the tiered volumes in the cluster. This value does not include erasure-coded backend volumes and cache-volumes. • <code>replicatedLogicalUsed</code> — The logical size in gigabytes, of disk used by the tiered volumes and all associated replicas. This value is calculated as follows: <i>disk space (before compression) used by volume * number of replicas</i>. This value does not include erasure-coded backend volumes and cache-volumes. • <code>replicatedTotalUsed</code> — The total space after compression (in GB) used by tiered volumes and associated snapshots and replicas. This value is calculated as follows: <i>total space used by volume * number of replicas</i>. This value does not include EC-backend volumes and cache-volumes since their <code>replicatedTotalUsed</code> is already accounted for by the front-end and parent volumes respectively. • <code>metaDBUsedMB</code> — The disk space (in MB) used by the metadata volume associated with the tier. • <code>replicatedMetaDBUsedMB</code> — The disk space (in MB) used by the replicas of the metadata volume associated with the tier. • <code>offloaded</code> — The total physical data (in GB) offloaded to the cold tier. This value is calculated as follows: <i>amount of data purged from the hot tier (data-fabric cluster) + amount of data recalled to the hot tier (data-fabric cluster)</i>. • <code>recalled</code> — The total physical data (in GB) recalled from the cold tier. This value is calculated as follows: <i>amount of data recalled to the hot tier (data-fabric cluster) + total amount of disk space used by the cache-volume</i>. • <code>cvTotalUsed</code> — The total disk space (in GB) used by all the cache-volumes. At the volume level, for mirror volumes, this is the total size of the cache volume and its replicas. • <code>replicatedCvTotalUsed</code> — The total disk space (in GB) used by all the cache-volumes and |

| Field | Description |
|--------------------|---|
| clusterReplication | The following cluster replication information: <ul style="list-style-type: none"> bytesReceived bytesSend |
| streamThroughput | The following stream throughput information: <ul style="list-style-type: none"> bytesProduced bytesConsumed |
| label_stats | Information about the labels registered and assigned. |
| services | The number of active, stopped, failed, and total installed services on the cluster, for example: <ul style="list-style-type: none"> API server CLDB Fileserver File Migrate ResourceManager NodeManager NFSv4 hoststats MAST Gateway |
| yarn | The following mapreduce information: <ul style="list-style-type: none"> Running applications Queued applications Number of NodeManagers Total memory Total VCores Total disks Used memory Used VCores Used disks |

Examples

Display dashboard information:

```

View the master security policy cluster:

CLI

```

/opt/mapr/bin/maprcli dashboard
info -json | grep globalPolicyMaster
{
  "globalPolicyMaster":true
}

```

dialhome

The `dialhome` commands are used to change the Dial Home status of the cluster:

dialhome ackdial

Acknowledges the most recent Dial Home on the cluster. Permissions required: `login`

Syntax**CLI**

```
maprcli dialhome ackdial
  [ -forDay <date> ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | <code>http[s]://<host>:<port>/rest/dialhome/ackdial[?<parameters>]</code> |

Parameters

| Parameter | Description |
|---------------------|--|
| <code>forDay</code> | Date for which the recorded metrics were successfully dialed home. Accepted values: UTC timestamp or a UTC date in MM/DD/YY format. Default: yesterday |

Sample Output

```
# maprcli dialhome ackdial -forDate 5/26/15
dialhome ackdial
  -forDay Date for which the recorded metrics were successfully dialed
home. Accepted values: UTC timestamp in millisecond or a UTC date in
MM/DD/YY format. default: 5/31/15
```

Examples**Acknowledge Dial Home:****CLI**

```
maprcli dialhome ackdial
```

REST

```
https://abc.sj.us:8443/rest/dialhome/ackdial
```

dialhome enable

Enables Dial Home on the cluster. Permissions required: `fc` or `a`

Syntax**CLI**

```
maprcli dialhome enable
  -enable 0|1
```

REST

| | |
|--------------|------|
| Request Type | POST |
|--------------|------|

| | |
|-------------|--|
| Request URL | http[s]://<host>:<port>/rest/dialhome/enable |
|-------------|--|

Parameters

| Parameter | Description |
|-----------|---|
| enable | Specifies whether to enable or disable Dial Home: <ul style="list-style-type: none"> • 0 - Disable • 1 - Enable |

Output

A success or failure message.

Sample output

```
# maprcli dialhome enable -enable 1
enabled
1

# maprcli dialhome status
enabled
1
```

Examples

Enable Dial Home:

CLI

```
maprcli dialhome enable -enable 1
```

REST

```
https://abc.sj.us:8443/rest/dialhome/enable?enable=1
```

dialhome lastdialed

Displays the date of the last successful Dial Home call. Permissions required: fc or a.

Syntax

CLI

```
maprcli dialhome lastdialed
```

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/dialhome/lastdialed |

Output

The date of the last successful Dial Home call.

Sample output

```
$ maprcli dialhome lastdialed
date
1322438400000
```

Examples

Show the date of the most recent Dial Home:

CLI

```
maprcli dialhome lastdialed
```

REST

```
https://abc.sj.us:8443/rest/dialhome/lastdialed
```

dialhome metrics

Returns a compressed metrics object. Permissions required: login.

Syntax

CLI

```
maprcli dialhome metrics [ -forDay <date> ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/dialhome/metrics |

Parameters

| Parameter | Description |
|-----------|--|
| forDay | Date for which the recorded metrics were successfully dialed home. Accepted values: UTC timestamp or a UTC date in MM/DD/YY format. Default: yesterday |

Output

Sample output

```
$ maprcli dialhome metrics
metrics
[B@48067064
```

Examples

Show the Dial Home metrics:

CLI

```
maprcli dialhome metrics
```

REST

```
https://abc.sj.us:8443/rest/dialhome/metrics
```

dialhome status

Displays the Dial Home status. Permissions required: login.

Syntax

CLI

```
maprcli dialhome status
```

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/dialhome/status |

Output

The current Dial Home status.

Sample output

```
$ maprcli dialhome status
enabled
1
```

Examples

Display the Dial Home status:

CLI

```
maprcli dialhome status
```

REST

```
https://abc.sj.us:8443/rest/dialhome/status
```

disk

Lists disk parameters.

Disk Fields

The following table shows the fields displayed in the output of the disk list and disk listall commands. You can choose which fields (columns) to display and sort in ascending or descending order by any single field.

| | |
|-----------------------|--|
| availablespace | Terse Name: dsa Description: Disk space available, in MB. |
| diskname | Terse Name: n Description: Name of the disk or partition |

| | |
|------------------------|---|
| error | <p>Terse Name: err</p> <p>Description: Disk error message, in English. Only sent if status is 1.</p> <p> Note: This message is not translated.</p> |
| failuretime | <p>Terse Name: ft</p> <p>Description: Disk failure time, This field is applicable only for MapR disks. Only sent if status is 1.</p> |
| firmwareversion | <p>Terse Name: fw</p> <p>Description: Firmware version</p> |
| fstype | <p>Terse Name: fs</p> <p>Description: File system type</p> |
| hostname | <p>Terse Name: hn</p> <p>Description: Hostname of the node that owns this disk/partition</p> |
| labelname | <p>Terse Name: ln</p> <p>Description: The label assigned to the disk. See Using Storage Labels on page 1068 for more information on labels.</p> |
| modelnum | <p>Terse Name: mn</p> <p>Description: The model number of the disk</p> |
| mount | <p>Terse Name: mt</p> <p>Description: Disk mount status</p> <ul style="list-style-type: none"> • 0 = unmounted • 1 = mounted |
| powerstatus | <p>Terse Name: pst</p> <p>Description: Disk power status:</p> <ul style="list-style-type: none"> • 0 = Active/idle (normal operation) • 1 = Standby (low power mode) • 2 = Sleeping (lowest power mode, drive is completely shut down) |
| status | <p>Terse Name: st</p> <p>Description: Disk status:</p> <ul style="list-style-type: none"> • 0 = Good • 1 = Bad disk • 2 = Offline disk |
| storagepoolid | <p>Terse Name: sp</p> <p>Description: The ID of the storage pool that comprises the disk</p> |

Returns information about volumes and the associated containers. For JSON formatted output, use the `-json` option from the command line.

[configure.sh](#) on page 2331

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

disk add

Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

Syntax**CLI**

```
maprcli disk add
  -disks <disk names>
  -host <host>
  [ -cluster <cluster> ]
  [ -label <class of the disks>]
  [ -stripeWidth <stripe-width> ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | <code>http[s]://<host>:<port>/rest/disk/add?<parameters></code> |

Parameters

Parameter: cluster

Default Value: No default value

Possible Values: Any valid cluster.

Description: The cluster on which to add disks. If not specified, the default is the current cluster.

Parameter: disks

Default Value: No default value

Possible Values: Any valid disk names

Description: A comma-separated list of disk names.
Examples:

- /dev/sdc
- /dev/sdd,/dev/sde,/dev/sdf

Parameter: host

Default Value: No default value

Possible Values: Any valid host or IP

Description: The hostname or IP address of the machine on which to add the disk.

Parameter: label

Default Value: HDD

Possible Values: Any label

Description: The label to use for the storage pool.
See [Using Storage Labels](#) on page 1068 for more information on labels.

The label should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

Parameter: stripeWidth

Default Value: No default value

Possible Values: Any integer

Description: The number of disks per storage pool.

Output

Output Fields

| Field | Description |
|-------|--|
| ip | The IP address of the machine that owns the disk(s). |
| disk | The name of a disk or partition. Example sca or sca/sca1 |
| all | The string all , meaning all unmounted disks for this node. |

Examples

Add a disk:

CLI

```
maprcli disk add -disks /dev/
sda1 -host 10.250.1.79
```

REST

```
https://abc.sj.us:8443/rest/disk/add?
disks=["/dev/sda1"]&host="10.250.1.79"
```

disk setlabel

Adds a label to disks or a storage pool. Permissions required: `fc` or `a`.

Syntax**CLI**

```
maprcli disk setlabel
  -host name/ip
  -disks comma-separated list of
  disks
  -label label-name
  [ -force Need this parameter to
  reassign label to sp, otherwise
  reassignment of label
  will not happen on sp.
  Parameter takes no value]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/disk/setlabel?<parameters> |

Parameters

Parameter: host*Default Value:* No default value

Possible Values: Any valid host or IP

Description: The hostname or IP address of the machine on which to add the disk.

Parameter: disks*Default Value:* No default value

Possible Values: Any valid disk names

Description: A comma-separated list of disk names.
Examples:

- /dev/sdc
- /dev/sdd,/dev/sde,/dev/sdf

Parameter: label*Default Value:* HDD

Possible Values: Any label

Description: The label to use for the storage pool.
See [Using Storage Labels](#) on page 1068 for more information on labels.

The label should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

Parameter: force*Default Value:* Not Applicable

Possible Values: Not Applicable

Description: Forces reassignment of the label to a storage pool.

Output

```
# maprcli disk setlabel -host atsq4-161.qa.lab -disks /dev/sdd -label
label1 -json
{
  "timestamp":1590420155635,
  "timeofday":"2020-05-25 08:22:35.635 GMT-0700 AM",
  "status":"OK",
  "total":0,
  "data":[          ]
}
```

Examples

Set label label1 on disk /dev/sdd:

CLI

```
# maprcli disk setlabel -host
atsq4-161.qa.lab -disks /dev/sdd -lab
el label1 -json
{
  "timestamp":1590420155635,
  "timeofday":"2020-05-25
08:22:35.635 GMT-0700 AM",
  "status":"OK",
  "total":0,
```

```
    "data": [
  ]
}
```

disk list

Lists the disks on a node.

Syntax**CLI**

```
maprcli disk list
  -host name/ip
  [ -system 1/0 ]
  [ -output <terse|verbose>. default:
  verbose ]
  [ -startdisk index of the first node
  (starting from 0). default: 0 ]
  [ -limitdisk number of nodes to
  query. default: 2147483647 ]
  [ -sortby <hostname|diskname|
  mount|vendor|modelnum|serialnum|
  firmwareversion|totalspace|usedspace|
  availablespace|
  fstype|powerstatus|status|errormsg|
  storagepoolid|failuretime> ]
  [ -sortorder <asc|desc> ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/ rest/disk/list? <parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| host | The node on which to list the disks. |
| output | Whether the output should be <code>terse</code> or <code>verbose</code> . Default is <code>verbose</code> . |
| sortby | Specifies one of the following attributes to sort the list of disks by: <code>hostname</code> , <code>diskname</code> , <code>mount</code> , <code>vendor</code> , <code>modelnum</code> , <code>serialnum</code> , <code>firmwareversion</code> , <code>totalspace</code> , <code>usedspace</code> , <code>availablespace</code> , <code>fstype</code> , <code>powerstatus</code> , <code>status</code> , <code>errormsg</code> , <code>storagepoolid</code> , <code>failuretime</code> |
| sortorder | The order to sort the results by. Value can be: <ul style="list-style-type: none"> • <code>asc</code> - for ascending order • <code>desc</code> - for descending order |
| startdisk | The disk from which to start listing. |
| limitdisk | The number of disks to list starting from the <code>startdisk</code> parameter. |

| Parameter | Description |
|-----------|--|
| system | Show only operating system disks: <ul style="list-style-type: none"> • 0 - shows only filesystem disks • 1 - shows only operating system disks • Not specified - shows both filesystem and operating system disks |

Output

Information about the specified disks. See the [Disk Fields](#) table.

Sample Output

```
# maprcli disk list -host 10.10.82.23 -output terse
mn          pst          sp  fw  mt  fs          dsu  n          st  dsa

disk listall

Lists all disks.

Syntax

CLI

```
maprcli disk listall
[ -cluster <cluster> ]
[ -limit <limit> ]
[ -output terse|verbose ]
[ -start <offset> ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | <code>http[s]://<host>:<port>/rest/disk/listall[?<parameters>]</code> |

Parameters

| Parameter | Description |
|----------------------|--|
| <code>cluster</code> | The cluster on which to run the command. |
| <code>limit</code> | The number of rows to return, beginning at start. Default: 0 |

| Parameter | Description |
|-----------|---|
| output | Always the string <code>terse</code> . |
| start | The offset from the starting row according to sort. Default: 0 |

Output

Information about all disks. See the [Disk Fields](#) table.

Sample Output

```
# maprcli disk listall -output terse

```

Examples

List all disks:

CLI

```
maprcli disk listall
```

REST

```
https://abc.sj.us:8443/rest/disk/
listall
```

disk remove

Removes a disk from filesystem. Permissions required: `fc` or `a`.

The `disk remove` command does not remove a disk containing unreplicated data, unless forced. To force disk removal, specify `-force` with the value `1` or `true`.

Note:

- Use the `-force 1`, or the equivalent `-force true` option only if you are sure that you do not need the data on the disk. This option removes the disk without regard to the replication factor or other data protection mechanisms, and may result in permanent data loss.
- Removing a disk in the storage pool that contains Container ID 1 stops the cluster. Container ID 1 contains CLDB data for the master CLDB. Run `disk remove` without the `-force 1`, or the equivalent `-force true` option first, and examine the warning messages to make sure that you are not removing the disk with Container ID 1. If you try to remove a disk associated with the storage pool that contains Container ID 1, you receive an error message similar to the following:

```
ERROR (151) - Failed operation for disk /dev/sdb, Operation may
bring
down cluster due to loss of cluster meta-data.
```

Tip: If necessary, run the following command for information on the disk associated with the storage pool that contains Container ID 1:

```
/opt/mapr/server/mrconfig info dumpcontainers | grep cid:1
```

The command output may look similar to the following:

```
cid:1 valid:1 sp:SP1:/dev/sdb
spid:82380c287085486f0058112ecf016b76
prev:0 next:0 issnap:0 isclone:0 deleteinprog:0 fixedbyfsck:0
stale:0
querycldb:0 resyncinprog:0 shared:0 owned:206 logical:206
snapusage:0
snapusageupdated:1 ismirror:0 isrwmirrorcapable:0 role:1
maxUniq:2100150
isResyncSnapshot:0 snapId:0 port:5660
```

To safely remove such a disk, first perform a [CLDB Failover](#) to make one of the other CLDB nodes the primary CLDB, and then remove the disk as normal.

Syntax

CLI

```
/opt/mapr/bin/maprcli disk remove
-host name/ip
-disks comma-separated list of
disks
[ -force <true|false OR 1|0>.
Required to remove the disk when
errors have been reported; otherwise,
the command behaves like a test
remove when errors are reported.
If -force is set to false and there
are no errors, the disk is removed.
Default: false ]
[ -cluster cluster_name ]
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | <code>http[s]://<host>:<port>/rest/disk/remove?<parameters></code> |

Parameters

| Parameter | Description |
|----------------------|--|
| <code>host</code> | The hostname or ip address of the node from which to remove the disk. |
| <code>disks</code> | A list of disks in the form: <code>["disk"]or["disk", "disk", "disk"...]or[]</code> |
| <code>force</code> | Whether to force disk removal. <ul style="list-style-type: none"> • 0 or <code>false</code> (default) - do not remove the disk or disks if there is unreplicated data on the disk • 1 or <code>true</code> - remove the disk or disks regardless of data loss, or other consequences |
| <code>cluster</code> | The cluster on which to run the command. |

Output**Output Fields**

| Field | Description |
|--------------------|---|
| <code>disk</code> | The name of a disk or partition. Example: <code>sca</code> or <code>sca/sca1</code> |
| <code>all</code> | The string <code>all</code> , meaning all unmounted disks attached to the node. |
| <code>disks</code> | A comma-separated list of disks which have non-replicated volumes. For example, <code>"sca"</code> or <code>"sca/sca1,scb"</code> |

Examples**Remove a disk:****CLI**

```
/opt/mapr/bin/maprcli disk
remove -disks /dev/sda
```

REST

```
https://abc.sj.us:8443/rest/disk/
remove?disks=/dev/sda
```

dump

Returns key information about volumes, containers, storage pools, and MapR cluster services for debugging and troubleshooting.

dump balancerinfo

Returns detailed information about the storage pools on a cluster. If there are any active container moves, the command returns information about the source and destination storage pools.

The `maprcli dump balancerinfo` command enables you to see how much space is used in storage pools and to track active container moves. For best results, use the `-json` option when running `dump balancerinfo` from the command line.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between storage pools. Whenever a storage pool is over 70% full (or a threshold defined by the `cldb.balancer.disk.threshold.percentage` parameter), the disk space balancer distributes containers to other storage pools that have lower utilization than the average for that cluster. The disk space balancer aims to ensure that the percentage of space used on all the disks in the node is similar. For more information, see [Disk Space Balancer](#).

Syntax**CLI**

```
maprcli dump balancerinfo
[-cluster <cluster name>]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |

Output

The `maprcli dump balancerinfo` command returns detailed information about the storage pools on a cluster. If there are any active container moves, the command returns information about the source and destination storage pools.

```
# maprcli dump balancerinfo -cluster my.cluster.com -json
{
  "timestamp":1337036566035,
  "status":"OK",
  "total":187,
  "data":[
    {
      "spid":"4bc329ce06752062004fala537abcdef",
      "fsid":5410063549464613987,
      "ip:port":"10.50.60.72:5660-",
      "capacityMB":1585096,
      "usedMB":1118099,
      "percentage":70,
      "fullnessLevel":"AboveAverage",
      "inTransitMB":0,
      "outTransitMB":31874
    }
  ],
}
```

```

{
    "spid": "761feclfabf32104004fad9630ghijkl",
    "fsid": 3770844641152008527,
    "ip:port": "10.50.60.73:5660-",
    "capacityMB": 1830364,
    "usedMB": 793679,
    "percentage": 47,
    "fullnessLevel": "BelowAverage",
    "inTransitMB": 79096,
    "outTransitMB": 0
},
....
{
    "containerid": 4034,
    "sizeMB": 16046,
    "From fsid": 5410063549464613987,
    "From IP:Port": "10.50.60.72:5660-",
    "From SP": "4bc329ce06752062004fala537abcefg",
    "To fsid": 3770844641152008527,
    "To IP:Port": "10.50.60.73:5660-",
    "To SP": "761feclfabf32104004fad9630ghijkl"
},

```

Output fields

| Field | Description |
|---------------|--|
| spid | The unique ID number of the storage pool. |
| fsid | The unique ID number of the file server. The FSID identifies an filesystem instance or a node that has filesystem running in the cluster. Typically, each node has a group of storage pools, so the same FSID will correspond to multiple SPIDs. |
| ip:port | The host IP address and filesystem port. |
| capacityMB | The total capacity of the storage pool (in MB). |
| usedMB | The amount of space used on the storage pool (in MB). |
| percentage | The percentage of the storage pool currently utilized. A ratio of the space used (<i>usedMB</i>) to the total capacity (<i>capacityMB</i>) of the storage pool. |
| fullnessLevel | The fullness of the storage pool relative to the fullness of the rest of the cluster. Possible values are <i>OverUsed</i> , <i>AboveAverage</i> , <i>Average</i> , <i>BelowAverage</i> , and <i>UnderUsed</i> . For more information, see Monitoring storage pool space usage below. |
| inTransitMB | The amount of data (in MB) that the disk space balancer is currently moving into a storage pool. |
| outTransitMB | The amount of data (in MB) that the disk space balancer is currently moving out of a storage pool. |

The following fields are returned only if the disk space balancer is actively moving one or more containers at the time the command is run.

| Field | Description |
|--------------|--|
| containerid | The unique ID number of the container. |
| sizeMB | The amount of data (in MB) being moved. |
| From fsid | The FSID (file server ID number) of the source file server. |
| From IP:Port | The IP address and port number of the source node. |
| From SP | The SPID (storage pool ID) of the source storage pool. |
| To fsid | The FSID (file server ID number) of the destination file server. |
| To IP:Port | The IP address and port number of the destination node. |
| To SP | The SPID (storage pool ID number) of the destination storage pool. |

Examples

Monitoring storage pool space usage

You can use the `maprcli dump balancerinfo` command to monitor space usage on storage pools.

```
# maprcli dump balancerinfo -json

....
{
    "spid": "4bc329ce06752062004fala537abcefg",
    "fsid": "5410063549464613987",
    "ip:port": "10.50.60.72:5660-",
    "capacityMB": 1585096,
    "usedMB": 1118099,
    "percentage": 70,
    "fullnessLevel": "AboveAverage",
    "inTransitMB": 0,
    "outTransitMB": 31874
},
```

Tracking active container moves

Using the `maprcli dump balancerinfo` command you can monitor the activity of the disk space balancer. Whenever there are active container moves, the command returns information about the source and destination storage pools.

```
# maprcli dump balancerinfo -json

....
{
    "containerid": 7840,
    "sizeMB": 15634,
    "From fsid": 8081858704500413174,
    "From IP:Port": "10.50.60.64:5660-",
    "From SP": "9e649bf0ac6fb9f7004fal9d20rstuvw",
    "To fsid": 3770844641152008527,
    "To IP:Port": "10.50.60.73:5660-",
```

```
    "To SP" : "fefcc342475f0286004fad963flmnopq"
  }
```

The example shows that a container (7840) is being moved from a storage pool on node 10.50.60.64 to a storage pool on node 10.50.60.73.

Tip: You can use the storage pool IDs (SPIDs) to search the CLDB and filesystem logs for activity (balancer moves, container moves, creates, deletes, etc.) related to specific storage pools.

dump balancermetrics

Returns a cumulative count of container moves and MB of data moved between storage pools.

The `maprcli dump balancermetrics` command returns a cumulative count of container moves and MB of data moved between storage pools. You can run this command periodically to determine how much data has been moved by the disk space balancer between two intervals. For best results, use the `-json` option when running `dump balancermetrics` from the command line.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between storage pools. Whenever a storage pool is over 70% full (or it reaches a threshold defined by the `cldb.balancer.disk.threshold.percentage` parameter), the disk space balancer distributes containers to other storage pools that have lower utilization than the average for that cluster. The disk space balancer aims to ensure that the percentage of space used on all the disks in the node is similar. For more information, see [Disk Space Balancer](#).

Syntax

CLI

```
maprcli dump balancermetrics
[-cluster <cluster name>]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |

Output

The `maprcli dump balancermetrics` command returns a cumulative count of container moves and MB of data moved between storage pools since the current CLDB became the master CLDB.

```
# maprcli dump balancermetrics -json
{
  "timestamp":1337770325979,
  "status":"OK",
  "total":1,
  "data":[
    {
      "numContainersMoved":10090,
      "numMBMoved":3147147,
      "timeOfLastMove": "Wed May 23 03:51:44 PDT 2012"
    }
  ]
}
```

```
]
}
```

Output fields

| Field | Description |
|--------------------|--|
| numContainersMoved | The number of containers moved between storage pools by the disk space balancer. |
| numMBMoved | The total MB of data moved between storage pools on the cluster. |
| timeOfLastMove | The date and time of most recent container move. |

Example**CLI**

```
maprcli dump balancermetrics -cluster
10.10.82.23 -json
```

dump cldbnodes

Lists the nodes that contain *container location database* (CLDB) data.

The CLDB is a service running on one or more MapR nodes that maintains the location of cluster containers, services, and other information. The CLDB automatically replicates its data to other nodes in the cluster, preserving at least two (and generally three) copies of the CLDB data. If the CLDB process dies, it is automatically restarted on the node.

Syntax**CLI**

```
maprcli dump cldbnodes
[-cluster <cluster name>]
-zkconnect <ZooKeeper Connect
String>
-json | -long
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| zkconnect | A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: '<host>[:<port>][,<host>[:<port>]...]'. To obtain zookeeper connection strings, use the <code>maprcli node listzookeepers</code> command. |

| Parameter | Description |
|-------------|---|
| json long | This command returns multiple levels of data. You need to specify either JSON format or "long" format to see the full output. |

Output

The `maprcli dump cldbnodes` command returns the IP address and port number of the CLDB nodes on the cluster.

```
$ maprcli dump cldbnodes -zkconnect centos23.lab:5181 -json
{
  "timestamp":1433270634424,
  "timeofday":"2015-06-02 06:43:54.424 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "valid":[
        "10.10.82.23:5660-",
        "10.10.82.28:5660-",
        "10.10.82.29:5660-",
        "10.10.82.22:5660-"
      ]
    }
  ]
}
```

Example

CLI

```
maprcli dump cldbnodes -zkconnect
centos23.lab:5181 -json
```

dump containerinfo

Returns detailed information about one or more specified containers.

A *container* is a unit of sharded storage in a data-fabric cluster. Every container in a data-fabric volume is either a *name container* or a *data container*.

Tip: For an explanation of sharding, see the [Configuring the Chunk Size](#) topic.

The name container is the first container in a volume and holds that volume's namespace and file chunk locations. Depending on its replication role, a name container may be either a *master container* (part of the original copy of the volume) or a *replica container* (one of the replicas in the replication chain).

Every data container is either a *master container*, an *intermediate container*, or a *tail container*.

Syntax

CLI

```
maprcli dump containerinfo
  [-cluster <cluster name>]
  -ids <id1,id2,id3 ...>
  [-ctime <true|false>]
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| ids | Specifies one or more container IDs. Container IDs are comma separated. The <code>maprcli dump containers</code> command provides the container ID required for <code>-ids</code> parameter. |
| ctime | Set to <code>true</code> to display container state/role change time. Default: <code>false</code> |

Output

The `maprcli dump containerinfo` command returns information about one or more containers.

```
# maprcli dump containerinfo -ids 1 -ctime true -json
{
  "timestamp":1507024362685,
  "timeofday":"2017-10-03 02:52:42.685 GMT-0700 AM",

        "CreatorContainerId": 0,
        "CreatorVolumeUuid": "",
        "UseActualCreatorId": false,
        "VolumeName": "mapr.cldb.internal",
        "VolumeId": 1,
        "VolumeReplication": 3,
        "NameSpaceReplication": 3,
        "VolumeMounted": false,
        "AccessTime": "September 29, 2017"
    }
}

```

Output fields

| Field | Description |
|-----------------|--|
| ContainerID | The unique ID number for the container. |
| Epoch | A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container. |
| Master | The physical IP address and port number of the <i>master copy</i> . The master copy is part of the original copy of the volume. |
| ActiveServers | The physical IP address and port number of each active node on which the container resides. |
| InactiveServers | The physical IP address and port number of each inactive node on which the container resides. |
| UnusedServers | The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time. |
| OwnedSizeMB | The size on disk (in MB) dedicated to the container. |
| SharedSizeMB | The size on disk (in MB) shared by the container. |
| LogicalSizeMB | The logical size on disk (in MB) of the container. |
| TotalSizeMB | The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size. |
| Mtime | The time of the last modification to the contents of the container. |
| NameContainer | Indicates if the container is the <i>name container</i> for the volume. If <i>true</i> , the container holds the volume's namespace information and file chunk locations. |
| VolumeName | The name of the volume. |
| VolumeId | The unique ID number of the volume. |

| Field | Description |
|-------------------|---|
| VolumeReplication | The <i>replication factor</i> , the number of copies of a volume excluding the original. |
| VolumeMounted | Indicates whether the volume is mounted. If <code>true</code> , the volume is currently mounted. If <code>false</code> , the volume is not mounted. |

Example

CLI

```
maprcli dump containerinfo -ids 2049
-ctime true -json
```

dump cldbmetainfo

Prints metadata from the *container location database* (CLDB) tables.

Syntax

CLI

```
maprcli dump cldbmetainfo
-json
```

Note: For formatted results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|--------------------------|
| json | Returns formatted output |

Output

The `maprcli dump cldbmetainfo` command lists meta information from the CLDB tables, For an explanation of the output fields, see [fid stat](#) on page 1851.

```
$ maprcli dump cldbmetainfo -json
{
  "timestamp":1433270634424,
  "timeofday":"2020-06-02 06:43:54.424 GMT+0000",

        "nlevels": 0
    }
]
}

```

Example**CLI**

```
maprcli dump cldbmetainfo -json
```

dump cldbstatePrints the state of the *container location database* (CLDB).**Syntax****CLI**

```
maprcli dump cldbstate
[ -cluster cluster_name ]
[ -hostip host name or ip ]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| hostip | The node from which to retrieve the state of CLDB. If this parameter is omitted, the command returns the CLDB state from all nodes in the cluster. |

Output

The `maprcli dump cldbstate` command lists the state of the CLDB database.

```
$ maprcli dump cldbstate
mode           ip           state           stateDuration  desc
SLAVE_READ_ONLY x.x.x.x CLDB_IS_SLAVE_READ_ONLY 03:54:25      cldb
running as slave
SLAVE_READ_ONLY x.x.x.x CLDB_IS_SLAVE_READ_ONLY 03:54:16      cldb
running as slave
MASTER_READ_WRITE x.x.x.x CLDB_IS_MASTER_READ_WRITE 04:07:58      kvstore
tables loading complete,
                                                    cldb
running as master
```

Output Fields

| Field | Description |
|---------------|--|
| mode | The CLDB mode. A CLDB instance can either run as a Primary or a Secondary instance. The only two states that a CLDB instance should settle in are: <ul style="list-style-type: none"> SLAVE_READ_ONLY MASTER_READ_WRITE If a CLDB instance spends a significant amount of time in a state other than these two, then it is highly likely that there is an issue that requires administrative intervention. |
| ip | The IP address of the node from which the CLDB state is retrieved. |
| state | Indicates whether the CLDB instance is run as a Secondary with READ_ONLY privilege, or as a Primary with READ_WRITE privilege. |
| stateDuration | The amount of time in HH:MM:SS format that the CLDB instance has spent in this state. |
| desc | The description of the state (either Primary or Secondary). |

dump containers

Returns information about containers in a cluster.

This command provides information about containers based on the following `-type` criteria:

- offline - Returns information about containers that have no valid copies online. This command is useful when you need to find out exactly what data is offline (for example, when a "volume data unavailable" alarm is raised).
- resync - Returns information about containers that are resynchronizing.

- `bm` - Returns information about containers that are becoming master but are not yet master.
- `unused` - Returns information about containers that are unused.
- `waiting` - Returns information about containers that are waiting for a role.

A *container* is a unit of sharded storage in a HPE Ezmeral Data Fabric cluster. Every container in a HPE Ezmeral Data Fabric volume is either a *name container* or a *data container*. The name container is the first container in a volume and holds that volume's namespace and file chunk locations. Depending on its replication role, a name container may be either a *master container* (part of the original copy of the volume) or a *replica container* (one of the replicas in the replication chain).

Every data container is either a *master container*, an *intermediate container*, or a *tail container*.

Syntax

CLI

```
maprcli dump containers
[ -cluster <cluster_name> ]
  -type offline|resync|bm|waiting|
  unused
```

 **Note:** For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|----------------------|--|
| <code>cluster</code> | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| <code>type</code> | Specifies the type of information that is returned about the containers: <ul style="list-style-type: none"> • <code>offline</code> - Returns information about containers that have no valid copies online. • <code>resync</code> - Returns information about containers that are resynchronizing. • <code>bm</code> - Returns information about containers that are becoming master but are not yet master. • <code>unused</code> - Returns information about containers that are unused. • <code>waiting</code> - Returns information about containers that are waiting for a role. |

Output fields

| Field | Description |
|-------------|---|
| ContainerID | The unique ID number for the container. |

| Field | Description |
|-------------------|---|
| Epoch | A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container. |
| Master | The physical IP address and port number of the <i>primary copy</i> . The primary copy is part of the original copy of the volume. |
| ActiveServers | The physical IP address and port number of each active node on which the container resides. |
| InactiveServers | The physical IP address and port number of each inactive node on which the container resides. |
| UnusedServers | The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time. |
| OwnedSizeMB | The size on disk (in MB) dedicated to the container. |
| SharedSizeMB | The size on disk (in MB) shared by the container. |
| LogicalSizeMB | The logical size on disk (in MB) of the container. |
| TotalSizeMB | The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size. |
| Mtime | The time of the last modification to the contents of the container. |
| NameContainer | Indicates if the container is the <i>name container</i> for the volume. If <code>true</code> , the container holds the volume's namespace information and file chunk locations. |
| VolumeName | The name of the volume. |
| Volumeld | The unique ID number of the volume. |
| VolumeReplication | The <i>replication factor</i> , the number of copies of a volume excluding the original. |
| VolumeMounted | Indicates whether the volume is mounted. If <code>true</code> , the volume is currently mounted. If <code>false</code> , the volume is not mounted. |

Example

CLI

```
maprcli dump containers -type
offline -cluster my.cluster -json
```

Output Samples

The following `maprcli dump containers -type offline` command returns information about all offline containers.

```
# maprcli dump containers -type offline -json
{
  "timestamp":1348174731389,
  "status":"OK",
  "total":11,
  "data":[
    {
      "ContainerId":2060,
      "Epoch":3,
      "Master":"unknown ip (0)-0-VALID",
      "ActiveServers":{
      },
      "InactiveServers":{
      },
      "UnusedServers":{

"CreatorContainerId":0,
"CreatorVolumeUuid":""
}
]

```

dump ecginfo

Indicates whether rebuild is in progress for a container from CLDB.

Syntax**CLI**

```

maprcli dump ecginfo -h
dump ecginfo
    [ -cluster cluster_name ]
    -ids ids

```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| ids | The container gateway ID to use to retrieve rebuild information. |

Output fields

| Field | Description |
|-------------|---|
| ContainerID | The unique ID number for the container. |

| Field | Description |
|---------------------|---|
| Epoch | A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container. |
| Master | The physical IP address and port number of the <i>master copy</i> . The master copy is part of the original copy of the volume. |
| ActiveServers | The physical IP address and port number of each active node on which the container resides. |
| InactiveServers | The physical IP address and port number of each inactive node on which the container resides. |
| UnusedServers | The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time. |
| OwnedSizeMB | The size on disk (in MB) dedicated to the container. |
| SharedSizeMB | The size on disk (in MB) shared by the container. |
| LogicalSizeMB | The logical size on disk (in MB) of the container. |
| TotalSizeMB | The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size. |
| NumNodesInUse | The total number of nodes that this container occupies. |
| Mtime | The time of the last modification to the contents of the container. |
| NameContainer | Indicates if the container is the <i>name container</i> for the volume. If <code>true</code> , the container holds the volume's namespace information and file chunk locations. |
| ecCgid | The gateway ID of this container. |
| isRebuildInProgress | <code>true</code> indicates that the container is being rebuilt. |
| CreatorContainerId | TBD |
| CreatorVolumeUuid | TBD |
| UseActualCreatorId | TBD |

Example

CLI

```
maprcli dump ecginfo -ids <cgid> -json
```

Output Samples

The following command returns information about container gateway ID 2351 .

```
maprcli dump ecginfo -ids 2351 -json

"cid2":{
  "ContainerId":2353,
  "Epoch":5,
  "Master":"10.10.102.51:5660--5-VALID",
  "ActiveServers":{
    "IP":"10.10.102.51:5660--5-VALID"
  },
  "InactiveServers":{
  },
  "UnusedServers":{
    "IP":"10.10.102.49:5660--3"
  },
  "OwnedSizeMB":"381 MB",
  "SharedSizeMB":"0 MB",
  "LogicalSizeMB":"381 MB",
  "TotalSizeMB":"381 MB",
  "NumInodesInUse":229,
  "Mtime":"June 10, 2020",
  "NameContainer":"false",
  "ecCgId ":2351,
  "isRebuildInProgress ":true,
  "CreatorContainerId":0,
  "CreatorVolumeUuid":"","
  "UseActualCreatorId":true
},
```

Related reference

[mastgateway ecgstats](#) on page 2447

Returns the list of containers under rebuild from CGManager.

dump replicationmanagerinfo

Returns information about which containers are under or over replicated in a specified volume.

For each container, the command displays the current state of that container.

Syntax

CLI

```
maprcli dump replicationmanagerinfo
[-cluster <cluster name>]
-volumename <volume name>
[-ctime <true|false>]
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|------------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| volumename | Specifies the name of the volume. To obtain a volume name, use the <code>maprcli volume list</code> command. |
| ctime | Set to <code>true</code> to display container state/role change time. Default: <code>false</code> |

Output

The `maprcli dump replicationmanagerinfo` returns information about volumes and the containers on those volumes including the nodes on which the containers have been replicated and the space allocated to each container. If replication activity is not underway when the `maprcli` command is executed, no container information is included. If replication activity is underway, details of containers are listed.

```
# maprcli dump replicationmanagerinfo -volumename mapr.metrics -ctime true
-json
{
  "timestamp":1433449934381,
  "timeofday":"2015-06-04 08:32:14.381 GMT+0000",

      "SharedSizeMB":"0 MB",
```

```

        "LogicalSizeMB": "1 MB",
        "Mtime": "Mon Apr 30 16:40:41 PDT 2012",
        "NameContainer": "true"
    }
}

```

Output fields

| Field | Description |
|----------------------|--|
| VolumeName | Indicates the name of the volume. |
| Volumeld | Indicates the ID number of the volume. |
| VolumeTopology | The volume topology corresponds to the node topology of the rack or nodes where the volume resides. By default, new volumes are created with a topology of / (root directory). For more information, see Volume Topology . |
| VolumeUsedSizeMB | The size on disk (in MB) of the volume. |
| VolumeReplication | The desired replication factor, the number of copies of a volume excluding the original. The default value is 3. |
| VolumeMinReplication | The minimum replication factor, the number of copies of a volume (excluding the original) that should be maintained by the data-fabric cluster for normal operation. When the replication factor falls below this minimum, writes to the volume are disabled. The default value is 2. |
| MirrorThrottle | Specifies whether mirror throttling is enabled (true) or disabled (false). Throttling is set on the source volume and applies to all its mirrors. This property was introduced in version 4.0.2. |
| AccessTime | A value that can be used to determine which volumes are accessed regularly. This value is updated every 6 hours with the last time that an operation occurred on the volume. The access time is not updated for changes to volume properties, creation of a snapshot, or synchronization between a volume and a mirror. However, the volume access time is updated the first time you upgrade to a data-fabric version that includes this property. This property was introduced in version 4.0.2. |
| limitSpread | An internal flag for data-fabric volumes to control the growth of volume in terms of number of containers. When this flag is set, cldb tries to limit the number of new containers created depending on the present size of volume. If volume size (data in volume) is small, cldb tries to reuse space in existing containers to avoid the creation of new containers. This helps reduce the wasting of containers IDs in an environment that has small volumes. |
| ContainerId | The unique ID number for the container. |
| Epoch | A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container. |

| Field | Description |
|-----------------|---|
| Master | The physical IP address and port number of the <i>master copy</i> . The master copy is part of the original copy of the volume. |
| ActiveServers | The physical IP address and port number of each active node on which the container resides. |
| InactiveServers | The physical IP address and port number of each inactive node on which the container resides. |
| UnusedServers | The physical IP address and port number of each on which the container does not reside. |
| OwnedSizeMB | The size on disk (in MB) dedicated to the container. |
| SharedSizeMB | The size on disk (in MB) shared by the container. |
| LogicalSizeMB | The logical size on disk (in MB) of the container. |
| Mtime | Indicates the time of the last modification to the container's contents. |
| NameContainer | Indicates if the container is the <i>name container</i> for the volume. If <code>true</code> , the container is the volume's first container and replication occurs simultaneously from the master to the intermediate and tail containers. |

Example

CLI

```
maprcli dump
replicationmanagerinfo -cluster
docs41cluster -volumename
mapr.metrics -ctime true -json
```

dump replicationmanagerqueueinfo

Returns information that enables you to check the status of containers in various replication manager queues like under-replicated containers, and over-replicated containers, etc.

Syntax

CLI

```
maprcli dump
replicationmanagerqueueinfo
[-cluster <cluster name>]
-queue <queue>
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| queue | The name of the queue. Valid values are 0, 1, 2, or 5. Queue 0 includes containers that have copies below the minimum replication factor for the volume. Queue 1 includes containers that have copies below the replication for the volume, but above the minimum replication factor. Queue 2 includes containers that are over-replicated. Queue 5 includes containers which are not rack aware. |

Output

The `maprcli dump replicationmanagerqueueinfo` command returns information about one of these queues: 0, 1, 2, or 5. Depending on the queue value entered, the command displays information about containers that are under-replicated or over-replicated. You can use this information to decide if you need to change the replication factor for that volume.

```
# maprcli dump replicationmanagerqueueinfo -queue 0

Output fields

| Field | Description |
|-------------|--|
| ContainerID | The unique ID number of the container. |
| Epoch | A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container. |

| Field | Description |
|-----------------|---|
| Master | The physical IP address and port number of the <i>master copy</i> . The master copy is part of the original copy of the volume. |
| ActiveServers | The physical IP address and port number of each active node on which the container resides. |
| InactiveServers | The physical IP address and port number of each inactive node on which the container resides. |
| UnusedServers | The physical IP address and port number of servers from which no "heartbeat" has been received for quite some time. |
| OwnedSizeMB | The size on disk (in MB) dedicated to the container. |
| SharedSizeMB | The size on disk (in MB) shared by the container. |
| LogicalSizeMB | The logical size on disk (in MB) of the container. |
| TotalSizeMB | The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size. |
| Mtime | The time of the last modification to the contents of the container. |
| NameContainer | Indicates if the container is the <i>name container</i> for the volume. If <code>true</code> , the container holds the volume's namespace information and file chunk locations. |

Example

CLI

```
maprcli dump
replicationmanagerqueueinfo -queue
0 -json
```

dump rereplicationinfo

Returns information about the ongoing re-replication of replica containers.

This information includes the destination IP address and port number, the ID number of the destination file server, and the ID number of the destination storage pool.

Re-replication occurs whenever the number of available replica containers drops below the number prescribed by that volume's replication factor. Re-replication may occur for a variety of reasons including replica container corruption, node unavailability, hard disk failure, or an increase in replication factor.

Syntax

CLI

```
maprcli dump rereplicationinfo
[-cluster <cluster name>]
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |

Output

The `maprcli dump rereplicationinfo` command returns information about the ongoing re-replication of replica containers including the destination IP address and port number, the ID number of the destination file server, and the ID number of the destination storage pool.

```
# maprcli dump rereplicationinfo -json

    {
      "containerid":8833,
      "replica":{
        "sizeMB":7327,
        "To fsid":9057314602141502940,
```

```

    "To IP:Port" : "192.0.2.28:5660- " ,
    "To SP" : "33885e3c5be9a04d004f828abcstuvwxyz"
  }
]
}

```

Output fields

| Field | Description |
|------------|---|
| sizeMB | The amount of data (in MB) being moved. |
| To fsid | The ID number (FSID) of the destination file server. |
| To IP:Port | The IP address and port number of the destination node. |
| To SP | The ID number (SPID) of the destination storage pool. |

Example

CLI

```
maprcli dump rereplicationinfo -json
```

dump rereplicationmetrics

Displays information about containers that were copied by the replication manager.

This command displays the following fields :

- `numContainersCopied` - The number of containers that were copied by the replication manager to maintain the volume's replication factor or topology since the current CLDB was the master.
- `numMBCopied` -The cumulative size of the containers that were copied by the replication manager to maintain the volume's replication factor or topology since the current CLDB was the master.

Syntax

CLI

```
maprcli dump rereplicationmetrics
[-cluster <cluster name>]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---------------|
| cluster | Cluster name. |

Example

CLI

```
maprcli dump rereplicationmetrics
```

Example Output

```
# maprcli dump rereplicationmetrics
numContainersCopied  numMBCopied
0                      0
```

dump rolebalancerinfo

Returns information about active replication role switches.

Use the `dump rolebalancerinfo` command to see if the replication role balancer is currently switching the replication roles of any containers in a cluster. For example, if too many data containers with the master or intermediate roles exist within a storage pool, the replication role balancer switches the role of some of these containers to the tail role to evenly spread the load across nodes during the replication process. If the role balancer is not currently switching the roles of any containers, the command returns a message stating that there are no active role switches.

You can include some additional parameters with the `dump rolebalancerinfo` command, such as the `volumeinfo` parameter, which provides information about how the replication role balancer balanced container roles across each storage pool in a particular volume.

See [Replication Role Balancer](#) for more information about how the replication role balancer works.

For the best readability, use the `-json` option at the end of the command.

Syntax

CLI

```
maprcli dump rolebalancerinfo
      [ -cluster cluster_name ]
      [ -namectrinfo Get
NameContainers Info Parameter takes
no value ]
      [ -stats Gets RoleBalancer
AcitveSwitches Info Parameter takes
no value ]
      [ -volumeinfo Gets Balancing
Info for Volumes(s) Parameter takes
no value ]
      [ -volumename Specifies the
name of the volumes ]
```

REST

N/A

Parameters

| Parameter | Description |
|------------|---|
| cluster | The cluster on which to run the command. When you omit this parameter, the command runs on the same cluster where it is issued. In a multi-cluster environment, use this parameter to specify a particular cluster. |
| stats | Provides a list of active switches for the role balancer. The command returns the same information with or without this parameter. |
| volumeinfo | Provides the volume balancing information and details how the container roles are balanced across each storage pool in a volume. Requires the <code>volumename</code> parameter. |
| volumename | The name of the volume. To obtain volume names, use the <code>maprcli volume list</code> command. |

| | |
|-------------|---|
| namectrinfo | Provides information about how the name containers are distributed across the storage pools in the cluster, including how many name containers are master and tail containers. Useful when the replication role balancer is configured to balance container roles by count instead of size. |
|-------------|---|

Output

The following example shows the output of the `dump rolebalancerinfo` command when the replication role balancer switches a container to the tail role:

```
# maprcli dump rolebalancerinfo -json
{
  "timestamp":1452150159265,
  "timeofday":"2016-01-07 07:02:39.265 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "containerid":57482,
      "Tail IP:Port":"10.10.104.37:5660-10.10.105.37:5660-",
      "Updates blocked Since":"Thu Jan 07 07:02:24 UTC 2016"
    }
  ]
}
```

The following example shows the `dump rolebalancerinfo -volumeinfo -volumename` command:

```
# maprcli dump rolebalancerinfo -volumeinfo -volumename vol2 -json
{
  "timestamp":1452218225547,
  "timeofday":"2016-01-08 01:57:05.547 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[

        "SizeOfTails":48267,
        "DesiredSizeOfTails":35849,
        "Assign Cache Containers Count":0,
        "Assign Cache Containers Size":0
    }
]
}

```

Output

| Field | Description |
|-------------------------------|---|
| containerID | The unique ID number of the container. |
| Tail IP:Port | The IP address and port number of the tail container node. |
| Updates blocked Since | During a replication role switch, updates to that container are blocked during the date and time indicated. |
| Volume | Name of the volume. |
| Assign Cache Containers Count | The total number of containers in the assign cache. The assign cache is a list of containers that the CLDB has reserved on a particular file server node. The CLDB allocates containers from the cache when it receives a request from the file server for more containers. |
| Assign Cache Containers Size | The total size of the containers in the assigned cache. The assign cache is a list of containers that the CLDB has reserved on a particular file server node. The CLDB allocates containers from the cache when it receives a request from the file server for more containers. |
| Zero Size Containers Count | The number of empty cache containers. |
| Storage Pools | The list of storage pools in the specified volume. |
| SpId | The ID of the storage pool located within the specified volume. |
| HostAddress | The server on which the storage pool resides. |
| NumContainers | The total number of containers that reside on the storage pool in the specified volume. |

| | |
|----------------------|--|
| NumMasters | The total number of master containers that reside on the storage pool in the specified volume. |
| NumTails | The total number of tail containers that reside on the storage pool in the specified volume. |
| SizeOfContainers | The total size of the containers that reside on the storage pool in the specified volume. |
| SizeOfMasters | The total size of the master containers that reside on the storage pool in the specified volume. |
| DesiredSizeOfMasters | The cumulative size of master replicas on a specific storage pool within a volume. Typically, this is 1/ReplicationFactor of all containers on a storage pool for a particular volume. For example, if the replication factor is set to 3, then 1/3 of all containers on a storage pool should have the master container role. |
| SizeOfTails | The total size of the tail containers that reside on the storage pool in the specified volume. |
| DesiredSizeOfTails | The cumulative size of tail replicas on a specific storage pool within a volume. Typically, this is 1/ReplicationFactor of all containers on a storage pool for a particular volume. For example, if the replication factor is set to 3, then 1/3 of all containers on a storage pool should have the tail container role. |

Example

CLI

```
maprcli dump rolebalancerinfo -json
```

dump rolebalancermetrics

Returns the cumulative number of times that the replication role balancer has switched the replication role of name containers and data containers on the cluster.

The `maprcli dump rolebalancermetrics` command enables you to view the number of times that the replication role balancer has switched the replication role of the name containers and data containers to ensure that containers are balanced across the nodes in the cluster. For best results, use the `-json` option when running `dump rolebalancermetrics` from the command line.

The *replication role balancer* is a tool that switches the replication roles of containers to ensure that every node has an equal share of master and replica containers (for name containers) and an equal share of master, intermediate, and tail containers (for data containers).

The replication role balancer changes the replication role of the containers in a cluster so that network bandwidth is spread evenly across all nodes during the replication process. A container's replication role determines how it is replicated to the other nodes in the cluster. For *name containers* (the volume's first container), replication occurs simultaneously from the master to all replica containers. For *data containers*, replication proceeds from the master to the intermediate container(s) until it reaches the tail containers. For more information, see [Replication Role Balancer](#).

Syntax

CLI

```
maprcli dump rolebalancermetrics
[-cluster <cluster name>]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |

Output

The `maprcli dump rolebalancerinfo` command returns the cumulative number of times that the replication role balancer has switched the replication role of name containers and data containers on the cluster.

```
# maprcli dump rolebalancermetrics -json
{
  "timestamp":1433372048169,
  "timeofday":"2015-06-03 10:54:08.169 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "numNameContainerSwitches":60,
      "numDataContainerSwitches":28,
      "timeOfLastMove":"Wed May 23 05:48:00 PDT 2015"
    }
  ]
}
```

Output fields

| Field | Description |
|--------------------------|--|
| numNameContainerSwitches | The number of times that the replication role balancer has switched the replication role of name containers. |
| numDataContainerSwitches | The number of times that the replication role balancer has switched the replication role of data containers. |
| timeOfLastMove | The date and time of the last replication role change. |

Example

CLI

```
maprcli dump rolebalancermetrics -json
```

dump supportdump

Collects logs and other information about the node to help troubleshoot issues.

Syntax

CLI

```
maprcli dump supportdump [ -cluster
<cluster name> ] [ -nodes <node
names> ] [ -params <parameter
string> ] [ -zkconnect <ZK connect
string> ]
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|--|
| cluster | Cluster name. |
| nodes | Node names for which support dump is needed. Space separated. Default: all |
| params | Parameter string to create a dump. |
| zkconnect | ZK connection string. |

Output

```
# maprcli dump supportdump
node
centos29.lab
centos23.lab
centos28.lab
centos22.lab
```

Example

CLI

maprcli dump supportdump

dump volumeinfo

Returns information about volumes and the associated containers. For JSON formatted output, use the `-json` option from the command line.

A *volume* is a logical unit that allows you to apply policies to a set of files, directories, and sub-volumes. Using volumes, you can enforce disk usage limits, set replication levels, establish ownership and accountability, and measure the cost generated by different projects or departments. For more information, see [Administering Volumes](#) on page 933.

Syntax

CLI

```
maprcli dump volumeinfo
  [-cluster <cluster name>]
  [-volumename <volume name>]
  [-ctime <true|false>]
```

REST

N/A

Parameters**ctime**Set to `true` to display container state/role change time.Default: `false`**cluster**

The cluster on which to run the command. If this parameter is omitted, the command is run on the cluster on which it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command.

volumename The name of the volume. To obtain volume names, use the [volume list](#) on page 2247 `maprcli volume list` command. This parameter is mandatory.

Output

The `maprcli volume info` returns information about the volume and the containers associated with that volume. Volume information includes the ID, volume name, and replication factor. For each container on the specified volume, the command returns information about nodes and storage. See the following [Example](#) on page 1833 for sample output.

| | |
|------------------------------------|---|
| AccessTime | Indicates the volumes that are accessed regularly. This value is updated every 6 hours with the last time that an operation occurred on the volume. The access time is not updated for changes to volume properties, creation of a snapshot, or synchronization between a volume and a mirror. However, the volume access time is updated the first time you upgrade to a data-fabric version that includes this property. This property was introduced in data-fabric version 4.0.2. |
| ActiveServers | The IP address and port number of each active node on which the container resides. |
| allowGrant | Indicates whether (<code>true</code>) or not (<code>false</code>) a parent volume grants permission for a child volume to inherit its properties. |
| Audited | Indicates whether (1) or not (0) auditing is enabled for the volume. |
| AuditVolume | Indicates whether (1) or not (0) the volume accommodates audit logs. |
| CoalesceInterval | The interval of time to elapse after the first instance of an operation on a node is recorded in audit logs, if auditing is enabled. Subsequent identical operations performed on the same node from the same client are ignored during the interval. |
| ContainerId | The unique ID number of the container. |
| CreatorContainerId | The container ID of the read-write container. The container ID is retained in all mirrors of those containers (in all mirrors of the volume). The container ID enables the identification of the correct containers to source from, when mirror sources are changed in a mirror chain. |
| CreatorVolumeUuid | A randomly generated unique ID that is shared by all mirrors of a volume, and all containers of them. You can use this ID to avoid undesirable chaining of containers when mirror sources are changed in a mirror chain. |
| dareEnabled | Indicates whether (1) or not (0) data-at-rest encryption (DARE) is enabled for the volume. |
| DisabledDataAuditOperations | The list of operations excluded from auditing. |
| EnabledDataAuditOperations | The list of operations selected for auditing. |
| enforcementMode | The data access enforcement mode. |
| Epoch | A sequence number that indicates the most recent copy of the container. The CLDB uses the epoch to ensure that an out-of-date copy cannot become the master for the container. |

| | |
|--------------------------------|--|
| fixCreatorId | An internal flag for data-fabric volumes to fix the creator container ID. |
| ForceAudit | Indicates whether (1) or not (0) to force audit of operations on all files, tables, and streams in the volume. |
| InactiveServers | The IP address and port number of each inactive node on which the container resides. |
| label | The label associated with the volume. See Using Storage Labels on page 1068 for more information on labels. |
| limitSpread | An internal flag for data-fabric volumes to control the growth of a volume in terms of number of containers. When this flag is set, CLDB tries to limit the number of new containers created, depending on the present size of a volume. If a volume size (data in volume) is small, CLDB tries to reuse space in existing containers to avoid the creation of new containers. This reuse helps reduce wastage of containers IDs in an environment that has small volumes. |
| LogicalSizeMB | The logical size on disk (in MB) of the container. |
| Master | The IP address and port number of the <i>master copy</i> . The master copy is part of the original copy of the volume. |
| MetricsEnabled | Indicates whether (1) or not (0) metrics collection is enabled for the volume. |
| MirrorThrottle | Specifies whether mirror throttling is enabled (true) or disabled (false). Throttling is set on the source volume and applies to all its mirrors. This property was introduced in MapR version 4.0.2. |
| Mtime | Indicates the time when the last modification was made to the contents of the container. |
| NameContainer | Indicates if the container is the <i>name container</i> for the volume. If <code>true</code> , the container is the first container of the volume. Replication then occurs simultaneously from the master to the intermediate and tail containers. |
| NameSpaceMinReplication | The minimum replication factor or the number of copies of the name container associated with the volume that should be maintained by the data-fabric cluster for normal operation. When the replication factor falls below this minimum value, writes to the volume are disabled. The default value is 2. |
| NameSpaceReplication | The desired replication factor or the number of copies of the name container associated with the volume. The default value is 3. The maximum value is 6. |
| nslabel | The name container label. See Using Storage Labels on page 1068 for more information on labels. |
| NumInodesInUse | Indicates the number of inodes used by the container. |
| OwnedSizeMB | The size on disk (in MB) dedicated to the container. |
| ReReplicationTimeOutSec | The timeout (in seconds) period until CLDB starts re-replicating the containers on the node of the volume, when CLDB stops receiving a heartbeat from the node. |
| securityPolicyTags | The list of security policy tags to be associated with this volume. |

| | |
|-----------------------------|--|
| SharedSizeMB | The size on disk (in MB) shared by the container. |
| TenantUser | Displays the name of the tenant user, if any. |
| TotalSizeMB | The total size on disk (in MB) allocated to the container. Combines the Owned Size and Shared Size. |
| UnusedServers | The IP address and port number of servers from which no "heartbeat" has been received for quite some time. |
| VolumeId | The unique ID number of the volume. |
| VolumeMinReplication | The minimum replication factor. Indicates the number of copies of a volume (including the original) that should be maintained by the data-fabric cluster for normal operation. When the replication factor falls below this minimum value, writes to the volume are disabled. The default value is 2. A replication factor of 2 indicates that the number of copies of a volume is 2 (original +1 copy). A replication factor of 3 indicates that the number of copies of a volume is 3 (original + 2 copies). |
| VolumeName | The name of the volume. |
| VolumeReplication | The desired replication factor. Indicates the number of copies of a volume. The default value is 3. The maximum value is 6. |
| VolumeTopology | The volume topology corresponds to the node topology of the rack or nodes where the volume resides. By default, new volumes are created with a topology of / (root directory). For more information, see Setting Up Node Topology on page 882. |
| VolumeUsedSizeMB | The size on disk (in MB) of the volume. |
| WireSecurityEnabled | Indicates whether (1) or not (0) wire-level security is enabled. |

Adds a label to disks or a storage pool. Permissions required: `fc` or `a`.

[label add](#) on page 1891

Registers a label. Permissions required: `fc` or `a`.

[volume create](#) on page 2190

Creates a volume.

[volume move](#) on page 2294

Moves the specified volume or mirror to a different topology. Permissions required: `m` or `fc` on the volume.

[label list](#) on page 1895

Lists registered labels. Permissions required: `fc` or `a`.

[node list](#) on page 1911

Lists nodes in the cluster.

[configure.sh](#) on page 2331

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

dump volumenodes

Returns information about the nodes on a volume.

Syntax**CLI**

```
maprcli dump volumenodes
  [-cluster <cluster name>]
  -volumename <volume name>
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|------------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| volumename | The name of the volume. To obtain volume names, use the <code>maprcli volume list</code> command. |

Output

The `maprcli dump volumenodes` command returns the IP address and port number of volume nodes.

```
# maprcli dump volumenodes -volumename mapr.hbase -json
{
  "timestamp":1433372931725,
  "timeofday":"2015-06-03 11:08:51.725 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "Servers":{
        "IP:Port":[
          "10.10.82.23:5660--3-VALID",
          "10.10.82.28:5660--3-VALID",
          "10.10.82.29:5660--3-VALID"
        ]
      }
    }
  ]
}
```

Output fields

| Field | Description |
|---------|-------------------------------------|
| IP:Port | The IP address and filesystem port. |

Example

CLI

```
maprcli dump volumenodes -volumename
mapr.hbase -json
```

dump zkinfo

Returns the ZooKeeper znodes.

Note: This command is used by the `mapr-support-collect.sh` script to gather cluster diagnostics for troubleshooting.

This command enables you to view a snapshot of the data stored in Zookeeper as a result of cluster operations

ZooKeeper prevents service coordination conflicts by enforcing a rigid set of rules and conditions, provides cluster-wide information about running services and their configuration, and provides a mechanism for

almost instantaneous service failover. Warden will not start any services unless ZooKeeper is reachable and more than half of the configured ZooKeeper nodes are live.

The `mapr-support-collect.sh` script calls the `maprcli dump supportdump` command to gather cluster diagnostics for troubleshooting. For more information, see [mapr-support-collect.sh](#).

Syntax

CLI

```
maprcli dump zkinfo
  [-cluster <cluster name>]
  [-zkconnect <connect string>]
```

Note: For best results, use the `-json` option from the command line.

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| zkconnect | A ZooKeeper connect string, which specifies a list of the hosts running ZooKeeper, and the port to use on each, in the format: ' <code><host>[:<port>][,<host>[:<port>]...]</code> '. To obtain zookeeper connection strings, use the <code>maprcli node listzookeepers</code> command. |

Output

The `maprcli dump zkinfo` command is run as part of support dump tools to view the current state of the Zookeeper service. The command should always be run using the `-json` option, since output in the default tabular format is not useful. Command output displays the data stored in the ZooKeeper hierarchical tree of znodes.

```
# maprcli dump zkinfo -json
{
  "timestamp":1335825202157,
  "status":"OK",
  "total":1,
  "data":[
    {
      "/_Stats":"\ncZxid = 0,ctime = Wed Dec 31 16:00:00 PST
1969,mZxid = 0,mtime = Wed Dec 31 16:00:00 PST 1969,pZxid = 516,cversion
= 12,dataVersion = 0,aclVersion = 0,ephemeralOwner = 0,dataLength =
0,numChildren = 13",
      "/" : [
        {
          ....
        }
      ]
    }
  ]
}
```

Output fields

You can use the `maprcli dump zkinfo` command as you would use a database snapshot. The `/services`, `/services_config`, `/servers`, and `/*_locks` znodes are used by Warden to store and exchange information.

| Field | Description |
|-----------------|--|
| services | The <code>/services</code> directory is used by Warden to store and exchange information about services. |
| datacenter | The <code>/datacenter</code> directory contains CLDB "vital signs" that you can use to identify the CLDB master, the most recent epoch, and other key data. For more information, see Moving CLDB Data . |
| services_config | The <code>/services_config</code> directory is used by Warden to store and exchange information. |
| zookeeper | The <code>/zookeeper</code> directory stores information about the ZooKeeper service. |
| servers | The <code>/servers</code> directory is used by Warden to store and exchange information. |
| nodes | The <code>/nodes</code> directory (znode) stores key information about the nodes. |

Moving CLDB Data

Describes how to move CLDB data to another node.

In a Community Edition-licensed cluster, CLDB data must be recovered from a failed CLDB node and installed on another node. The cluster can continue normally as soon as the CLDB is started on another node.

For more information, see [CLDB Failover](#) on page 1677.

Use the `maprcli dump zkinfo` command to identify the latest epoch of the CLDB, identify the nodes where replicates of the CLDB are stored, and select one of those nodes to serve the new CLDB node. Perform the following steps on any cluster node:

1. Log in as `root` or use `sudo` for the following commands.
2. Issue the `maprcli dump zkinfo` command using the `-json` flag.

```
# maprcli dump zkinfo -json
```

The output displays the ZooKeeper znodes.
3. In the `/datacenter/controlnodes/cldb/epoch/1` directory, locate the CLDB with the latest epoch.

```
{ "/datacenter/controlnodes/cldb/epoch/1/KvStoreContainerInfo": "  
Container ID:1 VolumeId:1  
Master:10.250.1.15:5660-172.16.122.1:5660-192.168.115.1:5660--13-VALID  
Servers: 10.250.1.15:5660-172.16.122.1:5660-192.168.115.1:5660--13-VALID  
Inactive Servers: Unused Servers: Latest epoch:13" }
```

The Latest Epoch field identifies the current epoch of the CLDB data. In this example, the latest epoch is 13.

4. Select a CLDB from among the copies at the latest epoch. For example, `10.250.2.41:5660--13-VALID` indicates that the node has a copy at epoch 13 (the latest epoch).

entity

Manages *entities* (users and groups).

entity info

Displays information about an entity.

Syntax**CLI**

```
maprcli entity info
[ -cluster <cluster> ]
-name <entity name>
[ -output terse|verbose ]
-type <type>
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/entity/info?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. |
| name | The <i>entity</i> name. Obtain the entity name by running the <code>maprcli entity list</code> command. |
| output | Whether to display terse or verbose output. |
| type | The entity type. Obtain the entity type by running the <code>maprcli entity list</code> command. |

Output**Sample Output**

```
DiskUsage EntityQuota EntityType EntityName VolumeCount
EntityAdvisoryquota EntityId
864415 0 0 root 208
0 0
```

Output Fields

| Field | Short Name | Description |
|-------------|------------|---|
| DiskUsage | dsu | Disk space used by the user or group |
| EntityQuota | qta | The user or group quota |
| EntityType | t | The entity type |
| EntityName | n | The entity name |
| VolumeCount | vct | The number of volumes associated with the user or group |

| Field | Short Name | Description |
|---------------------|------------|----------------------------------|
| EntityAdvisoryquota | aqt | The user or group advisory quota |
| EntityId | id | The ID of the user or group |

Examples

Display information for the user 'root':

CLI

```
maprcli entity info -type 0 -name root
```

REST

```
https://abc.sj.us:8443/rest/entity/info?type=0&name=root
```

entity list

Lists and displays information about entities.

Syntax

CLI

```
maprcli entity list
[ -alarmedentities true|false ]
[ -cluster <cluster> ]
[ -columns <columns> ]
[ -filter <filter> ]
[ -limit <rows> ]
[ -output terse|verbose ]
[ -sortby ]
[ -start <start> ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host>:<port>/rest/entity/list[?<parameters>] |

Parameters

| Parameter | Description |
|-----------------|--|
| alarmedentities | Specifies whether to list only entities that have exceeded a quota or advisory quota. |
| cluster | The cluster on which to run the command. |
| columns | A comma-separated list of fields to return in the query. See the Fields table below. |
| filter | A filter specifying entities to display. See Filters for more information. |
| limit | The number of rows to return, beginning at start. Default: 0 |
| output | Specifies whether output should be <code>terse</code> or <code>verbose</code> . |

| Parameter | Description |
|-----------|--|
| sortby | Specifies one of the following attributes to sort the list of entities by: entityname, entitytype, entityid, entityemail, entityquota, entityadvisoryquota, entitydiskusage, entityvolumecount. By default, the list of entities sorted by entityname. |
| start | The offset from the starting row according to sort. Default: 0 |

Output

Information about the users and groups. Only users and groups with associated volumes are returned in the output.

Table

| Field | Short Name | Description |
|---------------------|------------|---|
| EntityType | t | Entity type <ul style="list-style-type: none"> 0 = User 1 = Group |
| EntityName | n | User or Group name |
| EntityId | id | User or Group id |
| EntityQuota | qta | Quota, in MB. 0 = no quota. |
| EntityAdvisoryquota | aqt | Advisory quota, in MB. 0 = no advisory quota. |
| VolumeCount | vct | The number of volumes this entity owns. |
| DiskUsage | dsu | Disk space used for all entity's volumes, in MB. |

Sample Output

```
DiskUsage  EntityQuota  EntityType  EntityName  VolumeCount
EntityAdvisoryquota  EntityId
5859220    0              0          root        209
0          0
```

Examples

List all entities:

CLI

```
maprcli entity list
```

REST

```
https://abc.sj.us:8443/rest/entity/
list
```

Filter entities by entity name:

CLI

```
maprcli entity list -filter "[EntityName==mapr]"
```

REST

```
https://abc.sj.us:8443/rest/entity/list?filter=[EntityName%3D%3Dmapr]
```

entity modify

Modifies a user or group quota or email address. Permissions required: *fc* or *a*.

Syntax

CLI

```
maprcli entity modify
[ -advisoryquota <advisory quota>
[ -cluster <cluster> ]
[ -email <email>]
[ -entities <entities> ]
-name <entityname>
[ -quota <quota> ]
-type <type>
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/entity/modify?<parameters> |

Parameters

| Parameter | Description |
|---------------|---|
| advisoryquota | The advisory quota. |
| cluster | The cluster on which to run the command. |
| email | Email address. |
| entities | A comma-separated list of entities, in the format <type>:<name>. Example: 0:<user1>,0:<user2>,1:<group1>,1:<group2>. .. |
| name | The <i>entity</i> name. |
| quota | The quota for the entity. |
| type | The entity type: <ul style="list-style-type: none"> 0=user 1-group |

Examples

Modify the email address for the user 'root':

CLI

```
maprcli entity modify -name
root -type 0 -email test@example.com
```

REST

```
https://abc.sj.us:8443/rest/entity/
modify?
name=root&type=0&email=test@example.co
m
```

Related tasks

[Setting Quota Defaults for Users and Groups](#) on page 857

Explains how to set disk space quotas for users and groups.

Related reference

[rlimit set](#) on page 1945

Sets the resource usage limit for the cluster's disk resource.

entity remove

Removes an entity (specified by name and type).

Note: Entity can be removed only when there are no resources associated with the entity.

Syntax**CLI**

```
maprcli entity remove
-name <entity name>
-type <type>
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/entity/remove?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| name | The <i>entity</i> name. Obtain the entity name by running the <code>maprcli entity list</code> command. |
| type | The entity type. Value can be: <ul style="list-style-type: none"> 0 - for user 1 - for group If necessary, obtain the entity type by running the <code>maprcli entity list</code> command. |

Example**Remove an entity by name and type:**

```
maprcli entity remove -name mapruser1 -type 1
```

fid

Displays information about HPE Ezmeral Data Fabric Database or file-system components that are identified by a FID.

fid dump

Displays detailed information for HPE Ezmeral Data Fabric Database or file-system components that are identified by an FID.

Note: Only the root user and the MAPR_USER user (user under which HPE Ezmeral Data Fabric services runs) have permissions to run this command.

Syntax

CLI

```
maprcli fid dump
  [ -cluster <cluster_name> ]
  -fid <file identified for the
  element>
```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| fid | The file identifier for the element (region, kvstore, etc.) for which you want detailed information. The output of maprcli table region list lists the FIDs for the table's regions. |

Note: You can run this command on any FID available on the HPE Ezmeral Data Fabric filesystem.

Tablet Map

Displays output for a tablet map includes the key for each tablet and its corresponding FID.

Each tablet contains a range of data starting with the key associated with the tablet and ending before the key associated with the next tablet

FID for a Tablet Map

Describes how to determine the FID for a tablet map.

To determine the FID for a tablet map:

1. Run `hadoop mfs -ls <table path>` to determine the table FID. The table FID is the FID that displays after the "p."

Example:

```
[mapr@hostname ~]$ hadoop mfs -ls /testdst
Found 1 items
tr----- Z U 3 mapr mapr 2 2015-02-18 15:24 0 /
testdst
p 2049.49.131220 hostname:5660
r 2061.32.131258 hostname:5660
```

2. Run `maprcli fid dump` on the table FID to determine the tablet map FID.

Example:

```
[mapr@hostname ~]$ maprcli fid dump -fid
2049.49.131220
value key
{"value":{"fid":"<parentCID>.51.131224"}} schema
{"value":{"fid":"<parentCID>.50.131222"}}
tabletmap
```

3. Construct the tablet map FID for the `maprcli fid dump` command by replacing `<parentCID>` with the set of numbers before the first period four numbers in the table FID.

Example: 2049.50.131222

Output Example for a Tablet Map

Example command and output.

```
maprcli fid dump -fid 2049.50.131222 -json
{
  "timestamp":1425579595296,
  "timeofday":"2015-03-05 06:19:55.296 GMT+0000",
  "status":"OK",
  "total":4,
  "data":[
    {
      "key": "",
      "value":{
        "fid":"2116.59.131462"
      }
    },
    {
      "key":"user3155781742051747178",
      "value":{
        "fid":"2114.49.131348"
      }
    },
    {
      "key":"user5238840414188136300",
      "value":{
        "fid":"2118.49.131394"
      }
    },
    {
      "key":"user7257930685533675764",
      "value":{
        "fid":"2115.59.131316"
      }
    }
  ]
}
```

Tablet

Describes output for a tablet.

The `maprcli fid dump` output for a tablet includes key and value pairs for the following:

- **startkey.** The first key value in the tablet.
- **pmap.** Each partition.

- **endkey.** The last key value in the tablet.

Output Fields for a Tablet

This table describes a majority of the output values for each partition (pmap) in the tablet.

| Field | Description |
|----------------------|--|
| key | The partition key. |
| segfid | The FID of the segment map associated with this partition. |
| isFrozen | A Boolean value that indicates if a partition is in a frozen state or not. Internally, a partition is sometimes temporarily marked as frozen in order for certain operations to complete. |
| inSplit | A Boolean value that indicates if a partition split is in progress for this partition. |
| useBucketDesc | This property is for internal use only. |
| lastFlushedBucketFid | The FID of the bucket file (WAL) which was last flushed for this partition. |
| numLogicalBlocks | The number of logical blocks (8K) for this partition. |
| numPhysicalBlocks | The number of physical blocks (8K) for this partition. |
| numRows | The number of rows stored in this partition. |
| numRowsWithDelete | The number of rows which are marked for delete in this partition. |
| numRemoteBlocks | The number of disk blocks which are not local to this partition. When a region splits, a partition moves from one node to another and it is possible to temporarily have some remote blocks. |
| numSpills | The number of spills. |
| numSegments | The number of segments. |

Output Example for a Tablet

```
maprcli fid dump -fid 2116.59.131462 -json
{
  "timestamp":1425579636931,
  "timeofday":"2015-03-05 06:20:36.931 GMT+0000",
  "status":"OK",
  "total":6,
  "data":[
    {
      "key":"endkey.user3155781742051747178",
      "value":{
      }
    },
    {
      "key":"pmap.",
      "value":{
        "segfid":"<parentCID>.1065.133486",
        "isFrozen":false,
        "inSplit":false,

```

```

        "useBucketDesc":true,
        "lastFlushedBucketFid":"2116.901.133158",
        "numLogicalBlocks":34921,
        "numPhysicalBlocks":21976,
        "numRows":9332,
        "numRowsWithDelete":0,
        "numRemoteBlocks":0,
        "numSpills":137,
        "numSegments":74
    },
    {
        "key":"pmap.user1523186274532578170",
        "value":{
            "segfid":"<parentCID>.1066.133488",
            "isFrozen":false,
            "inSplit":false,
            "useBucketDesc":true,
            "lastFlushedBucketFid":"2116.902.133160",
            "numLogicalBlocks":37011,
            "numPhysicalBlocks":23260,
            "numRows":9868,
            "numRowsWithDelete":0,
            "numRemoteBlocks":168,
            "numSpills":147,
            "numSegments":78
        }
    },
    {
        "key":"pmap.user2078250355776544396",
        "value":{
            "segfid":"<parentCID>.445.132238",
            "isFrozen":false,
            "inSplit":false,
            "useBucketDesc":true,
            "lastFlushedBucketFid":"2116.447.132242",
            "numLogicalBlocks":71124,
            "numPhysicalBlocks":44797,
            "numRows":18991,
            "numRowsWithDelete":0,
            "numRemoteBlocks":172,
            "numSpills":300,
            "numSegments":152
        }
    },
    {
        "key":"postSplitCopy",
        "value":{
            "raw":"dummy"
        }
    },
    {
        "key":"startkey.",
        "value":{
        }
    }
]
}

```

 **Note:** The postSpitCopy key and value are for internal use only.

Segment Map

Describes output of a segment map.

The `maprcli fid dump` output of a segment map includes a map of row keys and the corresponding segment FID.

Output Fields for a Segment Map

| Field | Description |
|-------|--|
| key | The row key |
| value | The FID corresponding to the segment associated with this key. |

Output Example for a Segment Map

```
maprcli fid dump -fid 2116.1065.133486 -json
{
  "timestamp":1425579702407,
  "timeofday":"2015-03-05 06:21:42.407 GMT+0000",
  "status":"OK",
  "total":74,
  "data":[
    {
      "key": "",
      "value":{
        "fid": "<parentCID>.943.133242"
      }
    },
    {
      "key": "user1006417450462802131",
      "value":{
        "fid": "<parentCID>.945.133246"
      }
    },
    ...
  ]
}
```

Segment

Describes output for a segment.

The output of `maprcli fid dump` for a segment includes details about each spill.

Output Fields for a Segment

| Field | Description |
|-----------------|------------------------------|
| key | The index of the spill. |
| numRemoteBlocks | The number of remote blocks. |
| numspills | The number of spills. |

| Field | Description |
|-------|--|
| value | <p>The property contains the following values:</p> <ul style="list-style-type: none"> • fid: The FID of the spill containing row and value data. • smeSize: The spill map entry size. • keyIdxOffset: The offsets and length inside the spill for the index • keyIdxLength: The length inside the spill for the index • ldbIdxLength: The length of the index portion in the spill. • bloomBitsPerKey: The number of bits used in the bloom filter per key. • numLogicalBlocks: The number of logical blocks in the spill. • numPhysicalBlocks: The number of physical blocks in the spill. • numRows: The number of rows in the spill. • numRowsWithDelete: The number of rows which are marked for delete in the spill. • families: Information about the location of different column family data in the spill and the time range of that data. |

Output Example for a Segment

```
maprcli fid dump -fid 2116.945.133246 -json
{
  "timestamp":1425579733821,
  "timeofday":"2015-03-05 06:22:13.821 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "key":0,
      "numRemoteBlocks":0,
      "numSpills":0,
      "numSegments":0,
      "value":{
        "fid":"<parentCID>.946.133248",
        "smeSize":55,
        "keyIdxOffset":12,
        "keyIdxLength":3587,
        "ldbIdxLength":20,
        "bloomBitsPerKey":80,
        "numLogicalBlocks":369,

        "numRows":99,
        "numRowsWithDelete":0,
        "families":{
          "id":1,
          "offset":524288,
          "length":2976835,
          "minTimeStamp":1425578650850,
```

```

    "maxTimeStamp" : 1425578856492
  }
}
]
}

```

fid stat

Displays statistics for HPE Ezmeral Data Fabric Database or filesystem components that are identified by a FID.

Only the root user and the MAPR_USER user (user name under which MapR services runs) have permissions to run this command.

 **Note:** This command is similar to the UNIX `stat` command.

Syntax

CLI

```

/opt/mapr/bin/maprcli fid stat
[ -cluster <cluster name> ]
-fid <file identifier for the
element>

```

REST

N/A

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. If this parameter is omitted, the command is run on the same cluster where it is issued. In multi-cluster contexts, you can use this parameter to specify a different cluster on which to run the command. |
| fid | The file identifier for the element (region, kvstore, etc.) for which you want detailed information. The output of the <code>maprcli table region list</code> command lists the FIDs for the regions of the table. |

Output Fields

| Columns | Description |
|-------------|---|
| atime | The last access time for this FID. For more information, see the <code>atimeUpdateTimeInterval</code> entry in volume create on page 2190. |
| compression | The compression setting, either <code>on</code> or <code>off</code> . If <code>on</code> , this parameter displays the compression type. |
| deleteFlags | An internal delete flag that is set on the FID for transactions involving multiple nodes. If deleted, this parameter denotes the deletion type, either <code>self</code> or <code>recursive delete</code> . |
| diskflush | Indicates whether persistent flush is enabled (<code>true</code>) or not (<code>false</code>) for this inode. |
| gid | The group ID |

| Columns | Description |
|-------------------|---|
| lblocks | Number of logical B-Tree blocks |
| mode | The UNIX style permission mode bits for the FID |
| mtime | Last modification time |
| nblocks | Total number of B-Tree blocks used |
| networkencryption | Indicates whether wire encryption is enabled or disabled |
| nlevels | Number of B-Tree levels |
| nlink | Number of links to this inode |
| parent | The parent FID |
| size | The size of the FID. Depending on the type of FID, it can be the actual size (in bytes), or the number of entries |
| subtype | The subtype of the FID |
| type | The type of the FID. For example, regular file, dir, filelet, kvstore, fidmap etc. |
| uid | The user ID of the owner |
| version | The current version of the FID. |
| xattrInum | The extended attribute of the FID |

Example

Displays statistics for a specified FID:

```
[user@hostname ~]$ maprcli fid stat -fid 2062.32.131252 -json
{
  "timestamp":1586935733623,
  "timeofday":"2020-04-15 12:28:53.623 GMT-0700 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "type":"FTDirectory",
      "subtype":"FSTInval",
      "parent":"<parentCID>.35.131200",
      "size":1,
      "nblocks":1,
      "lblocks":0,
      "compression":"off",
      "deleteFlags":"DeleteTypeNone",
      "atime":1583751630,
      "mtime":1583751630,
      "mode":"755",
      "uid":1000,
      "gid":1000,
      "nlink":3,
      "xattrInum":0,
      "version":1048589,
      "networkencryption":true,
      "diskflush":false,
      "nlevels":1
    }
  ]
}
```

file

Lets you perform tiering operations at the file level.

file offload

Initiates offload of a file using a MAST Gateway.

Permissions Required

The user running the command must have (mode bit or [ACE](#)) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file offload
-name <file_name>
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/file/offload?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| name | The name (including the path) of the file to offload. |

Error Message

The OP_TIMEOUT message that indicates that the operation timed out, is returned if the connection to the gateway is lost.

Example

Offload file named test1 in volume named vol1:

CLI

```
/opt/mapr/bin/maprcli file
offload -name /vol1/test1
{
  "timestamp":1520277246831,
  "timeofday":"2018-03-05
07:14:06.831 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":12,
      "message":"File transfer
request queued.",
      "gateway":"10.10.88.200:8660",
      "jobid":"0x37d7c7738cd0991f.0xe35d5f0e
5b24cda.0x4"
    }
  ]
}
```

```
]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/file/offload?
name=/voll/test1' --user mapr:mapr

{"timestamp":1520277246831,"timeofday"
:"2018-03-05 07:14:06.831
GMT+0000","status":"OK","total":1,
"data":
[{"status":12,"message":"File
transfer request
queued.","gateway":"10.10.88.200:8660"
,
"jobid":"0x37d7c7738cd0991f.0xe35d5f0e
5b24cda.0x4"}]}
```

Offload a file named mfs in volume named voll:**CLI**

```
/opt/mapr/bin/maprcli file
offload -name /voll/mfs -json
{
  "timestamp":1534141379576,
  "timeofday":"2018-08-12
11:22:59.576 GMT-0700 PM",
  "status":"ERROR",
  "errors":[
    {
      "id":6,
      "desc":"Lost connection
to gateway."
    }
  ]
}
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/
tierjobstatus?name=/voll/mfs' --user
mapr:mapr

{"timestamp":1534141379576,"timeofday"
:"2018-08-12 11:22:59.576 GMT-0700
PM","status":"ERROR",
"errors":[{"id":6,"desc":"Lost
connection to gateway."}]}
```

file recall

Initiates recall of a file from a storage tier using a MAST Gateway.

Permissions Required

The user running the command must have (mode bit or [ACE](#)) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file recall
-name <file_name>
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host:port>/rest/file/recall?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| name | The name (including the path) of the file to recall. |

Example

Recall file named file1 in volume named vol1:

CLI

```
/opt/mapr/bin/maprcli file
recall -name /voll/test1 -json
{
  "timestamp":1516337242973,
  "timeofday":"2018-01-19
04:47:22.973 GMT+0000",
  "status":"OK",
  "total":1,
  "data":[{"
    "status":12,
    "message":"File transfer
request
queued.",
    "gateway":"10.10.88.198:8660",

"jobid":"0xb76f872c64fe4677.0x3673092f
759a500d.0x1"
  }]}
}
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/recall?
<parameters>' --user mapr:mapr
{"timestamp":1516337242973,"timeofday"
:"2018-01-19 04:47:22.973
GMT+0000","status":"OK","total":1,"dat
a":[{"status":12,"message":"File
transfer request
queued.", "gateway":"10.10.88.198:8660"
,"jobid":"0xb76f872c64fe4677.0x3673092
f759a500d.0x1"}]}
```

file tierjobabort

Initiates abort of an ongoing offload or recall operation.

Permissions Required

The user running the command must have (mode bit or [ACE](#)) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file
tierjobabort
  -name <file_name>
  [ -job <jobID> ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/file/tierjobabort?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| name | The name (including the path) of the file being offloaded/recalled. |
| job | <p>The ID of the job, which was specified with the offload or recall command, to abort. This must be specified to ensure that the correct offload or recall task is aborted. If this is not specified, the command picks a job to abort in the following order:</p> <ol style="list-style-type: none"> 1. Job that is in “already aborting progress” status. 2. Job that is in “running jobs with latest jobid” status. <p>If there are no jobs in progress, the command returns “no active transfer in progress” error.</p> |

Examples

CLI

```
/opt/mapr/bin/maprcli file
tierjobabort -name /c1/file5G -json
{
  "timestamp":1557734728770,
  "timeofday":"2019-05-13
01:05:28.770 GMT-0700 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":10,
      "message":"File
transfer being aborted.",
      "gateway":"10.10.103.79:8660",
      "jobid":"0x140dea11228a3211.0x18565bc5
d5e4e4fe.0x2"
    }
  ]
}
```

```
    ]
}
```

REST

```
curl -k -X POST 'https://host:port/
rest/file/tierjobabort?name=/cl/
file5G' --user mapr:mapr
{"timestamp":1557738947905,"timeofday"
:"2019-05-13 02:15:47.905 GMT-0700
AM","status":"OK","total":1,"data":
[{"status":10,"message":"File
transfer being
aborted.","gateway":"host:port","jobid
":"0x140dea11228a3211.0x18565bc5d5e4e4
fe.0x3"}]}
```

file tierjobstatus

Checks the status of a previous offload or recall operation.

Permissions Required

The user running the command must have (mode bit or [ACE](#)) permissions to write to the file.

Syntax

CLI

```
/opt/mapr/bin/maprcli file
tierjobstatus
    -name <file_name>
    [ -job <jobID> ]
```

REST

| | |
|--------------|--|
| Request Type | GET |
| Request URL | http[s]://<host:port>/rest/file/tierjobstatus?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| name | The name (including the path) of the file. |
| job | The ID of the job specified with the offload or recall command. |

Output

The command returns **one** of the following messages:

FTOS_SUCCESS

Indicates that the file tiering operation was successful. For example:

CLI

```
/opt/mapr/bin/
maprcli file
```

```

tierjobstatus -n
ame /v5/
nfile2 -json
{
  "timestamp":15335
55093521,
  "timeofday":"201
8-08-06
04:31:33.521
GMT-0700 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":0,
      "message":"File
offload
completed.",
      "gateway":"10.10.
104.21:8660",
      "op":"Offload",
      "completedFids":2
,
      "failedFids":0,
      "totalFids":2
    }
  ]
}

```

REST

```

curl -k -X GET
'https://
abc.sj.us/rest/
file/
tierjobstatus?
name=/v5/
nfile2' -- user
mapr:mapr

{"timestamp":1533
555093521,"timeof
day":"2018-08-06
04:31:33.521
GMT-0700
AM","status":"OK"
,"total":1,
  "data":
  [{"status":0,"mes
sage":"File
offload
completed.,"gate

```

```
way": "10.10.104.2
1:8660", "op": "Off
load",
```

```
"completedFids": 2
, "failedFids": 0, "
totalFids": 2]]}
```

OP_FAIL

Indicates that the operation failed. For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /
volume_cold_aws/
sampleFile2 -json
{
  "timestamp": 15339
37284242,
  "timeofday": "201
8-08-10
02:41:24.242
GMT-0700 PM",
  "status": "ERROR",
  "errors": [
    {
      "id": 2,
      "desc": "File
offload failed."
    }
  ]
}
```

REST

```
curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/
volume_cold_aws/
sampleFile2' --us
er mapr:mapr
{"timestamp": 1533
937284242, "timeof
day": "2018-08-10
02:41:24.242
GMT-0700
PM", "status": "ERR
OR",
  "errors":
  [{"id": 2, "desc": "
```

```
File offload
failed."}}}
```

INVALID_FILE

Indicates that the specified file does not exist. For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /ecvoll/
file3_24 -json
{
  "timestamp":15341
88250720,
  "timeofday":"201
8-08-13
12:24:10.720
GMT-0700 PM",
  "status":"ERROR",
  "errors":[
    {
      "id":3,
      "desc":"Tierfile
transfer failed,
Could not open
file /ecvoll/
file3_24"
    }
  ]
}
```

REST

```
curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/ecvoll/
file3_24' --user
mapr:mapr
{"timestamp":1534
188250720,"timeof
day":"2018-08-13
12:24:10.720
GMT-0700
PM","status":"ERR
OR",
  "errors":
  [{"id":3,"desc":"
Tierfile
transfer failed,
Could not open
```

```
file /ecvoll/
file3_24"]}]}
```

FILE_EMPTY

Indicates that the file contains no data and is empty.
For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /voll/
test1 -json
{
  "timestamp":15341
41220360,
  "timeofday":"201
8-08-12
11:20:20.360
GMT-0700 PM",
  "status":"ERROR",
  "errors":[
    {
      "id":5,
      "desc":"File
empty."
    }
  ]
}
```

REST

```
curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/voll/
test1' --user
mapr:mapr
{"timestamp":1534
142083085,"timeof
day":"2018-08-12
11:34:43.085
GMT-0700
PM","status":"ERR
OR",
  "errors":
  [{"id":5,"desc":
  "File empty."}]}
```

NO_GATEWAY

Indicates that there is no MAST Gateway available. For
example:

CLI

```

/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /ecvoll/
file2 -json
{
  "timestamp":15341
85984585,
  "timeofday":"201
8-08-13
11:46:24.585
GMT-0700 AM",
  "status":"ERROR",
  "errors":[
    {
      "id":6,
      "desc":"Lost
connection to
gateway."
    }
  ]
}

```

REST

```

curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/ecvoll/
file2' --user
mapr:mapr

{"timestamp":1534
185984585,"timeof
day":"2018-08-13
11:46:24.585
GMT-0700
AM", "status": "ERR
OR",
  "errors":
  [{"id":6,"desc":
  "Lost connection
to gateway."}]
}

```

HAS_LOCAL_DATA

Indicates that the data is still on the cluster. For example:

CLI

```

/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /voll/
mfs1 -json
File has local

```

```
data.
{
  "timestamp":15341
41820011,
  "timeofday":"201
8-08-12
11:30:20.011
GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":8,
      "message":"File
has local data."
    }
  ]
}
```

REST

```
curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/voll/
mfs1' --user
mapr:mapr
```

```
{"timestamp":153414
1975490,"timeofday"
:"2018-08-12

GMT-0700
PM","status":"OK",
  "total":1,"data":
[{"status":8,"messa
ge":"File has
local data."}]}
```

FTOS_ABORTED

Indicates that the file tiering operation was aborted.
For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /v3/dataVol/
file5 -json
{
  "timestamp":15338
45080525,
  "timeofday":"201
8-08-09
01:04:40.525
```

```

GMT-0700 PM",
  "status": "OK",
  "total": 1,
  "data": [
    {
      "status": 9,
      "message": "Transfer aborted.",
      "gateway": "10.10.25.22:8660",
      "op": "Offload",
      "completedFids": 9,
      "failedFids": 0,
      "totalFids": 9
    }
  ]
}

```

REST

```

curl -k -X GET
'https://
abc.sj.us:8443/

ompletedFids": 5, "
failedFids": 0, "to
talFids": 9]]}
```

FTOS_TRANSFER_IN_PROGRESS

Indicates that offload or recall of file data is currently in progress. For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /v3/dataVol/
file5 -json
{

"timestamp":15338
44965363,

"timeofday": "201
8-08-09
01:02:45.363
GMT-0700 PM",
  "status": "OK",
  "total": 1,
  "data": [
    {

"status": 11,

"message": "File
transfer in
progress.",

"gateway": "10.10.
25.22:8660",

"op": "Offload",

"completedFids": 2
,

"failedFids": 0,

"totalFids": 9
}
]
}
```

REST

```
curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/v3/dataVol/
```

```
file5' --user
mapr:mapr

{"timestamp":1533
844965363,"timeof
day":"2018-08-09
01:02:45.363

```

FTOS_JOB_NOT_AVAILABLE

Indicates that the job ID associated with the specified file tiering operation is not available or is invalid. For example:

CLI

```
/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /v5/
nfile2 -json
{
```

```
"timestamp":15338
41993320,
```

```
"timeofday":"201
8-08-09
12:13:13.320
GMT-0700 PM",
```

```
"status":"ERROR",
"errors":[
```

```

    {
      "id":13,
      "desc":"File has
no active
transfer in
progress."
    }
  ]
}

```

REST

```

curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/v5/
nfile2' --user
mapr:mapr

{"timestamp":1533
841993320,"timeof
day":"2018-08-09

GMT-0700
PM","status":"ERR
OR",
  "errors":
  [{"id":13,"desc":
"File has no
active transfer
in progress."}]}

```

FTOS_EPERM

Indicates that the user cannot perform the tiering operation. For example:

CLI

```

/opt/mapr/bin/
maprcli file
tierjobstatus -na
me /ecvoll/
file3_1 -json
{
  "timestamp":15341
88598543,
  "timeofday":"201
8-08-13
12:29:58.543
GMT-0700 PM",
  "status":"ERROR",
  "errors":[
    {
      "id":14,
      "desc":"File

```

```
transfer request
permission
denied."
    ]
}
```

REST

```
curl -k -X GET
'https://
abc.sj.us:8443/
rest/file/
tierjobstatus?
name=/ecvoll/
file3_1' --user
mapr:mapr

{"timestamp":1534
188598543,"timeof
day":"2018-08-13
12:29:58.543
GMT-0700
PM","status":"ERR
OR",
  "errors":
  [{"id":14,"desc":
  "File transfer
request
permission
denied."}]}
```

file tierstatus

Checks the status of the file offload operation and returns information on whether or not the file has any local data.

This command does not require a MAST Gateway.

Syntax**CLI**

```
maprcli file tierstatus
-name <file_name>
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | http[s]://<host:port>/rest/file/tierstatus?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| name | The name (including the path) of the file. |

Output

The output of this command varies based on whether or not data is local, was offloaded, or was recalled. The output returns *one* of the following messages:

- Data was completely offloaded:

```
File does not have local data
```

- Data could not be completely offloaded or data was recalled:

```
File has local data
```

- File is not configured for tiering:

```
File is not on a tiered volume
```

Examples

Retrieve the status of file named `new2test4` in volume name `testvol2`:

CLI

```
maprcli file tierstatus -name /
testvol2/new2test4 -json
File does not have local data.
{
  "timestamp":1514877988773,
  "timeofday":"2018-01-01
11:26:28.773 GMT-0800",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":1,
      "message":"File
does not have local data."
    }
  ]
}
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/file/tierstatus?
name=/testvol2/new2test4' --user
mapr:mapr

{"timestamp":1514877988773,"timeofday"
:"2018-01-01 11:26:28.773
GMT-0800","status":"OK","total":1,
  "data":[{"status":1,"message":"File
does not have local data."}]}
```

Retrieve the status of file named `new2test3` in volume named `testvol2`:

CLI

```
maprcli file tierstatus -name /
testvol2/new2test3 -json
File has local data.
```

```

{
  "timestamp":1514878021374,
  "timeofday":"2018-01-01
11:27:01.374 GMT-0800",
  "status":"OK",
  "total":1,
  "data":[
    {
      "status":0,
      "message":"File
has local data."
    }
  ]
}

```

REST

Send a request of type GET. For example:

```

curl -k -X GET 'https://
abc.sj.us:8443/rest/file/tierstatus?
name=/testvol2/new2test3' --user
mapr:mapr

{"timestamp":1514878021374,"timeofday"
:"2018-01-01 11:27:01.374
GMT-0800","status":"OK","total":1,
 "data":[{"status":0,"message":"File
has local data."}]

```

Retrieve the status of file named file0 in volume named dir1 inside a volume called std_volume:

CLI

```

/opt/mapr/bin/maprcli
file tierstatus -name /std_volume/
dir1/file0 -json
File is not on a tiered volume.
{
  "timestamp":1609831337961,
  "timeofday":"2021-01-04
11:22:17.961 GMT-0800 PM",
  "status":"ERROR",
  "errors":[
    {
      "id":4,
      "desc":"File is not on a
tiered volume."
    }
  ]
}

```

REST

Send a request of type GET. For example:

```

curl -k -X
GET 'https://abc.sj.us:8443/rest/
file/tierstatus?name=/std_volume/dir1/
file0' --user mapr:mapr

```

filefilter

Creates and modifies filters to restrict certain file types from being stored on specified volumes.

filefilter create

Creates a filter to disallow the specified file type.

Syntax**CLI**

```
/opt/mapr/bin/maprcli filefilter
create
    -name name
    [ -description description ]
    -fileextensions extension
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/filefilter/create?<parameters> |

Parameters

| Parameter | Description |
|----------------|---|
| name | The name of the filter to create. |
| description | An optional description. |
| fileextensions | Comma separated list of extensions to block. For example, <i>exe,bat</i> blocks <i>exe</i> and <i>bat</i> files from being created and stored.  Note: The extensions are NOT case sensitive. Setting the extension to <i>exe</i> blocks <i>file1.exe</i> but does not block <i>file1.EXE</i> . |

Example

Create a filter named *noxebat* to disallow *exe* and *bat* files:

CLI

```
/opt/mapr/bin/maprcli filefilter
create -name noxebat -description No
EXE and BAT files \
    -fileextensions
exe,bat -json
{
    "timestamp":1609740883440,
    "timeofday":"2021-01-03
10:14:43.440 GMT-0800 PM",
    "status":"OK",
    "total":0,
    "data":[
    ],
    "messages":[
        "Filter Created
successfully"
    ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/filefilter/create?
name=noexebat&description=No%20EXE%20a
nd%20BAT%20files&fileextensions=exe,ba
t' --user mapr:mapr
{"timestamp":1609743797218,"timeofday"
:"2021-01-03 11:03:17.218 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Filter Created
successfully"]}
```

filefilter modify

Modifies a filter that disallows the specified file type.

Syntax

CLI

```
/opt/mapr/bin/maprcli filefilter
modify
    -name name
    [ -description description ]
    -fileextensions extension
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/filefilter/modify?<parameters> |

Parameters

| Parameter | Description |
|----------------|---|
| name | Identifies the filter to modify. The name cannot be modified. |
| description | An optional description. |
| fileextensions | Comma separated list of extensions to block. For example, <i>exe,bat</i> blocks <i>exe</i> and <i>bat</i> files from being created and stored.  Note: The extensions are NOT case sensitive. Setting the extension to <i>exe</i> blocks <i>file1.exe</i> but does not block <i>file1.EXE</i> |

 **Note:** Modifying file filters does not delete files already present in accordance with the current extensions. They only block new files henceforth. For example, if you modify a filter that currently has *jpg,png*, and now add *txt* to it, files with an extension of *txt* that are already present in the volume are not deleted. New files with the *txt* extension are prevented from being created hereafter.

Example

Modify a filter named *noexebat* to disallow *exe*, *bat*, and *sh* files:

CLI

```
/opt/mapr/bin/maprcli filefilter
modify -name noextbat -description No
EXE BAT and sh files \
      -fileextensions
exe,bat,sh -json
{
  "timestamp":1609747228371,
  "timeofday":"2021-01-04
12:00:28.371 GMT-0800 AM",
  "status":"OK",
  "total":0,
  "data":[
  ],
  "messages":["
    "Filter Updated
successfully"
  ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/filefilter/modify?
name=noexeabat&description=No%20EXE%20B
AT%20and%20sh%20files&fileextensions=e
xe,bat,sh' --user mapr:mapr
{"timestamp":1609747413152,"timeofday"
:"2021-01-04 12:03:33.152 GMT-0800
AM","status":"OK","total":0,"data":
[],"messages":["Filter Updated
successfully"]}
```

filefilter list

Lists filters specified by filtering criteria.

Syntax

CLI

```
/opt/mapr/bin/maprcli filefilter list
[ -columns all. default: all ]
[ -filter none. default:
none ]
[ -limit limit. default:
2147483647 ]
[ -output verbose. default:
verbose ]
[ -sortby <filtername|
filterid>, column names of supported
fields. ]
[ -sortorder <asc|desc> ]
[ -start start. default: 0 ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/filefilter/list?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| columns | A comma-separated list of fields to return in the query. |
| filter | A filter specifying file filters to list. See Filters on page 1703 for more information. Default: none |
| limit | Number of filters to list. |
| output | Either terse or verbose. |
| sortby | Field on which to sort the output. |
| sortorder | Either ascending or descending. |
| start | Filter to start with when listing multiple filters. |

Examples

List all file filters:

CLI

```

/opt/mapr/bin/maprcli filefilter
list -json

{
  "timestamp":1609826179089,
  "timeofday":"2021-01-04
09:56:19.089 GMT-0800 PM",
  "status":"OK",
  "total":3,
  "data":[
    {
      "filterid":1,
      "filtername":"nojpg",
      "description":"NO",
      "fileExtention":"jpg,txt"
    },
    {
      "filterid":3,
      "filtername":"notextjpg",
      "description":"No text jpg and mov
files",
      "fileExtention":"jpg,txt,mov"
    },
    {
      "filterid":4,
      "filtername":"noexec",
      "description":"No",
      "fileExtention":"exe,bat,sh"
    }
  ]
}

```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/filefilter/
list' --user mapr:mapr
{"timestamp":1609826294528,"timeofday"
:"2021-01-04 09:58:14.528 GMT-0800
PM","status":"OK","total":3,"data":
[{"filterid":1,"filtername":"nojpg","d
escription":"NO","fileExtention":"jpg,
txt"},
{"filterid":3,"filtername":"notextjpg"
,"description":"No text jpg and mov
files","fileExtention":"jpg,txt,mov"},
{"filterid":4,"filtername":"noexec","d
escription":"No","fileExtention":"exe,
bat,sh"}]}
```

List the first two file filters

The `start` and `limit` parameters are useful for limiting the results. You can list the first two file filters as follows:

CLI

```
/opt/mapr/bin/maprcli filefilter
list -start 0 -limit 2 -json
{
  "timestamp":1609826503471,
  "timeofday":"2021-01-04
10:01:43.471 GMT-0800 PM",
  "status":"OK",
  "total":2,
  "data":[
    {
      "filterid":1,
      "filtername":"nojpg",
      "description":"NO",
      "fileExtention":"jpg,txt"
    },
    {
      "filterid":3,
      "filtername":"notextjpg",
      "description":"No text jpg and mov
files",
      "fileExtention":"jpg,txt,mov"
    }
  ]
}
```

REST

```
curl -k -X GET 'https://
abc.sj.us:8443/rest/filefilter/list?
start=0&limit=2' --user mapr:mapr
{"timestamp":1609826617711,"timeofday"
:"2021-01-04 10:03:37.711 GMT-0800
PM","status":"OK","total":2,"data":
[{"filterid":1,"filtername":"nojpg","d
```

```
escription":"NO", "fileExtention":"jpg,
txt"},
{"filterid":3, "filtername":"notextjpg"
, "description":"No text jpg and mov
files", "fileExtention":"jpg,txt,mov"}]
}
```

filefilter info

Displays information about a specified filter.

Syntax

CLI

```
/opt/mapr/bin/maprcli filefilter info
-name filterName
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/filefilter/info?<parameters> |

Parameters

| Parameter | Description |
|-----------|--|
| name | Filter for which to display information. |

Examples

Display information for the filter named notextjpg:

CLI

```
/opt/mapr/bin/maprcli filefilter
info -name notextjpg -json
{
  "timestamp":1609830546149,
  "timeofday":"2021-01-04
11:09:06.149 GMT-0800 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "filterid":3,
      "filtername":"notextjpg",
      "description":"No text jpg and mov
files",
      "fileExtention":"jpg,txt,mov"
    }
  ]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/filefilter/info?
name=notextjpg' --user mapr:mapr
{"timestamp":1609833232278,"timeofday"
:"2021-01-04 11:53:52.278 GMT-0800
PM","status":"OK","total":1,"data":
[{"filterid":3,"filtername":"notextjpg
","description":"No text jpg and mov
files","fileExtention":"jpg,txt,mov"}]
}
```

filefilter remove

Removes a file filter.

Syntax

CLI

```
/opt/mapr/bin/maprcli filefilter
remove
        -name filterName
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host:port>/rest/filefilter/remove?<parameters> |

Parameters

| Parameter | Description |
|-----------|-------------------|
| name | Filter to remove. |

Note: Filters that are attached to volumes cannot be removed. [Modify the volumes](#) to remove the filters, before deleting the filters.

Example

Remove filter :

CLI

```
/opt/mapr/bin/maprcli filefilter
remove -name notextjpg -json
{
    "timestamp":1609834952199,
    "timeofday":"2021-01-05
12:22:32.199 GMT-0800 AM",
    "status":"OK",
    "total":0,
    "data":[
    ],
    "messages":[
        "Filter Removed
successfully"
```

```
]
}
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/filefilter/remove?
name=notextjpg' --user mapr:mapr
{"timestamp":1609835456331,"timeofday"
:"2021-01-05 12:30:56.331 GMT-0800
AM","status":"OK","total":0,"data":
[],"messages":["Filter Removed
successfully"]}
```

job

Manages Hadoop jobs running on the cluster.

job linklogs

Creates symbolic links to all the logs relating to the activity of a specific job.

The `maprcli job linklogs` command works with the [Centralized Logging](#) to provide a job-centric view or an application-centric view of all log files generated during job or application execution.

The output of `job linklogs` is a directory populated with symbolic links to all log files related to the specified job(s) or to the application. The command can be performed during or after a job or application is processed.

Syntax**CLI**

```
maprcli job linklogs
  -jobid <jobPattern>
  -todir <desinationDirectory>
  [-jobconf <pathToJobXml>]
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/job/linklogs?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| jobid | For MapReduce version 2, specify the application ID. |
| todir | The target directory for the symbolic links to the log files. |
| jobconf | For MapReduce version 2, this parameter is not applicable. |

Output

For MapReduce version 2, the following directory will be created in the location specified by `todir` for the application ID that you specify for the `jobid` parameter:

- <applicationId>/hosts/<host>/ contains symbolic links to log directories of tasks executed for <applicationId> on <host>

Examples

Link logs for all jobs named "wordcount1" and dump output to /myvolume/joblogviewdir:

CLI

```
maprcli job linklogs -jobid
job_*_wordcount1 -todir /myvolume/
joblogviewdir
```

REST

```
https://abc.sj.us:8443/
rest/job/linklogs?
jobid=job_*_wordcount1&todir=/
myvolume/joblogviewdir
```

license

Manages MapR licenses.

license add

Adds a license. Permissions required: fc or a.

You can specify the license either by passing the license string itself to `license add`, or by specifying a file containing the license string. In a multinode cluster, add the license to one node (any node). Adding the same license to more than one node returns an error.

Syntax

CLI

```
maprcli license add
[ -cluster cluster name ]
[ -is_file true|false. default:
false ]
-license long_license_string
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/license/add?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. |
| is_file | Specifies whether the license specifies a file. If false, the license parameter contains a long license string. |
| license | The license to add to the cluster. If -is_file is true, license specifies the file name of a license file. Otherwise, license contains the license string itself. |

Examples

Note: After obtaining a valid license file from your data-fabric sale representative, copy the license file to a cluster node, for example in the path `/tmp/license.txt`.

To add a license from a file:

CLI

```
maprcli license add -is_file
true -license /tmp/license.txt
```

REST

```
https://abc.sj.us:8443/rest/license/
add?
is_file=true&license=%2Ftmp%2Flicense.
txt
```

Displays the cluster ID for use when creating a new license. Permissions required: `login`.

license addcrl

Adds a certificate revocation list (CRL). Permissions required: `fc` or `a`.

Syntax

CLI

```
maprcli license addcrl
[ -cluster <cluster> ]
-crl <crlstring>
```

```
[ -is_file true|false. default:
false ]
```

REST

| | |
|--------------|--|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/license/addcrl?<parameters> |

Parameters

| Parameter | Description |
|-----------|---|
| cluster | The cluster on which to run the command. |
| crl | The CRL to add to the cluster. If file is set, crl specifies the filename of a CRL file. Otherwise, crl contains the CRL string itself. |
| is_file | Specifies whether the license is contained in a file. |

Examples**CLI**

```
maprcli license addcrl
-crl crl.txt
-is_file true
```

REST

```
https://centos26.lab:8443/
rest/license/addcrl?
crl=crl.txt&is_file=true
```

[license list](#) on page 1885

Lists licenses on the cluster. Permissions required: `login`. For best results, use the `-json` option when running the command.

[license listcrl](#) on page 1887

Lists certificate revocation lists (CRLs) on the cluster. Permissions required: `login`.

[license remove](#) on page 1888

Removes a license. Permissions required: `fc` or `a`.

[license showid](#) on page 1890

Displays the cluster ID for use when creating a new license. Permissions required: `login`.

license apps

Displays the features authorized for the current license. Permissions required: `login`

Syntax

CLI

```
maprcli license apps
[ -cluster <cluster> ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | <code>http[s]://<host>:<port>/rest/license/apps[?<parameters>]</code> |

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |

Output

Sample Output

```
# maprcli license apps
capability          grace  featuredata
NFS                 false  unlimited
NFS_MULTINODE      false
NFS_HA              false

Displays the cluster ID for use when creating a new license. Permissions required: `login`.

license list

Lists licenses on the cluster. Permissions required: `login`. For best results, use the `-json` option when running the command.

Syntax**CLI**

```
maprcli license list
[ -cluster <cluster> ]
```

REST

| | |
|--------------|-----|
| Request Type | GET |
|--------------|-----|

| | |
|-------------|--|
| Request URL | http[s]://<host>:<port>/rest/license/list[?<parameters>] |
|-------------|--|

Parameters

| Parameter | Description |
|-----------|--|
| cluster | The cluster on which to run the command. |

Note: If you use the `-json` option with this command, and you pipe the output into another program, you may find that the result cannot be parsed by certain JSON libraries, such as the JSON library for Python. To work around this problem, you can replace the single-escape characters (`\`) in the JSON output that the `license list` command returns, with double-escape characters (`\\`).

Output

Sample Output

```
# maprcli license list -json
{
  "timestamp":1433543033194,
  "timeofday":"2015-06-05 10:23:53.194 GMT+0000",

license showid

Displays the cluster ID for use when creating a new license. Permissions required: `login`.

Syntax

CLI

```
maprcli license showid
[ -cluster <cluster> ]
-showNodes show the total licensed
nodes available. default: false ]
```

REST

| | |
|--------------|---|
| Request Type | GET |
| Request URL | <code>http[s]://<host>:<port>/rest/license/showid[?<parameters>]</code> |

Parameters

| Parameter | Description |
|------------------------|--|
| <code>cluster</code> | The cluster on which to run the command. |
| <code>showNodes</code> | When set to <code>true</code> , displays both the number of nodes that the license supports, and the current number of nodes to which the license applies. A value of <code>-1</code> indicates that there is no limit to the number of nodes to which this license applies. Default Value: <code>false</code> |

Output

Sample Output

```
# maprcli license showid
id
5119043355327235351
```

```
# maprcli license showid -showNodes true
maxLicensedNodes id currentLicensedNodes
-1 5119043355327235351 1
```

Examples

CLI

```
maprcli license showid -showNodes true
```

[license remove](#) on page 1888

Removes a license. Permissions required: `fc` or `a`.

label

Manages registration and modification of labels.

label add

Registers a label. Permissions required: `fc` or `a`.

Registers a label. See [Using Storage Labels](#) on page 1068 for more information on labels. Attempting to register a label that is already registered, results in an error.

When registering a label for a Storage Pool, the label and its associated values apply to all the disks in the Storage Pool.

Syntax

CLI

```
maprcli label add
  -label <label to be registered>
  [ -maxactiveioperdisk max active
    io per disk ]
```

```
[ -numdisksperinstance num disks
per mfs instance ]
[ -isssd is solid state drive ]
[ -istrimenabled is trim enabled ]
```

REST

| | |
|--------------|---|
| Request Type | POST |
| Request URL | http[s]://<host>:<port>/rest/ label/add?<parameters> |

Parameters

label

Default Value: default

Possible Values: Any label

Description: The label to use for the storage pool. See [Using Storage Labels](#) on page 1068 for more information on labels.

The label should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

maxactiveioperdisk

Default Value: 100

Possible Values: Any integer value between 100 and 50000.

The number of concurrent IO operations per second that can be issued on the disk. Not specifying this value uses the default value specified in the `mfs.conf` file.

numdisksperinstance

Default Value: 20

Possible Values: Any integer value between 1 and 24.

Used in partitioning disks of the same type among multiple instances of file servers on the same node.

isssd

Default Value: true

Possible Values: true or false

Set to true to indicate that the disk is an SSD.

istrimenabled

Default Value: false

Possible Values: true or false

Set to true to indicate that the SSD disk is TRIM enabled.

TRIM enables the File System to inform a SSD disk which data blocks it can erase because they are no longer in use. The use of TRIM can improve the performance of writing data to SSDs and contribute to longer SSD life. Set this parameter to true only if the SSD vendor recommends it.

Examples

1. Register a label, before using it to label a storage pool.

CLI

```
maprcli label add -label WDCheetah
```

REST

```
https://abc.sj.us:8443/rest/labels/
add?label=WDCheetah
```

2. Register a label with additional settings such as the maximum active IO per disk and marking it as a SSD, before using it to label a storage pool.

CLI

```
maprcli label add -label
WDCheetah -maxactiveioperdisk
5000 -issd true -istrimenabled true
```

REST

```
https://abc.sj.us:8443/rest/labels/
add?
label=WDCheetah&maxactiveioperdisk=500
0&-issd=true&istrimenabled=true
```

Related concepts

Manages nodes in the cluster

[Using Storage Labels](#) on page 1068

Describes the Storage Labels feature.

Related reference

[disk add](#) on page 1786

Adds one or more disks to the specified node. Permissions required: `fc` or `a`.

[disk setlabel](#) on page 1788

Adds a label to disks or a storage pool. Permissions required: `fc` or `a`.

[volume create](#) on page 2190

Creates a volume.

[volume move](#) on page 2294

Moves the specified volume or mirror to a different topology. Permissions required: `m` or `fc` on the volume.

[label list](#) on page 1895

Lists registered labels. Permissions required: `fc` or `a`.

[node list](#) on page 1911

Lists nodes in the cluster.

[configure.sh](#) on page 2331

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

label modify

Modifies a label. Permissions required: `fc` or `a`.

Modifies a label. See [Using Storage Labels](#) on page 1068 for more information on labels.

When modifying a label for a Storage Pool, the label and its associated values apply to all the disks in the Storage Pool.

Syntax**CLI**

```
maprcli label modify
-label <label to be modified>
```

```
[ -maxactiveioperdisk max active
io per disk ]
[ -isssd is solid state drive ]
[ -istrimenabled is trim enabled ]
```

REST
